

# User and Reference Manual: All Parts

Release 3.4

18 December 2008

Built from 3.4-I-540

# Contents

<b>I</b>	<b>General Introduction</b>	<b>1</b>
<b>1</b>	<b>Introduction</b>	<b>3</b>
1.1	Organization of the Manual . . . . .	3
1.2	Demos and Examples . . . . .	3
1.3	Hello World . . . . .	4
1.4	Further Reading . . . . .	6
	Reference Manual . . . . .	7
<b>2</b>	<b>Preliminaries</b>	<b>9</b>
2.1	License Issues . . . . .	9
2.2	Third Party Software . . . . .	10
2.3	Marking of Advanced Features . . . . .	12
2.4	Namespace CGAL . . . . .	13
2.5	Inclusion Order of Header Files . . . . .	13
2.6	Compile-time Flags to Control Inlining . . . . .	13
2.7	Identifying the Version of CGAL . . . . .	13
2.8	Thread Safety . . . . .	14
2.9	Code Deprecation . . . . .	14
2.10	Checks . . . . .	14
	Reference Manual . . . . .	19

<b>II</b>	<b>Arithmetic and Algebra</b>	<b>21</b>
<b>3</b>	<b>Algebraic Foundations</b>	<b>23</b>
3.1	Introduction . . . . .	23
3.2	Algebraic Structures . . . . .	23
3.3	Real Embeddable . . . . .	26
3.4	Real Number Types . . . . .	27
3.5	Interoperability . . . . .	27
3.6	Fractions . . . . .	29
	Reference Manual . . . . .	33
3.7	Classified Reference Pages . . . . .	33
3.8	Alphabetical List of Reference Pages . . . . .	36
<b>4</b>	<b>Number Types</b>	<b>123</b>
4.1	Introduction . . . . .	123
4.2	Built-in Number Types . . . . .	123
4.3	Number Types Provided by CGAL . . . . .	124
4.4	Number Types Provided by GMP . . . . .	124
4.5	Number Types Provided by LEDA . . . . .	125
4.6	Number Types Provided by CORE . . . . .	125
4.7	User-supplied Number Types . . . . .	125
	Reference Manual . . . . .	127
4.8	Classified Reference Pages . . . . .	127
4.9	Alphabetical List of Reference Pages . . . . .	129
<b>5</b>	<b>Polynomial</b>	<b>187</b>
5.1	Fundamentals . . . . .	187
5.2	General Design . . . . .	188
5.3	Constructing a multivariate polynomial . . . . .	188
5.4	Coefficient Access . . . . .	190
5.5	Degree, total degree and degree vector . . . . .	191

5.6	Changing the order of variables . . . . .	193
5.7	GCD and More . . . . .	194
5.8	Evaluation and Substitution . . . . .	196
5.9	Design and Implementation History . . . . .	198
	Reference Manual . . . . .	199
5.10	Classified Reference Pages . . . . .	199
5.11	Alphabetical List of Reference Pages . . . . .	202
<b>6</b>	<b>Modular Arithmetic</b>	<b>299</b>
6.1	Introduction . . . . .	299
6.2	Design and Implementation History . . . . .	302
	Reference Manual . . . . .	303
6.3	Classified Reference Pages . . . . .	303
6.4	Alphabetical List of Reference Pages . . . . .	303
<b>III</b>	<b>Geometry Kernels</b>	<b>311</b>
<b>7</b>	<b>2D and 3D Geometry Kernel</b>	<b>313</b>
7.1	Introduction . . . . .	314
7.2	Kernel Representations . . . . .	315
7.3	Kernel Geometry . . . . .	318
7.4	Predicates and Constructions . . . . .	319
7.5	Extensible Kernel . . . . .	322
	Reference Manual . . . . .	329
7.6	Concepts . . . . .	333
7.7	Kernel Classes and Operations . . . . .	339
7.8	Predefined Kernels . . . . .	353
7.9	Kernel Objects . . . . .	356
7.10	Constants and Enumerations . . . . .	421
7.11	Global Functions . . . . .	433

7.12	Kernel Geometric Object Concepts . . . . .	522
7.13	Kernel Function Object Concepts . . . . .	547
7.14	Dimension handling tools . . . . .	779
<b>8</b>	<b>dD Geometry Kernel</b>	<b>783</b>
8.1	Introduction . . . . .	783
8.2	Kernel Representations . . . . .	784
8.3	Kernel Geometry . . . . .	787
8.4	Predicates and Constructions . . . . .	788
	Reference Manual . . . . .	791
8.5	Linear Algebra Concepts and Classes . . . . .	793
8.6	Kernels . . . . .	803
8.7	Kernel Objects . . . . .	805
8.8	Global Kernel Functions . . . . .	833
8.9	Kernel Concept . . . . .	855
<b>9</b>	<b>2D Circular Geometry Kernel</b>	<b>889</b>
9.1	Introduction . . . . .	889
9.2	Software Design . . . . .	889
9.3	Examples . . . . .	890
9.4	Design and Implementation History . . . . .	892
	Reference Manual . . . . .	893
9.5	Geometric Concepts . . . . .	893
9.6	Geometric Kernels and Classes . . . . .	894
9.7	Geometric Global Functions . . . . .	894
9.8	Algebraic Concepts . . . . .	895
9.9	Algebraic Kernel and Classes . . . . .	895
9.10	Alphabetical List of Reference Pages . . . . .	896
<b>10</b>	<b>3D Spherical Geometry Kernel</b>	<b>973</b>
10.1	Introduction . . . . .	973

10.2 Spherical Kernel Objects . . . . .	973
10.3 Software Design . . . . .	974
10.4 Examples . . . . .	974
10.5 Design and Implementation History . . . . .	976
Reference Manual . . . . .	977
10.6 Geometric Concepts . . . . .	977
10.7 Geometric Kernels and Classes . . . . .	978
10.8 Geometric Global Functions . . . . .	978
10.9 Algebraic Concepts . . . . .	979
10.10Algebraic Kernel and Classes . . . . .	979
10.11Alphabetical List of Reference Pages . . . . .	980
<b>IV Convex Hull Algorithms</b>	<b>1061</b>
<b>11 2D Convex Hulls and Extreme Points</b>	<b>1063</b>
11.1 Introduction . . . . .	1063
11.2 Convex Hull . . . . .	1064
11.3 Example using Graham-Andrew's Algorithm . . . . .	1064
11.4 Extreme Points and Hull Subsequences . . . . .	1065
11.5 Traits Classes . . . . .	1065
11.6 Convexity Checking . . . . .	1066
Reference Manual . . . . .	1067
11.7 Classified Reference Pages . . . . .	1067
11.8 Alphabetical List of Reference Pages . . . . .	1069
<b>12 3D Convex Hulls</b>	<b>1109</b>
12.1 Introduction . . . . .	1109
12.2 Static Convex Hull Construction . . . . .	1110
12.3 Incremental Convex Hull Construction . . . . .	1111
12.4 Dynamic Convex Hull Construction . . . . .	1113

Reference Manual . . . . .	1115
12.5 Classified Reference Pages . . . . .	1115
12.6 Alphabetical List of Reference Pages . . . . .	1117
<b>13 dD Convex Hulls and Delaunay Triangulations</b>	<b>1135</b>
13.1 Introduction . . . . .	1135
13.2 dD Convex Hull . . . . .	1135
13.3 Delaunay Triangulation . . . . .	1136
Reference Manual . . . . .	1137
13.4 Classified Reference Pages . . . . .	1137
13.5 Alphabetical List of Reference Pages . . . . .	1138
<b>V Polygons</b>	<b>1161</b>
<b>14 2D Polygons</b>	<b>1163</b>
14.1 Introduction . . . . .	1163
14.2 Example . . . . .	1164
Reference Manual . . . . .	1167
14.3 Classified Reference Pages . . . . .	1167
14.4 Alphabetical List of Reference Pages . . . . .	1168
<b>15 2D Regularized Boolean Set-Operations</b>	<b>1191</b>
15.1 Introduction . . . . .	1191
15.2 Boolean Set-Operations on Linear Polygons . . . . .	1193
15.3 Boolean Set-Operations on General Polygons . . . . .	1205
Reference Manual . . . . .	1217
15.4 Classified Reference Pages . . . . .	1217
15.5 Alphabetical List of Reference Pages . . . . .	1218
<b>16 2D Boolean Operations on Nef Polygons</b>	<b>1265</b>
16.1 Introduction . . . . .	1265

16.2 Construction and Composition . . . . .	1266
16.3 Exploration . . . . .	1267
16.4 Traits Classes . . . . .	1268
16.5 Implementation . . . . .	1269
Reference Manual . . . . .	1271
16.6 Classified Reference Pages . . . . .	1271
16.7 Alphabetical List of Reference Pages . . . . .	1271
<b>17 2D Boolean Operations on Nef Polygons Embedded on the Sphere</b>	<b>1293</b>
17.1 Introduction . . . . .	1293
17.2 Restricted Spherical Geometry . . . . .	1294
17.3 Example Programs . . . . .	1295
Reference Manual . . . . .	1301
17.4 Classified Reference Pages . . . . .	1301
17.5 Alphabetical List of Reference Pages . . . . .	1301
<b>18 2D Polygon Partitioning</b>	<b>1323</b>
18.1 Introduction . . . . .	1323
18.2 Monotone Partitioning . . . . .	1323
18.3 Convex Partitioning . . . . .	1324
Reference Manual . . . . .	1327
18.4 Classified Reference Pages . . . . .	1327
18.5 Alphabetical List of Reference Pages . . . . .	1328
<b>19 2D Straight Skeleton and Polygon Offsetting</b>	<b>1371</b>
19.1 Definitions . . . . .	1371
19.2 Representation . . . . .	1377
19.3 API . . . . .	1379
19.4 Straight Skeletons, Medial Axis and Voronoi Diagrams . . . . .	1391
19.5 Usages of the Straight Skeletons . . . . .	1391
19.6 Straight Skeleton of a General Figure in the Plane . . . . .	1393

Reference Manual . . . . .	1395
19.7 Classified Reference Pages . . . . .	1395
19.8 Alphabetical List of Reference Pages . . . . .	1396
<b>20 2D Minkowski Sums</b>	<b>1447</b>
20.1 Introduction . . . . .	1447
20.2 Computing the Minkowski Sum of Two Polygons . . . . .	1447
20.3 Offsetting a Polygon . . . . .	1453
Reference Manual . . . . .	1463
20.4 Alphabetical List of Reference Pages . . . . .	1464
<b>VI Polyhedra</b>	<b>1477</b>
<b>21 3D Polyhedral Surfaces</b>	<b>1479</b>
21.1 Introduction . . . . .	1479
21.2 Definition . . . . .	1480
21.3 Example Programs . . . . .	1480
21.4 File I/O . . . . .	1487
21.5 Extending Vertices, Halfedges, and Facets . . . . .	1488
21.6 Advanced Example Programs . . . . .	1490
Reference Manual . . . . .	1495
21.7 Classified Reference Pages . . . . .	1495
21.8 Alphabetical List of Reference Pages . . . . .	1496
<b>22 Halfedge Data Structures</b>	<b>1533</b>
22.1 Introduction . . . . .	1533
22.2 Software Design . . . . .	1534
22.3 Example Programs . . . . .	1535
Reference Manual . . . . .	1543
22.4 Classified Reference Pages . . . . .	1543
22.5 Alphabetical List of Reference Pages . . . . .	1544

<b>23 3D Boolean Operations on Nef Polyhedra</b>	<b>1591</b>
23.1 Introduction . . . . .	1591
23.2 Definition . . . . .	1592
23.3 Infimal Box . . . . .	1595
23.4 Regularized Set Operations . . . . .	1595
23.5 Example Programs . . . . .	1596
23.6 File I/O . . . . .	1601
23.7 Further Example Programs . . . . .	1603
23.8 Visualization . . . . .	1607
Reference Manual . . . . .	1611
23.9 Classified Reference Pages . . . . .	1611
23.10 Alphabetical List of Reference Pages . . . . .	1612
<b>24 Convex Decomposition of Polyhedra</b>	<b>1639</b>
24.1 Introduction . . . . .	1639
24.2 Interface and Usage . . . . .	1640
Reference Manual . . . . .	1643
24.3 Classified Reference Pages . . . . .	1643
24.4 Alphabetical List of Reference Pages . . . . .	1643
<b>25 3D Minkowski Sum of Polyhedra</b>	<b>1645</b>
25.1 Introduction . . . . .	1645
25.2 Decomposition Method . . . . .	1645
25.3 Features and Restrictions . . . . .	1647
25.4 Usage . . . . .	1648
25.5 Glide . . . . .	1648
Reference Manual . . . . .	1651
25.6 Classified Reference Pages . . . . .	1651
25.7 Alphabetical List of Reference Pages . . . . .	1651

<b>VII Arrangements</b>	<b>1653</b>
<b>26 2D Arrangements</b>	<b>1655</b>
26.1 Introduction . . . . .	1656
26.2 The Main Arrangement Class . . . . .	1658
26.3 Issuing Queries on an Arrangement . . . . .	1673
26.4 Free Functions in the Arrangement Package . . . . .	1681
26.5 Arrangements of Unbounded Curves . . . . .	1689
26.6 Traits Classes . . . . .	1697
26.7 The Notification Mechanism . . . . .	1730
26.8 Extending the DCEL . . . . .	1734
26.9 Overlaying Arrangements . . . . .	1739
26.10 Storing the Curve History . . . . .	1746
26.11 Input/Output Streams . . . . .	1752
26.12 Adapting to BOOST Graphs . . . . .	1758
26.13 How To Speed Up Your Computation . . . . .	1765
Reference Manual . . . . .	1767
26.14 Classified Reference Pages . . . . .	1767
26.15 Alphabetical List of Reference Pages . . . . .	1769
<b>27 2D Intersection of Curves</b>	<b>1945</b>
27.1 Introduction . . . . .	1945
27.2 Example . . . . .	1946
27.3 Design and Implementation History . . . . .	1948
Reference Manual . . . . .	1949
27.4 Alphabetical List of Reference Pages . . . . .	1949
<b>28 2D Snap Rounding</b>	<b>1953</b>
28.1 Introduction . . . . .	1953
28.2 What is Snap Rounding/Iterated Snap Rounding . . . . .	1954
28.3 Terms and Software Design . . . . .	1954

28.4 Four Line Segment Example . . . . .	1954
Reference Manual . . . . .	1957
28.5 Alphabetical List of Reference Pages . . . . .	1957
<b>29 Envelopes of Curves in 2D</b>	<b>1965</b>
29.1 Introduction . . . . .	1965
29.2 The Envelope Diagram . . . . .	1966
29.3 Examples . . . . .	1968
Reference Manual . . . . .	1975
29.4 Alphabetical List of Reference Pages . . . . .	1975
<b>30 Envelopes of Surfaces in 3D</b>	<b>1989</b>
30.1 Introduction . . . . .	1989
30.2 The Envelope-Traits Concept . . . . .	1990
30.3 Examples . . . . .	1992
Reference Manual . . . . .	1999
30.4 Alphabetical List of Reference Pages . . . . .	1999
<b>VIII Triangulations and Delaunay Triangulations</b>	<b>2017</b>
<b>31 2D Triangulations</b>	<b>2019</b>
31.1 Definitions . . . . .	2020
31.2 Representation . . . . .	2021
31.3 Software Design . . . . .	2022
31.4 Basic Triangulations . . . . .	2024
31.5 Delaunay Triangulations . . . . .	2027
31.6 Regular Triangulations . . . . .	2029
31.7 Constrained Triangulations . . . . .	2032
31.8 Constrained Delaunay Triangulations . . . . .	2033
31.9 Constrained Triangulations Plus . . . . .	2035
31.10The Triangulation Hierarchy . . . . .	2036

31.11 Flexibility: Using Customized Vertices and Faces . . . . .	2039
31.12 Design and Implementation History . . . . .	2042
Reference Manual . . . . .	2043
31.13 Classified Reference Pages . . . . .	2043
31.14 Alphabetical List of Reference Pages . . . . .	2044
<b>32 2D Triangulation Data Structure</b>	<b>2125</b>
32.1 Definition . . . . .	2125
32.2 The Concept of Triangulation Data Structure . . . . .	2126
32.3 The Default Triangulation Data Structure . . . . .	2127
Reference Manual . . . . .	2131
32.4 Classified Reference Pages . . . . .	2131
32.5 Alphabetical List of Reference Pages . . . . .	2132
<b>33 3D Triangulations</b>	<b>2155</b>
33.1 Representation . . . . .	2156
33.2 Delaunay Triangulation . . . . .	2157
33.3 Regular Triangulation . . . . .	2158
33.4 Triangulation Hierarchy . . . . .	2158
33.5 Software Design . . . . .	2159
33.6 Examples . . . . .	2163
33.7 Design and Implementation History . . . . .	2172
Reference Manual . . . . .	2173
33.8 Classified Reference Pages . . . . .	2173
33.9 Alphabetical List of Reference Pages . . . . .	2174
<b>34 3D Triangulation Data Structure</b>	<b>2237</b>
34.1 Representation . . . . .	2237
34.2 Software Design . . . . .	2241
34.3 Examples . . . . .	2243
34.4 Design and Implementation History . . . . .	2247

Reference Manual . . . . .	2249
34.5 Classified Reference Pages . . . . .	2249
34.6 Alphabetical List of Reference Pages . . . . .	2250
<b>35 2D Alpha Shapes</b>	<b>2277</b>
35.1 Definitions . . . . .	2278
35.2 Functionality . . . . .	2278
35.3 Concepts and Models . . . . .	2279
35.4 Examples . . . . .	2279
Reference Manual . . . . .	2281
35.5 Classified Reference Pages . . . . .	2281
35.6 Alphabetical List of Reference Pages . . . . .	2282
<b>36 3D Alpha Shapes</b>	<b>2297</b>
36.1 Definitions . . . . .	2299
36.2 Functionality . . . . .	2300
36.3 Concepts and Models . . . . .	2300
36.4 Examples . . . . .	2301
Reference Manual . . . . .	2305
36.5 Classified Reference Pages . . . . .	2306
36.6 Alphabetical List of Reference Pages . . . . .	2306
<b>IX Voronoi Diagrams</b>	<b>2323</b>
<b>37 2D Segment Delaunay Graphs</b>	<b>2325</b>
37.1 Definitions . . . . .	2325
37.2 Software Design . . . . .	2327
37.3 The Geometric Traits . . . . .	2330
37.4 The Segment Delaunay Graph Hierarchy . . . . .	2331
37.5 Examples . . . . .	2332
Reference Manual . . . . .	2337

37.6	Classified Reference Pages . . . . .	2337
37.7	Alphabetical List of Reference Pages . . . . .	2338
<b>38</b>	<b>2D Apollonius Graphs (Delaunay Graphs of Disks)</b>	<b>2377</b>
38.1	Definitions . . . . .	2377
38.2	Software Design . . . . .	2379
38.3	The Geometric Traits . . . . .	2380
38.4	The Apollonius Graph Hierarchy . . . . .	2383
38.5	Examples . . . . .	2383
	Reference Manual . . . . .	2389
38.6	Classified Reference Pages . . . . .	2389
38.7	Alphabetical List of Reference Pages . . . . .	2390
<b>39</b>	<b>2D Voronoi Diagram Adaptor</b>	<b>2417</b>
39.1	Introduction . . . . .	2417
39.2	Software Design . . . . .	2419
39.3	The Adaptation Traits . . . . .	2420
39.4	The Adaptation Policy . . . . .	2421
39.5	Examples . . . . .	2423
	Reference Manual . . . . .	2427
39.6	Classified Reference Pages . . . . .	2427
39.7	Alphabetical List of Reference Pages . . . . .	2428
<b>X</b>	<b>Mesh Generation</b>	<b>2463</b>
<b>40</b>	<b>2D Conforming Triangulations and Meshes</b>	<b>2465</b>
40.1	Conforming Triangulations . . . . .	2465
40.2	Meshes . . . . .	2469
	Reference Manual . . . . .	2477
40.3	Classified Reference Pages . . . . .	2477
40.4	Alphabetical List of Reference Pages . . . . .	2477

<b>41 3D Surface Mesh Generation</b>	<b>2499</b>
41.1 Introduction . . . . .	2500
41.2 The Surface Mesh Generator Interface for Smooth Surfaces . . . . .	2501
41.3 Examples . . . . .	2502
41.4 Meshing Criteria, Guarantees and Variations . . . . .	2506
41.5 Undocumented Features Available in Demos . . . . .	2506
41.6 Design and Implementation History . . . . .	2506
Reference Manual . . . . .	2507
41.7 Classified Reference Pages . . . . .	2507
41.8 Alphabetical List of Reference Pages . . . . .	2508
 <b>42 3D Skin Surface Meshing</b>	 <b>2545</b>
42.1 Introduction . . . . .	2546
42.2 Definition of a Skin Surface . . . . .	2546
42.3 The Interface . . . . .	2547
42.4 Timings . . . . .	2548
42.5 Example Programs . . . . .	2548
Reference Manual . . . . .	2551
42.6 Alphabetical List of Reference Pages . . . . .	2551
 <b>XI Geometry Processing</b>	 <b>2561</b>
 <b>43 3D Surface Subdivision Methods</b>	 <b>2563</b>
43.1 Introduction . . . . .	2563
43.2 Subdivision Method . . . . .	2564
43.3 A Quick Example: Catmull-Clark Subdivision . . . . .	2565
43.4 Catmull-Clark Subdivision . . . . .	2566
43.5 Refinement Host . . . . .	2569
43.6 Geometry Policy . . . . .	2570
43.7 The Four Subdivision Methods . . . . .	2572

43.8 Other Subdivision Methods . . . . .	2573
Reference Manual . . . . .	2577
43.9 Classified Reference Pages . . . . .	2577
43.10Alphabetical List of Reference Pages . . . . .	2577
<b>44 Triangulated Surface Mesh Simplification</b>	<b>2591</b>
44.1 Introduction . . . . .	2591
44.2 Overview of the Simplification Process . . . . .	2592
44.3 Cost Strategy . . . . .	2593

## **Part I**

# **General Introduction**

# Chapter 1

## Introduction

*CGAL Editorial Board*

The goal of the CGAL Open Source Project is to provide *easy access to efficient and reliable geometric algorithms* in the form of a C++ library.

The Computational Geometry Algorithms Library offers data structures and algorithms like triangulations, Voronoi diagrams, Boolean operations on polygons and on polyhedra, arrangements of curves, mesh generation, geometry processing, convex hull algorithms, to name just a few.

All these data structures and algorithms operate on geometric objects like points and segments, and perform geometric tests on them. These objects and predicates are regrouped in *CGAL Kernels*.

Finally, the *CGAL Support Library* offers geometric object generators and spatial sorting functions, as well as a matrix search framework and a solver for linear and quadratic programs. It further offers interfaces to third party software such as the GUI libraries Qt, Geomview, and the Boost Graph Library.

### 1.1 Organization of the Manual

This manual is organized in several parts covering the many domains of computational geometry. Each part consists of several chapters, and each chapter is split into a *user manual* and a *reference manual*. The user manual gives the general idea and comes with examples. The reference manual presents the API of the various classes and functions.

The manual has a table of contents, and an index, as well as a package overview, which gives a short paragraph what the package is about, what license it has, and on which other packages it depends. It further provides links to precompiled demo programs for the Windows platform.

### 1.2 Demos and Examples

In the distribution of the library you find the two directories *demo* and *examples*. They contain subdirectories for the CGAL packages. The demos use third party libraries for the graphical user interface. The examples don't have this dependency and most examples are referred to in the user manual.

## 1.3 Hello World

In this section we will take a closer look at three CGAL example programs, all of them computing the 2D convex hull of a set of points.

### 1.3.1 Points in a built-in array

In the first example we have an array of five points. As the convex hull of these points is a subset of the input it is safe to provide an array for storing the result which has the same size.

```
#include <iostream>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/convex_hull_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;

int main()
{
    Point_2 points[5] = { Point_2(0,0), Point_2(10,0), Point_2(10,10), Point_2(6,5), Point_2(4,1) };
    Point_2 result[5];

    Point_2 *ptr = CGAL::convex_hull_2( points, points+5, result );
    std::cout << ptr - result << " points on the convex hull" << std::endl;
    return 0;
}
```

**File:** examples/Convex\_hull\_2/array\_convex\_hull\_2.cpp

All CGAL header files are in the subdirectory “include/CGAL”. All CGAL classes and functions are in the namespace “CGAL”. The geometric primitives, like the point type, are defined in a kernel. CGAL comes with several kernels, and as the convex hull algorithm only makes comparisons of coordinates and orientation tests of input points, we can choose a kernel that provides exact predicates, but no exact geometric construction.

The convex hull function takes three arguments, the start and past-the-end pointer for the input, and the start pointer of the array for the result. The function returns the pointer into the result array just behind the last convex hull point written, so the pointer difference tells us how many points are on the convex hull.

### 1.3.2 Points in a STL vector

In the second example we replace the built-in array by a *std::vector* of the Standard Template Library.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/convex_hull_2.h>

#include <vector>
```

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;
typedef std::vector<Point_2> Points;

int main()
{
    Points points, result;
    points.push_back(Point_2(0,0));
    points.push_back(Point_2(10,0));
    points.push_back(Point_2(10,10));
    points.push_back(Point_2(6,5));
    points.push_back(Point_2(4,1));

    CGAL::convex_hull_2( points.begin(), points.end(), std::back_inserter(result) );
    std::cout << result.size() << " points on the convex hull" << std::endl;
    return 0;
}

```

**File:** examples/Convex\_hull\_2/vector\_convex\_hull\_2.cpp

We put some points in the vector calling the *push\_back()* method of the *std::vector* class.

We then call the convex hull function. The first two arguments, *points.begin()* and *points.end()* are *iterators*, which are a generalization of pointers: they can be dereferenced and incremented. The convex hull function is *generic* in the sense that it takes as input whatever can be dereferenced and incremented.

The third argument is where the result gets written to. In the previous example we provided a pointer to allocated memory. The generalization of such a pointer is the *output iterator*, which allows to increment and assign a value to the dereferenced iterator. In this example we start with an empty vector which grows as needed. Therefore, we cannot simply pass it *result.begin()*, but an output iterator generated by the helper function *std::back\_inserter(result)*. This output iterator does nothing when incremented, and calls *result.push\_back(..)* on the assignment.

### 1.3.3 Points in Streams

The last example program reads a sequence of points from standard input *std::cin* and writes the points on the convex hull to standard output *std::cout*.

Instead of storing the points in a container such as an *std::vector*, and passing the begin/end iterator of the vector to the convex hull function, we use helper classes that turn file pointers into iterators.

```

#include <iostream>
#include <iterator>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/convex_hull_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;

int main()

```

```

{
    std::istream_iterator< Point_2 > input_begin( std::cin );
    std::istream_iterator< Point_2 > input_end;
    std::ostream_iterator< Point_2 > output( std::cout, "\n" );
    CGAL::convex_hull_2( input_begin, input_end, output );
    return 0;
}

```

**File:** examples/Convex\_hull\_2/iostream\_convex\_hull\_2.cpp

In the example code you see input and output stream iterators templated with the point type. A *std::istream\_iterator<Point\_2>* hence allows to traverse a sequence of objects of type *Point\_2*, which come from standard input as we pass *std::cin* to the constructor of the iterator. The variable *input\_end* denotes end-of-file.

A *std::ostream\_iterator<Point\_2>* is an output iterator, that is an iterator to which, when dereferenced, we can assign a value. When such an assignment to the output iterator happens somewhere inside the convex hull function, the iterator just writes the assigned point to standard output, because the iterator was constructed with *std::cout*.

The call to the convex hull function takes three arguments, the input iterator range, and the output iterator to which the result gets written.

If you know the STL, the Standard Template Library, the above makes perfect sense, as this is the way the STL decouples algorithms from containers. If you don't know the STL, you maybe better first familiarize yourself with its basic ideas.

## 1.4 Further Reading

Additional documents accompanying the CGAL distribution are the 'Installation Guide'. We also recommend the standard text books by Josuttis [Jos99], or Austern [Aus98] for the STL and its notion of *concepts* and *models*.

Other resources for CGAL are the tutorials at <http://www.cgal.org/Tutorials/> and the user support page at <http://www.cgal.org/>.

# **Introduction**

# **Reference Manual**

*CGAL Editorial Board*

This chapter contains no Reference Manual pages.

# Chapter 2

## Preliminaries

*CGAL Editorial Board*

This chapter lists the licenses under which the CGAL datastructures and algorithms are distributed, and the third party libraries on which CGAL depends, or for which CGAL provides interfaces. The chapter further explains how to control inlining, thread safety, code deprecation, checking of pre- and postconditions, and how to alter the failure behavior.

### 2.1 License Issues

CGAL is Open Source software, and consists of different parts covered by different licenses. In this section we explain the essence of the different licenses, as well as the rationale why we have chosen them.

The fact that CGAL is Open Source software does not mean that users are free to do whatever they want with the software. Using the software means to accept the license, which has the status of a contract between the user and the owner of the CGAL software. A more detailed description of the license terms is available in the CGAL software tarball.

#### 2.1.1 QPL

The QPL is an Open Source license that obliges you to distribute your software based on QPLed CGAL data structures. The rationale behind this is that we can claim access to your software. The license further obliges you to put your software under an Open Source license as well. The rationale behind is that we can distribute your software, even if this is not your intention. Finally, the QPL requires that, if you modify CGAL, you distribute the modifications in the form of patches and you distribute the sources of your changes as well.

The exact license terms can be found at the Trolltech web site: <http://doc.trolltech.com/4.3/qpl.html>.

#### 2.1.2 LGPL

The LGPL is an Open Source license that obliges you to distribute modifications you make on CGAL software accessible to the users. There is no obligation to make the source code of software you build on top of LGPLed CGAL data structures available.

Currently the linear kernel, the support library, the halfedge data structure, the kinetic data structures, and the mesh subdivision framework are distributed under the LGPL. The rationale behind is that we want to promote them as de facto standards.

The exact license terms can be found at the Free Software Foundation web site: <http://www.gnu.org/copyleft/lesser.html>.

### **2.1.3 Commercial Licenses**

Users who cannot comply to the Open Source license terms can buy individual data structures under various commercial licenses from GeometryFactory: <http://www.geometryfactory.com>.

### **2.1.4 License Compatibility**

The General Public License (GPL) has a viral effect which makes it incompatible with the QPL. For more information, please refer to the paragraph about the QPL on the licenses web page of the Free Software Foundation (FSF): <http://www.fsf.org/licensing/licenses/index.html>. It is therefore not possible to build a program including GPL code and some QPL parts of CGAL. In this case, if you are the copyright owner of the GPL code, you can amend the license by adding an exception allowing the use of CGAL with it (see again the FSF web page).

## **2.2 Third Party Software**

In this section we list the software that is used by the various CGAL packages.

### **2.2.1 Standard Template Library**

CGAL heavily uses the STL, and in particular adopted many of its design ideas. The STL comes with the compiler, but it is possible to use the compiler together with an alternative STL implementation. You can find online documentation for the STL at various web sites, e.g., <http://www.sgi.com/tech/stl/>, <http://www.cplusplus.com/reference/stl/>, or [http://msdn.microsoft.com/en-us/library/1fe2x6kt\(VS.71\).aspx](http://msdn.microsoft.com/en-us/library/1fe2x6kt(VS.71).aspx).

### **2.2.2 Boost**

Boost is a collection of libraries. CGAL needs some of them, that is it is mandatory. If Boost is not already on your system, e.g., on Windows, you can download it from <http://www.boost.org>.

### **2.2.3 Blas**

The BLAS (Basic Linear Algebra Subprograms) are routines that provide standard building blocks for performing basic vector and matrix operations. In CGAL, BLAS is required by the packages Estimation of Local Differential Properties (Page ??) and Approximation of Ridges and Umbilics (Page ??) only.

You can download the official release from <http://www.netlib.org/blas/> or download optimized implementations from <http://www.netlib.org/blas/faq.html#5>. Alternatively, installing TAUCS provides BLAS.

## 2.2.4 Lapack

LAPACK provides routines for solving systems of simultaneous linear equations, least-squares solutions of linear systems of equations, eigenvalue problems, and singular value problems. In CGAL, LAPACK is required by the packages Estimation of Local Differential Properties (Page ??) and Approximation of Ridges and Umbilics (Page ??) only.

You can download the official release from <http://www.netlib.org/lapack/>. Alternatively, installing TAUCS customized for CGAL provides LAPACK.

## 2.2.5 GMP

A library for multi precision integers and rational numbers. CGAL offers adapters for these number types. The usage of the GMP library is optional. If it is not already on your system, e.g., on Windows, you can download it from <http://gmplib.org/> or from the download section of <http://www.cgal.org>.

## 2.2.6 MPFR

A library for multi precision floating point numbers. The usage of the MPFR library is optional, and you must install it when you use GMP. You can download MPFR from <http://www.mpfr.org> or from the download section of <http://www.cgal.org>.

## 2.2.7 Leda

A library of efficient data structures and algorithms. CGAL offers adapters to the LEDA number types. The usage is optional. It is available commercially from <http://www.algorithmic-solutions.com>, and there exists a binary “free edition”.

## 2.2.8 Taucs

TAUCS is a library of sparse linear solvers. In CGAL, it is used to improve the computations within the Planar Parameterization of Triangulated Surface Meshes (Page ??) package only.

The TAUCS web site is <http://www.tau.ac.il/~stoledo/taucs/>.

The latest official version is TAUCS version 2.2, September 4, 2003. Copyright (c) 2001, 2002, 2003 by Sivan Toledo, Tel-Aviv University, [stoledo@tau.ac.il](mailto:stoledo@tau.ac.il). All Rights Reserved.

See <http://www.tau.ac.il/~stoledo/taucs/> for the license and the availability note.

Used by permission of Sivan Toledo.

The CGAL project provides a modified version of TAUCS in the download section of <http://www.cgal.org>. This version fixes some bugs, supports 64-bit platforms and allows a simplified installation process. It also contains a complete LAPACK implementation.

*CAUTION:* Since version 3.3.1, CGAL is no longer compatible with the official release of TAUCS (currently 2.2). Make sure to use the modified version provided in the download section.

## 2.2.9 OpenNL

OpenNL (Open Numerical Library) is a library to easily construct and solve sparse linear systems. It is the default solver of the Surface Mesh Parameterization (Page ??) package.

OpenNL's main page is <http://www.loria.fr/~levy/software/>.

CGAL includes a version of OpenNL in C++, made especially for CGAL by Bruno Lévy.

## 2.2.10 zlib

A data compression library. It is used in the examples of the Surface Mesh Generation (Page ??) package. If it is not already on your system, e.g., on Windows, you can download it from <http://www.gzip.org/zlib>.

## 2.2.11 Qt

Qt is a cross-platform application framework. The usage of Qt is optional, but note that it is used for many CGAL 2D as well as 3D demos.

As Qt is the layer underneath KDE, Qt is installed on many Linux systems. Otherwise you can download it from <http://www.trolltech.com>.

## 2.2.12 libQGLViewer

A 3D widget based on QT 4's *QGLWidget*. It can be downloaded from <http://www.libqglviewer.com/>.

## 2.2.13 Coin

An implementation of Open Inventor. It is used in the demo of the Kinetic Data Structures (Page ??) package. You can download it from <http://www.coin3d.org>.

## 2.3 Marking of Advanced Features

In this manual you will encounter sections marked as follows.

————— *advanced* —————

Some functionality is considered more advanced. Such functionality is described in sections such as this one that are bounded by horizontal brackets.

————— *advanced* —————

## 2.4 Namespace CGAL

All names introduced by CGAL, especially those documented in these manuals, are in a namespace called *CGAL*, which is in global scope. A user can either qualify names from CGAL by adding *CGAL::*, e.g., *CGAL::Point\_2* < *CGAL::Homogeneous* < *int* > >, make a single name from CGAL visible in a scope via a *using* statement, e.g., *using CGAL::Cartesian*;; and then use this name unqualified in this scope, or even make all names from namespace *CGAL* visible in a scope with *using namespace CGAL*;;. The latter, however, is likely to give raise to name conflicts and is therefore not recommended.

## 2.5 Inclusion Order of Header Files

Not all compilers fully support standard header names. CGAL provides workarounds for these problems in *CGAL/basic.h*. Consequently, as a golden rule, you should always include *CGAL/basic.h* first in your programs (or *CGAL/Cartesian.h*, or *CGAL/Homogeneous.h*, since they include *CGAL/basic.h* first).

## 2.6 Compile-time Flags to Control Inlining

Making functions inlined can, at times, improve the efficiency of your code. However this is not always the case and it can differ for a single function depending on the application in which it is used. Thus CGAL defines a set of compile-time macros that can be used to control whether certain functions are designated as inlined functions or not. The following table lists the macros and their default values, which are set in one of the CGAL include files.

macro name	default
<i>CGAL_KERNEL_INLINE</i>	inline
<i>CGAL_KERNEL_MEDIUM_INLINE</i>	
<i>CGAL_KERNEL_LARGE_INLINE</i>	
<i>CGAL_MEDIUM_INLINE</i>	inline
<i>CGAL_LARGE_INLINE</i>	
<i>CGAL_HUGE_INLINE</i>	

If you wish to change the value of one or more of these macros, you can simply give it a new value when compiling. For example, to make functions that use the macro *CGAL\_KERNEL\_MEDIUM\_INLINE* inline functions, you should set the value of this macro to *inline* instead of the default blank.

## 2.7 Identifying the Version of CGAL

*#include <CGAL/version.h>*

Every release of CGAL defines the following preprocessor macros:

**CGAL\_VERSION** – a textual description of the current release (e.g., or 3.3 or 3.2.1 or 3.2.1-I-15), and

**CGAL\_VERSION\_NR** – a numerical description of the current release such that more recent releases have higher number.

More precisely, it is defined as *1MMmmbi*, where *MM* is the major release number (e.g. 03), *mm* is the minor release number (e.g. 02), *b* is the bug-fix release number (e.g. 0), and *iiii* is the internal release

number (e.g. 0001). For public releases, the latter is defined as 1000. Examples: for the public release 3.2.4 this number is 1030241000; for internal release 3.2-I-1, it is 1030200001. Note that this scheme was modified around 3.2-I-30.

**CGAL\_VERSION\_NUMBER (M,m,b)** – a function macro computing the version number macro from the M.m.b release version. Note that the internal release number is dropped here. Example: `CGAL_VERSION_NUMBER(3,2,4)` is equal to 1030241000.

## 2.8 Thread Safety

CGAL is progressively being made thread-safe. The guidelines which are followed are:

- it should be possible to use different objects in different threads at the same time (of the same type or not),
- it is not safe to access the same object from different threads at the same time, unless otherwise specified in the class documentation.

If the macro `CGAL_HAS_THREADS` is not defined, then CGAL assumes it can use any thread-unsafe code (such as static variables). By default, this macro is not defined, unless `BOOST_HAS_THREADS` or `_OPENMP` is defined. It is possible to force its definition on the command line, and it is possible to prevent its default definition by setting `CGAL_HAS_NO_THREADS` from the command line.

## 2.9 Code Deprecation

Sometimes, the CGAL project decides that a feature is deprecated. This means that it still works in the current release, but it will be removed in the next, or a subsequent release. This can happen when we have found a better way to do something, and we would like to reduce the maintenance cost of CGAL at some point in the future. There is a trade-off between maintaining backward compatibility and implementing new features more easily.

In order to help users manage the changes to apply to their code, we attempt to make CGAL code emit warnings when deprecated code is used. This can be done using some compiler specific features. Those warnings can be disabled by defining the macro `CGAL_NO_DEPRECATED_WARNINGS`. On top of this, we also provide a macro, `CGAL_NO_DEPRECATED_CODE`, which, when defined, disables all deprecated features. This allows users to easily test if their code relies on deprecated features.

## 2.10 Checks

Much of the CGAL code contains checks. For example, all checks used in the kernel code are prefixed by `CGAL_KERNEL`. Other packages have their own prefixes, as documented in the corresponding chapters. Some are there to check if the kernel behaves correctly, others are there to check if the user calls kernel routines in an acceptable manner.

There are four types of checks. The first three are errors and lead to a halt of the program if they fail. The last only leads to a warning.

**Preconditions** check if the caller of a routine has called it in a proper fashion. If such a check fails it is the responsibility of the caller (usually the user of the library).

**Postconditions** check if a routine does what it promises to do. If such a check fails it is the fault of this routine, so of the library.

**Assertions** are other checks that do not fit in the above two categories.

**Warnings** are checks for which it is not so severe if they fail.

By default, all of these checks are performed. It is however possible to turn them off through the use of compile time switches. For example, for the checks in the kernel code, these switches are the following: *CGAL\_KERNEL\_NO\_PRECONDITIONS*, *CGAL\_KERNEL\_NO\_POSTCONDITIONS*, *CGAL\_KERNEL\_NO\_ASSERTIONS* and *CGAL\_KERNEL\_NO\_WARNINGS*. So, in order to compile the file `foo.cpp` with the postcondition checks off, you can do:

```
CC -DCGAL_KERNEL_NO_POSTCONDITIONS foo.cpp
```

This is also preferably done by modifying your makefile by adding *-DCGAL\_KERNEL\_NO\_POSTCONDITIONS* to the *CXXFLAGS* variable.

The name *KERNEL* in the macro name can be replaced by a package specific name in order to control assertions done in a given package. This name is given in the documentation of the corresponding package, in case it exists.

Note that global macros can also be used to control the behavior over the whole CGAL library:

- *CGAL\_NO\_PRECONDITIONS*,
- *CGAL\_NO\_POSTCONDITIONS*,
- *CGAL\_NO\_ASSERTIONS*,
- *CGAL\_NO\_WARNINGS* and
- *CGAL\_NDEBUG*.

Setting the macro *CGAL\_NDEBUG* disables all checks. Note that the standard flag *NDEBUG* sets *CGAL\_NDEBUG*, but it also affects the standard *assert* macro. This way, adding *-DCGAL\_NDEBUG* to your compilation flags removes absolutely all checks. This is the default recommended setup for performing timing benchmarks for example.

Not all checks are on by default. All four types of checks can be marked as expensive or exactness checks (or both). These checks need to be turned on explicitly by supplying one or both of the compile time switches *CGAL\_KERNEL\_CHECK\_EXPENSIVE* and *CGAL\_KERNEL\_CHECK\_EXACTNESS*.

Expensive checks are, as the word says, checks that take a considerable time to compute. Considerable is an imprecise phrase. Checks that add less than 10 percent to the execution time of the routine they are in are not expensive. Checks that can double the execution time are. Somewhere in between lies the border line. Checks that increase the asymptotic running time of an algorithm are always considered expensive. Exactness checks are checks that rely on exact arithmetic. For example, if the intersection of two lines is computed, the postcondition of this routine may state that the intersection point lies on both lines. However, if the computation is done with doubles as number type, this may not be the case, due to round off errors. So, exactness checks should only be turned on if the computation is done with some exact number type.

### 2.10.1 Altering the Failure Behavior

As stated above, if a postcondition, precondition or assertion is violated, an exception is thrown, and if nothing is done to catch it, the program will abort. This behavior can be changed by means of the following function.

```
#include <CGAL/assertions_behaviour.h>

Failure_behaviour set_error_behaviour( Failure_behaviour eb)
```

The parameter should have one of the following values.

```
enum Failure_behaviour { ABORT, EXIT, EXIT_WITH_SUCCESS, CONTINUE, THROW_EXCEPTION};
```

The *THROW\_EXCEPTION* value is the default, which throws an exception.

If the *EXIT* value is set, the program will stop and return a value indicating failure, but not dump the core. The *CONTINUE* value tells the checks to go on after diagnosing the error. Note that since CGAL 3.4, *CONTINUE* has the same effect as *THROW\_EXCEPTION* for errors (but it keeps its meaning for warnings), it is not possible anymore to let assertion failures simply continue (except by totally disabling them).

————— *advanced* —————

If the *EXIT\_WITH\_SUCCESS* value is set, the program will stop and return a value corresponding to successful execution and not dump the core.

————— *advanced* —————

The value that is returned by *set\_error\_behaviour* is the value that was in use before.

For warnings there is a separate routine, which works in the same way. The only difference is that for warnings the default value is *CONTINUE*.

```
Failure_behaviour set_warning_behaviour( Failure_behaviour eb)
```

### 2.10.2 Control at a Finer Granularity

The compile time flags as described up to now all operate on the whole library. Sometimes you may want to have a finer control. CGAL offers the possibility to turn checks on and off with a bit finer granularity, namely the module in which the routines are defined. The name of the module is to be appended directly after the CGAL prefix. So, the flag *CGAL\_KERNEL\_NO\_ASSERTIONS* switches off assertions in the kernel only, the flag *CGAL\_CH\_CHECK\_EXPENSIVE* turns on expensive checks in the convex hull module. The name of a particular module is documented with that module.

————— *advanced* —————

### 2.10.3 Customizing how Errors are Reported

Normally, error messages are written to the standard error output. It is possible to do something different with them. To that end you can register your own handler. This function should be declared as follows.

```

void                my_failure_function(
                    const char *type,
                    const char *expression,
                    const char *file,
                    int line,
                    const char *explanation)

```

Your failure function will be called with the following parameters. *type* is a string that contains one of the words precondition, postcondition, assertion or warning. The parameter *expression* contains the expression that was violated. *file* and *line* contain the place where the check was made. The *explanation* parameter contains an explanation of what was checked. It can be *NULL*, in which case the *expression* is thought to be descriptive enough.

There are several things that you can do with your own handler. You can display a diagnostic message in a different way, for instance in a pop up window or to a log file (or a combination). You can also implement a different policy on what to do after an error. For instance, you can throw an exception or ask the user in a dialog whether to abort or to continue. If you do this, it is best to set the error behavior to *CONTINUE*, so that it does not interfere with your policy.

You can register two handlers, one for warnings and one for errors. Of course, you can use the same function for both if you want. When you set a handler, the previous handler is returned, so you can restore it if you want.

```

#include <CGAL/assertions.h>
Failure_function    set_error_handler( Failure_function handler)
Failure_function    set_warning_handler( Failure_function handler)

```

## Example

```

#include <CGAL/assertions.h>

void my_failure_handler(
    const char *type,
    const char *expr,
    const char* file,
    int line,
    const char* msg)
{
    /* report the error in some way. */
}

void foo()
{
    CGAL::Failure_function prev;
    prev = CGAL::set_error_handler(my_failure_handler);
    /* call some routines. */
    CGAL::set_error_handler(prev);
}

```

### 3.1 Introduction

CGAL is targeting towards exact computation with non-linear objects, in particular objects defined on algebraic curves and surfaces. As a consequence types representing polynomials, algebraic extensions and finite fields play a more important role in related implementations. This package has been introduced to stay abreast of these changes. Since in particular polynomials must be supported by the introduced framework the package avoids the term *number type*. Instead the package distinguishes between the *algebraic structure* of a type and whether a type is embeddable on the real axis, or *real embeddable* for short. Moreover, the package introduces the notion of *interoperable* types which allows an explicit handling of mixed operations.

### 3.2 Algebraic Structures

The algebraic structure concepts introduced within this section are motivated by their well known counterparts in traditional algebra, but we also had to pay tribute to existing types and their restrictions. To keep the interface

minimal, it was not desirable to cover all known algebraic structures, e.g., we did not introduce concepts for such basic structures as *groups* or exceptional structures as *skew fields*.

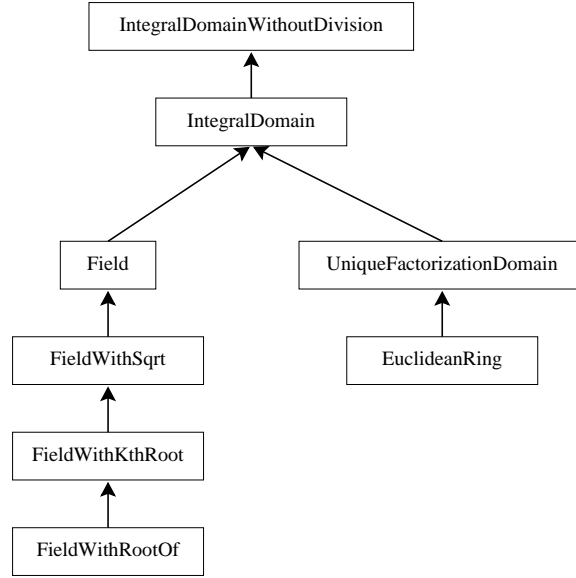

Figure 3.1: Concept Hierarchy of Algebraic Structures

Figure 3.1 shows the refinement relationship of the algebraic structure concepts. *IntegralDomain*, *UniqueFactorizationDomain*, *EuclideanRing* and *Field* correspond to the algebraic structures with the same name. *FieldWithSqrt*, *FieldWithKthRoot* and *FieldWithRootOf* are fields that in addition are closed under the operations 'sqrt', 'k-th root' and 'real root of a polynomial', respectively. The concept *IntegralDomainWithoutDivision* also corresponds to integral domains in the algebraic sense, the distinction results from the fact that some implementations of integral domains lack the (algebraically always well defined) integral division. Note that *Field* refines *IntegralDomain*. This is because most ring-theoretic notions like greatest common divisors become trivial for *Fields*. Hence we see *Field* as a refinement of *IntegralDomain* and not as a refinement of one of the more advanced ring concepts. If an algorithm wants to rely on gcd or remainder computation, it is trying to do things it should not do with a *Field* in the first place.

The main properties of an algebraic structure are collected in the class *Algebraic\_structure\_traits*. In particular the (most refined) concept each concrete model *AS* fulfills is encoded in the tag *Algebraic\_structure\_traits<AS>::Algebraic\_category*. An algebraic structure is at least *Assignable*, *CopyConstructible*, *DefaultConstructible* and *EqualityComparable*. Moreover, we require that it is constructible from *int*. For ease of use and since their semantic is sufficiently standard to presume their existence, the usual arithmetic and comparison operators are required to be realized via C++ operator overloading. The division operator is reserved for division in fields. All other unary (e.g., sqrt) and binary functions (e.g., gcd, div) must be models of the well known STL-concepts *AdaptableUnaryFunction* or *AdaptableBinaryFunction* concept and local to the traits class (e.g., *Algebraic\_structure\_traits<AS>::Sqrt()(x)*). This design allows us to profit from all parts in the STL and its programming style and avoids the name-lookup and two-pass template compilation problems experienced with the old design using overloaded functions. However, for ease of use and backward compatibility all functionality is also accessible through global functions defined within namespace *CGAL*, e.g., *CGAL::sqrt(x)*. This is realized via function templates using the according functor of the traits class. For an overview see Section 3.7 in the reference manual.

### 3.2.1 Tags in Algebraic Structure Traits

#### Algebraic Category

For a type *AS*, *Algebraic\_structure\_traits*<*AS*> provides several tags. The most important tag is the *Algebraic\_category* tag, which indicates the most refined algebraic concept the type *AS* fulfills. The tag is one of; *Integral\_domain\_without\_division\_tag*, *Integral\_domain\_tag*, *Field\_tag*, *Field\_with\_sqrt\_tag*, *Field\_with\_kth\_root\_tag*, *Field\_with\_root\_of\_tag*, *Unique\_factorization\_domain\_tag*, *Euclidean\_ring\_tag*, or even *Null\_tag* in case the type is not a model of an algebraic structure concept. The tags are derived from each other such that they reflect the hierarchy of the algebraic structure concept, e.g., *Field\_with\_sqrt\_tag* is derived from *Field\_tag*.

#### Exact and Numerical Sensitive

Moreover, *Algebraic\_structure\_traits*<*AS*> provides the tags *Is\_exact* and *Is\_numerical\_sensitive*, which are both *Boolean\_tags*.

An algebraic structure is considered *exact*, if all operations required by its concept are computed such that a comparison of two algebraic expressions is always correct.

An algebraic structure is considered as *numerically sensitive*, if the performance of the type is sensitive to the condition number of an algorithm. Note that there is really a difference among these two notions, e.g., the fundamental type *int* is not numerical sensitive but considered inexact due to overflow. Conversely, types as *leda\_real* or *CORE::Expr* are exact but sensitive to numerical issues due to the internal use of multi precision floating point arithmetic. We expect that *Is\_numerical\_sensitive* is used for dispatching of algorithms, while *Is\_exact* is useful to enable assertions that can be check for exact types only.

Tags are very useful to dispatch between alternative implementations. The following example illustrates a dispatch for *Fields* using overloaded functions. The example only needs two overloads since the algebraic category tags reflect the algebraic structure hierarchy.

```
#include <CGAL/basic.h>
#include <CGAL/IO/io.h>
#include <CGAL/Algebraic_structure_traits.h>

template< typename NT > NT unit_part(const NT& x);
template< typename NT >
NT unit_part(const NT& x, CGAL::Field_tag);
template< typename NT >
NT unit_part(const NT& x, CGAL::Integral_domain_without_division_tag);

template< typename NT >
NT unit_part(const NT& x){
    // the unit part of 0 is defined as 1.
    if (x == 0 ) return NT(1);

    typedef CGAL::Algebraic_structure_traits<NT> AST;
    typedef typename AST::Algebraic_category Algebraic_category;
    return unit_part_(x,Algebraic_category());
}

template< typename NT >
NT unit_part(const NT& x, CGAL::Integral_domain_without_division_tag){
```

```

    // For many other types the only units are just -1 and +1.
    return NT(int(CGAL::sign(x)));
}

template< typename NT >
NT unit_part_(const NT& x, CGAL::Field_tag){
    // For Fields every x != 0 is a unit.
    // Therefore, every x != 0 is its own unit part.
    return x;
}

int main(){
    // Function call for a model of EuclideanRing, i.e. int.
    std::cout<< "int:    unit_part(-3 ) : " << unit_part(-3 ) << std::endl;
    // Function call for a model of FieldWithSqrt, i.e. double
    std::cout<< "double: unit_part(-3.0): " << unit_part(-3.0) << std::endl;
    return 0;
}

// Note that this is just an example
// This implementation for unit part won't work for some types, e.g.,
// types that are not RealEmbeddable or types representing structures that have
// more units than just -1 and +1. (e.g. MP_Float representing  $\mathbb{Z}[1/2]$ )
// From there Algebraic_structure_traits provides the functor Unit_part.

```

**File:** examples/Algebraic\_foundations/algebraic\_structure\_dispatch.cpp

### 3.3 Real Embeddable

Most number types represent some subset of the real numbers. From those types we expect functionality to compute the sign, absolute value or double approximations. In particular we can expect an order on such a type that reflects the order along the real axis. All these properties are gathered in the concept *RealComparable*. The concept is orthogonal to the algebraic structure concepts, i.e., it is possible that a type is a model of *RealEmbeddable* only, since the type may just represent values on the real axis but does not provide any arithmetic operations.

As for algebraic structures this concept is also traits class oriented. The main functionality related to *RealEmbeddable* is gathered in the class *Real\_embeddable\_traits*. In particular, it provides the boolean tag *Is\_real\_embeddable* indicating whether a type is a model of *RealEmbeddable*. The comparison operators are required to be realized via C++ operator overloading. All unary functions (e.g. *sign*, *to\_double*) and binary functions (e.g. *compare*) are models of the STL-concepts *AdaptableUnaryFunction* and *AdaptableBinaryFunction* and are local to *Real\_embeddable\_traits*.

In case a type is a model of *IntegralDomainWithoutDivision* and *RealEmbeddable* the number represented by an object of this type is the same for arithmetic and comparison. It follows that the ring represented by this type is a superset of the integers and a subset of the real numbers and hence has characteristic zero. In case the type is a model of *Field* and *RealEmbeddable* it is a superset of the rational numbers.

## 3.4 Real Number Types

Every CGAL *Kernel* comes with two *real number types* (number types embeddable into the real numbers). One of them is a *FieldNumberType*, and the other a *RingNumberType*. The coordinates of the basic kernel objects (points, vectors, etc.) come from one of these types (the *FieldNumberType* in case of Cartesian kernels, and the *RingNumberType* for Homogeneous kernels).

The concept *FieldNumberType* combines the requirements of the concepts *Field* and *RealEmbeddable*, while *RingNumberType* combines *IntegralDomainWithoutDivision* and *RealEmbeddable*. Algebraically, the real number types do not form distinct structures and are therefore not listed in the concept hierarchy of Figure 3.1.

## 3.5 Interoperability

This section introduces two concepts for interoperability of types, namely *ImplicitInteroperable* and *ExplicitInteroperable*. While *ExplicitInteroperable* is the base concept, we start with *ImplicitInteroperable* since it is the more intuitive one.

In general mixed operations are provided by overloaded operators and functions or just via implicit constructor calls. This level of interoperability is reflected by the concept *ImplicitInteroperable*. However, within template code the result type, or so called coercion type, of an mixed arithmetic operation may be unclear. Therefore, the package introduces *CGAL::Coercion\_traits* giving access to the coercion type via *CGAL::Coercion\_traits<A,B>::Type* for two interoperable types *A* and *B*.

Some trivial example are *int* and *double* with coercion type *double* or *CGAL::Gmpz* and *CGAL::Gmpq* with coercion type *CGAL::Gmpq*. However, the coercion type is not necessarily one of the input types, e.g. the coercion type of a polynomial with integer coefficients that is multiplied by a rational type is supposed to be a polynomial with rational coefficients.

*CGAL::Coercion\_traits* is also required to provide a functor *CGAL::Coercion\_traits<A,B>::Cast()*, that converts from an input type into the coercion type. This is in fact the core of the more basic concept *ExplicitInteroperable*. *ExplicitInteroperable* has been introduced to cover more complex cases for which it is hard or impossible to guarantee implicit interoperability. Note that this functor can be useful for *ImplicitInteroperable* types as well, since it can be used to void redundant type conversions.

In case two types *A* and *B* are *ExplicitInteroperable* with coercion type *C* they are valid argument types for all binary functors provided by *Algebraic\_structure\_traits* and *Real\_embeddable\_traits* of *C*. This is also true for the according global functions.

### 3.5.1 Examples

The following example illustrates how two write code for *ExplicitInteroperable* types.

```
#include <CGAL/basic.h>
#include <CGAL/Coercion_traits.h>
#include <CGAL/IO/io.h>

// this is an implementation for ExplicitInteroperable types
// the result type is determined via Coercion_traits<A,B>
template <typename A, typename B>
```

```

typename CGAL::Coercion_traits<A,B>::Type
binary_func(const A& a , const B& b){
    typedef CGAL::Coercion_traits<A,B> CT;

    // check for explicit interoperability
    BOOST_STATIC_ASSERT((CT::Are_explicit_interoperable::value));

    // CT::Cast is used to to convert both types into the coercion type
    typename CT::Cast cast;
    // all operations are performed in the coercion type
    return cast(a)*cast(b);
}

int main(){
    // Function call for the interoperable types
    std::cout<< binary_func(double(3), int(5)) << std::endl;
    // Note that Coercion_traits is symmetric
    std::cout<< binary_func(int(3), double(5)) << std::endl;
    return 0;
}

```

**File:** examples/Algebraic\_foundations/interoperable.cpp

The following example illustrates a dispatch for *ImplicitInteroperable* and *ExplicitInteroperable* types. The binary function (that just multiplies its two arguments) is supposed to take two *ExplicitInteroperable* arguments. For *ImplicitInteroperable* types a variant that avoids the explicit cast is selected.

```

#include <CGAL/basic.h>
#include <CGAL/Coercion_traits.h>
#include <CGAL/Quotient.h>
#include <CGAL/Sqrt_extension.h>
#include <CGAL/IO/io.h>

// this is the implementation for ExplicitInteroperable types
template <typename A, typename B>
typename CGAL::Coercion_traits<A,B>::Type
binary_function_(const A& a , const B& b, CGAL::Tag_false){
    std::cout << "Call for ExplicitInteroperable types: " << std::endl;
    typedef CGAL::Coercion_traits<A,B> CT;
    typename CT::Cast cast;
    return cast(a)*cast(b);
}

// this is the implementation for ImplicitInteroperable types
template <typename A, typename B>
typename CGAL::Coercion_traits<A,B>::Type
binary_function_(const A& a , const B& b, CGAL::Tag_true){
    std::cout << "Call for ImplicitInteroperable types: " << std::endl;
    return a*b;
}

// this function selects the correct implementation

```

```

typename CGAL::Coercion_traits<A,B>::Type
binary_func(const A& a , const B& b){
    typedef CGAL::Coercion_traits<A,B> CT;
    typedef typename CT::Are_implicit_interoperable Are_implicit_interoperable;
    return binary_function_(a,b,Are_implicit_interoperable());
}

int main(){
    CGAL::set_pretty_mode(std::cout);

    // Function call for ImplicitInteroperable types
    std::cout<< binary_func(double(3), int(5)) << std::endl;

    // Function call for ExplicitInteroperable types
    CGAL::Quotient<int>          rational(1,3);    // == 1/3
    CGAL::Sqrt_extension<int,int> extension(1,2,3); // == 1+2*sqrt(3)
    CGAL::Sqrt_extension<CGAL::Quotient<int>,int> result = binary_func(rational, extension);
    std::cout<< result << std::endl;

    return 0;
}

```

## 3.6 Fractions

Beyond the need for performing algebraic operations on objects as a whole, there are also number types which one would like to decompose into numerator and denominator. This does not only hold for rational numbers as *Quotient*, *Gmpq*, *mpq\_class* or *leda\_rational*, but also for compound objects as *Sqrt\_extension* or *Polynomial* which may decompose into a (scalar) denominator and a compound numerator with a simpler coefficient type (e.g. integer instead of rational). Often operations can be performed faster on these denominator-free multiples. In case a type is a *Fraction* the relevant functionality as well as the numerator and denominator type are provided by *CGAL::Fraction\_traits*. In particular *CGAL::Fraction\_traits* provides a tag *Is\_fraction* that can be used for dispatching.

A related class is *CGAL::Rational\_traits* which has been kept for backward compatibility reasons. However, we recommend to use *Fraction\_traits* since it is more general and offers dispatching functionality.

### 3.6.1 Examples

The following example show a simple use of *Fraction\_traits*:

```

#include <CGAL/basic.h>
#include <CGAL/Fraction_traits.h>
#include <CGAL/IO/io.h>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
#include <CGAL/Gmpq.h>

```

```

int main(){
    typedef CGAL::Fraction_traits<CGAL::Gmpq> FT;
    typedef FT::Numerator_type Numerator_type;
    typedef FT::Denominator_type Denominator_type;

    BOOST_STATIC_ASSERT((boost::is_same<Numerator_type,CGAL::Gmpq>::value));
    BOOST_STATIC_ASSERT((boost::is_same<Denominator_type,CGAL::Gmpz>::value));

    Numerator_type numerator;
    Denominator_type denominator;
    CGAL::Gmpq fraction(4,5);
    FT::Decompose()(fraction,numerator,denominator);

    CGAL::set_pretty_mode(std::cout);
    std::cout << "decompose fraction: "<< std::endl;
    std::cout << "fraction    : " << fraction << std::endl;
    std::cout << "numerator   : " << numerator<< std::endl;
    std::cout << "denominator: " << denominator << std::endl;

    std::cout << "re-compose fraction: "<< std::endl;
    fraction = FT::Compose()(numerator,denominator);
    std::cout << "fraction    : " << fraction << std::endl;
}
#else
int main(){ std::cout << "This examples needs GMP" << std::endl; }
#endif

```

**File:** examples/Algebraic\_foundations/fraction\_traits.cpp

The following example illustrates the integralization of a vector, i.e., the coefficient vector of a polynomial. Note that for minimizing coefficient growth *Fraction\_traits<Type>::Common\_factor* is used to compute the 'least' common multiple of the denominators.

```

#include <CGAL/basic.h>
#include <CGAL/Fraction_traits.h>
#include <CGAL/IO/io.h>
#include <vector>

template <class Fraction>
std::vector<typename CGAL::Fraction_traits<Fraction>::Numerator_type >
integralize(
    const std::vector<Fraction>& vec,
    typename CGAL::Fraction_traits<Fraction>::Denominator_type& d
) {
    typedef CGAL::Fraction_traits<Fraction> FT;
    typedef typename FT::Numerator_type Numerator_type;
    typedef typename FT::Denominator_type Denominator_type;
    typename FT::Decompose decompose;

    std::vector<Numerator_type> num(vec.size());
    std::vector<Denominator_type> den(vec.size());

    // decompose each coefficient into integral part and denominator

```

```

    for (unsigned int i = 0; i < vec.size(); i++) {
        decompose(vec[i], num[i], den[i]);
    }

    // compute 'least' common multiple of all denominator
    // We would like to use gcd, so let's think of Common_factor as gcd.
    typename FT::Common_factor gcd;
    d = 1;
    for (unsigned int i = 0; i < vec.size(); i++) {
        d *= CGAL::integral_division(den[i], gcd(d, den[i]));
    }

    // expand each (numerator, denominator) pair to common denominator
    for (unsigned int i = 0; i < vec.size(); i++) {
        // For simplicity ImplicitInteroperability is expected in this example
        num[i] *= CGAL::integral_division(d, den[i]);
    }
    return num;
}

#ifdef CGAL_USE_GMP

#include <CGAL/Gmpz.h>
#include <CGAL/Gmpq.h>

int main(){
    std::vector<CGAL::Gmpq> vec(3);
    vec[0]=CGAL::Gmpq(1,4);
    vec[1]=CGAL::Gmpq(1,6);
    vec[2]=CGAL::Gmpq(1,10);
    std::cout<< "compute an integralized vector" << std::endl;
    std::cout<<"input vector:  ["
        << vec[0] << "," << vec[1] << "," << vec[2] << "]" << std::endl;
    CGAL::Gmpz d;
    std::vector<CGAL::Gmpz> integral_vec = integralize(vec,d);
    std::cout<<"output vector: ["
        << integral_vec[0] << ","
        << integral_vec[1] << ","
        << integral_vec[2] << "]" << std::endl;
    std::cout<<"denominator  : "<< d <<std::endl;
}
#else
int main(){ std::cout << "This examples needs GMP" << std::endl; }
#endif

```

## FromIntConstructible

### Definition

A model of the concept *FromIntConstructible* is required to be constructible from `int`.

### Creation

```
FromIntConstructible type( int& i);
```

### Has Models

*int*

*long*

*double*

## FromDoubleConstructible

### Definition

A model of the concept *FromDoubleConstructible* is required to be constructible from the type *double*.

In case the type is a model of *RealEmbeddable* too, for any double *d* the identity:  $d == \text{CGAL}::\text{to\_double}(T(d))$ , is guaranteed.

### Creation

*FromDoubleConstructible* *type*( *double d*);      conversion constructor from double.

## ExplicitInteroperable

### Definition

Two types  $A$  and  $B$  are a model of the *ExplicitInteroperable* concept, if it is possible to derive a superior type for  $A$  and  $B$ , such that both types are embeddable into this type. This type is *Coercion\_traits* $\langle A, B \rangle :: \text{Type}$ .

In this case *Coercion\_traits* $\langle A, B \rangle :: \text{Are\_explicit\_interoperable}$  is *Tag\_true*.

$A$  and  $B$  are valid argument types for all binary functors in *Algebraic\_structure\_traits* $\langle \text{Type} \rangle$  and *Real\_embeddable\_traits* $\langle \text{Type} \rangle$ . This is also the case for the respective global functions.

### See Also

# ImplicitInteroperable

## Definition

Two types  $A$  and  $B$  are a model of the concept *ImplicitInteroperable*, if there is a superior type, such that binary arithmetic operations involving  $A$  and  $B$  result in this type. This type is *Coercion\_traits* $\langle A, B \rangle :: \text{Type}$ .

The type *Coercion\_traits* $\langle A, B \rangle :: \text{Type}$  is required to be implicit constructible from  $A$  and  $B$ .

In this case *Coercion\_traits* $\langle A, B \rangle :: \text{Are\_implicit\_interoperable}$  is *Tag\_true*.

## Refines

*ExplicitInteroperable*

## CGAL::Coercion\_traits<A,B>

### Definition

An instance of *Coercion\_traits*<A,B> reflects the type coercion of the types A and B, it is symmetric in the two template arguments.

```
#include <CGAL/Coercion_traits.h>
```

### Types

*Coercion\_traits*<A,B>:: *Are\_explicit\_interoperable*

Tag indicating whether the two types A and B are a model of *ExplicitInteroperable*  
This is either *CGAL::Tag\_true* or *CGAL::Tag\_false*.

*Coercion\_traits*<A,B>:: *Are\_implicit\_interoperable*

Tag indicating whether the two types A and B are a model of *ImplicitInteroperable*  
This is either *CGAL::Tag\_true* or *CGAL::Tag\_false*.

*Coercion\_traits*<A,B>:: *Type*

The coercion type of A and B.  
In case A and B are not *ExplicitInteroperable* this is undefined.

*Coercion\_traits*<A,B>:: *Cast*

A model of the *AdaptableFunctor* concept, providing the conversion of A or B to *Type*.  
In case A and B are not *ExplicitInteroperable* this is undefined.

# IntegralDomainWithoutDivision

## Definition

This is the most basic concept for algebraic structures considered within CGAL.

A model *IntegralDomainWithoutDivision* represents an integral domain, i.e. commutative ring with 0, 1, +, \* and unity free of zero divisors.

**Note:** A model is not required to offer the always well defined integral division.

It refines *Assignable*, *CopyConstructible*, *DefaultConstructible* and *FromIntConstructible*.

It refines *EqualityComparable*, where equality is defined w.r.t. the ring element being represented.

The operators unary and binary plus +, unary and binary minus -, multiplication \* and their compound forms +=, -=, \*= are required and implement the respective ring operations.

Moreover, *CGAL::Algebraic\_structure\_traits< IntegralDomainWithoutDivision >* is a model of *AlgebraicStructureTraits* providing:

- *CGAL::Algebraic\_structure\_traits< IntegralDomainWithoutDivision >::Algebraic\_type* derived from *Integral\_domain\_without\_division\_tag*
- *CGAL::Algebraic\_structure\_traits< IntegralDomainWithoutDivision >::Is\_zero*
- *CGAL::Algebraic\_structure\_traits< IntegralDomainWithoutDivision >::Is\_one*
- *CGAL::Algebraic\_structure\_traits< IntegralDomainWithoutDivision >::Square*
- *CGAL::Algebraic\_structure\_traits< IntegralDomainWithoutDivision >::Simplify*
- *CGAL::Algebraic\_structure\_traits< IntegralDomainWithoutDivision >::Unit\_part*

## Refines

*Assignable*

*CopyConstructible*

*DefaultConstructible*

*EqualityComparable*

*FromIntConstructible*

## Operations

*IntegralDomainWithoutDivision*

$+a$                       unary plus

*IntegralDomainWithoutDivision*

$-a$                       unary minus

*IntegralDomainWithoutDivision*

$a + b$

*IntegralDomainWithoutDivision*

$a - b$

*IntegralDomainWithoutDivision*

$$a * b$$

*IntegralDomainWithoutDivision*

$$a + = b$$

*IntegralDomainWithoutDivision*

$$a - = b$$

*IntegralDomainWithoutDivision*

$$a * = b$$

Equality comparable:

*result\_type*                     $a == b$

The *result\_type* is convertible to *bool*.

*result\_type*                     $a != b$

The *result\_type* is convertible to *bool*.

# IntegralDomain

## Definition

*IntegralDomain* refines *IntegralDomainWithoutDivision* by providing an integral division.

**Note:** The concept does not require the operator / for this operation. We intend to reserve the operator syntax for use with a *Field*.

Moreover, *CGAL::Algebraic\_structure\_traits*< *IntegralDomain* > is a model of *AlgebraicStructureTraits* providing:

- *CGAL::Algebraic\_structure\_traits*< *IntegralDomain* >::*Algebraic\_type* derived from *Integral\_domain\_tag*
- *CGAL::Algebraic\_structure\_traits*< *IntegralDomain* >::*Integral\_division*
- *CGAL::Algebraic\_structure\_traits*< *IntegralDomain* >::*Divides*

# UniqueFactorizationDomain

## Definition

A model of *UniqueFactorizationDomain* is an *IntegralDomain* with the additional property that the ring it represents is a unique factorization domain (a.k.a. UFD or factorial ring), meaning that every non-zero non-unit element has a factorization into irreducible elements that is unique up to order and up to multiplication by invertible elements (units). (An irreducible element is a non-unit ring element that cannot be factored further into two non-unit elements. In a UFD, the irreducible elements are precisely the prime elements.)

In a UFD, any two elements, not both zero, possess a greatest common divisor (gcd).

Moreover, *CGAL::Algebraic\_structure\_traits< UniqueFactorizationDomain >* is a model of *AlgebraicStructureTraits* providing:

- *CGAL::Algebraic\_structure\_traits< UniqueFactorizationDomain >::Algebraic\_type* derived from *Unique\_factorization\_domain\_tag*
- *CGAL::Algebraic\_structure\_traits< UniqueFactorizationDomain >::Gcd*

## Refines

# EuclideanRing

## Definition

A model of *EuclideanRing* represents an euclidean ring (or Euclidean domain). It is an *UniqueFactorizationDomain* that affords a suitable notion of minimality of remainders such that given  $x$  and  $y \neq 0$  we obtain an (almost) unique solution to  $x = qy + r$  by demanding that a solution  $(q, r)$  is chosen to minimize  $r$ . In particular,  $r$  is chosen to be 0 if possible.

Moreover, `CGAL::Algebraic_structure_traits< EuclideanRing >` is a model of *AlgebraicStructureTraits* providing:

- `CGAL::Algebraic_structure_traits< EuclideanRing >::Algebraic_type` derived from *Unique\_factorization\_domain\_tag*
- `CGAL::Algebraic_structure_traits< EuclideanRing >::Mod`
- `CGAL::Algebraic_structure_traits< EuclideanRing >::Div`
- `CGAL::Algebraic_structure_traits< EuclideanRing >::Div_mod`

## Remarks

The most prominent example of a Euclidean ring are the integers. Whenever both  $x$  and  $y$  are positive, then it is conventional to choose the smallest positive remainder  $r$ .

# Field

## Definition

A model of *Field* is an *IntegralDomain* in which every non-zero element has a multiplicative inverse. Thus, one can divide by any non-zero element. Hence division is defined for any divisor  $\neq 0$ . For a *Field*, we require this division operation to be available through operators  $/$  and  $/=$ .

Moreover, `CGAL::Algebraic_structure_traits< Field >` is a model of *AlgebraicStructureTraits* providing:  
 - `CGAL::Algebraic_structure_traits< Field >::Algebraic_type` derived from *Field\_tag*

## FieldWithSqrt

### Definition

A model of *FieldWithSqrt* is a *Field* that has operations to take square roots.

Moreover, *CGAL::Algebraic\_structure\_traits*< *FieldWithSqrt* > is a model of *AlgebraicStructureTraits* providing:

- *CGAL::Algebraic\_structure\_traits*< *FieldWithSqrt* >::*Algebraic\_type* derived from *Field\_with\_sqrt\_tag*
- *CGAL::Algebraic\_structure\_traits*< *FieldWithSqrt* >::*Sqrt*

## FieldWithRootOf

### Definition

A model of *FieldWithRootOf* is a *FieldWithKthRoot* with the possibility to construct it as the root of a univariate polynomial.

Moreover, *CGAL::Algebraic\_structure\_traits< FieldWithRootOf >* is a model of *AlgebraicStructureTraits* providing:

- *CGAL::Algebraic\_structure\_traits< FieldWithRootOf >::Algebraic\_type* derived from *Field\_with\_kth\_root\_tag*
- *CGAL::Algebraic\_structure\_traits< FieldWithRootOf >::Root\_of*

### Refines

## AlgebraicStructureTraits

### Definition

A model of *AlgebraicStructureTraits* reflects the algebraic structure of an associated type *Type*.

Depending on the concepts that *Type* fulfills, it contains various functors and descriptive tags. Moreover it gives access to the several possible algebraic operations within that structure.

### Types

A model of *AlgebraicStructureTraits* is supposed to provide:

*AlgebraicStructureTraits::Type*

The associated type.

*AlgebraicStructureTraits::Algebraic\_category*

Tag indicating the algebraic structure of the associated type.

Tag is:	<i>Type</i> is model of:
<i>CGAL::Null_tag</i>	no algebraic concept
<i>CGAL::Integral_domain_without_division_tag</i>	<i>IntegralDomainWithoutDivision</i>
<i>CGAL::Integral_domain_tag</i>	<i>IntegralDomain</i>
<i>CGAL::Unique_factorization_domain_tag</i>	<i>UniqueFactorizationDomain</i>
<i>CGAL::Euclidean_ring_tag</i>	<i>EuclideanRing</i>
<i>CGAL::Field_tag</i>	<i>Field</i>
<i>CGAL::Field_with_sqrt_tag</i>	<i>FieldWithSqrt</i>
<i>CGAL::Field_with_kth_root_tag</i>	<i>FieldWithKthRoot</i>
<i>CGAL::Field_with_root_of_tag</i>	<i>FieldWithRootOf</i>

*AlgebraicStructureTraits::Is\_exact*

Tag indicating whether *Type* is exact.

This is either *CGAL::Tag\_true* or *CGAL::Tag\_false*.

An algebraic structure is considered exact, if all operations required by its concept are computed such that a comparison of two algebraic expressions is always correct. The exactness covers only those operations that are required by the algebraic structure concept. e.g. an exact *Field* may have a *Sqrt* functor that is not exact.

*AlgebraicStructureTraits::Is\_numerical\_sensitive*

Tag indicating whether *Type* is numerical sensitive.

This is either *CGAL::Tag\_true* or *CGAL::Tag\_false*.

An algebraic structure is considered as numerically sensitive, if the performance of the type is sensitive to the condition number of an algorithm.

*AlgebraicStructureTraits:: Boolean*

This type specifies the return type of the predicates provided by this traits. The type must be convertible to *bool* and typically the type indeed maps to *bool*. However, there are also cases such as interval arithmetic, in which it is *Uncertain<bool>* or some similar type.

## **Functors**

In case a functor is not provided, it is set to *CGAL::Null\_functor*.

*AlgebraicStructureTraits:: Is\_zero*

A model of *AlgebraicStructureTraits::IsZero*.  
Required by the concept *IntegralDomainWithoutDivision*. In case *Type* is also model of *RealEmbeddable* this is a model of *RealEmbeddableTraits::IsZero*.

*AlgebraicStructureTraits:: Is\_one*

A model of *AlgebraicStructureTraits::IsOne*.  
Required by the concept *IntegralDomainWithoutDivision*.

*AlgebraicStructureTraits:: Square*

A model of *AlgebraicStructureTraits::Square*.  
Required by the concept *IntegralDomainWithoutDivision*.

*AlgebraicStructureTraits:: Simplify*

A model of *AlgebraicStructureTraits::Simplify*.  
Required by the concept *IntegralDomainWithoutDivision*.

*AlgebraicStructureTraits:: Unit\_part*

A model of *AlgebraicStructureTraits::UnitPart*.  
Required by the concept *IntegralDomainWithoutDivision*.

*AlgebraicStructureTraits:: Integral\_division*

A model of *AlgebraicStructureTraits::IntegralDivision*.  
Required by the concept *IntegralDomain*.

*AlgebraicStructureTraits:: Divides*

A model of *AlgebraicStructureTraits::Divides*.  
Required by the concept *IntegralDomain*.

*AlgebraicStructureTraits:: Is\_square*

A model of *AlgebraicStructureTraits::IsSquare*.  
Required by the concept *IntegralDomainWithoutDivision*.

*AlgebraicStructureTraits:: Gcd*

A model of *AlgebraicStructureTraits::Gcd*.  
Required by the concept *UniqueFactorizationDomain*.

*AlgebraicStructureTraits:: Mod*

A model of *AlgebraicStructureTraits::Mod*.  
Required by the concept *EuclideanRing*.

*AlgebraicStructureTraits:: Div*

A model of *AlgebraicStructureTraits::Div*.  
Required by the concept *EuclideanRing*.

*AlgebraicStructureTraits:: Div\_mod*

A model of *AlgebraicStructureTraits::DivMod*.  
Required by the concept *EuclideanRing*.

*AlgebraicStructureTraits:: Sqrt*

A model of *AlgebraicStructureTraits::Sqrt*.  
Required by the concept *FieldWithSqrt*.

*AlgebraicStructureTraits:: Kth\_root*

A model of *AlgebraicStructureTraits::KthRoot*.  
Required by the concept *FieldWithKthRoot*.

*AlgebraicStructureTraits:: Root\_of*

A model of *AlgebraicStructureTraits::RootOf*.  
Required by the concept *FieldWithRootOf*.

## AlgebraicStructureTraits::IsZero

### Definition

*AdaptableUnaryFunction*, returns true in case the argument is the zero element of the ring.

### Refines

*AdaptableUnaryFunction*

### Types

*AlgebraicStructureTraits::IsZero::result\_type*    Is *AlgebraicStructureTraits::Boolean*.

*AlgebraicStructureTraits::IsZero::argument\_type*

Is *AlgebraicStructureTraits::Type*.

### Operations

*result\_type*    *is\_zero( argument\_type x)*

returns true in case *x* is the zero element of the ring.

### See Also

*AlgebraicStructureTraits* ..... page [52](#) *RealEmbeddableTraits::IsZero* ..... page [98](#)

# AlgebraicStructureTraits::IsOne

## Definition

*AdaptableUnaryFunction*, returns true in case the argument is the one of the ring.

## Refines

*AdaptableUnaryFunction*

## Types

*AlgebraicStructureTraits::IsOne::result\_type*      Is *AlgebraicStructureTraits::Boolean*.

*AlgebraicStructureTraits::IsOne::argument\_type*  
Is *AlgebraicStructureTraits::Type*.

## Operations

*result\_type*      *is\_one( argument\_type x)*  
returns true in case *x* is the one of the ring.

## See Also

*AlgebraicStructureTraits* ..... page [52](#)

## AlgebraicStructureTraits::Square

### Definition

*AdaptableUnaryFunction*, computing the square of the argument.

### Refines

*AdaptableUnaryFunction*

### Types

*AlgebraicStructureTraits::Square:: result\_type*

Is *AlgebraicStructureTraits::Type*.

*AlgebraicStructureTraits::Square:: argument\_type*

Is *AlgebraicStructureTraits::Type*.

### Operations

*result\_type*     *square( argument\_type x)*

returns the square of *x*.

### See Also

*AlgebraicStructureTraits* ..... page [52](#)

# AlgebraicStructureTraits::Simplify

## Definition

This *AdaptableUnaryFunction* may simplify a given object.

## Refines

*AdaptableUnaryFunction*

## Types

*AlgebraicStructureTraits::Simplify:: result\_type*

Is void.

*AlgebraicStructureTraits::Simplify:: argument\_type*

Is *AlgebraicStructureTraits::Type*.

## Operations

*result\_type*     *simplify*( *argument\_type* *x*)

may simplify *x*.

## See Also

*AlgebraicStructureTraits* ..... page [52](#)

## AlgebraicStructureTraits::UnitPart

### Definition

This *AdaptableUnaryFunction* computes the unit part of a given ring element.

The mathematical definition of unit part is as follows: Two ring elements  $a$  and  $b$  are said to be associate if there exists an invertible ring element (i.e. a unit)  $u$  such that  $a = ub$ . This defines an equivalence relation. We can distinguish exactly one element of every equivalence class as being unit normal. Then each element of a ring possesses a factorization into a unit (called its unit part) and a unit-normal ring element (called its unit normal associate).

For the integers, the non-negative numbers are by convention unit normal, hence the unit-part of a non-zero integer is its sign. For a *Field*, every non-zero element is a unit and is its own unit part, its unit normal associate being one. The unit part of zero is, by convention, one.

### Refines

*AdaptableUnaryFunction*

### Types

*AlgebraicStructureTraits::UnitPart::result\_type*

Is *AlgebraicStructureTraits::Type*.

*AlgebraicStructureTraits::UnitPart::argument\_type*

Is *AlgebraicStructureTraits::Type*.

### Operations

*result\_type*      *unit\_part*( *argument\_type*  $x$  )

returns the unit part of  $x$ .

### See Also

*AlgebraicStructureTraits* ..... [page 52](#)

# AlgebraicStructureTraits::IntegralDivision

## Definition

*AdaptableBinaryFunction* providing an integral division.

Integral division (a.k.a. exact division or division without remainder) maps ring elements  $(x, y)$  to ring element  $z$  such that  $x = yz$  if such a  $z$  exists (i.e. if  $x$  is divisible by  $y$ ). Otherwise the effect of invoking this operation is undefined. Since the ring represented is an integral domain,  $z$  is uniquely defined if it exists.

## Refines

*AdaptableBinaryFunction*

## Types

*AlgebraicStructureTraits::IntegralDivision::result\_type*

Is *AlgebraicStructureTraits::Type*.

*AlgebraicStructureTraits::IntegralDivision::first\_argument*

Is *AlgebraicStructureTraits::Type*.

*AlgebraicStructureTraits::IntegralDivision::second\_argument*

Is *AlgebraicStructureTraits::Type*.

## Operations

*result\_type*     *integral\_division*( *first\_argument\_type*  $x$ , *second\_argument\_type*  $y$ )

returns  $x/y$ , this is an integral division.

*template* <class *NT1*, class *NT2*>

*result\_type*     *integral\_division*( *NT1*  $x$ , *NT2*  $y$ )

This operator is well defined if *NT1* and *NT2* are *ExplicitInteroperable* with coercion type *AlgebraicStructureTraits::Type*.

## See Also

*AlgebraicStructureTraits* ..... page [52](#)

*AlgebraicStructureTraits::Divides* ..... page [62](#)

## AlgebraicStructureTraits::Divides

### Definition

*AdaptableBinaryFunction*, returns true if the first argument divides the second argument.

Integral division (a.k.a. exact division or division without remainder) maps ring elements  $(n, d)$  to ring element  $c$  such that  $n = dc$  if such a  $c$  exists. In this case it is said that  $d$  divides  $n$ .

This functor is required to provide two operators. The first operator takes two arguments and returns true if the first argument divides the second argument. The second operator returns  $c$  via the additional third argument.

### Refines

*AdaptableBinaryFunction*

### Types

*AlgebraicStructureTraits::Divides::result\_type*

Is *AlgebraicStructureTraits::Boolean*.

*AlgebraicStructureTraits::Divides::first\_argument*

Is *AlgebraicStructureTraits::Type*.

*AlgebraicStructureTraits::Divides::second\_argument*

Is *AlgebraicStructureTraits::Type*.

### Operations

*result\_type*     *divides( first\_argument\_type d, second\_argument\_type n)*

Computes whether  $d$  divides  $n$ .

*result\_type*     *divides( first\_argument\_type d, second\_argument\_type n, AlgebraicStructureTraits::Type& c)*

Computes whether  $d$  divides  $n$ . Moreover it computes  $c$  if  $d$  divides  $n$ , otherwise the value of  $c$  is undefined.

### See Also

*AlgebraicStructureTraits* ..... page [52](#)  
*AlgebraicStructureTraits::IntegralDivision* ..... page [61](#)

## AlgebraicStructureTraits::IsSquare

### Definition

*AdaptableBinaryFunction* providing an integral square root.

An ring element  $x$  is said to be a square iff there exists a ring element  $y$  such that  $x = y * y$ . In case the ring is a *UniqueFactorizationDomain*,  $y$  is uniquely defined up to multiplication by units.

### Refines

*AdaptableBinaryFunction*

### Types

*AlgebraicStructureTraits::IsSquare::result\_type*

Is *AlgebraicStructureTraits::Boolean*.

*AlgebraicStructureTraits::IsSquare::first\_argument*

Is *AlgebraicStructureTraits::Type*.

*AlgebraicStructureTraits::IsSquare::second\_argument*

Is *AlgebraicStructureTraits::Type&*.

### Operations

*result\_type*     *is\_square( first\_argument\_type x, second\_argument\_type y)*

returns `true` in case  $x$  is a square, i.e.  $x = y * y$ .

*Postcondition:* `unit_part(y) == 1`.

*result\_type*     *is\_square( first\_argument\_type x)*

returns `true` in case  $x$  is a square.

### See Also

*AlgebraicStructureTraits* ..... page [52](#)

# AlgebraicStructureTraits::Gcd

## Definition

*AdaptableBinaryFunction* providing the gcd.

The greatest common divisor (*gcd*) of ring elements *x* and *y* is the unique ring element *d* (up to a unit) with the property that any common divisor of *x* and *y* also divides *d*. (In other words: *d* is the greatest lower bound of *x* and *y* in the partial order of divisibility.) We demand the *gcd* to be unit-normal (i.e. have unit part 1).

*gcd*(0,0) is defined as 0, since 0 is the greatest element with respect to the partial order of divisibility. This is because an element  $a \in R$  is said to divide  $b \in R$ , iff  $\exists r \in R$  such that  $a \cdot r = b$ . Thus, 0 is divided by every element of the Ring, in particular by itself.

## Refines

*AdaptableBinaryFunction*

## Types

*AlgebraicStructureTraits::Gcd::result\_type*      Is *AlgebraicStructureTraits::Type*.  
*AlgebraicStructureTraits::Gcd::first\_argument*

Is *AlgebraicStructureTraits::Type*.

*AlgebraicStructureTraits::Gcd::second\_argument*

Is *AlgebraicStructureTraits::Type*.

## Operations

*result\_type*      *gcd*( *first\_argument\_type* *x*, *second\_argument\_type* *y*)

returns *gcd*(*x*,*y*).

*template* <*class* *NT1*, *class* *NT2*>  
*result\_type*      *gcd*( *NT1* *x*, *NT2* *y*)

This operator is well defined if *NT1* and *NT2* are *ExplicitInteroperable* with coercion type *AlgebraicStructureTraits::Type*.

## See Also

*AlgebraicStructureTraits* ..... page [52](#)

## AlgebraicStructureTraits::DivMod

### Definition

*AdaptableFunctor* computes both integral quotient and remainder of division with remainder. The quotient  $q$  and remainder  $r$  are computed such that  $x = q * y + r$  and  $|r| < |y|$  with respect to the proper integer norm of the represented ring.<sup>1</sup> In particular,  $r$  is chosen to be 0 if possible. Moreover, we require  $q$  to be minimized with respect to the proper integer norm.

Note that the last condition is needed to ensure a unique computation of the pair  $(q, r)$ . However, an other option is to require minimality for  $|r|$ , with the advantage that a  $mod(x, y)$  operation would return the unique representative of the residue class of  $x$  with respect to  $y$ , e.g.  $mod(2, 3)$  should return  $-1$ . But this conflicts with nearly all current implementation of integer types. From there, we decided to stay conform with common implementations and require  $q$  to be computed as  $x/y$  rounded towards zero.

The following table illustrates the behavior for integers:

$x$	$y$	$q$	$r$		$x$	$y$	$q$	$r$
3	3	1	0	-	3	-3	-1	0
2	3	0	2		2	-3	0	2
1	3	0	1		1	-3	0	1
0	3	0	0		0	-3	0	0
-1	3	0	-1		-1	-3	0	-1
-2	3	0	-2		-2	-3	0	-2
-3	3	-1	0		-3	-3	1	0

### Refines

## CGAL::is\_zero

### Definition

The function *is\_zero* determines if a value is equal to 0 or not.

The function is guaranteed to be well defined in case the argument type is a model of the *RealEmbeddable* or of the *IntegralDomainWithoutDivision* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
```

```
result_type      is_zero( NT x)           The result_type is convertible to bool.
```

### See Also

## CGAL::is\_one

### Definition

The function *is\_one* determines if a value is equal to 1 or not.

The function is guaranteed to be well defined in case the argument type is a model of the *IntegralDomainWithoutDivision* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
```

```
result_type      is_one( NT x)           The result_type is convertible to bool.
```

### See Also

IntegralDomainWithoutDivision.....page [43](#)

## CGAL::square

### Definition

The function *square* returns the square of a number.

The function is guaranteed to be well defined in case the argument type is a model of the *IntegralDomainWithoutDivision* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
NT square( NT x)
```

### See Also

IntegralDomainWithoutDivision ..... page [43](#)  
 AlgebraicStructureTraits::Square ..... page [58](#)

## CGAL::is\_square

### Definition

An ring element  $x$  is said to be a square iff there exists a ring element  $y$  such that  $x = y * y$ . In case the ring is a *UniqueFactorizationDomain*,  $y$  is uniquely defined up to multiplication by units.

The function *is\_square* is available if *Algebraic\_structure\_traits::Is\_square* is not the *CGAL::Null\_functor*.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
result_type      is_square( NT x)           The result_type is convertible to bool.
```

```
template <class NT>
result_type      is_square( NT x, NT& y)

The result_type is convertible to bool.
```

### See Also

UniqueFactorizationDomain ..... [page 46](#)  
 AlgebraicStructureTraits::IsSquare ..... [page 63](#)

## CGAL::simplify

### Definition

The function *simplify* may simplify a given object.

The function is guaranteed to be well defined in case the argument type is a model of the *IntegralDomainWithoutDivision* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
void      simplify( NT x)
```

### See Also

IntegralDomainWithoutDivision ..... page [43](#)  
 AlgebraicStructureTraits::Simplify ..... page [59](#)

## CGAL::unit\_part

### Definition

The function *unit\_part* computes the unit part of a given ring element.

The function is guaranteed to be well defined in case the argument type is a model of the *IntegralDomainWithoutDivision* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
NT          unit_part( NT x)
```

### See Also

IntegralDomainWithoutDivision.....page [43](#)  
 AlgebraicStructureTraits::UnitPart.....page [60](#)

## CGAL::integral\_division

### Definition

The function *integral\_division* (a.k.a. exact division or division without remainder) maps ring elements  $(x, y)$  to ring element  $z$  such that  $x = yz$  if such a  $z$  exists (i.e. if  $x$  is divisible by  $y$ ). Otherwise the effect of invoking this operation is undefined. Since the ring represented is an integral domain,  $z$  is uniquely defined if it exists.

In case the argument types *NT1* and *NT2* differ, the *result\_type* is determined via *Coercion\_traits*.

Thus, the *result\_type* is well defined if *NT1* and *NT2* are a model of *ExplicitInteroperable*.

The actual *integral\_division* is performed with the semantic of that type.

The function is guaranteed to be well defined in case *result\_type* is a model of the *IntegralDomain* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT1, class NT2>
result_type          integral_division( NT1 x, NT2 y)
```

### See Also

IntegralDomain ..... page [45](#)  
 AlgebraicStructureTraits::IntegralDivision ..... page [61](#)

## CGAL::gcd

### Definition

The function *gcd* computes the greatest common divisor of two values.

In case the argument types *NT1* and *NT2* differ, the *result\_type* is determined via *Coercion\_traits*.

Thus, the *result\_type* is well defined if *NT1* and *NT2* are a model of *ExplicitInteroperable*.

The actual *gcd* is performed with the semantic of that type.

The function is guaranteed to be well defined in case *result\_type* is a model of the *UniqueFactorizationDomain* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT1, class NT2>
result_type          gcd( NT1 x, NT2 y)
```

### See Also

UniqueFactorizationDomain ..... page [46](#)

## CGAL::div\_mod

### Definition

The function *div\_mod* computes the integral quotient and remainder of division with remainder.

In case the argument types *NT1* and *NT2* differ, the *result\_type* is determined via *Coercion\_traits*. Thus, the *result\_type* is well defined if *NT1* and *NT2* are a model of *ExplicitInteroperable*. The actual *div\_mod* is performed with the semantic of that type.

The function is guaranteed to be well defined in case *result\_type* is a model of the *EuclideanRing* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT1, class NT2>
void      div_mod( NT1 x, NT2 y, result_type& q, result_type& r)
```

computes the quotient *q* and remainder *r*, such that  $x = q * y + r$  and *r* minimal with respect to the Euclidean Norm of the *result\_type*.

### See Also

## CGAL::div

### Definition

The function *div* computes the integral quotient of division with remainder.

In case the argument types *NT1* and *NT2* differ, the *result\_type* is determined via *Coercion\_traits*. Thus, the *result\_type* is well defined if *NT1* and *NT2* are a model of *ExplicitInteroperable*. The actual *div* is performed with the semantic of that type.

The function is guaranteed to be well defined in case *result\_type* is a model of the *EuclideanRing* concept.

```
#include <CGAL/number_utils.h>
```

```
template< class NT1, class NT2>
result_type      div( NT1 x, NT2 y)
```

## CGAL::mod

### Definition

The function *mod* computes the remainder of division with remainder.

In case the argument types *NT1* and *NT2* differ, the *result\_type* is determined via *Coercion\_traits*. Thus, the *result\_type* is well defined if *NT1* and *NT2* are a model of *ExplicitInteroperable*. The actual *mod* is performed with the semantic of that type.

The function is guaranteed to be well defined in case *result\_type* is a model of the *EuclideanRing* concept.

```
#include <CGAL/number_utils.h>
```

```
template< class NT1, class NT2>
result_type      mod( NT1 x, NT2 y)
```

## CGAL::sqrt

### Definition

The function *sqrt* returns the square root of a value.

The function is guaranteed to be well defined in case the argument type is a model of the *FieldWithSqrt* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
NT sqrt( NT x)
```

### See Also

FieldWithSqrt ..... [page 49](#)  
 AlgebraicStructureTraits::Sqrt ..... [page 69](#)

## CGAL::kth\_root

### Definition

The function *kth\_root* returns the k-th root of a value.

The function is guaranteed to be well defined in case the second argument type is a model of the *FieldWithKth-Root* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
NT kth_root( int k, NT x)
```

### See Also

FieldWithKthRoot ..... page [50](#)  
 AlgebraicStructureTraits::KthRoot ..... page [70](#)

## CGAL::root\_of

### Definition

The function *root\_of* computes a real root of a square-free univariate polynomial.

The function is guaranteed to be well defined in case the value type, *NT*, of the iterator range is a model of the *FieldWithRootOf* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class InputIterator>
NT      root_of( int k, InputIterator begin, InputIterator end)
```

returns the k-th real root of the univariate polynomial, which is defined by the iterator range, where begin refers to the constant term.

*Precondition:* The polynomial is square-free.

# RealEmbeddable

## Definition

A model of this concepts represents numbers that are embeddable on the real axis. The type obeys the algebraic structure and compares two values according to the total order of the real numbers.

Moreover, `CGAL::Real_embeddable_traits< RealEmbeddable >` is a model of `RealEmbeddableTraits` with:

- `CGAL::Real_embeddable_traits< RealEmbeddable >::Is_real_embeddable` set to `Tag_true`
- and functors :
- `CGAL::Real_embeddable_traits< RealEmbeddable >::Is_zero`
- `CGAL::Real_embeddable_traits< RealEmbeddable >::Abs`
- `CGAL::Real_embeddable_traits< RealEmbeddable >::Sgn`
- `CGAL::Real_embeddable_traits< RealEmbeddable >::Is_positive`
- `CGAL::Real_embeddable_traits< RealEmbeddable >::Is_negative`
- `CGAL::Real_embeddable_traits< RealEmbeddable >::Compare`
- `CGAL::Real_embeddable_traits< RealEmbeddable >::To_double`
- `CGAL::Real_embeddable_traits< RealEmbeddable >::To_interval`

Remark:

If a number type is a model of both `IntegralDomainWithoutDivision` and `RealComparable`, it follows that the ring represented by such a number type is a sub-ring of the real numbers and hence has characteristic zero.

## Refines

*Equality Comparable*  
*LessThanComparable*

## Operations

*bool*                      *a == b*  
*bool*                      *a != b*

*bool*                      *a < b*  
*bool*                      *a <= b*  
*bool*                      *a > b*  
*bool*                      *a >= b*

## See Also

*RealEmbeddableTraits* ..... page 96

## RealEmbeddableTraits

### Definition

A model of *RealEmbeddableTraits* is associated to a number type *Type* and reflects the properties of this type with respect to the concept *RealEmbeddable*.

### Types

A model of *RealEmbeddableTraits* is supposed to provide:

<i>RealEmbeddableTraits:: Type</i>	The associated number type.
<i>RealEmbeddableTraits:: Is_real_embeddable</i>	Tag indicating whether the associated type is real embeddable. This is either <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>RealEmbeddableTraits:: Boolean</i>	This type specifies the return type of the predicates provided by this traits. The type must be convertible to <i>bool</i> and typically the type indeed maps to <i>bool</i> . However, there are also cases such as interval arithmetic, in which it is <i>Uncertain&lt;bool&gt;</i> or some similar type.
<i>RealEmbeddableTraits:: Sign</i>	This type specifies the return type of the <i>Sgn</i> functor. The type must be convertible to <i>CGAL::Sign</i> and typically the type indeed maps to <i>CGAL::Sign</i> . However, there are also cases such as interval arithmetic, in which it is <i>Uncertain&lt;CGAL::Sign&gt;</i> or some similar type.
<i>RealEmbeddableTraits:: Comparison_result</i>	This type specifies the return type of the <i>Compare</i> functor. The type must be convertible to <i>CGAL::Comparison_result</i> and typically the type indeed maps to <i>CGAL::Comparison_result</i> . However, there are also cases such as interval arithmetic, in which it is <i>Uncertain&lt;CGAL::Comparison_result&gt;</i> or some similar type.

### Functors

In case the associated type is *RealEmbeddable* all functors are provided.  
In case a functor is not provided, it is set to *CGAL::Null\_functor*.

<i>RealEmbeddableTraits:: Is_zero</i>	A model of <i>RealEmbeddableTraits::IsZero</i> In case <i>Type</i> is also model of <i>IntegralDomainWithoutDivision</i> this is a model of <i>AlgebraicStructureTraits::IsZero</i> .
<i>RealEmbeddableTraits:: Abs</i>	A model of <i>RealEmbeddableTraits::Abs</i>

<i>RealEmbeddableTraits:: Sgn</i>	A model of <i>RealEmbeddableTraits::Sgn</i>
<i>RealEmbeddableTraits:: Is_positive</i>	A model of <i>RealEmbeddableTraits::IsPositive</i>
<i>RealEmbeddableTraits:: Is_negative</i>	A model of <i>RealEmbeddableTraits::IsNegative</i>
<i>RealEmbeddableTraits:: Compare</i>	A model of <i>RealEmbeddableTraits::Compare</i>
<i>RealEmbeddableTraits:: To_double</i>	A model of <i>RealEmbeddableTraits::ToDouble</i>
<i>RealEmbeddableTraits:: To_interval</i>	A model of <i>RealEmbeddableTraits::ToInterval</i>

## Has Models

*CGAL::Real\_embeddable\_traits<T>* ..... page [106](#)

## RealEmbeddableTraits::IsZero

### Definition

*AdaptableUnaryFunction*, returns true in case the argument is 0.

### Refines

*AdaptableUnaryFunction*

### Types

*RealEmbeddableTraits::IsZero:: result\_type*      Type convertible to *bool*.

*RealEmbeddableTraits::IsZero:: argument\_type*

Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*      *is\_zero( argument\_type x)*

returns true in case *x* is the zero element of the ring.

### See Also

*RealEmbeddableTraits* ..... page [96](#) *AlgebraicStructureTraits::IsZero* ..... page [56](#)

## RealEmbeddableTraits::Abs

### Definition

*AdaptableUnaryFunction* computes the absolute value of a number.

### Refines

*AdaptableUnaryFunction*

### Types

*RealEmbeddableTraits::Abs:: result\_type*      Is *RealEmbeddableTraits::Type*.

*RealEmbeddableTraits::Abs:: argument\_type*      Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*      *abs( argument\_type x)*

computes the absolute value of *x*.

### See Also

*RealEmbeddableTraits* ..... page [96](#)

## RealEmbeddableTraits::Sgn

### Definition

This *AdaptableUnaryFunction* computes the sign of a real embeddable number.

### Refines

*AdaptableUnaryFunction*

### Types

*RealEmbeddableTraits::Sgn:: result\_type*      Type convertible to *CGAL::Sign*.

*RealEmbeddableTraits::Sgn:: argument\_type*      Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*      *sign( argument\_type x)*

Computes the sign of *x*.

### See Also

*RealEmbeddableTraits* ..... page [96](#)

## RealEmbeddableTraits::IsPositive

### Definition

*AdaptableUnaryFunction*, returns true in case the argument is positive.

### Refines

*AdaptableUnaryFunction*

### Types

*RealEmbeddableTraits::IsPositive:: result\_type*

Type convertible to *bool*.

*RealEmbeddableTraits::IsPositive:: argument\_type*

Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*     *is\_positive( argument\_type x)*

returns true in case *x* is positive.

### See Also

*RealEmbeddableTraits* ..... [page 96](#)

## RealEmbeddableTraits::IsNegative

### Definition

*AdaptableUnaryFunction*, returns true in case the argument is negative.

### Refines

*AdaptableUnaryFunction*

### Types

*RealEmbeddableTraits::IsNegative::result\_type*

Type convertible to *bool*.

*RealEmbeddableTraits::IsNegative::argument\_type*

Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*     *is\_negative( argument\_type x)*

returns true in case *x* is negative.

### See Also

*RealEmbeddableTraits* ..... page [96](#)

## RealEmbeddableTraits::Compare

### Definition

*AdaptableBinaryFunction* compares two real embeddable numbers.

### Refines

*AdaptableBinaryFunction*

### Types

*RealEmbeddableTraits::Compare::result\_type*

Type convertible to *CGAL::Comparison\_result*.

*RealEmbeddableTraits::Compare::first\_argument\_type*

Is *RealEmbeddableTraits::Type*.

*RealEmbeddableTraits::Compare::second\_argument\_type*

Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*     *compare*( *first\_argument\_type* *x*, *second\_argument\_type* *y*)

compares *x* with respect to *y*.

*template* <*class NT1*, *class NT2*>  
*result\_type*     *compare*( *NT1* *x*, *NT2* *y*)

This operator is well defined if *NT1* and *NT2* are *ExplicitInteroperable* with coercion type *RealEmbeddableTraits::Type*.

### See Also

*RealEmbeddableTraits* ..... page 96

## RealEmbeddableTraits::ToDouble

### Definition

*AdaptableUnaryFunction* computes a double approximation of a real embeddable number.

### Refines

*AdaptableUnaryFunction*

### Types

*RealEmbeddableTraits::ToDouble:: result\_type*

Is *double*.

*RealEmbeddableTraits::ToDouble:: argument\_type*

Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*      *to\_double( argument\_type x)*

computes a double approximation of a real embeddable number.

### See Also

*RealEmbeddableTraits* ..... page [96](#)

## RealEmbeddableTraits::ToInterval

### Definition

*AdaptableUnaryFunction* computes for a given real embeddable number  $x$  a double interval containing  $x$ . This interval is represented by *std::pair<double,double>*.

### Refines

*AdaptableUnaryFunction*

### Types

*RealEmbeddableTraits::ToInterval::result\_type*

Is *std::pair<double,double>*.

*RealEmbeddableTraits::ToInterval::argument\_type*

Is *RealEmbeddableTraits::Type*.

### Operations

*result\_type*     *to\_interval( argument\_type x)*

computes a double interval containing  $x$ .

### See Also

*RealEmbeddableTraits* ..... page [96](#)

## CGAL::Real\_embeddable\_traits<T>

### Definition

An instance of *Real\_embeddable\_traits*<*T*> is a model of *RealEmbeddableTraits*, where *T* is the associated type.

*#include* <CGAL/Real\_embeddable\_traits.h>

### Is Model for the Concepts

RealEmbeddableTraits ..... page [96](#)

## CGAL::abs

### Definition

The template function *abs* returns the absolute value of a number.

The function is guaranteed to be well defined in case the argument type is a model of the *RealEmbeddable* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
NT abs( NT x)
```

### See Also

RealEmbeddable ..... page [95](#)  
 RealEmbeddableTraits::Abs ..... page [99](#)

## CGAL::sign

### Definition

The template function *sign* returns the sign of a number.

The function is guaranteed to be well defined in case the argument type is a model of the *RealEmbeddable* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
```

```
result_type      sign( NT x)
```

returns the sign of the argument. The *result\_type* is convertible to *CGAL::Sign*.

### See Also

RealEmbeddable ..... page [95](#)

RealEmbeddableTraits::Sgn ..... page [100](#)

## CGAL::is\_positive

### Definition

The template function *is\_positive* determines if a value is positive or not. The function is guaranteed to be well defined in case the argument type is a model of the *RealEmbeddable* concept.

```
#include <CGAL/number_utils.h>
```

```
result_type      is_positive( NT x)      The result_type is convertible to bool.
```

### See Also

RealEmbeddable ..... [page 95](#)  
 RealEmbeddableTraits::IsPositive ..... [page 101](#)

## CGAL::is\_negative

### Definition

The template function *is\_negative* determines if a value is negative or not. The function is guaranteed to be well defined in case the argument type is a model of the *RealEmbeddable* concept.

*#include* <CGAL/number\_utils.h>

*result\_type*                    *is\_negative*( *NT* *x*)                    The *result\_type* is convertible to *bool*.

### See Also

RealEmbeddable ..... [page 95](#)  
RealEmbeddableTraits::IsNegative ..... [page 102](#)

## CGAL::compare

### Definition

The template function *compare* compares the first argument with respect to the second, i.e. it returns *CGAL::LARGER* if *x* is larger than *y*.

In case the argument types *NT1* and *NT2* differ, *compare* is performed with the semantic of the type determined via *Coercion\_traits*. The function is guaranteed to be well defined in case this type is a model of the *RealEmbeddable* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT1, class NT2>
result_type          compare( NT x, NT y)    The result_type is convertible to CGAL::Comparison_result.
```

*RealEmbeddable* ..... [page 95](#)  
*RealEmbeddableTraits::Compare* ..... [page 103](#)

## CGAL::to\_double

### Definition

The template function *to\_double* returns an double approximation of a number. The function is guaranteed to be well defined in case the argument type is a model of the *RealEmbeddable* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>  
double          to_double( NT x)
```

### See Also

RealEmbeddable ..... [page 95](#)  
RealEmbeddableTraits::ToDouble ..... [page 104](#)

## CGAL::to\_interval

### Definition

The template function *to\_interval* computes for a given real embeddable number  $x$  a double interval containing  $x$ . This interval is represented by a *CGAL::Interval\_nt*. The function is guaranteed to be well defined in case the argument type is a model of the *RealEmbeddable* concept.

```
#include <CGAL/number_utils.h>
```

```
template <class NT>
Interval_nt          to_interval( NT x)
```

### See Also

RealEmbeddable ..... page [95](#)  
 RealEmbeddableTraits::ToInterval ..... page [105](#)

## Fraction

### Definition

A type is considered as a *Fraction*, if there is a reasonable way to decompose it into a numerator and denominator. In this case the relevant functionality for decomposing and re-composing as well as the numerator and denominator type are provided by *CGAL::Fraction\_traits*.

### See Also

*FractionTraits* .....page [115](#)  
*CGAL::Fraction\_traits<T>* ..... page [119](#)

## FractionTraits

### Definition

A model of FractionTraits is associated with a type *Type*.

In case the associated type is a *Fraction*, a model of FractionTraits provides the relevant functionality for decomposing and re-composing as well as the numerator and denominator type.

```
#include <CGAL/Fraction_traits.h>
```

### Types

<i>FractionTraits:: Type</i>	the associated type
<i>FractionTraits:: Is_fraction</i>	Tag indicating whether the associated type is a fraction and can be decomposed into a numerator and denominator. This is either <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>FractionTraits:: Numerator_type</i>	The type to represent the numerator. This is undefined in case the associated type is not a fraction.
<i>FractionTraits:: Denominator_type</i>	The (simpler) type to represent the denominator. This is undefined in case the associated type is not a fraction.

### Functors

In case *Type* is not a *Fraction* all functors are *Null\_functor*.

<i>FractionTraits:: Decompose</i>	A model of <i>FractionTraits::Decompose</i> .
<i>FractionTraits:: Compose</i>	A model of <i>FractionTraits::Compose</i> .
<i>FractionTraits:: Common_factor</i>	A model of <i>FractionTraits::CommonFactor</i> .

### Has Models

*CGAL::Fraction\_traits<T>* ..... page [119](#)

### See Also

*FractionTraits::Decompose* ..... page [116](#)  
*FractionTraits::Compose* ..... page [117](#)  
*FractionTraits::CommonFactor* ..... page [118](#)

## FractionTraits::Decompose

### Definition

Functor decomposing a *Fraction* into its numerator and denominator.

### Types

### Operations

*result\_type*                      *decompose.operator()*( *FractionTraits::Type* *f*,  
    *FractionTraits::Numerator\_type* & *n*,  
    *FractionTraits::Denominator\_type* & *d*)  
    decompose *f* into numerator *n* and denominator *d*.

### See Also

[Fraction](#) ..... page [114](#)  
[FractionTraits](#) ..... page [115](#)  
[FractionTraits::Compose](#) ..... page [117](#)  
[FractionTraits::CommonFactor](#) ..... page [118](#)

## FractionTraits::Compose

### Definition

*AdaptableBinaryFunction*, returns the fraction of its arguments.

### Refines

*AdaptableBinaryFunction*

### Types

*typedef FractionTraits::Type*

*result\_type;*

*typedef FractionTraits::Numerator\_type*

*first\_argument\_type;*

*typedef FractionTraits::Denominator\_type*

*second\_argument\_type;*

### Operations

*result\_type*                      *compose( first\_argument\_type n, second\_argument\_type d)*

return the fraction  $n/d$ .

### See Also

Fraction.....page [114](#)  
 FractionTraits.....page [115](#)  
 FractionTraits::Decompose.....page [116](#)  
 FractionTraits::CommonFactor.....page [118](#)

## FractionTraits::CommonFactor

### Definition

*AdaptableBinaryFunction*, finds great common factor of denominators.

This can be considered as a relaxed version of *AlgebraicStructureTraits::Gcd*, this is needed because it is not guaranteed that *FractionTraits::Denominator\_type* is a model of *UniqueFactorizationDomain*.

### Refines

*AdaptableBinaryFunction*

### Types

*typedef FractionTraits::Denominator\_type*

*result\_type;*

*typedef FractionTraits::Denominator\_type*

*first\_argument\_type;*

*typedef FractionTraits::Denominator\_type*

*second\_argument\_type;*

### Operations

*result\_type*                      *common\_factor( first\_argument\_type d1, second\_argument\_type d2)*

return a great common factor of *d1* and *d2*.

Note: `operator()(0,0) = 0`

## CGAL::Fraction\_traits<T>

### Definition

An instance of *Fraction\_traits*<*T*> is a model of *FractionTraits*, where *T* is the associated type.

*#include* <CGAL/Fraction\_traits.h>

### Is Model for the Concepts

FractionTraits ..... page [115](#)

# RingNumberType

## Definition

The concept `RingNumberType` combines the requirements of the concepts *IntegralDomainWithoutDivision* and *RealEmbeddable*. A model of `RingNumberType` can be used as a template parameter for Homogeneous kernels.

## Refines

*IntegralDomainWithoutDivision*  
*RealEmbeddable*

## Has Models

C++ built-in number types  
`CGAL::Gmpq`  
`CGAL::Gmpz`  
`CGAL::Interval_nt`  
`CGAL::Interval_nt_advanced`  
`CGAL::Lazy_exact_nt<RingNumberType>`

### 4.1 Introduction

This chapter gives an overview of the number types supported by CGAL. Number types must fulfill certain syntactical and semantic requirements, such that they can be successfully used in CGAL code. In general they are expected to be a model of an algebraic structure concepts and in case they model a subring of the real numbers they are also a model of *RealEmbeddable*. For an overview of the algebraic structure concepts see Section 3.7.

### 4.2 Built-in Number Types

The built-in number types *float*, *double* and *long double* have the required arithmetic and comparison operators. They lack some required routines though which are automatically included by CGAL.<sup>1</sup>

All built-in number types of C++ can represent a discrete (bounded) subset of the rational numbers only. We assume that the floating-point arithmetic of your machine follows IEEE floating-point standard. Since the floating-point culture has much more infrastructural support (hardware, language definition and compiler) than exact

---

<sup>1</sup> The functions can be found in the header files `CGAL/int.h`, `CGAL/float.h`, `CGAL/double.h` and `CGAL/long-long.h`.

computation, it is very efficient. Like with all number types with finite precision representation which are used as approximations to the infinite ranges of integers or real numbers, the built-in number types are inherently potentially inexact. Be aware of this if you decide to use the efficient built-in number types: you have to cope with numerical problems. For example, you can compute the intersection point of two lines and then check whether this point lies on the two lines. With floating point arithmetic, roundoff errors may cause the answer of the check to be *false*. With the built-in integer types overflow might occur.

## 4.3 Number Types Provided by CGAL

CGAL provides several number types that can be used for exact computation. These include the *Quotient* class that can be used to create, for example, a number type that behaves like a rational number when parameterized with a number type which can represent integers.

The number type *MP\_Float* is able to represent multi-precision floating point values, a generalization of integers scaled by a (potentially negative) power of 2. It allows to deal with ring operations over floating-point values with requiring rational numbers. By plugging it in *Quotient*, one obtains rational numbers. Note that *MP\_Float* may not be as efficient as the integer types provided by GMP or LEDA, but it has the advantage to make more parts of CGAL independent on these external libraries for handling robustness issues.

The templated number type *Lazy\_exact\_nt<NT>* is able to represent any number that *NT* is able to represent, but because it first tries to use an approximate value to perform computations it can be faster than *NT*.

A number type for doing interval arithmetic, *Interval\_nt*, is provided. This number type helps in doing arithmetic filtering in many places such as *Filtered\_predicate*.

*CGAL::Root\_of\_2* is a number type that allows to represent algebraic numbers of degree up to 2 over a *RingNumberType*. A generic function *CGAL::make\_root\_of\_2* allows to build this type generically.

A debugging helper *Number\_type\_checker<NT1,NT2,Comparator>* is also provided which allows to compare the behavior of operations over two number types.

## 4.4 Number Types Provided by GMP

CGAL provides wrapper classes for number types defined in the GNU Multiple Precision arithmetic library [Gra]. The file *CGAL/Gmpz.h* provides the class *Gmpz*, a wrapper class for the integer type *mpz\_t*, that is compliant with the CGAL number type requirements. The file *CGAL/Gmpq.h* provides the class *Gmpq*, a wrapper class for the rational type *mpq\_t*, that is compliant with the CGAL number type requirements.

The file *CGAL/Gmpzf.h* provides the class *Gmpzf*, an exact floating-point type based on *mpz\_t*, that is compliant with the CGAL number type requirements.

In addition, it is possible to directly use the C++ number types provided by GMP : *mpz\_class*, *mpq\_class* (note that support for *mpf\_class* is incomplete). The file *CGAL/gmpxx.h* provides the necessary functions to make these classes compliant to the CGAL number type requirements.

To use this, GMP must be installed.

## 4.5 Number Types Provided by LEDA

LEDA provides number types that can be used for exact computation with both Cartesian and homogeneous representations. If you are using homogeneous representation with the built-in integer types *short*, *int*, and *long* as ring type, exactness of computations can be guaranteed only if your input data come from a sufficiently small integral range and the depth of the computations is sufficiently small. LEDA provides the number type *leda\_integer* for integers of arbitrary length. (Of course the length is somehow bounded by the resources of your computer.) It can be used as ring type in homogeneous kernels and leads to exact computation as long as all intermediate results are rational. For the same kind of problems, Cartesian representation with number type *leda\_rational* leads to exact computation as well. The number type *leda\_bigfloat* in LEDA is a variable precision floating-point type. Rounding mode and precision (i.e. mantissa length) of *leda\_bigfloat* can be set.

The most sophisticated number type in LEDA is the number type called *leda\_real*. Like in Pascal, where the name *real* is used for floating-point numbers, the name *leda\_real* does not describe the number type precisely, but intentionally. *leda\_reals* are a subset of real algebraic numbers. Any integer is *leda\_real* and *leda\_reals* are closed under the operations  $+$ ,  $-$ ,  $*$ ,  $/$  and  $k$ -th root computation. For LEDA version 5.0 and or later *leda\_real* is also able to represent real roots of polynomials. *leda\_reals* guarantee that all comparisons between expressions involving *leda\_reals* produce the exact result.

The files `CGAL/leda_integer.h`, `CGAL/leda_rational.h`, `CGAL/leda_bigfloat.h` and `CGAL/leda_real.h` provide the necessary functions to make these classes compliant to the CGAL number type requirements.

## 4.6 Number Types Provided by CORE

In principle CORE [KLPY99] provides the same set of number types as LEDA. The type `CORE::BigInt` represent integers and `CORE::BigRat` represent rationals of arbitrary length. The number type `CORE::BigFloat` is a variable precision floating-point type. It is also possible to interpret it as an interval type, since it also carries the error of a computed value. As for LEDA, the most sophisticated number type in CORE is `CORE::Expr`, which is in its functionality equivalent to *leda\_real*.

The files `CGAL/CORE_BigInt.h`, `CGAL/CORE_BigRat.h`, `CGAL/CORE_BigFloat.h` and `CGAL/CORE_Expr.h` provide the necessary functions to make these classes compliant to the CGAL number type requirements.

CORE version 1.7 or later is required.

## 4.7 User-supplied Number Types

In order to use your own number type it must be a model of the according algebraic structure concept, in particular you must provide a specialization of `CGAL::Algebraic_structure_traits` and also of `Real_embeddable_traits` in case it is a sub ring of the real numbers. If you even want to provide a related ensemble of number types you should also provide specializations for `CGAL::Coercion_traits` in order to reflect their interoperability.

## int

### Definition

The fundamental type *int* is an *RealEmbeddable EuclideanRing*. Due to overflow *int* is considered as not exact.

`#include <CGAL/int.h>` **Is Model for the Concepts**

*EuclideanRing*  
*RealEmbeddable*

## short int

### Definition

The fundamental type *short int* is an *RealEmbeddable EuclideanRing*. Due to overflow *short int* is considered as not exact.

`#include <CGAL/int.h>` **Is Model for the Concepts**

*EuclideanRing*  
*RealEmbeddable*

## long int

### Definition

The fundamental type *long int* is an *RealEmbeddable EuclideanRing*. Due to overflow *long int* is considered as not exact.

`#include <CGAL/int.h>` **Is Model for the Concepts**

*EuclideanRing*  
*RealEmbeddable*

## long long int

### Definition

The fundamental type *long long int* is an *RealEmbeddable EuclideanRing*. Due to overflow *long long int* is considered as not exact.

`#include <CGAL/long_long.h>` **Is Model for the Concepts**

*EuclideanRing*  
*RealEmbeddable*

## float

### Definition

The fundamental type *float* is an *RealEmbeddable FieldWithSqrt*. Due to rounding errors and overflow *float* is considered as not exact.

`#include <CGAL/float.h>` **Is Model for the Concepts**

*FieldWithSqrt*  
*RealEmbeddable*

### Query Functions

<i>bool</i>	<code>CGAL::is_finite( <i>x</i> )</code>	Determines whether the argument represents a value in $\mathbb{R}$ .
-------------	--	--

## double

### Definition

The fundamental type *double* is an *RealEmbeddable Field*. Due to rounding errors and overflow *double* is considered as not exact.

`#include <CGAL/double.h>` **Is Model for the Concepts**

*FieldWithSqrt*  
*RealEmbeddable*

### Query Functions

*bool*                      *CGAL::is\_finite( x )*            Determines whether the argument represents a value in  $\mathbb{R}$ .

## long double

### Definition

The fundamental type *long double* is an *RealEmbeddable FieldWithSqrt*. Due to rounding errors and overflow *long double* is considered as not exact.

`#include <CGAL/long_double.h>` **Is Model for the Concepts**

*FieldWithSqrt*  
*RealEmbeddable*

### Query Functions

*bool*                      *CGAL::is\_finite( x )*            Determines whether the argument represents a value in  $\mathbb{R}$ .

## CORE::BigInt

### Definition

The class *CORE::BigInt* provides exact computation in  $\mathbb{Z}$ . Operations and comparisons between objects of this type are guaranteed to be exact. This number type is provided by the CORE library [KLPY99].

CGAL defines the necessary functions so that this class complies to the requirements on number types.

```
#include <CGAL/CORE_BigInt.h>
```

### Is Model for the Concepts

*EuclideanRing*

*RealEmbeddable*

## CORE::BigRat

### Definition

The class *CORE::BigRat* provides exact computation in  $\mathbb{R}$ . Operations and comparisons between objects of this type are guaranteed to be exact. This number type is provided by the CORE library [KLPY99].

CGAL defines the necessary functions so that this class complies to the requirements on number types.

```
#include <CGAL/CORE_BigRat.h>
```

### Is Model for the Concepts

*Field*

*RealEmbeddable*

*Fraction*

## CORE::BigFloat

### Definition

The class *CORE::BigFloat* is a variable precision floating-point type. Rounding mode and precision (i.e. mantissa length) of *leda\_bigfloat* can be set. Since it also carries the error of a computed value, *CORE::BigFloat* can be considered as an interval type,

This number type is provided by the CORE library [KL<sup>99</sup>].

CGAL defines the necessary functions so that this class complies to the requirements on number types.

```
#include <CGAL/CORE_BigFloat.h>
```

### Is Model for the Concepts

*FieldWithKthRoot*

*RealEmbeddable*

## CORE::Expr

### Definition

The class *CORE::Expr* provides exact computation over the subset of real numbers that contains integers, and which is closed by the operations  $+$ ,  $-$ ,  $\times$ ,  $/$ ,  $\sqrt{\phantom{x}}$  and *kth\_root*. Operations and comparisons between objects of this type are guaranteed to be exact. This number type is provided by the CORE library [KLPY99].

CGAL defines the necessary functions so that this class complies to the requirements on number types.

```
#include <CGAL/CORE_Expr.h>
```

### Is Model for the Concepts

*FieldWithRootOf*

*RealEmbeddable*

## leda\_integer

### Definition

The class *leda\_integer* provides exact computation in  $\mathbb{Z}$ . The class *leda\_integer* is a wrapper class that provides the functions needed to use the number type *leda::integer*, representing exact multiprecision integers provided by LEDA.

```
#include <CGAL/leda_integer.h>
```

### Is Model for the Concepts

*EuclideanRing*

*RealEmbeddable*

For more details on the number types of LEDA we refer to the LEDA manual [[MNSU](#)].

## leda\_rational

### Definition

The class *leda\_rational* provides exact computation in  $\mathbb{R}$ . The class *leda\_rational* is a wrapper class that provides the functions needed to use the number type *rational*, representing exact multiprecision rational numbers provided by LEDA.

```
#include <CGAL/leda_rational.h>
```

### Is Model for the Concepts

*Field*

*RealEmbeddable*

*Fraction*

For more details on the number types of LEDA we refer to the LEDA manual [[MNSU](#)].

## leda\_bigfloat

### Definition

The class *leda\_bigfloat* is a wrapper class that provides the functions needed to use the number type *bigfloat*. *bigfloat* Rounding mode and precision (i.e. mantissa length) of *leda\_bigfloat* can be set.

For more details on the number types of LEDA we refer to the LEDA manual [[MNSU](#)].

```
#include <CGAL/leda_bigfloat.h>
```

### Is Model for the Concepts

*FieldWithKthRoot*

*RealEmbeddable*

## leda\_real

### Definition

The class *leda\_real* is a wrapper class that provides the functions needed to use the number type *real*, representing exact real numbers provided by LEDA. The class *leda\_real* provides exact computation over the subset of real numbers that contains integers, and which is closed by the operations  $+$ ,  $-$ ,  $\times$ ,  $/$ ,  $\sqrt{\phantom{x}}$  and *kth\_root*. For LEDA version 5.0 or later *leda\_real* is also able to represent real roots of polynomials. Operations and comparisons between objects of this type are guaranteed to be exact.

```
#include <CGAL/leda_real.h>
```

### Is Model for the Concepts

*FieldWithRootOf*

*RealEmbeddable*

For more details on the number types of LEDA we refer to the LEDA manual [[MNSU](#)].

## **mpz\_class**

### **Definition**

The class *mpz\_class* is an exact multiprecision integer number type, provided by GMP. CGAL provides the necessary functions to make it compliant to the number type concept.

```
#include <CGAL/gmpxx.h>
```

### **Is Model for the Concepts**

*EuclideanRing*

*RealEmbeddable*

See the GMP documentation for additional details.

## **mpq\_class**

### **Definition**

The class *mpq\_class* is an exact multiprecision rational number type, provided by GMP. CGAL provides the necessary functions to make it compliant to the number type concept.

```
#include <CGAL/gmpxx.h>
```

### **Is Model for the Concepts**

*Field*

*RealEmbeddable*

*Fraction*

See the GMP documentation for additional details.

# CGAL::Gmpz

## Definition

An object of the class *Gmpz* is an arbitrary precision integer based on the GNU Multiple Precision Arithmetic Library.

```
#include <CGAL/Gmpz.h>
```

## Is Model for the Concepts

*EuclideanRing*

*RealEmbeddable*

## Creation

<i>Gmpz</i> <i>z</i> ;	creates an uninitialized multiple precision integer <i>z</i> .
<i>Gmpz</i> <i>z</i> ( <i>int</i> <i>i</i> );	creates a multiple-precision integer initialized with <i>i</i> .
<i>Gmpz</i> <i>z</i> ( <i>double</i> <i>d</i> );	creates a multiple-precision integer initialized with the integral part of <i>d</i> .

## Operations

<i>std::ostream&amp;</i>	<i>std::ostream&amp; out</i> << <i>z</i>	writes <i>z</i> to the ostream <i>out</i> .
<i>std::istream&amp;</i>	<i>std::istream&amp; in</i> >> & <i>z</i>	reads an integer from <i>in</i> , then converts it to a <i>Gmpz</i> .

## Implementation

*Gmpz*s are reference counted.

## CGAL::Gmpq

### Definition

An object of the class *Gmpq* is an arbitrary precision rational number based on the GNU Multiple Precision Arithmetic Library.

```
#include <CGAL/Gmpq.h>
```

### Is Model for the Concepts

*Field*  
*RealEmbeddable*  
*Fraction*

### Types

*Gmpq::NT* the field type, which is *Gmpz*.

### Creation

*Gmpq* *q*; creates an uninitialized multiple precision rational number *q*.

*Gmpq* *q*( *int i*); creates a multiple-precision rational number initialized with *i*.

*Gmpq* *q*( *Gmpz n*); creates a multiple-precision rational number initialized with *n*.

*Gmpq* *q*( *int n*, *int d*); creates a multiple-precision rational number initialized with *n/d*.

*Gmpq* *q*( *signed long n*, *unsigned long d*); creates a multiple-precision rational number initialized with *n/d*.

*Gmpq* *q*( *unsigned long n*, *unsigned long d*); creates a multiple-precision rational number initialized with *n/d*.

*Gmpq* *q*( *Gmpz n*, *Gmpz d*); creates a multiple-precision rational number initialized with *n/d*.

*Gmpq* *q*( *double d*); creates a multiple-precision rational number initialized with *d*.

*Gmpq* *q*( *std::string str*); creates a multiple-precision rational number initialized with *str*.

*Gmpq* *q*( *std::string str*, *int base*); creates a multiple-precision rational number initialized with *str*.

## Operations

`std::ostream&`                      `std::ostream& out << q`

writes  $q$  to the ostream  $out$ , in the form  $n/d$ .

`std::istream&`                      `std::istream& in >> & q`

reads a number from  $in$ , then converts it to a  $Gmpq$ . The number may be an integer, a rational number in the form  $n/d$ , or a floating-point number.

There are two access functions, namely to the numerator and the denominator of a rational. Note that these values are not uniquely defined. It is guaranteed that  $q.numerator()$  and  $q.denominator()$  return values  $nt\_num$  and  $nt\_den$  such that  $q = nt\_num/nt\_den$ , only if  $q.numerator()$  and  $q.denominator()$  are called consecutively wrt.  $q$ , i.e.  $q$  is not involved in any other operation between these calls.

$Gmpz$	$q.numerator()$	returns the numerator of $q$ .
$Gmpz$	$q.denominator()$	returns the denominator of $q$ .

## Implementation

$Gmpqs$  are reference counted.

## CGAL::Gmpzf

### Definition

This is an exact floating-point type; it can represent numbers of the form  $m * 2^e$ , where  $m$  is an arbitrary precision integer based on the GNU Multiple Precision Arithmetic Library, and  $e$  is of type *long*. This number type offers functionality very similar to *MP\_Float* but is generally faster.

```
#include <CGAL/Gmpzf.h>
```

### Is Model for the Concepts

*EuclideanRing*

*RealEmbeddable*

### Creation

*Gmpzf*  $f$ ; creates a multiple precision floating-point number initialized with 0.

*Gmpzf*  $f$ ( *int*  $i$ ); creates a multiple-precision floating-point number initialized with  $i$ .

*Gmpzf*  $f$ ( *long int*  $l$ ); creates a multiple-precision floating-point number initialized with  $l$ .

*Gmpzf*  $f$ ( *Gmpz*  $i$ ); creates a multiple-precision floating-point number initialized with  $i$ .

*Gmpzf*  $f$ ( *double*  $d$ ); creates a multiple-precision floating-point number initialized with  $d$ .

### Operations

*std::ostream&*      *std::ostream&*  $out \ll f$   
writes a double approximation of  $f$  to the ostream  $out$ .

*std::ostream&*      *print*( *std::ostream&*  $out, f$ )  
writes an exact representation of  $f$  to the ostream  $out$ .

*std::istream&*      *std::istream&*  $in \gg \&f$   
reads a *double* from  $in$ , then converts it to a *Gmpzf*.

## Implementation

The significand  $m$  of a  $Gmpzf$  is reference counted.

## CGAL::MP\_Float

### Definition

An object of the class *MP\_Float* is able to represent a floating point value with arbitrary precision. This number type has the property that additions, subtractions and multiplications are computed exactly, as well as the construction from *float*, *double* and *long double*.

Division and square root are not enabled by default since CGAL release 3.2, since they are computed approximately. We suggest that you use rationals like *Quotient<MP\_Float>* when you need exact divisions.

Note on the implementation : although the mantissa length is basically only limited by the available memory, the exponent is currently represented by a (integral valued) *double*, which can overflow in some circumstances. We plan to also have a multiprecision exponent to fix this issue.

```
#include <CGAL/MP_Float.h>
```

### Is Model for the Concepts

*EuclideanRing*.

*RealEmbeddable*

### Creation

<i>MP_Float</i> <i>m</i> ;	introduces an uninitialized variable <i>m</i> .
<i>MP_Float</i> <i>m</i> ( <i>MP_Float</i> );	copy constructor.
<i>MP_Float</i> <i>m</i> ( int <i>i</i> );	introduces the integral value <i>i</i> .
<i>MP_Float</i> <i>m</i> ( float <i>d</i> );	introduces the floating point value <i>d</i> (exact conversion).
<i>MP_Float</i> <i>m</i> ( double <i>d</i> );	introduces the floating point value <i>d</i> (exact conversion).
<i>MP_Float</i> <i>m</i> ( long double <i>d</i> );	introduces the floating point value <i>d</i> (exact conversion).

### Operations

<i>std::ostream&amp;</i>	<i>std::ostream&amp; out</i> << <i>m</i>	writes a double approximation of <i>m</i> to the ostream <i>out</i> .
--------------------------	--	---

<i>std::istream&amp;</i>	<i>std::istream&amp; in</i> >> & <i>m</i>	reads a <i>double</i> from <i>in</i> , then converts it to an <i>MP_Float</i> .
--------------------------	---	---

<i>MP_Float</i>	<i>approximate_division</i> ( <i>a</i> , <i>b</i> )	computes an approximation of the division by converting the operands to <i>double</i> , performing the division on <i>double</i> , and converting back to <i>MP_Float</i> .
-----------------	---	---

<i>MP_Float</i>	<i>approximate_sqrt( a )</i>	computes an approximation of the square root by converting the operand to <i>double</i> , performing the square root on <i>double</i> , and converting back to <i>MP_Float</i> .
-----------------	------------------------------	--

### **Implementation**

The implementation of *MP\_Float* is simple but provides a quadratic complexity for multiplications. This can be a problem for large operands. For faster implementations of the same functionality with large integral values, you may want to consider using *GMP* or *LEDA* instead.

## CGAL::Interval\_nt<Protected>

### Definition

This section describes briefly what interval arithmetic is, its implementation in CGAL, and its possible use by geometric programs. The main reason for having interval arithmetic in CGAL is its integration into the filtered robust and fast predicates scheme, but we also provide a number type so that you can use it separately if you find any use for it, such as interval analysis, or to represent data with tolerance...

The purpose of interval arithmetic is to provide an efficient way to bound the roundoff errors made by floating point computations. You can choose the behavior of your program depending on these errors. You can find more theoretical information on this topic in [BBP01].

Interval arithmetic is a large concept and we will only consider here a simple arithmetic based on intervals whose bounds are *doubles*. So each variable is an interval representing any value inside the interval. All arithmetic operations (+, -, \*, /,  $\sqrt{\phantom{x}}$ , *square()*, *min()*, *max()* and *abs()*) on intervals preserve the inclusion. This property can be expressed by the following formula (*x* and *y* are reals, *X* and *Y* are intervals, *OP* is an arithmetic operation):

$$\forall x \in X, \forall y \in Y, (x \text{ OP } y) \in (X \text{ OP } Y)$$

For example, if the final result of a sequence of arithmetic operations is an interval that does not contain zero, then you can safely determine its sign.

```
#include <CGAL/Interval_nt.h>
```

### Parameters

The template parameter *Protected* is a Boolean parameter, which defaults to *true*. It provides a way to select faster computations by avoiding rounding mode switches, at the expense of more care to be taken by the user (see below). The default value, *true*, is the safe way, and takes care of proper rounding mode changes. When specifying *false*, the user has to take care about setting the rounding mode towards plus infinity before doing any computations with the interval class. He can do so using the *Protect\_FPU\_rounding* class for example.

### Is Model for the Concepts

*FieldWithSqrt*

*RealEmbeddable*

### Types

The class *Interval\_nt* defines the following types: `typedef double value_type;` The type of the bounds of the interval.  
`typedef Uncertain_conversion_exception`

`unsafe_comparison;` The type of the exceptions raised when uncertain comparisons are performed.

*Interval\_nt<Protected>:: Protector*

A type whose default constructor and destructor allow to protect a block of code from FPU rounding modes necessary for the computations with *Interval\_nt<false>*. It does nothing for *Interval\_nt<true>*. It is implemented as *Protect\_FPU\_rounding<!Protected>*.

## Creation

<i>Interval_nt&lt;Protected&gt; I( int i);</i>	introduces the interval $[i;i]$ .
<i>Interval_nt&lt;Protected&gt; I( double d);</i>	introduces the interval $[d;d]$ .
<i>Interval_nt&lt;Protected&gt; I( double i, double s);</i>	introduces the interval $[i;s]$ .
<i>Interval_nt&lt;Protected&gt; I( std::pair&lt;double, double&gt; p);</i>	introduces the interval $[p.first;p.second]$ .

## Operations

All functions required by a class to be considered as a CGAL number type (see 4) are present, as well as the utility functions, sometimes with a particular semantic which is described below. There are also a few additional functions.

<i>Interval_nt</i>	<i>I / Interval_nt J</i>	returns $[-\infty; +\infty]$ when the denominator contains 0.
<i>Interval_nt</i>	<i>sqrt( Interval_nt I)</i>	returns $[0; \sqrt{upper\_bound(I)}]$ when only the lower bound is negative (expectable case with roundoff errors), and is unspecified when the upper bound also is negative (unexpected case).
<i>double</i>	<i>to_double( Interval_nt I)</i>	returns the middle of the interval, as a double approximation of the interval.
<i>double</i>	<i>I.inf()</i>	returns the lower bound of the interval.
<i>double</i>	<i>I.sup()</i>	returns the upper bound of the interval.
<i>bool</i>	<i>I.is_point()</i>	returns whether both bounds are equal.
<i>bool</i>	<i>I.is_same( Interval_nt J)</i>	returns whether both intervals have the same bounds.
<i>bool</i>	<i>I.do_overlap( Interval_nt J)</i>	returns whether both intervals have a non empty intersection.

The comparison operators ( $<$ ,  $>$ ,  $<=$ ,  $>=$ ,  $==$ ,  $!=$ ,  $sign()$  and  $compare()$ ) have the following semantic: it is the intuitive one when for all couples of values in both intervals, the comparison is identical (case of non-overlapping intervals). This can be expressed by the following formula ( $x$  and  $y$  are reals,  $X$  and  $Y$  are intervals,  $OP$  is a comparison operator):

$$(\forall x \in X, \forall y \in Y, (x \text{ OP } y) = \text{true}) \Rightarrow (X \text{ OP } Y) = \text{true}$$

and

$$(\forall x \in X, \forall y \in Y, (x \text{ OP } y) = \text{false}) \Rightarrow (X \text{ OP } Y) = \text{false}$$

Otherwise, the comparison is not safe, and we specify this by returning a type encoding this uncertainty, namely using *Uncertain<bool>* or *Uncertain<Sign>*, which can be probed for uncertainty explicitly, and which has a conversion to the normal type (e.g. *bool*) which throws an exception when the conversion is not certain. Note that each failed conversion increments a profiling counter (see *CGAL\_PROFILE*), and then throws the exception of type *unsafe\_comparison*.

```
Uncertain<bool>      Interval_nt i < Interval_nt j
Uncertain<bool>      Interval_nt i > Interval_nt j
Uncertain<bool>      Interval_nt i <= Interval_nt j
Uncertain<bool>      Interval_nt i >= Interval_nt j
Uncertain<bool>      Interval_nt i == Interval_nt j
Uncertain<bool>      Interval_nt i != Interval_nt j
Uncertain<Comparison_result>
```

```
Uncertain<Sign>      compare( Interval_nt i, Interval_nt j)
Uncertain<Sign>      sign( Interval_nt i)
```

```
typedef Interval_nt<false>
```

```
Interval_nt_advanced;
```

This typedef (at namespace CGAL scope) exists for backward compatibility, as well as removing the need to remember the Boolean value for the template parameter.

advanced

## Implementation

The operations on *Interval\_nt* with the default parameter *true*, are automatically protected against rounding modes, and are thus slower than those on *Interval\_nt\_advanced*, but easier to use. Users that need performance are encouraged to use *Interval\_nt\_advanced* instead.

Changing the rounding mode affects all floating point computations, and might cause problems with parts of your code, or external libraries (even CGAL), that expect the rounding mode to be the default (round to the nearest).

We provide two interfaces to change the rounding mode. The first one is to use a protector object whose default constructor and destructor will take care of changing the rounding mode. The protector is implemented using *Protect\_FPU\_rounding*.

The second one is the following detailed set of functions :

<i>typedef int</i>	<i>FPU_CW_t</i> ;	The type used by the following functions to deal with rounding modes. This is usually an <i>int</i> .
<i>void</i>	<i>FPU_set_cw( FPU_CW_t R)</i>	sets the rounding mode to <i>R</i> .
<i>FPU_CW_t</i>	<i>FPU_get_cw( void)</i>	returns the current rounding mode.
<i>FPU_CW_t</i>	<i>FPU_get_and_set_cw( FPU_CW_t R)</i>	sets the rounding mode to <i>R</i> and returns the old one.

The macros *CGAL\_FE\_TONEAREST*, *CGAL\_FE\_TOWARDZERO*, *CGAL\_FE\_UPWARD* and *CGAL\_FE\_DOWNWARD* are the values corresponding to the rounding modes.

### Example

Protecting an area of code that uses operations on the class *Interval\_nt\_advanced* can be done in the following way:

```
{
    Interval_nt_advanced::Protector P;
    ... // The code to be protected.
}
```

The basic idea is to use the directed rounding modes specified by the *IEEE 754* standard, which are implemented by almost all processors nowadays. It states that you have the possibility, concerning the basic floating point operations (+, −, \*, /, √) to specify the rounding mode of each operation instead of using the default, which is set to 'round to the nearest'. This feature allows us to compute easily on intervals. For example, to add the two intervals [a.i;a.s] and [b.i;b.s], compute  $c.i = a.i + b.i$  rounded towards minus infinity, and  $c.s = a.s + b.s$  rounded towards plus infinity, and the result is the interval [c.i;c.s]. This method can be extended easily to the other operations.

The problem is that we have to change the rounding mode very often, and the functions of the C library doing this operation are slow and not portable. That's why assembly versions are used as often as possible. Another trick is to store the opposite of the lower bound, instead of the lower bound itself, which allows us to never change the rounding mode inside simple operations. Therefore, all basic operations, which are in the class *Interval\_nt\_advanced* assume that the rounding mode is set to 'round to infinity', and everything works with this correctly set.

So, if the user needs the speed of *Interval\_nt\_advanced*, he must take care of setting the rounding mode to 'round to infinity' before each block of operations on this number type. And if other operations might be affected by this, he must take care to reset it to 'round to the nearest' before they are executed.

Notes:

- On Intel platforms (with any operating system and compiler), due to a misfeature of the floating point unit, which does not handle exactly IEEE compliant operations on doubles, we are forced to use a workaround

which slows down the code, but is only useful when the intervals can overflow or underflow. If you know that the intervals will never overflow nor underflow for your code, then you can disable this workaround with the flag `CGAL_IA_NO_X86_OVER_UNDER_FLOW_PROTECT`. Other platforms are not affected by this flag.

- When optimizing, compilers usually propagate the value of variables when they know it's a constant. This can break the interval routines because the compiler then does some floating point operations on these constants with the default rounding mode, which is wrong. This kind of problem is avoided by stopping constant propagation in the interval routines. However, this solution slows down the code and is rarely useful, so you can disable it by setting the flag `CGAL_IA_DONT_STOP_CONSTANT_PROPAGATION`.

└────────── *advanced* ─────────┘

## CGAL::Lazy\_exact\_nt<NT>

### Definition

An object of the class *Lazy\_exact\_nt<NT>* is able to represent any real embeddable number which *NT* is able to represent. The idea is that *Lazy\_exact\_nt<NT>* works exactly like *NT*, except that it is expected to be faster because it tries to only compute an approximation of the value, and only refers to *NT* when needed. The goal is to speed up exact computations done by any exact but slow number type *NT*.

*NT* must be a model of concept *RealEmbeddable*.

*NT* must be at least model of concept *IntegralDomainWithoutDivision*.

Note that some filtering mechanism is available at the predicate level using *Filtered\_predicate* and *Filtered\_kernel*.

```
#include <CGAL/Lazy_exact_nt.h>
```

### Is Model for the Concepts

<i>IntegralDomainWithoutDivision</i>	same as <i>NT</i>
<i>RealEmbeddable</i>	
<i>Fraction</i>	if <i>NT</i> is a <i>Fraction</i>

### Creation

<i>Lazy_exact_nt&lt;NT&gt;</i> <i>m</i> ;	introduces an uninitialized variable <i>m</i> .
<i>Lazy_exact_nt&lt;NT&gt;</i> <i>m</i> ( int <i>i</i> );	introduces the integral value <i>i</i> .
<i>Lazy_exact_nt&lt;NT&gt;</i> <i>m</i> ( double <i>d</i> );	introduces the floating point value <i>d</i> (works only if <i>NT</i> has a constructor from a double too).
<i>Lazy_exact_nt&lt;NT&gt;</i> <i>m</i> ( NT <i>n</i> );	introduces the value <i>n</i> .
template <class NT1> <i>Lazy_exact_nt&lt;NT&gt;</i> <i>m</i> ( <i>Lazy_exact_nt&lt;NT1&gt;</i> <i>n</i> );	introduces the value <i>n</i> . <i>NT1</i> needs to be convertible to <i>NT</i> (and this conversion will only be done if necessary).

### Operations

<i>NT</i>	<i>m</i> . <i>exact</i> ()	returns the corresponding NT value.
<i>Interval_nt&lt;true&gt;</i>	<i>m</i> . <i>approx</i> ()	returns an interval containing the exact value.
<i>Interval_nt&lt;false&gt;</i>	<i>m</i> . <i>interval</i> ()	returns an interval containing the exact value.

<i>static void</i>	<i>m.set_relative_precision_of_to_double( double d)</i>	specifies the relative precision that <i>to_double()</i> has to fulfill. The default value is $10^{-5}$ . <i>Precondition:</i> $d \geq 0$ and $d \leq 1$ .
<i>static double</i>	<i>m.get_relative_precision_of_to_double()</i>	returns the relative precision that <i>to_double()</i> currently fulfills.
<i>std::ostream&amp;</i>	<i>std::ostream&amp; out &lt;&lt; m</i>	writes <i>m</i> to ostream <i>out</i> in an interval format.
<i>std::istream&amp;</i>	<i>std::istream&amp; in &gt;&gt; &amp; m</i>	reads a <i>NT</i> from <i>in</i> , then converts it to a <i>Lazy_exact_nt&lt;NT&gt;</i> .

## Example

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Lazy_exact_nt.h>
#include <CGAL/Quotient.h>

typedef CGAL::Lazy_exact_nt<CGAL::Quotient<CGAL::MP_Float> > NT;
typedef CGAL::Cartesian<NT> K;
```

## CGAL::Quotient<NT>

### Definition

An object of the class *Quotient*<*NT*> is an element of the field of quotients of the integral domain type *NT*. If *NT* behaves like an integer, *Quotient*<*NT*> behaves like a rational number. LEDA's class *rational* (see Section 4.5) has been the basis for *Quotient*<*NT*>. A *Quotient*<*NT*> *q* is represented as a pair of *NT*s, representing numerator and denominator.

*NT* must be at least model of concept *IntegralDomainWithoutDivision*.

*NT* must be a model of concept *RealEmbeddable*.

```
#include <CGAL/Quotient.h>
```

### Is Model for the Concepts

*Field*

*RealEmbeddable*

*Fraction*

### Creation

<i>Quotient</i> < <i>NT</i> > <i>q</i> ;	introduces an uninitialized variable <i>q</i> .
template <class <i>T</i> >	
<i>Quotient</i> < <i>NT</i> > <i>q</i> ( <i>T</i> <i>t</i> );	introduces the quotient <i>t</i> / <i>I</i> . <i>NT</i> needs to have a constructor from <i>T</i> .
template <class <i>T</i> >	
<i>Quotient</i> < <i>NT</i> > <i>q</i> ( <i>Quotient</i> < <i>T</i> > <i>t</i> );	introduces the quotient <i>NT</i> ( <i>t</i> . <i>numerator</i> ())/ <i>NT</i> ( <i>t</i> . <i>denominator</i> ()).
<i>Quotient</i> < <i>NT</i> > <i>q</i> ( <i>NT</i> <i>n</i> , <i>NT</i> <i>d</i> );	<i>NT</i> needs to have a constructor from <i>T</i> . introduces the quotient <i>n</i> / <i>d</i> .

*Precondition*:  $d \neq 0$ .

### Operations

There are two access functions, namely to the numerator and the denominator of a quotient. Note that these values are not uniquely defined. It is guaranteed that *q*.*numerator*() and *q*.*denominator*() return values *nt\_num* and *nt\_den* such that  $q = nt\_num/nt\_den$ , only if *q*.*numerator*() and *q*.*denominator*() are called consecutively wrt *q*, i.e. *q* is not involved in any other operation between these calls.

<i>NT</i>	<i>q</i> . <i>numerator</i> ()	returns a numerator of <i>q</i> .
<i>NT</i>	<i>q</i> . <i>denominator</i> ()	returns a denominator of <i>q</i> .

The stream operations are available as well. They assume that corresponding stream operators for type *NT* exist.

```
std::ostream&          std::ostream& out << q
```

writes *q* to ostream *out* in format “n/d”, where  $n == q.numerator()$  and  $d == q.denominator()$ .

*std::istream&*                      *std::istream& in >> & q*

reads  $q$  from istream  $in$ . Expected format is “n/d”, where n and d are of type  $NT$ . A single n which is not followed by a / is also accepted and interpreted as n/1.

The following functions are added to fulfill the CGAL requirements on number types.

<i>double</i>	<i>to_double( q)</i>	returns some double approximation to $q$ .
<i>bool</i>	<i>is_valid( q)</i>	returns true, if numerator and denominator are valid.
<i>bool</i>	<i>is_finite( q)</i>	returns true, if numerator and denominator are finite.
<i>Quotient&lt;NT&gt;</i>	<i>sqrt( q)</i>	returns the square root of $q$ . This is supported if and only if $NT$ supports the square root as well.

## CGAL::Number\_type\_checker<NT1,NT2,Comparator>

### Definition

*Number\_type\_checker* is a number type whose instances store two numbers of types *NT1* and *NT2*. It forwards all arithmetic operations to them, and calls the binary predicate *Comparator* to check the equality of the instances after each modification, as well as for each comparison.

This is a debugging tool which is useful when dealing with number types.

### Parameters

*NT1* must be a model of some algebraic structure concept. *NT2* must be a model of the same algebraic structure concept. *NT1* and *NT2* must be *FromDoubleConstructible*. *Comparator* has to be a model of a binary predicate taking *NT1* as first argument, and *NT2* as second. The *Comparator* parameter has a default value which is a functor calling *operator==* between the two arguments.

```
#include <CGAL/Number_type_checker.h>
```

### Is Model for the Concepts

*IntegralDomainWithoutDivision* (same as *NT1*)

*RealEmbeddable* **Creation**

```
Number_type_checker<NT1,NT2,Comparator> c;
```

introduces an uninitialized variable *c*.

```
Number_type_checker<NT1,NT2,Comparator> c( int i);
```

introduces the integral value *i*.

```
Number_type_checker<NT1,NT2,Comparator> c( double d);
```

introduces the floating point value *d*.

```
Number_type_checker<NT1,NT2,Comparator> c( NT1 n1, NT2 n2);
```

introduces a variable storing the pair *n1*, *n2*.

### Operations

Some operations have a particular behavior documented here.

<i>NT1</i>	<i>c.n1()</i>	returns a const reference to the object of type <i>NT1</i> .
<i>NT2</i>	<i>c.n2()</i>	returns a const reference to the object of type <i>NT2</i> .
<i>NT1</i> &	<i>c.n1()</i>	returns a reference to the object of type <i>NT1</i> .
<i>NT2</i> &	<i>c.n2()</i>	returns a reference to the object of type <i>NT2</i> .

<i>bool</i>	<i>c.is_valid()</i>	calls the <i>Comparator</i> binary predicate on the two stored objects and returns its result.
<i>std::ostream&amp;</i>	<i>std::ostream&amp; out &lt;&lt; Number_type_checker c</i>	writes <i>c.n1()</i> to the ostream <i>out</i> .
<i>std::istream&amp;</i>	<i>std::istream&amp; in &gt;&gt; Number_type_checker&amp; c</i>	reads an <i>NT1</i> from <i>in</i> , then converts it to an <i>NT2</i> , so a conversion from <i>NT1</i> to <i>NT2</i> is required here.

## CGAL::Sqrt\_extension<NT,ROOT>

### Definition

An instance of this class represents an extension of the type *NT* by **one** square root of the type *ROOT*.

*NT* is required to be constructible from *ROOT*.

*NT* is required to be an *IntegralDomainWithoutDivision*.

*Sqrt\_extension<NT,ROOT>* is *RealEmbeddable* if *NT* is *RealEmbeddable*.

For example: Let *Integer* be some type representing  $\mathbb{Z}$ , then *Sqrt\_extension<Integer,Integer>* is able to represent  $\mathbb{Z}[\sqrt{root}]$  for some arbitrary value *root*. The value of *root* is set at construction time, or left open if *root* is not specified.

Note that the given *root* is stored as it is given to the constructor. In particular, an extension by a square root of a square is considered as an extension.

**It is not possible to interoperate two values from two different extensions  $\mathbb{Z}[\sqrt{a}]$  and  $\mathbb{Z}[\sqrt{b}]$ , since the result is in  $\mathbb{Z}[\sqrt{a}, \sqrt{b}]$ , which is not representable by *Sqrt\_extension<Integer,Integer>*.**

— advanced —

Since elements of *Sqrt\_extension<NT,ROOT>* that lie in different extensions are not interoperable with respect to any arithmetic operations, the full value range of *Sqrt\_extension<NT,ROOT>* does not represent an algebraic structure. However, each subset of the value range that represents the extension of *NT* by a particular square root is a valid algebraic structure, since this subset is closed under all provided arithmetic operations.

From there, *Sqrt\_extension<NT,ROOT>* can be used as if it were a model of an algebraic structure concept, with the following correspondence:

NT	<i>Sqrt_extension&lt;NT,ROOT&gt;</i>
<i>IntegralDomainWithoutDivision</i>	<i>IntegralDomainWithoutDivision</i>
<i>IntegralDomain</i>	<i>IntegralDomain</i>
<i>UniqueFactorizationDomain</i>	<i>IntegralDomain</i>
<i>EuclideanRing</i>	<i>IntegralDomain</i>
<i>Field</i>	<i>Field</i>

The extension of an *UniqueFactorizationDomain* or *EuclideanRing* is just an *IntegralDomain*, since the extension in general destroys the unique factorization property, e.g.,

$$10 = \sqrt{10} \cdot \sqrt{10} = 2 \cdot 5 \text{ over } \mathbb{Z}[\sqrt{10}]$$

**Note that the user is responsible for checking that the elements of *Sqrt\_extension<NT,ROOT>* that are manipulated are actually in a same extension field. If different extension fields are mixed together, the code may crash at runtime!**

In the same way *Sqrt\_extension* can be used as if it were a model of *RealEmbeddable* if *NT* is model of *RealEmbeddable*. **Comparisons of two values from different extension via operators is not allowed.** However, the member function *compare* provides this comparison.

— advanced —

## Is Model for the Concepts

*Assignable*  
*CopyConstructible*  
*DefaultConstructible*  
*EqualityComparable*  
*ImplicitInteroperable* with int  
*ImplicitInteroperable* with NT  
*Fraction* if NT is a *Fraction*

## Creation

*Sqrt\_extension*<NT,ROOT> *ext*; Introduces an variable initialized with 0.

*Sqrt\_extension*<NT,ROOT> *ext*( *Sqrt\_extension* *x*);  
 copy constructor.

*Sqrt\_extension*<NT,ROOT> *ext*( int *i*); Constructor from int.

*Sqrt\_extension*<NT,ROOT> *ext*( NT *x*); Constructor from type NT.

*Sqrt\_extension*<NT,ROOT> *ext*( int *a0*, int *a1*, int *r*);  
 Constructor from int:  $ext = a0 + a1 \cdot \sqrt{r}$ .

*Sqrt\_extension*<NT,ROOT> *ext*( NT *a0*, NT *a1*, ROOT *r*);  
 General constructor:  $ext = a0 + a1 \cdot \sqrt{r}$ .

## Operations

An object of type *Sqrt\_extension* represent an expression of the form:  $a0 + a1 \cdot \sqrt{root}$ .

*bool* *ext.is\_extended()* Returns true in case root of *ext* is not zero.  
 Note that  $a1 == 0$  does not imply  $root == 0$ .

*NT* *ext.a0()* Const access operator for a0  
*NT* *ext.a1()* Const access operator for a1  
*ROOT* *ext.root()* Const access operator for root  
*void* *ext.simplify()* Propagates the simplify command to members of *ext*.  
 see also: *AlgebraicStructureTraits::Simplify*.

*bool* *ext.is\_zero()* returns true if *ext* represents the value zero.

*CGAL::Sign* *ext.sign()* Determines sign of *ext* by (repeated) squaring.  
*Precondition: Sqrt\_extension is RealEmbeddable.*

<i>Sqrt_extension</i>	<i>ext.abs()</i>	returns the absolute value of <i>ext</i> . <i>Precondition: Sqrt_extension is RealEmbeddable.</i>
<i>Sqrt_extension</i>	<i>ext.compare( Sqrt_extension y, bool in_same_extension = false)</i>	Compares <i>ext</i> with <i>y</i> . The optional bool <i>in_same_extension</i> indicates whether <i>ext</i> and <i>y</i> are in the same extension of NT.
<i>Sqrt_extension</i>	<i>operator+( Sqrt_extension a, Sqrt_extension b)</i>	<i>Precondition: (a.root()==0 — b.root()==0 — a.root() == b.root())</i>
<i>Sqrt_extension</i>	<i>operator-( Sqrt_extension a, Sqrt_extension b)</i>	<i>Precondition: (a.root()==0 — b.root()==0 — a.root() == b.root())</i>
<i>Sqrt_extension</i>	<i>operator*( Sqrt_extension a, Sqrt_extension b)</i>	<i>Precondition: (a.root()==0 — b.root()==0 — a.root() == b.root())</i>
<i>Sqrt_extension&amp;</i>	<i>ext.operator+=( Sqrt_extension a)</i>	<i>Precondition: (this-&gt;root()==0 — a.root()==0 — this-&gt;root() == a.root())</i>
<i>Sqrt_extension&amp;</i>	<i>ext.operator-=( Sqrt_extension a)</i>	<i>Precondition: (this-&gt;root()==0 — a.root()==0 — this-&gt;root() == a.root())</i>
<i>Sqrt_extension&amp;</i>	<i>ext.operator*=( Sqrt_extension a)</i>	<i>Precondition: (this-&gt;root()==0 — a.root()==0 — this-&gt;root() == a.root())</i>
In case <i>NT</i> is an <i>IntegralDomain</i> operator/ implements integral division.		
<i>Sqrt_extension</i>	<i>operator/( Sqrt_extension a, Sqrt_extension b)</i>	<i>Precondition: (a.root()==0 — b.root()==0 — a.root() == b.root())</i>
<i>Sqrt_extension&amp;</i>	<i>ext.operator/=( Sqrt_extension a)</i>	<i>Precondition: (this-&gt;root()==0 — a.root()==0 — this-&gt;root() == a.root())</i>
<i>bool</i>	<i>operator==( Sqrt_extension a, Sqrt_extension b)</i>	<i>Precondition: (a.root()==0 — b.root()==0 — a.root() == b.root())</i>
<i>bool</i>	<i>operator!=( Sqrt_extension a, Sqrt_extension b)</i>	<i>Precondition: (a.root()==0 — b.root()==0 — a.root() == b.root())</i>

In case *Sqrt\_extension* is *RealEmbeddable*:

<i>bool</i>	<i>operator&lt;( Sqrt_extension a, Sqrt_extension b)</i>  <i>Precondition: (a.root()==0 — b.root()==0 — a.root()  == b.root())</i>
<i>bool</i>	<i>operator&lt;=( Sqrt_extension a, Sqrt_extension b)</i>  <i>Precondition: (a.root()==0 — b.root()==0 — a.root()  == b.root())</i>
<i>bool</i>	<i>operator&gt;( Sqrt_extension a, Sqrt_extension b)</i>  <i>Precondition: (a.root()==0 — b.root()==0 — a.root()  == b.root())</i>
<i>bool</i>	<i>operator&gt;=( Sqrt_extension a, Sqrt_extension b)</i>  <i>Precondition: (a.root()==0 — b.root()==0 — a.root()  == b.root())</i>

The stream operations are available as well. They assume that corresponding stream operators for type *NT* and *ROOT* exist.

<i>std::ostream&amp;</i>	<i>operator&lt;&lt;( std::ostream&amp; os, ext)</i>  writes <i>ext</i> to ostream <i>os</i> . The format depends on the <i>CGAL::IO::MODE</i> of <i>os</i> . In case the mode is <i>CGAL::IO::ASCII</i> the format is <code>EXT[a0,a1,root]</code> . In case the mode is <i>CGAL::IO::PRETTY</i> the format is human readable.
--------------------------	--

<i>std::istream&amp;</i>	<i>operator&gt;&gt;( std::istream&amp; is, ext)</i>  reads <i>ext</i> from istream <i>is</i> in format <code>EXT[a0,a1,root]</code> , the output format in mode <i>CGAL::IO::ASCII</i>
--------------------------	--

## CGAL::Max<T,Less>

### Definition

The function object class `Max<T, Less>` returns the larger of two values. The order is induced by the second template argument `Less`. The default value for `Less` is `std::less`.

Note that  $T$  must be a model of *LessThanComparable* in case `std::less` is used.

```
#include <CGAL/Utils_classes.h>
```

## Is Model for the Concepts

AdaptableFunctor ..... page ??

## Creation

<code>Max&lt;T,Less&gt; max;</code>	default constructor.
<code>Max&lt;T,Less&gt; max( Less c);</code>	The constructed object will use <code>c</code> to compare the arguments.

## Operations

$T$	<i>operator()</i> ( $Tx, Ty$ )	returns the larger of $x$ and $y$ , with respect to the order induced by <i>Less</i> .
-----	--------------------------------	--

## CGAL::Min<T,Less>

### Definition

The function object class *Min*<*T*,*Less*> returns the smaller of two values. The order is induced by the second template argument *Less*. The default value for *Less* is *std::less*.

Note that *T* must be a model of *LessThanComparable* in case *std::less* is used.

```
#include <CGAL/Utils_classes.h>
```

### Is Model for the Concepts

AdaptableFunctor ..... page ??

### Creation

<i>Min</i> < <i>T</i> , <i>Less</i> > <i>min</i> ;	default constructor.
<i>Min</i> < <i>T</i> , <i>Less</i> > <i>min</i> ( <i>Less</i> <i>c</i> );	The constructed object will use <i>c</i> to compare the arguments.

### Operations

<i>T</i>	<i>operator()</i> ( <i>T</i> <i>x</i> , <i>T</i> <i>y</i> )	returns the larger of <i>x</i> and <i>y</i> , with respect to the order induced by <i>Less</i> .
----------	---	--

# CGAL::Is\_valid<T>

## Definition

Not all values of a type need to be valid. The function object class *Is\_valid*<*T*> checks this.

For example, an expression like *NT(0)/NT(0)* can result in an invalid number. Routines may have as a precondition that all values are valid.

```
#include <CGAL/Utils_classes.h>
```

## Is Model for the Concepts

AdaptableFunctor .....page ??

*bool*                      *operator()( T x)*                      returns if the argument is valid.

## CGAL::max

### Definition

The function *max* returns the larger of two values.

```
#include <CGAL/Utils.h>
```

*T*  $\quad \quad \quad \text{max}(T\ x, T\ y)$

*Max* ..... page ??

## CGAL::min

### Definition

The function *min* returns the smaller of two values.

```
#include <CGAL/Utils.h>
```

```
T min( T x, T y)
```

### See Also

*Min*.....page ??

## CGAL::is\_valid

### Definition

Not all values of a type need to be valid. The function *is\_valid* returns whether the argument is valid.

```
#include <CGAL/Utils.h>
```

```
bool is_valid( T x)
```

## CGAL::Rational\_traits<NT>

### Definition

The class *Rational\_traits<NT>* can be used to determine the type of the numerator and denominator of a rational number type as *Quotient*, *Gmpq*, *mpq\_class* or *leda\_rational*.

```
#include <CGAL/Rational_traits.h>
```

### Types

*Rational\_traits<NT>::RT* the type of the numerator and denominator.

### Operations

*RT* *t.numerator( NT r)* returns the numerator of *r*.

*RT* *t.denominator( NT r)* returns the denominator of *r*.

*NT* *t.make\_rational( RT n, RT d)*  
constructs a rational number.

*NT* *t.make\_rational( NT n, NT d)*  
constructs a rational number.

## CGAL::simplest\_rational\_in\_interval

### Definition

The function *simplest\_rational\_in\_interval* computes the simplest rational number in an interval of two *double* values.

```
#include <CGAL/simplest_rational_in_interval.h>
```

*Rational*                    *simplest\_rational\_in\_interval*( *double* *d1*, *double* *d2*)

computes the rational number with the smallest denominator  
in the interval  $[d1, d2]$ .

### Implementation

See Knuth, "Seminumerical algorithms", page 654, answer to exercise 4.53-39.

### See Also

*Rational* *CGAL::to\_rational*<*Rational*>(double *d*).

## CGAL::to\_rational

### Definition

The function *to\_rational* computes the rational number representing a given double precision floating point number.

```
#include <CGAL/to_rational.h>
```

*Rational*                    *to\_rational*( *double d*)    computes the rational number that equals *d*.

### Implementation

### See Also

*CGAL::simplest\_rational\_in\_interval*<*Rational*>(*double d1*, *double d2*).

## RootOf\_2

### Definition

Concept to represent algebraic numbers of degree up to 2 over a *RingNumberType* denoted as *RT*.

### Creation

*RootOf\_2*                      *make\_root\_of\_2( RT a, RT b, RT c, bool s)*

Returns the smaller or larger root of the equation  $aX^2 + bX + c = 0$ , if *s* is *true* or *false*, respectively.  
Precondition:  $b^2 - 4ac \geq 0$

*RootOf\_2*                      *make\_root\_of\_2( FT a, FT b, FT c, bool s)*

Returns the smaller or larger root of the equation  $aX^2 + bX + c = 0$ , if *s* is *true* or *false*, respectively.  
Precondition:  $b^2 - 4ac \geq 0$

*RootOf\_2*                      *make\_root\_of\_2( FT alpha, FT beta, FT gamma)*

Constructs the number  $\alpha + \beta\sqrt{\gamma}$ .  
Precondition:  $\gamma \geq 0$

### Operations

The comparison operators `==`, `!=`, `<`, `>`, `<=`, `>=` as well as the *sign* and *compare* functions need to be provided to compare elements of types *RootOf\_2*, *RT* and *FT*.

In addition, the following operations must be provided:

*RootOf\_2*                      *RT a + RootOf\_2 r*

*RootOf\_2*                      *FT a + RootOf\_2 r*

*RootOf\_2*                      *RootOf\_2 r + RT a*

*RootOf\_2*                      *RootOf\_2 r + FT a*

as well as

*RootOf\_2*                      *RootOf\_2 r + RootOf\_2 r*

Addition of two algebraic numbers, in the special case when they have been constructed from equations having the same discriminant.

and similarly for operators `-`, `*` and `/`.

*RootOf\_2*                      *square( RootOf\_2 r)*

*RootOf\_2*                    *inverse( RootOf\_2 r)*

*RootOf\_2*                    *make\_sqrt( RT r)*

*RootOf\_2*                    *make\_sqrt( FT f)*

## Has Models

## CGAL::make\_root\_of\_2

### Definition

The function *make\_root\_of\_2* constructs an algebraic number of degree 2 over a ring number type.

```
#include <CGAL/Root_of_traits.h>
```

```
template <typename RT>
Root_of_traits<RT>::RootOf_2
```

```
make_root_of_2( RT a, RT b, RT c, bool s)
```

Returns the real root of the polynomial  $aX^2 + bX + c$  which is the smallest if  $s$  is true, or the largest if  $s$  is false.

*Precondition:*  $RT$  is a *RingNumberType*.

*Precondition:* The polynomial has at least one real root.

```
template <typename RT>
Root_of_traits<RT>::RootOf_2
```

```
make_root_of_2( RT alpha, RT beta, RT gamma)
```

Constructs the number  $\alpha + \beta\sqrt{\gamma}$ .

*Precondition:*  $RT$  is a *RingNumberType*.

*Precondition:*  $\gamma \geq 0$

## CGAL::Set\_ieee\_double\_precision

### Definition

The IEEE754 standard specifies that the precision of double precision floating-point numbers should be 53 bits, with 11 bits for the exponent range.

Some processors violate this rule by providing excess precision during some computations (when values are in registers). This is the case of the x86 Intel processor and compatible processors (note that the SSE2 more recent alternative FPU is fortunately not affected by this issue). The effect of such excess precision can be a problem for some computations, since it can produce so-called double rounding effects, where actually *less* precision is actually provided! It can also be the root of non-deterministic computations depending on compiler optimizations or not (since this affects how long variables are kept in registers), for example numerical floating-point values get computed with slightly different results. Finally, it affects code that carefully makes use of cancellation properties, like *Residue*.

The class *Set\_ieee\_double\_precision* provides a mechanism to set the correct 53 bits precision for a block of code. It does so by having a default constructor that sets a particular mode on the FPU which corrects the problem, and have its destructor reset the mode to its previous state.

Note that nothing can be done for the excess range of the exponent, which affects underflow and overflow cases, fortunately less frequent.

Note also that in the process of setting the correct precision, the rounding mode is also set to the nearest.

Moreover, some compilers provide a flag that performs this setting at the time of program startup. For example, GCC provides the option `-mpc64` since release 4.3 which does exactly this. Other compilers may have similar options.

Similarly, some third-party libraries may do the same thing as part of their startup process, and this is notably the case of LEDA (at least some versions of it). CGAL does not enforce this at startup as it would impact computations with long double performed by other codes in the same program.

Note that this property is notably required for proper functioning of the *Residue* class that performs modular arithmetic using efficient floating-point operations.

Note concerning Visual C++ 64-bit: due to a compiler bug, the stack unwinding process happening when an exception is thrown does not correctly execute the restoring operation when the *Set\_ieee\_double\_precision* object is destroyed. Therefore, for this configuration, some explicit code has to be added if you care about the state being restored.

```
#include <CGAL/FPU.h>
```

### Creation

If the platform is not affected by the excess precision problem, this class becomes an empty class doing nothing.

```
Set_ieee_double_precision P;
```

Sets the precision of operations on double to 53bits. Note that the rounding mode is set to the nearest in the same process.

*void* *~Set\_ieee\_double\_precision()*

The precision and rounding modes are reset to the values they held before the constructor was called.

Also note that the following free function is also provided that does the same thing as the default constructor of *Set\_ieee\_double\_precision* except that it does not perform the save and restore of the previous state.

*void* *force\_ieee\_double\_precision()*

Sets the precision of operations on double to 53bits. Note that the rounding mode is set to the nearest in the same process.

*CGAL::Residue* .....page [304](#)

## CGAL::Protect\_FPU\_rounding<Protected>

### Definition

Floating-point arithmetic, as specified by the IEEE-754 standard, allows to use so-called directed rounding for the following arithmetic operations: addition, subtraction, multiplication, division and square root. The default behavior is that the result of such an arithmetic operation is the closest floating-point number to the exact real result of the operation (rounding to the nearest). The other rounding modes are: round towards plus infinity, round towards minus infinity, and round towards zero.

Interval arithmetic uses such directed rounding modes to offer guaranteed enclosures for the evaluation of real functions, such as with CGAL's *Interval\_nt* class.

In order to efficiently evaluate sequences of interval arithmetic operations, such as a geometric predicate computing for example a determinant, it is advised to reduce the number of rounding mode changes, which otherwise are performed for each arithmetic operation. CGAL exploits the fact that it is possible to compute a sequence of interval arithmetic operations by doing only one rounding mode change around the whole function evaluation in order to benefit from this optimization.

The class *Protect\_FPU\_rounding* allows to easily benefit from this. Its constructor saves the current rounding mode in the object, and then sets the current rounding mode to the value provided as argument to the constructor. The destructor sets the rounding mode back to the saved value. This allows to protect a block of code determined by a C++ scope, and have the destructor take care of restoring the value automatically.

The related class *Set\_ieee\_double\_precision* allows to similarly protect a block of code from excess precision on some machines (x86 typically with the traditional FPU, not the more recent SSE2). Note that *Protect\_FPU\_rounding\_mode*, when changing rounding modes, also sets the precision to the correct 46 bit precision, hence providing a similar effect to *Set\_ieee\_double\_precision*. This notably affects the *Residue* class.

Note for Visual C++ 64-bit users: due to a compiler bug, the stack unwinding process happening when an exception is thrown does not correctly execute the rounding mode restoration when the *Protect\_FPU\_rounding* object is destroyed. Therefore, for this configuration, some explicit code has to be added.

```
#include <CGAL/FPU.h>
```

### Parameters

The template parameter *Protected* is a Boolean parameter, which defaults to *true*. It follows the same parameter of the *Interval\_nt* class. When it is *false*, the constructor and the destructor of the class do nothing (this is meant to be used in a context where you know that the rounding mode change has been taken care of at a higher level in the call stack).

What follows describes the behavior when the parameter has its default value, *true*.

### Creation

```
Protect_FPU_rounding<Protected> P( FPU_CW_t r = CGAL_FE_UPWARD);
```

The current rounding mode is saved in the object, and rounding mode is set to *r* which can be any of *CGAL\_FE\_TONEAREST*, *CGAL\_FE\_TOWARDZERO*, *CGAL\_FE\_UPWARD* (the default) and *CGAL\_FE\_DOWNWARD*.

*void* *~Protect\_FPU\_rounding()*

The rounding mode is restored to the saved value.

# Chapter 5

## Polynomial

Michael Hemmer

### 5.1 Fundamentals

Note that this is just a very brief introduction to polynomials. For a quick reference we refer to the Wikipedia or for a more elaborate introduction to any class book on elementary algebra.

A *polynomial* is either zero, or can be written as the sum of one or more non-zero *terms*. The number of terms is finite. A term consist of a constant *coefficient* and a *monomial*, that is, the product of zero or more variables. Each variable may have an exponent that is a non-negative integer. The exponent on a variable in a term is equal to the *degree* of that variable in that term. A term with no variables is called a constant term. The degree of a constant term is 0.

For example,  $-7x^3y$  is a term. The coefficient is  $-7$ , the monomial is  $x^3y$ , comprised of the variables  $x$  and  $y$ , the degree of  $x$  is three, and the degree of  $y$  is one. The *total degree* of the entire term is the sum of the degrees in each variable. In the example above, the degree is  $3 + 1 = 4$ .

A one-variable (univariate) polynomial  $f$  of degree  $n$  has the following form:

$$f = a_nx^n + a_{n-1}x^{n-1} + \dots + a_2x^2 + a_1x + a_0$$

The coefficient  $a_0$  is called the *constant coefficient*,  $a_n$  is called the *leading coefficient*. If  $f$  is not the zero polynomial the leading coefficient is not zero. The polynomial is called monic if  $a_n = 1$ . In case the coefficient domain of  $f$  possess a greatest common divisor (gcd) the *content* of  $f$  is the gcd of all coefficients of  $f$ . For instance, the content of  $12x^3 + 6$  is 6.

A multivariate polynomial is a polynomial in more than one variable. According to the number of variables it is possible to further classify multivariate polynomials as bivariate, trivariate etc. In contrast to univariate polynomials the terms of a multivariate polynomial are not completely ordered by their total degree. However, given a certain order on the variables it is possible to define a lexicographic order on the terms. Given this order the leading coefficient of a multivariate polynomial is defined as the coefficient of the highest term. For instance the leading coefficient of the multivariate polynomial  $p = 5x^3y + 7xy^2$  is 7, given that  $y$  has an higher order than  $x$ .

However, it is also possible to interpret a multivariate polynomial as a univariate polynomial in that variable.

For instance the trivariate polynomial

$$q = x^5 + 7x^2y^1z^2 + 13x^1y^2z^2 \in \mathbb{Z}[x, y, z]$$

may be interpreted as a univariate polynomial in  $z$ , that is,  $q$  is interpreted as an element of  $R[z]$ , with  $R = \mathbb{Z}[x, y]$ .

$$q = (13x^1y^2 + 7x^2y^1)z^2 + x^5z^0 \in R[z]$$

In this case the leading coefficient of  $q$  with respect to  $z$  is  $13x^1y^2 + 7x^2y^1$  and  $x^5$  becomes the 'constant' term.

A *homogeneous polynomial* is a polynomial whose terms do all have the same total degree. For example,  $h = x^5 + 7x^2y^1z^2 + 13x^1y^2z^2$  is a homogeneous polynomial of degree 5, in three variables.

## 5.2 General Design

The package introduces a concept *Polynomial\_d*, a concept for multivariate polynomials in  $d$  variables. Though the concept is written for an arbitrary number of variables, the number of variables is considered as fixed for a particular model of *Polynomial\_d*. The concept also allows univariate polynomials.

First of all a model of *Polynomial\_d* is considered as an algebraic structure, that is, the ring operations  $\{+, -, \cdot\}$  are provided due to the fact that *Polynomial\_d* refines at least the concept *IntegralDomainWithoutDivision*. However, a model of *Polynomial\_d* has to be accompanied by a traits class *CGAL::Polynomial\_traits\_d* being a model of *PolynomialTraits\_d*. In principal the traits class provides all further functionalities on polynomials.

Given a  $d$ -variate polynomial over some base ring  $R$  there are at least two different possible views on such a polynomial.

- The recursive or univariate view: In this view, a polynomial is considered as an element of  $R[x_0, \dots, x_{d-2}][x_{d-1}]$ . That is, the polynomial is treated as a univariate polynomial over the ring  $R[x_0, \dots, x_{d-2}]$ .
- The symmetric or multivariate view: This view is almost symmetric with respect to all variables. It considers the polynomial as an element of  $R[x_0, \dots, x_{d-1}]$ .

According to these two different views the traits class is required to provide two different coefficient types:

- *CGAL::Polynomial\_traits\_d*<*Polynomial\_d*>::*Coefficient\_type* representing  $R[x_0, \dots, x_{d-2}]$ .
- *CGAL::Polynomial\_traits\_d*<*Polynomial\_d*>::*Innermost\_coefficient\_type* representing the base ring  $R$ .

Another important type which is introduced by this package is *CGAL::Exponent\_vector*. It is derived from *std::vector<int>* and used to identify multivariate monomials. For instance the exponent vector containing the sequence  $[3, 2, 4]$  corresponds to the trivariate monomial  $x_0^3x_1^2x_2^4$ . Note that a vector with negative exponents is considered as invalid. However, we decided to in principal allow negative exponents as they may appear as intermediate results, in particular we did **not** derive from *std::vector<unsigned int>*.

## 5.3 Constructing a multivariate polynomial

First of all the concept *Polynomial\_d* requires that the model is constructible from *int*. This is due to the fact that *Polynomial\_d* refines *IntegralDomainWithoutDivision* which in turn refines *FromIntConstructible*. Of course this allows only the construction of constant polynomials.

In general a polynomial is constructed using the functor `CGAL::Polynomial_traits_d<Polynomial_d>::Construct_polynomial` a model of `PolynomialTraits_d::ConstructPolynomial`. Basically there are two options:

- The polynomial is constructed from an iterator range with value type `CGAL::Polynomial_traits_d<Polynomial_d>::Coefficient_type`, where the *begin* iterator refers to the constant term (constant with respect to the outermost variable).
- The polynomial is constructed from an iterator range with value type `std::pair<CGAL::Exponent_vector, CGAL::Polynomial_traits_d<Polynomial_d>::Innermost_coefficient_type>`, where each pair defines the coefficient for the monomial defined by the exponent vector.

However, in some cases it might be more convenient to just construct the polynomials representing the different variables and to obtain the final polynomial using algebraic expressions. The most elegant way to construct a certain variable is `CGAL::Polynomial_traits_d<Polynomial_d>::Shift` being a model of `PolynomialTraits_d::Shift`.

### 5.3.1 Examples

The following example illustrates different ways to construct a bivariate polynomial:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
    CGAL::set_pretty_mode(std::cout);

    typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;
    typedef CGAL::Polynomial_traits_d<Poly_2> PT_2;
    typedef PT_2::Coefficient_type Poly_1;
    typedef PT_2::Innermost_coefficient_type Integer;

    PT_2::Construct_polynomial construct_polynomial;

    // constructing a constant polynomial from int
    Poly_2 two(2); // = 2
    std::cout << "A constant polynomial: " << two << std::endl;

    // construction from an iterator range of univariate polynomials

    std::list<Poly_1> univariate_coeffs;
    univariate_coeffs.push_back(Poly_1(3));
    univariate_coeffs.push_back(Poly_1(0));
    univariate_coeffs.push_back(Poly_1(5));
    Poly_2 F = // 5*y^2 + 3
        construct_polynomial(univariate_coeffs.begin(),univariate_coeffs.end());
    std::cout << "The bivariate polynomial F: " << F << std::endl;

    // construction from an iterator range over monomials
```

```

std::list<std::pair<CGAL::Exponent_vector, Integer> > innermost_coeffs;
innermost_coeffs.push_back(std::make_pair(CGAL::Exponent_vector(0,0),-2));
innermost_coeffs.push_back(std::make_pair(CGAL::Exponent_vector(3,5),2));
Poly_2 G = // (2*x^3)*y^5 + (-2)
    construct_polynomial(innermost_coeffs.begin(),innermost_coeffs.end());
std::cout << "The bivariate polynomial G: " << G << std::endl;

//construction using shift
PT_2::Shift shift;
Poly_2 x = shift(Poly_2(1),1,0); // 'multiply' 1 by x_0^1
Poly_2 y = shift(Poly_2(1),1,1); // 'multiply' 1 by x_1^1

Poly_2 H = 5 * x * y + 3 * y * y; // = 3*y^2 + (5*x)*y
std::cout << "The bivariate polynomial H: " << H << std::endl;
}

```

**File:** examples/Polynomial/construction.cpp

## 5.4 Coefficient Access

In order to obtain a certain coefficient the traits class provides several functors. Note that the functors do not allow a write access to the coefficients.

- *PolynomialTraits\_d::GetCoefficient*: a model of this concept provides access to a coefficient in the univariate view, that is, it returns elements of  $R[x_0, \dots, x_{d-2}]$ .
- *PolynomialTraits\_d::GetInnermostCoefficient*: a model of this concept provides access to a coefficient in the multivariate view, that is, it returns elements of  $R$ .
- *PolynomialTraits\_d::LeadingCoefficient*: a model of this concept provides access to the leading coefficient in the univariate view.
- *PolynomialTraits\_d::InnermostLeadingCoefficient*: a model of this concept provides access to the leading coefficient in the multivariate view, that is, it returns the (innermost) coefficient of the leading multivariate monomial. See also *PolynomialTraits\_d::DegreeVector*.

### 5.4.1 Examples

The following example illustrates the application of the functors discussed above:

```

#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main() {
    CGAL::set_pretty_mode(std::cout);
    typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;

```

```

typedef CGAL::Polynomial_traits_d<Poly_2>          PT_2;

//construction using shift
Poly_2 x = PT_2::Shift() (Poly_2(1),1,0); // = x^1
Poly_2 y = PT_2::Shift() (Poly_2(1),1,1); // = y^1

Poly_2 F // = (11*x^2 + 5*x)*y^4 + (7*x^2)*y^3
    = 11 * CGAL::ipower(y,4) * CGAL::ipower(x,2)
    + 5 * CGAL::ipower(y,4) * CGAL::ipower(x,1)
    + 7 * CGAL::ipower(y,3) * CGAL::ipower(x,2);
std::cout << "The bivariate polynomial F: " << F << "\n" << std::endl;

PT_2::Get_coefficient get_coefficient;
std::cout << "Coefficient of y^0: " << get_coefficient(F,0) << std::endl;
std::cout << "Coefficient of y^1: " << get_coefficient(F,1) << std::endl;
std::cout << "Coefficient of y^2: " << get_coefficient(F,2) << std::endl;
std::cout << "Coefficient of y^3: " << get_coefficient(F,3) << std::endl;
std::cout << "Coefficient of y^4: " << get_coefficient(F,4) << std::endl;
std::cout << "Coefficient of y^5: " << get_coefficient(F,5) << std::endl;
std::cout << std::endl;

PT_2::Leading_coefficient lcoeff;
std::cout << "Leading coefficient with respect to y: "
    << lcoeff(F) // = 11*x^2 + 5*x
    << std::endl;

PT_2::Get_innermost_coefficient get_icoeff;
std::cout << "Innermost coefficient of monomial x^1y^4: "
    << get_icoeff(F,CGAL::Exponent_vector(1,4)) // = 5
    << std::endl;

PT_2::Innermost_leading_coefficient ilcoeff;
std::cout << "Innermost leading coefficient with respect to y: "
    << ilcoeff(F) // = 11
    << std::endl;
}

```

**File:** examples/Polynomial/coefficient\_access.cpp

## 5.5 Degree, total degree and degree vector

There are three functors in *PolynomialTraits\_d* related to the degree of a polynomial.

- *PolynomialTraits\_d::Degree*: a model of this concept returns the degree of the polynomial in the univariate view. By default this is the degree with respect to the outermost variable, but it is also possible to select another variable.
- *PolynomialTraits\_d::TotalDegree*: a model of this concept returns the *total degree* of a polynomial. The polynomial is considered as a multivariate polynomial. The total degree is the maximum over the sums of the exponents of each multivariate monomial.

- *PolynomialTraits\_d::DegreeVector*: a model of this concept returns the exponent vector of the leading monomial, where the monomial order is lexicographic and starts with the outermost variable. See also *PolynomialTraits\_d::InnermostLeadingCoefficient*.

### 5.5.1 Examples

The following example illustrates the application of the functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
    CGAL::set_pretty_mode(std::cout);
    typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;
    typedef CGAL::Polynomial_traits_d<Poly_2> PT_2;

    //construction using shift
    Poly_2 x = PT_2::Shift()(Poly_2(1),1,0); // x_0^1
    Poly_2 y = PT_2::Shift()(Poly_2(1),1,1); // x_1^1

    Poly_2 F // = (11*x^2 + 5*x)*y^4 + (7*x^2)*y^3
    = 11 * CGAL::ipower(y,4) * CGAL::ipower(x,2)
    + 5 * CGAL::ipower(y,4) * CGAL::ipower(x,1)

## 5.6 Changing the order of variables

Given for instance a bivariate polynomial it is conceivable that one wants to interchange the role of  $x$  and  $y$ . That is one wants to interpret the  $x$  as  $y$  and vice versa. For such a case the polynomial traits provides *PolynomialTraits\_d::Swap*:

Given a polynomial  $p$  and to two indices  $i$  and  $j$ , the functor returns the polynomial in which  $x_i$  is substituted by  $x_j$  and vice versa, that is, the variables swap their positions. The order of the other variables remains untouched.

Another scenario is, that a particular variable should be moved to another position, for instance, it should become the outermost variable while the relative order of the other variables remains unchanged. For such a case the polynomial traits provides *PolynomialTraits\_d::Move*.

Of course there is also a general method to interchange the order of variables, namely *PolynomialTraits\_d::Permute*.

### 5.6.1 Examples

The following example illustrates the application of the functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main() {
    CGAL::set_pretty_mode(std::cout);
    typedef CGAL::Polynomial_type_generator<int,3>::Type Poly_3;
    typedef CGAL::Polynomial_traits_d<Poly_3> PT_3;

    //construction using shift
    Poly_3 x = PT_3::Shift()(Poly_3(1),1,0); // x_0^1
    Poly_3 y = PT_3::Shift()(Poly_3(1),1,1); // x_1^1
    Poly_3 z = PT_3::Shift()(Poly_3(1),1,2); // x_2^1

    Poly_3 F = x*y*z*z*z;
    std::cout << "The trivariate polynomial F: " << F << std::endl;
    std::cout << std::endl;

    PT_3::Swap swap;
    PT_3::Move move;
    PT_3::Permute permute;

    std::cout << "x and z swapped: " << swap(F,0,2) // = x^3*y^2*z
    << std::endl;
    std::cout << "x and y swapped: " << swap(F,0,1) // = x^2*y*z^3
    << std::endl << std::endl;

    std::cout << "x moved to outermost position : "
    << move(F,0,2) // = x^2*y^3*z
    << std::endl;
    std::cout << "Same as swap(swap(F,0,1),1,2) : "
```

```

        << swap(swap(F,0,1),1,2) // = x^2*y^3*z
        << std::endl;

std::cout << "Same as the permutation (0,1,2)->(2,0,1): ";
std::vector<int> perm;
perm.push_back(2);perm.push_back(0);perm.push_back(1);
std::cout << permute(F,perm.begin(),perm.end())// = x^2*y^3*z
        << std::endl;
}

```

**File:** examples/Polynomial/swap\_move.cpp

## 5.7 GCD and More

Since the concept *PolynomialTraits\_d* refines the concept *AlgebraicStructureTraits* the polynomial traits provides functors for integral division, division with remainder, greatest common divisor, etc. But note that the algebraic structure of a polynomial depends on the algebraic structure of the innermost coefficient, for instance, a gcd is available if and only if the innermost coefficient is a *Field* or a *UniqueFactorizationDomain*. Hence, we can not provide a gcd if the innermost coefficient is just an *IntegralDomain* since it is simply not well defined<sup>1</sup>. However, if we would consider the polynomial over the quotient field of the integral domain the gcd would be well defined. The only problem is that the result can not be represented over the ring since it contains denominators. Therefore, the *PolynomialTraits\_d* requires functors such as *PolynomialTraits\_d::GcdUpToConstantFactor*. This functor computes the gcd of two polynomials up to a constant factor (utcf). That is, it returns the correct gcd for polynomials over the quotient field, but multiplied by some constant such that the result is representable with coefficients in the ring.

However, note that these 'utcf' functions are usually a bit faster than their strict counter parts. This is due to the fact that the 'utcf' functions are allowed to skip the computation of the correct constant factor. Note that in many cases the constant factor is in fact not needed. In particular if the polynomials are supposed to represent some zero set, that is, an algebraic curve or surface.

The concepts for the related functors are:

- *AlgebraicStructureTraits::Gcd*  
*PolynomialTraits\_d::GcdUpToConstantFactor*
- *AlgebraicStructureTraits::IntegralDivision*  
*PolynomialTraits\_d::IntegralDivisionUpToConstantFactor*
- *PolynomialTraits\_d::UnivariateContent*  
*PolynomialTraits\_d::UnivariateContentUpToConstantFactor*
- *PolynomialTraits\_d::SquareFreeFactorize*  
*PolynomialTraits\_d::SquareFreeFactorizeUpToConstantFactor*

Another analog functionality is the pseudo division. The related functors replace the usual division with remainder in case the Polynomial is not a *EuclideanRing*.

The concepts for the related functors are:

---

<sup>1</sup>An example for such a number type is the template *CGAL::Sqrt\_extension<NT,ROOT>* representing an algebraic extension of degree two. This is just an *IntegralDomain* if NT is not a *Field*.

- *AlgebraicStructureTraits::Div\_mod*  
*PolynomialTraits\_d::PseudoDivision*
- *AlgebraicStructureTraits::Div*  
*PolynomialTraits\_d::PseudoDivisionQuotient*
- *AlgebraicStructureTraits::Mod*  
*PolynomialTraits\_d::PseudoDivisionRemainder*

## 5.7.1 Examples

The following example illustrates the application of some functors discussed above:

```
#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main() {
    CGAL::set_pretty_mode(std::cout);
    typedef CGAL::Polynomial_type_generator<int,1>::Type Poly_1;
    typedef CGAL::Polynomial_traits_d<Poly_1> PT_1;

    PT_1::Shift shift;
    PT_1::Gcd gcd;
    PT_1::Gcd_up_to_constant_factor gcd_utcf;
    PT_1::Multivariate_content mcontent;
    PT_1::Canonicalize canonicalize;

    //construction using shift
    Poly_1 x = shift(Poly_1(1),1,0); // x^1

    // common factor 7 * (x^2-2)
    Poly_1 F = 21*(x-5)*(x*x-2); // = 21*x^3 + (-105)*x^2 + (-42)*x + 210
    Poly_1 G = 14*(x-3)*(x*x-2); // = 14*x^3 + (-42)*x^2 + (-28)*x + 84

    std::cout << "The univariate polynomial F: " << F << std::endl;
    std::cout << "The univariate polynomial G: " << G << std::endl;
    std::cout << "Common multivariate content: "
        << CGAL::gcd(mcontent(F),mcontent(G)) // = 7
        << std::endl;
    std::cout << "The gcd of F and G: "
        << gcd(F,G) // = 7*x^2 + (-14)
        << std::endl;
    std::cout << "The gcd up to constant factor of F and G: "
        << gcd_utcf(F,G) // = x^2 + (-2)
        << std::endl;
    std::cout << "Same as canonicalized gcd of F and G: "
        << canonicalize(gcd_utcf(F,G)) // = x^2 + (-2)
        << std::endl;
}
```

**File:** examples/Polynomial/gcd\_up\_to\_constant\_factor.cpp

## 5.8 Evaluation and Substitution

Of course, it should also be possible to evaluate a polynomial or substitute its variables. We also require a special functor to determine whether a polynomial is zero at a given point. In case the inner most coefficient is *RealEmbeddable* the traits also must provide a function to compute the sign at a given point.

The concepts for the related functors are:

- *PolynomialTraits\_d::Substitute*
- *PolynomialTraits\_d::Evaluate*
- *PolynomialTraits\_d::IsZeroAt*
- *PolynomialTraits\_d::SignAt*

The traits is also required to provide variants of these functors that interpret the polynomial as a homogeneous polynomial by adding a virtual homogeneous variable such that each term has the same degree, namely the degree of the polynomial. Of course there is a difference between the univariate and multivariate view. For instance the polynomial

$$5x^3 + 7x - 3$$

has degree 3, hence it is interpreted as the homogeneous polynomial

$$5x^3 + 7xw^2 - 3w^3$$

by adding the homogeneous variable  $w$ . In case of the multivariate view each term is filled up by the homogeneous variable such that the degree of each term is equal to the total degree of the polynomial. Note that these functors may significantly improve efficiency. For instance, it is possible to determine the sign of a polynomial over integer coefficients at a rational point without changing the coefficient domain of the polynomial. For more details have a look at the following concepts:

- *PolynomialTraits\_d::SubstituteHomogeneous*
- *PolynomialTraits\_d::EvaluateHomogeneous*
- *PolynomialTraits\_d::IsZeroAtHomogeneous*
- *PolynomialTraits\_d::SignAtHomogeneous*

Note that substitute allows the substitution of the variables by any type that is *ExplicitInteroperable* with the innermost coefficient type. This is a very powerful tool since it allows the substitution of the variables by polynomials. However, for some standard manipulations such as translation or scaling we require special functors since they are expected to be faster than their equivalent implementation using substitution:

- *PolynomialTraits\_d::Shift*
- *PolynomialTraits\_d::Negate*
- *PolynomialTraits\_d::Invert*
- *PolynomialTraits\_d::Translate*
- *PolynomialTraits\_d::TranslateHomogeneous*
- *PolynomialTraits\_d::Scale*
- *PolynomialTraits\_d::ScaleHomogeneous*

### 5.8.1 Examples

The following example illustrates the application of some functors discussed above:

```

#include <CGAL/config.h>
#include <CGAL/Polynomial.h>
#include <CGAL/Polynomial_traits_d.h>
#include <CGAL/Polynomial_type_generator.h>

int main(){
    CGAL::set_pretty_mode(std::cout);
    typedef CGAL::Polynomial_type_generator<int,2>::Type Poly_2;
    typedef CGAL::Polynomial_traits_d<Poly_2> PT_2;

    //construction using shift
    Poly_2 x = PT_2::Shift() (Poly_2(1),1,0); // x^1
    Poly_2 y = PT_2::Shift() (Poly_2(1),1,1); // y^1

    Poly_2 F = 2*x*y + 3*CGAL::ipower(y,3);
    std::cout << "The bivariate polynomial F: " << F // = 3*y^3 + (2*x)*y
                << std::endl << std::endl;

    PT_2::Evaluate evaluate;
    PT_2::Evaluate_homogeneous hevaluate;

    // Evaluation considers a polynomials as univariate:
    std::cout << "F(5): " << evaluate(F,5) // = 10*x + 375
                << std::endl;
    // Evaluate_homogeneous considers F as a homogeneous polynomial in
    // the outermost variable only, that is, F is interpreted as
    // F(u,v) = 2*x*u*v^2 + 3 * u^3
    std::cout << "F(5,7): " << hevaluate(F,5,7) // = 490*x + 375
                << std::endl << std::endl;

    PT_2::Substitute substitute;
    PT_2::Substitute_homogeneous hsubstitute;

    // Substitute considers a polynomials as multivariate, that is, the
    // new values for the variables are given by an iterator range
    // Note that the value type only has to be interoperable with the innermost
    // coefficient
    std::list<Poly_2> replacements;
    replacements.push_back(x-1); // replace x by x-1
    replacements.push_back(y); // replace y by y, i.e., do nothing

    std::cout << "The bivariate polynomial F: " << F // = 3*y^3 + (2*x)*y
                << std::endl;
    std::cout << "F(x-1,y): " // = 3*y^3 + (2*x + (-2))*y
                << substitute(F,replacements.begin(),replacements.end())
                << std::endl;
    // Substitute_homogeneous considers F as a homogeneous polynomial in
    // all variable, that is, F is interpreted as
    // F(x,y,w) = 2*x*y*w + 3 * y^3
    replacements.push_back(y); // replace z by y

    std::cout << "F(x-1,y,y): " // = 3*y^3 + (2*x + (-2))*y^2

```

```

    << hsubstitute(F,replacements.begin(),replacements.end())
    << std::endl;
}

```

**File:** examples/Polynomial/substitute.cpp

## 5.9 Design and Implementation History

This package is the result of the integration process of the NumeriX library of EXACUS [BEH<sup>+</sup>05] into CGAL.

The class *CGAL::Polynomial<Coeff>* had been started by Michael Seel within CGAL as part of the Nef\_2 package. As part of the EXACUS project it got significantly improved by Arno Eigenwillig and Michael Hemmer.

However, due to the recursive definition the class was rather restricted to the univariate view. Moreover, it is clear that depending on the context other classes that are symmetric in all variables or dedicated for sparse polynomials may be more efficient. As a consequence this package introduced the *CGAL::Polynomial\_traits\_d<Polynomial\_d>* giving also the symmetric view on polynomials and the opportunity to introduce and use other classes representing polynomials within CGAL.

# Polynomial\_d

## Definition

A model of `Polynomial_d` is representing a multivariate polynomial in  $d \geq 1$  variables over some basic ring  $R$ . This type is denoted as the innermost coefficient. A model of `Polynomial_d` accompanied by a traits class `CGAL::Polynomial_traits_d<Polynomial_d>`, which is a model of `PolynomialTraits_d`. Please have a look at the concept `PolynomialTraits_d`, since nearly all functionality related to polynomials is provided by the traits.

## Refines

*IntegralDomainWithoutDivision*

The algebraic structure of *Polynomial\_d* depends on the algebraic structure of *Innermost\_coefficient\_type*:

<i>Innermost_coefficient_type</i>	<i>Polynomial_d</i>
<i>IntegralDomainWithoutDivision</i>	<i>IntegralDomainWithoutDivision</i>
<i>IntegralDomain</i>	<i>IntegralDomain</i>
<i>UniqueFactorizationDomain</i>	<i>UniqueFactorizationDomain</i>
<i>EuclideanRing</i>	<i>UniqueFactorizationDomain</i>
<i>Field</i>	<i>UniqueFactorizationDomain</i>

Note: In case the polynomial is univariate and the innermost coefficient is a *Field* the polynomial is model of *EuclideanRing*.

## PolynomialTraits\_d

### Definition

A model of *PolynomialTraits\_d* is associated with a type *Polynomial\_d*. The type *Polynomial\_d* represents a multivariate polynomial. The number of variables is denoted as the dimension  $d$  of the polynomial, it is arbitrary but fixed for a certain model of this concept. Note that univariate polynomials are not excluded by this concept. In this case  $d$  is just set to one.

*PolynomialTraits\_d* provides two different views on the multivariate polynomial.

- The recursive view: In this view, the polynomial is considered as an element of  $R[x_0, \dots, x_{d-2}][x_{d-1}]$ . That is, the polynomial is treated as a univariate polynomial over the ring  $R[x_0, \dots, x_{d-2}]$ .
- The symmetric or multivariate view: This view is symmetric with respect to all variables, considering the polynomial as an element of  $R[x_0, \dots, x_{d-1}]$ .

Many functors consider the polynomial as a univariate polynomial in one variable. By default this is the outermost variable  $x_{d-1}$ . However, in general it is possible to select a certain variable.

### Refines

*AlgebraicStructureTraits*

### Constants

*static const int*                       $d$ ;                      The dimension and the number of variables respectively.

### Types

*PolynomialTraits\_d::Polynomial\_d*                      Type representing  $R[x_0, \dots, x_{d-1}]$ .

*PolynomialTraits\_d::Coefficient\_type*                      Type representing  $R[x_0, \dots, x_{d-2}]$ .

*PolynomialTraits\_d::Innermost\_coefficient\_type*                      Type representing the base ring  $R$ .

*PolynomialTraits\_d::Coefficient\_const\_iterator*

Const iterator used to iterate through all coefficients of the polynomial.

*PolynomialTraits\_d::Innermost\_coefficient\_const\_iterator*

Const iterator used to iterate through all innermost coefficients of the polynomial.

*PolynomialTraits\_d:: template <typename T, int d> struct Rebind*

This nested template class has to define a type *Other* which is a model of the concept *PolynomialTraits\_d*, where *d* is the number of variables and *T* the *Innermost\_coefficient\_type*.

## Functors

In case a functor is not provided it is set to *CGAL::Null\_functor*.

*PolynomialTraits\_d:: Construct\_polynomial*      A model of *PolynomialTraits\_d::ConstructPolynomial*.

*PolynomialTraits\_d:: Get\_coefficient*      A model of *PolynomialTraits\_d::GetCoefficient*.

*PolynomialTraits\_d:: Get\_innermost\_coefficient*      A      model      of      *PolynomialTraits\_d::GetInnermostCoefficient*.

*PolynomialTraits\_d:: Construct\_coefficient\_const\_iterator\_range*  
A      model      of      *PolynomialTraits\_d::ConstructCoefficientConstIteratorRange*.

*PolynomialTraits\_d:: Construct\_innermost\_coefficient\_const\_iterator\_range*  
A      model      of      *PolynomialTraits\_d::ConstructInnermostCoefficientConstIteratorRange*.

*PolynomialTraits\_d:: Swap*      A model of *PolynomialTraits\_d::Swap*.

*PolynomialTraits\_d:: Move*      A model of *PolynomialTraits\_d::Move*.

*PolynomialTraits\_d:: Degree*      A model of *PolynomialTraits\_d::Degree*.

*PolynomialTraits\_d:: Total\_degree*      A model of *PolynomialTraits\_d::TotalDegree*.

*PolynomialTraits\_d:: Degree\_vector*      A model of *PolynomialTraits\_d::DegreeVector*.

*PolynomialTraits\_d:: Leading\_coefficient*      A model of *PolynomialTraits\_d::LeadingCoefficient*.

## PolynomialTraits\_d::ConstructPolynomial

### Definition

This *AdaptableFunctor* provides several operators to construct objects of type *PolynomialTraits\_d::Polynomial\_d*.

### Refines

*AdaptableFunctor*

### Types

*typedef PolynomialTraits\_d::Polynomial\_d*

*result\_type;*

### Operations

<i>result_type</i>	<i>fo()</i>	Construct the zero polynomial.
<i>result_type</i>	<i>fo( int i)</i>	Construct the constant polynomial equal to <i>i</i> .
<i>result_type</i>	<i>fo( PolynomialTraits_d::Innermost_coefficient_type a)</i>	Construct the constant polynomial equal to <i>a</i> .
<i>result_type</i>	<i>fo( PolynomialTraits_d::Coefficient_type a)</i>	Construct the polynomial equal to <i>a</i> .

*template < class InputIterator >*

*result\_type* *fo( InputIterator begin, InputIterator end)*

*Precondition:* The value type of *InputIterator* is *PolynomialTraits\_d::Coefficient\_type*.

The operator constructs the a polynomial from the iterator range, with respect to the outermost variable,  $x_{d-1}$ .

The range starts with the coefficient for  $x_{d-1}^0$ .

In case the range is empty, the zero polynomial is constructed.

*template < class InputIterator >*

*result\_type*

*fo( InputIterator begin, InputIterator end, bool is\_sorted= false)*

Constructs a *Polynomial\_d* from a given iterator range of *std::pair< Exponent\_vector, PolynomialTraits\_d::Innermost\_coefficient\_type>*.

The optional parameter *is\_sorted* indicates whether the given iterator range is already sorted.

*Precondition:* The value type of *InputIterator* is *std::pair<Exponent\_vector, PolynomialTraits\_d::Innermost\_coefficient\_type>*.

*Precondition:* Each *Exponent\_vector* must have size *d*.

*Precondition:* All appearing *Exponent\_vectors* are different.

# PolynomialTraits\_d::GetCoefficient

## Definition

This *AdaptableBinaryFunction* provides access to coefficients of a *PolynomialTraits\_d::Polynomial\_d*.

## Refines

*AdaptableBinaryFunction*

## Types

*typedef PolynomialTraits\_d::Coefficient\_type*

*result\_type;*

*typedef PolynomialTraits\_d::Polynomial\_d*

*first\_argument\_type;*

*typedef int second\_argument\_type;*

## Operations

*result\_type fo( first\_argument\_type p, second\_argument\_type e)*

For given polynomial  $p$  this operator returns the coefficient of  $x_{d-1}^e$ , where  $x_{d-1}$  is the outermost variable.

## PolynomialTraits\_d::GetInnermostCoefficient

### Definition

For the given *PolynomialTraits\_d::Polynomial\_d* this *AdaptableBinaryFunction* returns the coefficient of the (multivariate) monomial specified by the given *Exponent\_vector*.

### Refines

*AdaptableBinaryFunction*

### Types

*typedef PolynomialTraits\_d::Innermost\_coefficient\_type*

*typedef PolynomialTraits\_d::Polynomial\_d*

*typedef Exponent\_vector*

*second\_argument\_type;*

### Operations

*result\_type* *fo( first\_argument\_type p, second\_argument\_type v)*

For given polynomial *p* this operator returns the innermost coefficient of the monomial corresponding to the given *Exponent\_vector v*.

# PolynomialTraits\_d::MonomialRepresentation

## Definition

This *Functor* outputs the monomial representation of the given polynomial, that is, it writes all non zero terms of the polynomial as `std::pair<CGAL::Exponent_vector, PolynomialTraits_d::Innermost_coefficient_type>` into the given output iterator.

## Refines

Assignable  
CopyConstructible  
DefaultConstructible

## Operations

`template<class OutputIterator>`  
`OutputIterator`

`fo( PolynomialTraits_d::Polynomial_d p, OutputIterator it)`

Writes the monom representation of *p* into the given output iterator *it*.

*Precondition:* `std::iterator_traits< OutputIterator >::value_type` must be constructible from `std::pair<CGAL::Exponent_vector, PolynomialTraits_d::Innermost_coefficient_type>`.

## PolynomialTraits\_d::ConstructCoefficientConstIteratorRange

### Definition

This *AdaptableUnaryFunction* returns a const iterator range over the coefficients of the given polynomial, with respect to the outermost variable,  $x_{d-1}$ . The range starts with the coefficient for  $x_{d-1}^0$ .

### Refines

*AdaptableUnaryFunction*

### Types

```
typedef std::pair< PolynomialTraits_d::Coefficient_const_iterator, PolynomialTraits_d::Coefficient_const_iterator >
```

```

                                result_type;
typedef PolynomialTraits_d::Polynomial_d argument_type;
```

### Operations

```
result_type fo( argument_type p)
```

Returns a const iterator range over the coefficients of  $p$ .

### See Also

# PolynomialTraits\_d::ConstructInnermostCoefficientConstIteratorRange

## Definition

This *AdaptableUnaryFunction* returns a const iterator range over all innermost coefficients of the given polynomial.

## Refines

*AdaptableUnaryFunction*

## Types

```
typedef std::pair< PolynomialTraits_d::Innermost_coefficient_const_iterator, PolynomialTraits_d::Innermost_
coefficient_const_iterator >
```

```
typedef PolynomialTraits_d::Polynomial_d      result_type;
typedef PolynomialTraits_d::Polynomial_d      argument_type;
```

## Operations

```
result_type      fo( argument_type p)
```

Returns a const iterator range over all innermost coefficients of *p*.

## See Also

## PolynomialTraits\_d::Permute

### Definition

This *AdaptableFunctor* permutes the variables of the given polynomial with respect to a permutation  $\sigma$ , that is, each monomial  $\prod x_i^{e_i}$  will be mapped to the monomial  $\prod x_{\sigma(i)}^{e_i}$ . The permutation  $\sigma$  is given by the iterator range of length *PolynomialTraits\_d::d*, which is supposed to contain the second row of the permutation.

For instance, let *p* be a polynomial in 4 variables and it is intended to change the order of the variables such that  $x_0 \mapsto x_2$ ,  $x_1 \mapsto x_0$ ,  $x_2 \mapsto x_1$  and  $x_3 \mapsto x_3$ . In this case the iterator range should contain the sequence [2, 0, 1, 3].

### Refines

*AdaptableFunctor*

### Types

`typedef PolynomialTraits_d::Polynomial_d     result_type;`

### Operations

#### Operations

`template<class Input_iterator>  
result_type`

`fo.operator()( PolynomialTraits_d::Polynomial_d p,  
                  Input_iterator begin,  
                  Input_iterator end)`

Returns *p* with interchanged variables as defined by the iterator range.

*Precondition:* (end-begin == *PolynomialTraits\_d::d*)

*Precondition:* `std::iterator_traits< InputIterator >::value_type` is convertible to int.

*Precondition:* The iterator range contains each value in  $\{0, \dots, d-1\}$  exactly once.

### See Also

## PolynomialTraits\_d::Swap

### Definition

This *AdaptableFunctor* swaps two variables of a multivariate polynomial.

### Refines

*AdaptableFunctor*

### Types

*typedef PolynomialTraits\_d::Polynomial\_d result\_type;*

### Operations

*result\_type* *fo( PolynomialTraits\_d::Polynomial\_d p, int i, int j)*

Returns polynomial  $p$  with interchanged variables  $x_i, x_j$ .  
*Precondition:*  $0 \leq i < d$   
*Precondition:*  $0 \leq j < d$

### See Also

*Polynomial\_d* .....page [204](#)

## PolynomialTraits\_d::Move

### Definition

This *AdaptableFunctor* moves a variable at position  $i$  to a new position  $j$ . The relative order of the other variables is preserved, that is, the variables between  $x_i$  and  $x_j$  (including  $x_j$ ) are moved by one position while  $x_i$  is moved to the former position of  $x_j$ .

This function may be used to make a certain variable the outer most variable.

## Refines

AdaptableFunctor

## Types

```
typedef PolynomialTraits_d::Polynomial_d    result_type;
```

## Operations

<i>result_type</i>	<i>fo( PolynomialTraits_d::Polynomial_d, int i, int j)</i>
--------------------	--

This function moves the variable at position  $i$  to its new position  $j$  and returns the new polynomial. The relative order of the other variables is preserved.

*Precondition:*  $0 \leq i < d$

*Precondition:*  $0 \leq j < d$

## PolynomialTraits\_d::Degree

### Definition

This *AdaptableUnaryFunction* computes the degree of a *PolynomialTraits\_d::Polynomial\_d* with respect to a certain variable.

The degree of  $p$  with respect to a certain variable  $x_i$ , is the highest power  $e$  of  $x_i$  such that the coefficient of  $x_i^e$  in  $p$  is not zero.

For instance the degree of  $p = x_0^2 x_1^3 + x_1^4$  with respect to  $x_1$  is 4.

The degree of the zero polynomial is set to 0. From the mathematical point of view this should be *−infinity*, but this would imply an inconvenient return type.

### Refines

*AdaptableUnaryFunction*

### Types

```
typedef int result_type;
typedef PolynomialTraits_d::Polynomial_d argument_type;
```

### Operations

```
result_type fo( argument_type p)

Computes the degree of  $p$  with respect to the outermost
variable  $x_{d-1}$ .
```

```
result_type fo( argument_type p, int i)

Computes the degree of  $p$  with respect to variable  $x_i$ .
Precondition:  $0 \leq i < d$ 
```

# PolynomialTraits\_d::TotalDegree

## Definition

This *AdaptableUnaryFunction* computes the total degree of a *PolynomialTraits\_d::Polynomial\_d*.

Given a (multivariate) monomial the sum of all appearing exponents is the total degree of this monomial. The total degree of a polynomial  $p$  is the maximum of the total degrees of all appearing (multivariate) monomials in  $p$ .

For instance the total degree of  $p = x_0^2 x_1^3 + x_1^4$  is 5.

The total degree of the zero polynomial is set to 0. From the mathematical point of view this should be  $-\infty$ , but this would imply an inconvenient return type.

## Refines

*AdaptableUnaryFunction*

## Types

```
typedef int result_type;
typedef PolynomialTraits_d::Polynomial_d argument_type;
```

## Operations

```
result_type fo( argument_type p)

Computes the total degree of  $p$ .
```

<i>PolynomialTraits_d</i> .....	page 205

## PolynomialTraits\_d::InnermostLeadingCoefficient

### Definition

This *AdaptableUnaryFunction* computes the innermost leading coefficient of a *PolynomialTraits\_d::Polynomial\_d*  $p$ . The innermost leading coefficient is recursively defined as the innermost leading coefficient of the leading coefficient of  $p$ . In case  $p$  is univariate it coincides with the leading coefficient.

## Refines

### *AdaptableUnaryFunction*

## Types

```
typedef PolynomialTraits_d::Innermost_coefficient_type
```

```

    result_type;
typedef PolynomialTraits_d::Polynomial_d
    argument_type;

```

## Operations

$$result\_type \quad fo( argument\_type\ p)$$

Computes the innermost leading coefficient of  $p$ .

## See Also

<i>Polynomial_d</i> .....	page 204
<i>PolynomialTraits_d</i> .....	page 205

## PolynomialTraits\_d::Canonicalize

### Definition

For a given polynomial  $p$  this *AdaptableUnaryFunction* computes the unique representative of the set

$$\mathcal{P} := \{q \mid \lambda * q = p \text{ for some } \lambda \in R\},$$

where  $R$  is the base of the polynomial ring.

In case *PolynomialTraits::Innermost\_coefficient\_type* is a model of *Field*, the computed polynomial is the *monic* polynomial in  $\mathcal{P}$ , that is, the innermost leading coefficient equals one.

In case *PolynomialTraits::Innermost\_coefficient\_type* is a model of *UniqueFactorizationDomain*, the computed polynomial is the one with a multivariate content of one.

For all other cases the notion of uniqueness is up to the concrete model.

Note that the computed polynomial has the same zero set as the given one.

### Refines

*AdaptableUnaryFunction*

### Types

```
typedef PolynomialTraits_d::Polynomial_d    result_type;
typedef PolynomialTraits_d::Polynomial_d    argument_type;
```

### Operations

```
result_type    fo( first_argument_type p)
```

Returns the canonical representative of  $p$ .

# PolynomialTraits\_d::EvaluateHomogeneous

## Definition

This *AdaptableFunctor* provides evaluation of a *PolynomialTraits\_d::Polynomial\_d* interpreted as a homogeneous polynomial **in one variable**.

For instance the polynomial  $p = 5x^2y^3 + y$  is interpreted as the homogeneous polynomial  $p[x](u, v) = 5x^2u^3 + uv^2$  and evaluated as such.

## Refines

*AdaptableFunctor*

## Types

```
typedef PolynomialTraits_d::Coefficient_type
                                     result_type;
```

## Operations

```
result_type          fo.operator()( PolynomialTraits_d::Polynomial_d p,
                                   PolynomialTraits_d::Coefficient_type u,
                                   PolynomialTraits_d::Coefficient_type v)
```

Returns  $p(u, v)$ , with respect to the outermost variable.

## See Also

## PolynomialTraits\_d::Substitute

### Definition

This *Functor* substitutes all variables of a given multivariate *PolynomialTraits\_d::Polynomial\_d* by the values given in the iterator range, where *begin* refers to the value for the innermost variable.

### Refines

Assignable  
CopyConstructible  
DefaultConstructible

### Types

Note that the *result\_type* is the coercion type of the value type of the given iterator range and *PolynomialTraits\_d::Innermost\_coefficient\_type*. In particular *std::iterator\_traits<Input\_iterator>::value\_type* must be *Explicit-Interoperable* with *PolynomialTraits\_d::Innermost\_coefficient\_type*. Hence, it can not be provided as a public type in advance.

### Operations

```
template<class Input_iterator>
result_type
```

```
fo.operator()( PolynomialTraits_d::Polynomial_d p,
               Input_iterator begin,
               Input_iterator end)
```

Substitutes each variable of *p* by the values given in the iterator range, where *begin* refers to the innermost variable  $x_0$ .

*Precondition:*  $(\text{end} - \text{begin} == \text{PolynomialTraits\_d::d})$

## PolynomialTraits\_d::SubstituteHomogeneous

### Definition

This *Functor* substitutes all variables of a given multivariate *PolynomialTraits\_d::Polynomial\_d*  $p$  by the values given in the iterator range, where *begin* refers to the value for the innermost variable. In contrast to *PolynomialTraits\_d::Substitute* the given polynomial  $p$  is interpreted as a homogeneous polynomial. Hence the iterator range is required to be of length *PolynomialTraits\_d::d+1*.

For instance the polynomial  $p(x_0, x_1) = x_0^2 x_1^3 + x_1^4$  is interpreted as the homogeneous polynomial  $p(x_0, x_1, w) = x_0^2 x_1^3 + x_1^4 w^1$ .

### Refines

Assignable  
CopyConstructible  
DefaultConstructible

### Types

Note that the *result\_type* is the coercion type of the value type of the given iterator range and *PolynomialTraits\_d::Innermost\_coefficient\_type*. In particular *std::iterator\_traits<Input\_iterator>::value\_type* must be *Explicit-Interoperable* with *PolynomialTraits\_d::Innermost\_coefficient\_type*. Hence, it can not be provided as a public type in advance.

### Operations

```
template<class Input_iterator>
result_type
```

```
fo.operator()( PolynomialTraits_d::Polynomial_d p,
               Input_iterator begin,
               Input_iterator end)
```

Substitutes each variable of  $p$  by the values given in the iterator range, where  $p$  is interpreted as a homogeneous polynomial in all variables. The *begin* iterator refers to the innermost variable  $x_0$ .

*Precondition:*  $(\text{end}-\text{begin} == \text{PolynomialTraits\_d::d})+1$

## PolynomialTraits\_d::IsZeroAt

### Definition

This *AdaptableFunctor* returns whether a *PolynomialTraits\_d::Polynomial\_d* *p* is zero at a given Cartesian point, which is represented as an iterator range.

### Refines

*AdaptableFunctor*

### Types

*typedef bool* *result\_type*;

### Operations

```
template <class InputIterator>
result_type
fo.operator()( PolynomialTraits_d::Polynomial_d p,
              InputIterator begin,
              InputIterator end)
```

Computes whether *p* is zero at the Cartesian point given by the iterator range, where *begin* is referring to the innermost variable.

*Precondition:* (end-begin == *PolynomialTraits\_d::d*)

*Precondition:* *std::iterator\_traits< InputIterator >::value\_type* is *ExplicitInteroperable* with *PolynomialTraits\_d::Innermost\_coefficient\_type*.

## PolynomialTraits\_d::IsZeroAtHomogeneous

### Definition

This *AdaptableFunctor* returns whether a *PolynomialTraits\_d::Polynomial\_d*  $p$  is zero at a given homogeneous point, which is given by an iterator range.

The polynomial is interpreted as a homogeneous polynomial in all variables.

For instance the polynomial  $p(x_0, x_1) = x_0^2 x_1^3 + x_1^4$  is interpreted as the homogeneous polynomial  $p(x_0, x_1, w) = x_0^2 x_1^3 + x_1^4 w^1$ .

### Refines

*AdaptableFunctor*

### Types

*typedef bool* *result\_type*;

### Operations

```
template <class InputIterator>
result_type
fo.operator()( PolynomialTraits_d::Polynomial_d p,
               InputIterator begin,
               InputIterator end)
```

Computes whether  $p$  is zero at the homogeneous point given by the iterator range, where *begin* is referring to the innermost variable.

*Precondition:*  $(\text{end}-\text{begin} == \text{PolynomialTraits\_d::d}+1)$

*Precondition:*  $\text{std::iterator\_traits}< \text{InputIterator}>::\text{value\_type}$  is *ExplicitInteroperable* with *PolynomialTraits\_d::Innermost\\_coefficient\\_type*.

## PolynomialTraits\_d::SignAt

### Definition

This *AdaptableFunctor* returns the sign of a *PolynomialTraits\_d::Polynomial\_d*  $p$  at given Cartesian point represented as an iterator range.

This functor is well defined if *PolynomialTraits\_d::Innermost\_coefficient\_type* is *RealEmbeddable*.

### Refines

*AdaptableFunctor*

### Types

*typedef* CGAL::Sign *result\_type*;

### Operations

```
template <class InputIterator>
result_type
fo.operator()( PolynomialTraits_d::Polynomial_d p,
               InputIterator begin,
               InputIterator end)
```

Returns the sign of  $p$  at the given Cartesian point, where *begin* is referring to the innermost variable.

*Precondition:* (end-begin == *PolynomialTraits\_d::d*)

*Precondition:* *std::iterator\_traits< InputIterator >::value\_type* is *ExplicitInteroperable* with *PolynomialTraits\_d::Innermost\_coefficient\_type*.

### See Also

## PolynomialTraits\_d::SignAtHomogeneous

### Definition

This *AdaptableFunctor* returns the sign of a *PolynomialTraits\_d::Polynomial\_d*  $p$  at a given homogeneous point, which is given by an iterator range.

The polynomial is interpreted as a homogeneous polynomial in all variables.

For instance the polynomial  $p(x_0, x_1) = x_0^2 x_1^3 + x_1^4$  is interpreted as the homogeneous polynomial  $p(x_0, x_1, w) = x_0^2 x_1^3 + x_1^4 w^1$ .

This functor is well defined if *PolynomialTraits\_d::Innermost\_coefficient\_type* is *RealEmbeddable*.

### Refines

*AdaptableFunctor*

### Types

*typedef CGAL::Sign* *result\_type*;

### Operations

```
template <class InputIterator>
result_type fo.operator()( PolynomialTraits_d::Polynomial_d p,
                          InputIterator begin,
                          InputIterator end)
```

Returns the sign of  $p$  at the given homogeneous point, where *begin* is referring to the innermost variable.

*Precondition:*  $(\text{end} - \text{begin} == \text{PolynomialTraits\_d::d} + 1)$

*Precondition:* *std::iterator\_traits< InputIterator >::value\_type* is *ExplicitInteroperable* with *PolynomialTraits\_d::Innermost\_coefficient\_type*.

## PolynomialTraits\_d::SquareFreeFactorize

### Definition

This *Functor* computes a square-free factorization of a *PolynomialTraits\_d::Polynomial\_d*.

A polynomial  $p$  is factored into square-free and pairwise coprime non-constant factors  $g_i$  with multiplicities  $m_i$  and a constant factor  $a$ , such that  $p = a \cdot g_1^{m_1} \cdot \dots \cdot g_n^{m_n}$ .

The pairs  $(g_i, m_i)$  are written into the given output iterator.

This functor is well defined if *PolynomialTraits\_d::Polynomial\_d* is a *UniqueFactorizationDomain*.

### Refines

Assignable  
CopyConstructible  
DefaultConstructible

### Operations

```
template<class OutputIterator>
OutputIterator
    fo.operator()( PolynomialTraits_d::Polynomial_d p,
                  OutputIterator it,
                  PolynomialTraits_d::Innermost_coefficient_
type& a)
```

Computes the square-free factorization of  $p$  and returns the past-the-end iterator of the written range.

*Precondition:* `std::iterator_traits< OutputIterator >::value_type` must be constructible from `std::pair< PolynomialTraits_d::Polynomial_d,int>`.

```
template<class OutputIterator>
OutputIterator
    fo( PolynomialTraits_d::Polynomial_d p, OutputIterator it)
```

As the first operator, just not computing the factor  $a$ .

## PolynomialTraits\_d::MakeSquareFree

### Definition

This *AdaptableBinaryFunction* computes the square-free part of a polynomial of type *PolynomialTraits\_d::Polynomial\_d* up to a constant factor.

A polynomial  $p$  can be factored into square-free and pairwise coprime non-constant factors  $g_i$  with multiplicities  $m_i$  and a constant factor  $a$ , such that  $p = a \cdot g_1^{m_1} \cdot \dots \cdot g_n^{m_n}$ , where all  $g_i$  are canonicalized.

Given this decomposition, the square free part is defined as the product  $g_1 \cdot \dots \cdot g_n$ , which is computed by this functor.

### Refines

# PolynomialTraits\_d::PseudoDivision

## Definition

This *AdaptableFunctor* computes the *pseudo division* of two polynomials  $f$  and  $g$ .

Given  $f$  and  $g \neq 0$  this functor computes quotient  $q$  and remainder  $r$  such that  $D \cdot f = g \cdot q + r$  and  $\text{degree}(r) < \text{degree}(g)$ , where  $D = \text{leading\_coefficient}(g)^{\max(0, \text{degree}(f) - \text{degree}(g) + 1)}$

This functor is useful if the regular division is not available, which is the case if *PolynomialTraits\_d::Coefficient\_type* is not a *Field*. Hence in general it is not possible to invert the leading coefficient of  $g$ . Instead  $f$  is extended by  $D$  allowing integral divisions in the internal computation.

## Refines

*AdaptableFunctor*

## Types

*typedef void* *result\_type*;

## Operations

*result\_type* *fo.operator()*( *PolynomialTraits\_d::Polynomial\_d*  $f$ ,  
*PolynomialTraits\_d::Polynomial\_d*  $g$ ,  
*PolynomialTraits\_d::Polynomial\_d* &  $q$ ,  
*PolynomialTraits\_d::Polynomial\_d* &  $r$ ,  
*PolynomialTraits\_d::Coefficient\_type* &  $D$ )

Computes the pseudo division with respect to the outermost variable  $x_{d-1}$ .

## PolynomialTraits\_d::GcdUpToConstantFactor

### Definition

This *AdaptableBinaryFunction* computes the *gcd up to a constant factor (utcf)* of two polynomials of type *PolynomialTraits\_d::Polynomial\_d*.

In case the base ring  $R$  (*PolynomialTraits\_d::Innermost\_coefficient\_type*) is not a *UniqueFactorizationDomain* or not a *Field* the polynomial ring  $R[x_0, \dots, x_{d-1}]$  (*PolynomialTraits\_d::Polynomial\_d*) may not possess greatest common divisors. However, since  $R$  is an integral domain one can consider its quotient field  $Q(R)$  for which *gcds* of polynomials exist.

This functor computes  $\text{gcd\_utcf}(f, g) = D * \text{gcd}(f, g)$ , for some  $D \in R$  such that  $\text{gcd\_utcf}(f, g) \in R[x_0, \dots, x_{d-1}]$ . Hence,  $\text{gcd\_utcf}(f, g)$  may not be a divisor of  $f$  and  $g$  in  $R[x_0, \dots, x_{d-1}]$ .

## PolynomialTraits\_d::ScaleHomogeneous

### Definition

Given a numerator  $a$  and a denominator  $b$  this *AdaptableFunctor* scales a *PolynomialTraits\_d::Polynomial\_d*  $p$  with respect to one variable, that is, it computes  $b^{\text{degree}(p)} \cdot p(a/b \cdot x)$ .

Note that this functor operates on the polynomial in the univariate view, that is, the polynomial is considered as a univariate homogeneous polynomial in one specific variable.

### Refines

## PolynomialTraits\_d::Resultant

### Definition

This *AdaptableBinaryFunction* computes the *resultant* of two polynomials  $f$  and  $g$  of type *PolynomialTraits\_d::Polynomial\_d* with respect to a certain variable.

Note that this functor operates on the polynomial in the univariate view, that is, the polynomial is considered as a univariate polynomial in one specific variable.

Let  $f$  and  $g$  be two univariate polynomials over some commutative ring  $A$ , where

$$f = f_m X^m + \dots + f_0$$

and

$$g = g_n X^n + \dots + g_0.$$

The resultant of  $f$  and  $g$  is defined as the determinant of the *Sylvester matrix*:

$$\begin{pmatrix} f_m & \dots & f_0 & & & \\ & f_m & \dots & f_0 & & \\ & & \ddots & & \ddots & \\ & & & f_m & \dots & f_0 \\ g_n & \dots & g_0 & & & \\ & g_n & \dots & g_0 & & \\ & & \ddots & & \ddots & \\ & & & g_n & \dots & g_0 \end{pmatrix}$$

Note that this is a  $(n+m) \times (n+m)$  matrix as there are  $n$  rows for  $f$  and  $m$  rows that are used for  $g$ . The blank spaces are supposed to be filled with zeros.

— advanced —

Let  $L$  be the algebraic closure of  $A$ , and write  $f$  and  $g$  as

$$f := f_m \prod_{i=1}^m (x - \alpha_i), \quad \alpha_i \in L$$

and

$$g := g_n \prod_{j=1}^n (x - \beta_j), \quad \beta_j \in L,$$

then the resultant of  $f$  and  $g$  is (up to leading coefficients) the product of all pairwise differences of the roots of  $f$  and  $g$ , namely

$$\text{res}(f, g) = f_m^n g_n^m \prod_{i=1}^m \prod_{j=1}^n (\alpha_i - \beta_j).$$

— advanced —

In particular,  $\text{res}(f, g) \neq 0$  iff  $f$  and  $g$  have a common factor with a positive degree in  $X$ .

There are various ways to compute the resultant. Naive options are the computation of the resultant as the determinant of the Sylvester Matrix or the Bezout Matrix as well as the so called subresultant algorithm, which is a variant of the Euclidean Algorithm. More sophisticated methods may use modular arithmetic and interpolation. For more information we refer to, e.g., [vzGG99].

## CGAL::Polynomial<Coeff>

### Definition

An instance of the data type *Polynomial* represents a polynomial  $p = a_0 + a_1 * x + \dots a_i * x^i$  from the ring  $Coeff[x]$ . *Coeff* can itself be an instance of *Polynomial*, yielding a form of multivariate polynomials.

The template argument *Coeff* must be at least a model of *IntegralDomainWithoutDivision*. For all operations naturally involving division, an *IntegralDomain* is required. *Polynomial* offers a full set of algebraic operators, i.e. binary  $+$ ,  $-$ ,  $*$ ,  $/$  as well as  $+=$ ,  $-=$ ,  $*=$ ,  $/=$ ; not only for polynomials but also for a polynomial and a number of the coefficient type. (The  $/$  operator must only be used for integral divisions, i.e. those with remainder zero.) The operations are implemented naively:  $+$  and  $-$  need a number of *Coeff* operations which is linear in the degree while  $*$  is quadratic. Unary  $+$  and  $-$  and (in)equality  $==$ ,  $!=$  are provided as well.

*Polynomial* is a model of *LessThanComparable* if *Coeff* is a model of *LessThanComparable*. In this case *Polynomial* provides comparison operators  $<$ ,  $>$ ,  $<=$ ,  $>=$ , where the comparison amounts to lexicographic comparison of the coefficient sequence, with the coefficient of the highest power taking precedence over those of lower powers.

*Polynomial* is a model of *Fraction* if *Coeff* is a model of *Fraction*. In this case *Polynomial* may be decomposed into a (scalar) denominator and a compound numerator with a simpler coefficient type. Often operations can be performed faster on these denominator-free multiples.

*Polynomial* is a model of *Modularizable* if *Coeff* is a model of *Modularizable*, where the homomorphic map on the polynomials is simply defined as the canonical extension of the homomorphic map which is defined on the coefficient type.

### Implementation

Inexact and limited-precision types can be used as coefficients, but at the user's risk. The algorithms implemented were written with exact number types in mind.

This data type is implemented as a handle type with value semantics using *CGAL::Handle\_with\_policy*, where *HandlePolicy* is *Handle\_policy\_no\_union*. An important invariant to be preserved by all methods is that the coefficient sequence does not contain leading zero coefficients (where leading means at the high-degree end), with the exception that the zero polynomial is represented by a single zero coefficient.

### Is Model for the Concepts

<i>Polynomial_d</i>	
<i>Assignable</i>	
<i>CopyConstructible</i>	
<i>DefaultConstructible</i>	
<i>EqualityComparable</i>	
<i>ImplicitInteroperable</i>	with int
<i>ImplicitInteroperable</i>	with Coeff
<i>Fraction</i>	if <i>Coeff</i> is model of <i>Fraction</i>
<i>LessThanComparable</i>	if <i>Coeff</i> is model of <i>LessThanComparable</i>
<i>Modularizable</i>	if <i>Coeff</i> is model of <i>Modularizable</i> .

## Creation

<code>Polynomial&lt;Coeff&gt; fo;</code>	Introduces an variable initialized with 0.
<code>Polynomial&lt;Coeff&gt; fo( Polynomial x);</code>	copy constructor.
<code>Polynomial&lt;Coeff&gt; fo( int i);</code>	Constructor from int.
<code>Polynomial&lt;Coeff&gt; fo( Coeff x);</code>	Constructor from type Coeff.
<code>template &lt;class Forward_iterator&gt;</code>	
<code>Polynomial&lt;Coeff&gt; fo( Forward_iterator first, Forward_iterator last);</code>	Constructor from iterator range with value type Coeff.

## Types

## Operations

<code>const_iterator</code>	<code>fo.begin()</code>	A const random access iterator pointing to the constant coefficient.
<code>const_iterator</code>	<code>fo.end()</code>	A const random access iterator pointing beyond the leading coefficient.
<code>int</code>	<code>fo.degree()</code>	The degree of the polynomial in $x$ . The degree of the zero polynomial is 0.
<code>NT</code>	<code>fo.operator[]( unsigned int i)</code>	Const access to the coefficient of $x^i$ .
<code>NT</code>	<code>fo.lcoeff()</code>	Const access to the leading coefficient.
<code>std::ostream&amp;</code>	<code>operator&lt;&lt;( std::ostream&amp; os, poly)</code>	Writes <i>poly</i> to ostream <i>os</i> . The format depends on the <code>CGAL::IO::MODE</code> of <i>os</i> . In case the mode is <code>CGAL::IO::ASCII</code> the format is $P[d, a_0, \dots, a_d]$ , where $d$ is the degree of the polynomial. In case the mode is <code>CGAL::IO::PRETTY</code> the format is human readable.
<code>std::istream&amp;</code>	<code>operator&gt;&gt;( std::istream&amp; is, poly)</code>	Reads <i>poly</i> from istream <i>is</i> in format $POLY[d, a_0, \dots, a_d]$ , the output format in mode <code>CGAL::IO::ASCII</code>

## CGAL::Polynomial\_traits\_d<Polynomial\_d>

### Definition

A model of concept *PolynomialTraits\_d*

*#include <CGAL/Polynomial\_traits\_d.h>*

### Is Model for the Concepts

## CGAL::Exponent\_vector

### Definition

For a given (multivariate) monomial the vector of its exponents is called the exponent vector. The class is meant to represent such a vector.

A vector is considered as valid, in case it represents a valid monomial. that is, it should not contain negative exponents. We decided to use `int` as the value type, since negative exponents may appear in intermediate results. The set of exponent vectors with elementwise addition forms an *Abelian Group*.

Though this class is derived from `std::vector<int>` the comparison is changes such that the lexicographic order starts with the last entry. This reflects the fact that the last entry corresponds to the last/outermost variable of a multivariate polynomial.

```
#include <CGAL/Exponent_vector.h>
```

### Inherits From

`std::vector<int>`

### Is Model for the Concepts

*Random Access Container*

*Back Insertion Sequence*

*DefaultConstructible*

*Assignable*

*CopyConstructible*

*EqualityComparable*

*LessThanComparable*

### Creation

`Exponent_vector fo;`

introduces an uninitialized variable *fo*.

`Exponent_vector fo( ev_ );`

The copy constructor

`Exponent_vector fo( int e1 );`

Creates a vector containing the given element.

`Exponent_vector fo( int e1, int e2 );`

Creates a vector containing the given elements.

`Exponent_vector fo( int e1, int e2, int e3 );`

Creates a vector containing the given elements.

`Exponent_vector fo( int e1, int e2, int e3, int e4 );`

Creates a vector containing the given elements.

`template < class InputIterator >`

`Exponent_vector fo( InputIterator begin, InputIterator end );`

Creates a vector with a copy of the given range.

*Precondition:* *InputIterator* must allow the value type *int*.

<b>Operations</b>		
<i>bool</i>	<i>is_valid( ev )</i>	Returns true if all entries of <i>ev</i> are not negative.

## Operations

Group Operation:

<i>Exponent_vector</i>	$+ev1$	
<i>Exponent_vector</i>	$-ev1$	
<i>Exponent_vector</i>	$ev1 + ev2$	<i>Precondition:</i> $ev1.size() == ev2.size()$
<i>Exponent_vector</i>	$ev1 - ev2$	<i>Precondition:</i> $ev1.size() == ev2.size()$
<i>Exponent_vector</i>	$fo += ev2$	<i>Precondition:</i> $fo.size() == ev2.size()$
<i>Exponent_vector</i>	$fo -= ev2$	<i>Precondition:</i> $fo.size() == ev2.size()$

*EqualityComparable:*

<i>bool</i>	$ev1 == ev2$
<i>bool</i>	$ev1 != ev2$

*LessThanComparable:*

<i>bool</i>	$ev1 < ev2$	Lexicographic compare, starting with the <i>last</i> variable.

## CGAL::Polynomial\_type\_generator<T,d>

### Definition

This class template provides a convenient way to obtain the type representing a multivariate polynomial with  $d$  variables, where  $T$  is the innermost coefficient type. In case  $T$  happens to be a *CGAL::Polynomial* the generator will add  $d$  variables to  $T$ .

$T$  must be a model of *IntegralDomainWithoutDivision*.  
 $d$  must be of type `int`.

### Types

*Polynomial\_type\_generator*< $T,d$ >::*Type*                      The generated type.

`#include <CGAL/Polynomial_type_generator.h>`

# Chapter 6

## Modular Arithmetic

Michael Hemmer

### 6.1 Introduction

Modular arithmetic is a fundamental tool in modern algebra systems. In conjunction with the Chinese remainder theorem it serves as the workhorse in several algorithms computing the gcd, resultant etc. Moreover, it can serve as a very efficient filter, since it is often possible to exclude that some value is zero by computing its modular correspondent with respect to one prime only.

First of all, this package introduces a type `CGAL::Residue`. It represents  $\mathbb{Z}_p\mathbb{Z}$  for some prime  $p$ . The prime number  $p$  is stored in a static member variable. The class provides static member functions to change this value. **Note that changing the prime invalidates already existing objects of this type.** However, already existing objects do not lose their value with respect to the old prime and can be reused after restoring the old prime. Since the type is based on double arithmetic the prime is restricted to values less than  $2^{26}$ . The initial value of  $p$  is 67111067.

Please note that the implementation of class `CGAL::Residue` requires a mantissa precision according to the IEEE Standard for Floating-Point Arithmetic (IEEE 754). However, on some processors the traditional FPU uses an extended precision. Hence, it is indispensable that the proper mantissa length is enforced before performing any arithmetic operations. Moreover, it is required that numbers are rounded to the next nearest value. This can be ensured using `CGAL::Protect_FPU_rounding` with `CGAL_FE_TONEAREST`, which also enforces the required precision as a side effect.

— advanced —

In case the flag `CGAL_HAS_THREADS` is undefined the prime is just stored in a static member of the class, that is, `CGAL::Residue` is not thread-safe in this case. In case `CGAL_HAS_THREADS` the implementation of the class is thread safe using `boost::thread_specific_ptr`. However, this may cause some performance penalty. Hence, it may be advisable to configure `CGAL` with `CGAL_HAS_NO_THREADS`.

— advanced —

Moreover, the package introduces the concept *Modularizable*. An algebraic structure  $T$  is considered as *Modularizable* if there is a mapping from  $T$  into an algebraic structure that is based on the type `CGAL::Residue`. For scalar types, e.g. Integers, this mapping is just the canonical homomorphism into  $\mathbb{Z}_p\mathbb{Z}$  represented by `CGAL::Residue`. For compound types, e.g. Polynomials, the mapping is applied to the coefficients of the compound type. The mapping is provided by the class `CGAL::Modular_traits<T>`. The class `CGAL::Modular_`

*traits<T>* is designed such that the concept *Modularizable* can be considered as optional, i.e., *CGAL::Modular\_traits<T>* provides a tag that can be used for dispatching.

### 6.1.1 Example

In the following example modular arithmetic is used as a filter.

```
/* Modular arithmetic can be used as a filter, in this example modular
   arithmetic is used to avoid unnecessary gcd computations of polynomials.
   A gcd computation can be very costly due to coefficient growth within the
   Euclidean algorithm.

   The general idea is that firstly the gcd is computed with respect
   to one prime only. If this modular gcd is constant we can (in most cases)
   conclude that the actual gcd is constant as well.

   For this purpose the example introduces the function may_have_common_factor.
   Note that there are two versions of this function, namely for the case
   that the coefficient type is Modularizable and that it is not.
   If the type is not Modularizable the filter is just not applied and the
   function returns true.
*/

#include <CGAL/basic.h>

#ifdef CGAL_USE_GMP

#include <CGAL/Gmpz.h>
#include <CGAL/Polynomial.h>

// Function in case Polynomial is Modularizable
template< typename Polynomial >

## 6.2 Design and Implementation History

The class *CGAL::Residue* is based on the C-code of Sylvain Pion et. al. as it was presented in [BEP99].

The remaining part of the package is the result of the integration process of the NumeriX library of EXACUS [BEH<sup>+</sup>05] into CGAL.

## CGAL::Residue

### Definition

The class *Residue* represents a finite field  $\mathbb{Z}/p\mathbb{Z}$ , for some prime number  $p$ .

The prime number  $p$  is stored in a static member variable. The class provides static member functions to change this value. **Note that changing the prime invalidates already existing objects of this type.** However, already existing objects do not lose their value with respect to the old prime and can be reused after restoring the old prime. Since the type is based on double arithmetic the prime is restricted to values less than  $2^{26}$ . The initial value of  $p$  is 67111067.

Please note that the implementation of class *CGAL::Residue* requires a mantissa precision according to the IEEE Standard for Floating-Point Arithmetic (IEEE 754). However, on some processors the traditional FPU uses an extended precision. Hence, it is indispensable that the proper mantissa length is enforced before performing any arithmetic operations. Moreover, it is required that numbers are rounded to the next nearest value. This can be ensured using *CGAL::Protect\_FPU\_rounding* with *CGAL\_FE\_TONEAREST*, which also enforces the required precision as a side effect.

In case the flag *CGAL\_HAS\_THREADS* is undefined the prime is just stored in a static member of the class, that is, *Residue* is not thread-safe in this case. In case *CGAL\_HAS\_THREADS* the implementation of the class is thread safe using *boost::thread\_specific\_ptr*. However, this may cause some performance penalty. Hence, it may be advisable to configure *CGAL* with *CGAL\_HAS\_NO\_THREADS*.

```
#include <CGAL/Residue.h>
```

### Is Model for the Concepts

*Field*

### Creation

<i>Residue</i> $x$ ;	introduces a variable $x$ , which is initialized with zero;
<i>Residue</i> $x(m)$ ;	copy constructor;
<i>Residue</i> $x(\text{int } i)$ ;	introduces a variable $x$ , which is initialized with $i\%p$ ;
<i>Residue</i> $x(\text{long } i)$ ;	introduces a variable $x$ , which is initialized with $i\%p$ ;

### Operations

<i>static int</i>	<i>x.set_current_prime(int p)</i>	Static member function; sets current prime to the given value and returns the old prime.
<i>static int</i>	<i>x.get_current_prime()</i>	Static member function; returns the value of the current prime.

<i>int</i>	<i>x.get_value()</i>	Returns the unique representative of <i>x</i> within the range $[-p/2, p/2]$ , where <i>p</i> is the current prime.
<i>Residue</i>	$+a$	
<i>Residue</i>	$-a$	
<i>Residue</i>	$a + b$	
<i>Residue</i>	$a - b$	
<i>Residue</i>	$a * b$	
<i>Residue</i>	$a / b$	
<i>Residue</i> &	$x += a$	
<i>Residue</i> &	$x -= a$	
<i>Residue</i> &	$x *= a$	
<i>Residue</i> &	$x /= a$	
<i>Residue</i>	$a == b$	
<i>Residue</i>	$a != b$	

## Modularizable

### Definition

An algebraic structure is called *Modularizable*, if there is a suitable mapping into an algebraic structure which is based on the type `CGAL::Residue`. For scalar types, e.g. Integers, this mapping is just the canonical homomorphism into the type `CGAL::Residue` with respect to the current prime. For compound types, e.g. Polynomials, the mapping is applied to the coefficients of the compound type.

The mapping is provided via `CGAL::Modular_traits<Modularizable>`, being a model of *ModularTraits*.

Note that types representing rationals, or types which do have some notion of denominator, are not *Modularizable*. This is due to the fact that the denominator may be zero modulo the prime, which can not be represented.

# ModularTraits

## Definition

A model of *ModularTraits* is associated to a specific *Type*. In case this associated type is *Modularizable*, this is indicated by the boolean tag *Is\_modularizable*. The mapping into the *Residue\_type* is provided by the functor *Modular\_image*.

## Types

A model of *ModularTraits* is supposed to provide:

<i>ModularTraits:: Type</i>	The associated type.
<i>ModularTraits:: Is_modularizable</i>	Tag indicating whether the associated type is modularizable. This is either <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>ModularTraits:: Residue_type</i>	The type of the modular image. In case the type is not <i>Modularizable</i> this is undefined.

## Functors

In case the associated type is *Modularizable* all functors are provided.  
In case a functor is not provided, it is set to *CGAL::Null\_functor*.

<i>ModularTraits:: Modular_image</i>	A model of <i>ModularTraits::ModularImage</i>
<i>ModularTraits:: Modular_image_representative</i>	A model of <i>ModularTraits::ModularImageRepresentative</i>

## 7.1 Introduction

CGAL, the *Computational Geometry Algorithms Library*, is written in C++ and consists of three major parts. The first part is the kernel, which consists of constant-size non-modifiable geometric primitive objects and operations on these objects. The objects are represented both as stand-alone classes that are parameterized by a representation class, which specifies the underlying number types used for calculations and as members of the kernel classes, which allows for more flexibility and adaptability of the kernel. The second part is a collection of basic geometric data structures and algorithms, which are parameterized by traits classes that define the interface between the data structure or algorithm and the primitives they use. In many cases, the kernel classes provided in CGAL can be used as traits classes for these data structures and algorithms. The third part of the library consists of non-geometric support facilities, such as circulators, random sources, I/O support for debugging and for interfacing CGAL to various visualization tools.

This part of the reference manual covers the kernel. The kernel contains objects of constant size, such as point, vector, direction, line, ray, segment, triangle, iso-oriented rectangle and tetrahedron. With each type comes a set of functions which can be applied to an object of this type. You will typically find access functions (e.g. to the coordinates of a point), tests of the position of a point relative to the object, a function returning the bounding box, the length, or the area of an object, and so on. The CGAL kernel further contains basic operations such as affine transformations, detection and computation of intersections, and distance computations.

### 7.1.1 Robustness

The correctness proof of nearly all geometric algorithms presented in theory papers assumes exact computation with real numbers. This leads to a fundamental problem with the implementation of geometric algorithms. Naively, often the exact real arithmetic is replaced by inexact floating-point arithmetic in the implementation. This often leads to acceptable results for many input data. However, even for the implementation of the simplest geometric algorithms this simplification occasionally does not work. Rounding errors introduced by an inaccurate arithmetic may lead to inconsistent decisions, causing unexpected failures for some correct input data. There are many approaches to this problem, one of them is to compute exactly (compute so accurate that all decisions made by the algorithm are exact) which is possible in many cases but more expensive than standard floating-point arithmetic. C. M. Hoffmann [[Hof89a](#), [Hof89b](#)] illustrates some of the problems arising in the implementation of geometric algorithms and discusses some approaches to solve them. A more recent overview is given in [[Sch00](#)]. The exact computation paradigm is discussed by Yap and Dubé [[YD95](#)] and Yap [[Yap97](#)].

In CGAL you can choose the underlying number types and arithmetic. You can use different types of arithmetic simultaneously and the choice can be easily changed, e.g. for testing. So you can choose between implementations with fast but occasionally inexact arithmetic and implementations guaranteeing exact computation and exact results. Of course you have to pay for the exactness in terms of execution time and storage space. See the dedicated chapter for more details on number types and their capabilities and performance.

## 7.2 Kernel Representations

Our object of study is the  $d$ -dimensional affine Euclidean space. Here we are mainly concerned with cases  $d = 2$  and  $d = 3$ . Objects in that space are sets of points. A common way to represent the points is the use of Cartesian coordinates, which assumes a reference frame (an origin and  $d$  orthogonal axes). In that framework, a point is represented by a  $d$ -tuple  $(c_0, c_1, \dots, c_{d-1})$ , and so are vectors in the underlying linear space. Each point is represented uniquely by such Cartesian coordinates. Another way to represent points is by homogeneous coordinates. In that framework, a point is represented by a  $(d + 1)$ -tuple  $(h_0, h_1, \dots, h_d)$ . Via the formulae  $c_i = h_i/h_d$ , the corresponding point with Cartesian coordinates  $(c_0, c_1, \dots, c_{d-1})$  can be computed. Note that homogeneous coordinates are not unique. For  $\lambda \neq 0$ , the tuples  $(h_0, h_1, \dots, h_d)$  and  $(\lambda \cdot h_0, \lambda \cdot h_1, \dots, \lambda \cdot h_d)$  represent the same point. For a point with Cartesian coordinates  $(c_0, c_1, \dots, c_{d-1})$  a possible homogeneous representation is  $(c_0, c_1, \dots, c_{d-1}, 1)$ . Homogeneous coordinates in fact allow to represent objects in a more general space, the projective space  $\mathbb{P}_d$ . In CGAL, we do not compute in projective geometry. Rather, we use homogeneous coordinates to avoid division operations, since the additional coordinate can serve as a common denominator.

### 7.2.1 Genericity through Parameterization

Almost all the kernel objects (and the corresponding functions) are templates with a parameter that allows the user to choose the representation of the kernel objects. A type that is used as an argument for this parameter must fulfill certain requirements on syntax and semantics. The list of requirements defines an abstract kernel concept. For all kernel objects types, the types `CGAL::Type<Kernel>` and `Kernel::Type` are identical.

CGAL offers four families of concrete models for the concept `Kernel`, two based on the Cartesian representation of points and two based on the homogeneous representation of points. The interface of the kernel objects is designed such that it works well with both Cartesian and homogeneous representation. For example, points in 2D have a constructor with three arguments as well (the three homogeneous coordinates of the point). The common interfaces parameterized with a kernel class allow one to develop code independent of the chosen representation. We said “families” of models, because both families are parameterized too. A user can choose the number type used to represent the coordinates.

For reasons that will become evident later, a kernel class provides two typenames for number types, namely `Kernel::FT` and `Kernel::RT`.<sup>1</sup> The type `Kernel::FT` must fulfill the requirements on what is called a *FieldNumberType* in CGAL. This roughly means that `Kernel::FT` is a type for which operations  $+$ ,  $-$ ,  $*$  and  $/$  are defined with semantics (approximately) corresponding to those of a field in a mathematical sense. Note that, strictly speaking, the built-in type `int` does not fulfill the requirements on a field type, since *ints* correspond to elements of a ring rather than a field, especially operation  $/$  is not the inverse of  $*$ . The requirements on the type `Kernel::RT` are weaker. This type must fulfill the requirements on what is called a *RingNumberType* in CGAL. This roughly means that `Kernel::RT` is a type for which operations  $+$ ,  $-$ ,  $*$  are defined with semantics (approximately) corresponding to those of a ring in a mathematical sense.

### 7.2.2 Cartesian Kernels

With `Cartesian<FieldNumberType>` you can choose a Cartesian representation of coordinates. When you choose Cartesian representation you have to declare at the same time the type of the coordinates. A number type used with the `Cartesian` representation class should be a *FieldNumberType* as described above. As mentioned above, the built-in type `int` is not a *FieldNumberType*. However, for some computations with Cartesian representation, no division operation is needed, i.e., a *RingNumberType* is sufficient in this case. With `Carte-`

---

<sup>1</sup>The double colon `::` is the C++ scope operator.

*sian*<*FieldNumberType*>, both *Cartesian*<*FieldNumberType*>::*FT* and *Cartesian*<*FieldNumberType*>::*RT* are mapped to *FieldNumberType*.

*Cartesian*<*FieldNumberType*> uses reference counting internally to save copying costs. CGAL also provides *Simple\_cartesian*<*FieldNumberType*>, a kernel that uses Cartesian representation but no reference counting. Debugging is easier with *Simple\_cartesian*<*FieldNumberType*>, since the coordinates are stored within the class and hence direct access to the coordinates is possible. Depending on the algorithm, it can also be slightly more or less efficient than *Cartesian*<*FieldNumberType*>. Again, in *Simple\_cartesian*<*FieldNumberType*> both *Simple\_cartesian*<*FieldNumberType*>::*FT* and *Simple\_cartesian*<*FieldNumberType*>::*RT* are mapped to *FieldNumberType*.

### 7.2.3 Homogeneous Kernels

Homogeneous coordinates permit to avoid division operations in numerical computations, since the additional coordinate can serve as a common denominator. Avoiding divisions can be useful for exact geometric computation. With *Homogeneous*<*RingNumberType*> you can choose a homogeneous representation for the coordinates of the kernel objects. As for the Cartesian representation, one has to declare the type used to store the coordinates. Since the homogeneous representation does not use divisions, the number type associated with a homogeneous representation class must be a model for the weaker concept *RingNumberType* only. However, some operations provided by this kernel involve divisions, for example computing squared distances or Cartesian coordinates. To keep the requirements on the number type parameter of *Homogeneous* low, the number type *Quotient*<*RingNumberType*> is used for operations that require divisions. This number type can be viewed as an adaptor which turns a *RingNumberType* into a *FieldNumberType*. It maintains numbers as quotients, i.e., a numerator and a denominator. With *Homogeneous*<*RingNumberType*>, *Homogeneous*<*RingNumberType*>::*FT* is equal to *Quotient*<*RingNumberType*>, while *Homogeneous*<*RingNumberType*>::*RT* is equal to *RingNumberType*.

*Homogeneous*<*RingNumberType*> uses reference counting internally to save copying costs. CGAL also provides *Simple\_homogeneous*<*RingNumberType*>, a kernel that uses homogeneous representation but no reference counting. Debugging is easier with *Simple\_homogeneous*<*RingNumberType*>, since the coordinates are stored within the class and hence direct access to the coordinates is possible. Depending on the algorithm, it can also be slightly more or less efficient than *Homogeneous*<*RingNumberType*>. Again, in *Simple\_homogeneous*<*RingNumberType*> the type *Simple\_homogeneous*<*RingNumberType*>::*FT* is equal to *Quotient*<*RingNumberType*> while *Simple\_homogeneous*<*RingNumberType*>::*RT* is equal to *RingNumberType*.

### 7.2.4 Naming conventions

The use of kernel classes not only avoids problems, it also makes all CGAL classes very uniform. They **always** consist of:

1. The *capitalized base name* of the geometric object, such as *Point*, *Segment*, or *Triangle*.
2. An *underscore* followed by the *dimension* of the object, for example *\_2*, *\_3*, or *\_d*.
3. A *kernel class* as parameter, which itself is parameterized with a number type, such as *Cartesian*<*double*> or *Homogeneous*<*leda\_integer*>.

### 7.2.5 Kernel as a Traits Class

Algorithms and data structures in the basic library of CGAL are parameterized by a traits class that subsumes the objects on which the algorithm or data structure operates as well as the operations to do so. For most of the algorithms and data structures in the basic library you can use a kernel as a traits class. For some algorithms you even do not have to specify the kernel; it is detected automatically using the types of the geometric objects passed to the algorithm. In some other cases, the algorithms or data structures needs more than is provided by the kernel concept. In these cases, a kernel can not be used as a traits class.

### 7.2.6 Choosing a Kernel and Predefined Kernels

If you start with integral Cartesian coordinates, many geometric computations will involve integral numerical values only. Especially, this is true for geometric computations that evaluate only predicates, which are tantamount to determinant computations. Examples are triangulation of point sets and convex hull computation. In this case, the Cartesian representation is probably the first choice, even with a ring type. You might use limited precision integer types like *int* or *long*, use *double* to present your integers (they have more bits in their mantissa than an *int* and overflow nicely), or an arbitrary precision integer type like the wrapper *Gmpz* for the GMP integers, *leda\_integer*, or *MP\_Float*. Note, that unless you use an arbitrary precision ring type, incorrect results might arise due to overflow.

If new points are to be constructed, for example the intersection point of two lines, computation of Cartesian coordinates usually involves divisions. Hence, one needs to use a *FieldNumberType* with Cartesian representation, or alternatively, switch to homogeneous representation. The type *double* is a – though imprecise – model for *FieldNumberType*. You can also put any *RingNumberType* into the *Quotient* adaptor to get a field type which then can be put into *Cartesian*. But using homogeneous representation on the *RingNumberType* is usually the better option. Other valid *FieldNumberTypes* are *leda\_rational* and *leda\_real*.

If it is crucial for you that the computation is reliable, the right choice is probably a number type that guarantees exact computation. The *Filtered\_kernel* provides a way to apply filtering techniques [BBP01] to achieve a kernel with exact and efficient predicates. Still other people will prefer the built-in type *double*, because they need speed and can live with approximate results, or even algorithms that, from time to time, crash or compute incorrect results due to accumulated rounding errors.

**Predefined kernels.** For the user’s convenience, CGAL provides 3 typedefs to generally useful kernels.

- They are all Cartesian kernels.
- They all support constructions of points from *double* Cartesian coordinates.
- All these 3 kernels provide exact geometric predicates.
- They handle geometric constructions differently:
  - *Exact\_predicates\_exact\_constructions\_kernel*: provides exact geometric constructions, in addition to exact geometric predicates.
  - *Exact\_predicates\_exact\_constructions\_kernel\_with\_sqrt*: same as *Exact\_predicates\_exact\_constructions\_kernel*, but the number type it provides (*Exact\_predicates\_exact\_constructions\_kernel\_with\_sqrt::FT*) supports the square root operation exactly <sup>2</sup>.

---

<sup>2</sup>Currently it requires having either LEDA or CORE installed

- *Exact\_predicates\_inexact\_constructions\_kernel*: provides exact geometric predicates, but geometric constructions may be inexact due to round-off errors. It is however enough for most CGAL algorithms, and faster than both *Exact\_predicates\_exact\_constructions\_kernel* and *Exact\_predicates\_exact\_constructions\_kernel\_with\_sqrt*.

## 7.3 Kernel Geometry

### 7.3.1 Points and Vectors

In CGAL, we strictly distinguish between points, vectors and directions. A *point* is a point in the Euclidean space  $\mathbb{E}^d$ , a *vector* is the difference of two points  $p_2, p_1$  and denotes the direction and the distance from  $p_1$  to  $p_2$  in the vector space  $\mathbb{R}^d$ , and a *direction* is a vector where we forget about its length. They are different mathematical concepts. For example, they behave different under affine transformations and an addition of two points is meaningless in affine geometry. By putting them in different classes we not only get cleaner code, but also type checking by the compiler which avoids ambiguous expressions. Hence, it pays twice to make this distinction.

CGAL defines a symbolic constant *ORIGIN* of type *Origin* which denotes the point at the origin. This constant is used in the conversion between points and vectors. Subtracting it from a point  $p$  results in the locus vector of  $p$ .

```
Point_2< Cartesian<double> >  p(1.0, 1.0), q;
Vector_2< Cartesian<double> >  v;
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

In order to obtain the point corresponding to a vector  $v$  you simply have to add  $v$  to *ORIGIN*. If you want to determine the point  $q$  in the middle between two points  $p_1$  and  $p_2$ , you can write<sup>3</sup>

```
q = p_1 + (p_2 - p_1) / 2.0;
```

Note that these constructions do not involve any performance overhead for the conversion with the currently available representation classes.

### 7.3.2 Kernel Objects

Besides points (*Point\_2<Kernel>*, *Point\_3<Kernel>*, *Point\_d<Kernel>*), vectors (*Vector\_2<Kernel>*, *Vector\_3<Kernel>*), and directions (*Direction\_2<Kernel>*, *Direction\_3<Kernel>*), CGAL provides lines, rays, segments, planes, triangles, tetrahedra, iso-rectangles, iso-cuboids, circles and spheres.

Lines (*Line\_2<Kernel>*, *Line\_3<Kernel>*) in CGAL are oriented. In two-dimensional space, they induce a partition of the plane into a positive side and a negative side. Any two points on a line induce an orientation of this line. A ray (*Ray\_2<Kernel>*, *Ray\_3<Kernel>*) is semi-infinite interval on a line, and this line is oriented from the finite endpoint of this interval towards any other point in this interval. A segment (*Segment\_2<Kernel>*, *Segment\_3<Kernel>*) is a bounded interval on a directed line, and the endpoints are ordered so that they induce the same direction as that of the line.

---

<sup>3</sup>you might call *midpoint(p\_1,p\_2)* instead

Planes are affine subspaces of dimension two in  $\mathbb{E}^3$ , passing through three points, or a point and a line, ray, or segment. CGAL provides a correspondence between any plane in the ambient space  $\mathbb{E}^3$  and the embedding of  $\mathbb{E}^2$  in that space. Just like lines, planes are oriented and partition space into a positive side and a negative side. In CGAL, there are no special classes for half-spaces. Half-spaces in 2D and 3D are supposed to be represented by oriented lines and planes, respectively.

Concerning polygons and polyhedra, the kernel provides triangles, iso-oriented rectangles, iso-oriented cuboids and tetrahedra. More complex polygons<sup>4</sup> and polyhedra or polyhedral surfaces can be obtained from the basic library (*Polygon\_2*, *Polyhedron\_3*), so they are not part of the kernel. As with any Jordan curves, triangles, iso-oriented rectangles and circles separate the plane into two regions, one bounded and one unbounded.

### 7.3.3 Orientation and Relative Position

Geometric objects in CGAL have member functions that test the position of a point relative to the object. Full dimensional objects and their boundaries are represented by the same type, e.g. half-spaces and hyperplanes are not distinguished, neither are balls and spheres and discs and circles. Such objects split the ambient space into two full-dimensional parts, a bounded part and an unbounded part (e.g. circles), or two unbounded parts (e.g. hyperplanes). By default these objects are oriented, i.e., one of the resulting parts is called the positive side, the other one is called the negative side. Both of these may be unbounded.

For these objects there is a function *oriented\_side()* that determines whether a test point is on the positive side, the negative side, or on the oriented boundary. This function returns a value of type *Oriented\_side*.

Those objects that split the space in a bounded and an unbounded part, have a member function *bounded\_side()* with return type *Bounded\_side*.

If an object is lower dimensional, e.g. a triangle in three-dimensional space or a segment in two-dimensional space, there is only a test whether a point belongs to the object or not. This member function, which takes a point as an argument and returns a Boolean value, is called *has\_on()*.

## 7.4 Predicates and Constructions

### 7.4.1 Predicates

Predicates are at the heart of a geometry kernel. They are basic units for the composition of geometric algorithms and encapsulate decisions. Hence their correctness is crucial for the control flow and hence for the correctness of an implementation of a geometric algorithm. CGAL uses the term predicate in a generalized sense. Not only components returning a Boolean value are called predicates but also components returning an enumeration type like a *Comparison\_result* or an *Orientation*. We say components, because predicates are implemented both as functions and function objects (provided by a kernel class).

CGAL provides predicates for the orientation of point sets (*orientation*, *leftturn*, *rightturn*, *collinear*, *coplanar*), for comparing points according to some given order, especially for comparing Cartesian coordinates (e.g. *lexicographically\_xy\_smaller*), in-circle and in-sphere tests, and predicates to compare distances.

---

<sup>4</sup>Any sequence of points can be seen as a (not necessary simple) polygon or polyline. This view is used frequently in the basic library as well.

### 7.4.2 Constructions

Functions and function objects that generate objects that are neither of type *bool* nor enum types are called constructions. Constructions involve computation of new numerical values and may be imprecise due to rounding errors unless a kernel with an exact number type is used.

Affine transformations (*Aff\_transformation\_2<Kernel>*, *Aff\_transformation\_3<Kernel>*) allow to generate new object instances under arbitrary affine transformations. These transformations include translations, rotations (in 2D only) and scaling. Most of the geometric objects in a kernel have a member function *transform(Aff\_transformation t)* which applies the transformation to the object instance.

CGAL also provides a set of functions that detect or compute the intersection between objects of the 2D kernel, and many objects in the 3D kernel, and functions to calculate their squared distance. Moreover, some member functions of kernel objects are constructions.

So there are routines that compute the square of the Euclidean distance, but no routines that compute the distance itself. Why? First of all, the two values can be derived from each other quite easily (by taking the square root or taking the square). So, supplying only the one and not the other is only a minor inconvenience for the user. Second, often either value can be used. This is for example the case when (squared) distances are compared. Third, the library wants to stimulate the use of the squared distance instead of the distance. The squared distance can be computed in more cases and the computation is cheaper. We do this by not providing the perhaps more natural routine. The problem of a distance routine is that it needs the *sqrt* operation. This has two drawbacks:

- The *sqrt* operation can be costly. Even if it is not very costly for a specific number type and platform, avoiding it is always cheaper.
- There are number types on which no *sqrt* operation is defined, especially integer types and rationals.

### 7.4.3 Polymorphic Return Values

Some functions can return different types of objects. A typical C++ solution to this problem is to derive all possible return types from a common base class, to return a pointer to this class and to perform a dynamic cast on this pointer. The class *Object* provides an abstraction. An object *obj* of the class *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make\_object()*. This encapsulation mechanism requires the use of *object\_cast* to access the encapsulated class (a less efficient way, which is now discouraged, used to be to use the *assign* function).

#### Example

In the following example, the object class is used as return value for the intersection computation, as there are possibly different return values.

```
{
    typedef Cartesian<double> K;
    typedef K::Point_2      Point_2;
    typedef K::Segment_2    Segment_2;

    Segment_2 segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;
```

```

Object obj = intersection(segment_1, segment_2);

if (const Point_2 *point = object_cast<Point_2>(&obj)) {
    /* do something with *point */
} else if (const Segment_2 *segment = object_cast<Segment_2>(&obj)) {
    /* do something with *segment */
}

/* there was no intersection */
}

```

The intersection routine itself looks roughly as follows:

```

template < class Kernel >
Object intersection(Segment_2<Kernel> s1, Segment_2<Kernel> s2)
{

    if (/* intersection in a point */ ) {

        Point_2<Kernel> p = ... ;
        return make_object(p);

    } else if (/* intersection in a segment */ ) {

        Segment_2<Kernel> s = ... ;
        return make_object(s);
    }
    return Object();
}

```

#### 7.4.4 Constructive Predicates

For testing where a point  $p$  lies with respect to a plane defined by three points  $q$ ,  $r$  and  $s$ , one may be tempted to construct the plane  $\text{Plane}_3<\text{Kernel}>(q,r,s)$  and use the method  $\text{oriented\_side}(p)$ . This may pay off if many tests with respect to the plane are made. Nevertheless, unless the number type is exact, the constructed plane is only approximated, and round-off errors may lead  $\text{oriented\_side}(p)$  to return an orientation which is different from the orientation of  $p$ ,  $q$ ,  $r$ , and  $s$ .

In CGAL, we provide predicates in which such geometric decisions are made directly with a reference to the input points  $p$ ,  $q$ ,  $r$ ,  $s$ , without an intermediary object like a plane. For the above test, the recommended way to get the result is to use  $\text{orientation}(p,q,r,s)$ . For exact number types, the situation is different. If several tests are to be made with the same plane, it pays off to construct the plane and to use  $\text{oriented\_side}(p)$ .

## 7.5 Extensible Kernel

This manual section describe how users can plug user defined geometric classes in existing CGAL kernels. This is best illustrated by an example.

### 7.5.1 Introduction

CGAL defines the concept of a geometry kernel. Such a kernel provides types, construction objects and generalized predicates. Most implementations of Computational Geometry algorithms and data structures in the basic library of CGAL were done in a way that classes or functions can be parametrized with a geometric traits class.

In most cases this geometric traits class must be a model of the CGAL geometry kernel concept (but there are some exceptions).

### 7.5.2 An Extensive Example

Assume you have the following point class, where the coordinates are stored in an array of *doubles*, where we have another data member *color*, which shows up in the constructor.

```
class MyPointC2 {

private:
    double vec[2];
    int col;

public:

    MyPointC2()
        : col(0)
    {
        *vec = 0;
        *(vec+1) = 0;
    }

    MyPointC2(const double x, const double y, int c)
        : col(c)
    {
        *vec = x;
        *(vec+1) = y;
    }

    const double& x() const { return *vec; }

    const double& y() const { return *(vec+1); }

    double & x() { return *vec; }

    double& y() { return *(vec+1); }
```

```

int color() const { return col; }

int& color() { return col; }

bool operator==(const MyPointC2 &p) const
{
    return ( *vec == *(p.vec) ) && ( *(vec+1) == *(p.vec + 1) && ( col == p.col) );
}

bool operator!=(const MyPointC2 &p) const
{
    return !(*this == p);
}

};

```

As said earlier the class is pretty minimalistic, for example it has no *bbox()* method. One might assume that a basic library algorithm which computes a bounding box (e.g. to compute the bounding box of a polygon), will not compile. Luckily it will, because it does not use of member functions of geometric objects, but it makes use of the functor *Kernel::Construct\_bbox\_2*.

To make the right thing happen with *MyPointC2* we have to provide the following functor.

```

template <class ConstructBbox_2>
class MyConstruct_bbox_2 : public ConstructBbox_2 {
public:
    CGAL::Bbox_2 operator()(const typename MyPointC2& p) const {
        return CGAL::Bbox_2(p.x(), p.y(), p.x(), p.y());
    }
};

```

Things are similar for random access to the Cartesian coordinates of a point. As the coordinates are stored in an array of *doubles* we can use *double\** as random access iterator.

```

class MyConstruct_coord_iterator {
public:
    const double* operator()(const MyPointC2& p)
    {
        return &p.x();
    }

    const double* operator()(const MyPointC2& p, int)
    {
        const double* pyptr = &p.y();
        pyptr++;
        return pyptr;
    }
};

```

The last functor we have to provide is the one which constructs points. That is you are not forced to add the constructor with the *Origin* as parameter to your class, nor the constructor with homogeneous coordinates. The functor is a kind of glue layer between the CGAL algorithms and your class.

```

template <typename K>
class MyConstruct_point_2
{
    typedef typename K::RT          RT;
    typedef typename K::Point_2     Point_2;
public:
    typedef Point_2                  result_type;

    Point_2
    operator() (CGAL::Origin o) const
    { return Point_2(0,0, 0); }

    Point_2
    operator() (const RT& x, const RT& y) const
    { return Point_2(x, y, 0); }

    // We need this one, as such a functor is in the Filtered_kernel
    Point_2
    operator() (const RT& x, const RT& y, const RT& w) const
    {
        if(w != 1){
return Point_2(x/w, y/w, 0);
        } else {
return Point_2(x,y, 0);
        }
    }
};

```

Now we are ready to put the puzzle together. We won't explain it in detail, but you see that there are *typedefs* to the new point class and the functors. All the other types are inherited.

```

#ifndef MYKERNEL_H
#define MYKERNEL_H

#include <CGAL/Cartesian.h>
#include "MyPointC2.h"
#include "MySegmentC2.h"

// K_ is the new kernel, and K_Base is the old kernel
template < typename K_, typename K_Base >
class MyCartesian_base
    : public K_Base::template Base<K_>::Type
{
    typedef typename K_Base::template Base<K_>::Type    OldK;
public:
    typedef K_                                           Kernel;
    typedef MyPointC2                                    Point_2;
    typedef MySegmentC2<Kernel>                          Segment_2;
    typedef MyConstruct_point_2<Kernel, OldK>             Construct_point_2;
    typedef const double*                                Cartesian_const_iterator_2;
    typedef MyConstruct_coord_iterator                    Construct_cartesian_const_iterator_2;

```

```

typedef MyConstruct_bbox_2<typename OldK::Construct_bbox_2>
                                Construct_bbox_2;

Construct_point_2
construct_point_2_object() const
{ return Construct_point_2(); }

template < typename Kernel2 >
struct Base { typedef MyCartesian_base<Kernel2, K_Base>  Type; };
};

template < typename FT_ >
struct MyKernel
    : public CGAL::Type_equality_wrapper<
        MyCartesian_base<MyKernel<FT_>, CGAL::Cartesian<FT_> >,
        MyKernel<FT_> >
{};

#endif // MYKERNEL_H

```

**File:** examples/Kernel\_23/MyKernel.h

Finally, we give an example how this new kernel can be used. Predicates and constructions work with the new point, they can be used to construct segments and triangles with, and data structures from the Basic Library, as the Delaunay triangulation work with them.

The kernel itself can be made robust by plugging it in the *Filtered\_kernel*.

```

#include <CGAL/basic.h>
#include <CGAL/Filtered_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/squared_distance_2.h>
#include <cassert>
#include "MyKernel.h"

typedef MyKernel<double>          MK;
typedef CGAL::Filtered_kernel_adaptor<MK>  K;
typedef CGAL::Delaunay_triangulation_2<K>  Delaunay_triangulation_2;

typedef K::Point_2      Point;
typedef K::Segment_2    Segment;
typedef K::Ray_2        Ray;
typedef K::Line_2       Line;
typedef K::Triangle_2   Triangle;
typedef K::Iso_rectangle_2 Iso_rectangle;

const int RED= 1;
const int BLACK=2;

int main()

```

```

{
    Point a(0,0), b(1,0), c(1,1), d(0,1);
    a.color()=RED;
    b.color()=BLACK;
    d.color()=RED;

    Delaunay_triangulation_2 dt;
    dt.insert(a);

    K::Orientation_2 orientation;
    orientation(a,b,c);

    Point p(1,2), q;
    p.color() = RED;
    q.color() = BLACK;
    std::cout << p << std::endl;

    K::Compute_squared_distance_2 squared_distance;

    std::cout << "squared_distance(a, b) == "
                << squared_distance(a, b) << std::endl;

    Segment s1(p,q), s2(a, c);

    K::Construct_midpoint_2 construct_midpoint_2;

    Point mp = construct_midpoint_2(p,q);

    assert(s1.source().color() == RED);

    K::Intersect_2 intersection;

    CGAL::Object o = intersection(s1, s2);

    K::Construct_cartesian_const_iterator_2 construct_it;
    K::Cartesian_const_iterator_2 cit = construct_it(a);
    assert(*cit == a.x());

    cit = construct_it(a,0);

    cit--;
    assert(*cit == a.y());

    Line l1(a,b), l2(p, q);

    intersection(l1, l2);

    intersection(s1, l1);

    Ray r1(d,b), r2(d,c);
    intersection(r1, r2);

```

```

intersection(r1, l1);

squared_distance(r1, r2);
squared_distance(r1, l2);
squared_distance(r1, s2);

Triangle t1(a,b,c), t2(a,c,d);
intersection(t1, t2);
intersection(t1, l1);

intersection(t1, s1);

intersection(t1, r1);

Iso_rectangle i1(a,c), i2(d,p);
intersection(i1, i2);
intersection(i1, s1);

intersection(i1, r1);
intersection(i1, l1);

t1.orientation();

std::cout << s1.source() << std::endl;

std::cout << t1.bbox() << std::endl;

std::cout << "done" << std::endl;
return 0;
}

```

**File:** examples/Kernel\_23/MyKernel.cpp

### 7.5.3 Limitations

The point class must have member functions  $x()$  and  $y()$  (and  $z()$  for the 3d point). We will probably introduce function objects that take care of coordinate access.

As we enforce type equality between *MyKernel::Point\_2* and *Point\_2<MyKernel>*, the constructor with the color as third argument is not available.

## 7.6 Concepts

### Kernel

The concept of a *kernel* is defined by a set of requirements on the provision of certain types and access member functions to create objects of these types. The types are function object classes to be used within the algorithms and data structures of CGAL. This allows you to use any model of a kernel as a traits class in the CGAL algorithms and data structures, unless they require types beyond those provided by a kernel.

A kernel provides types, construction objects, and generalized predicates. The former replace constructors of the kernel classes and constructive procedures in the kernel. There are also function objects replacing operators, especially for equality testing.

#### Has Models

<i>CGAL::Cartesian</i> < <i>FieldNumberType</i> > .....	page 339
<i>CGAL::Homogeneous</i> < <i>RingNumberType</i> > .....	page 804
<i>CGAL::Simple_cartesian</i> < <i>FieldNumberType</i> > .....	page 351
<i>CGAL::Simple_homogeneous</i> < <i>RingNumberType</i> > .....	page 352

#### Types

<i>Kernel::FT</i>	a model of <i>FieldNumberType</i>
<i>Kernel::RT</i>	a model of <i>RingNumberType</i>

The following types describe the return types of predicates. They typically map to *bool* and CGAL kernel enum types, except when an interval arithmetic number type is used such as within the filtering kernels, in which case it is *Uncertain*<*bool*> or similar.

<i>Kernel::Boolean</i>	<i>bool</i> or <i>Uncertain</i> < <i>bool</i> >
<i>Kernel::Sign</i>	<i>CGAL::Sign</i> or <i>Uncertain</i> < <i>CGAL::Sign</i> >
<i>Kernel::Comparison_result</i>	<i>CGAL::Comparison_result</i> or <i>Uncertain</i> < <i>CGAL::Comparison_result</i> >
<i>Kernel::Orientation</i>	<i>CGAL::Orientation</i> or <i>Uncertain</i> < <i>CGAL::Orientation</i> >
<i>Kernel::Oriented_side</i>	<i>CGAL::Oriented_side</i> or <i>Uncertain</i> < <i>CGAL::Oriented_side</i> >
<i>Kernel::Bounded_side</i>	<i>CGAL::Bounded_side</i> or <i>Uncertain</i> < <i>CGAL::Bounded_side</i> >
<i>Kernel::Angle</i>	<i>CGAL::Angle</i> or <i>Uncertain</i> < <i>CGAL::Angle</i> >

#### Two-dimensional Kernel

##### Coordinate Access

<i>Kernel::Cartesian_const_iterator_2</i>	a model of <i>Kernel::CartesianConstIterator_2</i>
---	--

## Geometric Objects

<i>Kernel:: Point_2</i>	a model of <i>Kernel::Point_2</i>
<i>Kernel:: Vector_2</i>	a model of <i>Kernel::Vector_2</i>
<i>Kernel:: Direction_2</i>	a model of <i>Kernel::Direction_2</i>
<i>Kernel:: Line_2</i>	a model of <i>Kernel::Line_2</i>
<i>Kernel:: Ray_2</i>	a model of <i>Kernel::Ray_2</i>
<i>Kernel:: Segment_2</i>	a model of <i>Kernel::Segment_2</i>
<i>Kernel:: Triangle_2</i>	a model of <i>Kernel::Triangle_2</i>
<i>Kernel:: Iso_rectangle_2</i>	a model of <i>Kernel::IsoRectangle_2</i>
<i>Kernel:: Circle_2</i>	a model of <i>Kernel::Circle_2</i>
<i>Kernel:: Object_2</i>	a model of <i>Kernel::Object_2</i>

## Constructions

<i>Kernel:: Construct_point_2</i>	a model of <i>Kernel::ConstructPoint_2</i>
<i>Kernel:: Construct_vector_2</i>	a model of <i>Kernel::ConstructVector_2</i>
<i>Kernel:: Construct_direction_2</i>	a model of <i>Kernel::ConstructDirection_2</i>
<i>Kernel:: Construct_segment_2</i>	a model of <i>Kernel::ConstructSegment_2</i>
<i>Kernel:: Construct_line_2</i>	a model of <i>Kernel::ConstructLine_2</i>
<i>Kernel:: Construct_ray_2</i>	a model of <i>Kernel::ConstructRay_2</i>
<i>Kernel:: Construct_circle_2</i>	a model of <i>Kernel::ConstructCircle_2</i>
<i>Kernel:: Construct_triangle_2</i>	a model of <i>Kernel::ConstructTriangle_2</i>
<i>Kernel:: Construct_iso_rectangle_2</i>	a model of <i>Kernel::ConstructIsoRectangle_2</i>
<i>Kernel:: Construct_object_2</i>	a model of <i>Kernel::ConstructObject_2</i>
<i>Kernel:: Construct_scaled_vector_2</i>	a model of <i>Kernel::ConstructScaledVector_2</i>
<i>Kernel:: Construct_translated_point_2</i>	a model of <i>Kernel::ConstructTranslatedPoint_2</i>
<i>Kernel:: Construct_point_on_2</i>	a model of <i>Kernel::ConstructPointOn_2</i>
<i>Kernel:: Construct_projected_point_2</i>	a model of <i>Kernel::ConstructProjectedPoint_2</i>
<i>Kernel:: Construct_projected_xy_point_2</i>	a model of <i>Kernel::ConstructProjectedXYPoint_2</i>
<i>Kernel:: Construct_cartesian_const_iterator_2</i>	a model of <i>Kernel::ConstructCartesianConstIterator_2</i>
<i>Kernel:: Construct_vertex_2</i>	a model of <i>Kernel::ConstructVertex_2</i>
<i>Kernel:: Construct_bbox_2</i>	a model of <i>Kernel::ConstructBbox_2</i>
<i>Kernel:: Construct_perpendicular_vector_2</i>	a model of <i>Kernel::ConstructPerpendicularVector_2</i>
<i>Kernel:: Construct_perpendicular_direction_2</i>	a model of <i>Kernel::ConstructPerpendicularDirection_2</i>
<i>Kernel:: Construct_perpendicular_line_2</i>	a model of <i>Kernel::ConstructPerpendicularLine_2</i>
<i>Kernel:: Construct_max_vertex_2</i>	a model of <i>Kernel::ConstructMaxVertex_2</i>
<i>Kernel:: Construct_midpoint_2</i>	a model of <i>Kernel::ConstructMidpoint_2</i>
<i>Kernel:: Construct_equidistant_line_3</i>	a model of <i>Kernel::ConstructEquidistantLine_3</i>
<i>Kernel:: Construct_min_vertex_2</i>	a model of <i>Kernel::ConstructMinVertex_2</i>
<i>Kernel:: Construct_center_2</i>	a model of <i>Kernel::ConstructCenter_2</i>
<i>Kernel:: Construct_centroid_2</i>	a model of <i>Kernel::ConstructCentroid_2</i>
<i>Kernel:: Construct_circumcenter_2</i>	a model of <i>Kernel::ConstructCircumcenter_2</i>
<i>Kernel:: Construct_bisector_2</i>	a model of <i>Kernel::ConstructBisector_2</i>
<i>Kernel:: Construct_opposite_direction_2</i>	a model of <i>Kernel::ConstructOppositeDirection_2</i>
<i>Kernel:: Construct_opposite_segment_2</i>	a model of <i>Kernel::ConstructOppositeSegment_2</i>
<i>Kernel:: Construct_opposite_ray_2</i>	a model of <i>Kernel::ConstructOppositeRay_2</i>
<i>Kernel:: Construct_opposite_line_2</i>	a model of <i>Kernel::ConstructOppositeLine_2</i>
<i>Kernel:: Construct_opposite_triangle_2</i>	a model of <i>Kernel::ConstructOppositeTriangle_2</i>
<i>Kernel:: Construct_opposite_circle_2</i>	a model of <i>Kernel::ConstructOppositeCircle_2</i>
<i>Kernel:: Construct_opposite_vector_2</i>	a model of <i>Kernel::ConstructOppositeVector_2</i>

If the result type is not determined, there is no *Construct\_* prefix:

<i>Kernel:: Intersect_2</i>	a model of <i>Kernel::Intersect_2</i>
<i>Kernel:: Assign_2</i>	a model of <i>Kernel::Assign_2</i>

If the result type is a number type, the prefix is *Compute\_*:

<i>Kernel:: Compute_squared_distance_2</i>	a model of <i>Kernel::ComputeSquaredDistance_2</i>
<i>Kernel:: Compute_squared_length_2</i>	a model of <i>Kernel::ComputeSquaredLength_2</i>
<i>Kernel:: Compute_squared_radius_2</i>	a model of <i>Kernel::ComputeSquaredRadius_2</i>
<i>Kernel:: Compute_area_2</i>	a model of <i>Kernel::ComputeArea_2</i>

## Generalized Predicates

<i>Kernel:: Angle_2</i>	a model of <i>Kernel::Angle_2</i>
<i>Kernel:: Equal_2</i>	a model of <i>Kernel::Equal_2</i>
<i>Kernel:: Equal_x_2</i>	a model of <i>Kernel::EqualX_2</i>
<i>Kernel:: Equal_y_2</i>	a model of <i>Kernel::EqualY_2</i>
<i>Kernel:: Less_x_2</i>	a model of <i>Kernel::LessX_2</i>
<i>Kernel:: Less_y_2</i>	a model of <i>Kernel::LessY_2</i>
<i>Kernel:: Less_xy_2</i>	a model of <i>Kernel::LessXY_2</i>
<i>Kernel:: Less_yx_2</i>	a model of <i>Kernel::LessYX_2</i>
<i>Kernel:: Compare_x_2</i>	a model of <i>Kernel::CompareX_2</i>
<i>Kernel:: Compare_x_at_y_2</i>	a model of <i>Kernel::CompareXAtY_2</i>
<i>Kernel:: Compare_y_2</i>	a model of <i>Kernel::CompareY_2</i>
<i>Kernel:: Compare_xy_2</i>	a model of <i>Kernel::CompareXY_2</i>
<i>Kernel:: Compare_yx_2</i>	a model of <i>Kernel::CompareYX_2</i>
<i>Kernel:: Compare_y_at_x_2</i>	a model of <i>Kernel::CompareYAtX_2</i>
<i>Kernel:: Compare_distance_2</i>	a model of <i>Kernel::CompareDistance_2</i>
<i>Kernel:: Compare_angle_with_x_axis_2</i>	a model of <i>Kernel::CompareAngleWithXAxis_2</i>
<i>Kernel:: Compare_slope_2</i>	a model of <i>Kernel::CompareSlope_2</i>
<i>Kernel:: Less_distance_to_point_2</i>	a model of <i>Kernel::LessDistanceToPoint_2</i>
<i>Kernel:: Less_signed_distance_to_line_2</i>	a model of <i>Kernel::LessSignedDistanceToLine_2</i>
<i>Kernel:: Less_rotate_ccw_2</i>	a model of <i>Kernel::LessRotateCCW_2</i>
<i>Kernel:: Left_turn_2</i>	a model of <i>Kernel::LeftTurn_2</i>
<i>Kernel:: Collinear_2</i>	a model of <i>Kernel::Collinear_2</i>
<i>Kernel:: Orientation_2</i>	a model of <i>Kernel::Orientation_2</i>
<i>Kernel:: Side_of_oriented_circle_2</i>	a model of <i>Kernel::SideOfOrientedCircle_2</i>
<i>Kernel:: Side_of_bounded_circle_2</i>	a model of <i>Kernel::SideOfBoundedCircle_2</i>
<i>Kernel:: Is_horizontal_2</i>	a model of <i>Kernel::IsHorizontal_2</i>
<i>Kernel:: Is_vertical_2</i>	a model of <i>Kernel::IsVertical_2</i>
<i>Kernel:: Is_degenerate_2</i>	a model of <i>Kernel::IsDegenerate_2</i>
<i>Kernel:: Has_on_2</i>	a model of <i>Kernel::HasOn_2</i>
<i>Kernel:: Collinear_has_on_2</i>	a model of <i>Kernel::CollinearHasOn_2</i>
<i>Kernel:: Has_on_bounded_side_2</i>	a model of <i>Kernel::HasOnBoundedSide_2</i>
<i>Kernel:: Has_on_unbounded_side_2</i>	a model of <i>Kernel::HasOnUnboundedSide_2</i>
<i>Kernel:: Has_on_boundary_2</i>	a model of <i>Kernel::HasOnBoundary_2</i>
<i>Kernel:: Has_on_positive_side_2</i>	a model of <i>Kernel::HasOnPositiveSide_2</i>
<i>Kernel:: Has_on_negative_side_2</i>	a model of <i>Kernel::HasOnNegativeSide_2</i>
<i>Kernel:: Oriented_side_2</i>	a model of <i>Kernel::OrientedSide_2</i>
<i>Kernel:: Bounded_side_2</i>	a model of <i>Kernel::BoundedSide_2</i>
<i>Kernel:: Are_parallel_2</i>	a model of <i>Kernel::AreParallel_2</i>
<i>Kernel:: Are_ordered_along_line_2</i>	a model of <i>Kernel::AreOrderedAlongLine_2</i>
<i>Kernel:: Are_strictly_ordered_along_line_2</i>	a model of <i>Kernel::AreStrictlyOrderedAlongLine_2</i>
<i>Kernel:: Collinear_are_ordered_along_line_2</i>	a model of <i>Kernel::CollinearAreOrderedAlongLine_2</i>

*Kernel:: Collinear\_are\_strictly\_ordered\_along\_line\_2*

a model of *Kernel::CollinearAreStrictlyOrderedAlongLine\_2*

*Kernel:: Counterclockwise\_in\_between\_2*

a model of *Kernel::CounterclockwiseInBetween\_2*

*Kernel:: Do\_intersect\_2*

a model of *Kernel::DoIntersect\_2*

## Three-dimensional Kernel

### Coordinate Access

*Kernel:: Cartesian\_const\_iterator\_3*

a model of *Kernel::CartesianConstIterator\_3*

### Geometric Objects

*Kernel:: Point\_3*

a model of *Kernel::Point\_3*

*Kernel:: Vector\_3*

a model of *Kernel::Vector\_3*

*Kernel:: Direction\_3*

a model of *Kernel::Direction\_3*

*Kernel:: Iso\_cuboid\_3*

a model of *Kernel::IsoCuboid\_3*

*Kernel:: Line\_3*

a model of *Kernel::Line\_3*

*Kernel:: Ray\_3*

a model of *Kernel::Ray\_3*

*Kernel:: Circle\_3*

a model of *Kernel::Circle\_3*

*Kernel:: Sphere\_3*

a model of *Kernel::Sphere\_3*

*Kernel:: Segment\_3*

a model of *Kernel::Segment\_3*

*Kernel:: Plane\_3*

a model of *Kernel::Plane\_3*

*Kernel:: Triangle\_3*

a model of *Kernel::Triangle\_3*

*Kernel:: Tetrahedron\_3*

a model of *Kernel::Tetrahedron\_3*

*Kernel:: Object\_3*

a model of *Kernel::Object\_3*

### Constructions

*Kernel:: Construct\_point\_3*

a model of *Kernel::ConstructPoint\_3*

*Kernel:: Construct\_vector\_3*

a model of *Kernel::ConstructVector\_3*

*Kernel:: Construct\_direction\_3*

a model of *Kernel::ConstructDirection\_3*

*Kernel:: Construct\_plane\_3*

a model of *Kernel::ConstructPlane\_3*

*Kernel:: Construct\_iso\_cuboid\_3*

a model of *Kernel::ConstructIsoCuboid\_3*

*Kernel:: Construct\_line\_3*

a model of *Kernel::ConstructLine\_3*

*Kernel:: Construct\_ray\_3*

a model of *Kernel::ConstructRay\_3*

*Kernel:: Construct\_sphere\_3*

a model of *Kernel::ConstructSphere\_3*

*Kernel:: Construct\_segment\_3*

a model of *Kernel::ConstructSegment\_3*

*Kernel:: Construct\_triangle\_3*

a model of *Kernel::ConstructTriangle\_3*

*Kernel:: Construct\_tetrahedron\_3*

a model of *Kernel::ConstructTetrahedron\_3*

*Kernel:: Construct\_object\_3*

a model of *Kernel::ConstructObject\_3*

*Kernel:: Construct\_scaled\_vector\_3*

a model of *Kernel::ConstructScaledVector\_3*

*Kernel:: Construct\_translated\_point\_3*

a model of *Kernel::ConstructTranslatedPoint\_3*

*Kernel:: Construct\_point\_on\_3*

a model of *Kernel::ConstructPointOn\_3*

*Kernel:: Construct\_projected\_point\_3*

a model of *Kernel::ConstructProjectedPoint\_3*

*Kernel:: Construct\_lifted\_point\_3*

a model of *Kernel::ConstructLiftedPoint\_3*

*Kernel:: Construct\_cartesian\_const\_iterator\_3*

a model of *Kernel::ConstructCartesianConstIterator\_3*

*Kernel:: Construct\_vertex\_3*

a model of *Kernel::ConstructVertex\_3*

<i>Kernel:: Construct_bbox_3</i>	a model of <i>Kernel::ConstructBbox_3</i>
<i>Kernel:: Construct_supporting_plane_3</i>	a model of <i>Kernel::ConstructSupportingPlane_3</i>
<i>Kernel:: Construct_orthogonal_vector_3</i>	a model of <i>Kernel::ConstructOrthogonalVector_3</i>
<i>Kernel:: Construct_base_vector_3</i>	a model of <i>Kernel::ConstructBaseVector_3</i>
<i>Kernel:: Construct_perpendicular_plane_3</i>	a model of <i>Kernel::ConstructPerpendicularPlane_3</i>
<i>Kernel:: Construct_radical_plane_3</i>	a model of <i>Kernel::ConstructRadicalPlane_3</i>
<i>Kernel:: Construct_perpendicular_line_3</i>	a model of <i>Kernel::ConstructPerpendicularLine_3</i>
<i>Kernel:: Construct_midpoint_3</i>	a model of <i>Kernel::ConstructMidpoint_3</i>
<i>Kernel:: Construct_center_3</i>	a model of <i>Kernel::ConstructCenter_3</i>
<i>Kernel:: Construct_centroid_3</i>	a model of <i>Kernel::ConstructCentroid_3</i>
<i>Kernel:: Construct_circumcenter_3</i>	a model of <i>Kernel::ConstructCircumcenter_3</i>
<i>Kernel:: Construct_bisector_3</i>	a model of <i>Kernel::ConstructBisector_3</i>
<i>Kernel:: Construct_cross_product_vector_3</i>	a model of <i>Kernel::ConstructCrossProductVector_3</i>
<i>Kernel:: Construct_opposite_direction_3</i>	a model of <i>Kernel::ConstructOppositeDirection_3</i>
<i>Kernel:: Construct_opposite_segment_3</i>	a model of <i>Kernel::ConstructOppositeSegment_3</i>
<i>Kernel:: Construct_opposite_ray_3</i>	a model of <i>Kernel::ConstructOppositeRay_3</i>
<i>Kernel:: Construct_opposite_line_3</i>	a model of <i>Kernel::ConstructOppositeLine_3</i>
<i>Kernel:: Construct_opposite_plane_3</i>	a model of <i>Kernel::ConstructOppositePlane_3</i>
<i>Kernel:: Construct_opposite_sphere_3</i>	a model of <i>Kernel::ConstructOppositeSphere_3</i>
<i>Kernel:: Construct_opposite_vector_3</i>	a model of <i>Kernel::ConstructOppositeVector_3</i>

If the result type is not determined, there is no *Construct\_* prefix:

<i>Kernel:: Intersect_3</i>	a model of <i>Kernel::Intersect_3</i>
<i>Kernel:: Assign_3</i>	a model of <i>Kernel::Assign_3</i>

If the result type is a number type, the prefix is *Compute\_*:

<i>Kernel:: Compute_area_3</i>	a model of <i>Kernel::ComputeArea_3</i>
<i>Kernel:: Compute_squared_area_3</i>	a model of <i>Kernel::ComputeSquaredArea_3</i>
<i>Kernel:: Compute_area_divided_by_pi_3</i>	a model of <i>Kernel::ComputeAreaDividedByPi_3</i>
<i>Kernel:: Compute_approximate_area_3</i>	a model of <i>Kernel::ComputeApproximateArea_3</i>
<i>Kernel:: Compute_squared_distance_3</i>	a model of <i>Kernel::ComputeSquaredDistance_3</i>
<i>Kernel:: Compute_squared_length_3</i>	a model of <i>Kernel::ComputeSquaredLength_3</i>
<i>Kernel:: Compute_squared_length_divided_by_pi_square_3</i>	a model of <i>Kernel::ComputeSquaredLengthDividedByPiSquare_3</i>
<i>Kernel:: Compute_approximate_squared_length_3</i>	a model of <i>Kernel::ComputeApproximateSquaredLength_3</i>
<i>Kernel:: Compute_squared_radius_3</i>	a model of <i>Kernel::ComputeSquaredRadius_3</i>
<i>Kernel:: Compute_volume_3</i>	a model of <i>Kernel::ComputeVolume_3</i>

## Generalized Predicates

<i>Kernel:: Angle_3</i>	a model of <i>Kernel::Angle_3</i>
<i>Kernel:: Equal_3</i>	a model of <i>Kernel::Equal_3</i>
<i>Kernel:: Equal_x_3</i>	a model of <i>Kernel::EqualX_3</i>
<i>Kernel:: Equal_y_3</i>	a model of <i>Kernel::EqualY_3</i>
<i>Kernel:: Equal_z_3</i>	a model of <i>Kernel::EqualZ_3</i>

<i>Kernel:: Are_ordered_along_line_3</i>	a model of <i>Kernel::AreOrderedAlongLine_3</i>
<i>Kernel:: Are_strictly_ordered_along_line_3</i>	a model of <i>Kernel::AreStrictlyOrderedAlongLine_3</i>
<i>Kernel:: Collinear_are_ordered_along_line_3</i>	a model of <i>Kernel::CollinearAreOrderedAlongLine_3</i>
	a model of <i>Kernel::CollinearAreStrictlyOrderedAlongLine_3</i>
<i>Kernel:: Do_intersect_3</i>	a model of <i>Kernel::DoIntersect_3</i>

## Operations

For each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *\_object* appended. For example, for the function object *Kernel::Construct\_vector\_2* the following member function must exist:

*Kernel::Construct\_vector\_2*                      *kernel.construct\_vector\_2\_object()*

## 7.7 Kernel Classes and Operations

### CGAL::Cartesian<FieldNumberType>

```
#include <CGAL/Cartesian.h>
```

#### Definition

A model for *Kernel* that uses Cartesian coordinates to represent the geometric objects. In order for *Cartesian<FieldNumberType>* to model Euclidean geometry in  $E^2$  and/or  $E^3$ , for some mathematical field  $E$  (e.g., the rationals  $\mathbb{Q}$  or the reals  $\mathbb{R}$ ), the template parameter *FieldNumberType* must model the mathematical field  $E$ . That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for *FieldNumberType* is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

#### Is Model for the Concepts

Kernel ..... page [333](#)

#### Types

```
typedef FieldNumberType    FT;
typedef FieldNumberType    RT;
```

#### Implementation

All geometric objects in *Cartesian<FieldNumberType>* are reference counted.

## CGAL::Cartesian\_converter<K1, K2, NTConverter>

### Definition

*Cartesian\_converter*<*K1*, *K2*, *NTConverter*> converts objects from the kernel traits *K1* to the kernel traits *K2* using *Converter* to do the conversion. Those traits must be of the form *Cartesian*<*FT1*> and *Cartesian*<*FT2*> (or the equivalent with *Simple\_cartesian*). It then provides the following operators to convert objects from *K1* to *K2*.

The third template parameter *NTConverter* is a function object that must provide *K2::FT operator()(K1::FT n)* that converts *n* to an *K2::FT* which has the same value.

The default value of this parameter is *CGAL::NT\_converter*<*K1::FT*, *K2::FT*>.

```
#include <CGAL/Cartesian_converter.h>
```

### Creation

```
Cartesian_converter<K1, K2, NTConverter> conv;
```

Default constructor.

### Operations

```
K2::Point_2                      conv.operator()( K1::Point_2 p)
```

returns a *K2::Point\_2* which coordinates are those of *p*, converted by *NTConverter*.

Similar operators are defined for the other kernel traits types *Point\_3*, *Vector\_2*...

## CGAL::cartesian\_to\_homogeneous

```
#include <CGAL/cartesian_homogeneous_conversion.h>
```

```
Point_2< Homogeneous<RT> > cartesian_to_homogeneous( Point_2< Cartesian<RT> > cp)
```

converts 2d point *cp* with Cartesian representation into a 2d point with homogeneous representation with the same number type.

```
Point_3< Homogeneous<RT> > cartesian_to_homogeneous( Point_3< Cartesian<RT> > cp)
```

converts 3d point *cp* with Cartesian representation into a 3d point with homogeneous representation with the same number type.

## CGAL::Filtered\_kernel<CK>

### Definition

*Filtered\_kernel<CK>* is a kernel that uses the filtering technique based on interval arithmetic from [BBP01] to achieve exact and efficient predicates. In addition, a few selected important predicates are implemented using the formally proved, semi-static, filtering techniques from [MP05].

The geometric constructions are exactly those of the kernel *CK*, which means that they are not necessarily exact.

### Is Model for the Concepts

*Kernel*

```
#include <CGAL/Filtered_kernel.h>
```

### Types

<i>typedef EK</i>	<i>Exact_kernel;</i>	The type of the exact kernel.
<i>typedef FK</i>	<i>Approximate_kernel;</i>	The type of the approximate "filtering" kernel.

### Example

The following example shows how to produce a kernel whose geometric objects and constructions are those of *Simple\_cartesian<double>* but the predicates are exact.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Filtered_kernel<CK> K;
```

### Implementation

The implementation uses *CGAL::Filtered\_predicate<EP, FP, C2E, C2F>* over each predicate of the kernel traits interface. Additionally, faster static filters are used for a few selected critical predicates. The static filters can be disabled by compiling with *-DCGAL\_NO\_STATIC\_FILTERS*.

## CGAL::Filtered\_kernel\_adaptor<CK>

### Definition

*Filtered\_kernel\_adaptor*<CK> is a kernel that uses the filtering technique [BBP01] to obtain a kernel with exact and efficient predicate functors. The geometric constructions are exactly those of the kernel CK, which means that they are not necessarily exact.

In contrast to *Filtered\_kernel*, the global functions are those of CK.

### Is Model for the Concepts

*Kernel*

```
#include <CGAL/Filtered_kernel.h>
```

### Example

The following example shows how to produce a kernel whose geometric objects and constructions are those of *Simple\_cartesian*<double>. The predicate functors of the kernel are exact, the global functions are not.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Filtered_kernel_adaptor<CK> K;

typedef K::Point_2 p(0,0), q(1,1), r(1,5);

CGAL::orientation(p,q,r);           // not exact

typedef K::Orientation_2 orientation;
orientation(p,q,r);                 // exact
```

## CGAL::Filtered\_predicate<EP, FP, C2E, C2F>

### Definition

*Filtered\_predicate*<EP, FP, C2E, C2F> is an adaptor for predicate function objects that allows one to produce efficient and exact predicates. It is used to build *CGAL::Filtered\_kernel*<CK> and can be used for other predicates too.

*EP* is the exact but supposedly slow predicate that is able to evaluate the predicate correctly. It will be called only when the filtering predicate, *FP*, cannot compute the correct result. This failure of *FP* must be done by throwing an exception.

To convert the geometric objects that are the arguments of the predicate, we use the function objects *C2E* and *C2F*, which must be of the form *Cartesian\_converter* or *Homogeneous\_converter*.

```
#include <CGAL/Filtered_predicate.h>
```

### Types

```
typedef FP::result_type    result_type;
```

The return type of the function operators. It must also be the same type as *EP::result\_type*.

### Creation

```
Filtered_predicate<EP, FP, C2E, C2F> fo;
```

Default constructor.

### Operations

```
template <class A1>
result_type    fo.operator()( A1 a1)
```

The unary function operator for unary predicates.

```
template <class A1, class A2>
result_type    fo.operator()( A1 a1, A2 a2)
```

The binary function operator for binary predicates.

Similar function operators are defined for up to 7 arguments.

### Example

The following example defines an efficient and exact version of the orientation predicate over three points using the Cartesian representation with double coordinates and without reference counting (*Simple\_cartesian*<*double*>::*Point\_2*). Of course, the orientation predicate can already be found in the kernel, but you can follow this example to filter your own predicates. It uses the fast but inexact predicate based on interval arithmetic for filtering and the slow but exact predicate based on multi-precision floats when the filtering predicate fails.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_predicate.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Cartesian_converter.h>

typedef CGAL::Simple_cartesian<double> K;
typedef CGAL::Simple_cartesian<CGAL::Interval_nt_advanced> FK;
typedef CGAL::Simple_cartesian<CGAL::MP_Float> EK;
typedef CGAL::Cartesian_converter<K, EK> C2E;
typedef CGAL::Cartesian_converter<K, FK> C2F;

// Define my predicate, parameterized by a kernel.
template < typename K >
struct My_orientation_2
{
    typedef typename K::RT          RT;
    typedef typename K::Point_2     Point_2;

    typedef typename K::Orientation result_type;

    result_type
    operator()(const Point_2 &p, const Point_2 &q, const Point_2 &r) const
    {
        RT prx = p.x() - r.x();
        RT pry = p.y() - r.y();
        RT qrx = q.x() - r.x();
        RT qry = q.y() - r.y();
        return CGAL::sign( prx*qry - qrx*pry );
    }
};

typedef CGAL::Filtered_predicate<My_orientation_2<EK>,
                                My_orientation_2<FK>, C2E, C2F> Orientation_2;

int main()
{
    K::Point_2 p(1,2), q(2,3), r(3,4);
    Orientation_2 orientation;
    orientation(p, q, r);
    return 0;
}

```

## CGAL::Homogeneous<RingNumberType>

```
#include <CGAL/Homogeneous.h>
```

### Definition

A model for a *Kernel* using homogeneous coordinates to represent the geometric objects. In order for *Homogeneous<RingNumberType>* to model Euclidean geometry in  $E^2$  and/or  $E^3$ , for some mathematical ring  $E$  (e.g., the integers  $\mathbb{Z}$  or the rationals  $\mathbb{Q}$ ), the template parameter *RingNumberType* must model the mathematical ring  $E$ . That is, the ring operations on this number type must compute the mathematically correct results. If the number type provided as a model for *RingNumberType* is only an approximation of a ring (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

### Is Model for the Concepts

Kernel ..... page [333](#)

### Types

```
typedef Quotient<RingNumberType>    FT;
typedef RingNumberType               RT;
```

### Implementation

This model of a kernel uses reference counting.

## CGAL::Homogeneous\_converter<K1, K2, RTConverter, FTConverter>

### Definition

*Homogeneous\_converter*<*K1*, *K2*, *RTConverter*, *FTConverter*> converts objects from the kernel traits *K1* to the kernel traits *K2*. Those traits must be of the form *Homogeneous*<*RT1*> and *Homogeneous*<*RT2*> (or the equivalent with *Simple\_homogeneous*). It then provides the following operators to convert objects from *K1* to *K2*.

The third template parameter *RT\_Converter* is a function object that must provide *K2::RT operator()(const K1::RT &n)*; that converts *n* to an *K2::RT* that has the same value.

The default value of this parameter is *CGAL::NT\_converter*<*K1::RT*, *K2::RT*>, which uses the conversion operator from *K1::RT* to *K2::RT*.

Similarly, the fourth template parameter must provide *K2::FT operator()(const K1::FT &n)*; that converts *n* to an *K2::FT* that has the same value. Its default value is *CGAL::NT\_converter*<*K1::FT*, *K2::FT*>.

#include <CGAL/Homogeneous\_converter.h>

### Creation

*Homogeneous\_converter*<*K1*, *K2*, *RTConverter*, *FTConverter*> *conv*;

Default constructor.

### Operations

*K2::Point\_2*                      *conv.operator()( K1::Point\_2 p)*

returns a *K2::Point\_2* which coordinates are those of *p*, converted by *RTConverter*.

Similar operators are defined for the other kernel traits geometric types *Point\_3*, *Vector\_2*...

## CGAL::homogeneous\_to\_cartesian

```
#include <CGAL/cartesian_homogeneous_conversion.h>
```

```
Point_2< Cartesian<FT> >      homogeneous_to_cartesian( Point_2< Homogeneous<FT> > hp)
```

converts 2d point *hp* with homogeneous representation into a 2d point with Cartesian representation with the same number type.

```
Point_3< Cartesian<FT> >      homogeneous_to_cartesian( Point_3< Homogeneous<FT> > hp)
```

converts 3d point *hp* with homogeneous representation into a 3d point with Cartesian representation with the same number type.

## CGAL::Kernel\_traits<T>

```
#include <CGAL/Kernel_traits.h>
```

### Definition

The class *Kernel\_traits*<*T*> provides access to the kernel model to which the argument type *T* belongs. (Provided *T* belongs to some kernel model.) The default implementation assumes there is a local type *T::Kernel* referring to the kernel model of *T*. If this type does not exist, a specialization of *Kernel\_traits*<*T*> can be used to provide the desired information.

This class is, for example, useful in the following context. Assume you want to write a generic function that accepts two points *p* and *q* as argument and constructs the line segment between *p* and *q*. In order to specify the return type of this function, you need to know what is the segment type corresponding to the Point type representing *p* and *q*. Using *Kernel\_traits*<*T*>, this can be done as follows.

```
template < class Point >
typename Kernel_traits<Point>::Kernel::Segment
construct_segment(Point p, Point q)
{ ... }
```

### Types

<i>typedef T::R</i>	<i>Kernel</i> ;	If <i>T</i> is a type <i>K::Point_2</i> of some kernel model <i>K</i> , then <i>Kernel</i> is equal to <i>K</i> .
---------------------	-----------------	---

## CGAL::Simple\_cartesian<FieldNumberType>

```
#include <CGAL/Simple_cartesian.h>
```

### Definition

A model for a *Kernel* using Cartesian coordinates to represent the geometric objects. In order for *Simple\_cartesian*<*FieldNumberType*> to model Euclidean geometry in  $E^2$  and/or  $E^3$ , for some mathematical field  $E$  (e.g., the rationals  $\mathbb{Q}$  or the reals  $\mathbb{R}$ ), the template parameter *FieldNumberType* must model the mathematical field  $E$ . That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for *FieldNumberType* is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

### Is Model for the Concepts

Kernel ..... page [333](#)

### Types

```
typedef FieldNumberType
```

```
FT;
```

```
typedef FieldNumberType
```

```
RT;
```

### Implementation

In contrast to *Cartesian*, no reference counting is used internally. This eases debugging, but may slow down algorithms that copy objects intensively.

## 7.8 Predefined Kernels

### **CGAL::Exact\_predicates\_exact\_constructions\_kernel**

#### **Definition**

A typedef to a kernel which has the following properties:

- It uses Cartesian representation.
- It supports constructions of points from `double` Cartesian coordinates.
- It provides both exact geometric predicates and exact geometric constructions.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
```

## CGAL::Exact\_predicates\_exact\_constructions\_kernel\_with\_sqrt

### Definition

A typedef to a kernel which has the following properties:

- It uses Cartesian representation.
- It supports constructions of points from `double` Cartesian coordinates.
- It provides both exact geometric predicates and exact geometric constructions.
- Its *FT* nested type supports the square root operation *sqrt()*.

Note that it requires CORE or LEDA installed.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel_with_sqrt.h>
```

## 7.9 Kernel Objects

### 7.9.1 Two-dimensional Objects

#### CGAL::Aff\_transformation\_2<Kernel>

##### Definition

The class *Aff\_transformation\_2<Kernel>* represents two-dimensional affine transformations. The general form of an affine transformation is based on a homogeneous representation of points. Thereby all transformations can be realized by matrix multiplications.

Multiplying the transformation matrix by a scalar does not change the represented transformation. Therefore, any transformation represented by a matrix with rational entries can be represented by a transformation matrix with integer entries as well. (Multiply the matrix with the common denominator of the rational entries.) Hence, it is sufficient to use the number type *Kernel::RT* to represent the entries of the transformation matrix.

CGAL offers several specialized affine transformations. Different constructors are provided to create them. They are parameterized with a symbolic name to denote the transformation type, followed by additional parameters. The symbolic name tags solve ambiguities in the function overloading and they make the code more readable, i.e., what type of transformation is created.

Since two-dimensional points have three homogeneous coordinates, we have a  $3 \times 3$  matrix  $(m_{ij})_{i,j=0\dots 2}$ .

If the homogeneous representations are normalized (the homogenizing coordinate is 1), then the upper left  $2 \times 2$  matrix realizes linear transformations. In the matrix form of a translation, the translation vector  $(v_0, v_1, 1)$  appears in the last column of the matrix. The entries  $m_{20}$  and  $m_{21}$  are always zero and therefore do not appear in the constructors.

##### Creation

```
Aff_transformation_2<Kernel> t( Identity_transformation);
```

introduces an identity transformation.

```
Aff_transformation_2<Kernel> t( const Translation, Vector_2<Kernel> v);
```

introduces a translation by a vector  $v$ .

```
Aff_transformation_2<Kernel> t( const Rotation,  
                                Direction_2<Kernel> d,  
                                Kernel::RT num,
```

*Kernel::RT den = RT(1)*

approximates the rotation over the angle indicated by direction  $d$ , such that the differences between the sines and cosines of the rotation given by  $d$  and the approximating rotation are at most  $num/den$  each.

*Precondition:*  $num/den > 0$  and  $d \neq 0$ .

*Aff\_transformation\_2<Kernel> t( const Rotation,*  
*Kernel::RT sine\_rho,*  
*Kernel::RT cosine\_rho,*  
*Kernel::RT hw = RT(1))*

introduces a rotation by the angle  $\rho$ .

*Precondition:*  $sine\_rho^2 + cosine\_rho^2 == hw^2$ .

*Aff\_transformation\_2<Kernel> t( const Scaling, Kernel::RT s, Kernel::RT hw = RT(1));*

introduces a scaling by a scale factor  $s/hw$ .

*Aff\_transformation\_2<Kernel> t( Kernel::RT m00,*  
*Kernel::RT m01,*  
*Kernel::RT m02,*  
*Kernel::RT m10,*  
*Kernel::RT m11,*  
*Kernel::RT m12,*  
*Kernel::RT hw = RT(1))*

introduces a general affine transformation in the  $3 \times 3$  matrix form  $\begin{pmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ 0 & 0 & hw \end{pmatrix}$ . The sub-matrix  $\frac{1}{hw} \begin{pmatrix} m_{00} & m_{01} \\ m_{10} & m_{11} \end{pmatrix}$  contains the scaling and rotation information, the vector  $\frac{1}{hw} \begin{pmatrix} m_{02} \\ m_{12} \end{pmatrix}$  contains the translational part of the transformation.

*Aff\_transformation\_2<Kernel> t( Kernel::RT m00,*  
*Kernel::RT m01,*  
*Kernel::RT m10,*  
*Kernel::RT m11,*  
*Kernel::RT hw = RT(1))*

introduces a general linear transformation  $\begin{pmatrix} m_{00} & m_{01} & 0 \\ m_{10} & m_{11} & 0 \\ 0 & 0 & hw \end{pmatrix}$ , i.e. there is no translational part.

## Operations

The main thing to do with transformations is to apply them on geometric objects. Each class *Class\_2<Kernel>* representing a geometric object has a member function:

*Class\_2<Kernel>* *transform*(*Aff\_transformation\_2<Kernel>* *t*).

The transformation classes provide a member function *transform()* for points, vectors, directions, and lines:

<i>Point_2&lt;Kernel&gt;</i>	<i>t.transform( Point_2&lt;Kernel&gt; p)</i>
<i>Vector_2&lt;Kernel&gt;</i>	<i>t.transform( Vector_2&lt;Kernel&gt; p)</i>
<i>Direction_2&lt;Kernel&gt;</i>	<i>t.transform( Direction_2&lt;Kernel&gt; p)</i>
<i>Line_2&lt;Kernel&gt;</i>	<i>t.transform( Line_2&lt;Kernel&gt; p)</i>

CGAL provides function operators for these member functions:

<i>Point_2&lt;Kernel&gt;</i>	<i>t.operator()( Point_2&lt;Kernel&gt; p)</i>
<i>Vector_2&lt;Kernel&gt;</i>	<i>t.operator()( Vector_2&lt;Kernel&gt; p)</i>
<i>Direction_2&lt;Kernel&gt;</i>	<i>t.operator()( Direction_2&lt;Kernel&gt; p)</i>
<i>Line_2&lt;Kernel&gt;</i>	<i>t.operator()( Line_2&lt;Kernel&gt; p)</i>

## Miscellaneous

*Aff\_transformation\_2<Kernel>*

<i>t.operator*( s)</i>	composes two affine transformations.
------------------------	--------------------------------------

*Aff\_transformation\_2<Kernel>*

<i>t.inverse()</i>	gives the inverse transformation.
--------------------	-----------------------------------

<i>bool</i>	<i>t.is_even()</i>	returns <i>true</i> , if the transformation is not reflecting, i.e. the determinant of the involved linear transformation is non-negative.
-------------	--------------------	--

<i>bool</i>	<i>t.is_odd()</i>	returns <i>true</i> , if the transformation is reflecting.
-------------	-------------------	--

The matrix entries of a matrix representation of a *Aff\_transformation\_2<Kernel>* can be accessed through the following member functions:

<i>Kernel::FT</i>	<i>t.cartesian( int i, int j)</i>	returns entry $m_{ij}$ in a matrix representation in which $m_{22}$ is 1.
<i>Kernel::FT</i>	<i>t.m( int i, int j)</i>	

<i>Kernel::RT</i>	<i>t.homogeneous( int i, int j)</i>	returns entry $m_{ij}$ in some fixed matrix representation.
<i>Kernel::RT</i>	<i>t.hm( int i, int j)</i>	

For affine transformations no I/O operators are defined.

## See Also

*Identity\_transformation, Rotation, Scaling, Translation*  
*rational\_rotation\_approximation*

## Example

```
typedef Cartesian<double>      K;
typedef Aff_transformation_2<K> Transformation;
typedef Point_2<K>            Point;
typedef Vector_2<K>            Vector;
typedef Direction_2<K>         Direction;

Transformation rotate(ROTATION, sin(pi), cos(pi));
Transformation rational_rotate(ROTATION, Direction(1,1), 1, 100);
Transformation translate(TRANSLATION, Vector(-2, 0));
Transformation scale(SCALING, 3);

Point q(0, 1);
q = rational_rotate(q);

Point p(1, 1);

p = rotate(p);

p = translate(p);

p = scale(p);
```

The same would have been achieved with

```
Transformation transform = scale * (translate * rotate);
p = transform(Point(1.0, 1.0));
```

# CGAL::Bbox\_2

`#include <CGAL/Bbox_2.h>`

## Definition

An object  $b$  of the class  $Bbox\_2$  is a bounding box in the two-dimensional Euclidean plane  $\mathbb{E}^2$ . This class is not templated.

## Creation

$Bbox\_2\ b( double\ x\_min, double\ y\_min, double\ x\_max, double\ y\_max );$

introduces a bounding box  $b$  with lower left corner at  $(xmin, ymin)$  and with upper right corner at  $(xmax, ymax)$ .

## Operations

$bool$	$b.operator==( c )$	Test for equality.
$bool$	$b.operator!=( q )$	Test for inequality.
$int$	$b.dimension()$	Returns 2.
$double$	$b.xmin()$	
$double$	$b.ymin()$	
$double$	$b.xmax()$	
$double$	$b.ymax()$	
$double$	$b.min( int\ i )$	Returns $xmin()$ if $i==0$ or $ymin()$ if $i==1$ . Precondition: $i==0$ or $i==1$
$double$	$b.max( int\ i )$	Returns $xmax()$ if $i==0$ or $ymax()$ if $i==1$ . Precondition: $i==0$ or $i==1$
$Bbox\_2$	$b.operator+( c )$	returns a bounding box of $b$ and $c$ .

## CGAL::Circle\_2<Kernel>

### Definition

An object of type *Circle\_2<Kernel>* is a circle in the two-dimensional Euclidean plane  $\mathbb{E}^2$ . The circle is oriented, i.e. its boundary has clockwise or counterclockwise orientation. The boundary splits  $\mathbb{E}^2$  into a positive and a negative side, where the positive side is to the left of the boundary. The boundary also splits  $\mathbb{E}^2$  into a bounded and an unbounded side. Note that the circle can be degenerated, i.e. the squared radius may be zero.

### Creation

*Circle\_2<Kernel>* *c*( *Point\_2<Kernel>* *center*,  
                   *Kernel::FT* *squared\_radius*,  
                   Orientation *ori* = COUNTERCLOCKWISE)

introduces a variable *c* of type *Circle\_2<Kernel>*. It is initialized to the circle with center *center*, squared radius *squared\_radius* and orientation *ori*.

*Precondition*: *ori*  $\neq$  COLLINEAR, and further, *squared\_radius*  $\geq$  0.

*Circle\_2<Kernel>* *c*( *Point\_2<Kernel>* *p*, *Point\_2<Kernel>* *q*, *Point\_2<Kernel>* *r*);

introduces a variable *c* of type *Circle\_2<Kernel>*. It is initialized to the unique circle which passes through the points *p*, *q* and *r*. The orientation of the circle is the orientation of the point triple *p*, *q*, *r*.

*Precondition*: *p*, *q*, and *r* are not collinear.

*Circle\_2<Kernel>* *c*( *Point\_2<Kernel>* *p*, *Point\_2<Kernel>* *q*, Orientation *ori* = COUNTERCLOCKWISE);

introduces a variable *c* of type *Circle\_2<Kernel>*. It is initialized to the circle with diameter  $\overline{pq}$  and orientation *ori*.

*Precondition*: *ori*  $\neq$  COLLINEAR.

*Circle\_2<Kernel>* *c*( *Point\_2<Kernel>* *center*, Orientation *ori* = COUNTERCLOCKWISE);

introduces a variable *c* of type *Circle\_2<Kernel>*. It is initialized to the circle with center *center*, squared radius zero and orientation *ori*.

*Precondition*: *ori*  $\neq$  COLLINEAR.

*Postcondition*: *c.is\_degenerate()* = true.

### Access Functions

*Point\_2<Kernel>*                    *c.center()*                    returns the center of *c*.

<i>Kernel::FT</i>	<i>c.squared_radius()</i>	returns the squared radius of <i>c</i> .
<i>Orientation</i>	<i>c.orientation()</i>	returns the orientation of <i>c</i> .
<i>bool operator</i>	<i>c.==( circle2)</i>	returns <i>true</i> , iff <i>c</i> and <i>circle2</i> are equal, i.e. if they have the same center, same squared radius and same orientation.
<i>bool operator</i>	<i>c.!=( circle2)</i>	returns <i>true</i> , iff <i>c</i> and <i>circle2</i> are not equal.

## Predicates

<i>bool</i>	<i>c.is_degenerate()</i>	returns <i>true</i> , iff <i>c</i> is degenerate, i.e. if <i>c</i> has squared radius zero.
<i>Oriented_side</i>	<i>c.oriented_side( Point_2&lt;Kernel&gt; p)</i>	returns either the constant <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_POSITIVE_SIDE</i> , or <i>ON_NEGATIVE_SIDE</i> , iff <i>p</i> lies on the boundary, properly on the positive side, or properly on the negative side of <i>c</i> , resp.
<i>Bounded_side</i>	<i>c.bounded_side( Point_2&lt;Kernel&gt; p)</i>	returns <i>ON_BOUNDED_SIDE</i> , <i>ON_BOUNDARY</i> , or <i>ON_UNBOUNDED_SIDE</i> iff <i>p</i> lies properly inside, on the boundary, or properly outside of <i>c</i> , resp.
<i>bool</i>	<i>c.has_on_positive_side( Point_2&lt;Kernel&gt; p)</i>	
<i>bool</i>	<i>c.has_on_negative_side( Point_2&lt;Kernel&gt; p)</i>	
<i>bool</i>	<i>c.has_on_boundary( Point_2&lt;Kernel&gt; p)</i>	
<i>bool</i>	<i>c.has_on_bounded_side( Point_2&lt;Kernel&gt; p)</i>	
<i>bool</i>	<i>c.has_on_unbounded_side( Point_2&lt;Kernel&gt; p)</i>	

## Miscellaneous

<i>Circle_2&lt;Kernel&gt;</i>	<i>c.opposite()</i>	returns the circle with the same center and squared radius as <i>c</i> but with opposite orientation.
<i>Circle_2&lt;Kernel&gt;</i>	<i>c.orthogonal_transform( Aff_transformation_2&lt;Kernel&gt; at)</i>	returns the circle obtained by applying <i>at</i> on <i>c</i> . <i>Precondition:</i> <i>at</i> is an orthogonal transformation.
<i>Bbox_2</i>	<i>c.bbox()</i>	returns a bounding box containing <i>c</i> .

*Kernel::Circle\_2* ..... page [523](#)

## CGAL::Direction\_2<Kernel>

### Definition

An object of the class *Direction\_2<Kernel>* is a vector in the two-dimensional vector space  $\mathbb{R}^2$  where we forget about its length. They can be viewed as unit vectors, although there is no normalization internally, since this is error prone. Directions are used whenever the length of a vector does not matter. They also characterize a set of parallel oriented lines that have the same orientations. For example, you can ask for the direction orthogonal to an oriented plane, or the direction of an oriented line. Further, they can be used to indicate angles. The slope of a direction is  $dy()/dx()$ .

### Creation

*Direction\_2<Kernel>*  $d$ ( *Vector\_2<Kernel>*  $v$ );      introduces the direction  $d$  of vector  $v$ .

*Direction\_2<Kernel>*  $d$ ( *Line\_2<Kernel>*  $l$ );      introduces the direction  $d$  of line  $l$ .

*Direction\_2<Kernel>*  $d$ ( *Ray\_2<Kernel>*  $r$ );      introduces the direction  $d$  of ray  $r$ .

*Direction\_2<Kernel>*  $d$ ( *Segment\_2<Kernel>*  $s$ );      introduces the direction  $d$  of segment  $s$ .

*Direction\_2<Kernel>*  $d$ ( *Kernel::RT*  $x$ , *Kernel::RT*  $y$ );      introduces a direction  $d$  passing through the origin and the point with Cartesian coordinates  $(x,y)$ .

### Operations

*Kernel::RT*       $d.delta( int\ i )$       returns values, such that  $d == Direction\_2<Kernel>(delta(0),delta(1))$ .  
Precondition: :  $0 \leq i \leq 1$ .

*Kernel::RT*       $d.dx()$       returns  $delta(0)$ .

*Kernel::RT*       $d.dy()$       returns  $delta(1)$ .

There is a total order on directions. We compare the angles between the positive  $x$ -axis and the directions in counterclockwise order.

*bool*       $d.operator==( e )$   
*bool*       $d.operator!=( e )$   
*bool*       $d.operator<( e )$   
*bool*       $d.operator>( e )$   
*bool*       $d.operator<=( e )$   
*bool*       $d.operator>=( e )$

Furthermore, we have

<i>bool</i>	<i>d.counterclockwise_in_between( d1, d2)</i>	returns true, iff <i>d</i> is not equal to <i>d1</i> , and while rotating counterclockwise starting at <i>d1</i> , <i>d</i> is reached strictly before <i>d2</i> is reached. Note that true is returned if <i>d1</i> == <i>d2</i> , unless also <i>d</i> == <i>d1</i> .
-------------	---	---

<i>Direction_2&lt;Kernel&gt;</i>	<i>d.operator-()</i>	The direction opposite to <i>d</i> .
----------------------------------	----------------------	--------------------------------------

### Miscellaneous

<i>Vector_2&lt;Kernel&gt;</i>	<i>d.vector()</i>	returns a vector that has the same direction as <i>d</i> .
-------------------------------	-------------------	--

<i>Direction_2&lt;Kernel&gt;</i>	<i>d.transform( Aff_transformation_2&lt;Kernel&gt; t)</i>	returns the direction obtained by applying <i>t</i> on <i>d</i> .
----------------------------------	---	---

## CGAL::Iso\_rectangle\_2<Kernel>

### Definition

An object  $s$  of the data type *Iso\_rectangle\_2*<Kernel> is a rectangle in the Euclidean plane  $\mathbb{E}^2$  with sides parallel to the  $x$  and  $y$  axis of the coordinate system.

Although they are represented in a canonical form by only two vertices, namely the lower left and the upper right vertex, we provide functions for “accessing” the other vertices as well. The vertices are returned in counterclockwise order.

Iso-oriented rectangles and bounding boxes are quite similar. The difference however is that bounding boxes have always double coordinates, whereas the coordinate type of an iso-oriented rectangle is chosen by the user.

### Creation

*Iso\_rectangle\_2*<Kernel>  $r$ ( *Point\_2*<Kernel>  $p$ , *Point\_2*<Kernel>  $q$ );

introduces an iso-oriented rectangle  $r$  with diagonal opposite vertices  $p$  and  $q$ . Note that the object is brought in the canonical form.

*Iso\_rectangle\_2*<Kernel>  $r$ ( *Point\_2*<Kernel>  $p$ , *Point\_2*<Kernel>  $q$ , *int*);

introduces an iso-oriented rectangle  $r$  with diagonal opposite vertices  $p$  and  $q$ . The *int* argument value is only used to distinguish the two overloaded functions.

*Precondition:*  $p.x() \leq q.x()$  and  $p.y() \leq q.y()$ .

*Iso\_rectangle\_2*<Kernel>  $r$ ( *Point\_2*<Kernel>  $left$ ,  
*Point\_2*<Kernel>  $right$ ,  
*Point\_2*<Kernel>  $bottom$ ,  
*Point\_2*<Kernel>  $top$ )

introduces an iso-oriented rectangle  $r$  whose minimal  $x$  coordinate is the one of  $left$ , the maximal  $x$  coordinate is the one of  $right$ , the minimal  $y$  coordinate is the one of  $bottom$ , the maximal  $y$  coordinate is the one of  $top$ .

*Iso\_rectangle\_2*<Kernel>  $r$ ( *Kernel::RT*  $min\_hx$ ,  
*Kernel::RT*  $min\_hy$ ,  
*Kernel::RT*  $max\_hx$ ,  
*Kernel::RT*  $max\_hy$ ,  
*Kernel::RT*  $hw = RT(1)$ )

introduces an iso-oriented rectangle  $r$  with diagonal opposite vertices  $(min\_hx/hw, min\_hy/hw)$  and  $(max\_hx/hw, max\_hy/hw)$ .

*Precondition:*  $hw \neq 0$ .

## Operations

<i>bool</i>	<i>r.operator==( r2)</i>	Test for equality: two iso-oriented rectangles are equal, iff their lower left and their upper right vertices are equal.
<i>bool</i>	<i>r.operator!=( r2)</i>	Test for inequality.
<i>Point_2&lt;Kernel&gt;</i>	<i>r.vertex( int i)</i>	returns the <i>i</i> 'th vertex modulo 4 of <i>r</i> in counterclockwise order, starting with the lower left vertex.
<i>Point_2&lt;Kernel&gt;</i>	<i>r.operator[]( int i)</i>	returns <i>vertex(i)</i> .
<i>Point_2&lt;Kernel&gt;</i>	<i>r.min()</i>	returns the lower left vertex of <i>r</i> (= <i>vertex(0)</i> ).
<i>Point_2&lt;Kernel&gt;</i>	<i>r.max()</i>	returns the upper right vertex of <i>r</i> (= <i>vertex(2)</i> ).
<i>Kernel::FT</i>	<i>r.xmin()</i>	returns the <i>x</i> coordinate of lower left vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.ymin()</i>	returns the <i>y</i> coordinate of lower left vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.xmax()</i>	returns the <i>x</i> coordinate of upper right vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.ymax()</i>	returns the <i>y</i> coordinate of upper right vertex of <i>r</i> .
<i>Kernel::FT</i>	<i>r.min_coord( int i)</i>	returns the <i>i</i> 'th Cartesian coordinate of the lower left vertex of <i>r</i> . <i>Precondition:</i> $0 \leq i \leq 1$ .
<i>Kernel::FT</i>	<i>r.max_coord( int i)</i>	returns the <i>i</i> 'th Cartesian coordinate of the upper right vertex of <i>r</i> . <i>Precondition:</i> $0 \leq i \leq 1$ .

## Predicates

<i>bool</i>	<i>r.is_degenerate()</i>	<i>r</i> is degenerate, if all vertices are collinear.
<i>Bounded_side</i>	<i>r.bounded_side( Point_2&lt;Kernel&gt; p)</i>	returns either <i>ON_UNBOUNDED_SIDE</i> , <i>ON_BOUNDED_SIDE</i> , or the constant <i>ON_BOUNDARY</i> , depending on where point <i>p</i> is.
<i>bool</i>	<i>r.has_on_boundary( Point_2&lt;Kernel&gt; p)</i>	
<i>bool</i>	<i>r.has_on_bounded_side( Point_2&lt;Kernel&gt; p)</i>	
<i>bool</i>	<i>r.has_on_unbounded_side( Point_2&lt;Kernel&gt; p)</i>	

## Miscellaneous

<i>Kernel::FT</i>	<i>r.area()</i>	returns the area of <i>r</i> .
<i>Bbox</i>	<i>r.bbox()</i>	returns a bounding box containing <i>r</i> .

*Iso\_rectangle\_2*<Kernel>

*r.transform( Aff\_transformation\_2*<Kernel> *t*)

returns the iso-oriented rectangle obtained by applying *t* on the lower left and the upper right corner of *r*.

*Precondition:* The angle at a rotation must be a multiple of  $\pi/2$ , otherwise the resulting rectangle does not have the same side length. Note that rotating about an arbitrary angle can even result in a degenerate iso-oriented rectangle.

## CGAL::Line\_2<Kernel>

### Definition

An object  $l$  of the data type  $Line\_2<Kernel>$  is a directed straight line in the two-dimensional Euclidean plane  $\mathbb{E}^2$ . It is defined by the set of points with Cartesian coordinates  $(x, y)$  that satisfy the equation

$$l : ax + by + c = 0.$$

The line splits  $\mathbb{E}^2$  in a *positive* and a *negative* side. A point  $p$  with Cartesian coordinates  $(px, py)$  is on the positive side of  $l$ , iff  $apx + bpy + c > 0$ , it is on the negative side of  $l$ , iff  $apx + bpy + c < 0$ . The positive side is to the left of  $l$ .

### Creation

$Line\_2<Kernel> \ l( Kernel::RT \ a, Kernel::RT \ b, Kernel::RT \ c);$

introduces a line  $l$  with the line equation in Cartesian coordinates  $ax + by + c = 0$ .

$Line\_2<Kernel> \ l( Point\_2<Kernel> \ p, Point\_2<Kernel> \ q);$

introduces a line  $l$  passing through the points  $p$  and  $q$ . Line  $l$  is directed from  $p$  to  $q$ .

$Line\_2<Kernel> \ l( Point\_2<Kernel> \ p, Direction\_2<Kernel> \ d);$

introduces a line  $l$  passing through point  $p$  with direction  $d$ .

$Line\_2<Kernel> \ l( Point\_2<Kernel> \ p, Vector\_2<Kernel> \ v);$

introduces a line  $l$  passing through point  $p$  and oriented by  $v$ .

$Line\_2<Kernel> \ l( Segment\_2<Kernel> \ s);$

introduces a line  $l$  supporting the segment  $s$ , oriented from source to target.

$Line\_2<Kernel> \ l( Ray\_2<Kernel> \ r);$

introduces a line  $l$  supporting the ray  $r$ , with same orientation.

### Operations

$bool \quad \quad \quad l.operator==( h)$

Test for equality: two lines are equal, iff they have a non empty intersection and the same direction.

<i>bool</i>	<i>l.operator!=( h)</i>	Test for inequality.
<i>Kernel::RT</i>	<i>l.a()</i>	returns the first coefficient of <i>l</i> .
<i>Kernel::RT</i>	<i>l.b()</i>	returns the second coefficient of <i>l</i> .
<i>Kernel::RT</i>	<i>l.c()</i>	returns the third coefficient of <i>l</i> .
<i>Point_2&lt;Kernel&gt;</i>	<i>l.point( int i)</i>	returns an arbitrary point on <i>l</i> . It holds <i>point(i) == point(j)</i> , iff <i>i==j</i> . Furthermore, <i>l</i> is directed from <i>point(i)</i> to <i>point(j)</i> , for all <i>i &lt; j</i> .
<i>Point_2&lt;Kernel&gt;</i>	<i>l.projection( Point_2&lt;Kernel&gt; p)</i>	returns the orthogonal projection of <i>p</i> onto <i>l</i> .
<i>Kernel::FT</i>	<i>l.x_at_y( Kernel::FT y)</i>	returns the <i>x</i> -coordinate of the point at <i>l</i> with given <i>y</i> -coordinate. <i>Precondition: l</i> is not horizontal.
<i>Kernel::FT</i>	<i>l.y_at_x( Kernel::FT x)</i>	returns the <i>y</i> -coordinate of the point at <i>l</i> with given <i>x</i> -coordinate. <i>Precondition: l</i> is not vertical.

## Predicates

<i>bool</i>	<i>l.is_degenerate()</i>	line <i>l</i> is degenerate, if the coefficients <i>a</i> and <i>b</i> of the line equation are zero.
<i>bool</i>	<i>l.is_horizontal()</i>	
<i>bool</i>	<i>l.is_vertical()</i>	
<i>Oriented_side</i>	<i>l.oriented_side( Point_2&lt;Kernel&gt; p)</i>	returns <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_NEGATIVE_SIDE</i> , or the constant <i>ON_POSITIVE_SIDE</i> , depending on the position of <i>p</i> relative to the oriented line <i>l</i> .

For convenience we provide the following Boolean functions:

<i>bool</i>	<i>l.has_on( Point_2&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>l.has_on_positive_side( Point_2&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>l.has_on_negative_side( Point_2&lt;Kernel&gt; p)</i>

## Miscellaneous

<i>Vector_2&lt;Kernel&gt;</i>	<i>l.to_vector()</i>	returns a vector having the direction of <i>l</i> .
<i>Direction_2&lt;Kernel&gt;</i>	<i>l.direction()</i>	returns the direction of <i>l</i> .

<i>Line_2</i> < <i>Kernel</i> >	<i>l.opposite()</i>	returns the line with opposite direction.
<i>Line_2</i> < <i>Kernel</i> >	<i>l.perpendicular( Point_2</i> < <i>Kernel</i> > <i>p</i> )	returns the line perpendicular to <i>l</i> and passing through <i>p</i> , where the direction is the direction of <i>l</i> rotated counterclockwise by 90 degrees.
<i>Line_2</i> < <i>Kernel</i> >	<i>l.transform( Aff_transformation_2</i> < <i>Kernel</i> > <i>t</i> )	returns the line obtained by applying <i>t</i> on a point on <i>l</i> and the direction of <i>l</i> .

### Example

Let us first define two Cartesian two-dimensional points in the Euclidean plane  $\mathbb{E}^2$ . Their dimension and the fact that they are Cartesian is expressed by the suffix *\_2* and the representation type *Cartesian*.

```
Point_2< Cartesian<double> >  p(1.0,1.0), q(4.0,7.0);
```

To define a line *l* we write:

```
Line_2< Cartesian<double> >  l(p,q);
```

Kernel::Line\_2 ..... page [528](#)

## CGAL::Point\_2<Kernel>

### Definition

An object of the class *Point\_2<Kernel>* is a point in the two-dimensional Euclidean plane  $\mathbb{E}^2$ .

Remember that *Kernel::RT* and *Kernel::FT* denote a *RingNumberType* and a *FieldNumberType*, respectively. For the kernel model *Cartesian<T>*, the two types are the same. For the kernel model *Homogeneous<T>*, *Kernel::RT* is equal to *T*, and *Kernel::FT* is equal to *Quotient<T>*.

### Types

*Point\_2<Kernel>:: Cartesian\_const\_iterator*

An iterator for enumerating the Cartesian coordinates of a point.

### Creation

*Point\_2<Kernel> p( Origin ORIGIN);*

introduces a variable *p* with Cartesian coordinates (0,0).

*Point\_2<Kernel> p( int x, int y);* introduces a point *p* initialized to (x,y).

*Point\_2<Kernel> p( double x, double y);*

introduces a point *p* initialized to (x,y) provided *RT* supports construction from *double*.

*Point\_2<Kernel> p( Kernel::RT hx, Kernel::RT hy, Kernel::RT hw = RT(1));*

introduces a point *p* initialized to (hx/hw,hy/hw).

*Precondition:*  $hw \neq \text{Kernel::RT}(0)$

*Point\_2<Kernel> p( Kernel::FT x, Kernel::FT y);*

introduces a point *p* initialized to (x,y).

### Operations

*bool p.operator==( q)*

Test for equality. Two points are equal, iff their *x* and *y* coordinates are equal. The point can be compared with *ORIGIN*.

*bool*                      *p.operator!=( q)*

Test for inequality. The point can be compared with *ORIGIN*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

*Kernel::RT*                      *p.hx()*

returns the homogeneous *x* coordinate.

*Kernel::RT*                      *p.hy()*

returns the homogeneous *y* coordinate.

*Kernel::RT*                      *p.hw()*

returns the homogenizing coordinate.

Note that you do not loose information with the homogeneous representation, because the *FieldNumberType* is a quotient.

*Kernel::FT*                      *p.x()*      returns the Cartesian *x* coordinate, that is *hx/hw*.

*Kernel::FT*                      *p.y()*      returns the Cartesian *y* coordinate, that is *hy/hw*.

The following operations are for convenience and for compatibility with higher dimensional points. Again they come in a Cartesian and in a homogeneous flavor.

*Kernel::RT*                      *p.homogeneous( int i)*

returns the *i*'th homogeneous coordinate of *p*, starting with 0.  
*Precondition:*  $0 \leq i \leq 2$ .

*Kernel::FT*                      *p.cartesian( int i)*

returns the *i*'th Cartesian coordinate of *p*, starting with 0.  
*Precondition:*  $0 \leq i \leq 1$ .

*Kernel::FT*                      *p.operator[]( int i)*

returns *cartesian(i)*.  
*Precondition:*  $0 \leq i \leq 1$ .

*Cartesian\_const\_iterator*    *p.cartesian\_begin()*

returns an iterator to the Cartesian coordinates of *p*, starting with the 0th coordinate.

*Cartesian\_const\_iterator*    *p.cartesian\_end()*

returns an off the end iterator to the Cartesian coordinates of *p*.

<i>int</i>	<i>p.dimension()</i>	returns the dimension (the constant 2).
<i>Bbox_2</i>	<i>p.bbox()</i>	returns a bounding box containing <i>p</i> . Note that bounding boxes are not parameterized with whatsoever.
<i>Point_2&lt;Kernel&gt;</i>	<i>p.transform( Aff_transformation_2&lt;Kernel&gt; t)</i>	returns the point obtained by applying <i>t</i> on <i>p</i> .

## Operators

The following operations can be applied on points:

<i>bool</i>	<i>operator&lt;( p, q)</i>	returns true iff <i>p</i> is lexicographically smaller than <i>q</i> , i.e. either if <i>p.x()</i> < <i>q.x()</i> or if <i>p.x()</i> == <i>q.x()</i> and <i>p.y()</i> < <i>q.y()</i> .
<i>bool</i>	<i>operator&gt;( p, q)</i>	returns true iff <i>p</i> is lexicographically greater than <i>q</i> .
<i>bool</i>	<i>operator&lt;=( p, q)</i>	returns true iff <i>p</i> is lexicographically smaller or equal to <i>q</i> .
<i>bool</i>	<i>operator&gt;=( p, q)</i>	returns true iff <i>p</i> is lexicographically greater or equal to <i>q</i> .
<i>Vector_2&lt;Kernel&gt;</i>	<i>operator-( p, q)</i>	returns the difference vector between <i>q</i> and <i>p</i> . You can substitute <i>ORIGIN</i> for either <i>p</i> or <i>q</i> , but not for both.
<i>Point_2&lt;Kernel&gt;</i>	<i>operator+( p, Vector_2&lt;Kernel&gt; v)</i>	returns the point obtained by translating <i>p</i> by the vector <i>v</i> .
<i>Point_2&lt;Kernel&gt;</i>	<i>operator-( p, Vector_2&lt;Kernel&gt; v)</i>	returns the point obtained by translating <i>p</i> by the vector <i>-v</i> .

## Example

The following declaration creates two points with Cartesian double coordinates.

```
Point_2< Cartesian<double> > p, q(1.0, 2.0);
```

The variable `p` is uninitialized and should first be used on the left hand side of an assignment.

```
p = q;  
  
std::cout << p.x() << " " << p.y() << std::endl;
```

## CGAL::Ray\_2<Kernel>

### Definition

An object  $r$  of the data type  $\text{Ray}_2<\text{Kernel}>$  is a directed straight ray in the two-dimensional Euclidean plane  $\mathbb{E}^2$ . It starts in a point called the *source* of  $r$  and goes to infinity.

### Creation

$\text{Ray}_2<\text{Kernel}> \ r( \text{Point}_2<\text{Kernel}> \ p, \text{Point}_2<\text{Kernel}> \ q);$

introduces a ray  $r$  with source  $p$  and passing through point  $q$ .

$\text{Ray}_2<\text{Kernel}> \ r( \text{Point}_2<\text{Kernel}> \ p, \text{Direction}_2<\text{Kernel}> \ d);$

introduces a ray  $r$  starting at source  $p$  with direction  $d$ .

$\text{Ray}_2<\text{Kernel}> \ r( \text{Point}_2<\text{Kernel}> \ p, \text{Vector}_2<\text{Kernel}> \ v);$

introduces a ray  $r$  starting at source  $p$  with the direction of  $v$ .

$\text{Ray}_2<\text{Kernel}> \ r( \text{Point}_2<\text{Kernel}> \ p, \text{Line}_2<\text{Kernel}> \ l);$

introduces a ray  $r$  starting at source  $p$  with the same direction as  $l$ .

### Operations

<i>bool</i>	$r.operator==( h)$	Test for equality: two rays are equal, iff they have the same source and the same direction.
<i>bool</i>	$r.operator!=( h)$	Test for inequality.
$\text{Point}_2<\text{Kernel}>$	$r.source()$	returns the source of $r$ .
$\text{Point}_2<\text{Kernel}>$	$r.point( \text{int } i)$	returns a point on $r$ . $point(0)$ is the source, $point(i)$ , with $i > 0$ , is different from the source. <i>Precondition:</i> $i \geq 0$ .
$\text{Direction}_2<\text{Kernel}>$	$r.direction()$	returns the direction of $r$ .
$\text{Vector}_2<\text{Kernel}>$	$r.to\_vector()$	returns a vector giving the direction of $r$ .

<i>Line_2&lt;Kernel&gt;</i>	<i>r.supporting_line()</i>	returns the line supporting <i>r</i> which has the same direction.
<i>Ray_2&lt;Kernel&gt;</i>	<i>r.opposite()</i>	returns the ray with the same source and the opposite direction.

## Predicates

<i>bool</i>	<i>r.is_degenerate()</i>	ray <i>r</i> is degenerate, if the source and the second defining point fall together (that is if the direction is degenerate).
<i>bool</i> <i>bool</i>	<i>r.is_horizontal()</i> <i>r.is_vertical()</i>	
<i>bool</i>	<i>r.has_on( Point_2&lt;Kernel&gt; p)</i>	A point is on <i>r</i> , iff it is equal to the source of <i>r</i> , or if it is in the interior of <i>r</i> .
<i>bool</i>	<i>r.collinear_has_on( Point_2&lt;Kernel&gt; p)</i>	checks if point <i>p</i> is on <i>r</i> . This function is faster than function <i>has_on()</i> if the precondition checking is disabled. <i>Precondition:</i> <i>p</i> is on the supporting line of <i>r</i> .

## Miscellaneous

<i>Ray_2&lt;Kernel&gt;</i>	<i>r.transform( Aff_transformation_2&lt;Kernel&gt; t)</i>	returns the ray obtained by applying <i>t</i> on the source and on the direction of <i>r</i> .
----------------------------	---	--

## See Also

Kernel::Ray\_2 ..... page [537](#)

## CGAL::Segment\_2<Kernel>

### Definition

An object  $s$  of the data type  $\text{Segment\_2}<\text{Kernel}>$  is a directed straight line segment in the two-dimensional Euclidean plane  $\mathbb{E}^2$ , i.e. a straight line segment  $[p, q]$  connecting two points  $p, q \in \mathbb{R}^2$ . The segment is topologically closed, i.e. the end points belong to it. Point  $p$  is called the *source* and  $q$  is called the *target* of  $s$ . The length of  $s$  is the Euclidean distance between  $p$  and  $q$ . Note that there is only a function to compute the square of the length, because otherwise we had to perform a square root operation which is not defined for all number types, which is expensive, and may not be exact.

### Creation

$\text{Segment\_2}<\text{Kernel}> \ s(\text{Point\_2}<\text{Kernel}> \ p, \text{Point\_2}<\text{Kernel}> \ q);$

introduces a segment  $s$  with source  $p$  and target  $q$ . The segment is directed from the source towards the target.

### Operations

$\text{bool}$	$s.\text{operator}==(q)$	Test for equality: Two segments are equal, iff their sources and targets are equal.
$\text{bool}$	$s.\text{operator}!=(q)$	Test for inequality.
$\text{Point\_2}<\text{Kernel}>$	$s.\text{source}()$	returns the source of $s$ .
$\text{Point\_2}<\text{Kernel}>$	$s.\text{target}()$	returns the target of $s$ .
$\text{Point\_2}<\text{Kernel}>$	$s.\text{min}()$	returns the point of $s$ with lexicographically smallest coordinate.
$\text{Point\_2}<\text{Kernel}>$	$s.\text{max}()$	returns the point of $s$ with lexicographically largest coordinate.
$\text{Point\_2}<\text{Kernel}>$	$s.\text{vertex}(\text{int } i)$	returns source or target of $s$ : $\text{vertex}(0)$ returns the source of $s$ , $\text{vertex}(1)$ returns the target of $s$ . The parameter $i$ is taken modulo 2, which gives easy access to the other vertex.
$\text{Point\_2}<\text{Kernel}>$	$s.\text{point}(\text{int } i)$	returns $\text{vertex}(i)$ .
$\text{Point\_2}<\text{Kernel}>$	$s.\text{operator}[](\text{int } i)$	returns $\text{vertex}(i)$ .
$\text{Kernel}::\text{FT}$	$s.\text{squared\_length}()$	returns the squared length of $s$ .
$\text{Direction\_2}<\text{Kernel}>$	$s.\text{direction}()$	returns the direction from source to target of $s$ .

<i>Vector_2&lt;Kernel&gt;</i>	<i>s.to_vector()</i>	returns the vector <i>s.target()</i> - <i>s.source()</i> .
<i>Segment_2&lt;Kernel&gt;</i>	<i>s.opposite()</i>	returns a segment with source and target point interchanged.
<i>Line_2&lt;Kernel&gt;</i>	<i>s.supporting_line()</i>	returns the line <i>l</i> passing through <i>s</i> . Line <i>l</i> has the same orientation as segment <i>s</i> .

## Predicates

<i>bool</i>	<i>s.is_degenerate()</i>	segment <i>s</i> is degenerate, if source and target are equal.
<i>bool</i>	<i>s.is_horizontal()</i>	
<i>bool</i>	<i>s.is_vertical()</i>	
<i>bool</i>	<i>s.has_on( Point_2&lt;Kernel&gt; p)</i>	A point is on <i>s</i> , iff it is equal to the source or target of <i>s</i> , or if it is in the interior of <i>s</i> .
<i>bool</i>	<i>s.collinear_has_on( Point_2&lt;Kernel&gt; p)</i>	checks if point <i>p</i> is on segment <i>s</i> . This function is faster than function <i>has_on()</i> . <i>Precondition:</i> <i>p</i> is on the supporting line of <i>s</i> .

## Miscellaneous

<i>Bbox_2</i>	<i>s.bbox()</i>	returns a bounding box containing <i>s</i> .
<i>Segment_2&lt;Kernel&gt;</i>	<i>s.transform( Aff_transformation_2&lt;Kernel&gt; t)</i>	returns the segment obtained by applying <i>t</i> on the source and the target of <i>s</i> .

## See Also

Kernel::Segment\_2.....page [539](#)

## CGAL::Triangle\_2<Kernel>

### Definition

An object  $t$  of the class *Triangle\_2<Kernel>* is a triangle in the two-dimensional Euclidean plane  $\mathbb{E}^2$ . Triangle  $t$  is oriented, i.e., its boundary has clockwise or counterclockwise orientation. We call the side to the left of the boundary the positive side and the side to the right of the boundary the negative side.

The boundary of a triangle splits the plane in two open regions, a bounded one and an unbounded one.

### Creation

*Triangle\_2<Kernel>*  $t$ ( *Point\_2<Kernel>*  $p$ , *Point\_2<Kernel>*  $q$ , *Point\_2<Kernel>*  $r$ );

introduces a triangle  $t$  with vertices  $p$ ,  $q$  and  $r$ .

### Operations

*bool*  $t.operator==(t2)$  Test for equality: two triangles are equal, iff there exists a cyclic permutation of the vertices of  $t2$ , such that they are equal to the vertices of  $t$ .

*bool*  $t.operator!=(t2)$  Test for inequality.

*Point\_2<Kernel>*  $t.vertex(int\ i)$  returns the  $i$ 'th vertex modulo 3 of  $t$ .

*Point\_2<Kernel>*  $t.operator[](int\ i)$  returns  $vertex(i)$ .

### Predicates

*bool*  $t.is_degenerate()$  triangle  $t$  is degenerate, if the vertices are collinear.

*Orientation*  $t.orientation()$  returns the orientation of  $t$ .

*Oriented\_side*  $t.oriented\_side(Point\_2<Kernel>\ p)$

returns *ON\_ORIENTED\_BOUNDARY*, or *POSITIVE\_SIDE*, or the constant *ON\_NEGATIVE\_SIDE*, determined by the position of point  $p$ .  
*Precondition:*  $t$  is not degenerate.

*Bounded\_side*  $t.bounded\_side(Point\_2<Kernel>\ p)$

returns the constant *ON\_BOUNDARY*, *ON\_BOUNDED\_SIDE*, or else *ON\_UNBOUNDED\_SIDE*, depending on where point  $p$  is.  
*Precondition:*  $t$  is not degenerate.

For convenience we provide the following Boolean functions:

<i>bool</i>	<i>t.has_on_positive_side( Point_2&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>t.has_on_negative_side( Point_2&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>t.has_on_boundary( Point_2&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>t.has_on_bounded_side( Point_2&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>t.has_on_unbounded_side( Point_2&lt;Kernel&gt; p)</i>

*Precondition: t is not degenerate.*

## Miscellaneous

<i>Triangle_2&lt;Kernel&gt;</i>	<i>t.opposite()</i>	returns a triangle where the boundary is oriented the other way round (this flips the positive and the negative side, but not the bounded and unbounded side).
<i>Kernel::FT</i>	<i>t.area()</i>	returns the signed area of <i>t</i> .
<i>Bbox_2</i>	<i>t.bbox()</i>	returns a bounding box containing <i>t</i> .
<i>Triangle_2&lt;Kernel&gt;</i>	<i>t.transform( Aff_transformation_2&lt;Kernel&gt; at)</i>	returns the triangle obtained by applying <i>at</i> on the three vertices of <i>t</i> .

## CGAL::Vector\_2<Kernel>

### Definition

An object of the class *Vector\_2<Kernel>* is a vector in the two-dimensional vector space  $\mathbb{R}^2$ . Geometrically spoken, a vector is the difference of two points  $p_2$ ,  $p_1$  and denotes the direction and the distance from  $p_1$  to  $p_2$ .

CGAL defines a symbolic constant *NULL\_VECTOR*. We will explicitly state where you can pass this constant as an argument instead of a vector initialized with zeros.

### Types

*Vector\_2<Kernel>::Cartesian\_const\_iterator*

An iterator for enumerating the Cartesian coordinates of a vector.

### Creation

*Vector\_2<Kernel> v( Point\_2<Kernel> a, Point\_2<Kernel> b);*

introduces the vector  $b - a$ .

*Vector\_2<Kernel> v( Segment\_2<Kernel> s);*

introduces the vector  $s.target() - s.source()$ .

*Vector\_2<Kernel> v( Ray\_2<Kernel> r);*

introduces the vector having the same direction as  $r$ .

*Vector\_2<Kernel> v( Line\_2<Kernel> l);*

introduces the vector having the same direction as  $l$ .

*Vector\_2<Kernel> v( Null\_vector NULL\_VECTOR);*

introduces a null vector  $v$ .

*Vector\_2<Kernel> v( int x, int y);* introduces a vector  $v$  initialized to  $(x, y)$ .

*Vector\_2<Kernel> v( double x, double y);*

introduces a vector  $v$  initialized to  $(x, y)$ .

*Vector\_2<Kernel> v( Kernel::RT hx, Kernel::RT hy, Kernel::RT hw = RT(1));*

introduces a vector  $v$  initialized to  $(hx/hw, hy/hw)$ .

*Precondition:*  $hw \neq 0$

*Vector\_2<Kernel> v( Kernel::FT x, Kernel::FT y);*

introduces a vector  $v$  initialized to  $(x, y)$ .

## Operations

*bool v.operator==( w)*

Test for equality: two vectors are equal, iff their  $x$  and  $y$  coordinates are equal. You can compare a vector with the *NULL\_VECTOR*.

*bool v.operator!=( w)*

Test for inequality. You can compare a vector with the *NULL\_VECTOR*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

*Kernel::RT v.hx()*

returns the homogeneous  $x$  coordinate.

*Kernel::RT v.hy()*

returns the homogeneous  $y$  coordinate.

*Kernel::RT v.hw()*

returns the homogenizing coordinate.

Note that you do not lose information with the homogeneous representation, because the *FieldNumberType* is a quotient.

*Kernel::FT v.x()* returns the  $x$ -coordinate of  $v$ , that is  $hx/hw$ .

*Kernel::FT v.y()* returns the  $y$ -coordinate of  $v$ , that is  $hy/hw$ .

The following operations are for convenience and for compatibility with higher dimensional vectors. Again they come in a Cartesian and homogeneous flavor.

*Kernel::RT v.homogeneous( int i)*

returns the  $i$ 'th homogeneous coordinate of  $v$ , starting with 0.

*Precondition:*  $0 \leq i \leq 2$ .

*Kernel::FT v.cartesian( int i)*

returns the  $i$ 'th Cartesian coordinate of  $v$ , starting at 0.

*Precondition:*  $0 \leq i \leq 1$ .

<i>Kernel::FT</i>	<i>v.operator[]( int i)</i>  returns <i>cartesian(i)</i> . Precondition: $0 \leq i \leq 1$ .
<i>Cartesian_const_iterator</i>	<i>v.cartesian_begin()</i>  returns an iterator to the Cartesian coordinates of <i>v</i> , starting with the 0th coordinate.
<i>Cartesian_const_iterator</i>	<i>v.cartesian_end()</i>  returns an off the end iterator to the Cartesian coordinates of <i>v</i> .
<i>int</i>	<i>v.dimension()</i>  returns the dimension (the constant 2).
<i>Direction_2&lt;Kernel&gt;</i>	<i>v.direction()</i>  returns the direction which passes through <i>v</i> .
<i>Vector_2&lt;Kernel&gt;</i>	<i>v.transform( Aff_transformation_2&lt;Kernel&gt; t)</i>  returns the vector obtained by applying <i>t</i> on <i>v</i> .
<i>Vector_2&lt;Kernel&gt;</i>	<i>v.perpendicular( Orientation o)</i>  returns the vector perpendicular to <i>v</i> in clockwise or counterclockwise orientation.

## Operators

The following operations can be applied to vectors:

<i>Vector_2&lt;Kernel&gt;</i>	<i>v.operator+( w)</i>  Addition.
<i>Vector_2&lt;Kernel&gt;</i>	<i>v.operator-( w)</i>  Subtraction.
<i>Vector_2&lt;Kernel&gt;</i>	<i>v.operator-()</i>  returns the opposite vector.

<i>Kernel::FT</i>	<i>v.operator*( w)</i>	returns the scalar product (= inner product) of the two vectors.
-------------------	------------------------	--

<i>Vector_2&lt;Kernel&gt;</i>	<i>operator*( v, Kernel::RT s)</i>	Multiplication with a scalar from the right.
-------------------------------	------------------------------------	--

<i>Vector_2&lt;Kernel&gt;</i>	<i>operator*( v, Kernel::FT s)</i>	Multiplication with a scalar from the right.
-------------------------------	------------------------------------	--

<i>Vector_2&lt;Kernel&gt;</i>	<i>operator*( Kernel::RT s, v)</i>	Multiplication with a scalar from the left.
-------------------------------	------------------------------------	---

<i>Vector_2&lt;Kernel&gt;</i>	<i>operator*( Kernel::FT s, v)</i>	Multiplication with a scalar from the left.
-------------------------------	------------------------------------	---

<i>Vector_2&lt;Kernel&gt;</i>	<i>v.operator/( Kernel::RT s)</i>	Division by a scalar.
-------------------------------	-----------------------------------	-----------------------

<i>Kernel::FT</i>	<i>v.squared_length()</i>	returns the squared length of <i>v</i> .
-------------------	---------------------------	--

## 7.9.2 Three-dimensional Objects

### CGAL::Bbox\_3

```
#include <CGAL/Bbox_3.h>
```

#### Definition

An object  $b$  of the class *Bbox\_3* is a bounding box in the three-dimensional Euclidean space  $\mathbb{E}^3$ .

#### Creation

```
Bbox_3 b( double x_min, double y_min, double z_min, double x_max, double y_max, double z_max);
```

introduces a bounding box  $b$  with lexicographically smallest corner point at  $(x_{min}, y_{min}, z_{min})$  lexicographically largest corner point at  $(x_{max}, y_{max}, z_{max})$ .

#### Operations

<i>bool</i>	<i>b.operator==( c)</i>	Test for equality.
<i>bool</i>	<i>b.operator!=( q)</i>	Test for inequality.
<i>int</i>	<i>b.dimension()</i>	Returns 3.
<i>double</i>	<i>b.xmin()</i>	
<i>double</i>	<i>b.ymin()</i>	
<i>double</i>	<i>b.zmin()</i>	
<i>double</i>	<i>b.xmax()</i>	
<i>double</i>	<i>b.ymax()</i>	
<i>double</i>	<i>b.zmax()</i>	
<i>double</i>	<i>b.min( int i)</i>	Returns <i>xmin()</i> if $i==0$ or <i>ymin()</i> if $i==1$ or <i>zmin()</i> if $i==2$ . <i>Precondition:</i> $i_i=0$ and $i_i=2$
<i>double</i>	<i>b.max( int i)</i>	Returns <i>xmax()</i> if $i==0$ or <i>ymax()</i> if $i==1$ or <i>zmax()</i> if $i==2$ . <i>Precondition:</i> $i_i=0$ and $i_i=2$
<i>Bbox_3</i>	<i>b.operator+( c)</i>	returns a bounding box of $b$ and $c$ .

## CGAL::Aff\_transformation\_3<Kernel>

### Definition

The class *Aff\_transformation\_3<Kernel>* represents three-dimensional affine transformations. The general form of an affine transformation is based on a homogeneous representation of points. Thereby all transformations can be realized by matrix multiplication.

Multiplying the transformation matrix by a scalar does not change the represented transformation. Therefore, any transformation represented by a matrix with rational entries can be represented by a transformation matrix with integer entries as well. (Multiply the matrix with the common denominator of the rational entries.) Hence, it is sufficient to use the number type *Kernel::RT* to represent the entries of the transformation matrix.

CGAL offers several specialized affine transformations. Different constructors are provided to create them. They are parameterized with a symbolic name to denote the transformation type, followed by additional parameters. The symbolic name tags solve ambiguities in the function overloading and they make the code more readable, i.e., what type of transformation is created.

In three-dimensional space we have a  $4 \times 4$  matrix  $(m_{ij})_{i,j=0\dots 3}$ . Entries  $m_{30}$ ,  $m_{31}$ , and  $m_{32}$  are always zero and therefore do not appear in the constructors.

### Creation

```
Aff_transformation_3<Kernel> t( Identity_transformation);
```

introduces an identity transformation.

```
Aff_transformation_3<Kernel> t( const Translation, Vector_3<Kernel> v);
```

introduces a translation by a vector  $v$ .

```
Aff_transformation_3<Kernel> t( const Scaling, Kernel::RT s, Kernel::RT hw = RT(1));
```

introduces a scaling by a scale factor  $s/hw$ .

```
Aff_transformation_3<Kernel> t( Kernel::RT m00,
                               Kernel::RT m01,
                               Kernel::RT m02,
                               Kernel::RT m03,
                               Kernel::RT m10,
                               Kernel::RT m11,
                               Kernel::RT m12,
                               Kernel::RT m13,
                               Kernel::RT m20,
                               Kernel::RT m21,
                               Kernel::RT m22,
                               Kernel::RT m23,
```

$$\text{Kernel}::RT\ hw = RT(1)$$

introduces a general affine transformation of the matrix form  $\begin{pmatrix} m_{00} & m_{01} & m_{02} & m_{03} \\ m_{10} & m_{11} & m_{12} & m_{13} \\ m_{20} & m_{21} & m_{22} & m_{23} \\ 0 & 0 & 0 & hw \end{pmatrix}$ . The part  $\frac{1}{hw}$   $\begin{pmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ m_{20} & m_{21} & m_{22} \end{pmatrix}$  defines the scaling and rotational part of the transformation, while the vector  $\frac{1}{hw} \begin{pmatrix} m_{03} \\ m_{13} \\ m_{23} \end{pmatrix}$  contains the translational part.

```
Aff_transformation_3<Kernel> t( Kernel::RT m00,
                                Kernel::RT m01,
                                Kernel::RT m02,
                                Kernel::RT m10,
                                Kernel::RT m11,
                                Kernel::RT m12,
                                Kernel::RT m20,
                                Kernel::RT m21,
                                Kernel::RT m22,
                                Kernel::RT hw = RT(1))
```

introduces a general linear transformation of the matrix form  $\begin{pmatrix} m_{00} & m_{01} & m_{02} & 0 \\ m_{10} & m_{11} & m_{12} & 0 \\ m_{20} & m_{21} & m_{22} & 0 \\ 0 & 0 & 0 & hw \end{pmatrix}$ , i.e. an affine transformation without translational part.

## Operations

Each class *Class\_3*<Kernel> representing a geometric object in 3D has a member function:

```
Class_3<Kernel> transform(Aff_transformation_3<Kernel> t).
```

The transformation classes provide a member function *transform*() for points, vectors, directions, and planes:

```
Point_3<Kernel>      t.transform( Point_3<Kernel> p)
Vector_3<Kernel>    t.transform( Vector_3<Kernel> p)
Direction_3<Kernel> t.transform( Direction_3<Kernel> p)
Plane_3<Kernel>     t.transform( Plane_3<Kernel> p)
```

CGAL provides four function operators for these member functions:

```
Point_3<Kernel>      t.operator()( Point_3<Kernel> p)
Vector_3<Kernel>    t.operator()( Vector_3<Kernel> p)
Direction_3<Kernel> t.operator()( Direction_3<Kernel> p)
Plane_3<Kernel>     t.operator()( Plane_3<Kernel> p)
```

*Aff\_transformation\_3<Kernel>*

*t.operator\*( s)* composes two affine transformations.

*Aff\_transformation\_3<Kernel>*

*t.inverse()* gives the inverse transformation.

*bool* *t.is\_even()* returns *true*, if the transformation is not reflecting, i.e. the determinant of the involved linear transformation is non-negative.

*bool* *t.is\_odd()* returns *true*, if the transformation is reflecting.

The matrix entries of a matrix representation of a *Aff\_transformation\_3<Kernel>* can be accessed through the following member functions:

*Kernel::FT* *t.cartesian( int i, int j)*  
*Kernel::FT* *t.m( int i, int j)* returns entry  $m_{ij}$  in a matrix representation in which  $m_{33}$  is 1.

*Kernel::RT* *t.homogeneous( int i, int j)*  
*Kernel::RT* *t.hm( int i, int j)* returns entry  $m_{ij}$  in some fixed matrix representation.

For affine transformations no I/O operators are defined.

## CGAL::Direction\_3<Kernel>

### Definition

An object of the class *Direction\_3<Kernel>* is a vector in the three-dimensional vector space  $\mathbb{R}^3$  where we forget about their length. They can be viewed as unit vectors, although there is no normalization internally, since this is error prone. Directions are used whenever the length of a vector does not matter. They also characterize a set of parallel lines that have the same orientation or the direction normal to parallel planes that have the same orientation. For example, you can ask for the direction orthogonal to an oriented plane, or the direction of an oriented line.

### Creation

<i>Direction_3&lt;Kernel&gt;</i> <i>d</i> ( <i>Vector_3&lt;Kernel&gt;</i> <i>v</i> );	introduces a direction <i>d</i> initialized with the direction of vector <i>v</i> .
<i>Direction_3&lt;Kernel&gt;</i> <i>d</i> ( <i>Line_3&lt;Kernel&gt;</i> <i>l</i> );	introduces the direction <i>d</i> of line <i>l</i> .
<i>Direction_3&lt;Kernel&gt;</i> <i>d</i> ( <i>Ray_3&lt;Kernel&gt;</i> <i>r</i> );	introduces the direction <i>d</i> of ray <i>r</i> .
<i>Direction_3&lt;Kernel&gt;</i> <i>d</i> ( <i>Segment_3&lt;Kernel&gt;</i> <i>s</i> );	introduces the direction <i>d</i> of segment <i>s</i> .
<i>Direction_3&lt;Kernel&gt;</i> <i>d</i> ( <i>Kernel::RT</i> <i>x</i> , <i>Kernel::RT</i> <i>y</i> , <i>Kernel::RT</i> <i>z</i> );	introduces a direction <i>d</i> initialized with the direction from the origin to the point with Cartesian coordinates ( <i>x</i> , <i>y</i> , <i>z</i> ).

### Operations

<i>Kernel::RT</i>	<i>d</i> .delta( int <i>i</i> )	returns values, such that <i>d</i> == <i>Direction_3&lt;Kernel&gt;</i> (delta(0),delta(1),delta(2)). Precondition: : 0 ≤ <i>i</i> ≤ 2.
<i>Kernel::RT</i>	<i>d</i> .dx()	returns delta(0).
<i>Kernel::RT</i>	<i>d</i> .dy()	returns delta(1).
<i>Kernel::RT</i>	<i>d</i> .dz()	returns delta(2).
bool	<i>d</i> .operator==( <i>e</i> )	Test for equality.
bool	<i>d</i> .operator!=( <i>e</i> )	Test for inequality.
<i>Direction_3&lt;Kernel&gt;</i>	<i>d</i> .operator-()	The direction opposite to <i>d</i> .
<i>Vector_3&lt;Kernel&gt;</i>	<i>d</i> .vector()	returns a vector that has the same direction as <i>d</i> .
<i>Direction_3&lt;Kernel&gt;</i>	<i>d</i> .transform( <i>Aff_transformation_3&lt;Kernel&gt;</i> <i>t</i> )	returns the direction obtained by applying <i>t</i> on <i>d</i> .

## See Also

## CGAL::Iso\_cuboid\_3<Kernel>

### Definition

An object  $s$  of the data type *Iso\_cuboid\_3<Kernel>* is a cuboid in the Euclidean space  $\mathbb{E}^3$  with edges parallel to the  $x$ ,  $y$  and  $z$  axis of the coordinate system.

Although they are represented in a canonical form by only two vertices, namely the lexicographically smallest and largest vertex with respect to Cartesian  $xyz$  coordinates, we provide functions for “accessing” the other vertices as well.

Iso-oriented cuboids and bounding boxes are quite similar. The difference however is that bounding boxes have always double coordinates, whereas the coordinate type of an iso-oriented cuboid is chosen by the user.

### Creation

*Iso\_cuboid\_3<Kernel>*  $c$ ( *Point\_3<Kernel>*  $p$ , *Point\_3<Kernel>*  $q$ );

introduces an iso-oriented cuboid  $c$  with diagonal opposite vertices  $p$  and  $q$ . Note that the object is brought in the canonical form.

*Iso\_cuboid\_3<Kernel>*  $c$ ( *Point\_3<Kernel>*  $p$ , *Point\_3<Kernel>*  $q$ , *int*);

introduces an iso-oriented cuboid  $c$  with diagonal opposite vertices  $p$  and  $q$ . The *int* argument value is only used to distinguish the two overloaded functions.

*Precondition:*  $p.x() \leq q.x()$ ,  $p.y() \leq q.y()$  and  $p.z() \leq q.z()$ .

*Iso\_cuboid\_3<Kernel>*  $c$ ( *Point\_3<Kernel>*  $left$ ,  
*Point\_3<Kernel>*  $right$ ,  
*Point\_3<Kernel>*  $bottom$ ,  
*Point\_3<Kernel>*  $top$ ,  
*Point\_3<Kernel>*  $far$ ,  
*Point\_3<Kernel>*  $close$ )

introduces an iso-oriented cuboid  $c$  whose minimal  $x$  coordinate is the one of *left*, the maximal  $x$  coordinate is the one of *right*, the minimal  $y$  coordinate is the one of *bottom*, the maximal  $y$  coordinate is the one of *top*, the minimal  $z$  coordinate is the one of *far*, the maximal  $z$  coordinate is the one of *close*.

*Iso\_cuboid\_3<Kernel>*  $c$ ( *Kernel::RT*  $min\_hx$ ,  
*Kernel::RT*  $min\_hy$ ,  
*Kernel::RT*  $min\_hz$ ,  
*Kernel::RT*  $max\_hx$ ,  
*Kernel::RT*  $max\_hy$ ,  
*Kernel::RT*  $max\_hz$ ,

*Kernel::RT*  $hw = RT(1)$ )

introduces an iso-oriented cuboid  $c$  with diagonal opposite vertices  $(min\_hx/hw, min\_hy/hw, min\_hz/hw)$  and  $(max\_hx/hw, max\_hy/hw, max\_hz/hw)$ .

*Precondition:*  $hw \neq 0$ .

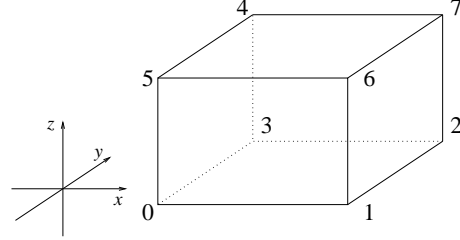

## Operations

*bool*  $c.operator==(c2)$  Test for equality: two iso-oriented cuboid are equal, iff their lower left and their upper right vertices are equal.

*bool*  $c.operator!=(c2)$  Test for inequality.

*Point\_3<Kernel>*  $c.vertex(int i)$  returns the  $i$ 'th vertex modulo 8 of  $c$ . starting with the lower left vertex.

*Point\_3<Kernel>*  $c.operator[] (int i)$  returns  $vertex(i)$ , as indicated in the figure below:

*Point\_3<Kernel>*  $c.min()$  returns the smallest vertex of  $c$  ( $= vertex(0)$ ).

*Point\_3<Kernel>*  $c.max()$  returns the largest vertex of  $c$  ( $= vertex(7)$ ).

*Kernel::FT*  $c.xmin()$  returns smallest Cartesian  $x$ -coordinate in  $c$ .

*Kernel::FT*  $c.ymin()$  returns smallest Cartesian  $y$ -coordinate in  $c$ .

*Kernel::FT*  $c.zmin()$  returns smallest Cartesian  $z$ -coordinate in  $c$ .

*Kernel::FT*  $c.xmax()$  returns largest Cartesian  $x$ -coordinate in  $c$ .

*Kernel::FT*  $c.ymax()$  returns largest Cartesian  $y$ -coordinate in  $c$ .

*Kernel::FT*  $c.zmax()$  returns largest Cartesian  $z$ -coordinate in  $c$ .

*Kernel::FT*  $c.min\_coord(int i)$  returns  $i$ -th Cartesian coordinate of the smallest vertex of  $c$ .

*Precondition:*  $0 \leq i \leq 2$ .

*Kernel::FT*  $c.max\_coord(int i)$  returns  $i$ -th Cartesian coordinate of the largest vertex of  $c$ .

*Precondition:*  $0 \leq i \leq 2$ .

## Predicates

*bool*  $c.is\_degenerate()$   $c$  is degenerate, if all vertices are coplanar.

<i>Bounded_side</i>	<i>c.bounded_side( Point_3&lt;Kernel&gt; p)</i>	returns either <i>ON_UNBOUNDED_SIDE</i> , <i>ON_BOUNDED_SIDE</i> , or the constant <i>ON_BOUNDARY</i> , depending on where point <i>p</i> is.
---------------------	---	---

<i>bool</i>	<i>c.has_on_boundary( Point_3&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>c.has_on_bounded_side( Point_3&lt;Kernel&gt; p)</i>
<i>bool</i>	<i>c.has_on_unbounded_side( Point_3&lt;Kernel&gt; p)</i>

## Miscellaneous

<i>Kernel::FT</i>	<i>c.volume()</i>	returns the volume of <i>c</i> .
<i>Bbox_3</i>	<i>c.bbox()</i>	returns a bounding box containing <i>c</i> .
<i>Iso_cuboid_3&lt;Kernel&gt;</i>	<i>c.transform( Aff_transformation_3&lt;Kernel&gt; t)</i>	<p>returns the iso-oriented cuboid obtained by applying <i>t</i> on the smallest and the largest of <i>c</i>.</p> <p><i>Precondition:</i> The angle at a rotation must be a multiple of <math>\pi/2</math>, otherwise the resulting cuboid does not have the same size. Note that rotating about an arbitrary angle can even result in a degenerate iso-oriented cuboid.</p>

*Kernel::IsoCuboid\_3* ..... page [526](#)

## CGAL::Line\_3<Kernel>

### Definition

An object  $l$  of the data type  $Line\_3<Kernel>$  is a directed straight line in the three-dimensional Euclidean space  $\mathbb{E}^3$ .

### Creation

$Line\_3<Kernel> \ l( Point\_3<Kernel> \ p, Point\_3<Kernel> \ q);$

introduces a line  $l$  passing through the points  $p$  and  $q$ .  
Line  $l$  is directed from  $p$  to  $q$ .

$Line\_3<Kernel> \ l( Point\_3<Kernel> \ p, Direction\_3<Kernel> \ d);$

introduces a line  $l$  passing through point  $p$  with direction  $d$ .

$Line\_3<Kernel> \ l( Point\_3<Kernel> \ p, Vector\_3<Kernel> \ v);$

introduces a line  $l$  passing through point  $p$  and oriented by  $v$ .

$Line\_3<Kernel> \ l( Segment\_3<Kernel> \ s);$

returns the line supporting the segment  $s$ , oriented from source to target.

$Line\_3<Kernel> \ l( Ray\_3<Kernel> \ r);$

returns the line supporting the ray  $r$ , with the same orientation.

### Operations

$bool \quad \quad \quad l.operator==( h )$

Test for equality: two lines are equal, iff they have a non empty intersection and the same direction.

$bool \quad \quad \quad l.operator!=( h )$

Test for inequality.

$Point\_3<Kernel> \quad \quad l.projection( Point\_3<Kernel> \ p )$

returns the orthogonal projection of  $p$  on  $l$ .

$Point\_3<Kernel> \quad \quad l.point( int \ i )$

returns an arbitrary point on  $l$ . It holds  $point(i) = point(j)$ , iff  $i=j$ .

## Predicates

<i>bool</i>	<i>lis_degenerate()</i>	returns <i>true</i> iff line <i>l</i> is degenerated to a point.
-------------	-------------------------	--

*bool* *l.has\_on( Point\_3<Kernel> p)*  
returns *true* iff *p* lies on *l*.

## Miscellaneous

*Plane\_3<Kernel>* *l.perpendicular\_plane( Point\_3<Kernel> p)*  
returns the plane perpendicular to *l* passing through *p*.

*Line\_3<Kernel>*      *l.opposite()*      returns the line with opposite direction.

*Vector\_3<Kernel>* *l.to\_vector()* returns a vector having the same direction as *l*.

*Direction\_3<Kernel>* *l.direction()* returns the direction of *l*.

<i>Line_3&lt;Kernel&gt;</i>	<i>l.transform( Aff_transformation_3&lt;Kernel&gt; t)</i>	
		returns the line obtained by applying <i>t</i> on a point on <i>l</i> and the direction of <i>l</i> .

## CGAL::Plane\_3<Kernel>

### Definition

An object  $h$  of the data type  $\text{Plane}_3<\text{Kernel}>$  is an oriented plane in the three-dimensional Euclidean space  $\mathbb{E}^3$ . It is defined by the set of points with Cartesian coordinates  $(x, y, z)$  that satisfy the plane equation

$$h: ax + by + cz + d = 0.$$

The plane splits  $\mathbb{E}^3$  in a *positive* and a *negative side*. A point  $p$  with Cartesian coordinates  $(px, py, pz)$  is on the positive side of  $h$ , iff  $apx + bpy + cpz + d > 0$ . It is on the negative side, iff  $apx + bpy + cpz + d < 0$ .

### Creation

$\text{Plane}_3<\text{Kernel}> \ h( \text{Kernel}::\text{RT } a, \text{Kernel}::\text{RT } b, \text{Kernel}::\text{RT } c, \text{Kernel}::\text{RT } d);$

creates a plane  $h$  defined by the equation  $apx + bpy + cpz + d = 0$ . Notice that  $h$  is degenerate if  $a = b = c = 0$ .

$\text{Plane}_3<\text{Kernel}> \ h( \text{Point}_3<\text{Kernel}> \ p, \text{Point}_3<\text{Kernel}> \ q, \text{Point}_3<\text{Kernel}> \ r);$

creates a plane  $h$  passing through the points  $p$ ,  $q$  and  $r$ . The plane is oriented such that  $p$ ,  $q$  and  $r$  are oriented in a positive sense (that is counterclockwise) when seen from the positive side of  $h$ . Notice that  $h$  is degenerate if the points are collinear.

$\text{Plane}_3<\text{Kernel}> \ h( \text{Point}_3<\text{Kernel}> \ p, \text{Vector}_3<\text{Kernel}> \ v);$

introduces a plane  $h$  that passes through point  $p$  and that is orthogonal to  $v$ .

$\text{Plane}_3<\text{Kernel}> \ h( \text{Point}_3<\text{Kernel}> \ p, \text{Direction}_3<\text{Kernel}> \ d);$

introduces a plane  $h$  that passes through point  $p$  and that has as an orthogonal direction equal to  $d$ .

$\text{Plane}_3<\text{Kernel}> \ h( \text{Line}_3<\text{Kernel}> \ l, \text{Point}_3<\text{Kernel}> \ p);$

introduces a plane  $h$  that is defined through the three points  $l.\text{point}(0)$ ,  $l.\text{point}(1)$  and  $p$ .

$\text{Plane}_3<\text{Kernel}> \ h( \text{Ray}_3<\text{Kernel}> \ r, \text{Point}_3<\text{Kernel}> \ p);$

introduces a plane  $h$  that is defined through the three points  $r.\text{point}(0)$ ,  $r.\text{point}(1)$  and  $p$ .

*Plane\_3<Kernel> h( Segment\_3<Kernel> s, Point\_3<Kernel> p);*

introduces a plane *h* that is defined through the three points *s.source()*, *s.target()* and *p*.

*Plane\_3<Kernel> h( Circle\_3<Kernel> c);*

introduces a plane *h* that is defined as the plane containing the circle.

## Operations

*bool h.operator==( h2)* Test for equality: two planes are equal, iff they have a non empty intersection and the same orientation.

*bool h.operator!=( h2)* Test for inequality.

*Kernel::RT h.a()* returns the first coefficient of *h*.  
*Kernel::RT h.b()* returns the second coefficient of *h*.  
*Kernel::RT h.c()* returns the third coefficient of *h*.  
*Kernel::RT h.d()* returns the fourth coefficient of *h*.

*Line\_3<Kernel> h.perpendicular\_line( Point\_3<Kernel> p)*  
 returns the line that is perpendicular to *h* and that passes through point *p*. The line is oriented from the negative to the positive side of *h*.

*Point\_3<Kernel> h.projection( Point\_3<Kernel> p)*  
 returns the orthogonal projection of *p* on *h*.

*Plane\_3<Kernel> h.opposite()* returns the plane with opposite orientation.

*Point\_3<Kernel> h.point()* returns an arbitrary point on *h*.

*Vector\_3<Kernel> h.orthogonal\_vector()*  
 returns a vector that is orthogonal to *h* and that is directed to the positive side of *h*.

*Direction\_3<Kernel> h.orthogonal\_direction()*  
 returns the direction that is orthogonal to *h* and that is directed to the positive side of *h*.

*Vector\_3<Kernel> h.base1()* returns a vector orthogonal to *orthogonal\_vector()*.

<i>Vector_3&lt;Kernel&gt;</i>	<i>h.base2()</i>	returns a vector that is both orthogonal to <i>base1()</i> , and to <i>orthogonal_vector()</i> , and such that the result of <i>orientation( point(), point() + base1(), point()+base2(), point() + orthogonal_vector() )</i> is positive.
-------------------------------	------------------	--

## 2D Conversion

The following functions provide conversion between a plane and CGAL's two-dimensional space. The transformation is affine, but not necessarily an isometry. This means, the transformation preserves combinatorics, but not distances.

<i>Point_2&lt;Kernel&gt;</i>	<i>h.to_2d( Point_3&lt;Kernel&gt; p )</i>	returns the image point of the projection of <i>p</i> under an affine transformation, which maps <i>h</i> onto the <i>xy</i> -plane, with the <i>z</i> -coordinate removed.
------------------------------	---	---

<i>Point_3&lt;Kernel&gt;</i>	<i>h.to_3d( Point_2&lt;Kernel&gt; p )</i>	returns a point <i>q</i> , such that <i>to_2d( to_3d( p ) )</i> is equal to <i>p</i> .
------------------------------	---	--

## Predicates

<i>Oriented_side</i>	<i>h.oriented_side( Point_3&lt;Kernel&gt; p )</i>	returns either <i>ON_ORIENTED_BOUNDARY</i> , or the constant <i>ON_POSITIVE_SIDE</i> , or the constant <i>ON_NEGATIVE_SIDE</i> , determined by the position of <i>p</i> relative to the oriented plane <i>h</i> .
----------------------	---	---

For convenience we provide the following Boolean functions:

<i>bool</i>	<i>h.has_on( Point_3&lt;Kernel&gt; p )</i>	
<i>bool</i>	<i>h.has_on_positive_side( Point_3&lt;Kernel&gt; p )</i>	
<i>bool</i>	<i>h.has_on_negative_side( Point_3&lt;Kernel&gt; p )</i>	
<i>bool</i>	<i>h.has_on( Line_3&lt;Kernel&gt; l )</i>	
<i>bool</i>	<i>h.has_on( Circle_3&lt;Kernel&gt; l )</i>	
<i>bool</i>	<i>h.is_degenerate()</i>	Plane <i>h</i> is degenerate, if the coefficients <i>a</i> , <i>b</i> , and <i>c</i> of the plane equation are zero.

## Miscellaneous

<i>Plane_3&lt;Kernel&gt;</i>	<i>h.transform( Aff_transformation_3&lt;Kernel&gt; t )</i>	returns the plane obtained by applying <i>t</i> on a point of <i>h</i> and the orthogonal direction of <i>h</i> .
------------------------------	--	---

## CGAL::Point\_3<Kernel>

### Definition

An object of the class *Point\_3<Kernel>* is a point in the three-dimensional Euclidean space  $\mathbb{E}^3$ .

Remember that *Kernel::RT* and *Kernel::FT* denote a *RingNumberType* and a *FieldNumberType*, respectively. For the kernel model *Cartesian<T>*, the two types are the same. For the kernel model *Homogeneous<T>*, *Kernel::RT* is equal to *T*, and *Kernel::FT* is equal to *Quotient<T>*.

### Types

*Point\_3<Kernel>:: Cartesian\_const\_iterator*

An iterator for enumerating the Cartesian coordinates of a point.

### Creation

*Point\_3<Kernel> p( Origin ORIGIN);*

introduces a point with Cartesian coordinates(0,0,0).

*Point\_3<Kernel> p( int x, int y, int z);*

introduces a point *p* initialized to  $(x,y,z)$ .

*Point\_3<Kernel> p( double x, double y, double z);*

introduces a point *p* initialized to  $(x,y,z)$  provided *RT* supports it.

*Point\_3<Kernel> p( Kernel::RT hx, Kernel::RT hy, Kernel::RT hz, Kernel::RT hw = RT(1));*

introduces a point *p* initialized to  $(hx/hw, hy/hw, hz/hw)$ .

*Precondition:*  $hw \neq 0$ .

*Point\_3<Kernel> p( Kernel::FT x, Kernel::FT y, Kernel::FT z);*

introduces a point *p* initialized to  $(x,y,z)$ .

### Operations

*bool p.operator==( q)*

Test for equality: Two points are equal, iff their *x*, *y* and *z* coordinates are equal.

*bool*                      *p.operator!=( q)*

Test for inequality.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

*Kernel::RT*                      *p.hx()*

returns the homogeneous  $x$  coordinate.

*Kernel::RT*                      *p.hy()*

returns the homogeneous  $y$  coordinate.

*Kernel::RT*                      *p.hz()*

returns the homogeneous  $z$  coordinate.

*Kernel::RT*                      *p.hw()*

returns the homogenizing coordinate.

Note that you do not lose information with the homogeneous representation, because the `FieldNumberType` is a quotient.

*Kernel::FT*                      *p.x()*      returns the Cartesian  $x$  coordinate, that is  $hx/hw$ .

*Kernel::FT*                      *p.y()*      returns the Cartesian  $y$  coordinate, that is  $hy/hw$ .

*Kernel::FT*                      *p.z()*      returns the Cartesian  $z$  coordinate, that is  $hz/hw$ .

The following operations are for convenience and for compatibility with code for higher dimensional points. Again they come in a Cartesian and in a homogeneous flavor.

*Kernel::RT*                      *p.homogeneous( int i)*

returns the  $i$ 'th homogeneous coordinate of  $p$ , starting with 0.  
*Precondition:*  $0 \leq i \leq 3$ .

*Kernel::FT*                      *p.cartesian( int i)*

returns the  $i$ 'th Cartesian coordinate of  $p$ , starting with 0.  
*Precondition:*  $0 \leq i \leq 2$ .

*Kernel::FT*                      *p.operator[]( int i)*

returns *cartesian(i)*.  
*Precondition:*  $0 \leq i \leq 2$ .

*Cartesian\_const\_iterator*    *p.cartesian\_begin()*

returns an iterator to the Cartesian coordinates of  $p$ , starting with the 0th coordinate.

*Cartesian\_const\_iterator*     *p.cartesian\_end()*

returns an off the end iterator to the Cartesian coordinates of *p*.

*int*     *p.dimension()*

returns the dimension (the constant 3).

*Bbox\_3*     *p.bbox()*

returns a bounding box containing *p*.

*Point\_3<Kernel>*     *p.transform( Aff\_transformation\_3<Kernel> t)*

returns the point obtained by applying *t* on *p*.

## Operators

The following operations can be applied on points:

*bool*     *operator<( p, q)*

returns true iff *p* is lexicographically smaller than *q* (the lexicographical order being defined on the Cartesian coordinates).

*bool*     *operator>( p, q)*

returns true iff *p* is lexicographically greater than *q*.

*bool*     *operator<=( p, q)*

returns true iff *p* is lexicographically smaller or equal to *q*.

*bool*     *operator>=( p, q)*

returns true iff *p* is lexicographically greater or equal to *q*.

*Vector\_3<Kernel>*     *operator-( p, q)*

returns the difference vector between *q* and *p*. You can substitute *ORIGIN* for either *p* or *q*, but not for both.

*Point\_3<Kernel>*     *operator+( p, Vector\_3<Kernel> v)*

returns the point obtained by translating *p* by the vector *v*.

*Point\_3<Kernel>*                    *operator-( p, Vector\_3<Kernel> v)*

returns the point obtained by translating  $p$  by the vector  $-v$ .

## CGAL::Ray\_3<Kernel>

### Definition

An object  $r$  of the data type  $\text{Ray}_3<\text{Kernel}>$  is a directed straight ray in the three-dimensional Euclidean space  $\mathbb{E}^3$ . It starts in a point called the *source* of  $r$  and it goes to infinity.

### Creation

$\text{Ray}_3<\text{Kernel}> \ r( \text{Point}_3<\text{Kernel}> \ p, \text{Point}_3<\text{Kernel}> \ q);$

introduces a ray  $r$  with source  $p$  and passing through point  $q$ .

$\text{Ray}_3<\text{Kernel}> \ r( \text{Point}_3<\text{Kernel}> \ p, \text{Direction}_3<\text{Kernel}> \ d);$

introduces a ray  $r$  with source  $p$  and with direction  $d$ .

$\text{Ray}_3<\text{Kernel}> \ r( \text{Point}_3<\text{Kernel}> \ p, \text{Vector}_3<\text{Kernel}> \ v);$

introduces a ray  $r$  with source  $p$  and with a direction given by  $v$ .

$\text{Ray}_3<\text{Kernel}> \ r( \text{Point}_3<\text{Kernel}> \ p, \text{Line}_3<\text{Kernel}> \ l);$

introduces a ray  $r$  starting at source  $p$  with the same direction as  $l$ .

### Operations

$bool$	$r.operator==( h)$	Test for equality: two rays are equal, iff they have the same source and the same direction.
$bool$	$r.operator!=( h)$	Test for inequality.
$\text{Point}_3<\text{Kernel}>$	$r.source()$	returns the source of $r$
$\text{Point}_3<\text{Kernel}>$	$r.point( \text{int } i)$	returns a point on $r$ . $point(0)$ is the source. $point(i)$ , with $i > 0$ , is different from the source. <i>Precondition:</i> $i \geq 0$ .
$\text{Direction}_3<\text{Kernel}>$	$r.direction()$	returns the direction of $r$ .
$\text{Vector}_3<\text{Kernel}>$	$r.to\_vector()$	returns a vector giving the direction of $r$ .

<i>Line_3&lt;Kernel&gt;</i>	<i>r.supporting_line()</i>	returns the line supporting <i>r</i> which has the same direction.
<i>Ray_3&lt;Kernel&gt;</i>	<i>r.opposite()</i>	returns the ray with the same source and the opposite direction.
<i>bool</i>	<i>r.is_degenerate()</i>	ray <i>r</i> is degenerate, if the source and the second defining point fall together (that is if the direction is degenerate).
<i>bool</i>	<i>r.has_on( Point_3&lt;Kernel&gt; p)</i>	A point is on <i>r</i> , iff it is equal to the source of <i>r</i> , or if it is in the interior of <i>r</i> .
<i>Ray_3&lt;Kernel&gt;</i>	<i>r.transform( Aff_transformation_3&lt;Kernel&gt; t)</i>	returns the ray obtained by applying <i>t</i> on the source and on the direction of <i>r</i> .

Kernel::Ray\_3 ..... page [538](#)

## CGAL::Segment\_3<Kernel>

### Definition

An object  $s$  of the data type  $\text{Segment}_3<\text{Kernel}>$  is a directed straight line segment in the three-dimensional Euclidean space  $\mathbb{E}^3$ , i.e. a straight line segment  $[p, q]$  connecting two points  $p, q \in \mathbb{R}^3$ . The segment is topologically closed, i.e. the end points belong to it. Point  $p$  is called the *source* and  $q$  is called the *target* of  $s$ . The length of  $s$  is the Euclidean distance between  $p$  and  $q$ . Note that there is only a function to compute the square of the length, because otherwise we had to perform a square root operation which is not defined for all number types, which is expensive, and may not be exact.

### Creation

$\text{Segment}_3<\text{Kernel}> \ s(\text{Point}_3<\text{Kernel}> \ p, \text{Point}_3<\text{Kernel}> \ q);$

introduces a segment  $s$  with source  $p$  and target  $q$ . It is directed from the source towards the target.

### Operations

$\text{bool}$	$s.\text{operator}==(q)$	Test for equality: Two segments are equal, iff their sources and targets are equal.
$\text{bool}$	$s.\text{operator}!=(q)$	Test for inequality.
$\text{Point}_3<\text{Kernel}>$	$s.\text{source}()$	returns the source of $s$ .
$\text{Point}_3<\text{Kernel}>$	$s.\text{target}()$	returns the target of $s$ .
$\text{Point}_3<\text{Kernel}>$	$s.\text{min}()$	returns the point of $s$ with smallest coordinate (lexicographically).
$\text{Point}_3<\text{Kernel}>$	$s.\text{max}()$	returns the point of $s$ with largest coordinate (lexicographically).
$\text{Point}_3<\text{Kernel}>$	$s.\text{vertex}(\text{int } i)$	returns source or target of $s$ : $\text{vertex}(0)$ returns the source, $\text{vertex}(1)$ returns the target. The parameter $i$ is taken modulo 2, which gives easy access to the other vertex.
$\text{Point}_3<\text{Kernel}>$	$s.\text{point}(\text{int } i)$	returns $\text{vertex}(i)$ .
$\text{Point}_3<\text{Kernel}>$	$s.\text{operator}[(\text{int } i)]$	returns $\text{vertex}(i)$ .
$\text{Kernel}::\text{FT}$	$s.\text{squared\_length}()$	returns the squared length of $s$ .
$\text{Vector}_3<\text{Kernel}>$	$s.\text{to\_vector}()$	returns the vector $s.\text{target}() - s.\text{source}()$ .
$\text{Direction}_3<\text{Kernel}>$	$s.\text{direction}()$	returns the direction from source to target.

<i>Segment_3&lt;Kernel&gt;</i>	<i>s.opposite()</i>	returns a segment with source and target interchanged.
<i>Line_3&lt;Kernel&gt;</i>	<i>s.supporting_line()</i>	returns the line <i>l</i> passing through <i>s</i> . Line <i>l</i> has the same orientation as segment <i>s</i> , that is from the source to the target of <i>s</i> .
<i>bool</i>	<i>s.is_degenerate()</i>	segment <i>s</i> is degenerate, if source and target fall together.
<i>bool</i>	<i>s.has_on( Point_3&lt;Kernel&gt; p)</i>	A point is on <i>s</i> , iff it is equal to the source or target of <i>s</i> , or if it is in the interior of <i>s</i> .
<i>Bbox_3</i>	<i>s.bbox()</i>	returns a bounding box containing <i>s</i> .
<i>Segment_3&lt;Kernel&gt;</i>	<i>s.transform( Aff_transformation_3&lt;Kernel&gt; t)</i>	returns the segment obtained by applying <i>t</i> on the source and the target of <i>s</i> .

## CGAL::Circle\_3<Kernel>

### Definition

An object of type *Circle\_3<Kernel>* is a circle in the three-dimensional Euclidean space  $\mathbb{E}^3$ . Note that the circle can be degenerate, i.e. the squared radius may be zero.

### Creation

*Circle\_3<Kernel>* *c*( *Point\_3<Kernel>* *center*, *Kernel::FT* *sq\_r*, *Plane\_3<Kernel>* *plane*);

introduces a variable *c* of type *Circle\_3<Kernel>*. It is initialized to the circle of center *center* and squared radius *sq\_r* in plane *plane*.

*Precondition:* *center* lies in *plane* and *sq\_r*  $\geq 0$ .

*Circle\_3<Kernel>* *c*( *Point\_3<Kernel>* *center*, *Kernel::FT* *sq\_r*, *Vector\_3<Kernel>* *n*);

introduces a variable *c* of type *Circle\_3<Kernel>*. It is initialized to the circle of center *center* and squared radius *sq\_r* in a plane normal to the vector *n*.

*Precondition:* *sq\_r*  $\geq 0$ .

*Circle\_3<Kernel>* *c*( *Point\_3<Kernel>* *p*, *Point\_3<Kernel>* *q*, *Point\_3<Kernel>* *r*);

introduces a variable *c* of type *Circle\_3<Kernel>*. It is initialized to the circle passing through the three points.

*Precondition:* The three points are not collinear.

*Circle\_3<Kernel>* *c*( *Sphere\_3<Kernel>* *sphere1*, *Sphere\_3<Kernel>* *sphere2*);

introduces a variable *c* of type *Circle\_3<Kernel>*. It is initialized to the circle along which the two spheres intersect.

*Precondition:* The two spheres intersect along a circle.

*Circle\_3<Kernel>* *c*( *Sphere\_3<Kernel>* *sphere*, *Plane\_3<Kernel>* *plane*);

introduces a variable *c* of type *Circle\_3<Kernel>*. It is initialized to the circle along which the sphere and the plane intersect.

*Precondition:* The sphere and the plane intersect along a circle.

*Circle\_3<Kernel>* *c*( *Plane\_3<Kernel>* *plane*, *Sphere\_3<Kernel>* *sphere*);

introduces a variable *c* of type *Circle\_3<Kernel>*. It is initialized to the circle along which the sphere and the plane intersect.

*Precondition:* The sphere and the plane intersect along a circle.

## Access Functions

<i>Point_3&lt;Kernel&gt;</i>	<i>c.center()</i>	returns the center of <i>c</i> .
<i>Kernel::FT</i>	<i>c.squared_radius()</i>	returns the squared radius of <i>c</i> .
<i>Plane_3&lt;Kernel&gt;</i>	<i>c.supporting_plane()</i>	returns the supporting plane of <i>c</i> .
<i>Sphere_3&lt;Kernel&gt;</i>	<i>c.diametral_sphere()</i>	returns the diametral sphere of <i>c</i> .
<i>Kernel::FT</i>	<i>c.area_divided_by_pi()</i>	returns the area of <i>c</i> , divided by $\pi$ .
<i>double</i>	<i>c.approximate_area()</i>	returns an approximation of the area of <i>c</i> .
<i>Kernel::FT</i>	<i>c.squared_length_divided_by_pi_square()</i>	returns the squared length of <i>c</i> , divided by $\pi^2$ .
<i>double</i>	<i>c.approximate_squared_length()</i>	returns an approximation of the squared length (i.e. perimeter) of <i>c</i> .

## Predicates

<i>bool</i>	<i>c.has_on( Point_3&lt;Kernel&gt; p)</i>
-------------	---

## Operations

<i>bool operator</i>	<i>c.==( c1, c2)</i>	returns <i>true</i> , iff <i>c1</i> and <i>c2</i> are equal, i.e. if they have the same center, the same squared radius and the same supporting plane.
<i>bool operator</i>	<i>c.!=( c1, c2)</i>	
<i>Bbox_3</i>	<i>c.bbox()</i>	returns a bounding box containing <i>c</i> .

## CGAL::Sphere\_3<Kernel>

### Definition

An object of type *Sphere\_3<Kernel>* is a sphere in the three-dimensional Euclidean space  $\mathbb{E}^3$ . The sphere is oriented, i.e. its boundary has clockwise or counterclockwise orientation. The boundary splits  $\mathbb{E}^3$  into a positive and a negative side, where the positive side is to the left of the boundary. The boundary also splits  $\mathbb{E}^3$  into a bounded and an unbounded side. Note that the sphere can be degenerated, i.e. the squared radius may be zero.

### Creation

*Sphere\_3<Kernel>* *c*( *Point\_3<Kernel>* *center*,  
                   *Kernel::FT* *squared\_radius*,  
                   *Orientation* *orientation* = *COUNTERCLOCKWISE*)

introduces a variable *c* of type *Sphere\_3<Kernel>*. It is initialized to the sphere with center *center*, squared radius *squared\_radius* and orientation *orientation*.

*Precondition:* *orientation*  $\neq$  *COPLANAR*, and furthermore, *squared\_radius*  $\geq 0$ .

*Sphere\_3<Kernel>* *c*( *Point\_3<Kernel>* *p*, *Point\_3<Kernel>* *q*, *Point\_3<Kernel>* *r*, *Point\_3<Kernel>* *s*);

introduces a variable *c* of type *Sphere\_3<Kernel>*. It is initialized to the unique sphere which passes through the points *p*, *q*, *r* and *s*. The orientation of the sphere is the orientation of the point quadruple *p*, *q*, *r*, *s*.

*Precondition:* *p*, *q*, *r*, and *s* are not coplanar.

*Sphere\_3<Kernel>* *c*( *Point\_3<Kernel>* *p*,  
                   *Point\_3<Kernel>* *q*,  
                   *Point\_3<Kernel>* *r*,  
                   *Orientation* *o* = *COUNTERCLOCKWISE*)

introduces a variable *c* of type *Sphere\_3<Kernel>*. It is initialized to the smallest sphere which passes through the points *p*, *q*, and *r*. The orientation of the sphere is *o*.

*Precondition:* *o* is not *COPLANAR*.

*Sphere\_3<Kernel>* *c*( *Point\_3<Kernel>* *p*, *Point\_3<Kernel>* *q*, *Orientation* *o* = *COUNTERCLOCKWISE*);

introduces a variable *c* of type *Sphere\_3<Kernel>*. It is initialized to the smallest sphere which passes through the points *p* and *q*. The orientation of the sphere is *o*.

*Precondition:* *o* is not *COPLANAR*.

*Sphere\_3<Kernel>* *c*( *Point\_3<Kernel>* *center*, *Orientation* *orientation* = *COUNTERCLOCKWISE*);

introduces a variable *c* of type *Sphere\_3<Kernel>*. It is initialized to the sphere with center *center*, squared radius zero and orientation *orientation*.

*Precondition*: *orientation*  $\neq$  *COPLANAR*.

*Postcondition*: *c.is\_degenerate()* = *true*.

*Sphere\_3<Kernel>* *c*( *Circle\_3<Kernel>* *c*);

introduces a variable *c* of type *Sphere\_3<Kernel>*. It is initialized to the diametral sphere of the circle.

## Access Functions

*Point\_3<Kernel>*  
*Kernel::FT*  
*Orientation*

*c.center()*  
*c.squared\_radius()*  
*c.orientation()*

returns the center of *c*.  
returns the squared radius of *c*.  
returns the orientation of *c*.

*bool operator*

*c.==( sphere2)*

returns *true*, iff *c* and *sphere2* are equal, i.e. if they have the same center, same squared radius and same orientation.

*bool operator*

*c.!=( sphere2)*

returns *true*, iff *c* and *sphere2* are not equal.

## Predicates

*bool*

*c.is\_degenerate()*

returns *true*, iff *c* is degenerate, i.e. if *c* has squared radius zero.

*Oriented\_side*

*c.oriented\_side( Point\_3<Kernel> p)*

returns either the constant *ON\_ORIENTED\_BOUNDARY*, *ON\_POSITIVE\_SIDE*, or *ON\_NEGATIVE\_SIDE*, iff *p* lies on the boundary, properly on the positive side, or properly on the negative side of *c*, resp.

*Bounded\_side*

*c.bounded\_side( Point\_3<Kernel> p)*

returns *ON\_BOUNDED\_SIDE*, *ON\_BOUNDARY*, or *ON\_UNBOUNDED\_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *c*, resp.

*bool*

*c.has\_on\_positive\_side( Point\_3<Kernel> p)*

*bool*

*c.has\_on\_negative\_side( Point\_3<Kernel> p)*

*bool*

*c.has\_on\_boundary( Point\_3<Kernel> p)*

*bool*

*c.has\_on\_bounded\_side( Point\_3<Kernel> p)*

*bool*

*c.has\_on\_unbounded\_side( Point\_3<Kernel> p)*

*bool*

*c.has\_on( Point\_3<Kernel> p)*

*bool*                                      *c.has\_on( Circle\_3<Kernel> p)*

## Miscellaneous

*Sphere\_3<Kernel>*                      *c.opposite()*                      returns the sphere with the same center and squared radius as *c* but with opposite orientation.

*Sphere\_3<Kernel>*                      *c.orthogonal\_transform( Aff\_transformation\_3<Kernel> at)*

returns the sphere obtained by applying *at* on *c*.  
*Precondition: at* is an orthogonal transformation.

*Bbox\_3*                                      *c.bbox()*                      returns a bounding box containing *c*.

## CGAL::Tetrahedron\_3<Kernel>

### Definition

An object  $t$  of the class *Tetrahedron\_3<Kernel>* is an oriented tetrahedron in the three-dimensional Euclidean space  $\mathbb{E}^3$ .

It is defined by four vertices  $p_0$ ,  $p_1$ ,  $p_2$  and  $p_3$ . The orientation of a tetrahedron is the orientation of its four vertices. That means it is positive when  $p_3$  is on the positive side of the plane defined by  $p_0$ ,  $p_1$  and  $p_2$ .

The tetrahedron itself splits the space  $\mathbb{E}_3$  in a *positive* and a *negative* side.

The boundary of a tetrahedron splits the space in two open regions, a bounded one and an unbounded one.

### Creation

```
Tetrahedron_3<Kernel> t( Point_3<Kernel> p0,
                        Point_3<Kernel> p1,
                        Point_3<Kernel> p2,
                        Point_3<Kernel> p3)
```

introduces a tetrahedron  $t$  with vertices  $p_0$ ,  $p_1$ ,  $p_2$  and  $p_3$ .

### Operations

<i>bool</i>	<i>t.operator==( t2)</i>	Test for equality: two tetrahedra $t$ and $t2$ are equal, iff $t$ and $t2$ have the same orientation and their sets (not sequences) of vertices are equal.
<i>bool</i>	<i>t.operator!=( t2)</i>	Test for inequality.
<i>Point_3&lt;Kernel&gt;</i>	<i>t.vertex( int i)</i>	returns the $i$ 'th vertex modulo 4 of $t$ .
<i>Point_3&lt;Kernel&gt;</i>	<i>t.operator[]( int i)</i>	returns <i>vertex(int i)</i> .

### Predicates

<i>bool</i>	<i>t.is_degenerate()</i>	Tetrahedron $t$ is degenerate, if the vertices are coplanar.
<i>Orientation</i>	<i>t.orientation()</i>	
<i>Oriented_side</i>	<i>t.oriented_side( Point_3&lt;Kernel&gt; p)</i>	

*Precondition:* :  $t$  is not degenerate.

*Bounded\_side*                      *t.bounded\_side( Point\_3<Kernel> p)*

*Precondition:* : *t* is not degenerate.

For convenience we provide the following Boolean functions:

*bool*                                      *t.has\_on\_positive\_side( Point\_3<Kernel> p)*  
*bool*                                      *t.has\_on\_negative\_side( Point\_3<Kernel> p)*  
*bool*                                      *t.has\_on\_boundary( Point\_3<Kernel> p)*  
*bool*                                      *t.has\_on\_bounded\_side( Point\_3<Kernel> p)*  
*bool*                                      *t.has\_on\_unbounded\_side( Point\_3<Kernel> p)*

## Miscellaneous

*Kernel::FT*                              *t.volume()*                      returns the signed volume of *t*.

*Bbox\_3*                                      *t.bbox()*                      returns a bounding box containing *t*.

*Tetrahedron\_3<Kernel>*      *t.transform( Aff\_transformation\_3<Kernel> at)*  
  
returns the tetrahedron obtained by applying *at* on the three vertices of *t*.

## See Also

*Kernel::Tetrahedron\_3* ..... page [542](#)

## CGAL::Triangle\_3<Kernel>

### Definition

An object  $t$  of the class *Triangle\_3<Kernel>* is a triangle in the three-dimensional Euclidean space  $\mathbb{E}^3$ . As the triangle is not a full-dimensional object there is only a test whether a point lies on the triangle or not.

### Creation

*Triangle\_3<Kernel>*  $t$ ( *Point\_3<Kernel>*  $p$ , *Point\_3<Kernel>*  $q$ , *Point\_3<Kernel>*  $r$ );

introduces a triangle  $t$  with vertices  $p$ ,  $q$  and  $r$ .

### Operations

<i>bool</i>	$t.operator==(t_2)$	Test for equality: two triangles $t$ and $t_2$ are equal, iff there exists a cyclic permutation of the vertices of $t_2$ , such that they are equal to the vertices of $t$ .
<i>bool</i>	$t.operator!=(t_2)$	Test for inequality.
<i>Point_3&lt;Kernel&gt;</i>	$t.vertex(int\ i)$	returns the $i$ 'th vertex modulo 3 of $t$ .
<i>Point_3&lt;Kernel&gt;</i>	$t.operator[](int\ i)$	returns $vertex(int\ i)$ .
<i>Plane_3&lt;Kernel&gt;</i>	$t.supporting\_plane()$	returns the supporting plane of $t$ , with same orientation.

### Predicates

<i>bool</i>	$t.is\_degenerate()$	$t$ is degenerate if its vertices are collinear.
<i>bool</i>	$t.has\_on( Point_3<Kernel> p)$	A point is on $t$ , if it is on a vertex, an edge or the face of $t$ .

### Miscellaneous

<i>Kernel::FT</i>	$t.squared\_area()$	returns a square of the area of $t$ .
<i>Bbox_3</i>	$t.bbox()$	returns a bounding box containing $t$ .

*Triangle\_3<Kernel>*      *t.transform( Aff\_transformation\_3<Kernel> at)*

returns the triangle obtained by applying *at* on the three vertices of *t*.

## CGAL::Vector\_3<Kernel>

### Definition

An object of the class *Vector\_3<Kernel>* is a vector in the three-dimensional vector space  $\mathbb{R}^3$ . Geometrically spoken a vector is the difference of two points  $p_2, p_1$  and denotes the direction and the distance from  $p_1$  to  $p_2$ .

CGAL defines a symbolic constant *NULL\_VECTOR*. We will explicitly state where you can pass this constant as an argument instead of a vector initialized with zeros.

### Types

*Vector\_3<Kernel>::Cartesian\_const\_iterator*

An iterator for enumerating the Cartesian coordinates of a vector.

### Creation

*Vector\_3<Kernel> v( Point\_3<Kernel> a, Point\_3<Kernel> b);*

introduces the vector  $b - a$ .

*Vector\_3<Kernel> v( Segment\_3<Kernel> s);*

introduces the vector  $s.target() - s.source()$ .

*Vector\_3<Kernel> v( Ray\_3<Kernel> r);*

introduces a vector having the same direction as  $r$ .

*Vector\_3<Kernel> v( Line\_3<Kernel> l);*

introduces a vector having the same direction as  $l$ .

*Vector\_3<Kernel> v( Null\_vector NULL\_VECTOR);*

introduces a null vector  $v$ .

*Vector\_3<Kernel> v( int x, int y, int z);*

introduces a vector  $v$  initialized to  $(x, y, z)$ .

*Vector\_3<Kernel> v( double x, double y, double z);*

introduces a vector *v* initialized to  $(x, y, z)$ .

*Vector\_3<Kernel> v( Kernel::RT hx, Kernel::RT hy, Kernel::RT hz, Kernel::RT hw = RT(1));*

introduces a vector *v* initialized to  $(hx/hw, hy/hw, hz/hw)$ .

*Vector\_3<Kernel> v( Kernel::FT x, Kernel::FT y, Kernel::FT z);*

introduces a vector *v* initialized to  $(x, y, z)$ .

## Operations

*bool v.operator==( w)*

Test for equality: two vectors are equal, iff their *x*, *y* and *z* coordinates are equal. You can compare a vector with the *NULL\_VECTOR*.

*bool v.operator!=( w)*

Test for inequality. You can compare a vector with the *NULL\_VECTOR*.

There are two sets of coordinate access functions, namely to the homogeneous and to the Cartesian coordinates. They can be used independently from the chosen kernel model.

*Kernel::RT v.hx()*

returns the homogeneous *x* coordinate.

*Kernel::RT v.hy()*

returns the homogeneous *y* coordinate.

*Kernel::RT v.hz()*

returns the homogeneous *z* coordinate.

*Kernel::RT v.hw()*

returns the homogenizing coordinate.

Note that you do not loose information with the homogeneous representation, because the *FieldNumberType* is a quotient.

*Kernel::FT v.x()* returns the *x*-coordinate of *v*, that is  $hx/hw$ .

*Kernel::FT v.y()* returns the *y*-coordinate of *v*, that is  $hy/hw$ .

*Kernel::FT v.z()* returns the *z* coordinate of *v*, that is  $hz/hw$ .

The following operations are for convenience and for compatibility with higher dimensional vectors. Again they come in a Cartesian and homogeneous flavor.

<i>Kernel::RT</i>	<i>v.homogeneous( int i)</i>	returns the i`th homogeneous coordinate of <i>v</i> , starting with 0. <i>Precondition:</i> $0 \leq i \leq 3$ .
<i>Kernel::FT</i>	<i>v.cartesian( int i)</i>	returns the i`th Cartesian coordinate of <i>v</i> , starting at 0. <i>Precondition:</i> $0 \leq i \leq 2$ .
<i>Kernel::FT</i>	<i>v.operator[] ( int i)</i>	returns <i>cartesian(i)</i> . <i>Precondition:</i> $0 \leq i \leq 2$ .
<i>Cartesian_const_iterator</i>	<i>v.cartesian_begin()</i>	returns an iterator to the Cartesian coordinates of <i>v</i> , starting with the 0th coordinate.
<i>Cartesian_const_iterator</i>	<i>v.cartesian_end()</i>	returns an off the end iterator to the Cartesian coordinates of <i>v</i> .
<i>int</i>	<i>v.dimension()</i>	returns the dimension (the constant 3).
<i>Vector_3&lt;Kernel&gt;</i>	<i>v.transform( Aff_transformation_3&lt;Kernel&gt; t)</i>	returns the vector obtained by applying <i>t</i> on <i>v</i> .
<i>Direction_3&lt;Kernel&gt;</i>	<i>v.direction()</i>	returns the direction of <i>v</i> .

## Operators

The following operations can be applied on vectors:

<i>Vector_3&lt;Kernel&gt;</i>	<i>v.operator+( w)</i>	Addition.
<i>Vector_3&lt;Kernel&gt;</i>	<i>v.operator-( w)</i>	Subtraction.

<i>Vector_3&lt;Kernel&gt;</i>	<i>v.operator-()</i>	Returns the opposite vector.
<i>Kernel::FT</i>	<i>v.operator*( w)</i>	returns the scalar product (= inner product) of the two vectors.
<i>Vector_3&lt;Kernel&gt;</i>	<i>operator*( v, Kernel::RT s)</i>	Multiplication with a scalar from the right.
<i>Vector_3&lt;Kernel&gt;</i>	<i>operator*( v, Kernel::FT s)</i>	Multiplication with a scalar from the right.
<i>Vector_3&lt;Kernel&gt;</i>	<i>operator*( Kernel::RT s, v)</i>	Multiplication with a scalar from the left.
<i>Vector_3&lt;Kernel&gt;</i>	<i>operator*( Kernel::FT s, v)</i>	Multiplication with a scalar from the left.
<i>Vector_3&lt;Kernel&gt;</i>	<i>v.operator/( Kernel::RT s)</i>	Division by a scalar.
<i>Kernel::FT</i>	<i>v.squared_length()</i>	returns the squared length of <i>v</i> .

## CGAL::ORIGIN

`const Origin`                      *ORIGIN*;

### Definition

A symbolic constant which denotes the point at the origin. This constant is used in the conversion between points and vectors.

### Example

```
Point_2< Cartesian<Exact_NT> >  p(1.0, 1.0), q;
Vector2< Cartesian<Exact_NT> >  v;
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

## 7.11 Global Functions

### CGAL::angle

*Angle*  $\text{angle}(\text{Point\_2<Kernel>} p, \text{Point\_2<Kernel>} q, \text{Point\_2<Kernel>} r)$

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points  $p, q, r$  ( $q$  being the vertex of the angle).

*Angle*  $\text{angle}(\text{Point\_3<Kernel>} p, \text{Point\_3<Kernel>} q, \text{Point\_3<Kernel>} r)$

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points  $p, q, r$  ( $q$  being the vertex of the angle).

## CGAL::are\_ordered\_along\_line

```
bool are_ordered_along_line( Point_2<Kernel> p,
                             Point_2<Kernel> q,
                             Point_2<Kernel> r)
```

returns *true*, iff the three points are collinear and  $q$  lies between  $p$  and  $r$ . Note that *true* is returned, if  $q==p$  or  $q==r$ .

```

bool      are_ordered_along_line( Point_3<Kernel> p,
                                   Point_3<Kernel> q,
                                   Point_3<Kernel> r)

```

returns *true*, iff the three points are collinear and  $q$  lies between  $p$  and  $r$ . Note that *true* is returned, if  $q==p$  or  $q==r$ .

**CGAL::area***Kernel::FT**area( Point\_2<Kernel> p, Point\_2<Kernel> q, Point\_2<Kernel> r)*

returns the signed area of the triangle defined by the points  $p$ ,  $q$  and  $r$ .

```

barycenter( Point_2<Kernel> p1,
            Kernel::FT w1,
            Point_2<Kernel> p2,
            Kernel::FT w2,
            Point_2<Kernel> p3,
            Kernel::FT w3,
            Point_2<Kernel> p4,
            Kernel::FT w4)

```

compute the barycenter of the points  $p_1, p_2, p_3$  and  $p_4$  with corresponding weights  $w_1, w_2, w_3$  and  $w_4$ .

*Precondition:*  $w_1 + w_2 + w_3 + w_4 \neq 0$ .

$$\text{barycenter}( \text{Point\_3}\langle\text{Kernel}\rangle p1, \text{Kernel}::\text{FT } w1, \text{Point\_3}\langle\text{Kernel}\rangle p2)$$

compute the barycenter of the points  $p_1$  and  $p_2$  with corresponding weights  $w_1$  and  $1 - w_1$ .

```

barycenter( Point_3<Kernel> p1,
            Kernel::FT w1,
            Point_3<Kernel> p2,
            Kernel::FT w2)

```

compute the barycenter of the points  $p_1$  and  $p_2$  with corresponding weights  $w_1$  and  $w_2$ .

*Precondition:*  $w_1 + w_2 \neq 0$ .

```
barycenter( Point_3<Kernel> p1,
            Kernel::FT w1,
            Point_3<Kernel> p2,
            Kernel::FT w2,
            Point_3<Kernel> p3)
```

compute the barycenter of the points  $p_1$ ,  $p_2$  and  $p_3$  with corresponding weights  $w_1$ ,  $w_2$  and  $1 - w_1 - w_2$ .

```

barycenter( Point_3<Kernel> p1,
            Kernel::FT w1,
            Point_3<Kernel> p2,
            Kernel::FT w2,
            Point_3<Kernel> p3,
            Kernel::FT w3)

```

compute the barycenter of the points  $p_1$ ,  $p_2$  and  $p_3$  with corresponding weights  $w_1$ ,  $w_2$  and  $w_3$ .

*Precondition:*  $w_1 + w_2 + w_3 \neq 0$ .

$$\text{barycenter}( \text{Point\_3}\langle \text{Kernel} \rangle p1,$$

```

Kernel::FT w1,
Point_3<Kernel> p2,
Kernel::FT w2,
Point_3<Kernel> p3,
Kernel::FT w3,
Point_3<Kernel> p4)

```

compute the barycenter of the points  $p1$ ,  $p2$ ,  $p3$  and  $p4$  with corresponding weights  $w1$ ,  $w2$ ,  $w3$  and  $1 - w1 - w2 - w3$ .

```

Point_3<Kernel>      barycenter( Point_3<Kernel> p1,
                                Kernel::FT w1,
                                Point_3<Kernel> p2,
                                Kernel::FT w2,
                                Point_3<Kernel> p3,
                                Kernel::FT w3,
                                Point_3<Kernel> p4,
                                Kernel::FT w4)

```

compute the barycenter of the points  $p1$ ,  $p2$ ,  $p3$  and  $p4$  with corresponding weights  $w1$ ,  $w2$ ,  $w3$  and  $w4$ .  
*Precondition:*  $w1+w2+w3+w4 \neq 0$ .

## See Also

*CGAL::centroid* ..... [page 3161](#)

## CGAL::bisector

*Line\_2<Kernel>*      *bisector( Point\_2<Kernel> p, Point\_2<Kernel> q)*

constructs the bisector line of the two points  $p$  and  $q$ . The bisector is oriented in such a way that  $p$  lies on its positive side.

*Precondition:*  $p$  and  $q$  are not equal.

*Line\_2<Kernel>*      *bisector( Line\_2<Kernel> l1, Line\_2<Kernel> l2)*

constructs the bisector of the two lines  $l1$  and  $l2$ . In the general case, the bisector has the direction of the vector which is the sum of the normalized directions of the two lines, and which passes through the intersection of  $l1$  and  $l2$ . If  $l1$  and  $l2$  are parallel, then the bisector is defined as the line which has the same direction as  $l1$ , and which is at the same distance from  $l1$  and  $l2$ . This function requires that *Kernel::RT* supports the *sqrt()* operation.

*Plane\_3<Kernel>*      *bisector( Point\_3<Kernel> p, Point\_3<Kernel> q)*

constructs the bisector plane of the two points  $p$  and  $q$ . The bisector is oriented in such a way that  $p$  lies on its positive side.

*Precondition:*  $p$  and  $q$  are not equal.

*Plane\_3<Kernel>*      *bisector( Plane\_3<Kernel> h1, Plane\_3<Kernel> h2)*

constructs the bisector of the two planes  $h1$  and  $h2$ . In the general case, the bisector has a normal vector which has the same direction as the sum of the normalized normal vectors of the two planes, and passes through the intersection of  $h1$  and  $h2$ . If  $h1$  and  $h2$  are parallel, then the bisector is defined as the plane which has the same oriented normal vector as  $h1$ , and which is at the same distance from  $h1$  and  $h2$ . This function requires that *Kernel::RT* supports the *sqrt()* operation.

## CGAL::centroid

*Point\_2<Kernel>*      *centroid( Point\_2<Kernel> p, Point\_2<Kernel> q, Point\_2<Kernel> r)*  
    compute the centroid of the points *p*, *q*, and *r*.

*Point\_2<Kernel>*      *centroid( Point\_2<Kernel> p,*  
    *Point\_2<Kernel> q,*  
    *Point\_2<Kernel> r,*  
    *Point\_2<Kernel> s)*  
    compute the centroid of the points *p*, *q*, *r*, and *s*.

*Point\_2<Kernel>*      *centroid( Triangle\_2<Kernel> t)*  
    compute the centroid of the triangle *t*.

*Point\_3<Kernel>*      *centroid( Point\_3<Kernel> p, Point\_3<Kernel> q, Point\_3<Kernel> r)*  
    compute the centroid of the points *p*, *q*, and *r*.

*Point\_3<Kernel>*      *centroid( Point\_3<Kernel> p,*  
    *Point\_3<Kernel> q,*  
    *Point\_3<Kernel> r,*  
    *Point\_3<Kernel> s)*  
    compute the centroid of the points *p*, *q*, *r*, and *s*.

*Point\_3<Kernel>*      *centroid( Triangle\_3<Kernel> t)*  
    compute the centroid of the triangle *t*.

*Point\_3<Kernel>*      *centroid( Tetrahedron\_3<Kernel> t)*  
    compute the centroid of the tetrahedron *t*.

**CGAL::circumcenter**

<i>Point_2&lt;Kernel&gt;</i>	<i>circumcenter( Point_2&lt;Kernel&gt; p, Point_2&lt;Kernel&gt; q)</i>	compute the center of the smallest circle passing through the points $p$ and $q$ . Note: this is the same as <i>CGAL::midpoint</i> ( $p, q$ ) but is provided for homogeneity.
<i>Point_2&lt;Kernel&gt;</i>	<i>circumcenter( Point_2&lt;Kernel&gt; p, Point_2&lt;Kernel&gt; q, Point_2&lt;Kernel&gt; r)</i>	compute the center of the circle passing through the points $p, q$ , and $r$ . <i>Precondition:</i> $p, q$ , and $r$ are not collinear.
<i>Point_2&lt;Kernel&gt;</i>	<i>circumcenter( Triangle_2&lt;Kernel&gt; t)</i>	compute the center of the circle passing through the vertices of $t$ . <i>Precondition:</i> $t$ is not degenerate.
<i>Point_3&lt;Kernel&gt;</i>	<i>circumcenter( Point_3&lt;Kernel&gt; p, Point_3&lt;Kernel&gt; q)</i>	compute the center of the smallest sphere passing through the points $p$ and $q$ . Note: this is the same as <i>CGAL::midpoint</i> ( $p, q$ ) but is provided for homogeneity.
<i>Point_3&lt;Kernel&gt;</i>	<i>circumcenter( Point_3&lt;Kernel&gt; p, Point_3&lt;Kernel&gt; q, Point_3&lt;Kernel&gt; r)</i>	compute the center of the circle passing through the points $p, q$ , and $r$ . <i>Precondition:</i> $p, q$ , and $r$ are not collinear.
<i>Point_3&lt;Kernel&gt;</i>	<i>circumcenter( Triangle_3&lt;Kernel&gt; t)</i>	compute the center of the circle passing through the vertices of $t$ . <i>Precondition:</i> $t$ is not degenerate.
<i>Point_3&lt;Kernel&gt;</i>	<i>circumcenter( Point_3&lt;Kernel&gt; p, Point_3&lt;Kernel&gt; q, Point_3&lt;Kernel&gt; r, Point_3&lt;Kernel&gt; s)</i>	compute the center of the sphere passing through the points $p, q, r$ , and $s$ . <i>Precondition:</i> $p, q, r$ , and $s$ are not coplanar.

*Point\_3<Kernel>*

*circumcenter( Tetrahedron\_3<Kernel> t)*

compute the center of the sphere passing through the vertices of  $t$ .

*Precondition:*  $t$  is not degenerate.

returns *true*, iff  $p$ ,  $q$ , and  $r$  are collinear.

returns *true*, iff  $p$ ,  $q$ , and  $r$  are collinear.

compares the squared radius of the sphere defined by the points  $p, q, r$ , and  $r$  to  $sr$ .

## CGAL::compare\_x

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

**With the basic 2D and 3D Kernel** (see Chapter 7)

*Comparison\_result*      *compare\_x*( *Point\_2<Kernel>* *p*, *Point\_2<Kernel>* *q*)

compares the *x*-coordinates of *p* and *q*.

*Comparison\_result*      *compare\_x*( *Point\_3<Kernel>* *p*, *Point\_3<Kernel>* *q*)

compares the *x*-coordinates of *p* and *q*.

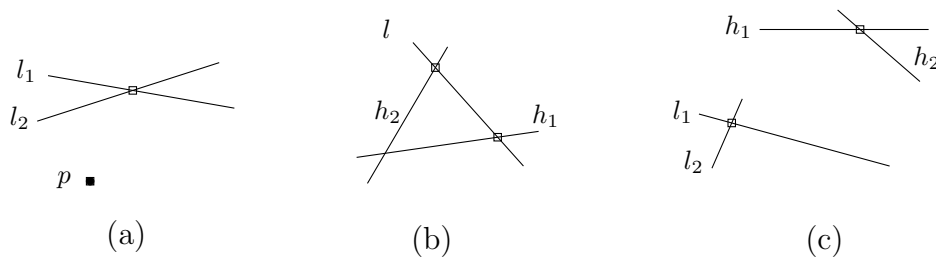

Figure 7.1: Comparison of the *x* or *y*-coordinates of the (implicitly given) points in the boxes.

*Comparison\_result*      *compare\_x*( *Point\_2<Kernel>* *p*, *Line\_2<Kernel>* *l1*, *Line\_2<Kernel>* *l2*)

compares the *x*-coordinates of *p* and the intersection of lines *l1* and *l2* (Figure 7.1 (a)).

*Comparison\_result*      *compare\_x*( *Line\_2<Kernel>* *l*, *Line\_2<Kernel>* *h1*, *Line\_2<Kernel>* *h2*)

compares the *x*-coordinates of the intersection of line *l* with line *h1* and with line *h2* (Figure 7.1 (b)).

*Comparison\_result*      *compare\_x*( *Line\_2<Kernel>* *l1*,  
                                  *Line\_2<Kernel>* *l2*,  
                                  *Line\_2<Kernel>* *h1*,  
                                  *Line\_2<Kernel>* *h2*)

compares the *x*-coordinates of the intersection of lines *l1* and *l2* and the intersection of lines *h1* and *h2* (Figure 7.1 (c)).

### With the 2D Circular Kernel (see Chapter 9)

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

<i>Comparison_result</i>	<i>compare_x</i> ( <i>Circular_arc_point_2</i> < <i>CircularKernel</i> > <i>p</i> , <i>Circular_arc_point_2</i> < <i>CircularKernel</i> > <i>q</i> )	compares the <i>x</i> -coordinates of <i>p</i> and <i>q</i> .
--------------------------	---	---

<i>Comparison_result</i>	<i>compare_x</i> ( <i>Circular_arc_point_2</i> < <i>CircularKernel</i> > <i>p</i> , <i>Point_2</i> < <i>CircularKernel</i> > <i>q</i> )	compares the <i>x</i> -coordinates of <i>p</i> and <i>q</i> .
--------------------------	--	---

### With the 3D Spherical Kernel (see Chapter 10)

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

<i>Comparison_result</i>	$\text{compare\_x}(\text{Circular\_arc\_point\_3}\langle\text{SphericalKernel}\rangle p,$ $\text{Circular\_arc\_point\_3}\langle\text{SphericalKernel}\rangle q)$	compares the $x$ -coordinates of $p$ and $q$ .
--------------------------	--	--

<i>Comparison_result</i>	$\text{compare\_x}(\text{Circular\_arc\_point\_3}\langle\text{SphericalKernel}\rangle p,$ $\text{Point\_3}\langle\text{SphericalKernel}\rangle q)$	compares the $x$ -coordinates of $p$ and $q$ .
--------------------------	---	--

## CGAL::compare\_xy

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

**With the basic 2D and 3D Kernel** (see Chapter 7)

*Comparison\_result*      *compare\_xy*( *Point\_2*<*Kernel*> *p*, *Point\_2*<*Kernel*> *q*)

Compares the Cartesian coordinates of points *p* and *q* lexicographically in *xy* order: first *x*-coordinates are compared, if they are equal, *y*-coordinates are compared.

*Comparison\_result*      *compare\_xy*( *Point\_3*<*Kernel*> *p*, *Point\_3*<*Kernel*> *q*)

Compares the Cartesian coordinates of points *p* and *q* lexicographically in *xy* order: first *x*-coordinates are compared, if they are equal, *y*-coordinates are compared.

**With the 2D Circular Kernel** (see Chapter 9)

*#include* <CGAL/global\_functions\_circular\_kernel\_2.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

*Comparison\_result*      *compare\_xy*( *Circular\_arc\_point\_2*<*CircularKernel*> *p*,  
   *Circular\_arc\_point\_2*<*CircularKernel*> *q*)

Compares the *x* and *y* Cartesian coordinates of points *p* and *q* lexicographically.

*Comparison\_result*      *compare\_xy*( *Circular\_arc\_point\_2*<*CircularKernel*> *p*,  
   *Point\_2*<*CircularKernel*> *q*)

Compares the *x* and *y* Cartesian coordinates of points *p* and *q* lexicographically.

**With the 3D Spherical Kernel** (see Chapter 10)

*#include* <CGAL/global\_functions\_spherical\_kernel\_3.h>

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

<i>Comparison_result</i>	<i>compare_xy</i> ( <i>Circular_arc_point_3</i> < <i>SphericalKernel</i> > <i>p</i> , <i>Circular_arc_point_3</i> < <i>SphericalKernel</i> > <i>q</i> )	Compares the <i>x</i> and <i>y</i> Cartesian coordinates of points <i>p</i> and <i>q</i> lexicographically.
--------------------------	--	--

<i>Comparison_result</i>	<i>compare_xy</i> ( <i>Circular_arc_point_3</i> < <i>SphericalKernel</i> > <i>p</i> , <i>Point_3</i> < <i>SphericalKernel</i> > <i>q</i> )	Compares the <i>x</i> and <i>y</i> Cartesian coordinates of points <i>p</i> and <i>q</i> lexicographically.
--------------------------	---	--

## CGAL::compare\_xyz

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

**With the basic 3D Kernel** (see Chapter 7)

<i>Comparison_result</i>	<i>compare_xyz( Point_3&lt;Kernel&gt; p, Point_3&lt;Kernel&gt; q)</i>
--------------------------	---

Compares the Cartesian coordinates of points  $p$  and  $q$  lexicographically in  $xyz$  order: first  $x$ -coordinates are compared, if they are equal,  $y$ -coordinates are compared, and if both  $x$ - and  $y$ - coordinate are equal,  $z$ -coordinates are compared.

### With the 3D Spherical Kernel (see Chapter 10)

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

<i>Comparison_result</i>	<i>compare_xyz( Circular_arc_point_3&lt;SphericalKernel&gt; p,</i> <i>Circular_arc_point_3&lt;SphericalKernel&gt; q)</i>
--------------------------	---

Compares the Cartesian coordinates of points  $p$  and  $q$  lexicographically.

<i>Comparison_result</i>	<i>compare_xyz( Circular_arc_point_3&lt;SphericalKernel&gt; p,</i> <i>Point_3&lt;SphericalKernel&gt; q)</i>
--------------------------	--

Compares the Cartesian coordinates of points  $p$  and  $q$  lexicographically.

<i>CGAL::compare_z</i> .....	page 465

## CGAL::compare\_x\_at\_y

Comparison\_result

`compare_x_at_y( Point_2<Kernel> p, Line_2<Kernel> h )`

compares the  $x$ -coordinates of  $p$  and the horizontal projection of  $p$  on  $h$  (Figure 7.2 (a)).

*Precondition:*  $h$  is not horizontal.

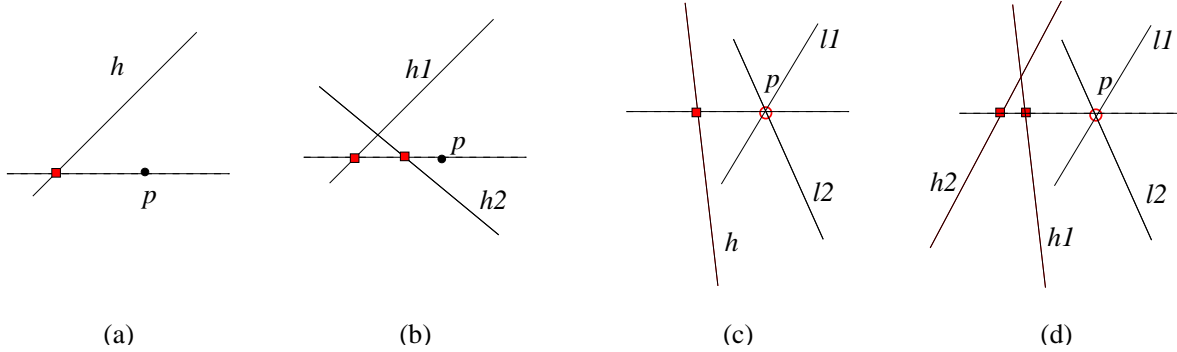

Figure 7.2: Comparison of the  $x$ -coordinates of the (implicitly given) points in the boxes, at a  $y$ -coordinate. The  $y$ -coordinate is either given explicitly (disc) or implicitly (circle).

Comparison\_result

`compare_x_at_y( Point_2<Kernel> p, Line_2<Kernel> h1, Line_2<Kernel> h2 )`

This function compares the  $x$ -coordinates of the horizontal projection of  $p$  on  $h1$  and on  $h2$  (Figure 7.2 (b)).

*Precondition:*  $h1$  and  $h2$  are not horizontal.

Comparison\_result

`compare_x_at_y( Line_2<Kernel> l1, Line_2<Kernel> l2, Line_2<Kernel> h )`

Let  $p$  be the intersection of lines  $l1$  and  $l2$ . This function compares the  $x$ -coordinates of  $p$  and the horizontal projection of  $p$  on  $h$  (Figure 7.2 (c)).

*Precondition:*  $l1$  and  $l2$  intersect and are not horizontal;  $h$  is not horizontal.

Comparison\_result

`compare_x_at_y( Line_2<Kernel> l1,  
Line_2<Kernel> l2,  
Line_2<Kernel> h1,  
Line_2<Kernel> h2 )`

Let  $p$  be the intersection of lines  $l1$  and  $l2$ . This function compares the  $x$ -coordinates of the horizontal projection of  $p$  on  $h1$  and on  $h2$  (Figure 7.2 (d)).

*Precondition:*  $l1$  and  $l2$  intersect and are not horizontal;  $h1$  and  $h2$  are not horizontal.

## CGAL::compare\_y

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

**With the basic 2D and 3D Kernel** (see Chapter 7)

*Comparison\_result*      `compare_y( Point_2<Kernel> p, Point_2<Kernel> q)`

compares Cartesian y-coordinates of  $p$  and  $q$ .

*Comparison\_result*      `compare_y( Point_3<Kernel> p, Point_3<Kernel> q)`

compares Cartesian y-coordinates of  $p$  and  $q$ .

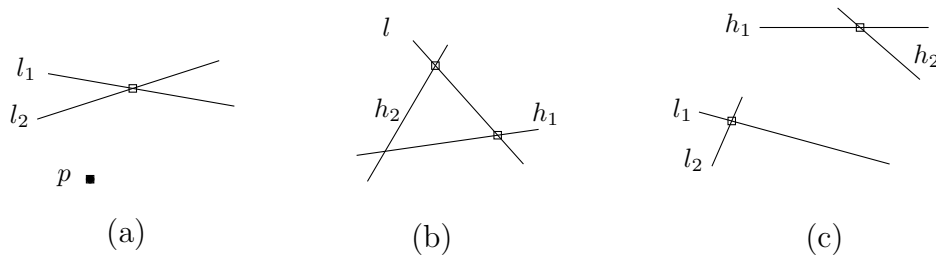

Figure 7.3: Comparison of the x or y-coordinates of the (implicitly given) points in the boxes.

*Comparison\_result*      `compare_y( Point_2<Kernel> p, Line_2<Kernel> l1, Line_2<Kernel> l2)`

compares the y-coordinates of  $p$  and the intersection of lines  $l_1$  and  $l_2$  (Figure 7.3 (a)).

*Comparison\_result*      `compare_y( Line_2<Kernel> l, Line_2<Kernel> h1, Line_2<Kernel> h2)`

compares the y-coordinates of the intersection of line  $l$  with line  $h_1$  and with line  $h_2$  (Figure 7.3 (b)).

*Comparison\_result*      `compare_y( Line_2<Kernel> l1,  
Line_2<Kernel> l2,  
Line_2<Kernel> h1,  
Line_2<Kernel> h2)`

compares the y-coordinates of the intersection of lines  $l_1$  and  $l_2$  and the intersection of lines  $h_1$  and  $h_2$  (Figure 7.3 (c)).

### With the 2D Circular Kernel (see Chapter 9)

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

<i>Comparison_result</i>	<code>compare_y( Circular_arc_point_2&lt;CircularKernel&gt; p,</code> <code>          Circular_arc_point_2&lt;CircularKernel&gt; q)</code>	<p>compares the y-coordinates of <math>p</math> and <math>q</math>.</p>
--------------------------	---	---

<i>Comparison_result</i>	<code>compare_y( Circular_arc_point_2&lt;CircularKernel&gt; p,</code> <code>          Point_2&lt;CircularKernel&gt; q)</code>	compares the y-coordinates of $p$ and $q$ .
--------------------------	--	---

### With the 3D Spherical Kernel (see Chapter 10)

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

<i>Comparison_result</i>	<code>compare_y( Circular_arc_point_3&lt;SphericalKernel&gt; p,</code> <code>          Circular_arc_point_3&lt;SphericalKernel&gt; q)</code>	compares the y-coordinates of $p$ and $q$ .
--------------------------	---	---

<i>Comparison_result</i>	<i>compare_y</i> ( <i>Circular_arc_point_3</i> < <i>SphericalKernel</i> > <i>p</i> , <i>Point_3</i> < <i>SphericalKernel</i> > <i>q</i> )	compares the y-coordinates of <i>p</i> and <i>q</i> .

## CGAL::compare\_y\_at\_x

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

**With the basic 2D and 3D Kernel** (see Chapter 7)

*Comparison\_result*      *compare\_y\_at\_x*( *Point\_2<Kernel>* *p*, *Line\_2<Kernel>* *h*)

compares the *y*-coordinates of *p* and the vertical projection of *p* on *h* (Figure 7.4 (d)).

*Precondition: h* is not vertical.

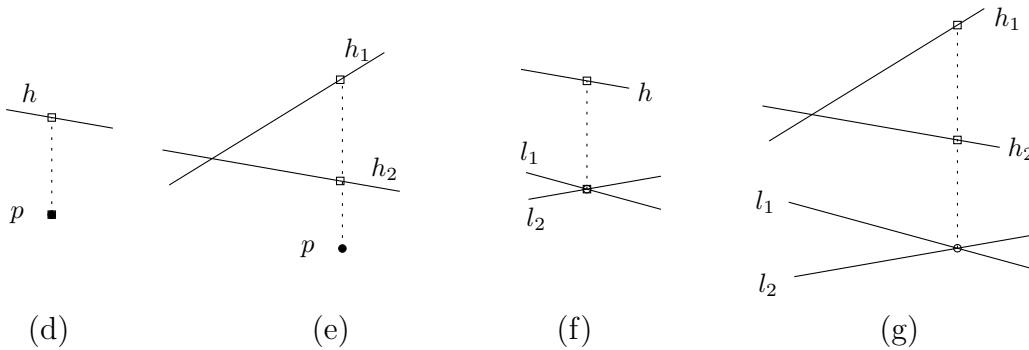

Figure 7.4: Comparison of the *y*-coordinates of the (implicitly given) points in the boxes, at an *x*-coordinate. The *x*-coordinate is either given explicitly (disc) or implicitly (circle).

*Comparison\_result*      *compare\_y\_at\_x*( *Point\_2<Kernel>* *p*, *Line\_2<Kernel>* *h1*, *Line\_2<Kernel>* *h2*)

compares the *y*-coordinates of the vertical projection of *p* on *h1* and on *h2* (Figure 7.4 (e)).

*Precondition: h1* and *h2* are not vertical.

*Comparison\_result*      *compare\_y\_at\_x*( *Line\_2<Kernel>* *l1*, *Line\_2<Kernel>* *l2*, *Line\_2<Kernel>* *h*)

Let *p* be the intersection of lines *l1* and *l2*. This function compares the *y*-coordinates of *p* and the vertical projection of *p* on *h* (Figure 7.4 (f)).

*Precondition: l1, l2* intersect and *h* is not vertical.

*Comparison\_result*      *compare\_y\_at\_x*( *Line\_2<Kernel>* *l1*,  
*Line\_2<Kernel>* *l2*,  
*Line\_2<Kernel>* *h1*,  
*Line\_2<Kernel>* *h2*)

Let *p* be the intersection of lines *l1* and *l2*. This function compares the *y*-coordinates of the vertical projection of *p* on *h1* and on *h2* (Figure 7.4 (g)).

*Precondition: l1* and *l2* intersect; *h1* and *h2* are not vertical.

<i>Comparison_result</i>	<code>compare_y_at_x( Point_2&lt;Kernel&gt; p, Segment_2&lt;Kernel&gt; s)</code>	<p>compares the y-coordinates of <math>p</math> and the vertical projection of <math>p</math> on <math>s</math>. If <math>s</math> is vertical, then return <i>EQUAL</i> when <math>p</math> lies on <math>s</math>, <i>SMALLER</i> when <math>p</math> lies under <math>s</math>, and <i>LARGER</i> otherwise.</p> <p><i>Precondition:</i> <math>p</math> is within the x range of <math>s</math>.</p>
--------------------------	--	---

<i>Comparison_result</i>	<code>compare_y_at_x( Point_2&lt;Kernel&gt; p, Segment_2&lt;Kernel&gt; s1, Segment_2&lt;Kernel&gt; s2)</code>	<p>compares the y-coordinates of the vertical projection of <math>p</math> on <math>s1</math> and on <math>s2</math>. If <math>s1</math> or <math>s2</math> is vertical, then return <i>EQUAL</i> if they intersect, otherwise return <i>SMALLER</i> if <math>s1</math> lies below <math>s2</math>, and return <i>LARGER</i> otherwise.</p> <p><i>Precondition:</i> <math>p</math> is within the x range of <math>s1</math> and <math>s2</math>.</p>
--------------------------	---	--

**With the 2D Circular Kernel** (see Chapter 9)

`#include <CGAL/global_functions_circular_kernel_2.h>`

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

<i>Comparison_result</i>	<code>compare_y_at_x( Circular_arc_point_2&lt;CircularKernel&gt; p, Circular_arc_2&lt;CircularKernel&gt; a)</code>	<p>Same as above, for a point and a circular arc.</p>
--------------------------	--	---

<i>Comparison_result</i>	<code>compare_y_at_x( Circular_arc_point_2&lt;CircularKernel&gt; p, Line_arc_2&lt;CircularKernel&gt; a)</code>	<p>Same as above, for a point and a line segment.</p>
--------------------------	--	---

<code>CGAL::compare_z</code> .....	page 465

## CGAL::compare\_yx

*Comparison\_result*      *compare\_yx*( *Point\_2<Kernel> p*, *Point\_2<Kernel> q* )

Compares the Cartesian coordinates of points  $p$  and  $q$  lexicographically in  $yx$  order: first  $y$ -coordinates are compared, if they are equal,  $x$ -coordinates are compared.

## CGAL::compare\_z

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

**With the basic 3D Kernel** (see Chapter 7)

*Comparison\_result*      `compare_z( Point_3<Kernel> p, Point_3<Kernel> q)`  
 compares the  $z$ -coordinates of  $p$  and  $q$ .

**With the 3D Spherical Kernel** (see Chapter 10)

`#include <CGAL/global_functions_spherical_kernel_3.h>`

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

*Comparison\_result*      `compare_z( Circular_arc_point_3<SphericalKernel> p,  
    Circular_arc_point_3<SphericalKernel> q)`  
 compares the  $z$ -coordinates of  $p$  and  $q$ .

*Comparison\_result*      `compare_z( Circular_arc_point_3<SphericalKernel> p,  
    Point_3<SphericalKernel> q)`  
 compares the  $z$ -coordinates of  $p$  and  $q$ .

## CGAL::coplanar

*bool*

```
coplanar( Point_3<Kernel> p,  
          Point_3<Kernel> q,  
          Point_3<Kernel> r,  
          Point_3<Kernel> s)
```

returns *true*, if  $p$ ,  $q$ ,  $r$ , and  $s$  are coplanar.

### See Also

*CGAL::coplanar\_orientation* ..... page [467](#)  
*CGAL::coplanar\_side\_of\_bounded\_circle* ..... page [468](#)

## CGAL::coplanar\_orientation

## Orientation

```
coplanar_orientation( Point_3<Kernel> p,
                      Point_3<Kernel> q,
                      Point_3<Kernel> r,
                      Point_3<Kernel> s)
```

Let  $P$  be the plane defined by the points  $p$ ,  $q$ , and  $r$ . Note that the order defines the orientation of  $P$ . The function computes the orientation of points  $p$ ,  $q$ , and  $s$  in  $P$ : If  $p$ ,  $q$ ,  $s$  are collinear, *COLLINEAR* is returned. If  $P$  and the plane defined by  $p$ ,  $q$ , and  $s$  have the same orientation, *POSITIVE* is returned; otherwise *NEGATIVE* is returned. *Precondition*:  $p$ ,  $q$ ,  $r$ , and  $s$  are coplanar and  $p$ ,  $q$ , and  $r$  are not collinear.

### Orientation

```
coplanar_orientation( Point_3<Kernel> p,
                      Point_3<Kernel> q,
                      Point_3<Kernel> r)
```

If  $p, q, r$  are collinear, then *COLLINEAR* is returned. If not, then  $p, q, r$  define a plane  $P$ . The return value in this case is either *POSITIVE* or *NEGATIVE*, but we don't specify it explicitly. However, we guarantee that all calls to this predicate over 3 points in  $P$  will return a coherent orientation if considered a 2D orientation in  $P$ .

## See Also

<i>CGAL::orientation</i> .....	page 850

## CGAL::coplanar\_side\_of\_bounded\_circle

```
Bounded_side          coplanar_side_of_bounded_circle( Point_3<Kernel> p,
```

*Point\_3<Kernel> q,*

*Point\_3<Kernel> r,*

*Point\_3<Kernel> s)*

returns the bounded side of the circle defined by  $p$ ,  $q$ , and  $r$  on which  $s$  lies.

*Precondition:*  $p$ ,  $q$ ,  $r$ , and  $s$  are coplanar and  $p$ ,  $q$ , and  $r$  are not collinear.

## CGAL::cross\_product

*Vector\_3<Kernel>*      *cross\_product*( *Vector\_3<Kernel> u*, *Vector\_3<Kernel> v* )  
returns the cross product of *u* and *v*.

*Kernel::FT*      *determinant*( *Vector\_3<Kernel> u*, *Vector\_3<Kernel> v*, *Vector\_3<Kernel> w* )

returns the determinant of *u*, *v* and *w*.

<i>CGAL::orientation</i> .....	page 850
<i>CGAL::collinear</i> .....	page 444
<i>CGAL::left_turn</i> .....	page 487
<i>CGAL::right_turn</i> .....	page 509

## CGAL::do\_intersect

*bool* *do\_intersect*( *Type1 obj1*, *Type2 obj2*)

checks whether *obj1* and *obj2* intersect. Two objects *obj1* and *obj2* intersect if there is a point  $p$  that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points  $p$  that are part of both *obj1* and *obj2*. Note that for objects like triangles and polygons that enclose a bounded region, this region is part of the object.

Depending on which CGAL kernel is used, *Type1* and *Type2* can be of different types.

**With the basic 2D and 3D Kernel** (see Chapter 7)

```
#include <CGAL/intersections.h>
```

The types *Type1* and *Type2* can be any of the following:

- *Point\_2<Kernel>*
- *Line\_2<Kernel>*
- *Ray\_2<Kernel>*
- *Segment\_2<Kernel>*
- *Triangle\_2<Kernel>*
- *Iso\_rectangle\_2<Kernel>*

Also, *Type1* and *Type2* can be both of type

- *Line\_2<Kernel>*
- *Circle\_2<Kernel>*

In three-dimensional space, *Type1* can be *Plane\_3<Kernel>* or *Triangle\_3<Kernel>* and *Type2* any of

- *Plane\_3<Kernel>*
- *Line\_3<Kernel>*
- *Ray\_3<Kernel>*
- *Segment\_3<Kernel>*
- *Triangle\_3<Kernel>*

Also, *Type1* and *Type2* can be respectively of types

- *Triangle\_3<Kernel>* and *Tetrahedron\_3<Kernel>*
- *Line\_3<Kernel>* and *Line\_3<Kernel>*
- *Plane\_3<Kernel>* and *Sphere\_3<Kernel>* (or the contrary)
- *Sphere\_3<Kernel>* and *Sphere\_3<Kernel>*.

### With the 2D Circular Kernel (see Chapter 9)

```
#include <CGAL/Circular_kernel_intersections.h>
```

If this kernel is used, in addition to the combinations of 2D types previously listed, *Type1* and *Type2* can be any of the following:

- *Line\_2*<*CircularKernel*>
- *Circle\_2*<*CircularKernel*>
- *Line\_arc\_2*<*CircularKernel*>
- *Circular\_arc\_2*<*CircularKernel*>

An example illustrating this is presented in Chapter 9.

### With the 3D Spherical Kernel (see Chapter 10)

```
#include <CGAL/Spherical_kernel_intersections.h>
```

If this kernel is used, in addition to the combinations of 3D types previously listed, *Type1* and *Type2* can be any of the following:

- *Line\_3*<*SphericalKernel*>
- *Circle\_3*<*SphericalKernel*>
- *Plane\_3*<*SphericalKernel*>
- *Sphere\_3*<*SphericalKernel*>
- *Line\_arc\_3*<*SphericalKernel*>
- *Circular\_arc\_3*<*SphericalKernel*>

An example illustrating this is presented in Chapter 10.

Also, another predicate is provided with this kernel:

```
bool do_intersect( Type1 obj1, Type2 obj2, Type3 obj3)
```

checks whether *obj1*, *obj2* and *obj3* intersect.

where *Type1*, *Type2* and *Type3* can be:

- *Sphere\_3*<*SphericalKernel*>
- *Plane\_3*<*SphericalKernel*>

### See Also

## CGAL::do\_overlap

*#include* <CGAL/Bbox\_2.h>

*bool* *do\_overlap*( *Bbox\_2* *bb1*, *Bbox\_2* *bb2* )

returns *true* iff *bb1* and *bb2* overlap, i.e., iff their intersection is non-empty.

*#include* <CGAL/Bbox\_3.h>

*bool* *do\_overlap*( *Bbox\_3* *bb1*, *Bbox\_3* *bb2* )

returns *true* iff *bb1* and *bb2* overlap, i.e., iff their intersection is non-empty.

## CGAL::enum\_cast

```
#include <CGAL/enum.h>
```

```
template < typename T, typename U >
```

```
T          enum_cast( U u)
```

converts between the various enums provided by the CGAL kernel. The conversion preserves the order of the values.

## CGAL::equidistant\_line

*Line\_3<Kernel>*                    *equidistant\_line( Point\_3<Kernel> p, Point\_3<Kernel> q, Point\_3<Kernel> r)*

constructs the line which is at the same distance from the three points  $p$ ,  $q$  and  $r$ .

*Precondition:*  $p$ ,  $q$  and  $r$  are not collinear.

## CGAL::has\_larger\_distance\_to\_point

*bool* *has\_larger\_distance\_to\_point*( *Point\_2*<*Kernel*> *p*,  
*Point\_2*<*Kernel*> *q*,  
*Point\_2*<*Kernel*> *r*)

returns *true* iff the distance between *q* and *p* is larger than the distance between *r* and *p*.

*bool* *has\_larger\_distance\_to\_point*( *Point\_3*<*Kernel*> *p*,  
*Point\_3*<*Kernel*> *q*,  
*Point\_3*<*Kernel*> *r*)

returns *true* iff the distance between *q* and *p* is larger than the distance between *r* and *p*.

## CGAL::has\_larger\_signed\_distance\_to\_line

*bool* *has\_larger\_signed\_distance\_to\_line*( *Line\_2*<*Kernel*> *l*,  
*Point\_2*<*Kernel*> *p*,  
*Point\_2*<*Kernel*> *q*)

returns *true* iff the signed distance of *p* and *l* is larger than the signed distance of *q* and *l*.

*bool* *has\_larger\_signed\_distance\_to\_line*( *Point\_2*<*Kernel*> *p*,  
*Point\_2*<*Kernel*> *q*,  
*Point\_2*<*Kernel*> *r*,  
*Point\_2*<*Kernel*> *s*)

returns *true* iff the signed distance of *r* and *l* is larger than the signed distance of *s* and *l*, where *l* is the directed line through points *p* and *q*.

## CGAL::intersection

Depending on which CGAL kernel is used, different versions of this global function are available. This is described below.

**With the basic 2D and 3D Kernel** (see Chapter 7)

```
#include <CGAL/intersections.h>
```

*Object*                      *intersection( Type1<Kernel> obj1, Type2<Kernel> obj2)*

Two objects *obj1* and *obj2* intersect if there is a point *p* that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points *p* that are part of both *obj1* and *obj2*. Note that for objects like triangles and polygons that enclose a bounded region, this region is considered part of the object. If a segment lies completely inside a triangle, then those two objects intersect and the intersection region is the complete segment.

The possible value for types *Type1* and *Type2* and the possible return values wrapped in *Object* are the following:

type A	type B	return type
<i>Line_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Line_2</i>
<i>Segment_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Segment_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Ray_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Ray_2</i>
<i>Ray_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Ray_2</i>	<i>Ray_2</i>	<i>Point_2</i> <i>Segment_2</i> <i>Ray_2</i>
<i>Triangle_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Triangle_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Triangle_2</i>	<i>Ray_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Triangle_2</i>	<i>Triangle_2</i>	<i>Point_2</i> <i>Segment_2</i> <i>Triangle_2</i> <i>std::vector&lt;Point_2&gt;</i>

*continued*

<i>Iso_rectangle_2</i>	<i>Line_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Iso_rectangle_2</i>	<i>Segment_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Iso_rectangle_2</i>	<i>Ray_2</i>	<i>Point_2</i> <i>Segment_2</i>
<i>Iso_rectangle_2</i>	<i>Iso_rectangle_2</i>	<i>Iso_rectangle_2</i>
<i>Line_3</i>	<i>Line_3</i>	<i>Point_3</i> <i>Line_3</i>
<i>Plane_3</i>	<i>Line_3</i>	<i>Point_3</i> <i>Line_3</i>
<i>Plane_3</i>	<i>Ray_3</i>	<i>Point_3</i> <i>Ray_3</i>
<i>Plane_3</i>	<i>Segment_3</i>	<i>Point_3</i> <i>Segment_3</i>
<i>Plane_3</i>	<i>Plane_3</i>	<i>Line_3</i> <i>Plane_3</i>
<i>Plane_3</i>	<i>Sphere_3</i>	<i>Point_3</i> <i>Circle_3</i>
<i>Sphere_3</i>	<i>Sphere_3</i>	<i>Point_3</i> <i>Circle_3</i> <i>Sphere_3</i>

There is also an intersection function between 3 planes.

<i>Object</i>	<i>intersection( Plane_3&lt;Kernel&gt; pl1, Plane_3&lt;Kernel&gt; pl2, Plane_3&lt;Kernel&gt; pl3)</i>
---------------	---

returns the intersection of 3 planes, which can be either a point, a line, a plane, or empty.

### With the 2D Circular Kernel (see Chapter 9)

```
#include <CGAL/Circular_kernel_intersections.h>
```

If this kernel is used, in addition to the function and the combination of 2D types described above, another version of the function is provided.

Since both the number of intersections, if any, and their type, depend on the arguments, the function returns an output iterator on *Object*'s, as presented below.

```
template < class OutputIterator >
OutputIterator      intersection( Type1 obj1, Type2 obj2, OutputIterator intersections)
```

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order,

where *Type1* and *Type2* can both be either

- *Line\_2<CircularKernel>* or
- *Line\_arc\_2<CircularKernel>* or
- *Circle\_2<CircularKernel>* or
- *Circular\_arc\_2<CircularKernel>*.

Depending on the types *Type1* and *Type2*, these elements can be assigned to

- *std::pair<Circular\_arc\_point\_2<CircularKernel>, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj1* and *obj2*,
- *Circular\_arc\_2<CircularKernel>* in case of an overlap of two circular arcs,
- *Line\_arc\_2<CircularKernel>* in case of an overlap of two line segments or
- *Line\_2<CircularKernel>* or *Circle\_2<CircularKernel>* in case of two equal input lines or circles.

### With the 3D Spherical Kernel (see Chapter 10)

```
#include <CGAL/Spherical_kernel_intersections.h>
```

If this kernel is used, in addition to the function and the combination of 3D types described above, two other versions of the function are provided.

Since both the number of intersections, if any, and their type, depend on the arguments, the functions return an output iterator on *Object*'s, as presented below.

The **first function** is:

```
template < class OutputIterator >
OutputIterator intersection( Type1 obj1, Type2 obj2, OutputIterator intersections)
```

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order, when this ordering is defined on the computed objects,

where *Type1* and *Type2* can both be either:

- *Sphere\_3<SphericalKernel>*,
- *Plane\_3<SphericalKernel>*,
- *Line\_3<SphericalKernel>*,
- *Circle\_3<SphericalKernel>*,
- *Line\_arc\_3<SphericalKernel>* or
- *Circular\_arc\_3<SphericalKernel>*,

and depending on the types *Type1* and *Type2*, the computed *CGAL::Objects* can be assigned to

- *std::pair<Circular\_arc\_point\_3<SphericalKernel>, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj1* and *obj2*,
- *Type1*, when *Type1* and *Type2* are equal, and if the two objects *obj1* and *obj2* are equal,
- *Line\_3<SphericalKernel>* or *Circle\_3<SphericalKernel>* when *Type1* and *Type2* are two-dimensional objects intersecting along a curve (2 planes, or 2 spheres, or one plane and one sphere),
- *Circular\_arc\_3<SphericalKernel>* in case of an overlap of two circular arcs or
- *Line\_arc\_3<SphericalKernel>* in case of an overlap of two line segments.

The **second function** is:

```
template < class OutputIterator >
OutputIterator      intersection( Type1 obj1, Type2 obj2, Type3 obj3, OutputIterator intersections)
```

Copies in the output iterator the intersection elements between the three objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order when this ordering is defined on the computed objects

where *Type1*, *Type2* and *Type3* can be either

- *Sphere\_3<SphericalKernel>* or
- *Plane\_3<SphericalKernel>*

and depending of these types, the computed *CGAL::Objects* can be assigned to

- *std::pair<Circular\_arc\_point\_3<SphericalKernel>, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point,
- *Circle\_3<SphericalKernel>* or
- *Type1*, when *Type1*, *Type2* and *Type3* are equal, and if the three objects *obj1* and *obj2* and *obj3* are equal.

## Example

The following example demonstrates the most common use of *intersection* routines with the basic 2D and 3D Kernels.

```
#include <CGAL/intersections.h>

void foo(CGAL::Segment_2<Kernel> seg, CGAL::Line_2<Kernel> line)
{
    CGAL::Object result = CGAL::intersection(seg, line);
    if (const CGAL::Point_2<Kernel> *ipoint = CGAL::object_cast<CGAL::Point_2<Kernel>>(&result)) {

        // handle the point intersection case with *ipoint.
```

```

    } else
        if (const CGAL::Segment_2<Kernel> *iseg = CGAL::object_cast<CGAL::Segment_2<Kernel> >(&result)) {

            // handle the segment intersection case with *iseg.

        } else {

            // handle the no intersection case.
        }
    }
}

```

Examples illustrating the use of this function in the case of the 2D Circular Kernel and the 3D Spherical Kernel are presented respectively in Chapters [9](#) and [10](#).

## CGAL::lexicographically\_xyz\_smaller\_or\_equal

*bool* *lexicographically\_xyz\_smaller\_or\_equal*( *Point\_3*<*Kernel*> *p*, *Point\_3*<*Kernel*> *q*)  
returns *true* iff *p* is lexicographically not larger than *q*  
with respect to *xyz* order.

### See Also

*CGAL::compare\_xyz* ..... page [457](#)  
*CGAL::lexicographically\_xyz\_smaller* ..... page [488](#)

## CGAL::lexicographically\_xy\_larger

*bool*

*lexicographically\_xy\_larger( Point\_2<Kernel> p, Point\_2<Kernel> q)*

returns *true* iff *p* is lexicographically larger than *q* with respect to *xy* order.

### See Also

*CGAL::compare\_xy* ..... page [455](#)

**CGAL::max\_vertex**

*Point\_2<Kernel>*      *max\_vertex( Iso\_box\_2<Kernel> ir)*

computes the vertex with the lexicographically largest coordinates of the iso rectangle *ir*.

*Point\_3<Kernel>*      *max\_vertex( Iso\_cuboid\_3<Kernel> ic)*

computes the vertex with the lexicographically largest coordinates of the iso cuboid *ic*.

## CGAL::midpoint

*Point\_2<Kernel>*      *midpoint( Point\_2<Kernel> p, Point\_2<Kernel> q)*  
computes the midpoint of the segment  $pq$ .

*Point\_3<Kernel>*      *midpoint( Point\_3<Kernel> p, Point\_3<Kernel> q)*  
computes the midpoint of the segment  $pq$ .

**CGAL::normal**

*Vector\_3<Kernel>*      *normal( Point\_3<Kernel> p, Point\_3<Kernel> q, Point\_3<Kernel> r)*

computes the normal vector for the vectors  $q-p$  and  $r-p$ .  
*Precondition:* The points  $p$ ,  $q$ , and  $r$  must not be collinear.

## CGAL::min\_vertex

*Point\_2<Kernel>*      *min\_vertex( Iso\_box\_2<Kernel> ir)*

computes the vertex with the lexicographically smallest coordinates of the iso rectangle *ir*.

*Point\_3<Kernel>*      *min\_vertex( Iso\_cuboid\_3<Kernel> ic)*

computes the vertex with the lexicographically smallest coordinates of the iso cuboid *ic*.

**CGAL::operator+**

*Point\_2<Kernel>*      *operator+( Point\_2<Kernel> p, Vector\_2<Kernel> v)*

returns the point obtained by translating  $p$  by vector  $v$ .

*Point\_3<Kernel>*      *operator+( Point\_3<Kernel> p, Vector\_3<Kernel> v)*

returns a point obtained by translating  $p$  by vector  $v$ .

**See Also**

*CGAL::operator-* ..... [page 499](#)  
*CGAL::operator\** ..... [page 500](#)

## CGAL::operator-

*Vector\_2<Kernel>*      *operator-( Point\_2<Kernel> p, Point\_2<Kernel> q)*

returns the difference vector between  $q$  and  $p$ . You can substitute *ORIGIN* for either  $p$  or  $q$ , but not for both.

*Point\_2<Kernel>*      *operator-( Point\_2<Kernel> p, Vector\_2<Kernel> v)*

returns the point obtained by translating  $p$  by the vector  $-v$ .

*Vector\_3<Kernel>*      *operator-( Point\_3<Kernel> p, Point\_3<Kernel> q)*

returns the difference vector between  $q$  and  $p$ . You can substitute *ORIGIN* for either  $p$  or  $q$ , but not both.

*Point\_3<Kernel>*      *operator-( Point\_3<Kernel> p, Vector\_3<Kernel> v)*

returns a point obtained by translating  $p$  by the vector  $-v$ .

### See Also

*CGAL::operator+* ..... page 498  
*CGAL::operator\** ..... page 500

## CGAL::operator\*

*Vector\_2<Kernel>*     *operator\*( Kernel::RT s, Vector\_2<Kernel> w)*

Multiplication with a scalar from the left.

*Vector\_3<Kernel>*     *operator\*( Kernel::RT s, Vector\_3<Kernel> w)*

Multiplication with a scalar from the left.

### See Also

*CGAL::operator+* ..... page [498](#)  
*CGAL::operator-* ..... page [499](#)

## CGAL::opposite

*#include <CGAL/enum.h>*

*Oriented\_side*                      *opposite( Oriented\_side o)*

returns the opposite side (for example *ON\_POSITIVE\_SIDE* if *o==ON\_NEGATIVE\_SIDE*), or *ON\_ORIENTED\_BOUNDARY* if *o==ON\_ORIENTED\_BOUNDARY*.

*Bounded\_side*                      *opposite( Bounded\_side o)*

returns the opposite side (for example *BOUNDED\_SIDE* if *o==UNBOUNDED\_SIDE*), or returns *ON\_BOUNDARY* if *o==ON\_BOUNDARY*.

## CGAL::orthogonal\_vector

*Vector\_3<Kernel>*      *orthogonal\_vector( Plane\_3<Kernel> p )*

computes an orthogonal vector of the plane  $p$ , which is directed to the positive side of this plane.

*Vector\_3<Kernel>*      *orthogonal\_vector( Point\_3<Kernel> p, Point\_3<Kernel> q, Point\_3<Kernel> r )*

computes an orthogonal vector of the plane defined by  $p$ ,  $q$  and  $r$ , which is directed to the positive side of this plane.

## CGAL::orientation

<i>Orientation</i>	<i>orientation</i> ( <i>Point_2</i> < <i>Kernel</i> > <i>p</i> , <i>Point_2</i> < <i>Kernel</i> > <i>q</i> , <i>Point_2</i> < <i>Kernel</i> > <i>r</i> )	returns <i>LEFT_TURN</i> , if <i>r</i> lies to the left of the oriented line <i>l</i> defined by <i>p</i> and <i>q</i> , returns <i>RIGHT_TURN</i> if <i>r</i> lies to the right of <i>l</i> , and returns <i>COLLINEAR</i> if <i>r</i> lies on <i>l</i> .
<i>Orientation</i>	<i>orientation</i> ( <i>Vector_2</i> < <i>Kernel</i> > <i>u</i> , <i>Vector_2</i> < <i>Kernel</i> > <i>v</i> )	returns <i>LEFT_TURN</i> if <i>u</i> and <i>v</i> form a left turn, returns <i>RIGHT_TURN</i> if <i>u</i> and <i>v</i> form a right turn, and returns <i>COLLINEAR</i> if <i>u</i> and <i>v</i> are collinear.
<i>Orientation</i>	<i>orientation</i> ( <i>Point_3</i> < <i>Kernel</i> > <i>p</i> , <i>Point_3</i> < <i>Kernel</i> > <i>q</i> , <i>Point_3</i> < <i>Kernel</i> > <i>r</i> , <i>Point_3</i> < <i>Kernel</i> > <i>s</i> )	returns <i>POSITIVE</i> , if <i>s</i> lies on the positive side of the oriented plane <i>h</i> defined by <i>p</i> , <i>q</i> , and <i>r</i> , returns <i>NEGATIVE</i> if <i>s</i> lies on the negative side of <i>h</i> , and returns <i>COPLANAR</i> if <i>s</i> lies on <i>h</i> .
<i>Orientation</i>	<i>orientation</i> ( <i>Vector_3</i> < <i>Kernel</i> > <i>u</i> , <i>Vector_3</i> < <i>Kernel</i> > <i>v</i> , <i>Vector_3</i> < <i>Kernel</i> > <i>w</i> )	returns <i>POSITIVE</i> if <i>u</i> , <i>v</i> and <i>w</i> are positively oriented, returns <i>NEGATIVE</i> if <i>u</i> , <i>v</i> and <i>w</i> are negatively oriented, and returns <i>COPLANAR</i> if <i>u</i> , <i>v</i> and <i>w</i> are coplanar.

**CGAL::parallel**

<i>bool</i>	<i>parallel( Line_2&lt;Kernel&gt; l1, Line_2&lt;Kernel&gt; l2)</i>	returns <i>true</i> , if <i>l1</i> and <i>l2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel( Ray_2&lt;Kernel&gt; r1, Ray_2&lt;Kernel&gt; r2)</i>	returns <i>true</i> , if <i>r1</i> and <i>r2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel( Segment_2&lt;Kernel&gt; s1, Segment_2&lt;Kernel&gt; s2)</i>	returns <i>true</i> , if <i>s1</i> and <i>s2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel( Line_3&lt;Kernel&gt; l1, Line_3&lt;Kernel&gt; l2)</i>	returns <i>true</i> , if <i>l1</i> and <i>l2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel( Plane_3&lt;Kernel&gt; h1, Plane_3&lt;Kernel&gt; h2)</i>	returns <i>true</i> , if <i>h1</i> and <i>h2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel( Ray_3&lt;Kernel&gt; r1, Ray_3&lt;Kernel&gt; r2)</i>	returns <i>true</i> , if <i>r1</i> and <i>r2</i> are parallel or if one of those (or both) is degenerate.
<i>bool</i>	<i>parallel( Segment_3&lt;Kernel&gt; s1, Segment_3&lt;Kernel&gt; s2)</i>	returns <i>true</i> , if <i>s1</i> and <i>s2</i> are parallel or if one of those (or both) is degenerate.

## CGAL::quotient\_cartesian\_to\_homogeneous

```
#include <CGAL/cartesian_homogeneous_conversion.h>
```

```
Point_2< Homogeneous<RT> >
```

```
quotient_cartesian_to_homogeneous( Point_2< Cartesian< Quotient<RT> > > cp)
```

converts 2d point *cp* with Cartesian representation with number type *Quotient<RT>* into a 2d point with homogeneous representation with number type *RT*.

```
Point_3< Homogeneous<RT> >
```

```
quotient_cartesian_to_homogeneous( Point_3< Cartesian< Quotient<RT> > > cp)
```

converts 3d point *cp* with Cartesian representation with number type *Quotient<RT>* into a 3d point with homogeneous representation with number type *RT*.

## CGAL::radical\_plane

*Plane\_3<Kernel>*      *radical\_plane( Sphere\_3<Kernel> s1, Sphere\_3<Kernel> s2)*

returns the radical plane of the two spheres.

*Precondition:* *s1* and *s2* are not cocentric.

## CGAL::radical\_line

*Line\_2<Kernel>*      *radical\_line( Circle\_2<Kernel> c1, Circle\_2<Kernel> c2)*

returns the radical line of the two circles.  
*Precondition:* *c1* and *c2* are not cocentric.

## CGAL::rational\_rotation\_approximation

```
#include <CGAL/rational_rotation.h>
```

```
template <RingNumberType>
void rational_rotation_approximation( RingNumberType dirx,
                                     RingNumberType diry,
                                     RingNumberType & sin_num,
                                     RingNumberType & cos_num,
                                     RingNumberType & denom,
                                     RingNumberType eps_num,
                                     RingNumberType eps_den)
```

computes integers *sin\_num*, *cos\_num* and *denom*, such that *sin\_num/denom* approximates the sine of direction (*dirx,diry*). The difference between the sine and the approximating rational is bounded by *eps\_num/eps\_den*.

*Precondition:* *eps\_num*  $\neq$  0.

### Implementation

The approximation is based on Farey sequences as described in the rational rotation method presented by Canny and Ressler at the 8th SoCG 1992. We use a slower version which needs no division operation in the approximation.

## CGAL::right\_turn

*bool* *right\_turn*( *Point\_2<Kernel> p*, *Point\_2<Kernel> q*, *Point\_2<Kernel> r* )  
returns *true* iff *p*, *q*, and *r* form a right turn.

### See Also

*CGAL::collinear* ..... page [444](#)  
*CGAL::left\_turn* ..... page [487](#)

## CGAL::side\_of\_bounded\_circle

*Bounded\_side*

*side\_of\_bounded\_circle*( *Point\_2*<*Kernel*> *p*,  
*Point\_2*<*Kernel*> *q*,  
*Point\_2*<*Kernel*> *r*,  
*Point\_2*<*Kernel*> *t*)

returns the relative position of point *t* to the circle defined by *p*, *q* and *r*. The order of the points *p*, *q* and *r* does not matter.

*Precondition:* *p*, *q* and *r* are not collinear.

*Bounded\_side*

*side\_of\_bounded\_circle*( *Point\_2*<*Kernel*> *p*,  
*Point\_2*<*Kernel*> *q*,  
*Point\_2*<*Kernel*> *t*)

returns the position of the point *t* relative to the circle that has *pq* as its diameter.

### See Also

*CGAL::coplanar\_side\_of\_bounded\_circle* ..... page [468](#)  
*CGAL::side\_of\_oriented\_circle* ..... page [512](#)

## CGAL::side\_of\_bounded\_sphere

$$Bounded\_side \quad side\_of\_bounded\_sphere( Point\_3<Kernel> p,$$
$$Point\_3<Kernel> q,$$
$$Point\_3<Kernel> r,$$
$$Point\_3<Kernel> s,$$
$$Point\_3<Kernel> t)$$

returns the relative position of point  $t$  to the sphere defined by  $p, q, r$ , and  $s$ . The order of the points  $p, q, r$ , and  $s$  does not matter.

*Precondition:*  $p, q, r$  and  $s$  are not coplanar.

*Bounded\_side*                  *side\_of\_bounded\_sphere*( Point\_3<Kernel> p,  
Point\_3<Kernel> q,  
Point\_3<Kernel> r,  
Point\_3<Kernel> t)

returns the position of the point  $t$  relative to the sphere passing through  $p$ ,  $q$ , and  $r$  and whose center is in the plane defined by these three points.

$$\text{Bounded\_side} \quad \text{side\_of\_bounded\_sphere}( \text{Point\_3}\langle\text{Kernel}\rangle p, \\ \text{Point\_3}\langle\text{Kernel}\rangle q, \\ \text{Point\_3}\langle\text{Kernel}\rangle t )$$

returns the position of the point  $t$  relative to the sphere that has  $pq$  as its diameter.

## See Also

CGAL::side\_of\_oriented\_sphere ..... page 853

*Oriented\_side*                  side\_of\_oriented\_circle( Point\_2<Kernel> p,  
Point\_2<Kernel> q,  
Point\_2<Kernel> r,  
Point\_2<Kernel> test)

returns the relative position of point *test* to the oriented circle defined by *p*, *q* and *r*. The order of the points *p*, *q* and *r* is important, since it determines the orientation of the implicitly constructed circle.

*Precondition:*  $p$ ,  $q$  and  $r$  are not collinear.

## See Also

CGAL::side\_of\_bounded\_circle.....page 510

## CGAL::squared\_area

*Kernel::FT*

*squared\_area( Point\_3<Kernel> p, Point\_3<Kernel> q, Point\_3<Kernel> r)*

returns the squared area of the triangle defined by the points  $p$ ,  $q$  and  $r$ .

## CGAL::squared\_distance

```
#include <CGAL/squared_distance_2.h>
#include <CGAL/squared_distance_3.h>
```

```
Kernel::FT          squared_distance( Type1<Kernel> obj1, Type2<Kernel> obj2)
```

computes the square of the Euclidean distance between two geometric objects. For arbitrary geometric objects *obj1* and *obj2* the squared distance is defined as the minimal *squared\_distance(p1, p2)*, where *p1* is a point of *obj1* and *p2* is a point of *obj2*. Note that for objects that have an inside (a bounded region), this inside is part of the object. So, the squared distance from a point inside is zero, not the squared distance to the closest point on the boundary.

In 2D, the types *Type1* and *Type2* can be any of the following:

- *Point\_2*
- *Line\_2*
- *Ray\_2*
- *Segment\_2*
- *Triangle\_2*

In 3D, the types *Type1* and *Type2* can be any of the following:

- *Point\_3*
- *Line\_3*
- *Ray\_3*
- *Segment\_3*
- *Plane\_3*

**CGAL::squared\_radius**

*FT* `squared_radius( Point_2<Kernel> p, Point_2<Kernel> q, Point_2<Kernel> r)`

compute the squared radius of the circle passing through the points  $p$ ,  $q$ , and  $r$ .  
*Precondition:*  $p$ ,  $q$ , and  $r$  are not collinear.

*FT* `squared_radius( Point_2<Kernel> p, Point_2<Kernel> q)`

compute the squared radius of the smallest circle passing through  $p$ , and  $q$ , i.e. one fourth of the squared distance between  $p$  and  $q$ .

*FT* `squared_radius( Point_3<Kernel> p,  
Point_3<Kernel> q,  
Point_3<Kernel> r,  
Point_3<Kernel> s)`

compute the squared radius of the sphere passing through the points  $p$ ,  $q$ ,  $r$  and  $s$ .  
*Precondition:*  $p$ ,  $q$ ,  $r$  and  $s$  are not coplanar.

*FT* `squared_radius( Point_3<Kernel> p, Point_3<Kernel> q, Point_3<Kernel> r)`

compute the squared radius of the sphere passing through the points  $p$ ,  $q$ , and  $r$  and whose center is in the same plane as those three points.

*FT* `squared_radius( Point_3<Kernel> p, Point_3<Kernel> q)`

compute the squared radius of the smallest circle passing through  $p$ , and  $q$ , i.e. one fourth of the squared distance between  $p$  and  $q$ .

**See Also**

## CGAL::unit\_normal

*Vector\_3<Kernel>*      *unit\_normal( Point\_3<Kernel> p, Point\_3<Kernel> q, Point\_3<Kernel> r )*

computes the unit normal vector for the vectors  $q-p$  and  $r-p$ .

*Precondition:* The points  $p$ ,  $q$ , and  $r$  must not be collinear.

## CGAL::volume

*Kernel::FT*                      *volume*( *Point\_3*<*Kernel*> *p0*,  
                                  *Point\_3*<*Kernel*> *p1*,  
                                  *Point\_3*<*Kernel*> *p2*,  
                                  *Point\_3*<*Kernel*> *p3*)

Computes the signed volume of the tetrahedron defined by the four points *p0*, *p1*, *p2* and *p3*.

### See Also

*CGAL::Tetrahedron\_3*<*Kernel*> .....page [413](#)

## CGAL::x\_equal

*bool* *x\_equal*( *Point\_2*<*Kernel*> *p*, *Point\_2*<*Kernel*> *q*)  
returns *true*, iff *p* and *q* have the same *x*-coordinate.

*bool* *x\_equal*( *Point\_3*<*Kernel*> *p*, *Point\_3*<*Kernel*> *q*)  
returns *true*, iff *p* and *q* have the same *x*-coordinate.

## **7.13 Kernel Function Object Concepts**

## Kernel::Angle\_2

A model for this must provide:

*Angle* *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*  
returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the  
angle formed by the three points *p*, *q*, *r* (*q* being the vertex  
of the angle).

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::angle* ..... [page 433](#)

## Kernel::Angle\_3

A model for this must provide:

*Angle* *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

returns *OBTUSE*, *RIGHT* or *ACUTE* depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle).

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::angle* .....page [433](#)

## Kernel::AreOrderedAlongLine\_2

A model for this must provide:

*bool* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Point\_2* *q*, *Kernel::Point\_2* *r*)

returns *true*, iff the three points are collinear and *q* lies between *p* and *r*. Note that *true* is returned, if  $q=p$  or  $q=r$ .

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::are\_ordered\_along\_line* ..... [page 434](#)

## Kernel::AreOrderedAlongLine\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

returns *true*, iff the three points are collinear and *q* lies between *p* and *r*. Note that *true* is returned, if  $q=p$  or  $q=r$ .

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::are\_ordered\_along\_line* ..... page [434](#)

## Kernel::AreParallel\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Line\_2 l1, Kernel::Line\_2 l2)*  
returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

*bool* *fo.operator()( Kernel::Ray\_2 r1, Kernel::Ray\_2 r2)*  
returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

*bool* *fo.operator()( Kernel::Segment\_2 s1, Kernel::Segment\_2 s2)*  
returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::parallel* .....page [504](#)

## Kernel::AreParallel\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Line\_3 l1, Kernel::Line\_3 l2)*  
returns *true*, if *l1* and *l2* are parallel or if one of those (or both) is degenerate.

*bool* *fo.operator()( Kernel::Plane\_3 h1, Kernel::Plane\_3 h2)*  
returns *true*, if *h1* and *h2* are parallel or if one of those (or both) is degenerate.

*bool* *fo.operator()( Kernel::Ray\_3 r1, Kernel::Ray\_3 r2)*  
returns *true*, if *r1* and *r2* are parallel or if one of those (or both) is degenerate.

*bool* *fo.operator()( Kernel::Segment\_3 s1, Kernel::Segment\_3 s2)*  
returns *true*, if *s1* and *s2* are parallel or if one of those (or both) is degenerate.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::parallel*.....page [504](#)

## Kernel::AreStrictlyOrderedAlongLine\_2

A model for this must provide:

*bool* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Point\_2* *q*, *Kernel::Point\_2* *r*)

returns *true*, iff the three points are collinear and *q* lies strictly between *p* and *r*. Note that *false* is returned, if  $q==p$  or  $q==r$ .

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::are\_strictly\_ordered\_along\_line* ..... [page 435](#)

## Kernel::AreStrictlyOrderedAlongLine\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*  
 returns *true*, iff the three points are collinear and *q* lies strictly between *p* and *r*. Note that *false* is returned, if  $q==p$  or  $q==r$ .

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::are\_strictly\_ordered\_along\_line* ..... page [435](#)

## Kernel::Assign\_2

A model for this must provide:

```
template <class T>
bool fo.operator()( T& t, Kernel::Object_2 o)
```

assigns *o* to *t* if *o* was constructed from an object of type *T*. Returns *true*, if the assignment was possible.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Object*.....page [3352](#)  
 Kernel::Object\_2.....page [530](#)  
 Kernel::Intersect\_2.....page [749](#)

## Kernel::Assign\_3

A model for this must provide:

```
template <class T>
bool fo.operator()( T& t, Kernel::Object_3 o)
```

assigns *o* to *t* if *o* was constructed from an object of type *T*. Returns *true*, if the assignment was possible.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Object*.....page [3352](#)

 Kernel::Intersect\_3.....page [750](#)

## Kernel::BoundedSide\_2

A model for this must provide:

*Bounded\_side*                      *fo.operator()( Kernel::Circle\_2 c, Kernel::Point\_2 p)*

returns either *ON\_UNBOUNDED\_SIDE*, *ON\_BOUNDED\_SIDE*, or the constant *ON\_BOUNDARY*, depending on where point *p* is relative to circle *c*.

*Bounded\_side*                      *fo.operator()( Kernel::Triangle\_2 t, Kernel::Point\_2 p)*

returns either *ON\_UNBOUNDED\_SIDE*, *ON\_BOUNDED\_SIDE*, or the constant *ON\_BOUNDARY*, depending on where point *p* is relative to triangle *t*.

*Bounded\_side*                      *fo.operator()( Kernel::Iso\_rectangle\_2 r, Kernel::Point\_2 p)*

returns either *ON\_UNBOUNDED\_SIDE*, *ON\_BOUNDED\_SIDE*, or the constant *ON\_BOUNDARY*, depending on where point *p* is relative to rectangle *r*.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

## Kernel::BoundedSide\_3

A model for this must provide:

*Bounded\_side*                      *fo.operator()( Kernel::Sphere\_3 s, Kernel::Point\_3 p)*

returns either *ON\_UNBOUNDED\_SIDE*, *ON\_BOUNDED\_SIDE*, or the constant *ON\_BOUNDARY*, depending on where point *p* is with respect to sphere *s*.

*Bounded\_side*                      *fo.operator()( Kernel::Tetrahedron\_3 t, Kernel::Point\_3 p)*

returns either *ON\_UNBOUNDED\_SIDE*, *ON\_BOUNDED\_SIDE*, or the constant *ON\_BOUNDARY*, depending on where point *p* is with respect to tetrahedron *t*.

*Bounded\_side*                      *fo.operator()( Kernel::Iso\_cuboid\_3 c, Kernel::Point\_3 p)*

returns either *ON\_UNBOUNDED\_SIDE*, *ON\_BOUNDED\_SIDE*, or the constant *ON\_BOUNDARY*, depending on where point *p* is with respect to iso-cuboid *c*.

## Kernel::CollinearAreOrderedAlongLine\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*

returns *true*, iff *q* lies between *p* and *r*.

*Precondition:* *p*, *q* and *r* are collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::collinear\_are\_ordered\_along\_line* ..... page [445](#)

## Kernel::CollinearAreOrderedAlongLine\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

returns *true*, iff *q* lies between *p* and *r*.

*Precondition:* *p*, *q* and *r* are collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::collinear\_are\_ordered\_along\_line* ..... page [445](#)

## Kernel::CollinearAreStrictlyOrderedAlongLine\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*

returns *true*, iff *q* lies strictly between *p* and *r*.  
*Precondition*: *p*, *q* and *r* are collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::collinear\_are\_strictly\_ordered\_along\_line* .....page [446](#)

## Kernel::CollinearAreStrictlyOrderedAlongLine\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

returns *true*, iff *q* lies strictly between *p* and *r*.  
*Precondition*: *p*, *q* and *r* are collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::collinear\_are\_strictly\_ordered\_along\_line* ..... [page 446](#)

## Kernel::CollinearHasOn\_2

A model for this must provide:

*bool* *fo.operator()*( *Kernel::Ray\_2* *r*, *Kernel::Point\_2* *p*)

checks if point *p* is on *r*.

*Precondition:* *p* is on the supporting line of *r*.

*bool* *fo.operator()*( *Kernel::Segment\_2* *s*, *Kernel::Point\_2* *p*)

checks if point *p* is on *s*.

*Precondition:* *p* is on the supporting line of *s*.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Ray\_2<Kernel>* .....page [375](#)

*CGAL::Segment\_2<Kernel>* .....page [377](#)

## Kernel::Collinear\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*  
returns *true*, if *p*, *q*, and *r* are collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::collinear* .....page [444](#)

## Kernel::Collinear\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*  
returns *true*, if *p*, *q*, and *r* are collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::collinear* .....page [444](#)

## Kernel::CompareAngleWithXAxis\_2

A model for this must provide:

*Comparison\_result*      *fo.operator()( Kernel::Direction\_2 d, Kernel::Direction\_2 e)*

compares the angles between the positive  $x$ -axis and the directions in counterclockwise order.

### Refines

*AdaptableFunctor* (with two arguments)

## Kernel::CompareDistance\_2

A model for this must provide:

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Kernel::Point_2</i> <i>p</i> , <i>Kernel::Point_2</i> <i>q</i> , <i>Kernel::Point_2</i> <i>r</i> )
	compares the distances of points <i>q</i> and <i>r</i> to point <i>p</i>

## Refines

*AdaptableFunctor* (with three arguments)

## See Also

<i>Kernel::CompareSquaredDistance_2</i> .....	page 572
<i>CGAL::compare_distance_to_point</i> .....	page 447
<i>CGAL::compare_squared_distance</i> .....	page 451

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Kernel::Point_3</i> <i>p</i> , <i>Kernel::Point_3</i> <i>q</i> , <i>Kernel::Point_3</i> <i>r</i> )
	compares the distances of points <i>q</i> and <i>r</i> to point <i>p</i>

*AdaptableFunctor* (with three arguments)

<i>Kernel::CompareSquaredDistance_3</i> .....	page 573
<i>CGAL::compare_distance_to_point</i> .....	page 447
<i>CGAL::compare_squared_distance</i> .....	page 451

### Kernel::CompareSlope\_2

A model for this must provide:

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Kernel::Line_2 l1</i> , <i>Kernel::Line_2 l2</i> )
--------------------------	--

compares the slopes of the lines  $l1$  and  $l2$

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Kernel::Segment_2 s1</i> , <i>Kernel::Segment_2 s2</i> )
--------------------------	--

compares the slopes of the segments  $s1$  and  $s2$

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

CGAL::compare\_slopes ..... page 450

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Kernel::Point_2</i> <i>p</i> , <i>Kernel::Point_2</i> <i>q</i> , <i>Kernel::FT</i> <i>d2</i> )
	compares the squared distance of points <i>p</i> and <i>q</i> to <i>d2</i>

*AdaptableFunctor* (with three arguments)

<i>CGAL::compare_distance_to_point</i> .....	page 447
<i>CGAL::compare_squared_distance</i> .....	page 451

### Kernel::CompareSquaredDistance\_3

A model for this must provide:

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Kernel::Point_3</i> <i>p</i> , <i>Kernel::Point_3</i> <i>q</i> , <i>Kernel::FT</i> <i>d2</i> )
--------------------------	--

compares the squared distance of points  $p$  and  $q$  to  $d2$

## Refines

*AdaptableFunctor* (with three arguments)

## See Also

---

*Kernel::CompareDistance\_3* ..... page 570

<i>CGAL::compare_distance_to_point</i> .....	page 447
--	----------

## Kernel::CompareSquaredRadius\_3

A model for this must provide:

*Comparison\_result*      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::FT sr)*  
 compares the squared radius of the sphere defined by the points *p* and *q* to *sr*.

*Comparison\_result*      *fo.operator()( Kernel::Point\_3 p,*  
    *Kernel::Point\_3 q,*  
    *Kernel::Point\_3 r,*  
    *Kernel::FT sr)*  
 compares the squared radius of the sphere defined by the points *p*, *q*, and *r* to *sr*.

*Comparison\_result*      *fo.operator()( Kernel::Point\_3 p,*  
    *Kernel::Point\_3 q,*  
    *Kernel::Point\_3 r,*  
    *Kernel::Point\_3 s,*  
    *Kernel::FT sr)*  
 compares the squared radius of the sphere defined by the points *p*, *q*, *r*, and *s* to *sr*.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::compare\_squared\_radius* ..... page [452](#)

## Kernel::CompareXAtY\_2

A model for this must provide:

*Comparison\_result*  $fo.operator()( \text{Kernel::Point\_2 } p, \text{Kernel::Line\_2 } h )$

compares the  $x$ -coordinates of  $p$  and the horizontal projection of  $p$  on  $h$  (Figure 7.5 (a)).

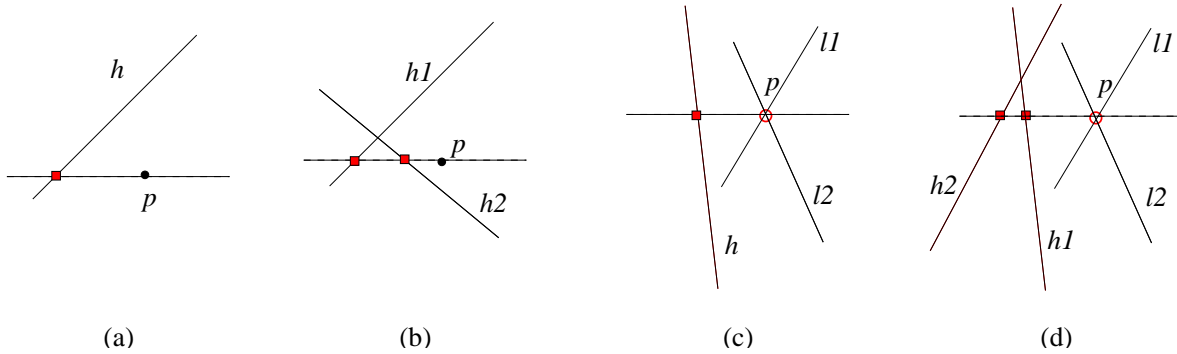

Figure 7.5: Comparison of the  $x$ -coordinates of the (implicitly given) points in the boxes, at a  $y$ -coordinate. The  $y$ -coordinate is either given explicitly (disc) or implicitly (circle).

*Comparison\_result*  $fo.operator()( \text{Kernel::Point\_2 } p, \text{Kernel::Line\_2 } h1, \text{Kernel::Line\_2 } h2 )$

compares the  $x$ -coordinates of the horizontal projection of  $p$  on  $h1$  and on  $h2$  (Figure 7.5 (b)).

*Comparison\_result*  $fo.operator()( \text{Kernel::Line\_2 } l1, \text{Kernel::Line\_2 } l2, \text{Kernel::Line\_2 } h )$

Let  $p$  be the intersection of lines  $l1$  and  $l2$ . This function compares the  $x$ -coordinates of  $p$  and the horizontal projection of  $p$  on  $h$  (Figure 7.5 (c)).

*Comparison\_result*  $fo.operator()( \text{Kernel::Line\_2 } l1, \text{Kernel::Line\_2 } l2, \text{Kernel::Line\_2 } h1, \text{Kernel::Line\_2 } h2 )$

Let  $p$  be the intersection of lines  $l1$  and  $l2$ . This function compares the  $x$ -coordinates of the horizontal projection of  $p$  on  $h1$  and on  $h2$  (Figure 7.5 (d)).

### Refines

*AdaptableFunctor* (with three arguments)

## See Also

*CGAL::compare\_x\_at\_y* ..... page [458](#)

**Kernel::CompareXYZ\_3**

A model for this must provide:

*Comparison\_result*            *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q)*

Compares the Cartesian coordinates of points *p* and *q* lexicographically in *xy* order: first *x*-coordinates are compared, if they are equal, *y*-coordinates are compared. If they are equal, *z*-coordinates are compared.

**Refines**

*AdaptableFunctor* (with two arguments)

**See Also**

*CGAL::compare\_xyz* ..... [page 457](#)

## Kernel::CompareXY\_2

A model for this must provide:

*Comparison\_result*      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q)*

Compares the Cartesian coordinates of points  $p$  and  $q$  lexicographically in  $xy$  order: first  $x$ -coordinates are compared, if they are equal,  $y$ -coordinates are compared.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::compare\_xy* ..... [page 455](#)  
*Kernel::CompareYX\_2* ..... [page 586](#)

## Kernel::CompareXY\_3

A model for this must provide:

*Comparison\_result* *fo.operator()*( *Kernel::Point\_3* *p*, *Kernel::Point\_3* *q*)

Compares the Cartesian coordinates of points *p* and *q* lexicographically in *xy* order: first *x*-coordinates are compared, if they are equal, *y*-coordinates are compared.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::compare\_xy* ..... page [455](#)

## Kernel::CompareX\_2

A model for this must provide:

*Comparison\_result* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Point\_2* *q*)

compares the Cartesian *x*-coordinates of points *p* and *q*

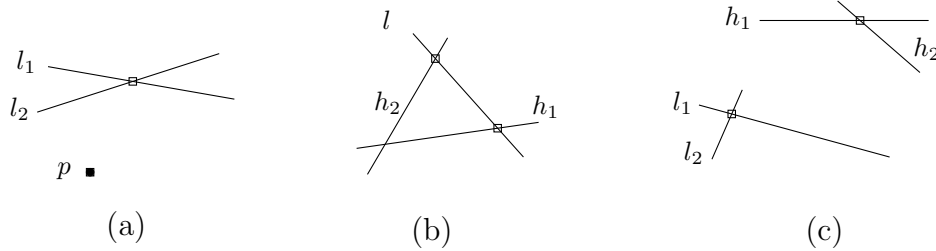

Figure 7.6: Comparison of the *x* or *y*-coordinates of the (implicitly given) points in the boxes.

*Comparison\_result* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Line\_2* *l1*, *Kernel::Line\_2* *l2*)

compares the *x*-coordinates of *p* and the intersection of lines *l1* and *l2* (Figure 7.6 (a)).

*Comparison\_result* *fo.operator()*( *Kernel::Line\_2* *l*, *Kernel::Line\_2* *h1*, *Kernel::Line\_2* *h2*)

compares the *x*-coordinates of the intersection of line *l* with line *h1* and with line *h2* (Figure 7.6 (b)).

*Comparison\_result* *fo.operator()*( *Kernel::Line\_2* *l1*,  
*Kernel::Line\_2* *l2*,  
*Kernel::Line\_2* *h1*,  
*Kernel::Line\_2* *h2*)

compares the *x*-coordinates of the intersection of lines *l1* and *l2* and the intersection of lines *h1* and *h2* (Figure 7.6 (c)).

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::compare\_x* ..... page 453

## Kernel::CompareX\_3

A model for this must provide:

*Comparison\_result*      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q)*

Compares the Cartesian  $x$ -coordinates of points  $p$  and  $q$

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::compare\_x* ..... page [453](#)

## Kernel::CompareYAtX\_2

A model for this must provide:

*Comparison\_result*  $fo.operator()( \text{Kernel::Point\_2 } p, \text{Kernel::Line\_2 } h )$

compares the y-coordinates of  $p$  and the vertical projection of  $p$  on  $h$  (Figure 7.7 (d)).  
*Precondition:*  $h$  is not vertical.

Figure 7.7: Comparison of the y-coordinates of the (implicitly given) points in the boxes, at an  $x$ -coordinate. The  $x$ -coordinate is either given explicitly (disc) or implicitly (circle).

*Comparison\_result*  $fo.operator()( \text{Kernel::Point\_2 } p, \text{Kernel::Line\_2 } h1, \text{Kernel::Line\_2 } h2 )$

This function compares the y-coordinates of the vertical projection of  $p$  on  $h1$  and on  $h2$  (Figure 7.4 (e)).  
*Precondition:*  $h1$  and  $h2$  are not vertical.

*Comparison\_result*  $fo.operator()( \text{Kernel::Line\_2 } l1, \text{Kernel::Line\_2 } l2, \text{Kernel::Line\_2 } h )$

Let  $p$  be the intersection of lines  $l1$  and  $l2$ . This function compares the y-coordinates of  $p$  and the vertical projection of  $p$  on  $h$  (Figure 7.4 (f)).  
*Precondition:*  $l1, l2$  intersect and  $h$  is not vertical.

*Comparison\_result*  $fo.operator()( \text{Kernel::Line\_2 } l1, \text{Kernel::Line\_2 } l2, \text{Kernel::Line\_2 } h1, \text{Kernel::Line\_2 } h2 )$

Let  $p$  be the intersection of lines  $l1$  and  $l2$ . This function compares the y-coordinates of the vertical projection of  $p$  on  $h1$  and on  $h2$  (Figure 7.4 (g)).  
*Precondition:*  $l1$  and  $l2$  intersect;  $h1$  and  $h2$  are not vertical.

*Comparison\_result*      *fo.operator()( Kernel::Point\_2 p, Kernel::Segment\_2 s)*

compares the y-coordinates of *p* and the vertical projection of *p* on *s*. If *s* is vertical, then return *EQUAL* when *p* lies on *s*, *SMALLER* when *p* lies under *s*, and *LARGER* otherwise.

*Precondition:* *p* is within the x range of *s*.

*Comparison\_result*      *fo.operator()( Kernel::Point\_2 p, Kernel::Segment\_2 s1, Kernel::Segment\_2 s2)*

This function compares the y-coordinates of the vertical projection of *p* on *s1* and on *s2*. If *s1* or *s2* is vertical, then return *EQUAL* if they intersect, otherwise return *SMALLER* if *s1* lies below *s2*, and return *LARGER* otherwise.

*Precondition:* *p* is within the x range of *s1* and *s2*.

## Kernel::CompareY\_2

A model for this must provide:

*Comparison\_result* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Point\_2* *q*)

Compares the Cartesian y-coordinates of points *p* and *q*

Figure 7.8: Comparison of the x or y-coordinates of the (implicitly given) points in the boxes.

*Comparison\_result* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Line\_2* *l1*, *Kernel::Line\_2* *l2*)

compares the y-coordinates of *p* and the intersection of lines *l1* and *l2* (Figure 7.8 (a)).

*Comparison\_result* *fo.operator()*( *Kernel::Line\_2* *l*, *Kernel::Line\_2* *h1*, *Kernel::Line\_2* *h2*)

compares the y-coordinates of the intersection of line *l* with line *h1* and with line *h2* (Figure 7.8 (b)).

*Comparison\_result* *fo.operator()*( *Kernel::Line\_2* *l1*,  
*Kernel::Line\_2* *l2*,  
*Kernel::Line\_2* *h1*,  
*Kernel::Line\_2* *h2*)

compares the y-coordinates of the intersection of lines *l1* and *l2* and the intersection of lines *h1* and *h2* (Figure 7.8 (c)).

*CGAL::compare\_z*..... page [465](#)

## Kernel::ComputeA\_2

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Kernel::Line\_2 l)*

returns the coefficient  $a$  of the line with equation  $ax + by + c = 0$ .

### Refines

*AdaptableFunctor*

## Kernel::ComputeB\_2

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Kernel::Line\_2 l)*

returns the coefficient  $b$  of the line with equation  $ax + by + c = 0$ .

### Refines

*AdaptableFunctor*

## Kernel::ComputeC\_2

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Kernel::Line\_2 l)*

returns the coefficient  $c$  of the line with equation  $ax + by + c = 0$ .

### Refines

*AdaptableFunctor*

## Kernel::ComputeApproximateArea\_3

A model for this must provide:

*double* *fo.operator()( Kernel::Circle\_3 c)*  
returns an approximation of the area of *c*.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Circle\_3<Kernel>* .....page [408](#)

## Kernel::ComputeApproximateSquaredLength\_3

A model for this must provide:

*double* *fo.operator()( Kernel::Circle\_3 c)* returns an approximation of the squared length (i.e. perimeter) of *c*.

### Refines

*CGAL::determinant* ..... page [470](#)

A model for this must provide:

*Kernel::FT* *fo.operator() (Kernel::Direction\_2 v)*

returns an *x*-coordinate of the direction.

## Refines

*AdaptableFunctor*

# Functor Concept

*Kernel::FT* *fo.operator()*( *Kernel::Direction\_2 v*)

returns an y-coordinate of the direction.

*AdaptableFunctor*

*Kernel::FT* *fo.operator() ( Kernel::Point\_2 p)*

returns the homogeneous x-coordinate of the point.

*Kernel::FT* *fo.operator() (Kernel::Vector\_2 v)*

returns the homogeneous *x*-coordinate of the vector.

## Refines

*AdaptableFunctor*

## Kernel::ComputeHy\_2

A model for this must provide:

$$Kernel::FT \quad fo.operator()(Kernel::Point_2 p)$$

returns the homogeneous y-coordinate of the point.

```
Kernel::FT      fo.operator()( Kernel::Vector_2 v)
```

returns the homogeneous  $y$ -coordinate of the vector.

## Refines

*AdaptableFunctor*

## Kernel::ComputeScalarProduct\_2

A model for this must provide:

*Kernel::FT* *fo.operator()( Kernel::Vector\_2 v, Kernel::Vector\_2 w)*

returns the scalar (inner) product of the two vectors  $v$  and  $w$ .

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Vector\_2<Kernel>* ..... page [381](#)

## Kernel::ComputeScalarProduct\_3

A model for this must provide:

*Kernel::FT* *fo.operator()( Kernel::Vector\_3 v, Kernel::Vector\_3 w)*

returns the scalar (inner) product of the two vectors *v* and *w*.

### Refines

<i>Kernel::FT</i>	<i>fo.operator() ( Kernel::Triangle_3 t)</i>	
		returns the square of the area of <i>t</i> .

*Kernel::FT* *fo.operator()*( *Kernel::Point\_3* *p*, *Kernel::Point\_3* *q*, *Kernel::Point\_3* *r*)

returns the square of the area of the triangle *p*, *q*, *r*.

*AdaptableFunctor* (with one argument)

## CGAL::Triangle\_3&lt;Kernel&gt; ..... page 415

## Kernel::ComputeSquaredDistance\_2

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Type1 obj1, Type2 obj2)*

returns the squared distance between two geometrical objects of type *Type1* and *Type2*

for all pairs *Type1* and *Type2*, where the types *Type1* and *Type2* can be any of the following:

- *Kernel::Point\_2*
- *Kernel::Line\_2*
- *Kernel::Ray\_2*
- *Kernel::Segment\_2*
- *Kernel::Triangle\_2*

## Kernel::ComputeSquaredLengthDividedByPiSquare\_3

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Kernel::Circle\_3 c)*

returns the squared length of  $c$ , divided by  $\pi^2$ .

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Circle\_3<Kernel>* .....page [408](#)

## Kernel::ComputeSquaredRadius\_2

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Kernel::Circle\_2 c)*

returns the squared radius of *c*.

*Kernel::FT*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*

returns the squared radius of the circle passing through *p*,  
*q* and *r*.

*Precondition:* *p*, *q* and *r* are not collinear.

*Kernel::FT*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q)*

returns the squared radius of the smallest circle passing  
through *p*, and *q*, i.e. one fourth of the squared distance  
between *p* and *q*.

### Refines

*AdaptableFunctor* (with one argument)

## Kernel::ComputeSquaredRadius\_3

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Kernel::Sphere\_3 s)*

returns the squared radius of *s*.

*Kernel::FT*                      *fo.operator()( Kernel::Circle\_3 c)*

returns the squared radius of *c*.

*Kernel::FT*                      *fo.operator()( Kernel::Point\_3 p,*  
   *Kernel::Point\_3 q,*  
   *Kernel::Point\_3 r,*  
   *Kernel::Point\_3 s)*

returns the squared radius of the sphere passing through  
*p*, *q*, *r* and *s*.

*Precondition:* *p*, *q*, *r* and *s* are not coplanar.

*Kernel::FT*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

returns the squared radius of the sphere passing through  
*p*, *q* and *r*, and whose center is in the plane defined by  
these three points.

*Kernel::FT*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q)*

returns the squared radius of the smallest circle passing  
through *p*, and *q*, i.e. one fourth of the squared distance  
between *p* and *q*.

### Refines

**Kernel::ComputeX\_2**

A model for this must provide:

*Kernel::FT* *fo.operator() (Kernel::Point\_2 p)*

returns the x-coordinate of the point.

*Kernel::FT* *fo.operator() ( Kernel::Vector\_2 v)*  
returns the *x*-coordinate of the vector.

## Refines

*AdaptableFunctor*

*Kernel::FT* *fo.operator() (Kernel::Point\_3 p)*

returns the x-coordinate of the point.

*Kernel::FT* *fo.operator() ( Kernel::Vector\_3 v)*  
returns the *x*-coordinate of the vector.

*AdaptableFunctor*

**Kernel::ComputeY\_2**

A model for this must provide:

*Kernel::FT* *fo.operator() (Kernel::Point\_2 p)*

returns the y-coordinate of the point.

*Kernel::FT* *fo.operator() (Kernel::Vector\_2 v)*

returns the y-coordinate of the vector.

## Refines

*AdaptableFunctor*

*Kernel::FT* *fo.operator() (Kernel::Point\_3 p)*

returns the y-coordinate of the point.

*Kernel::FT* *fo.operator() (Kernel::Vector\_3 v)*

returns the y-coordinate of the vector.

*AdaptableFunctor*

### Kernel::ComputeZ\_3

A model for this must provide:

*Kernel::FT* *fo.operator() (Kernel::Point\_3 p)* returns the z-coordinate of the point.

*Kernel::FT* *fo.operator() ( Kernel::Vector\_3 v)*

returns the z-coordinate of the vector.

## Refines

*AdaptableFunctor*

*Kernel::FT*      *fo.operator() (Kernel::Iso\_rectangle\_2 r)*

returns the smallest x-coordinate of the iso-rectangle.

*AdaptableFunctor*

## Kernel::ComputeYmin\_2

A model for this must provide:

*Kernel::FT* *fo.operator()( Kernel::Iso\_rectangle\_2 r)*  
returns the smallest y-coordinate of the iso-rectangle.

### Refines

*AdaptableFunctor*

## Kernel::ComputeXmax\_2

A model for this must provide:

*Kernel::FT* *fo.operator()( Kernel::Iso\_rectangle\_2 r)*  
returns the largest  $x$ -coordinate of the iso-rectangle.

### Refines

*AdaptableFunctor*

## Kernel::ComputeYmax\_2

A model for this must provide:

*Kernel::FT* *fo.operator()( Kernel::Iso\_rectangle\_2 r)*  
returns the largest y-coordinate of the iso-rectangle.

### Refines

*AdaptableFunctor*

## Kernel::ComputeYAtX\_2

A model for this must provide:

*Kernel::FT*                      *fo.operator()( Kernel::Line\_2 l, Kernel::FT x)*

returns the y-coordinate of the point at *l* with given *x*-coordinate.

*Precondition:* *l* is not vertical.

### Refines

*AdaptableFunctor*

### See Also

*CGAL::compare\_y\_at\_x* ..... page [462](#)

## Kernel::ConstructBisector\_2

A model for this must provide:

*Kernel::Line\_2*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q)*

constructs the bisector of  $p$  and  $q$ . The bisector is oriented in such a way that  $p$  lies on its positive side.

*Precondition:*  $p$  and  $q$  are not equal.

*Kernel::Line\_2*                      *fo.operator()( Kernel::Line\_2 l1, Kernel::Line\_2 l2)*

constructs the bisector of the two lines  $l1$  and  $l2$ . In the general case, the bisector has the direction of the vector which is the sum of the normalized directions of the two lines, and which passes through the intersection of  $l1$  and  $l2$ . If  $l1$  and  $l2$  are parallel, then the bisector is defined as the line which has the same direction as  $l1$ , and which is at the same distance from  $l1$  and  $l2$ . This function requires that *Kernel::RT* supports the *sqrt()* operation.

## Kernel::ConstructBisector\_3

A model for this must provide:

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q)*

constructs the bisector plane of  $p$  and  $q$ . The bisector is oriented in such a way that  $p$  lies on its positive side.  
*Precondition:*  $p$  and  $q$  are not equal.

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Plane\_3 h1, Kernel::Plane\_3 h2)*

constructs the bisector of the two planes  $h1$  and  $h2$ . In the general case, the bisector has a normal vector which has the same direction as the sum of the normalized normal vectors of the two planes, and passes through the intersection of  $h1$  and  $h2$ . If  $h1$  and  $h2$  are parallel, then the bisector is defined as the plane which has the same oriented normal vector as  $h1$ , and which is at the same distance from  $h1$  and  $h2$ . This function requires that *Kernel::RT* supports the *sqrt()* operation.

## Kernel::ConstructCartesianConstIterator\_2

A model for this must provide:

*Kernel::Cartesian\_const\_iterator\_2*

*fo.operator()( Kernel::Point\_2 p)*

returns an iterator on the 0'th Cartesian coordinate of *p*.

*Kernel::Cartesian\_const\_iterator\_2*

*fo.operator()( Kernel::Point\_2 p, int)*

returns the past the end iterator of the Cartesian coordinates of *p*.

*Kernel::Cartesian\_const\_iterator\_2*

*fo.operator()( Kernel::Vector\_2 v)*

returns an iterator on the 0'th Cartesian coordinate of *v*.

*Kernel::Cartesian\_const\_iterator\_2*

*fo.operator()( Kernel::Vector\_2 v, int)*

returns the past the end iterator of the Cartesian coordinates of *v*.

### Refines

## Kernel::ConstructCartesianConstIterator\_3

A model for this must provide:

*Kernel::Cartesian\_const\_iterator\_3*

*fo.operator()( Kernel::Point\_3 p)*

returns an iterator on the 0'th Cartesian coordinate of *p*.

*Kernel::Cartesian\_const\_iterator\_3*

*fo.operator()( Kernel::Point\_3 p, int)*

returns the past the end iterator of the Cartesian coordinates of *p*.

*Kernel::Cartesian\_const\_iterator\_3*

*fo.operator()( Kernel::Vector\_3 v)*

returns an iterator on the 0'th Cartesian coordinate of *v*.

*Kernel::Cartesian\_const\_iterator\_3*

*fo.operator()( Kernel::Vector\_3 v, int)*

returns the past the end iterator of the Cartesian coordinates of *v*.

## Kernel::ConstructCentroid\_3

A model for this must provide:

*Kernel::Point\_3*                    *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*  
compute the centroid of the points *p*, *q*, and *r*.

*Kernel::Point\_3*                    *fo.operator()( Kernel::Point\_3 p,*  
   *Kernel::Point\_3 q,*  
   *Kernel::Point\_3 r,*  
   *Kernel::Point\_3 s)*  
compute the centroid of the points *p*, *q*, *r* and *s*.

*Kernel::Point\_3*                    *fo.operator()( Kernel::Triangle\_3 t)*  
compute the centroid of the triangle *t*.

*Kernel::Point\_3*                    *fo.operator()( Kernel::Tetrahedron\_3 t)*  
compute the centroid of the tetrahedron *t*.

### Refines

*AdaptableFunctor* (with three arguments)

### Kernel::ConstructCircle\_2

A model for this must provide:

```
Kernel::Circle_2      fo.operator() ( Kernel::Point_2 center,  
                        Kernel::FT squared_radius,  
                        Orientation orientation = COUNTERCLOCKWISE)
```

introduces a variable of type *Kernel::Circle\_2*. It is initialized to the circle with center *center*, squared radius *squared\_radius* and orientation *orientation*.

*Precondition:* *orientation*  $\neq$  *COLLINEAR*, and further, *squared\_radius*  $> 0$ .

$$\text{Kernel::Circle\_2} \quad fo.operator()( \text{Kernel::Point\_2 } p, \text{Kernel::Point\_2 } q, \text{Kernel::Point\_2 } r )$$

introduces a variable of type *Kernel::Circle\_2*. It is initialized to the unique circle which passes through the points  $p$ ,  $q$  and  $r$ . The orientation of the circle is the orientation of the point triple  $p$ ,  $q$ ,  $r$ .

*Precondition:*  $p$ ,  $q$ , and  $r$  are not collinear.

```
Kernel::Circle_2      fo.operator() ( Kernel::Point_2 p,  
                       Kernel::Point_2 q,  
                       Orientation orientation = COUNTERCLOCKWISE)
```

introduces a variable of type *Kernel::Circle\_2*. It is initialized to the circle with diameter  $\overline{pq}$  and orientation *orientation*.

*Precondition:*  $orientation \neq \text{COLLINEAR}$ .

```
Kernel::Circle_2      fo.operator() ( Kernel::Point_2 center,  
                        Orientation orientation = COUNTERCLOCKWISE)
```

introduces a variable of type *Kernel::Circle\_2*. It is initialized to the circle with center *center*, squared radius zero and orientation *orientation*.

*Precondition:*  $orientation \neq \text{COLLINEAR}$ .

*Postcondition:* `.is_degenerate() = true`.

## Refines

*AdaptableFunctor* (with three arguments)

## See Also

CGAL::Circle\_2&lt;Kernel&gt; ..... page 361

## Kernel::ConstructCircle\_3

A model for this must provide:

*Kernel::Circle\_3*      *fo.operator()( Kernel::Point\_3 center, Kernel::FT sq\_r, Kernel::Plane\_3 plane)*

introduces a variable of type *Kernel::Circle\_3*. It is initialized to the circle with center *center*, and squared radius *sq\_r* in the plane *plane*.

*Precondition:* *center* lies in *plane* and  $sq\_r \geq 0$ .

*Kernel::Circle\_3*      *fo.operator()( Kernel::Point\_3 center, Kernel::FT sq\_r, Kernel::Vector\_3 n)*

introduces a variable of type *Kernel::Circle\_3*. It is initialized to the circle with center *center*, and squared radius *sq\_r* in the plane containing *center* and normal to *n*.

*Precondition:*  $sq\_r \geq 0$ .

*Kernel::Circle\_3*      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

introduces a variable of type *Kernel::Point\_3*. It is initialized to the circle passing through the three points.

*Precondition:* The three points are not collinear.

*Kernel::Circle\_3*      *fo.operator()( Kernel::Sphere\_3 sphere1, Kernel::Sphere\_3 sphere2)*

introduces a variable of type *Kernel::Circle\_3*. It is initialized to the circle along which the two spheres intersect.

*Precondition:* The two spheres intersect along a circle.

*Kernel::Circle\_3*      *fo.operator()( Kernel::Sphere\_3 sphere, Kernel::Plane\_3 plane)*

introduces a variable of type *Kernel::Circle\_3*. It is initialized to the circle along which the sphere and the plane intersect.

*Precondition:* The sphere and the plane intersect along a circle.

*Kernel::Circle\_3*      *fo.operator()( Kernel::Plane\_3 plane, Kernel::Sphere\_3 sphere)*

introduces a variable of type *Kernel::Circle\_3*. It is initialized to the circle along which the sphere and the plane intersect.

*Precondition:* The sphere and the plane intersect along a circle.

## Refines

## Kernel::ConstructCircumcenter\_2

A model for this must provide:

*Kernel::Point\_2*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q)*

compute the center of the smallest circle passing through the points *p* and *q*. Note : this is the same as *Kernel::ConstructMidPoint\_2*.

*Kernel::Point\_2*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*

compute the center of the circle passing through the points *p*, *q*, and *r*.  
*Precondition:* *p*, *q*, and *r* are not collinear.

*Kernel::Point\_2*                      *fo.operator()( Kernel::Triangle\_2 t)*

compute the center of the circle passing through the three vertices of *t*.  
*Precondition:* *t* is not degenerate.

### Refines

*CGAL::Vector\_3<Kernel>* ..... page [417](#)

## Kernel::ConstructDirection\_2

A model for this must provide:

*Kernel::Direction\_2*      *fo.operator()( Kernel::Vector\_2 v)*  
introduces the direction of vector *v*.

*Kernel::Direction\_2*      *fo.operator()( Kernel::Line\_2 l)*  
introduces the direction of line *l*.

*Kernel::Direction\_2*      *fo.operator()( Kernel::Ray\_2 r)*  
introduces the direction of ray *r*.

*Kernel::Direction\_2*      *fo.operator()( Kernel::Segment\_2 s)*  
introduces the direction of segment *s*.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Direction\_2<Kernel>* .....page [363](#)

## Kernel::ConstructDirection\_3

A model for this must provide:

*Kernel::Direction\_3*      *fo.operator()( Kernel::Vector\_3 v)*

introduces a direction initialized with the direction of vector *v*.

*Kernel::Direction\_3*      *fo.operator()( Kernel::Line\_3 l)*

introduces the direction of line *l*.

*Kernel::Direction\_3*      *fo.operator()( Kernel::Ray\_3 r)*

introduces the direction of ray *r*.

*Kernel::Direction\_3*      *fo.operator()( Kernel::Segment\_3 s)*

introduces the direction of segment *s*.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

## Kernel::ConstructEquidistantLine\_3

A model for this must provide:

*Kernel::Line\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

constructs the line which is at the same distance from the three points *p*, *q* and *r*.

*Precondition:* *p*, *q* and *r* are not collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::equidistant\_line* ..... [page 475](#)

A model for this must provide:

introduces an iso-oriented cuboid with diagonal opposite vertices  $p$  and  $q$  such that  $p$  is the lexicographically smallest point in the cuboid.

introduces an iso-oriented cuboid with diagonal opposite vertices  $p$  and  $q$ . The *int* argument value is only used to distinguish the two overloaded functions.

introduces an iso-oriented cuboid *fo* whose minimal *x* coordinate is the one of *left*, the maximal *x* coordinate is the one of *right*, the minimal *y* coordinate is the one of *bottom*, the maximal *y* coordinate is the one of *top*, the minimal *z* coordinate is the one of *far*, the maximal *z* coordinate is the one of *close*.

### *AdaptableFunctor* (with two arguments)

## CGAL::Iso\_cuboid\_3&lt;Kernel&gt; ..... page 391

## Kernel::ConstructIsoRectangle\_2

A model for this must provide:

*Kernel::Iso\_rectangle\_2* *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q)*

introduces an iso-oriented rectangle with diagonal opposite vertices *p* and *q* such that *p* is the lexicographically smallest point in the rectangle.

*Kernel::Iso\_rectangle\_2* *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, int)*

introduces an iso-oriented rectangle with diagonal opposite vertices *p* and *q*. The *int* argument value is only used to distinguish the two overloaded functions.

*Precondition:* *p.x() <= q.x()* and *p.y() <= q.y()*.

*Kernel::Iso\_rectangle\_2* *fo.operator()( Kernel::Point\_2 left,  
Kernel::Point\_2 right,  
Kernel::Point\_2 bottom,  
Kernel::Point\_2 top)*

introduces an iso-oriented rectangle *fo* whose minimal *x* coordinate is the one of *left*, the maximal *x* coordinate is the one of *right*, the minimal *y* coordinate is the one of *bottom*, the maximal *y* coordinate is the one of *top*.

### Refines

## Kernel::ConstructLine\_3

A model for this must provide:

*Kernel::Line\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q)*

introduces a line passing through the points *p* and *q*. Line is directed from *p* to *q*.

*Kernel::Line\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Vector\_3 v)*

introduces a line passing through point *p* and oriented by *v*.

*Kernel::Line\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Direction\_3 d)*

introduces a line passing through point *p* with direction *d*.

*Kernel::Line\_3*                      *fo.operator()( Kernel::Segment\_3 s)*

returns the line supporting the segment *s*, oriented from source to target.

*Kernel::Line\_3*                      *fo.operator()( Kernel::Ray\_3 r)*

returns the line supporting the ray *r*, with the same orientation.

### Refines

*AdaptableFunctor* (with two arguments)

### Kernel::ConstructOppositeDirection\_3

A model for this must provide:

$$\text{Kernel}::\text{Direction\_3} \quad fo.operator()(\text{Kernel}::\text{Direction\_3 } d)$$

returns the direction opposite to  $d$ .

## Refines

*AdaptableFunctor* (with one argument)

## See Also

*CGAL::Direction\_3<Kernel>* .....page 389

## Kernel::ConstructOppositeLine\_2

A model for this must provide:

*Kernel::Line\_2*                      *fo.operator()( Kernel::Line\_2 l)*

returns the line representing the same set of points as *l*,  
but with opposite direction.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Line\_2<Kernel>* ..... [page 368](#)

## Kernel::ConstructOppositeLine\_3

A model for this must provide:

*Kernel::Line\_3*                      *fo.operator()( Kernel::Line\_3 l)*

returns the line representing the same set of points as *l*,  
but with opposite direction.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Line\_3<Kernel>* ..... [page 394](#)

## Kernel::ConstructOppositePlane\_3

A model for this must provide:

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Plane\_3 p)*

returns the plane representing the same set of points as *p*,  
but with opposite orientation.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Plane\_3<Kernel>* ..... [page 396](#)

## Kernel::ConstructOppositeRay\_2

A model for this must provide:

*Kernel::Ray\_2*                      *fo.operator()( Kernel::Ray\_2 r)*

returns the ray with the same source as *r*, but in opposite direction.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Ray\_2<Kernel>* .....page [375](#)

## Kernel::ConstructOppositeRay\_3

A model for this must provide:

*Kernel::Ray\_3*                      *fo.operator()( Kernel::Ray\_3 r)*

returns the ray with the same source as *r*, but in opposite direction.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Ray\_3<Kernel>* .....page [404](#)

## Kernel::ConstructOppositeSegment\_2

A model for this must provide:

*Kernel::Segment\_2*      *fo.operator()( Kernel::Segment\_2 s)*

returns the segment representing the same set of points as *s*, but with opposite orientation.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Segment\_2<Kernel>*.....page [377](#)

## Kernel::ConstructOppositeSegment\_3

A model for this must provide:

*Kernel::Segment\_3*      *fo.operator()( Kernel::Segment\_3 s)*

returns the segment representing the same set of points as *s*, but with opposite orientation.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Segment\_3<Kernel>*.....page [406](#)

## Kernel::ConstructOppositeSphere\_3

A model for this must provide:

*Kernel::Sphere\_3*                      *fo.operator()( Kernel::Sphere\_3 s)*

returns the sphere with the same center and squared radius as *s*, but with opposite orientation.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Sphere\_3<Kernel>* ..... [page 410](#)

## Kernel::ConstructOppositeTriangle\_2

A model for this must provide:

*Kernel::Triangle\_2*      *fo.operator()( Kernel::Triangle\_2 t)*

returns the triangle with opposite orientation to *t* (this flips the positive and the negative side, but not bounded and unbounded side).

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Triangle\_2<Kernel>* ..... [page 379](#)

## Kernel::ConstructOppositeVector\_2

A model for this must provide:

```
Kernel::Vector_2      fo.operator()( Kernel::Vector_2 v)
                        returns the vector -v.
```

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Vector\_2<Kernel>* ..... page [381](#)

*Kernel::Vector\_3*      *fo.operator() ( Kernel::Vector\_3 v)*

returns the vector -v.

*AdaptableFunctor* (with one argument)

## CGAL::Vector\_3&lt;Kernel&gt; ..... page 417

## Kernel::ConstructOrthogonalVector\_3

A model for this must provide:

*Kernel::Vector\_3*                      *fo.operator()( Kernel::Plane\_3 p)*

returns a vector that is orthogonal to the plane *p* and directed to the positive side of *p*.

*Kernel::Vector\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

returns a vector that is orthogonal to the plane defined by *Kernel::ConstructPlane\_3()(p, q, r)* and directed to the positive side of this plane.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Plane\_3<Kernel>* ..... page [396](#)  
*Kernel::ConstructCrossProductVector\_3* ..... page [643](#)

## Kernel::ConstructPerpendicularDirection\_2

A model for this must provide:

*Kernel::Direction\_2*      *fo.operator()( Kernel::Direction\_2 d, Orientation o)*

introduces a direction orthogonal to *d*. If *o* is *CLOCKWISE*, *d* is rotated clockwise; if *o* is *COUNTERCLOCKWISE*, *d* is rotated counterclockwise.  
*Precondition: o* is not *COLLINEAR*.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Direction\_2<Kernel>* .....page [363](#)

## Kernel::ConstructPerpendicularLine\_2

A model for this must provide:

*Kernel::Line\_2*                      *fo.operator()( Kernel::Line\_2 l, Kernel::Point\_2 p)*

returns the line perpendicular to *l* and passing through *p*, where the direction is the direction of *l* rotated counter-clockwise by 90 degrees.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Line\_2<Kernel>* ..... page [368](#)

## Kernel::ConstructPerpendicularLine\_3

A model for this must provide:

*Kernel::Line\_3*                      *fo.operator()( Kernel::Plane\_3 pl, Kernel::Point\_3 p)*

returns the line that is perpendicular to *pl* and that passes through point *p*. The line is oriented from the negative to the positive side of *pl*

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Plane\_3<Kernel>* ..... [page 396](#)

## Kernel::ConstructPerpendicularPlane\_3

A model for this must provide:

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Line\_3 l, Kernel::Point\_3 p)*

returns the plane perpendicular to *l* passing through *p*,  
such that the normal direction of the plane coincides with  
the direction of the line.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Plane\_3<Kernel>* ..... page [396](#)

## Kernel::ConstructPerpendicularVector\_2

A model for this must provide:

*Kernel::Vector\_2*            *fo.operator()( Kernel::Vector\_2 v, Orientation o)*

returns *v* rotated clockwise by 90 degrees, if *o* is *CLOCKWISE*, and rotated counterclockwise otherwise.  
*Precondition: o* is not *COLLINEAR*.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Vector\_2<Kernel>* ..... page [381](#)

## Kernel::ConstructPlane\_3

A model for this must provide:

*Kernel::Plane\_3*                      *fo.operator()( Kernel::RT a, Kernel::RT b, Kernel::RT c, Kernel::RT d)*

creates a plane defined by the equation  $ax + by + cz + d = 0$ . Notice that it is degenerate if  $a = b = c = 0$ .

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

creates a plane passing through the points  $p$ ,  $q$  and  $r$ . The plane is oriented such that  $p$ ,  $q$  and  $r$  are oriented in a positive sense (that is counterclockwise) when seen from the positive side of the plane. Notice that it is degenerate if the points are collinear.

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Direction\_3 d)*

introduces a plane that passes through point  $p$  and that has as an orthogonal direction equal to  $d$ .

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Vector\_3 v)*

introduces a plane that passes through point  $p$  and that is orthogonal to  $v$ .

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Line\_3 l, Kernel::Point\_3 p)*

introduces a plane that is defined through the three points  $l.point(0)$ ,  $l.point(1)$  and  $p$ .

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Ray\_3 r, Kernel::Point\_3 p)*

introduces a plane that is defined through the three points  $r.point(0)$ ,  $r.point(1)$  and  $p$ .

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Segment\_3 s, Kernel::Point\_3 p)*

introduces a plane that is defined through the three points  $s.source()$ ,  $s.target()$  and  $p$ .

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Circle\_3 c)*

introduces a plane that is defined as the plane containing the circle.

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

*CGAL::Plane\_3<Kernel>* ..... [page 396](#)

## Kernel::ConstructPointOn\_2

A model for this must provide:

*Kernel::Point\_2*                      *fo.operator()( Kernel::Line\_2 l, int i)*

returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all *i < j*.

*Kernel::Point\_2*                      *fo.operator()( Kernel::Ray\_2 r, int i)*

returns a point on *r*. *point(0)* is the source, *point(i)*, with *i > 0*, is different from the source.  
*Precondition: i ≥ 0.*

*Kernel::Point\_2*                      *fo.operator()( Kernel::Segment\_2 s, int i)*

returns source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. The parameter *i* is taken modulo 2, which gives easy access to the other end point.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

## Kernel::ConstructPointOn\_3

A model for this must provide:

*Kernel::Point\_3*                      *fo.operator()( Kernel::Line\_3 l, int i)*

returns an arbitrary point on *l*. It holds *point(i) == point(j)*, iff *i==j*. Furthermore, is directed from *point(i)* to *point(j)*, for all *i < j*.

*Kernel::Point\_3*                      *fo.operator()( Kernel::Plane\_3 h)*

returns an arbitrary point on *h*.

*Kernel::Point\_3*                      *fo.operator()( Kernel::Ray\_3 r, int i)*

returns a point on *r*. *point(0)* is the source, *point(i)*, with *i > 0*, is different from the source.  
*Precondition: i ≥ 0.*

*Kernel::Point\_3*                      *fo.operator()( Kernel::Segment\_3 s, int i)*

returns source or target of *s*: *point(0)* returns the source of *s*, *point(1)* returns the target of *s*. The parameter *i* is taken modulo 2, which gives easy access to the other end point.

*CGAL::Segment\_3<Kernel>* ..... page [406](#)

## Kernel::ConstructPoint\_2

A model for this must provide:

*Kernel::Point\_2*                      *fo.operator()( Origin ORIGIN)*

introduces a variable with Cartesian coordinates (0,0).

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Point\_2<Kernel>* ..... page [371](#)

## Kernel::ConstructPoint\_3

A model for this must provide:

*Kernel::Point\_3*                      *fo.operator()( Origin ORIGIN)*

introduces a point with Cartesian coordinates(0,0,0).

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Point\_3<Kernel>* ..... page [400](#)

## Kernel::ConstructProjectedPoint\_2

A model for this must provide:

```
Kernel::Point_2      fo.operator()( Kernel::Line_2 l, Kernel::Point_2 p)
```

returns the orthogonal projection of  $p$  onto  $l$ .

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

*CGAL::Line\_2<Kernel>* ..... page 368

*Kernel::Point\_3*      *fo.operator()( Kernel::Line\_3 l, Kernel::Point\_3 p)*

returns the orthogonal projection of *p* onto *l*.

*Kernel::Point\_3*      *fo.operator() ( Kernel::Plane\_3 h, Kernel::Point\_3 p)*

returns the orthogonal projection of  $p$  onto  $h$ .

*AdaptableFunctor* (with two arguments)

<i>CGAL::Line_3&lt;Kernel&gt;</i> .....	page 394
<i>CGAL::Plane_3&lt;Kernel&gt;</i> .....	page 396

## Kernel::ConstructProjectedXYPoint\_2

A model for this must provide:

*Kernel::Point\_2*                      *fo.operator()( Kernel::Plane\_3 h, Kernel::Point\_3 p)*

returns the image point of the projection of  $p$  under an affine transformation, which maps  $h$  onto the  $xy$ -plane, with the  $z$ -coordinate removed.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Plane\_3<Kernel>* ..... page [396](#)

## Kernel::ConstructRadicalLine\_2

A model for this must provide:

*Kernel::Line\_2*                      *fo.operator()( Kernel::Circle\_2 c1, Kernel::Circle\_2 c2)*

returns the radical line of the circles.

*Precondition:* The two circles don't have the same center.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Circle\_2<Kernel>* .....page [361](#)

## Kernel::ConstructRadicalPlane\_3

A model for this must provide:

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Sphere\_3 sphere1, Kernel::Sphere\_3 sphere2)*

returns the radical plane of the spheres.

*Precondition:* The two spheres don't have the same center.

### Refines

*AdaptableFunctor* (with two argument)

### See Also

*CGAL::Sphere\_3<Kernel>* ..... page [410](#)

## Kernel::ConstructRay\_2

A model for this must provide:

*Kernel::Ray\_2*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q)*  
introduces a ray with source *p* and passing through point *q*.

*Kernel::Ray\_2*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Vector\_2 v)*  
introduces a ray starting at source *p* with the direction given by *v*.

*Kernel::Ray\_2*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Direction\_2 d)*  
introduces a ray starting at source *p* with direction *d*.

*Kernel::Ray\_2*                      *fo.operator()( Kernel::Point\_2 p, Kernel::Line\_2 l)*  
introduces a ray starting at source *p* with the same direction as *l*.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Ray\_2<Kernel>* .....page [375](#)

### Kernel::ConstructRay\_3

A model for this must provide:

$$\text{Kernel::Ray\_3} \quad fo.operator()(\text{Kernel::Point\_3 } p, \text{Kernel::Point\_3 } q)$$

introduces a ray with source  $p$  and passing through point  $q$ .

```
Kernel::Ray_3      fo.operator()( Kernel::Point_3 p, Kernel::Vector_3 v)
```

introduces a ray with source  $p$  and with the direction given by  $v$ .

```
Kernel::Ray_3 fo.operator() ( Kernel::Point_3 p, Kernel::Direction_3 d)
```

introduces a ray with source  $p$  and with direction  $d$ .

```
Kernel::Ray_3      fo.operator()( Kernel::Point_3 p, Kernel::Line_3 l)
```

introduces a ray with source  $p$  and with the same direction as  $l$ .

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

CGAL::Ray\_3&lt;Kernel&gt; ..... page 404

A model for this must provide:

```
Kernel::Vector_2 fo.operator()( Kernel::Vector_2 v, Kernel::RT scale)
```

produces the vector  $v$  scaled by a factor  $scale$ .

```
Kernel::Vector_2 fo.operator()( Kernel::Vector_2 v, Kernel::FT scale)
```

produces the vector  $v$  scaled by a factor  $scale$ .

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

CGAL::Vector\_2&lt;Kernel&gt; ..... page 381

## Kernel::ConstructScaledVector\_3

A model for this must provide:

```
Kernel::Vector_3      fo.operator()( Kernel::Vector_3 v, Kernel::RT scale)
```

produces the vector  $v$  scaled by a factor  $scale$ .

```
Kernel::Vector_3      fo.operator()( Kernel::Vector_3 v, Kernel::FT scale)
```

produces the vector  $v$  scaled by a factor  $scale$ .

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

CGAL::Vector\_3&lt;Kernel&gt; ..... page 417

## Kernel::ConstructSecondPoint\_2

A model for this must provide:

*Kernel::Point\_2*                      *fo.operator()( Kernel::Ray\_2 r)*

returns a point different from the source on the ray *r*.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Ray\_2<Kernel>* .....page [375](#)

## Kernel::ConstructSegment\_2

A model for this must provide:

*Kernel::Segment\_2*      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q)*

introduces a segment with source *p* and target *q*. The segment is directed from the source towards the target.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Segment\_2<Kernel>*.....page [377](#)

## Kernel::ConstructSegment\_3

A model for this must provide:

*Kernel::Segment\_3*      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q)*

introduces a segment with source *p* and target *q*. It is directed from the source towards the target.

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Segment\_3<Kernel>*.....page [406](#)

## Kernel::ConstructSource\_2

A model for this must provide:

$$Kernel::Point\_2 \quad fo.operator()( \textit{Kernel::Segment\_2} \, s)$$

returns the source of the segment  $s$ .

$$Kernel::Point\_2 \quad fo.operator() (Kernel::Ray\_2 \, r)$$

returns the source of the ray  $r$ .

## Refines

*AdaptableFunctor* (with one argument)

## See Also

<i>CGAL::Segment_2&lt;Kernel&gt;</i> .....	page 377
<i>CGAL::Ray_2&lt;Kernel&gt;</i> .....	page 375

## Kernel::ConstructSphere\_3

A model for this must provide:

*Kernel::Sphere\_3*      *fo.operator()*( *Kernel::Point\_3* center,  
    *Kernel::FT* squared\_radius,  
    Orientation orientation = COUNTERCLOCKWISE)

introduces a sphere initialized to the sphere with center *center*, squared radius *squared\_radius* and orientation *orientation*.

*Precondition:* *orientation*  $\neq$  COPLANAR, and furthermore, *squared\_radius*  $\geq$  0.

*Kernel::Sphere\_3*      *fo.operator()*( *Kernel::Point\_3* p,  
    *Kernel::Point\_3* q,  
    *Kernel::Point\_3* r,  
    *Kernel::Point\_3* s)

introduces a sphere initialized to the unique sphere which passes through the points *p*, *q*, *r* and *s*. The orientation of the sphere is the orientation of the point quadruple *p*, *q*, *r*, *s*.

*Precondition:* *p*, *q*, *r*, and *s* are not coplanar.

*Kernel::Sphere\_3*      *fo.operator()*( *Kernel::Point\_3* p,  
    *Kernel::Point\_3* q,  
    *Kernel::Point\_3* r,  
    Orientation o = COUNTERCLOCKWISE)

introduces a sphere initialized to the smallest sphere which passes through the points *p*, *q*, and *r*. The orientation of the sphere is *o*.

*Precondition:* *o* is not COPLANAR.

*Kernel::Sphere\_3*      *fo.operator()*( *Kernel::Point\_3* p,  
    *Kernel::Point\_3* q,  
    Orientation o = COUNTERCLOCKWISE)

introduces a sphere initialized to the smallest sphere which passes through the points *p* and *q*. The orientation of the sphere is *o*.

*Precondition:* *o* is not COPLANAR.

*Kernel::Sphere\_3*      *fo.operator()*( *Kernel::Point\_3* center,  
    Orientation orientation = COUNTERCLOCKWISE)

introduces a sphere *s* initialized to the sphere with center *center*, squared radius zero and orientation *orientation*.

*Precondition:* *orientation*  $\neq$  COPLANAR.

*Postcondition:* *s.is\_degenerate()* = true.

*Kernel::Sphere\_3*      *fo.operator()( Kernel::Circle\_3 c)*

introduces a sphere initialized to the diametral sphere of the circle.

## Refines

*AdaptableFunctor* (with four arguments)

## See Also

*CGAL::Sphere\_3<Kernel>* ..... [page 410](#)

## Kernel::ConstructSumOfVectors\_2

A model for this must provide:

*Kernel::Vector\_2*                      *fo.operator()( Kernel::Vector\_2 v1, Kernel::Vector\_2 v2)*

introduces the vector  $v1 + v2$ .

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

*CGAL::Vector\_2<Kernel>* ..... page [381](#)

# Kernel::ConstructSumOfVectors\_3

A model for this must provide:

*Kernel::Vector\_3*                *fo.operator()( Kernel::Vector\_3 v1, Kernel::Vector\_3 v2)*  
introduces the vector  $v1 + v2$ .

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

*CGAL::Vector\_3<Kernel>* ..... page [417](#)

## Kernel::ConstructSupportingPlane\_3

A model for this must provide:

*Kernel::Plane\_3*                      *fo.operator()( Kernel::Triangle\_3 t)*

returns the supporting plane of *t*, with same orientation.

### Refines

*AdaptableFunctor* (with one argument)

### See Also

*CGAL::Triangle\_3<Kernel>* ..... page [415](#)

# Kernel::ConstructTarget\_2

A model for this must provide:

*Kernel::Point\_2*

*fo.operator()( Kernel::Segment\_2 s)*

returns the target of the segment *s*.

## Refines

*AdaptableFunctor* (with one argument)

## See Also

*CGAL::Segment\_2<Kernel>*.....page [377](#)

## Kernel::ConstructTetrahedron\_3

A model for this must provide:

```
Kernel::Tetrahedron_3    fo.operator()( Kernel::Point_3 p0,
                                         Kernel::Point_3 p1,
                                         Kernel::Point_3 p2,
                                         Kernel::Point_3 p3)
```

introduces a tetrahedron with vertices  $p_0$ ,  $p_1$ ,  $p_2$  and  $p_3$ .

### Refines

*AdaptableFunctor* (with four arguments)

### See Also

*CGAL::Tetrahedron\_3<Kernel>* ..... page [413](#)

## Kernel::ConstructTranslatedPoint\_2

A model for this must provide:

```
Kernel::Point_2      fo.operator()( Kernel::Point_2 p, Kernel::Vector_2 v)
```

returns the point obtained by translating  $p$  by the vector  $v$ .

$$\text{Kernel}::\text{Point}_2 \quad fo.operator()(\text{Origin } o, \text{Kernel}::\text{Vector}_2 v)$$

returns the point obtained by translating a point at the origin by the vector  $v$ .

## Refines

*AdaptableFunctor* (with two arguments)

## See Also

CGAL::Point\_2&lt;Kernel&gt; ..... page 371

$$\text{Kernel::Point}_3 \quad \text{fo.operator()}(\text{Kernel::Point}_3 p, \text{Kernel::Vector}_3 v)$$

## Kernel::ConstructTriangle\_2

A model for this must provide:

*Kernel::Triangle\_2*      *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*

introduces a triangle with vertices *p*, *q* and *r*.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::Triangle\_2<Kernel>* ..... page [379](#)

## Kernel::ConstructTriangle\_3

A model for this must provide:

*Kernel::Triangle\_3*      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

introduces a triangle with vertices *p*, *q* and *r*.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::Triangle\_3<Kernel>* ..... page [415](#)

## Kernel::ConstructUnitNormal\_3

A model for this must provide:

*Kernel::Vector\_3*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

computes the unit normal of the vectors  $q-p$  and  $r-p$ . This requires that *Kernel::FT* supports the *sqrt* operation.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::normal* ..... page [496](#)

## Kernel::ConstructVector\_2

A model for this must provide:

*Kernel::Vector\_2*      *fo.operator()( Kernel::Point\_2 a, Kernel::Point\_2 b)*

introduces the vector  $b - a$ .

*Kernel::Vector\_2*      *fo.operator()( Origin o, Kernel::Point\_2 b)*

introduces the vector  $b$ .

*Kernel::Vector\_2*      *fo.operator()( Kernel::Point\_2 a, Origin o)*

introduces the vector  $-a$ .

*Kernel::Vector\_2*      *fo.operator()( Kernel::Segment\_2 s)*

introduces the vector  $s.target() - s.source()$ .

*Kernel::Vector\_2*      *fo.operator()( Kernel::Ray\_2 r)*

introduces a vector having the same direction as  $r$ .

*Kernel::Vector\_2*      *fo.operator()( Kernel::Line\_2 l)*

introduces a vector having the same direction as  $l$ .

*Kernel::Vector\_2*      *fo.operator()( Null\_vector NULL\_VECTOR)*

introduces a null vector .

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

## Kernel::ConstructVector\_3

A model for this must provide:

*Kernel::Vector\_3*            *fo.operator()( Kernel::Point\_3 a, Kernel::Point\_3 b)*  
introduces the vector  $b - a$ .

*Kernel::Vector\_3*            *fo.operator()( Origin o, Kernel::Point\_3 b)*  
introduces the vector  $b$ .

*Kernel::Vector\_3*            *fo.operator()( Kernel::Point\_3 a, Origin o)*  
introduces the vector  $-a$ .

*Kernel::Vector\_3*            *fo.operator()( Kernel::Segment\_3 s)*  
introduces the vector  $s.target() - s.source()$ .

*Kernel::Vector\_3*            *fo.operator()( Kernel::Ray\_3 r)*  
introduces a vector having the same direction as  $r$ .

*Kernel::Vector\_3*            *fo.operator()( Kernel::Line\_3 l)*  
introduces a vector having the same direction as  $l$ .

*Kernel::Vector\_3*            *fo.operator()( Null\_vector NULL\_VECTOR)*  
introduces a null vector .

### Refines

*AdaptableFunctor* (with two arguments)

### See Also

## Kernel::ConstructVertex\_2

A model for this must provide:

*Kernel::Point\_2*                      *fo.operator()( Kernel::Segment\_2 s, int i)*

returns source or target of *s*: *fo(s,0)* returns the source of *s*, *fo(s,1)* returns the target of *s*. The parameter *i* is taken modulo 2.

*Kernel::Point\_2*                      *fo.operator()( Kernel::Iso\_rectangle\_2 r, int i)*

returns the *i*'th vertex of *r* in counterclockwise order, starting with the lower left vertex. The parameter *i* is taken modulo 4.

*Kernel::Point\_2*                      *fo.operator()( Kernel::Triangle\_2 t, int i)*

returns the *i*'th vertex of *t*. The parameter *i* is taken modulo 3.

## Kernel::ConstructVertex\_3

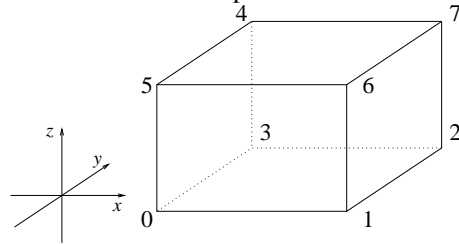

A model for this must provide:

*Kernel::Point\_3* *fo.operator()( Kernel::Segment\_3 s, int i)*

returns source or target of  $s$ :  $fo(s,0)$  returns the source of  $s$ ,  $fo(s,1)$  returns the target of  $s$ . The parameter  $i$  is taken modulo 2.

*Kernel::Point\_3* *fo.operator()( Kernel::Iso\_cuboid\_3 c, int i)*

returns the  $i$ 'th vertex of  $c$ , as indicated in the figure below. The parameter  $i$  is taken modulo 8.

*Kernel::Point\_3* *fo.operator()( Kernel::Triangle\_3 t, int i)*

returns the  $i$ 'th vertex of  $t$ . The parameter  $i$  is taken modulo 3.

*Kernel::Point\_3* *fo.operator()( Kernel::Tetrahedron\_3 t, int i)*

returns the  $i$ 'th vertex of  $t$ . The parameter  $i$  is taken modulo 4.

Kernel::ConstructCartesianConstIterator\_3 ..... page [633](#)

## Kernel::CoplanarOrientation\_3

A model for this must provide:

*Orientation*                      *fo.operator()( Kernel::Point\_3 p,*  
    *Kernel::Point\_3 q,*  
    *Kernel::Point\_3 r,*  
    *Kernel::Point\_3 s)*

Let  $P$  be the plane defined by the points  $p$ ,  $q$ , and  $r$ . Note that the order defines the orientation of  $P$ . The function computes the orientation of points  $p$ ,  $q$ , and  $s$  in  $P$ : Iff  $p$ ,  $q$ ,  $s$  are collinear, *COLLINEAR* is returned. Iff  $P$  and the plane defined by  $p$ ,  $q$ , and  $s$  have the same orientation, *POSITIVE* is returned; otherwise *NEGATIVE* is returned. *Precondition:*  $p$ ,  $q$ ,  $r$ , and  $s$  are coplanar and  $p$ ,  $q$ , and  $r$  are not collinear.

*Orientation*                      *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*

If  $p, q, r$  are collinear, then *COLLINEAR* is returned. If not, then  $p, q, r$  define a plane  $P$ . The return value in this case is either *POSITIVE* or *NEGATIVE*, but we don't specify it explicitly. However, we guarantee that all calls to this predicate over 3 points in  $P$  will return a coherent orientation if considered a 2D orientation in  $P$ .

### Kernel::CoplanarSideOfBoundedCircle\_3

A model for this must provide:

```
Bounded_side      fo.operator()( Kernel::Point_3 p,
                                   Kernel::Point_3 q,
                                   Kernel::Point_3 r,
                                   Kernel::Point_3 s)
```

returns the bounded side of the circle defined by  $p$ ,  $q$ , and  $r$  on which  $s$  lies.

*Precondition:*  $p$ ,  $q$ ,  $r$ , and  $s$  are coplanar and  $p$ ,  $q$ , and  $r$  are not collinear.

## Refines

## Kernel::Coplanar\_3

A model for this must provide:

```
bool                                fo.operator()( Kernel::Point_3 p,
                                                    Kernel::Point_3 q,
                                                    Kernel::Point_3 r,
                                                    Kernel::Point_3 s)

                                returns true, if p, q, r, and s are coplanar.
```

## Kernel::CounterclockwiseInBetween\_2

A model for this must provide:

```
bool                                fo.operator()( Kernel::Direction_2 d,
                                                    Kernel::Direction_2 d1,
                                                    Kernel::Direction_2 d2)
```

returns *true* iff *d* is not equal to *d1*, and while rotating counterclockwise starting at *d1*, *d* is reached strictly before *d2* is reached. Note that true is returned if *d1* == *d2*, unless also *d* == *d1*.

## Kernel::Intersect\_3

A model for this must provide

*Kernel::Object\_3*      *fo.operator()( Type1 obj1, Type2 obj2)*

computes the intersection region of two geometrical objects of type *Type1* and *Type2*

for all pairs *Type1* and *Type2*, where the type *Type1* is *Kernel::Plane\_3* and *Type2* can be any of the following:

- *Kernel::Plane\_3*
- *Kernel::Line\_3*
- *Kernel::Ray\_3*
- *Kernel::Segment\_3*
- *Kernel::Sphere\_3*.

*Kernel::Object\_3*      *fo.operator()( Kernel::Line\_3 l1, Kernel::Line\_3 l2)*

computes the intersection of two lines. The result can be either a *Kernel::Point\_3*, a *Kernel::Line\_3*, or empty.

*Kernel::Object\_3*      *fo.operator()( Kernel::Sphere\_3 s1, Kernel::Sphere\_3 s2)*

computes the intersection of two spheres. The result can be either a *Kernel::Point\_3*, a *Kernel::Circle\_3*, a *Kernel::Sphere\_3* or empty.

*Kernel::Object\_3*      *fo.operator()( Kernel::Plane\_3 pl1, Kernel::Plane\_3 pl2, Kernel::Plane\_3 pl3)*

computes the intersection of three planes. The result can be either a *Kernel::Point\_3*, a *Kernel::Line\_3*, a *Kernel::Plane\_3*, or empty.

## Kernel::IsDegenerate\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Circle\_2 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Iso\_rectangle\_2 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Line\_2 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Ray\_2 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Segment\_2 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Triangle\_2 o)*  
returns true iff *o* is degenerate.

### Refines

*AdaptableFunctor* (with one argument)

## Kernel::IsDegenerate\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Circle\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Iso\_cuboid\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Line\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Plane\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Ray\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Segment\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Sphere\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Tetrahedron\_3 o)*  
returns true iff *o* is degenerate.

*bool* *fo.operator()( Kernel::Triangle\_3 o)*  
returns true iff *o* is degenerate.

## Kernel::IsHorizontal\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Line\_2 o)*  
returns true iff *o* is horizontal.

*bool* *fo.operator()( Kernel::Ray\_2 o)*  
returns true iff *o* is horizontal.

*bool* *fo.operator()( Kernel::Segment\_2 o)*  
returns true iff *o* is horizontal.

## Kernel::IsVertical\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Line\_2 o)*  
returns true iff *o* is vertical.

*bool* *fo.operator()( Kernel::Ray\_2 o)*  
returns true iff *o* is vertical.

*bool* *fo.operator()( Kernel::Segment\_2 o)*  
returns true iff *o* is vertical.

## Kernel::LeftTurn\_2

A model for this must provide:

*bool* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Point\_2* *q*, *Kernel::Point\_2* *r*)  
returns *true*, iff the three points *p*, *q* and *r* form a left turn.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::left\_turn* ..... page [487](#)

## Kernel::LessDistanceToPoint\_2

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_2 p, Kernel::Point\_2 q, Kernel::Point\_2 r)*  
 returns true iff the distance of *q* to *p* is smaller than the distance of *r* to *p*.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::has\_smaller\_distance\_to\_point* ..... page [479](#)

## Kernel::LessDistanceToPoint\_3

A model for this must provide:

*bool* *fo.operator()( Kernel::Point\_3 p, Kernel::Point\_3 q, Kernel::Point\_3 r)*  
 returns true iff the distance of *q* to *p* is smaller than the distance of *r* to *p*.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

## Kernel::LessRotateCCW\_2

A model for this must provide:

*bool* *fo.operator()*( *Kernel::Point\_2* *p*, *Kernel::Point\_2* *q*, *Kernel::Point\_2* *r*)

returns true iff the three points *p*, *q* and *r* form a left turn or if they are collinear and the distance of *q* to *p* is larger than the distance of *r* to *p*, where *p* is the point passed to the object at construction.

*Precondition:* *p* does not lie in the interior of the segment *rq*, i.e. *p* is an extreme point with respect to  $\{p, q, r\}$ .

### Refines

*AdaptableFunctor* (with three arguments)

## Kernel::LessSignedDistanceToLine\_2

A model for this must provide:

*bool* *fo.operator()*( *Kernel::Line\_2* *l*, *Kernel::Point\_2* *p*, *Kernel::Point\_2* *q*)

returns *true* if the signed distance from *p* and the oriented line *l* is smaller than the signed distance of *q* and *l*.

*bool* *fo.operator()*( *Kernel::Point\_2* *p*,  
*Kernel::Point\_2* *q*,  
*Kernel::Point\_2* *r*,  
*Kernel::Point\_2* *s*)

returns *true* if the signed distance from *r* and the oriented line *l* defined by *p* and *q* is smaller than the signed distance of *s* and *l*.  
*Precondition:* *p*! = *q*.

### Refines

*AdaptableFunctor* (with four arguments)

### See Also

## Kernel::LessSignedDistanceToPlane\_3

A model for this must provide:

*bool* *fo.operator()*( *Kernel::Plane\_3* *p*, *Kernel::Point\_3* *q*, *Kernel::Point\_3* *r*)

returns true, iff the signed distance from point *q* to plane *p* is smaller than the signed distance from point *r* to *p*.

*bool* *fo.operator()*( *Kernel::Point\_3* *p1*,  
*Kernel::Point\_3* *p2*,  
*Kernel::Point\_3* *p3*,  
*Kernel::Point\_3* *q*,  
*Kernel::Point\_3* *r*)

returns true, iff the signed distance from point *q* to the plane *p* defined by *p1*, *p2*, *p3* is smaller than the signed distance from point *r* to *p*.  
*Precondition:* *p*, *q*, and *r* are not collinear.

### Refines

*CGAL::compare\_z* ..... [page 465](#)

## Kernel::Orientation\_2

A model for this must provide:

*Orientation*  $fo.operator()( \text{Kernel::Point\_2 } p, \text{Kernel::Point\_2 } q, \text{Kernel::Point\_2 } r )$

returns *LEFT\_TURN*, if  $r$  lies to the left of the oriented line  $l$  defined by  $p$  and  $q$ , returns *RIGHT\_TURN* if  $r$  lies to the right of  $l$ , and returns *COLLINEAR* if  $r$  lies on  $l$ .

*Orientation*  $fo.operator()( \text{Kernel::Vector\_2 } u, \text{Kernel::Vector\_2 } v )$

returns *LEFT\_TURN* if  $u$  and  $v$  form a left turn, returns *RIGHT\_TURN* if  $u$  and  $v$  form a right turn, and returns *COLLINEAR* if  $u$  and  $v$  are collinear.

### Refines

*AdaptableFunctor* (with three arguments)

### See Also

*CGAL::orientation* .....page [850](#)

## Kernel::Orientation\_3

A model for this must provide:

*Orientation*                      *fo.operator()( Kernel::Point\_3 p,*  
    *Kernel::Point\_3 q,*  
    *Kernel::Point\_3 r,*  
    *Kernel::Point\_3 s)*

returns *POSITIVE*, if *s* lies on the positive side of the oriented plane *h* defined by *p*, *q*, and *r*, returns *NEGATIVE* if *s* lies on the negative side of *h*, and returns *COPLANAR* if *s* lies on *h*.

*Orientation*                      *fo.operator()( Kernel::Vector\_3 u, Kernel::Vector\_3 v, Kernel::Vector\_3 w)*

returns *POSITIVE* if *u*, *v* and *w* are positively oriented, returns *NEGATIVE* if *u*, *v* and *w* are negatively oriented, and returns *COPLANAR* if *u*, *v* and *w* are coplanar.

*Orientation*                      *fo.operator()( Kernel::Sphere\_3 s)*

returns the orientation of the sphere *s*.

### Refines

*AdaptableFunctor* (with four arguments)

### See Also

## Kernel::SideOfBoundedCircle\_2

A model for this must provide:

```
Bounded_side      fo.operator()( Kernel::Point_2 p,
                                   Kernel::Point_2 q,
                                   Kernel::Point_2 r,
                                   Kernel::Point_2 t)
```

returns the relative position of point  $t$  to the circle defined by  $p$ ,  $q$  and  $r$ . The order of the points  $p$ ,  $q$  and  $r$  does not matter.

*Precondition:*  $p, q$  and  $r$  are not collinear.

<i>Bounded_side</i>	<i>fo.operator()</i> ( <i>Kernel::Point_2</i> <i>p</i> , <i>Kernel::Point_2</i> <i>q</i> , <i>Kernel::Point_2</i> <i>t</i> )
---------------------	--

returns the position of the point  $t$  relative to the circle that has  $pq$  as its diameter.

## Refines

*AdaptableFunctor* (with four arguments)

## See Also

CGAL::side\_of\_bounded\_circle.....page 510

## Kernel::SideOfOrientedCircle\_2

A model for this must provide:

*Oriented\_side*                      *fo.operator()( Kernel::Point\_2 p,*  
    *Kernel::Point\_2 q,*  
    *Kernel::Point\_2 r,*  
    *Kernel::Point\_2 t)*

returns the relative position of point *t* to the oriented circle defined by *p*, *q* and *r*. The order of the points *p*, *q* and *r* is important, since it determines the orientation of the implicitly constructed circle.

*Precondition:* *p*, *q* and *r* are not collinear.

### Refines

*AdaptableFunctor* (with four arguments)

### See Also

*CGAL::side\_of\_oriented\_circle* ..... [page 512](#)

<i>Oriented_side</i>	<i>fo.operator()</i> ( <i>Kernel::Point_3</i> <i>p</i> , <i>Kernel::Point_3</i> <i>q</i> , <i>Kernel::Point_3</i> <i>r</i> , <i>Kernel::Point_3</i> <i>s</i> , <i>Kernel::Point_3</i> <i>t</i> )
----------------------	--

*Precondition:*  $p, q, r$  and  $s$  are not coplanar.

*AdaptableFunctor* (with five arguments)

## 7.14 Dimension handling tools

### CGAL::Ambient\_dimension<T, K = Kernel\_traits<T>::Kernel>

#### Definition

The class *Ambient\_dimension*<T, K = *Kernel\_traits*<T>::Kernel> allows to retrieve the dimension of the ambient space of a type.

```
#include <CGAL/Dimension.h>
```

#### Constants

<i>static const int</i>	<i>value;</i>	The dimension value as a compile-time integral constant. It is implemented as <i>K::Dimension&lt;T&gt;::type::value</i> . It exists only when the dimension is a compile-time constant.
-------------------------	---------------	---

#### Types

*Ambient\_dimension*<T, K = *Kernel\_traits*<T>::Kernel>:: *type*

Either *Dimension\_tag*<*dim*> if the dimension is a compile-time constant of value *dim*, or *Dynamic\_dimension\_tag* otherwise. It is implemented as *K::Ambient\_dimension*<T>::*type*.

#### Example

The following retrieves the dimension of a point type.

```
typedef K::Point_2 Point;
int dimension = Ambient_dimension<Point, K>::value;
assert (dimension == 2);
```

#### See Also

CGAL::Dimension\_tag<int dim> ..... page [781](#)  
 CGAL::Dynamic\_dimension\_tag ..... page [782](#)  
 CGAL::Feature\_dimension<T, K = Kernel\_traits<T>::Kernel> ..... page [779](#)

### CGAL::Feature\_dimension<T, K = Kernel\_traits<T>::Kernel>

## Definition

The class *Feature\_dimension*<*T*, *K* = *Kernel\_traits*<*T*>::*Kernel*> allows to retrieve the geometric dimension of a type.

```
#include <CGAL/Dimension.h>
```

## Constants

<i>static const int</i>	<i>value</i> ;	The dimension value as a compile-time integral constant. It is implemented as <i>K::Feature_dimension</i> < <i>T</i> >:: <i>type::value</i> . It exists only when the dimension is a compile-time constant.
-------------------------	----------------	---

## Types

*Feature\_dimension*<*T*, *K* = *Kernel\_traits*<*T*>::*Kernel*>::*type*

Either *Dimension\_tag*<*dim*> if the dimension is a compile-time constant of value *dim*, or *Dynamic\_dimension\_tag* otherwise. It is implemented as *K::Feature\_dimension*<*T*>::*type*.

## Example

The following retrieves the dimension of a point type.

```
typedef K::Point_2 Point;
int dimension = Feature_dimension<Point, K>::value;
assert(dimension == 0);
```

## See Also

CGAL::Dimension\_tag<int dim> ..... page [781](#)  
CGAL::Dynamic\_dimension\_tag ..... page [782](#)  
CGAL::Ambient\_dimension<*T*, *K* = *Kernel\_traits*<*T*>::*Kernel*> ..... page [779](#)

## CGAL::Dimension\_tag<int dim>

### Definition

An object of the class *Dimension\_tag<int dim>* is an empty object which can be used for dispatching functions based on the dimension of an object, as provided by the *dim* parameter. It is useful in cases where it is not more practical to pass the dimension as a template parameter directly.

```
#include <CGAL/Dimension.h>
```

### Constants

<i>static const int</i>	<i>value;</i>	The value of the <i>dim</i> parameter.
-------------------------	---------------	--

### Example

The following code declares two functions constructing two points at the origin, either in 2D or in 3D.

```
Point_2<K> get_origin(Dimension_tag<2>) { return Point_2<K>(ORIGIN); }
Point_3<K> get_origin(Dimension_tag<3>) { return Point_3<K>(ORIGIN); }

std::cout << get_origin(Dimension_tag<2>()) << std::endl;
```

### See Also

CGAL::Feature_dimension<T, K = Kernel_traits<T>::Kernel> .....	page <a href="#">779</a>
CGAL::Dynamic_dimension_tag .....	page <a href="#">782</a>

## CGAL::Dynamic\_dimension\_tag

### Definition

An object of the class *Dynamic\_dimension\_tag* is an empty object which can be used for dispatching functions based on the dimension of an object. *Dynamic\_dimension\_tag* indicates that the dimension is not known at compile-time. *Dimension\_tag* is the tag class dealing with compile-time dimensions.

```
#include <CGAL/Dimension.h>
```

### Example

The following code declares two functions constructing two points at the origin, either in 2D or in 3D.

```
Point_2<K> get_origin(Dimension_tag<2>) { return Point_2<K>(ORIGIN); }
Point_3<K> get_origin(Dimension_tag<3>) { return Point_3<K>(ORIGIN); }
Point_d<K> get_origin(Dynamic_dimension_tag) { return Point_d<K>(ORIGIN); }

std::cout << get_origin(Dynamic_dimension_tag()) << std::endl;
```

### 8.1 Introduction

This part of the reference manual covers the higher-dimensional kernel. The kernel contains objects of constant size, such as point, vector, direction, line, ray, segment, circle. With each type comes a set of functions which can

be applied to an object of this type. You will typically find access functions (e.g. to the coordinates of a point), tests of the position of a point relative to the object, a function returning the bounding box, the length, or the area of an object, and so on. The CGAL kernel further contains basic operations such as affine transformations, detection and computation of intersections, and distance computations. Note that this section partly recapitulates facts already mentioned for the lower-dimensional kernel.

### 8.1.1 Robustness

The correctness proof of nearly all geometric algorithms presented in theory papers assumes exact computation with real numbers. This leads to a fundamental problem with the implementation of geometric algorithms. Naively, often the exact real arithmetic is replaced by inexact floating-point arithmetic in the implementation. This often leads to acceptable results for many input data. However, even for the implementation of the simplest geometric algorithms this simplification occasionally does not work. Rounding errors introduced by inaccurate arithmetic may lead to inconsistent decisions, causing unexpected failures for some correct input data. There are many approaches to this problem, one of them is to compute exactly (compute so accurate that all decisions made by the algorithm are exact) which is possible in many cases but more expensive than standard floating-point arithmetic. C. M. Hoffmann [Hof89a, Hof89b] illustrates some of the problems arising in the implementation of geometric algorithms and discusses some approaches to solve them. A more recent overview is given in [Sch00]. The exact computation paradigm is discussed by Yap and Dubé [YD95] and Yap [Yap97].

In CGAL you can choose the underlying number types and arithmetic. You can use different types of arithmetic simultaneously and the choice can be easily changed, e.g. for testing. So you can choose between implementations with fast but occasionally inexact arithmetic and implementations guaranteeing exact computation and exact results. Of course you have to pay for the exactness in terms of execution time and storage space. See the dedicated chapter for more details on number types and their capabilities and performance.

### 8.1.2 Genericity

To increase generic usage of objects and predicates the higher-dimensional kernel makes heavy use of iterator ranges as defined in the STL for modeling tuples. Iterators conceptualize C++ pointers.

For an iterator range  $[first, last)$  we define  $T = tuple [first, last)$  as the ordered tuple  $(T[0], T[1], \dots, T[d-1])$  where  $S[i] = * +^{(i)} first$  (the element obtained by  $i$  times forwarding the iterator by operator  $++$  and then dereferencing it to get the value to which it points). We write  $d = size [first, last)$  and  $S = set [first, last)$  to denote the unordered set of elements of the corresponding tuple.

This extends the syntax of random access iterators to input iterators. If we index the tuple as above then we require that  $++^{(d+1)} first = last$ .

## 8.2 Kernel Representations

Our object of study is the  $d$ -dimensional affine Euclidean space, where  $d$  is a parameter of our geometry. Objects in that space are sets of points. A common way to represent the points is the use of Cartesian coordinates, which assumes a reference frame (an origin and  $d$  orthogonal axes). In that framework, a point is represented by a  $d$ -tuple  $(c_0, c_1, \dots, c_{d-1})$ , and so are vectors in the underlying linear space. Each point is represented uniquely by such Cartesian coordinates.

Another way to represent points is by homogeneous coordinates. In that framework, a point is represented by a  $(d+1)$ -tuple  $(h_0, h_1, \dots, h_d)$ . Via the formulae  $c_i = h_i/h_d$ , the corresponding point with Cartesian coordinates

$(c_0, c_1, \dots, c_{d-1})$  can be computed. Note that homogeneous coordinates are not unique. For  $\lambda \neq 0$ , the tuples  $(h_0, h_1, \dots, h_d)$  and  $(\lambda \cdot h_0, \lambda \cdot h_1, \dots, \lambda \cdot h_d)$  represent the same point. For a point with Cartesian coordinates  $(c_0, c_1, \dots, c_{d-1})$  a possible homogeneous representation is  $(c_0, c_1, \dots, c_{d-1}, 1)$ . Homogeneous coordinates in fact allow to represent objects in a more general space, the projective space  $\mathbb{P}_d$ . In CGAL, we do not compute in projective geometry. Rather, we use homogeneous coordinates to avoid division operations, since the additional coordinate can serve as a common denominator.

### 8.2.1 Genericity through Parameterization

Almost all the kernel objects (and the corresponding functions) are templates with a parameter that allows the user to choose the representation of the kernel objects. A type that is used as an argument for this parameter must fulfill certain requirements on syntax and semantics. The list of requirements defines an abstract kernel concept. In CGAL such a kernel concept is often also called a *representation class* and denoted by  $R$ . A representation class provides the actual implementations of the kernel objects. For all kernel objects *Kernel\_object*, the types  $\text{CGAL}::\text{Kernel\_object}<R>$  and  $R::\text{Kernel\_object}$  are identical.

CGAL offers two families of concrete models for the concept representation class, one based on the Cartesian representation of points and one based on the homogeneous representation of points. The interface of the kernel objects is designed such that it works well with both Cartesian and homogeneous representation, for example, points have a constructor with a range of coordinates plus a common denominator (the  $d + 1$  homogeneous coordinates of the point). The common interfaces parameterized with a representation class allow one to develop code independent of the chosen representation. We said “families” of models, because both families are parameterized too. A user can choose the number type used to represent the coordinates and the linear algebra module used to calculate the result of predicates and constructions.

For reasons that will become evident later, a representation class provides two typenamees for number types, namely  $R::FT$  and  $R::RT$  and one typename for the linear algebra module  $R::LA$ .<sup>1</sup> The type  $R::FT$  must fulfill the requirements on what is called a *field type* in CGAL. This roughly means that  $R::FT$  is a type for which operations  $+$ ,  $-$ ,  $*$  and  $/$  are defined with semantics (approximately) corresponding to those of a field in a mathematical sense. Note that, strictly speaking, the built-in type *int* does not fulfill the requirements on a field type, since *ints* correspond to elements of a ring rather than a field, especially operation  $/$  is not the inverse of  $*$ . The requirements on the type  $R::RT$  are weaker. This type must fulfill the requirements on what is called an *Euclidean ring type* in CGAL. This roughly means that  $R::RT$  is a type for which operations  $+$ ,  $-$ ,  $*$  are defined with semantics (approximately) corresponding to those of a ring in a mathematical sense. A very limited division operation  $/$  must be available as well. It must work for exact (i.e., no remainder) integer divisions only. Furthermore, both number types should fulfill CGAL’s requirements on a number type.

### 8.2.2 Cartesian Kernel

With  $\text{Cartesian}_d<\text{FieldNumberType}, \text{LinearAlgebra}>$  you can choose Cartesian representation of coordinates. The type *LinearAlgebra* must be a linear algebra module working on numbers of type *FieldNumberType*. The second parameter defaults to module delivered with the kernel so for short a user can just write  $\text{Cartesian}_d<\text{FieldNumberType}>$  when not providing her own linear algebra.

When you choose Cartesian representation you have to declare at least the type of the coordinates. A number type used with the  $\text{Cartesian}_d$  representation class should be a *field type* as described above. Both  $\text{Cartesian}<\text{FieldNumberType}>::FT$  and  $\text{Cartesian}<\text{FieldNumberType}>::RT$  are mapped to number type *FieldNumberType*.  $\text{Cartesian}_d<\text{FieldNumberType}, \text{LinearAlgebra}>::LA$  is mapped to the type *LinearAlgebra*.  $\text{Cartesian}<\text{FieldNumberType}>$  uses reference counting internally to save copying costs.

---

<sup>1</sup>The double colon  $::$  is the C++ scope operator.

### 8.2.3 Homogeneous Kernel

As we mentioned before, homogeneous coordinates permit to avoid division operations in numerical computations, since the additional coordinate can serve as a common denominator. Avoiding divisions can be useful for exact geometric computation. With *Homogeneous\_d<RingNumberType,LinearAlgebra>* you can choose homogeneous representation of coordinates with the kernel objects. As for Cartesian representation you have to declare at the same time the type used to store the homogeneous coordinates. Since the homogeneous representation allows one to avoid the divisions, the number type associated with a homogeneous representation class must be a model for the weaker concept Euclidean ring type only.

The type *LinearAlgebra* must be a linear algebra module working on numbers of type *RingNumberType*. Again the second parameter defaults to module delivered with the kernel so for short one can just write *Homogeneous\_d<RingNumberType>* when replacing the default is no issue.

However, some operations provided by this kernel involve division operations, for example computing squared distances or returning a Cartesian coordinate. To keep the requirements on the number type parameter of *Homogeneous* low, the number type *Quotient<RingNumberType>* is used instead. This number type turns a ring type into a field type. It maintains numbers as quotients, i.e. a numerator and a denominator. Thereby, divisions are circumvented. With *Homogeneous\_d<RingNumberType>*, *Homogeneous\_d<RingNumberType>::FT* is equal to *Quotient<RingNumberType>* while *Homogeneous\_d<RingNumberType>::RT* is equal to *RingNumberType*. *Homogeneous\_d<RingNumberType,LinearAlgebra>::LA* is mapped to the type *LinearAlgebra*.

### 8.2.4 Naming conventions

The use of representation classes not only avoids problems, it also makes all CGAL classes very uniform. They **always** consist of:

1. The *capitalized base name* of the geometric object, such as *Point*, *Segment*, *Triangle*.
2. Followed by *\_d*.
3. A *representation class* as parameter, which itself is parameterized with a number type, such as *Cartesian\_d<double>* or *Homogeneous\_d<leda\_integer>*.

### 8.2.5 Kernel as a Traits Class

Algorithms and data structures in the basic library of CGAL are parameterized by a traits class that subsumes the objects on which the algorithm or data structure operates as well as the operations to do so. For most of the algorithms and data structures in the basic library you can use a kernel as a traits class. For some algorithms you even do not have to specify the kernel; it is detected automatically using the types of the geometric objects passed to the algorithm. In some other cases, the algorithms or data structures needs more than is provided by a kernel. In these cases, a kernel can not be used as a traits class.

### 8.2.6 Choosing a Kernel

If you start with integral Cartesian coordinates, many geometric computations will involve integral numerical values only. Especially, this is true for geometric computations that evaluate only predicates, which are tantamount to determinant computations. Examples are triangulation of point sets and convex hull computation.

The dimension  $d$  of our affine space determines the dimension of the matrix computations in the mathematical evaluation of predicates. As rounding errors accumulate fast the homogeneous representation used with multi-precision integers is the kernel of choice for well-behaved algorithms. Note, that unless you use an arbitrary precision integer type, incorrect results might arise due to overflow.

If new points are to be constructed, for example the intersection point of two lines, computation of Cartesian coordinates usually involves divisions, so you need to use a field type with Cartesian representation or have to switch to homogeneous representation. *double* is a possible, but imprecise field type. You can also put any ring type into *Quotient* to get a field type and put it into *Cartesian*, but you better put the ring type into *Homogeneous*. *leda\_rational* and *leda\_real* are valid field types, too.

Still other people will prefer the built-in type *double*, because they need speed and can live with approximate results, or even algorithms that, from time to time, crash or compute incorrect results due to accumulated rounding errors.

### 8.2.7 Inclusion of Header Files

You need just to include a representation class to obtain the geometric objects of the kernel that you would like to use with the representation class, i.e., *CGAL/Cartesian\_d.h* or *CGAL/Homogeneous\_d.h*

## 8.3 Kernel Geometry

### 8.3.1 Points and Vectors

In CGAL, we strictly distinguish between points, vectors and directions. A *point* is a point in the Euclidean space  $\mathbb{E}^d$ , a *vector* is the difference of two points  $p_2, p_1$  and denotes the direction and the distance from  $p_1$  to  $p_2$  in the vector space  $\mathbb{R}^d$ , and a *direction* is a vector where we forget about its length. They are different mathematical concepts. For example, they behave different under affine transformations and an addition of two points is meaningless in affine geometry. By putting them in different classes we not only get cleaner code, but also type checking by the compiler which avoids ambiguous expressions. Hence, it pays twice to make this distinction.

CGAL defines a symbolic constant *ORIGIN* of type *Origin* which denotes the point at the origin. This constant is used in the conversion between points and vectors. Subtracting it from a point  $p$  results in the locus vector of  $p$ .

```
double coord[] = {1.0, 1.0, 1.0, 1.0};
Point_d< Cartesian_d<double> > p(4,coord,coord+4), q(4);
Vector_d< Cartesian_d<double> > v(4);
v = p - ORIGIN;
q = ORIGIN + v;
assert( p == q );
```

In order to obtain the point corresponding to a vector  $v$  you simply have to add  $v$  to *ORIGIN*. If you want to determine the point  $q$  in the middle between two points  $p_1$  and  $p_2$ , you can write<sup>2</sup>

```
q = p_1 + (p_2 - p_1) / 2.0;
```

---

<sup>2</sup>you might call *midpoint(p\_1,p\_2)* instead

Note that these constructions do not involve any performance overhead for the conversion with the currently available representation classes.

### 8.3.2 Kernel Objects

Besides points (*Point\_d<R>*), vectors (*Vector\_d<R>*), and directions (*Direction\_d<R>*), CGAL provides lines, rays, segments, hyperplanes, and spheres.

Lines (*Line\_d<R>*) in CGAL are oriented. A ray (*Ray\_d<R>*) is a semi-infinite interval on a line, and this line is oriented from the finite endpoint of this interval towards any other point in this interval. A segment (*Segment\_d<R>*) is a bounded interval on a directed line, and the endpoints are ordered so that they induce the same direction as that of the line.

Hyperplanes are affine subspaces of dimension  $d - 1$  in  $\mathbb{E}^d$ , passing through  $d$  points. Hyperplanes are oriented and partition space into a positive side and a negative side. In CGAL, there are no special classes for halfspaces. Halfspaces are supposed to be represented by oriented hyperplanes. All kernel objects are equality comparable via *operator==* and *operator!=*. For those oriented objects whose orientation can be reversed (segments, lines, hyperplanes, spheres) there is also a global function *weak\_equality* that allows to test for point set equality disregarding the orientation.

### 8.3.3 Orientation and Relative Position

Geometric objects in CGAL have member functions that test the position of a point relative to the object. Full dimensional objects and their boundaries are represented by the same type, e.g. halfspaces and hyperplanes are not distinguished, neither are balls and spheres. Such objects split the ambient space into two full-dimensional parts, a bounded part and an unbounded part (e.g. spheres), or two unbounded parts (e.g. hyperplanes). By default these objects are oriented, i.e., one of the resulting parts is called the positive side, the other one is called the negative side. Both of these may be unbounded.

For these objects there is a function *oriented\_side()* that determines whether a test point is on the positive side, the negative side, or on the oriented boundary. These function returns a value of type *Oriented\_side*.

Those objects that split the space in a bounded and an unbounded part, have a member function *bounded\_side()* with return type *Bounded\_side*.

If an object is lower dimensional, e.g. a segment in  $d$ -dimensional space, there is only a test whether a point belongs to the object or not. This member function, which takes a point as an argument and returns a Boolean value, is called *has\_on()*

## 8.4 Predicates and Constructions

### 8.4.1 Predicates

Predicates are at the heart of a geometry kernel. They are basic units for the composition of geometric algorithms and encapsulate decisions. Hence their correctness is crucial for the control flow and hence for the correctness of an implementation of a geometric algorithm. CGAL uses the term predicate in a generalized sense. Not only components returning a Boolean value are called predicates but also components returning an enumeration type

like a *Comparison\_result* or an *Orientation*. We say components, because predicates are implemented both as functions and function objects (also called functors and provided by a kernel class).

CGAL provides predicates for the orientation of point sets (*orientation*), for comparing points according to some given order, especially for comparing Cartesian coordinates (e.g. *lexicographically\_xy\_smaller*), in-sphere tests, and predicates to compare distances.

### 8.4.2 Constructions

Functions and function objects that generate objects that are neither of type *bool* nor enum types are called constructions. Constructions involve computation of new numerical values and may be imprecise due to rounding errors unless a kernel with an exact number type is used.

Affine transformations (*Aff\_transformation\_d<R>*) allow to generate new object instances under arbitrary affine transformations. These transformations include translations, rotations (within planes) and scaling. Most of the geometric objects in a kernel have a member function *transform(Aff\_transformation t)* which applies the transformation to the object instance.

CGAL also provides a set of functions that detect or compute the intersection between objects and functions to calculate their squared distance. Moreover, some member functions of kernel objects are constructions.

So there are routines that compute the square of the Euclidean distance, but no routines that compute the distance itself. Why? First of all, the two values can be derived from each other quite easily (by taking the square root or taking the square). So, supplying only the one and not the other is only a minor inconvenience for the user. Second, often either value can be used. This is for example the case when (squared) distances are compared. Third, the library wants to stimulate the use of the squared distance instead of the distance. The squared distance can be computed in more cases and the computation is cheaper. We do this by not providing the perhaps more natural routine. The problem of a distance routine is that it needs the *sqrt* operation. This has two drawbacks:

- The *sqrt* operation can be costly. Even if it is not very costly for a specific number type and platform, avoiding it is always cheaper.
- There are number types on which no *sqrt* operation is defined, especially integer types and rationals.

### 8.4.3 Intersection and Polymorphic Return Values

Intersections on kernel objects currently cover only those objects that are part of flats (*Segment\_d<R>*, *Ray\_d<R>*, *Line\_c<R>*, and *Hyperplane\_d<R>*). For any pair of objects *o1*, *o2* of these types the operation *intersection(o1,o2)* returns a polymorphic object that wraps the result of the intersection operation.

The class *Object* provides the polymorphic abstraction. An object *obj* of type *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make\_object()*. This encapsulation mechanism requires the use of *object\_cast* to unwrap the encapsulated class.

#### Example

In the following example, the object type is used as a return value for the intersection computation, as there are possibly different return values.

```

typedef Point_d< Cartesian_d<double> >    Point;
typedef Segment_d< Cartesian_d<double> >  Segment;
Segment s1, s2;
std::cin >> s1 >> s2;
Object obj = intersection(s1, s2);
if (const Point *p = object_cast<Point>(&obj) ) {
    /* do something with *p */
} else if (const Segment *s = object_cast<Segment>(&obj) ) {
    /* do something with *s */
}
/* there was no intersection */

```

#### 8.4.4 Constructive Predicates

For testing where a point  $p$  lies with respect to a hyperplane defined by an array  $P$  of points  $p_1, \dots, p_d$ , one may be tempted to construct the hyperplane  $Hyperplane\_d<R>(d, P, P+d)$  and use the method  $oriented\_side(p)$ . This may pay off if many tests with respect to the plane are made. Nevertheless, unless the number type is exact, the constructed plane is only approximated, and round-off errors may lead  $oriented\_side(p)$  to return an orientation which is different from the orientation of  $p_1, \dots, p_d, p$ .

In CGAL, we provide predicates in which such geometric decisions are made directly with a reference to the input points in  $P$  without an intermediary object like a plane. For the above test, the recommended way to get the result is to use  $orientation(P', P'+d)$ , where  $P'$  is an array containing the points  $p_1, \dots, p_d, p$ .

For exact number types like *leda\_real*, the situation is different. If several tests are to be made with the same plane, it pays off to construct the plane and to use  $oriented\_side(p)$ .

## 8.5 Linear Algebra Concepts and Classes

### LinearAlgebraTraits\_d

#### Definition

The data type *LinearAlgebraTraits\_d* encapsulates two classes *Matrix*, *Vector* and many functions of basic linear algebra. An instance of data type *Matrix* is a matrix of variables of type *NT*. Accordingly, *Vector* implements vectors of variables of type *NT*. Most functions of linear algebra are *checkable*, i.e., the programs can be asked for a proof that their output is correct. For example, if the linear system solver declares a linear system  $Ax = b$  unsolvable it also returns a vector  $c$  such that  $c^T A = 0$  and  $c^T b \neq 0$ .

#### Types

*LinearAlgebraTraits\_d:: NT*                      the number type of the components.

*LinearAlgebraTraits\_d:: Vector*                      the vector type.

*LinearAlgebraTraits\_d:: Matrix*                      the matrix type.

#### Operations

*static Matrix*      *LA.transpose( Matrix M)*

returns  $M^T$  (a  $M.column\_dimension() \times M.column\_dimension()$  - matrix).

*static bool*      *LA.inverse( Matrix M, Matrix& I, NT& D, Vector& c)*

determines whether  $M$  has an inverse. It also computes either the inverse as  $(1/D) \cdot I$  or when no inverse exists, a vector  $c$  such that  $c^T \cdot M = 0$ .

*Precondition:*  $M$  is square.

*static Matrix*      *LA.inverse( Matrix M, NT& D)*

returns the inverse matrix of  $M$ . More precisely,  $1/D$  times the matrix returned is the inverse of  $M$ .

*Precondition:*  $determinant(M) \neq 0$ .

*Precondition:*  $M$  is square.

<i>static bool</i>	<i>LA.linear_solver( Matrix M, Vector b, Vector&amp; x, NT&amp; D)</i>	<p>as above, but without the witness <math>c</math></p> <p><i>Precondition:</i> <math>M.\text{row\_dimension}() = b.\text{dimension}()</math>.</p>
<i>static bool</i>	<i>LA.is_solvable( Matrix M, Vector b)</i>	<p>determines whether the system <math>M \cdot x = b</math> is solvable</p> <p><i>Precondition:</i> <math>M.\text{row\_dimension}() = b.\text{dimension}()</math>.</p>
<i>static bool</i>	<i>LA.homogeneous_linear_solver( Matrix M, Vector&amp; x)</i>	<p>determines whether the homogeneous linear system <math>M \cdot x = 0</math> has a non - trivial solution. If yes, then <math>x</math> is such a solution.</p>
<i>static int</i>	<i>LA.homogeneous_linear_solver( Matrix M, Matrix&amp; spanning_vecs)</i>	<p>determines the solution space of the homogeneous linear system <math>M \cdot x = 0</math>. It returns the dimension of the solution space. Moreover the columns of <i>spanning_vecs</i> span the solution space.</p>
<i>static int</i>	<i>LA.independent_columns( Matrix M, std::vector&lt;int&gt;&amp; columns)</i>	<p>returns the indices of a maximal subset of independent columns of <math>M</math>.</p>
<i>static int</i>	<i>LA.rank( Matrix M)</i>	<p>returns the rank of matrix <math>M</math></p>

## Vector

### Definition

An instance of data type *Vector* is a vector of variables of number type *NT*. Together with the type *Matrix* it realizes the basic operations of linear algebra.

### Types

<i>Vector::NT</i>	the ring type of the components.
<i>Vector::iterator</i>	the iterator type for accessing components.
<i>Vector::const_iterator</i>	the const iterator type for accessing components.

### Creation

<i>Vector v;</i>	creates an instance <i>v</i> of type <i>Vector</i> .
<i>Vector v( int d);</i>	creates an instance <i>v</i> of type <i>Vector</i> . <i>v</i> is initialized to a vector of dimension <i>d</i> .
<i>Vector v( int d, NT x);</i>	creates an instance <i>v</i> of type <i>Vector</i> . <i>v</i> is initialized to a vector of dimension <i>d</i> with entries <i>x</i> .
<i>template &lt;class Forward_iterator&gt;</i> <i>Vector v( Forward_iterator first, Forward_iterator last);</i>	
	creates an instance <i>v</i> of type <i>Vector</i> ; <i>v</i> is initialized to the vector with entries set <i>[first,last)</i> . <i>Requirement: Forward_iterator has value type NT.</i>

### Operations

<i>int</i>	<i>v.dimension()</i>	returns the dimension of <i>v</i> .
<i>bool</i>	<i>v.is_zero()</i>	returns true iff <i>v</i> is the zero vector.
<i>NT&amp;</i>	<i>v[ int i]</i>	returns the <i>i</i> -th component of <i>v</i> .  <i>Precondition:</i> $0 \leq i \leq v.dimension() - 1$ .
<i>iterator</i>	<i>v.begin()</i>	iterator to the first component.
<i>iterator</i>	<i>v.end()</i>	iterator beyond the last component.

The same operations *begin()*, *end()* exist for *const\_iterator*.

<i>Vector</i>	$v + vI$	Addition. <i>Precondition:</i> $v.dimension() == vI.dimension()$ .
<i>Vector</i>	$v - vI$	Subtraction. <i>Precondition:</i> $v.dimension() = vI.dimension()$ .
<i>NT</i>	$v * vI$	Inner Product. <i>Precondition:</i> $v.dimension() = vI.dimension()$ .
<i>Vector</i>	$-v$	Negation.
<i>Vector&amp;</i>	$v += vI$	Addition plus assignment. <i>Precondition:</i> $v.dimension() == vI.dimension()$ .
<i>Vector&amp;</i>	$v -= vI$	Subtraction plus assignment. <i>Precondition:</i> $v.dimension() == vI.dimension()$ .
<i>Vector&amp;</i>	$v *= NT\ s$	Scalar multiplication plus assignment.
<i>Vector&amp;</i>	$v /= NT\ s$	Scalar division plus assignment.
<i>Vector</i>	$NT\ r * v$	Component-wise multiplication with number $r$ .
<i>Vector</i>	$v * NT\ r$	Component-wise multiplication with number $r$ .

# Matrix

## Definition

An instance of data type *Matrix* is a matrix of variables of number type *NT*. The types *Matrix* and *Vector* together realize many functions of basic linear algebra.

## Types

<i>Matrix::NT</i>	the ring type of the components.
<i>Matrix::iterator</i>	bidirectional iterator for accessing all components row-wise.
<i>Matrix::row_iterator</i>	random access iterator for accessing row entries.
<i>Matrix::column_iterator</i>	random access iterator for accessing column entries.

There also constant versions of the above iterators: *const\_iterator*, *row\_const\_iterator*, and *column\_const\_iterator*.

<i>Matrix::Identity</i>	a tag class for identity initialization
<i>Matrix::Vector</i>	the vector type used.

## Creation

<i>Matrix M</i> ;	creates an instance <i>M</i> of type <i>Matrix</i> .
<i>Matrix M</i> ( <i>int n</i> );	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $n \times n$ initialized to the zero matrix.
<i>Matrix M</i> ( <i>int m</i> , <i>int n</i> );	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $m \times n$ initialized to the zero matrix.
<i>Matrix M</i> ( <i>std::pair&lt;int,int&gt; p</i> );	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $p.first \times p.second$ initialized to the zero matrix.
<i>Matrix M</i> ( <i>int n</i> , <i>Identity</i> , <i>NT x</i> = <i>NT(1)</i> );	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $n \times n$ initialized to the identity matrix (times <i>x</i> ).
<i>Matrix M</i> ( <i>int m</i> , <i>int n</i> , <i>NT x</i> );	creates an instance <i>M</i> of type <i>Matrix</i> of dimension $m \times n$ initialized to the matrix with <i>x</i> entries.

```
template <class Forward_iterator>
```

```
Matrix M( Forward_iterator first, Forward_iterator last);
```

creates an instance  $M$  of type *Matrix*. Let  $S$  be the ordered set of  $n$  column-vectors of common dimension  $m$  as given by the iterator range  $[first, last)$ .  $M$  is initialized to an  $m \times n$  matrix with the columns as specified by  $S$ .

*Precondition:* *Forward\_iterator* has a value type  $V$  from which we require to provide a iterator type  $V::const\_iterator$ , to have  $V::value\_type == NT$ .

Note that *Vector* or  $std::vector<NT>$  fulfill these requirements.

```
Matrix M( std::vector< Vector > A);
```

creates an instance  $M$  of type *Matrix*. Let  $A$  be an array of  $n$  column-vectors of common dimension  $m$ .  $M$  is initialized to an  $m \times n$  matrix with the columns as specified by  $A$ .

## Operations

<i>int</i>	<i>M.row_dimension()</i>	returns $n$ , the number of rows of $M$ .
<i>int</i>	<i>M.column_dimension()</i>	returns $m$ , the number of columns of $M$ .
<i>std::pair&lt;int,int&gt;</i>	<i>M.dimension()</i>	returns $(m, n)$ , the dimension pair of $M$ .
<i>Vector</i>	<i>M.row( int i)</i>	returns the $i$ -th row of $M$ (an $m$ - vector). <i>Precondition:</i> $0 \leq i \leq m - 1$ .
<i>Vector</i>	<i>M.column( int i)</i>	returns the $i$ -th column of $M$ (an $n$ - vector). <i>Precondition:</i> $0 \leq i \leq n - 1$ .
<i>NT&amp;</i>	<i>M( int i, int j)</i>	returns $M_{i,j}$ . <i>Precondition:</i> $0 \leq i \leq m - 1$ and $0 \leq j \leq n - 1$ .
<i>void</i>	<i>M.swap_rows( int i, int j)</i>	swaps rows $i$ and $j$ . <i>Precondition:</i> $0 \leq i \leq m - 1$ and $0 \leq j \leq m - 1$ .
<i>void</i>	<i>M.swap_columns( int i, int j)</i>	swaps columns $i$ and $j$ . <i>Precondition:</i> $0 \leq i \leq n - 1$ and $0 \leq j \leq n - 1$ .
<i>row_iterator</i>	<i>M.row_begin( int i)</i>	an iterator pointing to the first entry of the $i$ th row. <i>Precondition:</i> $0 \leq i \leq m - 1$ .
<i>row_iterator</i>	<i>M.row_end( int i)</i>	an iterator pointing beyond the last entry of the $i$ th row. <i>Precondition:</i> $0 \leq i \leq m - 1$ .

<i>column_iterator</i>	<i>M.column_begin( int i )</i>	an iterator pointing to the first entry of the <i>i</i> th column. <i>Precondition:</i> $0 \leq i \leq n - 1$ .
<i>column_iterator</i>	<i>M.column_end( int i )</i>	an iterator pointing beyond the last entry of the <i>i</i> th column. <i>Precondition:</i> $0 \leq i \leq n - 1$ .
<i>iterator</i>	<i>M.begin()</i>	an iterator pointing to the first entry of <i>M</i> .
<i>iterator</i>	<i>M.end()</i>	an iterator pointing beyond the last entry of <i>M</i> .

The same operations exist for *row\_const\_iterator*, *column\_const\_iterator* and *const\_iterator*.

<i>bool</i>	<i>M == M1</i>	Test for equality.
<i>bool</i>	<i>M != M1</i>	Test for inequality.

### Arithmetic Operators

<i>Matrix</i>	<i>M + M1</i>	Addition. <i>Precondition:</i> <i>M.row_dimension() == M1.row_dimension()</i> and <i>M.column_dimension() == M1.column_dimension()</i> .
<i>Matrix</i>	<i>M - M1</i>	Subtraction. <i>Precondition:</i> <i>M.row_dimension() == M1.row_dimension()</i> and <i>M.column_dimension() == M1.column_dimension()</i> .
<i>Matrix</i>	<i>-M</i>	Negation.
<i>Matrix</i>	<i>M * M1</i>	Multiplication. <i>Precondition:</i> <i>M.column_dimension() == M1.row_dimension()</i> .
<i>Vector</i>	<i>M * Vector vec</i>	Multiplication with vector. <i>Precondition:</i> <i>M.column_dimension() == vec.dimension()</i> .
<i>Matrix</i>	<i>NT x * M</i>	Multiplication of every entry with <i>x</i> .
<i>Matrix</i>	<i>M * NT x</i>	Multiplication of every entry with <i>x</i> .

## CGAL::Linear\_algebraCd<FT>

### Definition

The class *Linear\_algebraCd*<FT> serves as the default traits class for the LA parameter of *CGAL::Cartesian\_d*<FT,LA>. It implements linear algebra for field number types *FT*.

```
#include <CGAL/Linear_algebraCd.h>
```

### Is Model for the Concepts

LinearAlgebraTraits\_d ..... page [793](#)

### Requirements

*FT* must be a field number type.

### Operations

Fits all operation requirements of the concept.

## CGAL::Linear\_algebraHd<RT>

### Definition

The class *Linear\_algebraHd*<*RT*> serves as the default traits class for the LA parameter of *CGAL::Homogeneous\_d*<*RT*,*LA*>. It implements linear algebra for Euclidean ring number types *RT*.

```
#include <CGAL/Linear_algebraHd.h>
```

### Is Model for the Concepts

LinearAlgebraTraits\_d ..... page [793](#)

### Requirements

To make a ring number type *RT* work with this class it has to provide a division *operator/* with remainder.

### Operations

Fits all operation requirements of the concept.

## 8.6 Kernels

### CGAL::Cartesian\_d<FieldNumberType>

`#include <CGAL/Cartesian_d.h>`

#### Definition

A model for *Kernel\_d* that uses Cartesian coordinates to represent the geometric objects. In order for *Cartesian\_d<FieldNumberType>* to model Euclidean geometry in  $E^d$ , for some mathematical field  $E$  (e.g., the rationals  $\mathbb{Q}$  or the reals  $\mathbb{R}$ ), the template parameter *FieldNumberType* must model the mathematical field  $E$ . That is, the field operations on this number type must compute the mathematically correct results. If the number type provided as a model for *FieldNumberType* is only an approximation of a field (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

## CGAL::Homogeneous<RingNumberType>

```
#include <CGAL/Homogeneous_d.h>
```

### Definition

A model for a *Kernel\_d* using homogeneous coordinates to represent the geometric objects. In order for *Homogeneous<RingNumberType>* to model Euclidean geometry in  $E^d$ , for some mathematical ring  $E$  (e.g., the integers  $\mathbb{Z}$  or the rationals  $\mathbb{Q}$ ), the template parameter  $RT$  must model the mathematical ring  $E$ . That is, the ring operations on this number type must compute the mathematically correct results. If the number type provided as a model for *RingNumberType* is only an approximation of a ring (such as the built-in type *double*), then the geometry provided by the kernel is only an approximation of Euclidean geometry.

## 8.7 Kernel Objects

### CGAL::Point\_d<Kernel>

#### Definition

An instance of data type *Point\_d<Kernel>* is a point of Euclidean space in dimension  $d$ . A point  $p = (p_0, \dots, p_{d-1})$  in  $d$ -dimensional space can be represented by homogeneous coordinates  $(h_0, h_1, \dots, h_d)$  of number type  $RT$  such that  $p_i = h_i/h_d$ , which is of type  $FT$ . The homogenizing coordinate  $h_d$  is positive.

We call  $p_i$ ,  $0 \leq i < d$  the  $i$ -th Cartesian coordinate and  $h_i$ ,  $0 \leq i \leq d$ , the  $i$ -th homogeneous coordinate. We call  $d$  the dimension of the point.

#### Types

*Point\_d<Kernel>::LA*                      the linear algebra layer.

*Point\_d<Kernel>::Cartesian\_const\_iterator*  
a read-only iterator for the Cartesian coordinates.

*Point\_d<Kernel>::Homogeneous\_const\_iterator*  
a read-only iterator for the homogeneous coordinates.

#### Creation

*Point\_d<Kernel> p;*                      introduces a variable  $p$  of type *Point\_d<Kernel>*.

*Point\_d<Kernel> p( int d, Origin);*  
introduces a variable  $p$  of type *Point\_d<Kernel>* in  $d$ -dimensional space, initialized to the origin.

*template <class InputIterator>*  
*Point\_d<Kernel> p( int d, InputIterator first, InputIterator last);*  
introduces a variable  $p$  of type *Point\_d<Kernel>* in dimension  $d$ . If *size*  $[first, last) == d$  this creates a point with Cartesian coordinates *set*  $[first, last)$ . If *size*  $[first, last) == d+1$  the range specifies the homogeneous coordinates  $H = \text{set } [first, last) = (\pm h_0, \pm h_1, \dots, \pm h_d)$  where the sign chosen is the sign of  $h_d$ .  
*Precondition:*  $d$  is nonnegative,  $[first, last)$  has  $d$  or  $d+1$  elements where the last has to be non-zero.  
*Requirement:* The value type of *InputIterator* is  $RT$ .

*template <class InputIterator>*

*Point\_d<Kernel> p( int d, InputIterator first, InputIterator last, RT D);*

introduces a variable  $p$  of type  $Point\_d<Kernel>$  in dimension  $d$  initialized to the point with homogeneous coordinates as defined by  $H = set [first, last)$  and  $D: (\pm H[0], \pm H[1], \dots, \pm H[d-1], \pm D)$ . The sign chosen is the sign of  $D$ .

*Precondition:*  $D$  is non-zero, the iterator range defines a  $d$ -tuple of  $RT$ .

*Requirement:* The value type of  $InputIterator$  is  $RT$ .

*Point\_d<Kernel> p( RT x, RT y, RT w = 1);*

introduces a variable  $p$  of type  $Point\_d<Kernel>$  in 2-dimensional space.

*Precondition:*  $w \neq 0$ .

*Point\_d<Kernel> p( RT x, RT y, RT z, RT w);*

introduces a variable  $p$  of type  $Point\_d<Kernel>$  in 3-dimensional space.

*Precondition:*  $w \neq 0$ .

## Operations

<i>int</i>	<i>p.dimension()</i>	returns the dimension of $p$ .
<i>FT</i>	<i>p.cartesian( int i)</i>	returns the $i$ -th Cartesian coordinate of $p$ . <i>Precondition:</i> $0 \leq i < d$ .
<i>FT</i>	<i>p[ int i]</i>	returns the $i$ -th Cartesian coordinate of $p$ . <i>Precondition:</i> $0 \leq i < d$ .
<i>RT</i>	<i>p.homogeneous( int i)</i>	returns the $i$ -th homogeneous coordinate of $p$ . <i>Precondition:</i> $0 \leq i \leq d$ .
<i>Cartesian_const_iterator</i>	<i>p.cartesian_begin()</i>	returns an iterator pointing to the zeroth Cartesian coordinate $p_0$ of $p$ .
<i>Cartesian_const_iterator</i>	<i>p.cartesian_end()</i>	returns an iterator pointing beyond the last Cartesian coordinate of $p$ .
<i>Homogeneous_const_iterator</i>	<i>p.homogeneous_begin()</i>	returns an iterator pointing to the zeroth homogeneous coordinate $h_0$ of $p$ .

*Homogeneous\_const\_iterator*

*p.homogeneous\_end()*

returns an iterator pointing beyond the last homogeneous coordinate of *p*.

*Point\_d<Kernel>*

*p.transform( Aff\_transformation\_d<Kernel> t)*

returns  $t(p)$ .

### Arithmetic Operators, Tests and IO

*Vector\_d<Kernel>*

$p - \text{Origin } o$

returns the vector  $p - O$ .

*Vector\_d<Kernel>*

$p - q$

returns  $p - q$ .  
*Precondition:*  $p.\text{dimension}() == q.\text{dimension}()$ .

*Point\_d<Kernel>*

$p + \text{Vector}_d<\text{Kernel}> v$

returns  $p + v$ .  
*Precondition:*  $p.\text{dimension}() == v.\text{dimension}()$ .

*Point\_d<Kernel>*

$p - \text{Vector}_d<\text{Kernel}> v$

returns  $p - v$ .  
*Precondition:*  $p.\text{dimension}() == v.\text{dimension}()$ .

*Point\_d<Kernel>&*

$p += \text{Vector}_d<\text{Kernel}> v$

adds  $v$  to  $p$ .  
*Precondition:*  $p.\text{dimension}() == v.\text{dimension}()$ .

*Point\_d<Kernel>&*

$p -= \text{Vector}_d<\text{Kernel}> v$

subtracts  $v$  from  $p$ .  
*Precondition:*  $p.\text{dimension}() == v.\text{dimension}()$ .

*bool*

$p == \text{Origin}$

returns true if  $p$  is the origin.

### Downward compatibility

We provide operations of the lower dimensional interface  $x()$ ,  $y()$ ,  $z()$ ,  $hx()$ ,  $hy()$ ,  $hz()$ ,  $hw()$ .

## Implementation

Points are implemented by arrays of  $RT$  items. All operations like creation, initialization, tests, point - vector arithmetic, input and output on a point  $p$  take time  $O(p.dimension())$ .  $dimension()$ , coordinate access and conversions take constant time. The space requirement for points is  $O(p.dimension())$ .

## CGAL::Vector\_d<Kernel>

### Definition

An instance of data type *Vector\_d<Kernel>* is a vector of Euclidean space in dimension  $d$ . A vector  $r = (r_0, \dots, r_{d-1})$  can be represented in homogeneous coordinates  $(h_0, \dots, h_d)$  of number type  $RT$ , such that  $r_i = h_i/h_d$  which is of type  $FT$ . We call the  $r_i$ 's the Cartesian coordinates of the vector. The homogenizing coordinate  $h_d$  is positive.

This data type is meant for use in computational geometry. It realizes free vectors as opposed to position vectors (type *Point\_d*). The main difference between position vectors and free vectors is their behavior under affine transformations, e.g., free vectors are invariant under translations.

### Types

*Vector\_d<Kernel>::LA*            the linear algebra layer.

*Vector\_d<Kernel>::Cartesian\_const\_iterator*  
a read-only iterator for the Cartesian coordinates.

*Vector\_d<Kernel>::Homogeneous\_const\_iterator*  
a read-only iterator for the homogeneous coordinates.

*Vector\_d<Kernel>::Base\_vector*  
construction tag.

### Creation

*Vector\_d<Kernel> v;*            introduces a variable  $v$  of type *Vector\_d<Kernel>*.

*Vector\_d<Kernel> v( int d, Null\_vector);*  
introduces the zero vector  $v$  of type *Vector\_d<Kernel>* in  $d$ -dimensional space.  
For the creation flag *CGAL::NULL\_VECTOR* can be used.

*template <class InputIterator>*

*Vector\_d<Kernel> v( int d, InputIterator first, InputIterator last);*

introduces a variable  $v$  of type *Vector\_d<Kernel>* in dimension  $d$ . If *size*  $[first, last) == d$  this creates a vector with Cartesian coordinates *set*  $[first, last)$ . If *size*  $[first, last) == p+1$  the range specifies the homogeneous coordinates  $H = \text{set } [first, last) = (\pm h_0, \pm h_1, \dots, \pm h_d)$  where the sign chosen is the sign of  $h_d$ .

*Precondition:*  $d$  is nonnegative,  $[first, last)$  has  $d$  or  $d+1$  elements where the last has to be non-zero.

*Requirement:* The value type of *InputIterator* is *RT*.

*template <class InputIterator>*

*Vector\_d<Kernel> v( int d, InputIterator first, InputIterator last, RT D);*

introduces a variable  $v$  of type *Vector\_d<Kernel>* in dimension  $d$  initialized to the vector with homogeneous coordinates as defined by  $H = \text{set } [first, last)$  and  $D: (\pm H[0], \pm H[1], \dots, \pm H[d-1], \pm D)$ . The sign chosen is the sign of  $D$ .

*Precondition:*  $D$  is non-zero, the iterator range defines a  $d$ -tuple of *RT*.

*Requirement:* The value type of *InputIterator* is *RT*.

*Vector\_d<Kernel> v( int d, Base\_vector, int i);*

returns a variable  $v$  of type *Vector\_d<Kernel>* initialized to the  $i$ -th base vector of dimension  $d$ .

*Precondition:*  $0 \leq i < d$ .

*Vector\_d<Kernel> v( RT x, RT y, RT w = 1);*

introduces a variable  $v$  of type *Vector\_d<Kernel>* in 2-dimensional space.

*Precondition:*  $w \neq 0$ .

*Vector\_d<Kernel> v( RT x, RT y, RT z, RT w);*

introduces a variable  $v$  of type *Vector\_d<Kernel>* in 3-dimensional space.

*Precondition:*  $w \neq 0$ .

## Operations

<i>int</i>	<i>v.dimension()</i>	returns the dimension of $v$ .
<i>FT</i>	<i>v.cartesian( int i)</i>	returns the $i$ -th Cartesian coordinate of $v$ . <i>Precondition:</i> $0 \leq i < d$ .
<i>FT</i>	<i>v[ int i]</i>	returns the $i$ -th Cartesian coordinate of $v$ . <i>Precondition:</i> $0 \leq i < d$ .
<i>RT</i>	<i>v.homogeneous( int i)</i>	returns the $i$ -th homogeneous coordinate of $v$ . <i>Precondition:</i> $0 \leq i \leq d$ .

<i>FT</i>	<i>v.squared_length()</i>	returns the square of the length of <i>v</i> .
<i>Cartesian_const_iterator</i>	<i>v.cartesian_begin()</i>	returns an iterator pointing to the zeroth Cartesian coordinate of <i>v</i> .
<i>Cartesian_const_iterator</i>	<i>v.cartesian_end()</i>	returns an iterator pointing beyond the last Cartesian coordinate of <i>v</i> .
<i>Homogeneous_const_iterator</i>	<i>v.homogeneous_begin()</i>	returns an iterator pointing to the zeroth homogeneous coordinate of <i>v</i> .
<i>Homogeneous_const_iterator</i>	<i>v.homogeneous_end()</i>	returns an iterator pointing beyond the last homogeneous coordinate of <i>v</i> .
<i>Direction_d&lt;Kernel&gt;</i>	<i>v.direction()</i>	returns the direction of <i>v</i> .
<i>Vector_d&lt;Kernel&gt;</i>	<i>v.transform( Aff_transformation_d&lt;Kernel&gt; t)</i>	returns $t(v)$ .

### Arithmetic Operators, Tests and IO

<i>Vector_d&lt;Kernel&gt;&amp;</i>	$v * = RT\ n$	multiplies all Cartesian coordinates by $n$ .
<i>Vector_d&lt;Kernel&gt;&amp;</i>	$v * = FT\ r$	multiplies all Cartesian coordinates by $r$ .
<i>Vector_d&lt;Kernel&gt;</i>	$v / RT\ n$	returns the vector with Cartesian coordinates $v_i/n, 0 \leq i < d$ .
<i>Vector_d&lt;Kernel&gt;</i>	$v / FT\ r$	returns the vector with Cartesian coordinates $v_i/r, 0 \leq i < d$ .
<i>Vector_d&lt;Kernel&gt;&amp;</i>	$v /= RT\ n$	divides all Cartesian coordinates by $n$ .
<i>Vector_d&lt;Kernel&gt;&amp;</i>	$v /= FT\ r$	divides all Cartesian coordinates by $r$ .
<i>FT</i>	$v * w$	inner product, i.e., $\sum_{0 \leq i < d} v_i w_i$ , where $v_i$ and $w_i$ are the Cartesian coordinates of $v$ and $w$ respectively.
<i>Vector_d&lt;Kernel&gt;</i>	$v + w$	returns the vector with Cartesian coordinates $v_i + w_i, 0 \leq i < d$ .
<i>Vector_d&lt;Kernel&gt;&amp;</i>	$v += w$	addition plus assignment.

<i>Vector_d&lt;Kernel&gt;</i>	$v - w$	returns the vector with Cartesian coordinates $v_i - w_i, 0 \leq i < d$ .
<i>Vector_d&lt;Kernel&gt;&amp;</i>	$v -= w$	subtraction plus assignment.
<i>Vector_d&lt;Kernel&gt;</i>	$-v$	returns the vector in opposite direction.
<i>bool</i>	<i>v.is_zero()</i>	returns true if <i>v</i> is the zero vector.

### Downward compatibility

We provide all operations of the lower dimensional interface *x()*, *y()*, *z()*, *hx()*, *hy()*, *hz()*, *hw()*.

<i>Vector_d&lt;Kernel&gt;</i>	<i>RT n * v</i>	returns the vector with Cartesian coordinates $nv_i$ .
<i>Vector_d&lt;Kernel&gt;</i>	<i>FT r * v</i>	returns the vector with Cartesian coordinates $rv_i, 0 \leq i < d$ .

### Implementation

Vectors are implemented by arrays of variables of type *RT*. All operations like creation, initialization, tests, vector arithmetic, input and output on a vector *v* take time  $O(v.dimension())$ . coordinate access, *dimension()* and conversions take constant time. The space requirement of a vector is  $O(v.dimension())$ .

## CGAL::Direction\_d<Kernel>

### Definition

A *Direction\_d* is a vector in the  $d$ -dimensional vector space where we forget about its length. We represent directions in  $d$ -dimensional space as a tuple  $(h_0, \dots, h_d)$  of variables of type *RT* which we call the homogeneous coordinates of the direction. The coordinate  $h_d$  must be positive. The Cartesian coordinates of a direction are  $c_i = h_i/h_d$  for  $0 \leq i < d$ , which are of type *FT*. Two directions are equal if their Cartesian coordinates are positive multiples of each other. Directions are in one-to-one correspondence to points on the unit sphere.

### Types

*Direction\_d<Kernel>::LA*      the linear algebra layer.

*Direction\_d<Kernel>::Delta\_const\_iterator*

a read-only iterator for the deltas of *dir*.

*Direction\_d<Kernel>::Base\_direction*

construction tag.

### Creation

*Direction\_d<Kernel> dir;*      introduces a variable *dir* of type *Direction\_d<Kernel>*.

*Direction\_d<Kernel> dir( Vector\_d<Kernel> v);*

introduces a variable *dir* of type *Direction\_d<Kernel>* initialized to the direction of *v*.

*template <class InputIterator>*

*Direction\_d<Kernel> dir( int d, InputIterator first, InputIterator last);*

introduces a variable *dir* of type *Direction\_d<Kernel>* in dimension  $d$  with representation tuple *set*  $[first, last)$ .

*Precondition:*  $d$  is nonnegative,  $[first, last)$  has  $d$  elements.

*Requirement:* The value type of *InputIterator* is *RT*.

*Direction\_d<Kernel> dir( int d, Base\_direction, int i);*

returns a variable *dir* of type *Direction\_d<Kernel>* initialized to the direction of the  $i$ -th base vector of dimension  $d$ .

*Precondition:*  $0 \leq i < d$ .

*Direction\_d<Kernel> dir( RT x, RT y);*

introduces a variable *dir* of type *Direction\_d<Kernel>* in 2-dimensional space.

*Direction\_d<Kernel> dir( RT x, RT y, RT z);*

introduces a variable *dir* of type *Direction\_d<Kernel>* in 3-dimensional space.

## Operations

<i>int</i>	<i>dir.dimension()</i>	returns the dimension of <i>dir</i> .
<i>RT</i>	<i>dir.delta( int i)</i>	returns the <i>i</i> -th component of <i>dir</i> . <i>Precondition:</i> $0 \leq i < d$ .
<i>RT</i>	<i>dir[ int i]</i>	returns the <i>i</i> -th delta of <i>dir</i> . <i>Precondition:</i> $0 \leq i < d$ .
<i>Delta_const_iterator</i>	<i>dir.deltas_begin()</i>	returns an iterator pointing to the first delta of <i>dir</i> .
<i>Delta_const_iterator</i>	<i>dir.deltas_end()</i>	returns an iterator pointing beyond the last delta of <i>dir</i> .
<i>Vector_d&lt;Kernel&gt;</i>	<i>dir.vector()</i>	returns a vector pointing in direction <i>dir</i> .
<i>bool</i>	<i>dir.is_degenerate()</i>	returns true iff $dir.delta(i)=0$ for all $0 \leq i < d$ .
<i>Direction_d&lt;Kernel&gt;</i>	<i>dir.transform( Aff_transformation_d&lt;Kernel&gt; t)</i>	returns $t(p)$ .
<i>Direction_d&lt;Kernel&gt;</i>	<i>dir.opposite()</i>	returns the direction opposite to <i>dir</i> .
<i>Direction_d&lt;Kernel&gt;</i>	$-dir$	returns the direction opposite to <i>dir</i> .

## Downward compatibility

We provide the operations of the lower dimensional interface *dx()*, *dy()*, *dz()*.

## Implementation

Directions are implemented by arrays of integers as an item type. All operations like creation, initialization, tests, inversion, input and output on a direction *d* take time  $O(d.dimension())$ . *dimension()*, coordinate access and conversion take constant time. The space requirement is  $O(d.dimension())$ .

## CGAL::Line\_d<Kernel>

### Definition

An instance of data type *Line\_d* is an oriented line in *d*-dimensional Euclidean space.

### Types

*Line\_d<Kernel>::LA* the linear algebra layer.

### Creation

*Line\_d<Kernel> l;* introduces a variable *l* of type *Line\_d<Kernel>*.

*Line\_d<Kernel> l( Point\_d<Kernel> p, Point\_d<Kernel> q);*

introduces a line through *p* and *q* and oriented from *p* to *q*.

*Precondition:* *p* and *q* are distinct and have the same dimension.

*Line\_d<Kernel> l( Point\_d<Kernel> p, Direction\_d<Kernel> dir);*

introduces a line through *p* with direction *dir*.

*Precondition:* *p.dimension()==dir.dimension()*, *dir* is not degenerate.

*Line\_d<Kernel> l( Segment\_d<Kernel> s);*

introduces a variable *l* of type *Line\_d<Kernel>* and initializes it to the line through *s.source()* and *s.target()* with direction from *s.source()* to *s.target()*.

*Precondition:* *s* is not degenerate.

*Line\_d<Kernel> l( Ray\_d<Kernel> r);*

introduces a variable *l* of type *Line\_d<Kernel>* and initializes it to the line through *r.point(1)* and *r.point(2)*.

### Operations

<i>int</i>	<i>l.dimension()</i>	returns the dimension of the ambient space.
<i>Point_d&lt;Kernel&gt;</i>	<i>l.point( int i)</i>	returns an arbitrary point on <i>l</i> . It holds that <i>point(i) == point(j)</i> , iff <i>i==j</i> . Furthermore, <i>l</i> is directed from <i>point(i)</i> to <i>point(j)</i> , for all <i>i &lt; j</i> .
<i>Line_d&lt;Kernel&gt;</i>	<i>l.opposite()</i>	returns the line ( <i>point(2),point(1)</i> ) of opposite direction.

<i>Direction_d&lt;Kernel&gt;</i>	<i>l.direction()</i>	returns the direction of <i>l</i> .
<i>Line_d&lt;Kernel&gt;</i>	<i>l.transform( Aff_transformation_d&lt;Kernel&gt; t)</i>	returns <i>t(l)</i> . Precondition: <i>l.dimension()==t.dimension()</i> .
<i>Line_d&lt;Kernel&gt;</i>	<i>l + Vector_d&lt;Kernel&gt; v</i>	returns <i>l+v</i> , i.e., <i>l</i> translated by vector <i>v</i> . Precondition: <i>l.dimension()==v.dimension()</i> .
<i>Point_d&lt;Kernel&gt;</i>	<i>l.projection( Point_d&lt;Kernel&gt; p)</i>	returns the point of intersection of <i>l</i> with the hyperplane that is orthogonal to <i>l</i> and that contains <i>p</i> . Precondition: <i>l.dimension()==p.dimension()</i> .
<i>bool</i>	<i>l.has_on( Point_d&lt;Kernel&gt; p)</i>	returns true if <i>p</i> lies on <i>l</i> and false otherwise. Precondition: <i>l.dimension()==p.dimension()</i> .

### Non-Member Functions

<i>bool</i>	<i>weak_equality( l1, l2)</i>	Test for equality as unoriented lines. Precondition: <i>l1.dimension()==l2.dimension()</i> .
<i>bool</i>	<i>parallel( l1, l2)</i>	returns true if <i>l1</i> and <i>l2</i> are parallel as unoriented lines and false otherwise. Precondition: <i>l1.dimension()==l2.dimension()</i> .

### Implementation

Lines are implemented by a pair of points as an item type. All operations like creation, initialization, tests, direction calculation, input and output on a line *l* take time  $O(l.dimension())$ . *dimension()*, coordinate and point access, and identity test take constant time. The operations for intersection calculation also take time  $O(l.dimension())$ . The space requirement is  $O(l.dimension())$ .

## CGAL::Ray\_d<Kernel>

### Definition

An instance of data type *Ray\_d* is a ray in *d*-dimensional Euclidean space. It starts in a point called the source of *r* and it goes to infinity.

### Types

*Ray\_d<Kernel>::LA*                      the linear algebra layer.

### Creation

*Ray\_d<Kernel> r;*                      introduces some ray in *d*-dimensional space.

*Ray\_d<Kernel> r( Point\_d<Kernel> p, Point\_d<Kernel> q);*

introduces a ray through *p* and *q* and starting at *p*.

*Precondition:* *p* and *q* are distinct and have the same dimension.

*Precondition:* *p.dimension()==q.dimension()*.

*Ray\_d<Kernel> r( Point\_d<Kernel> p, Direction\_d<Kernel> dir);*

introduces a ray starting in *p* with direction *dir*.

*Precondition:* *p* and *dir* have the same dimension and *dir* is not degenerate.

*Precondition:* *p.dimension()==dir.dimension()*.

*Ray\_d<Kernel> r( Segment\_d<Kernel> s);*

introduces a ray through *s.source()* and *s.target()* and starting at *s.source()*.

*Precondition:* *s* is not degenerate.

### Operations

*int*                      *r.dimension()*                      returns the dimension of the ambient space.

*Point\_d<Kernel>*                      *r.source()*                      returns the source point of *r*.

*Point\_d<Kernel>*                      *r.point( int i)*                      returns a point on *r*. *point(0)* is the source. *point(i)*, with *i* > 0, is different from the source.  
*Precondition:* *i* ≥ 0.

*Direction\_d<Kernel>*                      *r.direction()*                      returns the direction of *r*.

<i>Line_d&lt;Kernel&gt;</i>	<i>r.supporting_line()</i>	returns the supporting line of <i>r</i> .
<i>Ray_d&lt;Kernel&gt;</i>	<i>r.opposite()</i>	returns the ray with direction opposite to <i>r</i> and starting in <i>source</i> .
<i>Ray_d&lt;Kernel&gt;</i>	<i>r.transform( Aff_transformation_d&lt;Kernel&gt; t)</i>	returns $t(r)$ . Precondition: $r.dimension()=t.dimension()$ .
<i>Ray_d&lt;Kernel&gt;</i>	$r + \text{Vector\_d<Kernel>} v$	returns $r+v$ , i.e., <i>r</i> translated by vector <i>v</i> . Precondition: $r.dimension()=v.dimension()$ .
<i>bool</i>	<i>r.has_on( Point_d&lt;Kernel&gt; p)</i>	A point is on <i>r</i> , iff it is equal to the source of <i>r</i> , or if it is in the interior of <i>r</i> . Precondition: $r.dimension()=p.dimension()$ .

### Non-Member Functions

<i>bool</i>	<i>parallel( r1, r2)</i>	returns true if the unoriented supporting lines of <i>r1</i> and <i>r2</i> are parallel and false otherwise. Precondition: $r1.dimension()=r2.dimension()$ .
-------------	--------------------------	---

### Implementation

Rays are implemented by a pair of points as an item type. All operations like creation, initialization, tests, direction calculation, input and output on a ray *r* take time  $O(r.dimension())$ . *dimension()*, coordinate and point access, and identity test take constant time. The space requirement is  $O(r.dimension())$ .

## CGAL::Segment\_d<Kernel>

### Definition

An instance  $s$  of the data type *Segment\_d* is a directed straight line segment in  $d$ -dimensional Euclidean space connecting two points  $p$  and  $q$ .  $p$  is called the source point and  $q$  is called the target point of  $s$ , both points are called endpoints of  $s$ . A segment whose endpoints are equal is called *degenerate*.

### Types

*Segment\_d<Kernel>::LA*                      the linear algebra layer.

### Creation

*Segment\_d<Kernel> s;*

introduces a variable  $s$  of type *Segment\_d<Kernel>*.

*Segment\_d<Kernel> s( Point\_d<Kernel> p, Point\_d<Kernel> q);*

introduces a variable  $s$  of type *Segment\_d<Kernel>* which is initialized to the segment  $(p, q)$ .

*Precondition:*  $p.\text{dimension}()=q.\text{dimension}()$ .

*Segment\_d<Kernel> s( Point\_d<Kernel> p, Vector\_d<Kernel> v);*

introduces a variable  $s$  of type *Segment\_d<Kernel>* which is initialized to the segment  $(p, p+v)$ .

*Precondition:*  $p.\text{dimension}()==v.\text{dimension}()$ .

### Operations

<i>int</i>	<i>s.dimension()</i>	returns the dimension of the ambient space.
<i>Point_d&lt;Kernel&gt;</i>	<i>s.source()</i>	returns the source point of segment $s$ .
<i>Point_d&lt;Kernel&gt;</i>	<i>s.target()</i>	returns the target point of segment $s$ .
<i>Point_d&lt;Kernel&gt;</i>	<i>s.vertex( int i)</i>	returns source or target of $s$ : <i>vertex(0)</i> returns the source, <i>vertex(1)</i> returns the target. The parameter $i$ is taken modulo 2, which gives easy access to the other vertex. <i>Precondition:</i> $i \geq 0$ .
<i>Point_d&lt;Kernel&gt;</i>	<i>s.point( int i)</i>	returns <i>vertex(i)</i> .

<i>Point_d&lt;Kernel&gt;</i>	<i>s[ int i]</i>	returns <i>vertex(i)</i> .
<i>Point_d&lt;Kernel&gt;</i>	<i>s.min()</i>	returns the lexicographically smaller vertex.
<i>Point_d&lt;Kernel&gt;</i>	<i>s.max()</i>	returns the lexicographically larger vertex.
<i>Segment_d&lt;Kernel&gt;</i>	<i>s.opposite()</i>	returns the segment ( <i>target()</i> , <i>source()</i> ).
<i>Direction_d&lt;Kernel&gt;</i>	<i>s.direction()</i>	returns the direction from source to target. <i>Precondition: s</i> is non-degenerate.
<i>Vector_d&lt;Kernel&gt;</i>	<i>s.vector()</i>	returns the vector from source to target.
<i>FT</i>	<i>s.squared_length()</i>	returns the square of the length of <i>s</i> .
<i>bool</i>	<i>s.has_on( Point_d&lt;Kernel&gt; p)</i>	returns true if <i>p</i> lies on <i>s</i> and false otherwise. <i>Precondition: s.dimension()==p.dimension()</i> .
<i>Line_d&lt;Kernel&gt;</i>	<i>s.supporting_line()</i>	returns the supporting line of <i>s</i> . <i>Precondition: s</i> is non-degenerate.
<i>Segment_d&lt;Kernel&gt;</i>	<i>s.transform( Aff_transformation_d&lt;Kernel&gt; t)</i>	returns <i>t(s)</i> . <i>Precondition: s.dimension()==t.dimension()</i> .
<i>Segment_d&lt;Kernel&gt;</i>	<i>s + Vector_d&lt;Kernel&gt; v</i>	returns <i>s + v</i> , i.e., <i>s</i> translated by vector <i>v</i> . <i>Precondition: s.dimension()==v.dimension()</i> .
<i>bool</i>	<i>s.is_degenerate()</i>	returns true if <i>s</i> is degenerate i.e. <i>s.source()==s.target()</i> .

### Non-Member Functions

<i>bool</i>	<i>weak_equality( s1, s2)</i>	Test for equality as unoriented segments. <i>Precondition: s1.dimension()==s2.dimension()</i> .
<i>bool</i>	<i>parallel( s1, s2)</i>	return true if one of the segments is degenerate or if the un-oriented supporting lines are parallel. <i>Precondition: s1.dimension()==s2.dimension()</i> .

*bool*

*common\_endpoint( s1, s2, Point\_d<Kernel>& common)*

if *s1* and *s2* touch in a common end point, this point is assigned to *common* and the result is *true*, otherwise the result is *false*. If *s1==s2* then one of the endpoints is returned.

*Precondition: s1.dimension()==s2.dimension().*

## Implementation

Segments are implemented by a pair of points as an item type. All operations like creation, initialization, tests, the calculation of the direction and source - target vector, input and output on a segment *s* take time  $O(s.dimension())$ . *dimension()*, coordinate and end point access, and identity test take constant time. The operations for intersection calculation also take time  $O(s.dimension())$ . The space requirement is  $O(s.dimension())$ .

## CGAL::Hyperplane\_d<Kernel>

### Definition

An instance of data type *Hyperplane\_d* is an oriented hyperplane in  $d$  - dimensional space. A hyperplane  $h$  is represented by coefficients  $(c_0, c_1, \dots, c_d)$  of type  $RT$ . At least one of  $c_0$  to  $c_{d-1}$  must be non-zero. The plane equation is  $\sum_{0 \leq i < d} c_i x_i + c_d = 0$ , where  $x_0$  to  $x_{d-1}$  are Cartesian point coordinates. For a particular  $x$  the sign of  $\sum_{0 \leq i < d} c_i x_i + c_d$  determines the position of a point  $x$  with respect to the hyperplane (on the hyperplane, on the negative side, or on the positive side).

There are two equality predicates for hyperplanes. The (weak) equality predicate (*weak\_equality*) declares two hyperplanes equal if they consist of the same set of points, the strong equality predicate (*operator==*) requires in addition that the negative halfspaces agree. In other words, two hyperplanes are strongly equal if their coefficient vectors are positive multiples of each other and they are (weakly) equal if their coefficient vectors are multiples of each other.

### Types

*Hyperplane\_d<Kernel>::LA*

the linear algebra layer.

*Hyperplane\_d<Kernel>::Coefficient\_const\_iterator*

a read-only iterator for the coefficients.

### Creation

*Hyperplane\_d<Kernel> h;* introduces a variable  $h$  of type *Hyperplane\_d<Kernel>*.

*template <class InputIterator>*

*Hyperplane\_d<Kernel> h( int d, InputIterator first, InputIterator last, RT D);*

introduces a variable  $h$  of type *Hyperplane\_d<Kernel>* initialized to the hyperplane with coefficients set  $[first, last)$  and  $D$ .

*Precondition:*  $size [first, last) == d$ .

*Requirement:* The value type of *InputIterator* is  $RT$ .

*template <class InputIterator>*

*Hyperplane\_d<Kernel> h( int d, InputIterator first, InputIterator last);*

introduces a variable  $h$  of type *Hyperplane\_d<Kernel>* initialized to the hyperplane with coefficients set  $[first, last)$ .

*Precondition:*  $size [first, last) == d + 1$ .

*Requirement:* The value type of *InputIterator* is  $RT$ .

*template <class ForwardIterator>*

*Hyperplane\_d<Kernel> h( ForwardIterator first,  
ForwardIterator last,  
Point\_d<Kernel> o,  
Oriented\_side side = ON\_ORIENTED\_BOUNDARY)*

constructs some hyperplane that passes through the points in *set*  $[first, last)$ . If *side* is *ON\_POSITIVE\_SIDE* or *ON\_NEGATIVE\_SIDE* then *o* is on that side of the constructed hyperplane.

*Precondition:* A hyperplane with the stated properties must exist.

*Requirement:* The value type of *ForwardIterator* is *Point\_d<Kernel>*.

*Hyperplane\_d<Kernel> h( Point\_d<Kernel> p, Direction\_d<Kernel> dir);*

constructs the hyperplane with normal direction *dir* that passes through *p*. The direction *dir* points into the positive side.

*Precondition:*  $p.dimension() == dir.dimension()$  and *dir* is not degenerate.

*Hyperplane\_d<Kernel> h( RT a, RT b, RT c);*

introduces a variable *h* of type *Hyperplane\_d<Kernel>* in 2-dimensional space with equation  $ax + by + c = 0$ .

*Hyperplane\_d<Kernel> h( RT a, RT b, RT c, RT d);*

introduces a variable *h* of type *Hyperplane\_d<Kernel>* in 3-dimensional space with equation  $ax + by + cz + d = 0$ .

## Operations

*int*                      *h.dimension()*      returns the dimension of *h*.

*RT*                      *h[ int i]*              returns the *i*-th coefficient of *h*.  
*Precondition:*  $0 \leq i \leq d$ .

*RT*                      *h.coefficient( int i)*  
  
returns the *i*-th coefficient of *h*.  
*Precondition:*  $0 \leq i \leq d$ .

*Coefficient\_const\_iterator*      *h.coefficients\_begin()*  
  
returns an iterator pointing to the first coefficient.

*Coefficient\_const\_iterator*      *h.coefficients\_end()*  
  
returns an iterator pointing beyond the last coefficient.

<i>Vector_d&lt;Kernel&gt;</i>	<i>h.orthogonal_vector()</i>	returns the orthogonal vector of <i>h</i> . It points from the negative halfspace into the positive halfspace and its homogeneous coordinates are $(c_0, \dots, c_{d-1}, 1)$ .
<i>Direction_d&lt;Kernel&gt;</i>	<i>h.orthogonal_direction()</i>	returns the orthogonal direction of <i>h</i> . It points from the negative halfspace into the positive halfspace.
<i>Oriented_side</i>	<i>h.oriented_side( Point_d&lt;Kernel&gt; p)</i>	returns the side of the hyperplane <i>h</i> containing <i>p</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on( Point_d&lt;Kernel&gt; p)</i>	returns true iff point <i>p</i> lies on the hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on_boundary( Point_d&lt;Kernel&gt; p)</i>	returns true iff point <i>p</i> lies on the boundary of hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on_positive_side( Point_d&lt;Kernel&gt; p)</i>	returns true iff point <i>p</i> lies on the positive side of hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>bool</i>	<i>h.has_on_negative_side( Point_d&lt;Kernel&gt; p)</i>	returns true iff point <i>p</i> lies on the negative side of hyperplane <i>h</i> . <i>Precondition:</i> <i>h.dimension() == p.dimension()</i> .
<i>Hyperplane_d&lt;Kernel&gt;</i>	<i>h.transform( Aff_transformation_d&lt;Kernel&gt; t)</i>	returns $t(h)$ . <i>Precondition:</i> <i>h.dimension() == t.dimension()</i> .

## Non-Member Functions

<i>bool</i>	<i>weak_equality( h1, h2)</i>	test for weak equality. <i>Precondition:</i> <i>h1.dimension() == h2.dimension()</i> .
-------------	-------------------------------	---

## Implementation

Hyperplanes are implemented by arrays of integers as an item type. All operations like creation, initialization, tests, vector arithmetic, input and output on a hyperplane  $h$  take time  $O(h.dimension())$ . coordinate access and  $dimension()$  take constant time. The space requirement is  $O(h.dimension())$ .

## CGAL::Sphere\_d<Kernel>

### Definition

An instance  $S$  of the data type  $Sphere\_d$  is an oriented sphere in some  $d$ -dimensional space. A sphere is defined by  $d + 1$  points (class  $Point\_d<Kernel>$ ). We use  $A$  to denote the array of the defining points. A set  $A$  of defining points is *legal* if either the points are affinely independent or if the points are all equal. Only a legal set of points defines a sphere in the geometric sense and hence many operations on spheres require the set of defining points to be legal. The orientation of  $S$  is equal to the orientation of the defining points, i.e.,  $orientation(A)$ .

### Types

$Sphere\_d<Kernel>::LA$       the linear algebra layer.

$Sphere\_d<Kernel>::point\_iterator$   
    a read-only iterator for points defining the sphere.

### Creation

$Sphere\_d<Kernel> S;$       introduces a variable  $S$  of type  $Sphere\_d<Kernel>$ .

*template <class ForwardIterator>*  
 $Sphere\_d<Kernel> S( int d, ForwardIterator first, ForwardIterator last);$   
    introduces a variable  $S$  of type  $Sphere\_d<Kernel>$ .  $S$  is initialized to the sphere through the points in  $A = tuple [first, last)$ .  
*Precondition:*  $A$  consists of  $d + 1$   $d$ -dimensional points.  
*Requirement:* The value type of  $ForwardIterator$  is  $Point\_d<Kernel>$ .

### Operations

$int$        $S.dimension()$       returns the dimension of the ambient space.

$Point\_d<Kernel>$        $S.point( int i)$       returns the  $i$ th defining point.  
*Precondition:*  $0 \leq i \leq dim$ .

$point\_iterator$        $S.points\_begin()$   
    returns an iterator pointing to the first defining point.

$point\_iterator$        $S.points\_end()$   
    returns an iterator pointing beyond the last defining point.

<i>bool</i>	<i>S.is_degenerate()</i>	returns true iff the defining points are not full dimensional.
<i>bool</i>	<i>S.is_legal()</i>	returns true iff the set of defining points is legal. A set of defining points is legal iff their orientation is non-zero or if they are all equal.
<i>Point_d&lt;Kernel&gt;</i>	<i>S.center()</i>	returns the center of <i>S</i> . <i>Precondition: S is legal.</i>
<i>FT</i>	<i>S.squared_radius()</i>	returns the squared radius of the sphere. <i>Precondition: S is legal.</i>
<i>Orientation</i>	<i>S.orientation()</i>	returns the orientation of <i>S</i> .
<i>Oriented_side</i>	<i>S.oriented_side( Point_d&lt;Kernel&gt; p)</i>	returns either the constant <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_POSITIVE_SIDE</i> , or <i>ON_NEGATIVE_SIDE</i> , iff <i>p</i> lies on the boundary, properly on the positive side, or properly on the negative side of sphere, resp. <i>Precondition: S.dimension()==p.dimension().</i>
<i>Bounded_side</i>	<i>S.bounded_side( Point_d&lt;Kernel&gt; p)</i>	returns <i>ON_BOUNDED_SIDE</i> , <i>ON_BOUNDARY</i> , or <i>ON_UNBOUNDED_SIDE</i> iff <i>p</i> lies properly inside, on the boundary, or properly outside of sphere, resp. <i>Precondition: S.dimension()==p.dimension().</i>
<i>bool</i>	<i>S.has_on_positive_side( Point_d&lt;Kernel&gt; p)</i>	returns <i>S.oriented_side(p)==ON_POSITIVE_SIDE</i> . <i>Precondition: S.dimension()==p.dimension().</i>
<i>bool</i>	<i>S.has_on_negative_side( Point_d&lt;Kernel&gt; p)</i>	returns <i>S.oriented_side(p)==ON_NEGATIVE_SIDE</i> . <i>Precondition: S.dimension()==p.dimension().</i>
<i>bool</i>	<i>S.has_on_boundary( Point_d&lt;Kernel&gt; p)</i>	returns <i>S.oriented_side(p)==ON_ORIENTED_BOUNDARY</i> , which is the same as <i>S.bounded_side(p)==ON_BOUNDARY</i> . <i>Precondition: S.dimension()==p.dimension().</i>

*bool* *S.has\_on\_bounded\_side( Point\_d<Kernel> p)*

returns *S.bounded\_side(p)==ON\_BOUNDED\_SIDE*.  
*Precondition: S.dimension()==p.dimension()*.

*bool* *S.has\_on\_unbounded\_side( Point\_d<Kernel> p)*

returns *S.bounded\_side(p)==ON\_UNBOUNDED\_SIDE*.  
*Precondition: S.dimension()==p.dimension()*.

*Sphere\_d<Kernel>*

*S.opposite()* returns the sphere with the same center and squared radius as *S* but with opposite orientation.

*Sphere\_d<Kernel>*

*S + Vector\_d<Kernel> v*

returns the sphere translated by *v*.  
*Precondition: S.dimension()==v.dimension()*.

## Non-Member Functions

*bool* *weak\_equality( S1, S2)*

Test for equality as unoriented spheres.  
*Precondition: S1.dimension()==S2.dimension()*.

## Implementation

Spheres are implemented by a vector of points as a handle type. All operations like creation, initialization, tests, input and output of a sphere *s* take time  $O(s.dimension())$ . *dimension()*, point access take constant time. The *center()*-operation takes time  $O(d^3)$  on its first call and constant time thereafter. The sidedness and orientation tests take time  $O(d^3)$ . The space requirement for spheres is  $O(s.dimension())$  neglecting the storage room of the points.

## CGAL::Iso\_box\_d<Kernel>

### Definition

An object  $b$  of the data type  $Iso\_box\_d<Kernel>$  is an iso-box in the Euclidean space  $\mathbb{E}^d$  with edges parallel to the axes of the coordinate system.

### Creation

$Iso\_box\_d<Kernel> \ b( \text{const } Point\_d<Kernel>\& \ p, \text{const } Point\_d<Kernel>\& \ q);$

introduces an iso-oriented iso-box  $b$  with diagonal opposite vertices  $p$  and  $q$ .

### Operations

$bool \qquad b.operator==( \text{const } Iso\_box\_d<Kernel>\& \ b2) \text{ const}$

Test for equality: two iso-oriented cuboid are equal, iff their lower left and their upper right vertices are equal.

$bool \qquad b.operator!=( \text{const } Iso\_box\_d<Kernel>\& \ b2) \text{ const}$

Test for inequality.

$\text{const } Point\_d<Kernel>\& \quad b.min() \text{ const} \qquad$  returns the smallest vertex of  $b$ .

$\text{const } Point\_d<Kernel>\& \quad b.max() \text{ const} \qquad$  returns the largest vertex of  $b$ .

### Predicates

$bool \qquad b.is\_degenerate() \text{ const}$

$b$  is degenerate, if all vertices are collinear.

$Bounded\_side \quad b.bounded\_side( \text{const } Point\_d<Kernel>\& \ p) \text{ const}$

returns either  $ON\_UNBOUNDED\_SIDE$ ,  $ON\_BOUNDED\_SIDE$ , or the constant  $ON\_BOUNDARY$ , depending on where point  $p$  is.

$bool \quad b.has\_on\_boundary( \text{const } Point\_d<Kernel>\& \ p) \text{ const}$

$bool \quad b.has\_on\_bounded\_side( \text{const } Point\_d<Kernel>\& \ p) \text{ const}$

$bool \quad b.has\_on\_unbounded\_side( \text{const } Point\_d<Kernel>\& \ p) \text{ const}$

## Miscellaneous

*Kernel::FT*

*b.volume() const*

returns the volume of *b*.

## CGAL::Aff\_transformation\_d<Kernel>

### Definition

An instance of the data type *Aff\_transformation\_d<Kernel>* is an affine transformation of  $d$ -dimensional space. It is specified by a square matrix  $M$  of dimension  $d + 1$ . All entries in the last row of  $M$  except the diagonal entry must be zero; the diagonal entry must be non-zero. A point  $p$  with homogeneous coordinates  $(p[0], \dots, p[d])$  can be transformed into the point  $p.transform(A) = Mp$ , where  $A$  is an affine transformation created from  $M$  by the constructors below.

### Types

*Aff\_transformation\_d<Kernel>::LA*

the linear algebra layer.

*Aff\_transformation\_d<Kernel>::Matrix*

the matrix type.

### Creation

*Aff\_transformation\_d<Kernel> t;*

introduces some transformation.

*Aff\_transformation\_d<Kernel> t( int d, Identity\_transformation);*

introduces the identity transformation in  $d$ -dimensional space.

*Aff\_transformation\_d<Kernel> t( Matrix M);*

introduces the transformation of  $d$ -space specified by matrix  $M$ .

*Precondition:*  $M$  is a square matrix of dimension  $d + 1$  where entries in the last row of  $M$  except the diagonal entry must be zero; the diagonal entry must be non-zero.

*template <typename Forward\_iterator>*

*Aff\_transformation\_d<Kernel> t( Scaling, Forward\_iterator start, Forward\_iterator end);*

introduces the transformation of  $d$ -space specified by a diagonal matrix with entries *set*  $[start, end)$  on the diagonal (a scaling of the space).

*Precondition:* *set*  $[start, end)$  is a vector of dimension  $d + 1$ .

*Aff\_transformation\_d<Kernel> t( Translation, Vector\_d<Kernel> v);*

introduces the translation by vector  $v$ .

*Aff\_transformation\_d<Kernel>* *t*( *int d*, *Scaling*, *RT num*, *RT den*);

returns a scaling by a scale factor  $num/den$ .  
*Precondition*:  $den \neq 0$ .

*Aff\_transformation\_d<Kernel>* *t*( *int d*, *Rotation*, *RT sin\_num*, *RT cos\_num*, *RT den*, *int e1 = 0*, *int e2 = 1*);

returns a planar rotation with sine and cosine values  $sin\_num/den$  and  $cos\_num/den$  in the plane spanned by the base vectors  $b_{e1}$  and  $b_{e2}$  in  $d$ -space. Thus the default use delivers a planar rotation in the  $x$ - $y$  plane.  
*Precondition*:  $sin\_num^2 + cos\_num^2 = den^2$  and  $0 \leq e_1 < e_2 < d$ .  
*Precondition*:  $den \neq 0$

*Aff\_transformation\_d<Kernel>* *t*( *int d*,  
*Rotation*,  
*Direction\_d<Kernel> dir*,  
*RT num*,  
*RT den*,  
*int e1 = 0*,  
*int e2 = 1*)

returns a planar rotation within a two-dimensional linear subspace. The subspace is spanned by the base vectors  $b_{e1}$  and  $b_{e2}$  in  $d$ -space. The rotation parameters are given by the 2-dimensional direction *dir*, such that the difference between the sines and cosines of the rotation given by *dir* and the approximated rotation are at most  $num/den$  each.

*Precondition*:  $dir.dimension()=2$ ,  $!dir.is\_degenerate()$  and  $num < den$  is positive,  $den \neq 0$ ,  $0 \leq e_1 < e_2 < d$ .

## Operations

<i>int</i>	<i>t.dimension()</i>	the dimension of the underlying space
<i>Matrix</i>	<i>t.matrix()</i>	returns the transformation matrix
<i>Aff_transformation_d&lt;Kernel&gt;</i>	<i>t.inverse()</i>	returns the inverse transformation. <i>Precondition</i> : <i>t.matrix()</i> is invertible.
<i>Aff_transformation_d&lt;Kernel&gt;</i>	<i>t * s</i>	composition of transformations. Note that transformations are not necessarily commutative. <i>t*s</i> is the transformation which transforms first by <i>t</i> and then by <i>s</i> .

## Implementation

Affine Transformations are implemented by matrices of number type *RT* as a handle type. All operations like creation, initialization, input and output on a transformation *t* take time  $O(t.dimension()^2)$ . *dimension()* takes constant time. The operations for inversion and composition have the cubic costs of the used matrix operations. The space requirement is  $O(t.dimension()^2)$ .

## 8.8 Global Kernel Functions

### CGAL::affinely\_independent

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool          affinely_independent( ForwardIterator first, ForwardIterator last)
```

returns true iff the points in  $A = \text{tuple } [first, last)$  are affinely independent.

*Precondition:* The objects are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*

## CGAL::affine\_rank

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
int affine_rank( ForwardIterator first, ForwardIterator last)
```

computes the affine rank of the points in  $A = \text{tuple}[first, last)$ .

*Precondition:* The objects in  $A$  are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*.

## CGAL::center\_of\_sphere

```
#include <CGAL/constructions_d.h>
```

```
template <class ForwardIterator>
```

```
Point_d<R> center_of_sphere( ForwardIterator first, ForwardIterator last)
```

returns the center of the sphere spanned by the points in  $A = \text{tuple}[first, last)$ .

*Precondition:*  $A$  contains  $d + 1$  affinely independent points of dimension  $d$ .

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*.

## CGAL::compare\_lexicographically

```
#include <CGAL/predicates_d.h>
```

```
Comparison_result    compare_lexicographically( Point_d<R> p, Point_d<R> q)
```

Compares the Cartesian coordinates of points  $p$  and  $q$  lexicographically in ascending order of its Cartesian components  $p[i]$  and  $q[i]$  for  $i = 0, \dots, d - 1$ .

*Precondition:*  $p.\text{dimension}() == q.\text{dimension}()$

## CGAL::contained\_in\_affine\_hull

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool contained_in_affine_hull( ForwardIterator first,  
                               ForwardIterator last,  
                               Point_d<R> p)
```

determines whether  $p$  is contained in the affine hull of the points in  $A = \text{tuple } [first, last)$ .

*Precondition:* The objects in  $A$  are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*.

## CGAL::contained\_in\_linear\_hull

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool contained_in_linear_hull( ForwardIterator first,  
                               ForwardIterator last,  
                               Vector_d<R> v)
```

determines whether  $v$  is contained in the linear hull of the vectors in  $A = \text{tuple } [first, last)$ .

*Precondition:* The objects in  $A$  are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Vector\_d<R>*.

## CGAL::contained\_in\_simplex

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool contained_in_simplex( ForwardIterator first, ForwardIterator last, Point_d<R> p)
```

determines whether  $p$  is contained in the simplex of the points in  $A = \text{tuple } [first, last)$ .

*Precondition:* The objects in  $A$  are of the same dimension and affinely independent.

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*.

## CGAL::do\_intersect

```
#include <CGAL/intersections_d.h>
```

```
bool do_intersect( Type1<R> obj1, Type2<R> obj2)
```

checks whether *obj1* and *obj2* intersect. Two objects *obj1* and *obj2* intersect if there is a point *p* that is part of both *obj1* and *obj2*. The intersection region of those two objects is defined as the set of all points *p* that are part of both *obj1* and *obj2*.

*Precondition:* the objects are of the same dimension.

The types *Type1* and *Type2* can be any of the following:

- *Point\_d<R>*
- *Line\_d<R>*
- *Ray\_d<R>*
- *Segment\_d<R>*
- *Hyperplane\_d<R>*

### See Also

*intersection*

## CGAL::intersection

```
#include <CGAL/intersections_d.h>
```

*Object*                      *intersection*( *Type1*<*R*> *f1*, *Type2*<*R*> *f2*)

returns the intersection result of *f1* and *f2* by means of the polymorphic wrapper type *Object*. The returned object can be tested for the intersection result and assigned by means of the *object\_cast* function.

*Precondition*: The objects are of the same dimension.

The possible value for types *Type1* and *Type2* and the possible return values wrapped in *Object* are the following:

Type1	Type2	Return Type
<i>Line_d</i>	<i>Line_d</i>	<i>Point_d</i> , <i>Line_d</i>
<i>Segment_d</i>	<i>Line_d</i>	<i>Point_d</i> , <i>Segment_d</i>
<i>Segment_d</i>	<i>Segment_d</i>	<i>Point_d</i> , <i>Segment_d</i>
<i>Ray_d</i>	<i>Line_d</i>	<i>Point_d</i> , <i>Ray_d</i>
<i>Ray_d</i>	<i>Segment_d</i>	<i>Point_d</i> , <i>Segment_d</i>
<i>Ray_d</i>	<i>Ray_d</i>	<i>Point_d</i> , <i>Segment_d</i> , <i>Ray_d</i>
<i>Hyperplane_d</i>	<i>Line_d</i>	<i>Point_3</i> , <i>Line_3</i>
<i>Hyperplane_d</i>	<i>Ray_d</i>	<i>Point_d</i> , <i>Ray_d</i>
<i>Hyperplane_d</i>	<i>Segment_d</i>	<i>Point_d</i> , <i>Segment_d</i>

### Example

The following example demonstrates the most common use of *intersection* routines.

```
#include <CGAL/intersections_d.h>

template <class R>
void foo(Segment_d<R> seg, Line_d<R> lin)
{
    Object result = intersection(seg, lin);
    if (const Point_d<R> *ipnt = object_cast<Point_d<R> >(&result) ) {
        // handle the point intersection case with *ipnt.
    } else if (const Segment_d<R> *iseg = object_cast<Segment_d<R> >(&result) ) {
        // handle the segment intersection case with *iseg.
    } else {
        // handle the no intersection case.
    }
}
```

**See Also**

*do\_intersect*, *Kernel::Intersect\_d*

## CGAL::lexicographically\_smaller

```
#include <CGAL/predicates_d.h>
```

```
bool                                lexicographically_smaller( Point_d<R> p, Point_d<R> q)
```

returns *true* iff *p* is lexicographically smaller than *q* with respect to Cartesian lexicographic order of points.

*Precondition:* *p.dimension() == q.dimension()*.

## CGAL::lexicographically\_smaller\_or\_equal

```
#include <CGAL/predicates_d.h>
```

```
bool lexicographically_smaller_or_equal( Point_d<R> p, Point_d<R> q)
```

returns *true* iff  $p$  is lexicographically smaller than  $q$  with respect to Cartesian lexicographic order of points or equal to  $q$ .

*Precondition:*  $p.dimension() == q.dimension()$ .

## CGAL::lift\_to\_paraboloid

```
#include <CGAL/constructions_d.h>
```

```
Point_d<R> lift_to_paraboloid( Point_d<R> p)
```

returns the projection of  $p = (x_0, \dots, x_{d-1})$  onto the paraboloid of revolution which is the point  $(p_0, \dots, p_{d-1}, \sum_{0 \leq i < d} p_i^2)$  in  $(d+1)$ -space.

## CGAL::linearly\_independent

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
bool linearly_independent( ForwardIterator first, ForwardIterator last)
```

decides whether the vectors in  $A = \text{tuple } [first, last)$  are linearly independent.

*Precondition:* The objects in  $A$  are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Vector\_d<R>*.

## CGAL::linear\_base

```
#include <CGAL/constructions_d.h>
```

```
template <class ForwardIterator, class OutputIterator>
```

```
OutputIterator linear_base( ForwardIterator first, ForwardIterator last, OutputIterator result)
```

computes a basis of the linear space spanned by the vectors in  $A = \text{tuple } [first, last)$  and returns it via an iterator range starting in *result*. The returned iterator marks the end of the output.

*Precondition:*  $A$  contains vectors of the same dimension  $d$ .

*Requirement:* The value type of *ForwardIterator* and *OutputIterator* is  $\text{Vector}_d<R>$ .

## CGAL::linear\_rank

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
int linear_rank( ForwardIterator first, ForwardIterator last)
```

computes the linear rank of the vectors in  $A = \text{tuple}[first, last)$ .

*Precondition:* The objects are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Vector\_d<R>*.

## CGAL::midpoint

```
#include <CGAL/constructions_d.h>
```

```
Point_d<R> midpoint( Point_d<R> p, Point_d<R> q)
```

computes the midpoint of the segment  $pq$ .

*Precondition:*

*Precondition:*  $p.dimension() == q.dimension()$ .

**CGAL::orientation**

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
Orientation orientation( ForwardIterator first, ForwardIterator last)
```

determines the orientation of the points of the tuple  $A = \text{tuple } [first, last)$  where  $A$  consists of  $d + 1$  points in  $d$ -space. This is the sign of the determinant

$$\begin{vmatrix} 1 & 1 & 1 & 1 \\ A[0] & A[1] & \dots & A[d] \end{vmatrix}$$

where  $A[i]$  denotes the Cartesian coordinate vector of the  $i$ -th point in  $A$ .

*Precondition:*  $\text{size } [first, last) == d + 1$  and  $A[i].\text{dimension}() == d \forall 0 \leq i \leq d$ .

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*.

## CGAL::project\_along\_d\_axis

```
#include <CGAL/constructions_d.h>
```

```
Point_d<R> project_along_d_axis( Point_d<R> p)
```

returns  $p$  projected along the  $d$ -axis onto the hyperspace spanned by the first  $d - 1$  standard base vectors.

**CGAL::side\_of\_bounded\_sphere**

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
Bounded_side      side_of_bounded_sphere( ForwardIterator first,
                                           ForwardIterator last,
                                           Point_d<R> p)
```

returns the relative position of point  $p$  to the sphere defined by  $A = \text{tuple } [first, last)$ . The order of the points of  $A$  does not matter.

*Precondition:*  $\text{orientation}(first, last)$  is not *ZERO*.

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*.

## CGAL::side\_of\_oriented\_sphere

```
#include <CGAL/predicates_d.h>
```

```
template <class ForwardIterator>
```

```
Oriented_side      side_of_oriented_sphere( ForwardIterator first,
                                             ForwardIterator last,
                                             Point_d<R> p)
```

returns the relative position of point  $p$  to the oriented sphere defined by the points in  $A = \text{tuple } [first, last)$ . The order of the points in  $A$  is important, since it determines the orientation of the implicitly constructed sphere. If the points in  $A$  are positively oriented, the positive side is the bounded interior of the sphere.

*Precondition:*  $A$  contains  $d + 1$  points in  $d$ -space.

*Requirement:* The value type of *ForwardIterator* is *Point\_d<R>*.

## CGAL::squared\_distance

```
#include <CGAL/constructions_d.h>
```

```
FT squared_distance( Point_d<R> p, Point_d<R> q)
```

computes the square of the Euclidean distance between the two points  $p$  and  $q$ .

*Precondition:* The dimensions of  $p$  and  $q$  are the same.

## 8.9 Kernel Concept

### Kernel\_d

The concept of a *kernel* is defined by a set of requirements on the provision of certain types and access member functions to create objects of these types. The types are function object classes to be used within the algorithms and data structures in the basic library of CGAL. This allows you to use any model of a kernel as a traits class in the CGAL algorithms and data structures, unless they require types beyond those provided by a kernel.

*Kernel\_d* subsumes the concept of a *d-dimensional kernel*.

A kernel provides types, construction objects, and generalized predicates. The former replace constructors of the kernel classes and constructive procedures in the kernel. There are also function objects replacing operators, especially for equality testing.

### Types

<i>Kernel_d:: FT</i>	a number type that is a model for <i>FieldNumberType</i>
<i>Kernel_d:: RT</i>	a number type that is a model for <i>RingNumberType</i>

### Coordinate Access

<i>Kernel_d:: Cartesian_const_iterator_d</i>	a type that allows to iterate over the Cartesian coordinates
--	--

### Geometric Objects

*Kernel\_d:: Point\_d*  
*Kernel\_d:: Vector\_d*  
*Kernel\_d:: Direction\_d*  
*Kernel\_d:: Hyperplane\_d*  
*Kernel\_d:: Line\_d*  
*Kernel\_d:: Ray\_d*  
*Kernel\_d:: Segment\_d*  
*Kernel\_d:: Iso\_box\_d*  
*Kernel\_d:: Sphere\_d*  
*Kernel\_d:: Aff\_transformation\_d*

### Constructions

*Kernel\_d:: Construct\_point\_d*  
*Kernel\_d:: Construct\_vector\_d*  
*Kernel\_d:: Construct\_direction\_d*  
*Kernel\_d:: Construct\_hyperplane\_d*  
*Kernel\_d:: Construct\_segment\_d*  
*Kernel\_d:: Construct\_iso\_box\_d*  
*Kernel\_d:: Construct\_line\_d*

*Kernel\_d:: Construct\_ray\_d*  
*Kernel\_d:: Construct\_sphere\_d*  
*Kernel\_d:: Construct\_aff\_transformation\_d*  
*Kernel\_d:: Construct\_cartesian\_const\_iterator\_d*

## Generalized Predicates

*Kernel\_d:: Affine\_rank\_d*  
*Kernel\_d:: Affinely\_independent\_d*  
*Kernel\_d:: Barycentric\_coordinates\_d*  
*Kernel\_d:: Center\_of\_sphere\_d*  
*Kernel\_d:: Compare\_lexicographically\_d*  
*Kernel\_d:: Component\_accessor\_d*  
*Kernel\_d:: Contained\_in\_affine\_hull\_d*  
*Kernel\_d:: Contained\_in\_linear\_hull\_d*  
*Kernel\_d:: Contained\_in\_simplex\_d*  
*Kernel\_d:: Equal\_d*  
*Kernel\_d:: Has\_on\_positive\_side\_d*  
*Kernel\_d:: Intersect\_d*  
*Kernel\_d:: Less\_lexicographically\_d*  
*Kernel\_d:: Less\_or\_equal\_lexicographically\_d*  
*Kernel\_d:: Lift\_to\_paraboloid\_d*  
*Kernel\_d:: Linear\_base\_d*  
*Kernel\_d:: Linear\_rank\_d*  
*Kernel\_d:: Linearly\_independent\_d*  
*Kernel\_d:: Midpoint\_d*  
*Kernel\_d:: Orientation\_d*  
*Kernel\_d:: Oriented\_side\_d*  
*Kernel\_d:: Orthogonal\_vector\_d*  
*Kernel\_d:: Point\_of\_sphere\_d*  
*Kernel\_d:: Point\_to\_vector\_d*  
*Kernel\_d:: Position\_on\_line\_d*  
*Kernel\_d:: Project\_along\_d\_axis\_d*  
*Kernel\_d:: Side\_of\_bounded\_sphere\_d*  
*Kernel\_d:: Side\_of\_oriented\_sphere\_d*  
*Kernel\_d:: Squared\_distance\_d*  
*Kernel\_d:: Value\_at\_d*  
*Kernel\_d:: Vector\_to\_point\_d*

## Operations

The following member functions return function objects of the types listed above. The name of the access function is the name of the type returned with an *\_object* suffix and no capital letter at the beginning. We only give two examples to show the scheme. For the functors *Construct\_point\_d* and *Orientation\_d* the corresponding functions are:

*Kernel::Construct\_point\_d*     *kernel.construct\_point\_d\_object()*  
*Kernel::Orientation\_d*         *kernel.orientation\_d\_object()*

## Has Models

*Cartesian\_d<FieldNumberType>, Homogeneous\_d<RingNumberType>*

## Kernel::Affinely\_independent\_d

A model for this must provide:

```
template <class ForwardIterator>
bool fo( ForwardIterator first, ForwardIterator last)
```

returns true iff the points in  $A = \text{tuple } [first, last)$  are affinely independent.

*Precondition:* The objects are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::Affine\_rank\_d

A model for this must provide:

```
template <class ForwardIterator>
int fo( ForwardIterator first, ForwardIterator last)
```

computes the affine rank of the points in  $A = \text{tuple}[first, last)$ .

*Precondition:* The objects are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::CartesianConstIterator\_d

A type representing an iterator to the Cartesian coordinates of a point in  $d$  dimensions.

### Refines

CopyConstructible, Assignable, DefaultConstructible

### Is Model for the Concepts

*BidirectionalIterator*

### See Also

Kernel::ConstructCartesianConstIterator\_d ..... page [863](#)

## Kernel::Center\_of\_sphere\_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Kernel::Point_d fo( ForwardIterator first, ForwardIterator last)
```

computes the affine rank of the points in  $A = \text{tuple}[first, last)$ .

*Precondition:* The objects are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::Compare\_lexicographically\_d

A model for this must provide:

*Comparison\_result*      *fo*( *Kernel::Point\_d* *p*, *Kernel::Point\_d* *q*)

Compares the Cartesian coordinates of points *p* and *q* lexicographically in ascending order of its Cartesian components *p*[*i*] and *q*[*i*] for *i* = 0, ..., *d* − 1.

*Precondition*: The objects are of the same dimension.

## Kernel::Component\_accessor\_d

A model for this must provide:

<i>int</i>	<i>fo.dimension( Kernel::Point_d p)</i>	returns the dimension of <i>p</i> .
<i>Kernel::RT</i>	<i>fo.homogeneous( Kernel::Point_d p, int i)</i>	returns the <i>i</i> th homogeneous coordinate of <i>p</i> . <i>Precondition: <math>0 \leq i \leq \text{dimension}(p)</math>.</i>
<i>Kernel::FT</i>	<i>fo.cartesian( Kernel::Point_d p, int i)</i>	returns the <i>i</i> th Cartesian coordinate of <i>p</i> . <i>Precondition: <math>0 \leq i &lt; \text{dimension}(p)</math>.</i>

## Kernel::ConstructCartesianConstIterator\_d

A model for this must provide:

*Kernel::Cartesian\_const\_iterator\_d*

*fo( Kernel::Point\_d p)*

returns an iterator on the 0'th Cartesian coordinate of *p*.

*Kernel::Cartesian\_const\_iterator\_d*

*fo( Kernel::Point\_d p, int)*

returns the past the end iterator of the Cartesian coordinates of *p*.

### Refines

AdaptableFunctor (with one argument)

### See Also

## Kernel::Contained\_in\_affine\_hull\_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

determines whether  $p$  is contained in the affine hull of the points in  $A = \text{tuple } [first, last)$ .

*Precondition:* The objects are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::Contained\_in\_linear\_hull\_d

A model for this must provide:

```
template <class ForwardIterator>
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Vector_d v)
```

determines whether  $v$  is contained in the linear hull of the vectors in  $A = \text{tuple } [first, last)$ .

*Precondition:* The objects are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Vector\_d*.

## Kernel::Contained\_in\_simplex\_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

determines whether  $p$  is contained in the simplex of the points in  $A = \text{tuple } [first, last)$ .

*Precondition:* The objects in  $A$  are of the same dimension and affinely independent.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::Equal\_d

A model for this must provide:

*bool*

*fo( Kernel::Point\_d p, Kernel::Point\_d q)*

returns true iff  $p$  and  $q$  are equal (as  $d$ -dimensional points).

*Precondition:*  $p$  and  $q$  have the same dimension.

## Kernel::Has\_on\_positive\_side\_d

A model for this must provide:

```
template <class Kernel_object>
bool fo( Kernel_object o, Kernel::Point_d p)
```

returns true iff  $p$  is on the positive side of  $o$ .  
*Kernel\_object* may be any of *Kernel::Sphere\_d*,  
*Kernel::Hyperplane\_d*.

*Precondition:*  $p$  and  $o$  have the same dimension.

## Kernel::Intersect\_d

A model for this must provide:

```
template <class Kernel_object>
Object fo( Kernel_object p, Kernel_object q)
```

returns the result of the intersection of  $p$  and  $q$  in form of a polymorphic object. *Kernel\_object* may be any of *Kernel::Segment\_d*, *Kernel::Ray\_d*, *Kernel::Line\_d*, *Kernel::Hyperplane\_d*.

*Precondition:*  $p$  and  $q$  have the same dimension.

## Kernel::Less\_lexicographically\_d

A model for this must provide:

*bool* *fo( Kernel::Point\_d p, Kernel::Point\_d q)*

returns *true* iff *p* is lexicographically smaller than *q* with respect to Cartesian lexicographic order of points.

*Precondition:* *p* and *q* have the same dimension.

## Kernel::Less\_or\_equal\_lexicographically\_d

A model for this must provide:

*bool*

*fo( Kernel::Point\_d p, Kernel::Point\_d q)*

returns *true* iff *p* is lexicographically smaller than *q* with respect to Cartesian lexicographic order of points or equal to *q*.

*Precondition:* *p* and *q* have the same dimension.

## Kernel::Lift\_to\_paraboloid\_d

A model for this must provide:

*Kernel::Point\_d*  $\rightarrow$  *fo( Kernel::Point\_d p)*

returns  $p = (x_0, \dots, x_{d-1})$  lifted to the paraboloid of revolution which is the point  $(p_0, \dots, p_{d-1}, \sum_{0 \leq i < d} p_i^2)$  in  $(d+1)$ -space.

## Kernel::Linearly\_independent\_d

A model for this must provide:

```
template <class ForwardIterator>
bool fo( ForwardIterator first, ForwardIterator last)
```

decides whether the vectors in  $A = \text{tuple } [first, last)$  are linearly independent.

*Precondition:* The objects in  $A$  are of the same dimension.

*Requirement:* The value type of *ForwardIterator* is *Kernel\_d::Vector\_d*.

## Kernel::Linear\_base\_d

A model for this must provide:

```
template <class ForwardIterator, class OutputIterator>
int fo( ForwardIterator first, ForwardIterator last, OutputIterator result)
```

computes a basis of the linear space spanned by the vectors in  $A = \text{tuple } [first, last)$  and returns it via an iterator range starting in *result*. The returned iterator marks the end of the output.

*Precondition:*  $A$  contains vectors of the same dimension  $d$ .

*Requirement:* The value type of *ForwardIterator* and *OutputIterator* is *Kernel::Vector\_d*.

## Kernel::Linear\_rank\_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
int fo( ForwardIterator first, ForwardIterator last)
```

computes the linear rank of the vectors in  $A = \text{tuple}[first, last)$ .

*Precondition:*

*Precondition:*  $A$  contains vectors of the same dimension  $d$ .

*Requirement:* The value type of *ForwardIterator* is *Kernel::Vector\_d*.

## Kernel::Midpoint\_d

A model for this must provide:

*Kernel::Point\_d*                      *fo( Kernel::Point\_d p, Kernel::Point\_d q)*

computes the midpoint of the segment  $pq$ .

*Precondition:*  $p$  and  $q$  have the same dimension.

## Kernel::Orientation\_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Orientation fo( ForwardIterator first, ForwardIterator last)
```

determines the orientation of the points of the tuple  $A = \text{tuple } [first, last)$  where  $A$  consists of  $d + 1$  points in  $d$ -space. This is the sign of the determinant

$$\begin{vmatrix} 1 & 1 & 1 & 1 \\ A[0] & A[1] & \dots & A[d] \end{vmatrix}$$

where  $A[i]$  denotes the Cartesian coordinate vector of the  $i$ -th point in  $A$ .

*Precondition:*  $\text{size } [first, last) == d + 1$  and  $A[i].\text{dimension}() == d \forall 0 \leq i \leq d$ .

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::Oriented\_side\_d

A model for this must provide:

```
template <class Kernel_object>
Oriented_side          fo( Kernel_object o, Kernel::Point_d p)
```

returns the side of  $p$  with respect to  $o$ . *Kernel\_object* may be any of *Kernel::Sphere\_d* or *Kernel::Hyperplane\_d*.  
*Precondition:*  $p$  and  $o$  have the same dimension.

## Kernel::Orthogonal\_vector\_d

A model for this must provide:

*Kernel::Vector\_d*                      *fo( Kernel::Hyperplane\_d h)*  
computes an orthogonal vector to *h*.

## Kernel::Point\_of\_sphere\_d

A model for this must provide:

*bool* *fo( Kernel::Sphere\_d s, int i)*  
returns the ith point defining the sphere *s*.

## Kernel::Point\_to\_vector\_d

A model for this must provide:

*Kernel::Vector\_d*      *fo( Kernel::Point\_d p)*

converts  $p$  to its geometric vector.

## Kernel::Project\_along\_d\_axis\_d

A model for this must provide:

*Kernel::Point\_d*  $\rightarrow$  *fo( Kernel::Point\_d p)*

returns  $p$  projected along the  $d$ -axis onto the hyperspace spanned by the first  $d - 1$  standard base vectors.

## Kernel::Side\_of\_bounded\_sphere\_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

returns the relative position of point  $p$  to the sphere defined by  $A = \text{tuple } [first, last]$ . The order of the points of  $A$  does not matter.

*Precondition:*  $\text{orientation}(first, last)$  is not ZERO.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::Side\_of\_oriented\_sphere\_d

A model for this must provide:

```
template <class ForwardIterator>
```

```
Bounded_side          fo( ForwardIterator first, ForwardIterator last, Kernel::Point_d p)
```

returns the relative position of point  $p$  to the oriented sphere defined by the points in  $A = \text{tuple } [first, last)$ . The order of the points in  $A$  is important, since it determines the orientation of the implicitly constructed sphere. If the points in  $A$  are positively oriented, the positive side is the bounded interior of the sphere.

*Precondition:*  $A$  contains  $d + 1$  points in  $d$ -space.

*Requirement:* The value type of *ForwardIterator* is *Kernel::Point\_d*.

## Kernel::Squared\_distance\_d

A model for this must provide:

*Kernel::FT*                      *fo( Kernel::Point\_d p, Kernel::Point\_d q)*

computes the square of the Euclidean distance between the two points  $p$  and  $q$ .

*Precondition:* The dimensions of  $p$  and  $q$  are the same.

## Kernel::Value\_at\_d

A model for this must provide:

*Kernel::FT*  $fo( \textit{Kernel::Hyperplane\_d } h, \textit{Kernel::Point\_d } p )$

computes the value of  $h$  evaluated at  $p$ .

*Precondition:*  $p$  and  $h$  have the same dimension.

## Kernel::Vector\_to\_point\_d

A model for this must provide:

*Kernel::Point\_d*                      *fo( Kernel::Vector\_d v)*

converts  $v$  to the affine point  $0 + v$ .

## 9.1 Introduction

The goal of the circular kernel is to offer to the user a large set of functionalities on circles and circular arcs in the plane. All the choices (interface, robustness, representation, and so on) made here are consistent with the choices made in the CGAL kernel, for which we refer the user to the 2D kernel manual.

In this first release, all functionalities necessary for computing an arrangement of circular arcs and these line segments are defined. Three traits classes are provided for the CGAL arrangement package.

## 9.2 Software Design

The design is done in such a way that the algebraic concepts and the geometric concepts are clearly separated. *Circular\_kernel\_2* has therefore two template parameters:

- the first parameter must model the CGAL three dimensional *Kernel* concept. The circular kernel derives

from it, and it provides all elementary geometric objects like points, lines, circles, and elementary functionality on them.

- the second parameter is the algebraic kernel, which is responsible for computations on polynomials and algebraic numbers. It has to be a model of concept *AlgebraicKernelForCircles*. The robustness of the package relies on the fact that the algebraic kernel provides exact computations on algebraic objects.

The circular kernel uses the extensibility scheme presented in the 2D kernel manual (see Section 7.5). The types of *Kernel* are inherited by the circular kernel and some types are taken from the *AlgebraicKernelForCircles* parameter. Three new main geometric objects are introduced by *Circular\_kernel\_2*: circular arcs, points of circular arcs (used in particular for endpoints of arcs and intersection points between arcs) and line segments whose endpoints are points of this new type.

In fact, the circular kernel is documented as a concept, *CircularKernel*, and two models are provided:

- *Circular\_kernel\_2*<*Kernel*,*AlgebraicKernelForCircles*>, the basic kernel,
- and a predefined filtered kernel *Exact\_circular\_kernel\_2*, that is based on similar techniques as *Exact\_predicates\_exact\_constructions\_kernel*.

## 9.3 Examples

The first example shows how to construct circles or circular arcs from points, and how to compute intersections between them using the global function.

```
#include <CGAL/Exact_circular_kernel_2.h>
#include <CGAL/point_generators_2.h>

typedef CGAL::Exact_circular_kernel_2      Circular_k;

typedef CGAL::Point_2<Circular_k>         Point_2;
typedef CGAL::Circle_2<Circular_k>        Circle_2;
typedef CGAL::Circular_arc_2<Circular_k>   Circular_arc_2;

template <typename T>
double prob_2() {
    CGAL::Random_points_in_square_2<Point_2> g(1.0);
    double prob = 0.0;
    for (int i = 0; i < 10000; i++) {

        Point_2 p1, p2, p3, p4, p5, p6;
        p1 = *g++; p2 = *g++; p3 = *g++;
        p4 = *g++; p5 = *g++; p6 = *g++;

        // the pi's are points inherited from the Cartesian kernel Point_2, so,
        // the orientation predicate can be called on them
        if(CGAL::orientation(p1, p2, p3) != CGAL::COUNTERCLOCKWISE) std::swap(p1, p3);
        T o1 = T(p1, p2, p3);
        if(CGAL::orientation(p4, p5, p6) != CGAL::COUNTERCLOCKWISE) std::swap(p4, p6);
        T o2 = T(p4, p5, p6);
```

```

    std::vector< CGAL::Object > res;
    CGAL::intersection(o1, o2, std::back_inserter(res));

    prob += (res.size() != 0) ? 1.0 : 0.0;
}
return prob/10000.0;
}

int main()
{
    std::cout << "What is the probability that two arcs formed by" << std::endl;
    std::cout << "three random counterclockwise-oriented points on" << std::endl;
    std::cout << "an unit square intersect? (wait a second please)" << std::endl;
    std::cout << "The probability is: " << prob_2<Circular_arc_2>() <<
        std::endl << std::endl;

    std::cout << "And what about the probability that two circles formed by"
        << std::endl;
    std::cout << "three random counterclockwise-oriented points on" << std::endl;
    std::cout << "an unit square intersect? (wait a second please)" << std::endl;
    std::cout << "The probability is: " << prob_2<Circle_2>() << std::endl;
    return 0;
};

```

**File:** examples/Circular\_kernel\_2/intersecting\_arcs.cpp

The following example shows how to use a functor of the kernel.

```

#include <CGAL/Exact_circular_kernel_2.h>
#include <CGAL/point_generators_2.h>

typedef CGAL::Exact_circular_kernel_2      Circular_k;

typedef CGAL::Point_2<Circular_k>          Point_2;
typedef CGAL::Circular_arc_2<Circular_k>   Circular_arc_2;

int main()
{
    int n = 0;
    Circular_arc_2 c = Circular_arc_2(Point_2(10,0), Point_2(5,5), Point_2(0, 0));

    for(int i = 0; i <= 10; i++) {
        for(int j = 0; j <= 10; j++) {
            Point_2 p = Point_2(i, j);
            if(Circular_k().has_on_2_object()(c,p)) {
n++;
std::cout << "(" << i << "," << j << ")" << std::endl;
            }
        }
    }
    std::cout << "There are " << n << " points in the [0,...,10]x[0,...,10] "
        << "grid on the circular" << std::endl
        << " arc defined counterclockwisely by the points (0,0), (5,5), (10,0)"

```

```

    << std::endl << "See the points above." << std::endl;
    return 0;
};

```

**File:** examples/Circular\_kernel\_2/functor\_has\_on\_2.cpp

## 9.4 Design and Implementation History

The first pieces of prototype code were comparisons of algebraic numbers of degree 2, written by Olivier Devillers [DFMT00, DFMT02], and that are still used in the current implementation of *CGAL::Root\_of\_2*.

Some work was then done in the direction of a “kernel” for CGAL.<sup>1</sup> and the first design emerged in [EKP<sup>+</sup>04].

The code of this package was initially written by Sylvain Pion and Monique Teillaud who also wrote the manual. Athanasios Kakargias had worked on a prototype version of this kernel in 2003. Julien Hazebrouck participated in the implementation in July and August 2005. The contribution of Pedro Machado Manhães de Castro in summer 2006 improved significantly the efficiency of this kernel. He also added more functionality in 2008.

This work was partially supported by the IST Programme of the EU as a Shared-cost RTD (FET Open) Project under Contract No IST-2000-26473 (ECG - Effective Computational Geometry for Curves and Surfaces) and by the IST Programme of the 6th Framework Programme of the EU as a STREP (FET Open Scheme) Project under Contract No IST-006413 (ACS - Algorithms for Complex Shapes).

# CircularKernel

## Refines

*Kernel*

## Has Models

*CGAL::Circular\_kernel\_2* <*Kernel*, *AlgebraicKernelForCircles*>

*CGAL::Exact\_circular\_kernel\_2*

## Types

A model of *CircularKernel* is supposed to provide some basic types

*CircularKernel::Linear\_kernel*

Model of *LinearKernel*.

*CircularKernel::Algebraic\_kernel*

Model of *AlgebraicKernelForCircles*.

*CircularKernel::RT*

Model of *RingNumberType*.

*CircularKernel::FT*

Model of *FieldNumberType*.

*CircularKernel::Root\_of\_2*

Model of *RootOf\_2*.

*CircularKernel::Root\_for\_circles\_2\_2*

Model of *AlgebraicKernelForCircles::RootForCircles\_2\_2*.

*CircularKernel::Polynomial\_1\_2*

Model of *AlgebraicKernelForCircles::Polynomial\_1\_2*.

*CircularKernel::Polynomial\_for\_circles\_2\_2*

Model of *AlgebraicKernelForCircles::PolynomialForCircles\_2\_2*.

and to define the following geometric objects

*CircularKernel::Point\_2*

Model of *Kernel::Point\_2*.

*CircularKernel::Circle\_2*

Model of *Kernel::Circle\_2*.

*CircularKernel::Line\_arc\_2*

Model of *CircularKernel::LineArc\_2*.

*CircularKernel::Circular\_arc\_2*

Model of *CircularKernel::CircularArc\_2*.

*CircularKernel::Circular\_arc\_point\_2*

Model of *CircularKernel::CircularArcPoint\_2*.

Moreover, a model of *CircularKernel* must provide predicates, constructions and other functionalities.

## Predicates

*CircularKernel::Compare\_x\_2*

Model of *CircularKernel::CompareX\_2*.

*CircularKernel::Compare\_y\_2*

Model of *CircularKernel::CompareY\_2*.

*CircularKernel::Compare\_xy\_2*

Model of *CircularKernel::CompareXY\_2*.

*CircularKernel::Equal\_2*

Model of *CircularKernel::Equal\_2*.

*CircularKernel::Compare\_y\_at\_x\_2*

Model of *CircularKernel::CompareYatX\_2*.

<i>CircularKernel:: Compare_y_to_right_2</i>	Model of <i>CircularKernel::CompareYtoRight_2</i> .
<i>CircularKernel:: Has_on_2</i>	Model of <i>CircularKernel::HasOn_2</i> .
<i>CircularKernel:: Do_overlap_2</i>	Model of <i>CircularKernel::DoOverlap_2</i> .
<i>CircularKernel:: Do_intersect_2</i>	Model of <i>CircularKernel::DoIntersect_2</i> .
<i>CircularKernel:: Bounded_side_2</i>	Model of <i>CircularKernel::BoundedSide_2</i> .
<i>CircularKernel:: Has_on_bounded_side_2</i>	Model of <i>CircularKernel::HasOnBoundedSide_2</i> .
<i>CircularKernel:: Has_on_unbounded_side_2</i>	Model of <i>CircularKernel::HasOnUnboundedSide_2</i> .
<i>CircularKernel:: In_x_range_2</i>	Model of <i>CircularKernel::InXRange_2</i> .
<i>CircularKernel:: Is_vertical_2</i>	Model of <i>CircularKernel::IsVertical_2</i> .
<i>CircularKernel:: Is_x_monotone_2</i>	Model of <i>CircularKernel::IsXMonotone_2</i> .
<i>CircularKernel:: Is_y_monotone_2</i>	Model of <i>CircularKernel::IsYMonotone_2</i> .

## **Constructions**

<i>CircularKernel:: Construct_line_2</i>	Model of <i>CircularKernel::ConstructLine_2</i> .
<i>CircularKernel:: Construct_circle_2</i>	Model of <i>CircularKernel::ConstructCircle_2</i> .
<i>CircularKernel:: Construct_circular_arc_point_2</i>	Model of <i>CircularKernel::ConstructCircularArcPoint_2</i> .
<i>CircularKernel:: Construct_line_arc_2</i>	Model of <i>CircularKernel::ConstructLineArc_2</i> .
<i>CircularKernel:: Construct_circular_arc_2</i>	Model of <i>CircularKernel::ConstructCircularArc_2</i> .
<i>CircularKernel:: Compute_circular_x_2</i>	Model of <i>CircularKernel::ComputeCircularX_2</i>
<i>CircularKernel:: Compute_circular_y_2</i>	Model of <i>CircularKernel::ComputeCircularY_2</i>
<i>CircularKernel:: Construct_circular_min_vertex_2</i>	Model of <i>CircularKernel::ConstructCircularMinVertex_2</i> .
<i>CircularKernel:: Construct_circular_max_vertex_2</i>	Model of <i>CircularKernel::ConstructCircularMaxVertex_2</i> .
<i>CircularKernel:: Construct_circular_source_vertex_2</i>	Model of <i>CircularKernel::ConstructCircularSourceVertex_2</i> .

*CircularKernel:: Construct\_circular\_target\_vertex\_2*

Model of *CircularKernel::ConstructCircularTargetVertex\_2*.

*CircularKernel:: Intersect\_2*

Model of *CircularKernel::Intersect\_2*.

*CircularKernel:: Split\_2*

Model of *CircularKernel::Split\_2*.

*CircularKernel:: Make\_x\_monotone\_2*

Model of *CircularKernel::MakeXMonotone\_2*.

*CircularKernel:: Make\_xy\_monotone\_2*

Model of *CircularKernel::MakeXYMonotone\_2*.

### **Link with the algebraic kernel**

*CircularKernel:: Get\_equation*

Model of *CircularKernel::GetEquation*.

### **Operations**

As in the *Kernel* concept, for each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *\_object* appended. For example, for the function object *CircularKernel::Construct\_circular\_arc\_2* the following member function must exist:

*Construct\_circular\_arc\_2*

*ck.construct\_circular\_arc\_2\_object()*

### **See Also**

*Kernel* ..... page [333](#)

## CGAL::Circular\_kernel\_2<Kernel,AlgebraicKernelForCircles>

`#include <CGAL/Circular_kernel_2.h>`

### Is Model for the Concepts

*CircularKernel*

### Parameters

The first parameter of the circular kernel must be instantiated with a model of the *Kernel* concept. The *Circular\_kernel\_2* class template derives from this first parameter, in order to reuse all needed functionalities on basic objects provided by a model of the *Kernel* concept.

The second parameter, *AlgebraicKernelForCircles*, is meant to provide the circular kernel with all the algebraic functionalities required for the manipulation of algebraic curves.

### Inherits From

*Kernel*

### Types

The circular kernel uses basic number types of the algebraic kernel:  
`typedef AlgebraicKernelForCircles::RT`      *RT*;      Ring number type.

`typedef AlgebraicKernelForCircles::FT`      *FT*;      Field number type.

In fact, the two number types *AlgebraicKernelForCircles::RT* and *Kernel::RT* must coincide, as well as *AlgebraicKernelForCircles::FT* and *Kernel::FT*.

The following types are available, as well as all the functionality on them described in the *CircularKernel* concept.

```
typedef Line_arc_2<Circular_kernel_2>      Line_arc_2;
typedef Circular_arc_2<Circular_kernel_2>   Circular_arc_2;
typedef Circular_arc_point_2<Circular_kernel_2>
                                           Circular_arc_point_2;
```

## CGAL::Exact\_circular\_kernel\_2

*#include <CGAL/Exact\_circular\_kernel\_2.h>*

### Definition

A typedef to a circular kernel that provides both exact geometric predicates and exact geometric constructions. This kernel uses some geometric filtering (based on bounding boxes) to gain efficiency.

### Is Model for the Concepts

*CircularKernel*

### See Also

*CGAL::Circular\_kernel\_2<Kernel,AlgebraicKernelForCircles>* ..... page [901](#)

## **CircularKernel::CircularArc\_2**

Concept for arcs of circles.

### **Refines**

CopyConstructible, Assignable, DefaultConstructible

### **Has Models**

*CGAL::Circular\_arc\_2<CircularKernel>*

## CircularKernel::LineArc\_2

### Definition

Concept for line segments supported by a line that is a model of *Kernel::Line\_2* and whose endpoints are models of the *CircularKernel::CircularArcPoint\_2* concept.

### Refines

CopyConstructible, Assignable, DefaultConstructible

### Has Models

*CGAL::Line\_arc\_2*<*CircularKernel*>

## CircularKernel::CircularArcPoint\_2

### Definition

Concept for points on circles, circular arcs or line arcs.

### Refines

CopyConstructible, Assignable, DefaultConstructible

### Has Models

*CGAL::Circular\_arc\_point\_2<CircularKernel>*

**CGAL::Circular\_arc\_2<CircularKernel>**

```
#include <CGAL/Circular_arc_2.h>
```

**Is Model for the Concepts**

```
CircularKernel::CircularArc_2
```

**Creation**

```
Circular_arc_2<CircularKernel> ca( Circle_2<CircularKernel> c);
```

Constructs an arc from a full circle.

```
Circular_arc_2<CircularKernel> ca( Circle_2<CircularKernel> c,
    Circular_arc_point_2<CircularKernel> p,
    Circular_arc_point_2<CircularKernel> q)
```

Constructs the circular arc supported by  $c$ , whose source is  $p$  and whose target is  $q$  when traversing the circle in counterclockwise direction.

*Precondition:*  $p$  and  $q$  lie on  $c$ .

```
Circular_arc_2<CircularKernel> ca( Point_2<CircularKernel> p,
    Point_2<CircularKernel> q,
    Point_2<CircularKernel> r)
```

Constructs an arc that is supported by the circle of type  $Circle\_2<CircularKernel>$  passing through the points  $p$ ,  $q$  and  $r$ . The source and target are respectively  $p$  and  $r$ , when traversing the supporting circle in the counterclockwise direction. Note that, depending on the orientation of the point triple  $(p,q,r)$ ,  $q$  may not lie on the arc.

*Precondition:*  $p$ ,  $q$ , and  $r$  are not collinear.

**Access Functions**

```
Circle_2<CircularKernel> ca.supporting_circle()
```

```
Point_2<CircularKernel> ca.center()          returns the center of the supporting circle.
CircularKernel::FT ca.squared_radius()
```

returns the squared radius of the supporting circle.

A circular arc is not oriented. Still, its source and target endpoints can be defined, supposing that its supporting circle is traversed the counterclockwise direction from *source* to *target*.

<i>Circular_arc_point_2</i> < <i>CircularKernel</i> >	<i>ca.source()</i>
<i>Circular_arc_point_2</i> < <i>CircularKernel</i> >	<i>ca.target()</i>

When the methods *source* and *target* return the same point, then the arc is in fact a full circle.

When an arc is x-monotone, its left and right points can be accessed directly:

<i>Circular_arc_point_2</i> < <i>CircularKernel</i> >	<i>ca.left()</i>	<i>Precondition: ca.is_x_monotone().</i>
<i>Circular_arc_point_2</i> < <i>CircularKernel</i> >	<i>ca.right()</i>	<i>Precondition: ca.is_x_monotone().</i>

<i>Bbox_2</i>	<i>ca.bbox()</i>	Returns a bounding box containing the arc.
---------------	------------------	--

## Query Functions

<i>bool</i>	<i>ca.is_x_monotone()</i>	Tests whether the arc is x-monotone.
<i>bool</i>	<i>ca.is_y_monotone()</i>	Tests whether the arc is y-monotone.

## Operations

<i>bool</i>	<i>ca1 == ca2</i>	Test for equality. Two arcs are equal, iff their non-oriented supporting circles are equal (i.e. they have same center and same squared radius) and their endpoints are equal.
<i>bool</i>	<i>ca1 != ca2</i>	Test for non-equality

## I/O

<i>istream</i> &	<i>std::istream&amp; is &gt;&gt; Circular_arc_2 &amp; ca</i>
<i>ostream</i> &	<i>std::ostream&amp; os &lt;&lt; Circular_arc_2 ca</i>

## See Also

<i>CGAL::Circular_arc_point_2</i> < <i>CircularKernel</i> > .....	page <a href="#">910</a>
<i>CGAL::Line_arc_2</i> < <i>CircularKernel</i> > .....	page <a href="#">908</a>

## CGAL::Line\_arc\_2<CircularKernel>

```
#include <CGAL/Line_arc_2.h>
```

### Is Model for the Concepts

```
CircularKernel::LineArc_2
```

### Creation

```
Line_arc_2<CircularKernel> la( Line_2<CircularKernel> l,
                               Circular_arc_point_2<CircularKernel> p1,
                               Circular_arc_point_2<CircularKernel> p2)
```

Construct the line segment supported by  $l$ , whose source is  $p1$  and whose target is  $p2$ .

*Precondition:*  $p1$  and  $p2$  lie on  $l$ .

```
Line_arc_2<CircularKernel> la( Line_2<CircularKernel> l,
                               Point_2<CircularKernel> p1,
                               Point_2<CircularKernel> p2)
```

Same.

```
Line_arc_2<CircularKernel> la( Segment_2<CircularKernel> s);
```

### Access Functions

```
Line_2<CircularKernel>          la.supporting_line()
```

```
Circular_arc_point_2<CircularKernel> la.source()
```

```
Circular_arc_point_2<CircularKernel> la.target()
```

```
Circular_arc_point_2<CircularKernel> la.left()
```

```
Circular_arc_point_2<CircularKernel> la.right()
```

```
Bbox_2                          la.bbox()
```

Returns a bounding box containing the line segment.

### Query Functions

```
bool                             la.is_vertical()
```

## Operations

<i>bool</i>	<i>la1 == la2</i>	Test for equality. Two arcs are equal, iff their non-oriented supporting lines are equal (i.e. they contain the same set of points) and their endpoints are equal.
-------------	-------------------	--

<i>bool</i>	<i>la1 != la2</i>	Test for non-equality.
-------------	-------------------	------------------------

## I/O

<i>istream&amp;</i>	<i>std::istream&amp; is &gt;&gt; Line_arc_2 &amp; ca</i>
<i>ostream&amp;</i>	<i>std::ostream&amp; os &lt;&lt; Line_arc_2 ca</i>

The format for input/output is, for each line arc: a *Line\_2* (the supporting line) and two *Circular\_arc\_point\_2* (the two endpoints), under the condition that the endpoints are actually lying on the line.

## See Also

<i>CGAL::Circular_arc_point_2&lt;CircularKernel&gt;</i> .....	page <a href="#">910</a>
<i>CGAL::Circular_arc_2&lt;CircularKernel&gt;</i> .....	page <a href="#">906</a>

## CGAL::Circular\_arc\_point\_2<CircularKernel>

```
#include <CGAL/Circular_arc_point_2.h>
```

### Is Model for the Concepts

```
CircularKernel::CircularArcPoint_2
```

### Creation

```
Circular_arc_point_2<CircularKernel> p( CircularKernel::Point_2 q);
```

```
Circular_arc_point_2<CircularKernel> p( CircularKernel::Root_for_circles_2_2 r);
```

### Access Functions

<i>CircularKernel::Root_of_2</i>	<i>p.x()</i>	<i>x</i> -coordinate of the point.
<i>CircularKernel::Root_of_2</i>	<i>p.y()</i>	<i>y</i> -coordinate of the point.

<i>Bbox_2</i>	<i>p.bbox()</i>	Returns a bounding box around the point.
---------------	-----------------	--

### Operations

<i>bool</i>	<i>p == q</i>	Test for equality. Two points are equal, iff their <i>x</i> and <i>y</i> coordinates are equal.
-------------	---------------	---

<i>bool</i>	<i>p != q</i>	Test for nonequality.
-------------	---------------	-----------------------

<i>bool</i>	<i>p &lt; q</i>	Returns true iff <i>p</i> is lexicographically smaller than <i>q</i> , i.e. either if <i>p.x()</i> < <i>q.x()</i> or if <i>p.x()</i> == <i>q.x()</i> and <i>p.y()</i> < <i>q.y()</i> .
-------------	-----------------	--

<i>bool</i>	<i>p &gt; q</i>	Returns true iff <i>p</i> is lexicographically greater than <i>q</i> .
-------------	-----------------	--

<i>bool</i>	<i>p &lt;= q</i>	Returns true iff <i>p</i> is lexicographically smaller than or equal to <i>q</i> .
-------------	------------------	--

<i>bool</i>	<i>p &gt;= q</i>	Returns true iff <i>p</i> is lexicographically greater than or equal to <i>q</i> .
-------------	------------------	--

### I/O

<i>istream&amp;</i>	<i>std::istream&amp; is &gt;&gt; Circular_arc_point_2 &amp; cp</i>
<i>ostream&amp;</i>	<i>std::ostream&amp; os &lt;&lt; Circular_arc_point_2 ce</i>

## See Also

*CGAL::Line\_arc\_2<CircularKernel>* ..... page [908](#)

## CircularKernel::ConstructLine\_2

### Refines

*Kernel::ConstructLine\_2*

A model *fo* of this type must provide:

*CircularKernel::Line\_2*     *fo*( *CircularKernel::LineArc\_2*)

Constructs the supporting line of a line segment.

*CircularKernel::Line\_2*     *fo*( *CircularKernel::Polynomial\_1\_2*)

Constructs a line from an equation.

### See Also

*CircularKernel::GetEquation* ..... page [943](#)

## CircularKernel::ConstructCircle\_2

### Refines

*Kernel::ConstructCircle\_2*

A model *fo* of this type must provide:

*CircularKernel::Circle\_2*

*fo( CircularKernel::CircularArc\_2)*

Constructs the supporting circle of a circular arc.

*CircularKernel::Circle\_2*

*fo( CircularKernel::Polynomial\_for\_circles\_2\_2)*

Constructs a circle from an equation.

### See Also

*CircularKernel::GetEquation* ..... page [943](#)

## CircularKernel::ConstructCircularArcPoint\_2

A model *fo* of this type must provide:

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Root\_for\_circles\_2\_2 r)*

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Point\_2 p)*

## CircularKernel::ConstructLineArc\_2

A model *fo* of this type must provide:

*CircularKernel::Line\_arc\_2*

```
fo.operator()( CircularKernel::Line_2 l,
                CircularKernel::Circular_arc_point_2 p1,
                CircularKernel::Circular_arc_point_2 p2)
```

Constructs the line segment supported by *l*, whose source is *p1* and whose target is *p2*.

*Precondition:* *p1* and *p2* lie on *l*.

*CircularKernel::Line\_arc\_2*

```
fo( CircularKernel::Segment_2 s)
```

*CircularKernel::Line\_arc\_2*

```
fo( CircularKernel::Point_2 p1, CircularKernel::Point_2 p2)
```

*CircularKernel::Line\_arc\_2*

```
fo.operator()( CircularKernel::Line_2 l,
                CircularKernel::Circle_2 c1,
                bool b1,
                CircularKernel::Circle_2 c2,
                bool b2)
```

Constructs the line segment whose supporting line is *l*, whose source endpoint is the  $b_1^h$  intersection of *l* with *c1*, and whose target endpoint is the  $b_2^h$  intersection of *l* and *c2*, where intersections are ordered lexicographically.

*Precondition:* *l* intersects both *c1* and *c2*, and the arc defined by the intersections has non-zero length.

*CircularKernel::Line\_arc\_2*

```
fo.operator()( CircularKernel::Line_2 l,
                CircularKernel::Line_2 l1,
                CircularKernel::Line_2 l2)
```

Same, for intersections defined by lines instead of circles.

## CircularKernel::ConstructCircularArc\_2

A model *fo* of this type must provide:

*CircularKernel::Circular\_arc\_2*

*fo*( *CircularKernel::Circle\_2* *c*)

Constructs an arc from a full circle.

*CircularKernel::Circular\_arc\_2*

*fo.operator*)( *CircularKernel::Circle\_2* *c*,  
*CircularKernel::Circular\_arc\_point\_2* *p1*,  
*CircularKernel::Circular\_arc\_point\_2* *p2*)

Construct the circular arc supported by *c*, whose source is *p1* and whose target is *p2* when traversing the circle in counterclockwise direction.

*Precondition:* *p1* and *p2* lie on *c*.

*CircularKernel::Circular\_arc\_2*

*fo.operator*)( *CircularKernel::Circle\_2* *c*,  
*CircularKernel::Circle\_2* *c1*,  
*bool* *b1*,  
*CircularKernel::Circle\_2* *c2*,  
*bool* *b2*)

Constructs the unique circular arc whose supporting circle is *c*, and whose source is the intersection of *c* and *c1* with index *b1*, and whose target is the intersection of *c* and *c2* of index *b2*, where intersections are ordered lexicographically, and when traversing the circle in counterclockwise direction.

*Precondition:* *c* intersects both *c1* and *c2*, and the arc defined by the intersections has non-zero length.

*CircularKernel::Circular\_arc\_2*

*fo.operator*)( *CircularKernel::Circle\_2* *c*,  
*CircularKernel::Line\_2* *l1*,  
*bool* *b1*,  
*CircularKernel::Line\_2* *l2*,  
*bool* *b2*)

Same, for intersections defined by lines instead of circles.

*CircularKernel::Circular\_arc\_2*

*fo.operator()( CircularKernel::Point\_2 p,  
CircularKernel::Point\_2 q,  
CircularKernel::Point\_2 r)*

Constructs an arc that is supported by the circle of type *CircularKernel::Circle\_2* passing through the points *p*, *q* and *r*. The source and target are respectively *p* and *r*, when traversing the supporting circle in the counterclockwise direction. Note that, depending on the orientation of the point triple  $(p,q,r)$ , *q* may not lie on the arc.  
*Precondition:* *p*, *q*, and *r* are not collinear.

## CircularKernel::ConstructCircularMinVertex\_2

A model *fo* of this type must provide:

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Circular\_arc\_2 c)*

Constructs the *x*-minimal vertex of *c*.  
*Precondition:* The arc *c* is *x*-monotone.

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Line\_arc\_2 l)*

Same, for a line segment.

## CircularKernel::ConstructCircularMaxVertex\_2

A model *fo* of this type must provide:

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Circular\_arc\_2 c)*

Constructs the *x*-maximal vertex of *c*.  
*Precondition:* The arc *c* is *x*-monotone.

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Line\_arc\_2 l)*

Same, for a line segment.

## CircularKernel::ConstructCircularSourceVertex\_2

A model *fo* of this type must provide:

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Circular\_arc\_2 c)*

Constructs the source vertex of *c*.

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Line\_arc\_2 l)*

Same, for a line segment.

## CircularKernel::ConstructCircularTargetVertex\_2

A model *fo* of this type must provide:

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Circular\_arc\_2 c)*

Constructs the target vertex of *c*.

*CircularKernel::Circular\_arc\_point\_2*

*fo( CircularKernel::Line\_arc\_2 l)*

Same, for a line segment.

## CircularKernel::ConstructBbox\_2

A model *fo* of this type must provide operators to construct a bounding box of geometric objects:

*CGAL::Bbox\_2*                      *fo( CircularKernel::Circular\_arc\_point\_2 p)*

*CGAL::Bbox\_2*                      *fo( CircularKernel::Line\_arc\_2 l)*

*CGAL::Bbox\_2*                      *fo( CircularKernel::Circular\_arc\_2 c)*

## Refines

An object *fo* of this type must provide in addition:

Compares the  $x$ -coordinates of  $p$  and  $q$ .

<i>CircularKernel::CompareY_2</i> .....	page 924
<i>CircularKernel::CompareXY_2</i> .....	page 925
<i>CircularKernel::Equal_2</i> .....	page 932

### CircularKernel::CompareY\_2

## Refines

*Kernel::CompareY\_2*

An object *fo* of this type must provide in addition:

```
Comparison_result    fo.operator()( CircularKernel::Circular_arc_point_2 p,
                  CircularKernel::Circular_arc_point_2 q)
```

Compares the  $y$ -coordinates of  $p$  and  $q$ .

## See Also

<i>CircularKernel::CompareX_2</i> .....	page 923
<i>CircularKernel::CompareXY_2</i> .....	page 925
<i>CircularKernel::Equal_2</i> .....	page 932

## CircularKernel::CompareXY\_2

## Refines

*Kernel::CompareXY\_2*

An object *fo* of this type must provide in addition:

[illegible]

Compares  $p$  and  $q$  according to the lexicographic ordering on  $x$ - and  $y$ -coordinates.

## See Also

<i>CircularKernel::CompareX_2</i> .....	page 923
<i>CircularKernel::CompareY_2</i> .....	page 924
<i>CircularKernel::Equal_2</i> .....	page 932

## CircularKernel::CompareYatX\_2

An object *fo* of this type must provide two operators that compare a point *p* and an arc *a* on the vertical line passing through *p*.

*Comparison\_result*      *fo*( *CircularKernel::Circular\_arc\_point\_2* *p*, *CircularKernel::Circular\_arc\_2* *a*)

For a circular arc.

*Precondition:* The arc *a* must be monotone and *p* must be in the vertical range of *a*.

*Comparison\_result*      *fo*( *CircularKernel::Circular\_arc\_point\_2* *p*, *CircularKernel::Line\_arc\_2* *a*)

Same for a segment.

## CircularKernel::CompareYtoRight\_2

An object *fo* of this type must provide operators that compare vertically two arcs on the right side of a common point *p*:

<i>Comparison_result</i>	<i>fo.operator()( Circular_kernel_2::Circular_arc_2 a1,</i> <i>Circular_kernel_2::Circular_arc_2 a2,</i> <i>Circular_kernel_2::Circular_arc_point_2 p)</i>
--------------------------	--

For two circular arcs.

*Precondition:*  $p$  must be a common point to  $a_1$  and  $a_2$ , and  $a_1$  and  $a_2$  must be defined to the right of  $p$ .

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Circular_kernel_2::Line_arc_2 a1</i> , <i>Circular_kernel_2::Line_arc_2 a2</i> , <i>Circular_kernel_2::Circular_arc_point_2 p</i> )
--------------------------	---

Same for two segments.

<i>Comparison_result</i>	<i>fo.operator()</i> ( <i>Circular_kernel_2::Line_arc_2 a1</i> , <i>Circular_kernel_2::Circular_arc_2 a2</i> , <i>Circular_kernel_2::Circular_arc_point_2 p</i> )
--------------------------	---

For a segment and an arc.

[illegible]

Same as previous.

## CircularKernel::MakeXMonotone\_2

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator fo( CircularKernel::Circular_arc_2 ca, OutputIterator oit)
```

Splits the arc *ca* into *x*-monotone arcs that are returned through the output iterator. Note that, to ensure an easy interface with the *Arrangement\_2* package, the arcs are returned as *CGAL::Object*'s (see the *ArrangementTraits\_2* concept).

For the sake of completeness, the *operator()* must also be defined for a *Line\_arc\_2*. In this case, the input line arc itself is the only arc returned through the *OutputIterator*.

### See Also

*CircularKernel::MakeXYMonotone\_2* ..... page [929](#)

## CircularKernel::MakeXYMonotone\_2

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator          fo( CircularKernel::Circular_arc_2 ca, OutputIterator oit)
```

Splits the arc *ca* into *xy*-monotone arcs that are returned through the output iterator. Note that, to ensure an easy interface with the *Arrangement\_2* package, the arcs are returned as *CGAL::Object*'s (see the *ArrangementTraits\_2* concept).

For the sake of completeness, the *operator()* must also be defined for a *Line\_arc\_2*. In this case, the input line arc itself is the only arc returned through the *OutputIterator*.

### See Also

*CircularKernel::MakeXMonotone\_2* ..... page [928](#)

## CircularKernel::Intersect\_2

### Refines

*Kernel::Intersect\_2*

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator fo( Type1 obj1, Type2 obj2, OutputIterator intersections)
```

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order.

where *Type\_1* and *Type\_2* can both be either

- *CircularKernel::Line\_2* or
- *CircularKernel::Line\_arc\_2* or
- *CircularKernel::Circle\_2* or
- *CircularKernel::Circular\_arc\_2*.

Depending on the types *Type\_1* and *Type\_2*, these elements can be assigned to

- *std::pair<CircularKernel::Circular\_arc\_point\_2, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj\_1* and *obj\_2*,
- *CircularKernel::Circular\_arc\_2* in case of an overlap of two circular arcs,
- *CircularKernel::Line\_arc\_2* in case of an overlap of two line segments or
- *CircularKernel::Line\_2* or *CircularKernel::Circle\_2* in case of two equal input lines or circles.

### See Also

*CGAL::intersection* ..... page [1254](#)

## CircularKernel::Split\_2

A model *fo* of this type must provide:

```
void fo.operator()( CircularKernel::Circular_arc_2 a,
                   CircularKernel::Circular_arc_point_2 p,
                   CircularKernel::Circular_arc_2 &a1,
                   CircularKernel::Circular_arc_2 &a2)
```

Splits arc *a* at point *p*, which creates arcs *a1* and *a2*.  
*Precondition:* The point lies on the input arc.

```
void fo.operator()( CircularKernel::Line_arc_2 l,
                   CircularKernel::Circular_arc_point_2 p,
                   CircularKernel::Line_arc_2 &l1,
                   CircularKernel::Line_arc_2 &l2)
```

Same for a line arc.

## CircularKernel::Equal\_2

### Definition

Testing equality between objects.

### Refines

*Kernel::Equal\_2*

An object *fo* of this type must provide in addition:

*bool* *fo.operator()*( *CircularKernel::Circular\_arc\_point\_2* p0,  
                                  *CircularKernel::Circular\_arc\_point\_2* p1)

For two points.

*bool* *fo*( *CircularKernel::Circular\_arc\_2* a0, *CircularKernel::Circular\_arc\_2* a1)

For two arcs.

*bool* *fo*( *CircularKernel::Line\_arc\_2* a0, *CircularKernel::Line\_arc\_2* a1)

For two segments.

For the sake of completeness, the *operator()* must also be defined for a *Line\_arc\_2* and a *Circular\_arc\_2* as arguments (in any order), and it always returns *false*.

### See Also

*CircularKernel::CompareX\_2* ..... page [923](#)

*CircularKernel::CompareXY\_2* ..... page [925](#)

## CircularKernel::HasOn\_2

### Definition

To test whether a point lies on a curve.

### Refines

*Kernel::HasOn\_2*

An object *fo* of this type must provide:

*bool* *fo*( *CircularKernel::Line\_2* l, *CircularKernel::Circular\_arc\_point\_2* p)

For a line.

*bool* *fo*( *CircularKernel::Circle\_2* c, *CircularKernel::Circular\_arc\_point\_2* p)

For a circle.

*bool* *fo*( *CircularKernel::Line\_arc\_2* l, *CircularKernel::Circular\_arc\_point\_2* p)

For a line arc.

*bool* *fo*( *CircularKernel::Circular\_arc\_2* c, *CircularKernel::Circular\_arc\_point\_2* p)

For a circular arc.

## CircularKernel::DoOverlap\_2

### Definition

Testing whether the interiors of two curves overlap.

### Refines

*Kernel::DoOverlap\_2*

An object *fo* of this type must provide:

*bool* *fo*( *CircularKernel::Line\_arc\_2* l0, *CircularKernel::Line\_arc\_2* l1)

For two line arcs.

*bool* *fo*( *CircularKernel::Circular\_arc\_2* a0, *CircularKernel::Circular\_arc\_2* a1)

For two circular arcs.

## CircularKernel::DoIntersect\_2

### Definition

Testing whether two curves intersect.

### Refines

*Kernel::DoIntersect\_2*

An object *fo* of this type must provide:

*bool* *fo*( *Type1 obj1*, *Type2 obj2*)

determines if two geometric objects of type *Type1* and *Type2* intersect or not.

for all pairs *Type1* and *Type2*, where the types *Type1* and *Type2* can be any of the following:

- *CircularKernel::Line\_2*
- *CircularKernel::Line\_arc\_2*
- *CircularKernel::Circle\_2*
- *CircularKernel::Circular\_arc\_2*

### See Also

*CGAL::do\_intersect* .....page [1802](#)

## CircularKernel::BoundedSide\_2

### Refines

*Kernel::BoundedSide\_2*

An object *fo* of this type must provide:

*Bounded\_side*                      *fo*( *CircularKernel::Circle\_2 s*, *CircularKernel::Circular\_arc\_point\_2 p*)

### See Also

# CircularKernel::HasOnBoundedSide\_2

## Refines

*Kernel::HasOnBoundedSide\_2*

An object *fo* of this type must provide:

*bool* *fo*( *CircularKernel::Circle\_2* *s*, *CircularKernel::Circular\_arc\_point\_2* *p*)

## See Also

<i>CircularKernel::BoundedSide_2</i> .....	page <a href="#">936</a>
<i>CircularKernel::HasOnUnboundedSide_2</i> .....	page <a href="#">938</a>

## CircularKernel::HasOnUnboundedSide\_2

### Refines

*Kernel::HasOnUnboundedSide\_2*

An object *fo* of this type must provide:

*bool* *fo*( *CircularKernel::Circle\_2* s, *CircularKernel::Circular\_arc\_point\_2* p)

### See Also

*CircularKernel::BoundedSide\_2* ..... [page 936](#)  
*CircularKernel::HasOnBoundedSide\_2* ..... [page 937](#)

## CircularKernel::InXRange\_2

### Definition

To test whether a point lies in the vertical range of a curve.

An object *fo* of this type must provide:

*bool* *fo*( CircularKernel::Line\_arc\_2 l, CircularKernel::Circular\_arc\_point\_2 p)

For a line arc.

*bool* *fo*( CircularKernel::Circular\_arc\_2 c, CircularKernel::Circular\_arc\_point\_2 p)

For a circular arc.

*Precondition:* *c* is *x*-monotone.

## CircularKernel::IsVertical\_2

### Refines

*Kernel::IsVertical\_2*

An object *fo* of this type must provide:

*bool* *fo( CircularKernel::Line\_arc\_2 l)*  
For a line arc.

*bool* *fo( CircularKernel::Circular\_arc\_2 c)*  
For a circular arc, always returns *false*.

## CircularKernel::IsXMonotone\_2

An object *fo* of this type must provide:

<i>bool</i>	<i>fo</i> ( <i>CircularKernel::Circular_arc_2</i> <i>c</i> )	Tests whether the arc is <i>x</i> -monotone.
<i>bool</i>	<i>fo</i> ( <i>CircularKernel::Line_arc_2</i> <i>l</i> )	For a line arc, always returns <i>true</i> .

## CircularKernel::IsYMonotone\_2

An object *fo* of this type must provide:

<i>bool</i>	<i>fo</i> ( <i>CircularKernel::Circular_arc_2</i> <i>c</i> )	Tests whether the arc is y-monotone.
<i>bool</i>	<i>fo</i> ( <i>CircularKernel::Line_arc_2</i> <i>l</i> )	For a line arc, always returns <i>true</i> .

## CircularKernel::GetEquation

A model *fo* of this type must provide:

*CircularKernel::Polynomial\_1\_2*

*fo( CircularKernel::Line\_2 c)*

Returns the equation of the line.

*CircularKernel::Polynomial\_for\_circles\_2\_2*

*fo( CircularKernel::Circle\_2 c)*

Returns the equation of the circle.

### See Also

*CircularKernel::ConstructLine\_2* .....page [912](#)

*CircularKernel::ConstructCircle\_2* ..... page [913](#)

## CircularKernel::ComputeCircularX\_2

A model *fo* of this type must provide:

*CircularKernel::Root\_of\_2*

*fo( CircularKernel::Circular\_arc\_point\_2 p)*

Computes the *x*-coordinate of the point.

## CircularKernel::ComputeCircularY\_2

A model *fo* of this type must provide:

*CircularKernel::Root\_of\_2*

*fo( CircularKernel::Circular\_arc\_point\_2 p)*

Computes the y-coordinate of the point.

## CGAL::x\_extremal\_point

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
Circular_arc_point_2<CircularKernel>
```

```
    x_extremal_point( Circle_2<CircularKernel> c, bool b)
```

Returns the leftmost (resp. rightmost) point of the circle  
if *b* is *true* (resp. *false*).

## CGAL::y\_extremal\_point

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
Circular_arc_point_2<CircularKernel>
```

```
    y_extremal_point( Circle_2<CircularKernel> c, bool b)
```

Returns the bottommost (resp. topmost) point of the circle if *b* is *true* (resp. *false*).

## CGAL::x\_extremal\_points

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
template < class OutputIterator >
```

```
OutputIterator x_extremal_points( Circle_2<CircularKernel> c, OutputIterator res)
```

Copies in the output iterator the  $x$ -extremal points of the circle. *res* iterates on elements of type *Circular\_arc\_point\_2*<*CircularKernel*>, sorted in  $x$ .

## CGAL::y\_extremal\_points

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
template < class OutputIterator >
```

```
OutputIterator y_extremal_points( Circle_2<CircularKernel> c, OutputIterator res)
```

Copies in the output iterator the y-extremal points of the circle. *res* iterates on elements of type *Circular\_arc\_point\_2<CircularKernel>*, sorted in y.

**CGAL::has\_on**

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
bool has_on( Circle_2<CircularKernel> c, Circular_arc_point_2<CircularKernel> p)
```

Checks whether the point lies on the circle.

## CGAL::compare\_y\_to\_right

*CGAL::Comparison\_result*

```
compare_y_to_right( Circular_arc_2<CircularKernel> ca1,  
                    Circular_arc_2<CircularKernel> ca2,  
                    Circular_arc_point_2<CircularKernel> &p)
```

Compares vertically the two arcs, to the right of the point *p*,

*Precondition:* *p* is an intersection point of the arcs, and the arcs are defined to the right of *p*.

## CGAL::has\_in\_x\_range

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
bool has_in_x_range( Circular_arc_2<CircularKernel> ca,  
                    Circular_arc_point_2<CircularKernel> p)
```

Checks whether the point lies in the vertical range defined by the arc.

```
bool has_in_x_range( Line_arc_2<CircularKernel> ca,  
                    Circular_arc_point_2<CircularKernel> p)
```

Checks whether the point lies in the vertical range defined by the line segment.

## CGAL::make\_x\_monotone

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
template < class OutputIterator >
```

```
OutputIterator make_x_monotone( Circular_arc_2<CircularKernel> ca, OutputIterator res)
```

Copies in the output iterator the  $x$ -monotone sub-arcs of  $ca$ .

## CGAL::make\_xy\_monotone

```
#include <CGAL/global_functions_circular_kernel_2.h>
```

```
template < class OutputIterator >
```

```
OutputIterator make_xy_monotone( Circular_arc_2<CircularKernel> ca, OutputIterator res)
```

Copies in the output iterator the *xy*-monotone sub-arcs of *ca*.

# AlgebraicKernelForCircles

## Definition

The *AlgebraicKernelForCircles* concept is meant to provide the curved kernel with all the algebraic functionalities required for the manipulation of circular arcs.

## Has Models

*Algebraic\_kernel\_for\_circles\_2\_2*

## Types

A model of *AlgebraicKernelForCircles* is supposed to provide

*AlgebraicKernelForCircles:: RT*  
*AlgebraicKernelForCircles:: FT*

A model of *RingNumberType*.  
 A model of *FieldNumberType*<*RT*>.

*AlgebraicKernelForCircles:: Polynomial\_1\_2*

A model of *AlgebraicKernelForCircles::Polynomial\_1\_2*, for bivariate polynomials of degree up to 1.

*AlgebraicKernelForCircles:: Polynomial\_for\_circles\_2\_2*

A model of *AlgebraicKernelForCircles::PolynomialForCircles\_2\_2*, for bivariate polynomials of degree up to 2 that can store equations of circles.

*AlgebraicKernelForCircles:: Root\_of\_2*

A model of *RootOf\_2*, for algebraic numbers of degree up to 2.

*AlgebraicKernelForCircles:: Root\_for\_circles\_2\_2*

A model of *AlgebraicKernelForCircles::RootForCircles\_2\_2*, for solutions of systems of two models of *AlgebraicKernelForCircles::PolynomialForCircles\_2\_2*.

*AlgebraicKernelForCircles:: Construct\_polynomial\_1\_2*

A model of *AlgebraicKernelForCircles::ConstructPolynomial\_1\_2*.

*AlgebraicKernelForCircles:: Construct\_polynomial\_for\_circles\_2\_2*

A model of *AlgebraicKernelForCircles::ConstructPolynomialForCircles\_2\_2*.

*AlgebraicKernelForCircles:: Compare\_x*

A model of the concept *AlgebraicKernelForCircles::CompareX*.

<i>AlgebraicKernelForCircles:: Compare_y</i>	A model of the concept <i>AlgebraicKernelForCircles::CompareY</i> .
<i>AlgebraicKernelForCircles:: Compare_xy</i>	A model of the concept <i>AlgebraicKernelForCircles::CompareXY</i> .
<i>AlgebraicKernelForCircles:: Sign_at</i>	A model of the concept <i>AlgebraicKernelForCircles::SignAt</i> .
<i>AlgebraicKernelForCircles:: X_critical_points</i>	A model of the concept <i>AlgebraicKernelForCircles::XCriticalPoints</i> .
<i>AlgebraicKernelForCircles:: Y_critical_points</i>	A model of the concept <i>AlgebraicKernelForCircles::YCriticalPoints</i> .
<i>AlgebraicKernelForCircles:: Solve</i>	A model of the concept <i>AlgebraicKernelForCircles::Solve</i> .

## AlgebraicKernelForCircles::CompareX

A model *fo* of this type must provide:

```
template < class OutputIterator >
CGAL::Comparison_result
```

```
fo.operator()( AlgebraicKernelForCircles::Root_for_circles_2_2 r1,
               AlgebraicKernelForCircles::Root_for_circles_2_2 r2)
```

Compares the *x* (first) variables of two *Root\_for\_circles\_2\_2*.

## AlgebraicKernelForCircles::SignAt

### Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
CGAL::Sign          fo.operator()( AlgebraicKernelForCircles::Polynomial_1_2 p,
                                   AlgebraicKernelForCircles::Root_for_circles_2_2 r)
```

Computes the sign of polynomial *p* evaluated at a root *r*.

```
template < class OutputIterator >
CGAL::Sign          fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p,
                                   AlgebraicKernelForCircles::Root_for_circles_2_2 r)
```

Same as previous.

## AlgebraicKernelForCircles::ConstructPolynomial\_1\_2

A model *fo* of this type must provide:

*AlgebraicKernelForCircles::Polynomial\_1\_2*

```
fo.operator()( AlgebraicKernelForCircles::RT a,
               AlgebraicKernelForCircles::RT b,
               AlgebraicKernelForCircles::RT c)
```

Constructs polynomial  $ax+by+c$ .

### See Also

## AlgebraicKernelForCircles::Solve

### Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_1_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_1_2 p2,
                                   OutputIterator res)
```

Copies in the output iterator the common roots of *p1* and *p2*, with their multiplicity, as objects of type *std::pair< AlgebraicKernelForCircles::Root\_for\_circles\_2\_2, int>*.

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_1_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p2,
                                   OutputIterator res)
```

Same as previous.

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_1_2 p2,
                                   OutputIterator res)
```

Same as previous.

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p1,
                                   AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p2,
                                   OutputIterator res)
```

Same as previous.

## AlgebraicKernelForCircles::XCriticalPoints

### Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p,
                                OutputIterator res)
```

Copies in the output iterator the *x*-critical points of polynomial *p*, as objects of type *AlgebraicKernelForCircles::Root\_for\_circles\_2\_2*.

```
template < class OutputIterator >
AlgebraicKernelForCircles::Root_for_circles_2_2
```

```
fo( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, bool b)
```

Computes the *x*-critical point with smallest (resp. largest) *x* of polynomial *p* if *b* is *true* (resp. *false*).

### See Also

*AlgebraicKernelForCircles::YCriticalPoints* ..... page [972](#)

## AlgebraicKernelForCircles::YCriticalPoints

### Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p,
                                   OutputIterator res)
```

Copies in the output iterator the y-critical points of polynomial *p*, as objects of type *AlgebraicKernelForCircles::Root\_for\_circles\_2\_2*.

```
template < class OutputIterator >
AlgebraicKernelForCircles::Root_for_circles_2_2
```

```
fo( AlgebraicKernelForCircles::Polynomial_for_circles_2_2 p, bool i)
```

Computes the y-critical point with smallest (resp. largest) y of polynomial *p* if *b* is *true* (resp. *false*).

### 10.1 Introduction

The goal of the 3D spherical kernel is to offer to the user a large set of functionalities on spheres, circles and circular arcs in the 3D space. These functionalities require computing on algebraic numbers, which motivates the creation of a new kernel concept extending the CGAL *Kernel* concept, which is restricted to objects and functionality in a *FieldNumberType*.

All the choices (interface, robustness, representation, and so on) made here are consistent with the choices made in the CGAL kernel, for which we refer the user to the kernel manual (Chapter 7).

### 10.2 Spherical Kernel Objects

New main geometric objects are introduced by *Spherical\_kernel\_3*: circular arcs (model of *SphericalKernel::CircularArc\_3*), points of circular arcs (model of *SphericalKernel::CircularArcPoint\_3*), and line segments (model of *SphericalKernel::LineArc\_3*) whose endpoints are points of this new type.

*SphericalKernel::CircularArcPoint\_3* is used in particular for endpoints of arcs and intersection points between spheres, circles or arcs. The coordinates of these points are algebraic numbers of degree two. Therefore, general predicates offered by the *Kernel* on *Point\_3*, which have coordinates in a *FieldNumberType*, would require heavy algebraic computations in algebraic extensions of higher degrees and thus are not provided on them, which explains the need for a new point type.

A consistent set of predicates and constructions is offered on this new type of points. The spherical kernel currently implements a set of fundamental functionalities like intersection, comparisons, inclusion, etc. More might be provided in the future, as long as only algebraic numbers of degree two are used.

## 10.3 Software Design

The design of *Spherical\_kernel\_3* is similar to the design of *Circular\_kernel\_2* (see Chapter 9). It has two template parameters:

- the first parameter must model the CGAL three dimensional *Kernel* concept. The spherical kernel derives from it, and it provides all elementary geometric objects like points, lines, spheres, circles and elementary functionality on them.
- the second parameter is the algebraic kernel, which is responsible for computations on polynomials and algebraic numbers. It must model the concept *AlgebraicKernelForSpheres*. The robustness of the package relies on the fact that the algebraic kernel provides exact computations on algebraic objects.

The 3D spherical kernel uses the extensibility scheme presented in the kernel manual (see Section 7.5). The types of *Kernel* are inherited by the 3D spherical kernel and some types are taken from the *AlgebraicKernelForSpheres* parameter. *Spherical\_kernel\_3* introduces new geometric objects as mentioned in Section 10.2.

In fact, the spherical kernel is documented as a concept, *SphericalKernel* and two models are provided:

- *Spherical\_kernel\_3<Kernel,AlgebraicKernelForSpheres>*, the basic kernel,
- and a predefined kernel *Exact\_spherical\_kernel\_3*.

## 10.4 Examples

The first example shows how to construct spheres and compute intersections on them using the global function.

```
#include <CGAL/Exact_spherical_kernel_3.h>
#include <CGAL/Random.h>

typedef CGAL::Exact_spherical_kernel_3      Spherical_k;

typedef CGAL::Point_3<Spherical_k>         Point_3;
typedef CGAL::Sphere_3<Spherical_k>        Sphere_3;

int main() {

    CGAL::Random generatorOfgenerator;
```

```

int random_seed = generatorOfgenerator.get_int(0, 123456);
CGAL::Random theRandom(random_seed);
int count = 0;

std::cout << "We will compute the approximate probability that 3 spheres wit"
<< "h radius 1 intersect on a 5x5x5 box, it might take some time." << std::endl;

for(int i=0; i<10000; i++) {

    double x1 = theRandom.get_double(0.0,5.0);
    double y1 = theRandom.get_double(0.0,5.0);
    double z1 = theRandom.get_double(0.0,5.0);
    double r = 1.0;
    double x2 = theRandom.get_double(0.0,5.0);
    double y2 = theRandom.get_double(0.0,5.0);
    double z2 = theRandom.get_double(0.0,5.0);
    double x3 = theRandom.get_double(0.0,5.0);
    double y3 = theRandom.get_double(0.0,5.0);
    double z3 = theRandom.get_double(0.0,5.0);

    Sphere_3 s1 = Sphere_3(Point_3(x1,y1,z1), r);
    Sphere_3 s2 = Sphere_3(Point_3(x2,y2,z2), r);
    Sphere_3 s3 = Sphere_3(Point_3(x3,y3,z3), r);

    std::vector< CGAL::Object > intersecs;
    CGAL::intersection(s1, s2, s3, std::back_inserter(intersecs));
    if(intersecs.size() > 0) count++;
}

std::cout << "The approximate probability that 3 spheres with radius 1"
<< std::endl;
std::cout << "choosen (uniformly) randomly on a 5x5x5 box intersect is: "
<< ((double)count)/((double)(10000)) << std::endl;

return 0;
}

```

**File:** examples/Circular\_kernel\_3/intersecting\_spheres.cpp

The second example illustrates the use of a functor.

```

#include <CGAL/Exact_spherical_kernel_3.h>
#include <CGAL/Random.h>

typedef CGAL::Exact_spherical_kernel_3      Spherical_k;

typedef CGAL::Point_3<Spherical_k>         Point_3;
typedef CGAL::Circular_arc_3<Spherical_k>   Circular_arc_3;

int main()
{
    int n = 0;
    Circular_arc_3 c = Circular_arc_3(Point_3(10,10,0), Point_3(5,5,5), Point_3(0, 0, 0));

```

```

    for(int i = 0; i <= 10; i++) {
        for(int j = 0; j <= 10; j++) {
            for(int k = 0; k <= 10; k++) {
Point_3 p = Point_3(i, j, k);
if(Spherical_k().has_on_3_object()(c,p)) {
    n++;
    std::cout << "(" << i << "," << j << "," << k << ")" << std::endl;
}
            }
        }
    }

    std::cout << "There are " << n << " points in the "
        << "[0,...,10]x[0,...,10]x[0,...,10] "
        << "grid on the circular" << std::endl
        << " arc defined by the points (10,10,0), (5,5,5), (0,0,0)"
        << std::endl << "See the points above." << std::endl;
    return 0;
};

```

## 10.5 Design and Implementation History

This package follows the 2D circular kernel package (see Chapter 9), which induced the basic choices of design.

Julien Hazebrouck and Damien Leroy participated in a first prototype. Sylvain Pion is acknowledged for helpful discussions.

This work was partially supported by the IST Programme of the 6th Framework Programme of the EU as a STREP (FET Open Scheme) Project under Contract No IST-006413 (**ACS** - Algorithms for Complex Shapes).

# SphericalKernel

## Refines

*Kernel*

## Has Models

*CGAL::Spherical\_kernel\_3* <*Kernel*, *AlgebraicKernelForSpheres*>

*CGAL::Exact\_spherical\_kernel\_3*

## Types

A model of *SphericalKernel* is supposed to provide some basic types

*SphericalKernel::Linear\_kernel*

Model of *Kernel*.

*SphericalKernel::Algebraic\_kernel*

Model of *AlgebraicKernelForSpheres*.

*SphericalKernel::Root\_of\_2*

Model of *RootOf\_2*.

*SphericalKernel::Root\_for\_spheres\_2\_3*

Model of *AlgebraicKernelForSpheres::RootForSpheres\_2\_3*.

*SphericalKernel::Polynomial\_1\_3*

Model of *AlgebraicKernelForSpheres::Polynomial\_1\_3*.

*SphericalKernel::Polynomials\_for\_line\_3*

Model of *AlgebraicKernelForSpheres::PolynomialsForLines\_3*.

*SphericalKernel::Polynomial\_for\_spheres\_2\_3*

Model of *AlgebraicKernelForSpheres::PolynomialForSpheres\_2\_3*.

*SphericalKernel::Polynomials\_for\_circle\_3*

Model of *AlgebraicKernelForSpheres::PolynomialsForCircles\_3*.

and to define the following geometric objects

*SphericalKernel::Point\_3*

Model of *Kernel::Point\_3*.

*SphericalKernel::Line\_3*

Model of *Kernel::Line\_3*.

*SphericalKernel::Plane\_3*

Model of *Kernel::Plane\_3*.

*SphericalKernel::Sphere\_3*

Model of *Kernel::Sphere\_3*.

*SphericalKernel::Circle\_3*

Model of *Kernel::Circle\_3*.

*SphericalKernel::Line\_arc\_3*

Model of *SphericalKernel::LineArc\_3*.

*SphericalKernel::Circular\_arc\_3*

Model of *SphericalKernel::CircularArc\_3*.

*SphericalKernel::Circular\_arc\_point\_3*

Model of *SphericalKernel::CircularArcPoint\_3*.

Moreover, a model of *SphericalKernel* must provide predicates, constructions and other functionalities.

## Predicates

*SphericalKernel::Compare\_x\_3*

Model of *SphericalKernel::CompareX\_3*.

*SphericalKernel::Compare\_y\_3*

Model of *SphericalKernel::CompareY\_3*.

<i>SphericalKernel:: Compare_z_3</i>	Model of <i>SphericalKernel::CompareZ_3</i> .
<i>SphericalKernel:: Compare_xy_3</i>	Model of <i>SphericalKernel::CompareXY_3</i> .
<i>SphericalKernel:: Compare_xyz_3</i>	Model of <i>SphericalKernel::CompareXYZ_3</i> .
<i>SphericalKernel:: Equal_3</i>	Model of <i>SphericalKernel::Equal_3</i> .
<i>SphericalKernel:: Has_on_3</i>	Model of <i>SphericalKernel::HasOn_3</i> .
<i>SphericalKernel:: Do_overlap_3</i>	Model of <i>SphericalKernel::DoOverlap_3</i> .
<i>SphericalKernel:: Do_intersect_3</i>	Model of <i>SphericalKernel::DoIntersect_3</i> .
<i>SphericalKernel:: Bounded_side_3</i>	Model of <i>SphericalKernel::BoundedSide_3</i> .
<i>SphericalKernel:: Has_on_bounded_side_3</i>	Model of <i>SphericalKernel::HasOnBoundedSide_3</i> .
<i>SphericalKernel:: Has_on_unbounded_side_3</i>	Model of <i>SphericalKernel::HasOnUnboundedSide_3</i> .

## Constructions

<i>SphericalKernel:: Construct_line_3</i>	Model of <i>SphericalKernel::ConstructLine_3</i> .
<i>SphericalKernel:: Construct_plane_3</i>	Model of <i>SphericalKernel::ConstructPlane_3</i> .
<i>SphericalKernel:: Construct_sphere_3</i>	Model of <i>SphericalKernel::ConstructSphere_3</i> .
<i>SphericalKernel:: Construct_circle_3</i>	Model of <i>SphericalKernel::ConstructCircle_3</i> .
<i>SphericalKernel:: Construct_line_arc_3</i>	Model of <i>SphericalKernel::ConstructLineArc_3</i> .
<i>SphericalKernel:: Construct_circular_arc_3</i>	Model of <i>SphericalKernel::ConstructCircularArc_3</i> .
<i>SphericalKernel:: Construct_circular_arc_point_3</i>	Model of <i>SphericalKernel::ConstructCircularArcPoint_3</i> .
<i>SphericalKernel:: Construct_circular_min_vertex_3</i>	Model of <i>SphericalKernel::ConstructCircularMinVertex_3</i> .
<i>SphericalKernel:: Construct_circular_max_vertex_3</i>	Model of <i>SphericalKernel::ConstructCircularMaxVertex_3</i> .
<i>SphericalKernel:: Construct_circular_source_vertex_3</i>	Model of <i>SphericalKernel::ConstructCircularSourceVertex_3</i> .
<i>SphericalKernel:: Construct_circular_target_vertex_3</i>	Model of <i>SphericalKernel::ConstructCircularTargetVertex_3</i> .
<i>SphericalKernel:: Construct_bbox_3</i>	Model of <i>SphericalKernel::ConstructBbox_3</i> .
<i>SphericalKernel:: Intersect_3</i>	Model of <i>SphericalKernel::Intersect_3</i> .
<i>SphericalKernel:: Split_3</i>	Model of <i>SphericalKernel::Split_3</i> .

## Computations

*SphericalKernel:: Compute\_circular\_x\_3*  
*SphericalKernel:: Compute\_circular\_y\_3*  
*SphericalKernel:: Compute\_circular\_z\_3*

Model of *SphericalKernel::ComputeCircularX\_3*.  
Model of *SphericalKernel::ComputeCircularY\_3*.  
Model of *SphericalKernel::ComputeCircularZ\_3*.

*SphericalKernel:: ComputeApproximateSquaredLength\_3*

Model of *SphericalKernel::ComputeApproximateSquaredLength\_3*.

*SphericalKernel:: ComputeApproximateAngle\_3*

Model of *SphericalKernel::ComputeApproximateAngle\_3*.

## Link with the algebraic kernel

*SphericalKernel:: Get\_equation*

Model of *SphericalKernel::GetEquation*.

## Operations

As in the *Kernel* concept, for each of the function objects above, there must exist a member function that requires no arguments and returns an instance of that function object. The name of the member function is the uncapitalized name of the type returned with the suffix *\_object* appended. For example, for the function object *SphericalKernel::Construct\_circular\_arc\_3* the following member function must exist:

*Construct\_circular\_arc\_3*

*ck.construct\_circular\_arc\_3\_object()*

## See Also

## CGAL::Spherical\_kernel\_3<Kernel,AlgebraicKernelForSpheres>

```
#include <CGAL/Spherical_kernel_3.h>
```

### Is Model for the Concepts

*SphericalKernel*

### Parameters

The first parameter of the spherical kernel must be instantiated with a model of the *Kernel* concept. The *Spherical\_kernel\_3* class template derives from this first parameter, in order to reuse all needed functionalities on basic objects provided by a model of the *Kernel* concept.

The second parameter, *AlgebraicKernelForSpheres*, is meant to provide the spherical kernel with all the algebraic functionalities required for the manipulation of algebraic curves.

### Inherits From

*Kernel*

### Types

The spherical kernel uses basic number types of the algebraic kernel:

```
typedef AlgebraicKernelForSpheres::RT      RT;      Ring number type.
typedef AlgebraicKernelForSpheres::FT      FT;      Field number type.
```

In fact, the two number types *AlgebraicKernelForSpheres::RT* and *Kernel::RT* must refer to the same type, as well as *AlgebraicKernelForSpheres::FT* and *Kernel::FT*.

The following types are available, as well as all the functionality on them described in the *SphericalKernel* concept.

```
typedef Line_arc_3<Spherical_kernel_3>      Line_arc_3;
typedef Circular_arc_3<Spherical_kernel_3>    Circular_arc_3;
typedef Circular_arc_point_3<Spherical_kernel_3> Circular_arc_point_3;
```

*Polynomials\_for\_circle\_3* is implemented as a `std::pair<Polynomial_for_spheres_2_3, Polynomial_1_3>` and is a model of *AlgebraicKernelForSpheres::PolynomialsForCircles\_3*.

## CGAL::Exact\_spherical\_kernel\_3

*#include <CGAL/Exact\_spherical\_kernel\_3.h>*

### Definition

A typedef to a spherical kernel that provides both exact geometric predicates and exact geometric constructions.

It defines the same types as *CGAL::Spherical\_kernel\_3*.

### Is Model for the Concepts

*SphericalKernel*

## SphericalKernel::CircularArcPoint\_3

### Definition

Concept for points on spheres, circles, circular arcs or line arcs.

### Refines

CopyConstructible, Assignable, DefaultConstructible

### Has Models

*CGAL::Circular\_arc\_point\_3<SphericalKernel>*

## CGAL::Circular\_arc\_point\_3<SphericalKernel>

```
#include <CGAL/Circular_arc_point_3.h>
```

### Is Model for the Concepts

```
SphericalKernel::CircularArcPoint_3
```

### Creation

```
Circular_arc_point_3<SphericalKernel> p( Point_3<SphericalKernel> q);
```

```
Circular_arc_point_3<SphericalKernel> p( SphericalKernel::Root_for_spheres_2_3 r);
```

### Access Functions

<i>SphericalKernel::Root_of_2</i>	<i>p.x()</i>	<i>x</i> -coordinate of the point.
<i>SphericalKernel::Root_of_2</i>	<i>p.y()</i>	<i>y</i> -coordinate of the point.
<i>SphericalKernel::Root_of_2</i>	<i>p.z()</i>	<i>z</i> -coordinate of the point.

<i>Bbox_3</i>	<i>p.bbox()</i>	Returns a bounding box around the point.
---------------	-----------------	--

### Operations

<i>bool</i>	<i>p == q</i>	Test for equality. Two points are equal, iff their <i>x</i> , <i>y</i> and <i>z</i> coordinates are equal.
-------------	---------------	--

<i>bool</i>	<i>p != q</i>	Test for nonequality.
-------------	---------------	-----------------------

<i>bool</i>	<i>p &lt; q</i>	Returns true iff <i>p</i> is lexicographically smaller than <i>q</i> , i.e. either if <i>p.x()</i> < <i>q.x()</i> or if <i>p.x()</i> == <i>q.x()</i> and <i>p.y()</i> < <i>q.y()</i> or if <i>p.x()</i> == <i>q.x()</i> and <i>p.y()</i> == <i>q.y()</i> and <i>p.z()</i> < <i>q.z()</i> .
-------------	-----------------	--

<i>bool</i>	<i>p &gt; q</i>	Returns true iff <i>p</i> is lexicographically greater than <i>q</i> .
-------------	-----------------	--

<i>bool</i>	<i>p &lt;= q</i>	Returns true iff <i>p</i> is lexicographically smaller than or equal to <i>q</i> .
-------------	------------------	--

<i>bool</i>	<i>p &gt;= q</i>	Returns true iff <i>p</i> is lexicographically greater than or equal to <i>q</i> .
-------------	------------------	--

### I/O

```
istream& std::istream& is >> Circular_arc_point_3 & p
```

*ostream*  $\&$  *std::ostream*  $\&$  *os* << *Circular\_arc\_point\_3* *p*

## See Also

*CGAL::Circular\_arc\_3<SphericalKernel>* ..... page [994](#)  
*CGAL::Line\_arc\_3<SphericalKernel>* ..... page [991](#)

## SphericalKernel::LineArc\_3

### Definition

Concept for line segments supported by a line that is a model of *Kernel::Line\_3*, and whose endpoints are models of the *SphericalKernel::CircularArcPoint\_3* concept.

### Refines

CopyConstructible, Assignable, DefaultConstructible

### Has Models

*CGAL::Line\_arc\_3*<*SphericalKernel*>

## CGAL::Line\_arc\_3<SphericalKernel>

```
#include <CGAL/Line_arc_3.h>
```

### Is Model for the Concepts

```
SphericalKernel::LineArc_3
```

### Creation

```
Line_arc_3<SphericalKernel> la( Line_3<SphericalKernel> l,
                                Circular_arc_point_3<SphericalKernel> p1,
                                Circular_arc_point_3<SphericalKernel> p2)
```

Construct the line segment supported by  $l$ , whose source is  $p1$ , and whose target is  $p2$ .

*Precondition:*  $p1$  and  $p2$  lie on  $l$ .  $p1$  and  $p2$  are different.

```
Line_arc_3<SphericalKernel> la( Line_3<SphericalKernel> l,
                                Point_3<SphericalKernel> p1,
                                Point_3<SphericalKernel> p2)
```

Same.

```
Line_arc_3<SphericalKernel> la( Segment_3<SphericalKernel> s);
```

### Access Functions

```
Line_3<SphericalKernel> la.supporting_line()
```

```
Circular_arc_point_3<SphericalKernel> la.source()
```

```
Circular_arc_point_3<SphericalKernel> la.target()
```

```
Circular_arc_point_3<SphericalKernel> la.min()
```

Constructs the minimum vertex according to the lexicographic ordering of coordinates.

```
Circular_arc_point_3<SphericalKernel> la.max()
```

Same for the maximum vertex.

### Query Functions

```
bool la.is_vertical()
```

Returns true *iff* the segment is vertical.

### Operations

<i>bool</i>	<i>s1 == s2</i>	Test for equality. Two segments are equal, iff their non-oriented supporting lines are equal (i.e. they define the same set of points), and if their endpoints are the same.
<i>bool</i>	<i>s1 != s2</i>	Test for nonequality.

## I/O

<i>istream&amp;</i>	<i>std::istream&amp; is &gt;&gt; Line_arc_3 &amp; ca</i>
<i>ostream&amp;</i>	<i>std::ostream&amp; os &lt;&lt; Line_arc_3 ca</i>

The format for input/output is, for each line arc: a *Line\_3* (the supporting line) and two *Circular\_arc\_point\_3* (the two endpoints), under the condition that the endpoints are actually lying on the line.

## See Also

*CGAL::Circular\_arc\_point\_3<SphericalKernel>* ..... page [988](#)  
*CGAL::Circular\_arc\_3<SphericalKernel>* ..... page [994](#)

## SphericalKernel::CircularArc\_3

Concept for arcs of circles.

### Refines

CopyConstructible, Assignable, DefaultConstructible

### Has Models

*CGAL::Circular\_arc\_3<SphericalKernel>*

## CGAL::Circular\_arc\_3<SphericalKernel>

```
#include <CGAL/Circular_arc_3.h>
```

### Is Model for the Concepts

```
SphericalKernel::CircularArc_3
```

### Creation

```
Circular_arc_3<SphericalKernel> ca( Circle_3<SphericalKernel> c);
```

Constructs an arc from a full circle.

```
Circular_arc_3<SphericalKernel> ca( Circle_3<SphericalKernel> c,
    Circular_arc_point_3<SphericalKernel> p,
    Circular_arc_point_3<SphericalKernel> q)
```

Constructs the circular arc supported by  $c$ , whose source and target are respectively  $p$  and  $q$ .

*Precondition:*  $p$  and  $q$  lie on  $c$  and are different.

The circular arc constructed from a circle, a source, and a target, is defined as the set of points of the circle that lie between the source  $p_1$  and the target  $p_2$ , when traversing the circle counterclockwise seen from the side of the plane of the circle pointed by its *positive* normal vectors.

In this definition, we say that a normal vector  $(a,b,c)$  is *positive* if  $(a,b,c) \neq (0,0,0)$  (i.e.  $(a > 0) \vee ((a == 0) \wedge (b > 0)) \vee ((a == 0) \wedge (b == 0) \wedge (c > 0))$ ).

```
Circular_arc_3<SphericalKernel> ca( Point_3<SphericalKernel> p,
    Point_3<SphericalKernel> q,
    Point_3<SphericalKernel> r)
```

Constructs an arc that is supported by the circle of type `Circle_3<SphericalKernel>` passing through the points  $p$ ,  $q$  and  $r$ . The source and target are respectively  $p$  and  $r$ , when traversing the supporting circle in the counterclockwise direction seen from the side of the plane containing the circle pointed by its *positive* normal vectors. Note that, depending on the orientation of the point triple  $(p,q,r)$ ,  $q$  may not lie on the arc.

*Precondition:*  $p$ ,  $q$ , and  $r$  are not collinear.

### Access Functions

```
Circle_3<SphericalKernel> ca.supporting_circle()
```

```
Point_3<SphericalKernel> ca.center() returns the center of the supporting circle.
```

<i>SphericalKernel::FT</i>	<i>ca.squared_radius()</i>	returns the squared radius of the supporting circle.
----------------------------	----------------------------	--

<i>Plane_3&lt;SphericalKernel&gt;</i>	<i>ca.supporting_plane()</i>
<i>Sphere_3&lt;SphericalKernel&gt;</i>	<i>ca.diametral_sphere()</i>

<i>Circular_arc_point_3&lt;SphericalKernel&gt;</i>	
	<i>ca.source()</i>
<i>Circular_arc_point_3&lt;SphericalKernel&gt;</i>	<i>ca.target()</i>

When the methods *source* and *target* return the same point, then the arc is in fact a full circle.

When the arc was constructed from its (full) underlying circle, then *source* and *target* both return the smallest *x*-extremal point of the circle if the circle is not contained in a plane  $x = A$ , and the smallest *y*-extremal point otherwise.

## Operations

<i>bool</i>	<i>a1 == a2</i>	Test for equality. Two arcs are equal, iff their non-oriented supporting planes are equal, if the centers and squared radii of their respective supporting circles are equal, and if their sources and targets are equal.
-------------	-----------------	---

<i>bool</i>	<i>a1 != a2</i>	Test for nonequality.
-------------	-----------------	-----------------------

## I/O

<i>istream&amp;</i>	<i>std::istream&amp; is &gt;&gt; Circular_arc_3 &amp; ca</i>
<i>ostream&amp;</i>	<i>std::ostream&amp; os &lt;&lt; Circular_arc_3 ca</i>

The format for input/output is, for each circular arc: a *Circle\_3* (the supporting circle) and two *Circular\_arc\_point\_3* (the source and the target), under the condition that the endpoints are actually lying on the circle.

## SphericalKernel::ConstructPlane\_3

### Refines

*Kernel::ConstructPlane\_3*

A model *fo* of this type must provide:

*SphericalKernel::Plane\_3*

*fo( SphericalKernel::Circular\_arc\_3 a)*

Constructs the plane containing the arc.

*SphericalKernel::Plane\_3*

*fo( SphericalKernel::Polynomial\_1\_3 p)*

Constructs a plane from an equation.

### See Also

*SphericalKernel::GetEquation* ..... page [1028](#)

## SphericalKernel::ConstructSphere\_3

### Refines

*Kernel::ConstructSphere\_3*

A model *fo* of this type must provide:

*SphericalKernel::Sphere\_3*

*fo( SphericalKernel::Circular\_arc\_3 a)*

Returns the sphere having the supporting circle of *a* as diameter (ie, returns the diametral sphere of the supporting circle of the arc).

*SphericalKernel::Sphere\_3*

*fo( SphericalKernel::Polynomial\_2\_3 p)*

Constructs a sphere from an equation.

### See Also

*SphericalKernel::GetEquation* ..... page [1028](#)

## SphericalKernel::ConstructLine\_3

### Refines

*Kernel::ConstructLine\_3*

A model *fo* of this type must provide:

*SphericalKernel::Line\_3*    *fo*( *SphericalKernel::Line\_arc\_3* *s* )

Constructs the line containing the segment.

*SphericalKernel::Line\_3*    *fo*( *SphericalKernel::Polynomials\_for\_lines\_3* *p* )

Constructs a line from an equation.

### See Also

*SphericalKernel::GetEquation* ..... page [1028](#)

## SphericalKernel::ConstructCircle\_3

A model *fo* of this type must provide:

*SphericalKernel::Circle\_3*

*fo( SphericalKernel::Circular\_arc\_3 a)*

Constructs the circle containing the arc.

*SphericalKernel::Circle\_3*

*fo( SphericalKernel::Polynomials\_for\_circles\_3 p)*

Constructs a circle from an equation.

### See Also

*SphericalKernel::GetEquation* ..... page [1028](#)

## SphericalKernel::ConstructCircularArcPoint\_3

A model *fo* of this type must provide:

*SphericalKernel::Circular\_arc\_point\_3*

*fo( SphericalKernel::Root\_for\_spheres\_2\_3 r)*

*SphericalKernel::Circular\_arc\_point\_3*

*fo( SphericalKernel::Point\_3 p)*

## SphericalKernel::ConstructLineArc\_3

A model *fo* of this type must provide:

*SphericalKernel::Line\_arc\_3*

*fo.operator()( SphericalKernel::Line\_3 l,  
SphericalKernel::Circular\_arc\_point\_3 p,  
SphericalKernel::Circular\_arc\_point\_3 q)*

Constructs the line segment supported by *l*, whose source is *p* and whose target is *q*.

*Precondition:* *p* and *q* lie on *l* and are different.

*SphericalKernel::Line\_arc\_3*

*fo( SphericalKernel::Segment\_3 s)*

*SphericalKernel::Line\_arc\_3*

*fo( SphericalKernel::Point\_3 p, SphericalKernel::Point\_3 q)*

## SphericalKernel::ConstructCircularArc\_3

A model *fo* of this type must provide:

*SphericalKernel::Circular\_arc\_3*

*fo*( *SphericalKernel::Circle\_3* *c*)

Constructs an arc from a full circle.

*SphericalKernel::Circular\_arc\_3*

*fo.operator()*( *SphericalKernel::Circle\_3* *c*,  
*SphericalKernel::Circular\_arc\_point\_3* *p*,  
*SphericalKernel::Circular\_arc\_point\_3* *q*)

Constructs the circular arc supported by *c*, whose source and target are respectively *p* and *q*.

*Precondition:* *p* and *q* lie on *c* and they are different.

The circular arc constructed from a circle, a source, and a target, is defined as the set of points of the circle that lie between the source *p1* and the target *p2*, when traversing the circle counterclockwise seen from the side of the plane of the circle pointed by its *positive* normal vectors.

In this definition, we say that a normal vector (a,b,c) is *positive* if (a,b,c)  $\neq$  (0,0,0) (i.e.  $(a > 0) \vee ((a == 0) \wedge (b > 0)) \vee ((a == 0) \wedge (b == 0) \wedge (c > 0))$ ).

*SphericalKernel::ConstructCircularArc\_3 fo;*

Constructs an arc that is supported by the circle of type *SphericalKernel::Circle\_3* passing through the points *p*, *q* and *r*. The source and target are respectively *p* and *r*, when traversing the supporting circle in the counterclockwise direction seen from the side of the plane containing the circle pointed by its *positive* normal vectors. the circle. Note that, depending on the orientation of the point triple (*p,q,r*), *q* may not lie on the arc.

*Precondition:* *p*, *q*, and *r* are not collinear.

## SphericalKernel::ConstructCircularMinVertex\_3

A model *fo* of this type must provide:

*SphericalKernel::Circular\_arc\_point\_3*

*fo*( *SphericalKernel::Line\_arc\_3* *l* )

Constructs the minimal vertex of *l* with lexicographically smallest coordinates.

## SphericalKernel::ConstructCircularMaxVertex\_3

A model *fo* of this type must provide:

*SphericalKernel::Circular\_arc\_point\_3*

*fo( SphericalKernel::Line\_arc\_3 l)*

Constructs the maximal vertex of *l* with lexicographically largest coordinates.

## SphericalKernel::ConstructCircularSourceVertex\_3

A model *fo* of this type must provide:

*SphericalKernel::Circular\_arc\_point\_3*

*fo( SphericalKernel::Circular\_arc\_3 c)*

Constructs the source vertex of *c*.

*SphericalKernel::Circular\_arc\_point\_3*

*fo( SphericalKernel::Line\_arc\_3 l)*

Same, for a line segment.

## SphericalKernel::ConstructCircularTargetVertex\_3

A model *fo* of this type must provide:

*SphericalKernel::Circular\_arc\_point\_3*

*fo( SphericalKernel::Circular\_arc\_3 c)*

Constructs the target vertex of *c*.

*SphericalKernel::Circular\_arc\_point\_3*

*fo( SphericalKernel::Line\_arc\_3 l)*

Same, for a line segment.

## SphericalKernel::ConstructBbox\_3

A model *fo* of this type must provide operators to construct a bounding box of geometric objects:

*CGAL::Bbox\_3*                      *fo*( *SphericalKernel::Circular\_arc\_point\_3* *p*)

*CGAL::Bbox\_3*                      *fo*( *SphericalKernel::Line\_arc\_3* *l*)

*CGAL::Bbox\_3*                      *fo*( *SphericalKernel::Circular\_arc\_3* *c*)

## SphericalKernel::Split\_3

A model *fo* of this type must provide:

```
void                                fo.operator()( SphericalKernel::Circular_arc_3 a,
                                                    SphericalKernel::Circular_arc_point_3 p,
                                                    SphericalKernel::Circular_arc_3 &a1,
                                                    SphericalKernel::Circular_arc_3 &a2)
```

Splits arc *a* at point *p*, which creates arcs *a1* and *a2*.  
*Precondition:* The point lies on the input arc.

```
void                                fo.operator()( SphericalKernel::Line_arc_3 l,
                                                    SphericalKernel::Circular_arc_point_3 p,
                                                    SphericalKernel::Line_arc_3 &l1,
                                                    SphericalKernel::Line_arc_3 &l2)
```

Same for a line arc.

## Refines

An object *fo* of this type must provide in addition:

Compares the  $x$ -coordinates of  $p$  and  $q$ .

<i>SphericalKernel::CompareY_3</i> .....	page 1010
<i>SphericalKernel::CompareZ_3</i> .....	page 1011
<i>SphericalKernel::CompareXY_3</i> .....	page 1012
<i>SphericalKernel::CompareXYZ_3</i> .....	page 1013
<i>SphericalKernel::Equal_3</i> .....	page 1014

### SphericalKernel::CompareY\_3

## Refines

*Kernel::CompareY\_3*

An object *fo* of this type must provide in addition:

<i>Comparison_result</i>	<i>fo.operator() ( SphericalKernel::Circular_arc_point_3 p,</i> <i>SphericalKernel::Circular_arc_point_3 q)</i>
--------------------------	--

Compares the  $y$ -coordinates of  $p$  and  $q$ .

## See Also

<i>SphericalKernel::Equal_3</i> .....	page 1014

### SphericalKernel::CompareXY\_3

## Refines

*Kernel::CompareXY\_3*

An object *fo* of this type must provide in addition:

<i>Comparison_result</i>	<i>fo.operator() ( SphericalKernel::Circular_arc_point_3 p,</i> <i>SphericalKernel::Circular_arc_point_3 q)</i>
--------------------------	--

Compares  $p$  and  $q$  according to the lexicographic ordering on  $x$ - and  $y$ -coordinates.

## See Also

<i>SphericalKernel::CompareX_3</i> .....	page 1009
<i>SphericalKernel::CompareY_3</i> .....	page 1010
<i>SphericalKernel::CompareZ_3</i> .....	page 1011

<i>SphericalKernel::CompareZ_3</i> .....	page 1011
<i>SphericalKernel::CompareXY_3</i> .....	page 1012
<i>SphericalKernel::Equal_3</i> .....	page 1014

### Testing equality between objects.

*Kernel::Equal\_3*

An object *fo* of this type must provide in addition:

For two points.

For two arcs. Two arcs are equal, iff their non-oriented supporting planes are equal, if the centers and squared radii of their respective supporting circles are equal, and if their sources and targets are equal.

For two segments. Two segments are equal, iff their non-oriented supporting lines are equal (i.e. they define the same set of points), and if their endpoints are the same.

<i>SphericalKernel::CompareX_3</i> .....	page 1009
<i>SphericalKernel::CompareY_3</i> .....	page 1010
<i>SphericalKernel::CompareZ_3</i> .....	page 1011
<i>SphericalKernel::CompareXY_3</i> .....	page 1012
<i>SphericalKernel::CompareXYZ_3</i> .....	page 1013

## SphericalKernel::HasOn\_3

### Refines

*Kernel::HasOn\_3*

An object *fo* of this type must provide:

*bool* *fo*( *Type1 obj1*, *Type2 obj2*)

Returns *true* when *obj1* contains *obj2*,

where *Type1* and *Type2* can be respectively:

<i>Type1</i>	<i>Type2</i>
<i>SphericalKernel::Sphere_3</i> , <i>SphericalKernel::Plane_3</i> , <i>SphericalKernel::Line_3</i> , <i>SphericalKernel::Circle_3</i> , <i>SphericalKernel::Line_arc_3</i> , or <i>SphericalKernel::Circular_arc_3</i>	<i>SphericalKernel::Circular_arc_point_3</i>
<i>SphericalKernel::Plane_3</i> , <i>SphericalKernel::Line_3</i>	<i>SphericalKernel::Line_arc_3</i>
<i>SphericalKernel::Plane_3</i> , <i>SphericalKernel::Circle_3</i> , or <i>SphericalKernel::Sphere_3</i>	<i>SphericalKernel::Circular_arc_3</i>

## SphericalKernel::DoOverlap\_3

### Refines

*Kernel::DoOverlap\_3*

An object *fo* of this type must provide:

```
bool                                fo.operator()( SphericalKernel::Line_arc_3 l0,
                                                    SphericalKernel::Line_arc_3 l1,
                                                    const bool known_equal_supporting_line = false)
```

For two line arcs.

```
bool                                fo.operator()( SphericalKernel::Circular_arc_3 a0,
                                                    SphericalKernel::Circular_arc_3 a1,
                                                    const bool known_equal_supporting_circle = false)
```

For two circular arcs.

The computation may be faster when the boolean is set to *true*.

## SphericalKernel::DoIntersect\_3

### Definition

Testing whether two curves intersect.

### Refines

*Kernel::DoIntersect\_3*

An object *fo* of this type must provide:

*bool* *fo*( *Type1 obj1*, *Type2 obj2*)

determines if two geometric objects of type *Type1* and *Type2* intersect or not.

for all pairs *Type1* and *Type2*, where the types *Type1* and *Type2* can be any of the following:

- *SphericalKernel::Plane\_3*
- *SphericalKernel::Line\_3*
- *SphericalKernel::Line\_arc\_3*
- *SphericalKernel::Sphere\_3*
- *SphericalKernel::Circle\_3*
- *SphericalKernel::Circular\_arc\_3*

### See Also

*CGAL::do\_intersect* .....page [1802](#)

## SphericalKernel::BoundedSide\_3

### Refines

*Kernel::BoundedSide\_3*

An object *fo* of this type must provide:

*Bounded\_side* *fo*( *SphericalKernel::Sphere\_3 s*, *SphericalKernel::Circular\_arc\_point\_3 p*)

For a sphere.

*Bounded\_side* *fo*( *SphericalKernel::Circle\_3 s*, *SphericalKernel::Circular\_arc\_point\_3 p*)

For a circle.

### See Also

*SphericalKernel::HasOnBoundedSide\_3* . . . . . page [1019](#)

*SphericalKernel::HasOnUnboundedSide\_3* . . . . . page [1020](#)

## SphericalKernel::HasOnBoundedSide\_3

### Refines

*Kernel::HasOnBoundedSide\_3*

An object *fo* of this type must provide:

*bool* *fo*( *SphericalKernel::Sphere\_3* *s*, *SphericalKernel::Circular\_arc\_point\_3* *p*)

For a sphere.

*bool* *fo*( *SphericalKernel::Circle\_3* *s*, *SphericalKernel::Circular\_arc\_point\_3* *p*)

For a circle.

### See Also

*SphericalKernel::BoundedSide\_3* .....page [1018](#)

*SphericalKernel::HasOnUnboundedSide\_3* .....page [1020](#)

## SphericalKernel::HasOnUnboundedSide\_3

### Refines

*Kernel::HasOnUnboundedSide\_3*

An object *fo* of this type must provide:

*bool* *fo*( *SphericalKernel::Sphere\_3* *s*, *SphericalKernel::Circular\_arc\_point\_3* *p*)

For a sphere.

*bool* *fo*( *SphericalKernel::Circle\_3* *s*, *SphericalKernel::Circular\_arc\_point\_3* *p*)

For a circle.

### See Also

*SphericalKernel::BoundedSide\_3* .....page [1018](#)

*SphericalKernel::HasOnBoundedSide\_3* .....page [1019](#)

## SphericalKernel::Intersect\_3

### Refines

*Kernel::Intersect\_3*

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo( Type1 obj1, Type2 obj2, OutputIterator intersections)
```

Copies in the output iterator the intersection elements between the two objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order when this ordering is defined on the computed objects.

```
template < class OutputIterator >
OutputIterator      fo( Type1 obj1, Type2 obj2, Type3 obj3, OutputIterator intersections)
```

Copies in the output iterator the intersection elements between the three objects. *intersections* iterates on elements of type *CGAL::Object*, in lexicographic order when this ordering is defined on the computed objects.

For the **first operator**, *Type1* and *Type2* can both be either

- *SphericalKernel::Sphere\_3*,
- *SphericalKernel::Plane\_3*,
- *SphericalKernel::Line\_3*,
- *SphericalKernel::Circle\_3*,
- *SphericalKernel::Line\_arc\_3* or
- *SphericalKernel::Circular\_arc\_3*,

and depending on the types *Type1* and *Type2*, the computed *CGAL::Objects* can be assigned to

- *std::pair<SphericalKernel::Circular\_arc\_point\_3, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point between *obj\_1* and *obj\_2*,
- *Type1*, when *Type1* and *Type2* are equal, and if the two objects *obj1* and *obj2* are equal,
- *SphericalKernel::Line\_3* or *SphericalKernel::Circle\_3* when *Type1* and *Type2* are two-dimensional objects intersecting along a curve (2 planes, or 2 spheres, or one plane and one sphere),
- *SphericalKernel::Circular\_arc\_3* in case of an overlap of two circular arcs or
- *SphericalKernel::Line\_arc\_3* in case of an overlap of two line segments.

For the **second operator**, *Type1*, *Type2* and *Type3* can be either

- *SphericalKernel::Sphere\_3* or
- *SphericalKernel::Plane\_3*

and depending of these types, the computed *CGAL::Objects* can be assigned to

- *std::pair<SphericalKernel::Circular\_arc\_point\_3, unsigned>*, where the unsigned integer is the multiplicity of the corresponding intersection point,
- *SphericalKernel::Circle\_3* or
- *Type1*, when *Type1*, *Type2* and *Type3* are equal, and if the three objects *obj1* and *obj2* and *obj3* are equal.

## SphericalKernel::ComputeCircularX\_3

*SphericalKernel::Root\_of\_2*

*fo( SphericalKernel::Circular\_arc\_point\_3 p)*

returns the  $x$ -coordinate of the point.

## SphericalKernel::ComputeCircularY\_3

*SphericalKernel::Root\_of\_2*

*fo( SphericalKernel::Circular\_arc\_point\_3 p)*

returns the y-coordinate of the point.

## SphericalKernel::ComputeCircularZ\_3

*SphericalKernel::Root\_of\_2*

*fo( SphericalKernel::Circular\_arc\_point\_3 p)*

returns the  $z$ -coordinate of the point.

## SphericalKernel::ComputeApproximateSquaredLength\_3

### Refines

*Kernel::ComputeApproximateSquaredLength\_3*

In addition, an object *fo* of this type must provide:

*double* *fo*( *SphericalKernel::Circular\_arc\_3 c*)

Computes an approximation of the squared length of the arc.

## SphericalKernel::ComputeApproximateAngle\_3

An object *fo* of this type must provide:

*double*

*fo( SphericalKernel::Circular\_arc\_3 c)*

Computes an approximation of the angle of the arc in radians.

## SphericalKernel::GetEquation

A model *fo* of this type must provide:

*SphericalKernel::Polynomial\_1\_3*

*fo( SphericalKernel::Plane\_3 p)*

Returns the equation of the plane.

*SphericalKernel::Polynomial\_for\_spheres\_2\_3*

*fo( SphericalKernel::Sphere\_3 p)*

Returns the equation of the sphere.

*SphericalKernel::Polynomials\_for\_line\_3*

*fo( SphericalKernel::Line\_3 c)*

Returns the equations of the line.

*SphericalKernel::Polynomials\_for\_circle\_3*

*fo( SphericalKernel::Circle\_3 c)*

Returns the equations of the circle.

## CGAL::x\_extremal\_point

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

```
Circular_arc_point_3<SphericalKernel>
```

```
    x_extremal_point( Const Sphere_3<SphericalKernel> & c, bool b)
```

Returns the point on the sphere that is extremal in the  $x$ -direction, and that is the smallest (resp. largest) of the two  $x$ -extremal points for the lexicographic order if  $b$  is *true* (resp. *false*).

```
Circular_arc_point_3<SphericalKernel>
```

```
    x_extremal_point( Circle_3<SphericalKernel> c, bool b)
```

Same for a circle.

*Precondition:* The circle is not contained in a plane orthogonal to the  $x$ -axis.

## CGAL::y\_extremal\_point

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

```
Circular_arc_point_3<SphericalKernel>
```

```
    y_extremal_point( Sphere_3<SphericalKernel> c, bool b)
```

Returns the point on the sphere that is extremal in the  $y$ -direction, and that is the smallest (resp. largest) of the two  $y$ -extremal points for the lexicographic order if  $b$  is *true* (resp. *false*).

```
Circular_arc_point_3<SphericalKernel>
```

```
    y_extremal_point( Circle_3<SphericalKernel> c, bool b)
```

Same for a circle.

*Precondition:* The circle is not contained in a plane orthogonal to the  $y$ -axis.

## CGAL::z\_extremal\_point

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

```
Circular_arc_point_3<SphericalKernel>
```

```
z_extremal_point( Sphere_3<SphericalKernel> c, bool b)
```

Returns the point on the sphere that is extremal in the  $z$ -direction, and that is the smallest (resp. largest) of the two  $z$ -extremal points for the lexicographic order if  $b$  is *true* (resp. *false*).

```
Circular_arc_point_3<SphericalKernel>
```

```
z_extremal_point( Circle_3<SphericalKernel> c, bool b)
```

Same for a circle.

*Precondition:* The circle is not contained in a plane orthogonal to the  $z$ -axis.

## CGAL::x\_extremal\_points

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

```
template < class OutputIterator >
```

```
OutputIterator x_extremal_points( Sphere_3<SphericalKernel> c, OutputIterator res)
```

Copies in the output iterator the  $x$ -extremal points of the sphere. *res* iterates on elements of type *Circular\_arc\_point\_3<SphericalKernel>*, lexicographically sorted.

```
template < class OutputIterator >
```

```
OutputIterator x_extremal_points( Circle_3<SphericalKernel> c, OutputIterator res)
```

Copies in the output iterator the  $x$ -extremal points of the circle. *res* iterates on elements of type *Circular\_arc\_point\_3<SphericalKernel>*, lexicographically sorted.

*Precondition:* The circle is not contained in a plane orthogonal to the  $x$ -axis.

## CGAL::y\_extremal\_points

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

```
template < class OutputIterator >
```

```
OutputIterator y_extremal_points( Sphere_3<SphericalKernel> c, OutputIterator res)
```

Copies in the output iterator the y-extremal points of the sphere. *res* iterates on elements of type *Circular\_arc\_point\_3<SphericalKernel>*, lexicographically sorted.

```
template < class OutputIterator >
```

```
OutputIterator y_extremal_points( Circle_3<SphericalKernel> c, OutputIterator res)
```

Copies in the output iterator the y-extremal points of the circle. *res* iterates on elements of type *Circular\_arc\_point\_3<SphericalKernel>*, lexicographically sorted.

*Precondition:* The circle is not contained in a plane orthogonal to the y-axis.

**CGAL::z\_extremal\_points**

```
#include <CGAL/global_functions_spherical_kernel_3.h>
```

```
template < class OutputIterator >
```

```
OutputIterator z_extremal_points( Sphere_3<SphericalKernel> c, OutputIterator res)
```

Copies in the output iterator the  $z$ -extremal points of the sphere. *res* iterates on elements of type *Circular\_arc\_point\_3<SphericalKernel>*, lexicographically sorted.

```
template < class OutputIterator >
```

```
OutputIterator z_extremal_points( Circle_3<SphericalKernel> c, OutputIterator res)
```

Copies in the output iterator the  $z$ -extremal points of the circle. *res* iterates on elements of type *Circular\_arc\_point\_3<SphericalKernel>*, lexicographically sorted.

*Precondition:* The circle is not contained in a plane orthogonal to the  $z$ -axis.

# AlgebraicKernelForSpheres

## Definition

The *AlgebraicKernelForSpheres* concept is meant to provide the curved kernel with all the algebraic functionalities required for the manipulation of spheres, circles, and circular arcs in 3D.

## Has Models

*Algebraic\_kernel\_for\_spheres\_2\_3*

## Types

A model of *AlgebraicKernelForSpheres* is supposed to provide

*AlgebraicKernelForSpheres:: RT*

A model of *RingNumberType*.

*AlgebraicKernelForSpheres:: FT*

A model of *FieldNumberType<RT>*.

*AlgebraicKernelForSpheres:: Polynomial\_1\_3*

A model of *AlgebraicKernelForSpheres::Polynomial\_1\_3*, for trivariate polynomials of degree up to 1.

*AlgebraicKernelForSpheres:: Polynomial\_for\_spheres\_2\_3*

A model of *AlgebraicKernelForSpheres::PolynomialForSpheres\_2\_3*, for trivariate polynomials of degree up to 2 that can store equations of spheres.

*AlgebraicKernelForSpheres:: Polynomials\_for\_lines\_3*

A model of *AlgebraicKernelForSpheres::PolynomialsForLines\_3*, for systems of polynomials that can store equations of lines in 3D.

*AlgebraicKernelForSpheres:: Root\_of\_2*

A model of *RootOf\_2*, for algebraic numbers of degree up to 2.

*AlgebraicKernelForSpheres:: Root\_for\_spheres\_2\_3*

A model of *AlgebraicKernelForSpheres::RootForSpheres\_2\_3*, for solutions of systems of three models of *AlgebraicKernelForSpheres::PolynomialForSpheres\_2\_3*.

*AlgebraicKernelForSpheres:: Construct\_polynomial\_1\_3*

A model of *AlgebraicKernelForSpheres::ConstructPolynomial\_1\_3*.

*AlgebraicKernelForSpheres:: Construct\_polynomial\_for\_spheres\_2\_3*

A model of *AlgebraicKernelForSpheres::ConstructPolynomialForSpheres\_2\_3*.

*AlgebraicKernelForSpheres:: Construct\_polynomials\_for\_lines\_3*

A model of *AlgebraicKernelForSpheres::ConstructPolynomialsForLines\_3*.

*AlgebraicKernelForSpheres:: Compare\_x*

A model of the concept *AlgebraicKernelForSpheres::CompareX*.

*AlgebraicKernelForSpheres:: Compare\_y*

A model of the concept *AlgebraicKernelForSpheres::CompareY*.

*AlgebraicKernelForSpheres:: Compare\_z*

A model of the concept *AlgebraicKernelForSpheres::CompareZ*.

*AlgebraicKernelForSpheres:: Compare\_xy*

A model of the concept *AlgebraicKernelForSpheres::CompareXY*.

*AlgebraicKernelForSpheres:: Compare\_xyz*

A model of the concept *AlgebraicKernelForSpheres::CompareXYZ*.

*AlgebraicKernelForSpheres:: Sign\_at*

A model of the concept *AlgebraicKernelForSpheres::SignAt*.

*AlgebraicKernelForSpheres:: X\_critical\_points*

A model of the concept *AlgebraicKernelForSpheres::XCriticalPoints*.

*AlgebraicKernelForSpheres:: Y\_critical\_points*

A model of the concept *AlgebraicKernelForSpheres::YCriticalPoints*.

*AlgebraicKernelForSpheres:: Z\_critical\_points*

A model of the concept *AlgebraicKernelForSpheres::ZCriticalPoints*.

*AlgebraicKernelForSpheres:: Solve*

A model of the concept *AlgebraicKernelForSpheres::Solve*.

## AlgebraicKernelForSpheres::SignAt

### Definition

A model *fo* of this type must provide:

*CGAL::Sign*  $fo.operator()( \text{AlgebraicKernelForSpheres::Polynomial\_1\_3 } p, \\ \text{AlgebraicKernelForSpheres::Root\_for\_spheres\_2\_3 } r )$

Computes the sign of polynomial  $p$  evaluated at a root  $r$ .

*CGAL::Sign*  $fo.operator()( \text{AlgebraicKernelForSpheres::Polynomial\_for\_spheres\_2\_3 } p, \\ \text{AlgebraicKernelForSpheres::Root\_for\_spheres\_2\_3 } r )$

Same as previous.

## AlgebraicKernelForSpheres::ConstructPolynomial\_1\_3

A model *fo* of this type must provide:

*AlgebraicKernelForSpheres::Polynomial\_1\_3*

```
fo.operator()( AlgebraicKernelForSpheres::RT a,
               AlgebraicKernelForSpheres::RT b,
               AlgebraicKernelForSpheres::RT c,
               AlgebraicKernelForSpheres::RT d)
```

Constructs polynomial  $ax+by+cz+d$ .

## AlgebraicKernelForSpheres::Solve

### Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo( Type1 p1, Type2 p2, Type3 p3, OutputIterator res)
```

Copies in the output iterator the common roots of *p1*, *p2*, and *p3*, with their multiplicity, as objects of type *std::pair< AlgebraicKernelForSpheres::Root\_for\_spheres\_2\_3, int>*.

*Precondition:* The set of solutions of the system is 0-dimensional.

Here, *Type1*, *Type2*, and *Type3* can all be either *AlgebraicKernelForSpheres::Polynomial\_1\_3* or *AlgebraicKernelForSpheres::Polynomial\_for\_spheres\_2\_3*.

## AlgebraicKernelForSpheres::XCriticalPoints

### Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForSpheres::Polynomial_for_spheres_2_3 p,
                                   OutputIterator res)
```

Copies in the output iterator the *x*-critical points of polynomial *p*, as objects of type *AlgebraicKernelForSpheres::Root\_for\_spheres\_2\_3*.

```
template < class OutputIterator >
AlgebraicKernelForSpheres::Root_for_spheres_2_3
```

```
fo( AlgebraicKernelForSpheres::Polynomial_for_spheres_2_3 p, bool i)
```

Computes the *i*th *x*-critical point of polynomial *p*.

### See Also

## AlgebraicKernelForSpheres::YCriticalPoints

### Definition

A model *fo* of this type must provide:

```
template < class OutputIterator >
OutputIterator      fo.operator()( AlgebraicKernelForSpheres::Polynomial_for_spheres_2_3 p,
                                   OutputIterator res)
```

Copies in the output iterator the y-critical points of polynomial *p*, as objects of type *AlgebraicKernelForSpheres::Root\_for\_spheres\_2\_3*.

```
template < class OutputIterator >
AlgebraicKernelForSpheres::Root_for_spheres_2_3
```

```
fo( AlgebraicKernelForSpheres::Polynomial_for_spheres_2_3 p, bool i)
```

Computes the *i*th y-critical point of polynomial *p*.

### 11.1 Introduction

A subset  $S \subseteq \mathbb{R}^2$  is convex if for any two points  $p$  and  $q$  in the set the line segment with endpoints  $p$  and  $q$  is contained in  $S$ . The convex hull of a set  $S$  is the smallest convex set containing  $S$ . The convex hull of a set of points  $P$  is a convex polygon with vertices in  $P$ . A point in  $P$  is an extreme point (with respect to  $P$ ) if it is a vertex of the convex hull of  $P$ . A set of points is said to be strongly convex if it consists of only extreme points.

This chapter describes the functions provided in CGAL for producing convex hulls in two dimensions as well as functions for checking if sets of points are strongly convex or not. There are also a number of functions described for computing particular extreme points and subsequences of hull points, such as the lower and upper hull of a set of points.

## 11.2 Convex Hull

CGAL provides implementations of several classical algorithms for computing the counterclockwise sequence of extreme points for a set of points in two dimensions (*i.e.*, the counterclockwise sequence of points on the convex hull). The algorithms have different asymptotic running times and require slightly different sets of geometric primitives. Thus you may choose the algorithm that best fits your setting.

Each of the convex hull functions presents the same interface to the user. That is, the user provides a pair of iterators, *first* and *beyond*, an output iterator *result*, and a traits class *traits*. The points in the range  $[first, beyond)$  define the input points whose convex hull is to be computed. The counterclockwise sequence of extreme points is written to the sequence starting at position *result*, and the past-the-end iterator for the resulting set of points is returned. The traits classes for the functions specify the types of the input points and the geometric primitives that are required by the algorithms. All functions provide an interface in which this class need not be specified and defaults to types and operations defined in the kernel in which the input point type is defined.

Given a sequence of  $n$  input points with  $h$  extreme points, the function `convex_hull_2` uses either the output-sensitive  $O(nh)$  algorithm of Bykat [Byk78] (a non-recursive version of the quickhull [BDH96] algorithm) or the algorithm of Akl and Toussaint, which requires  $O(n \log n)$  time in the worst case. The algorithm chosen depends on the kind of iterator used to specify the input points. These two algorithms are also available via the functions `ch_bykat` and `ch_akl_toussaint`, respectively. Also available are the  $O(n \log n)$  Graham-Andrew scan algorithm [And79, Meh84] (`ch_graham_andrew`), the  $O(nh)$  Jarvis march algorithm [Jar73] (`ch_jarvis`), and Eddy's  $O(nh)$  algorithm [Edd77] (`ch_eddy`), which corresponds to the two-dimensional version of the quickhull algorithm. The linear-time algorithm of Melkman for producing the convex hull of simple polygonal chains (or polygons) is available through the function `ch_melkman`.

## 11.3 Example using Graham-Andrew's Algorithm

In the following example a convex hull is constructed from point data read from standard input using `Graham-Andrew` algorithm. The resulting convex polygon is shown at the standard output console. The same results could be achieved by substituting the function `CGAL::ch_graham_andrew` by other function like `CGAL::ch_bykat`.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/ch_graham_andrew.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point_2;

int main()
{
    CGAL::set_ascii_mode(std::cin);
    CGAL::set_ascii_mode(std::cout);
    std::istream_iterator< Point_2 > in_start( std::cin );
    std::istream_iterator< Point_2 > in_end;
    std::ostream_iterator< Point_2 > out( std::cout, "\n" );
    CGAL::ch_graham_andrew( in_start, in_end, out );
    return 0;
}

```

**File:** examples/Convex\_hull\_2/ch\_from\_cin\_to\_cout.cpp

## 11.4 Extreme Points and Hull Subsequences

In addition to the functions for producing convex hulls, there are a number of functions for computing sets and sequences of points related to the convex hull. The functions *lower\_hull\_points\_2* and *upper\_hull\_points\_2* provide the computation of the counterclockwise sequence of extreme points on the lower hull and upper hull, respectively. The algorithm used in these functions is Andrew's variant of Graham's scan algorithm [And79, Meh84], which has worst-case running time of  $O(n \log n)$ .

There are also functions available for computing certain subsequences of the sequence of extreme points on the convex hull. The function *ch\_jarvis\_march* generates the counterclockwise ordered subsequence of extreme points between a given pair of points and *ch\_graham\_andrew\_scan* computes the sorted sequence of extreme points that are not left of the line defined by the first and last input points.

Finally, a set of functions (*ch\_nswe\_point*, *ch\_ns\_point*, *ch\_we\_point*, *ch\_n\_point*, *ch\_s\_point*, *ch\_w\_point*, *ch\_e\_point*) is provided for computing extreme points of a 2D point set in the coordinate directions.

## 11.5 Traits Classes

Each of the functions used to compute convex hulls or extreme points is parameterized by a traits class, which specifies the types and geometric primitives to be used in the computation. There are several implementations of 2D traits classes provided in the library. The class *Convex\_hull\_traits\_2<R>* corresponds to the default traits class that provides the types and predicates presented in the 2-dimensional CGAL kernel in which the input points lie. The class *Convex\_hull\_constructive\_traits<R>* is a second traits class based on CGAL primitives but differs from *Convex\_hull\_traits\_2* in that some of its primitives reuse intermediate results to speed up computation. In addition, there are three projective traits classes (*Convex\_hull\_projective\_xy\_traits\_2*, *Convex\_hull\_projective\_xz\_traits\_2*, and *Convex\_hull\_projective\_yz\_traits\_2*), which may be used to compute the convex hull of a set of three-dimensional points projected into each of the three coordinate planes.

## 11.6 Convexity Checking

The functions *is\_ccw\_strongly\_convex\_2* and *is\_cw\_strongly\_convex\_2* check whether a given sequence of 2D points forms a (counter)clockwise strongly convex polygon.. These are used in postcondition testing of the two-dimensional convex hull functions.

# 2D Convex Hulls and Extreme Points

## Reference Manual

*Susan Hert and Stefan Schirra*

A subset  $S \subseteq \mathbb{R}^2$  is convex if for any two points  $p$  and  $q$  in the set the line segment with endpoints  $p$  and  $q$  is contained in  $S$ . The convex hull of a set  $S$  is the smallest convex set containing  $S$ . The convex hull of a set of points  $P$  is a convex polygon with vertices in  $P$ . A point in  $P$  is an extreme point (with respect to  $P$ ) if it is a vertex of the convex hull of  $P$ .

CGAL provides functions for computing convex hulls in two dimensions as well as functions for testing if a given set of points is strongly convex or not. There are also a number of functions available for computing particular extreme points in 2D and subsequences of the hull points, such as the lower hull or upper hull of a set of points.

## 11.7 Classified Reference Pages

### Assertions

The assertion flags for the convex hull and extreme point algorithms use *CH* in their names (e.g., *CGAL\_CH\_NO\_POSTCONDITIONS*). For the convex hull algorithms, the postcondition check tests only convexity (if not disabled), but not containment of the input points in the polygon or polyhedron defined by the output points. The latter is considered an expensive checking and can be enabled by defining *CGAL\_CH\_CHECK\_EXPENSIVE*.

## CGAL::ch\_akl\_toussaint

### Definition

The function *ch\_akl\_toussaint* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_akl_toussaint.h>
```

```
template <class ForwardIterator, class OutputIterator, class Traits>
OutputIterator ch_akl_toussaint( ForwardIterator first,
                                ForwardIterator beyond,
                                OutputIterator result,
                                Traits ch_traits = Default_traits())
```

generates the counterclockwise sequence of extreme points of the points in the range  $[first, beyond)$ . The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

*Precondition:* The source range  $[first, beyond)$  does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

1. *ForwardIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Less\_xy\_2*,
  - *Traits::Less\_yx\_2*,
  - *Traits::Left\_turn\_2*,
  - *Traits::Equal\_2*.

*CGAL::ch\_melkman* ..... page [1085](#)  
*CGAL::convex\_hull\_2* ..... page [1093](#)

## Implementation

This function uses the algorithm of Akl and Toussaint [[AT78](#)] that requires  $O(n \log n)$  time for  $n$  input points.

## CGAL::ch\_bykat

### Definition

The function *ch\_bykat* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_bykat.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator ch_bykat( InputIterator first,
                        InputIterator beyond,
                        OutputIterator result,
                        Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range  $[first, beyond)$ . The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

*Precondition:* The source range  $[first, beyond)$  does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Less\_signed\_distance\_to\_line\_2*,
  - *Traits::Left\_turn\_2*,
  - *Traits::Less\_xy\_2*,
  - *Traits::Equal\_2*.

*CGAL::convex\_hull\_2* ..... page [1093](#)

## Implementation

This function implements the non-recursive variation of Eddy's algorithm [Edd77] described in [Byk78]. This algorithm requires  $O(nh)$  time in the worst case for  $n$  input points with  $h$  extreme points.

## CGAL::ch\_eddy

### Definition

The function *ch\_eddy* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_eddy.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      ch_eddy( InputIterator first,
                             InputIterator beyond,
                             OutputIterator result,
                             Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

*Precondition:* The source range *[first,beyond)* does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Equal\_2*,
  - *Traits::Less\_signed\_distance\_to\_line\_2*,
  - *Traits::Left\_turn\_2*,
  - *Traits::Less\_xy\_2*.

*CGAL::ch\_melkman* ..... page [1085](#)  
*CGAL::convex\_hull\_2* ..... page [1093](#)

## Implementation

This function implements Eddy's algorithm [Edd77], which is the two-dimensional version of the quickhull algorithm [BDH96] . This algorithm requires  $O(nh)$  time in the worst case for  $n$  input points with  $h$  extreme points.

## CGAL::ch\_e\_point

### Definition

The function *ch\_e\_point* finds a point of a given set of input points with maximal  $x$  coordinate.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_e_point( ForwardIterator first,
                     ForwardIterator beyond,
                     ForwardIterator& e,
                     Traits ch_traits = Default_traits)
```

traverses the range  $[first, beyond)$ . After execution, the value of  $e$  is an iterator in the range such that  $*e \geq_{xy} *it$  for all iterators  $it$  in the range.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

*Traits* defines a type *Traits::Less\_xy\_2* as described in the concept *ConvexHullTraits\_2* and the corresponding member function that returns an instance of this type.

## CGAL::ch\_graham\_andrew

### Definition

The function *ch\_graham\_andrew* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_graham_andrew.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      ch_graham_andrew( InputIterator first,
                                     InputIterator beyond,
                                     OutputIterator result,
                                     Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

*Precondition:* The source range *[first,beyond)* does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *InputIterator::value\_type* is defined.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Less\_xy\_2*,
  - *Traits::Left\_turn\_2*,
  - *Traits::Equal\_2*.

<i>CGAL::lower_hull_points_2</i> .....	page <a href="#">1104</a>
<i>CGAL::upper_hull_points_2</i> .....	page <a href="#">1106</a>

## Implementation

This function implements Andrew’s variant of the Graham scan algorithm [[And79](#)] and follows the presentation of Mehlhorn [[Meh84](#)]. This algorithm requires  $O(n \log n)$  time in the worst case for  $n$  input points.

## CGAL::ch\_graham\_andrew\_scan

### Definition

The function `ch_graham_andrew_scan` generates the counterclockwise sequence of extreme points from a given set of input points that are not left of the line defined by the first and last points in this sequence.

```
#include <CGAL/ch_graham_andrew.h>
```

```
template <class BidirectionalIterator, class OutputIterator, class Traits>
OutputIterator      ch_graham_andrew_scan( BidirectionalIterator first,
                                           BidirectionalIterator beyond,
                                           OutputIterator result,
                                           Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points that are not left of  $pq$ , where  $p$  is the value of *first* and  $q$  is the value of *beyond* - 1. The resulting sequence is placed starting at *result* with  $p$ ; point  $q$  is omitted. The past-the-end iterator for the sequence is returned.

*Precondition:* The range  $[first, beyond)$  contains at least two different points. The points in  $[first, beyond)$  are “sorted” with respect to  $pq$ , i.e., the sequence of points in  $[first, beyond)$  define a counterclockwise polygon, for which the Graham-Sklansky-procedure [Sk172] works.

The default traits class *Default\_traits* is the kernel in which the type *BidirectionalIterator::value\_type* is defined.

### Requirements

1. *BidirectionalIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* defines the following two types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Left\_turn\_2*.

### See Also

CGAL::ch\_graham\_andrew ..... page [1077](#)  
 CGAL::lower\_hull\_points\_2 ..... page [1104](#)  
 CGAL::upper\_hull\_points\_2 ..... page [1106](#)

### Implementation

The function uses Andrew’s variant of the Graham scan algorithm [And79] . This algorithm requires  $O(n \log n)$  time in the worst case for  $n$  input points.

## Example

In the following example *ch\_graham\_andrew\_scan()* is used to realize Anderson's variant [And78] of the Graham Scan [Gra72]. The points are sorted counterclockwise around the leftmost point using the *Less\_rotate\_ccw\_2* predicate, as defined in the concept *ConvexHullTraits\_2*. According to the definition of *Less\_rotate\_ccw\_2*, the leftmost point is the last point in the sorted sequence and its predecessor on the convex hull is the first point in the sorted sequence. It is not hard to see that the preconditions of *ch\_graham\_andrew\_scan()* are satisfied. Anderson's variant of the Graham scan is usually inferior to Andrew's variant because of its higher arithmetic demand.

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator
ch_graham_anderson( InputIterator first, InputIterator beyond,
                    OutputIterator result, const Traits& ch_traits)
{
    typedef typename Traits::Less_xy_2          Less_xy_2;
    typedef typename Traits::Point_2            Point_2;
    typedef typename Traits::Less_rotate_ccw_2   Less_rotate_ccw_2;

    if (first == beyond) return result;
    std::vector< Point_2 > V;
    copy( first, beyond, back_inserter(V) );
    typename std::vector< Point_2 >::iterator it =
        std::min_element(V.begin(), V.end(), Less_xy_2());
    std::sort( V.begin(), V.end(), CGAL::bind_1(Less_rotate_ccw_2(), *it) );
    if ( *(V.begin()) == *(V.rbegin()) )
    {
        *result = *(V.begin()); ++result;
        return result;
    }
    return ch_graham_andrew_scan( V.begin(), V.end(), result, ch_traits);
}
```

## CGAL::ch\_jarvis

### Definition

The function *ch\_jarvis* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/ch_jarvis.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      ch_jarvis( InputIterator first,
                              InputIterator beyond,
                              OutputIterator result,
                              Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

*Precondition:* The source range *[first,beyond)* does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *InputIterator::value\_type* is defined.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Equal\_2*,
  - *Traits::Less\_rotate\_ccw\_2*,
  - *Traits::Less\_xy\_2*.

*CGAL::ch\_jarvis\_march* ..... page 1083  
*CGAL::ch\_melkman* ..... page 1085  
*CGAL::convex\_hull\_2* ..... page 1093

## Implementation

This function uses the Jarvis march (gift-wrapping) algorithm [Jar73]. This algorithm requires  $O(nh)$  time in the worst case for  $n$  input points with  $h$  extreme points.

## CGAL::ch\_jarvis\_march

### Definition

The function *ch\_jarvis\_march* generates the counterclockwise sequence of extreme points from a given set of input points that line between two input points.

```
#include <CGAL/ch_jarvis.h>
```

```
template <class ForwardIterator, class OutputIterator, class Traits>
OutputIterator ch_jarvis_march( ForwardIterator first,
                               ForwardIterator beyond,
                               Traits::Point_2 start_p,
                               Traits::Point_2 stop_p,
                               OutputIterator result,
                               Traits ch_traits = Default_traits)
```

generates the counterclockwise subsequence of extreme points between *start\_p* and *stop\_p* of the points in the range *[first,beyond)*, starting at position *result* with point *start\_p*. The last point generated is the point preceding *stop\_p* in the counterclockwise order of extreme points.

*Precondition:* *start\_p* and *stop\_p* are extreme points with respect to the points in the range *[first,beyond)* and *stop\_p* is an element of range *[first,beyond)*.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

1. *ForwardIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* defines the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Equal\_2*,
  - *Traits::Less\_rotate\_ccw\_2*.

*CGAL::lower\_hull\_points\_2* ..... page [1104](#)  
*CGAL::upper\_hull\_points\_2* ..... page [1106](#)

## Implementation

The function uses the Jarvis march (gift-wrapping) algorithm [Jar73]. This algorithm requires  $O(nh)$  time in the worst case for  $n$  input points with  $h$  extreme points.

## CGAL::ch\_melkman

### Definition

The function *ch\_melkman* computes the counterclockwise sequence of extreme points of a sequence of points that forms a simple polyline or polygon.

```
#include <CGAL/ch_melkman.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator      ch_melkman( InputIterator first,
                               InputIterator last,
                               OutputIterator result,
                               Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range  $[first, beyond)$ . The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned.

*Precondition:* The source range  $[first, beyond)$  corresponds to a simple polyline.  $[first, beyond)$  does not contain *result*

The default traits class *Default\_traits* is the kernel in which the type *InputIterator::value\_type* is defined.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Equal\_2*,
  - *Traits::Less\_xy\_2*,
  - *Traits::Left\_turn\_2*.

*CGAL::ch\_jarvis* ..... page [1081](#)  
*CGAL::ch\_melkman* ..... page [1085](#)  
*CGAL::convex\_hull\_2* ..... page [1093](#)

**Implementation**

It uses an implementation of Melkman's algorithm [Me187]. Running time of this is linear.

## CGAL::ch\_nswe\_point

### Definition

The function *ch\_nswe\_point* finds the four extreme points of a given set of input points using a linear scan of the input points. That is, it determines the points with maximal y, minimal y, minimal x, and maximal x coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void ch_nswe_point( ForwardIterator first,
                   ForwardIterator beyond,
                   ForwardIterator& n,
                   ForwardIterator& s,
                   ForwardIterator& w,
                   ForwardIterator& e,
                   Traits ch_traits = Default_traits)
```

traverses the range  $[first, beyond)$ . After execution, the value of  $n$  is an iterator in the range such that  $*n \geq_{yx} *it$  for all iterators  $it$  in the range. Similarly, for  $s$ ,  $w$ , and  $e$  the inequalities  $*s \leq_{yx} *it$ ,  $*w \leq_{xy} *it$ , and  $*e \geq_{xy} *it$  hold for all iterators  $it$  in the range.

### Requirements

*Traits* contains the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:

- *Traits::Less\_xy\_2*,
- *Traits::Less\_yx\_2*.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

## CGAL::ch\_ns\_point

### Definition

The function *ch\_ns\_point* finds the points of a given set of input points with minimal and maximal  $x$  coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_ns_point( ForwardIterator first,
                      ForwardIterator beyond,
                      ForwardIterator& n,
                      ForwardIterator& s,
                      Traits ch_traits = Default_traits)
```

traverses the range  $[first, beyond)$ . After execution, the value of  $n$  is an iterator in the range such that  $*n \geq_{yx} *it$  for all iterators  $it$  in the range. Similarly, for  $s$  the inequality  $*s \leq_{yx} *it$  holds for all iterators in the range.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

*Traits* defines the type *Traits::Less\_yx\_2* as specified in the concept *ConvexHullTraits\_2* and the corresponding member function that returns an instance of this type.

## CGAL::ch\_n\_point

### Definition

The function *ch\_n\_point* finds a point in a given set of input points with maximal y coordinate.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_n_point( ForwardIterator first,
                     ForwardIterator beyond,
                     ForwardIterator& n,
                     Traits ch_traits = Default_traits)
```

traverses the range  $[first, beyond)$ . After execution, the value of  $n$  is an iterator in the range such that  $*n \geq_{yx} *it$  for all iterators  $it$  in the range.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

*Traits* defines the type *Traits::Less\_yx\_2* as specified in the concept *ConvexHullTraits\_2* and the corresponding member function that returns an instance of this type.

## CGAL::ch\_s\_point

### Definition

The function *ch\_s\_point* finds a points in a given set of input points with minimal y coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_s_point( ForwardIterator first,
                      ForwardIterator beyond,
                      ForwardIterator& s,
                      Traits ch_traits = Default_traits)
```

traverses the range *[first,beyond)*. After execution, the value of *s* is an iterator in the range such that  $*s \leq_{yx} *it$  for all iterators *it* in the range.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

*Traits* defines the type *Traits::Less\_yx\_2* as specified in the concept *ConvexHullTraits\_2* and the corresponding member function that returns an instance of this type.

## CGAL::ch\_we\_point

### Definition

The function *ch\_we\_point* finds two points of a given set of input points with minimal and maximal  $x$  coordinates.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void      ch_we_point( ForwardIterator first,
                      ForwardIterator beyond,
                      ForwardIterator& w,
                      ForwardIterator& e,
                      Traits ch_traits = Default_traits)
```

traverses the range  $[first, beyond)$ . After execution, the value of  $w$  is an iterator in the range such that  $*w \leq_{xy} *it$  for all iterators  $it$  in the range. Similarly, for  $e$  the inequality  $*e \geq_{xy} *it$  holds for all iterators in the range.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

*Traits* defines the type *Traits::Less\_xy\_2* as specified in the concept *ConvexHullTraits\_2* and the corresponding member function that returns an instance of this type.

## CGAL::ch\_w\_point

### Definition

The function *ch\_w\_point* finds a point in a given set of input points with minimal  $x$  coordinate.

```
#include <CGAL/ch_selected_extreme_points_2.h>
```

```
template <class ForwardIterator>
void ch_w_point( ForwardIterator first,
                 ForwardIterator beyond,
                 ForwardIterator& w,
                 Traits ch_traits = Default_traits)
```

traverses the range  $[first, beyond)$ . After execution, the value of  $w$  is an iterator in the range such that  $*w \leq_{xy} *it$  for all iterators  $it$  in the range.

### Requirements

*Traits* defines the type *Traits::Less\_xy\_2* as specified in the concept *ConvexHullTraits\_2* and the corresponding member function that returns an instance of this type.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

## CGAL::convex\_hull\_2

### Definition

The function *convex\_hull\_2* generates the counterclockwise sequence of extreme points from a given set of input points.

```
#include <CGAL/convex_hull_2.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator          convex_hull_2( InputIterator first,
                                      InputIterator beyond,
                                      OutputIterator result,
                                      Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points of the points in the range *[first,beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. It is not specified at which point the cyclic sequence of extreme points is cut into a linear sequence.

*Precondition:* The source range *[first,beyond)* does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *InputIterator::value\_type* is defined.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Equal\_2*,
  - *Traits::Less\_xy\_2*,
  - *Traits::Less\_yx\_2*,
  - *Traits::Left\_turn\_2*.

## Implementation

One of two algorithms is used, depending on the type of iterator used to specify the input points. For input iterators, the algorithm used is that of Bykat [Byk78], which has a worst-case running time of  $O(nh)$ , where  $n$  is the number of input points and  $h$  is the number of extreme points. For all other types of iterators, the  $O(n \log n)$  algorithm of Akl and Toussaint [AT78] is used.

## ConvexHullTraits\_2

### Definition

All convex hull and extreme point algorithms provided in CGAL are parameterized with a traits class *Traits*, which defines the primitives (objects and predicates) that the convex hull algorithms use. ConvexHullTraits\_2 defines the complete set of primitives required in these functions. The specific subset of these primitives required by each function is specified with each function.

### Types

<i>ConvexHullTraits_2:: Point_2</i>	The point type on which the convex hull functions operate.
<i>ConvexHullTraits_2:: Equal_2</i>	Binary predicate object type comparing <i>Point_2</i> s. Must provide <i>bool operator()(Point_2 p, Point_2 q)</i> where <i>true</i> is returned iff $p ==_{xy} q$ , false otherwise.
<i>ConvexHullTraits_2:: Less_xy_2</i>	Binary predicate object type comparing <i>Point_2</i> s lexicographically. Must provide <i>bool operator()(Point_2 p, Point_2 q)</i> where <i>true</i> is returned iff $p <_{xy} q$ . We have $p <_{xy} q$ , iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$ , where $p_x$ and $p_y$ denote $x$ and $y$ coordinate of point $p$ , respectively.
<i>ConvexHullTraits_2:: Less_yx_2</i>	Same as <i>Less_xy_2</i> with the roles of $x$ and $y$ interchanged.
<i>ConvexHullTraits_2:: Left_turn_2</i>	Predicate object type that must provide <i>bool operator()(Point_2 p, Point_2 q, Point_2 r)</i> , which returns <i>true</i> iff $r$ lies to the left of the oriented line through $p$ and $q$ .
<i>ConvexHullTraits_2:: Less_signed_distance_to_line_2</i>	Predicate object type that must provide <i>bool operator()(Point_2 p, Point_2 q, Point_2 r, Point_2 s)</i> , which returns <i>true</i> iff the signed distance from $r$ to the line $l_{pq}$ through $p$ and $q$ is smaller than the distance from $s$ to $l_{pq}$ . It is used to compute the point right of a line with maximum unsigned distance to the line. The predicate must provide a total order compatible with convexity, <i>i.e.</i> , for any line segment $s$ one of the endpoints of $s$ is the smallest point among the points on $s$ , with respect to the order given by <i>Less_signed_distance_to_line_2</i> .
<i>ConvexHullTraits_2:: Less_rotate_ccw_2</i>	Predicate object type that must provide <i>bool operator()(Point_2 e, Point_2 p, Point_2 q)</i> , where <i>true</i> is returned iff a tangent at $e$ to the point set $\{e, p, q\}$ hits $p$ before $q$ when rotated counterclockwise around $e$ . Ties are broken such that the point with larger distance to $e$ is smaller!

## Creation

Only a copy constructor is required.

```
ConvexHullTraits_2 traits( & t);
```

## Operations

The following member functions to create instances of the above predicate object types must exist.

<i>Equal_2</i>	<i>traits.equal_2_object()</i>
<i>Less_xy_2</i>	<i>traits.less_xy_2_object()</i>
<i>Less_yx_2</i>	<i>traits.less_yx_2_object()</i>
<i>Less_signed_distance_to_line_2</i>	<i>traits.less_signed_distance_to_line_2_object()</i>
<i>Less_rotate_ccw_2</i>	<i>traits.less_rotate_ccw_2_object()</i>
<i>Left_turn_2</i>	<i>traits.left_turn_2_object()</i>

## CGAL::Convex\_hull\_constructive\_traits\_2<R>

### Definition

The class *Convex\_hull\_constructive\_traits\_2<R>* serves as a traits class for all the two-dimensional convex hull and extreme point calculation function. Unlike the class *CGAL::Convex\_hull\_traits\_2<R>*, this class makes use of previously computed results to avoid redundancy. For example, in the sidedness tests, lines (of type *R::Line\_2*) are constructed, which is equivalent to the precomputation of subdeterminants of the orientation-determinant for three points.

```
#include <CGAL/convex_hull_constructive_traits_2.h>
```

## CGAL::is\_ccw\_strongly\_convex\_2

### Definition

The function *is\_ccw\_strongly\_convex\_2* determines if a given sequence of points defines a counterclockwise-oriented, strongly convex polygon. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

```
#include <CGAL/convexity_check_2.h>
```

```
template <class ForwardIterator, class Traits>
```

```
bool is_ccw_strongly_convex_2( ForwardIterator first,
                               ForwardIterator beyond,
                               Traits ch_traits = Default_traits)
```

returns *true*, iff the point elements in  $[first, beyond)$  form a counterclockwise-oriented strongly convex polygon.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

*Traits* contains the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:

- *Traits::Less\_xy\_2*,
- *Traits::Equal\_2*,
- *Traits::Left\_turn\_2*.

### See Also

*CGAL::is\_cw\_strongly\_convex\_2* ..... page [1103](#)

*CGAL::is\_strongly\_convex\_3* ..... page [1132](#)

### Implementation

The algorithm requires  $O(n)$  time for a set of  $n$  input points.

## CGAL::is\_cw\_strongly\_convex\_2

### Definition

The function *is\_cw\_strongly\_convex\_2* determines if a given sequence of points defines a clockwise-oriented, strongly convex polygon. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

```
#include <CGAL/convexity_check_2.h>
```

```
template <class ForwardIterator, class Traits>
```

```
bool is_cw_strongly_convex_2( ForwardIterator first,
                             ForwardIterator beyond,
                             Traits ch_traits = Default_traits)
```

returns *true*, iff the point elements in  $[first, beyond)$  form a clockwise-oriented strongly convex polygon.

The default traits class *Default\_traits* is the kernel in which the type *ForwardIterator::value\_type* is defined.

### Requirements

*Traits* contains the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:

- *Traits::Equal\_2*,
- *Traits::Less\_xy\_2*,
- *Traits::Left\_turn\_2*.

### See Also

*CGAL::is\_ccw\_strongly\_convex\_2* ..... page [1102](#)

*CGAL::is\_strongly\_convex\_3* ..... page [1132](#)

### Implementation

The algorithm requires  $O(n)$  time for a set of  $n$  input points.

## CGAL::lower\_hull\_points\_2

### Definition

The function *lower\_hull\_points\_2* generates the counterclockwise sequence of extreme points on the lower hull of a given set of input points.

```
#include <CGAL/convex_hull_2.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator          lower_hull_points_2( InputIterator first,
                                           InputIterator beyond,
                                           OutputIterator result,
                                           Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points on the lower hull of the points in the range *[first, beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. The sequence starts with the leftmost point; the rightmost point is not included. If there is only one extreme point (*i.e.*, leftmost and rightmost point are equal) the extreme point is reported.

*Precondition:* The source range *[first,beyond)* does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *InputIterator::value\_type* is defined.

The different treatment by *CGAL::upper\_hull\_points\_2* of the case that all points are equal ensures that concatenation of lower and upper hull points gives the sequence of extreme points.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Equal\_2*,
  - *Traits::Less\_xy\_2*,
  - *Traits::Less\_yx\_2*,
  - *Traits::Left\_turn\_2*.

*CGAL::ch\_graham\_andrew\_scan* ..... page [1079](#)  
*CGAL::upper\_hull\_points\_2* ..... page [1106](#)

## Implementation

This function uses Andrew's variant of Graham's scan algorithm [And79, Meh84]. The algorithm has worst-case running time of  $O(n \log n)$  for  $n$  input points.

## CGAL::upper\_hull\_points\_2

### Definition

The function *upper\_hull\_points\_2* generates the counterclockwise sequence of extreme points on the upper hull of a given set of input points.

```
#include <CGAL/convex_hull_2.h>
```

```
template <class InputIterator, class OutputIterator>
OutputIterator      upper_hull_points_2( InputIterator first,
                                         InputIterator beyond,
                                         OutputIterator result,
                                         Traits ch_traits = Default_traits)
```

generates the counterclockwise sequence of extreme points on the upper hull of the points in the range *[first, beyond)*. The resulting sequence is placed starting at position *result*, and the past-the-end iterator for the resulting sequence is returned. The sequence starts with the rightmost point, the leftmost point is not included. If there is only one extreme point (*i.e.*, the leftmost and rightmost point are equal), the extreme point is not reported.

*Precondition:* The source range *[first,beyond)* does not contain *result*.

The default traits class *Default\_traits* is the kernel in which the type *InputIterator::value\_type* is defined.

The different treatment by *CGAL::lower\_hull\_points\_2* of the case that all points are equal ensures that concatenation of lower and upper hull points gives the sequence of extreme points.

### Requirements

1. *InputIterator::value\_type* and *OutputIterator::value\_type* are equivalent to *Traits::Point\_2*.
2. *Traits* contains the following subset of types from the concept *ConvexHullTraits\_2* and their corresponding member functions that return instances of these types:
  - *Traits::Point\_2*,
  - *Traits::Equal\_2*,
  - *Traits::Less\_xy\_2*,
  - *Traits::Less\_yx\_2*,
  - *Traits::Left\_turn\_2*.

### 12.1 Introduction

A subset  $S \subseteq \mathbb{R}^3$  is convex if for any two points  $p$  and  $q$  in the set the line segment with endpoints  $p$  and  $q$  is contained in  $S$ . The convex hull of a set  $S$  is the smallest convex set containing  $S$ . The convex hull of a set of points  $P \in \mathbb{R}^3$  is a convex polytope with vertices in  $P$ . A point in  $P$  is an extreme point (with respect to  $P$ ) if it is a vertex of the convex hull of  $P$ . A set of points is said to be strongly convex if it consists of only extreme points.

This chapter describes the functions provided in CGAL for producing convex hulls in three dimensions as well as functions for checking if sets of points are strongly convex or not. One can compute the convex hull of a set of points in three dimensions in one of three ways in CGAL: using a static algorithm, using an incremental construction algorithm, or using a triangulation to get a fully dynamic computation.

## 12.2 Static Convex Hull Construction

The function `convex_hull_3` provides an implementation of the quickhull algorithm [BDH96] for three dimensions. There are two versions of this function available, one that can be used when it is known that the output will be a polyhedron (*i.e.*, there are more than three points and they are not all collinear) and one that handles all degenerate cases and returns a `CGAL::Object`, which may be a point, a segment, a triangle, or a polyhedron. Both versions accept a range of input iterators defining the set of points whose convex hull is to be computed and a traits class defining the geometric types and predicates used in computing the hull.

### 12.2.1 Traits Class

The function `convex_hull_3` is parameterized by a traits class, which specifies the types and geometric primitives to be used in the computation. The default for this traits class is `Convex_hull_traits_3`.

### 12.2.2 Convexity Checking

The function `is_strongly_convex_3` implements the algorithm of Mehlhorn *et al.* [MNS<sup>+</sup>96] to determine if the vertices of a given polytope constitute a strongly convex point set or not. This function is used in postcondition testing for `convex_hull_3`.

### 12.2.3 Example

The following program computes the convex hull of a set of 250 random points chosen from a sphere of radius 100. It then determines if the resulting hull is a segment or a polyhedron.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/Convex_hull_traits_3.h>
#include <CGAL/convex_hull_3.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Convex_hull_traits_3<K> Traits;
typedef Traits::Polyhedron_3 Polyhedron_3;
typedef K::Segment_3 Segment_3;

// define point creator
typedef K::Point_3 Point_3;
typedef CGAL::Creator_uniform_3<double, Point_3> PointCreator;

int main()
{
    CGAL::Random_points_in_sphere_3<Point_3, PointCreator> gen(100.0);

    // generate 250 points randomly on a sphere of radius 100.0
```

```

// and copy them to a vector
std::vector<Point_3> points;
CGAL::copy_n( gen, 250, std::back_inserter(points) );

// define object to hold convex hull
CGAL::Object ch_object;

// compute convex hull
CGAL::convex_hull_3(points.begin(), points.end(), ch_object);

// determine what kind of object it is
if (CGAL::object_cast<Segment_3>(&ch_object) )
    std::cout << "convex hull is a segment " << std::endl;
else if (CGAL::object_cast<Polyhedron_3>(&ch_object) )
    std::cout << "convex hull is a polyhedron " << std::endl;
else
    std::cout << "convex hull error!" << std::endl;

return 0;
}

```

**File:** examples/Convex\_hull\_3/quickhull\_3.cpp

## 12.3 Incremental Convex Hull Construction

The function *convex\_hull\_incremental\_3* provides an interface similar to *convex\_hull\_3* for the  $d$ -dimensional incremental construction algorithm [CMS93], implemented by the class *CGAL::Convex\_hull\_d<R>* that is specialized to three dimensions. This function accepts an iterator range over a set of input points and returns a polyhedron, but it does not have a traits class in its interface. It uses the kernel class *Kernel* used in the polyhedron type to define an instance of the adapter traits class *CGAL::Convex\_hull\_d\_traits\_3<Kernel>*.

In most cases, the function *convex\_hull\_3* will be faster than *convex\_hull\_incremental\_3*. The latter is provided mainly for comparison purposes.

To use the full functionality available with the  $d$ -dimensional class *CGAL::Convex\_hull\_d<R>* in three dimensions (e.g., the ability to insert new points and to query if a point lies in the convex hull or not), you can instantiate the class *CGAL::Convex\_hull\_d<K>* with the adapter traits class *CGAL::Convex\_hull\_d\_traits\_3<K>*, as shown in the following example.

### 12.3.1 Example

```

#include <CGAL/Homogeneous.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Convex_hull_d.h>
#include <CGAL/Convex_hull_d_traits_3.h>
#include <CGAL/Convex_hull_d_to_polyhedron_3.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/IO/Geomview_stream.h>
#include <CGAL/IO/Polyhedron_geomview_ostream.h>

```

```

#include <vector>
#include <cassert>

#ifdef CGAL_USE_GEOVIEW

#ifdef CGAL_USE_LEDA
#include <CGAL/leda_integer.h>
typedef leda_integer RT;
#else
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
// NOTE: the choice of double here for a number type may cause problems
//       for degenerate point sets
#include <CGAL/double.h>
typedef double RT;
#endif
#endif

typedef CGAL::Homogeneous<RT>          K;
typedef K::Point_3                     Point_3;
typedef CGAL::Polyhedron_3< K>         Polyhedron_3;

typedef CGAL::Convex_hull_d_traits_3<K> Hull_traits_3;
typedef CGAL::Convex_hull_d< Hull_traits_3 > Convex_hull_3;
typedef CGAL::Creator_uniform_3<double, Point_3> Creator;

int main ()
{
    Convex_hull_3 CH(3); // create instance of the class with dimension == 3

    // generate 250 points randomly on a sphere of radius 100
    // and insert them into the convex hull
    CGAL::Random_points_in_sphere_3<Point_3, Creator> gen(100);

    for (int i = 0; i < 250 ; i++, ++gen)
        CH.insert(*gen);

    assert(CH.is_valid());

    // define polyhedron to hold convex hull and create it
    Polyhedron_3 P;
    CGAL::convex_hull_d_to_polyhedron_3(CH,P);

    // display polyhedron in a geomview window
    CGAL::Geomview_stream geomview;
    geomview << CGAL::RED;
    geomview << P;

    std::cout << "Press any key to end the program: ";
    std::cout.flush();
    char ch;

```

```

    std::cin.get(ch);

    return 0;
}

#else

int main() {
    std::cerr <<
        "This demo requires geomview, which is not present on this platform\n";
    return 0;
}

#endif

```

**File:** demo/Convex\_hull\_3/incremental\_hull\_3\_demo.cpp

## 12.4 Dynamic Convex Hull Construction

Fully dynamic maintenance of a convex hull can be achieved by using the class *CGAL::Delaunay\_triangulation\_3*. This class supports insertion and removal of points (*i.e.*, vertices of the triangulation) and the convex hull edges are simply the finite edges of infinite faces. The following example illustrates the dynamic construction of a convex hull. First, random points from a sphere of a certain radius are generated and are inserted into a triangulation. Then the number of points of the convex hull are obtained by counting the number of triangulation vertices incident to the infinite vertex. Some of the points are removed and then the number of points remaining on the hull are determined. Notice that the vertices incident to the infinite vertex of the triangulation are on the convex hull but it may be that not all of them are vertices of the hull.

### 12.4.1 Example

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/algorithm.h>

#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_3 Point_3;
typedef CGAL::Delaunay_triangulation_3<K> Delaunay;
typedef Delaunay::Vertex_handle Vertex_handle;

int main()
{
    CGAL::Random_points_in_sphere_3<Point_3> gen(100.0);
    std::list<Point_3> points;

    // generate 250 points randomly on a sphere of radius 100.0
    // and insert them into the triangulation

```

```

CGAL::copy_n(gen, 250, std::back_inserter(points) );
Delaunay T;
T.insert(points.begin(), points.end());

std::list<Vertex_handle> vertices;
T.incident_vertices(T.infinite_vertex(), std::back_inserter(vertices));
std::cout << "This convex hull of the 250 points has "
          << vertices.size() << " points on it." << std::endl;

// remove 25 of the input points
std::list<Vertex_handle>::iterator v_set_it = vertices.begin();
for (int i = 0; i < 25; i++)
{
    T.remove(*v_set_it);
    v_set_it++;
}

vertices.clear();
T.incident_vertices(T.infinite_vertex(), std::back_inserter(vertices));
std::cout << "After removal of 25 points, there are "
          << vertices.size() << " points on the convex hull." << std::endl;
return 0;
}

```

# 3D Convex Hulls

## Reference Manual

*Susan Hert and Stefan Schirra*

A subset  $S \subseteq \mathbb{R}^3$  is convex if for any two points  $p$  and  $q$  in the set the line segment with endpoints  $p$  and  $q$  is contained in  $S$ . The convex hull of a set  $S$  is the smallest convex set containing  $S$ . The convex hull of a set of points  $P$  is a convex polytope with vertices in  $P$ . A point in  $P$  is an extreme point (with respect to  $P$ ) if it is a vertex of the convex hull of  $P$ .

CGAL provides functions for computing convex hulls in two, three and arbitrary dimensions as well as functions for testing if a given set of points is strongly convex or not. This chapter describes the functions available for three dimensions.

### Assertions

The assertion flags for the convex hull and extreme point algorithms use *CH* in their names (e.g., *CGAL\_CH\_NO\_POSTCONDITIONS*). For the convex hull algorithms, the postcondition check tests only convexity (if not disabled), but not containment of the input points in the polygon or polyhedron defined by the output points. The latter is considered an expensive checking and can be enabled by defining *CGAL\_CH\_CHECK\_EXPENSIVE*.

## CGAL::convex\_hull\_3

### Definition

The function *convex\_hull\_3* computes the convex hull of a given set of three-dimensional points. Two versions of this function are available. The first can be used when it is known that the result will be a polyhedron and the second when a degenerate hull may also be possible.

```
#include <CGAL/convex_hull_3.h>
```

```
template <class InputIterator, class Polyhedron_3, class Traits>
void convex_hull_3( InputIterator first,
                   InputIterator last,
                   Polyhedron_3& P,
                   Traits ch_traits = Default_traits)
```

computes the convex hull of the set of points in the range  $[first, last)$ . The polyhedron  $P$  is cleared, then the convex hull is stored in  $P$  and the plane equations of each face are computed.

*Precondition:* : There are at least four points in the range  $[first, last)$  not all of which are collinear.

```
template <class InputIterator, class Polyhedron_3, class Traits>
void convex_hull_3( InputIterator first,
                   InputIterator last,
                   Object& ch_object,
                   Traits ch_traits = Default_traits)
```

computes the convex hull of the set of points in the range  $[first, last)$ . The result, which may be a point, a segment, a triangle, or a polyhedron, is stored in *ch\_object*. When the result is a polyhedron, the plane equations of each face are computed.

### Requirements

Both functions require the following:

1. *InputIterator::value\_type* is equivalent to *Traits::Point\_3*.
2. *Traits* is a model of the concept *ConvexHullTraits\_3*. When it is known that the input points are not all coplanar, the types *Traits\_xy*, *Traits\_yx*, and *Traits\_yz* need not be provided. For the purposes of checking the postcondition that the convex hull is valid, *Traits* should also be a model of the concept *IsStronglyConvexTraits\_3*.

Both functions have an additional requirement for the polyhedron that is to be constructed. For the first version this is that:

- *Polyhedron\_3* is a model of *ConvexHullPolyhedron\_3*,

and for the second, it is required that

- *Traits* defines a type *Polyhedron\_3* that is a model of *ConvexHullPolyhedron\_3*.

The default traits class for both versions of *convex\_hull\_3* is *Convex\_hull\_traits\_3<R>*, with the representation *R* determined by *InputIterator::value\_type*.

*CGAL::ch\_eddy* ..... page [1074](#)  
*CGAL::convex\_hull\_2* ..... page [1093](#)

## Implementation

The algorithm implemented by these functions is the quickhull algorithm of Barnard *et al.* [[BDH96](#)].

## Example

The following program computes the convex hull of a set of 250 random points chosen from a sphere of radius 100. It then determines if the resulting hull is a segment or a polyhedron. Notice that the traits class is not necessary in the call to *convex\_hull\_3* but is used in the definition of *Polyhedron\_3*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/Convex_hull_traits_3.h>
#include <CGAL/convex_hull_3.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Convex_hull_traits_3<K> Traits;
typedef Traits::Polyhedron_3 Polyhedron_3;
typedef K::Segment_3 Segment_3;

// define point creator
typedef K::Point_3 Point_3;
typedef CGAL::Creator_uniform_3<double, Point_3> PointCreator;

int main()
{
    CGAL::Random_points_in_sphere_3<Point_3, PointCreator> gen(100.0);

    // generate 250 points randomly on a sphere of radius 100.0
    // and copy them to a vector
    std::vector<Point_3> points;
```

```

CGAL::copy_n( gen, 250, std::back_inserter(points) );

// define object to hold convex hull
CGAL::Object ch_object;

// compute convex hull
CGAL::convex_hull_3(points.begin(), points.end(), ch_object);

// determine what kind of object it is
if (CGAL::object_cast<Segment_3>(&ch_object) )
    std::cout << "convex hull is a segment " << std::endl;
else if (CGAL::object_cast<Polyhedron_3>(&ch_object) )
    std::cout << "convex hull is a polyhedron " << std::endl;
else
    std::cout << "convex hull error!" << std::endl;

return 0;
}

```

## CGAL::convex\_hull\_incremental\_3

### Definition

The function *convex\_hull\_incremental\_3* computes the convex hull polyhedron from a set of given three-dimensional points.

```
#include <CGAL/convex_hull_incremental_3.h>
```

```
template <class InputIterator, class Polyhedron>
void convex_hull_incremental_3( InputIterator first,
                               InputIterator beyond,
                               Polyhedron& P,
                               bool test_correctness = false)
```

computes the convex hull polyhedron of the points in the range  $[first, beyond)$  and assigns it to  $P$ . If *test\_correctness* is set to *true*, the tests described in [MNS<sup>+</sup>96] are used to determine the correctness of the resulting polyhedron.

### Requirements

1. *Polyhedron* must provide a type *Polyhedron::Traits* that defines the following types
  - *Polyhedron::Traits::R*, which is a model of the representation class  $R$  required by *CGAL::Convex\_hull\_d\_traits\_3*< $R$ >
  - *Polyhedron::Traits::Point*
2. *InputIterator::value\_type* must be the same as *Polyhedron::Traits::Point*

### See Also

*CGAL::convex\_hull\_3* .....page [1118](#)  
*CGAL::convex\_hull\_2* .....page [1093](#)

### Implementation

This function uses the  $d$ -dimensional convex hull incremental construction algorithm [CMS93] with  $d$  fixed to 3. The algorithm requires  $O(n^2)$  time in the worst case and  $O(n \log n)$  expected time.

# ConvexHullPolyhedronFacet\_3

## Definition

The requirements of the facet type of a polyhedron to be built by the function *convex\_hull\_3*.

## Has Models

*CGAL::Polyhedron\_3<Traits>::Facet* ..... page [1509](#)

## Types

*ConvexHullPolyhedronFacet\_3::Plane* plane equation type stored in facets.

*ConvexHullPolyhedronFacet\_3::Halfedge\_handle*  
handle to halfedge.

*ConvexHullPolyhedronFacet\_3::Halfedge\_around\_facet\_circulator*  
circulator of halfedges around a facet.

## Creation

*ConvexHullPolyhedronFacet\_3 f;* default constructor.

## Operations

*Plane&* *f.plane()*  
*const Plane&* *f.plane() const* plane equation.

*Halfedge\_handle* *f.halfedge()* an incident halfedge that points to *f*.  
*Halfedge\_around\_facet\_circulator*

*f.facet\_begin()* circulator of halfedges around the facet (counterclockwise).

## See Also

*CGAL::Polyhedron\_3<Traits>* ..... page [1497](#)

*ConvexHullPolyhedronHalfedge\_3* ..... page [1124](#)

## ConvexHullPolyhedronHalfedge\_3

### Definition

The requirements of the halfedge type required for the polyhedron built by the function *convex\_hull\_3*.

### Has Models

*CGAL::Polyhedron\_3<Traits>::Halfedge* ..... page [1511](#)

### Creation

*ConvexHullPolyhedronHalfedge\_3* *h*;                      default constructor.

### Operations

*Halfedge\_handle*                      *h.opposite()*                      the opposite halfedge.

*Halfedge\_handle*                      *h.next()*                      the next halfedge around the facet.

*Halfedge\_handle*                      *h.prev()*                      the previous halfedge around the facet.

*bool*                      *h.is\_border() const*                      is true if *h* is a border halfedge.

*Halfedge\_around\_facet\_circulator*

*h.facet\_begin()*                      circulator of halfedges around the facet (counterclockwise).

*Vertex\_handle*                      *h.vertex()*                      the incident vertex of *h*.

*Facet\_handle*                      *h.facet()*                      the incident facet of *h*. If *h* is a border halfedge the result is default construction of the handle.

## ConvexHullPolyhedron\_3

### Definition

The requirements of the polyhedron type to be built by the function *convex\_hull\_3*.

### Has Models

*CGAL::Polyhedron\_3<Traits>* ..... page [1497](#)

### Types

<i>ConvexHullPolyhedron_3:: Point_3</i>	type of point stored in a vertex
<i>ConvexHullPolyhedron_3:: Vertex</i>	a model of <i>ConvexHullPolyhedronVertex_3</i>
<i>ConvexHullPolyhedron_3:: Halfedge</i>	a model of <i>ConvexHullPolyhedronHalfedge_3</i>
<i>ConvexHullPolyhedron_3:: Facet</i>	a model of <i>ConvexHullPolyhedronFacet_3</i>
<i>ConvexHullPolyhedron_3:: Halfedge_data_structure</i>	halfedge data structure
<i>ConvexHullPolyhedron_3:: Halfedge_handle</i>	handle to halfedge
<i>ConvexHullPolyhedron_3:: Halfedge_iterator</i>	iterator for halfedge
<i>ConvexHullPolyhedron_3:: Facet_handle</i>	handle to facet
<i>ConvexHullPolyhedron_3:: Facet_iterator</i>	iterator for facet

### Creation

Only a default constructor is required.

*ConvexHullPolyhedron\_3* *p*;

### Operations

<i>Facet_iterator</i>	<i>p.facets_begin()</i>	iterator over all facets (excluding holes).
<i>Facet_iterator</i>	<i>p.facets_end()</i>	past-the-end iterator.
<i>Halfedge_iterator</i>	<i>p.P.halfedges_begin()</i>	iterator over all halfedges.
<i>Halfedge_iterator</i>	<i>p.P.halfedges_end()</i>	past-the-end iterator.
<i>Halfedge_handle</i>	<i>p.make_tetrahedron( Point_3 p1, Point_3 p2, Point_3 p3, Point_3 p4)</i>	adds a new tetrahedron to the polyhedral surface with its vertices initialized with <i>p1</i> , <i>p2</i> , <i>p3</i> and <i>p4</i> . Returns that halfedge of the tetrahedron which incident vertex is initialized with <i>p1</i> , the incident vertex of the next halfedge with <i>p2</i> , and the vertex thereafter with <i>p3</i> . The remaining fourth vertex is initialized with <i>p4</i> .

<i>void</i>	<i>p.erase_facet( Halfedge_handle h)</i>	removes the incident facet of <i>h</i> and changes all halfedges incident to the facet into border edges or removes them from the polyhedral surface if they were already border edges.
<i>Halfedge_handle</i>	<i>p.add_vertex_and_facet_to_border( Halfedge_handle h, Halfedge_handle g)</i>	creates a new facet within the hole incident to <i>h</i> and <i>g</i> by connecting the tip of <i>g</i> with the tip of <i>h</i> with two new halfedges and a new vertex and filling this separated part of the hole with a new facet, such that the new facet is incident to <i>g</i> . Returns the halfedge of the new edge that is incident to the new facet and the new vertex.
<i>Halfedge_handle</i>	<i>p.add_facet_to_border( Halfedge_handle h, Halfedge_handle g)</i>	creates a new facet within the hole incident to <i>h</i> and <i>g</i> by connecting the tip of <i>g</i> with the tip of <i>h</i> with a new halfedge and filling this separated part of the hole with a new facet, such that the new facet is incident to <i>g</i> . Returns the halfedge of the new edge that is incident to the new facet.
<i>Halfedge_handle</i>	<i>p.fill_hole( Halfedge_handle h)</i>	fills a hole with a newly created facet. Makes all border halfedges of the hole denoted by <i>h</i> incident to the new facet. Returns <i>h</i> .
<i>void</i>	<i>p.delegate( Modifier_base&lt;Halfedge_data_structure&gt;&amp; m)</i>	calls the <i>operator()</i> of the modifier <i>m</i> . See <i>Modifier_base</i> for a description of modifier design and its usage.

## ConvexHullTraits\_3

### Definition

Requirements of the traits class to be used with the function *convex\_hull\_3*.

### Types

<i>ConvexHullTraits_3:: Point_3</i>	The point type on which the convex hull algorithm operates
<i>ConvexHullTraits_3:: Plane_3</i>	a 3D plane
<i>ConvexHullTraits_3:: Segment_3</i>	a 3D segment
<i>ConvexHullTraits_3:: Triangle_3</i>	a 3D triangle
<i>ConvexHullTraits_3:: Vector_3</i>	a 3D vector
<i>ConvexHullTraits_3:: Construct_plane_3</i>	Function object type that provides <i>Plane_3 operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which constructs and returns a plane passing through <i>p</i> , <i>q</i> , and <i>r</i> and oriented in a positive sense when seen from the positive side of the plane.
<i>ConvexHullTraits_3:: Construct_segment_3</i>	Function object type that provides <i>Segment_3 operator()(Point_3 p, Point_3 q)</i> , which constructs and returns the segment with source <i>p</i> and target <i>q</i> .
<i>ConvexHullTraits_3:: Construct_triangle_3</i>	Function object type that provides <i>Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which constructs and returns the triangle with vertices <i>p</i> , <i>q</i> , and <i>r</i>
<i>ConvexHullTraits_3:: Construct_vector_3</i>	Function object type that provides <i>Vector_3 operator()(Point_3 p, Point_3 q)</i> , which constructs and returns the vector <i>q-p</i>
<i>ConvexHullTraits_3:: Equal_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q)</i> , which determines if points <i>p</i> and <i>q</i> are equal or not
<i>ConvexHullTraits_3:: Collinear_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which determines if points <i>p</i> , <i>q</i> and <i>r</i> are collinear or not
<i>ConvexHullTraits_3:: Coplanar_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s)</i> , which determines if points <i>p</i> , <i>q</i> , <i>r</i> , and <i>s</i> are coplanar or not
<i>ConvexHullTraits_3:: Has_on_positive_side_3</i>	Predicate object type that provides <i>bool operator()(Plane_3 h, Point_3 q)</i> , which determines if the point <i>q</i> is on the positive side of the halfspace <i>h</i>

<i>ConvexHullTraits_3:: Less_distance_to_point_3</i>	Predicate object type that provides a constructor taking a single <i>Point_3</i> object and <i>bool operator()(Point_3 q, Point_3 r)</i> , which returns true iff the distance from <i>q</i> to <i>p</i> is smaller than the distance from <i>r</i> to <i>p</i> , where <i>p</i> is the point passed to the object at construction.
--	---

<i>ConvexHullTraits_3:: Less_signed_distance_to_plane_3</i>	Predicate object type that provides <i>bool operator()(Plane_3 p, Point_3 q, Point_3 r)</i> , which returns true iff the signed distance from <i>q</i> to <i>p</i> is smaller than the signed distance from <i>r</i> to <i>p</i>
---	--

To handle the degenerate case when all points are coplanar, the following three types that are default-constructable are necessary:

<i>ConvexHullTraits_3:: Traits_xy</i>	A model of <i>ConvexHullTraits_2</i> for points projected into the <i>xy</i> -plane
---------------------------------------	---

<i>ConvexHullTraits_3:: Traits_xz</i>	A model of <i>ConvexHullTraits_2</i> for points projected into the <i>xz</i> -plane
---------------------------------------	---

<i>ConvexHullTraits_3:: Traits_yz</i>	A model of <i>ConvexHullTraits_2</i> for points projected into the <i>yz</i> -plane
---------------------------------------	---

One also needs the following function object to help choose which of the above traits classes to use:

<i>ConvexHullTraits_3:: Max_coordinate_3</i>	Function object type that provides <i>int operator()(Vector_3 v)</i> , which returns the index (0, 1, or 2 for <i>x</i> , <i>y</i> , or <i>z</i> , respectively) of the coordinate of <i>v</i> with maximum absolute value.
--	---

These types need not be provided when it is known that the points are not all coplanar.

## Creation

Only a copy constructor is required.

```
ConvexHullTraits_3 traits( & ch);
```

## Operations

For each of the above function and predicate object types, *Func\_obj\_type*, a function must exist with the name *func\_obj\_type\_object* that creates an instance of the function or predicate object type. For example:

```
Construct_plane_3 traits.construct_plane_3_object()
```

## Has Models

*CGAL::Convex\_hull\_traits\_3<R>* ..... [page 1130](#)

## CGAL::Convex\_hull\_traits\_3<R>

### Definition

The class *Convex\_hull\_traits\_3<R>* serves as a traits class for the function *convex\_hull\_3*. This is the default traits class for this function.

```
#include <CGAL/Convex_hull_traits_3.h>
```

### Is Model for the Concepts

## See Also

*CGAL::convex\_hull\_2* ..... [page 1093](#)

## CGAL::is\_strongly\_convex\_3

### Definition

The function *is\_strongly\_convex\_3* determines if the vertices of a given polyhedron represents a strongly convex set of points or not. A set of points is said to be strongly convex if it consists of only extreme points (*i.e.*, vertices of the convex hull).

```
#include <CGAL/convexity_check_3.h>
```

```
template<class Polyhedron_3, class Traits>
bool is_strongly_convex_3( Polyhedron_3& P, Traits traits = Default_traits)
```

determines if the set of vertices of the polyhedron *P* represent a strongly convex set of points or not.

*Precondition:* The equations of the facet planes of the polyhedron must have already been computed.

The default traits class is the kernel in which the type *Polyhedron\_3::Point\_3* is defined.

### Requirements

1. *Polyhedron\_3::Point\_3* is equivalent to *Traits::Point\_3*.
2. *Traits* is a model of the concept *IsStronglyConvexTraits\_3*
3. *Polyhedron\_3* must define the following types:

- *Polyhedron\_3::Facet\_iterator*
- *Polyhedron\_3::Vertex\_iterator*

and the following member functions:

- *facets\_begin()*
- *facets\_end()*
- *vertices\_begin()*
- *vertices\_end()*

The vertex type of *Polyhedron\_3* must be a model of *ConvexHullPolyhedronVertex\_3*; the facet type must be *ConvexHullPolyhedronFacet\_3*.

### See Also

*CGAL::is\_ccw\_strongly\_convex\_2* ..... page [1102](#)  
*CGAL::is\_cw\_strongly\_convex\_2* ..... page [1103](#)

### Implementation

This function implements the tests described in [MNS<sup>+</sup>96] to determine convexity and requires  $O(e + f)$  time for a polyhedron with  $e$  edges and  $f$  faces.

## IsStronglyConvexTraits\_3

### Definition

Requirements of the traits class used by the function *is\_strongly\_convex\_3*, which is used for postcondition checking by *convex\_hull\_3*.

### Types

<i>IsStronglyConvexTraits_3:: Plane_3</i>	a 3D plane
<i>IsStronglyConvexTraits_3:: Point_3</i>	a 3D point
<i>IsStronglyConvexTraits_3:: Ray_3</i>	a 3D ray
<i>IsStronglyConvexTraits_3:: Triangle_3</i>	a 3D triangle
<i>IsStronglyConvexTraits_3:: Construct_ray_3</i>	Function object type that provides <i>Ray_3 operator()(Point_3 p, Point_3 q)</i> , which constructs and returns the ray based at point <i>p</i> and passing through <i>q</i>
<i>IsStronglyConvexTraits_3:: Construct_triangle_3</i>	Function object type that provides <i>Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r)</i> , which constructs and returns the triangle with vertices <i>p</i> , <i>q</i> , and <i>r</i>
<i>IsStronglyConvexTraits_3:: Coplanar_3</i>	Predicate object type that provides <i>bool operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s)</i> , which determines if points <i>p</i> , <i>q</i> , <i>r</i> , and <i>s</i> are coplanar or not
<i>IsStronglyConvexTraits_3:: Do_intersect_3</i>	Function object type that provides <i>CGAL::Object operator()(Triangle_3 t, Ray_3 r)</i> , which returns <i>true</i> iff <i>t</i> and <i>r</i> intersect.
<i>IsStronglyConvexTraits_3:: Has_on_positive_side_3</i>	Predicate object type that provides <i>bool operator()(Plane_3 h, Point_3 q)</i> , which determines if the point <i>q</i> is on the positive side of the halfspace <i>h</i>
<i>IsStronglyConvexTraits_3:: Oriented_side_3</i>	Predicate object type that provides <i>Oriented_side operator()(Plane_3 p, Point_3 q)</i> , which determines the position of point <i>q</i> relative to plane <i>p</i>

### Creation

Only a copy constructor is required.

```
IsStronglyConvexTraits_3 traits( & t);
```

## Operations

For each of the above function and predicate object types, *Func\_obj\_type*, a function must exist with the name *func\_obj\_type\_object* that creates an instance of the function or predicate object type. For example:

*Construct\_ray\_3*                      *traits.construct\_ray\_3\_object()*

### 13.1 Introduction

A subset  $S \subseteq \mathbb{R}^d$  is convex if for any two points  $p$  and  $q$  in the set the line segment with endpoints  $p$  and  $q$  is contained in  $S$ . The convex hull of a set  $S$  is the smallest convex set containing  $S$ . The convex hull of a set of points  $P$  is a convex polytope with vertices in  $P$ . A point in  $P$  is an extreme point (with respect to  $P$ ) if it is a vertex of the convex hull of  $P$ . A set of points is said to be strongly convex if it consist of only extreme points.

This chapter describes the class provided in CGAL for producing convex hull in arbitrary dimensions. There is an intimate relationship between the Delaunay triangulation of a point set  $S$  and the convex hull of  $\text{lift}(S)$ : The nearest site Delaunay triangulation is the projection of the lower hull and the furthest site Delaunay triangulation is the upper hull. Here we also describe the companion class to the convex hull class that computes nearest and furthest site Delaunay triangulations.

### 13.2 dD Convex Hull

The class `CGAL::Convex_hull_d<R>` is used to represent the convex hull of a set of points in  $d$ -dimensional space. This class supports incremental construction of hulls, and provides a rich interface for exploration. There are also output routines for hulls of dimension 2 and 3.

The convex hull class is parameterized by a traits class that provides  $d$ -dimensional data types and predicates. The class *Convex\_hull\_d\_traits\_3* adapts any low-dimensional standard kernel model *e.g.*, *Homogeneous<RT>* or *Cartesian<FT>* for use with *Convex\_hull\_d*, where the dimension is fixed to three. The validity of the computed convex hull can be checked using the member function *is\_valid*, which implements the algorithm of Mehlhorn *et al.* [MNS<sup>+</sup>96] to determine if the vertices of a given polytope constitute a strongly convex point set or not.

The implementation follows the papers [CMS93] and [BMS94].

### 13.3 Delaunay Triangulation

There is a class type with a thorough interface providing the construction and exploration of closest and furthest site Delaunay simplicial complexes in arbitrary higher dimension. The class *CGAL::Delaunay\_d<R, Lifted\_R>* provides an implementation via the lifting map to higher dimensional convex hulls.. The class supports incremental construction of Delaunay triangulations and various kind of query operations (in particular, nearest and furthest neighbor queries and range queries with spheres and simplices).

# dD Convex Hulls and Delaunay Triangulations Reference Manual

*Susan Hert and Michael Seel*

A subset  $S \subseteq \mathbb{R}^3$  is convex if for any two points  $p$  and  $q$  in the set the line segment with endpoints  $p$  and  $q$  is contained in  $S$ . The convex hull of a set  $S$  is the smallest convex set containing  $S$ . The convex hull of a set of points  $P$  is a convex polytope with vertices in  $P$ . A point in  $P$  is an extreme point (with respect to  $P$ ) if it is a vertex of the convex hull of  $P$ .

CGAL provides functions for computing convex hulls in two, three and arbitrary dimensions as well as functions for testing if a given set of points is strongly convex or not. This chapter describes the class available for arbitrary dimensions and its companion class for computing the nearest and furthest side Delaunay triangulation.

## ConvexHullTraits\_d

### Definition

Requirements of the traits class to be used with the class *Convex\_hull\_d*.

### Types

<i>ConvexHullTraits_d:: Point_d</i>	the dD point type on which the convex hull algorithm operates
<i>ConvexHullTraits_d:: Hyperplane_d</i>	a dD plane
<i>ConvexHullTraits_d:: Vector_d</i>	a dD vector
<i>ConvexHullTraits_d:: Ray_d</i>	a dD ray
<i>ConvexHullTraits_d:: RT</i>	an arithmetic ring type
<i>ConvexHullTraits_d:: Construct_vector_d</i>	Function object type that provides <i>Vector_d operator()(int d, CGAL::Null_vector)</i> , which constructs and returns the null vector.
<i>ConvexHullTraits_d:: Construct_hyperplane_d</i>	Function object type that provides <i>Hyperplane_d operator()(ForwardIterator first, ForwardIterator last, Point_d p, CGAL::Oriented_side side)</i> , which constructs and returns a hyperplane passing through the points in <i>tuple[first,last)</i> and oriented such that <i>p</i> is on the side <i>side</i> of the returned hyperplane. When <i>side==ON_ORIENTED_BOUNDARY</i> then any hyperplane containing the tuple is returned.
<i>ConvexHullTraits_d:: Vector_to_point_d</i>	Function object type that provides <i>Point_d operator()(Vector_d v)</i> , which constructs and returns the point defined by $0 + v$ .
<i>ConvexHullTraits_d:: Point_to_vector_d</i>	Function object type that provides <i>Vector_d operator()(Point_d v)</i> , which constructs and returns the vector defined by $p - 0$ .
<i>ConvexHullTraits_d:: Orientation_d</i>	Function object type that provides <i>Orientation operator()(ForwardIterator first, ForwardIterator last)</i> , which determines the orientation of the points <i>tuple[first,last)</i> .
<i>ConvexHullTraits_d:: Orthogonal_vector_d</i>	Function object type that provides <i>Vector_d operator()(Hyperplane_d h)</i> , which constructs and returns a vector orthogonal to <i>h</i> and pointing from the boundary into its positive halfspace.
<i>ConvexHullTraits_d:: Oriented_side_d</i>	Predicate object type that provides <i>Oriented_side operator()(Hyperplane_d h, Point_d p)</i> , which determines the oriented side of <i>p</i> with respect to <i>h</i> .

<i>ConvexHullTraits_d:: Has_on_positive_side_d</i>	Predicate object type that provides <i>bool operator()(Hyperplane_d h, Point_d p)</i> , which return true iff <i>p</i> lies in the positive halfspace determined by <i>h</i> .
<i>ConvexHullTraits_d:: Affinely_independent_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last)</i> , which determines if the points <i>tuple[first,last)</i> are affinely independent.
<i>ConvexHullTraits_d:: Contained_in_simplex_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the closed simplex defined by the points in <i>tuple[first,last)</i> .
<i>ConvexHullTraits_d:: Contained_in_affined_hull_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the affine hull of the points in <i>tuple[first,last)</i> .
<i>ConvexHullTraits_d:: Intersect_d</i>	Predicate object type that provides <i>Object operator()(Ray_d r, Hyperplane_d h)</i> , which determines if <i>r</i> and <i>h</i> intersect and returns the corresponding polymorphic object.

## Creation

A default constructor and copy constructor is required.

## Operations

For each of the above function and predicate object types, *Func\_obj\_type*, a function must exist with the name *func\_obj\_type\_object* that creates an instance of the function or predicate object type. For example:

*Construct\_vector\_d*                      *traits.construct\_vector\_d\_object()*

## CGAL::Convex\_hull\_d<R>

### Definition

An instance  $C$  of type *Convex\_hull\_d<R>* is the convex hull of a multi-set  $S$  of points in  $d$ -dimensional space. We call  $S$  the underlying point set and  $d$  or *dim* the dimension of the underlying space. We use  $d_{cur}$  to denote the affine dimension of  $S$ . The data type supports incremental construction of hulls.

The closure of the hull is maintained as a simplicial complex, i.e., as a collection of simplices. The intersection of any two is a face of both<sup>1</sup>. In the sequel we reserve the word simplex for the simplices of dimension  $d_{cur}$ . For each simplex there is a handle of type *Simplex\_handle* and for each vertex there is a handle of type *Vertex\_handle*. Each simplex has  $1 + d_{cur}$  vertices indexed from 0 to  $d_{cur}$ ; for a simplex  $s$  and an index  $i$ ,  $C.vertex(s,i)$  returns the  $i$ -th vertex of  $s$ . For any simplex  $s$  and any index  $i$  of  $s$  there may or may not be a simplex  $t$  opposite to the  $i$ -th vertex of  $s$ . The function  $C.opposite\_simplex(s,i)$  returns  $t$  if it exists and returns *Simplex\_handle()* (the undefined handle) otherwise. If  $t$  exists then  $s$  and  $t$  share  $d_{cur}$  vertices, namely all but the vertex with index  $i$  of  $s$  and the vertex with index  $C.index\_of\_vertex\_in\_opposite\_simplex(s,i)$  of  $t$ . Assume that  $t$  exists and let  $j = C.index\_of\_vertex\_in\_opposite\_simplex(s,i)$ . Then  $s = C.opposite\_simplex(t,j)$  and  $i = C.index\_of\_vertex\_in\_opposite\_simplex(t,j)$ .

The boundary of the hull is also a simplicial complex. All simplices in this complex have dimension  $d_{cur} - 1$ . For each boundary simplex there is a handle of type *Facet\_handle*. Each facet has  $d_{cur}$  vertices indexed from 0 to  $d_{cur} - 1$ . If  $d_{cur} > 1$  then for each facet  $f$  and each index  $i$ ,  $0 \leq i < d_{cur}$ , there is a facet  $g$  opposite to the  $i$ -th vertex of  $f$ . The function  $C.opposite\_facet(f,i)$  returns  $g$ . Two neighboring facets  $f$  and  $g$  share  $d_{cur} - 1$  vertices, namely all but the vertex with index  $i$  of  $f$  and the vertex with index  $C.index\_of\_vertex\_in\_opposite\_facet(f,i)$  of  $g$ . Let  $j = C.index\_of\_vertex\_in\_opposite\_facet(f,i)$ . Then  $f = C.opposite\_facet(g,j)$  and  $i = C.index\_of\_vertex\_in\_opposite\_facet(g,j)$ .

### Types

<i>Convex_hull_d&lt;R&gt;:: R</i>	the representation class.
<i>Convex_hull_d&lt;R&gt;:: Point_d</i>	the point type.
<i>Convex_hull_d&lt;R&gt;:: Hyperplane_d</i>	the hyperplane type.
<i>Convex_hull_d&lt;R&gt;:: Simplex_handle</i>	handle for simplices.
<i>Convex_hull_d&lt;R&gt;:: Facet_handle</i>	handle for facets.
<i>Convex_hull_d&lt;R&gt;:: Vertex_handle</i>	handle for vertices.
<i>Convex_hull_d&lt;R&gt;:: Simplex_iterator</i>	iterator for simplices.
<i>Convex_hull_d&lt;R&gt;:: Facet_iterator</i>	iterator for facets.
<i>Convex_hull_d&lt;R&gt;:: Vertex_iterator</i>	iterator for vertices.

<sup>1</sup>The empty set if a facet of every simplex.

<i>Convex_hull_d&lt;R&gt;::Hull_vertex_iterator</i>	iterator for vertices that are part of the convex hull.
---	---

Note that each iterator fits the handle concept, i.e. iterators can be used as handles. Note also that all iterator and handle types come also in a const flavor, e.g., *Vertex\_const\_iterator* is the constant version of *Vertex\_iterator*. Const correctness requires to use the const version whenever the convex hull object is referenced as constant. The *Hull\_vertex\_iterator* is convertible to *Vertex\_iterator* and *Vertex\_handle*.

*Convex\_hull\_d<R>::Point\_const\_iterator*     const iterator for all inserted points.

$$\text{Convex\_hull\_d}\langle R \rangle :: \text{Hull\_point\_const\_iterator}$$

const iterator for all points that are part of the convex hull.

## Creation

$$Convex\_hull\_d\langle R \rangle \quad C(\text{int } d, R \text{ Kernel} = R());$$

creates an instance  $C$  of type *Convex.hull.d*. The dimension of the underlying space is  $d$  and  $S$  is initialized to the empty point set. The traits class  $R$  specifies the models of all types and the implementations of all geometric primitives used by the convex hull class. The default model is one of the  $d$ -dimensional representation classes (e.g., *Homogeneous\_d*).

The data type *Convex\_hull\_d* offers neither copy constructor nor assignment operator.

## Requirements

$R$  is a model of the concept *ConvexHullTraits\_d*.

## Operations

All operations below that take a point  $x$  as argument have the common precondition that  $x$  is a point of ambient space.

<i>int</i>	<i>C.dimension()</i>
------------	----------------------

returns the dimension of ambient space

```
int C.current_dimension()
```

returns the affine dimension  $d_{cur}$  of  $S$ .

<i>Point_d</i>	<i>C.associated_point( Vertex_handle v )</i>
----------------	--

returns the point associated with vertex  $v$ .

<i>Vertex_handle</i>	<i>C.vertex_of_simplex( Simplex_handle s, int i)</i>	<p>returns the vertex corresponding to the <math>i</math>-th vertex of <math>s</math>.</p> <p><i>Precondition:</i> <math>0 \leq i \leq dcur</math>.</p>
<i>Point_d</i>	<i>C.point_of_simplex( Simplex_handle s, int i)</i>	<p>same as <i>C.associated_point(C.vertex_of_simplex(s,i))</i>.</p>
<i>Simplex_handle</i>	<i>C.opposite_simplex( Simplex_handle s, int i)</i>	<p>returns the simplex opposite to the <math>i</math>-th vertex of <math>s</math> (<i>Simplex_handle()</i> if there is no such simplex).</p> <p><i>Precondition:</i> <math>0 \leq i \leq dcur</math>.</p>
<i>int</i>	<i>C.index_of_vertex_in_opposite_simplex( Simplex_handle s, int i)</i>	<p>returns the index of the vertex opposite to the <math>i</math>-th vertex of <math>s</math>.</p> <p><i>Precondition:</i> <math>0 \leq i \leq dcur</math> and there is a simplex opposite to the <math>i</math>-th vertex of <math>s</math>.</p>
<i>Simplex_handle</i>	<i>C.simplex( Vertex_handle v)</i>	<p>returns a simplex of which <math>v</math> is a node. Note that this simplex is not unique.</p>
<i>int</i>	<i>C.index( Vertex_handle v)</i>	<p>returns the index of <math>v</math> in <i>simplex(v)</i>.</p>
<i>Vertex_handle</i>	<i>C.vertex_of_facet( Facet_handle f, int i)</i>	<p>returns the vertex corresponding to the <math>i</math>-th vertex of <math>f</math>.</p> <p><i>Precondition:</i> <math>0 \leq i &lt; dcur</math>.</p>
<i>Point_d</i>	<i>C.point_of_facet( Facet_handle f, int i)</i>	<p>same as <i>C.associated_point(C.vertex_of_facet(f,i))</i>.</p>
<i>Facet_handle</i>	<i>C.opposite_facet( Facet_handle f, int i)</i>	<p>returns the facet opposite to the <math>i</math>-th vertex of <math>f</math> (<i>Facet_handle()</i> if there is no such facet).</p> <p><i>Precondition:</i> <math>0 \leq i &lt; dcur</math> and <math>dcur &gt; 1</math>.</p>

<i>int</i>	<i>C.index_of_vertex_in_opposite_facet( Facet_handle f, int i)</i>  returns the index of the vertex opposite to the $i$ -th vertex of $f$ . <i>Precondition:</i> $0 \leq i < dcur$ and $dcur > 1$ .
<i>Hyperplane_d</i>	<i>C.hyperplane_supporting( Facet_handle f)</i>  returns a hyperplane supporting facet $f$ . The hyperplane is oriented such that the interior of $C$ is on the negative side of it. <i>Precondition:</i> $f$ is a facet of $C$ and $dcur > 1$ .
<i>Vertex_handle</i>	<i>C.insert( Point_d x)</i>  adds point $x$ to the underlying set of points. If $x$ is equal to (the point associated with) a vertex of the current hull this vertex is returned and its associated point is changed to $x$ . If $x$ lies outside the current hull, a new vertex $v$ with associated point $x$ is added to the hull and returned. In all other cases, i.e., if $x$ lies in the interior of the hull or on the boundary but not on a vertex, the current hull is not changed and <i>Vertex_handle()</i> is returned. If <i>CGAL_CHECK_EXPENSIVE</i> is defined then the validity check <i>is_valid(true)</i> is executed as a post condition.
<i>template &lt;typename Forward_iterator&gt;</i> <i>void</i>	<i>C.insert( Forward_iterator first, Forward_iterator last)</i>  adds $S = set [first, last)$ to the underlying set of points. If any point $S[i]$ is equal to (the point associated with) a vertex of the current hull its associated point is changed to $S[i]$ .
<i>bool</i>	<i>C.is_dimension_jump( Point_d x)</i>  returns true if $x$ is not contained in the affine hull of $S$ .
<i>std::list&lt;Facet_handle&gt;</i>	<i>C.facets_visible_from( Point_d x)</i>  returns the list of all facets that are visible from $x$ .  <i>Precondition:</i> $x$ is contained in the affine hull of $S$ .
<i>Bounded_side</i>	<i>C.bounded_side( Point_d x)</i>  returns <i>ON_BOUNDED_SIDE</i> ( <i>ON_BOUNDARY</i> , <i>ON_UNBOUNDED_SIDE</i> ) if $x$ is contained in the interior (lies on the boundary, is contained in the exterior) of $C$ . <i>Precondition:</i> $x$ is contained in the affine hull of $S$ .

<i>void</i>	<i>C.clear( int d)</i>	re-initializes <i>C</i> to an empty hull in <i>d</i> -dimensional space.
<i>int</i>	<i>C.number_of_vertices()</i>	returns the number of vertices of <i>C</i> .
<i>int</i>	<i>C.number_of_facets()</i>	returns the number of facets of <i>C</i> .
<i>int</i>	<i>C.number_of_simplices()</i>	returns the number of bounded simplices of <i>C</i> .
<i>void</i>	<i>C.print_statistics()</i>	gives information about the size of the current hull and the number of visibility tests performed.
<i>bool</i>	<i>C.is_valid( bool throw_exceptions = false)</i>	checks the validity of the data structure. If <i>throw_exceptions == true</i> then the program throws the following exceptions to inform about the problem. <i>chull_has_center_on_wrong_side_of_hull_facet</i> the hyperplane supporting a facet has the wrong orientation. <i>chull_has_local_non_convexity</i> a ridge is locally non convex. <i>chull_has_double_coverage</i> the hull has a winding number larger than 1.

## Lists and Iterators

<i>Vertex_iterator</i>	<i>C.vertices_begin()</i>	an iterator of <i>C</i> to start the iteration over all vertices of the complex.
<i>Vertex_iterator</i>	<i>C.vertices_end()</i>	the past the end iterator for vertices.
<i>Simplex_iterator</i>	<i>C.simplices_begin()</i>	an iterator of <i>C</i> to start the iteration over all simplices of the complex.
<i>Simplex_iterator</i>	<i>C.simplices_end()</i>	the past the end iterator for simplices.
<i>Facet_iterator</i>	<i>C.facets_begin()</i>	an iterator of <i>C</i> to start the iteration over all facets of the complex.

<i>Facet_iterator</i>	<i>C.facets_end()</i>	the past the end iterator for facets.
<i>Hull_vertex_iterator</i>	<i>C.hull_vertices_begin()</i>	
		an iterator to start the iteration over all vertices of <i>C</i> that are part of the convex hull.
<i>Hull_vertex_iterator</i>	<i>C.hull_vertices_end()</i>	the past the end iterator for hull vertices.
<i>Point_const_iterator</i>	<i>C.points_begin()</i>	returns the start iterator for all points that have been inserted to construct <i>C</i> .
<i>Point_const_iterator</i>	<i>C.points_end()</i>	returns the past the end iterator for points.
<i>Hull_point_const_iterator</i>	<i>C.hull_points_begin()</i>	
		returns an iterator to start the iteration over all points in the convex hull <i>C</i> . Included are points in the interior of facets.
<i>Hull_point_const_iterator</i>	<i>C.hull_points_end()</i>	returns the past the end iterator for points in the convex hull.
<i>template &lt;typename Visitor&gt;</i> <i>void</i>	<i>C.visit_all_facets( Visitor V)</i>	each facet of <i>C</i> is visited by the visitor object <i>V</i> . <i>V</i> has to have a function call operator: <i>void operator()(Facet_handle) const</i>
<i>std::list&lt;Point_d&gt;</i>	<i>C.all_points()</i>	returns a list of all points that have been inserted to construct <i>C</i> .
<i>std::list&lt;Vertex_handle&gt;</i>	<i>C.all_vertices()</i>	returns a list of all vertices of <i>C</i> (also interior ones).
<i>std::list&lt;Simplex_handle&gt;</i>	<i>C.all_simplices()</i>	returns a list of all simplices in <i>C</i> .
<i>std::list&lt;Facet_handle&gt;</i>	<i>C.all_facets()</i>	returns a list of all facets of <i>C</i> .

## Iteration Statements

**forall\_ch\_vertices**( $v, C$ ) { “the vertices of  $C$  are successively assigned to  $v$ ” }

**forall\_ch\_simplices**( $s, C$ ) { “the simplices of  $C$  are successively assigned to  $s$ ” }

**forall\_ch\_facets**( $f, C$ ) { “the facets of  $C$  are successively assigned to  $f$ ” }

## Implementation

The implementation of type *Convex\_hull\_d* is based on [CMS93] and [BMS94]. The details of the implementation can be found in the implementation document available at the download site of this package.

The time and space requirements are input dependent. Let  $C_1, C_2, C_3, \dots$  be the sequence of hulls constructed and for a point  $x$  let  $k_i$  be the number of facets of  $C_i$  that are visible from  $x$  and that are not already facets of  $C_{i-1}$ . Then the time for inserting  $x$  is  $O(\dim \sum_i k_i)$  and the number of new simplices constructed during the insertion of  $x$  is the number of facets of the hull which were not already facets of the hull before the insertion.

The data type *Convex\_hull\_d* is derived from *Regular\_complex\_d*. The space requirement of regular complexes is essentially  $12(\dim + 2)$  bytes times the number of simplices plus the space for the points. *Convex\_hull\_d* needs an additional  $8 + (4 + x)\dim$  bytes per simplex where  $x$  is the space requirement of the underlying number type and an additional 12 bytes per point. The total is therefore  $(16 + x)\dim + 32$  bytes times the number of simplices plus  $28 + x \cdot \dim$  bytes times the number of points.

## Low Dimensional Conversion Routine

```
include <CGAL/Convex_hull_d_to_polyhedron_3.h>
```

```
template <class R, class T, class HDS>
```

```
void convex_hull_d_to_polyhedron_3( C, Polyhedron_3<T,HDS>& P)
```

converts the convex hull  $C$  to polyhedral surface stored in  $P$ .

*Precondition:*  $\dim == 3$  and  $dcur == 3$ .

## Low Dimensional Output Routines

```
template <class R>
```

```
void d3_surface_map( C, GRAPH< typename ::Point_d,int>& G)
```

constructs the representation of the surface of  $C$  as a bidirected LEDA graph  $G$ .

*Precondition:*  $\dim == 3$ .

## CGAL::Convex\_hull\_d\_traits\_3<R>

### Definition

The class *Convex\_hull\_d\_traits\_3<R>* serves as a traits class for the class *Convex\_hull\_d*. This is a traits class that adapts any low-dimensional standard kernel model, e.g. *Homogeneous<RT>* or *Cartesian<FT>* for the fixed 3-dimensional usage of *Convex\_hull\_d*.

```
#include <CGAL/Convex_hull_d_traits_3.h>
```

### Is Model for the Concepts

*ConvexHullTraits\_d*

### Creation

*Convex\_hull\_d\_traits\_3<R>* traits;                      default constructor.

## DelaunayLiftedTraits\_d

### Definition

Requirements of the second traits class to be used with the class *Delaunay\_d*.

### Types

<i>DelaunayLiftedTraits_d:: Point_d</i>	the dD point type on which the Delaunay algorithm operates
<i>DelaunayLiftedTraits_d:: Hyperplane_d</i>	a dD plane
<i>DelaunayLiftedTraits_d:: Vector_d</i>	a dD vector
<i>DelaunayLiftedTraits_d:: Ray_d</i>	a dD ray
<i>DelaunayLiftedTraits_d:: RT</i>	a arithmetic ring type
<i>DelaunayLiftedTraits_d:: Construct_vector_d</i>	Function object type that provides <i>Vector_d operator()(int d, CGAL::Null_vector)</i> , which constructs and returns the null vector.
<i>DelaunayLiftedTraits_d:: Construct_hyperplane_d</i>	Function object type that provides <i>Hyperplane_d operator()(ForwardIterator first, ForwardIterator last, Point_d p, CGAL::Oriented_side side)</i> , which constructs and returns a hyperplane passing through the points in <i>tuple[first,last)</i> and oriented such that <i>p</i> is on the side <i>side</i> of the returned hyperplane. When <i>side==ON_ORIENTED_BOUNDARY</i> then any hyperplane containing the tuple is returned.
<i>DelaunayLiftedTraits_d:: Vector_to_point_d</i>	Function object type that provides <i>Point_d operator()(Vector_d v)</i> , which constructs and returns the point defined by $0 + v$ .
<i>DelaunayLiftedTraits_d:: Point_to_vector_d</i>	Function object type that provides <i>Vector_d operator()(Point_d p)</i> , which constructs and returns the vector defined by $p - 0$ .
<i>DelaunayLiftedTraits_d:: Orientation_d</i>	Function object type that provides <i>Orientation operator()(ForwardIterator first, ForwardIterator last)</i> , which determines the orientation of the points <i>tuple[first,last)</i> .
<i>DelaunayLiftedTraits_d:: Orthogonal_vector_d</i>	Function object type that provides <i>Vector_d operator()(Hyperplane_d h)</i> , which constructs and returns a vector orthogonal to <i>h</i> and pointing from the boundary into its positive halfspace.
<i>DelaunayLiftedTraits_d:: Oriented_side_d</i>	Predicate object type that provides <i>Oriented_side operator()(Hyperplane_d h, Point_d p)</i> , which determines the oriented side of <i>p</i> with respect to <i>h</i> .

<i>DelaunayLiftedTraits_d:: Has_on_positive_side_d</i>	Predicate object type that provides <i>bool operator()(Hyperplane_d h, Point_d p)</i> , which return true iff <i>p</i> lies in the positive halfspace determined by <i>h</i> .
<i>DelaunayLiftedTraits_d:: Affinely_independent_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last)</i> , which determines if the points <i>tuple[first,last)</i> are affinely independent.
<i>DelaunayLiftedTraits_d:: Contained_in_simplex_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the closed simplex defined by the points in <i>tuple[first,last)</i> .
<i>DelaunayLiftedTraits_d:: Contained_in_affined_hull_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the affine hull of the points in <i>tuple[first,last)</i> .
<i>DelaunayLiftedTraits_d:: Intersect_d</i>	Predicate object type that provides <i>Object operator()(Ray_d r, Hyperplane_d h)</i> , which determines if <i>r</i> and <i>h</i> intersect and returns the corresponding polymorphic object.
The previous requirements are all identical to the concept <i>ConvexHullTraits_d</i> . The Delaunay class adds the following requirements.	
<i>DelaunayLiftedTraits_d:: Project_along_d_axis_d</i>	Predicate object type that provides <i>DelaunayTraits_d::Point_d operator()(Point_d p)</i> , which determines the $d - 1$ -dimensional point from the $d$ -dimensional point <i>p</i> while discarding the last coordinate.
<i>DelaunayLiftedTraits_d:: Lift_to_paraboloid_d</i>	Predicate object type that provides <i>Point_d operator()(DelaunayTraits_d::Point_d p)</i> , which determines the $d$ -dimensional point from the $d - 1$ -dimensional point <i>p</i> while lifting it to the paraboloid of revolution.
<i>DelaunayLiftedTraits_d:: Component_accessor_d</i>	Predicate object type that provides <i>RT homogeneous(Vector_d v,int i)</i> and <i>int dimension(Vector_d v)</i> , where the former determines the <i>i</i> th coordinate of <i>v</i> and the latter the dimension of <i>v</i> .

## Creation

A default constructor and copy constructor is required.

## Operations

For each of the above function and predicate object types, *Func\_obj\_type*, a function must exist with the name *func\_obj\_type\_object* that creates an instance of the function or predicate object type. For example:

*Construct\_vector\_d*            *traits.construct\_vector\_d\_object()*

## Has Models

*CGAL::Homogeneous\_d<RT,LA>*

## DelaunayTraits\_d

### Definition

Requirements of the first traits class to be used with the class *Delaunay\_d*.

### Types

<i>DelaunayTraits_d:: Point_d</i>	the dD point type on which the Delaunay algorithm operates
<i>DelaunayTraits_d:: Sphere_d</i>	a dD sphere
<i>DelaunayTraits_d:: FT</i>	an arithmetic field type
<i>DelaunayTraits_d:: Point_of_sphere_d</i>	Predicate object type that provides <i>Point_d operator()(Sphere_d s, int i)</i> , which returns the <i>i</i> th point defining sphere <i>s</i> .
<i>DelaunayTraits_d:: Construct_sphere_d</i>	Predicate object type that provides <i>Sphere_d operator()(int d, ForwardIterator first, ForwardIterator last)</i> , which returns a dD sphere through the points in <i>tuple[first,last)</i> .
<i>DelaunayTraits_d:: Contained_in_simplex_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last, Point_d p)</i> , which determines if <i>p</i> is contained in the closed simplex defined by the points in <i>tuple[first,last)</i> .
<i>DelaunayTraits_d:: Squared_distance_d</i>	Predicate object type that provides <i>FT operator()(Point_d p, Point_d q)</i> , which determines the squared distance from <i>p</i> to <i>q</i> .
<i>DelaunayTraits_d:: Affinely_independent_d</i>	Predicate object type that provides <i>bool operator()(ForwardIterator first, ForwardIterator last)</i> , which determines if the points in <i>tuple[first,last)</i> are affinely independent.

### Creation

A default constructor and copy constructor is required.

### Operations

For each of the above function and predicate object types, *Func\_obj\_type*, a function must exist with the name *func\_obj\_type\_object* that creates an instance of the function or predicate object type. For example:

*Construct\_sphere\_d*      *traits.construct\_sphere\_d\_object()*

## Has Models

*CGAL::Cartesian\_d<FT,LA>*

*CGAL::Homogeneous\_d<RT,LA>*

## CGAL::Delaunay\_d< R, Lifted\_R >

### Definition

An instance *DT* of type *Delaunay\_d< R, Lifted\_R >* is the nearest and furthest site Delaunay triangulation of a set *S* of points in some *d*-dimensional space. We call *S* the underlying point set and *d* or *dim* the dimension of the underlying space. We use *dcur* to denote the affine dimension of *S*. The data type supports incremental construction of Delaunay triangulations and various kind of query operations (in particular, nearest and furthest neighbor queries and range queries with spheres and simplices).

A Delaunay triangulation is a simplicial complex. All simplices in the Delaunay triangulation have dimension *dcur*. In the nearest site Delaunay triangulation the circumsphere of any simplex in the triangulation contains no point of *S* in its interior. In the furthest site Delaunay triangulation the circumsphere of any simplex contains no point of *S* in its exterior. If the points in *S* are co-circular then any triangulation of *S* is a nearest as well as a furthest site Delaunay triangulation of *S*. If the points in *S* are not co-circular then no simplex can be a simplex of both triangulations. Accordingly, we view *DT* as either one or two collection(s) of simplices. If the points in *S* are co-circular there is just one collection: the set of simplices of some triangulation. If the points in *S* are not co-circular there are two collections. One collection consists of the simplices of a nearest site Delaunay triangulation and the other collection consists of the simplices of a furthest site Delaunay triangulation.

For each simplex of maximal dimension there is a handle of type *Simplex\_handle* and for each vertex of the triangulation there is a handle of type *Vertex\_handle*. Each simplex has  $1 + dcur$  vertices indexed from 0 to *dcur*. For any simplex *s* and any index *i*, *DT.vertex\_of(s,i)* returns the *i*-th vertex of *s*. There may or may not be a simplex *t* opposite to the vertex of *s* with index *i*. The function *DT.opposite\_simplex(s,i)* returns *t* if it exists and returns *Simplex\_handle()* otherwise. If *t* exists then *s* and *t* share *dcur* vertices, namely all but the vertex with index *i* of *s* and the vertex with index *DT.index\_of\_vertex\_in\_opposite\_simplex(s,i)* of *t*. Assume that *t = DT.opposite\_simplex(s,i)* exists and let *j = DT.index\_of\_vertex\_in\_opposite\_simplex(s,i)*. Then *s = DT.opposite\_simplex(t,j)* and *i = DT.index\_of\_vertex\_in\_opposite\_simplex(t,j)*. In general, a vertex belongs to many simplices.

Any simplex of *DT* belongs either to the nearest or to the furthest site Delaunay triangulation or both. The test *DT.simplex\_of\_nearest(dt\_simplex s)* returns true if *s* belongs to the nearest site triangulation and the test *DT.simplex\_of\_furthest(dt\_simplex s)* returns true if *s* belongs to the furthest site triangulation.

### Inherits From

*Convex\_hull\_d<Lifted\_R>*

### Types

<i>Delaunay_d&lt; R, Lifted_R &gt;:: Simplex_handle</i>	handles to the simplices of the complex.
<i>Delaunay_d&lt; R, Lifted_R &gt;:: Vertex_handle</i>	handles to vertices of the complex.
<i>Delaunay_d&lt; R, Lifted_R &gt;:: Point_d</i>	the point type
<i>Delaunay_d&lt; R, Lifted_R &gt;:: Sphere_d</i>	the sphere type

```
enum Delaunay_voronoi_kind { NEAREST, FURTHEST};
```

```
interface flags
```

To use these types you can typedef them into the global scope after instantiation of the class. We use *Vertex\_handle* instead of *Delaunay\_d< R, Lifted\_R >::Vertex\_handle* from now on. Similarly we use *Simplex\_handle*.

*Delaunay\_d< R, Lifted\_R >:: Point\_const\_iterator*    the iterator for points.

*Delaunay\_d< R, Lifted\_R >:: Vertex\_iterator*        the iterator for vertices.

*Delaunay\_d< R, Lifted\_R >:: Simplex\_iterator*       the iterator for simplices.

## Creation

```
Delaunay_d< R, Lifted_R > DT( int d, R k1 = R(), Lifted_R k2 = Lifted_R());
```

creates an instance *DT* of type *Delaunay\_d*. The dimension of the underlying space is *d* and *S* is initialized to the empty point set. The traits class *R* specifies the models of all types and the implementations of all geometric primitives used by the Delaunay class. The traits class *Lifted\_R* specifies the models of all types and the implementations of all geometric primitives used by the base class of *Delaunay\_d< R, Lifted\_R >*. The second template parameter defaults to the first: *Delaunay\_d<R> = Delaunay\_d<R, Lifted\_R = R >*.

The data type *Delaunay\_d* offers neither copy constructor nor assignment operator.

## Requirements

*R* is a model of the concept *DelaunayTraits\_d* . *Lifted\_R* is a model of the concept *DelaunayLiftedTraits\_d* .

## Operations

All operations below that take a point *x* as an argument have the common precondition that *x.dimension()* = *DT.dimension()*.

*int*                      *DT.dimension()*            returns the dimension of ambient space

*int*                      *DT.current\_dimension()*

returns the affine dimension of the current point set, i.e.,  $-1$  if *S* is empty, 0 if *S* consists of a single point, 1 if all points of *S* lie on a common line, etc.

*bool*                    *DT.is\_simplex\_of\_nearest( Simplex\_handle s)*

returns true if *s* is a simplex of the nearest site triangulation.

<i>bool</i>	<i>DT.is_simplex_of_furthest( Simplex_handle s)</i>	returns true if <i>s</i> is a simplex of the furthest site triangulation.
<i>Vertex_handle</i>	<i>DT.vertex_of_simplex( Simplex_handle s, int i)</i>	returns the vertex associated with the <i>i</i> -th node of <i>s</i> . <i>Precondition:</i> $0 \leq i \leq d_{cur}$ .
<i>Point_d</i>	<i>DT.associated_point( Vertex_handle v)</i>	returns the point associated with vertex <i>v</i> .
<i>Point_d</i>	<i>DT.point_of_simplex( Simplex_handle s, int i)</i>	returns the point associated with the <i>i</i> -th vertex of <i>s</i> . <i>Precondition:</i> $0 \leq i \leq d_{cur}$ .
<i>Simplex_handle</i>	<i>DT.opposite_simplex( Simplex_handle s, int i)</i>	returns the simplex opposite to the <i>i</i> -th vertex of <i>s</i> ( <i>Simplex_handle()</i> if there is no such simplex). <i>Precondition:</i> $0 \leq i \leq d_{cur}$ .
<i>int</i>	<i>DT.index_of_vertex_in_opposite_simplex( Simplex_handle s, int i)</i>	returns the index of the vertex opposite to the <i>i</i> -th vertex of <i>s</i> . <i>Precondition:</i> $0 \leq i \leq d_{cur}$ .
<i>Simplex_handle</i>	<i>DT.simplex( Vertex_handle v)</i>	returns a simplex of the nearest site triangulation incident to <i>v</i> .
<i>int</i>	<i>DT.index( Vertex_handle v)</i>	returns the index of <i>v</i> in <i>DT.simplex(v)</i> .
<i>bool</i>	<i>DT.contains( Simplex_handle s, Point_d x)</i>	returns true if <i>x</i> is contained in the closure of simplex <i>s</i> .
<i>bool</i>	<i>DT.empty()</i>	decides whether <i>DT</i> is empty.
<i>void</i>	<i>DT.clear()</i>	re-initializes <i>DT</i> to the empty Delaunay triangulation.

<i>Vertex_handle</i>	<i>DT.insert( Point_d x)</i>	inserts point $x$ into $DT$ and returns the corresponding <i>Vertex_handle</i> . More precisely, if there is already a vertex $v$ in $DT$ positioned at $x$ (i.e., <i>associated_point</i> ( $v$ ) is equal to $x$ ) then <i>associated_point</i> ( $v$ ) is changed to $x$ (i.e., <i>associated_point</i> ( $v$ ) is made identical to $x$ ) and if there is no such vertex then a new vertex $v$ with <i>associated_point</i> ( $v$ ) = $x$ is added to $DT$ . In either case, $v$ is returned.
<i>Simplex_handle</i>	<i>DT.locate( Point_d x)</i>	returns a simplex of the nearest site triangulation containing $x$ in its closure (returns <i>Simplex_handle</i> () if $x$ lies outside the convex hull of $S$ ).
<i>Vertex_handle</i>	<i>DT.lookup( Point_d x)</i>	if $DT$ contains a vertex $v$ with <i>associated_point</i> ( $v$ ) = $x$ the result is $v$ otherwise the result is <i>Vertex_handle</i> ().
<i>Vertex_handle</i>	<i>DT.nearest_neighbor( Point_d x)</i>	computes a vertex $v$ of $DT$ that is closest to $x$ , i.e., $\text{dist}(x, \text{associated\_point}(v)) = \min\{\text{dist}(x, \text{associated\_point}(u)) \mid u \in S\}.$
<i>std::list&lt;Vertex_handle&gt;</i>	<i>DT.range_search( Sphere_d C)</i>	returns the list of all vertices contained in the closure of sphere $C$ .
<i>std::list&lt;Vertex_handle&gt;</i>	<i>DT.range_search( std::vector&lt;Point_d&gt; A)</i>	returns the list of all vertices contained in the closure of the simplex whose corners are given by $A$ . <i>Precondition:</i> $A$ must consist of $d + 1$ affinely independent points in base space.
<i>std::list&lt;Simplex_handle&gt;</i>	<i>DT.all_simplices( Delaunay_voronoi_kind k = NEAREST)</i>	returns a list of all simplices of either the nearest or the furthest site Delaunay triangulation of $S$ .

*std::list<Vertex\_handle>*

*DT.all\_vertices( Delaunay\_voronoi\_kind k = NEAREST)*

returns a list of all vertices of either the nearest or the furthest site Delaunay triangulation of *S*.

*std::list<Point\_d>*

*DT.all\_points()*

returns *S*.

*Point\_const\_iterator*

*DT.points\_begin()*

returns the start iterator for points in *DT*.

*Point\_const\_iterator*

*DT.points\_end()*

returns the past the end iterator for points in *DT*.

*Simplex\_iterator*

*DT.simplices\_begin( Delaunay\_voronoi\_kind k = NEAREST)*

returns the start iterator for simplices of *DT*.

*Simplex\_iterator*

*DT.simplices\_end()*

returns the past the end iterator for simplices of *DT*.

## Implementation

The data type is derived from *Convex\_hull\_d* via the lifting map. For a point  $x$  in  $d$ -dimensional space let  $lift(x)$  be its lifting to the unit paraboloid of revolution. There is an intimate relationship between the Delaunay triangulation of a point set  $S$  and the convex hull of  $lift(S)$ : The nearest site Delaunay triangulation is the projection of the lower hull and the furthest site Delaunay triangulation is the upper hull. For implementation details we refer the reader to the implementation report available from the CGAL server.

The space requirement is the same as for convex hulls. The time requirement for an insert is the time to insert the lifted point into the convex hull of the lifted points.

## Example

The abstract data type *Delaunay\_d* has a default instantiation by means of the  $d$ -dimensional geometric kernel.

```
#include <CGAL/Homogeneous_d.h>
#include <CGAL/leda_integer.h>
#include <CGAL/Delaunay_d.h>

typedef leda_integer RT;
typedef CGAL::Homogeneous_d<RT> Kernel;
typedef CGAL::Delaunay_d<Kernel> Delaunay_d;
typedef Delaunay_d::Point_d Point;
typedef Delaunay_d::Simplex_handle Simplex_handle;
typedef Delaunay_d::Vertex_handle Vertex_handle;

int main()
{
    Delaunay_d T(2);
    Vertex_handle v1 = T.insert(Point_d(2,11));
    ...
}
```

## Traits requirements

*Delaunay\_d*< *R*, *Lifted\_R* > requires the following types from the kernel traits *Lifted\_R*:

RT Point\_d Vector\_d Ray\_d Hyperplane\_d

and uses the following function objects from the kernel traits:

Construct\_hyperplane\_d  
Construct\_vector\_d  
Vector\_to\_point\_d / Point\_to\_vector\_d  
Orientation\_d  
Orthogonal\_vector\_d  
Oriented\_side\_d / Has\_on\_positive\_side\_d  
Affinely\_independent\_d  
Contained\_in\_simplex\_d  
Contained\_in\_affine\_hull\_d  
Intersect\_d  
Lift\_to\_paraboloid\_d / Project\_along\_d\_axis\_d  
Component\_accessor\_d

*Delaunay\_d*< *R*, *Lifted\_R* > requires the following types from the kernel traits *R*:

FT Point\_d Sphere\_d

and uses the following function objects from the kernel traits *R*:

Construct\_sphere\_d  
Squared\_distance\_d  
Point\_of\_sphere\_d  
Affinely\_independent\_d  
Contained\_in\_simplex\_d

## Low Dimensional Output Routines

*template* <typename *R*, typename *Lifted\_R*>

*template* <typename *R*, typename *Lifted\_R*> void

*d2\_map*( *Delaunay\_d*<*R*,*Lifted\_R*> *D*,  
GRAPH< typename *Delaunay\_d*<*R*,*Lifted\_R*>::Point\_d, int >& *DTG*,  
typename *Delaunay\_d*<*R*,*Lifted\_R*>::Delaunay\_voronoi\_kind *k* = *Delaunay\_*  
*d*<*R*,*Lifted\_R*>::NEAREST)

constructs a LEDA graph representation of the nearest (*kind* = *NEAREST* or the furthest (*kind* = *FURTHEST*) site Delaunay triangulation.

*Precondition:* *dim()* == 2.

### 14.1 Introduction

A polygon is a closed chain of edges. Several algorithms are available for polygons. For some of those algorithms, it is necessary that the polygon is simple. A polygon is simple if edges don't intersect, except consecutive edges, which intersect in their common vertex.

The following algorithms are available:

- find the leftmost, rightmost, topmost and bottommost vertex.
- compute the (signed) area.
- check if a polygon is simple.
- check if a polygon is convex.
- find the orientation (clockwise or counterclockwise)
- check if a point lies inside a polygon.

All those operations take two forward iterators as parameters in order to describe the polygon. These parameters have a point type as value type.

The type *Polygon\_2* can be used to represent polygons. Polygons are dynamic. Vertices can be modified, inserted and erased. They provide the algorithms described above as member functions. Moreover, they provide ways of iterating over the vertices and edges.

Currently, the *Polygon\_2* class is a nice wrapper around a container of points, but little more. Especially, computed values are not cached. That is, when the *is\_simple()* member function is called twice or more, the result is computed each time anew.

## 14.2 Example

The following code fragment creates a polygon and does some checks.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Polygon_2.h>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;
typedef CGAL::Polygon_2<K> Polygon_2;
using std::cout; using std::endl;

int main()
{
    Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6) };
    Polygon_2 pgn(points, points+4);

    // check if the polygon is simple.
    cout << "The polygon is " <<
        (pgn.is_simple() ? "" : "not ") << "simple." << endl;

    // check if the polygon is convex
    cout << "The polygon is " <<
        (pgn.is_convex() ? "" : "not ") << "convex." << endl;

    return 0;
}
```

**File:** examples/Polygon/Polygon.cpp

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Polygon_2_algorithms.h>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;
using std::cout; using std::endl;

void check_inside(Point pt, Point *pgn_begin, Point *pgn_end, K traits)
{
    cout << "The point " << pt;
    switch(CGAL::bounded_side_2(pgn_begin, pgn_end, pt, traits)) {
        case CGAL::ON_BOUNDED_SIDE :
```

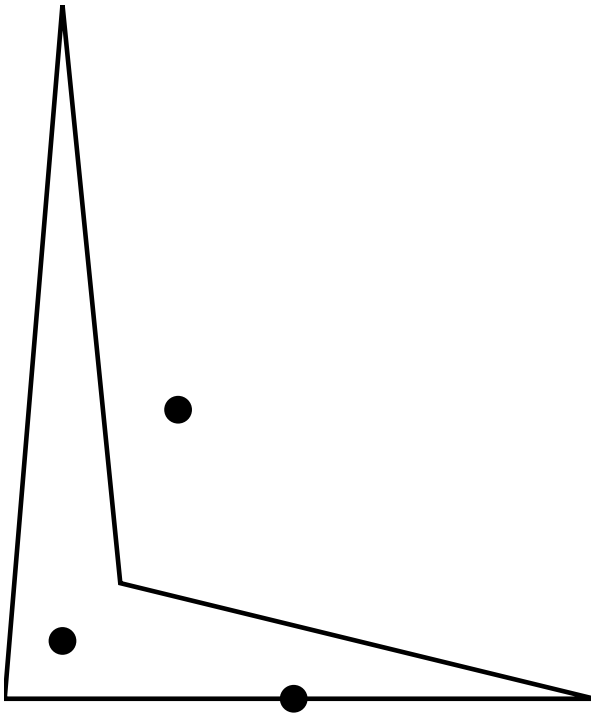

Figure 14.1: A polygon and some points

```

        cout << " is inside the polygon.\n";
        break;
    case CGAL::ON_BOUNDARY:
        cout << " is on the polygon boundary.\n";
        break;
    case CGAL::ON_UNBOUNDED_SIDE:
        cout << " is outside the polygon.\n";
        break;
    }
}

int main()
{
    Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6) };

    // check if the polygon is simple.
    cout << "The polygon is "
        << (CGAL::is_simple_2(points, points+4, K()) ? "" : "not ")
        << "simple." << endl;

    check_inside(Point(0.5, 0.5), points, points+4, K());
    check_inside(Point(1.5, 2.5), points, points+4, K());
    check_inside(Point(2.5, 0), points, points+4, K());

    return 0;
}

```

## CGAL::area\_2

### Definition

The function *area\_2* computes the signed area of a polygon.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
void      area_2( ForwardIterator first,
                  ForwardIterator last,
                  typename Traits::FT &result,
                  Traits traits)
```

Computes the signed area of the polygon defined by the range of points *first* ... *last*. The area is returned in the parameter *result*. The sign is positive for counterclockwise polygons, negative for clockwise polygons. If the polygon is not simple, the area is not well defined. The functionality is also available by the *polygon\_area\_2* function, which returns the area instead of taking it as a parameter.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. Only the following members of this traits class are used:
  - *Compute\_area\_2* : Computes the signed area of the oriented triangle defined by 3 *Point\_2* passed as arguments.
  - *FT*
  - *compute\_area\_2\_object()*
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

### See Also

*PolygonTraits\_2* ..... page [1178](#)  
*CGAL::orientation\_2* ..... page [1176](#)  
*CGAL::Polygon\_2<PolygonTraits\_2, Container>* ..... page [1180](#)

## CGAL::bbox\_2

### Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class InputIterator, class Traits>
Bbox_2          bbox_2( InputIterator first, InputIterator last, Traits traits)
```

Returns the bounding box of the range  $[first, last)$ .

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. In fact, only the members *Construct\_bbox\_2* and *construct\_bbox\_2\_object()* are used.
2. The value type of *InputIterator* must be *Traits::Point\_2*,

### See Also

*CGAL::Polygon\_2*<*PolygonTraits\_2*, *Container*> ..... [page 1180](#)

## CGAL::bottom\_vertex\_2

### Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator bottom_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the bottommost point from the range  $[first, last)$ . In case of a tie, the point with the smallest  $x$ -coordinate is taken.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. In fact, only the members *Less\_yx\_2* and *less\_yx\_2\_object()* are used.
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

### See Also

*CGAL::left\_vertex\_2* ..... page [1175](#)  
*CGAL::right\_vertex\_2* ..... page [1188](#)  
*CGAL::top\_vertex\_2* ..... page [1189](#)  
*CGAL::Polygon\_2*<*PolygonTraits\_2*, *Container*> ..... page [1180](#)  
*PolygonTraits\_2* ..... page [1178](#)

### Example

## CGAL::bounded\_side\_2

### Definition

The function *bounded\_side\_2* computes if a point lies inside a polygon.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
Bounded_side          bounded_side_2( ForwardIterator first,
                                      ForwardIterator last,
                                      Traits::Point_2 point,
                                      Traits traits)
```

The function *bounded\_side\_2* computes if a point lies inside a polygon. The polygon is defined by the sequence of points *first...last*. Being inside is defined by the odd-even rule. If we take a ray starting at the point and extending to infinity (in any direction), we count the number of intersections. If this number is odd, the point is inside, otherwise it is outside. If the point is on a polygon edge, a special value is returned. A simple polygon divides the plane in an unbounded and a bounded region. According to the definition points in the bounded region are inside the polygon.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. Only the following members of this traits class are used:
  - *Compare\_x\_2*
  - *Compare\_y\_2*
  - *Orientation\_2*
  - *compare\_x\_2\_object()*
  - *compare\_y\_2\_object()*
  - *orientation\_2\_object()*
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

### Implementation

The running time is linear in the number of vertices of the polygon. A horizontal ray is taken to count the number of intersections. Special care is taken that the result is correct even if there are degeneracies (if the ray passes through a vertex).

### See Also

*PolygonTraits\_2* ..... page [1178](#)  
*CGAL::oriented\_side\_2* ..... page [1177](#)  
*CGAL::Polygon\_2<PolygonTraits\_2, Container>* ..... page [1180](#)  
*CGAL::Bounded\_side*

## CGAL::is\_convex\_2

### Definition

The function *is\_convex\_2* computes if a polygon is convex.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
bool is_convex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. Only the following members of this traits class are used:
  - *Less\_xy\_2*
  - *Orientation\_2*
  - *less\_xy\_2\_object*
  - *orientation\_2\_object*
2. *ForwardIterator::value\_type* should be *Traits::Point\_2*,

### See Also

*PolygonTraits\_2* ..... page [1178](#)  
*CGAL::Polygon\_2*<*PolygonTraits\_2*, *Container*> ..... page [1180](#)

## CGAL::is\_simple\_2

### Definition

The function *is\_simple\_2* computes if a polygon is simple, that is, if the edges do not intersect, except consecutive edges in their common vertex.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
inline bool is_simple_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Checks if the polygon defined by the iterator range *first* ... *last* is simple.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. Only the following members of this traits class are used:
  - *Point\_2*
  - *Less\_xy\_2*
  - *Orientation\_2*
  - *less\_xy\_2\_object()*
  - *orientation\_2\_object()*
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

### Implementation

The simplicity test is implemented by means of a plane sweep algorithm. The algorithm is quite robust when used with inexact number types. The running time is  $O(n \log n)$ , where  $n$  is the number of vertices of the polygon.

### See Also

*PolygonTraits\_2* ..... [page 1178](#)

## CGAL::left\_vertex\_2

### Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator left_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the leftmost point from the range  $[first, last)$ . In case of a tie, the point with the smallest y-coordinate is taken.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. In fact, only the members *Less\_xy\_2* and *less\_xy\_2\_object()* are used.
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

### See Also

*CGAL::Polygon\_2*<*PolygonTraits\_2*, *Container*> ..... page [1180](#)

## CGAL::orientation\_2

### Definition

The function *orientation\_2* computes if a polygon is clockwise or counterclockwise oriented.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
Orientation orientation_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

*Precondition:* *is\_simple\_2*(first, last, traits);

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. Only the following members of this traits class are used:
  - *Less\_xy\_2*
  - *less\_xy\_2\_object*()
  - *orientation\_2\_object*()
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

### See Also

*PolygonTraits\_2* ..... page [1178](#)  
*CGAL::is\_simple\_2* ..... page [1174](#)  
*CGAL::Polygon\_2*<*PolygonTraits\_2*, *Container*> ..... page [1180](#)  
*CGAL::Orientation*

## CGAL::oriented\_side\_2

### Definition

The function *oriented\_side\_2* computes on which side of a polygon a point lies.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
Oriented_side          oriented_side_2( ForwardIterator first,
                                       ForwardIterator last,
                                       Traits::Point_2 point,
                                       Traits traits)
```

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. Only the following members of this traits class are used:
  - *Less\_xy\_2*
  - *Compare\_x\_2*
  - *Compare\_y\_2*

## PolygonTraits\_2

### Definition

The *Polygon\_2* class and the functions that implement the functionality found in that class each are parameterized by a traits class that defines the primitives used in the algorithms. The concept *PolygonTraits\_2* defines this common set of requirements.

The requirements of *PolygonTraits\_2* are a subset of the kernel requirements. We only list the types and methods which are required and refer to the description of the kernel concept for details.

### Types

*PolygonTraits\_2:: FT*

*PolygonTraits\_2:: Point\_2*

The point type.

*PolygonTraits\_2:: Segment\_2*

The segment type.

*PolygonTraits\_2:: Construct\_segment\_2*

*PolygonTraits\_2:: Equal\_2*

*PolygonTraits\_2:: Less\_xy\_2*

*PolygonTraits\_2:: Less\_yx\_2*

*PolygonTraits\_2:: Compare\_x\_2*

*PolygonTraits\_2:: Compare\_y\_2*

*PolygonTraits\_2:: Orientation\_2*

*PolygonTraits\_2:: Compute\_area\_2*

Computes the signed area of the oriented triangle defined by 3 *Point\_2* passed as arguments.

### Creation

A default constructor and copy constructor are required.

### Operations

The following functions that create instances of the above predicate object types must exist.

*Equal\_2*                      *traits.equal\_2\_object()*

<i>Less_xy_2</i>	<i>traits.less_xy_2_object()</i>
<i>Less_yx_2</i>	<i>traits.less_yx_2_object()</i>
<i>Compare_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Compare_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Orientation_2</i>	<i>traits.orientation_2_object()</i>
<i>Compute_area_2</i>	<i>traits.compute_area_2_object()</i>
<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>

### **Has Models**

The kernels supplied by CGAL are models of PolygonTraits\_2.

## CGAL::Polygon\_2<PolygonTraits\_2, Container>

### Definition

The class *Polygon\_2<PolygonTraits\_2, Container>* implements polygons. The *Polygon\_2<PolygonTraits\_2, Container>* is parameterized by a traits class and a container class. The latter can be any class that fulfills the requirements for an STL container. It defaults to the vector class.

```
#include <CGAL/Polygon_2.h>
```

### Types

*Polygon\_2<PolygonTraits\_2, Container>::Traits*      The traits type.

*Polygon\_2<PolygonTraits\_2, Container>::Container*

The container type.

*typedef Traits::FT*      *FT*;

The number type, which is the *field type* of the points of the polygon.

*typedef Traits::Point\_2*      *Point\_2*;

*typedef Traits::Segment\_2*

The point type of the polygon.

*Segment\_2*;

The type of a segment between two points of the polygon.

The following types denote iterators that allow to traverse the vertices and edges of a polygon. Since it is questionable whether a polygon should be viewed as a circular or as a linear data structure both circulators and iterators are defined. The circulators and iterators are non-mutable.<sup>1</sup> The iterator category is in all cases bidirectional, except for *Vertex\_iterator*, which has the same iterator category as *Container::iterator*. **N.B.** In fact all of them should have the same iterator category as *Container::iterator*. However, due to compiler problems this is currently not possible.

For vertices we define

*Polygon\_2<PolygonTraits\_2, Container>::Vertex\_iterator*

*Polygon\_2<PolygonTraits\_2, Container>::Vertex\_circulator*

Their value type is *Point\_2*.

For edges we define

*Polygon\_2<PolygonTraits\_2, Container>::Edge\_const\_circulator*

*Polygon\_2<PolygonTraits\_2, Container>::Edge\_const\_iterator*

Their value type is *Segment\_2*.

<sup>1</sup>At least conceptually. The enforcement depends on preprocessor flags.

## Creation

*Polygon\_2*<*PolygonTraits\_2*, *Container*> *pgn*( *Traits* *p\_traits* = *Traits*() );

Creates an empty polygon *pgn*.

*template* <*class InputIterator*>  
*Polygon\_2*<*PolygonTraits\_2*, *Container*> *pgn*( *InputIterator* *first*,  
  *InputIterator* *last*,  
  *Traits* *p\_traits* = *Traits*() )

Introduces a polygon *pgn* with vertices from the sequence defined by the range [*first*,*last*). The value type of *InputIterator* must be *Point\_2*.

## Modifiers

*void*                                    *pgn.set*( *Vertex\_iterator* *pos*, *Point\_2* *x* )

Acts as *\*pos = x*, except that that would be illegal because the iterator is not mutable.

*Vertex\_iterator*                    *pgn.insert*( *Vertex\_iterator* *i*, *Point\_2* *q* )

Inserts the vertex *q* before *i*. The return value points to the inserted vertex.

<i>template &lt;class InputIterator&gt;</i>	<i>pgn.insert( Vertex_iterator i, InputIterator first, InputIterator last)</i>	Inserts the vertices in the range <i>[first, last)</i> before <i>i</i> . The value type of points in the range <i>[first, last)</i> must be <i>Point_2</i> .
<i>void</i>	<i>pgn.push_back( Point_2 q)</i>	Has the same semantics as <i>p.insert(p.vertices_end(), q)</i> .
<i>void</i>	<i>pgn.erase( Vertex_iterator i)</i>	Erases the vertex pointed to by <i>i</i> .
<i>void</i>	<i>pgn.erase( Vertex_iterator first, Vertex_iterator last)</i>	Erases the vertices in the range <i>[first, last)</i> .
<i>void</i>	<i>pgn.clear()</i>	Erases all vertices.
<i>void</i>	<i>pgn.reverse_orientation()</i>	Reverses the orientation of the polygon. The vertex pointed to by <i>p.vertices_begin()</i> remains the same.

## Access Functions

The following methods of the class return circulators and iterators that allow to traverse the vertices and edges.

<i>Vertex_iterator</i>	<i>pgn.vertices_begin()</i>	Returns a constant iterator that allows to traverse the vertices of the polygon <i>pgn</i> .
<i>Vertex_iterator</i>	<i>pgn.vertices_end()</i>	Returns the corresponding past-the-end iterator.
<i>Vertex_circulator</i>	<i>pgn.vertices_circulator()</i>	Returns a mutable circulator that allows to traverse the vertices of the polygon <i>pgn</i> .
<i>Edge_const_iterator</i>	<i>pgn.edges_begin()</i>	Returns a non-mutable iterator that allows to traverse the edges of the polygon <i>pgn</i> .
<i>Edge_const_iterator</i>	<i>pgn.edges_end()</i>	Returns the corresponding past-the-end iterator.
<i>Edge_const_circulator</i>	<i>pgn.edges_circulator()</i>	Returns a non-mutable circulator that allows to traverse the edges of the polygon <i>pgn</i> .

## Predicates

<i>bool</i>	<i>pgn.is_simple()</i>	Returns whether <i>pgn</i> is a simple polygon.
<i>bool</i>	<i>pgn.is_convex()</i>	Returns whether <i>pgn</i> is convex.
<i>Orientation</i>	<i>pgn.orientation()</i>	Returns the orientation of <i>pgn</i> . If the number of vertices <i>p.size()</i> < 3 then <i>COLLINEAR</i> is returned. <i>Precondition: p.is_simple().</i>
<i>Oriented_side</i>	<i>pgn.oriented_side( Point_2 q)</i>	Returns <i>POSITIVE_SIDE</i> , or <i>NEGATIVE_SIDE</i> , or <i>ON_ORIENTED_BOUNDARY</i> , depending on where point <i>q</i> is. <i>Precondition: p.is_simple().</i>
<i>Bounded_side</i>	<i>pgn.bounded_side( Point_2 q)</i>	Returns the symbolic constant <i>ON_BOUNDED_SIDE</i> , <i>ON_BOUNDARY</i> or <i>ON_UNBOUNDED_SIDE</i> , depending on where point <i>q</i> is. <i>Precondition: p.is_simple().</i>
<i>Bbox_2</i>	<i>pgn.bbox()</i>	Returns the smallest bounding box containing <i>pgn</i> .
<i>Traits::FT</i>	<i>pgn.area()</i>	Returns the signed area of the polygon <i>pgn</i> . This means that the area is positive for counter clockwise polygons and negative for clockwise polygons.
<i>Vertex_iterator</i>	<i>pgn.left_vertex()</i>	Returns the leftmost vertex of the polygon <i>pgn</i> with the smallest y-coordinate.
<i>Vertex_iterator</i>	<i>pgn.right_vertex()</i>	Returns the rightmost vertex of the polygon <i>pgn</i> with the largest y-coordinate.
<i>Vertex_iterator</i>	<i>pgn.top_vertex()</i>	Returns topmost vertex of the polygon <i>pgn</i> with the largest x-coordinate.
<i>Vertex_iterator</i>	<i>pgn.bottom_vertex()</i>	Returns the bottommost vertex of the polygon <i>pgn</i> with the smallest x-coordinate.

For convenience we provide the following Boolean functions:

<i>bool</i>	<i>pgn.is_counterclockwise_oriented()</i>
<i>bool</i>	<i>pgn.is_clockwise_oriented()</i>
<i>bool</i>	<i>pgn.is_collinear_oriented()</i>
<i>bool</i>	<i>pgn.has_on_positive_side( Point_2 q)</i>
<i>bool</i>	<i>pgn.has_on_negative_side( Point_2 q)</i>
<i>bool</i>	<i>pgn.has_on_boundary( Point_2 q)</i>

*bool*            *pgn.has\_on\_bounded\_side( Point\_2 q)*  
*bool*            *pgn.has\_on\_unbounded\_side( Point\_2 q)*

## Random access methods

These methods are only available for random access containers.

*Point\_2*        *pgn.vertex( int i)*            Returns a (const) reference to the *i*-th vertex.

*Point\_2*        *pgn[ int i]*                Returns a (const) reference to the *i*-th vertex.

*Segment\_2*    *pgn.edge( int i)*            Returns a const reference to the *i*-th edge.

## Miscellaneous

*int*             *pgn.size()*                    Returns the number of vertices of the polygon *pgn*.

*bool*            *pgn.is\_empty()*                Returns *p.size() == 0*.

*Container*     *pgn.container()*           Returns a const reference to the sequence of vertices of the polygon *pgn*.

## Globally defined operators

*template <class Traits, class Container1, class Container2>*

*bool*            *Polygon\_2<Traits,Container1> p1 == Polygon\_2<Traits,Container2> p2*

Test for equality: two polygons are equal iff there exists a cyclic permutation of the vertices of *p2* such that they are equal to the vertices of *p1*. Note that the template argument *Container* of *p1* and *p2* may be different.

*template <class Traits, class Container1, class Container2>*

*bool*            *Polygon\_2<Traits,Container1> p1 != Polygon\_2<Traits,Container2> p2*

Test for inequality.

*template <class Transformation, class Traits, class Container>*

*Polygon\_2<Traits,Container>*

*transform( Transformation t, Polygon\_2<Traits,Container> p)*

Returns the image of the polygon *p* under the transformation *t*.

## I/O

The I/O operators are defined for *iostream*. The format for the *iostream* is an internal format.

```
ostream&      ostream& os << Polygon_2<Traits,Container> p
```

Inserts the polygon *pgn* into the stream *os*.

*Precondition:* The insert operator must be defined for *Point\_2*.

```
istream&      istream& is >> Polygon_2<Traits,Container> p
```

Reads a polygon from stream *is* and assigns it to *pgn*.

*Precondition:* The extract operator must be defined for *Point\_2*.

The information output in the *iostream* is the number of points followed by the output of the coordinates of the vertices.

## Implementation

The methods *is\_simple*, *is\_convex*, *orientation*, *oriented\_side*, *bounded\_side*, *bbox*, *area*, *left\_vertex*, *right\_vertex*, *top\_vertex* and *bottom\_vertex* are all implemented using the algorithms on sequences of 2D points. See the corresponding global functions for information about which algorithms were used and what complexity they have.

## Example

The following code fragment creates a polygon and checks if it is convex.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Polygon_2.h>
#include <iostream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;
typedef CGAL::Polygon_2<K> Polygon_2;
using std::cout; using std::endl;

int main()
{
    Point points[] = { Point(0,0), Point(5.1,0), Point(1,1), Point(0.5,6) };
    Polygon_2 pgn(points, points+4);

    // check if the polygon is simple.
    cout << "The polygon is " <<
        (pgn.is_simple() ? "" : "not ") << "simple." << endl;

    // check if the polygon is convex
    cout << "The polygon is " <<
        (pgn.is_convex() ? "" : "not ") << "convex." << endl;
```

```
    return 0;  
}
```

**File:** examples/Polygon/Polygon.cpp

## CGAL::polygon\_area\_2

### Definition

The function *polygon\_area\_2* computes the signed area of a polygon.

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
typename Traits::FT      polygon_area_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Computes the signed area of the polygon defined by the range of points *first* ... *last*. The sign is positive for counterclockwise polygons, negative for clockwise polygons. If the polygon is not simple, the area is not well defined.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. Only the following members of this traits class are used:
  - *Compute\_area\_2* : Computes the signed area of the oriented triangle defined by 3 *Point\_2* passed as arguments.
  - *FT*
  - *compute\_area\_2\_object*
2. *ForwardIterator::value\_type* should be *Traits::Point\_2*,

## CGAL::right\_vertex\_2

### Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator      right_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the rightmost point from the range  $[first, last)$ . In case of a tie, the point with the largest y-coordinate is taken.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. In fact, only the members *Less\_xy\_2* and *less\_xy\_2\_object()* are used.
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

## CGAL::top\_vertex\_2

### Definition

```
#include <CGAL/Polygon_2_algorithms.h>
```

```
template <class ForwardIterator, class Traits>
```

```
ForwardIterator top_vertex_2( ForwardIterator first, ForwardIterator last, Traits traits)
```

Returns an iterator to the topmost point from the range  $[first, last)$ . In case of a tie, the point with the largest  $x$ -coordinate is taken.

### Requirements

1. *Traits* is a model of the concept *PolygonTraits\_2*. In fact, only the members *Less\_yx\_2* and *less\_yx\_2\_object()* are used.
2. The value type of *ForwardIterator* must be *Traits::Point\_2*,

### 15.1 Introduction

Figure 15.1: Examples of Boolean set-operations on general polygons.

This package consists of the implementation of Boolean set-operations on point sets bounded by  $x$ -monotone curves<sup>1</sup> in 2-dimensional Euclidean space. In particular, it contains the implementation of *regularized* Boolean set-operations, intersection predicates, and point containment predicates. Figure 29 shows simple examples of such operations.

A regularized Boolean set-operation  $\text{op}^*$  can be obtained by first taking the interior of the resultant point set of an *ordinary* Boolean set-operation  $(P \text{ op } Q)$  and then by taking the closure [Hof04]. That is,  $P \text{ op}^* Q = \text{closure}(\text{interior}(P \text{ op } Q))$ . Regularized Boolean set-operations appear in Constructive Solid Geometry (CSG), because regular sets are closed under regularized Boolean set-operations, and because regularization eliminates lower dimensional features, namely isolated vertices and antennas, thus simplifying and restricting the representation to physically meaningful solids. Our package provides regularized operations on polygons and general polygons, where the edges of a general polygon may be general  $x$ -monotone curves, rather than being simple line segments. Ordinary Boolean set-operations, which distinguish between the interior and the boundary of a polygon, are not implemented within this package. The *Nef\_2* package supports these operations for (linear) polygons; see Chapter 16.

In the rest of this chapter we use — unless otherwise stated — the traditional notation to designate regularized operations; e.g.,  $P \cap Q$  means the *regularized* intersection of  $P$  and  $Q$ .

A polygon  $P$  is said to be *simple* (or Jordan) if the only points of the plane belonging to two polygon edges of  $P$  are the polygon vertices of  $P$ . Namely, the polygon edges are pairwise disjoint in their interior. Such a polygon has a well-defined interior and exterior and is topologically equivalent to a disk. A polygon in our context must be simple and its vertices must be ordered in a counterclockwise direction around the interior of the polygon.

The counterclockwise cyclic sequence of alternating polygon edges and polygon vertices is referred to as the polygon *boundary*. A polygon whose boundary contains the same vertex twice or more is connected and simple but not necessarily strictly simple, such as the polygon depicted on the right. We extend the notion of a polygon to a point set in  $\mathbb{R}^2$  that has a topology of a polygon and its boundary edges must map to  $x$ -monotone curves, and refer to it as a *general polygon*. We sometimes use the term *polygon* instead of general polygon for simplicity hereafter.

Our package supports the following Boolean set-operations on two point sets  $P$  and  $Q$  that are comprised of general polygons:

**Intersection** computes the intersection  $R = P \cap Q$ .

**Join** computes the union  $R = P \cup Q$ .

**Difference** computes the difference  $R = P \setminus Q$ .

**Symmetric Difference** computes the symmetric difference  $P \oplus Q = (P \setminus Q) \cup (Q \setminus P)$ .

**Complement** computes the complement  $R = \overline{P}$ .

**Intersection predicate** tests whether the two sets  $P$  and  $Q$  overlap, distinguishing three possible scenarios: (i) the two sets intersect on their interior (that is, their regularized intersection is not empty  $P \cap Q \neq \emptyset$ ); (ii) the boundaries of two sets intersect but their interiors are disjoint; namely they have a finite number of common points or even share a boundary curve (still in this case  $P \cap Q = \emptyset$ ); and (iii) the two sets are disjoint.

In general, the set  $R$ , resulting from a regularized Boolean set-operation, is considered as being a closed point-set.

<sup>1</sup>A continuous planar curve  $C$  is *x-monotone* if every vertical line intersects it at most once. We also allow vertical line segments, which are considered *weakly x-monotone*.

In the rest of this chapter we review the Boolean set-operations package in more depth. In Section 15.2 we focus on Boolean set-operations on linear polygons, introducing the notion of polygons with holes and of a general polygon set. Section 15.3 introduces general polygons. We first discuss polygons whose edges are either line segments or circular arcs and then explain how to construct and use general polygons whose edges can be arbitrary  $x$ -monotone curves.

## 15.2 Boolean Set-Operations on Linear Polygons

The basic library of CGAL includes the *Polygon\_2<Kernel, Container>* class-template that represents a linear polygon in the plane. The polygon is represented by its vertices stored in a container of objects of type *Kernel::Point\_2*. The polygon edges are line segments (*Kernel::Segment\_2* objects) between adjacent points in the container. By default, the *Container* is a vector of *Kernel::Point\_2* objects.

The following function demonstrates how to use the basic access functions of the *Polygon\_2* class. It accepts a polygon *P* and prints it in a readable format:

```
template<class Kernel, class Container>
void print_polygon (const CGAL::Polygon_2<Kernel, Container>& P)
{
    typename CGAL::Polygon_2<Kernel, Container>::Vertex_const_iterator vit;

    std::cout << "[ " << P.size() << " vertices:";
    for (vit = P.vertices_begin(); vit != P.vertices_end(); ++vit)
        std::cout << " (" << *vit << ')';
    std::cout << " ]" << std::endl;
}
```

In this section we use the term *polygon* to indicate a *Polygon\_2* instance, namely, a polygon having linear edges. General polygons are only discussed in Section 15.3.

The basic components of our package are the free (global) functions *complement()* that accepts a single *Polygon\_2* object, and *intersection()*, *join()*,<sup>2</sup> *difference()*, *symmetric\_difference()* and the predicate *do\_intersect()* that accept two *Polygon\_2* objects as their input. We explain how these functions should be used through several examples in the following sections.

### A Simple Example

Testing whether two polygons intersect results with a Boolean value, and does not require any additional data beyond the provision of the two input polygons. The example listed below tests whether the two triangles depicted on the right intersect. It uses, as do the other example programs in this chapter, the auxiliary header file *bso\_rational\_nt.h*, which defines the type *Number\_type* as GMP's rational number-type (*CGAL::Gmpq*), or as the number type *Quotient<MP\_Float>* that is included in the support library of CGAL, based on whether the GMP library is installed or not. It also uses the function *print\_polygon.h* listed above, which is located in the header file *print\_utils.h*.

```
/*! \file do_intersect.cpp
 * Determining whether two triangles intersect.
```

<sup>2</sup>The function that computes the union of two polygons is called *join()*, since the word *union* is reserved in C++.

```

*/

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Boolean_set_operations_2.h>
// instead of
//typedef CGAL::Cartesian<Number_type> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Cartesian<Number_type> {};

typedef Kernel::Point_2 Point_2;
typedef CGAL::Polygon_2<Kernel> Polygon_2;

#include "print_utils.h"

int main ()
{
    Polygon_2 P;
    P.push_back (Point_2 (-1,1));
    P.push_back (Point_2 (0,-1));
    P.push_back (Point_2 (1,1));
    std::cout << "P = "; print_polygon (P);

    Polygon_2 Q;
    Q.push_back(Point_2 (-1,-1));
    Q.push_back(Point_2 (1,-1));
    Q.push_back(Point_2 (0,1));
    std::cout << "Q = "; print_polygon (Q);

    if ((CGAL::do_intersect (P, Q)))
        std::cout << "The two polygons intersect in their interior." << std::endl;
    else
        std::cout << "The two polygons do not intersect." << std::endl;

    return 0;
}

```

**File:** examples/Boolean\_set\_operations\_2/do\_intersect.cpp

### 15.2.1 Polygons with Holes

In many cases a binary operation that operates on two strictly simple polygons that have no holes may result in a set of polygon that contains holes in their interior (see Figure 15.2.1 (a)), or a set of disjoint polygons (see Figure 15.2.1 (b)); a similar set may result from the union, or the symmetric difference, of two disjoint polygons). Moreover, the complement of a simple polygon is an unbounded set that contains a hole; see Figure 15.2.1 (c).

Regular sets are closed under regularized Boolean set-operations. These operations accept as input, and may result as output, polygons with holes. A *polygon with holes* represents a point set that may be bounded or unbounded. In case of a bounded set, its *outer boundary* is represented as a simple (but not necessarily strictly simple) polygon, whose vertices are oriented in a counterclockwise order around the interior of the set. In addition, the set may contain *holes*, where each hole is represented as a strictly simple polygon, whose vertices are oriented in a clockwise order around the interior of the hole. Note that an unbounded polygon without holes spans the entire plane. Vertices of holes may coincide with vertices of the boundary; see below for an example.

Figure 15.2: Operations on strictly simple polygons. (a) The union of two polygons, resulting in a point set whose outer boundary is defined by a simple polygon and contains a polygonal hole in its interior. (b) The intersection (darkly shaded) of two polygons (lightly shaded), resulting in two disjoint polygons. (c) The complement (darkly shaded) of a strictly simple polygon (lightly shaded).

A point set represented by a polygon with holes is considered to be closed. Therefore, the boundaries of the holes are parts of the set (and not part of the holes). The exact definition of the obtained polygon with holes as a result of a Boolean set-operation or a sequence of such operations is closely related to the definition of regularized Boolean set-operations, being the closure of the interior of the corresponding ordinary operation as explained next.

Consider, for example, the regular set depicted on the right, which is the result of the union of three small triangles translated appropriately. Alternatively, the same set can be reached by taking the difference between a large triangle and a small upside-down triangle. In general, there are many ways to arrive at a particular point set. However, the set of polygons with holes obtained through the application of any sequence of operations is unique. The set depicted on the right is represented as a single polygon having a triangular outer boundary with a single triangular hole in its interior — and not as three triangles that have no holes at all. As a general rule, if two point sets are connected, then they belong to the same polygon with holes.

The class template *Polygon\_with\_holes\_2*<Kernel,Container> represents polygons with holes as described above, where the outer boundary and the hole boundaries are realized as *Polygon\_2*<Kernel,Container> objects. Given an instance *P* of the *Polygon\_with\_holes\_2* class, you can use the predicate *is\_unbounded*() to check whether *P* is a unbounded set. If it is bounded, you can obtain the counterclockwise-oriented polygon that represents its outer boundary through the member function *outer\_boundary*(). You can also traverse the holes of *P* through *holes\_begin*() and *holes\_end*(). The two functions return iterators of the nested type *Polygon\_with\_holes\_2::Hole\_const\_iterator* that defines the valid range of *P*'s holes. The value type of this iterator is *Polygon\_2*.

The following function demonstrates how to traverse a polygon with holes. It accepts a *Polygon\_with\_holes\_2* object and uses the auxiliary function *print\_polygon*() to prints all its components in a readable format:

```
template<class Kernel, class Container>
void print_polygon_with_holes(const CGAL::Polygon_with_holes_2<Kernel, Container> & pwh)
{
    if (! pwh.is_unbounded()) {
        std::cout << "{ Outer boundary = ";
        print_polygon (pwh.outer_boundary());
    }
    else
        std::cout << "{ Unbounded polygon." << std::endl;

    typename CGAL::Polygon_with_holes_2<Kernel,Container>::Holes_const_iterator hit;
    unsigned int k = 1;

    std::cout << " " << pwh.number_of_holes() << " holes:" << std::endl;
    for (hit = pwh.holes_begin(); hit != pwh.holes_end(); ++hit, ++k) {
        std::cout << "    Hole #" << k << " = ";
        print_polygon (*hit);
    }
    std::cout << " }" << std::endl;
}
```

The simple versions of the free functions mentioned therefore accept two *Polygon\_2* object *P* and *Q* as their input, while their output is given using polygon with holes instances:

- The complement of a simple polygon *P* is always an unbounded set with a single polygonal hole. The function *complement(P)* therefore returns a polygon-with-holes object that represents the complement of *P*.
- The union of two polygons *P* and *Q* is always a single connected set, unless of course the two input polygons are completely disjoint. In the latter case  $P \cup Q$  trivially consists of the two input polygons. The free function *join(P, Q, R)* therefore returns a Boolean value indicating whether  $P \cap Q \neq \emptyset$ . If the two polygons are not disjoint, it assigns the a polygon with holes object *R* (which it accepts by reference) with the union of the regularized union operation  $P \cup Q$ .

- The other three functions, namely *intersection(P, Q, oi)*, *difference(P, Q, oi)* and *symmetric\_difference(P, Q, oi)*, all have a similar interface. As the result of these operation may consist of several disconnected components, they all accept an output iterator *oi*, whose value type is *Polygon\_with\_holes\_2*, and add the output polygons to its associated container.

### Example — Joining and Intersecting Simple Polygons

The following example demonstrates the usage of the free functions *join()* and *intersect()* for computing the union and the intersection of the two simple polygons depicted in Figure 15.2.1 (b). The example uses the auxiliary function *print\_polygon\_with\_holes()* listed above, which is located in the header file *print\_utils.h* under the examples folder.

```

/*! \file simple_join_intersect.cpp
 * Computing the union and the intersection of two simple polygons.
 */

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Boolean_set_operations_2.h>
#include <list>

// instead of
//typedef CGAL::Cartesian<Number_type> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Cartesian<Number_type> {};

typedef Kernel::Point_2 Point_2;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;
typedef std::list<Polygon_with_holes_2> Pwh_list_2;

#include "print_utils.h"

int main ()
{
    // Construct the two input polygons.
    Polygon_2 P;
    P.push_back (Point_2 (0, 0));
    P.push_back (Point_2 (5, 0));
    P.push_back (Point_2 (3.5, 1.5));
    P.push_back (Point_2 (2.5, 0.5));
    P.push_back (Point_2 (1.5, 1.5));

    std::cout << "P = "; print_polygon (P);

    Polygon_2 Q;
    Q.push_back (Point_2 (0, 2));
    Q.push_back (Point_2 (1.5, 0.5));
    Q.push_back (Point_2 (2.5, 1.5));
    Q.push_back (Point_2 (3.5, 0.5));
    Q.push_back (Point_2 (5, 2));

```

```

std::cout << "Q = "; print_polygon (Q);

// Compute the union of P and Q.
Polygon_with_holes_2 unionR;

if (CGAL::join (P, Q, unionR)) {
    std::cout << "The union: ";
    print_polygon_with_holes (unionR);
} else
    std::cout << "P and Q are disjoint and their union is trivial."
               << std::endl;
std::cout << std::endl;

// Compute the intersection of P and Q.
Pwh_list_2          intR;
Pwh_list_2::const_iterator it;

CGAL::intersection (P, Q, std::back_inserter(intR));

std::cout << "The intersection:" << std::endl;
for (it = intR.begin(); it != intR.end(); ++it) {
    std::cout << "--> ";
    print_polygon_with_holes (*it);
}

return 0;
}

```

## Operations on Polygons with Holes

Having introduced polygons with holes and explained how the free functions output such objects, it is only natural to perform operations on sets that are represented as polygon with holes, rather than simple polygons. Indeed, the Boolean set-operations package provides overridden free functions *complement()*, *intersection()*, *join()*, *difference()*, *symmetric\_difference()* and *do\_intersect()* that accept *General\_polygon\_with\_holes\_2* objects as their input. The prototypes of most functions is the same as of their simpler counterparts that operate on simple polygons. The only exception is *complement(P, oi)*, which outputs a range of polygons with holes that represents the complement of the polygon with holes *P*.

The following example demonstrates how to compute the symmetric difference between two sets that contain holes. Each set is a rectangle that contains a rectangular hole in its interior, such that the symmetric difference between the two sets is a single polygon that contains of five holes:

```

/*! \file symmetric_difference.cpp
 * Computing the symmetric difference of two polygons with holes.
 */

```

```

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Boolean_set_operations_2.h>
#include <list>

// instead of
//typedef CGAL::Cartesian<Number_type> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Cartesian<Number_type> {};

typedef Kernel::Point_2 Point_2;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;
typedef std::list<Polygon_with_holes_2> Pwh_list_2;

#include "print_utils.h"

int main ()
{
    // Construct P - a bounded rectangle that contains a rectangular hole.
    Polygon_2 outP;
    Polygon_2 holesP[1];

    outP.push_back (Point_2 (-3, -5)); outP.push_back (Point_2 (3, -5));
    outP.push_back (Point_2 (3, 5)); outP.push_back (Point_2 (-3, 5));
    holesP[0].push_back (Point_2 (-1, -3));
    holesP[0].push_back (Point_2 (-1, 3));
    holesP[0].push_back (Point_2 (1, 3));
    holesP[0].push_back (Point_2 (1, -3));

    Polygon_with_holes_2 P (outP, holesP, holesP + 1);
    std::cout << "P = "; print_polygon_with_holes (P);

    // Construct Q - a bounded rectangle that contains a rectangular hole.
    Polygon_2 outQ;
    Polygon_2 holesQ[1];

    outQ.push_back (Point_2 (-5, -3)); outQ.push_back (Point_2 (5, -3));
    outQ.push_back (Point_2 (5, 3)); outQ.push_back (Point_2 (-5, 3));
    holesQ[0].push_back (Point_2 (-3, -1));
    holesQ[0].push_back (Point_2 (-3, 1));
    holesQ[0].push_back (Point_2 (3, 1));
    holesQ[0].push_back (Point_2 (3, -1));

    Polygon_with_holes_2 Q (outQ, holesQ, holesQ + 1);
    std::cout << "Q = "; print_polygon_with_holes (Q);

    // Compute the symmetric difference of P and Q.
    Pwh_list_2 symmR;
    Pwh_list_2::const_iterator it;

    CGAL::symmetric_difference (P, Q, std::back_inserter(symmR));

```

```

std::cout << "The symmetric difference:" << std::endl;
for (it = symmR.begin(); it != symmR.end(); ++it) {
    std::cout << "--> ";
    print_polygon_with_holes (*it);
}

return 0;
}

```

**File:** examples/Boolean\_set\_operations\_2/symmetric\_difference.cpp

In some cases it is convenient to connect the outer boundary of a polygon with holes with the holes inside it. The function *connect\_holes()* accepts a polygon with holes, and connects the topmost vertex in each hole with the polygon feature located directly above it (a vertex or an edge of the outer boundary, or of another hole). It produces an output sequence of points that match the traversal of all vertices in the connected polygon (note that there are additional vertices, induced by the vertical walls).

```

/*! \file connect_polygon.cpp
 * Connecting a polygon with holes.
 */

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/connect_holes.h>
#include <list>

typedef CGAL::Cartesian<Number_type>      Kernel;
typedef Kernel::Point_2                   Point_2;
typedef CGAL::Polygon_2<Kernel>           Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;

int main (int argc, char **argv)
{
    // Get the name of the input file from the command line, or use the default
    // pgn_holes.dat file if no command-line parameters are given.
    //more data files can be found under test data
    //boundary no other connections are made.
    const char *filename = (argc > 1) ? argv[1] : "pgn_holes.dat";

    std::ifstream input_file (filename);

    if (! input_file.is_open())
    {
        std::cerr << "Failed to open the " << filename <<std::endl;
        return (1);
    }

    // Read a polygon with holes from a file.
    Polygon_2      outerP;
    unsigned int    num_holes;

    input_file >> outerP;

```

```

input_file >> num_holes;

std::vector<Polygon_2> holes (num_holes);
unsigned int          k;

for (k = 0; k < num_holes; k++)
    input_file >> holes[k];

Polygon_with_holes_2 P (outerP, holes.begin(), holes.end());

// Connect the outer boundary of the polygon with its holes.
std::list<Point_2> pts;
std::list<Point_2>::iterator pit;

connect_holes (P, std::back_inserter (pts));

for (pit = pts.begin(); pit != pts.end(); ++pit)
    std::cout << '(' << *pit << " " << " ";
std::cout << std::endl;

return (0);
}

```

**File:** examples/Boolean\_set\_operations\_2/connect\_polygon.cpp

## 15.2.2 Operating on Polygon Sets

We argue that the result of a regularized operations on two polygons (or polygons with holes)  $P$  and  $Q$  is typically a collection of several disconnected polygons with holes. It is only natural to represent such a collection in terms of a class, making it possible to operate on the set resulting from computing, for example,  $P \setminus Q$ .

A central component in the Boolean set-operations package is the *Polygon\_set\_2*<*Kernel*, *Container*, *Dcel*> class-template. An instance of this class represents a point set formed by the collection of several disconnected polygons with holes. It employs the *Arrangement\_2* class to represent this point set in the plane as a planar arrangement; see Chapter 26. The instantiated *Dcel* type is used to represent the underlying internal arrangement. It must model the concept *GeneralPolygonSetDcel*, and defaults to *Gps\_default\_dcel*. You can override this default, with a different DCEL class, typically an extension of the default. Overriding the default is necessary only if you intend to obtain the undelying internal arrangement and process it further.

An instance  $S$  of a *Polygon\_set\_2* class usually represents the result of a sequence of operations that were applied on some input polygons. The representation of  $S$  is unique, regardless of the particular sequence of operations that were applied in order to arrive at it.

In addition, a polygon-set object can be constructed from a single polygon object or from a polygon-with-holes object. Once constructed, it is possible to insert new polygons (or polygons with holes) into the set using the *insert()* method, as long as the inserted polygons and the existing polygons in the set are disjoint. The *Polygon\_set\_2* class also provides access functions for accessing the polygons with holes it contains, and a few queries. The most important query is  $S.oriented\_side(q)$ , which determined whether the query point  $q$  is contained in the interior of the set  $S$ , lies on the boundary of the set, or neither.

The *General\_polygon\_set\_2* class defines the predicate *do\_intersect()* and the methods *complement()*, *intersection()*, *join()*, *difference()* and *symmetric\_difference()* as member functions. The operands to these functions

may be simple polygons (*Polygon\_2* object), polygons with holes (*General\_polygon\_with\_holes\_2* objects), or polygon sets (*General\_polygon\_set\_2* objects). Thus, each of the function mentioned above is actually realized by a set overriding member functions.

Member functions of the *General\_polygon\_set\_2* that perform Boolean set-operations come in two flavors: for example, *S.join(P, Q)* computes the union of *P* and *Q* and assigned the result to *S*, while *S.join(P)* performs the operation  $S \leftarrow S \cup P$ . Similarly, *S.complement(P)* sets *S* to be the complement of *P*, while *S.complement()* simply negates the set *S*.

## A Sequence of Set Operations

The free functions reviewed in Section 15.2.1 serve as a wrapper for the polygon-set class, and are only provided for convenience. A typical such function constructs a pair of *General\_polygon\_set\_2* objects, invokes the appropriate method to apply the desired Boolean operation, and transforms the resulting polygon set to the required output format. Thus, when several operations are performed in a sequence, it is much more efficient to use the member functions of the *General\_polygon\_set\_2* type directly, as the extraction of the polygons from the internal representation for some operation, and the reconstruction of the internal representation for the succeeding operation could be time consuming.

The next example performs a sequence of three Boolean set-operations. First, it computes the union of two simple polygons depicted in Figure 15.2.1 (a). It then computes the complement of the result of the union operation. Finally, it computes the intersection of the result of the complement operation with a rectangle, confining the final result to the area of the rectangle. The resulting set *S* is comprised of two components: a polygon with a hole, and a simple polygon contained in the interior of this hole.

```

/*! \file sequence.cpp
 * Performing a sequence of Boolean set-operations.
 */

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/Polygon_with_holes_2.h>
#include <CGAL/Polygon_set_2.h>

#include <list>

// instead of
//typedef CGAL::Cartesian<Number_type> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Cartesian<Number_type> {};

typedef Kernel::Point_2 Point_2;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;
typedef CGAL::Polygon_set_2<Kernel> Polygon_set_2;

#include "print_utils.h"

int main ()
{
    // Construct the two initial polygons and the clipping rectangle.

```

```

Polygon_2 P;
P.push_back (Point_2 (0, 1));
P.push_back (Point_2 (2, 0));
P.push_back (Point_2 (1, 1));
P.push_back (Point_2 (2, 2));

Polygon_2 Q;
Q.push_back (Point_2 (3, 1));
Q.push_back (Point_2 (1, 2));
Q.push_back (Point_2 (2, 1));
Q.push_back (Point_2 (1, 0));

Polygon_2 rect;
rect.push_back (Point_2 (0, 0));
rect.push_back (Point_2 (3, 0));
rect.push_back (Point_2 (3, 2));
rect.push_back (Point_2 (0, 2));

// Perform a sequence of operations.
Polygon_set_2 S;
S.insert (P);
S.join (Q);           // Compute the union of P and Q.
S.complement();      // Compute the complement.
S.intersection (rect); // Intersect with the clipping rectangle.

// Print the result.
std::list<Polygon_with_holes_2> res;
std::list<Polygon_with_holes_2>::const_iterator it;

std::cout << "The result contains " << S.number_of_polygons_with_holes()
          << " components:" << std::endl;

S.polygons_with_holes (std::back_inserter (res));
for (it = res.begin(); it != res.end(); ++it) {
    std::cout << "--> ";
    print_polygon_with_holes (*it);
}

return 0;
}

```

**File:** examples/Boolean\_set\_operations\_2/sequence.cpp

### Inserting Non Intersecting Polygons

If you want to compute the union of a polygon  $P$  ( $P$  may be a simple polygon or a polygon-with-holes object) with a general-polygon set  $R$ , and store the result in  $R$ , you can construct a polygon set  $S(P)$ , and apply the *union* operation as follows:

```

General_polygon_2 S (P);
R.join (S);

```

As a matter of fact, you can apply the union operation directly:

```
R.join (P);
```

However, if you know that the polygon does not intersect any one of the polygons represented by  $R$ , you can use the more efficient method *insert()*:

```
R.insert (P);
```

As *insert()* assumes that  $P \cap R = \emptyset$ , it does not try to compute intersections between the boundaries of  $P$  and of  $R$ . This fact significantly speeds up the insertion process in comparison with the insertion of a non-disjoint polygon that intersects  $R$ .

The *insert()* function is also overloaded, so it can also accept a range of polygons. When a range of polygons are inserted into a polygon set  $S$ , all the polygons in the range and the polygons represented by  $S$  must be pairwise disjoint in their interiors.

### 15.2.3 Performing Aggregated Operations

There are a few options to compute the union of a set of polygons  $P_1, \dots, P_m$ . You can do it incrementally as follows. At each step compute the union of  $S_{k-1} = \bigcup_{i=1}^{k-1} P_i$  with  $P_k$  and obtain  $S_k$ . Namely, if the polygon set is given as a pair of iterator  $[begin, end)$ , the following loop computes their union in  $S$ .

```
InputIterator iter = begin;
Polygon_set_2 S (*iter);

while (++iter != end) {
    S.join (*iter);
    ++iter;
}
```

A second option is to use a divide-and-conquer approach. You bisect the set of polygons into two sets. Compute the union of each set recursively and obtain the partial results in  $S_1$  and  $S_2$ , and finally, you compute the union  $S_1 \cup S_2$ . However, the union operation can be done more efficiently for sparse polygons, having a relatively small number of intersections, using a third option that simultaneously computes the union of all polygons. This is done by constructing a planar arrangement of all input polygons, utilizing the sweep-line algorithm, then extracting the result from the arrangement. Similarly, it is also possible to aggregately compute the intersection  $\bigcap_{i=1}^m P_i$  of a set of input polygons.

Our package provides the free overloaded functions *join()* and *intersect()* that aggregately compute the union and the intersection of a range of input polygons. There is no restriction on the polygons in the range — naturally, they may intersect each other. The package provides the overloaded free function *do\_intersect(begin, end)* that determines whether the polygons in the range defined by the two input iterators  $[begin, end)$  intersect.

The class *General\_polygon\_set\_2* also provides equivalent member functions that aggregately operate on a range of input polygons or polygons with holes. When such a member function is called, the general polygons represented by the current object are considered operands as well. Thus, you can easily compute the union of our polygon range as follows:

```
Polygon_set_2 S;
S.join (begin, end);
```

## 15.3 Boolean Set-Operations on General Polygons

In previous sections ordinary polygons were dealt with. Namely, closed point sets bounded by piecewise linear curves. The Boolean set-operations package allows a more general geometric mapping of the polygon edges. The operations provided by the package operate on point sets bounded by  $x$ -monotone segments of general curves (e.g., conic arcs and segments of polynomial functions). For example, the point set depicted on the right is general polygon bounded by two  $x$ -monotone circular arcs that correspond to the lower half and the upper half of a circle.

Using the topological terminology, a general polygon can represent any simply-connected point set whose boundary is a strictly simple curve. Such a polygon is a model of the *GeneralPolygon\_2* concept. A model of this concept must fulfill the following requirements:

- A general polygon is constructible from a range of pairwise interior disjoint  $x$ -monotone curves  $c_1, \dots, c_n$ . The target point of the  $k$ th curve  $c_k$  and the source point of the next curve in the range (in a cyclic order) must coincide, such that this point defines the  $k$ th polygon vertex.
- It is possible to traverse the  $x$ -monotone curves that form the edges of a general polygon.

The concept *GeneralPolygonWithHoles\_2* is defined in an analogous way to the definition of linear polygons with holes. A model of this concept represent a bounded or an unbounded set that may not be simply connected, and must provide the following operations:

- Construction for a general polygon that represent the outer boundary and a range of general polygons that represent the holes.
- Accessing the general polygons that represents the outer boundary (in case of a bounded set).
- Traversing the holes.

In Section 15.2 we introduce the classes *Polygon\_2* and *Polygon\_with\_holes\_2* that model the concepts *GeneralPolygon\_2* and *GeneralPolygonWithHoles\_2* respectively. In this section we introduce other models of these two concepts.

The central class-template *General\_polygon\_set\_2*<*Traits*,*Dcel*> is used to represent point sets that are comprised of a finite number of pairwise disjoint general polygons with holes, and provides various Boolean set-operations on such sets. It is parameterized by a *traits* class and a DCEL class. The former defines the type of points used to represent polygon vertices and the type of  $x$ -monotone curves that represent the polygon edges. The traits class also provides primitive geometric operations that operate on objects of these types. The DCEL class is used to represent the underlying internal *Arrangement\_2* data structure. The instantiated *Dcel* type is used to represent the underlying internal arrangement. It must model the concept *GeneralPolygonSetDcel*, and defaults to *Gps\_default\_dcel*. You can override this default, with a different DCEL class, typically an extension of the default. Overriding the default is necessary only if you intend to obtain the underlying internal arrangement and process it further.

An instantiated *General\_polygon\_set\_2* class defines the nested types *General\_polygon\_set\_2*<*Traits*,*Dcel*>::*Polygon\_2* and *General\_polygon\_set\_2*<*Traits*,*Dcel*>::*Polygon\_with\_holes\_2*, which model the concepts *GeneralPolygon\_2* and *GeneralPolygonWithHoles\_2* respectively.

### 15.3.1 The Traits-Class Concepts

The traits class used to instantiate the *General\_polygon\_set\_2* class template must model the concept *GeneralPolygonSetTraits\_2*, and is tailored to handle a specific family of curves. The concept *GeneralPolygonSetTraits\_2* refines the concept *ArrangementDirectionalXMonotoneTraits\_2* specified next.

The concept *ArrangementDirectionalXMonotoneTraits\_2* refines the concept *ArrangementXMonotoneTraits\_2* (see Section 26.4.1 in the 2D Arrangements chapter). Thus, a model of this concept must define the type *X\_monotone\_curve\_2*, which represents an *x*-monotone curve, and the type *Point\_2*, which represents a planar point. Such a point may be an endpoint of an *x*-monotone curve or an intersection point between two curves. It must also provide various geometric predicates and operations on these types listed by the base concept, such as determining whether a point lies above or below an *x*-monotone curve, computing the intersections between two curves, etc. Note that the base concept does not assume that *x*-monotone curves are directed: an *x*-monotone curve is not required to have a designated *source* and *target*, it is only required to determine the left (lexicographically smaller) and the right (lexicographically larger) endpoints of a given curve.

The *ArrangementDirectionalXMonotoneTraits\_2* concept treats its *x*-monotone curves as directed objects. It thus requires two additional operations on *x*-monotone curves:

- Given an *x*-monotone curve, compare its source and target points lexicographically.
- Given an *x*-monotone curve, construct its opposite curve (namely, swap its source and target points).

The traits classes *Arr\_segment\_traits\_2*, *Arr\_non\_caching\_segment\_traits*, *Arr\_circle\_segment\_traits\_2*, *Arr\_conic\_traits\_2* and *Arr\_rational\_arc\_traits\_2*, which are bundled in the *Arrangement\_2* package and distributed with CGAL, are all models of the refined concept *ArrangementDirectionalXMonotoneTraits\_2*.<sup>3</sup>

Just as with the case of computations using models of the *ArrangementXMonotoneTraits\_2* concept, operations are robust only when exact arithmetic is used. When inexact arithmetic is used, (nearly) degenerate configurations may result in abnormal termination of the program or even incorrect results.

### 15.3.2 Operating on Polygons with Circular Arcs

Two traits classes are distributed with CGAL. The first one is named *Gps\_segment\_traits\_2*, and it is used to perform Boolean set-operations on ordinary polygons and polygons with holes. In fact, the class *Polygon\_set\_2* introduced in Section 15.2.2 is a specialization of *General\_polygon\_set\_2*<*Gps\_segment\_traits\_2*>. This class defined its polygon and polygon with holes types, such that the usage of this traits class is encapsulated in the polygon-set class.

The other predefined traits class is named *Gps\_circle\_segment\_traits\_2*<*Kernel*> and is parameterized by a geometric CGAL kernel. By instantiating the *General\_polygon\_set\_2* with this traits class, we obtain the representation of a polygon whose boundary may be comprised of line segments and circular arcs. The circle-segment traits class provides predicates and constructions on non-linear objects; yet, it uses only rational arithmetic and is very efficient as a consequence.

---

<sup>3</sup>The *Arr\_polyline\_traits\_2* class is *not* a model of the, *ArrangementDirectionalXMonotoneTraits\_2* concept, as the *x*-monotone curve it defines is always directed from left to right. Thus, an opposite curve cannot be constructed. However, it is not very useful to construct a polygon whose edges are polylines, as an ordinary polygon with linear edges can represent the same entity.

The following example uses the *Gps\_circle\_segment\_traits\_2* class to compute the union of four rectangles and four circles. Each circle is represented as a general polygon having two *x*-monotone circular arcs. The union is computed incrementally, resulting with a single polygon with a single hole, as depicted on the right. Note that as the four circles are disjoint, their union is computed with the *insert* method, while the union with the rectangles is computed with the *join* operator.

```

### 15.3.3 General Polygon Set Traits Adapter

The concept *GeneralPolygon\_2* and its generic model *General\_polygon\_2<ArrDirectionalXMonotoneTraits>* facilitate the production of general-polygon set traits classes. A model of the concept *GeneralPolygon\_2* represents a simple point-set in the plane bounded by *x*-monotone curves. As opposed to the plain *Traits::Polygon\_2* type defined by any traits class, it must define the type *X\_monotone\_curve\_2*, which represents an *x*-monotone curve of the point-set boundary. It must provide a constructor from a range of such curves, and a pair of methods, namely *curves\_begin()* and *curves\_end()*, that can be used to iterate over the point-set boundary curves.

The class-template *General\_polygon\_2<ArrDirectionalXMonotoneTraits>* models the concept *GeneralPolygon\_2*. Its sole template parameter must be instantiated with a model of the concept *ArrangementDirectionalXMonotoneTraits\_2* from which it obtains the *X\_monotone\_curve\_2* type. It uses the geometric operations on this type provided by such a model to maintain a container of directed curves of type *X\_monotone\_curve\_2*, which represents a boundary of the general polygon.

The class-template *Gps\_traits\_2<ArrDirectionalXMonotoneTraits,GeneralPolygon>* models the concept *GeneralPolygonSetTraits\_2*, and can be used to instantiate the class template *General\_polygon\_set\_2*. It serves as an adapter for a geometric traits class, which models the concept *ArrangementDirectionalXMonotoneTraits\_2*. It can be used for performing set-operations on general polygons. The implementation of the adapter is rather simple, as it is derived from the instantiated template-parameter *ArrXMonotoneTraits\_2* inheriting its necessary types and methods. It further exploits the methods provided by the instantiated parameter *GeneralPolygon*, which is a model of the concept *GeneralPolygon\_2*. By default, the *GeneralPolygon* parameter is defined as *General\_polygon\_2<ArrangementDirectionalXMonotoneTraits\_2>*.

The code excerpt listed below defines a general-polygon set type that can be used to perform Boolean set-operations on point sets bounded by the *x*-monotone curve type defined by the arrangement-traits class *Arr\_traits\_2*, which is some representative model of the concept *ArrangementDirectionalXMonotoneTraits\_2*.

```
#include <CGAL/General_polygon_2.h>
#include <CGAL/Gps_traits_2.h>

typedef CGAL::General_polygon_2<Arr_traits_2>          General_polygon_2;
typedef CGAL::Gps_traits_2<Arr_traits_2, General_polygon_2> Traits_2;
typedef CGAL::General_polygon_set_2<Traits_2>          General_polygon_set_2;
```

Instantiating the arrangement-traits *Arr\_traits\_2* above with the traits class that handle Bézier curves *Arr\_bezier\_traits\_2*, results with the definition of a general-polygon set type that can be used to perform Boolean set-operations on point sets bounded by Bézier curves.

The next example computes the intersection of two general polygons bounded by Bézier curves read from two input files respectively. The default input files our example uses (*char\_g.dat* and *char\_m.dat*) define two general polygons shaped in the form of the characters **g** and **m** in the Times New Roman font respectively. Their intersection comprises nine simple polygons, as depicted to the right.

Recall that every Bézier curve is defined by a sequence of control points that form chains (see Section 26.6.7). The last control point of every curve must be identical to the first control point of its successor. The function

*read\_Bezier\_polygon()* included in the example reads the curves from an input file until they form a closed chain, which is assumed to be the outer boundary of the polygon. If more curves are available, it starts constructing polygons that correspond to holes in the area bounded by the outer boundary. Note that this function is also responsible for subdividing the input Bézier curves into  $x$ -monotone subcurves, as required by the *Gps\_traits\_2* adapter.

### 15.3.4 Example - Aggregated Operations

In Section [15.2.3](#) we describe how aggregated union and intersection operations can be applied to a collection of ordinary polygons or polygons with holes. Naturally, the aggregated operations can be applied also to collections of general polygons. As was the case with ordinary polygons, using aggregated operations is recommended when the number of intersections of the input polygons is of the same order of magnitude as the complexity of the result. If this is not the case, computing the result incrementally may prove faster.

The next example computes the union of eight unit discs whose centers are placed a unit distance from the origin, as depicted to the right. The example also allows users to provide a different number of discs through the command line.

```

/*! \file set_union.cpp
 * Computing the union of a set of circles.
 */

#include "bso_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Gps_circle_segment_traits_2.h>

# 2D Regularized Boolean Set-Operations Reference Manual

*Efi Fogel, Ron Wein, Baruch Zukerman, and Dan Halperin*

## Introduction

This package consists of the implementation of Boolean set-operations on point sets bounded by  $x$ -monotone curves in 2-dimensional Euclidean space. In particular, it contains the implementation of regularized Boolean set-operations, intersection predicates, and point containment predicates.

## CGAL::General\_polygon\_set\_2<Traits,Dcel>

### Definition

An object of the *General\_polygon\_set\_2<Traits,Dcel>* class-template represents a point set in the plane bounded by  $x$  monotone curves. Points in the set lie on the boundary or on the positive side of the curves. This class template provides methods to apply regularized Boolean set-operations and few other utility methods. An *Arrangement\_2* data structure is internally used to represent the point set. The arrangement is represented as a doubly-connected edge-list (DCEL).

The *Traits* template-parameter should be instantiated with a model of the concept *GeneralPolygonSetTraits\_2*. The traits class defines the types of points,  $x$ -monotone curves, general polygons, and general polygons with holes, that is *Traits::Point\_2*, *Traits::X\_monotone\_curve\_2*, *Traits::Polygon\_2*, and *Traits::Polygon\_with\_holes\_2* respectively. *Traits::Point\_2* must be the type of the endpoints of *Traits::X\_monotone\_curve\_2*, and *Traits::X\_monotone\_curve\_2* must be the type of the curves that comprise the boundaries of the general polygons. The traits class supports geometric operations on the types above. We sometimes use the term *polygon* instead of general polygon for simplicity hereafter.

The template parameter *Dcel* should be instantiated with a model of the concept *GeneralPolygonSetDcel*. It is instantiated by default with the type *Gps\_default\_dcel<Traits>*. You can override this default, with a different DCEL class, typically an extension of the *Gps\_default\_dcel* class template. Overriding the default is necessary only if you intend to obtain the undelying internal arrangement and process it further.

The input and output of the Boolean set-operations methods consist of one or more general polygons, some of which may have holes. In particular, these methods operate on pairs of objects of type *General\_polygon\_set\_2<Traits,Dcel>*, or directly on objects of type *Traits::Polygon\_2* or *Traits::Polygon\_with\_holes\_2*. An object of type *Traits::Polygon\_2* is a valid operand, only if it is strictly simple and its boundary is oriented counterclockwise. An object of type *Traits::Polygon\_with\_holes\_2* is valid, only if its outer boundary is simple and oriented counterclockwise, and each one of its holes is a strictly simple polygon that oriented clockwise, contained inside its outer boundary, and they are all together pairwise disjoint, except perhaps at the vertices.

### Types

<i>General_polygon_set_2&lt;Traits,Dcel&gt;:: Traits_2</i>	the traits class in use.
<i>General_polygon_set_2&lt;Traits,Dcel&gt;:: Polygon_2</i>	the general polygon type. Must model the <i>GpsTraits::GeneralPolygon_2</i> Concept.
<i>General_polygon_set_2&lt;Traits,Dcel&gt;:: Polygon_with_holes_2</i>	the general polygon with holes type. Must model the <i>GpsTraits::GeneralPolygonWithHoles_2</i> Concept.
<i>General_polygon_set_2&lt;Traits,Dcel&gt;:: Size</i>	number of polygons with holes size type.
<i>General_polygon_set_2&lt;Traits,Dcel&gt;:: Arrangement_2</i>	the arrangement type used internally.

## Creation

*General\_polygon\_set\_2*<*Traits*,*Dcel*> *gps*; constructs an empty set of polygons represented by an empty arrangement.

*General\_polygon\_set\_2*<*Traits*,*Dcel*> *gps*( *Self* *other*); copy constructor.

*General\_polygon\_set\_2*<*Traits*,*Dcel*> *gps*( *Traits* & *traits*);  
constructs an empty set of polygons that uses the given *traits* instance for performing the geometric operations.

*General\_polygon\_set\_2*<*Traits*,*Dcel*> *gps*( *Polygon\_2* *pgn*);  
constructs a set of polygons that consists of the single polygon *pgn*.

*General\_polygon\_set\_2*<*Traits*,*Dcel*> *gps*( *Polygon\_with\_holes\_2* *pgn\_with\_holes*);  
constructs a set of polygons that consists of the single polygon with holes *pgn\_with\_holes*.

## Access Functions

template <class *OutputIterator*>  
*OutputIterator* *gps.polygons\_with\_holes*( *OutputIterator* *out*)  
obtains the polygons with holes represented by *gps*.

*Size* *gps.number\_of\_polygons\_with\_holes*() returns the total number of general polygons represented by *gps*.

*bool* *gps.is\_empty*() returns *true* if *gps* represents an empty set.

*bool* *gps.is\_plane*() returns *true* if *gps* represents the entire plane.

*Traits*& *gps.traits*() obtains an instance of the traits. If the traits was passed as a parameter to the constructor of *gps*, it is returned. Otherwise, a newly created instance is returned.

*Arrangement\_2* *gps.arrangement*() obtains the arrangement data structure that internally represents the general-polygon set.

## Modifiers

<code>void</code> <code>gps.clear()</code>	clears <i>gps</i> .
<code>void</code> <code>gps.insert( Polygon_2 &amp; pgn )</code>	inserts <i>pgn</i> into <i>gps</i> . <i>Precondition:</i> <i>pgn</i> and the point set represented by <i>gps</i> are disjoint. This precondition enables the use of very efficient insertion methods. Use the respective overloaded method that inserts a polygon of type <i>Polygon_with_holes_2</i> , if only a relaxed precondition can be guaranteed. If even the relaxed precondition cannot be guaranteed, use the <i>join</i> method.
<code>void</code> <code>gps.insert( Polygon_with_holes_2 &amp; pgn_with_holes )</code>	inserts <i>pgn_with_holes</i> into <i>gps</i> . <i>Precondition:</i> <i>pgn_with_holes</i> does not intersect with the point set represented by <i>gps</i> , except maybe at the vertices. If this relaxed precondition cannot be guaranteed, use the <i>join</i> method.
<code>template &lt;class InputIterator&gt;</code> <code>void</code> <code>gps.insert( InputIterator begin, InputIterator end )</code>	inserts the range of polygons (or polygons with holes) into <i>gps</i> . (The value type of the input iterator is used to distinguish between the two.) <i>Precondition:</i> If the given range contains objects of type <i>Polygon_with_holes_2</i> , then these polygons and the point set represented by <i>gps</i> are pairwise disjoint, except maybe at the vertices. If the given range contains objects of type <i>Polygon_2</i> , then these polygons and the point set represented by <i>gps</i> are pairwise disjoint without any exceptions.
<code>template &lt;class InputIterator1, class InputIterator2&gt;</code> <code>void</code> <code>gps.insert( InputIterator1 pgn_begin,</code> <code>          InputIterator1 pgn_end,</code> <code>          InputIterator2 pgn_with_holes_begin,</code> <code>          InputIterator2 pgn_with_holes_end )</code>	inserts the two ranges of polygons and polygons with holes into <i>gps</i> . <i>Precondition:</i> All polygons in the first range, all polygon with holes in the second range, and the point set represented by <i>gps</i> are pairwise disjoint, except maybe at the vertices
<code>void</code> <code>gps.complement()</code>	computes the complement of <i>gps</i> .
<code>void</code> <code>gps.complement( Polygon_set_2 other )</code>	computes the complement of <i>other</i> . <i>gps</i> is overridden by the result.

## Univariate Operations

In the following univariate and bivariate methods the result is placed in *gps* after it is cleared.

```
void    gps.intersection( General_polygon_set_2 other)
```

computes the intersection of *gps* and *other*.

```
void    gps.intersection( Polygon_2 pgn)
```

computes the intersection of *gps* and *pgn*.

```
void    gps.intersection( Polygon_with_holes_2 pgn)
```

computes the intersection of *gps* and *pgn*.

```
template <class InputIterator>
```

```
void    gps.intersection( InputIterator begin, InputIterator end)
```

computes the intersection of a collection of point sets. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

```
template <class InputIterator1, class InputIterator2>
```

```
void    gps.intersection( InputIterator1 pgn_begin,  
                        InputIterator1 pgn_end,  
                        InputIterator2 pgn_with_holes_begin,  
                        InputIterator2 pgn_with_holes_end)
```

computes the intersection of a collection of point sets. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

```
void    gps.join( General_polygon_set_2 other)
```

computes the union of *gps* and *other*.

```
void    gps.join( Polygon_2 pgn)
```

computes the union of *gps* and *pgn*.

```
void    gps.join( Polygon_with_holes_2 pgn)
```

computes the union of *gps* and *pgn*.

```
template <class InputIterator>
```

```
void    gps.join( InputIterator begin, InputIterator end)
```

computes the union of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

```
template <class InputIterator1, class InputIterator2>
```

```
void    gps.join( InputIterator1 pgn_begin,  
                InputIterator1 pgn_end,  
                InputIterator2 pgn_with_holes_begin,  
                InputIterator2 pgn_with_holes_end)
```

computes the union of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

*void*    *gps.difference( General\_polygon\_set\_2 other)*

computes the difference between *gps* and *other*.

*void*    *gps.difference( Polygon\_2 pgn)*

computes the difference between *gps* and *pgn*.

*void*    *gps.difference( Polygon\_with\_holes\_2 pgn)*

computes the difference between *gps* and *pgn*.

*void*    *gps.symmetric\_difference( General\_polygon\_set\_2 other)*

computes the symmetric difference between *gps* and *other*.

*void*    *gps.symmetric\_difference( Polygon\_2 pgn)*

computes the symmetric difference between *gps* and *pgn*.

*void*    *gps.symmetric\_difference( Polygon\_with\_holes\_2 pgn)*

computes the symmetric difference between *gps* and *pgn*.

*template* <*class InputIterator*>

*void*    *gps.symmetric\_difference( InputIterator begin, InputIterator end)*

computes the symmetric difference (xor) of a collection of point sets. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

*template* <*class InputIterator1, class InputIterator2*>

*void*    *gps.symmetric\_difference( InputIterator1 pgn\_begin,*  
                                  *InputIterator1 pgn\_end,*  
                                  *InputIterator2 pgn\_with\_holes\_begin,*  
                                  *InputIterator2 pgn\_with\_holes\_end)*

computes the symmetric difference (xor) of a collection of point sets. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

## **Bivariate Operations**

The following bivariate function replace *gps* with the result.

*void*    *gps.intersection( General\_polygon\_set\_2 gps1, General\_polygon\_set\_2 gps2)*

computes the intersection of *gps1* and *gps2*.

*void*    *gps.join( General\_polygon\_set\_2 gps1, General\_polygon\_set\_2 gps2)*

computes the union of *gps1* and *gps2*.

computes the difference between *gps1* and *gps2*.

computes the symmetric difference between *gps1* and *gps2*.

## Query Functions

<i>bool</i>	<i>gps.do_intersect( General_polygon_set_2 other)</i>	returns <i>true</i> if <i>gps</i> and <i>other</i> intersect in their interior, and <i>false</i> otherwise.
-------------	---	---

<i>bool</i>	<i>gps.do_intersect( Polygon_2 pgn)</i>	returns <i>true</i> if <i>gps</i> and <i>pgn</i> intersect in their interior, and <i>false</i> otherwise.
-------------	---	---

<i>bool</i>	<i>gps.do_intersect( Polygon_with_holes_2 pgn)</i>	returns <i>true</i> if <i>gps</i> and <i>pgn</i> intersect in their interior, and <i>false</i> otherwise.
-------------	--	---

```
template <class InputIterator>
```

```
void gps.do_intersect( InputIterator begin, InputIterator end)
```

returns *true* if the interior of the point sets in a collection intersect, and *false* otherwise. The collection consists of the polygons (or polygons with holes) in the given range and the point set represented by *gps*. (The value type of the input iterator is used to distinguish between the two options.)

```
template <class InputIterator1, class InputIterator2>
```

[illegible]

returns *true* if the interior of the point sets in a collection intersect, and *false* otherwise. The collection consists of the polygons and polygons with holes in the given two ranges and the point set represented by *gps*.

```
bool      gps.locate( Point_2 p, Polygon_with_holes_2 & pgn)
```

obtains a polygon with holes that contains the query point  $p$ , if exists, through  $pgn$ , and returns *true*. Otherwise, returns *false*.

<i>Oriented_side</i>	<i>gps.oriented_side( Point_2 q)</i>	returns either the constant <i>ON_ORIENTED_BOUNDARY</i> , <i>ON_POSITIVE_SIDE</i> , or <i>ON_NEGATIVE_SIDE</i> , iff <i>p</i> lies on the boundary, properly on the positive side, or properly on the negative side of <i>gps</i> respectively.
<i>Oriented_side</i>	<i>gps.oriented_side( General_polygon_set_2 other)</i>	returns either the constant <i>ON_NEGATIVE_SIDE</i> , <i>ON_ORIENTED_BOUNDARY</i> , or <i>ON_POSITIVE_SIDE</i> , iff <i>other</i> and <i>gps</i> are completely disjoint, in contact, or intersect in their interior, respectively.
<i>Oriented_side</i>	<i>gps.oriented_side( Polygon_2 pgn)</i>	returns either the constant <i>ON_NEGATIVE_SIDE</i> , <i>ON_ORIENTED_BOUNDARY</i> , or <i>ON_POSITIVE_SIDE</i> , iff <i>pgn</i> and <i>gps</i> are completely disjoint, in contact, or intersect in their interior, respectively.
<i>Oriented_side</i>	<i>gps.oriented_side( Polygon_with_holes_2 pgn)</i>	returns either the constant <i>ON_NEGATIVE_SIDE</i> , <i>ON_ORIENTED_BOUNDARY</i> , or <i>ON_POSITIVE_SIDE</i> , iff <i>pgn</i> and <i>gps</i> are completely disjoint, in contact, or intersect in their interior, respectively.

## Miscellaneous

<i>bool</i>	<i>gps.is_valid()</i>	returns <i>true</i> if <i>gps</i> represents a valid point set.
-------------	-----------------------	---

## GeneralPolygon\_2

### Refines

*GpsTraitsGeneralPloygon\_2*

### Types

<i>GeneralPolygon_2:: X_monotone_curve_2</i>	represents a planar (weakly) <i>x</i> -monotone curve. The type of the geometric mapping of the polygonal edges.
<i>GeneralPolygon_2:: Curve_iterator</i>	an iterator over the geometric mapping of the polygon edges. Its value type is <i>X_monotone_curve_2</i> .
<i>GeneralPolygon_2:: Curve_const_iterator</i>	a const iterator over the geometric mapping of the polygon edges. Its value type is <i>X_monotone_curve_2</i> .

### Definition

A model of this concept represents a simple general-polygon. The geometric mapping of the edges of the polygon must be *x*-monotone curves. The concept requires the ability to access these curves. The general polygon represented must be simple. That is, the only points of the plane belonging to two curves are the geometric mapping of the polygon vertices. In addition, the vertices of the represented polygon must be ordered consistently, and the curved must be directed accordingly. Only counterclockwise oriented polygons are valid operands of Boolean set-operations. General polygon that represent holes must be clockwise oriented.

### Creation

<i>GeneralPolygon_2 polygon;</i>	default constructor.
<i>GeneralPolygon_2 polygon( other);</i>	copy constructor.
<i>GeneralPolygon_2 polygon = other</i>	assignment operator.
<i>template &lt;class InputIterator&gt;</i> <i>GeneralPolygon_2 polygon( InputIterator begin, InputIterator end);</i>	constructs a general polygon from a given range of curves.

### Access Functions

<i>Curve_iterator</i>	<i>polygon.curves_begin()</i>	returns the begin iterator of the curves.
<i>Curve_iterator</i>	<i>polygon.curves_end()</i>	returns the past-the-end iterator of the curves.
<i>Curve_const_iterator</i>	<i>polygon.curves_begin()</i>	returns the begin const iterator of the curves.
<i>Curve_const_iterator</i>	<i>polygon.curves_end()</i>	returns the past-the-end const iterator of the curves.

## Modifiers

```
template <class Iterator>  
void polygon.init( Iterator begin, Iterator end)
```

initializes the polygon with the polygonal chain given by the range. The value type of *Iterator* must be *X\_monotone\_curve\_2*.

*Precondition:* The curves in the range must define a simple polygon.

## Has Models

```
CGAL::General_polygon_2<ArrTraits>  
CGAL::Polygon_2<PolygonTraits_2, Container>
```

## GeneralPolygonWithHoles\_2

### Refines

*GpsTraitsGeneralPloygonWithHoles\_2*

### Types

*GeneralPolygonWithHoles\_2:: General\_polygon\_2* the general-polygon type used to represent the outer boundary and each hole. Must Model the *GeneralPolygon\_2* Concept.

*GeneralPolygonWithHoles\_2:: Hole\_const\_iterator* a bidirectional iterator over the polygonal holes. Its value type is *General\_polygon\_2*.

### Definition

A model of this concept represents a general polygon with holes. The concept requires the ability to access the general polygon that represents the outer boundary and the general polygons that represent the holes.

### Creation

<i>GeneralPolygonWithHoles_2 polygon;</i>	default constructor.
<i>GeneralPolygonWithHoles_2 polygon( other);</i>	copy constructor.
<i>GeneralPolygonWithHoles_2 polygon = other</i>	assignment operator.

*template <class InputIterator>*

*GeneralPolygonWithHoles\_2 polygon( General\_polygon\_2 & outer, InputIterator begin, InputIterator end);*

constructs a general polygon with holes using a given general polygon *outer* as the outer boundary and a given range of holes. If *outer* is an empty general polygon, then an unbounded polygon with holes will be created. The holes must be contained inside the outer boundary, and the polygons representing the holes must be strictly simple and pairwise disjoint, except perhaps at the vertices.

### Predicates

<i>bool</i>	<i>polygon.is_unbounded()</i>	returns <i>true</i> if the outer boundary is empty, and <i>false</i> otherwise.
-------------	-------------------------------	---

## Access Functions

<i>General_polygon_2</i>	<i>polygon.outer_boundary()</i>	returns the general polygon that represents the outer boundary.
<i>Hole_const_iterator</i>	<i>polygon.holes_begin()</i>	returns the begin iterator of the holes.
<i>Hole_const_iterator</i>	<i>polygon.holes_end()</i>	returns the past-the-end iterator of the holes.

## Has Models

*CGAL::General\_polygon\_with\_holes\_2<General\_polygon>*  
*CGAL::Polygon\_with\_holes\_2<Kernel, Container>*  
*CGAL::Gps\_circle\_segment\_traits\_2<Kernel>::Polygon\_with\_holes\_2*  
*CGAL::Gps\_traits\_2<ArrTraits, GeneralPolygon>::Polygon\_with\_holes\_2*

## ArrangementDirectionalXMonotoneTraits\_2

### Definition

This concept refines the basic arrangement  $x$ -monotone traits concept. A model of this concept is able to handle *directed*  $x$ -monotone curves that intersect in their interior. Namely, an instance of the *X\_monotone\_curve\_2* type defined by a model of the concept *ArrangementXMonotoneTraits\_2* is only required to have a *left* (lexicographically smaller) endpoint and a *right* endpoint. If the traits class is also a model of *ArrangementDirectionalXMonotoneTraits\_2*, the  $x$ -monotone curve is also required to have a direction, namely one of these two endpoint is viewed as its *source* and the other as its *target*.

### Refines

*ArrangementXMonotoneTraits\_2*

### Functor Types

*ArrangementDirectionalXMonotoneTraits\_2:: Compare\_endpoints\_xy\_2*

provides the operator :

*Comparison\_result operator() (X\_monotone\_curve\_2 c)*

which accepts an input curve  $c$  and compare its source and target point. It returns *SMALLER* if the curve is directed from left to right (lexicographically — i.e., in case of a vertical line segment, this means it is directed upward), and *LARGER* if it is directed from right to left.

*ArrangementDirectionalXMonotoneTraits\_2:: Construct\_opposite\_2*

provides the operator :

*X\_monotone\_curve\_2 operator() (X\_monotone\_curve\_2 c)*

which accepts an  $x$ -monotone curve  $c$  and returns its opposite curve, namely a curve whose graph is the same as  $c$ 's, and whose source and target are swapped with respect to  $c$ 's source and target.

In addition, the two following functors, required by the concept *ArrangementXMonotoneTraits\_2* should operate as follows:

*ArrangementDirectionalXMonotoneTraits\_2:: Intersect\_2*

provides the operator (templated by the *OutputIterator* type) :

*OutputIterator operator() (X\_monotone\_curve\_2 c1, X\_monotone\_curve\_2 c2, OutputIterator oi)*

which computes the intersections of  $c1$  and  $c2$  and inserts them *in an ascending lexicographic xy-order* into the output iterator. The value-type of *OutputIterator* is *CGAL::Object*, where each *Object* either wraps a *pair<Point\_2, Multiplicity>* instance, which represents an intersection point with its multiplicity (in case the multiplicity is undefined or not known, it should be set to 0) or an *X\_monotone\_curve\_2* instance, representing an overlapping subcurve of  $c1$  and  $c2$ . In the latter case, if  $c1$  and  $c2$  have the same direction, then the overlapping subcurves should also be directed the same way; otherwise, they can be associated with an arbitrary direction. The operator returns a past-the-end iterator for the output sequence.

*ArrangementDirectionalXMonotoneTraits\_2:: Split\_2*

provides the operator :

```
void operator() (X_monotone_curve_2 c, Point_2 p, X_monotone_curve_2& c1, X_monotone_curve_2& c2)
```

which accepts an input curve *c* and a split point *p* in its interior. It splits *c* at the split point into two subcurves *c1* and *c2*, such that *p* is *c1*'s *right* endpoint and *c2*'s *left* endpoint. The direction of *c* should be preserved: in case *c* is directed from left to right then *p* becomes *c1*'s target and *c2*'s source; otherwise, *p* becomes *c2*'s target and *c1*'s source.

## Creation

*ArrangementDirectionalXMonotoneTraits\_2 traits;* default constructor.

*ArrangementDirectionalXMonotoneTraits\_2 traits( other);*

copy constructor

*ArrangementDirectionalXMonotoneTraits\_2*

*traits = other* assignment operator.

## GeneralPolygonSetTraits\_2

### Definition

This concept defines the minimal set of geometric predicates needed to perform the Boolean-set operations. It refines the directional  $x$ -monotone arrangement-traits concept. In addition to the *Point\_2* and *X\_monotone\_curve\_2* types defined in the generalized concept, it defines a type that represents a general polygon and another one that represents general polygon with holes. It also requires operations that operate on these types.

### Refines

*ArrangementDirectionalXMonotoneTraits\_2*

### Types

<i>GeneralPolygonSetTraits_2:: Polygon_2</i>	represents a general polygon. Must be a model of the <i>GpsTraitsGeneralPolygon_2</i> concept.
<i>GeneralPolygonSetTraits_2:: Polygon_with_holes_2</i>	represents a general polygon with holes. Must be a model of the <i>GpsTraitsGeneralPolygonWithHoles_2</i> concept.
<i>GeneralPolygonSetTraits_2:: Curve_const_iterator</i>	A const iterator of curves. Its value type is const <i>X_monotone_curve_2</i> .

### Functor Types

<i>GeneralPolygonSetTraits_2:: Construct_polygon_2</i>	a functor that constructs a general polygon from a range of $x$ -monotone curves. It uses the operator <i>void operator() (InputIterator begin, Input iterator end, Polygon_2 &amp; pgn)</i> , parameterized by the <i>InputIterator</i> type.
<i>GeneralPolygonSetTraits_2:: Construct_curves_2</i>	a functor that returns a pair that consists of the begin and past-the-end iterators of the $x$ monotone curves of the boundary of a given general polygon. It uses the operator <i>std::pair&lt;Curve_const_iterator, Curve_const_iterator&gt; operator() (const Polygon_2 &amp; pgn)</i> .

*GeneralPolygonSetTraits\_2:: Is\_valid\_2*

provides the operators :

*bool operator() (Polygon\_2 & pgn)*

which returns *true* if the *pgn* is valid, and *false* otherwise;

and :

*bool operator() (Polygon\_with\_holes\_2 & pgn\_with\_holes)*

which returns *true* if *pgn\_with\_holes* is valid, and *false* otherwise. A polygon of type *Polygon\_2* is valid, if it is strictly simple and oriented counterclockwise. A polygon of type *Polygon\_with\_holes\_2* is valid, if its outer boundary is simple and oriented counterclockwise, and each one of its holes is a strictly simple polygon that oriented clockwise, contained inside its outer boundary, and they are all together pairwise disjoint, except perhaps at the vertices.

This functionality is used to verify precondition of some of the operations.

*GeneralPolygonSetTraits\_2:: Construct\_general\_polygon\_with\_holes\_2*

a functor that constructs a general polygon with holes from a general polygon and, optionally, a range of holes. It uses the operator

*void operator() (const General\_polygon\_2& pgn\_boundary)* or

*void operator() (const General\_polygon\_2& pgn\_boundary, HolesInputIterator h\_begin, HolesInputIterator h\_end)* parameterized by the *HolesInputIterator* type.

*GeneralPolygonSetTraits\_2:: Construct\_outer\_boundary*

A functor for constructing the outer boundary of a polygon with holes. It uses the operator

*General\_polygon\_2 operator()(const General\_polygon\_with\_holes\_2& pol\_wh).*

*GeneralPolygonSetTraits\_2:: Construct\_holes*

A functor for constructing the container of holes of a polygon with holes. It returns the begin/end iterators for the holes It uses the operator

*std::pair<Hole\_const\_iterator, Hole\_const\_iterator> operator()(const General\_polygon\_with\_holes\_2& pol\_wh).*

*GeneralPolygonSetTraits\_2:: Is\_unbounded*

A functor for checking if polygon with holes has no outer boundary. It uses the operator

*bool operator()(const General\_polygon\_with\_holes\_2& pol\_wh).*

## Creation

<i>GeneralPolygonSetTraits_2 traits;</i>	default constructor.
<i>GeneralPolygonSetTraits_2 traits( other);</i>	copy constructor
<i>GeneralPolygonSetTraits_2</i>	
<i>traits = other</i>	assignment operator.

## Accessing Functor Objects

<i>Construct_polygon_2</i>	<i>traits.construct_polygon_2_object()</i>	
		returns a functor that constructs a polygon.

<i>Construct_curves_2</i>	<i>traits.construct_curves_2_object()</i>	
		returns a functor that obtains the curves of a polygon.

<i>Is_valid_2</i>	<i>traits.is_valid_2_object()</i>	returns a functor that checks the validity of a polygon.
-------------------	-----------------------------------	--

<i>Construct_general_polygon_with_holes_2</i>		
	<i>traits.construct_polygon_with_holes_2_object()</i>	
		returns a functor that constructs a polygon with holes.

<i>Construct_outer_boundary</i>		
	<i>traits.construct_outer_boundary_object()</i>	
		returns a functor that obtains the outer boundary of a polygon with holes.

<i>Construct_holes</i>	<i>traits.construct_holes_object()</i>	
		returns a functor that obtains begin/end iterators over a container of holes.

<i>Is_unbounded</i>	<i>traits.construct_is_unbounded_object()</i>	
		returns a functor that determines if the polygon with holes is unbounded

## Has Models

## CGAL::General\_polygon\_2<ArrTraits>

### Definition

The class *General\_polygon\_2<ArrTraits>* models the concept *GeneralPolygon\_2*. It represents a simple general-polygon. It is parameterized with the type *ArrTraits* that models the concept *ArrangementDirectionalXMonotoneTraits*. The latter is a refinement of the concept *ArrangementXMonotoneTraits\_2*. In addition to the requirements of the concept *ArrangementXMonotoneTraits\_2*, a model of the concept *ArrangementDirectionalXMonotoneTraits* must support the following functions:

- Given an *x*-monotone curve, construct its opposite curve.
- Given an *x*-monotone curve, compare its two endpoints lexicographically.

This class supports a few convenient operations in addition to the requirements that the concept *GeneralPolygon\_2* lists.

```
#include <CGAL/General_polygon_2.h>
```

### Types

*General\_polygon\_2<ArrTraits>::Size*                      number of edges size type.

### Creation

### Operations

*Size*                      *polygon.size()*                      returns the number of edges of *polygon*.

### Modifiers

*void*                      *polygon.clear()*                      clears *polygon*.

*void*                      *polygon.reverse\_orientation()*                      reverses the orientation of the polygon.  
*Precondition: is\_simple().*

### Predicates

*bool*                      *polygon.is\_empty()*                      returns *true* if *polygon* is empty, and *false* otherwise.

*Orientation*                      *polygon.orientation()*                      returns the orientation of *polygon*.  
*Precondition: is\_simple().*

### Is Model for the Concepts

*GeneralPolygon\_2*

## CGAL::Polygon\_with\_holes\_2<Kernel,Container>

### Definition

The class *Polygon\_with\_holes\_2<Kernel,Container>* models the concept *GeneralPolygonWithHoles\_2*. It represents a linear polygon with holes. It is parameterized with two types (*Kernel* and *Container*) that are used to instantiate the type *CGAL::Polygon\_2<Kernel,Container>*. The latter is used to represent the outer boundary and the boundary of the holes (if any exist).

```
#include <CGAL/Polygon_with_holes_2.h>
```

### Is Model for the Concepts

*GeneralPolygonWithHoles\_2*

## CGAL::Polygon\_set\_2<Kernel,Container,Dcel>

### Definition

The class *Polygon\_set\_2*<*Kernel*,*Container*,*Dcel*> represents sets of linear polygons with holes. The first two template parameters (*Kernel* and *Container*) are used to instantiate the type *CGAL::Polygon\_2*<*Kernel*,*Container*>. This type is used to represent the outer boundary of every set member and the boundaries of all holes of every set member.

The third template parameter *Dcel* should be instantiated with a model of the concept *GeneralPolygonSetDcel*. It is instantiated by default with the type *Gps\_default\_dcel*<*Traits*>. You can override this default, with a different DCEL class, typically an extension of the *Gps\_default\_dcel* class template. Overriding the default is necessary only if you intend to obtain the underlying internal arrangement and process it further.

```
#include <CGAL/Polygon_set_2.h>
```

### Inherits From

*General\_polygon\_set\_2*<*Gps\_segment\_traits\_2*<*Kernel*,*Container*> >

## CGAL::General\_polygon\_with\_holes\_2<Polygon>

### Definition

The class *General\_polygon\_with\_holes\_2<Polygon>* models the concept *GeneralPolygonWithHoles\_2*. It represents a general polygon with holes. It is parameterized with a type *Polygon* used to define the exposed type *General\_polygon\_2*. This type represents the outer boundary of the general polygon and the outer boundaries of each hole.

```
#include <CGAL/General_polygon_with_holes_2.h>
```

```
typedef Polygon          General_polygon_2;
```

### Is Model for the Concepts

*GeneralPolygonWithHoles\_2*

## CGAL::Gps\_segment\_traits\_2<Kernel,Container,ArrSegmentTraits>

### Definition

The traits class *Gps\_segment\_traits\_2<Kernel,Container,ArrSegmentTraits>* models the concept *GeneralPolygonSetTraits\_2*. It enables Boolean set-operations on (linear) polygons. It defines the exposed type *Polygon\_2* to be *CGAL::Polygon\_2<Kernel,Container>*. By default, the template parameter *Container* is instantiated by *std::vector<Kernel::Point\_2>* and the template parameter *ArrSegmentTraits* is instantiated by *CGAL::Arr\_segment\_traits\_2<Kernel>*.

```
#include <CGAL/Gps_segment_traits_2.h>
```

```
typedef CGAL::Polygon_2<Kernel,Container>
```

```
    Polygon_2;
```

### Is Model for the Concepts

*GeneralPolygonSetTraits\_2*

## CGAL::Gps\_circle\_segment\_traits\_2<Kernel>

### Definition

The traits class *Gps\_circle\_segment\_traits\_2<Kernel>* models the *GeneralPolygonSetTraits\_2* concept. It enables Boolean set-operations on general polygons bounded by linear segments or circular arcs. It should be parameterized with a kernel.

```
#include <CGAL/Gps_circle_segment_traits_2.h>
```

### Is Model for the Concepts

*GeneralPolygonSetTraits\_2*

### See Also

*CGAL::Arr\_circle\_segment\_traits\_2<Kernel>*(page ??)

## CGAL::Gps\_traits\_2<ArrTraits,GeneralPolygon\_t>

### Definition

The traits class *Gps\_traits\_2*<*ArrTraits*,*GeneralPolygon\_t*> models the concept *GeneralPolygonSetTraits\_2*. It inherits from the instantiated type of the template parameter *ArrTraits*, which must model the concept *ArrangementDirectionalXMonotoneTraits*, (which in turn refines the concept *ArrangementXMonotoneTraits*). The template parameter *GeneralPolygon\_t* must be instantiated with a model of the concept of *GpsTraitsGeneralPolygon\_2*. By default, the latter is instantiated by *CGAL::General\_polygon\_2*<*ArrTraits*>.

```
#include <CGAL/Gps_traits_2.h>
```

### Is Model for the Concepts

*GeneralPolygonSetTraits\_2*

## CGAL::Gps\_default\_dcel<Traits>

### Definition

The class *Gps\_default\_dcel<Traits>* is the default DCEL class used by the *General\_polygon\_set\_2* and *Polygon\_set\_2* class-templates to represent the underlying internal *Arrangement\_2* data structure.

```
#include <CGAL/Boolean_set_operations_2/Gps_default_dcel.h>
```

### Is Model for the Concepts

*GeneralPolygonSetDcel*

### Inherits From

```
Arr_dcel_base<Arr_vertex_base<typename Traits::Point_2>,
              Arr_halfedge_base<typename Traits::X_monotone_curve_2>,
              Gps_face_base>
```

### Types

```
Gps_default_dcel<Traits>:: template <class T> rebind
```

allows the rebinding of the DCEL with a different traits class *T*.

## GeneralPolygonSetDcel

### Definition

A doubly-connected edge-list (DCEL for short) data-structure. It consists of three containers of records: vertices  $V$ , halfedges  $E$ , and faces  $F$ . It maintains the incidence relation among them. The halfedges are ordered in pairs sometimes referred to as twins, such that each halfedge pair represent an edge.

A model of the GeneralPolygonSetDcel concept must provide the following types and operations. (In addition to the requirements here, the local types *Vertex*, *Halfedge*, *Face* *Hole* and *Isolated\_vertex* must be models of the concepts *ArrangementDcelVertex* (page 1817), *ArrangementDcelHalfedge* (page 1819), *GeneralPolygonSetDcelFace* (page 1247), *ArrangementDcelHole* (page 1824), and *ArrangementDcelIsolatedVertex* (page 1825) respectively.) Notice that this concept differs from the concept *ArrangementDcel* only in the type *Face*.

### Types

<i>GeneralPolygonSetDcel:: Vertex</i>	the vertex type.
<i>GeneralPolygonSetDcel:: Halfedge</i>	the halfedge type.
<i>GeneralPolygonSetDcel:: Face</i>	the face type.
<i>GeneralPolygonSetDcel:: Hole</i>	the hole type.
<i>GeneralPolygonSetDcel:: Isolated_vertex</i>	the isolated vertex type.
<i>GeneralPolygonSetDcel:: Size</i>	used to represent size values (e.g., <i>size_t</i> ).
<i>GeneralPolygonSetDcel:: Vertex_iterator</i>	a bidirectional iterator over the vertices. Its value-type is <i>Vertex</i> .
<i>GeneralPolygonSetDcel:: Halfedge_iterator</i>	a bidirectional iterator over the halfedges. Its value-type is <i>Halfedge</i> .
<i>GeneralPolygonSetDcel:: Face_iterator</i>	a bidirectional iterator over the faces. Its value-type is <i>Face</i> .

The non-mutable iterators *Vertex\_const\_iterator*, *Halfedge\_const\_iterator* and *Face\_const\_iterator* are also defined.

### Creation

<i>GeneralPolygonSetDcel dcel;</i>	constructs an empty DCEL with one unbounded face.
<i>Face*</i>	<i>dcel.assign( Self other, const Face *uf)</i>
	assigns the contents of the <i>other</i> DCEL whose unbounded face is given by <i>uf</i> , to <i>dcel</i> . The function returns a pointer to the unbounded face of <i>dcel</i> after the assignment.

## Access Functions

<i>Size</i>	<i>dcel.size_of_vertices()</i>	returns the number of vertices.
<i>Size</i>	<i>dcel.size_of_halfedges()</i>	returns the number of halfedges (always even).
<i>Size</i>	<i>dcel.size_of_faces()</i>	returns the number of faces.
<i>Size</i>	<i>dcel.size_of_holes()</i>	returns the number of holes (the number of connected components).
<i>Size</i>	<i>dcel.size_of_isolated_vertices()</i>	returns the number of isolated vertices.

The following operations have an equivalent *const* operations that return the corresponding non-mutable iterators:

<i>Vertex_iterator</i>	<i>dcel.vertices_begin()</i>	returns a begin-iterator of the vertices in <i>dcel</i> .
<i>Vertex_iterator</i>	<i>dcel.vertices_end()</i>	returns a past-the-end iterator of the vertices in <i>dcel</i> .
<i>Halfedge_iterator</i>	<i>dcel.halfedges_begin()</i>	returns a begin-iterator of the halfedges in <i>dcel</i> .
<i>Halfedge_iterator</i>	<i>dcel.halfedges_end()</i>	returns a past-the-end iterator of the halfedges in <i>dcel</i> .
<i>Vertex_iterator</i>	<i>dcel.faces_begin()</i>	returns a begin-iterator of the faces in <i>dcel</i> .
<i>Vertex_iterator</i>	<i>dcel.faces_end()</i>	returns a past-the-end iterator of the faces in <i>dcel</i> .

## Modifiers

The following operations allocate a new element of the respective type. Halfedges are always allocated in pairs of opposite halfedges. The halfedges and their opposite pointers are automatically set.

<i>Vertex*</i>	<i>dcel.new_vertex()</i>	creates a new vertex.
<i>Halfedge*</i>	<i>dcel.new_edge()</i>	creates a new pair of twin halfedges.
<i>Face*</i>	<i>dcel.new_face()</i>	creates a new face.
<i>Hole*</i>	<i>dcel.new_hole()</i>	creates a new hole record.
<i>Isolated_vertex*</i>	<i>dcel.new_isolated_vertex()</i>	creates a new isolated vertex record.

<i>void</i>	<i>dcel.delete_vertex( Vertex* v )</i>	deletes the vertex <i>v</i> .
<i>void</i>	<i>dcel.delete_edge( Halfedge* e )</i>	deletes the halfedge <i>e</i> as well as its twin.

<i>void</i>	<i>dcel.delete_face( Face* f)</i>	
		deletes the face <i>f</i> .
<i>void</i>	<i>dcel.delete_hole( Hole* ho)</i>	
		deletes the hole <i>ho</i> .
<i>void</i>	<i>dcel.delete_isolated_vertex( Isolated_vertex* iv)</i>	
		deletes the isolated vertex <i>iv</i> .

## GeneralPolygonSetDcelFace

### Definition

A face record in a DCEL data structure used by the *General\_polygon\_set\_2* and *Polygon\_set\_2* class-templates to represent the undelying internal *Arrangement\_2* data structure.

## Refines

ArrangementDcelFace

## Creation

*GeneralPolygonSetDcelFace* *f*;                      default constructor.

<i>void</i>	<i>f.assign( Self other)</i>	assigns <i>f</i> with the contents of the <i>other</i> face.
-------------	------------------------------	--

## Access Functions

<i>bool</i>	<i>f.contained()</i>	returns <i>true</i> if the face is contained in the general-polygon set, and <i>false</i> otherwise.
-------------	----------------------	--

<i>bool</i>	<i>f.visited()</i>	returns <i>true</i> if the face has been visited, and <i>false</i> otherwise. This is used internally by the some of the operations of the <i>General_polygon_set_2</i> class that traverse the arrangement faces.
-------------	--------------------	--

## Modifiers

<i>void</i>	<i>f.set_contained( bool flag)</i>	marks the face as contained (if <i>flag</i> is <i>true</i> ), or as a hole (if it is <i>false</i> ).
-------------	------------------------------------	--

<code>void</code>	<code>f.set_visited( bool flag)</code>
	<p>marks the face as visited (if <i>flag</i> is <i>true</i>), or as not visited (if it is <i>false</i>). This is used internally by the some of the operations of the <i>General_polygon_set_2</i> class that traverse the arrangement faces.</p>

## CGAL::complement

### Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
void                complement( Type pgn, Type & res)
```

Each one of these functions computes the complement of a given polygon *pgn*, and stores the resulting polygon with holes in *res*.

Arg Type
<i>Polygon_2</i>
<i>General_polygon_2</i>

```
OutputIterator      complement( Type pgn, OutputIterator oi)
```

Each one of these functions computes the complement of a given polygon *pgn*, inserts the resulting polygons with holes into an output container through a given output iterator *oi*, and returns the output iterator. The value type of the *OutputIterator* is either *Polygon\_with\_holes\_2* or *General\_polygon\_with\_holes\_2*.

Arg Type
<i>Polygon_with_holes_2</i>
<i>General_polygon_with_holes_2</i>

```
template <class Kernel, class Container>
void                complement( Polygon_2<Kernel, Container> pgn,
                               Polygon_with_holes_2<Kernel, Container> & res)
```

```
template <class Traits>
void                complement( General_polygon_2<Traits> pgn,
                               General_polygon_with_holes_2<Traits> & res)
```

```
template <class Traits, class OutputIterator>
OutputIterator      complement( Polygon_with_holes_2<Kernel, Container> pgn, OutputIterator oi)
template <class Traits, class OutputIterator>
OutputIterator      complement( General_polygon_with_holes_2<General_polygon_2<Traits> > pgn,
                               OutputIterator oi)
```

## CGAL::difference

### Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
OutputIterator difference( Type1 p1, Type2 p2, OutputIterator oi)
```

Each one of these functions computes the difference between two given polygons  $p1$  and  $p2$ , and inserts the resulting polygons with holes into an output container through the output iterator  $oi$ . The value type of the *OutputIterator* is either *Polygon\_with\_holes\_2* or *General\_polygon\_with\_holes\_2*.

Arg 1 Type	Arg 2 Type

## CGAL::do\_intersect

### Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
bool do_intersect( Type1 p1, Type2 p2)
```

Each one of these functions return *true*, if the two given polygons *p1* and *p2* intersect in their interior, and *false* otherwise.

Arg 1 Type	Arg 2 Type
<i>Polygon_2</i>	<i>Polygon_2</i>
<i>Polygon_2</i>	<i>Polygon_with_holes_2</i>
<i>Polygon_with_holes_2</i>	<i>Polygon_2</i>
<i>Polygon_with_holes_2</i>	<i>Polygon_with_holes_2</i>

```

```
template <class Traits>
bool do_intersect( General_polygon_with_holes_2<General_polygon_2<Traits> > p1,
                  General_polygon_2<Traits> p2)
```

```
template <class Polygon>
bool do_intersect( General_polygon_with_holes_2<Polygon> p1,
                  General_polygon_with_holes_2<Polygon> p2)
```

```
template <class InputIterator>
bool do_intersect( InputIterator begin, InputIterator end)
```

Returns *true*, if the set of general polygons (or general polygons with holes) in the given range intersect in their interior, and *false* otherwise. (The value type of the input iterator is used to distinguish between the two).

```
template <class InputIterator1, class InputIterator2>
bool    do_intersect( InputIterator1 pgn_begin1,
                      InputIterator1 pgn_end1,
                      InputIterator2 pgn_begin2,
                      InputIterator2 pgn_end2)
```

Returns *true*, if the set of general polygons and general polygons with holes in the given two ranges respectively intersect in their interior, and *false* otherwise.

## CGAL::intersection

### Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
OutputIterator intersection( Type1 p1, Type2 p2, OutputIterator oi)
```

Each one of these functions computes the intersection of two given polygons  $p1$  and  $p2$ , inserts the resulting polygons with holes into an output container through a given output iterator  $oi$ , and returns the output iterator. The value type of the *OutputIterator* is either *Polygon\_with\_holes\_2* or *General\_polygon\_with\_holes\_2*.

Arg 1 Type	Arg 2 Type
<i>Polygon_2</i>	<i>Polygon_2</i>
<i>Polygon_2</i>	<i>Polygon_with_holes_2</i>
<i>Polygon_with_holes_2</i>	<i>Polygon_2</i>
<i>Polygon_with_holes_2</i>	<i>Polygon_with_holes_2</i>

                           Polygon_2<Kernel, Container> p2,
                           OutputIterator oi)
```

```
template <class Kernel, class Container, class OutputIterator>
OutputIterator intersection( Polygon_with_holes_2<Kernel, Container> p1,
                           Polygon_with_holes_2<Kernel, Container> p2,
                           OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator intersection( General_polygon_2<Traits> p1,
                           General_polygon_2<Traits> p2,
                           OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator intersection( General_polygon_with_holes_2<General_polygon_2<Traits> > p1,
                           General_polygon_2<Traits> p2,
                           OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    intersection( General_polygon_2<Traits> p1,
                               General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                               OutputIterator oi)
```

```
template <class Polygon, class OutputIterator>
OutputIterator    intersection( General_polygon_with_holes_2<Polygon> p1,
                               General_polygon_with_holes_2<Polygon> p2,
                               OutputIterator oi)
```

```
template <class InputIterator, class OutputIterator>
OutputIterator    intersection( InputIterator begin, InputIterator end, OutputIterator oi)
```

Computes the intersection of the general polygons (or general polygons with holes) in the given range. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon\_with\_holes\_2*.

```
template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator    intersection( InputIterator1 pgn_begin1,
                               InputIterator1 pgn_end1,
                               InputIterator2 pgn_begin2,
                               InputIterator2 pgn_end2,
                               OutputIterator oi)
```

Computes the intersection of the general polygons and general polygons with holes in the given two ranges. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon\_with\_holes\_2*.

# CGAL::join

## Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
bool          join( Type1 p1, Type2 p2, General_polygon_with_holes_2 & p)
```

Each one of these functions computes the union of two given polygons *p1* and *p2*. If the two given polygons overlap, it returns *true*, and places the resulting polygon in *p*. Otherwise, it returns *false*.

                  General_polygon_with_holes_2<Polygon_2<Kernel, Container> > & p)
```

```
template <class Traits>
bool          join( General_polygon_2<Traits> p1,
                  General_polygon_2<Traits> p2,
                  General_polygon_with_holes_2<General_polygon_2<Traits> > & p)
```

```
template <class Traits>
bool          join( General_polygon_2<Traits> p1,
                  General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                  General_polygon_with_holes_2<General_polygon_2<Traits> > & p)
```

```
template <class Traits>
bool      join( General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                General_polygon_2<Traits> p1,
                General_polygon_with_holes_2<General_polygon_2<Traits> > & p)
```

```
template <class Polygon>
bool      join( General_polygon_with_holes_2<Polygon> p1,
                General_polygon_with_holes_2<Polygon> p2,
                Traits::Polygon_with_holes_2 & p)
```

```
template <class InputIterator, class OutputIterator>
OutputIterator  join( InputIterator begin, InputIterator end, OutputIterator oi)
```

Computes the union of the general polygons (or general polygons with holes) in the given range. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon\_with\_holes\_2*.

```
template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator  join( InputIterator1 pgn_begin1,
                    InputIterator1 pgn_end1,
                    InputIterator2 pgn_begin2,
                    InputIterator2 pgn_end2,
                    OutputIterator oi)
```

Computes the union of the general polygons and general polygons with holes in the given two ranges. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon\_with\_holes\_2*.

## CGAL::symmetric\_difference

### Definition

```
#include <CGAL/Boolean_set_operations_2.h>
```

```
OutputIterator    intersection( Type1 p1, Type2 p2, OutputIterator oi)
```

Each one of these functions computes the symmetric difference between two given polygons  $p1$  and  $p2$ , and inserts the resulting polygons with holes into an output container through the output iterator  $oi$ . The value type of the *OutputIterator* is either *Polygon\_with\_holes\_2* or *General\_polygon\_with\_holes\_2*.

                                       Polygon_with_holes_2<Kernel, Container> p2,
                                       OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_2<Traits> p1,
                                       General_polygon_2<Traits> p2,
                                       OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_with_holes_2<General_polygon_2<Traits> > p1,
                                       General_polygon_2<Traits> p2,
                                       OutputIterator oi)
```

```
template <class Traits, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_2<Traits> p1,
                                     General_polygon_with_holes_2<General_polygon_2<Traits> > p2,
                                     OutputIterator oi)
```

```
template <class Polygon, class OutputIterator>
OutputIterator    symmetric_difference( General_polygon_with_holes_2<Polygon> p1,
                                     General_polygon_with_holes_2<Polygon> p2,
                                     OutputIterator oi)
```

```
template <class InputIterator, class OutputIterator>
OutputIterator    symmetric_difference( InputIterator begin, InputIterator end, OutputIterator oi)
```

Computes the symmetric difference of the general polygons (or general polygons with holes) in the given range. A point is contained in the symmetric difference, if and only if it is contained in odd number of input polygons. (The value type of the input iterator is used to distinguish between the two.) The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon\_with\_holes\_2*.

```
template <class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator    symmetric_difference( InputIterator1 pgn_begin1,
                                     InputIterator1 pgn_end1,
                                     InputIterator2 pgn_begin2,
                                     InputIterator2 pgn_end2,
                                     OutputIterator oi)
```

Computes the union of the general polygons and general polygons with holes in the given two ranges. A point is contained in the symmetric difference, if and only if it is contained in odd number of input polygons. The result, represented by a set of general polygon with holes, is inserted into an output container through a given output iterator *oi*. The output iterator is returned. The value type of the *OutputIterator* is *Traits::Polygon\_with\_holes\_2*.

## CGAL::connect\_holes

### Definition

```
#include <CGAL/connect_holes.h>
```

```
template <class Kernel, class Container, class OutputIterator>  
OutputIterator connect_holes( Polygon_with_holes_2<Kernel,Container> pwh, OutputIterator oi)
```

Connects the holes of *pwh* with its outer boundary. This is done by locating the topmost vertex in each hole in the polygon with holes *pwh*, and connecting it by a vertical segment to the polygon feature located directly above it (a vertex or an edge of the outer boundary, or of another hole). The function produces an output sequence of points, which corresponds to the traversal of the vertices of the input polygon; this traversal starts from the outer boundary and moves to the holes using the auxiliary vertical segments that were added to connect the polygon with its holes. The value-type of *oi* is *Kernel::Point\_2*.

*Precondition:* The input polygon with holes *pwh* is bounded (namely it has a valid outer boundary).

## CGAL::operator<<

### Definition

This operator exports a polygon with holes, a general polygon, or a general polygon with holes  $P$  to the output stream *out*. The output is in ASCII format.

An ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, *set\_ascii\_mode* and *set\_binary\_mode* respectively. The modifier *set\_pretty\_mode* can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments.

```
#include <CGAL/Polygon_with_holes_2.h>          template <class Kernel, class Container>
ostream&                                         ostream& out << CGAL::Polygon_with_holes_2<Kernel, Container> P
```

The number of points of the outer boundary is exported followed by the points themselves in counterclockwise order. Then, the number of holes is exported, and for each hole, the number of points on its outer boundary is exported followed by the points themselves in clockwise order.

```
#include <CGAL/General_polygon_2.h>             template <class ArrTraits>
ostream&                                         ostream& out << CGAL::General_polygon_2<ArrTraits> P
```

The number of curves of the outer boundary is exported followed by the curves themselves in counterclockwise order.

```
#include <CGAL/General_polygon_with_holes_2.h>  template <class Polygon>
ostream&                                         ostream& out << CGAL::General_polygon_with_holes_2<Polygon> P
```

The number of curves of the outer boundary is exported followed by the curves themselves in counterclockwise order. Then, the number of holes is exported, and for each hole, the number of curves on its outer boundary is exported followed by the curves themselves in clockwise order.

[operator>> ..... page 1262](#)

## CGAL::operator>>

### Definition

This operator imports a polygon with holes, a general polygon, or a general polygon with holes from the input stream *in*.

An ASCII and a binary format exist. The stream detects the format automatically and can read both.

```
#include <CGAL/Polygon_with_holes_2.h>          template <class Kernel, Class Container>
istream&                                         istream& in >> CGAL::Polygon_with_holes_2<Kernel, Container>& P
```

The format consists of the number of points of the outer boundary followed by the points themselves in counter-clockwise order, followed by the number of holes, and for each hole, the number of points of the outer boundary is followed by the points themselves in clockwise order.

```
#include <CGAL/General_polygon_2.h>            template <class ArrTraits>
istream&                                         istream& in >> CGAL::General_polygon_2<ArrTraits>& P
```

The format consists of the number of curves of the outer boundary followed by the curves themselves in counter-clockwise order.

```
#include <CGAL/General_polygon_with_holes_2.h> template <class Polygon>
istream&                                         istream& in >> CGAL::General_polygon_with_holes_2<Polygon>& P
```

The format consists of the number of curves of the outer boundary followed by the curves themselves in counter-clockwise order, followed by the number of holes, and for each hole, the number of curves on its outer boundary is followed by the curves themselves in clockwise order.

### 16.1 Introduction

When working with polygonal and polyhedral sets, the mathematical model determines the kind of point set that can be represented. Nef polyhedra are the most general rectilinear polyhedral model.

Topological simpler models that are contained in the domain of Nef polyhedra are:

- *convex polytopes* normally defined as the convex hull of a nonempty finite set of points. Convex polytopes are compact closed and manifold sets.
- *elementary polyhedra* normally defined as the union of a finite number of convex polytopes.
- *polyhedral sets* normally defined as the intersection of a finite number of closed halfspaces. Such sets are closed and convex but need not to be compact.
- *linear polyhedra* normally defined as the set of all points belonging to the simplices of a *simplicial complex*.

A planar *Nef polyhedron* is any set that can be obtained from a finite set of open halfspaces by set complement and set intersection operations. Due to the fact that all other binary set operations like union, difference and symmetric difference can be reduced to intersection and complement calculations, Nef polyhedra are also closed under those operations. Apart from the set complement operation there are more topological unary set operations

that are closed in the domain of Nef polyhedra. Given a Nef polyhedron one can determine its interior, its boundary, and its closure, and also composed operations like regularization (defined to be the closure of the interior or a point set).

Figure 16.1: Two Nef polyhedra in the plane. A closed halfspace on the left and a complex polyhedron on the right. Note that the points on the squared boundary are at infinity.

## 16.2 Construction and Composition

Following the above definition, the data type *Nef\_polyhedron\_2<T>* allows construction of elementary Nef polyhedra and the binary and unary composition by the mentioned set operations.

In the following examples skip the typedefs at the beginning at first and take the types *Point* and *Line* to be models of the standard two-dimensional CGAL kernel (*CGAL::Point\_2<K>* and *CGAL::Line\_2<K>*). Their user interface is thus defined in the corresponding reference pages.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Filtered_extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Filtered_extended_homogeneous<RT> Extended_kernel;
typedef CGAL::Nef_polyhedron_2<Extended_kernel> Nef_polyhedron;
typedef Nef_polyhedron::Point Point;
typedef Nef_polyhedron::Line Line;

int main() {

    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    Line l(2,4,2); // l : 2x + 4y + 2 = 0
    Nef_polyhedron N2(l,Nef_polyhedron::INCLUDED);
    Nef_polyhedron N3 = N2.complement();
    CGAL_assertion(N1 == N2.join(N3));

    Point p1(0,0), p2(10,10), p3(-20,15);
    Point triangle[3] = { p1, p2, p3 };
    Nef_polyhedron N4(triangle, triangle+3);
```

```

Nef_polyhedron N5 = N2.intersection(N4);
CGAL_assertion(N5 <= N2 && N5 <= N4);

return 0;
}

```

**File:** examples/Nef\_2/nef\_2\_construction.cpp

Planar halfspaces (as used in the definition) are modelled by oriented lines. In the previous example  $N1$  is the Nef polyhedron representing the full plane,  $N2$  is the closed halfspace left of the oriented line with equation  $2x + 4y + 2 = 0$  including the line,  $N3$  is the complement of  $N2$  and therefore it must hold that  $N2 \cup N3 = N1$ .

Additionally one can construct Nef polyhedra from iterator ranges that hold simple polygonal chains. In the example  $N4$  is the triangle spanned by the vertices  $(0,0)$ ,  $(10,10)$ ,  $(-20,15)$ . Note that the construction from a simple polygonal chain has several cases and preconditions that are described in the reference manual page of *Nef\_polyhedron\_2<T>*. The *operator<=* in the last assertion is a subset-or-equal comparison of two polyhedra.

Nef polyhedra have input and output operators that allows one to output them via streams and read them from streams. Graphical output is currently possible. For an elaborate example see the demo programs in the directory *demo/Nef\_2*.

## 16.3 Exploration

By recursively composing binary and unary operations one can end with a very complex rectilinear structure. To explore that structure there is a data type *Nef\_polyhedron\_2<T>::Explorer* that allows read-only exploration of the rectilinear structure. To understand its usability we need more knowledge about the representation of Nef polyhedra.

The rectilinear structure underlying a Nef polyhedron is stored in a selective plane map. Plane map here means a straightline embedded bidirected graph with face objects such that each point in the plane can be uniquely assigned to an object (vertex, edge, face) of the planar subdivision defined by the graph. Selective means that each object (vertex, edge, face) has a Boolean value associated with it to indicate set inclusion or exclusion.

The plane map is defined by the interface data type *Nef\_polyhedron\_2<T>::Topological\_explorer*. Embedding the vertices by standard affine points does not suffice to model the unboundedness of halfspaces and ray-like structures. Therefore the planar subdivision is bounded symbolically by an axis-parallel square box of infimaximal size centered at the origin of our coordinate system. All structures extending to infinity are pruned by the box. Lines and rays have symbolic endpoints on the box. Faces are circularly closed. Infimaximal here means that its geometric extend is always large enough (but finite for our intuition). Assume you approach the box with an affine point, then this point is always inside the box. The same holds for straight lines; they always intersect the box. There are more accurate notions of “large enough”, but the previous propositions are enough at this point. Due to the fact that the infimaximal box is included in the plane map, the vertices and edges are partitioned with respect to this box.

Vertices inside the box are called standard vertices and they are embedded by affine points of type *Explorer::Point*. Vertices on the box are called non-standard vertices and they get their embedding where a ray intersects the box (their embedding is defined by an object of type *Explorer::Ray*). By their straightline embedding, edges represent either segments, rays, lines, or box segments depending on the character of their source and target vertices.

During exploration, box objects can be tracked down by the interface of *Nef\_polyhedron\_2<T>::Explorer* that is derived from *Nef\_polyhedron\_2<T>::Topological\_explorer* and adds just the box exploration functionality to

the interface of the latter. In the following code fragment we iterate over all vertices of a Nef polyhedron and check whether their embedding is an affine point or a point on the infimal frame.

```
typedef Nef_polyhedron::Explorer Explorer;
Explorer E = N4.explorer();
Explorer::Vertex_const_iterator v;
for (v = E.vertices_begin(); v != E.vertices_end(); ++v)
    if ( E.is_standard(v) )
        Explorer::Point p = E.point(v) // affine embedding of v
    else /* non-standard */
        Explorer::Ray r = E.ray(v) // extended embedding of v
```

Note that box edges only serve as boundary edges (combinatorically) to close the faces that extend to infinity (geometrically). Their status can be queried by the following operation:

```
typedef Nef_polyhedron::Explorer Explorer;
Explorer E = N4.explorer();
Explorer::Halfedge_const_iterator e;
for (e = E.halfedges_begin(); e != E.halfedges_end(); ++e)
    if ( E.is_frame_edge(e) ) // e is part of square box.
```

## 16.4 Traits Classes

Now finally we clarify what the template parameter of class *Nef\_polyhedron\_2*<*T*> actually models. *T* carries the implementation of a so-called extended geometric kernel.

Currently there are three kernel models: *CGAL::Extended\_cartesian*<*FT*>, *CGAL::Extended\_homogeneous*<*RT*>, and *CGAL::Filtered\_extended\_homogeneous*<*RT*>. The latter is the most optimized one. The former two are simpler versions corresponding to the simple planar affine kernels. Actually, it holds that (type equality in pseudo-code notation):

```
CGAL::Nef_polyhedron_2< CGAL::Extended_cartesian<FT> >::Point
== CGAL::Cartesian<FT>::Point_2
```

```
CGAL::Nef_polyhedron_2< CGAL::Extended_homogeneous<RT> >::Point
== CGAL::Homogeneous<RT>::Point_2
```

```
CGAL::Nef_polyhedron_2< CGAL::Filtered_extended_homogeneous<RT> >::Point
== CGAL::Homogeneous<RT>::Point_2
```

Similar equations hold for the types *Line* and *Direction* in the local scope of *Nef\_polyhedron\_2*<...>.

— advanced —

For its notions and requirements see the description of the concept *ExtendedKernelTraits\_2* in the reference manual.

— advanced —

## 16.5 Implementation

The underlying set operations are realized by an efficient and complete algorithm for the overlay of two plane maps. The algorithm is efficient in the sense that its running time is bounded by the size of the inputs plus the size of the output times a logarithmic factor. The algorithm is complete in the sense that it can handle all inputs and requires no general position assumption.

# 2D Boolean Operations on Nef Polygons

## Reference Manual

*Michael Seel*

Planar Nef Polyhedra are whatever can be constructed with a finite number of Boolean operations on halfspaces. See the user manual pages for a detailed introduction.

## CGAL::Nef\_polyhedron\_2<T>

### Definition

An instance of data type *Nef\_polyhedron\_2<T>* is a subset of the plane that is the result of forming complements and intersections starting from a finite set *H* of halfspaces. *Nef\_polyhedron\_2* is closed under all binary set operations *intersection*, *union*, *difference*, *complement* and under the topological operations *boundary*, *closure*, and *interior*.

The template parameter *T* is specified via an extended kernel concept. *T* must be a model of the concept *ExtendedKernelTraits\_2*.

```
#include <CGAL/Nef_polyhedron_2.h>
```

### Types

*Nef\_polyhedron\_2<T>::Line* the oriented lines modeling halfplanes

*Nef\_polyhedron\_2<T>::Point* the affine points of the plane.

*Nef\_polyhedron\_2<T>::Direction* directions in our plane.

*Nef\_polyhedron\_2<T>::Polygons\_tag* tag for calling polygon constructor.

*Nef\_polyhedron\_2<T>::Polylines\_tag* tag for calling polyline constructor.

*enum Boundary { EXCLUDED, INCLUDED};* construction selection.

*enum Content { EMPTY, COMPLETE};* construction selection

### Creation

```
Nef_polyhedron_2<T> N( Content plane = EMPTY);
```

creates an instance *N* of type *Nef\_polyhedron\_2<T>* and initializes it to the empty set if *plane == EMPTY* and to the whole plane if *plane == COMPLETE*.

```
Nef_polyhedron_2<T> N( Line l, Boundary line = INCLUDED);
```

creates a Nef polyhedron *N* containing the halfplane left of *l* including *l* if *line==INCLUDED*, excluding *l* if *line==EXCLUDED*.

```
template <class Forward_iterator>
```

```
Nef_polyhedron_2<T> N( Forward_iterator it, Forward_iterator end, Boundary b = INCLUDED);
```

creates a Nef polyhedron  $N$  from the simple polygon  $P$  spanned by the list of points in the iterator range  $[it, end)$  and including its boundary if  $b = INCLUDED$  excluding the boundary otherwise. *Forward\_iterator* has to be an iterator with value type *Point*. This construction expects that  $P$  is simple. The degenerate cases where  $P$  contains no point, one point or spans just one segment (two points) are correctly handled. In all degenerate cases there's only one unbounded face adjacent to the degenerate polygon. If  $b == INCLUDED$  then  $N$  is just the boundary. If  $b == EXCLUDED$  then  $N$  is the whole plane without the boundary.

```
template <class Forward_iterator>
```

```
Nef_polyhedron_2<T> N( Forward_iterator it, Forward_iterator end, Polygons_tag);
```

The iterator range  $[it, end)$  defines a set point ranges, each of which defines the boundary of simple polygon.

```
template <class Forward_iterator>
```

```
Nef_polyhedron_2<T> N( Forward_iterator it, Forward_iterator end, Polylines_tag);
```

The iterator range  $[it, end)$  defines a set point ranges, each of which defines a polyline.

## Operations

*void*

$N.clear()$  (*Content plane = EMPTY*)

makes  $N$  the empty set if *plane* == *EMPTY* and the full plane if *plane* == *COMPLETE*.

*bool*

$N.is\_empty()$

returns true if  $N$  is empty, false otherwise.

*bool*

$N.is\_plane()$

returns true if  $N$  is the whole plane, false otherwise.

## Constructive Operations

$Nef\_polyhedron\_2<T>$

$N.complement()$

returns the complement of  $N$  in the plane.

$Nef\_polyhedron\_2<T>$

$N.interior()$

returns the interior of  $N$ .

$Nef\_polyhedron\_2<T>$

$N.closure()$

returns the closure of  $N$ .

$Nef\_polyhedron\_2<T>$

$N.boundary()$

returns the boundary of  $N$ .

$Nef\_polyhedron\_2<T>$

$N.regularization()$

returns the regularized polyhedron (closure of interior).

<i>Nef_polyhedron_2</i> < <i>T</i> >	<i>N.intersection( NI )</i>	returns $N \cap NI$ .
<i>Nef_polyhedron_2</i> < <i>T</i> >	<i>N.join( NI )</i>	returns $N \cup NI$ . Note that “union” is a keyword of C++ and cannot be used for this operation.
<i>Nef_polyhedron_2</i> < <i>T</i> >	<i>N.difference( NI )</i>	returns $N - NI$ .
<i>Nef_polyhedron_2</i> < <i>T</i> >	<i>N.symmetric_difference( NI )</i>	returns the symmetric difference $N - T \cup T - N$ .

Additionally there are operators  $*, +, -, \wedge, !$  which implement the binary operations *intersection*, *join*, *difference*, *symmetric difference*, and the unary operation *complement*, respectively. There are also the corresponding modification operations  $*=, +=, -=, \wedge=$ .

There are also comparison operations like  $<, <=, >, >=, ==, !=$  which implement the relations subset, subset or equal, superset, superset or equal, equality, inequality, respectively.

### Exploration - Point location - Ray shooting

As Nef polyhedra are the result of forming complements and intersections starting from a set  $H$  of halfspaces that are defined by oriented lines in the plane, they can be represented by an attributed plane map  $M = (V, E, F)$ . For topological queries within  $M$  the following types and operations allow exploration access to this structure.

### Types

*Nef\_polyhedron\_2*<*T*>:: *Explorer*

a decorator to examine the underlying plane map. See the manual page of *Explorer*.

*Nef\_polyhedron\_2*<*T*>:: *Object\_handle*

a generic handle to an object of the underlying plane map. The kind of object (*vertex*, *halfedge*, *face*) can be determined and the object can be assigned to a corresponding handle by the three functions:

*bool assign(Vertex\_const\_handle& h, Object\_handle)*

*bool assign(Halfedge\_const\_handle& h, Object\_handle)*

*bool assign(Face\_const\_handle& h, Object\_handle)*

where each function returns *true* iff the assignment to *h* was done.

*enum Location\_mode { DEFAULT, NAIVE, LMWT};*

selection flag for the point location mode. LMWT stands for Locally Minimum Weight Triangulation, a locally optimized constrained triangulation where the weight corresponds to the length of the edges of the triangulation.

## Operations

<i>bool</i>	<i>N.contains( Object_handle h)</i>	returns true iff the object <i>h</i> is contained in the set represented by <i>N</i> .
<i>bool</i>	<i>N.contained_in_boundary( Object_handle h)</i>	returns true iff the object <i>h</i> is contained in the 1-skeleton of <i>N</i> .
<i>Object_handle</i>	<i>N.locate( Point p, Location_mode m = DEFAULT)</i>	returns a generic handle <i>h</i> to an object (face, halfedge, vertex) of the underlying plane map that contains the point <i>p</i> in its relative interior. The point <i>p</i> is contained in the set represented by <i>N</i> if <i>N.contains(h)</i> is true. The location mode flag <i>m</i> allows one to choose between different point location strategies.
<i>Object_handle</i>	<i>N.ray_shoot( Point p, Direction d, Location_mode m = DEFAULT)</i>	returns a handle <i>h</i> with <i>N.contains(h)</i> , that can be converted to a <i>Vertex_/Halfedge_/Face_const_handle</i> as described above. The object returned is intersected by the ray starting in <i>p</i> with direction <i>d</i> and has minimal distance to <i>p</i> . The operation returns an empty <i>Object_handle</i> if the ray shoot along <i>d</i> does not hit any object <i>h</i> of <i>N</i> with <i>N.contains(h)</i> . The location mode flag <i>m</i> allows one to choose between different point location strategies.
<i>Object_handle</i>	<i>N.ray_shoot_to_boundary( Point p, Direction d, Location_mode m = DEFAULT)</i>	returns a handle <i>h</i> , that can be converted to a <i>Vertex_/Halfedge_const_handle</i> as described above. The object returned is part of the 1-skeleton of <i>N</i> , intersected by the ray starting in <i>p</i> with direction <i>d</i> and has minimal distance to <i>p</i> . The operation returns an empty <i>Object_handle</i> if the ray shoot along <i>d</i> does not hit any 1-skeleton object <i>h</i> of <i>N</i> . The location mode flag <i>m</i> allows one to choose between different point location strategies.
<i>Explorer</i>	<i>N.explorer()</i>	returns a decorator object that allows read-only access of the underlying plane map. See the manual page <i>Explorer</i> for its usage.

## Implementation

Nef polyhedra are implemented on top of a halfedge data structure and use linear space in the number of vertices, edges and facets. Operations like *empty* take constant time. The operations *clear*, *complement*, *interior*, *closure*, *boundary*, *regularization*, input and output take linear time. All binary set operations and comparison operations take time  $O(n \log n)$  where  $n$  is the size of the output plus the size of the input.

The point location and ray shooting operations are implemented in two flavors. The *NAIVE* operations run in linear query time without any preprocessing, the *DEFAULT* operations (equals *LMWT*) run in sub-linear query time, but preprocessing is triggered with the first operation. Preprocessing takes time  $O(N^2)$ , the sub-linear point location time is either logarithmic when LEDA's persistent dictionaries are present or if not then the point location time is worst-case linear, but experiments show often sublinear runtimes. Ray shooting equals point location plus a walk in the constrained triangulation overlayed on the plane map representation. The cost of the walk is proportional to the number of triangles passed in direction  $d$  until an obstacle is met. In a minimum weight triangulation of the obstacles (the plane map representing the polyhedron) the theory provides a  $O(\sqrt{n})$  bound for the number of steps. Our locally minimum weight triangulation approximates the minimum weight triangulation only heuristically (the calculation of the minimum weight triangulation is conjectured to be NP hard). Thus we have no runtime guarantee but a strong experimental motivation for its approximation.

## Example

Nef polyhedra are parameterized by a so-called extended geometric kernel. There are three kernels, one based on a homogeneous representation of extended points called *Extended\_homogeneous<RT>* where *RT* is a ring type providing additionally a *gcd* operation, one based on a Cartesian representation of extended points called *Extended\_cartesian<NT>* where *NT* is a field type, and finally *Filtered\_extended\_homogeneous<RT>* (an optimized version of the first). The following example uses the filtered homogeneous kernel to construct the intersection of two halfspaces.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Filtered_extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Filtered_extended_homogeneous<RT> Extended_kernel;
typedef CGAL::Nef_polyhedron_2<Extended_kernel> Nef_polyhedron;
typedef Nef_polyhedron::Line Line;

int main()
{
    Nef_polyhedron N1(Line(1,0,0));
    Nef_polyhedron N2(Line(0,1,0), Nef_polyhedron::EXCLUDED);
    Nef_polyhedron N3 = N1 * N2; // line (*)
    return 0;
}
```

**File:** examples/Nef\_2/nef\_2\_intersection.cpp

After line (\*) *N3* is the intersection of *N1* and *N2*. The member types of *Nef\_polyhedron\_2< Extended\_homogeneous<NT> >* map to corresponding types of the standard CGAL geometry kernel (type equality in pseudo-code notation):

```
CGAL::Nef_polyhedron_2< CGAL::Extended_cartesian<FT> >::Point
    == CGAL::Cartesian<FT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Extended_homogeneous<RT> >::Point
    == CGAL::Homogeneous<RT>::Point_2

CGAL::Nef_polyhedron_2< CGAL::Filtered_extended_homogeneous<RT> >::Point
    == CGAL::Homogeneous<RT>::Point_2
```

The same holds for the types *Line* and *Direction* in the local scope of *Nef\_polyhedron\_2*<...>.

## CGAL::Topological\_explorer

### Definition

An instance  $D$  of the data type *Topological\_explorer* is a decorator for interfacing the topological structure of a plane map  $P$  (read-only).

A plane map  $P$  consists of a triple  $(V, E, F)$  of vertices, edges, and faces. We collectively call them objects. An edge  $e$  is a pair of vertices  $(v, w)$  with incidence operations  $v = \text{source}(e)$ ,  $w = \text{target}(e)$ . The list of all edges with source  $v$  is called the adjacency list  $A(v)$ .

Edges are paired into twins. For each edge  $e = (v, w)$  there's an edge  $\text{twin}(e) = (w, v)$  and  $\text{twin}(\text{twin}(e)) == e$ <sup>1</sup>.

An edge  $e = (v, w)$  knows two adjacent edges  $en = \text{next}(e)$  and  $ep = \text{previous}(e)$  where  $\text{source}(en) = w$ ,  $\text{previous}(en) = e$  and  $\text{target}(ep) = v$  and  $\text{next}(ep) = e$ . By this symmetric *previous-next* relationship all edges are partitioned into face cycles. Two edges  $e$  and  $e'$  are in the same face cycle if  $e = \text{next}^*(e')$ . All edges  $e$  in the same face cycle have the same incident face  $f = \text{face}(e)$ . The cyclic order on the adjacency list of a vertex  $v = \text{source}(e)$  is given by  $\text{cyclic\_adj\_succ}(e) = \text{twin}(\text{previous}(e))$  and  $\text{cyclic\_adj\_pred}(e) = \text{next}(\text{twin}(e))$ .

A vertex  $v$  is embedded via coordinates  $\text{point}(v)$ . By the embedding of its source and target an edge corresponds to a segment.  $P$  has the property that the embedding is always *order-preserving*. This means a ray fixed in  $\text{point}(v)$  of a vertex  $v$  and swept around counterclockwise meets the embeddings of  $\text{target}(e)$  ( $e \in A(v)$ ) in the cyclic order defined by the list order of  $A$ .

The embedded face cycles partition the plane into maximal connected subsets of points. Each such set corresponds to a face. A face is bounded by its incident face cycles. For all the edges in the non-trivial face cycles it holds that the face is left of the edges. There can also be trivial face cycles in form of isolated vertices in the interior of a face. Each such vertex  $v$  knows its surrounding face  $f = \text{face}(v)$ .

Plane maps are attributed, for each object  $u \in V \cup E \cup F$  we attribute an information  $\text{mark}(u)$  of type *Mark*. *Mark* fits the concepts assignable, default-constructible, and equal-comparable.

### Types

<i>Topological_explorer::Plane_map</i>	The underlying plane map type
<i>Topological_explorer::Point</i>	The point type of vertices.
<i>Topological_explorer::Mark</i>	All objects (vertices, edges, faces) are attributed by a <i>Mark</i> object.
<i>Topological_explorer::Size_type</i>	The size type.

Local types are handles, iterators and circulators of the following kind: *Vertex\_const\_handle*, *Vertex\_const\_iterator*, *Halfedge\_const\_handle*, *Halfedge\_const\_iterator*, *Face\_const\_handle*, *Face\_const\_iterator*. Additionally the following circulators are defined.

*Topological\_explorer::Halfedge\_around\_vertex\_const\_circulator*

circulating the outgoing halfedges in  $A(v)$ .

<sup>1</sup>The existence of the edge pairs makes  $P$  a bidirected graph, the *twin* links make  $P$  a map.

*Topological\_explorer:: Halfedge\_around\_face\_const\_circulator*

circulating the halfedges in the face cycle of a face  $f$ .

*Topological\_explorer:: Hole\_const\_iterator*

iterating all holes of a face  $f$ . The type is convertible to *Halfedge\_const\_handle*.

*Topological\_explorer:: Isolated\_vertex\_const\_iterator*

iterating all isolated vertices of a face  $f$ . The type generalizes *Vertex\_const\_handle*.

## Operations

*Vertex\_const\_handle*

*D.source( Halfedge\_const\_handle e)*

returns the source of  $e$ .

*Vertex\_const\_handle*

*D.target( Halfedge\_const\_handle e)*

returns the target of  $e$ .

*Halfedge\_const\_handle*

*D.twin( Halfedge\_const\_handle e)*

returns the twin of  $e$ .

*bool*

*D.is\_isolated( Vertex\_const\_handle v)*

returns *true* iff  $A(v) = \emptyset$ .

*Halfedge\_const\_handle*

*D.first\_out\_edge( Vertex\_const\_handle v)*

returns one halfedge with source  $v$ . It's the starting point for the circular iteration over the halfedges with source  $v$ .

*Precondition: !is\_isolated(v).*

*Halfedge\_const\_handle*

*D.last\_out\_edge( Vertex\_const\_handle v)*

returns the halfedge with source  $v$  that is the last in the circular iteration before encountering *first\_out\_edge(v)* again.

*Precondition: !is\_isolated(v).*

*Halfedge\_const\_handle*

*D.cyclic\_adj\_succ( Halfedge\_const\_handle e)*

returns the edge after  $e$  in the cyclic ordered adjacency list of *source(e)*.

<i>Halfedge_const_handle</i>	<i>D.cyclic_adj_pred( Halfedge_const_handle e)</i>	returns the edge before <i>e</i> in the cyclic ordered adjacency list of <i>source(e)</i> .
<i>Halfedge_const_handle</i>	<i>D.next( Halfedge_const_handle e)</i>	returns the next edge in the face cycle containing <i>e</i> .
<i>Halfedge_const_handle</i>	<i>D.previous( Halfedge_const_handle e)</i>	returns the previous edge in the face cycle containing <i>e</i> .
<i>Face_const_handle</i>	<i>D.face( Halfedge_const_handle e)</i>	returns the face incident to <i>e</i> .
<i>Face_const_handle</i>	<i>D.face( Vertex_const_handle v)</i>	returns the face incident to <i>v</i> . <i>Precondition: is_isolated(v)</i> .
<i>Halfedge_const_handle</i>	<i>D.halfedge( Face_const_handle f)</i>	returns a halfedge in the bounding face cycle of <i>f</i> ( <i>Halfedge_const_handle()</i> ) if there is no bounding face cycle).

## Iteration

<i>Vertex_const_iterator</i>	<i>D.vertices_begin()</i>	iterator over vertices of the map.
<i>Vertex_const_iterator</i>	<i>D.vertices_end()</i>	past-the-end iterator for vertices.
<i>Halfedge_const_iterator</i>	<i>D.halfedges_begin()</i>	iterator over halfedges of the map.
<i>Halfedge_const_iterator</i>	<i>D.halfedges_end()</i>	past-the-end iterator for halfedges.
<i>Face_const_iterator</i>	<i>D.faces_begin()</i>	iterator over faces of the map.
<i>Face_const_iterator</i>	<i>D.faces_end()</i>	past-the-end iterator for faces

*Halfedge\_around\_vertex\_const\_circulator*

*D.out\_edges( Vertex\_const\_handle v)*

returns a circulator for the cyclic adjacency list of *v*.

*Halfedge\_around\_face\_const\_circulator*

*D.face\_cycle( Face\_const\_handle f)*

returns a circulator for the outer face cycle of *f*.

*Hole\_const\_iterator*

*D.holes\_begin( Face\_const\_handle f)*

returns an iterator for all holes in the interior of *f*. A *Hole\_iterator* can be assigned to a *Halfedge\_around\_face\_const\_circulator*.

*Hole\_const\_iterator*

*D.holes\_end( Face\_const\_handle f)*

returns the past-the-end iterator of *f*.

*Isolated\_vertex\_const\_iterator*

*D.isolated\_vertices\_begin( Face\_const\_handle f)*

returns an iterator for all isolated vertices in the interior of *f*.

*Isolated\_vertex\_const\_iterator*

*D.isolated\_vertices\_end( Face\_const\_handle f)*

returns the past the end iterator of *f*.

### **Associated Information**

The type *Mark* is the general attribute of an object.

*Point*

*D.point( Vertex\_const\_handle v)*

returns the embedding of *v*.

*Mark*

*D.mark( Vertex\_const\_handle v)*

returns the mark of *v*.

<i>Mark</i>	<i>D.mark( Halfedge_const_handle e)</i>	returns the mark of <i>e</i> .
<i>Mark</i>	<i>D.mark( Face_const_handle f)</i>	returns the mark of <i>f</i> .
<b>Statistics and Integrity</b>		
<i>Size_type</i>	<i>D.number_of_vertices()</i>	returns the number of vertices.
<i>Size_type</i>	<i>D.number_of_halfedges()</i>	returns the number of halfedges.
<i>Size_type</i>	<i>D.number_of_edges()</i>	returns the number of halfedge pairs.
<i>Size_type</i>	<i>D.number_of_faces()</i>	returns the number of faces.
<i>Size_type</i>	<i>D.number_of_face_cycles()</i>	returns the number of face cycles.
<i>Size_type</i>	<i>D.number_of_connected_components()</i>	calculates the number of connected components of <i>P</i> .
<i>void</i>	<i>D.print_statistics( std::ostream&amp; os = std::cout)</i>	print the statistics of <i>P</i> : the number of vertices, edges, and faces.
<i>void</i>	<i>D.check_integrity_and_topological_planarity( bool faces=true)</i>	checks the link structure and the genus of <i>P</i> .

## CGAL::Explorer

### Definition

An instance  $E$  of the data type *Explorer* is a decorator to explore the structure of the plane map underlying the Nef polyhedron. It inherits all topological adjacency exploration operations from *Topological\_explorer*. *Explorer* additionally allows one to explore the geometric embedding.

The position of each vertex is given by a so-called extended point, which is either a standard affine point or the tip of a ray touching an infinimaximal square frame centered at the origin. A vertex  $v$  is called a *standard* vertex if its embedding is a *standard* point and *non-standard* if its embedding is a *non-standard* point. By the straightline embedding of their source and target vertices, edges correspond to either affine segments, rays or lines or are part of the bounding frame.

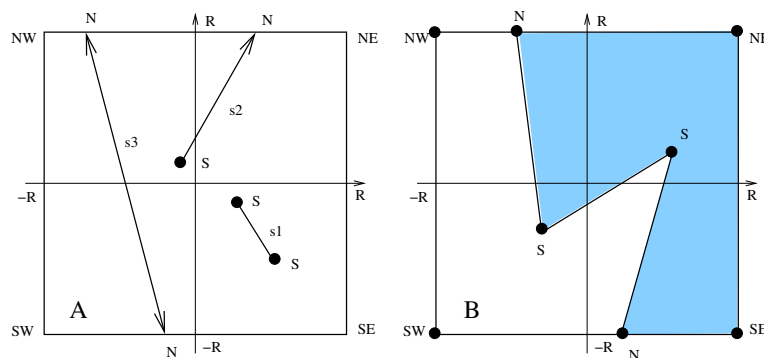

Figure 16.2: Extended geometry: standard vertices are marked by S, non-standard vertices are marked by N. **A:** The possible embeddings of edges: an affine segment  $s_1$ , an affine ray  $s_2$ , an affine line  $s_3$ . **B:** A plane map embedded by extended geometry: note that the frame is arbitrarily large, the 6 vertices on the frame are at infinity, the two faces represent a geometrically unbounded area, however they are topologically closed by the frame edges. No standard point can be placed outside the frame.

### Inherits From

Topological\_explorer

### Types

*Explorer::Point* the point type of finite vertices.

*Explorer::Ray* the ray type of vertices on the frame.

Iterators, handles, and circulators are inherited from *Topological\_explorer*.

### Creation

*Explorer* is copy constructable and assignable. An object can be obtained via the *Nef\_polyhedron\_2::explorer()* method of *Nef\_polyhedron\_2*.

## Operations

*bool* *E.is\_standard( Vertex\_const\_handle v)*

returns true iff  $v$ 's position is a standard point.

*Point* *E.point( Vertex\_const\_handle v)*

returns the standard point that is the embedding of  $v$ .

*Precondition:*  $E.is\_standard(v)$ .

*Ray* *E.ray( Vertex\_const\_handle v)*

returns the ray defining the non-standard point on the frame.

*Precondition:*  $!E.is\_standard(v)$ .

*bool* *E.is\_frame\_edge( Halfedge\_const\_handle e)*

returns true iff  $e$  is part of the infinimaximal frame.

## ExtendedKernelTraits\_2

### Definition

*ExtendedKernelTraits\_2* is a kernel concept providing extended geometry<sup>2</sup>. Let  $K$  be an instance of the data type *ExtendedKernelTraits\_2*. The central notion of extended geometry are extended points. An extended point represents either a standard affine point of the Cartesian plane or a non-standard point representing the equivalence class of rays where two rays are equivalent if one is contained in the other.

Let  $R$  be an infinimaximal number<sup>3</sup>,  $F$  be the square box with corners  $NW(-R, R)$ ,  $NE(R, R)$ ,  $SE(R, -R)$ , and  $SW(-R, -R)$ . Let  $p$  be a non-standard point and let  $r$  be a ray defining it. If the frame  $F$  contains the source point of  $r$  then let  $p(R)$  be the intersection of  $r$  with the frame  $F$ , if  $F$  does not contain the source of  $r$  then  $p(R)$  is undefined. For a standard point let  $p(R)$  be equal to  $p$  if  $p$  is contained in the frame  $F$  and let  $p(R)$  be undefined otherwise. Clearly, for any standard or non-standard point  $p$ ,  $p(R)$  is defined for any sufficiently large  $R$ . Let  $f$  be any function on standard points, say with  $k$  arguments. We call  $f$  *extensible* if for any  $k$  points  $p_1, \dots, p_k$  the function value  $f(p_1(R), \dots, p_k(R))$  is constant for all sufficiently large  $R$ . We define this value as  $f(p_1, \dots, p_k)$ . Predicates like lexicographic order of points, orientation, and incircle tests are extensible.

An extended segment is defined by two extended points such that it is either an affine segment, an affine ray, an affine line, or a segment that is part of the square box. Extended directions extend the affine notion of direction to extended objects.

This extended geometry concept serves two purposes. It offers functionality for changing between standard affine and extended geometry. At the same time it provides extensible geometric primitives on the extended geometric objects.

### Types

#### Affine kernel types

<i>ExtendedKernelTraits_2::Standard_kernel</i>	the standard affine kernel.
<i>ExtendedKernelTraits_2::Standard_RT</i>	the standard ring type.
<i>ExtendedKernelTraits_2::Standard_point_2</i>	standard points.
<i>ExtendedKernelTraits_2::Standard_segment_2</i>	standard segments.
<i>ExtendedKernelTraits_2::Standard_line_2</i>	standard oriented lines.
<i>ExtendedKernelTraits_2::Standard_direction_2</i>	standard directions.
<i>ExtendedKernelTraits_2::Standard_ray_2</i>	standard rays.

<sup>2</sup>It is called extended geometry for simplicity, though it is not a real geometry in the classical sense.

<sup>3</sup>A finite but very large number.

*ExtendedKernelTraits\_2:: Standard\_aff\_transformation\_2*

standard affine transformations.

## Extended kernel types

*ExtendedKernelTraits\_2:: RT*

the ring type of our extended kernel.

*ExtendedKernelTraits\_2:: Point\_2*

extended points.

*ExtendedKernelTraits\_2:: Segment\_2*

extended segments.

*ExtendedKernelTraits\_2:: Direction\_2*

extended directions.

```
enum Point_type { SWCORNER,
                  LEFTFRAME,
                  NWCORNER,
                  BOTTOMFRAME,
                  STANDARD,
                  TOPFRAME,
                  SECORNER,
                  RIGHTFRAME,
                  NECORNER }
```

a type descriptor for extended points.

## Operations

### Interfacing the affine kernel types

*Point\_2*                      *K.construct\_point( Standard\_point\_2 p)*

creates an extended point and initializes it to the standard point *p*.

*Point\_2*                      *K.construct\_point( Standard\_line\_2 l)*

creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line *l*.

*Point\_2*                      *K.construct\_point( Standard\_point\_2 p1, Standard\_point\_2 p2)*

creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line *l(p1,p2)*.

<i>Point_2</i>	<i>K.construct_point( Standard_point_2 p, Standard_direction_2 d)</i>	creates an extended point and initializes it to the equivalence class of all the rays underlying the ray starting in <i>p</i> in direction <i>d</i> .
<i>Point_2</i>	<i>K.construct_opposite_point( Standard_line_2 l)</i>	creates an extended point and initializes it to the equivalence class of all the rays underlying the oriented line opposite to <i>l</i> .
<i>Point_type</i>	<i>K.type( Point_2 p)</i>	determines the type of <i>p</i> and returns it.
<i>bool</i>	<i>K.is_standard( Point_2 p)</i>	returns <i>true</i> iff <i>p</i> is a standard point.
<i>Standard_point_2</i>	<i>K.standard_point( Point_2 p)</i>	returns the standard point represented by <i>p</i> . <i>Precondition: K.is_standard(p).</i>
<i>Standard_line_2</i>	<i>K.standard_line( Point_2 p)</i>	returns the oriented line representing the bundle of rays defining <i>p</i> . <i>Precondition: !K.is_standard(p).</i>
<i>Standard_ray_2</i>	<i>K.standard_ray( Point_2 p)</i>	a ray defining <i>p</i> . <i>Precondition: !K.is_standard(p).</i>
<i>Point_2</i>	<i>K.NE()</i>	returns the point on the northeast frame corner.
<i>Point_2</i>	<i>K.SE()</i>	returns the point on the southeast frame corner.
<i>Point_2</i>	<i>K.NW()</i>	returns the point on the northwest frame corner.
<i>Point_2</i>	<i>K.SW()</i>	returns the point on the southwest frame corner.

#### Geometric kernel calls

<i>Point_2</i>	<i>K.source( Segment_2 s)</i>	returns the source point of <i>s</i> .
----------------	-------------------------------	--

<i>Point_2</i>	<i>K.target( Segment_2 s)</i>	returns the target point of <i>s</i> .
<i>Segment_2</i>	<i>K.construct_segment( Point_2 p, Point_2 q)</i>	constructs a segment <i>pq</i> .
<i>int</i>	<i>K.orientation( Segment_2 s, Point_2 p)</i>	returns the orientation of <i>p</i> with respect to the line through <i>s</i> .
<i>int</i>	<i>K.orientation( Point_2 p1, Point_2 p2, Point_2 p3)</i>	returns the orientation of <i>p3</i> with respect to the line through <i>p1p2</i> .
<i>bool</i>	<i>K.left_turn( Point_2 p1, Point_2 p2, Point_2 p3)</i>	return true iff the <i>p3</i> is left of the line through <i>p1p2</i> .
<i>bool</i>	<i>K.is_degenerate( Segment_2 s)</i>	return true iff <i>s</i> is degenerate.
<i>int</i>	<i>K.compare_xy( Point_2 p1, Point_2 p2)</i>	returns the lexicographic order of <i>p1</i> and <i>p2</i> .
<i>int</i>	<i>K.compare_x( Point_2 p1, Point_2 p2)</i>	returns the order on the <i>x</i> -coordinates of <i>p1</i> and <i>p2</i> .
<i>int</i>	<i>K.compare_y( Point_2 p1, Point_2 p2)</i>	returns the order on the <i>y</i> -coordinates of <i>p1</i> and <i>p2</i> .
<i>Point_2</i>	<i>K.intersection( Segment_2 s1, Segment_2 s2)</i>	returns the point of intersection of the lines supported by <i>s1</i> and <i>s2</i> . <i>Precondition:</i> the intersection point exists.

<i>Direction_2</i>	<i>K.construct_direction( Point_2 p1, Point_2 p2)</i>	returns the direction of the vector $p2 - p1$ .
<i>bool</i>	<i>K.strictly_ordered_ccw( Direction_2 d1, Direction_2 d2, Direction_2 d3)</i>	returns <i>true</i> iff $d2$ is in the interior of the counterclockwise angular sector between $d1$ and $d3$ .
<i>bool</i>	<i>K.strictly_ordered_along_line( Point_2 p1, Point_2 p2, Point_2 p3)</i>	returns <i>true</i> iff $p2$ is in the relative interior of the segment $p1p3$ .
<i>bool</i>	<i>K.contains( Segment_2 s, Point_2 p)</i>	returns true iff $s$ contains $p$ .
<i>bool</i>	<i>K.first_pair_closer_than_second( Point_2 p1, Point_2 p2, Point_2 p3, Point_2 p4)</i>	returns true iff $\ p1 - p2\  < \ p3 - p4\ $ .
<i>const char*</i>	<i>K.output_identifier()</i>	returns a unique identifier for kernel object Input/Output. Usually this should be the name of the model.

## Has Models

<i>CGAL::Extended_cartesian&lt;FT&gt;</i> .....	page <a href="#">1290</a>
<i>CGAL::Extended_homogeneous&lt;RT&gt;</i> .....	page <a href="#">1291</a>
<i>CGAL::Filtered_extended_homogeneous&lt;RT&gt;</i> .....	page <a href="#">1292</a>

## CGAL::Extended\_cartesian<FT>

### Definition

The class *Extended\_cartesian*<FT> serves as a traits class for the class *CGAL::Nef\_polyhedron\_2*<T>. It uses a polynomial component representation based on a field number type *FT*.

```
#include <CGAL/Extended_cartesian.h>
```

### Is Model for the Concepts

ExtendedKernelTraits\_2 ..... page [1285](#)

### Creation

*Extended\_cartesian*<FT> traits;                      default constructor.

### Requirements

To make a field number type *FT\_model* work with this class, you must provide a traits class for this number type: *CGAL::Number\_type\_traits*<FT\_model> (See the support library manual.)

### Operations

Fits all operation requirements of the concept.

### See Also

*CGAL::Extended\_homogeneous*<RT> ..... page [1291](#)  
*CGAL::Filtered\_extended\_homogeneous*<RT> ..... page [1292](#)

## CGAL::Extended\_homogeneous<RT>

### Definition

The class *Extended\_homogeneous<RT>* serves as a traits class for the class *CGAL::Nef\_polyhedron\_2<T>*. It uses a polynomial component representation based on a Euclidean ring number type *RT*.

```
#include <CGAL/Extended_homogeneous.h>
```

### Is Model for the Concepts

ExtendedKernelTraits\_2 ..... page [1285](#)

### Creation

*Extended\_homogeneous<RT>* traits;                      default constructor.

### Requirements

To make an Euclidean ring number type *RT\_model* work with this class the number type must support a gcd computation in namespace *CGAL::NTS*. CGAL provides a function template for this, which will be used by default when your number type is not one of the built-in number types, one of the number types distributed with CGAL or one of the LEDA number types.

### Operations

Fits all operation requirements of the concept.

### 17.1 Introduction

Nef polyhedra are defined as a subset of the  $d$ -dimensional space obtained by a finite number of set complement and set intersection operations on halfspaces.

Due to the fact that all other binary set operations like union, difference and symmetric difference can be reduced to intersection and complement calculations, Nef polyhedra are also closed under those operations. Also, Nef polyhedra are closed under topological unary set operations. Given a Nef polyhedron one can determine its interior, its boundary, and its closure.

Additionally, a  $d$ -dimensional Nef polyhedron has the property, that its boundary is a  $(d-1)$ -dimensional Nef polyhedron. This property can be used as a way to represent 3-dimensional Nef polyhedra by means of planar Nef polyhedra. This is done by intersecting the neighborhood of a vertex in a 3D Nef polyhedron with an  $\varepsilon$ -sphere. The result is a planar Nef polyhedron embedded on the sphere.

The intersection of a halfspace going through the center of the  $\varepsilon$ -sphere, with the  $\varepsilon$ -sphere, results in a halfsphere which is bounded by a great circle. A binary operation of two halfspheres cuts the great circles into great arcs.

Figure 17.1: Two spherical Nef polyhedra. A closed halfspace on the left and a complex polyhedron on the right. The different colors indicate selected and unselected regions, lines and points.

The incidence structure of planar Nef polyhedra can be reused. The items are denoted as *svertex*, *shalfedge* and *sface*, analogous to their counterparts in *Nef\_polyhedron\_S2*. Additionally, there is the *shalfloop* representing the great circles. The incidences are illustrated in the figure above.

## 17.2 Restricted Spherical Geometry

We introduce geometric objects that are part of the spherical surface  $S_2$  and operations on them. We define types *Sphere\_point*, *Sphere\_circle*, *Sphere\_segment*, and *Sphere\_direction*. *Sphere\_points* are points on  $S_2$ , *Sphere\_circles* are oriented great circles of  $S_2$ , *Sphere\_segments* are oriented parts of *Sphere\_circles* bounded by a pair of *Sphere\_points*, and *Sphere\_directions* are directions that are part of great circles. (a direction is usually defined to be a vector without length, that floats around in its underlying space and can be used to specify a movement at any point of the underlying space; in our case we use directions only at points that are part of the great circle that underlies also the direction.)

Note that we have to consider special geometric properties of the objects. For example two points that are part of a great circle define two *Sphere\_segments*, and two arbitrary *Sphere\_segments* can intersect in two points.

If we restrict our geometric objects to a so-called perfect hemisphere of  $S_2$ <sup>1</sup> then the restricted objects behave like in classical geometry, e.g., two points define exactly one segment, two segments intersect in at most one

<sup>1</sup>A perfect hemisphere of  $S_2$  is an open half-sphere plus an open half-circle in the boundary of the open half-sphere plus one endpoint of the half-circle.

interior point (non-degenerately), or three non-cocircular sphere points can be qualified as being positively or negatively oriented.

## 17.3 Example Programs

### 17.3.1 First Example

In this first example *Nef\_polyhedron\_S2* is parametrized with a CGAL Kernel as traits class. The types comprising the spherical geometry can be retrieved from the type *Nef\_polyhedron\_S2<Traits>* as is done in the example with the type *Sphere\_circle*. Then three Nef polyhedra are created: *N1* is a halfsphere including the boundary, *N2* is another halfsphere without the boundary, and *N3* is the intersection of *N1* and *N2*.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Sphere_circle Sphere_circle;

int main()
{
    Nef_polyhedron N1(Sphere_circle(1,0,0));
    Nef_polyhedron N2(Sphere_circle(0,1,0), Nef_polyhedron::EXCLUDED);
    Nef_polyhedron N3 = N1 * N2;
    return 0;
}
```

**File:** examples/Nef\_S2/nef\_s2\_simple.cpp

### 17.3.2 Construction and Combinations

The example shows the different types of constructors: *N1* is the complete sphere, *N2* is a halfsphere which includes the boundary, *N3* is created with the copy constructor, *N4* is created as an arrangement of a set of *Sphere\_segments*, and *N5* is created as the empty set.

The example also shows the use of unary set operations, binary operations, and binary predicates: *N3* is defined as the complement of *N2*, *N1* is compared with the union of *N2* and *N3*, *N5* is united with *N2* and then intersected with *N4*. At last, it is tested if *N5* is a subset of *N2* and if *N5* is not equal to *N4*.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron;
```

```

typedef Nef_polyhedron::Sphere_point Sphere_point;
typedef Nef_polyhedron::Sphere_segment Sphere_segment;
typedef Nef_polyhedron::Sphere_circle Sphere_circle;

int main() {

    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    Sphere_circle c(1,1,1); // c : x + y + z = 0
    Nef_polyhedron N2(c, Nef_polyhedron::INCLUDED);
    Nef_polyhedron N3(N2.complement());
    CGAL_assertion(N1 == N2.join(N3));

    Sphere_point p1(1,0,0), p2(0,1,0), p3(0,0,1);
    Sphere_segment s1(p1,p2), s2(p2,p3), s3(p3,p1);
    Sphere_segment triangle[3] = { s1, s2, s3 };
    Nef_polyhedron N4(triangle, triangle+3);
    Nef_polyhedron N5;
    N5 += N2;
    N5 = N5.intersection(N4);
    CGAL_assertion(N5 <= N2 && N5 != N4);

    return 0;
}

```

**File:** examples/Nef\_S2/nef\_s2\_construction.cpp

### 17.3.3 Exploration

By recursively composing binary and unary operations one can end with a very complex rectilinear structure. *Nef\_polyhedron\_S2* allows read-only exploration of the structure.

In the following example, a random *Nef\_polyhedron\_S2* *S* created from *n* halfspheres is explored. Each sface is composed of one outer sface cycles and an arbitrary number of inner sfaces cycles. The outer cycle is either an shalfloop or a cycle of shalfedges. An inner cycles additionally can be an isolated vertex. The example shows how to get the entry item *it* to all sface cycles of an sface *sf* and how to find out what type of item it is.

The macro *CGAL\_forall\_sface\_cycles\_of* is equivalent to a for-loop on the range [*sf*->*sface\_cycles\_begin()*, *sf*->*sface\_cycles\_end()*). An *SFace\_cycle\_const\_iterator* either represents a *SVertex\_const\_handle*, a *SHalfedge\_const\_handle* or a *SHalfloop\_const\_handle*. In order to find out which handle type is represented, the functions *is\_svertex()*, *is\_shalfedge()* and *is\_shalfloop()* are provided. Afterwards the iterator can be casted to the proper handle type.

```

#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Nef_polyhedron_S2.h>
#include <CGAL/Nef_S2/create_random_Nef_S2.h>

typedef CGAL::Gmpq FT;
typedef CGAL::Cartesian<FT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;
typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;

```

```

typedef Nef_polyhedron_S2::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron_S2::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron_S2::SFace_const_iterator SFace_const_iterator;
typedef Nef_polyhedron_S2::SFace_cycle_const_iterator
        SFace_cycle_const_iterator;

int main() {

    Nef_polyhedron_S2 S;
    CGAL::create_random_Nef_S2(S,5);

    int i=0;
    SFace_const_iterator sf;
    CGAL_forall_sfaced(S) {
        SFace_cycle_const_iterator it;
        std::cout << "the sfaced cycles of sfaced " << i++;
        std::cout << " start with an " << std::endl;
        CGAL_forall_sfaced_cycles_of(it,sf) {
            if (it.is_svertex()) {
std::cout << " svertex at position ";
std::cout << SVertex_const_handle(it)->point() << std::endl;
            }
            else if (it.is_shalfedge()) {
std::cout << " shalfedge from ";
std::cout << SHalfedge_const_handle(it)->source()->point() << " to ";
std::cout << SHalfedge_const_handle(it)->target()->point() << std::endl;
            }
            else if (it.is_shalfloop()) {
std::cout << " shalfloop lying in the plane ";
std::cout << SHalfloop_const_handle(it)->circle() << std::endl;
            }
            else
std::cout << "something is wrong" << std::endl;
        }
    }
    return 0;
}

```

**File:** examples/Nef\_S2/nef\_s2\_exploration.cpp

### 17.3.4 Point Location

Using the *locate* function, it is possible to retrieve an item at a certain location on the sphere. In the following example, the item at location *Sphere\_point(1,0,0)* in a random *Nef\_polyhedron\_S2* is retrieved. *locate* returns an instance of type *Object\_handle*, which is a container for any handle type. Here, it either a *SVertex\_const\_handle*, a *SHalfedge\_const\_handle*, a *SHalfloop\_const\_handle* or a *SFace\_const\_handle*. The function *CGAL::assign* performs the cast operation and returns a boolean which indicates whether the cast was successful or not.

```

#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Nef_polyhedron_S2.h>

```

```

#include <CGAL/Nef_S2/create_random_Nef_S2.h>

typedef CGAL::Gmpq FT;
typedef CGAL::Cartesian<FT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;
typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
typedef Nef_polyhedron_S2::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron_S2::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron_S2::SFace_const_handle SFace_const_handle;
typedef Nef_polyhedron_S2::Object_handle Object_handle;
typedef Nef_polyhedron_S2::Sphere_point Sphere_point;

int main() {

    Nef_polyhedron_S2 S;
    CGAL::create_random_Nef_S2(S,5);

    SVertex_const_handle sv;
    SHalfedge_const_handle se;
    SHalfloop_const_handle sl;
    SFace_const_handle sf;
    Object_handle o = S.locate(Sphere_point(1,0,0));
    if(CGAL::assign(sv,o))
        std::cout << "Locating svertex" << std::endl;
    else if(CGAL::assign(se,o))
        std::cout << "Locating shalfedge" << std::endl;
    else if(CGAL::assign(sl,o))
        std::cout << "Locating shalfloop" << std::endl;
    else if(CGAL::assign(sf,o))
        std::cout << "Locating sface" << std::endl;
    else {
        std::cout << "something wrong" << std::endl;
        return 1;
    }
    return 0;
}

```

**File:** examples/Nef\_S2/nef\_s2\_point\_location.cpp

### 17.3.5 Visualization

*Nef\_polyhedron\_S2* provides an interface for OpenGL visualization via a Qt widget. The usage is shown in the following example:

```

#include <CGAL/basic.h>

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>
#include <CGAL/Nef_S2/create_random_Nef_S2.h>
#include <CGAL/IO/Qt_widget_Nef_S2.h>

```

```

#include <qapplication.h>

typedef CGAL::Gmpz RT;
typedef CGAL::Homogeneous<RT> Kernel;
typedef CGAL::Nef_polyhedron_S2<Kernel> Nef_polyhedron_S2;

int main(int argc, char* argv[]) {

    Nef_polyhedron_S2 S;
    create_random_Nef_S2(S,5);

    QApplication a(argc, argv);
    CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>* w =
        new CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>(S);
    a.setMainWidget(w);
    w->show();
    return a.exec();
}

```

## CGAL::Nef\_polyhedron\_S2<Traits>

### Definition

An instance of data type *Nef\_polyhedron\_S2<Traits>* is a subset of the sphere  $S_2$  that is the result of forming complements and intersections starting from a finite set  $H$  of halfspaces bounded by a plane containing the origin. Halfspaces correspond to hemispheres of  $S_2$  and are therefore modeled by oriented great circles of type *Sphere\_circle*. *Nef\_polyhedron\_S2* is closed under all binary set operations *intersection*, *union*, *difference*, *complement* and under the topological operations *boundary*, *closure*, and *interior*.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

### Parameters

```
template < class Nef_polyhedronTraits_S2,
            class Nef_polyhedronItems_S2 = CGAL::SM_items,
            class Nef_polyhedronMarks = bool
class Nef_polyhedron_S2;
```

The first parameter requires one of the following exact kernels: *Homogeneous*, *Simple\_homogeneous* parametrized with *Gmpz*, *leda\_integer* or any other number type modeling  $\mathbb{Z}$ , or *Cartesian*, *Simple\_cartesian* parametrized with *Gmpq*, *leda\_rational*, *Quotient<Gmpz>* or any other number type modeling  $\mathbb{Q}$ .

The second parameter and the third parameter are for future considerations. Neither *Nef\_polyhedronItems\_S2* nor *Nef\_polyhedronMarks* is specified, yet. Do not use other than the default types for these two template parameters.

### Types

<i>Nef_polyhedron_S2&lt;Traits&gt;::Sphere_point</i>	points in the sphere surface.
<i>Nef_polyhedron_S2&lt;Traits&gt;::Sphere_segment</i>	segments in the sphere surface.
<i>Nef_polyhedron_S2&lt;Traits&gt;::Sphere_circle</i>	oriented great circles modeling spatial half-spaces.

<i>Nef_polyhedron_S2&lt;Traits&gt;::SVertex_const_handle</i>	non-mutable handle to svertex.
<i>Nef_polyhedron_S2&lt;Traits&gt;::SHalfedge_const_handle</i>	non-mutable handle to shalfedge.
<i>Nef_polyhedron_S2&lt;Traits&gt;::SHalfloop_const_handle</i>	non-mutable handle to shalfloop.
<i>Nef_polyhedron_S2&lt;Traits&gt;::SFace_const_handle</i>	non-mutable handle to sface.

<i>Nef_polyhedron_S2&lt;Traits&gt;::SVertex_const_iterator</i>	non-mutable iterator over all svertices.
<i>Nef_polyhedron_S2&lt;Traits&gt;::SHalfedge_const_iterator</i>	non-mutable iterator over all shalfedges.
<i>Nef_polyhedron_S2&lt;Traits&gt;::SHalfloop_const_iterator</i>	non-mutable iterator over all shalfloops.
<i>Nef_polyhedron_S2&lt;Traits&gt;::SFace_const_iterator</i>	non-mutable iterator over all sfaces.

<i>Nef_polyhedron_S2&lt;Traits&gt;::SHalfedge_around_svertex_const_circulator</i>	circulating the adjacency list of an svertex $v$ .
---	--

*Nef\_polyhedron\_S2<Traits>:: SHalfedge\_around\_sface\_const\_circulator*

circulating the sface cycle of an sface *f*.

*Nef\_polyhedron\_S2<Traits>:: SFace\_cycle\_const\_iterator*

iterating all sface cycles of an sface *f*. The iterator has method *bool is\_svertex()*, *bool is\_shalfedge()*, *bool is\_shalfloop()*, and can be converted to the corresponding handles *SVertex\_const\_handle*, *SHalfedge\_const\_handle*, or *SHalfloop\_const\_handle*.

*Nef\_polyhedron\_S2<Traits>:: Mark*

attributes of objects (vertices, edges, faces).

*Nef\_polyhedron\_S2<Traits>:: size\_type*

size type

*enum Boundary { EXCLUDED, INCLUDED};*

construction selection.

*enum Content { EMPTY, COMPLETE};*

construction selection.

## Creation

*Nef\_polyhedron\_S2<Traits> N( Content sphere = EMPTY);*

creates an instance *N* of type *Nef\_polyhedron\_S2<K>* and initializes it to the empty set if *sphere == EMPTY* and to the whole sphere if *sphere == COMPLETE*.

*Nef\_polyhedron\_S2<Traits> N( Sphere\_circle c, Boundary circle = INCLUDED);*

creates a Nef polyhedron *N* containing the half-sphere left of *c* including *c* if *circle == INCLUDED*, excluding *c* if *circle == EXCLUDED*.

*template <class Forward\_iterator>*

*Nef\_polyhedron\_S2<Traits> N( Forward\_iterator first,*  
*Forward\_iterator beyond,*  
*Boundary b = INCLUDED)*

creates a Nef polyhedron *N* from the set of sphere segments in the iterator range *[first,beyond)*. If the set of sphere segments is a simple polygon that separates the sphere surface into two regions, then the polygonal region that is left of the segment *\*first* is selected. The polygonal region includes its boundary if *b = INCLUDED* and excludes the boundary otherwise. *Forward\_iterator* has to be an iterator with value type *Sphere\_segment*.

## Operations

*void N.clear( Content plane = EMPTY)*

makes *N* the empty set if *plane == EMPTY* and the full plane if *plane == COMPLETE*.

<i>bool</i>	<i>N.is_empty()</i>	returns true if <i>N</i> is empty, false otherwise.
<i>bool</i>	<i>N.is_sphere()</i>	returns true if <i>N</i> is the whole sphere, false otherwise.

### Constructive Operations

<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.complement()</i>	returns the complement of <i>N</i> in the plane.
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.interior()</i>	returns the interior of <i>N</i> .
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.closure()</i>	returns the closure of <i>N</i> .
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.boundary()</i>	returns the boundary of <i>N</i> .
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.regularization()</i>	returns the regularized polyhedron (closure of interior).
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.intersection( Nef_polyhedron_S2&lt;K&gt; N1)</i>	returns $N \cap N1$ .
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.join( Nef_polyhedron_S2&lt;K&gt; N1)</i>	returns $N \cup N1$ .
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.difference( Nef_polyhedron_S2&lt;K&gt; N1)</i>	returns $N - N1$ .
<i>Nef_polyhedron_S2&lt;K&gt;</i>	<i>N.symmetric_difference( Nef_polyhedron_S2&lt;K&gt; N1)</i>	returns the symmetric difference $N - T \cup T - N$ .

Additionally there are operators  $*, +, -, \wedge, !$  which implement the binary operations *intersection*, *union*, *difference*, *symmetric difference*, and the unary operation *complement* respectively. There are also the corresponding modification operations  $*=, +=, -=, \wedge=$ .

There are also comparison operations like  $<, <=, >, >=, ==, !=$  which implement the relations subset, subset or equal, superset, superset or equal, equality, inequality, respectively.

### Statistics and Integrity

<i>Size_type</i>	<i>N.number_of_svertices()</i>	returns the number of svertices.
<i>Size_type</i>	<i>N.number_of_shalfedges()</i>	returns the number of shalfedges.
<i>Size_type</i>	<i>N.number_of_sedges()</i>	returns the number of sedges.
<i>Size_type</i>	<i>N.number_of_shalfloops()</i>	returns the number of shalfloops.
<i>Size_type</i>	<i>N.number_of_sloops()</i>	returns the number of sloops.

<i>Size_type</i>	<i>N.number_of_sfaced()</i>	returns the number of sfaced.
<i>Size_type</i>	<i>N.number_of_sface_cycles()</i>	returns the number of sface cycles.
<i>Size_type</i>	<i>N.number_of_connected_components()</i>	
		calculates the number of connected components of <i>P</i> .
<i>void</i>	<i>N.print_statistics( std::ostream&amp; os = std::cout)</i>	
		print the statistics of <i>P</i> : the number of vertices, edges, and faces.
<i>void</i>	<i>N.check_integrity_and_topological_planarity( bool faces=true)</i>	
		checks the link structure and the genus of <i>P</i> .

### Exploration - Point location - Ray shooting

As Nef polyhedra are the result of forming complements and intersections starting from a set  $H$  of half-spaces that are defined by oriented lines in the plane, they can be represented by an attributed plane map  $M = (V, E, F)$ . For topological queries within  $M$  the following types and operations allow exploration access to this structure.

### Types

*Nef\_polyhedron\_S2<Traits>:: Object\_handle*

a generic handle to an object of the underlying plane map. The kind of object (*vertex*, *halfedge*, *face*) can be determined and the object can be assigned to a corresponding handle by the three functions:

*bool assign(Vertex\_const\_handle& h, Object\_handle)*

*bool assign(Halfedge\_const\_handle& h, Object\_handle)*

*bool assign(Face\_const\_handle& h, Object\_handle)*

where each function returns *true* iff the assignment to *h* was done.

### Operations

<i>bool</i>	<i>N.contains( Object_handle h)</i>	
		returns true iff the object <i>h</i> is contained in the set represented by <i>N</i> .

<i>bool</i>	<i>N.contained_in_boundary( Object_handle h)</i>	
		returns true iff the object <i>h</i> is contained in the 1-skeleton of <i>N</i> .

<i>Object_handle</i>	<i>N.locate( Sphere_point p)</i>	
		returns a generic handle <i>h</i> to an object (face, halfedge, vertex) of the underlying plane map that contains the point <i>p</i> in its relative interior. The point <i>p</i> is contained in the set represented by <i>N</i> if <i>N.contains(h)</i> is true. The location mode flag <i>m</i> allows one to choose between different point location strategies.

*Object\_handle*                      *N.ray\_shoot( Sphere\_point p, Sphere\_direction d)*

returns a handle *h* with *N.contains(h)* that can be converted to a *Vertex\_*/*Halfedge\_*/*Face\_const\_handle* as described above. The object returned is intersected by the ray starting in *p* with direction *d* and has minimal distance to *p*. The operation returns an empty *Object\_handle* if the ray shoot along *d* does not hit any object *h* of *N* with *N.contains(h)*.

*Object\_handle*                      *N.ray\_shoot\_to\_boundary( Sphere\_point p, Sphere\_direction d)*

returns a handle *h* that can be converted to a *Vertex\_*/*Halfedge\_const\_handle* as described above. The object returned is part of the 1-skeleton of *N*, intersected by the ray starting in *p* with direction *d* and has minimal distance to *p*. The operation returns an empty *Object\_handle* if the ray shoot along *d* does not hit any 1-skeleton object *h* of *N*. The location mode flag *m* allows one to choose between different point location strategies.

## Iteration

*bool*                                      *N.has\_shalfloop()*                      returns true iff there is a shalfloop.

*SHalfloop\_const\_handle*              *N.shalfloop()*                      returns access to the sloop.

The list of all objects can be accessed via iterator ranges. For comfortable iteration we also provide iterations macros. The iterator range access operations are of the following kind:

*SVertex\_iterator svertices\_begin()/svertices\_end()*  
*SHalfedge\_iterator shalfedges\_begin()/shalfedges\_end()*  
*SHalfloop\_iterator shalfloops\_begin()/shalfloops\_end()*  
*SFace\_iterator sfaces\_begin()/sfaces\_end()*

The macros are then *CGAL\_forall\_svertices(v,M)*, *CGAL\_forall\_shalfedges(e,M)*, *CGAL\_forall\_sfaces(f,M)*, *CGAL\_forall\_sface\_cycles\_of(fc,F)* where *M* is a sphere map and *F* is a sface.

## Input and Output

A Nef polyhedron *N* can be visualized in an open GL window. The output operator is defined in the file *CGAL/IO/Nef\_polyhedron\_2\_Window\_stream.h*.

## Implementation

Nef polyhedra are implemented on top of a halfedge data structure and use linear space in the number of vertices, edges and facets. Operations like *empty* take constant time. The operations *clear*, *complement*, *interior*, *closure*, *boundary*, *regularization*, input and output take linear time. All binary set operations and comparison operations take time  $O(n \log n)$  where *n* is the size of the output plus the size of the input.

The point location and ray shooting operations are implemented in the naive way. The operations run in linear query time without any preprocessing.

## CGAL::Nef\_polyhedron\_S2<Traits>::Sphere\_point

### Definition

An object  $p$  of type  $Sphere\_point<R>$  is a point on the surface of a unit sphere. Such points correspond to the nontrivial directions in space and similarly to the equivalence classes of all nontrivial vectors under normalization.

### Types

$Sphere\_point::RT$  ring number type.

### Creation

$Sphere\_point\ p;$  creates some sphere point.

$Sphere\_point\ p(RT\ x, RT\ y, RT\ z);$  creates a sphere point corresponding to the point of intersection of the ray starting at the origin in direction  $(x, y, z)$  and the surface of  $S_2$ .

### Operations

Access to the coordinates is provided by the following operations. Note that the vector  $(x, y, z)$  is not normalized.

$RT$   $p.x()$  the  $x$ -coordinate.

$RT$   $p.y()$  the  $y$ -coordinate.

$RT$   $p.z()$  the  $z$ -coordinate.

$bool$   $p == q$  Equality.

$bool$   $p != q$  Inequality.

$Sphere\_point$   $p.antipode()$  returns the antipode of  $p$ .

## CGAL::Nef\_polyhedron\_S2<Traits>::Sphere\_segment

### Definition

An object  $s$  of type *Sphere\_segment* is a segment in the surface of a unit sphere that is part of a great circle through the origin. Sphere segments are represented by two sphere points  $p$  and  $q$  plus an oriented plane  $h$  that contains  $p$  and  $q$ . The plane determines the sphere segment as follows. Let  $c$  be the circle in the intersection of  $h$  and  $S_2$ . Then  $s$  is that part of  $c$  that is swept, when we rotate  $p$  into  $q$  in counterclockwise rotation around the normal vector of  $h$  as seen from the positive halfspace.

### Creation

*Sphere\_segment*  $s$ ;                      creates some sphere segment.

*Sphere\_segment*  $s$ ( *Sphere\_point*  $p1$ , *Sphere\_point*  $p2$ , *bool*  $shorter\_arc=true$ );

creates a spherical segment spanning the shorter arc from  $p1$  to  $p2$  if  $shorter\_arc == true$ . Otherwise the longer arc is created.  
*Precondition:*  $p1 \neq p2$  and  $p1 \neq p2.opposite()$ .

*Sphere\_segment*  $s$ ( *Sphere\_point*  $p1$ , *Sphere\_point*  $p2$ , *Sphere\_circle*  $c$ );

creates a spherical segment spanning the arc from  $p1$  to  $p2$  as part of the oriented circle  $c$  ( $p1 == p2$  or  $p1 == p2.opposite()$  are possible.)  
*Precondition:*  $p1$  and  $p2$  are contained in  $c$ .

*Sphere\_segment*  $s$ ( *Sphere\_circle*  $c1$ , *Sphere\_circle*  $c2$ );

creates the spherical segment as part of  $c1$  that is part of the halfsphere left of the oriented circle  $c2$ .  
*Precondition:*  $c1 \neq c2$  as unoriented circles.

### Operations

*Sphere\_point*                       $s.source()$                       the source point of  $s$ .

*Sphere\_point*                       $s.target()$                       the target point of  $s$ .

*Sphere\_circle*                       $s.sphere\_circle()$                       the great circle supporting  $s$ .

*Sphere\_segment*                       $s.opposite()$                       returns the spherical segment oriented from  $target()$  to  $source()$  with the same point set as  $s$ .

*Sphere\_segment*                       $s.complement()$                       returns the spherical segment oriented from  $target()$  to  $source()$  with the point set completing  $s$  to a full circle.

<i>bool</i>	<i>s.is_short()</i>	a segment is short iff it is shorter than a half-circle.
<i>bool</i>	<i>s.is_long()</i>	a segment is long iff it is longer than a half-circle.
<i>bool</i>	<i>s.is_degenerate()</i>	return true iff <i>s</i> is degenerate, i.e. source and target are the same.
<i>bool</i>	<i>s.is_halfcircle()</i>	return true iff <i>s</i> is a perfect half-circle, i.e. <i>source().antipode</i> == <i>target()</i> .
<i>bool</i>	<i>s.has_on( Sphere_point p)</i>	 return true iff <i>s</i> contains <i>p</i> .
<i>bool</i>	<i>s.has_in_relative_interior( Sphere_point p)</i>	 return true iff <i>s</i> contains <i>p</i> in its relative interior.

## CGAL::Nef\_polyhedron\_S2<Traits>::Sphere\_circle

### Definition

An object  $c$  of type *Sphere\_circle* is an oriented great circle on the surface of a unit sphere. Such circles correspond to the intersection of an oriented plane (that contains the origin) and the surface of  $S_2$ . The orientation of the great circle is that of a counterclockwise walk along the circle as seen from the positive halfspace of the oriented plane.

### Types

*Sphere\_circle::RT* ring type.

*Sphere\_circle::Plane\_3* plane a *Sphere\_circle* lies in.

### Creation

*Sphere\_circle*  $c$ ; creates some great circle.

*Sphere\_circle*  $c$ ( *Sphere\_point*  $p$ , *Sphere\_point*  $q$ );

If  $p$  and  $q$  are opposite of each other, then we create the unique great circle on  $S_2$  which contains  $p$  and  $q$ . This circle is oriented such that a walk along  $c$  meets  $p$  just before the shorter segment between  $p$  and  $q$ . If  $p$  and  $q$  are opposite of each other then we create any great circle that contains  $p$  and  $q$ .

*Sphere\_circle*  $c$ ( *Plane\_3*  $h$ ); creates the circle corresponding to the plane  $h$ .  
*Precondition:*  $h$  contains the origin.

*Sphere\_circle*  $c$ ( *RT*  $x$ , *RT*  $y$ , *RT*  $z$ ); creates the circle orthogonal to the vector  $(x, y, z)$ .

*Sphere\_circle*  $c$ ( *Sphere\_circle*  $c$ , *Sphere\_point*  $p$ );

creates a great circle orthogonal to  $c$  that contains  $p$ .  
*Precondition:*  $p$  is not part of  $c$ .

### Operations

*Sphere\_circle*  $c$ .*opposite()* Returns a sphere circle in the opposite direction of  $c$ .

*bool*  $c$ .*has\_on*( *Sphere\_point*  $p$ ) returns true iff  $c$  contains  $p$ .

*Plane\_3*  $c$ .*plane*() returns the plane supporting  $c$ .

*Sphere\_point*  $c$ .*orthogonal\_pole*() returns the point that is the pole of the hemisphere left of  $c$ .

## Global functions

*bool*                    *equal\_as\_sets( const c1, const c2)*

returns true iff *c1* and *c2* are equal as unoriented circles.

## CGAL::Nef\_polyhedron\_S2<Traits>::SVertex

### Definition

Figure 17.2 illustrate the incidence of a svertex on a sphere map.

The member function *out\_sedge* returns the first outgoing shalfedge, and *incident\_sface* returns the incident sface.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

### Types

The following types are the same as in *Nef\_polyhedron\_S2<Traits>*.

<i>SVertex:: Mark</i>	type of mark.
<i>SVertex:: Sphere_point</i>	sphere point type stored in SVertex.
<i>SVertex:: SVertex_const_handle</i>	const handle to SVertex.
<i>SVertex:: SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>SVertex:: SFace_const_handle</i>	const handle to SFace.

### Creation

There is no need for a user to create a *SVertex* explicitly. The class *Nef\_polyhedron\_S2<Traits>* manages the needed svertices internally.

### Operations

<i>Mark</i>	<i>e.mark()</i>	the mark of <i>e</i> .
<i>Sphere_point</i>	<i>e.point()</i>	the sphere point of <i>e</i> .
<i>bool</i>	<i>e.is_isolated()</i>	returns —true— if <i>e</i> has no adjacent sedges.
<i>SVertex_const_handle</i>	<i>e.twin()</i>	the twin of <i>e</i> .
<i>SHalfedge_const_handle</i>	<i>e.out_sedge()</i>	the first out sedge of <i>e</i> .
<i>SFace_const_handle</i>	<i>e.incident_sface()</i>	the incident sface of <i>e</i> .

## CGAL::Nef\_polyhedron\_S2<Traits>::SHalfedge

### Definition

A shalfedge is a great arc on a sphere map. The figure below depicts the relationship between a shalfedge and its incident shalfedges, svertices, and sfaces on a sphere map. A shalfedge is an oriented sedge between two svertices. It is always paired with a shalfedge pointing in the opposite direction. The *twin()* member function returns this shalfedge of opposite orientation.

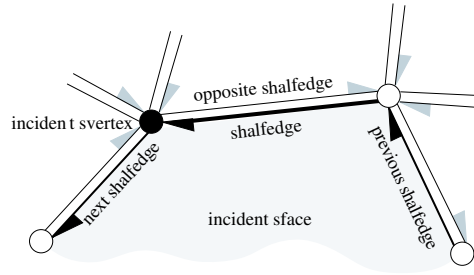

Figure 17.2: Incidences of an SHalfedge

The *snext()* member function points to the successor shalfedge around this sface while the *sprev()* member function points to the preceding shalfedge. An successive assignments of the form *se = se->snext()* cycles counterclockwise around the sface (or hole).

Similarly, the successive assignments of the form *se = se->snext()->twin()* cycle clockwise around the svertex and traverse all halfedges incident to this svertex. The assignment *se = se->cyclic\_adj\_succ()* can be used as a shortcut.

A const circulator is provided for each of the two circular orders. The circulators are bidirectional and assignable to *SHalfedge\_const\_handle*.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

### Types

The following types are the same as in *Nef\_polyhedron\_S2<Traits>*.

<i>SHalfedge::Mark</i>	type of mark.
<i>SHalfedge::Sphere_circle</i>	sphere circle type stored in SHalfedge.
<i>SHalfedge::SVertex_const_handle</i>	const handle to SVertex.
<i>SHalfedge::SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>SHalfedge::SFace_const_handle</i>	const handle to SFace.

### Creation

There is no need for a user to create a *SHalfedge* explicitly. The class *Nef\_polyhedron\_S2<Traits>* manages the needed shalfedges internally.

## Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .
<i>SHalfedge_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.source()</i>	the source svertex of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.target()</i>	equals <i>twin()</i> -> <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.sprev()</i>	the SHalfedge previous to <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.snext()</i>	the next SHalfedge of <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_pred()</i>	the edge before <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_succ()</i>	the edge after <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .
<i>bool</i>	<i>se.in_outer_sface_cycle()</i>	determines whether <i>se</i> is in an outer sface cycle.
<i>bool</i>	<i>se.in_inner_sface_cycle()</i>	determines whether <i>se</i> is in an inner sface cycle.

# CGAL::Nef\_polyhedron\_S2<Traits>::SHalfloop

## Definition

A sloop is a great circle on a sphere. A shalfloop is an oriented sloop. It is always paired with a shalfloop whose supporting *Sphere\_circle* is pointing in the opposite direction. The *twin()* member function returns this shalfloop of opposite orientation. Each *Nef\_polyhedron\_S2* can only have one sloop (resp. two shalfloops).

The figure below depicts the relationship between a shalfloop and sfaces on a sphere map.

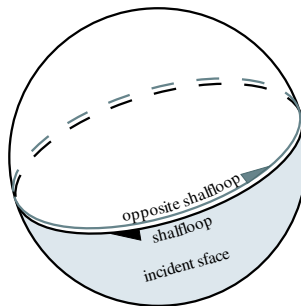

Figure 17.3: Incidences of an SHalfloop

```
#include <CGAL/Nef_polyhedron_S2.h>
```

## Types

The following types are the same as in *Nef\_polyhedron\_S2<Traits>*.

<i>SHalfloop:: Mark</i>	type of mark.
<i>SHalfloop:: Sphere_circle</i>	sphere circle type stored in SHalfloop.
<i>SHalfloop:: SHalfloop_const_handle</i>	const handle to SHalfloop.
<i>SHalfloop:: SFace_const_handle</i>	const handle to SFace.

## Creation

There is no need for a user to create a *SHalfloop* explicitly. The class *Nef\_polyhedron\_S2<Traits>* manages the needed shalfloops internally.

## Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .

<i>SHalfloop_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .

## CGAL::Nef\_polyhedron\_S2<Traits>::SFace

### Definition

Figure 17.2 on page 1314 and figure 17.3 on page 1316 illustrate the incidences of an sface. An sface is described by its boundaries. An entry item to each boundary cycle can be accessed using the iterator range (*sface\_cycles\_begin()*/*sface\_cycles\_end()*). Additionally, *Nef\_polyhedron\_S2* provides the macro *CGAL\_forall\_sface\_cycles\_of*. The iterators are of type *SFace\_cycle\_const\_iterator* and represent either a shalfedge, a shalfloop, or a svertex.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

### Types

The following types are the same as in *Nef\_polyhedron\_S2<Traits>*.

<i>SFace:: Mark</i>	type of mark.
<i>SFace:: Object_list</i>	list of Object handles.
<i>SFace:: Vertex_const_handle</i>	const handle to Vertex.
<i>SFace:: Volume_const_handle</i>	const handle to Volume.
<i>SFace:: SFace_const_handle</i>	const handle to SFace.
<i>SFace:: SFace_cycle_const_iterator</i>	const iterator over the entries to all sface cycles of a sface.

### Creation

There is no need for a user to create a *SFace* explicitly. The class *Nef\_polyhedron\_S2<Traits>* manages the needed sfaces internally.

### Operations

<i>Mark</i>	<i>sf.mark()</i>	the mark of <i>sf</i> .
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_begin()</i>	iterator over the entries to all sface cycles of <i>sf</i> .
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_end()</i>	past-the-end iterator.

## CGAL::Nef\_polyhedron\_S2<Traits>::SFace\_cycle\_iterator

### Definition

The type *SFace\_cycle\_iterator* iterates over a list of *Object\_handles*. Each item of that list can either be assigned to *SVertex\_handle*, *SHalfedge\_handle* or *SHalfloop\_handle*. To find out which of these assignment works out, the member functions *is\_svertex()*, *is\_shalfedge()* and *is\_shalfloop()* are provided.

```
#include <CGAL/Nef_polyhedron_S2.h>
```

### Types

<i>SFace_cycle_iterator::SVertex_handle</i>	const handle to <i>SVertex</i> .
<i>SFace_cycle_iterator::SHalfedge_handle</i>	const handle to <i>SHalfedge</i> .
<i>SFace_cycle_iterator::SHalfloop_handle</i>	const handle to <i>SHalfloop</i> .

### Creation

<i>SFace_cycle_iterator</i> <i>sfc</i> ;	default constructor.
--	----------------------

### Operations

<i>bool</i>	<i>sfc.is_svertex()</i>	returns true if <i>sfc</i> represents a <i>SVertex_handle</i> .
<i>bool</i>	<i>sfc.is_shalfedge()</i>	returns true if <i>sfc</i> represents a <i>SHalfedge_handle</i> .
<i>bool</i>	<i>sfc.is_shalfloop()</i>	returns true if <i>sfc</i> represents a <i>SHalfloop_handle</i> .
<i>SVertex_handle</i>	<i>SVertex_handle(sfc)</i>	casts <i>sfc</i> to <i>SVertex_handle</i> .
<i>SHalfedge_handle</i>	<i>SHalfedge_handle(sfc)</i>	casts <i>sfc</i> to <i>SHalfedge_handle</i> .
<i>SHalfloop_handle</i>	<i>SHalfloop_handle(sfc)</i>	casts <i>sfc</i> to <i>SHalfloop_handle</i> .

## CGAL::Qt\_widget\_Nef\_S2<Nef\_polyhedron\_S2>

### Definition

The class *Qt\_widget\_Nef\_S2* uses the OpenGL interface of Qt in order to display a *Nef\_polyhedron\_S2*. Its purpose is to provide an easy to use viewer for *Nef\_polyhedron\_S2*. There are no means provided to enhance the functionality of the viewer.

In addition to the functions inherited from the Qt class *QGLWidget*, *Qt\_widget\_Nef\_S2* only has a single public constructor. For the usage of *Qt\_widget\_Nef\_S2* see the example below.

```
#include <CGAL/IO/Qt_widget_Nef_S2.h>
```

### Parameters

The template parameter expects an instantiation of *Nef\_polyhedron\_S2<Traits>*.

### Creation

```
Qt_widget_Nef_S2<Nef_polyhedron_S2> W( Nef_polyhedron_S2 N);
```

Creates a widget *W* for displaying the *Nef\_polyhedron\_S2* *N*.

### See Also

*CGAL::Nef\_polyhedron\_S2<Traits>* ..... page [1303](#)

### Example

This example creates some random *Sphere\_segments* and distributes them on two *Nef\_polyhedron\_2*. The two Nef polyhedra are combined by a symmetric difference and the result is displayed in a Qt widget.

```
#include <CGAL/basic.h>

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_S2.h>
#include <CGAL/Nef_S2/create_random_Nef_S2.h>

### 18.1 Introduction

A *partition* of a polygon  $P$  is a set of polygons such that the interiors of the polygons do not intersect and the union of the polygons is equal to the interior of the original polygon  $P$ . This chapter describes functions for partitioning planar polygons into two types of subpolygons —  $y$ -monotone polygons and convex polygons. The partitions are produced without introducing new (Steiner) vertices.

All the partitioning functions present the same interface to the user. That is, the user provides a pair of input iterators, *first* and *beyond*, an output iterator *result*, and a traits class *traits*. The points in the range [*first*, *beyond*) are assumed to define a simple polygon whose vertices are in counterclockwise order. The computed partition polygons, whose vertices are also oriented counterclockwise, are written to the sequence starting at position *result* and the past-the-end iterator for the resulting sequence of polygons is returned. The traits classes for the functions specify the types of the input points and output polygons as well as a few other types and function objects that are required by the various algorithms.

### 18.2 Monotone Partitioning

A *y-monotone polygon* is a polygon whose vertices  $v_1, \dots, v_n$  can be divided into two chains  $v_1, \dots, v_k$  and  $v_k, \dots, v_n, v_1$ , such that any horizontal line intersects either chain at most once. For producing a  $y$ -monotone partition of a given polygon, the sweep-line algorithm presented in [dBvKOS97] is implemented by the function `y_monotone_partition_2`. This algorithm runs in  $O(n \log n)$  time and requires  $O(n)$  space. This algorithm does not guarantee a bound on the number of polygons produced with respect to the optimal number.

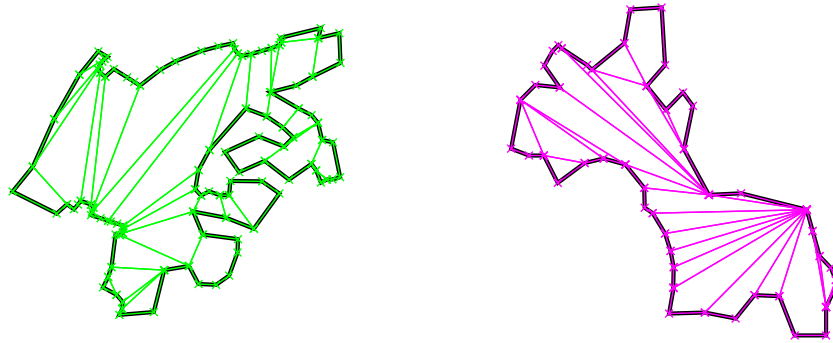

Figure 18.1: Examples of an optimal convex partition (left) and an approximately optimal convex partition (right).

For checking the validity of the partitions produced by `y_monotone_partition_2`, we provide a function `is_y_monotone_2`, which determines if a sequence of points in 2D defines a  $y$ -monotone polygon or not. For examples of the use of these functions, see the corresponding reference pages.

### 18.3 Convex Partitioning

Three functions are provided for producing convex partitions of polygons. One produces a partition that is optimal in the number of pieces. The other two functions produce approximately optimal convex partitions. Both these functions produce convex decompositions by first decomposing the polygon into simpler polygons; the first uses a triangulation and the second a monotone partition. These two functions both guarantee that they will produce no more than four times the optimal number of convex pieces but they differ in their runtime complexities. Though the triangulation-based approximation algorithm often results in fewer convex pieces, this is not always the case.

An optimal convex partition can be produced using the function `optimal_convex_partition_2`. This function provides an implementation of Greene’s dynamic programming algorithm for optimal partitioning [Gre83]. This algorithm requires  $O(n^4)$  time and  $O(n^3)$  space in the worst case.

The function `approx_convex_partition_2` implements the simple approximation algorithm of Hertel and Mehlhorn [HM83] that produces a convex partitioning of a polygon from a triangulation by throwing out unnecessary triangulation edges. The triangulation used in this function is one produced by the 2-dimensional constrained triangulation package of CGAL. For a given triangulation, this convex partitioning algorithm requires  $O(n)$  time and space to construct a decomposition into no more than four times the optimal number of convex pieces.

The sweep-line approximation algorithm of Greene [Gre83], which, given a monotone partition of a polygon, produces a convex partition in  $O(n \log n)$  time and  $O(n)$  space, is implemented by the function `greene_approx_convex_partition_2`. The function `y_monotone_partition_2` described in Section 18.2 is used to produce the monotone partition. This algorithm provides the same worst-case approximation guarantee as the algorithm of Hertel and Mehlhorn implemented with `approx_convex_partition_2` but can sometimes produce better results (*i.e.*, convex partitions with fewer pieces).

Examples of the uses of all of these functions are provided with the corresponding reference pages.

# 2D Polygon Partitioning

## Reference Manual

*Susan Hert*

A *partition* of a polygon is a set of polygons such that the interiors of the polygons do not intersect and the union of the polygons is equal to the interior of the original polygon. Functions are available for partitioning planar polygons into two types of subpolygons — *y-monotone* polygons and *convex* polygons.

The function that produces a *y-monotone* partitioning is based on the algorithm presented in [dBvKOS97] which requires  $O(n \log n)$  time and  $O(n)$  space for a polygon with  $n$  vertices and guarantees nothing about the number of polygons produced with respect to the optimal number. Three functions are provided for producing *convex* partitions. Two of these functions produce approximately optimal partitions and one results in an optimal partition, where “optimal” is defined in terms of the number of partition polygons. The two functions that implement approximation algorithms are guaranteed to produce no more than four times the optimal number of convex pieces. The optimal partitioning function provides an implementation of Greene’s dynamic programming algorithm [Gre83], which requires  $O(n^4)$  time and  $O(n^3)$  space to produce a convex partitioning. One of the approximation algorithms is also due to Greene [Gre83] and requires  $O(n \log n)$  time and  $O(n)$  space to produce a convex partitioning given a *y-monotone* partitioning. The other approximation algorithm is a result of Hertel and Mehlhorn [HM83], which requires  $O(n)$  time and space to produce a convex partitioning from a triangulation of a polygon. Each of the partitioning functions uses a traits class to supply the primitive types and predicates used by the algorithms.

### Assertions

The assertion flags for this package use *PARTITION* in their names (*e.g.*, *CGAL\_PARTITION\_NO\_POSTCONDITIONS*). The precondition checks for the planar polygon partitioning functions are: counterclockwise ordering of the input vertices and simplicity of the polygon these vertices represent. The postcondition checks are: simplicity, counterclockwise orientation, and convexity (or *y-monotonicity*) of the partition polygons and validity of the partition (*i.e.*, the partition polygons are nonoverlapping and the union of these polygons is the same as the original polygon).

## CGAL::approx\_convex\_partition\_2

### Definition

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is no more than four times the minimal number.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      approx_convex_partition_2( InputIterator first,
                                              InputIterator beyond,
                                              OutputIterator result,
                                              Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range  $[first, beyond)$  into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

*Precondition:* The points in the range  $[first, beyond)$  define a simple counterclockwise-oriented polygon.

### Requirements

1. *Traits* is a model of the concept *PartitionTraits\_2* and, for the purposes of checking the postcondition that the partition produced is valid, it should also be a model of the concept *ConvexPartitionIsValidTraits\_2*.
2. *OutputIterator::value\_type* should be *Traits::Polygon\_2*.
3. *InputIterator::value\_type* should be *Traits::Point\_2*, which should also be the type of the points stored in an object of type *Traits::Polygon\_2*.
4. Points in the range  $[first, beyond)$  must define a simple polygon whose vertices are oriented counterclockwise.

The default traits class *Default\_traits* is *Partition\_traits\_2*, with the representation type determined by *InputIterator1::value\_type*.

## Implementation

This function implements the algorithm of Hertel and Mehlhorn [HM83] and is based on the class `CGAL::Constrained_triangulation_2`. Given a triangulation of the polygon, the function requires  $O(n)$  time and space for a polygon with  $n$  vertices.

## Example

The following program computes an approximately optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition\_polys*.

```
#include <CGAL/basic.h>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K> Traits;
typedef Traits::Point_2 Point_2;
typedef Traits::Polygon_2 Polygon_2;
typedef Polygon_2::Vertex_iterator Vertex_iterator;
typedef std::list<Polygon_2> Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator> Point_generator;

void make_polygon(Polygon_2& polygon)
{
    polygon.push_back(Point_2(391, 374));
    polygon.push_back(Point_2(240, 431));
    polygon.push_back(Point_2(252, 340));
    polygon.push_back(Point_2(374, 320));
    polygon.push_back(Point_2(289, 214));
    polygon.push_back(Point_2(134, 390));
    polygon.push_back(Point_2( 68, 186));
    polygon.push_back(Point_2(154, 259));
    polygon.push_back(Point_2(161, 107));
    polygon.push_back(Point_2(435, 108));
    polygon.push_back(Point_2(208, 148));
    polygon.push_back(Point_2(295, 160));
    polygon.push_back(Point_2(421, 212));
    polygon.push_back(Point_2(441, 303));
}

int main()
{
    Polygon_2 polygon;
    Polygon_list partition_polys;
```

```

/*
    CGAL::random_polygon_2(50, std::back_inserter(polygon),
                          Point_generator(100));
*/
make_polygon(polygon);
CGAL::approx_convex_partition_2(polygon.vertices_begin(),
                                polygon.vertices_end(),
                                std::back_inserter(partition_polys));
assert(CGAL::convex_partition_is_valid_2(polygon.vertices_begin(),
                                         polygon.vertices_end(),
                                         partition_polys.begin(),
                                         partition_polys.end()));

return 0;
}

```

**File:** examples/Partition\_2/approx\_convex\_partition\_2.cpp

## CGAL::convex\_partition\_is\_valid\_2

### Definition

Function that determines if a given set of polygons represents a valid convex partitioning for a given sequence of points that represent a simple, counterclockwise-oriented polygon. A convex partition is valid if the polygons do not overlap, the union of the polygons is the same as the original polygon given by the sequence of points, and if each partition polygon is convex.

```
#include <CGAL/partition_is_valid_2.h>
```

```
template<class InputIterator, class ForwardIterator, class Traits>
bool      convex_partition_is_valid_2( InputIterator point_first,
                                      InputIterator point_beyond,
                                      ForwardIterator poly_first,
                                      ForwardIterator poly_beyond,
                                      Traits traits = Default_traits)
```

determines if the polygons in the range  $[poly\_first, poly\_beyond)$  define a valid convex partition of the polygon defined by the points in the range  $[point\_first, point\_beyond)$ . The function returns *true* iff the partition is valid and otherwise returns *false*.

*Precondition:* The points in the range  $[point\_first, point\_beyond)$  define a simple, counterclockwise-oriented polygon.

### Requirements

1. *Traits* is a model of the concept *ConvexPartitionIsValidTraits\_2*.
2. *InputIterator::value\_type* should be *Traits::Point\_2*, which should also be the type of the points stored in an object of type *Traits::Polygon\_2*.
3. *ForwardIterator::value\_type* should be *Traits::Polygon\_2*.

The default traits class *Default\_traits* is *Partition\_traits\_2*, with the representation type determined by *InputIterator::value\_type*.

 CGAL::is\_convex\_2

## Implementation

This function calls *partition\_is\_valid\_2* using the function object *Is\_convex\_2* to determine the convexity of each partition polygon. Thus the time required by this function is  $O(n \log n + e \log e)$  where  $n$  is the total number of vertices in the partition polygons and  $e$  the total number of edges.

## Example

See the example presented with the function *approx\_convex\_partition\_2* for an illustration of the use of this function.

\_\_\_\_\_ *advanced* \_\_\_\_\_

## ConvexPartitionIsValidTraits\_2

### Definition

Requirements of a traits class used by *convex\_partition\_is\_valid\_2* for testing the validity of a convex partition of a polygon.

### Types

All types required by the concept *PartitionIsValidTraits\_2* are required except the function object type *Is\_valid*. The following type is required instead:

*ConvexPartitionIsValidTraits\_2::Is\_convex\_2*      Model of the concept *PolygonIsValid* that tests if a sequence of points is convex or not.

### Creation

Only a copy constructor is required.

*ConvexPartitionIsValidTraits\_2* traits( & tr);

### Operations

The following function that creates an instance of the above predicate object type must exist instead of the function *is\_valid\_object* required by *PartitionIsValidTraits\_2*.

*Is\_convex\_2*      traits.is\_convex\_2\_object( t)

### Has Models

## CGAL::greene\_approx\_convex\_partition\_2

### Definition

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is no more than four times the minimal number.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      greene_approx_convex_partition_2( InputIterator first,
                                                    InputIterator beyond,
                                                    OutputIterator result,
                                                    Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range  $[first, beyond)$  into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

*Precondition:* The points in the range  $[first, beyond)$  define a simple, counterclockwise-oriented polygon.

### Requirements

1. *Traits* is a model of the concepts *PartitionTraits\_2* and *YMonotonePartitionTraits\_2*. For the purpose of checking the validity of the y-monotone partition produced as a preprocessing step for the convex partitioning, it must also be a model of *YMonotonePartitionIsValidTraits\_2*. For the purpose of checking the postcondition that the convex partition is valid, *Traits* must also be a model of *ConvexPartitionIsValidTraits\_2*.
2. *OutputIterator::value\_type* is equivalent to *Traits::Polygon\_2*.
3. *InputIterator::value\_type* is equivalent to *Traits::Point\_2*, which should also be equivalent to the type of the points stored in an object of type *Traits::Polygon\_2*.

The default traits class *Default\_traits* is *Partition\_traits\_2*, with the representation type determined by *InputIterator::value\_type*.

*CGAL::y\_monotone\_partition\_2* ..... page [1362](#)

## Implementation

This function implements the approximation algorithm of Greene [Gre83] and requires  $O(n \log n)$  time and  $O(n)$  space to produce a convex partitioning given a  $y$ -monotone partitioning of a polygon with  $n$  vertices. The function `y_monotone_partition_2` is used to produce the monotone partition.

## Example

The following program computes an approximately optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list `partition_polys`.

```
#include <CGAL/basic.h>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K> Traits;
typedef Traits::Point_2 Point_2;
typedef Traits::Polygon_2 Polygon_2;
typedef Polygon_2::Vertex_iterator Vertex_iterator;
typedef std::list<Polygon_2> Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2< Point_2, Creator > Point_generator;

void make_polygon(Polygon_2& polygon)
{
    polygon.push_back(Point_2(391, 374));
    polygon.push_back(Point_2(240, 431));
    polygon.push_back(Point_2(252, 340));
    polygon.push_back(Point_2(374, 320));
    polygon.push_back(Point_2(289, 214));
    polygon.push_back(Point_2(134, 390));
    polygon.push_back(Point_2( 68, 186));
    polygon.push_back(Point_2(154, 259));
    polygon.push_back(Point_2(161, 107));
    polygon.push_back(Point_2(435, 108));
    polygon.push_back(Point_2(208, 148));
    polygon.push_back(Point_2(295, 160));
    polygon.push_back(Point_2(421, 212));
    polygon.push_back(Point_2(441, 303));
}

int main()
{
    Polygon_2    polygon;
    Polygon_list partition_polys;
    Traits       partition_traits;
```

```

/*
    CGAL::random_polygon_2(50, std::back_inserter(polygon),

## CGAL::is\_y\_monotone\_2

### Definition

Function for testing the y-monotonicity of a sequence of points.

```
#include <CGAL/is_y_monotone_2.h>
```

```
template<class InputIterator, class Traits>
bool is_y_monotone_2( InputIterator first, InputIterator beyond, Traits traits)
```

Determines if the sequence of points in the range *[first, beyond)* define a y-monotone polygon or not. If so, the function returns *true*, otherwise it returns *false*.

### Requirements

1. *Traits* is a model of the concept *IsYMonotoneTraits\_2*.
2. *InputIterator::value\_type* should be *Traits::Point\_2*.

The default traits class *Default\_traits* is the kernel in which the type *InputIterator::value\_type* is defined.

### See Also

*CGAL::Is\_y\_monotone\_2<Traits>* ..... page [1345](#)  
*CGAL::y\_monotone\_partition\_2* ..... page [1362](#)  
*CGAL::y\_monotone\_partition\_is\_valid\_2* ..... page [1365](#)

### Implementation

This function requires  $O(n)$  time for a polygon with  $n$  vertices.

### Example

The following program computes a y-monotone partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition\_polys*. It then asserts that each of the partition polygons is, in fact, a y-monotone polygon and that the partition is valid. (Note that the assertions are superfluous unless the postcondition checking done by *y\_monotone\_partition\_2* has been turned off during compilation.)

```
#include <CGAL/basic.h>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
```

```

#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K> Traits;
typedef Traits::Point_2 Point_2;
typedef Traits::Polygon_2 Polygon_2;
typedef std::list<Polygon_2> Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator> Point_generator;

void make_polygon(Polygon_2& polygon)
{
    polygon.push_back(Point_2(391, 374));
    polygon.push_back(Point_2(240, 431));
    polygon.push_back(Point_2(252, 340));
    polygon.push_back(Point_2(374, 320));
    polygon.push_back(Point_2(289, 214));
    polygon.push_back(Point_2(134, 390));
    polygon.push_back(Point_2( 68, 186));
    polygon.push_back(Point_2(154, 259));
    polygon.push_back(Point_2(161, 107));
    polygon.push_back(Point_2(435, 108));
    polygon.push_back(Point_2(208, 148));
    polygon.push_back(Point_2(295, 160));
    polygon.push_back(Point_2(421, 212));
    polygon.push_back(Point_2(441, 303));
}

int main( )
{
    Polygon_2    polygon;

## IsYMonotoneTraits\_2

### Definition

Requirements of a traits class to be used with the function *is\_y\_monotone\_2* that tests whether a sequence of 2D points defines a y-monotone polygon or not.

### Types

The following two types are required:

*IsYMonotoneTraits\_2:: Point\_2*

The point type of the polygon vertices.

*IsYMonotoneTraits\_2:: Less\_yx\_2*

Predicate object type that compares *Point\_2*s lexicographically. Must provide *bool operator()(Point\_2 p, Point\_2 q)* where *true* is returned iff  $p <_{xy} q$ . We have  $p <_{xy} q$ , iff  $p_x < q_x$  or  $p_x = q_x$  and  $p_y < q_y$ , where  $p_x$  and  $p_y$  denote  $x$  and  $y$  coordinate of point  $p$  resp.

### Creation

Only a copy constructor is required.

*IsYMonotoneTraits\_2 traits( & tr);*

### Operations

The following function that creates an instance of the above predicate object type must exist:

*Less\_yx\_2 traits.less\_yx\_2\_object()*

### Has Models

*CGAL::Partition\_traits\_2<R>* ..... page [1359](#)

## CGAL::Is\_convex\_2<Traits>

### Definition

Function object class for testing if a sequence of points represents a convex polygon or not.

*#include <CGAL/polygon\_function\_objects.h>*

### Is Model for the Concepts

PolygonIsValid.....page [1361](#)

### Creation

*Is\_convex\_2<Traits> f( Traits t);*                      *Traits* satisfies the requirements of the function *is\_convex\_2*

### Operations

*template<class InputIterator>*  
*bool*                      *f( InputIterator first, InputIterator beyond)*

returns *true* iff the points of type *Triats::Point\_2* in the range *[first,beyond)* define a convex polygon.

### See Also

*CGAL::convex\_partition\_is\_valid\_2* ..... page [1333](#)  
*CGAL::Partition\_is\_valid\_traits\_2<Traits, PolygonIsValid>*.....page [1357](#)

### Implementation

This test requires  $O(n)$  time for a polygon with  $n$  vertices.

## CGAL::Is\_vacuously\_valid<Traits>

### Definition

Function object class that indicates all sequences of points are valid.

```
#include <CGAL/polygon_function_objects.h>
```

### Is Model for the Concepts

PolygonIsValid.....page [1361](#)

### Creation

```
Is_vacuously_valid<Traits> f( Traits t);
```

### Operations

```
template<class InputIterator>
bool      f( InputIterator first, InputIterator beyond)      returns true.
```

### See Also

### Implementation

This test requires  $O(1)$  time.

# CGAL::Is\_y\_monotone\_2<Traits>

## Definition

Function object class that tests whether a sequence of points represents a y-monotone polygon or not.

`#include <CGAL/polygon_function_objects.h>`

## Is Model for the Concepts

PolygonIsValid.....page [1361](#)

## Creation

`Is_y_monotone_2<Traits> f( Traits t);`      *Traits* is a model of the concept *IsYMonotoneTraits\_2*

## Operations

`template<class InputIterator>`  
`bool                      f( InputIterator first, InputIterator beyond)`

returns *true* iff the points of type *Traits::Point\_2* in the range *[first,beyond)* define a y-monotone polygon.

## See Also

`CGAL::convex_partition_is_valid_2` ..... page [1333](#)  
`CGAL::Partition_is_valid_traits_2<Traits, PolygonIsValid>`.....page [1357](#)

## Implementation

This test requires  $O(n)$  time for a polygon with  $n$  vertices.

## CGAL::optimal\_convex\_partition\_2

Function that produces a set of convex polygons that represent a partitioning of a polygon defined on a sequence of points. The number of convex polygons produced is minimal.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      optimal_convex_partition_2( InputIterator first,
                                                InputIterator beyond,
                                                OutputIterator result,
                                                Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range  $[first, beyond)$  into convex polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

*Precondition:* The points in the range  $[first, beyond)$  define a simple, counterclockwise-oriented polygon.

### Requirements

1. *Traits* is a model of the concept *OptimalConvexPartitionTraits\_2*. For the purposes of checking the postcondition that the partition is valid, *Traits* should also be a model of *ConvexPartitionIsValidTraits\_2*.
2. *OutputIterator::value\_type* should be *Traits::Polygon\_2*.
3. *InputIterator::value\_type* should be *Traits::Point\_2*, which should also be the type of the points stored in an object of type *Traits::Polygon\_2*.

The default traits class *Default\_traits* is *Partition\_traits\_2*, with the representation type determined by *InputIterator::value\_type*.

### See Also

 CGAL::partition\_is\_valid\_2 ..... page [1351](#)  
 CGAL::Partition\_is\_valid\_traits\_2<Traits, PolygonIsValid> ..... page [1357](#)

### Implementation

This function implements the dynamic programming algorithm of Greene [[Gre83](#)], which requires  $O(n^4)$  time and  $O(n^3)$  space to produce a partitioning of a polygon with  $n$  vertices.

## Example

The following program computes an optimal convex partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition\_polys*. It then asserts that the partition produced is valid. The traits class used for testing the validity is derived from the traits class used to produce the partition with the function object class *CGAL::Is\_convex\_2* used to define the required *Is\_valid* type. (Note that this assertion is superfluous unless the postcondition checking for *optimal\_convex\_partition\_2* has been turned off.)

```
#include <CGAL/basic.h>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/Partition_is_valid_traits_2.h>
#include <CGAL/polygon_function_objects.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>

## OptimalConvexPartitionTraits\_2

### Definition

Requirements of a traits class to be used with the function *optimal\_convex\_partition\_2* that computes an optimal convex partition of a polygon.

### Generalizes

PartitionTraits\_2 ..... page [1355](#)

### Types

In addition to the types listed with the concept *PartitionTraits\_2*, the following types are required:

*OptimalConvexPartitionTraits\_2:: Segment\_2*      A segment type

*OptimalConvexPartitionTraits\_2:: Ray\_2*      A ray type

*OptimalConvexPartitionTraits\_2:: Object\_2*      A general object type that can be either a point or a segment

*OptimalConvexPartitionTraits\_2:: Construct\_segment\_2*

Function object type that provides *Segment\_2* *operator()(Point\_2 p, Point\_2 q)*, which constructs and returns the segment defined by the points *p* and *q*.

*OptimalConvexPartitionTraits\_2:: Construct\_ray\_2*

Function object type that provides *Ray\_2* *operator()(Point\_2 p, Point\_2 q)*, which constructs and returns the ray from point *p* through point *q*.

*OptimalConvexPartitionTraits\_2:: Collinear\_are\_ordered\_along\_line\_2*

Predicate object type that determines orderings of *Point\_2*s on a line. Must provide *bool operator()(Point\_2 p, Point\_2 q, Point\_2 r)* that returns *true*, iff *q* lies between *p* and *r* and *p*, *q*, and *r* satisfy the precondition that they are collinear.

*OptimalConvexPartitionTraits\_2:: Are\_strictly\_ordered\_along\_line\_2*

Predicate object type that determines orderings of *Point\_2*s. Must provide *bool operator()(Point\_2 p, Point\_2 q, Point\_2 r)* that returns *true*, iff the three points are collinear and *q* lies strictly between *p* and *r*. Note that *false* should be returned if *q==p* or *q==r*.

<i>OptimalConvexPartitionTraits_2:: Intersect_2</i>	Function object type that provides <i>Object_2 operator()(Segment_2 s1, Segment_2 s2)</i> that returns the intersection of two segments (which may be either a segment or a point).
<i>OptimalConvexPartitionTraits_2:: Assign_2</i>	Function object type that provides <i>bool operator()(Segment_2 s1, Object_2 o)</i> that returns <i>true</i> if <i>o</i> is a segment and assigns the value of <i>o</i> to <i>s1</i> ; returns <i>false</i> otherwise.

## Creation

Only a copy constructor is required.

```
OptimalConvexPartitionTraits_2 traits( & tr);
```

## Operations

In addition to the functions required by *PartitionTraits\_2*, the following functions that create instances of the above function object types must exist:

<i>Collinear_are_ordered_along_line_2</i>	<i>traits.collinear_are_ordered_along_line_2_object()</i>
<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_ray_2</i>	<i>traits.construct_ray_2_object()</i>
<i>Are_strictly_ordered_along_line_2</i>	<i>traits.are_strictly_ordered_along_line_2_object()</i>

## Has Models

*CGAL::Partition\_traits\_2<R>* ..... page [1359](#)

## See Also

*CGAL::convex\_partition\_is\_valid\_2* ..... page [1333](#)  
*CGAL::Partition\_is\_valid\_traits\_2<Traits, PolygonIsValid>* ..... page [1357](#)

## CGAL::partition\_is\_valid\_2

### Definition

Function that determines if a given set of polygons represents a valid partition for a given sequence of points that define a simple, counterclockwise-oriented polygon. A valid partition is one in which the polygons are nonoverlapping and the union of the polygons is the same as the original polygon.

```
#include <CGAL/partition_is_valid_2.h>
```

```
template<class InputIterator, class ForwardIterator, class Traits>
bool partition_is_valid_2( InputIterator point_first,
                          InputIterator point_beyond,
                          ForwardIterator poly_first,
                          ForwardIterator poly_beyond,
                          Traits traits = Default_traits)
```

returns *true* iff the polygons in the range  $[poly\_first, poly\_beyond)$  define a valid partition of the polygon defined by the points in the range  $[point\_first, point\_beyond)$  and *false* otherwise. Each polygon must also satisfy the property tested by *Traits::Is\_valid()*.

*Precondition:* Points in the range  $[point\_first, point\_beyond)$  define a simple, counterclockwise-oriented polygon.

### Requirements

1. *Traits* is a model of the concept *PartitionIsValidTraits\_2* and the concept defining the requirements for the validity test implemented by *Traits::Is\_valid()*.
2. *InputIterator::value\_type* should be *Traits::Point\_2*, which should also be the type of the points stored in an object of type *Traits::Polygon\_2*.
3. *ForwardIterator::value\_type* should be *Traits::Polygon\_2*.

The default traits class *Default\_traits* is *Partition\_traits\_2*, with the representation type determined by *InputIterator::value\_type*.

*CGAL::y\_monotone\_partition\_2* ..... page 1362  
*CGAL::is\_convex\_2*

## Implementation

This function requires  $O(n \log n + e \log e + \sum_{i=1}^p m_i)$  where  $n$  is the total number of vertices of the  $p$  partition polygons,  $e$  is the total number of edges of the partition polygons and  $m_i$  is the time required by *Traits::Is\_valid()* to test if partition polygon  $p_i$  is valid.

## Example

See the example presented with the function *optimal\_convex\_partition\_2* for an illustration of the use of this function.

└────────── *advanced* ─────────┘

## PartitionIsValidTraits\_2

### Definition

Requirements of a traits class that is used by *partition\_is\_valid\_2*, *convex\_partition\_is\_valid\_2*, and *y\_monotone\_partition\_is\_valid\_2* for testing if a given set of polygons are nonoverlapping and if their union is a polygon that is the same as a polygon represented by a given sequence of points. Note that the traits class for *partition\_is\_valid\_2* may have to satisfy additional requirements if each partition polygon is to be tested for having a particular property; see, for example, the descriptions of the function *is\_convex\_2* and the concept *YMonotonePartitionTraits\_2* for the additional requirements for testing for convexity and y-monotonicity, respectively.

### Types

<i>PartitionIsValidTraits_2:: Point_2</i>	The point type on which the partitioning algorithm operates.
<i>PartitionIsValidTraits_2:: Polygon_2</i>	The polygon type created by the partitioning function. This type should provide a nested type <i>Vertex_const_iterator</i> that is the type of the non-mutable iterator over the polygon vertices.
<i>PartitionIsValidTraits_2:: Is_valid</i>	A model of the concept <i>PolygonIsValid</i>
<i>PartitionIsValidTraits_2:: Less_xy_2</i>	Predicate object type that compares <i>Point_2</i> s lexicographically. Must provide <i>bool operator()(Point_2 p, Point_2 q)</i> where <i>true</i> is returned iff $p <_{xy} q$ . We have $p <_{xy} q$ , iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$ , where $p_x$ and $p_y$ denote the $x$ and $y$ coordinates of point $p$ , respectively.
<i>PartitionIsValidTraits_2:: Left_turn_2</i>	Predicate object type that provides <i>bool operator()(Point_2 p, Point_2 q, Point_2 r)</i> , which returns <i>true</i> iff $r$ lies to the left of the oriented line through $p$ and $q$ .
<i>PartitionIsValidTraits_2:: Orientation_2</i>	Predicate object type that provides <i>CGAL::Orientation operator()(Point_2 p, Point_2 q, Point_2 r)</i> that returns <i>CGAL::LEFT_TURN</i> , if $r$ lies to the left of the oriented line $l$ defined by $p$ and $q$ , returns <i>CGAL::RIGHT_TURN</i> if $r$ lies to the right of $l$ , and returns <i>CGAL::COLLINEAR</i> if $r$ lies on $l$ .

### Creation

Only a copy constructor is required.

```
PartitionIsValidTraits_2 traits( & tr);
```

## Operations

The following functions that create instances of the above predicate object types must exist.

*Orientation\_2*                    *traits.is\_valid\_object()*

*Less\_xy\_2*                    *traits.less\_xy\_2\_object()*

*Left\_turn\_2*                    *traits.left\_turn\_2\_object()*

*Orientation\_2*                    *traits.orientation\_2\_object()*

## Has Models

## PartitionTraits\_2

### Definition

The polygon partitioning functions are each parameterized by a traits class that defines the primitives used in the algorithms. Many requirements are common to all traits classes. The concept `PartitionTraits_2` defines this common set of requirements.

### Types

<code>PartitionTraits_2:: Point_2</code>	The point type on which the partitioning algorithm operates.
<code>PartitionTraits_2:: Polygon_2</code>	The polygon type to be created by the partitioning algorithm. For testing the validity postcondition of the partition, this type should provide a nested type <code>Vertex_const_iterator</code> that is the type of the iterator over the polygon vertices and member functions <code>Vertex_const_iterator vertices_begin()</code> and <code>Vertex_const_iterator vertices_end()</code> .
<code>PartitionTraits_2:: Less_xy_2</code>	Predicate object type that compares <code>Point_2</code> s lexicographically. Must provide <code>bool operator()(Point_2 p, Point_2 q)</code> where <code>true</code> is returned iff $p <_{xy} q$ . We have $p <_{xy} q$ , iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$ , where $p_x$ and $p_y$ denote the $x$ and $y$ coordinates of point $p$ , respectively.
<code>PartitionTraits_2:: Less_yx_2</code>	Same as <code>Less_xy_2</code> with the roles of $x$ and $y$ interchanged.
<code>PartitionTraits_2:: Left_turn_2</code>	Predicate object type that provides <code>bool operator()(Point_2 p, Point_2 q, Point_2 r)</code> , which returns <code>true</code> iff $r$ lies to the left of the oriented line through $p$ and $q$ .
<code>PartitionTraits_2:: Orientation_2</code>	Predicate object type that provides <code>CGAL::Orientation operator()(Point_2 p, Point_2 q, Point_2 r)</code> that returns <code>CGAL::LEFT_TURN</code> , if $r$ lies to the left of the oriented line $l$ defined by $p$ and $q$ , returns <code>CGAL::RIGHT_TURN</code> if $r$ lies to the right of $l$ , and returns <code>CGAL::COLLINEAR</code> if $r$ lies on $l$ .
<code>PartitionTraits_2:: Compare_y_2</code>	Predicate object type that provides <code>CGAL::Comparison_result operator()(Point_2 p, Point_2 q)</code> to compare the $y$ values of two points. The operator must return <code>CGAL::SMALLER</code> if $p_y < q_y$ , <code>CGAL::LARGER</code> if $p_y > q_y$ and <code>CGAL::EQUAL</code> if $p_y = q_y$ .
<code>PartitionTraits_2:: Compare_x_2</code>	The same as <code>Compare_y_2</code> , except that $x$ coordinates are compared instead of $y$ .

## Creation

A copy constructor and default constructor are required.

```
PartitionTraits_2 traits;
```

```
PartitionTraits_2 traits( & tr);
```

## Operations

The following functions that create instances of the above predicate object types must exist.

```
Less_yx_2          traits.less_yx_2_object()
```

```

## CGAL::Partition\_is\_valid\_traits\_2<Traits, PolygonIsValid>

### Definition

Class that derives a traits class for *partition\_is\_valid\_2* from a given traits class by defining the validity testing function object in terms of a supplied template parameter.

```
#include <CGAL/Partition_is_valid_traits_2.h>
```

### Inherits From

*Traits*

### Is Model for the Concepts

*PartitionIsValidTraits\_2*

### Types

<code>typedef PolygonIsValid</code>	<code>Is_valid;</code>
<code>typedef Traits::Point_2</code>	<code>Point_2;</code>
<code>typedef Traits::Polygon_2</code>	<code>Polygon_2;</code>
<code>typedef Traits::Less_xy_2</code>	<code>Less_xy_2;</code>
<code>typedef Traits::Left_turn_2</code>	<code>Left_turn_2;</code>
<code>typedef Traits::Orientation_2</code>	<code>Orientation_2;</code>

### Operations

The constructors and member functions for creating instances of the above types are inherited from *Traits*. In addition, the following member function is defined:

<i>Is_valid</i>	<code>traits.is_valid_object( Traits traits)</code>	function returning an instance of <i>Is_valid</i>
-----------------	---	---

## PolygonIsValid

### Definition

Function object that determines if a sequence of points represents a valid partition polygon or not, where “valid” can assume any of several meanings (*e.g.*, convex or y-monotone).

### Creation

*PolygonIsValid* *f*( *Traits* *t*);

*Traits* is a model of the concept required by the function that checks for validity of the polygon.

### Operations

```
template<class InputIterator>
bool f( InputIterator first, InputIterator beyond)
```

returns *true* iff the points of type *Traits::Point\_2* in the range [*first*,*beyond*) define a valid polygon.

### Has Models

## CGAL::y\_monotone\_partition\_2

### Definition

Function that produces a set of y-monotone polygons that represent a partitioning of a polygon defined on a sequence of points.

```
#include <CGAL/partition_2.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      y_monotone_partition_2( InputIterator first,
                                           InputIterator beyond,
                                           OutputIterator result,
                                           Traits traits = Default_traits)
```

computes a partition of the polygon defined by the points in the range  $[first, beyond)$  into y-monotone polygons. The counterclockwise-oriented partition polygons are written to the sequence starting at position *result*. The past-the-end iterator for the resulting sequence of polygons is returned.

*Precondition:* The points in the range  $[first, beyond)$  define a simple, counterclockwise-oriented polygon.

### Requirements

1. *Traits* is a model of the concept *YMonotonePartitionTraits\_2* and, for the purposes of checking the post-condition that the partition is valid, it should also be a model of *YMonotonePartitionIsValidTraits\_2*.
2. *OutputIterator::value\_type* should be *Traits::Polygon\_2*.
3. *InputIterator::value\_type* should be *Traits::Point\_2*, which should also be the type of the points stored in an object of type *Traits::Polygon\_2*.

The default traits class *Default\_traits* is *Partition\_traits\_2*, with the representation type determined by *InputIterator::value\_type*.

 CGAL::partition\_is\_valid\_2 ..... page [1351](#)  
 CGAL::y\_monotone\_partition\_is\_valid\_2 ..... page [1365](#)

### Implementation

This function implements the algorithm presented by de Berg *et al.* [[dBvKOS97](#)] which requires  $O(n \log n)$  time and  $O(n)$  space for a polygon with  $n$  vertices.

## Example

The following program computes a y-monotone partitioning of a polygon using the default traits class and stores the partition polygons in the list *partition\_polys*. It then asserts that each partition polygon produced is, in fact, y-monotone and that the partition is valid. (Note that these assertions are superfluous unless the postcondition checking for *y\_monotone\_partition\_2* has been turned off.)

```
#include <CGAL/basic.h>
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Partition_traits_2.h>
#include <CGAL/partition_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <cassert>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Partition_traits_2<K> Traits;
typedef Traits::Point_2 Point_2;
typedef Traits::Polygon_2 Polygon_2;
typedef std::list<Polygon_2> Polygon_list;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator> Point_generator;

void make_polygon(Polygon_2& polygon)
{
    polygon.push_back(Point_2(391, 374));
    polygon.push_back(Point_2(240, 431));
    polygon.push_back(Point_2(252, 340));
    polygon.push_back(Point_2(374, 320));
    polygon.push_back(Point_2(289, 214));
    polygon.push_back(Point_2(134, 390));
    polygon.push_back(Point_2( 68, 186));
    polygon.push_back(Point_2(154, 259));
    polygon.push_back(Point_2(161, 107));
    polygon.push_back(Point_2(435, 108));
    polygon.push_back(Point_2(208, 148));
    polygon.push_back(Point_2(295, 160));
    polygon.push_back(Point_2(421, 212));
    polygon.push_back(Point_2(441, 303));
}

int main( )
{
    Polygon_2    polygon;
    Polygon_list partition_polys;

    /*
       CGAL::random_polygon_2(50, std::back_inserter(polygon),
                             Point_generator(100));
    */
    make_polygon(polygon);
```

```

CGAL::y_monotone_partition_2(polygon.vertices_begin(),
                             polygon.vertices_end(),
                             std::back_inserter(partition_polys));

std::list<Polygon_2>::const_iterator poly_it;
for (poly_it = partition_polys.begin(); poly_it != partition_polys.end();
     poly_it++)
{
    assert(CGAL::is_y_monotone_2((*poly_it).vertices_begin(),
                                (*poly_it).vertices_end()));
}

assert(CGAL::partition_is_valid_2(polygon.vertices_begin(),
                                polygon.vertices_end(),
                                partition_polys.begin(),
                                partition_polys.end()));

return 0;
}

```

## CGAL::y\_monotone\_partition\_is\_valid\_2

### Definition

Function that determines if a given set of polygons represents a valid y-monotone partitioning for a given sequence of points that define a simple, counterclockwise-oriented polygon. A valid partition is one in which the polygons are nonoverlapping and the union of the polygons is the same as the original polygon and each polygon is y-monotone

```
#include <CGAL/partition_is_valid_2.h>
```

```
template<class InputIterator, class ForwardIterator, class Traits>
bool y_monotone_partition_is_valid_2( InputIterator point_first,
                                     InputIterator point_beyond,
                                     ForwardIterator poly_first,
                                     ForwardIterator poly_beyond,
                                     Traits traits = Default_traits)
```

determines if the polygons in the range `[poly_first, poly_beyond)` define a valid y-monotone partition of the polygon represented by the points in the range `[point_first, point_beyond)`. The function returns *true* iff the partition is valid and otherwise returns false.

*Precondition:* Points in the range `[point_first, point_beyond)` define a simple, counterclockwise-oriented polygon.

### Requirements

1. *Traits* is a model of the concept *YMonotonePartitionIsValidTraits\_2*.
2. *InputIterator::value\_type* should be *Traits::Point\_2*, which should also be the type of the points stored in an object of type *Traits::Polygon\_2*.
3. *ForwardIterator::value\_type* should be *Traits::Polygon\_2*.

The default traits class *Default\_traits* is *Partition\_traits\_2*, with the representation type determined by *InputIterator::value\_type*.

### See Also

CGAL::y\_monotone\_partition\_2 ..... page 1362  
 CGAL::is\_y\_monotone\_2 ..... page 1339  
 CGAL::partition\_is\_valid\_2 ..... page 1351  
 CGAL::Partition\_is\_valid\_traits\_2<Traits, PolygonIsValid> ..... page 1357

## Implementation

This function uses the function *partition\_is\_valid\_2* together with the function object *Is\_y\_monotone\_2* to determine if each polygon is *y*-monotone or not. Thus the time required is  $O(n \log n + e \log e)$  where  $n$  is the total number of vertices of the partition polygons and  $e$  is the total number of edges.

## Example

See the example presented with the function *y\_monotone\_partition\_2* for an illustration of the use of this function.

\_\_\_\_\_ *advanced* \_\_\_\_\_

## YMonotonePartitionIsValidTraits\_2

### Definition

Requirements of a traits class that is used by *y\_monotone\_partition\_is\_valid\_2* for testing the validity of a y-monotone partition of a polygon.

### Types

All types required by the concept *PartitionIsValidTraits\_2* are required except the function object type *Is\_valid*. The following type is required instead:

*YMonotonePartitionIsValidTraits\_2::Is\_y\_monotone\_2*

Model of the concept *PolygonIsValid* that tests if a sequence of points is y-monotone or not.

### Creation

Only a copy constructor is required.

*YMonotonePartitionIsValidTraits\_2 traits( & tr);*

### Operations

The following function that creates an instance of the above predicate object type must exist instead of the function *is\_valid\_object* required by *PartitionIsValidTraits\_2*.

*Is\_y\_monotone\_2 traits.is\_y\_monotone\_2\_object( t)*

### Has Models

## YMonotonePartitionTraits\_2

### Definition

Requirements of a traits class to be used with the function `y_monotone_partition_2`.

### Generalizes

PartitionTraits\_2 ..... page [1355](#)

### Types

In addition to the types defined for the concept *PartitionTraits\_2*, the following types are also required:

*YMonotonePartitionTraits\_2:: Line\_2*

*YMonotonePartitionTraits\_2:: Compare\_x\_at\_y\_2*

Predicate object type that provides *CGAL::Comparison\_result operator()(Point\_2 p, Line\_2 h)* to compare the *x* coordinate of *p* and the horizontal projection of *p* on *h*.

*YMonotonePartitionTraits\_2:: Construct\_line\_2*

Function object type that provides *Line\_2 operator()(Point\_2 p, Point\_2 q)*, which constructs and returns the line defined by the points *p* and *q*.

*YMonotonePartitionTraits\_2:: Is\_horizontal\_2*

Function object type that provides *bool operator()(Line\_2 l)*, which returns *true* iff the line *l* is horizontal.

### Creation

A copy constructor and default constructor are required.

*YMonotonePartitionTraits\_2 traits;*

*YMonotonePartitionTraits\_2 traits( YMonotonePartitionTraits tr);*

### Operations

In addition to the functions required for the concept *PartitionTraits\_2*, the following functions that create instances of the above function object types must exist.

*Construct\_line\_2*      *traits.construct\_line\_2\_object()*

*Compare\_x\_at\_y\_2*      *traits.compare\_x\_at\_y\_2\_object()*

*Is\_horizontal\_2*      *traits.is\_horizontal\_2\_object()*

### 19.1 Definitions

#### 19.1.1 2D Contour

A *2D contour* is a closed sequence (a cycle) of 3 or more *connected 2D oriented straight line segments* called *contour edges*. The endpoints of the contour edges are called *vertices*. Each contour edge shares its endpoints with at least two other contour edges.

If the edges intersect only at the vertices and at most are coincident along a line but do not *cross* one another, the contour is classified as *simple*.

A contour is topologically equivalent to a *disk* and if it is simple, is said to be a *Jordan Curve*.

Contours partition the plane in two open regions: one bounded and one unbounded. If the bounded region of a

contour is only one *singly-connected set*, the contour is said to be *strictly-simple*.

The *Orientation* of a contour is given by the order of the vertices around the region they bound. It can be *CLOCKWISE* (CCW) or *COUNTERCLOCKWISE* (CW).

The *bounded side* of a contour edge is the side facing the bounded region of the contour. If the contour is oriented CCW, the bounded side of an edge is its left side.

A contour with a null edge (a segment of length zero given by two consecutive coincident vertices), or with edges not connected to the bounded region (an antenna: 2 consecutive edges going forth and back along the same line), is said to be *degenerate* (collinear edges are *not* considered a degeneracy).

### 19.1.2 2D Polygon with Holes

A *2D polygon* is a contour.

A *2D polygon with holes* is a contour, called the *outer contour*, having zero or more contours, called *inner contours*, or *holes*, in its bounded region. The intersection of the bounded region of the outer contour and the unbounded regions of each inner contour is the *interior* of the polygon with holes. The orientation of the holes must be opposite to the orientation of the outer contour and there cannot be any intersection among any contour. A hole cannot be in the bounded region of any other hole.

A polygon with holes is strictly-simple if its interior is a singly-connected set.

The orientation of a polygon with holes is the orientation of its outer contour. The bounded side of *any* edge, whether of the outer contour or a hole, is the *same* for all edges. That is, if the outer contour is oriented CCW and the holes CW, both contour and hole edges face the polygon interior to their left.

Throughout the rest of this chapter the term *polygon* will be used as a shortcut for *polygon with holes*.

Figure 19.1: Examples of strictly simple polygons: One with no holes and two edges coincident (left) and one with 2 holes (right).

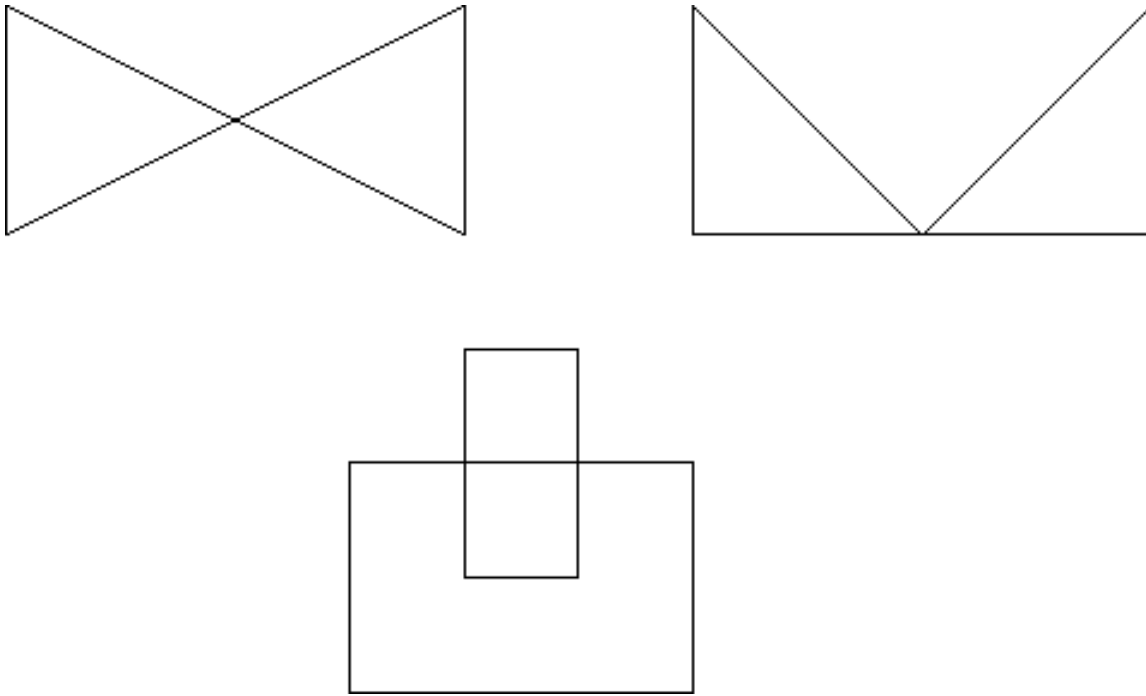

Figure 19.2: Examples of non-simple polygons: One folding into itself, that is, non-planar (left), one with a vertex touching an edge (right), and one with a hole crossing into the outside (bottom)

### 19.1.3 Inward Offset of a Non-degenerate Strictly-Simple Polygon with Holes

For any 2D non-degenerate strictly-simple polygon with holes called the *source*, there can exist a *set* of 0, 1 or more *inward offset polygons with holes*, or just offset polygons for short, at some euclidean distance  $t > 0$  (each being strictly simple and non-degenerate). Any contour edge of such offset polygon, called an *offset edge* corresponds to *some* contour edge of the source polygon, called its *source edge*. An offset edge is parallel to its source edge and has the same orientation. The Euclidean distance between the *lines* supporting an offset edge and its source edge is exactly  $t$ .

An offset edge is always located to the bounded side of its source edge (which is an oriented straight line segment).

An offset polygon can have less, equal or more sides as its source polygon.

If the source polygon has no holes, no offset polygon has holes. If the source polygon has holes, any of the offset polygons can have holes itself, but it might as well have no holes at all (if the distance is sufficiently large).

Each offset polygon has the same orientation as the source polygon.

### 19.1.4 Straight Skeleton of a 2D Non-degenerate Strictly-Simple Polygon with Holes

The *2D straight skeleton* of a non-degenerate strictly-simple polygon with holes [AAAG95] is a special partitioning of the polygon interior into *straight skeleton regions* corresponding to the monotone areas traced by a continuous *inward offsetting* of the contour edges. Each region corresponds to exactly 1 contour edge.

These regions are bounded by angular bisectors of the supporting lines of the contour edges and each such region is itself a non-convex non-degenerate strictly-simple polygon.

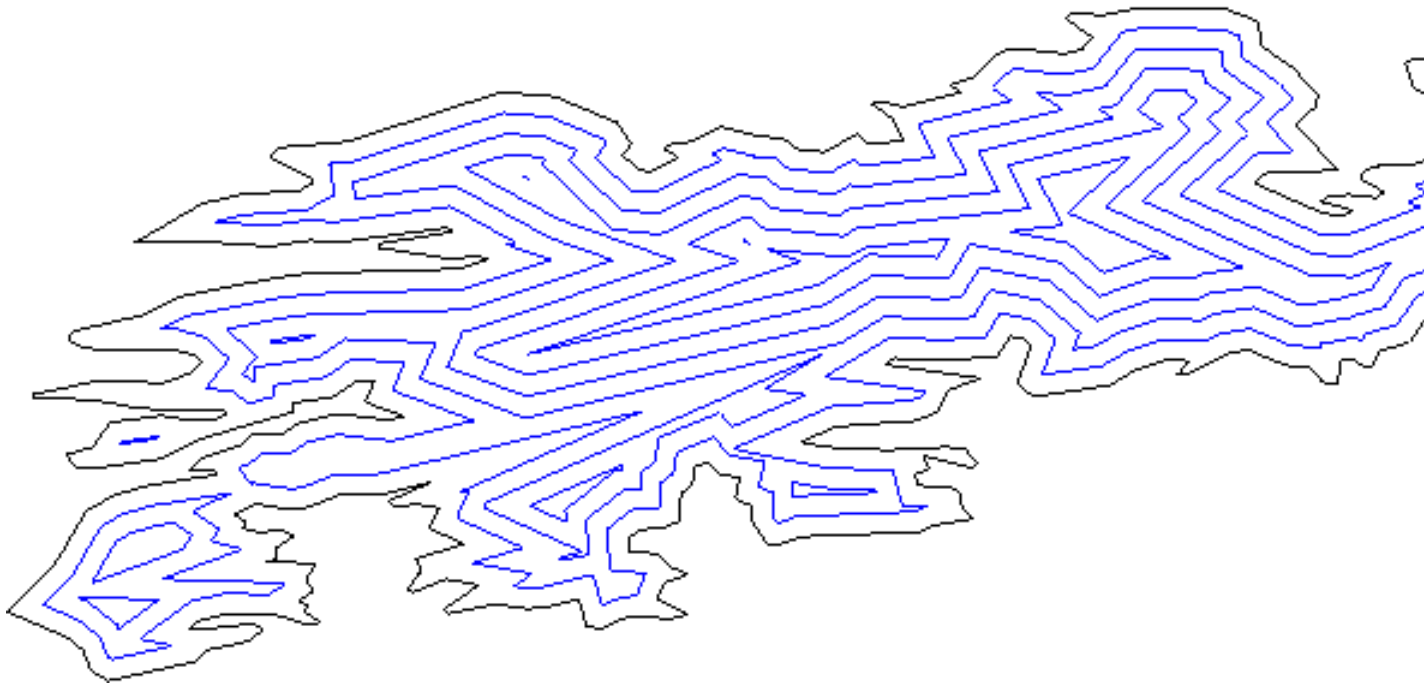

Figure 19.3: Offset contours of a sample polygon

### Angular Bisecting Lines and Offset Bisectors

Given two points and a line passing through them, the perpendicular line passing through the midpoint is the bisecting line (or bisector) of those points.

Two non-parallel lines, intersecting at a point, are bisected by two other lines passing through that intersection point.

Two parallel lines are bisected by another parallel line placed halfway in between.

Given just one line, any perpendicular line can be considered the bisecting line (any bisector of any two points along the single line).

The bisecting lines of two edges are the lines bisecting the supporting lines of the edges (if the edges are parallel or collinear, there is just one bisecting line).

The halfplane to the bounded side of the line supporting a contour edge is called the *offset zone* of the contour edge.

Given any number of contour edges (not necessarily consecutive), the intersection of their offset zones is called their *combined offset zone*.

Any two contour edges define an *offset bisector*, as follows: If the edges are non-parallel, their bisecting lines can be decomposed as 4 rays originating at the intersection of the supporting lines. Only one of these rays is contained in the combined offset zone of the edges (which one depends on the possible combinations of orientations). This ray is the offset bisector of the non-parallel contour edges.

If the edges are parallel (but not collinear) and have opposite orientation, the entire and unique bisecting line is their offset bisector. If the edges are parallel but have the same orientation, there is no offset bisector between

Figure 19.4: Straight skeleton of a complex shaggy contour

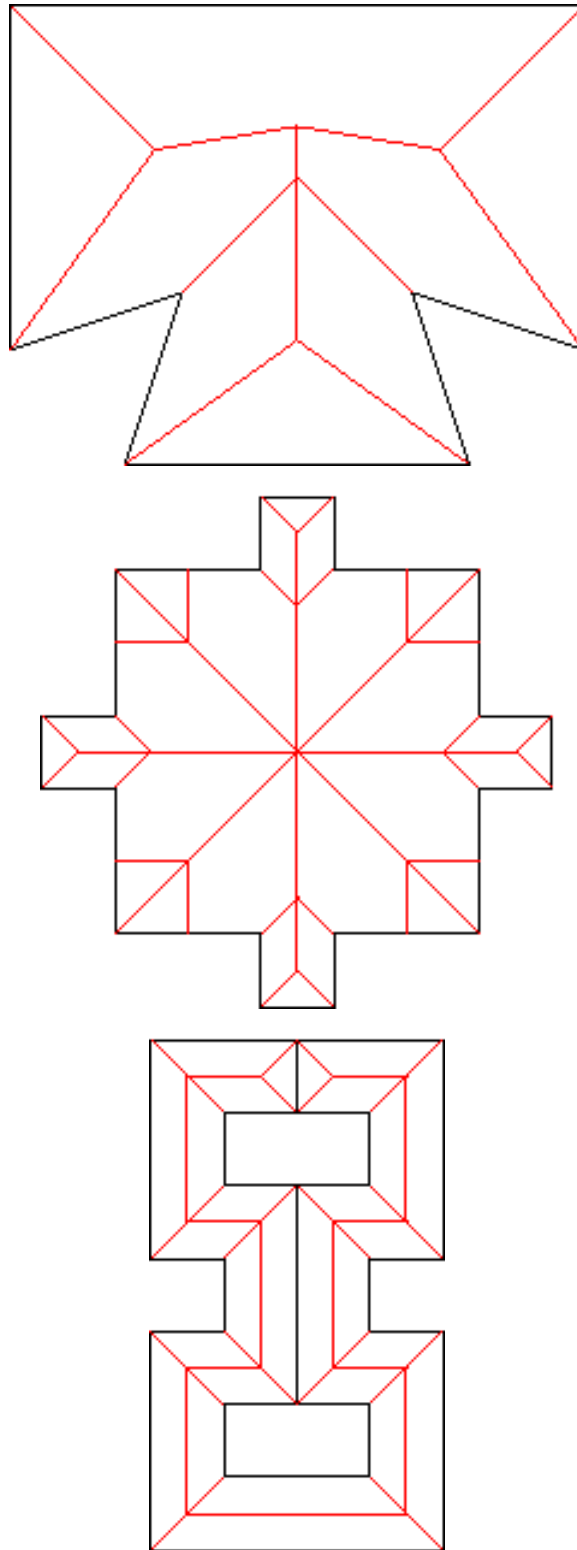

Figure 19.5: Other examples: A vertex-event (left), the case of several collinear edges (middle), and the case of a validly simple polygon with tangent edges (right).

them.

If the edges are collinear and have the same orientation, their offset bisector is given by a perpendicular ray to the left of the edges which originates at the midpoint of the combined complement of the edges. (The *complement* of an edge/segment are the two rays along its supporting line which are not the segment and the *combined complement* of  $N$  collinear segments is the intersection of the complements of each segment). If the edges are collinear but have opposite orientation, there is no offset bisector between them.

## Faces, Edges and Vertices

Each region of the partitioning defined by a straight skeleton is called a *face*. Each face is bounded by straight line segments, called *edges*. Exactly one edge per face is a *contour edge* (corresponds to a side of the polygon) and the rest of the edges, located in the interior of the polygon, are called *skeleton edges*, or *bisectors*.

The bisectors of the straight skeleton are segments of the offset bisectors as defined previously. Since an offset bisector is a ray of a bisecting line of 2 contour edges, each skeleton edge (or bisector) is uniquely given by two contour edges. These edges are called the *defining contour edges* of the bisector.

The intersection of the edges are called *vertices*. Although in a simple polygon, only 2 edges intersect at a vertex, in a straight skeleton, 3 or more edges intersect at any given vertex. That is, vertices in a straight skeleton have degree  $\geq 3$ .

A *contour vertex* is a vertex for which 2 of its incident edges are contour edges.

A *skeleton vertex* is a vertex whose incident edges are all skeleton edges.

A *contour bisector* is a bisector whose defining contour edges are consecutive. Such a bisector is incident upon 1 contour vertex and 1 skeleton vertex and touches the input polygon at exactly 1 endpoint.

An *inner bisector* is a bisector whose defining contour edges are not consecutive. Such a bisector is incident upon 2 skeleton vertices and is strictly contained in the interior of the polygon.

## 19.2 Representation

This CGAL package represents a straight skeleton as a specialized *Halfedge Data Structure* (HDS) whose vertices embeds 2D Points (see the *StraightSkeleton\_2* concept in the reference manual for details).

Its halfedges, by considering the source and target points, implicitly embeds 2D oriented straight line segments (each halfedge per se does not embed a segment explicitly).

A face of the straight skeleton is represented as a face in the HDS. Both contour and skeleton edges are represented by pairs of opposite HDS halfedges, and both contour and skeleton vertices are represented by HDS vertices.

In a HDS, a border halfedge is a halfedge which is incident upon an unbounded face. In the case of the straight skeleton HDS, such border halfedges are oriented such that their left side faces outwards the polygon. Therefore, the opposite halfedge of any border halfedge is oriented such that its left side faces inward the polygon.

This CGAL package requires the input polygon (with holes) to be non-degenerate, strictly-simple, and oriented counter-clockwise.

The skeleton halfedges are oriented such that their *left* side faces inward the region they bound. That is, the vertices (both contour and skeleton) of a face are circulated in counter-clockwise order. There is one and only one contour halfedge incident upon any face.

The contours of the input polygon are traced by the border halfedges of the HDS (those facing outward), but in the opposite direction. That is, the vertices of the contours can only be traced from the straight skeleton data structure by circulating the border halfedges, and the resulting vertex sequence will be reversed w.r.t the input vertex sequence.

A skeleton edge, according to the definition given in the previous section, is defined by 2 contour edges. In the representation, each one of the opposite halfedges that represent a skeleton edge is associated with one of the opposite halfedges that correspond to one of its defining contour edges. Thus, the 2 opposite halfedges of a skeleton edge link the edge to its 2 defining contour edges.

Starting from any border contour halfedge, circulating the structure walks through border counter halfedges and traces the vertices of the polygon's contours (in opposite order).

Starting from any non-border but contour halfedge, circulating the structure walks counter-clockwise around the face corresponding to that contour halfedge. The vertices around a face always describe a non-convex non-degenerate strictly-simple polygon.

A vertex is the intersection of contour and/or skeleton edges. Since a skeleton edge is defined by 2 contour edges, any vertex is itself defined by a unique set of contour edges. These are called the *defining contour edges* of the vertex.

A vertex is identified by its set of defining contour edges. Two vertices are distinct if they have differing sets of defining contour edges. Note that vertices can be distinct even if they are geometrically embedded at the same point.

The *degree* of a vertex is the number of halfedges around the vertex incident upon (pointing to) the vertex. As with any halfedge data structure, there is one outgoing halfedge for each incoming (incident) halfedge around a vertex. The degree of the vertex counts only incoming (incident) halfedges.

In a straight skeleton, the degree of a vertex is not only the number of incident halfedges around the vertex but also the number of defining contour halfedges. The vertex itself is the point where all the defining contour edges simultaneously collide.

Contour vertices have exactly two defining contour halfedges, which are the contour edges incident upon the vertex; and 3 incident halfedges. One and only one of the incident halfedges is a skeleton halfedge. The degree of a contour vertex is exactly 3.

Skeleton vertices have at least 3 defining contour halfedges and 3 incident skeleton halfedges. If more than 3 edges collide simultaneously at the same point and time (like in any regular polygon with more than 3 sides), the corresponding skeleton vertex will have more than 3 defining contour halfedges and incident skeleton halfedges. That is, the degree of a skeleton vertex is  $\geq 3$  (the algorithm initially produces nodes of degree 3 but in the end all coincident nodes are merged to form higher degree nodes). All halfedges incident upon a skeleton vertex are skeleton halfedges.

The defining contour halfedges and incident halfedges around a vertex can be traced using the circulators provided by the vertex class. The degree of a vertex is not cached and cannot be directly obtained from the vertex, but you can calculate this number by manually counting the number of incident halfedges around the vertex.

Each vertex stores a 2D point and a *time*, which is the euclidean distance from the vertex's point to the *lines* supporting each of the defining contour edges of the vertex (the distance is the same to each line). Unless the polygon is convex, this distance is not equidistant to the edges, as in the case of a Medial Axis, therefore, the time of a skeleton vertex does not correspond to the distance from the polygon to the vertex (so it cannot be

used to obtain the deep of a region in a shape, for instance).

If the polygon *is* convex, the straight skeleton is exactly equivalent to the polygon's Voronoi diagram and each vertex time is the equidistance to the defining edges.

Contour vertices have time zero.

## 19.3 API

The straight skeleton data structure is defined by the *StraightSkeleton\_2* concept and modeled in the *Straight\_skeleton\_2*<*Traits,Items,Alloc*> class.

The simplest way to construct a straight skeleton is via the free functions *create\_interior\_straight\_skeleton\_2* and *create\_exterior\_straight\_skeleton\_2*, as shown in the following example:

```
#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_2.h>
#include<CGAL/create_straight_skeleton_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2          Point ;
typedef CGAL::Polygon_2<K>  Polygon ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Ss> SsPtr ;

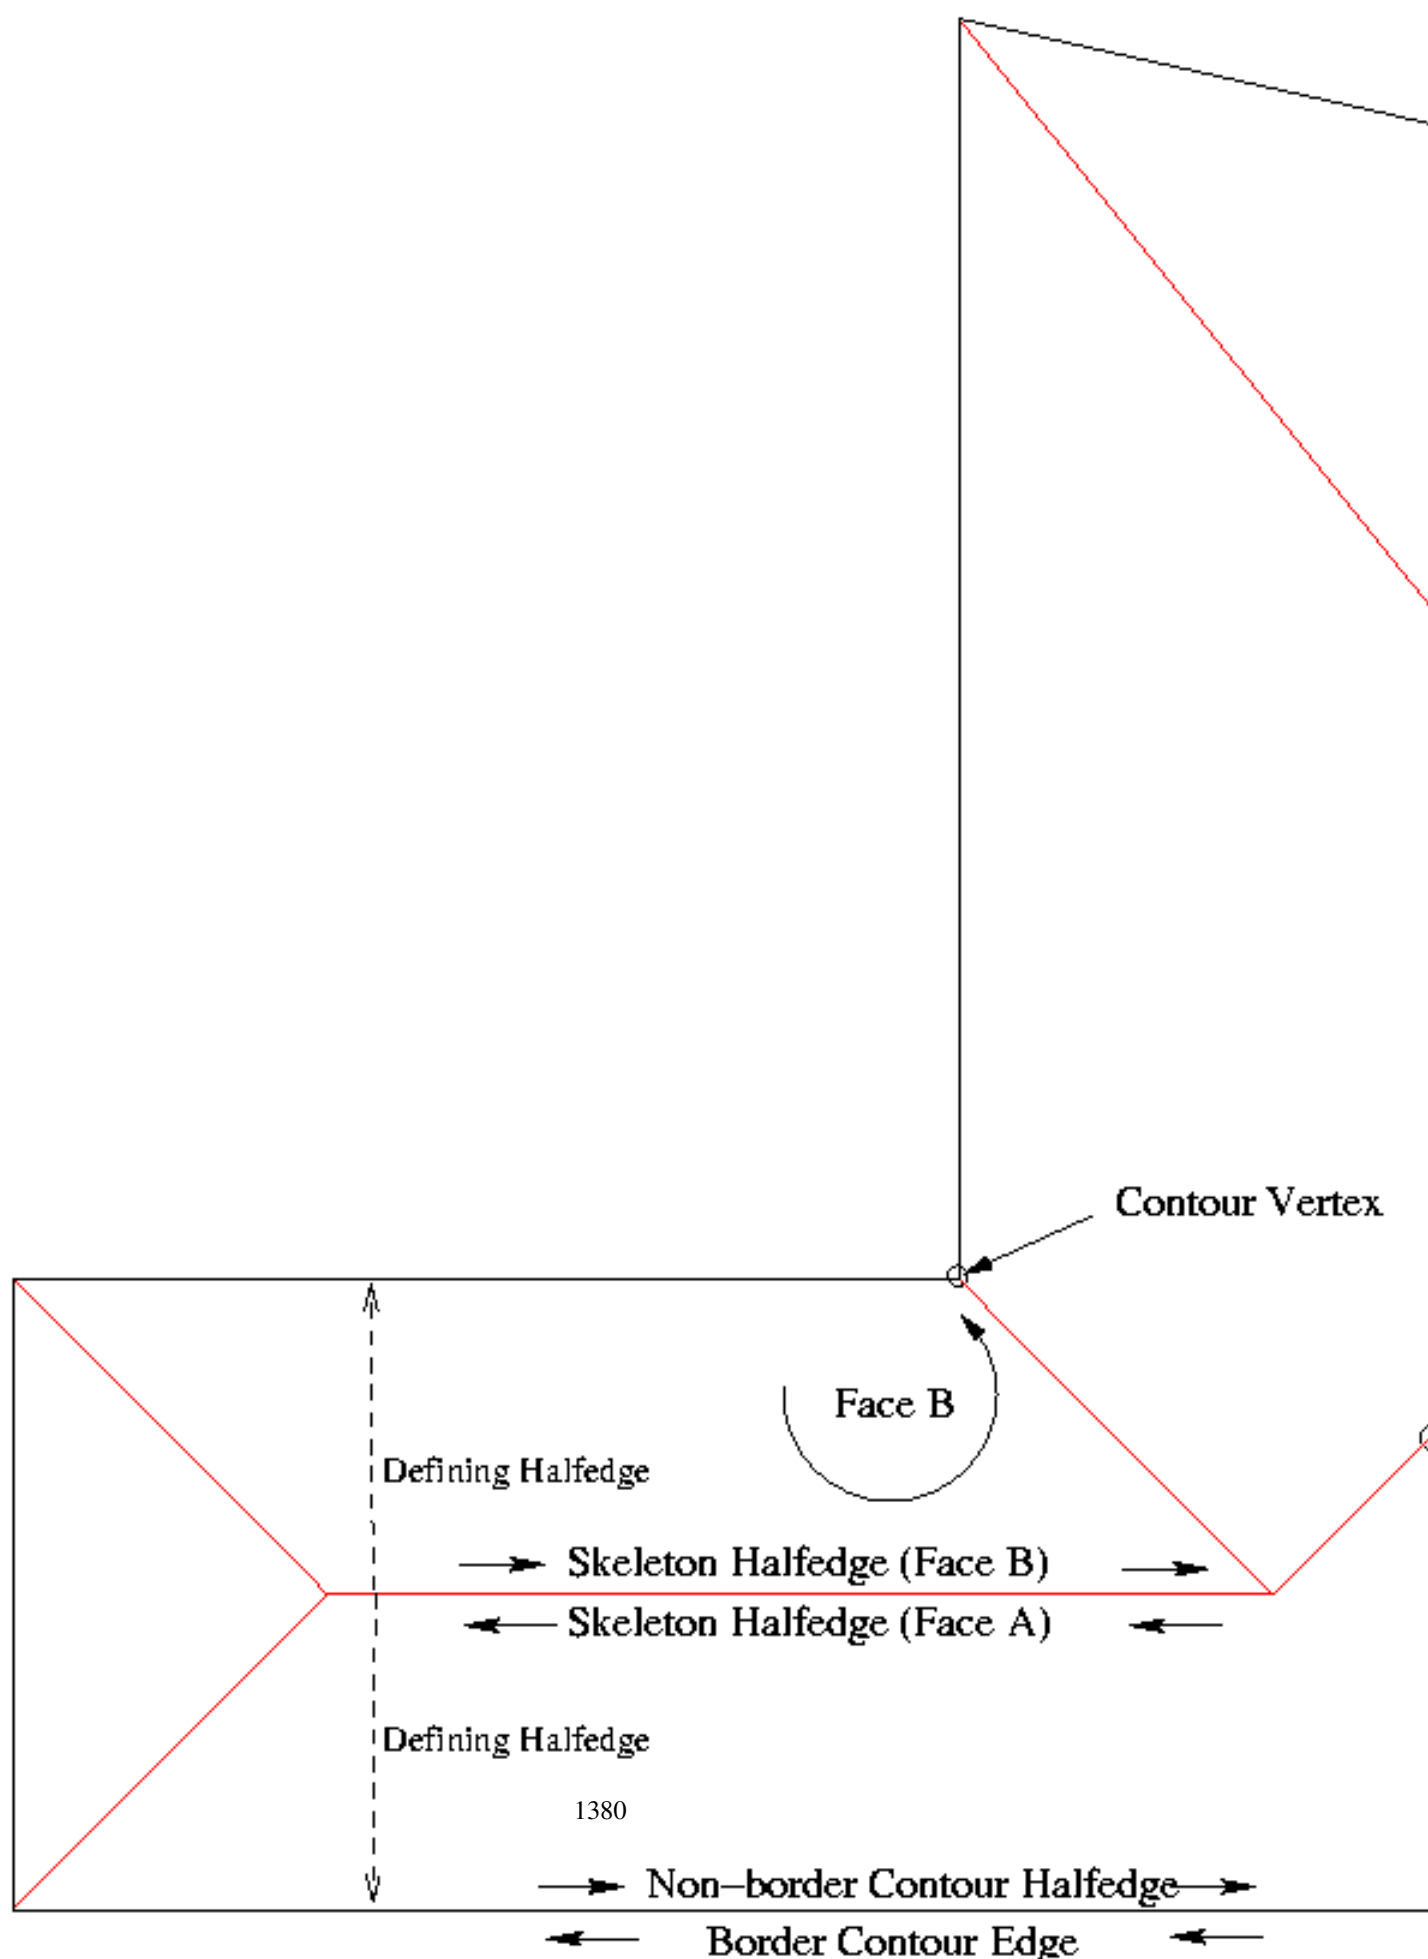

int main()
{
    Polygon poly ;

    poly.push_back( Point(-1,-1) ) ;
    poly.push_back( Point(0,-12) ) ;
    poly.push_back( Point(1,-1) ) ;
    poly.push_back( Point(12,0) ) ;
    poly.push_back( Point(1,1) ) ;
    poly.push_back( Point(0,12) ) ;
    poly.push_back( Point(-1,1) ) ;
    poly.push_back( Point(-12,0) ) ;

    // You can pass the polygon via an iterator pair
    SsPtr iss = CGAL::create_interior_straight_skeleton_2(poly.vertices_begin(), poly.vertices_end());

    // Or you can pass the polygon directly, as below.

    // To create an exterior straight skeleton you need to specify a maximum offset.
    double lMaxOffset = 5 ;
    SsPtr oss = CGAL::create_exterior_straight_skeleton_2(lMaxOffset, poly);
```

```

    print_straight_skeleton(*iss);
    print_straight_skeleton(*oss);

    return 0;
}

```

**File:** examples/Straight\_skeleton\_2/Create\_straight\_skeleton\_2.cpp

The input to these functions is the polygon, which can be given as an iterator pair or directly as a *Polygon\_2* object. In the case of the exterior skeleton, a maximum offset must be specified as well (see the ref manual for details on this max offset parameter).

If *Polygon\_with\_holes\_2* is used, you can pass an instance of it directly to the function creating the interior skeleton, as shown below. Notice that a different header must be included in this case.

```

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_with_holes_2.h>
#include<CGAL/create_straight_skeleton_from_polygon_with_holes_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2          Point ;
typedef CGAL::Polygon_2<K>   Polygon ;
typedef CGAL::Polygon_with_holes_2<K> Polygon_with_holes ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Ss> SsPtr ;

int main()
{
    Polygon outer ;

    outer.push_back( Point(-1,-1) ) ;
    outer.push_back( Point(0,-12) ) ;
    outer.push_back( Point(1,-1) ) ;
    outer.push_back( Point(12,0) ) ;
    outer.push_back( Point(1,1) ) ;
    outer.push_back( Point(0,12) ) ;
    outer.push_back( Point(-1,1) ) ;
    outer.push_back( Point(-12,0) ) ;

    Polygon hole ;

    hole.push_back( Point(-1,0) ) ;
    hole.push_back( Point(0,1) ) ;
    hole.push_back( Point(1,0) ) ;
    hole.push_back( Point(0,-1) ) ;
}

```

```

Polygon_with_holes poly( outer ) ;

poly.add_hole( hole ) ;

SsPtr iss = CGAL::create_interior_straight_skeleton_2(poly);

print_straight_skeleton(*iss);

return 0;
}

```

**File:** examples/Straight\_skeleton\_2/Create\_straight\_skeleton\_from\_polygon\_with\_holes\_2.cpp

If you already have a straight skeleton instance, the simpler way to generate offset polygons is to call *create\_offset\_polygons\_2* as shown in the next example, passing the desired offset and the straight skeleton. You can reuse the same skeleton to generate offsets at a different distance, which is recommended because producing the straight skeleton is much slower then generating offset polygons.

```

#include<vector>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_2.h>
#include<CGAL/create_offset_polygons_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2 Point ;
typedef CGAL::Polygon_2<K> Polygon ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Polygon> PolygonPtr ;
typedef boost::shared_ptr<Ss> SsPtr ;

typedef std::vector<PolygonPtr> PolygonPtrVector ;

int main()
{
    Polygon poly ;

    poly.push_back( Point(-1,-1) ) ;
    poly.push_back( Point(0,-12) ) ;
    poly.push_back( Point(1,-1) ) ;
    poly.push_back( Point(12,0) ) ;
    poly.push_back( Point(1,1) ) ;
    poly.push_back( Point(0,12) ) ;
    poly.push_back( Point(-1,1) ) ;
    poly.push_back( Point(-12,0) ) ;

    SsPtr ss = CGAL::create_interior_straight_skeleton_2(poly);

```

```

double lOffset = 1 ;

PolygonPtrVector offset_polygons = CGAL::create_offset_polygons_2<Polygon>(lOffset,*ss);

print_polygons(offset_polygons);

return 0;
}

```

**File:** examples/Straight\_skeleton\_2/Create\_offset\_polygons\_2.cpp

If you need offset polygons at just one single distance, you can hide away the construction of the straight skeleton by calling directly the functions *create\_interior\_skeleton\_and\_offset\_polygons\_2* and *create\_exterior\_skeleton\_and\_offset\_polygons\_2* as shown in the following examples:

```

#include<vector>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_2.h>
#include<CGAL/create_offset_polygons_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::FT FT ;
typedef K::Point_2 Point ;
typedef CGAL::Polygon_2<K> Polygon ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Polygon> PolygonPtr ;
typedef boost::shared_ptr<Ss> SsPtr ;

typedef std::vector<PolygonPtr> PolygonPtrVector ;

int main()
{
    Polygon poly ;

    poly.push_back( Point(-1,-1) ) ;
    poly.push_back( Point(0,-12) ) ;
    poly.push_back( Point(1,-1) ) ;
    poly.push_back( Point(12,0) ) ;
    poly.push_back( Point(1,1) ) ;
    poly.push_back( Point(0,12) ) ;
    poly.push_back( Point(-1,1) ) ;
    poly.push_back( Point(-12,0) ) ;

    FT lOffset = 1 ;

```

```

PolygonPtrVector inner_offset_polygons = CGAL::create_interior_skeleton_and_offset_polygons_2(10offset,p
PolygonPtrVector outer_offset_polygons = CGAL::create_exterior_skeleton_and_offset_polygons_2(10offset,p

print_polygons(inner_offset_polygons);
print_polygons(outer_offset_polygons);

return 0;
}

```

**File:** examples/Straight\_skeleton\_2/Create\_skeleton\_and\_offset\_polygons\_2.cpp

... and using a *Polygon\_with\_holes\_2* directly when available:

```

#include<vector>
#include<iterator>
#include<iostream>
#include<iomanip>
#include<string>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_with_holes_2.h>
#include<CGAL/create_offset_polygons_from_polygon_with_holes_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2          Point ;
typedef CGAL::Polygon_2<K>   Polygon ;
typedef CGAL::Polygon_with_holes_2<K> Polygon_with_holes ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<Polygon> PolygonPtr ;
typedef boost::shared_ptr<Ss> SsPtr ;

typedef std::vector<PolygonPtr> PolygonPtrVector ;

int main()
{
    Polygon outer ;

    outer.push_back( Point(-1,-1) ) ;
    outer.push_back( Point(0,-12) ) ;
    outer.push_back( Point(1,-1) ) ;
    outer.push_back( Point(12,0) ) ;
    outer.push_back( Point(1,1) ) ;
    outer.push_back( Point(0,12) ) ;
    outer.push_back( Point(-1,1) ) ;
    outer.push_back( Point(-12,0) ) ;

```

```

Polygon hole ;

hole.push_back( Point(-1,0) ) ;
hole.push_back( Point(0,1) ) ;
hole.push_back( Point(1,0) ) ;
hole.push_back( Point(0,-1) ) ;

Polygon_with_holes poly( outer ) ;

poly.add_hole( hole ) ;

double lOffset = 0.2 ;

PolygonPtrVector offset_polygons = CGAL::create_interior_skeleton_and_offset_polygons_2(lOffset,poly);

print_polygons(offset_polygons);

return 0;
}

```

**File:** examples/Straight\_skeleton\_2/Create\_skeleton\_and\_offset\_polygons\_from\_polygon\_with\_holes\_2.cpp

If the input polygon has holes, there can be holes in the offset polygons. However, the polygons generated by all the offsetting functions shown before do not have any parent-hole relationship computed; that is, they just instances of *Polygon\_2* instead of *Polygon\_with\_holes\_2*. If *Polygon\_with\_holes\_2* are available and you need the offsetting to produce them, you can call the function *arrange\_offset\_polygons\_2* passing the result of any of the offsetting functions described so far. That function arranges the offset polygons detecting and distributing holes within parents. As a shortcut, you can use the function *create\_interior\_skeleton\_and\_offset\_polygon\_with\_holes\_2* as shown below:

```

#include<vector>

#include<boost/shared_ptr.hpp>

#include<CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include<CGAL/Polygon_with_holes_2.h>
#include<CGAL/create_offset_polygons_from_polygon_with_holes_2.h>

#include "print.h"

typedef CGAL::Exact_predicates_inexact_constructions_kernel K ;

typedef K::Point_2 Point ;
typedef CGAL::Polygon_2<K> Polygon ;
typedef CGAL::Polygon_with_holes_2<K> PolygonWithHoles ;
typedef CGAL::Straight_skeleton_2<K> Ss ;

typedef boost::shared_ptr<PolygonWithHoles> PolygonWithHolesPtr ;

typedef std::vector<PolygonWithHolesPtr> PolygonWithHolesPtrVector;

```

```

int main()
{
    Polygon outer ;

    outer.push_back( Point( 0.0, 0.0) ) ;
    outer.push_back( Point(10.0, 0.0) ) ;
    outer.push_back( Point(10.0, 4.5) ) ;
    outer.push_back( Point(12.0, 4.5) ) ;
    outer.push_back( Point(12.0, 2.0) ) ;
    outer.push_back( Point(16.0, 2.0) ) ;
    outer.push_back( Point(16.0, 8.0) ) ;
    outer.push_back( Point(12.0, 8.0) ) ;
    outer.push_back( Point(12.0, 5.5) ) ;
    outer.push_back( Point(10.0, 5.5) ) ;
    outer.push_back( Point(10.0,10.0) ) ;
    outer.push_back( Point( 0.0,10.0) ) ;

    Polygon hole ;

    hole.push_back( Point(3.0,3.0) ) ;
    hole.push_back( Point(3.0,7.0) ) ;
    hole.push_back( Point(7.0,7.0) ) ;
    hole.push_back( Point(7.0,3.0) ) ;

    PolygonWithHoles poly( outer ) ;

    poly.add_hole( hole ) ;

    double lOffset = 1 ;

    PolygonWithHolesPtrVector offset_poly_with_holes = CGAL::create_interior_skeleton_and_offset_polygons_w

    print_polygons_with_holes(offset_poly_with_holes);

    return 0;
}

```

**File:** examples/Straight\_skeleton\_2/Create\_skeleton\_and\_offset\_polygons\_with\_holes\_2.cpp

---

*advanced*

Consider an input polygon with parallel edges separated a distance  $2 * t$ . If you produce an offset polygon at distance  $t$ , these parallel edges will just collapse each other and vanish from the result, keeping the output as a *simple polygon*, just like the input. However, if you request an offset polygon at a distance  $t - \epsilon$ , the result will still be a simple polygon but with edges that are so close to each other that will almost intersect. If a kernel with exact constructions is used, the offsetting algorithm can guarantee that the output contains only simple polygons. However, if inexact constructions are used the roundoff in the coordinates of the output points will cause parallel edges that *almost* collapse-but not so-to become really collinear or even cross each other.

Thus, it is necessary to use a kernel with exact constructions if offset polygons must be simple, yet computing a straight skeleton using that kernel is very slow, much more than computing the offset polygons. To help with this, it is possible to construct the straight skeleton using the recommended kernel *Exact\_predicates\_inexact\_constructions\_kernel*, then convert the skeleton to a different kernel via the function *convert\_straight\_skeleton\_2* and input the converted skeleton to the offsetting functions.

All the offsetting functions that take polygons as input (and create the straight skeleton under the hood) apply that optimization automatically: that is, the output polygons are defined over the same kernel of the input polygons, whatever that is, yet the straight skeleton is constructed with the faster recommended kernel and converted if necessary.

Notice how some of the examples above use *Exact\_predicates\_exact\_constructions\_kernel*. In all cases, the straight skeleton is constructed using *Exact\_predicates\_inexact\_constructions\_kernel*.

---

advanced

### 19.3.1 Low level API

All the high level functions described above are just wrappers around the low level API described here. This low level API is richer and provides options and configurations not covered by any of those functions.

The straight skeleton construction algorithm is encapsulated in the class *Straight\_skeleton\_builder\_2<Gt,Ss,Visitor>* which is parameterized on a geometric traits (class *Straight\_skeleton\_builder\_traits<Kernel>*) and the Straight Skeleton class (Ss).

The offset contours construction algorithm is encapsulated in the class *Polygon\_offset\_builder\_2<Ss,Gt,Container>* which is parameterized on the Straight Skeleton class (Ss), a geometric traits (class *Polygon\_offset\_builder\_traits<Kernel>*) and a container type where the resulting offset polygons are generated.

To construct the straight skeleton of a polygon with holes the user must:

- (1) Instantiate the straight skeleton builder.
- (2) Enter one contour at a time, starting from the outer contour, via the method *enter\_contour*. The input polygon with holes must be non-degenerate, strictly-simple and counter-clockwise oriented (see the definitions at the beginning of this chapter). Collinear edges are allowed. The insertion order of each hole is unimportant but the outer contour must be entered first.
- (3) Call *construct\_skeleton* once *all* the contours have been entered. You cannot enter another contour once the skeleton has been constructed.

To construct a set of inward offset contours the user must:

- (1) Construct the straight skeleton of the source polygon with holes.
- (2) Instantiate the polygon offset builder passing in the straight skeleton as a parameter.
- (3) Call *construct\_offset\_contours* passing the desired offset distance and an output iterator that can store a *boost::shared\_ptr* of *Container* instances into a resulting sequence (typically, a back insertion iterator)

Each element in the resulting sequence is an *offset contour*, given by a *boost::shared\_ptr* holding a dynamically allocated instance of the *Container* type. Such a container can be any model of the *VertexContainer\_2* concept, for example, a *CGAL::Polygon\_2*, or just a *std::vector* of 2D points.

The resulting sequence of offset contours can contain both outer and inner contours. Each offset hole (inner offset contour) would logically belong in the interior of some of the outer offset contours. However, this algorithm returns a sequence of contours in arbitrary order and there is no indication whatsoever of the parental relationship between inner and outer contours.

On the other hand, each outer contour is counter-clockwise oriented while each hole is clockwise-oriented. And since offset contours do form simple polygons with holes, it is guaranteed that no hole will be inside another hole, no outer contour will be inside any other contour, and each hole will be inside exactly 1 outer contour.

Parental relationships are *not* automatically reconstructed by this algorithm because this relation is not directly given by the input polygon with holes and must be done as a post processing step. The function *arrange\_offset\_polygons\_2* can be used to do that efficiently.

A user can reconstruct the parental relationships as a post processing operation by testing each inner contour (which is identified by being clockwise) against each outer contour (identified as being counter-clockwise) for insideness.

This algorithm requires exact predicates but not exact constructions Therefore, the *Exact\_predicates\_inexact\_constructions\_kernel* should be used.

```
#include<vector>

### 19.3.2 Exterior Skeletons and Exterior Offset contours

This CGAL package can only construct the straight skeleton and offset contours in the *interior* of a polygon with holes. However, constructing exterior skeletons and exterior offsets is possible:

Say you have some polygon made of 1 outer contour C0 and 1 hole C1, and you need to obtain some exterior offset contours.

The interior region of a polygon with holes is connected while the exterior region is not: there is an unbounded region outside the outer contour, and one bounded region inside each hole. To construct an offset contour you need to construct a straight skeleton. Thus, to construct exterior offset contours for a polygon with holes, you need to construct, *separately*, the exterior skeleton of the outer contour and the interior skeleton of each hole.

Constructing the interior skeleton of a hole is directly supported by this CGAL package; you just need to input the hole's vertices in reversed order as if it were an outer contour.

Constructing the exterior skeleton of the outer contour is possible by means of the following trick: place the contour as a hole of a big rectangle (call it *frame*). If the frame is sufficiently separated from the contour, the resulting skeleton will be practically equivalent to a *real* exterior skeleton.

To construct exterior offset contours in the inside of each hole you just use the skeleton constructed in the interior, and, if required, revert the orientation of each resulting offset contour.

Constructing exterior offset contours in the outside of the outer contour is just a little bit more involved: Since the contour is placed as a hole of a frame, you will always obtain 2 offset contours for any given distance; one is the offsetted frame and the other is the offsetted contour. Thus, from the resulting offset contour sequence, you always need to discard the offsetted frame, easily identified as the offset contour with the largest area.

It is necessary to place the frame sufficiently away from the contour. If it is not, it could occur that the outward offset contour collides and merges with the inward offset frame, resulting in 1 instead of 2 offset contours.

However, the proper separation between the contour and the frame is not directly given by the offset distance at which you want the offset contour. That distance must be at least the desired offset plus the largest euclidean distance between an offset vertex and its original.

This CGAL packages provides a helper function to compute the required separation: `compute_outer_frame_margin`

If you use this function to place the outer frame you are guaranteed to obtain an offset contour corresponding exclusively to the frame, which you can always identify as the one with the largest area and which you can simple remove from the result (to keep just the relevant outer contours).

## 19.4 Straight Skeletons, Medial Axis and Voronoi Diagrams

The straight skeleton of a polygon is similar to the medial axis and the Voronoi diagram of a polygon in the way it partitions it; however, unlike the medial axis and Voronoi diagram, the bisectors are not equidistant to its defining edges but to the supporting lines of such edges. As a result, Straight Skeleton bisectors might not be located in the center of the polygon and so cannot be regarded as a proper Medial Axis in its geometrical meaning.

On the other hand, only reflex vertices (whose internal angle  $> \pi$ ) are the source of deviations of the bisectors from its center location. Therefore, for convex polygons, the straight skeleton, the medial axis and the Voronoi diagram are exactly equivalent, and, if a non-convex polygon contains only vertices of low reflexivity, the straight skeleton bisectors will be placed nearly equidistant to their defining edges, producing a straight skeleton pretty much alike a proper medial axis.

## 19.5 Usages of the Straight Skeletons

The most natural usage of straight skeletons is offsetting: growing and shrinking polygons (provided by this CGAL package).

Another usage, perhaps its very first, is roof design: The straight skeleton of a polygonal roof directly gives the layout of each tent. If each skeleton edge is lifted from the plane a height equal to its offset distance, the

resulting roof is "correct" in that water will always fall down to the contour edges (roof border) regardless of where in the roof it falls. [LD03] gives an algorithm for roof design based on the straight skeleton.

Just like medial axes, 2D straight skeletons can also be used for 2D shape description and matching. Essentially, all the applications of image-based skeletonization (for which there is a vast literature) are also direct applications of the straight skeleton, specially since skeleton edges are simply straight line segments.

Consider the subgraph formed only by *inner bisectors* (that is, only the skeleton halfedges which are not incident upon a contour vertex). Call this subgraph a *skeleton axis*. Each node in the skeleton axis whose degree is  $\geq 3$  roots more than one skeleton tree. Each skeleton tree roughly corresponds to a region in the input topologically equivalent to a rectangle; that is, without branches. For example, a simple letter "H" would contain 2 higher degree nodes separating the skeleton axis in 5 trees; while the letter "@" would contain just 1 higher degree node separating the skeleton axis in 2 curly trees.

Since a skeleton edge is a 2D straight line, each branch in a skeleton tree is a polyline. Thus, the path-length of the tree can be directly computed. Furthermore, the polyline for a particular tree can be interpolated to obtain curve-related information.

Pruning each skeleton tree cutting off branches whose length is below some threshold; or smoothing a given branch, can be used to reconstruct the polygon without undesired details, or fit into a particular canonical shape.

Each skeleton edge in a skeleton branch is associated with 2 contour edges which are facing each other. If the polygon has a bottleneck (it almost touches itself), a search in the skeleton graph measuring the distance between each pair of contour edges will reveal the location of the bottleneck, allowing you to cut the shape in two. Likewise, if two shapes are too close to each other along some part of their boundaries (a near contact zone), a similar search in an exterior skeleton of the two shapes at once would reveal the parts of near contact, allowing you to stitch the shapes. These *cut and stitch* operations can be directly executed in the straight skeleton itself instead of the input polygon (because the straight skeleton contains a graph of the connected contour edges).

## 19.6 Straight Skeleton of a General Figure in the Plane

A straight skeleton can also be defined for a general multiply-connected planar directed straight-line graph [AA95] by considering all the edges as embedded in an unbounded region. The only difference is that in this case some faces will be only partially bounded.

The current version of this CGAL package can only construct the straight skeleton in the interior of a simple polygon with holes, that is it doesn't handle general polygonal figures in the plane.

# 2D Straight Skeleton and Polygon Offsetting

## Reference Manual

This chapter introduces the concepts and classes that correspond to the CGAL *2D Straight Skeleton* package. The packages provides an algorithm for the construction of the straight skeleton in the interior of a simple polygon with holes and an algorithm for the construction of inward offset contours based on the straight skeleton.

## StraightSkeleton\_2

### Definition

The concept `StraightSkeleton_2` describes the requirements for the data structure used to represent a straight skeleton.

### Refines

*HalfedgeDS*

### Types

*StraightSkeleton\_2:: Vertex*

A model of the *StraightSkeletonVertex\_2* concept used to represent the vertices of the straight skeleton

*StraightSkeleton\_2:: Halfedge*

A model of the *StraightSkeletonHalfedge\_2* concept used to represent the halfedges of the straight skeleton

*StraightSkeleton\_2:: Face*

Any model of the *StraightSkeletonFace\_2* concept used to represent the faces of the straight skeleton

### Has Models

*CGAL::Straight\_skeleton\_2<Traits,Items,Alloc>.*

This concept explicitly protects all the modifying operations of the base *HalfedgeDS* concept. Only the algorithm classes, or clients explicitly bypassing the protection mechanism, can modify a straight skeleton.

## StraightSkeletonVertex\_2

### Definition

The concept `StraightSkeletonVertex_2` describes the requirements for the vertex type of the *StraightSkeleton\_2* concept. It is a refinement of the *HalfedgeDSVertex* concept with support for storage of the incident halfedge. The `StraightSkeletonVertex_2` concept requires the geometric embedding to be a 2D point.

### Refines

*HalfedgeDSVertex*

### Types

<i>StraightSkeletonVertex_2:: Point_2</i>	The type of the 2D point being the geometric embedding of the vertex
<i>StraightSkeletonVertex_2:: FT</i>	A model of the <i>SqrtFieldNumberType</i> concept representing the time of a vertex (an Euclidean distance)
<i>StraightSkeletonVertex_2:: Halfedge_around_vertex_const_circulator</i>	
<i>StraightSkeletonVertex_2:: Halfedge_around_vertex_circulator</i>	The circulator type used to visit all the incident halfedges around a vertex
<i>StraightSkeletonVertex_2:: Defining_contour_halfedge_const_circulator</i>	
<i>StraightSkeletonVertex_2:: Defining_contour_halfedge_circulator</i>	The circulator type used to visit all the defining contour halfedges of a vertex

### Creation

<i>StraightSkeletonVertex_2</i> <i>v</i> ;	Default constructor
<i>StraightSkeletonVertex_2</i> <i>v</i> ( <i>int id</i> , <i>Point_2 p</i> );	Constructs a contour vertex with ID number <i>id</i> , at the point <i>p</i>
<i>StraightSkeletonVertex_2</i> <i>v</i> ( <i>int id</i> , <i>Point_2 p</i> , <i>FT time</i> );	Constructs a skeleton vertex with ID number <i>id</i> , at point <i>p</i> and time <i>time</i> .

### Access Functions

<i>int</i>	<i>v.id()</i>	The ID of the vertex.
<i>Point_2</i>	<i>v.point()</i>	The vertex point.
<i>FT</i>	<i>v.time()</i>	The time of the vertex: the distance from the vertex point to the lines supporting the defining contour edges
<i>Halfedge_handle</i>	<i>v.primary_bisector()</i>	

*Halfedge\_const\_handle*

*v.primary\_bisector()* Returns the skeleton halfedge incident upon the vertex (called the *primary* bisector).

*Halfedge\_around\_vertex\_circulator*

*v.halfedge\_around\_vertex\_begin()*

*Halfedge\_around\_vertex\_const\_circulator*

*v.halfedge\_around\_vertex\_begin()*

Returns a bi-directional circulator pointing to one of the incident halfedges (which one is unspecified).

There will always be as many incident halfedges as the degree of the vertex.

If this is a *contour* vertex, its degree is exactly 3, and from the halfedges pointed to by the circulator, 2 are contour and 1 is a bisector.

If this is an *skeleton* vertex, its degree is at least 3 and all of the halfedges pointed to by the circulator are bisectors.

Each halfedge pointed to by this circulator is the one which is oriented towards the vertex (according to the geometric embedding).

*Defining\_contour\_halfedge\_circulator*

*v.defining\_contour\_halfedges\_begin()*

*Defining\_contour\_halfedge\_const\_circulator*

*v.defining\_contour\_halfedges\_begin()*

Returns a bi-directional circulator pointing to one of the defining contour halfedges of the vertex (which one is unspecified).

There will always be as many incident defining contour halfedges as the degree of the vertex.

Each halfedge pointed to by this circulator is the one having its left side facing inwards (which happens to be the contour halfedge for which *is\_border()* is *false*).

## Queries

<i>bool</i>	<i>v.is_contour()</i>	Returns <i>true</i> iff this is a contour vertex.
<i>bool</i>	<i>v.is_skeleton()</i>	Returns <i>true</i> iff this is a skeleton vertex.

## Has Models

*CGAL::Straight\_skeleton\_vertex\_base\_2<Refs,Point,FT>*.

## See Also

## StraightSkeletonHalfedge\_2

### Definition

The concept `StraightSkeletonHalfedge_2` describes the requirements for the halfedge type of the `StraightSkeleton_2` concept. It is a refinement of the `HalfedgeDSHalfedge` concept. The `StraightSkeletonHalfedge_2` concept requires no geometric embedding at all. The only geometric embedding used by the Straight Skeleton Data Structure are the 2D points in the contour and skeleton vertices. However, for any halfedge, there is a 2D segment implicitly given by its *source* and *target* vertices.

### Refines

`HalfedgeDSHalfedge`

### Creation

<code>StraightSkeletonHalfedge_2 h;</code>	Default Constructor.
<code>StraightSkeletonHalfedge_2 h( int id);</code>	Constructs a halfedge with ID <i>id</i> . It is the links to other halfedges what determines if this is a contour edge, a contour-skeleton edge or an inner-skeleton edge.

### Access Functions

<code>Halfedge_handle</code>	<code>h.defining_contour_edge()</code>	
<code>Halfedge_const_handle</code>	<code>h.defining_contour_edge()</code>	If this is a bisector halfedge, returns a handle to the inward-facing (non-border) contour halfedge corresponding to the defining contour edge which is to its left; if this is a contour halfedge, returns a handle to itself if <code>is_border()</code> is <i>false</i> , or to its opposite if it is <i>true</i> .

### Queries

<code>bool</code>	<code>h.is_bisector()</code>	Returns <i>true</i> iff this is a bisector (or skeleton) halfedge (i.e. is not a contour halfedge).
<code>bool</code>	<code>h.is_inner_bisector()</code>	Returns <i>true</i> iff this is a bisector and is inner (i.e. is not incident upon a contour vertex).

### Has Models

`CGAL::Straight_skeleton_halfedge_2<Refs>`.

## StraightSkeletonFace\_2

### Definition

The concept `StraightSkeletonFace_2` describes the requirements for the face type of the *StraightSkeleton\_2* concept. It is a refinement of the *HalfedgeDSFace* concept with support for storage of the incident halfedge.

### Refines

*HalfedgeDSFace*

### Creation

<code>StraightSkeletonFace_2 f;</code>	Default constructor
<code>StraightSkeletonFace_2 f( int id);</code>	Constructs a face with ID number <i>id</i>

### Access Functions

<code>int</code>	<code>f.id()</code>	The ID of the face.
------------------	---------------------	---------------------

### Has Models

`CGAL::Straight_skeleton_face_base_2<Refs>.`

## StraightSkeletonItemsConverter\_2

### Definition

The concept `StraightSkeletonItemsConverter_2` describes the requirements for items converter passed as the third template argument to the class `Straight_skeleton_converter_2<SrcSs,TgtSs,ItemsConverter>`. It converts the *HDS* items from one type of straight skeleton to another

### Types

*StraightSkeletonItemsConverter\_2:: Source\_vertex\_const\_handle*

A constant handle to a model of the *StraightSkeletonVertex\_2* concept used to represent the vertices of the straight skeleton of the source type.

*StraightSkeletonItemsConverter\_2:: Source\_halfedge\_const\_handle*

A constant handle to model of the *StraightSkeletonHalfedge\_2* concept used to represent the halfedges of the straight skeleton of the source type.

*StraightSkeletonItemsConverter\_2:: Source\_face\_const\_handle*

A constant handle to model of the *StraightSkeletonFace\_2* concept used to represent the faces of the straight skeleton of the source type.

*StraightSkeletonItemsConverter\_2:: Target\_vertex*

A model of the *StraightSkeletonVertex\_2* concept used to represent the vertices of the straight skeleton of the target type.

*StraightSkeletonItemsConverter\_2:: Target\_halfedge*

A model of the *StraightSkeletonHalfedge\_2* concept used to represent the halfedges of the straight skeleton of the target type.

*StraightSkeletonItemsConverter\_2:: Target\_face*

Any model of the *StraightSkeletonFace\_2* concept used to represent the faces of the straight skeleton of the target type.

### Operations

*Target\_vertex*      *conv.operator()( Source\_vertex\_const\_handle v) const*

returns a new vertex with the same data as *v* converted to the corresponding target types.

*Target\_halfedge*                    *conv.operator()( Source\_halfedge\_const\_handle h) const*

returns a new halfedge with the same data as *h* converted to the corresponding target types.

*Target\_face*                    *conv.operator()( Source\_face\_const\_handle f) const*

returns a new face with the same data as *f* converted to the corresponding target types.

## StraightSkeletonBuilder\_2\_Visitor

### Definition

The concept `StraightSkeletonBuilder_2_Visitor` describes the requirements of the visitor class required by the algorithm class `Straight_skeleton_builder_2<Gt,Ss,Visitor>` in its third template parameter.

### Types

`StraightSkeletonBuilder_2_Visitor:: Halfedge_const_handle`

A constant handle to a straight skeleton halfedge.

`StraightSkeletonBuilder_2_Visitor:: Vertex_const_handle`

A constant handle to a straight skeleton vertex.

### Creation

### Operations

`void v.on_contour_edge_entered( Halfedge_const_handle const&)`

Called for each contour halfedge added to the skeleton).

`void v.on_initialization_started( std::size_t number_of_vertices)`

Called before the initialization stage (when initial events are discovered) is started.

`void v.on_contour_vertex_processed( Vertex_const_handle const& v,  
bool is_reflex,  
bool is_degenerate)`

Called after the events for contour vertex  $v$  have been discovered.  $is\_reflex$  is true if this vertex has an internal angle  $> PI$ , or  $is\_degenerate$  is true if the internal angle is  $= PI$ .

`void v.on_edge_event_created( Vertex_const_handle const& node0,  
Vertex_const_handle const& node1)`

Called after an edge event for nodes  $node0$  and  $node1$  has been discovered and put on the queue for later processing.

`void v.on_split_event_created( Vertex_const_handle const& node)`

Called after a split event for node  $node$  has been discovered and put on the queue for later processing.

`void v.on_pseudo_split_event_created( Vertex_const_handle const& node0,  
Vertex_const_handle const& node1)`

Called after a pseudo split event for nodes  $node0$  and  $node1$  has been discovered and put on the queue for later processing.

<i>void</i>	<i>v.on_initialization_finished()</i>	Called after all initial events have been discovered.
<i>void</i>	<i>v.on_propagation_started()</i>	Called before the propagation stage (when events are popped off the queue and processed) is started.
<i>void</i>	<i>v.on_anihilation_event_processed( Vertex_const_handle const&amp; node0, Vertex_const_handle const&amp; node1)</i>	Called after an anihilation event for nodes <i>node0</i> and <i>node1</i> has been processed. A new skeleton edge between these nodes has been added.
<i>void</i>	<i>v.on_edge_event_processed( Vertex_const_handle const&amp; seed0, Vertex_const_handle const&amp; seed1, Vertex_const_handle const&amp; newnode)</i>	Called after an edge for nodes <i>seed0</i> and <i>seed1</i> has been processed. Skeleton vertex <i>newnode</i> and edges from <i>node0</i> to <i>newnode</i> and <i>node1</i> to <i>newnode</i> has been added.
<i>void</i>	<i>v.on_split_event_processed( Vertex_const_handle const&amp; seed, Vertex_const_handle const&amp; newnode0, Vertex_const_handle const&amp; newnode1)</i>	Called after a split event for node <i>seed</i> has been processed. Skeleton vertices <i>newnode0</i> and <i>newnode1</i> have been added. An skeleton edge from <i>seed</i> to <i>newnode0</i> has been added. In the final skeleton, <i>newnode1</i> is removed and only <i>newnode0</i> remains.
<i>void</i>	<i>v.on_pseudo_split_event_processed( Vertex_const_handle const&amp; seed0, Vertex_const_handle const&amp; seed1, Vertex_const_handle const&amp; newnode0, Vertex_const_handle const&amp; newnode1)</i>	Called after a pseudo split event for nodes <i>seed0</i> and <i>seed1</i> has been processed. Skeleton vertices <i>newnode0</i> and <i>newnode1</i> have been added. Skeleton edges from <i>seed0</i> to <i>newnode0</i> and <i>seed1</i> to <i>newnode1</i> has been added.
<i>void</i>	<i>v.on_vertex_processed( Vertex_const_handle const&amp; v)</i>	Called after vertex <i>v</i> has been marked as already processed.
<i>void</i>	<i>v.on_propagation_finished()</i>	Called after all events have been processed.
<i>void</i>	<i>v.on_cleanup_started()</i>	Called when the skeleton clean up (when multiple nodes are merged) is started.
<i>void</i>	<i>v.on_cleanup_finished()</i>	Called when clean up finished.

*void* *v.on\_algorithm\_finished( bool finished\_ok)*

Called when the algorithm terminated. *finished\_ok* is false if it terminated before completion or the resulting skeleton was found to be invalid.

*void* *v.on\_error( char const\* msg)*

Called whenever an error was detected. *msg* is whatever error message accompanies the error. This pointer can be *null*.

## StraightSkeletonBuilderTraits\_2

### Definition

The concept `StraightSkeletonBuilderTraits_2` describes the requirements for the geometric traits class required by the algorithm class `Straight_skeleton_builder_2<Gt, Ss>`.

### Types

<code>StraightSkeletonBuilderTraits_2:: Kernel</code>	A model of the <i>Kernel</i> concept.
<code>StraightSkeletonBuilderTraits_2:: FT</code>	A <i>SqrtFieldNumberType</i> provided by the kernel. This type is used to represent the coordinates of the input points, of the skeleton nodes and as the event time stored in the skeleton nodes.
<code>boost::tuple&lt;FT, FT&gt; Vertex;</code>	A pair of (x,y) coordinates representing a 2D Cartesian point.
<code>boost::tuple&lt;Vertex, Vertex&gt;</code>	
<code>Edge;</code>	A pair of vertices representing an edge
<code>boost::tuple&lt;Edge, Edge, Edge&gt;</code>	
<code>EdgeTriple;</code>	A triple of edges representing an event
<code>StraightSkeletonBuilderTraits_2:: Equal_2</code>	
	A predicate object type being a model of the <i>Kernel::Equal_2</i> function object concept.
<code>StraightSkeletonBuilderTraits_2:: Left_turn_2</code>	
	A predicate object type being a model of the <i>Kernel::LeftTurn_2</i> function object concept.
<code>StraightSkeletonBuilderTraits_2:: Collinear_2</code>	
	A predicate object type being a model of the <i>Kernel::Collinear_2</i> function object concept.
<code>StraightSkeletonBuilderTraits_2:: Do_ss_event_exist_2</code>	
	A predicate object type. Must provide <i>bool operator()( EdgeTriple const&amp; et) const</i> , which determines if, given the 3 <i>oriented</i> lines defined by the 3 input edges (3 pair of points), there exist an Euclidean distance $t \geq 0$ for which the corresponding 3 <i>offset lines at t</i> (parallel lines at an Euclidean distance of $t$ ) intersect in a single point.  <i>Precondition:</i> each edge in the triple must properly define an oriented line, that is, such points cannot be coincident.

#### *StraightSkeletonBuilderTraits\_2:: Compare\_ss\_event\_times\_2*

A predicate object type.

Must provide *Comparison\_result operator()( EdgeTriple const& x, EdgeTriple const& y) const*, which compares the *times* for the events determined by the edge-triples *x* and *y*.

The time of an event given by an edge triple (which defines 3 oriented lines) is the Euclidean distance *t* at which the corresponding offset lines at *t* intersect in a single point.

*Precondition:* *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist\_sls\_event\_2*).

#### *StraightSkeletonBuilderTraits\_2:: Compare\_ss\_event\_distance\_to\_seed\_2*

A predicate object type.

Must provide *Comparison\_result operator()( Point\_2 const& p, EdgeTriple const& x, EdgeTriple const& y)*, which compares the Euclidean distance of the points of event for *x* and *y* to the point *p*.

The point of an event given by an edge triple (which defines 3 oriented lines) is the intersection point of the 3 corresponding offset lines at the time *t* of the event.

It must also provide *Comparison\_result operator( EdgeTriple const& seed, EdgeTriple const& x, EdgeTriple const& y)()* which makes the same comparison as the first overload but where the seed point is given implicitly as the point of event for *seed*.

*Precondition:* *seed*, *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist\_sls\_event\_2*).

#### *StraightSkeletonBuilderTraits\_2:: Is\_ss\_event\_inside\_offset\_zone\_2*

A predicate object type.

Must provide *bool operator()( EdgeTriple const& e, EdgeTriple const& zone)*, which determines if the point of event for *e* is inside the *offset zone* defined by the 3 *oriented* lines given by *zone*.

An offset zone given by 3 *oriented* lines is the intersection of the halfplanes to the left of each oriented line.

*Precondition:* *e* must be an edge-triple corresponding to an event that actually exist (as determined by the predicate *Exist\_sls\_event\_2*), and the 3 oriented lines given by *zone* must be well defined (no point-pair can have coincident points).

#### *StraightSkeletonBuilderTraits\_2:: Are\_ss\_events\_simultaneous\_2*

A predicate object type.

Must provide *bool operator()( EdgeTriple const& x, EdgeTriple const& y)*, which determines if the events given by *x* and *y* are coincident in time and space; that is, both triples of offset lines intersect at the same point and at the same Euclidean distance from their sources.

*Precondition:* *x* and *y* must be edge-triples corresponding to events that actually exist (as determined by the predicate *Exist\_sls\_event\_2*).

### *StraightSkeletonBuilderTraits\_2:: Construct\_ss\_event\_time\_and\_point\_2*

A construction object type.

Must provide *boost::tuple< boost::optional<FT>, boost::optional<Point\_2> > operator()( EdgeTriple const& e)*, which given the 3 *oriented* lines defined by the 3 input edges (3 pair of points), returns the Euclidean distance  $t \geq 0$  and intersection point at which the corresponding 3 *offset lines* at  $t$  intersect.

If the values cannot be computed, not even approximately (because of overflow for instance), an empty optional must be returned.

*Precondition:*  $e$  must be an edge-triple corresponding to an event that actually exist (as determined by the predicate *Exist\_sls\_event\_2*).

### *StraightSkeletonBuilderTraits\_2:: Construct\_ss\_vertex\_2*

A construction object type.

Must provide *Vertex operator()( Point\_2 const& p)*, which given a *Point\_2*  $p$  returns a Vertex encapsulating the corresponding (x,y) pair of *Cartesian* coordinates.

### *StraightSkeletonBuilderTraits\_2:: Construct\_ss\_edge\_2*

A construction object type.

Must provide *Edge operator()( Point\_2 const& s, Point\_2 const& t)*, which given source and target points  $s$  and  $t$  returns an Edge encapsulating the corresponding input segment (in *Cartesian* coordinates.)

### *StraightSkeletonBuilderTraits\_2:: Construct\_ss\_triedge\_2*

A construction object type.

Must provide *Triedge operator()( Edge const& e0, Edge const& e1, Edge const& e2)*, which given the 3 edges that define an event,  $e0$ ,  $e1$  and  $e2$ , returns a Triedge encapsulating them.

## **Has Models**

*CGAL::Straight\_skeleton\_builder\_traits\_2<K>*

## PolygonOffsetBuilderTraits\_2

### Definition

The concept `PolygonOffsetBuilderTraits_2` describes the requirements for the geometric traits class required by the algorithm class `Polygon_offset_builder_2<Ss,Gt,Polygon_2>`.

### Types

<code>PolygonOffsetBuilderTraits_2:: Kernel</code>	A model of the <i>Kernel</i> concept.
<code>PolygonOffsetBuilderTraits_2:: FT</code>	A <i>SqrtFieldNumberType</i> provided by the kernel. This type is used to represent the coordinates of the input points and to specify the desired offset distance.
<code>PolygonOffsetBuilderTraits_2:: Point_2</code>	A 2D point type
<code>boost::tuple&lt;FT,FT&gt; Vertex;</code>	A pair of (x,y) coordinates representing a 2D Cartesian point.
<code>boost::tuple&lt;Vertex,Vertex&gt;</code>	
<code>Edge;</code>	A pair of vertices representing an edge
<code>boost::tuple&lt;Edge,Edge,Edge&gt;</code>	
<code>EdgeTriple;</code>	A triple of edges representing an event

`PolygonOffsetBuilderTraits_2:: Compare_offset_against_event_time_2`

A predicate object type.  
 Must provide `Comparison_result operator()( FT d, EdgeTriple const& et ) const`, which compares the Euclidean distance  $d$  with the event time for  $et$ . Such event time is the Euclidean distance at which the *offset lines* intersect in a single point. The source of such offset lines is given by the 3 *oriented* lines defined by the edge-triple  $et$   
*Precondition:*  $et$  must be an edge-triple corresponding to an event that actually exist (that is, there must exist an offset distance  $t > 0$  at which the offset lines do intersect at a single point.

`PolygonOffsetBuilderTraits_2:: Construct_offset_point_2`

A construction object type.  
 Must provide `boost::optional<Point_2> operator()( FT t, Edge const& x, Edge const& y ) const`, which constructs the point of intersection of the lines obtained by offsetting the oriented lines given by  $x$  and  $y$  an Euclidean distance  $t$ . If the point cannot be computed, not even approximately (because of overflow for instance), an empty optional must be returned.

*Precondition:*  $x$  and  $y$  must intersect in a single point

`PolygonOffsetBuilderTraits_2:: Construct_ss_vertex_2`

A construction object type.  
 Must provide `Vertex operator()( Point_2 const& p )`, which given a *Point\_2*  $p$  returns a *Vertex* encapsulating the corresponding (x,y) pair of Cartesian coordinates.

*PolygonOffsetBuilderTraits\_2:: Construct\_ss\_edge\_2*

A construction object type.

Must provide *Edge operator()*( *Point\_2 const& s*, *Point\_2 const& t*), which given source and target points *s* and *t* returns an *Edge* encapsulating the corresponding input segment (in Cartesian coordinates.)

*PolygonOffsetBuilderTraits\_2:: Construct\_ss\_triedge\_2*

A construction object type.

Must provide *Triedge operator()*( *Edge const& e0*, *Edge const& e1*, *Edge const& e2*), which given the 3 edges that define an event, *e0*, *e1* and *e2*, returns a *Triedge* encapsulating them.

## **Has Models**

## VertexContainer\_2

### Introduction

A model for the `VertexContainer_2` concept defines the requirements for a resizable container of 2D points. It is used to output the offset polygons generated by the `Polygon_offset_builder_2<Ssds,Gt,Container>` class.

### Types

<code>VertexContainer_2:: Point_2</code>	A 2D point type used to represent a vertex. Must be a model of the <code>Kernel::Point_2</code> concept
<code>VertexContainer_2:: size_type</code>	A unsigned integral type that can represent the number of vertices in the container.

### Creation

<code>VertexContainer_2 c;</code>	Default constructor
<code>size_type</code> <code>c.size()</code>	Returns the number of vertices in the container.
<code>void</code> <code>c.push_back( Point_2 v)</code>	Adds the vertex <code>v</code> to the container, resizing its capacity if required.

### Has Models

`CGAL::Polygon_2`

Any standard `BackInsertionSequence`, such as `vector`, `list` or `deque`, with a `value_type` being a model of the `Kernel::Point_2` concept.

## CGAL::create\_interior\_straight\_skeleton\_2

### Definition

The function *create\_interior\_straight\_skeleton\_2* creates a straight skeleton in the interior of a 2D polygon with holes.

```
#include <CGAL/create_straight_skeleton_2.h>
```

```
template<class PointIterator, class HoleIterator, class K>
boost::shared_ptr< Straight_skeleton_2<K> >
```

```
    create_interior_straight_skeleton_2( PointIterator outer_contour_vertices_begin,
                                         PointIterator outer_contour_vertices_end,
                                         HoleIterator holes_begin,
                                         HoleIterator holes_end,
                                         K k = Exact_predicates_inexact_constructions_
kernel)
```

returns a new *Straight\_skeleton\_2<K>* in the interior of the 2D polygon with holes whose outer boundary is given by the point sequence *[outer\_contour\_vertices\_begin, outer\_contour\_vertices\_end]* and its holes given by *[holes\_begin, holes\_end]*.

```
template<class PointIterator, class K>
boost::shared_ptr< Straight_skeleton_2<K> >
```

```
    create_interior_straight_skeleton_2( PointIterator outer_contour_vertices_begin,
                                         PointIterator outer_contour_vertices_end,
                                         K k = Exact_predicates_inexact_constructions_
kernel)
```

returns a new *Straight\_skeleton\_2<K>* in the interior of the 2D polygon whose outer boundary is given by the point sequence *[outer\_contour\_vertices\_begin, outer\_contour\_vertices\_end]*.

```
template<class Polygon, class K>
boost::shared_ptr< Straight_skeleton_2<K> >
```

```
    create_interior_straight_skeleton_2( Polygon outer_contour,
                                         K k = Exact_predicates_inexact_constructions_
kernel)
```

returns a new *Straight\_skeleton\_2<K>* in the interior of the 2D polygon *outer\_contour*.

1. *K* is any CGAL kernel.

2. *PointIterator::value\_type* is equivalent to *K2::Point\_2*. A cartesian converter is used to convert from *K2::Point\_2* to *K::Point\_2*
3. *HoleIterator::value\_type* and *Polygon* are *Polygon\_2<K>* or a standard container of *K2::Point\_2* elements

```
#include <CGAL/create_straight_skeleton_from_polygon_with_holes_2.h>
```

```
template<class K>
```

```
boost::shared_ptr< Straight_skeleton_2<K> >
```

```
    create_interior_straight_skeleton_2( Polygon_with_holes<K> poly_with_holes,  
                                         K k = Exact_predicates_inexact_constructions_
```

```
kernel)
```

returns a new *Straight\_skeleton\_2<K>* in the interior of the 2D polygon with holes *poly\_with\_holes*.

## CGAL::create\_exterior\_straight\_skeleton\_2

### Definition

The function `create_exterior_straight_skeleton_2` creates a straight skeleton in the exterior of a 2D polygon with holes.

```
#include <CGAL/create_straight_skeleton_2.h>
```

```
template<class FT, class PointIterator, class K>
```

```
boost::shared_ptr< Straight_skeleton_2<K> >
```

```
    create_exterior_straight_skeleton_2( FT max_offset,
                                         PointIterator vertices_begin,
                                         PointIterator vertices_end,
                                         K k = Exact_predicates_inexact_constructions_
kernel)
```

returns a new *Straight\_skeleton\_2<K>* in the *limited exterior* of the 2D polygon *P* given by the point sequence *[vertices\_begin, vertices\_end]*. The skeleton in the *limited exterior* of *P* is the skeleton in the interior of a polygon *Q* with *P* as its hole and a rectangular frame *F* as outer boundary. The outer boundary *F* is constructed by enlarging the bounding box of *P* a distance *d*. *d* is a margin sufficiently large to allow an outer offset at distance *max\_offset* to be obtained from this exterior skeleton, as computed by the function *compute\_outer\_frame\_margin*

```
template<class FT, class Polygon, class K>
```

```
boost::shared_ptr< Straight_skeleton_2<K> >
```

```
    create_exterior_straight_skeleton_2( FT max_offset,
                                         Polygon P,
                                         K k = Exact_predicates_inexact_constructions_
kernel)
```

returns a new *Straight\_skeleton\_2<K>* in the *limited exterior* of the 2D polygon *P*. The skeleton in the *limited exterior* of *P* is the skeleton in the interior of a polygon *Q* with *P* as its hole and a rectangular frame *F* as outer boundary. The outer boundary *F* is constructed by enlarging the bounding box of *P* a distance *d*. *d* is a margin sufficiently large to allow an outer offset at distance *max\_offset* to be obtained from this exterior skeleton, as computed by the function *compute\_outer\_frame\_margin*

### Requirements

1.  $K$  is any CGAL kernel.
2. `PointIterator::value_type` is equivalent to `K2::Point_2`. A cartesian converter is used to convert from `K2::Point_2` to `K::Point_2`
3. `Polygon` is `Polygon_2<K>` or a standard container of `K2::Point_2` elements

## CGAL::Straight\_skeleton\_2<Traits,Items,Alloc>

### Definition

The class *Straight\_skeleton\_2*<Traits,Items,Alloc> provides a model for the *StraightSkeleton\_2* concept which is the class type used to represent a straight skeleton.

It inherits from *HalfedgeDS\_vector*<Traits,Items,Alloc>

```
#include <CGAL/Straight_skeleton_2.h>
```

### Is Model for the Concepts

*StraightSkeleton\_2*  
*DefaultConstructible*  
*CopyConstructible*  
*Assignable*

### See Also

*StraightSkeletonVertex\_2*  
*StraightSkeletonHalfedge\_2*  
*StraightSkeleton\_2*

The only purpose of this class is to protect all the modifying operations in a *HalfedgeDS*. Normal users should not modify a straight skeleton. If an advanced user needs to get access to the modifying operations, it must call the required methods through the *::Base* class.

## CGAL::Straight\_skeleton\_vertex\_base\_2<Refs,Point,FT>

### Definition

The class *Straight\_skeleton\_vertex\_base\_2<Refs,Point,FT>* provides a model for the *StraightSkeletonVertex\_2* concept which is the vertex type required by the *StraightSkeleton\_2* concept. The class *Straight\_skeleton\_vertex\_base\_2<Refs,Point,FT>* has three template arguments: the first is the model of the *StraightSkeleton\_2* concept (the vertex container), the second is a Point type, and the third is a model of the *SqrtFieldNumberType*, which is the numeric type used to represent the time of a vertex (a Euclidean distance).

This class can be used as a base class allowing users of the straight skeleton data structure to decorate a vertex with additional data. The concrete vertex class must be given in the *HalfedgeDSItems* template parameter of the instantiation of the *HalfedgeDS\_default* class used as the model for the *Straight\_skeleton\_2* concept.

```
#include <CGAL/Straight_skeleton_vertex_base_2.h>
```

### Is Model for the Concepts

## CGAL::Straight\_skeleton\_items\_converter\_2<SrcSs, TgtSs, NTConverter>

### Definition

*Straight\_skeleton\_items\_converter\_2<SrcSs, TgtSs, NTConverter>* is a model of the *StraightSkeletonItemsConverter\_2* concept

The first and second template parameters are the target and source straight skeleton types, resp.

The third template parameter *NTConverter* is a function object that must provide *TgtSs::Traits::FT operator()(SrcSs::Traits::FT n)* that converts *n* to an *TgtSs::Traits::FT* which has the same value. The default value of this parameter is *CGAL::NT\_converter<SrcSs::Traits::FT, TgtSs::Traits::FT>*.

### Is Model for the Concepts

*StraightSkeletonItemsConverter\_2*  
*DefaultConstructible*  
*CopyConstructible*  
*Assignable*

```
#include <CGAL/Straight_skeleton_converter_2.h>
```

### Creation

```
Straight_skeleton_items_converter_2<SrcSs, TgtSs, NTConverter> conv;
```

Default constructor.

## CGAL::Straight\_skeleton\_converter\_2<SrcSs,TgtSs,ItemsCvt>

### Definition

The class *Straight\_skeleton\_converter\_2*<SrcSs,TgtSs,ItemsCvt> converts a straight skeleton instantiated using certain traits into another straight skeleton instantiated using a different traits.

The first and second template parameters are the source and target straight skeleton types, resp.

The third template parameter *ItemsConverter* is a function object that must model the concept *StraightSkeletonItemsConverter\_2*. The default value of this parameter is *CGAL::Straight\_skeleton\_items\_converter\_2*<SrcSs,TgtSs>.

This conversion can be used to produce a straight skeleton with the fast *Exact\_predicates\_inexact\_constructions\_kernel* but then input that skeleton into *Polygon\_offset\_builder*<Ss,Gt,Container> instantiated with the slower *Exact\_predicates\_exact\_constructions\_kernel* obtaining only simple offset polygons without paying the runtime overhead of exact constructions for the straight skeleton itself.

### Types

<i>SrcSs</i>	<i>Source_skeleton;</i>	The <i>SrcSs</i> template parameter corresponding to the source straight skeleton.
<i>TgtSs</i>	<i>Target_skeleton;</i>	The <i>TgtSs</i> template parameter corresponding to the target straight skeleton.
<i>ItemsCvt</i>	<i>Items_converter;</i>	The <i>ItemsCvt</i> template parameter corresponding to the items converter.

```
#include <CGAL/Straight_skeleton_converter_2.h>
```

### Creation

```
Straight_skeleton_converter_2<SrcSs,TgtSs,ItemsCvt> c( Items_converter c);
```

Default constructor

### Operations

```
boost::shared_ptr<Target_skeleton>
```

```
c.operator()( Source_skeleton const& s) const
```

returns a new straight skeleton data structure with the same combinatorial and geometric data as *s* using the items converter to convert the geometric embedding to the types of the target traits.

## See Also

*StraightSkeletonItemsConverter\_2*

*Straight\_skeleton\_items\_converter\_2<SrcSs,TgtSs,NTConverter>*

*convert\_straight\_skeleton\_2<SrcSs,TgtSs,NTConverter>*

## CGAL::convert\_straight\_skeleton\_2

### Definition

The function *convert\_straight\_skeleton\_2* converts a straight skeleton instantiated using certain traits into another straight skeleton instantiated using a different traits.

```
#include <CGAL/Straight_skeleton_converter_2.h>
```

```
boost::shared_ptr<Target_skeleton, Source_skeleton, Items_converter>
```

```
    convert_straight_skeleton_2( Source_skeleton s,  
                                Items_converter ic = Items_converter())
```

returns a new straight skeleton data structure with the same combinatorial and geometric data as *s* using the items converter *ic* to convert the geometric embedding to the types of the target skeleton.

The first template parameter is the type of the target straight skeleton. This template parameter is not bound to a function argument so it must be explicitly specified.

## CGAL::Straight\_skeleton\_builder\_traits\_2<Kernel>

### Definition

The class *Straight\_skeleton\_builder\_traits\_2<Kernel>* provides a model for the *StraightSkeletonBuilderTraits\_2* concept which is the traits class required by the *Straight\_skeleton\_builder\_2* algorithm class. The class *Straight\_skeleton\_builder\_traits\_2<Kernel>* has one template argument: a 2D CGAL Kernel. This parameter must be a model for the *Kernel* concept, such as the *Exact\_predicates\_inexact\_constructions\_kernel*, which is the recommended one.

It is unspecified which subset of the kernel is used into the output sequence and the returned iterator will be equal to *out*.

For any given input polygon, it in this traits class (and by extension in the builder class). This is to avoid restricting the choices in the implementation.

```
#include <CGAL/Straight_skeleton_builder_traits_2.h>
```

### Is Model for the Concepts

*StraightSkeletonBuilderTraits\_2*

*DefaultConstructible*

*CopyConstructible*

### See Also

*CGAL::Straight\_skeleton\_builder\_2<Gt,Sds>*

## CGAL::Straight\_skeleton\_builder\_2<Gt,Ss,Visitor>

### Definition

The class *Straight\_skeleton\_builder\_2<Gt,Ss,Visitor>* encapsulates the construction of the 2D straight skeleton in the interior of a polygon with holes. Its first template parameter, *Gt*, must be a model of the *StraightSkeletonBuilderTraits\_2* concept, its second template parameter, *Ss*, must be a model of the *StraightSkeleton\_2* concept, and its third template parameter, *Visitor*, must be a model of the *StraightSkeletonBuilder\_2\_Visitor* concept. If this last parameter is omitted, the class *CGAL::Dummy\_straight\_skeleton\_builder\_2\_visitor<Skel>* is used.

```
#include <CGAL/Straight_skeleton_builder_2.h>
```

### Types

*Straight\_skeleton\_builder\_2<Gt,Ss,Visitor>:: Gt*

The geometric traits (first template parameter)

*Straight\_skeleton\_builder\_2<Gt,Ss,Visitor>:: Ss*

The straight skeleton (second template parameter)

*Straight\_skeleton\_builder\_2<Gt,Ss,Visitor>:: Point\_2*

The 2D point type as defined by the geometric traits

### Creation

*Straight\_skeleton\_builder\_2<Gt,Ss,Visitor> b;*    Default constructs the builder class.

### Methods

*template<class InputPointIterator>*

*b.enter\_contour( InputPointIterator aBegin, InputPointIterator aEnd)*

Defines the *contours* that form the *non-degenerate strictly-simple polygon with holes* whose *straight skeleton* is to be built.

Each contour must be input in turn starting with the *outer contour* and following with the holes (if any). The order of the holes is unimportant but the outer contour must be entered first. The outer contour must be oriented counter-clockwise while holes must be oriented clockwise.

It is an error to enter more than one outer contour or to enter a hole which is not inside the outer contour or inside another hole. It is also an error to enter a contour which crosses or touches any one another. It is possible however to enter a contour that touches itself in such a way that its interior region is still well defined and singly-connected (see the User Manual for examples).

The sequence [aBegin,aEnd) must iterate over each 2D point that corresponds to a vertex of the contour being entered. Vertices cannot be coincident (except consecutively since the method simply skip consecutive coincident vertices). Consecutive collinear edges are allowed.

InputPointIterator must be an *InputIterator* whose *value\_type* is *Point\_2*.

*boost::shared\_ptr<Ss>*

*b.construct\_skeleton()*

Constructs and returns the 2D straight skeleton in the interior of the polygon with holes as defined by the contours entered first by calling *enter\_contour*. All the contours of the polygon with holes must be entered before calling *construct\_skeleton*.

After *construct\_skeleton* completes, you cannot enter more contours and/or call *construct\_skeleton()* again. If you need another straight skeleton for another polygon you must instantiate and use another builder.

The result is a dynamically allocated instance of the *Ss* class, wrapped in a *boost::shared\_ptr*.

If the construction process fails for whatever reason (such as a nearly-degenerate vertex whose internal or external angle is almost zero), the return value will be *null*, represented by a default constructed *shared\_ptr*.

The algorithm automatically checks the consistency of the result, thus, if it is not *null*, it is guaranteed to be valid.

## Algorithm

The implemented algorithm is closely based on [FO98] with the addition of *vertex events* as described in [EE98].

It simulates a grassfire propagation of moving polygon edges as they move inward at constant and equal speed. That is, the continuous inward offsetting of the polygon.

Since edges move at equal speed their movement can be characterized in a simpler setup as the movement of vertices. Vertices move along the angular bisector of adjacent edges.

The trace of a moving vertex is described by the algorithm as a *bisector*. Every position along a bisector corresponds to the vertex between two offset (moved) edges. Since edges move at constant speed, every position along a bisector also corresponds to the distance those two edges moved so far.

From the perspective of a dynamic system of moving edges, such a distance can be regarded as an *instant* (in time). Therefore, every distinct position along a bisector corresponds to a distinct instant in the offsetting process.

As they move inward, edges can expand or contract w.r.t to the endpoints sharing a vertex. If a vertex has an internal angle  $< \pi$ , its incident edges will contract but if its internal angle  $> \pi$ , they will expand. The movement of the edges, along with their extent change, result in collisions between non-adjacent edges. These collisions are called *events*, and they occur when the colliding edges have moved a certain distance, that is, at certain *instants*.

If non-consecutive edges  $E(j), E(k)$  move while edge  $E(i)$  contracts, they can collide at the point when  $E(i)$  shrinks to nothing (that is, the three edges might meet at a certain offset). This introduces a *topological change* in the polygon: Edges  $E(j), E(k)$  are now adjacent, edge  $E(i)$  disappears, and a new vertex appears. This topological change is called an *edge event*.

Similarly, consecutive expanding edges  $E(i), E(i+1)$  sharing a reflex vertex (internal angle  $\geq \pi$ ) might collide with any edge  $E(j)$  on the rest of the same connected component of the polygon boundary (even far away from the initial edge's position). This also introduces a topological change:  $E(j)$  gets split in two edges and the connected component having  $E(i), E(i+1)$  and  $E(j)$  is split in two unconnected parts: one having  $E(i)$  and the corresponding subsegment of  $E(j)$  and the other with  $E(i+1)$  and the rest of  $E(j)$ . This is called a *split event*.

If a reflex vertex hits not an edge  $E(j)$  but another reflex vertex  $E(j), E(j+1)$ , and vice-versa (the reflex vertex  $V(j)$  hits  $V(i)$ ), there is no actual split and the two unconnected parts have  $E(i), E(j)$  and  $E(i+1), E(j+1)$  (or  $E(i), E(j+1)$  and  $E(i+1), E(j)$ ). This topological change is called a *vertex event*. Although similar to a split event in the sense that two new unconnected contours emerge introducing two new contour vertices, in the case of a vertex event one of the new contour vertices might be reflex; that is, a vertex event *may* result in one of the offset polygons having a *reflex* contour vertex which was not in the original polygon.

Edges movement is described by vertices movement, and these by bisectors. Therefore, the collision between edges  $E(j), E(i), E(k)$  (all in the same connected component) occurs when the moving vertices  $E(j) \rightarrow E(i)$  and  $E(i) \rightarrow E(k)$  meet; that is, when the two bisectors describing the moving vertices *intersect* (Note: as the edges move inward and events occur, a vertex between edges A and B might exist even if A and B are not consecutive; that is, j and k are not necessarily i-1 and i+1 respectively, although initially they are).

Similarly, the collision between  $E(i), E(i+1)$  with  $E(j)$  (all in the same connected component) occurs when the bisector corresponding to the moving vertex  $E(i) \rightarrow E(i+1)$  hits the moving edge  $E(j)$ .

Since each event changes the topology of the moving polygon, it is not possible or practical to foresee all events at once. Rather, the algorithm starts by estimating an initial set of potential events and from there it computes one next event at a time based on the previous one. The chaining of events is governed by their relative instants: events that occur first are processed first.

An initial set of *potential* split events is first computed independently (the computation of a potential split event is based solely on a reflex vertex and all other edges in the same connected component); and an initial set of *potential* edge events between initially consecutive bisectors is first computed independently (based solely on each bisector pair under consideration).

Events occur at certain instants and the algorithm must be able to order them accordingly. The correctness of the algorithm is uniquely and directly governed by the correct computation and ordering of the events. Any potential event might no longer be applicable after the topological change introduced by a prior event.

A grassfire propagation picks the next unprocessed event (starting from the first) and if it is still applicable processes it. Processing an event involves connecting edges, adding a new skeleton vertex (which corresponds to a contour vertex of the offset polygon) and calculating one new potential future event (which can be either an edge event or a split event -because of a prior vertex event-), based on the topological change just introduced. The propagation finishes when there are no new future events.

## CGAL::Dummy\_straight\_skeleton\_builder\_2\_visitor<Ss>

### Definition

The class *Dummy\_straight\_skeleton\_builder\_2\_visitor<Ss>* provides a model for the *StraightSkeletonBuilder\_2\_Visitor* concept which is the visitor type required by the *StraightSkeletonBuilder\_2* concept. The class *Dummy\_straight\_skeleton\_builder\_2\_visitor<Ss>* has only one template argument: a model of the *StraightSkeleton\_2* concept.

This class is the default visitor parameter of the straight skeleton builder. All its methods are empty.

```
#include <CGAL/Straight_skeleton_builder_2.h>
```

### Is Model for the Concepts

*StraightSkeletonBuilder\_2\_Visitor*  
*DefaultConstructible*

### See Also

## CGAL::create\_offset\_polygons\_2

### Definition

The function *create\_offset\_polygons\_2* creates a straight skeleton in the interior of a 2D polygon with holes.

```
#include <CGAL/create_straight_skeleton_2.h>
```

```
template<class Polygon, class FT, class Straight_skeleton, class K>
std::vector< boost::shared_ptr<Polygon> >
```

```
    create_offset_polygons_2( FT offset,
                             Straight_skeleton s,
                             ,
                             K k = Exact_predicates_inexact_constructions_kernel)
```

returns a container with all the offset polygons at distance *offset* obtained from the straight skeleton *s*.

1. *K* is any CGAL kernel.
2. *FT* is any number type implicitly convertible to *K::FT*.
3. *Straight\_skeleton* is *Straight\_skeleton\_2<K2>*. If *K1* = *K2* the straight skeleton is converted to *Straight\_skeleton\_2<K>*.
4. *Polygon* is a model of *VertexContainer\_2*. If this first template parameter is omitted, *Polygon\_2* is used.

## CGAL::arrange\_offset\_polygons\_2

### Definition

The function *arrange\_offset\_polygons\_2* arranges the sequence of *Polygon\_2* objects obtained by *create\_offset\_polygons\_2* into *Polygon\_with\_holes\_2* objects by determining geometric parent-hole relationships using a simple algorithm based on the particular characteristics of offset polygons. This function should not be used to arrange arbitrary polygons into polygons with holes unless they meet the requirements specified below.

```
#include <CGAL/arrange_offset_polygons_2.h>
```

```
template<class K, class InputPolygonPtrIterator, class OutputPolygonWithHolesPtrIterator>
void      arrange_offset_polygons_2( InputPolygonPtrIterator begin,
                                     InputPolygonPtrIterator end,
                                     OutputPolygonWithHolesPtrIterator out,
                                     K k)
```

determines parent-hole relationships among the polygons given by *[begin,end]* creating *boost::shared\_ptr< Polygon\_with\_holes\_2<K> >* objects added to the output sequence given *out*. A *CLOCKWISE* oriented polygon *H* is a hole of a *COUNTERCLOCKWISE* polygon *P*, iff at least one vertex of *H* is *ON\_BOUNDED\_SIDE* of *P*.

### Requirements

1. *K* is any CGAL kernel.
2. *InputPolygonPtrIterator* is an input iterator whose *value\_type* is a *smart ptr* (such as *boost::shared\_ptr*) whose *element\_type* is *Polygon\_2<K>*.
3. *InputPolygonPtrIterator* is an output iterator whose *value\_type* is a *smart ptr* (such as *boost::shared\_ptr*) whose *element\_type* is *Polygon\_with\_holes\_2<K>*.
4. The input polygons must be simple.
5. The set of input polygons are unique and interior disjoint. That is, given distinct polygons *P* and *Q*, there are vertices of *P* which are not on the boundary of *Q* and are all on the bounded or unbounded side of *Q* (but not both).

## CGAL::create\_interior\_skeleton\_and\_offset\_polygons\_2

### Definition

The function *create\_interior\_skeleton\_and\_offset\_polygons\_2* creates inner offset polygons directly from an input polygon via a temporarily created straight skeleton.

```
#include <CGAL/create_offset_polygons_2.h>
```

```
template<class FT, class Polygon, class HoleIterator, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr<Polygon> >
```

```
    create_interior_skeleton_and_offset_polygons_2( FT offset,
                                                    Polygon outer_boundary,
                                                    HoleIterator holes_begin,
                                                    HoleIterator holes_end,
                                                    OffsettingK ofk = CGAL::Exact_
predicates_inexact_constructions_kernel,
                                                    SkeletonK ssk = CGAL::Exact_
predicates_inexact_constructions_kernel)
```

returns a container with all the inner offset polygons at distance *offset* of the 2D polygon with holes whose outer boundary is *outer\_boundary* and its holes are given by *[holes\_begin,holes\_end]*. A temporary straight skeleton is constructed in the interior of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create\_interior\_straight\_skeleton\_2* and *create\_polygon\_offsets\_2* instead.

```
template<class FT, class Polygon, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr<Polygon> >
```

```
    create_interior_skeleton_and_offset_polygons_2( FT offset,
                                                    Polygon poly,
                                                    OffsettingK ofk = CGAL::Exact_
predicates_inexact_constructions_kernel,
                                                    SkeletonK ssk = CGAL::Exact_
predicates_inexact_constructions_kernel)
```

returns a container with all the inner offset polygons at distance *offset* of the 2D polygon *poly*. A temporary straight skeleton is constructed in the interior of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create\_interior\_straight\_skeleton\_2* and *create\_polygon\_offsets\_2* instead.

```
#include <CGAL/create_offset_polygons_from_polygon_with_holes_2.h>
```

```
template<class FT, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr< Polygon_2<OffsettingK> > >
```

```
    create_interior_skeleton_and_offset_polygons_2( FT offset,
                                                    CGAL::Polygon_with_holes<
OffsettingK> poly_with_holes,
                                                    OffsettingK ofk = CGAL::Exact_
predicates_inexact_constructions_kernel,
                                                    SkeletonK ssk = CGAL::Exact_
predicates_inexact_constructions_kernel)
```

returns a container with all the inner offset polygons at distance *offset* of the 2D polygon with holes *poly\_with\_holes*. A temporary straight skeleton is constructed in the interior of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create\_interior\_straight\_skeleton\_2* and *create\_polygon\_offsets\_2* instead.

```
template<class FT, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr< Polygon_with_holes_2<OffsettingK> > >
```

```
    create_interior_skeleton_and_offset_polygons_with_holes_2( FT offset,
                                                                CGAL::Polygon_2<
OffsettingK> poly,
                                                                OffsettingK ofk =
CGAL::Exact_predicates_inexact_constructions_kernel,
                                                                SkeletonK ssk =
CGAL::Exact_predicates_inexact_constructions_kernel)
```

returns a container with all the inner offset polygons *with holes* at distance *offset* of the 2D polygon *poly*. This is equivalent to *arrange\_offset\_polygons\_2(create\_interior\_skeleton\_and\_offset\_polygons\_2(offset,poly,okk,ssk))*.

```
template<class FT, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr< Polygon_with_holes_2<OffsettingK> > >
```

```
    create_interior_skeleton_and_offset_polygons_with_holes_2( FT offset,
                                                                CGAL::Polygon_with_
holes_2<OffsettingK> poly_with_holes,
                                                                OffsettingK ofk =
CGAL::Exact_predicates_inexact_constructions_kernel,
                                                                SkeletonK ssk =
CGAL::Exact_predicates_inexact_constructions_kernel)
```

returns a container with all the inner offset polygons *with holes* at distance *offset* of the 2D polygon with holes *poly\_with\_holes*. This is equivalent to *arrange\_offset\_polygons\_2(create\_interior\_skeleton\_and\_offset\_polygons\_2(offset,poly\_with\_holes,okk,ssk))*.

1. *OffsettingK* is the CGAL kernel used to instantiate *Polygon\_offset\_builder\_traits\_2<K>* for constructing the offset polygons.
2. *SkeletonK* is the CGAL kernel used to instantiate *Straight\_skeleton\_builder\_traits\_2<K>* for constructing the straight skeleton. If *SkeletonK*  $\neq$  *OffsettingK* the constructed straight skeleton is converted to *Straight\_skeleton\_2<OffsettingK>*.
3. *FT* is any number type implicitly convertible to *OffsettingK::FT*.
4. *Straight\_skeleton* is *Straight\_skeleton\_2<K2>*. If *K*  $\neq$  *K2* the straight skeleton is converted to *Straight\_skeleton\_2<K>*.
5. *HoleIterator::value\_type* and *Polygon* are *CGAL::Polygon\_2<OffsettingK>* or a standard container of *OffsettingK::Point\_2* elements

## CGAL::create\_exterior\_skeleton\_and\_offset\_polygons\_2

### Definition

The function *create\_exterior\_skeleton\_and\_offset\_polygons\_2* creates outer offset polygons directly from an input polygon via a temporarily created straight skeleton.

```
#include <CGAL/create_offset_polygons_2.h>
```

```
template<class FT, class Polygon, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr<Polygon> >
```

```
    create_exterior_skeleton_and_offset_polygons_2( FT offset,
                                                    Polygon poly,
                                                    OffsettingK ofk = Exact_predicates_
inexact_constructions_kernel,
                                                    SkeletonK ssk = Exact_predicates_
inexact_constructions_kernel)
```

returns a container with all the outer offset polygons at distance *offset* of the 2D polygon *poly*. A temporary straight skeleton is constructed in the *limited exterior* of the input polygon to obtain the offsets. The construction of this skeleton is the most expensive operation, therefore, to construct offsets at more than one single distance, use the separate functions *create\_exterior\_straight\_skeleton\_2* and *create\_polygon\_offsets\_2* instead. The exterior skeleton is limited by an outer rectangular frame placed at a margin sufficiently large to allow the offset polygons to be constructed.

```
#include <CGAL/create_offset_polygons_from_polygon_with_holes_2.h>
```

```
template<class FT, class OffsettingK, class SkeletonK>
std::vector< boost::shared_ptr< Polygon_with_holes_2<OffsettingK> > >
```

```
    create_exterior_skeleton_and_offset_polygons_with_holes_2( FT offset,
                                                                CGAL::Polygon_2<
OffsettingK> poly_with_holes,
                                                                OffsettingK ofk = Exact_
predicates_inexact_constructions_kernel,
                                                                SkeletonK ssk = Exact_
predicates_inexact_constructions_kernel)
```

returns a container with all the outer offset polygons *with holes* at distance *offset* of the 2D polygon *poly*. This is equivalent to *arrange\_offset\_polygons\_2(create\_exterior\_skeleton\_and\_offset\_polygons\_2(offset,poly,okk,ssk))*.

### Requirements

1. *OffsettingK* is the CGAL kernel used to instantiate *Polygon\_offset\_builder\_traits\_2<K>* for constructing the offset polygons.
2. *SkeletonK* is the CGAL kernel used to instantiate *Straight\_skeleton\_builder\_traits\_2<K>* for constructing the straight skeleton. If *SkeletonK*  $\neq$  *OffsettingK* the constructed straight skeleton is converted to *Straight\_skeleton\_2<OffsettingK>*.
3. *FT* is any number type implicitly convertible to *OffsettingK::FT*.
4. *Straight\_skeleton* is *Straight\_skeleton\_2<K2>*. If *K*  $\neq$  *K2* the straight skeleton is converted to *Straight\_skeleton\_2<K>*.

## CGAL::Polygon\_offset\_builder\_traits\_2<Kernel>

### Definition

The class *Polygon\_offset\_builder\_traits\_2<Kernel>* provides a model for the *PolygonOffsetBuilderTraits\_2* concept which is the traits class required by the *Polygon\_offset\_builder\_2* algorithm class. The class *Polygon\_offset\_builder\_traits\_2<Kernel>* has one template argument: a 2D CGAL::Kernel. This parameter must be a model for the *Kernel* concept, such as the *Exact\_predicates\_inexact\_constructions\_kernel*, which is the recommended one. It is unspecified which subset of the kernel is used in this traits class (and by extension in the builder class). This is to avoid restricting the choices in the implementation.

```
#include <CGAL/Polygon_offset_builder_traits_2.h>
```

### Is Model for the Concepts

*PolygonOffsetBuilderTraits\_2*  
*DefaultConstructible*  
*CopyConstructible*

### See Also

*CGAL::Polygon\_offset\_builder\_2<Ss,Gt,Polygon\_2>*

## CGAL::Polygon\_offset\_builder\_2<Ss,Gt,Container>

### Definition

The class *Polygon\_offset\_builder\_2*<*Ss,Gt,Container*> encapsulates the construction of inward offset contours of a 2D simple polygon with holes. The construction is based on the straight skeleton of the interior of the polygon. Its first template parameter, *Ss*, must be a model of the *StraightSkeleton\_2* concept, its second template parameter, *Gt*, must be a model of the *StraightSkeletonBuilderTraits\_2* concept, and its third template parameter must be a model of the *VertexContainer\_2* concept.

```
#include <CGAL/Polygon_offset_builder_2.h>
```

### Types

*Polygon\_offset\_builder\_2*<*Ss,Gt,Container*>:: *Ss*

The straight skeleton (first template parameter)

*Polygon\_offset\_builder\_2*<*Ss,Gt,Container*>:: *Gt*

The geometric traits (second template parameter)

*Polygon\_offset\_builder\_2*<*Ss,Gt,Container*>:: *Container*

The container of 2D vertices that represents each offset contour generated by the algorithm (third template parameter)

*Polygon\_offset\_builder\_2*<*Ss,Gt,Container*>:: *FT*

The *SqrtFieldNumberType* used to specify the desired offset distance, provided by the geometric traits *Gt*.

### Creation

*Polygon\_offset\_builder\_2*<*Ss,Gt,Container*> *b*( *Ss ss*);

Constructs the builder class using the given Straight Skeleton instance.

### Methods

```
template<class OutputIterator>
```

*OutputIterator*     *b.construct\_offset\_contours( FT t, OutputIterator out)*

Given the straight skeleton passed in the constructor which corresponds to the interior of a non-degenerate strictly-simple polygon with holes *P*, returns *all* the offset contours of *P* at the Euclidean distance *t*.

Such offset contours are polygons in the interior of *P*. Provided exact constructions are used, these polygons are simple.

For any offset distance *t* there are 0, 1 or more offset contours.

For each resulting offset contour, a default constructed instance of *Container* type (which must be a model of the *VertexContainer\_2* concept), is dynamically allocated and each offset vertex is added to it.

A *boost::shared\_ptr* holding onto the dynamically allocated container is inserted into the output sequence via the *OutputIterator out*.

*OutputIterator* must be a model of the *OutputIterator* category whose *value\_type* is a *boost::shared\_ptr* holding the dynamically allocated instances of type *Container*.

The method returns an *OutputIterator* past-the-end of the resulting sequence, which contains each offset contour generated.

You can call *construct\_offset\_contours* with different offset distances (there is no need to construct the builder again). If you call it with an offset distance so large that there are no offset contours at that distance, no contour is inserted into the output sequence and the returned iterator will be equal to *out*.

For any given input polygon, its offset polygons at a certain distance are composed of several contours. This method returns all such contours in an unspecified order and with no parental relationship between them (that is why it is called *construct\_offset\_contours* and not *construct\_offset\_polygons*).

Those offset contours in the resulting sequence which are oriented counter-clockwise are outer contours and those oriented clockwise are holes. It is up to the user to match each hole to its parent in order to reconstruct the parent-hole relationship of the conceptual output. It is sufficient to test each hole against each parent as there won't be a hole inside a hole, a parent inside any other contour, or a hole inside more than one parent. The recommended insideness test is to perform a regularized Boolean set operation. *do\_intersect* from the *Boolean Set Operations* package will work fine in our case since it is guaranteed that no hole would cross halfway outside any parent (in the presence of such cases, subtracting the parent from the hole works better as it correctly rejects halfway holes).

If there are degenerate, or nearly degenerate vertices; that is, vertices whose internal or external angle approaches 0, numerical overflow may prevent some of the polygon contours to be constructed. If that happens, the failed contour just won't be added into the resulting sequence.

*CGAL::Polygon\_offset\_builder\_traits\_2<Kernel>*

## CGAL::compute\_outer\_frame\_margin

### Definition

The function `compute_outer_frame_margin` computes the separation required between a polygon and the outer frame used to obtain an exterior skeleton suitable for the computation of outer offset polygons at a given distance.

```
#include <CGAL/compute_outer_frame_margin.h>
```

```
template <class InputIterator, class Traits>
boost::optional< typename Traits::FT >
```

```
compute_outer_frame_margin( InputIterator first,
                             InputIterator beyond,
                             typename Traits::FT offset,
                             Traits traits = Default_traits)
```

Given a non-degenerate strictly-simple 2D polygon whose vertices are passed in the range `[first,beyond)`, calculates the largest euclidean distance  $d$  between each input vertex and its corresponding offset vertex at a distance `offset`.

If such a distance can be approximately computed, returns an `optional<FT>` with the value  $d + (\text{offset} * 1.05)$ . If the distance cannot be computed, not even approximately, due to overflow for instance, returns an empty `optional<FT>` (an *absent result*).

This result is the required separation between the input polygon and the rectangular frame used to construct an exterior offset contour at distance `offset` (which is done by placing the polygon as a hole of that frame).

Such a separation must be computed in this way because if the frame is too close to the polygon, the inward offset contour from the frame could collide with the outward offset contour of the polygon, resulting in a merged contour offset instead of two contour offsets, one of them corresponding to the frame.

Simply using  $2 * \text{offset}$  as the separation is incorrect since `offset` is the distance between an offset line and its original, not between an offset vertex and its original. The later, which is calculated by this function and needed to place the frame sufficiently away from the polygon, can be thousands of times larger than `offset`.

If the result is *absent*, any attempt to construct an exterior offset polygon at distance `offset` will fail. This will occur whenever the polygon has a vertex with an internal angle approaching 0 (because the offset vertex of a vertex whose internal angle equals 0 is at *infinity*).

*Precondition:* `offset > 0`.

*Precondition:* The range `[first,beyond)` contains the vertices of a non-degenerate strictly-simple 2D polygon.

The default traits class *Default\_traits* is an instance of the class *Polygon\_offset\_builder\_traits\_2<Kernel>* parameterized on the kernel in which the type *InputIterator::value\_type* is defined.

## Requirements

1. *InputIterator::value\_type* is equivalent to *Traits::Point\_2*.
2. *Traits* must be a model for *PolygonOffsetBuilderTraits\_2*

### 20.1 Introduction

Given two sets  $A, B \in \mathbb{R}^d$ , their *Minkowski sum*, denoted by  $A \oplus B$ , is the set  $\{a + b \mid a \in A, b \in B\}$ . Minkowski sums are used in many applications, such as motion planning and computer-aided design and manufacturing. This package contains functions for computing planar Minkowski sums of two polygons (namely  $A$  and  $B$  are two closed polygons in  $\mathbb{R}^2$ ), and for a polygon and a disc (an operation also known as *offsetting* or *dilating* a polygon).

### 20.2 Computing the Minkowski Sum of Two Polygons

Computing the Minkowski sum of two convex polygons  $P$  and  $Q$  with  $m$  and  $n$  vertices respectively is very easy, as  $P \oplus Q$  is a convex polygon bounded by copies of the  $m + n$  edges, and these edges are sorted by the angle they form with the  $x$ -axis. As the two input polygons are convex, their edges are already sorted by the angle they form with the  $x$ -axis. The Minkowski sum can therefore be computed in  $O(m + n)$  time, by starting from two bottommost vertices in  $P$  and in  $Q$  and performing “merge sort” on the edges.

If the polygons are not convex, it is possible to use one of the following approaches:

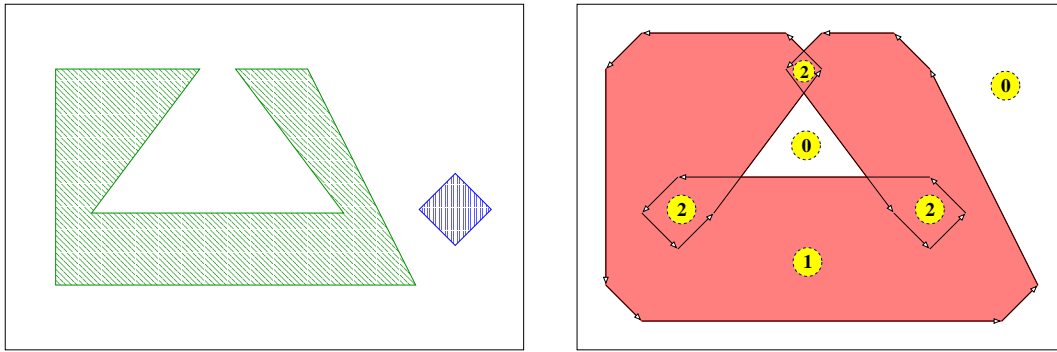

Figure 20.1: Computing the convolution of a convex polygon and a non-convex polygon (left). The convolution consists of a single self-intersecting cycle, drawn as a sequence of arrows (right). The winding number associated with each face of the arrangement induced by the segments forming the cycle appears in dashed circles. The Minkowski sum of the two polygons is shaded.

**Decomposition:** We decompose  $P$  and  $Q$  into convex sub-polygons, namely we obtain two sets of convex polygons  $P_1, \dots, P_k$  and  $Q_1, \dots, Q_\ell$  such that  $\bigcup_{i=1}^k P_i = P$  and  $\bigcup_{j=1}^\ell Q_j = Q$ . We then calculate the pairwise sums  $S_{ij} = P_i \oplus Q_j$  using the simple procedure described above, and compute the union  $P \oplus Q = \bigcup_{ij} S_{ij}$ .

This approach relies on a decomposition strategy that computes the convex decomposition of the input polygons and its performance depends on the quality of the decomposition.

**Convolution:** Let us denote the vertices of the input polygons by  $P = (p_0, \dots, p_{m-1})$  and  $Q = (q_0, \dots, q_{n-1})$ . We assume that both  $P$  and  $Q$  have positive orientations (i.e. their boundaries wind in a counterclockwise order around their interiors) and compute the convolution of the two polygon boundaries. The *convolution* of these two polygons [GRS83], denoted  $P * Q$ , is a collection of line segments of the form  $[p_i + q_j, p_{i+1} + q_j]$ ,<sup>1</sup> where the vector  $\mathbf{p}_i \mathbf{p}_{i+1}$  lies between  $\mathbf{q}_{j-1} \mathbf{q}_j$  and  $\mathbf{q}_j \mathbf{q}_{j+1}$ ,<sup>2</sup> and — symmetrically — of segments of the form  $[p_i + q_j, p_i + q_{j+1}]$ , where the vector  $\mathbf{q}_j \mathbf{q}_{j+1}$  lies between  $\mathbf{p}_{i-1} \mathbf{p}_i$  and  $\mathbf{p}_i \mathbf{p}_{i+1}$ .

The segments of the convolution form a number of closed (not necessarily simple) polygonal curves called *convolution cycles*. The Minkowski sum  $P \oplus Q$  is the set of points having a non-zero winding number with respect to the cycles of  $P * Q$ .<sup>3</sup> See Figure 20.1 for an illustration.

The number of segments in the convolution of two polygons is usually smaller than the number of segments that constitute the boundaries of the sub-sums  $S_{ij}$  when using the decomposition approach. As both approaches construct the arrangement of these segments and extract the sum from this arrangement, computing Minkowski sum using the convolution approach usually generates a smaller intermediate arrangement, hence it is faster and consumes less space.

## 20.2.1 Computing Minkowski Sum using Convolutions

The function `minkowski_sum_2` ( $P, Q$ ) accepts two simple polygons  $P$  and  $Q$ , represented using the `Polygon_2<Kernel, Container>` class-template and uses the convolution method in order to compute and return their Minkowski sum  $S = P \oplus Q$ .

As the input polygons may not be convex, their Minkowski sum may not be simply connected and contain polygonal holes; see for example Figure 20.1.  $S$  is therefore an instance of the `Polygon_with_holes_2<Kernel, Container>` class-template, defined in the Boolean Set-Operations package: The outer boundary of  $S$

<sup>1</sup>Throughout this chapter, we increment or decrement an index of a vertex modulo the size of the polygon.

<sup>2</sup>We say that a vector  $\mathbf{v}$  lies between two vectors  $\mathbf{u}$  and  $\mathbf{w}$  if we reach  $\mathbf{v}$  strictly before reaching  $\mathbf{w}$  if we move all three vectors to the origin and rotate  $\mathbf{u}$  counterclockwise. Note that this also covers the case where  $\mathbf{u}$  has the same direction as  $\mathbf{v}$ .

<sup>3</sup>Informally speaking, the winding number of a point  $p \in \mathbb{R}^2$  with respect to some planar curve  $\gamma$  is an integer number counting how many times does  $\gamma$  wind in a counterclockwise direction around  $p$ .

Figure 20.2: Computing the Minkowski sum of two triangles, as done in the example program *Minkowski\_sum\_2/sum\_triangles.cpp*.

is a polygon that can be accessed using *S.outer\_boundary()*, and its polygonal holes are given by the range *[S.holes\_begin(), S.holes\_end())* (where *S* contains *S.number\_of\_holes()* holes in its interior).

The following example program constructs the Minkowski sum of two triangles, as depicted in Figure 20.2. The result in this case is a convex hexagon. This program, as other example programs in this chapter, includes the auxiliary header file *ms\_rational\_nt.h* which defines *Number\_type* as either *Gmpq* or *Quotient<MP\_Float>*, depending on whether the GMP library is installed or not. The file *print\_util.h* includes auxiliary functions for printing polygons.

```
#include "ms_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/minkowski_sum_2.h>
#include <iostream>

#include "print_utils.h"

typedef CGAL::Cartesian<Number_type>      Kernel;
typedef Kernel::Point_2                   Point_2;
typedef CGAL::Polygon_2<Kernel>           Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;

int main ()
{
    // Construct the first polygon (a triangle).
    Polygon_2  P;

    P.push_back (Point_2 (0, 0));
    P.push_back (Point_2 (6, 0));
    P.push_back (Point_2 (3, 5));

    // Construct the second polygon (a triangle).
    Polygon_2  Q;

    Q.push_back (Point_2 (0, 0));
    Q.push_back (Point_2 (2, -2));
    Q.push_back (Point_2 (2, 2));

    // Compute the Minkowski sum.
    Polygon_with_holes_2  sum = minkowski_sum_2 (P, Q);

    CGAL_assertion (sum.number_of_holes() == 0);
}
```

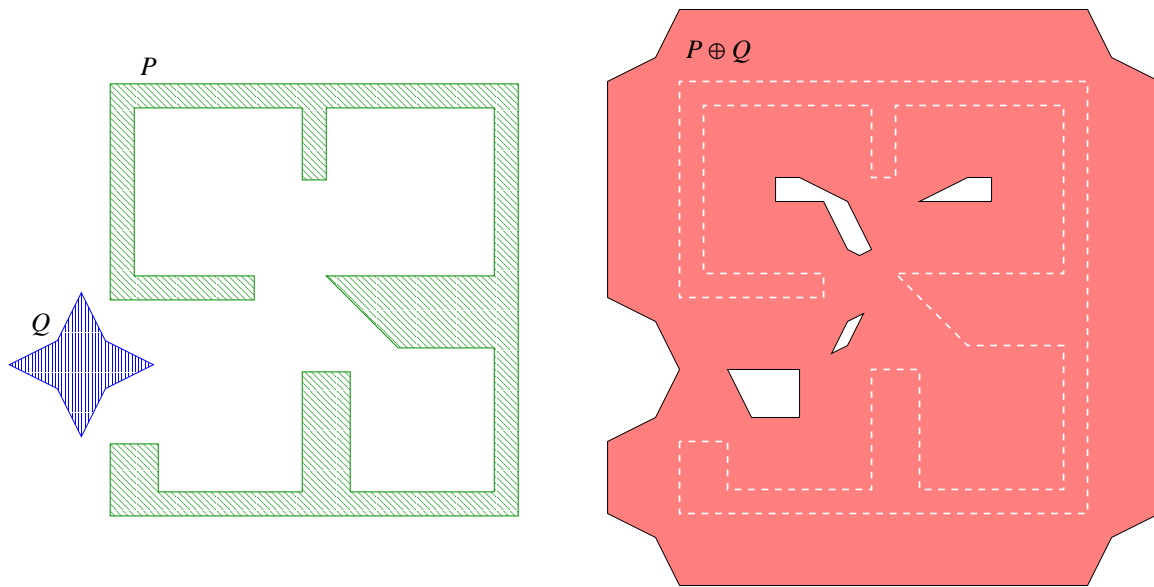

Figure 20.3: Computing the Minkowski sum of two non-convex polygons  $P$  and  $Q$ , as done in the example programs *Minkowski\_sum\_2/sum\_with\_holes.cpp* and *Minkowski\_sum\_2/sum\_by\_decomposition.cpp*.

```
std::cout << "P = "; print_polygon (P);
std::cout << "Q = "; print_polygon (Q);
std::cout << "P (+) Q = "; print_polygon (sum.outer_boundary());

return (0);
}
```

**File:** examples/Minkowski\_sum\_2/sum\_triangles.cpp

In the following program we compute the Minkowski sum of two polygons that are read from an input file. In this case, the sum is not simple and contains four holes, as illustrated in Figure 20.3. Note that this example uses the predefined CGAL kernel with exact constructions. In general, instantiating polygons with this kernel yields the fastest running times for Minkowski-sum computations.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/minkowski_sum_2.h>
#include <iostream>
#include <fstream>

#include "print_utils.h"

struct Kernel : public CGAL::Exact_predicates_exact_constructions_kernel {};

typedef Kernel::Point_2 Point_2;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;

int main ()
```

```

{
    // Open the input file.
    std::ifstream in_file ("rooms_star.dat");

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open the input file." << std::endl;
        return (1);
    }

    // Read the two polygons from the file and compute their Minkowski sum.
    Polygon_2 P, Q;

    in_file >> P >> Q;
    in_file.close();

    // Compute and print the Minkowski sum.
    Polygon_with_holes_2 sum = minkowski_sum_2 (P, Q);

    std::cout << "P (+) Q = "; print_polygon_with_holes (sum);

    return (0);
}

```

**File:** examples/Minkowski\_sum\_2/sum\_with\_holes.cpp

## 20.2.2 Decomposition Strategies

In order to compute Minkowski sums using the decomposition method, it is possible to call the function `minkowski_sum_2 (P, Q, decomp)`, where `decomp` is an instance of a class that models the concept `PolygonConvexDecomposition_2`, namely it should provide a method named `decompose()` that receives a planar polygon and returns a range of convex polygons that represents its convex decomposition.

The Minkowski-sum package includes four models of the concept `PolygonConvexDecomposition_2`. The first three are classes that wrap the decomposition functions included in the Planar Polygon Partitioning package, while the fourth is an implementation of a decomposition algorithm introduced in [AFH02]. The convex decompositions that it creates usually yield efficient running times for Minkowski sum computations:

- The class `Optimal_convex_decomposition<Kernel>` uses the dynamic-programming algorithm of Greene [Gre83] for computing an optimal decomposition of a polygon into a minimal number of convex sub-polygons. The main drawback of this strategy is that it runs in  $O(n^4)$  time and  $O(n^3)$  in the worst case, where  $n$  is the number of vertices in the input polygon.
- The class `Hertel_Mehlhorn_convex_decomposition<Kernel>` implements the approximation algorithm suggested by Hertel and Mehlhorn [HM83], which triangulates the input polygon and proceeds by throwing away unnecessary triangulation edges. This algorithm requires  $O(n)$  time and space and guarantees that the number of sub-polygons it generates is not more than four times the optimum.
- The class `Greene_convex_decomposition<Kernel>` is an implementation of Greene's approximation algorithm [Gre83], which computes a convex decomposition of the polygon based on its partitioning into  $y$ -monotone polygons. This algorithm runs in  $O(n \log n)$  time and  $O(n)$  space, and has the same approximation guarantee as Hertel and Mehlhorn's algorithm.

- The class *Small\_side\_angle\_bisector\_convex\_decomposition*<Kernel> uses a heuristic improvement to the angle-bisector decomposition method suggested by Chazelle and Dobkin [CD85], which runs in  $O(n^2)$  time. It starts by examining each pair of reflex vertices in the input polygon such that the entire interior of the diagonal connecting these vertices is contained in the polygon. Out of all available pairs, the vertices  $p_i$  and  $p_j$  are selected such that the number of reflex vertices from  $p_i$  to  $p_j$  (or from  $p_j$  to  $p_i$ ) is minimal. The polygon is split by the diagonal  $p_i p_j$  and we continue recursively on both resulting sub-polygons. In case it is not possible to eliminate two reflex vertices at once any more, each reflex vertex is eliminated by a diagonal that is closest to the angle bisector emanating from this vertex.

The following example demonstrates the computation of the Minkowski sum of the same input polygons as used in *Minkowski\_sum\_2/sum\_with\_holes.cpp* (as depicted in Figure 20.3), using the small-side angle-bisector decomposition strategy:

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/minkowski_sum_2.h>
#include <CGAL/Small_side_angle_bisector_decomposition_2.h>
#include <iostream>
#include <fstream>

#include "print_utils.h"

struct Kernel : public CGAL::Exact_predicates_exact_constructions_kernel {};

typedef Kernel::Point_2          Point_2;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Polygon_with_holes_2<Kernel> Polygon_with_holes_2;

int main ()
{
    // Open the input file.
    std::ifstream in_file ("rooms_star.dat");

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open the input file." << std::endl;
        return (1);
    }

    // Read the two polygons from the file and compute their Minkowski sum.
    Polygon_2 P, Q;

    in_file >> P >> Q;
    in_file.close();

    // Compute the Minkowski sum using the decomposition approach.
    CGAL::Small_side_angle_bisector_decomposition_2<Kernel> ssab_decomp;

    Polygon_with_holes_2 sum = minkowski_sum_2 (P, Q, ssab_decomp);

    std::cout << "P (+) Q = "; print_polygon_with_holes (sum);

    return (0);
}
```

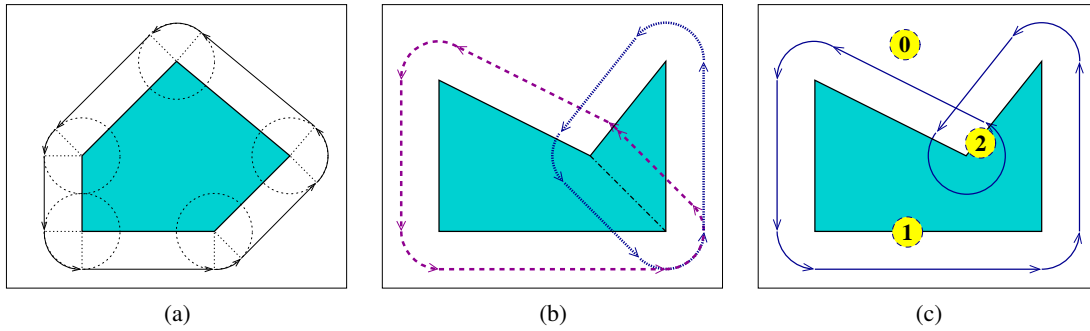

Figure 20.4: (a) Offsetting a convex polygon. (b) Computing the offset of a non-convex polygon by decomposing it to convex sub-polygons. (c) Offsetting a non-convex polygon by computing its convolution with a disc. The convolution cycle induces an arrangement with three faces, whose winding numbers are shown enclosed in dashed circles.

**File:** examples/Minkowski\_sum\_2/sum\_by\_decomposition.cpp

## 20.3 Offsetting a Polygon

The operation of computing the Minkowski sum  $P \oplus B_r$  of a polygon  $P$  with  $B_r$ , a disc of radius  $r$  centered at the origin, is widely known as *offsetting* the polygon  $P$  by a radius  $r$ .

Let  $P = (p_0, \dots, p_{n-1})$  be the polygon vertices, ordered in a counterclockwise orientation around its interior. If  $P$  is a convex polygon the offset is easily computed by shifting each polygon edge by  $r$  away from the polygon, namely to the right side of the edge. As a result we obtain a collection of  $n$  disconnected *offset edges*. Each pair of adjacent offset edges, induced by  $p_{i-1}p_i$  and  $p_ip_{i+1}$ , are connected by a circular arc of radius  $r$ , whose supporting circle is centered at  $p_i$ . The angle that defines such a circular arc equals  $180^\circ - \angle(p_{i-1}, p_i, p_{i+1})$ ; see Figure 20.4(a) for an illustration. The running time of this simple process is of course linear with respect to the size of the polygon.

If  $P$  is not convex, its offset can be obtained by decomposing it to convex sub-polygons  $P_1, \dots, P_m$  such that  $\bigcup_{i=1}^m P_i = P$ , computing the offset of each sub-polygon and finally calculating the union of these sub-offsets (see Figure 20.4(b)). However, as was the case with the Minkowski sum of a pair of polygons, here it is also more efficient to compute the *convolution cycle* of the polygon with the disc  $B_r$ ,<sup>4</sup> which can be constructed by applying the process described in the previous paragraph. The only difference is that a circular arc induced by a reflex vertex  $p_i$  is defined by an angle  $540^\circ - \angle(p_{i-1}, p_i, p_{i+1})$ ; see Figure 20.4(c) for an illustration. We finally compute the winding numbers of the faces of the arrangement induced by the convolution cycle to obtain the offset polygon.

### 20.3.1 Approximating the Offset with a Guaranteed Error-Bound

Let us assume that we are given a counterclockwise-oriented polygon  $P = (p_0, \dots, p_{n-1})$ , whose vertices all have rational coordinates (i.e., for each vertex  $p_i = (x_i, y_i)$  we have  $x_i, y_i \in \mathbb{Q}$ , and we wish to compute its Minkowski sum with a disc of radius  $r$ , where  $r$  is also a rational number. The boundary of this sum is comprised of line segments and circular arcs, where:

<sup>4</sup>As the disc is convex, it is guaranteed that the convolution curve is comprised of a single cycle.

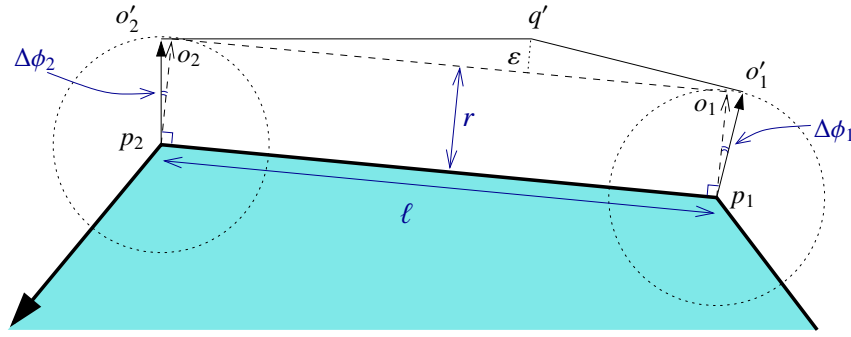

Figure 20.5: Approximating the offset edge  $o_1o_2$  induced by the polygon edge  $p_1p_2$  by two line segments  $o'_1q'$  and  $q'o'_2$ .

- Each circular arc is supported by a circle of radius  $r$  centered at one of the polygon vertices. The equation of this circle is  $(x - x_i)^2 + (y - y_i)^2 = r^2$ , and has only rational coefficients.
- Each line segment is supported by a line parallel to one of the polygon edges  $p_i p_{i+1}$ , which lies at distance  $r$  from this edge. If we denote the supporting line of  $p_i p_{i+1}$  by  $ax + by + c = 0$ , where  $a, b, c \in \mathbb{Q}$ , then the offset edge is supported by the line  $ax + by + (c + \ell \cdot r) = 0$ , where  $\ell$  is the length of the edge  $p_i p_{i+1}$  and is in general *not* a rational number. The line segments that comprise the offset boundaries therefore cannot be represented as segments of lines with rational coefficients. We mention that the locus of all points that lie at distance  $r$  from the line  $ax + by + c = 0$  is given by:

$$\frac{(ax + by + c)^2}{a^2 + b^2} = r^2.$$

Thus, the linear offset edges are segments of curves of an algebraic curve of degree 2 (a conic curve) with rational coefficients. This curve is actually a pair of the parallel lines  $ax + by + (c \pm \ell \cdot r) = 0$ . In Section 20.3.2 we use this representation to construct the offset polygon in an exact manner using the traits class for conic arcs.

The class-template *Gps\_circle\_segment\_traits\_2*<Kernel>, included in the Boolean Set-Operations package is used for representing general polygons whose edges are circular arcs or line segments, and for applying set operations (e.g. intersection, union, etc.) on such general polygon. It should be instantiated with a geometric kernel that employs exact rational arithmetic, such that the curves that comprise the polygon edges should be arcs of circles with rational coefficients or segments of lines with rational coefficients. As in our case the line segments do not satisfy this requirement, we apply a simple approximation scheme, such that each irrational line segment is approximated by two rational segments:

1. Consider the example depicted in Figure 20.5, where the exact offset edge  $o_1o_2$  is obtained by shifting the polygon edge  $p_1p_2$  by a vector whose length is  $r$  that form an angle  $\phi$  with the  $x$ -axis. We select two points  $o'_1$  and  $o'_2$  with rational coordinates on the two circles centered at  $p_1$  and  $p_2$ , respectively. These points are selected such that if we denote the angle that the vector  $\mathbf{p}_j \mathbf{o}_j$  forms with the  $x$ -axis by  $\phi'_j$  (for  $j = 1, 2$ ), we have  $\phi'_1 < \phi < \phi'_2$ .
2. We construct two tangents to the two circles at  $o'_1$  and  $o'_2$ , respectively. The tangent lines have rational coefficients.
3. We compute the intersection point of the two tangents, denoted  $q'$ . The two line segments  $o'_1q'$  and  $q'o'_2$  approximate the original offset edge  $o_1o_2$ .

The function *approximated\_offset\_2* ( $P, r, \epsilon$ ) accepts a polygon  $P$ , an offset radius  $r$  and  $\epsilon > 0$ . It constructs an approximation for the offset of  $P$  by the radius  $r$  using the procedure explained above. Furthermore, it

Figure 20.6: The offset computation performed by the example programs *Minkowski\_sum\_2/approx\_offset.cpp* and *Minkowski\_sum\_2/exact\_offset.cpp*. The input polygon is shaded and the boundary of its offset is drawn in a thick black line.

is guaranteed that the approximation error, namely the distance of the point  $q'$  from  $o_1o_2$  is bounded by  $\epsilon$ . Using this function, we are capable of working with the *Gps\_circle\_segment\_traits\_2<Kernel>* class, which considerably speeds up the (approximate) construction of the offset polygon and the application of set operations on such polygons. The function returns an object of the nested type *Gps\_circle\_segment\_traits\_2<Kernel>::Polygon\_with\_holes\_2* representing the approximated offset polygon (recall that if  $P$  is not convex, its offset may not be simple and may contain holes, whose boundary is also comprised of line segments and circular arcs).

The following example demonstrates the construction of an approximated offset of a non-convex polygon, as depicted in Figure 20.6. Note that we use a geometric kernel parameterized with a filtered rational number-type. Using filtering considerably speeds up the construction of the offset.

```
#include "ms_rational_nt.h"
#include <CGAL/Lazy_exact_nt.h>
#include <CGAL/Cartesian.h>
#include <CGAL/approximated_offset_2.h>
#include <CGAL/offset_polygon_2.h>
#include <CGAL/Timer.h>
#include <iostream>

typedef CGAL::Lazy_exact_nt<Number_type>          Lazy_exact_nt;

struct Kernel : public CGAL::Cartesian<Lazy_exact_nt> {};
typedef CGAL::Polygon_2<Kernel>                    Polygon_2;

typedef CGAL::Gps_circle_segment_traits_2<Kernel>  Gps_traits_2;
typedef Gps_traits_2::Polygon_2                    Offset_polygon_2;
typedef Gps_traits_2::Polygon_with_holes_2          Offset_polygon_with_holes_2;

int main ()
{
    // Open the input file.
```

```

std::ifstream    in_file ("spiked.dat");

if (! in_file.is_open())
{
    std::cerr << "Failed to open the input file." << std::endl;
    return (1);
}

// Read the input polygon.
Polygon_2        P;

in_file >> P;
in_file.close();

std::cout << "Read an input polygon with "
            << P.size() << " vertices." << std::endl;

// Approximate the offset polygon.
const Number_type    radius = 5;
const double          err_bound = 0.00001;
Offset_polygon_with_holes_2    offset;
CGAL::Timer           timer;

timer.start();
offset = approximated_offset_2 (P, radius, err_bound);
timer.stop();

std::cout << "The offset polygon has "
            << offset.outer_boundary().size() << " vertices, "
            << offset.number_of_holes() << " holes." << std::endl;
std::cout << "Offset computation took "
            << timer.time() << " seconds." << std::endl;
return (0);
}

```

**File:** examples/Minkowski\_sum\_2/approx\_offset.cpp

### 20.3.2 Computing the Exact Offset

As we previously mentioned, it is possible to represent offset polygons in an exact manner, if we treat their edges as arcs of conic curves with rational coefficients. The function *offset\_polygon\_2* ( $P, r, traits$ ) computes the offset of the polygon  $P$  by a rational radius  $r$  in an exact manner. The *traits* parameter should be an instance of an arrangement-traits class that is capable of handling conic arcs in an exact manner; using the *Arr\_conic\_traits\_2* class with the number types provided by the CORE library is the preferred option. The function returns an object of the nested type *Gps\_traits\_2*<*ArrConicTraits*>::*Polygons\_with\_holes\_2* (see the documentation of the Boolean Set-Operations package for more details on the traits-class adapter *Gps\_traits\_2*), which represented the exact offset polygon.

The following example demonstrates the construction of the offset of the same polygon that serves as an input for the example program *Minkowski\_sum\_2/approx\_offset.cpp*, presented in the previous subsection (see also Figure 20.6). Note that the resulting polygon is smaller than the one generated by the approximated-offset function (recall that each irrational line segment in this case is approximated by two rational line segments), but the offset computation is considerably slower:

```

#include <CGAL/basic.h>

#ifdef CGAL_USE_CORE
#include <iostream>
int main ()
{
    std::cout << "Sorry, this example needs CORE ..." << std::endl;
    return (0);
}
#else

#include <CGAL/Cartesian.h>
#include <CGAL/CORE_algebraic_number_traits.h>
#include <CGAL/Arr_conic_traits_2.h>
#include <CGAL/offset_polygon_2.h>
#include <CGAL/Timer.h>
#include <iostream>

typedef CGAL::CORE_algebraic_number_traits      Nt_traits;
typedef Nt_traits::Rational                    Rational;
typedef Nt_traits::Algebraic                   Algebraic;

struct Rat_kernel : public CGAL::Cartesian<Rational> {};
struct Alg_kernel : public CGAL::Cartesian<Algebraic> {};
struct Conic_traits_2 : public CGAL::Arr_conic_traits_2<Rat_kernel,
                                                         Alg_kernel,
                                                         Nt_traits> {};

typedef CGAL::Polygon_2<Rat_kernel>            Polygon_2;

typedef CGAL::Gps_traits_2<Conic_traits_2>     Gps_traits_2;
typedef Gps_traits_2::Polygon_2                Offset_polygon_2;
typedef Gps_traits_2::Polygon_with_holes_2     Offset_polygon_with_holes_2;

int main ()
{
    // Open the input file.
    std::ifstream    in_file ("spiked.dat");

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open the input file." << std::endl;
        return (1);
    }

    // Read the input polygon.
    Polygon_2        P;

    in_file >> P;
    in_file.close();

    std::cout << "Read an input polygon with "
               << P.size() << " vertices." << std::endl;

```

```

// Compute the offset polygon.
Conic_traits_2          traits;
const Rational          radius = 5;
Offset_polygon_with_holes_2 offset;
CGAL::Timer             timer;

timer.start();
offset = offset_polygon_2 (P, radius, traits);
timer.stop();

std::cout << "The offset polygon has "
            << offset.outer_boundary().size() << " vertices, "
            << offset.number_of_holes() << " holes." << std::endl;
std::cout << "Offset computation took "
            << timer.time() << " seconds." << std::endl;
return (0);
}

#endif

```

**File:** examples/Minkowski\_sum\_2/exact\_offset.cpp

— advanced —

Both functions *approximated\_offset\_2()* and *offset\_polygon\_2()* also have overloaded versions that accept a decomposition strategy and use the polygon-decomposition approach to compute (or approximate) the offset. These functions are less efficient than their counterparts that employ the convolution approach, and are only included in the package for the sake of completeness.

— advanced —

### 20.3.3 Computing Inner Offsets

An operation closely related to the offset computation, is obtaining the *inner offset* of a polygon, or *insetting* it by a given radius. The inset of a polygon  $P$  with radius  $r$  is the set of points inside  $P$  whose distance from the polygon boundary, denoted  $\partial P$ , is at least  $r$  — namely:  $\{p \in P \mid \text{dist}(p, \partial P) \geq r\}$ . Note that the resulting set may not be connected in case  $P$  is a non-convex polygon that has some narrow components, and thus is characterized by a (possibly empty) set of polygons whose edges are line segments and circular arcs of radius  $r$ .

The offset can be computed using the convolution method if we traverse the polygon in a *clockwise* orientation (and not in *counterclockwise* orientation, as done in case of offsetting a polygon). As in case of the offset functions, the Minkowski-sum package contains two functions for inseting a simple polygon:

The function *approximated\_inset\_2* ( $P, r, \epsilon, oi$ ) accepts a polygon  $P$ , an inset radius  $r$  and  $\epsilon > 0$ . It constructs an approximation for the inset of  $P$  by the radius  $r$ , with the approximation error bounded by  $\epsilon$ . The function returns its output via the output iterator  $oi$ , whose value-type must be *Gps\_circle\_segment\_traits\_2*<*Kernel*>::*Polygon\_2* representing the polygons that approximates the inset polygon.

```

#include "ms_rational_nt.h"
#include <CGAL/Lazy_exact_nt.h>
#include <CGAL/Cartesian.h>
#include <CGAL/approximated_offset_2.h>

```

```

#include <CGAL/offset_polygon_2.h>
#include <CGAL/Timer.h>
#include <iostream>

typedef CGAL::Lazy_exact_nt<Number_type>          Lazy_exact_nt;

struct Kernel : public CGAL::Cartesian<Lazy_exact_nt> {};
typedef CGAL::Polygon_2<Kernel>                   Polygon_2;

typedef CGAL::Gps_circle_segment_traits_2<Kernel> Gps_traits_2;
typedef Gps_traits_2::Polygon_2                   Offset_polygon_2;
typedef Gps_traits_2::Polygon_with_holes_2         Offset_polygon_with_holes_2;

int main ()
{
    // Open the input file.
    std::ifstream  in_file ("tight.dat");

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open the input file." << std::endl;
        return (1);
    }

    // Read the input polygon.
    Polygon_2      P;

    in_file >> P;
    in_file.close();

    std::cout << "Read an input polygon with "
                << P.size() << " vertices." << std::endl;

    // Approximate the offset polygon.
    const Number_type      radius = 1;
    const double           err_bound = 0.00001;
    std::list<Offset_polygon_2> inset_polygons;
    std::list<Offset_polygon_2>::iterator iit;
    CGAL::Timer            timer;

    timer.start();
    approximated_inset_2 (P, radius, err_bound,
                        std::back_inserter (inset_polygons));
    timer.stop();

    std::cout << "The inset comprises "
                << inset_polygons.size() << " polygon(s)." << std::endl;
    for (iit = inset_polygons.begin(); iit != inset_polygons.end(); ++iit)
    {
        std::cout << "    Polygon with "
                    << iit->size() << " vertices." << std::endl;
    }
    std::cout << "Inset computation took "
                << timer.time() << " seconds." << std::endl;
}

```

```

    return (0);
}

```

**File:** examples/Minkowski\_sum\_2/approx\_inset.cpp

Similarly, the function *inset\_polygon\_2* ( $P$ ,  $r$ , *traits*, *oi*) computes the exact inset of  $P$  with radius  $r$ , and returns its output via the given output iterator *oi*. The *traits* parameter should be an instance of an arrangement-traits class that is capable of handling conic arcs in an exact manner, whereas *oi*'s value-type must be *Gps\_traits\_2*<*ArrConicTraits*>::*Polygons\_2*.

#endif

```

**File:** examples/Minkowski\_sum\_2/exact\_inset.cpp

—advanced—

Unlike the offset functions, there are no overloaded versions of the inset functions that use convex polygon decomposition to compute insets, as this method cannot be easily generalized for inset computations.

—advanced—

In this context let us mention that there exist overloaded versions of the functions *approximated\_offset\_2* ( $P$ ,  $r$ ,  $eps$ ) and *offset\_polygon\_2* ( $P$ ,  $r$ ,  $traits$ ) that accept a *polygon with holes*  $P$  and computed its offset. This offset is obtain by taking the outer offset of  $P$ 's outer boundary, and computing the inner offsets of  $P$ 's holes. The former polygon defines the output boundary of  $P \oplus B_r$ , and the latter define the holes within the result.

## Acknowledgements

Andreas Fabri and Laurent Rineau helped tracing and solving several bugs in the approximated offset function. They have also suggested a few algorithmic improvements that made their way into version 3.4, yielding a faster approximation scheme.

# Planar Minkowski Sums

## Reference Manual

*Ron Wein*

### Introduction

This package consist of functions for computing the Minkowski sum of two polygons in the plane. Namely, given two polygons  $P, Q \in \mathbb{R}^2$  it computes  $P \oplus Q = \{p + q \mid p \in P, q \in Q\}$ .

In addition, the package also includes functions for offsetting a polygon, namely computing its Minkowski sum with a disc of a given radius, and for insetting a polygon (namely computing its inner offset). It is possible to compute the exact representation of the offset (or the inset), or to approximate it with guaranteed error bounds, in order to speed up the computation time.

## CGAL::minkowski\_sum\_2

```
#include <CGAL/minkowski_sum_2.h>
```

```
template<class Kernel, class Container>
Polygon_with_holes_2<Kernel, Container>
```

```
minkowski_sum_2( Polygon_2<Kernel, Container> P,
                 Polygon_2<Kernel, Container> Q)
```

Computes the Minkowski sum  $P \oplus Q$  of the two given polygons. The function computes the convolution cycles of the two polygons and extract the regions having positive winding number with respect to these cycles. This method work very efficiently, regardless of whether  $P$  and  $Q$  are convex or non-convex. Note that as the input polygons may not be convex, their Minkowski sum may not be a simple polygon. The result is therefore represented as a polygon with holes.

*Precondition:* Both  $P$  and  $Q$  are simple polygons.

```
template<class Kernel, class Container, class DecompositionStrategy>
Polygon_with_holes_2<Kernel, Container>
```

```
minkowski_sum_2( Polygon_2<Kernel, Container> P,
                 Polygon_2<Kernel, Container> Q,
                 DecompositionStrategy decomp)
```

Computes the Minkowski sum  $P \oplus Q$  of the two given polygons. If the input polygons  $P$  and  $Q$  are not convex, the function decomposes them into convex sub-polygons  $P_1, \dots, P_k$  and  $Q_1, \dots, Q_\ell$  and computes the union of pairwise sub-sums (namely  $\bigcup_{i,j} (P_i \oplus Q_j)$ ). The decomposition is performed using the given decomposition strategy *decomp*, which must be an instance of a class that models the concept *PolygonConvexDecomposition*. Note that as the input polygons may not be convex, their Minkowski sum may not be a simple polygon. The result is therefore represented as a polygon with holes.

*Precondition:* Both  $P$  and  $Q$  are simple polygons.

## CGAL::approximated\_offset\_2

```
#include <CGAL/approximated_offset_2.h>
```

```
template<class Kernel, class Container>
```

```
typename Gps_circle_segment_traits_2<Kernel>::Polygon_with_holes_2
```

```
    approximated_offset_2( Polygon_2<Kernel, Container> P,
                          typename Kernel::FT r,
                          double eps)
```

Provides a guaranteed approximation of the offset of the given polygon  $P$  by a given radius  $r$  — namely, the function computes the Minkowski sum  $P \oplus B_r$ , where  $B_r$  is a disc of radius  $r$  centered at the origin. The function actually outputs a set  $S$  that contains the Minkowski sum, such that the approximation error is bounded by  $eps$ . Note that as the input polygon may not be convex, its offset may not be a simple polygon. The result is therefore represented as a polygon with holes, whose edges are either line segments or circular arcs.

*Precondition:*  $P$  is a simple polygon.

```
template<class Kernel, class Container>
```

```
typename Gps_circle_segment_traits_2<Kernel>::Polygon_with_holes_2
```

```
    approximated_offset_2( Polygon_with_holes_2<Kernel, Container> wh,
                          typename Kernel::FT r,
                          double eps)
```

Provides a guaranteed approximation of offset the given polygon with holes  $pwh$  by a given radius  $r$ , such that the approximation error is bounded by  $eps$ . It does so by offsetting outer boundary of  $pwh$  and insetting its holes. The result is represented as a generalized polygon with holes, such that the edges of the polygon correspond to line segment and circular arcs.

*Precondition:*  $pwh$  is *not* unbounded (it has a valid outer boundary).

```
template<class Kernel, class Container, class DecompositionStrategy>
```

```
typename Gps_circle_segment_traits_2<Kernel>::Polygon_with_holes_2
```

```
    approximated_offset_2( Polygon_2<Kernel, Container> P,
                          typename Kernel::FT r,
                          double eps,
```

*DecompositionStrategy decomp)*

Provides a guaranteed approximation of the offset of the given polygon  $P$  by a radius  $r$ , as described above. If the input polygon  $P$  is not convex, the function decomposes it into convex sub-polygons  $P_1, \dots, P_k$  and computes the union of the sub-offsets (namely  $\bigcup_i (P_i \oplus B_r)$ ). The decomposition is performed using the given decomposition strategy *decomp*, which must be an instance of a class that models the concept *PolygonConvexDecomposition*.

*Precondition:*  $P$  is a simple polygon.

## CGAL::approximated\_inset\_2

```
#include <CGAL/approximated_offset_2.h>
```

```
template<class Kernel, class Container, class OutputIterator>
OutputIterator      approximated_inset_2( Polygon_2<Kernel, Container> pgn,
                                         typename Kernel::FT r,
                                         double eps,
                                         OutputIterator oi)
```

Provides a guaranteed approximation of the inset, or inner offset, of the given polygon  $P$  by a given radius  $r$ . Namely, the function computes the set of points inside the polygon whose distance from  $P$ 's boundary is at least  $r$ :  $\{p \in P \mid \text{dist}(p, \partial P) \geq r\}$ , with the approximation error bounded by  $\text{eps}$ . Note that as the input polygon may not be convex, its inset may comprise several disconnected components. The result is therefore represented as a sequence of generalized polygons, whose edges are either line segments or circular arcs. The output sequence is returned via the output iterator  $oi$ , whose value-type must be `Gps_circle_segment_traits_2<Kernel>::Polygon_2`.

*Precondition:*  $P$  is a simple polygon.

## CGAL::offset\_polygon\_2

```
#include <CGAL/offset_polygon_2.h>
```

```
template<class ConicTraits, class Container>
typename Gps_traits_2<ConicTraits>::Polygon_with_holes_2
```

```
offset_polygon_2( Polygon_2<typename ConicTraits::Rat_kernel, Container> P,
                 typename ConicTraits::Rat_kernel::FT r,
                 ConicTraits traits)
```

Computes the offset of the given polygon  $P$  by a given radius  $r$  — namely, the function computes the Minkowski sum  $P \oplus B_r$ , where  $B_r$  is a disc of radius  $r$  centered at the origin. Note that as the input polygon may not be convex, its offset may not be a simple polygon. The result is therefore represented as a generalized polygon with holes, such that the edges of the polygon correspond to line segments and circular arcs, both are special types of conic arcs, as represented by the *traits* class.

*Precondition:*  $P$  is a simple polygon.

```
template<class ConicTraits, class Container>
typename Gps_traits_2<ConicTraits>::Polygon_with_holes_2
```

```
offset_polygon_2( Polygon_with_holes_2<typename ConicTraits::Rat_kernel, Con-
tainer> pwh,
                 typename ConicTraits::Rat_kernel::FT r,
                 ConicTraits traits)
```

Computes the offset of the given polygon with holes  $pwh$  by a given radius  $r$ . It does so by offsetting outer boundary of  $pwh$  and insetting its holes. The result is represented as a generalized polygon with holes, such that the edges of the polygon correspond to line segments and circular arcs, both are special types of conic arcs, as represented by the *traits* class.

*Precondition:*  $pwh$  is *not* unbounded (it has a valid outer boundary).

```
template<class ConicTraits, class Container, class DecompositionStrategy>
typename Gps_traits_2<ConicTraits>::Polygon_with_holes_2
```

```
offset_polygon_2( Polygon_2<typename ConicTraits::Rat_kernel, Container> P,
                 typename ConicTraits::Rat_kernel::FT r,
                 DecompositionStrategy decomp,
```

*ConicTraits traits)*

Computes the exact representation of the offset of the given polygon  $P$  by a radius  $r$ , as described above. If  $P$  is not convex, the function decomposes it into convex sub-polygons  $P_1, \dots, P_k$  and computes the union of sub-offsets (namely  $\bigcup_i (P_i \oplus B_r)$ ). The decomposition is performed using the given decomposition strategy *decomp*, which must be an instance of a class that models the concept *PolygonConvexDecomposition*.

*Precondition:*  $P$  is a simple polygon.

## CGAL::inset\_polygon\_2

```
#include <CGAL/offset_polygon_2.h>
```

```
template<class ConicTraits, class Container, class OutputIterator>
OutputIterator      inset_polygon_2( Polygon_2<typename ConicTraits::Rat_kernel, Container> P,
                                   typename ConicTraits::Rat_kernel::FT r,
                                   ConicTraits traits,
                                   OutputIterator oi)
```

Computes the inset, or inner offset, of the given polygon  $P$  by a given radius  $r$  — namely, the function computes the set of points inside the polygon whose distance from  $P$ 's boundary is at least  $r$ :  $\{p \in P \mid \text{dist}(p, \partial P) \geq r\}$ . Note that as the input polygon may not be convex, its inset may comprise several disconnected components. The result is therefore represented as a sequence of generalized polygons, such that the edges of each polygon correspond to line segments and circular arcs, both are special types of conic arcs, as represented by the *traits* class. The output sequence is returned via the output iterator *oi*, whose value-type must be *Gps\_traits\_2*<*ConicTraits*>::*Polygon\_2*.

*Precondition:*  $P$  is a simple polygon.

## PolygonConvexDecomposition\_2

A model of the PolygonConvexDecomposition\_2 concept is capable of decomposing an input polygon  $P$  into a set of convex sub-polygons  $P_1, \dots, P_k$ , such that  $\cup_{i=1}^k P_k = P$ .

### Types

<i>PolygonConvexDecomposition_2::Kernel</i>	the geometric kernel type.
<i>PolygonConvexDecomposition_2::Point_2</i>	the point type, used to represent polygon vertices.
<i>PolygonConvexDecomposition_2::Polygon_2</i>	the polygon type.

### Creation

<i>PolygonConvexDecomposition_2 decomp;</i>	default constructor.
---	----------------------

### Operations

```
template <class OutputIterator>
OutputIterator      decomp( Polygon_2 P, OutputIterator oi)
```

decomposes the input polygon  $P$  into convex sub-polygons, and writes them to the output iterator  $oi$ . The value-type of the output iterator must be *Polygon\_2*. The function returns a past-the-end iterator for the convex sub-polygons.

### Has Models

*Small\_side\_angle\_bisector\_decomposition\_2*<Kernel,Container> (page [1473](#))  
*Optimal\_convex\_decomposition\_2*<Kernel,Container> (page [1474](#))

## CGAL::Small\_side\_angle\_bisector\_decomposition\_2<Kernel,Container>

### Definition

The *Small\_side\_angle\_bisector\_decomposition\_2*<*Kernel*,*Container*> class implements a simple yet efficient heuristic for decomposing an input polygon into convex sub-polygons. It is based on the algorithm suggested by Flato and Halperin [FH00], but without introducing Steiner points. The algorithm operates in two major steps. In the first step, it tries to subdivide the polygon by connect two reflex vertices with an edge. When this is not possible any more, it eliminates the reflex vertices one by one by connecting them to other convex vertices, such that the new edge best approximates the angle bisector of the reflex vertex. The algorithm operates in  $O(n^2)$  time and takes  $O(n)$  space at the worst case, where  $n$  is the size of the input polygon.

The *Polygon\_2* type defined by the class is simply *Polygon\_2*<*Kernel*,*Container*>. The *Container* parameter is by default *std::vector<typename Kernel::Point\_2>*.

```
#include <CGAL/Small_side_angle_bisector_decomposition_2.h>
```

### Is Model for the Concepts

*PolygonConvexDecomposition\_2*

## CGAL::Optimal\_convex\_decomposition\_2<Kernel,Container>

### Definition

The *Optimal\_convex\_decomposition\_2*<*Kernel*,*Container*> class provides an implementation of Greene's dynamic programming algorithm for optimal decomposition of a polygon into convex sub-polygons [Gre83]. Note that this algorithm requires  $O(n^4)$  time and  $O(n^3)$  space in the worst case, where  $n$  is the size of the input polygon.

The *Polygon\_2* type defined by the class is simply *Polygon\_2*<*Kernel*,*Container*>. The *Container* parameter is by default `std::vector<typename Kernel::Point_2>`.

```
#include <CGAL/Polygon_convex_decomposition_2.h>
```

*PolygonConvexDecomposition\_2*

### See Also

CGAL::optimal\_convex\_partition\_2 (page 1346)

## CGAL::Hertel\_Mehlhorn\_convex\_decomposition\_2<Kernel,Container>

### Definition

The *Hertel\_Mehlhorn\_convex\_decomposition\_2*<*Kernel*,*Container*> class implements the approximation algorithm of Hertel and Mehlhorn for decomposing a polygon into convex sub-polygons [HM83]. This algorithm constructs a triangulation of the input polygon and proceeds by removing unnecessary triangulation edges. Given the triangulation, the algorithm requires  $O(n)$  time and space to construct a convex decomposition (where  $n$  is the size of the input polygon), whose size is guaranteed to be no more than four times the size of the optimal decomposition.

The *Polygon\_2* type defined by the class is simply *Polygon\_2*<*Kernel*,*Container*>. The *Container* parameter is by default *std::vector<typename Kernel::Point\_2>*.

```
#include <CGAL/Polygon_convex_decomposition_2.h>
```

### 21.1 Introduction

Polyhedral surfaces in three dimensions are composed of vertices, edges, facets and an incidence relationship on them. The organization beneath is a halfedge data structure, which restricts the class of representable surfaces to orientable 2-manifolds – with and without boundary. If the surface is closed we call it a *polyhedron*, for example, see the above model of a hammerhead:

The polyhedral surface is realized as a container class that manages vertices, halfedges, facets with their incidences, and that maintains the combinatorial integrity of them. It is based on the highly flexible design of the halfedge data structure, see the introduction in Chapter 22 and [Ket99]. However, the polyhedral surface can be used and understood without knowing the underlying design. Some of the examples in this chapter introduce also gradually into first applications of this flexibility.

## 21.2 Definition

A polyhedral surface  $CGAL::Polyhedron_3<PolyhedronTraits_3>$  in three dimensions consists of vertices  $V$ , edges  $E$ , facets  $F$  and an incidence relation on them. Each edge is represented by two halfedges with opposite orientations. The incidences stored with a halfedge are illustrated in the following figure:

Vertices represent points in space. Edges are straight line segments between two endpoints. Facets are planar polygons without holes. Facets are defined by the circular sequence of halfedges along their boundary. The polyhedral surface itself can have holes (with at least two facets surrounding it since a single facet cannot have a hole). The halfedges along the boundary of a hole are called *border halfedges* and have no incident facet. An edge is a *border edge* if one of its halfedges is a border halfedge. A surface is *closed* if it contains no border halfedges. A closed surface is a boundary representation for polyhedra in three dimensions. The convention is that the halfedges are oriented counterclockwise around facets as seen from the outside of the polyhedron. An implication is that the halfedges are oriented clockwise around the vertices. The notion of the solid side of a facet as defined by the halfedge orientation extends to polyhedral surfaces with border edges although they do not define a closed object. If normal vectors are considered for the facets, normals point outwards (following the right-hand rule).

The strict definition can be found in [Ket99]. One implication of this definition is that the polyhedral surface is always an orientable and oriented 2-manifold with border edges, i.e., the neighborhood of each point on the polyhedral surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with boundary can join. Another implication is that the smallest representable surface avoiding self intersections is a triangle (for polyhedral surfaces with border edges) or a tetrahedron (for polyhedra). Boundary representations of orientable 2-manifolds are closed under Euler operations. They are extended with operations that create or close holes in the surface.

Other intersections besides the incidence relation are not allowed. However, this is not automatically verified in the operations, since self intersections are not easy to check efficiently.  $CGAL::Polyhedron_3<PolyhedronTraits_3>$  does only maintain the combinatorial integrity of the polyhedral surface (using Euler operations) and does not consider the coordinates of the points or any other geometric information.

$CGAL::Polyhedron_3<PolyhedronTraits_3>$  can represent polyhedral surfaces as well as polyhedra. The interface is designed in such a way that it is easy to ignore border edges and work only with polyhedra.

## 21.3 Example Programs

The polyhedral surface is based on the highly flexible design of the halfedge data structure. Examples for this flexibility can be found in Section 21.5 and in Section 22.3. This design is not a prerequisite to understand the following examples. See also the Section 21.6 below for some advanced examples.

### 21.3.1 First Example Using Defaults

The first example instantiates a polyhedron using a kernel as traits class. It creates a tetrahedron and stores the reference to one of its halfedges in a *Halfedge\_handle*. Handles, also known as *trivial iterators*, are used to keep references to halfedges, vertices, or facets for future use. There is also a *Halfedge\_iterator* type for enumerating halfedges. Such an iterator type can be used wherever a handle is required. Respective *Halfedge\_const\_handle* and *Halfedge\_const\_iterator* for a constant polyhedron and similar handles and iterators with *Vertex\_* and *Facet\_* prefix are provided too.

The example continues with a test if the halfedge actually refers to a tetrahedron. This test checks the connected component referred to by the halfedge *h* and not the polyhedral surface as a whole. This example works only on the combinatorial level of a polyhedral surface. The next example adds the geometry.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef Polyhedron::Halfedge_handle Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h) )
        return 0;
    return 1;
}
```

**File:** examples/Polyhedron/polyhedron\_prog\_simple.cpp

### 21.3.2 Example with Geometry in Vertices

We add geometry to our construction of a tetrahedron. Four points are passed as arguments to the construction. This example demonstrates in addition the use of the vertex iterator and the access to the point in the vertices. Note the natural access notation *v->point()*. Similarly, all information stored in a vertex, halfedge, and facet can be accessed with a member function given a handle or iterator. For example, given a halfedge handle *h* we can write *h->next()* to get a halfedge handle to the next halfedge, *h->opposite()* for the opposite halfedge, *h->vertex()* for the incident vertex at the tip of *h*, and so on. The output of the program will be “1 0 0\n0 1 0\n0 0 1\n0 0 0\n”.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double> Kernel;
typedef Kernel::Point_3 Point_3;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef Polyhedron::Vertex_iterator Vertex_iterator;

int main() {
```

```

Point_3 p( 1.0, 0.0, 0.0);
Point_3 q( 0.0, 1.0, 0.0);
Point_3 r( 0.0, 0.0, 1.0);
Point_3 s( 0.0, 0.0, 0.0);

Polyhedron P;
P.make_tetrahedron( p, q, r, s);
CGAL::set_ascii_mode( std::cout);
for ( Vertex_iterator v = P.vertices_begin(); v != P.vertices_end(); ++v)
    std::cout << v->point() << std::endl;
return 0;
}

```

**File:** examples/Polyhedron/polyhedron\_prog\_tetra.cpp

The polyhedron offers a point iterator for convenience. The above `for` loop simplifies to a single statement by using `std::copy` and the ostream iterator adaptor.

```

std::copy( P.points_begin(), P.points_end(),
           std::ostream_iterator<Point_3>(std::cout, "\n"));

```

### 21.3.3 Example for Affine Transformation

An affine transformation  $A$  can act as a functor transforming points and a point iterator is conveniently defined for polyhedral surfaces. So, assuming we want only the point coordinates of a polyhedron  $P$  transformed, `std::transform` does the job in a single line.

```

std::transform( P.points_begin(), P.points_end(), P.points_begin(), A);

```

### 21.3.4 Example Computing Plane Equations

The polyhedral surface has already provisions to store a plane equation for each facet. However, it does not provide a function to compute plane equations.

This example computes the plane equations of a polyhedral surface. The actual computation is implemented in the `compute_plane_equations` function. Depending on the arithmetic (exact/inexact) and the shape of the facets (convex/non-convex) different methods are useful. We assume here strictly convex facets and exact arithmetic. In our example a homogeneous representation with `int` coordinates is sufficient. The four plane equations of the tetrahedron are the output of the program.

```

#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>
#include <algorithm>

```

```

struct Plane_equation {
    template <class Facet>

```

```

typename Facet::Plane_3 operator()( Facet& f) {
    typename Facet::Halfedge_handle h = f.halfedge();
    typedef typename Facet::Plane_3 Plane;
    return Plane( h->vertex()->point(),
                  h->next()->vertex()->point(),
                  h->next()->next()->vertex()->point());
}
};

typedef CGAL::Homogeneous<int>      Kernel;
typedef Kernel::Point_3             Point_3;
typedef Kernel::Plane_3             Plane_3;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;

int main() {
    Point_3 p( 1, 0, 0);
    Point_3 q( 0, 1, 0);
    Point_3 r( 0, 0, 1);
    Point_3 s( 0, 0, 0);
    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    std::transform( P.facets_begin(), P.facets_end(), P.planes_begin(),
                    Plane_equation());
    CGAL::set_pretty_mode( std::cout);
    std::copy( P.planes_begin(), P.planes_end(),
               std::ostream_iterator<Plane_3>( std::cout, "\n"));
    return 0;
}

```

**File:** examples/Polyhedron/polyhedron\_prog\_planes.cpp

### 21.3.5 Example with a Vector Instead of a List Representation

The polyhedron class template has actually four parameters, where three of them have default values. Using the default values explicitly in our examples above for three parameter—ignoring the fourth parameter, which would be a standard allocator for container class— the definition of a polyhedron looks like:

```

typedef CGAL::Polyhedron_3< Traits,
                           CGAL::Polyhedron_items_3,
                           CGAL::HalfedgeDS_default> Polyhedron;

```

The *CGAL::Polyhedron\_items\_3* class contains the types used for vertices, edges, and facets. The *CGAL::HalfedgeDS\_default* class defines the halfedge data structure used, which is a list-based representation in this case. An alternative is a vector-based representation. Using a vector provides random access for the elements in the polyhedral surface and is more space efficient, but elements cannot be deleted arbitrarily. Using a list allows arbitrary deletions, but provides only bidirectional iterators and is less space efficient. The following example creates again a tetrahedron with given points, but in a vector-based representation.

The vector-based representation resizes automatically if the reserved capacity is not sufficient for the new items created. Upon resizing all handles, iterators, and circulators become invalid. Their correct update in the halfedge

data structure is costly, thus it is advisable to reserve enough space in advance as indicated with the alternative constructor in the comment.

—advanced—

Note that the polyhedron and not the underlying halfedge data structure triggers the resize operation, since the resize operation requires some preconditions, such as valid incidences, to be fulfilled that only the polyhedron can guarantee.

—advanced—

```
#include <CGAL/Cartesian.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Cartesian<double>          Kernel;
typedef Kernel::Point_3                  Point_3;
typedef CGAL::Polyhedron_3< Kernel,
                             CGAL::Polyhedron_items_3,
                             CGAL::HalfedgeDS_vector> Polyhedron;

int main() {
    Point_3 p( 1.0, 0.0, 0.0);
    Point_3 q( 0.0, 1.0, 0.0);
    Point_3 r( 0.0, 0.0, 1.0);
    Point_3 s( 0.0, 0.0, 0.0);

    Polyhedron P;    // alternative constructor: Polyhedron P(4,12,4);
    P.make_tetrahedron( p, q, r, s);
    CGAL::set_ascii_mode( std::cout);
    std::copy( P.points_begin(), P.points_end(),
               std::ostream_iterator<Point_3>( std::cout, "\n"));
    return 0;
}
```

**File:** examples/Polyhedron/polyhedron\_prog\_vector.cpp

### 21.3.6 Example with Circulator Writing Object File Format (OFF)

We create a tetrahedron and write it to *std::cout* using the Object File Format (OFF) [Phi96]. This example makes use of STL algorithms (*std::copy*, *std::distance*), STL *std::ostream\_iterator*, and CGAL circulators. The polyhedral surface provides convenient circulators for the counterclockwise circular sequence of halfedges around a facet and the clockwise circular sequence of halfedges around a vertex.

However, the computation of the vertex index in the inner loop of the facet output is not advisable with the *std::distance* function, since it takes linear time for non random-access iterators, which leads to quadratic run-time. For better runtime the vertex index needs to be stored separately and computed once before writing the facets. It can be stored, for example, in the vertex itself or in a hash-structure. See also the following Section 21.4 for file I/O.

```
#include <CGAL/Simple_cartesian.h>
```

```

#include <CGAL/Polyhedron_3.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double>          Kernel;
typedef Kernel::Point_3                          Point_3;
typedef CGAL::Polyhedron_3<Kernel>              Polyhedron;
typedef Polyhedron::Facet_iterator               Facet_iterator;
typedef Polyhedron::Halfedge_around_facet_circulator Halfedge_facet_circulator;

int main() {
    Point_3 p( 0.0, 0.0, 0.0);
    Point_3 q( 1.0, 0.0, 0.0);
    Point_3 r( 0.0, 1.0, 0.0);
    Point_3 s( 0.0, 0.0, 1.0);

    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);

    // Write polyhedron in Object File Format (OFF).
    CGAL::set_ascii_mode( std::cout);
    std::cout << "OFF" << std::endl << P.size_of_vertices() << ' '
                << P.size_of_facets() << " 0" << std::endl;
    std::copy( P.points_begin(), P.points_end(),
                std::ostream_iterator<Point_3>( std::cout, "\n"));
    for ( Facet_iterator i = P.facets_begin(); i != P.facets_end(); ++i) {
        Halfedge_facet_circulator j = i->facet_begin();
        // Facets in polyhedral surfaces are at least triangles.
        CGAL_assertion( CGAL::circulator_size(j) >= 3);
        std::cout << CGAL::circulator_size(j) << ' ';
        do {
            std::cout << ' ' << std::distance(P.vertices_begin(), j->vertex());
        } while ( ++j != i->facet_begin());
        std::cout << std::endl;
    }
    return 0;
}

```

**File:** examples/Polyhedron/polyhedron\_prog\_off.cpp

### 21.3.7 Example Using Euler Operators to Build a Cube

Euler operators are the natural way of modifying polyhedral surfaces. We provide a set of operations for polyhedra: *split\_facet()*, *join\_facet()*, *split\_vertex()*, *join\_vertex()*, *split\_loop()*, and *join\_loop()*. We add further convenient operators, such as *split\_edge()*. However, they could be implemented using the six operators above. Furthermore, we provide more operators to work with polyhedral surfaces with border edges, for example, creating and deleting holes. We refer to the references manual for the definition and illustrative figures of the Euler operators.

The following example implements a function that appends a unit cube to a polyhedral surface. To keep track of the different steps during the creation of the cube a sequence of sketches might help with labels for the different handles that occur in the program code. The following Figure shows six selected steps from the creation sequence. These steps are also marked in the program code.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>

template <class Poly>
typename Poly::Halfedge_handle make_cube_3( Poly& P ) {
    // appends a cube of size [0,1]^3 to the polyhedron P.
    CGAL_precondition( P.is_valid() );
    typedef typename Poly::Point_3      Point;
    typedef typename Poly::Halfedge_handle Halfedge_handle;
    Halfedge_handle h = P.make_tetrahedron( Point( 1, 0, 0),
                                           Point( 0, 0, 1),
                                           Point( 0, 0, 0),
                                           Point( 0, 1, 0));

    Halfedge_handle g = h->next()->opposite()->next();           // Fig. (a)
    P.split_edge( h->next() );
    P.split_edge( g->next() );
    P.split_edge( g );                                           // Fig. (b)
    h->next()->vertex()->point()      = Point( 1, 0, 1);
    g->next()->vertex()->point()      = Point( 0, 1, 1);
    g->opposite()->vertex()->point() = Point( 1, 1, 0);           // Fig. (c)
    Halfedge_handle f = P.split_facet( g->next(),
                                      g->next()->next()->next() ); // Fig. (d)

    Halfedge_handle e = P.split_edge( f );
    e->vertex()->point() = Point( 1, 1, 1);                       // Fig. (e)
    P.split_facet( e, f->next()->next() );                         // Fig. (f)
    CGAL_postcondition( P.is_valid() );
    return h;
}

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
typedef Polyhedron::Halfedge_handle         Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = make_cube_3( P );
    return ( P.is_tetrahedron(h) ? 1 : 0 );
}

```

**File:** examples/Polyhedron/polyhedron\_prog\_cube.cpp

## 21.4 File I/O

Simple file I/O for polyhedral surfaces is already provided in the library. The file I/O considers so far only the topology of the surface and its point coordinates. It ignores a possible plane equation or any user-added attributes, such as color.

The default file format supported in CGAL for output as well as for input is the Object File Format, OFF, with file extension `.off`, which is also understood by Geomview [Phi96]. For OFF an ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, `set_ascii_mode` and `set_binary_mode` respectively. The modifier `set_pretty_mode` can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments. Both, ASCII and binary format, can be read independent of the stream setting. Since this file format is the default format, `istream` operators are provided for it.

```
#include <CGAL/IO/Polyhedron_istream.h>
```

```
template <class PolyhedronTraits_3>
ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
istream& in >> CGAL::Polyhedron_3<PolyhedronTraits_3>& P
```

Additional formats supported for writing are OpenInventor (`.iv`) [Wer94], VRML 1.0 and 2.0 (`.wrl`) [BPP95, VRM96, HW96], and Wavefront Advanced Visualizer object format (`.obj`). Another convenient output function writes a polyhedral surface to a Geomview process spawned from the CGAL program. These output functions are provided as stream operators, now acting on the stream type of the respective format.

```
#include <CGAL/IO/Polyhedron_inventor_ostream.h>
#include <CGAL/IO/Polyhedron_VRML_1_ostream.h>
#include <CGAL/IO/Polyhedron_VRML_2_ostream.h>
#include <CGAL/IO/Polyhedron_geomview_ostream.h>
```

```
template <class PolyhedronTraits_3>
Inventor_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
VRML_1_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
VRML_2_ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

```
template <class PolyhedronTraits_3>
Geomview_stream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

All these file formats have in common that they represent a surface as a set of facets. Each facet is a list of indices pointing into a set of vertices. Vertices are represented as coordinate triples. The file I/O for polyhedral surfaces `CGAL::Polyhedron_3` imposes certain restrictions on these formats. They must represent a permissible polyhedral surface, e.g., a 2-manifold and no isolated vertices, see Section 21.1.

Some example programs around the different file formats are provided in the distribution under `examples/Polyhedron_IO/` and `demo/Polyhedron_IO/`. We show an example converting OFF input into VRML 1.0 output.

```
// examples/Polyhedron_IO/polyhedron2vrl.cpp
// -----

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/IO/Polyhedron_VRML_1_ostream.h>
#include <iostream>

typedef CGAL::Simple_cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;

int main() {
    Polyhedron P;
    std::cin >> P;
    CGAL::VRML_1_ostream out( std::cout);
    out << P;
    return ( std::cin && std::cout) ? 0 : 1;
}
```

## 21.5 Extending Vertices, Halfedges, and Facets

In Section [21.3.5](#) we have seen how to change the default list representation

```
typedef CGAL::Polyhedron_3< Traits,
                           CGAL::Polyhedron_items_3,
                           CGAL::HalfedgeDS_default> Polyhedron;
```

to a vector based representation of the underlying halfedge data structure. Now we want to look a bit closer at the second template argument, `Polyhedron_items_3`, that specifies what kind of vertex, halfedge, and facet is used. The implementation of `Polyhedron_items_3` looks a bit involved with nested wrapper class templates. But ignoring this technicality, what remains are three local typedefs that define the `Vertex`, the `Halfedge`, and the `Face` for the polyhedral surface. Note that we use here `Face` instead of `facet`. `Face` is the term used for the halfedge data structure. Only the top layer of the polyhedral surface gives alias names renaming `face` to `facet`.

```
class Polyhedron_items_3 {
public:
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_3 Point;
        typedef CGAL::HalfedgeDS_vertex_base<Refs, CGAL::Tag_true, Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_base<Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef typename Traits::Plane_3 Plane;
        typedef CGAL::HalfedgeDS_face_base<Refs, CGAL::Tag_true, Plane> Face;
    };
};
```

```
};
};
```

If we look up in the reference manual the definitions of the three classes used in the typedefs, we will see the confirmation that the default polyhedron uses all supported incidences, a point in the vertex class, and a plane equation in the face class. Note how the wrapper class provides two template parameters, `Refs`, which we discuss a bit later, and `Traits`, which is the geometric traits class used by the polyhedral surface and which provides us here with the types for the point and the plane equation.

Using this example code we can write our own items class. Instead, we illustrate an easier way if we only want to exchange one class. We use a simpler face without the plane equation but with a color attribute added. To simplify the creation of a vertex, halfedge, or face class, it is always recommended to derive from one of the given base classes. Even if the base class would contain no data it would provide convenient type definitions. So, we derive from the base class, repeat the mandatory constructors if necessary—which is not the case for faces but would be for vertices—and add the color attribute.

```
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};
```

The new items class is derived from the old items class and the wrapper containing the face typedef gets overridden. Note that the name of the wrapper and its template parameters are fixed. They cannot be changed even if, as in this example, a template parameter is not used.

```
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};
```

When we use our new items class with the polyhedral surface, our new face class is used in the halfedge data structure and the color attribute is available in the type `Polyhedron::Facet`. However, `Polyhedron::Facet` is not the same type as our local face typedef for `My_face`, but it is derived therefrom. Thus, everything that we put in the local face type except constructors is then available in the `Polyhedron::Facet` type. For more details, see the [Chapter 22](#) on the halfedge data structure design.

Pulling all pieces together, the full example program illustrates how easy the color attribute can be accessed once it is defined.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Polyhedron_3.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};
```

```
// An items type using my face.
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel, My_items> Polyhedron;
typedef Polyhedron::Halfedge_handle         Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    h->facet()->color = CGAL::RED;
    return 0;
}
```

**File:** examples/Polyhedron/polyhedron\_prog\_color.cpp

We come back to the first template parameter, `Refs`, of the wrapper classes. This parameter provides us with local types that allow us to make further references between vertices, halfedges, and facets, which have not already been prepared for in the current design. These local types are `Vertex_handle`, `Halfedge_handle`, `Face_handle`, and there respective `..._const_handle`. We add now a new vertex reference to a face class as follows. Encapsulation and access functions could be added for a more thorough design, but we omit that here for the sake of brevity. The integration of the face class with the items class works as illustrated above.

```
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    typedef typename Refs::Vertex_handle Vertex_handle;
    Vertex_handle vertex_ref;
};
```

More advanced examples can be found in the Section [22.3](#) illustrating further the design of the halfedge data structure.

## 21.6 Advanced Example Programs

### 21.6.1 Example Creating a Subdivision Surface

This program reads a polyhedral surface from the standard input and writes a refined polyhedral surface to the standard output. Input and output are in the Object File Format, OFF, with the common file extension `.off`, which is also understood by Geomview [\[Phi96\]](#).

The refinement is a single step of the  $\sqrt{3}$ -scheme for creating a subdivision surface [\[Kob00\]](#). Each step subdivides a facet into triangles around a new center vertex, smoothes the position of the old vertices, and flips the old edges. The program is organized along this outline. In each of these parts, the program efficiently uses the

knowledge that the newly created vertices, edges, and facets have been added to the end of the sequences. The program needs additional processing memory only for the smoothing step of the old vertices.

The above figure shows three example objects, each subdivided four times. The initial object for the left sequence is the closed surface of three unit cubes glued together to a corner. The example program shown here can handle only closed surfaces, but the extended example `examples/Polyhedron/polyhedron_prog_subdiv_with_boundary.cpp` handles surfaces with boundary. So, the middle sequence starts with the same surface where one of the facets has been removed. The boundary subdivides to a nice circle. The third sequence creates a sharp edge using a trick in the object presentation. The sharp edge is actually a hole whose vertex coordinates pinch the hole shut to form an edge. The example directory `examples/Polyhedron/` contains the OFF files used here.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <iostream>
#include <algorithm>
#include <vector>
#include <cmath>

typedef CGAL::Cartesian<double>          Kernel;
typedef Kernel::Vector_3                 Vector;
typedef Kernel::Point_3                  Point;
typedef CGAL::Polyhedron_3<Kernel>       Polyhedron;

typedef Polyhedron::Vertex                Vertex;
typedef Polyhedron::Vertex_iterator       Vertex_iterator;
typedef Polyhedron::Halfedge_handle       Halfedge_handle;
typedef Polyhedron::Edge_iterator         Edge_iterator;
typedef Polyhedron::Facet_iterator        Facet_iterator;
typedef Polyhedron::Halfedge_around_vertex_const_circulator HV_circulator;
typedef Polyhedron::Halfedge_around_facet_circulator         HF_circulator;
```

```

void create_center_vertex( Polyhedron& P, Facet_iterator f) {
    Vector vec( 0.0, 0.0, 0.0);
    std::size_t order = 0;
    HF_circulator h = f->facet_begin();
    do {
        vec = vec + ( h->vertex()->point() - CGAL::ORIGIN);
        ++ order;
    } while ( ++h != f->facet_begin());
    CGAL_assertion( order >= 3); // guaranteed by definition of polyhedron
    Point center = CGAL::ORIGIN + (vec / order);
    Halfedge_handle new_center = P.create_center_vertex( f->halfedge());
    new_center->vertex()->point() = center;
}

struct Smooth_old_vertex {
    Point operator()( const Vertex& v) const {
        CGAL_precondition((CGAL::circulator_size( v.vertex_begin()) & 1) == 0);
        std::size_t degree = CGAL::circulator_size( v.vertex_begin()) / 2;
        double alpha = ( 4.0 - 2.0 * std::cos( 2.0 * CGAL_PI / degree)) / 9.0;
        Vector vec = (v.point() - CGAL::ORIGIN) * ( 1.0 - alpha);
        HV_circulator h = v.vertex_begin();
        do {
            vec = vec + ( h->opposite()->vertex()->point() - CGAL::ORIGIN)
                * alpha / degree;
            ++ h;
            CGAL_assertion( h != v.vertex_begin()); // even degree guaranteed
            ++ h;
        } while ( h != v.vertex_begin());
        return (CGAL::ORIGIN + vec);
    }
};

void flip_edge( Polyhedron& P, Halfedge_handle e) {
    Halfedge_handle h = e->next();
    P.join_facet( e);
    P.split_facet( h, h->next()->next());
}

void subdiv( Polyhedron& P) {
    if ( P.size_of_facets() == 0)
        return;
    // We use that new vertices/halfedges/facets are appended at the end.
    std::size_t nv = P.size_of_vertices();
    Vertex_iterator last_v = P.vertices_end();
    -- last_v; // the last of the old vertices
    Edge_iterator last_e = P.edges_end();
    -- last_e; // the last of the old edges
    Facet_iterator last_f = P.facets_end();
    -- last_f; // the last of the old facets

    Facet_iterator f = P.facets_begin(); // create new center vertices
    do {
        create_center_vertex( P, f);
    } while ( f++ != last_f);
}

```

```

std::vector<Point> pts; // smooth the old vertices
pts.reserve( nv); // get intermediate space for the new points
++ last_v; // make it the past-the-end position again
std::transform( P.vertices_begin(), last_v, std::back_inserter( pts),
               Smooth_old_vertex());
std::copy( pts.begin(), pts.end(), P.points_begin());

Edge_iterator e = P.edges_begin(); // flip the old edges
++ last_e; // make it the past-the-end position again
while ( e != last_e) {
    Halfedge_handle h = e;
    ++e; // careful, incr. before flip since flip destroys current edge
    flip_edge( P, h);
};
CGAL_postcondition( P.is_valid());
}

int main() {
    Polyhedron P;
    std::cin >> P;
    P.normalize_border();
    if ( P.size_of_border_edges() != 0) {
        std::cerr << "The input object has border edges. Cannot subdivide."
                   << std::endl;
        std::exit(1);
    }
    subdiv( P);
    std::cout << P;
    return 0;
}

```

## 21.6.2 Example Using the Incremental Builder and Modifier Mechanism

A utility class *CGAL::Polyhedron\_incremental\_builder\_3* helps in creating polyhedral surfaces from a list of points followed by a list of facets that are represented as indices into the point list. This is particularly useful for implementing file reader for common file formats. It is used here to create a triangle.

A modifier mechanism allows to access the internal representation of the polyhedral surface, i.e., the halfedge data structure, in a controlled manner. A modifier is basically a callback mechanism using a function object. When called, the function object receives the internal halfedge data structure as a parameter and can modify it. On return, the polyhedron can check the halfedge data structure for validity. Such a modifier object must always return with a halfedge data structure that is a valid polyhedral surface. The validity check is implemented as an expensive postcondition at the end of the *delegate()* member function, i.e., it is not called by default, only when expensive checks are activated.

In this example, *Build\_triangle* is such a function object derived from *CGAL::Modifier\_base<HalfedgeDS>*. The *delegate()* member function of the polyhedron accepts this function object and calls its *operator()* with a reference to its internally used halfedge data structure. Thus, this member function in *Build\_triangle* can create the triangle in the halfedge data structure.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_incremental_builder_3.h>
#include <CGAL/Polyhedron_3.h>

// A modifier creating a triangle with the incremental builder.
template <class HDS>
class Build_triangle : public CGAL::Modifier_base<HDS> {
public:
    Build_triangle() {}
    void operator()( HDS& hds) {
        // Postcondition: 'hds' is a valid polyhedral surface.
        CGAL::Polyhedron_incremental_builder_3<HDS> B( hds, true);
        B.begin_surface( 3, 1, 6);
        typedef typename HDS::Vertex    Vertex;
        typedef typename Vertex::Point Point;
        B.add_vertex( Point( 0, 0, 0));
        B.add_vertex( Point( 1, 0, 0));
        B.add_vertex( Point( 0, 1, 0));
        B.begin_facet();
        B.add_vertex_to_facet( 0);
        B.add_vertex_to_facet( 1);
        B.add_vertex_to_facet( 2);
        B.end_facet();
        B.end_surface();
    }
};

typedef CGAL::Simple_cartesian<double>    Kernel;
typedef CGAL::Polyhedron_3<Kernel>        Polyhedron;
typedef Polyhedron::HalfedgeDS            HalfedgeDS;

int main() {
    Polyhedron P;
    Build_triangle<HalfedgeDS> triangle;
    P.delegate( triangle);
    CGAL_assertion( P.is_triangle( P.halfedges_begin()));
    return 0;
}

```

# 3D Polyhedral Surfaces

## Reference Manual

Lutz Kettner

Polyhedral surfaces in three dimensions are composed of vertices, edges, facets and an incidence relationship on them. The organization beneath is a halfedge data structure, which restricts the class of representable surfaces to orientable 2-manifolds – with and without boundary. If the surface is closed we call it a *polyhedron*.

The polyhedral surface is realized as a container class managing vertices, halfedges, facets with their incidences, and maintaining the combinatorial integrity of them. Its local types for the vertices, halfedges and facets are documented separately. A default traits class, a default items class and an incremental builder conclude the references. The polyhedral surface is based on the highly flexible design of the halfedge data structure, see the reference for *HalfedgeDS* in Chapter 22.3.7 or [Ket99], but the default instantiation of the polyhedral surface can be used without knowing the halfedge data structure.

## CGAL::Polyhedron\_3<Traits>

### Definition

A polyhedral surface *Polyhedron\_3<Traits>* consists of vertices  $V$ , edges  $E$ , facets  $F$  and an incidence relation on them. Each edge is represented by two halfedges with opposite orientations.

Vertices represent points in 3d-space. Edges are straight line segments between two endpoints. Facets are planar polygons without holes defined by the circular sequence of halfedges along their boundary. The polyhedral surface itself can have holes. The halfedges along the boundary of a hole are called *border halfedges* and have no incident facet. An edge is a *border edge* if one of its halfedges is a border halfedge. A surface is *closed* if it contains no border halfedges. A closed surface is a boundary representation for polyhedra in three dimensions. The convention is that the halfedges are oriented counterclockwise around facets as seen from the outside of the polyhedron. An implication is that the halfedges are oriented clockwise around the vertices. The notion of the solid side of a facet as defined by the halfedge orientation extends to polyhedral surfaces with border edges although they do not define a closed object. If normal vectors are considered for the facets, normals point outwards (following the right hand rule).

The strict definition can be found in [Ket99]. One implication of this definition is that the polyhedral surface is always an orientable and oriented 2-manifold with border edges, i.e., the neighborhood of each point on the polyhedral surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with boundary can join. Another implication is that the smallest representable surface is a triangle (for polyhedral surfaces with border edges) or a tetrahedron (for polyhedra). Boundary representations of orientable 2-manifolds are closed under Euler operations. They are extended with operations that create or close holes in the surface.

Other intersections besides the incidence relation are not allowed, although they are not automatically handled, since self intersections are not easy to check efficiently. *Polyhedron\_3<Traits>* does only maintain the combinatorial integrity of the polyhedral surface (using Euler operations) and does not consider the coordinates of the points or any geometric information.

The class *Polyhedron\_3<Traits>* can represent polyhedral surfaces as well as polyhedra. The interface is designed in such a way that it is easy to ignore border edges and work only with polyhedra.

The sequence of edges can be ordered in the data structure on request such that the sequence starts with the non-border edges and ends with the border edges. Border edges are then itself ordered such that the halfedge which is incident to the facet comes first and the halfedge incident to the hole comes thereafter. This normalization step counts simultaneously the number of border edges. This number is zero if and only if the surface is a closed polyhedron. Note that this class does not maintain this counter nor the halfedge order during further modifications. There is no automatic caching done for auxiliary information.

```
#include <CGAL/Polyhedron_3.h>
```

## Parameters

The full template declaration of *Polyhedron\_3*<*Traits*> states four template parameters:

```
template < class PolyhedronTraits_3,
           class PolyhedronItems_3 = CGAL::Polyhedron_items_3,
           template < class T, class I> class HalfedgeDS = CGAL::HalfedgeDS_default,
           class Alloc = CGAL_ALLOCATOR(int)>
class Polyhedron_3;
```

The first parameter requires a model of the *PolyhedronTraits\_3* concept as argument, for example *CGAL::Polyhedron\_traits\_3*. The second parameter expects a model of the *PolyhedronItems\_3* concept. By default, the class *CGAL::Polyhedron\_items\_3* is preselected. The third parameter is a class template. A model of the *HalfedgeDS* concept is expected. By default, the class *CGAL::HalfedgeDS\_default* is preselected, which is a list based implementation of the halfedge data structure. The fourth parameter *Alloc* requires a standard allocator for STL container classes. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally. A default is provided with the macro *CGAL\_ALLOCATOR(int)* from the *<CGAL/memory.h>* header file.

## Types

<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Traits</i>	traits class selected for <i>PolyhedronTraits_3</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Items</i>	items class selected for <i>PolyhedronItems_3</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>HalfedgeDS</i>	instantiated halfedge data structure.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>size_type</i>	size type of <i>HalfedgeDS</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>difference_type</i>	difference type of <i>HalfedgeDS</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>iterator_category</i>	iterator category of <i>HalfedgeDS</i> for all iterators.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>circulator_category</i>	circulator category of all circulators; bidirectional category if the <i>Items::Halfedge</i> provides a <i>prev()</i> member function, otherwise forward category.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>allocator_type</i>	allocator type <i>Alloc</i> .
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Vertex</i>	vertex type.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Halfedge</i>	halfedge type.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Facet</i>	facet type.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Point_3</i>	point stored in vertices.
<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Plane_3</i>	plane equation stored in facets (if supported).

The following handles, iterators, and circulators have appropriate non-mutable counterparts, i.e., *const\_handle*, *const\_iterator*, and *const\_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Halfedge\_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well. For convenience, the *Edge\_iterator* enumerates every other halfedge. It is based on the *CGAL::N\_step\_adaptor* class. For convenience, the *Point\_iterator* enumerates all points in the polyhedral surface in the same order as the *Vertex\_iterator*, but with the value type *Point*. It is based on the *CGAL::Iterator\_project* adaptor. Similarly, a *Plane\_iterator* is provided.

<i>Polyhedron_3</i> < <i>Traits</i> >:: <i>Vertex_handle</i>	handle to vertex.
--	-------------------

<i>Polyhedron_3&lt;Traits&gt;:: Halfedge_handle</i>	handle to halfedge.
<i>Polyhedron_3&lt;Traits&gt;:: Facet_handle</i>	handle to facet.
<i>Polyhedron_3&lt;Traits&gt;:: Vertex_iterator</i>	iterator over all vertices.
<i>Polyhedron_3&lt;Traits&gt;:: Halfedge_iterator</i>	iterator over all halfedges.
<i>Polyhedron_3&lt;Traits&gt;:: Facet_iterator</i>	iterator over all facets.
<i>Polyhedron_3&lt;Traits&gt;:: Halfedge_around_vertex_circulator</i>	
	circulator of halfedges around a vertex (cw).
<i>Polyhedron_3&lt;Traits&gt;:: Halfedge_around_facet_circulator</i>	
	circulator of halfedges around a facet (ccw).
<i>Polyhedron_3&lt;Traits&gt;:: Edge_iterator</i>	iterator over all edges (every other halfedge).
<i>Polyhedron_3&lt;Traits&gt;:: Point_iterator</i>	iterator over all points.
<i>Polyhedron_3&lt;Traits&gt;:: Plane_iterator</i>	iterator over all plane equations.

— advanced —

## Types for Tagging Optional Features

The following types are equal to either *CGAL::Tag\_true* or *CGAL::Tag\_false*, depending on whether the named feature is supported or not.

<i>Polyhedron_3&lt;Traits&gt;:: Supports_vertex_halfedge</i>	<i>Vertex::halfedge()</i> .
<i>Polyhedron_3&lt;Traits&gt;:: Supports_vertex_point</i>	<i>Vertex::point()</i> .
<i>Polyhedron_3&lt;Traits&gt;:: Supports_halfedge_prev</i>	<i>Halfedge::prev()</i> .
<i>Polyhedron_3&lt;Traits&gt;:: Supports_halfedge_vertex</i>	<i>Halfedge::vertex()</i> .
<i>Polyhedron_3&lt;Traits&gt;:: Supports_halfedge_facet</i>	<i>Halfedge::facet()</i> .
<i>Polyhedron_3&lt;Traits&gt;:: Supports_facet_halfedge</i>	<i>Facet::halfedge()</i> .
<i>Polyhedron_3&lt;Traits&gt;:: Supports_facet_plane</i>	<i>Facet::plane()</i> .
<i>Polyhedron_3&lt;Traits&gt;:: Supports_removal</i>	supports removal of individual elements.

— advanced —

## Creation

*Polyhedron\_3<Traits> P( Traits traits = Traits());*

*Polyhedron\_3<Traits> P( size\_type v, size\_type h, size\_type f, Traits traits = Traits());*

a polyhedron *P* with storage reserved for *v* vertices, *h* halfedges, and *f* facets.  
The reservation sizes are a hint for optimizing storage allocation.

*void P.reserve( size\_type v, size\_type h, size\_type f)*

reserve storage for *v* vertices, *h* halfedges, and *f* facets. The reservation sizes are a hint for optimizing storage allocation. If the *capacity* is already greater than the requested size nothing happens. If the *capacity* changes all iterators and circulators might invalidate.

<i>Halfedge_handle</i>	<i>P.make_tetrahedron()</i>	a tetrahedron is added to the polyhedral surface. Returns a halfedge of the tetrahedron.
<i>Halfedge_handle</i>	<i>P.make_tetrahedron( Point p1, Point p2, Point p3, Point p4)</i>	a tetrahedron is added to the polyhedral surface with its vertices initialized to $p_1, p_2, p_3$ , and $p_4$ . Returns that halfedge of the tetrahedron which incident vertex is initialized to $p_1$ . The incident vertex of the next halfedge is $p_2$ , and the vertex thereafter is $p_3$ . The remaining fourth vertex is initialized to $p_4$ .
<i>Halfedge_handle</i>	<i>P.make_triangle()</i>	a triangle with border edges is added to the polyhedral surface. Returns a non-border halfedge of the triangle.
<i>Halfedge_handle</i>	<i>P.make_triangle( Point p1, Point p2, Point p3)</i>	a triangle with border edges is added to the polyhedral surface with its vertices initialized to $p_1, p_2$ , and $p_3$ . Returns that non-border halfedge of the triangle which incident vertex is initialized to $p_1$ . The incident vertex of the next halfedge is $p_2$ , and the vertex thereafter is $p_3$ .

### Access Member Functions

<i>bool</i>	<i>P.empty()</i>	returns true if $P$ is empty.
<i>size_type</i>	<i>P.size_of_vertices()</i>	number of vertices.
<i>size_type</i>	<i>P.size_of_halfedges()</i>	number of halfedges (incl. border halfedges).
<i>size_type</i>	<i>P.size_of_facets()</i>	number of facets.
<i>size_type</i>	<i>P.capacity_of_vertices()</i>	space reserved for vertices.
<i>size_type</i>	<i>P.capacity_of_halfedges()</i>	space reserved for halfedges.
<i>size_type</i>	<i>P.capacity_of_facets()</i>	space reserved for facets.
<i>size_t</i>	<i>P.bytes()</i>	bytes used for the polyhedron.
<i>size_t</i>	<i>P.bytes_reserved()</i>	bytes reserved for the polyhedron.
<i>allocator_type</i>	<i>P.get_allocator()</i>	allocator object.
<i>Vertex_iterator</i>	<i>P.vertices_begin()</i>	iterator over all vertices.
<i>Vertex_iterator</i>	<i>P.vertices_end()</i>	past-the-end iterator.
<i>Halfedge_iterator</i>	<i>P.halfedges_begin()</i>	iterator over all halfedges.
<i>Halfedge_iterator</i>	<i>P.halfedges_end()</i>	past-the-end iterator.
<i>Facet_iterator</i>	<i>P.facets_begin()</i>	iterator over all facets (excluding holes).
<i>Facet_iterator</i>	<i>P.facets_end()</i>	past-the-end iterator.
<i>Edge_iterator</i>	<i>P.edges_begin()</i>	iterator over all edges.
<i>Edge_iterator</i>	<i>P.edges_end()</i>	past-the-end iterator.

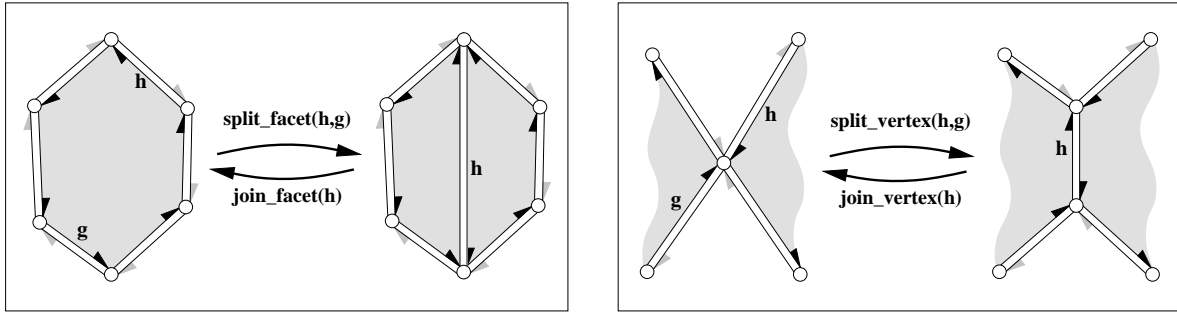

<i>Point_iterator</i>	<i>P.points_begin()</i>	iterator over all points.
<i>Point_iterator</i>	<i>P.points_end()</i>	past-the-end iterator.
<i>Plane_iterator</i>	<i>P.planes_begin()</i>	iterator over all plane equations.
<i>Plane_iterator</i>	<i>P.planes_end()</i>	past-the-end iterator.
<i>Traits</i>	<i>P.traits()</i>	returns the traits class.

### Combinatorial Predicates

<i>bool</i>	<i>P.is_closed()</i>	returns <i>true</i> if there are no border edges.
<i>bool</i>	<i>P.is_pure_bivalent()</i>	returns <i>true</i> if all vertices have exactly two incident edges.
<i>bool</i>	<i>P.is_pure_trivalent()</i>	returns <i>true</i> if all vertices have exactly three incident edges.
<i>bool</i>	<i>P.is_pure_triangle()</i>	returns <i>true</i> if all facets are triangles.
<i>bool</i>	<i>P.is_pure_quad()</i>	returns <i>true</i> if all facets are quadrilaterals.
<i>bool</i>	<i>P.is_triangle( Halfedge_const_handle h)</i>	<i>true</i> iff the connected component denoted by <i>h</i> is a triangle.
<i>bool</i>	<i>P.is_tetrahedron( Halfedge_const_handle h)</i>	<i>true</i> iff the connected component denoted by <i>h</i> is a tetrahedron.

### Euler Operators (Combinatorial Modifications)

The following Euler operations modify consistently the combinatorial structure of the polyhedral surface. The geometry remains unchanged.

*Halfedge\_handle* *P.split\_facet( Halfedge\_handle h, Halfedge\_handle g)*

splits the facet incident to *h* and *g* into two facets with a new diagonal between the two vertices denoted by *h* and *g* respectively. The second (new) facet is a copy of the first facet. Returns *h->next()* after the operation, i.e., the new diagonal. The new face is to the right of the new diagonal, the old face is to the left. The time is proportional to the distance from *h* to *g* around the facet.

*Precondition:* *h* and *g* are incident to the same facet. *h*  $\neq$  *g* (no loops). *h->next()*  $\neq$  *g* and *g->next()*  $\neq$  *h* (no multi-edges).

*Halfedge\_handle* *P.join\_facet( Halfedge\_handle h)*

joins the two facets incident to *h*. The facet incident to *h->opposite()* gets removed. Both facets might be holes. Returns the predecessor of *h* around the facet. The invariant *join\_facet( split\_facet( h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the size of the facet removed and the time to compute *h->prev()*.

*Precondition:* The degree of both vertices incident to *h* is at least three (no antennas).

*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

*Halfedge\_handle* *P.split\_vertex( Halfedge\_handle h, Halfedge\_handle g)*

splits the vertex incident to *h* and *g* into two vertices, the old vertex remains and a new copy is created, and connects them with a new edge. Let *hnew* be *h->next()->opposite()* after the split, i.e., a halfedge of the new edge. The split regroups the halfedges around the two vertices. The halfedge sequence *hnew*, *g->next()->opposite()*, ..., *h* remains around the old vertex, while the halfedge sequence *hnew->opposite()*, *h->next()->opposite()* (before the split), ..., *g* is regrouped around the new vertex. The split returns *hnew*, i.e., the new halfedge incident to the old vertex. The time is proportional to the distance from *h* to *g* around the vertex.

*Precondition:* *h* and *g* are incident to the same vertex. *h*  $\neq$  *g* (antennas are not allowed).

*Note:* A special application of the split is *split\_vertex(h, h->next()->opposite())* which is equivalent to an edge split of the halfedge *h->next()* that creates a new vertex on the halfedge *h->next()*. See also *split\_edge(h)* below.

*Halfedge\_handle* *P.join\_vertex( Halfedge\_handle h)*

joins the two vertices incident to *h*. The vertex denoted by *h->opposite()* gets removed. Returns the predecessor of *h* around the vertex, i.e., *h->opposite()->prev()*. The invariant *join\_vertex( split\_vertex( h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the degree of the vertex removed and the time to compute *h->prev()* and *h->opposite()->prev()*.

*Precondition:* The size of both facets incident to *h* is at least four (no multi-edges).

*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

*Halfedge\_handle* *P.split\_edge( Halfedge\_handle h)*

splits the halfedge *h* into two halfedges inserting a new vertex that is a copy of *h->opposite()->vertex()*. Is equivalent to *split\_vertex( h->prev(), h->opposite())*. The call of *prev()* can make this method slower than a direct call of *split\_vertex()* if the previous halfedge is already known and computing it would be costly when the halfedge data structure does not support the *prev()* member function. Returns the new halfedge *hnew* pointing to the inserted vertex. The new halfedge is followed by the old halfedge, i.e., *hnew->next() == h*.

*Halfedge\_handle* *P.flip\_edge( Halfedge\_handle h)*

performs an edge flip. It returns *h* after rotating the edge *h* one vertex in the direction of the face orientation.

*Precondition:* *h != Halfedge\_handle()* and both facets incident to *h* are triangles.

*Halfedge\_handle* *P.create\_center\_vertex( Halfedge\_handle h)*

barycentric triangulation of *h->facet()*. Creates a new vertex, a copy of *h->vertex()*, and connects it to each vertex incident to *h->facet()* splitting *h->facet()* into triangles. *h* remains incident to the original facet, all other triangles are copies of this facet. Returns the halfedge *h->next()* after the operation, i.e., a halfedge pointing to the new vertex. The time is proportional to the size of the facet.

*Precondition:* *h* is not a border halfedge.

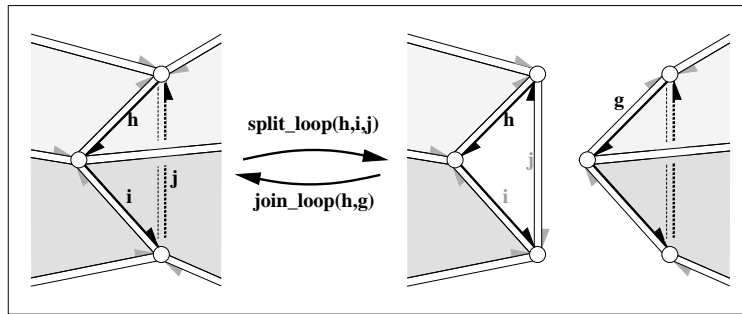

*Halfedge\_handle* *P.erase\_center\_vertex( Halfedge\_handle g )*

reverses *create\_center\_vertex*. Erases the vertex pointed to by *g* and all incident halfedges thereby merging all incident facets. Only *g->facet()* remains. The neighborhood of *g->vertex()* may not be triangulated, it can have larger facets. Returns the halfedge *g->prev()*. Thus, the invariant *h == erase\_center\_vertex( create\_center\_vertex(h) )* holds if *h* is not a border halfedge. The time is proportional to the sum of the size of all incident facets.

*Precondition:* None of the incident facets of *g->vertex()* is a hole. There are at least two distinct facets incident to the facets that are incident to *g->vertex()*. (This prevents the operation from collapsing a volume into two facets glued together with opposite orientations, such as would happen with any vertex of a tetrahedron.)

*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

## Euler Operators Modifying Genus

*Halfedge\_handle* *P.split\_loop( Halfedge\_handle h, Halfedge\_handle i, Halfedge\_handle j )*

cuts the polyhedron into two parts along the cycle  $(h, i, j)$  (edge  $j$  runs on the backside of the three dimensional figure above). Three new vertices (one copy for each vertex in the cycle) and three new halfedges (one copy for each halfedge in the cycle), and two new triangles are created.  $h, i, j$  will be incident to the first new triangle. The return value will be the halfedge incident to the second new triangle which is the copy of  $h\text{-opposite}()$ .

*Precondition:*  $h, i, j$  denote distinct, consecutive vertices of the polyhedron and form a cycle: i.e.,  $h\text{->vertex}() == i\text{->opposite}()\text{->vertex}()$ ,  $\dots$ ,  $j\text{->vertex}() == h\text{->opposite}()\text{->vertex}()$ . The six facets incident to  $h, i, j$  are all distinct.

*Halfedge\_handle* *P.join\_loop( Halfedge\_handle h, Halfedge\_handle g )*

glues the boundary of the two facets denoted by  $h$  and  $g$  together and returns  $h$ . Both facets and the vertices along the facet denoted by  $g$  gets removed. Both facets may be holes. The invariant  $\text{join\_loop}( h, \text{split\_loop}( h, i, j ) )$  returns  $h$  and keeps the polyhedron unchanged.

*Precondition:* The facets denoted by  $h$  and  $g$  are different and have equal degree (i.e., number of edges).

*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

## Modifying Facets and Holes

*Halfedge\_handle* *P.make\_hole( Halfedge\_handle h)*

removes the incident facet of *h* and changes all halfedges incident to the facet into border edges. Returns *h*. See *erase\_facet(h)* for a more generalized variant.

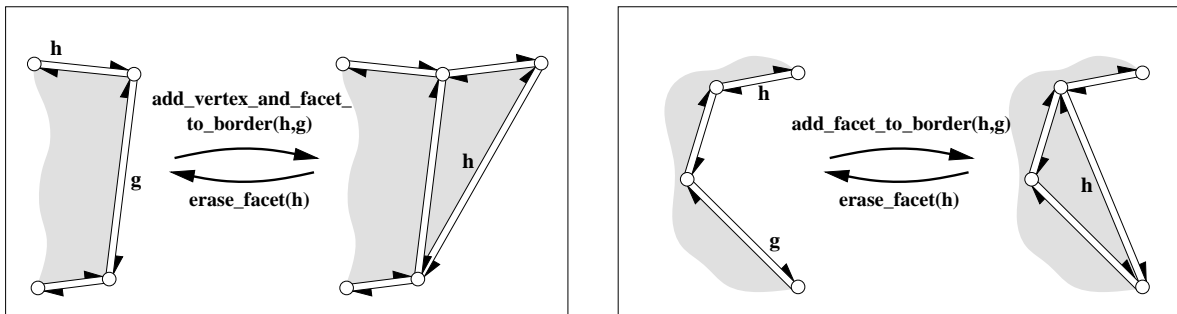

*Precondition:* None of the incident halfedges of the facet is a border edge.

*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

*Halfedge\_handle* *P.fill\_hole( Halfedge\_handle h)*

fills a hole with a newly created facet. Makes all border halfedges of the hole denoted by *h* incident to the new facet. Returns *h*.

*Precondition:* *h.is\_border()*.

*Halfedge\_handle* *P.add\_vertex\_and\_facet\_to\_border( Halfedge\_handle h, Halfedge\_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the tip of *g* with the tip of *h* with two new halfedges and a new vertex and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet and the new vertex.

*Precondition:* *h->is\_border()*, *g->is\_border()*, *h != g*, and *g* can be reached along the same hole starting with *h*.

*Halfedge\_handle* *P.add\_facet\_to\_border( Halfedge\_handle h, Halfedge\_handle g)*

creates a new facet within the hole incident to *h* and *g* by connecting the vertex denoted by *g* with the vertex denoted by *h* with a new halfedge and filling this separated part of the hole with a new facet, such that the new facet is incident to *g*. Returns the halfedge of the new edge that is incident to the new facet.

*Precondition:* *h->is\_border()*, *g->is\_border()*, *h != g*, *h->next() != g*, and *g* can be reached along the same hole starting with *h*.

## Erasing

*void* *P.erase\_facet( Halfedge\_handle h)*

removes the incident facet of *h* and changes all halfedges incident to the facet into border edges or removes them from the polyhedral surface if they were already border edges. If this creates isolated vertices they get removed as well. See *make\_hole(h)* for a more specialized variant.  
*Precondition:* *h->is\_border() == false*.  
*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

*void* *P.erase\_connected\_component( Halfedge\_handle h)*

removes the vertices, halfedges, and facets that belong to the connected component of *h*.  
*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

*void* *P.clear()*

removes all vertices, halfedges, and facets.

## Operations with Border Halfedges

— *advanced* —

Halfedges incident to a hole are called *border halfedges*. An halfedge is a *border edge* if itself or its opposite halfedge are border halfedges. The only requirement to work with border halfedges is that the *Halfedge* class provides a member function *is\_border()* returning a *bool*. Usually, the halfedge data structure supports facets and a *NULL* facet pointer will indicate a border halfedge, but this is not the only possibility. The *is\_border()* predicate divides the edges into two classes, the border edges and the non-border edges. The following normalization reorganizes the sequential storage of the edges such that the non-border edges precede the border edges, and that for each border edge the latter one of the two halfedges is a border halfedge (the first one is a non-border halfedge in conformance with the polyhedral surface definition). The normalization stores the number of border halfedges and the halfedge iterator the border edges start at within the data structure. Halfedge insertion or removal and changing the border status of a halfedge invalidate these values. They are not automatically updated.

*void* *P.normalize\_border()*

sorts halfedges such that the non-border edges precede the border edges. For each border edge the halfedge iterator will reference the halfedge incident to the facet right before the halfedge incident to the hole.

*size\_type* *P.size\_of\_border\_halfedges()*

number of border halfedges.  
*Precondition:* last *normalize\_border()* call still valid, see above.

*size\_type* *P.size\_of\_border\_edges()*

number of border edges. Since each border edge of a polyhedral surface has exactly one border halfedge, this number is equal to *size\_of\_border\_halfedges()*.  
*Precondition:* last *normalize\_border()* call still valid, see above.

*Halfedge\_iterator*     *P.border\_halfedges\_begin()*

halfedge iterator starting with the border edges. The range [*halfedges\_begin()*, *border\_halfedges\_begin()*) denotes all non-border halfedges. The range [*border\_halfedges\_begin()*, *halfedges\_end()*) denotes all border edges.  
*Precondition:* last *normalize\_border()* call still valid, see above.

*Edge\_iterator*     *P.border\_edges\_begin()*

edge iterator starting with the border edges. The range [*edges\_begin()*, *border\_edges\_begin()*) denotes all non-border edges. The range [*border\_edges\_begin()*, *edges\_end()*) denotes all border edges.  
*Precondition:* last *normalize\_border()* call still valid, see above.

└────────── *advanced* ─────────┘

## Miscellaneous

*void*     *P.inside\_out()*

reverses facet orientations (incl. plane equations if supported).

*bool*     *P.is\_valid( bool verbose = false, int level = 0)*

returns *true* if the polyhedral surface is combinatorially consistent. If *verbose* is *true*, statistics are printed to *cerr*. For *level == 1* the normalization of the border edges is checked too. This method checks in particular level 3 of *CGAL::Halfedge\_data\_structure\_decorator::is\_valid* from page 22.4 and that each facet is at least a triangle and that the two incident facets of a non-border edge are distinct.

*bool*     *P.normalized\_border\_is\_valid( bool verbose = false)*

returns *true* if the border halfedges are in normalized representation, which is when enumerating all halfedges with the iterator: The non-border edges precede the border edges and for border edges, the second halfedge is the border halfedge. The halfedge iterator *border\_halfedges\_begin()* denotes the first border edge. If *verbose* is *true*, statistics are printed to *cerr*.

advanced

```
void P.delegate( CGAL::Modifier_base<HDS>& m)
```

calls the *operator()* of the modifier *m*. See *CGAL::Modifier\_base* for a description of modifier design and its usage.

*Precondition:* The polyhedral surface must be valid when the modifier returns from execution.

## Example

This example program instantiates a polyhedron using the default traits class and creates a tetrahedron.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef Polyhedron::Halfedge_handle Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h) )
        return 0;
    return 1;
}
```

## CGAL::Polyhedron\_3&lt;Traits&gt;::Facet

### Definition

A facet optionally stores a plane equation, and a reference to an incident halfedge that points to the facet. Type tags indicate whether these member functions are supported. Figure 21.1 on page 1511 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. The circulator is assignable to the *Halfedge\_handle*. The circulator is bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise it is of the forward category.

```
#include <CGAL/Polyhedron_3.h>
```

## Types

<i>Facet:: Vertex</i>	type of incident vertices.
<i>Facet:: Halfedge</i>	type of incident halfedges.
<i>Facet:: Plane_3</i>	plane equation type stored in facets.

<i>Facet:: Vertex_handle</i>	handle to vertex.
<i>Facet:: Halfedge_handle</i>	handle to halfedge.
<i>Facet:: Facet_handle</i>	handle to facet.
<i>Facet:: Halfedge_around_facet_circulator</i>	circulator of halfedges around a facet.

*Facet::Vertex\_const\_handle*  
*Facet::Halfedge\_const\_handle*  
*Facet::Facet\_const\_handle*  
*Facet::Halfedge\_around\_facet\_const\_circulator*

<i>Facet:: Supports_facet_halfedge</i>	$\equiv$ <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>Facet:: Supports_facet_plane</i>	$\equiv$ <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

## Creation

*Facet*  $f$ ; default constructor.

### Operations available if *Supports\_facet\_plane* $\equiv$ *CGAL::Tag\_true*

<i>Plane_3&amp;</i>	<i>f.plane()</i>	
<i>const Plane_3&amp;</i>	<i>f.plane() const</i>	plane equation.

### Operations available if *Supports\_facet\_halfedge* $\equiv$ *CGAL::Tag\_true*

<i>Halfedge_handle</i>	<i>f.halfedge()</i>	
<i>Halfedge_const_handle</i>	<i>f.halfedge() const</i>	an incident halfedge that points to <i>f</i> .

*Halfedge\_around\_facet\_circulator*

*f.facet\_begin()*

*Halfedge\_around\_facet\_const\_circulator*

*f.facet\_begin() const*

circulator of halfedges around the facet (counterclockwise).

*void*

*f.set\_halfedge( Halfedge\_handle h)*

sets incident halfedge to *h*.

*Precondition:* *h* is incident, i.e., *h->facet() == f*.

*std::size\_t*

*f.facet\_degree() const*

the degree of the facet, i.e., number of edges on the boundary of this facet.

*bool*

*f.is\_triangle() const*

returns *true* if the facet is a triangle.

*bool*

*f.is\_quad() const*

returns *true* if the facet is a quadrilateral.

## CGAL::Polyhedron\_3<Traits>::Halfedge

### Definition

Figure 21.1 on page 1511 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. A halfedge is an oriented edge between two vertices. It is always paired with a halfedge pointing in the opposite direction. The *opposite()* member function returns this halfedge of opposite orientation. If a halfedge is incident to a facet the *next()* member function points to the successor halfedge around this facet. For border edges the *next()* member function points to the successor halfedge along the hole. For more than two border edges at a vertex, the next halfedge along a hole is not uniquely defined, but a consistent assignment of the next halfedge will be maintained in the data structure. An invariant is that successive assignments of the form  $h = h \rightarrow \text{next}()$  cycle counterclockwise around the facet (or hole) and traverse all halfedges incident to this facet (or hole). A similar invariant is that successive assignments of the form  $h = h \rightarrow \text{next}() \rightarrow \text{opposite}()$  cycle clockwise around the vertex and traverse all halfedges incident to this vertex. Two circulators are provided for these circular orders.

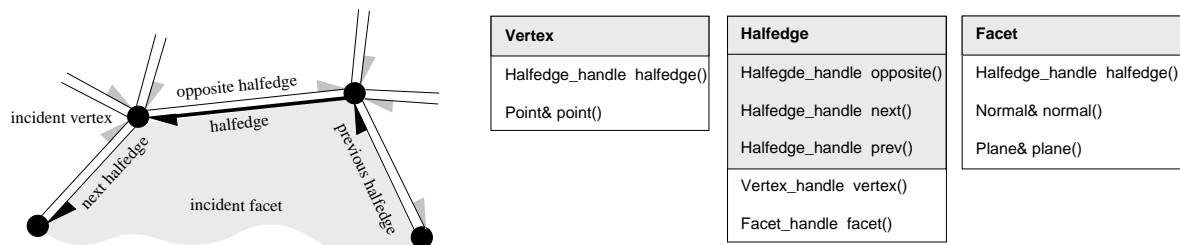

Figure 21.1: The three classes *Vertex*, *Halfedge*, and *Facet* of the polyhedral surface. Member functions with shaded background are mandatory. The others are optionally supported.

The incidences encoded in *opposite()* and *next()* are available for each instantiation of polyhedral surfaces. The other incidences are optionally available as indicated with type tags. The *prev()* member function points to the preceding halfedge around the same facet. It is always available, though it might perform a search around the facet using the *next()* member function to find the previous halfedge if the underlying halfedge data structure does not provide an efficient *prev()* member function for halfedges. Handles to the incident vertex and facet are optionally stored.

The circulators are assignable to the *Halfedge\_handle*. The circulators are bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise they are of the forward category.

```
#include <CGAL/Polyhedron_3.h>
```

### Types

*Halfedge::Vertex*

type of incident vertices.

*Halfedge::Facet*

type of incident facets.

*Halfedge::Vertex\_handle*

handle to vertex.

*Halfedge::Halfedge\_handle*

handle to halfedge.

*Halfedge::Facet\_handle*

handle to facet.

*Halfedge::Halfedge\_around\_vertex\_circulator*

circulator of halfedges around a vertex.

*Halfedge::Halfedge\_around\_facet\_circulator*

circulator of halfedges around a facet.

*Halfedge:: Vertex\_const\_handle*  
*Halfedge:: Halfedge\_const\_handle*  
*Halfedge:: Facet\_const\_handle*  
*Halfedge:: Halfedge\_around\_vertex\_const\_circulator*  
*Halfedge:: Halfedge\_around\_facet\_const\_circulator*

*Halfedge:: Supports\_halfedge\_prev*  $\equiv CGAL::Tag\_true$  or  $CGAL::Tag\_false$ .  
*Halfedge:: Supports\_halfedge\_vertex*  $\equiv CGAL::Tag\_true$  or  $CGAL::Tag\_false$ .  
*Halfedge:: Supports\_halfedge\_face*  $\equiv CGAL::Tag\_true$  or  $CGAL::Tag\_false$ .

## Creation

*Halfedge h;* default constructor.

## Operations

*Halfedge\_handle* *h.opposite()*  
*Halfedge\_const\_handle* *h.opposite() const* the opposite halfedge.

*Halfedge\_handle* *h.next()*  
*Halfedge\_const\_handle* *h.next() const* the next halfedge around the facet.

*Halfedge\_handle* *h.prev()*  
*Halfedge\_const\_handle* *h.prev() const* the previous halfedge around the facet.

*Halfedge\_handle* *h.next\_on\_vertex()*  
*Halfedge\_const\_handle* *h.next\_on\_vertex() const* the next halfedge around the vertex (clockwise). Is equal to *h.next()->opposite()*.

*Halfedge\_handle* *h.prev\_on\_vertex()*  
*Halfedge\_const\_handle* *h.prev\_on\_vertex() const* the previous halfedge around the vertex (counterclockwise). Is equal to *h.opposite()->prev()*.

*bool* *h.is\_border() const* is true if *h* is a border halfedge.  
*bool* *h.is\_border\_edge() const* is true if *h* or *h.opposite()* is a border halfedge.

*Halfedge\_around\_vertex\_circulator*

*h.vertex\_begin()*

*Halfedge\_around\_vertex\_const\_circulator*

*h.vertex\_begin() const* circulator of halfedges around the vertex (clockwise).

*Halfedge\_around\_facet\_circulator*

*h.facet\_begin()*

### *Halfedge\_around\_facet\_const\_circulator*

	<i>h.facet_begin() const</i>	circulator of halfedges around the facet (counterclockwise).
<i>std::size_t</i>	<i>h.vertex_degree() const</i>	the degree of the incident vertex, i.e., number of edges emanating from this vertex.
<i>bool</i>	<i>h.is_bivalent() const</i>	returns <i>true</i> if the incident vertex has exactly two incident edges.
<i>bool</i>	<i>h.is_trivalent() const</i>	returns <i>true</i> if the incident vertex has exactly three incident edges.
<i>std::size_t</i>	<i>h.facet_degree() const</i>	the degree of the incident facet, i.e., number of edges on the boundary of this facet.
<i>bool</i>	<i>h.is_triangle() const</i>	returns <i>true</i> if the incident facet is a triangle.
<i>bool</i>	<i>h.is_quad() const</i>	returns <i>true</i> if the incident facet is a quadrilateral.

### **Operations available if *Supports\_halfedge\_vertex* $\equiv$ *CGAL::Tag\_true***

<i>Vertex_handle</i>	<i>h.vertex()</i>	
<i>Vertex_const_handle</i>	<i>h.vertex() const</i>	the incident vertex of <i>h</i> .

### **Operations available if *Supports\_halfedge\_facet* $\equiv$ *CGAL::Tag\_true***

<i>Facet_handle</i>	<i>h.facet()</i>	
<i>Facet_const_handle</i>	<i>h.facet() const</i>	the incident facet of <i>h</i> . If <i>h</i> is a border halfedge the result is default construction of the handle.

<i>CGAL::Polyhedron_3&lt;Traits&gt;</i> .....	page <a href="#">1497</a>

### **Implementation**

The member functions *prev()* and *prev\_on\_vertex()* work in constant time if *Supports\_halfedge\_prev*  $\equiv$  *CGAL::Tag\_true*. Otherwise both methods search for the previous halfedge around the incident facet.

## CGAL::Polyhedron\_3<Traits>::Vertex

### Definition

A vertex optionally stores a point and a reference to an incident halfedge that points to the vertex. Type tags indicate whether these member functions are supported. Figure 21.1 on page 1511 depicts the relationship between a halfedge and its incident halfedges, vertices, and facets. The circulator is assignable to the *Halfedge\_handle*. The circulator is bidirectional if the halfedge provided to the polyhedron with the *Items* template argument provides a member function *prev()*, otherwise it is of the forward category.

```
#include <CGAL/Polyhedron_3.h>
```

### Types

<i>Vertex:: Halfedge</i>	type of incident halfedges.
<i>Vertex:: Facet</i>	type of incident facets.
<i>Vertex:: Point_3</i>	point type stored in vertices.
<i>Vertex:: Vertex_handle</i>	handle to vertex.
<i>Vertex:: Halfedge_handle</i>	handle to halfedge.
<i>Vertex:: Facet_handle</i>	handle to facet.
<i>Vertex:: Halfedge_around_vertex_circulator</i>	circulator of halfedges around a vertex.
<i>Vertex:: Vertex_const_handle</i>	
<i>Vertex:: Halfedge_const_handle</i>	
<i>Vertex:: Facet_const_handle</i>	
<i>Vertex:: Halfedge_around_vertex_const_circulator</i>	
<i>Vertex:: Supports_vertex_halfedge</i>	$\equiv$ <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>Vertex:: Supports_vertex_point</i>	$\equiv$ <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

### Creation

<i>Vertex v</i> ;	default constructor.
<i>Vertex v</i> ( <i>Point p</i> );	vertex initialized with a point.

**Operations available if** *Supports\_vertex\_point*  $\equiv$  *CGAL::Tag\_true*

<i>Point_3&amp;</i>	<i>v.point()</i>	
<i>const Point_3&amp;</i>	<i>v.point() const</i>	the point.

**Operations available if *Supports\_vertex\_halfedge*  $\equiv$  *CGAL::Tag\_true***

*Halfedge\_handle*            *v.halfedge()*  
*Halfedge\_const\_handle*   *v.halfedge() const*    an incident halfedge that points to *v*.

*Halfedge\_around\_vertex\_circulator*

*v.vertex\_begin()*

*Halfedge\_around\_vertex\_const\_circulator*

*v.vertex\_begin() const*

circulator of halfedges around the vertex (clockwise).

*void*                        *v.set\_halfedge( Halfedge\_handle h)*

sets incident halfedge to *h*.

*Precondition:* *h* is incident, i.e., *h->vertex() == v*.

*std::size\_t*                *v.vertex\_degree() const*

the degree of the vertex, i.e., number of edges emanating from this vertex.

*bool*                        *v.is\_bivalent() const*

returns *true* if the vertex has exactly two incident edges.

*bool*                        *v.is\_trivalent() const*

returns *true* if the vertex has exactly three incident edges.

## CGAL::Polyhedron\_incremental\_builder\_3<HDS>

### Definition

The auxiliary class *Polyhedron\_incremental\_builder\_3<HDS>* supports the incremental construction of polyhedral surfaces, which is for example convenient when constructing polyhedral surfaces from file formats, such as the Object File Format (OFF) [Phi96], OpenInventor [Wer94] or VRML [BPP95, VRM96]. *Polyhedron\_incremental\_builder\_3<HDS>* needs access to the internal halfedge data structure of type *HDS* of the polyhedral surface. It is intended to be used within a modifier, see *CGAL::Modifier\_base*.

The incremental builder might be of broader interest for other uses of the halfedge data structures, but it is specifically bound to the definition of polyhedral surfaces given here. During construction all conditions of polyhedral surfaces are checked and in case of violation an error status is set. A diagnostic message will be issued to *cerr* if the *verbose* flag has been set at construction time.

The incremental construction starts with a list of all point coordinates and concludes with a list of all facet polygons. Edges are not explicitly specified. They are derived from the vertex incidence information provided from the facet polygons. The polygons are given as a sequence of vertex indices. The halfedge data structure *HDS* must support vertices (i.e., *Supports\_halfedge\_vertex*  $\equiv$  *CGAL::Tag\_true*). Vertices and facets can be added in arbitrary order as long as a call to *add\_vertex\_to\_facet()* refers only to a vertex index that is already known. Some methods return already handles to vertices, facets, and halfedges newly constructed. They can be used to initialize additional fields, however, the incidences in the halfedge-data structure are not stable and are not allowed to be changed.

The incremental builder can work in two modes: *RELATIVE\_INDEXING* (the default), in which a polyhedral surface already contained in the halfedge data structure is ignored and all indices are relative to the newly added surface, or *ABSOLUTE\_INDEXING*, in which all indices are absolute indices including an already existing polyhedral surface. The former mode allows to create easily independent connected components, while the latter mode allows to continue the construction of an existing surface, the absolute indexing allows to address existing vertices when creating new facets.

```
#include <CGAL/Polyhedron_incremental_builder_3.h>
```

### Types

<i>Polyhedron_incremental_builder_3&lt;HDS&gt;::HalfedgeDS</i>	halfedge data structure <i>HDS</i> .
<i>Polyhedron_incremental_builder_3&lt;HDS&gt;::Point_3</i>	point type of the vertex.
<i>Polyhedron_incremental_builder_3&lt;HDS&gt;::size_type</i>	size type.

<i>typedef typename HalfedgeDS::Vertex_handle</i>	<i>Vertex_handle;</i>
<i>typedef typename HalfedgeDS::Halfedge_handle</i>	<i>Halfedge_handle;</i>
<i>typedef typename HalfedgeDS::Face_handle</i>	<i>Facet_handle;</i>

### Constants

```
enum { RELATIVE_INDEXING, ABSOLUTE_INDEXING};
```

two different indexing modes.

## Creation

*Polyhedron\_incremental\_builder\_3<HDS>* *B*( *HDS*& *hds*, *bool verbose* = *false*);

stores a reference to the halfedge data structure *hds* of a polyhedral surface in its internal state. An existing polyhedral surface in *hds* remains unchanged. The incremental builder appends the new polyhedral surface. If *verbose* is *true*, diagnostic messages will be printed to *cerr* in case of malformed input data.

## Surface Creation

To build a polyhedral surface, the following regular expression gives the correct and allowed order and nesting of method calls from this section:

*begin\_surface* (*add\_vertex* | (*begin\_facet add\_vertex\_to\_facet* \* *end\_facet*)) \* *end\_surface*

*void*                    *B.begin\_surface*( *size\_type v*,  
  *size\_type f*,  
  *size\_type h* = 0,  
  *int mode* = *RELATIVE\_INDEXING*)

starts the construction. *v* is the number of new vertices to expect, *f* the number of new facets, and *h* the number of new halfedges. If *h* is unspecified (*== 0*) it is estimated using Euler's equation (plus 5% for the so far unknown holes and genus of the object). These values are used to reserve space in the halfedge data structure *hds*. If the representation supports insertion these values do not restrict the class of constructible polyhedra. If the representation does not support insertion the object must fit into the reserved sizes. If *mode* is set to *ABSOLUTE\_INDEXING* the incremental builder uses absolute indexing and the vertices of the old polyhedral surface can be used in new facets (needs preprocessing time linear in the size of the old surface). Otherwise relative indexing is used starting with new indices for the new construction.

*Vertex\_handle*        *B.add\_vertex*( *Point\_3 p*)

adds a new vertex for *p* and returns its handle.

*Facet\_handle*        *B.begin\_facet*()        starts a new facet and returns its handle.

*void*                    *B.add\_vertex\_to\_facet*( *size\_type i*)

adds a vertex with index *i* to the current facet. The first point added with *add\_vertex()* has the index 0 if *mode* was set to *RELATIVE\_INDEXING*, otherwise the first vertex in the referenced *hds* has the index 0.

<i>Halfedge_handle</i>	<i>B.end_facet()</i>	ends a newly constructed facet. Returns the handle to the halfedge incident to the new facet that points to the vertex added first. The halfedge can be safely used to traverse the halfedge cycle around the new facet.
------------------------	----------------------	--

<i>void</i>	<i>B.end_surface()</i>	ends the construction.
-------------	------------------------	------------------------

## Additional Operations

*template <class InputIterator>*

*Halfedge\_handle B.add\_facet( InputIterator first, InputIterator beyond)*

is a synonym for *begin\_facet()*, a call to *add\_vertex\_to\_facet()* for each value in the range *[first,beyond)*, and a call to *end\_facet()*. Returns the return value of *end\_facet()*.

*Precondition:* The value type of *InputIterator* is *std::size\_t*. All indices must refer to vertices already added.

*template <class InputIterator>*

*bool B.test\_facet( InputIterator first, InputIterator beyond)*

returns *true* if a facet described by the vertex indices in the range *[first,beyond)* can be successfully inserted, e.g., with *add\_facet(first,beyond)*.

*Precondition:* The value type of *InputIterator* is *std::size\_t*. All indices must refer to vertices already added.

<i>Vertex_handle</i>	<i>B.vertex( std::size_t i)</i>	
----------------------	---------------------------------	--

returns handle for the vertex of index *i*, or *Vertex\_handle* if there is no *i*-th vertex.

<i>bool</i>	<i>B.error()</i>	returns error status of the builder.
-------------	------------------	--------------------------------------

<i>void</i>	<i>B.rollback()</i>	undoes all changes made to the halfedge data structure since the last <i>begin_surface()</i> in relative indexing, and deletes the whole surface in absolute indexing. It needs a new call to <i>begin_surface()</i> to start inserting again.
-------------	---------------------	--

<i>bool</i>	<i>B.check_unconnected_vertices()</i>	
-------------	---------------------------------------	--

returns *true* if unconnected vertices are detected. If *verbose* was set to *true* (see the constructor above) debug information about the unconnected vertices is printed.

<i>bool</i>	<i>B.remove_unconnected_vertices()</i>	
-------------	--	--

returns *true* if all unconnected vertices could be removed successfully. This happens either if no unconnected vertices had appeared or if the halfedge data structure supports the removal of individual elements.

## Example

A modifier class creates a new triangle in the halfedge data structure using the incremental builder.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_incremental_builder_3.h>
#include <CGAL/Polyhedron_3.h>

// A modifier creating a triangle with the incremental builder.
template <class HDS>
class Build_triangle : public CGAL::Modifier_base<HDS> {
public:
    Build_triangle() {}
    void operator()( HDS& hds) {
        // Postcondition: 'hds' is a valid polyhedral surface.
        CGAL::Polyhedron_incremental_builder_3<HDS> B( hds, true);
        B.begin_surface( 3, 1, 6);
        typedef typename HDS::Vertex    Vertex;
        typedef typename Vertex::Point Point;
        B.add_vertex( Point( 0, 0, 0));
        B.add_vertex( Point( 1, 0, 0));
        B.add_vertex( Point( 0, 1, 0));
        B.begin_facet();
        B.add_vertex_to_facet( 0);
        B.add_vertex_to_facet( 1);
        B.add_vertex_to_facet( 2);
        B.end_facet();
        B.end_surface();
    }
};

typedef CGAL::Simple_cartesian<double>    Kernel;
typedef CGAL::Polyhedron_3<Kernel>        Polyhedron;
typedef Polyhedron::HalfedgeDS            HalfedgeDS;

int main() {
    Polyhedron P;
    Build_triangle<HalfedgeDS> triangle;
    P.delegate( triangle);
    CGAL_assertion( P.is_triangle( P.halfedges_begin()));
    return 0;
}
```

**File:** examples/Polyhedron/polyhedron\_prog\_incr\_builder.cpp

## PolyhedronItems\_3

### Definition

The `PolyhedronItems_3` concept extends the `HalfedgeDSItems` concept on page 1577. In addition to the requirements stated there, a model for this concept must fulfill the following requirements for the local `PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex` type and `PolyhedronItems_3::Face_wrapper<Refs,Traits>::Face` type in order to support the point for vertices and the optional plane equation for facets. Note that the items class uses face instead of facet. Only the polyhedral surface renames faces to facets.

### Refines

`HalfedgeDSItems` ..... page 1557

### Types in `PolyhedronItems_3::Vertex_wrapper<Refs,Traits>::Vertex`

`Vertex::Point` point type stored in vertices. A `HalfedgeDS` has no dimension, so this type is named `Point` and not `Point_3`.

`Vertex::Supports_vertex_point`  $\equiv$  `CGAL::Tag_true`. A point is always required.

### Operations

<code>Point&amp;</code>	<code>v.point()</code>	
<code>const Point&amp;</code>	<code>v.point() const</code>	point.

### Types in `PolyhedronItems_3::Face_wrapper<Refs,Traits>::Face`

Types for (optionally) associated geometry in faces. If it is not supported the respective type has to be defined, although it can be an arbitrary dummy type, such as `void*` or `Tag_false`.

`Face::Plane` plane type stored in faces. A `HalfedgeDS` has no dimension, so this type is named `Plane` and not `Plane_3`.

`Face::Supports_face_plane` either `CGAL::Tag_true` or `CGAL::Tag_false`.

### Operations required if `Supports_face_plane $\equiv$ CGAL::Tag_true`

<code>Plane&amp;</code>	<code>f.plane()</code>	
<code>const Plane&amp;</code>	<code>f.plane() const</code>	plane equation.

### Has Models

`CGAL::Polyhedron_items_3` ..... page 1522

`CGAL::Polyhedron_min_items_3` ..... page 1524

## See Also

<i>CGAL::Polyhedron_3</i> <Traits> .....	page 1497
<i>HalfedgeDSItems</i> .....	page 1557
<i>CGAL::HalfedgeDS_items_2</i> .....	page 1577

<i>CGAL::HalfedgeDS_halfedge_base</i> <Refs> .....	page 1575
<i>CGAL::HalfedgeDS_face_base</i> <Refs> .....	page 1572

## Example

We define our own items class based on the available *CGAL::HalfedgeDS\_face\_base* base class for faces. We derive the *Halfedge\_wrapper* without further modifications from the *CGAL::HalfedgeDS\_items\_2*, replace the *Face\_wrapper* definition with our new definition, and also replace the *Vertex\_wrapper* with a definition that uses *Point\_3* instead of *Point\_2* as point type. The result is a model for the *PolyhedronItems\_3* concept similar to the available *CGAL::Polyhedron\_items\_3* class. See also there for another illustrative example.

```
#include <CGAL/HalfedgeDS_bases.h>

struct My_items : public CGAL::HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_3 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, CGAL::Tag_true, Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef typename Traits::Plane_3 Plane;
        typedef CGAL::HalfedgeDS_face_base< Refs, CGAL::Tag_true, Plane> Face;
    };
};
```

## CGAL::Polyhedron\_items\_3

### Definition

The class *Polyhedron\_items\_3* is a model of the *PolyhedronItems\_3* concept. It provides definitions for vertices with points, halfedges, and faces with plane equations. The polyhedron traits class must provide the respective types for the point and the plane equation. Vertices and facets both contain a halfedge handle to an incident halfedge.

```
#include <CGAL/Polyhedron_items_3.h>
```

### Is Model for the Concepts

*PolyhedronItems\_3* ..... page [1520](#)

**Types in *Polyhedron\_items\_3::Vertex\_wrapper<Refs,Traits>::Vertex***

```
typedef Traits::Point_3      Point;
typedef CGAL::Tag_true      Supports_vertex_point;
```

**Types in *Polyhedron\_items\_3::Face\_wrapper<Refs,Traits>::Face***

```
typedef Traits::Plane_3      Plane;
typedef CGAL::Tag_true      Supports_face_plane;
```

### Creation

*Polyhedron\_items\_3 items;*                      default constructor.

### Operations

Supported as required by the *PolyhedronItems\_3* concept.

### See Also

*CGAL::Polyhedron\_3<Traits>* ..... page [1497](#)  
*CGAL::Polyhedron\_min\_items\_3* ..... page [1524](#)  
*CGAL::HalfedgeDS\_min\_items* ..... page [1583](#)  
*CGAL::HalfedgeDS\_items\_2* ..... page [1577](#)

### Example

The following example program defines a new face class based on the *CGAL::HalfedgeDS\_face\_base* and adds a new color member variable. The new face class is used to replace the face definition in the *CGAL::Polyhedron\_items\_3* class. The main function illustrates the access to the new member variable. See also the *PolyhedronItems\_3* concept for another illustrative example.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Polyhedron_3.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
};

// An items type using my face.
struct My_items : public CGAL::Polyhedron_items_3 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

typedef CGAL::Simple_cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel, My_items>    Polyhedron;
typedef Polyhedron::Halfedge_handle             Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    h->facet()->color = CGAL::RED;
    return 0;
}

```

**File:** examples/Polyhedron/polyhedron\_prog\_color.cpp

## CGAL::Polyhedron\_min\_items\_3

### Definition

The class *Polyhedron\_min\_items\_3* is a minimal model of the *PolyhedronItems\_3* concept. It provides definitions for vertices containing points, halfedges, and faces. The polyhedron traits class must provide the respective type for the point. Vertices and facets both do *not* contain a halfedge handle to an incident halfedge.

```
#include <CGAL/Polyhedron_min_items_3.h>
```

### Is Model for the Concepts

*PolyhedronItems\_3* ..... page [1520](#)

### Types in *Polyhedron\_min\_items\_3::Vertex\_wrapper<Refs,Traits>::Vertex*

```
typedef Traits::Point_3      Point;
typedef CGAL::Tag_true      Supports_vertex_point;
```

### Types in *Polyhedron\_min\_items\_3::Face\_wrapper<Refs,Traits>::Face*

```
typedef CGAL::Tag_false      Supports_face_plane;
```

### Creation

*Polyhedron\_min\_items\_3 items;*                      default constructor.

### Operations

Supported as required by the *PolyhedronItems\_3* concept.

### See Also

*CGAL::HalfedgeDS\_items\_2* ..... page [1577](#)

## PolyhedronTraits\_3

Required types and member functions for the PolyhedronTraits\_3 concept. This geometric traits concept is used in the polyhedral surface data structure `CGAL::Polyhedron_3<Traits>`. This concept is a subset of the 3d kernel traits and any CGAL kernel model can be used directly as template argument.

### Refines

*CopyConstructable*, *Assignable*.

### Types

*PolyhedronTraits\_3::Point\_3* point type.

*PolyhedronTraits\_3::Plane\_3* plane equation. Even if plane equations are not supported with a particular polyhedral surface this type has to be defined (some dummy type).

*PolyhedronTraits\_3::Construct\_opposite\_plane\_3*

is an unary function object that reverses the plane orientation. Must provide *Plane\_3 operator()(Plane\_3 plane)* that returns the reversed plane. Required only if plane equations are supported and the *inside\_out()* method is used to reverse the polyhedral surface orientation.

### Creation

*PolyhedronTraits\_3 traits(traits2);* copy constructor.

*PolyhedronTraits\_3& traits = traits2* assignment.

### Operations

*Construct\_opposite\_plane\_3 traits.construct\_opposite\_plane\_3\_object()*

returns an instance of this function object.

### Has Models

*CGAL::Polyhedron\_traits\_3<Kernel>* ..... page [1526](#)

*CGAL::Polyhedron\_traits\_with\_normals\_3<Kernel>* ..... page [1528](#)

All models of the *CGAL::Kernel* concept, e.g., *Simple\_cartesian<FieldNumberType>*.

### See Also

*CGAL::Polyhedron\_3<Traits>* ..... page [1497](#)

## CGAL::Polyhedron\_traits\_3<Kernel>

### Definition

The class *Polyhedron\_traits\_3<Kernel>* is a model of the *PolyhedronTraits\_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron\_3<PolyhedronTraits\_3>* in terms of the CGAL *Kernel*. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

```
#include <CGAL/Polyhedron_traits_3.h>
```

### Is Model for the Concepts

PolyhedronTraits\_3 ..... page [1525](#)

### Types

<i>Polyhedron_traits_3&lt;Kernel&gt;::Kernel</i>	the <i>Kernel</i> model.
<i>typedef Kernel::Point_3</i>	<i>Point_3</i> ;
<i>typedef Kernel::Plane_3</i>	<i>Plane_3</i> ;
<i>typedef Kernel::Construct_opposite_plane_3</i>	<i>Construct_opposite_plane_3</i> ;

### Creation

<i>Polyhedron_traits_3&lt;Kernel&gt; traits</i> ;	default constructor, uses <i>Kernel()</i> as local reference to the kernel.
---	---

<i>Polyhedron_traits_3&lt;Kernel&gt; traits( Kernel kernel</i> );	stores <i>kernel</i> as local reference.
---	--

### Operations

<i>Construct_opposite_plane_3 traits.construct_opposite_plane_3_object()</i>	forwarded to <i>kernel</i> .
--	------------------------------

### See Also

*CGAL::Polyhedron\_traits\_with\_normals\_3<Kernel>* ..... page [1528](#)

### Implementation

Since the *PolyhedronTraits\_3* concept is a subset of the 3D kernel concept, this class just forwards the relevant types and access member functions from its template argument. However, it is useful for testing sufficiency of requirements.

### Example

Instantiation of a polyhedral surface with the Cartesian kernel based on double coordinates.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>

typedef CGAL::Simple_cartesian<double>      Kernel;
typedef CGAL::Polyhedron_3<Kernel>          Polyhedron;
typedef Polyhedron::Halfedge_handle          Halfedge_handle;

int main() {
    Polyhedron P;
    Halfedge_handle h = P.make_tetrahedron();
    if ( P.is_tetrahedron(h) )
        return 0;
    return 1;
}

```

**File:** examples/Polyhedron/polyhedron\_prog\_simple.cpp

# CGAL::Polyhedron\_traits\_with\_normals\_3<Kernel>

## Definition

The class *Polyhedron\_traits\_with\_normals\_3<Kernel>* is a model of the *PolyhedronTraits\_3* concept. It defines the geometric types and primitive operations used in the polyhedral surface data structure *CGAL::Polyhedron\_3<PolyhedronTraits\_3>*. *Polyhedron\_traits\_with\_normals\_3<Kernel>* uses the normal vector from *Kernel* for the plane equation in facets. It keeps a local copy of the kernel which makes it suitable for kernels with local state.

#include <CGAL/Polyhedron\_traits\_with\_normals\_3.h>

## Is Model for the Concepts

PolyhedronTraits\_3 ..... page [1525](#)

## Types

*Polyhedron\_traits\_with\_normals\_3<Kernel>::Kernel* the *Kernel* model.  
*typedef Kernel::Point\_3 Point\_3;*  
*typedef Kernel::Vector\_3 Plane\_3;*

*typedef Kernel::Construct\_opposite\_vector\_3 Construct\_opposite\_plane\_3;*

## Creation

*Polyhedron\_traits\_with\_normals\_3<Kernel> traits;* default constructor, uses *Kernel()* as local reference to the kernel.

*Polyhedron\_traits\_with\_normals\_3<Kernel> traits( Kernel kernel);* stores *kernel* as local reference.

## Operations

*Construct\_opposite\_plane\_3 traits.construct\_opposite\_plane\_3\_object()*  
forwarded to *kernel*.

## See Also

*CGAL::Polyhedron\_traits\_3<Kernel>* ..... page [1526](#)

## Example

We use this traits class to instantiate a polyhedral surface with a normal vector and no plane equation for each facet. We compute the normal vector assuming exact arithmetic (integers in this example) and convex planar facets.

```

#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_traits_with_normals_3.h>
#include <CGAL/Polyhedron_3.h>
#include <iostream>
#include <algorithm>

struct Normal_vector {
    template <class Facet>
    typename Facet::Plane_3 operator()( Facet& f) {
        typename Facet::Halfedge_handle h = f.halfedge();
        // Facet::Plane_3 is the normal vector type. We assume the
        // CGAL Kernel here and use its global functions.
        return CGAL::cross_product(
            h->next()->vertex()->point() - h->vertex()->point(),
            h->next()->next()->vertex()->point() - h->next()->vertex()->point());
    }
};

typedef CGAL::Homogeneous<int> Kernel;
typedef Kernel::Point_3 Point_3;
typedef Kernel::Vector_3 Vector_3;
typedef CGAL::Polyhedron_traits_with_normals_3<Kernel> Traits;
typedef CGAL::Polyhedron_3<Traits> Polyhedron;

int main() {
    Point_3 p( 1, 0, 0);
    Point_3 q( 0, 1, 0);
    Point_3 r( 0, 0, 1);
    Point_3 s( 0, 0, 0);
    Polyhedron P;
    P.make_tetrahedron( p, q, r, s);
    std::transform( P.facets_begin(), P.facets_end(), P.planes_begin(),
        Normal_vector());
    CGAL::set_pretty_mode( std::cout);
    std::copy( P.planes_begin(), P.planes_end(),
        std::ostream_iterator<Vector_3>( std::cout, "\n"));
    return 0;
}

```

**File:** examples/Polyhedron/polyhedron\_prog\_normals.cpp

## CGAL::operator<<

### Definition

This operator writes the polyhedral surface  $P$  to the output stream  $out$  using the Object File Format, OFF, with file extension `.off`, which is also understood by GeomView [\[Phi96\]](#). The output is in ASCII format. From the polyhedral surface, only the point coordinates and facets are written. Neither normal vectors nor color attributes are used.

For OFF an ASCII and a binary format exist. The format can be selected with the CGAL modifiers for streams, `set_ascii_mode` and `set_binary_mode` respectively. The modifier `set_pretty_mode` can be used to allow for (a few) structuring comments in the output. Otherwise, the output would be free of comments. The default for writing is ASCII without comments.

```
#include <CGAL/IO/Polyhedron_iostream.h>
```

```
template <class PolyhedronTraits_3>
ostream& ostream& out << CGAL::Polyhedron_3<PolyhedronTraits_3> P
```

### See Also

`CGAL::Polyhedron_3<Traits>` ..... [page 1497](#)  
`operator>>` ..... [page 1531](#)

## CGAL::operator>>

### Definition

This operator reads a polyhedral surface in Object File Format, OFF, with file extension `.off`, which is also understood by Geomview [Phi96], from the input stream *in* and appends it to the polyhedral surface *P*. Only the point coordinates and facets from the input stream are used to build the polyhedral surface. Neither normal vectors nor color attributes are evaluated. If the stream *in* does not contain a permissible polyhedral surface the `ios::badbit` of the input stream *in* is set and *P* remains unchanged.

For OFF an ASCII and a binary format exist. The stream detects the format automatically and can read both.

```
#include <CGAL/IO/Polyhedron_iostream.h>
```

```
template <class PolyhedronTraits_3>
istream& istream& in >> CGAL::Polyhedron_3<PolyhedronTraits_3>& P
```

### See Also

`CGAL::Polyhedron_incremental_builder_3<HDS>` ..... page [1516](#)  
`operator<<` ..... page [1530](#)

### Implementation

This operator is implemented using the modifier mechanism for polyhedral surfaces and the `CGAL::Polyhedron_incremental_builder_3` class, which allows the construction in a single, efficient scan pass of the input and handles also all the possible flexibility of the polyhedral surface.

## 22.1 Introduction

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence information of vertices, edges and faces, for example for planar maps, polyhedra, or other orientable, two-dimensional surfaces embedded in arbitrary dimension. Each edge is decomposed into two halfedges with opposite orientations. One incident face and one incident vertex are stored in each halfedge. For each face and each vertex, one incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these information, for example the halfedge pointers in faces or the storage of faces at all.

The halfedge data structure is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron\_3* class in Chapter 21.

The data structure provided here is also known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78]

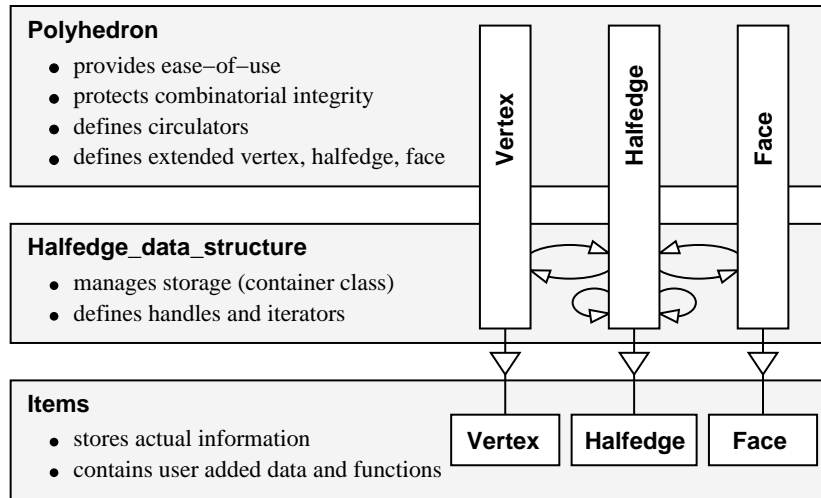

Figure 22.1: Responsibilities of the different layers in the halfedge data-structure design.

describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

The design presented here is a revised and incompatible version of the previous design [Ket98] as used in CGAL R2.2 and earlier releases. Files and identifier names are disjoint with the old design which allows for both versions to co-exists. However, classes using a halfedge data structure can only use one design. For example the polyhedral surface *Polyhedron\_3* uses by default the new design. See Chapter 21 for how to still select the old implementation.

## 22.2 Software Design

Figure 22.1 illustrates the responsibilities of the three layers of the software design, with the *CGAL::Polyhedron\_3* as an example for the top layer. The items provide the space for the information that is actually stored, i.e., with member variables and access member functions in *Vertex*, *Halfedge*, and *Face* respectively. Halfedges are required to provide a reference to the next halfedge and to the opposite halfedge. Optionally they may provide a reference to the previous halfedge, to the incident vertex, and to the incident face. Vertices and faces may be empty. Optionally they may provide a reference to the incident halfedge. The options mentioned are supported in the halfedge data structure and the polyhedron, for example, Euler operations update the optional references if they are present. Furthermore, the item classes can be extended with arbitrary attributes and member functions, which will be promoted by inheritance to the actual classes used for the polyhedron.

Vertices, halfedges, and faces are passed as local types of the *Items* class to the halfedge data structure and polyhedron. Implementations for vertices, halfedges and faces are provided that fulfill the mandatory part of the requirements. They can be used as base classes for extensions by the user. Richer implementations are also provided to serve as defaults; for polyhedra they provide all optional incidences, a three-dimensional point in the vertex type and a plane equation in the face type.

The *Halfedge\_data\_structure*, concept *HalfedgeDS*, is responsible for the storage organization of the items. Currently, implementations using internally a bidirectional list or a vector are provided. The *HalfedgeDS* defines

the handles and iterators belonging to the items. These types are promoted to the declaration of the items themselves and are used there to provide the references to the incident items. This promotion of types is done with a template parameter *Refs* of the item types. The halfedge data structure provides member functions to insert and delete items, to traverse all items, and it gives access to the items.

There are two different models for the *HalfedgeDS* concept available, *HalfedgeDS\_list* and *HalfedgeDS\_vector*, and more might come. Therefore we have kept their interface small and factored out common functionality into separate helper classes, *HalfedgeDS\_decorator*, *HalfedgeDS\_const\_decorator*, and *HalfedgeDS\_items\_decorator*, which are not shown in Figure 22.1, but would be placed at the side of the *HalfedgeDS* since they broaden that interface but do not hide it. These helper classes contain operations that are useful to implement the operations in the next layer, for example, the polyhedron. They add, for example, the Euler operations and partial operations from which further Euler operations can be built, such as inserting an edge into the ring of edges at a vertex. Furthermore, the helper classes contain adaptive functionality. For example, if the *prev()* member function is not provided for halfedges, the *find\_prev()* member function of a helper class searches in the positive direction along the face for the previous halfedge. But if the *prev()* member function is provided, the *find\_prev()* member function simply calls it. This distinction is resolved at compile time with a technique called *compile-time tags*, similar to iterator tags in [SL95].

The *Polyhedron\_3* as an example for the third layer adds the geometric interpretation, provides an easy-to-use interface of high-level functions, and unifies the access to the flexibility provided underneath. It renames face to facet, which is more common for three-dimensional surfaces. The interface is designed to protect the integrity of the internal representation, the handles stored in the items can no longer directly be written by the user. The polyhedron adds the convenient and efficient circulators, see *Circulator*, for accessing the circular sequence of edges around a vertex or around a facet. To achieve this, the *Polyhedron\_3* derives new vertices, halfedges and facets from those provided in *Items*. These new items are those actually used in the *HalfedgeDS*, which gives us the coherent type structure in this design, especially if compared to our previous design.

## 22.3 Example Programs

### 22.3.1 The Default Halfedge Data Structure

The following example program uses the default halfedge data structure and the decorator class. The default halfedge data structure uses a list-based representation. All incidences of the items and a point type for vertices are defined. The trivial traits class provides the type used for the point. The program creates a loop, consisting of two halfedges, one vertex and two faces, and checks its validity.

```
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;
```

```

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

**File:** examples/HalfedgeDS/hds\_prog\_default.cpp

### 22.3.2 A Minimal Halfedge Data Structure

The following program defines a minimal halfedge data structure using the minimal items class `CGAL::HalfedgeDS_min_items` and a list-based halfedge data structure. The result is a data structure maintaining only halfedges with next and opposite pointers. No vertices or faces are stored. The data structure represents an *undirected graph*.

```

#include <CGAL/HalfedgeDS_min_items.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

// no traits needed, argument can be arbitrary dummy.
typedef CGAL::HalfedgeDS_default<int, CGAL::HalfedgeDS_min_items> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

**File:** examples/HalfedgeDS/hds\_prog\_graph.cpp

### 22.3.3 The Default with a Vector Instead of a List

The default halfedge data structure uses a list internally and the maximal base classes. We change the list to a vector representation here. Again, a trivial traits class provides the type used for the point. Note that for the vector storage the size of the halfedge data structure should be reserved beforehand, either with the constructor as shown in the example or with the `reserve()` member function. One can later resize the data structure with further calls to the `reserve()` member function, but only if the data structure is in a consistent, i.e., *valid*, state.

Unfortunately this example has also to expose the workaround necessary for compilers that do not support templates as template parameters. The workaround is necessary if the symbolic constant `CGAL_CFG_NO_TMPL_IN_TMPL_PARAM` is set. It uses a member template instead of the class template.

```

#include <CGAL/HalfedgeDS_items_2.h>

```

```

#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_vector< Traits, CGAL::HalfedgeDS_items_2> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;

int main() {
    HDS hds(1,2,2);
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

**File:** examples/HalfedgeDS/hds\_prog\_vector.cpp

### 22.3.4 Example Adding Color to Faces

This example re-uses the base class available for faces and adds a member variable *color*.

```

#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/IO/Color.h>

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

struct My_traits { // arbitrary point type, not used here.
    typedef int Point_2;
};

typedef CGAL::HalfedgeDS_default<My_traits, My_items> HDS;
typedef HDS::Face Face;
typedef HDS::Face_handle Face_handle;

int main() {
    HDS hds;

```

```

    Face_handle f = hds.faces_push_back( Face( CGAL::RED));
    f->color = CGAL::BLUE;
    CGAL_assertion( f->color == CGAL::BLUE);
    return 0;
}

```

**File:** examples/HalfedgeDS/hds\_prog\_color.cpp

### 22.3.5 Example Defining a More Compact Halfedge

— advanced —

The halfedge data structure as presented here is slightly less space efficient as, for example, the winged-edge data structure [Bau75], the DCEL [MP78] or variants of the quad-edge data structure [GS85]. On the other hand, it does not require any search operations during traversals. A comparison can be found in [Ket99].

The following example trades traversal time for a compact storage representation using traditional C techniques (i.e., type casting and the assumption that pointers, especially those from `malloc` or `new`, point to even addresses). The idea goes as follows: The halfedge data structure allocates halfedges pairwise. Concerning the vector-based data structure this implies that the absolute value of the difference between a halfedge and its opposite halfedge is always one with respect to C pointer arithmetic. We can replace the opposite pointer by a single bit encoding the sign of this difference. We will store this bit as the least significant bit in the next halfedge handle. Furthermore, we do not implement a pointer to the previous halfedge. What remains are three pointers per halfedge.

We use the static member function `halfedge_handle()` to convert from pointers to halfedge handles. The same solution can be applied to the list-based halfedge data structure `CGAL::HalfedgeDS_list`, see examples/HalfedgeDS/hds\_prog\_compact2.cpp. Here is the example for the vector-based data structure.

```

#include <CGAL/HalfedgeDS_items_2.h>
#include <CGAL/HalfedgeDS_vector.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <cstdint>

// Define a new halfedge class. We assume that the Halfedge_handle can
// be created from a pointer (e.g. the HalfedgeDS is based here on the
// In_place_list or a std::vector with such property) and that halfedges
// are allocated in pairs. We encode the opposite pointer in a single bit,
// which is stored in the lower bit of the next-pointer. We use the
// static member function HDS::halfedge_handle to translate pointer to
// handles.
template <class Refs>
class My_halfedge {
public:
    typedef Refs                                HDS;
    typedef My_halfedge<Refs>                    Base_base;
    typedef My_halfedge<Refs>                    Base;
    typedef My_halfedge<Refs>                    Self;
    typedef CGAL::Tag_false                      Supports_halfedge_prev;
    typedef CGAL::Tag_true                      Supports_halfedge_vertex;
    typedef CGAL::Tag_true                      Supports_halfedge_face;
    typedef typename Refs::Vertex_handle        Vertex_handle;

```

```

typedef typename Refs::Vertex_const_handle    Vertex_const_handle;
typedef typename Refs::Halfedge              Halfedge;
typedef typename Refs::Halfedge_handle       Halfedge_handle;
typedef typename Refs::Halfedge_const_handle Halfedge_const_handle;
typedef typename Refs::Face_handle           Face_handle;
typedef typename Refs::Face_const_handle     Face_const_handle;
private:
    std::ptrdiff_t  nxt;
public:
    My_halfedge() : nxt(0), f( Face_handle()) {}

    Halfedge_handle opposite() {
        // Halfedge could be different from My_halfedge (e.g. pointer for
        // linked list). Get proper handle from 'this' pointer first, do
        // pointer arithmetic, then convert pointer back to handle again.
        Halfedge_handle h = HDS::halfedge_handle(this); // proper handle
        if ( nxt & 1)
            return HDS::halfedge_handle( &* h + 1);
        return HDS::halfedge_handle( &* h - 1);
    }
    Halfedge_const_handle opposite() const { // same as above
        Halfedge_const_handle h = HDS::halfedge_handle(this); // proper handle

typedef CGAL::HalfedgeDS_vector<Traits, My_items> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;

int main() {
    HDS hds(1,2,2);
    Decorator decorator(hds);
    decorator.create_loop();
    CGAL_assertion( decorator.is_valid());
    return 0;
}

```

**File:** examples/HalfedgeDS/hds\_prog\_compact.cpp

————— *advanced* —————

## 22.3.6 Example Using the Halfedge Iterator

Two edges are created in the default halfedge data structure. The halfedge iterator is used to count the halfedges.

```

#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits> HDS;
typedef CGAL::HalfedgeDS_decorator<HDS> Decorator;
typedef HDS::Halfedge_iterator          Iterator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    decorator.create_segment();
    CGAL_assertion( decorator.is_valid());
    int n = 0;
}

```

```

    for ( Iterator i = hds.halfedges_begin(); i != hds.halfedges_end(); ++i )
        ++n;
    CGAL_assertion( n == 4); // == 2 edges
    return 0;
}

```

**File:** examples/HalfedgeDS/hds\_prog\_halfedge\_iterator.cpp

### 22.3.7 Example for an Adapter to Build an Edge Iterator

Three edges are created in the default halfedge data structure. The adapter *N\_step\_adaptor* is used to declare the edge iterator used in counting the edges.

```

#include <CGAL/HalfedgeDS_default.h>
#include <CGAL/HalfedgeDS_decorator.h>
#include <CGAL/N_step_adaptor.h>

struct Traits { typedef int Point_2; };
typedef CGAL::HalfedgeDS_default<Traits>          HDS;
typedef CGAL::HalfedgeDS_decorator<HDS>          Decorator;
typedef HDS::Halfedge_iterator                   Halfedge_iterator;
typedef CGAL::N_step_adaptor< Halfedge_iterator, 2> Iterator;

int main() {
    HDS hds;
    Decorator decorator(hds);
    decorator.create_loop();
    decorator.create_segment();
    CGAL_assertion( decorator.is_valid());
    int n = 0;
    for ( Iterator e = hds.halfedges_begin(); e != hds.halfedges_end(); ++e)
        ++n;
    CGAL_assertion( n == 2); // == 2 edges
    return 0;
}

```

**File:** examples/HalfedgeDS/hds\_prog\_edge\_iterator.cpp

# Halfedge Data Structure

## Reference Manual

Lutz Kettner

A halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) is an edge-centered data structure capable of maintaining incidence information of vertices, edges and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure. These classes might be more convenient to use than the halfedge data structure directly, since the halfedge data structure is meant as an implementation layer. See for example the *CGAL::Polyhedron\_3* class in Chapter 21.6.2.

The data structure provided here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a related but different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

## HalfedgeDS<Traits,Items,Alloc>

### Release Note

Beginning with CGAL R2.3, this package has a new design. The old design is still available for backwards compatibility and to support older compiler, such as MSVC++6.0. However its use is deprecated and the manual pages are not converted into this new manual format. Instead, see its old documentation in the manual of deprecated packages. The two designs are not interchangeable.

### Definition

The concept of a halfedge data structure (abbreviated as *HalfedgeDS*, or *HDS* for template parameters) defines an edge-centered data structure capable of maintaining incidence information of vertices, edges, and faces, for example for planar maps or polyhedral surfaces. It is a combinatorial data structure, geometric interpretation is added by classes built on top of the halfedge data structure.

The data structure defined here is known as the FE-structure [Wei85], as halfedges [Män88, BFH95] or as the doubly connected edge list (DCEL) [dBvKOS97], although the original reference for the DCEL [MP78] describes a different data structure. The halfedge data structure can also be seen as one of the variants of the quad-edge data structure [GS85]. In general, the quad-edge data can represent non-orientable 2-manifolds, but the variant here is restricted to orientable 2-manifolds only. An overview and comparison of these different data structures together with a thorough description of the design implemented here can be found in [Ket99].

Each edge is represented by two halfedges with opposite orientations. Each halfedge can store a reference to an incident face and an incident vertex. For each face and each vertex an incident halfedge is stored. Reduced variants of the halfedge data structure can omit some of these incidences, for example the reference to halfedges in vertices or the storage of vertices at all. See Figure 22.2 for the incidences, the mandatory and optional member functions possible for vertices, halfedges, and faces.

Figure 22.2: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

A `HalfedgeDS<Traits,Items,Alloc>` organizes the internal storage of its items. Examples are a list-based or a vector-based storage. The `HalfedgeDS<Traits,Items,Alloc>` exhibits most of the characteristics of the container class used internally, for example the iterator category. A vector resizes automatically when a new item exceeds the reserved space. Since resizing is an expensive operation for a `HalfedgeDS<Traits,Items,Alloc>` in general and only possible in a well defined state of the data structure (no dangling handles), it must be called explicitly in advance for a `HalfedgeDS<Traits,Items,Alloc>` before inserting new items beyond the current capacity. Classes built on top of a `HalfedgeDS<Traits,Items,Alloc>` are advised to call the `reserve()` member function before creating new items.

## Parameters

A `HalfedgeDS<Traits,Items,Alloc>` is a class template and will be used as argument for other class templates, for example `CGAL::Polyhedron_3`. The template parameters to instantiate the `HalfedgeDS<Traits,Items,Alloc>` will be provided by this other class template. Therefore, the three template parameters and their meaning are mandatory. We distinguish between the template `HalfedgeDS<Traits,Items,Alloc>` and an instantiation of it.

*Traits* is a traits class that will be passed to the item types in *Items*. It will not be used in `HalfedgeDS<Traits,Items,Alloc>` itself. *Items* is a model of the *HalfedgeDSItems* concept. *Alloc* is a standard allocator that fulfills all requirements of allocators for STL container classes. The *rebind* mechanism from *Alloc* will be used to create appropriate allocators internally. A default argument is mandatory for *Alloc*, for example, the macro `CGAL_ALLOCATOR(int)` from the `<CGAL/memory.h>` header file can be used as default allocator.

## Types

<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Traits</code>	traits class.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Items</code>	model of <i>HalfedgeDSItems</i> concept.

<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: size_type</code>	size type.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: difference_type</code>	difference type.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: iterator_category</code>	iterator category for all iterators.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: allocator_type</code>	allocator type <i>Alloc</i> .

<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Vertex</code>	model of <i>HalfedgeDSVertex</i> concept.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Halfedge</code>	model of <i>HalfedgeDSHalfedge</i> concept.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Face</code>	model of <i>HalfedgeDSFace</i> concept.

The following handles and iterators have appropriate non-mutable counterparts, i.e., *const\_handle* and *const\_iterator*. The mutable types are assignable to their non-mutable counterparts. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well. **Note:** The handle types must have a default constructor that creates a unique and always the same handle value. It will be used in analogy to `NULL` for pointers.

<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Vertex_handle</code>	handle to vertex.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Halfedge_handle</code>	handle to halfedge.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Face_handle</code>	handle to face.

<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Vertex_iterator</code>	iterator over all vertices.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Halfedge_iterator</code>	iterator over all halfedges.
<code>HalfedgeDS&lt;Traits,Items,Alloc&gt;:: Face_iterator</code>	iterator over all faces.

## Types for Tagging Optional Features

The following types are equal to either `CGAL::Tag_true` or `CGAL::Tag_false`, depending on whether the named feature is supported or not.

<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_vertex_halfedge</i>	<i>Vertex</i> :: <i>halfedge</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_prev</i>	<i>Halfedge</i> :: <i>prev</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_vertex</i>	<i>Halfedge</i> :: <i>vertex</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_halfedge_face</i>	<i>Halfedge</i> :: <i>face</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_face_halfedge</i>	<i>Face</i> :: <i>halfedge</i> ()
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >:: <i>Supports_removal</i>	removal of individual elements.

The following dependencies among these options must be regarded:

Vertices are supported  $\iff$  *Supports\_halfedge\_vertex*  $\equiv$  *CGAL::Tag\_true*.  
 Faces are supported  $\iff$  *Supports\_halfedge\_face*  $\equiv$  *CGAL::Tag\_true*.  
*Supports\_halfedge*  $\equiv$  *CGAL::Tag\_true*  $\implies$  *Supports\_halfedge\_vertex*  $\equiv$  *CGAL::Tag\_true*.  
*Supports\_vertex\_point*  $\equiv$  *CGAL::Tag\_true*  $\implies$  *Supports\_halfedge\_vertex*  $\equiv$  *CGAL::Tag\_true*.  
*Supports\_face\_halfedge*  $\equiv$  *CGAL::Tag\_true*  $\implies$  *Supports\_halfedge\_face*  $\equiv$  *CGAL::Tag\_true*.

## Static Member Functions

When writing an items type, such as a user defined vertex, certain functions need to create a handle but knowing only a pointer, for example, the *this*-pointer. The following static member functions of *HalfedgeDS*<*Traits*,*Items*,*Alloc*> create such a corresponding handle for an item type from a pointer. This conversion encapsulates possible adjustments for hidden data members in the true item type, such as linked-list pointers. Note that the user provides item types with the *Items* template argument, which may differ from the *Vertex*, *Halfedge*, and *Face* types defined in *HalfedgeDS*<*Traits*,*Items*,*Alloc*>. If they differ, they are derived from the user provided item types. We denote the user item types with *Vertex\_base*, *Halfedge\_base*, and *Face\_base* in the following. The fully qualified name for *Vertex\_base* would be for example – assuming that the type *Self* refers to the instantiated *HalfedgeDS* –

```
typedef typename Items::template Vertex_wrapper<Self,Traits> Vertex_wrapper;
typedef typename Vertex_wrapper::Vertex Vertex_base;
```

Implementing these functions relies on the fundamental assumption that an iterator (or handle) of the internally used container class can be constructed from a pointer of a contained item only. This is true and controlled by us for *CGAL::In\_place\_list*. It is true for the *std::vector* of major STL distributions, but not necessarily guaranteed. We might switch to an internal implementation if need arises.

<i>static Vertex_handle</i>	<i>HalfedgeDS</i> :: <i>vertex_handle</i> ( <i>Vertex_base</i> * <i>v</i> )
<i>static Vertex_const_handle</i>	<i>HalfedgeDS</i> :: <i>vertex_handle</i> ( <i>const Vertex_base</i> * <i>v</i> )
<i>static Halfedge_handle</i>	<i>HalfedgeDS</i> :: <i>halfedge_handle</i> ( <i>Halfedge_base</i> * <i>h</i> )
<i>static Halfedge_const_handle</i>	<i>HalfedgeDS</i> :: <i>halfedge_handle</i> ( <i>const Halfedge_base</i> * <i>h</i> )
<i>static Face_handle</i>	<i>HalfedgeDS</i> :: <i>face_handle</i> ( <i>Face_base</i> * <i>f</i> )
<i>static Face_const_handle</i>	<i>HalfedgeDS</i> :: <i>face_handle</i> ( <i>const Face_items</i> * <i>f</i> )

— advanced —

## Creation

<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> ;	empty halfedge data structure.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> ( <i>size_type</i> <i>v</i> , <i>size_type</i> <i>h</i> , <i>size_type</i> <i>f</i> );	storage reserved for <i>v</i> vertices, <i>h</i> halfedges, and <i>f</i> faces.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> > <i>hds</i> ( <i>hds2</i> );	copy constructor. <i>Precondition</i> : <i>hds2</i> contains no dangling handles.
<i>HalfedgeDS</i> < <i>Traits</i> , <i>Items</i> , <i>Alloc</i> >& <i>hds</i> = <i>hds2</i>	assignment operator. <i>Precondition</i> : <i>hds2</i> contains no dangling handles.
<i>void</i> <i>hds.reserve</i> ( <i>size_type</i> <i>v</i> , <i>size_type</i> <i>h</i> , <i>size_type</i> <i>f</i> )	reserves storage for <i>v</i> vertices, <i>h</i> halfedges, and <i>f</i> faces. If all capacities are already greater or equal than the requested sizes nothing happens. Otherwise, <i>hds</i> will be resized and all handles, iterators and circulators invalidate. <i>Precondition</i> : If resizing is necessary <i>hds</i> contains no dangling handles.

## Access Member Functions

<i>Size</i> <i>hds.size_of_vertices</i> ()	number of vertices.
<i>Size</i> <i>hds.size_of_halfedges</i> ()	number of halfedges.
<i>Size</i> <i>hds.size_of_faces</i> ()	number of faces.
<i>Size</i> <i>hds.capacity_of_vertices</i> ()	space reserved for vertices.
<i>Size</i> <i>hds.capacity_of_halfedges</i> ()	space reserved for halfedges.
<i>Size</i> <i>hds.capacity_of_faces</i> ()	space reserved for faces.
<i>size_t</i> <i>hds.bytes</i> ()	bytes used for <i>hds</i> .
<i>size_t</i> <i>hds.bytes_reserved</i> ()	bytes reserved for <i>hds</i> .
<i>allocator_type</i> <i>hds.get_allocator</i> ()	allocator object.

The following member functions return the non-mutable iterator if *hds* is declared const.

<i>Vertex_iterator</i> <i>hds.vertices_begin</i> ()	iterator over all vertices.
<i>Vertex_iterator</i> <i>hds.vertices_end</i> ()	
<i>Halfedge_iterator</i> <i>hds.halfedges_begin</i> ()	iterator over all halfedges
<i>Halfedge_iterator</i> <i>hds.halfedges_end</i> ()	
<i>Face_iterator</i> <i>hds.faces_begin</i> ()	iterator over all faces.
<i>Face_iterator</i> <i>hds.faces_end</i> ()	

## Insertion

Note that the vertex-related and the face-related member functions may not be provided for a *HalfedgeDS*<*Traits*,*Items*,*Alloc*> that does not support vertices or faces respectively.

*Vertex\_handle*      *hds.vertices\_push\_back( const Vertex& v)*

appends a copy of *v* to *hds*. Returns a handle of the new vertex.

*Halfedge\_handle*      *hds.edges\_push\_back( const Halfedge& h, const Halfedge& g)*

appends a copy of *h* and a copy of *g* to *hds* and makes them opposite to each other. Returns a handle of the copy of *h*.

*Halfedge\_handle*      *hds.edges\_push\_back( const Halfedge& h)*

appends a copy of *h* and a copy of *h*→*opposite()* to *hds* and makes them opposite to each other. Returns a handle of the copy of *h*.  
*Precondition: h*→*opposite()* denotes a halfedge.

*Face\_handle*      *hds.faces\_push\_back( const Face& f)*

appends a copy of *f* to *hds*. Returns a handle of the new face.

## Removal

Erasing single elements is optional and indicated with the type tag *Supports\_removal*. The *pop\_back* and the *clear* member functions are mandatory. If vertices or faces are not supported for a *HalfedgeDS*< Traits,Items,Alloc> the *pop\_back* and the *clear* member functions must be provided as null operations.

*void*      *hds.vertices\_pop\_front()*      removes the first vertex if vertices are supported and *Supports\_removal* ≡ *CGAL::Tag\_true*.

*void*      *hds.vertices\_pop\_back()*      removes the last vertex.

*void*      *hds.vertices\_erase( Vertex\_handle v)*      removes the vertex *v* if vertices are supported and *Supports\_removal* ≡ *CGAL::Tag\_true*.

*void*      *hds.vertices\_erase( Vertex\_handle first, Vertex\_handle last)*

removes the range of vertices [*first*,*last*) if vertices are supported and *Supports\_removal* ≡ *CGAL::Tag\_true*.

*void*      *hds.edges\_pop\_front()*      removes the first two halfedges if *Supports\_removal* ≡ *CGAL::Tag\_true*.

*void*      *hds.edges\_pop\_back()*      removes the last two halfedges.

*void*      *hds.edges\_erase( Halfedge\_handle h)*      removes the pair of halfedges *h* and *h*→*opposite()* if *Supports\_removal* ≡ *CGAL::Tag\_true*.

<code>void</code>	<code>hds.edges_erase( Halfedge_handle first, Halfedge_handle last)</code>	removes the range of edges $[first, last)$ if <i>Supports_removal</i> $\equiv$ <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_pop_front()</code>	removes the first face if faces are supported and <i>Supports_removal</i> $\equiv$ <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_pop_back()</code>	removes the last face.
<code>void</code>	<code>hds.faces_erase( Face_handle f)</code>	removes the face <i>f</i> if faces are supported and <i>Supports_removal</i> $\equiv$ <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.faces_erase( Face_handle first, Face_handle last)</code>	removes the range of faces $[first, last)$ if faces are supported and <i>Supports_removal</i> $\equiv$ <i>CGAL::Tag_true</i> .
<code>void</code>	<code>hds.vertices_clear()</code>	removes all vertices.
<code>void</code>	<code>hds.edges_clear()</code>	removes all halfedges.
<code>void</code>	<code>hds.faces_clear()</code>	removes all faces.
<code>void</code>	<code>hds.clear()</code>	removes all elements.

— advanced —

## Operations with Border Halfedges

The following notion of *border halfedges* is particular useful where the halfedge data structure is used to model surfaces with boundary, i.e., surfaces with missing faces or open regions. Halfedges incident to an open region are called *border halfedges*. A halfedge is a *border edge* if the halfedge itself or its opposite halfedge is a border halfedge. The only requirement to work with border halfedges is that the *Halfedge* class provides a member function *is\_border()* returning a *bool*. Usually, the halfedge data structure supports faces and the value of the default constructor of the face handle will indicate a border halfedge, but this may not be the only possibility. The *is\_border()* predicate divides the edges into two classes, the border edges and the non-border edges. The following normalization reorganizes the sequential storage of the edges such that the non-border edges precede the border edges, and that for each border edge the latter of the two halfedges is a border halfedge (the first one might be a border halfedge too). The normalization stores the number of border halfedges, as well as the halfedge iterator where the border edges start at, within the halfedge data structure. These values will be invalid after further halfedge insertions or removals and changes in the border status of a halfedge. There is no automatic update required.

<code>void</code>	<code>hds.normalize_border()</code>	sorts halfedges such that the non-border edges precede the border edges. For each border edge that is incident to a face, the halfedge iterator will reference the halfedge incident to the face right before the halfedge incident to the open region.
-------------------	-------------------------------------	---

Size *hds.size\_of\_border\_halfedges() const*

number of border halfedges. An edge with no incident face counts as two border halfedges.

*Precondition:* *normalize\_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Size *hds.size\_of\_border\_edges() const*

number of border edges. If *size\_of\_border\_edges()* is equal to *size\_of\_border\_halfedges()* all border edges are incident to a face on one side and to an open region on the other side.

*Precondition:* *normalize\_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

Halfedge\_iterator *hds.border\_halfedges\_begin()*

halfedge iterator starting with the border edges. The range [*halfedges\_begin()*, *border\_halfedges\_begin()*) denotes all non-border edges. The range [*border\_halfedges\_begin()*, *halfedges\_end()*) denotes all border edges.

*Precondition:* *normalize\_border()* has been called and no halfedge insertion or removal and no change in border status of the halfedges have occurred since then.

## Implementation

Classes parameterized with a halfedge data structure, such as *CGAL::Polyhedron\_3*, need to declare a class template as one of its template parameters for the *HalfedgeDS<Traits,Items,Alloc>*. For compilers not supporting this (i.e. the flag *CGAL\_CFG\_NO\_TMPL\_IN\_TMPL\_PARAM* is set), the following workaround is required,

which defines a `HalfedgeDS<Traits,Items,Alloc>` as a normal class that contains a member class template named *HDS*, which is the actual halfedge data structure as defined here. The following program fragment illustrates this workaround:

```
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    template <class Traits, class Items, class Alloc>
    class HalfedgeDS {
    public:
        typedef HalfedgeDS<Traits,Items,Alloc> Self;
        HalfedgeDS_vector(); // constructors
#else
    struct HalfedgeDS {
    template <class Traits, class Items, class Alloc>
    class HDS {
    public:
        typedef HDS<Traits,Items,Alloc> Self;
        HDS(); // constructors
#endif
        // ... further member functions. Self denotes the HalfedgeDS.
    };
#ifdef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    };
#endif
```

# HalfedgeDSFace

## Definition

The concept `HalfedgeDSFace` defines the requirements for the local *Face* type in the *HalfedgeDS* concept. It is also required in the *Face\_wrapper*<*Refs*,*Traits*> member class template of an items class, see the *HalfedgeDSItems* concept.

A face optionally stores a reference to an incident halfedge that points to the face. A type tag indicates whether the related member functions are supported. Figure 22.3 on page 1555 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron\_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. (The protection can be bypassed by the user, but not by accident.)

## Types

<i>HalfedgeDSFace::HalfedgeDS</i>	instantiated <i>HalfedgeDS</i> ( $\equiv$ <i>Refs</i> ).

## HalfedgeDSHalfedge

### Definition

The concept `HalfedgeDSHalfedge` defines the requirements for the local *Halfedge* type in the *HalfedgeDS* concept. It is also required in the *Halfedge\_wrapper*<*Refs*,*Traits*> member class template of an items class, see the *HalfedgeDSItems* concept.

A halfedge is an oriented edge between two vertices. It is always paired with a halfedge pointing in the opposite direction. The *opposite()* member function returns this halfedge of opposite orientation. The *next()* member function points to the successor halfedge along the face – or if the halfedge is a border halfedge – along the open region. A halfedge optionally stores a reference to the previous halfedge along the face, a reference to an incident vertex, and a reference to an incident face. Type tags indicate whether the related member functions are supported. Figure 22.3 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

Figure 22.3: The three classes *Vertex*, *Halfedge*, and *Face* of the halfedge data structure. Member functions with shaded background are mandatory. The others are optionally supported.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron\_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. Even more protection is provided for the *set\_opposite()* member function. The base class *Base\_base* provides access to it. (The protection could be bypassed also by an user, but not by accident.)

### Types

<i>HalfedgeDSHalfedge:: HalfedgeDS</i>	instantiated <i>HalfedgeDS</i> ( $\equiv$ <i>Refs</i> ).
<i>HalfedgeDSHalfedge:: Base</i>	base class that allows modifications.
<i>HalfedgeDSHalfedge:: Base_base</i>	base class to access <i>set_opposite()</i> .
<i>HalfedgeDSHalfedge:: Vertex</i>	model of <i>HalfedgeDSVertex</i> .
<i>HalfedgeDSHalfedge:: Face</i>	model of <i>HalfedgeDSFace</i> .
<i>HalfedgeDSHalfedge:: Vertex_handle</i>	handle to vertex.
<i>HalfedgeDSHalfedge:: Halfedge_handle</i>	handle to halfedge.
<i>HalfedgeDSHalfedge:: Face_handle</i>	handle to face.

<i>HalfedgeDSHalfedge:: Halfedge_const_handle</i>	
<i>HalfedgeDSHalfedge:: Face_const_handle</i>	
<i>HalfedgeDSHalfedge:: Supports_halfedge_prev</i>	<i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

<i>HalfedgeDSHalfedge:: Supports_halfedge_vertex</i>	~
<i>HalfedgeDSHalfedge:: Supports_halfedge_face</i>	~

## Creation

<i>HalfedgeDSHalfedge h;</i>	default constructor.
------------------------------	----------------------

## Operations

<i>Halfedge_handle</i>	<i>h.opposite()</i>	
<i>Halfedge_const_handle</i>	<i>h.opposite() const</i>	the opposite halfedge.
<i>void</i>	<i>h.set_opposite( Halfedge_handle h)</i>	sets opposite halfedge to <i>h</i> .

<i>Halfedge_handle</i>	<i>h.next()</i>	
<i>Halfedge_const_handle</i>	<i>h.next() const</i>	the next halfedge around the face.
<i>void</i>	<i>h.set_next( Halfedge_handle h)</i>	sets next halfedge to <i>h</i> .

<i>bool</i>	<i>h.is_border() const</i>	is true if <i>h</i> is a border halfedge.
-------------	----------------------------	---

### Operations available if *Supports\_halfedge\_prev* $\equiv$ *CGAL::Tag\_true*

<i>Halfedge_handle</i>	<i>h.prev()</i>	
<i>Halfedge_const_handle</i>	<i>h.prev() const</i>	the previous halfedge around the face.
<i>void</i>	<i>h.set_prev( Halfedge_handle h)</i>	sets prev halfedge to <i>h</i> .

### Operations available if *Supports\_halfedge\_vertex* $\equiv$ *CGAL::Tag\_true*

<i>Vertex_handle</i>	<i>h.vertex()</i>	
<i>Vertex_const_handle</i>	<i>h.vertex() const</i>	the incident vertex of <i>h</i> .
<i>void</i>	<i>h.set_vertex( Vertex_handle v)</i>	sets incident vertex to <i>v</i> .

### Operations available if *Supports\_halfedge\_face* $\equiv$ *CGAL::Tag\_true*

<i>Face_handle</i>	<i>h.face()</i>	
<i>Face_const_handle</i>	<i>h.face() const</i>	the incident face of <i>h</i> . If <i>h</i> is a border halfedge the result is default construction of the handle.
<i>void</i>	<i>h.set_face( Face_handle f)</i>	sets incident face to <i>f</i> .

# HalfedgeDSItems

## Definition

The concept `HalfedgeDSItems` wraps the three item types – vertex, halfedge, and face – for a halfedge data structure. A `HalfedgeDSItems` contains three member class templates named `Vertex_wrapper`, `Halfedge_wrapper`, and `Face_wrapper`, each with two template parameters, `Refs` and `Traits`. `Refs` requires an instantiated halfedge data structure `HalfedgeDS` as argument, `Traits` is a geometric traits class supplied by the class that uses the halfedge data structure as internal representation. `Traits` is not used by the halfedge data structure itself. These three member class templates provide a local type named `Vertex`, `Halfedge`, and `Face` respectively. The requirements on these types are described on page [1559](#), page [1555](#), and page [1553](#) respectively.

## Types

<code>HalfedgeDSItems::Vertex_wrapper&lt;Refs,Traits&gt;::Vertex</code>	model of <code>HalfedgeDSVertex</code> .
<code>HalfedgeDSItems::Halfedge_wrapper&lt;Refs,Traits&gt;::Halfedge</code>	model of <code>HalfedgeDSHalfedge</code> .
<code>HalfedgeDSItems::Face_wrapper&lt;Refs,Traits&gt;::Face</code>	model of <code>HalfedgeDSFace</code> .

## Has Models

## Example

The following example shows the canonical implementation of the `CGAL::HalfedgeDS_min_items` class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>    Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
```

```

        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_min_base< Refs>      Face;
    };
};

```

See page [1577](#) for an example implementation of the *CGAL::HalfedgeDS\_items\_2* class.

## HalfedgeDSVertex

### Definition

The concept `HalfedgeDSVertex` defines the requirements for the local `Vertex` type in the `HalfedgeDS` concept. It is also required in the `Vertex_wrapper<Refs,Traits>` member class template of an items class, see the `HalfedgeDSItems` concept.

A vertex optionally stores a reference to an incident halfedge that points to the vertex. A type tag indicates whether the related member functions are supported. Figure 22.3 on page 1555 depicts the relationship between a halfedge and its incident halfedges, vertices, and faces.

For the protection of the integrity of the data structure classes such as *CGAL::Polyhedron\_3* are allowed to redefine the modifying member functions to be private. In order to make them accessible for the halfedge data structure they must be derived from a base class *Base* where the modifying member functions are still public. (The protection could be bypassed by an user, but not by accident.)

## Types

<i>HalfedgeDSVertex:: HalfedgeDS</i>	instantiated <i>HalfedgeDS</i> ( $\equiv$ <i>Refs</i> ).
<i>HalfedgeDSVertex:: Base</i>	base class that allows modifications.
<i>HalfedgeDSVertex:: Halfedge</i>	model of <i>HalfedgeDSHalfedge</i> .
<i>HalfedgeDSVertex:: Face</i>	model of <i>HalfedgeDSFace</i> .
<i>HalfedgeDSVertex:: Vertex_handle</i>	handle to vertex.
<i>HalfedgeDSVertex:: Halfedge_handle</i>	handle to halfedge.
<i>HalfedgeDSVertex:: Face_handle</i>	handle to face.
<i>HalfedgeDSVertex:: Vertex_const_handle</i>	
<i>HalfedgeDSVertex:: Halfedge_const_handle</i>	
<i>HalfedgeDSVertex:: Face_const_handle</i>	
<i>HalfedgeDSVertex:: Supports_vertex_halfedge</i>	<i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .

## Creation

<i>HalfedgeDSVertex</i> v;	default constructor.
----------------------------	----------------------

### Operations available if *Supports\_vertex\_halfedge* $\equiv$ *CGAL::Tag\_true*

<i>Halfedge_handle</i>	<i>v.halfedge()</i>	
<i>Halfedge_const_handle</i>	<i>v.halfedge() const</i>	incident halfedge that points to <i>v</i> .
<i>void</i>	<i>v.set_halfedge( Halfedge_handle h )</i>	sets incident halfedge to <i>h</i> .

## CGAL::HalfedgeDS\_const\_decorator<HDS>

### Definition

The classes *CGAL::HalfedgeDS\_items\_decorator<HDS>*, *CGAL::HalfedgeDS\_decorator<HDS>*, and *CGAL::HalfedgeDS\_const\_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS\_items\_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS\_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS\_const\_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_const_decorator.h>
```

### Inherits From

*CGAL::HalfedgeDS\_items\_decorator<HDS>* ..... page 1579

### Creation

```
HalfedgeDS_const_decorator<HDS> D( const HDS& hds);
```

keeps internally a const reference to *hds*.

### Validness Checks

A halfedge data structure has no definition of validness of its own, but a useful set of tests is defined with the following levels:

**Level 0** The number of halfedges is even. All pointers except the vertex pointer and the face pointer for border halfedges are unequal to their respective default construction value. For all halfedges *h*: The opposite halfedge is different from *h* and the opposite of the opposite is equal to *h*. The next of the previous halfedge is equal to *h*. For all vertices *v*: the incident vertex of the incident halfedge of *v* is equal to *v*. The halfedges around *v* starting with the incident halfedge of *v* form a cycle. For all faces *f*: the incident face of the incident halfedge of *f* is equal to *f*. The halfedges around *f* starting with the incident halfedge of *f* form a cycle. Redundancies among internal variables are tested, e.g., that iterators enumerate as many items as the related size value indicates.

**Level 1** All tests of level 0. For all halfedges *h*: The incident vertex of *h* exists and is equal to the incident vertex of the opposite of the next halfedge. The incident face (or hole) of *h* is equal to the incident face (or hole) of the next halfedge.

**Level 2** All tests of level 1. The sum of all halfedges that can be reached through the vertices must be equal to the number of all halfedges, i.e., all halfedges incident to a vertex must form a single cycle.

**Level 3** All tests of level 2. The sum of all halfedges that can be reached through the faces must be equal to the number of all halfedges, i.e., all halfedges surrounding a face must form a single cycle (no holes in faces).

**Level 4** All tests of level 3 and *normalized\_border\_is\_valid*.

*bool*

*D.is\_valid( bool verbose = false, int level = 0)*

returns *true* if the halfedge data structure *hds* is valid with respect to the *level* value as defined above. If *verbose* is *true*, statistics are written to *cerr*.

*bool*

*D.normalized\_border\_is\_valid( bool verbose = false)*

returns *true* if the border halfedges are in normalized representation, which is when enumerating all halfedges with the halfedge iterator the following holds: The non-border edges precede the border edges. For border edges, the second halfedge is a border halfedge. (The first halfedge may or may not be a border halfedge.) The halfedge iterator *border\_halfedges\_begin()* denotes the first border edge. If *verbose* is *true*, statistics are written to *cerr*.

## Example

The following program fragment illustrates the implementation of a *is\_valid()* member function for a simplified polyhedron class. We assume here that the level three check is the appropriate default for polyhedral surfaces.

```
namespace CGAL {
    template <class Traits>
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        bool is_valid( bool verb = false, int level = 0) const {
            Verbose_ostream verr(verb);
            verr << "begin Polyhedron::is_valid( verb=true, level = " << level
                << "):" << std::endl;
            HalfedgeDS_const_decorator<HDS> decorator(hds);
            bool valid = decorator.is_valid( verb, level + 3);
            // further checks ...
        }
    };
}
```

## CGAL::HalfedgeDS\_decorator<HDS>

### Definition

The classes *CGAL::HalfedgeDS\_items\_decorator<HDS>*, *CGAL::HalfedgeDS\_decorator<HDS>*, and *CGAL::HalfedgeDS\_const\_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS\_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS\_const\_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_decorator.h>
```

### Inherits From

*CGAL::HalfedgeDS\_items\_decorator<HDS>* ..... page 1579

### Creation

*HalfedgeDS\_decorator<HDS>* *D*( *HDS& hds*);                      keeps internally a reference to *hds*.

### Creation of New Items

*Vertex\_handle*        *D.vertices\_push\_back( Vertex v)*                      appends a copy of *v* to *hds* if vertices are supported. Returns a handle of the new vertex, or *Vertex\_handle()* otherwise.

*Face\_handle*        *D.faces\_push\_back( Face f)*                      appends a copy of *f* to *hds* if faces are supported. Returns a handle of the new face, or *Face\_handle()* otherwise.

### Creation of New Composed Items

*Halfedge\_handle*    *D.create\_loop()*                      returns handle of a halfedge from a newly created loop in *hds* consisting of a single closed edge, one vertex and two faces (if supported respectively).

*Halfedge\_handle*    *D.create\_segment()*                      returns a halfedge from a newly created segment in *hds* consisting of a single open edge, two vertices and one face (if supported respectively).

## Removal of Elements

The following member functions do *not* update affected incidence relations except if mentioned otherwise.

<code>void D.vertices_pop_front()</code>	removes the first vertex if vertices are supported. <i>Requirement:</i> <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
<code>void D.vertices_pop_back()</code>	removes the last vertex if vertices are supported.
<code>void D.vertices_erase( Vertex_handle v )</code>	removes the vertex <code>v</code> if vertices are supported. <i>Requirement:</i> <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
<code>void D.vertices_erase( Vertex_handle first, Vertex_handle last )</code>	removes the range <code>[first, last)</code> if vertices are supported. <i>Requirement:</i> <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
<code>void D.faces_pop_front()</code>	removes the first face if faces are supported. <i>Requirement:</i> <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
<code>void D.faces_pop_back()</code>	removes the last face if faces are supported.
<code>void D.faces_erase( Face_handle f )</code>	removes the face <code>f</code> if faces are supported. <i>Requirement:</i> <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
<code>void D.faces_erase( Face_handle first, Face_handle last )</code>	removes the range <code>[first, last)</code> if faces are supported. <i>Requirement:</i> <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
<code>void D.erase_face( Halfedge_handle h )</code>	removes the face incident to <code>h</code> from <code>hds</code> and changes all halfedges incident to the face into border edges or removes them from the halfedge data structure if they were already border edges. If this creates isolated vertices they get removed as well. See <code>make_hole(h)</code> for a more specialized variant. <i>Precondition:</i> <code>h-&gt;is_border()</code> $==$ <code>false</code> . <i>Requirement:</i> If faces are supported, <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
<code>void D.erase_connected_component( Halfedge_handle h )</code>	removes the vertices, halfedges, and faces that belong to the connected component of <code>h</code> . <i>Precondition:</i> For all halfedges <code>g</code> in the connected component <code>g.next() != Halfedge_handle()</code> . <i>Requirement:</i> <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .

## Modifying Functions (For Border Halfedges)

<code>Halfedge_handle D.make_hole( Halfedge_handle h )</code>	removes the face incident to <code>h</code> from <code>hds</code> and creates a hole. <i>Precondition:</i> <code>h != Halfedge_handle()</code> and <code>!(h-&gt;is_border())</code> . <i>Requirement:</i> If faces are supported, <code>Supports_removal</code> $\equiv$ <code>CGAL::Tag_true</code> .
---	---

*Halfedge\_handle*    *D.fill\_hole( Halfedge\_handle h)*

fills the hole incident to *h* with a new face from *hds*. Returns *h*.  
*Precondition:* *h*  $\neq$  *Halfedge\_handle()* and *h->is\_border()*.

*Halfedge\_handle*    *D.fill\_hole( Halfedge\_handle h, Face f)*

fills the hole incident to *h* with a copy of face *f*. Returns *h*.  
*Precondition:* *h*  $\neq$  *Halfedge\_handle()* and *h->is\_border()*.

*Halfedge\_handle*    *D.add\_face\_to\_border( Halfedge\_handle h, Halfedge\_handle g)*

extends the surface with a new face from *hds* into the hole incident to *h* and *g*. It creates a new edge connecting the vertex denoted by *g* with the vertex denoted by *h* and fills this separated part of the hole with a new face, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.  
*Precondition:* *h*  $\neq$  *Halfedge\_handle()*, *g*  $\neq$  *Halfedge\_handle()*, *h->is\_border()*, *g->is\_border()* and *g* can be reached along the hole starting with *h*.

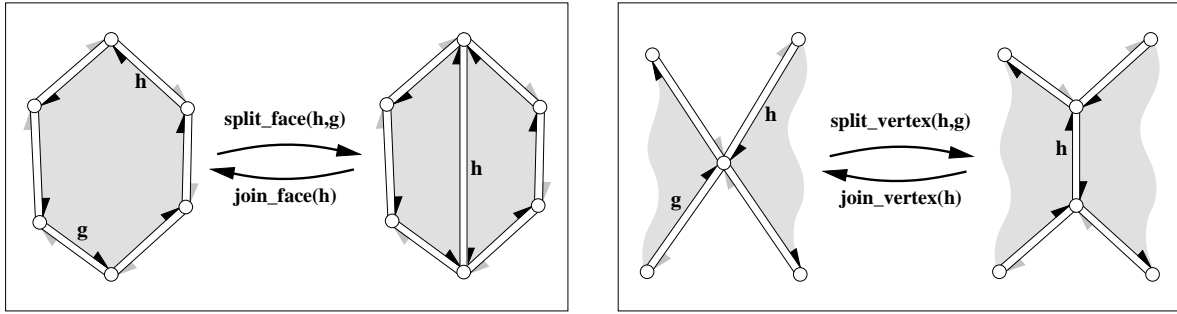

*Halfedge\_handle*    *D.add\_face\_to\_border( Halfedge\_handle h, Halfedge\_handle g, Face f)*

extends the surface with a copy of face *f* into the hole incident to *h* and *g*. It creates a new edge connecting the tip of *g* with the tip of *h* and fills this separated part of the hole with a copy of face *f*, such that the new face is incident to *g*. Returns the new halfedge that is incident to the new face.  
*Precondition:* *h*  $\neq$  *Halfedge\_handle()*, *g*  $\neq$  *Halfedge\_handle()*, *h->is\_border()*, *g->is\_border()* and *g* can be reached along the hole starting with *h*.

### Modifying Functions (Euler Operators)

The following Euler operations modify consistently the combinatorial structure of the halfedge data structure. The geometry remains unchanged. Note that well known graph operations are also captured with these Euler operators, for example an edge contraction is equal to a *join\_vertex()* operation, or an edge removal to *join\_face()*.

Given a halfedge data structure *hds* and a halfedge handle *h* four special applications of the Euler operators are worth mentioning: *split\_vertex(h,h)* results in an antenna emanating from the tip of *h*; *split\_vertex(h,h->next()->opposite())* results in an edge split of the halfedge *h->next* with a new vertex in-between; *split\_face(h,h)* results in a loop directly following *h*; and *split\_face(h,h->next())* results in a bridge parallel to the halfedge *h->next* with a new face in-between.

*Halfedge\_handle* *D.split\_face( Halfedge\_handle h, Halfedge\_handle g)*

splits the face incident to *h* and *g* into two faces with a new diagonal between the two vertices denoted by *h* and *g* respectively. The second (new) face obtained from *hds* is a copy of the first face. Returns *h->next()* after the operation, i.e., the new diagonal. The new face is to the right of the new diagonal, the old face is to the left. The time is proportional to the distance from *h* to *g* around the face.

*Halfedge\_handle* *D.join\_face( Halfedge\_handle h)*

joins the two faces incident to *h*. The face incident to *h->opposite()* gets removed from *hds*. Both faces might be holes. Returns the predecessor of *h* around the face. The invariant *join\_face( split\_face( h, g))* returns *h* and keeps the data structure unchanged. The time is proportional to the size of the face removed and the time to compute *h->prev()*.

*Requirement: Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

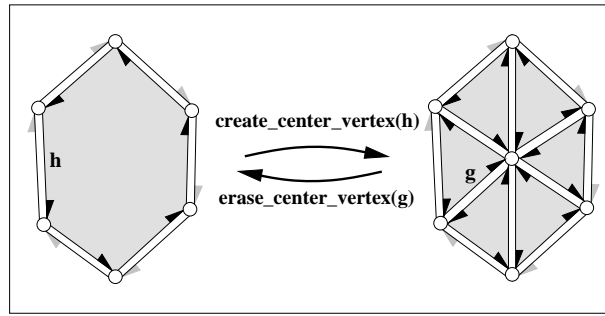

*Halfedge\_handle* *D.split\_vertex( Halfedge\_handle h, Halfedge\_handle g)*

splits the vertex incident to *h* and *g* into two vertices and connects them with a new edge. The second (new) vertex obtained from *hds* is a copy of the first vertex. Returns *h->next()->opposite()* after the operation, i.e., the new edge in the orientation towards the new vertex. The time is proportional to the distance from *h* to *g* around the vertex.

*Halfedge\_handle* *D.join\_vertex( Halfedge\_handle h)*

joins the two vertices incident to *h*. The vertex denoted by *h->opposite()* gets removed by *hds*. Returns the predecessor of *h* around the vertex, i.e., *h->opposite()->prev()*. The invariant *join\_vertex( split\_vertex( h, g))* returns *h* and keeps the polyhedron unchanged. The time is proportional to the degree of the vertex removed and the time to compute *h->prev()* and *h->opposite()->prev()*.

*Requirement: Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

*Halfedge\_handle* *D.create\_center\_vertex( Halfedge\_handle h)*

barycentric triangulation of  $h \rightarrow \text{face}()$ . Creates a new vertex, a copy of  $h \rightarrow \text{vertex}()$ , and connects it to each vertex incident to  $h \rightarrow \text{face}()$  splitting  $h \rightarrow \text{face}()$  into triangles.  $h$  remains incident to the original face, all other triangles are copies of this face. Returns the halfedge  $h \rightarrow \text{next}()$  after the operation, i.e., a halfedge pointing to the new vertex. The time is proportional to the size of the face.

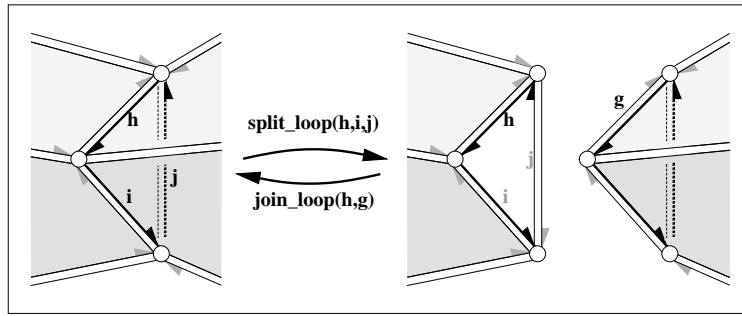

*Precondition:*  $h$  is not a border halfedge.

*Halfedge\_handle* *D.erase\_center\_vertex( Halfedge\_handle g)*

reverses *create\_center\_vertex*. Erases the vertex pointed to by  $g$  and all incident halfedges thereby merging all incident faces. Only  $g \rightarrow \text{face}()$  remains. The neighborhood of  $g \rightarrow \text{vertex}()$  may not be triangulated, it can have larger faces. Returns the halfedge  $g \rightarrow \text{prev}()$ . Thus, the invariant  $h == \text{erase\_center\_vertex}(\text{create\_center\_vertex}(h))$  holds if  $h$  is not a border halfedge. The time is proportional to the sum of the size of all incident faces.

*Precondition:* None of the incident faces of  $g \rightarrow \text{vertex}()$  is a hole. There are at least two distinct faces incident to the faces that are incident to  $g \rightarrow \text{vertex}()$ . (This prevents the operation from collapsing a volume into two faces glued together with opposite orientations, such as would happen with any vertex of a tetrahedron.)

*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

*Halfedge\_handle* *D.split\_loop( Halfedge\_handle h, Halfedge\_handle i, Halfedge\_handle j)*

cuts the halfedge data structure into two parts along the cycle  $(h, i, j)$ . Three new vertices (one copy for each vertex in the cycle) and three new halfedges (one copy for each halfedge in the cycle), and two new triangles are created.  $h, i, j$  will be incident to the first new triangle. The return value will be the halfedge incident to the second new triangle which is the copy of  $h$ -*opposite()*.

*Precondition:*  $h, i, j$  denote distinct, consecutive vertices of the halfedge data structure and form a cycle: i.e.,  $h \rightarrow \text{vertex}() == i \rightarrow \text{opposite}() \rightarrow \text{vertex}(), \dots, j \rightarrow \text{vertex}() == h \rightarrow \text{opposite}() \rightarrow \text{vertex}()$ .

*Halfedge\_handle* *D.join\_loop( Halfedge\_handle h, Halfedge\_handle g)*

glues the boundary of the two faces denoted by  $h$  and  $g$  together and returns  $h$ . Both faces and the vertices along the face denoted by  $g$  gets removed. Both faces may be holes. The invariant  $\text{join\_loop}(h, \text{split\_loop}(h, i, j))$  returns  $h$  and keeps the data structure unchanged.

*Precondition:* The faces denoted by  $h$  and  $g$  are different and have equal degree (i.e., number of edges).

*Requirement:* *Supports\_removal*  $\equiv$  *CGAL::Tag\_true*.

## Validness Checks

These operations are the same as for *CGAL::HalfedgeDS\_const\_decorator<HDS>*. See their documentation on page 1561.

*bool* *D.is\_valid( bool verbose = false, int level = 0)*

*bool* *D.normalized\_border\_is\_valid( bool verbose = false)*

## Miscellaneous

*void* *D.inside\_out()* reverses face orientations.  
*Precondition:* *is\_valid()* of level three.

## See Also

*CGAL::HalfedgeDS\_const\_decorator<HDS>* ..... [page 1561](#)

## Example

The following program fragment illustrates the implementation of the Euler operator *split\_vertex()* for a simplified polyhedron class.

```
template <class Traits>
namespace CGAL {
    class Polyhedron {
        typedef HalfedgeDS_default<Traits> HDS;
        HDS hds;
    public:
        // ...
        Halfedge_handle split_vertex( Halfedge_handle h, Halfedge_handle g) {
            HalfedgeDS_decorator<HDS> D(hds);
            // Stricter preconditions than for HalfedgeDS only.
            CGAL_precondition( D.get_vertex(h) == D.get_vertex(g));
            CGAL_precondition( h != g);
            return D.split_vertex( h, g);
        }
    };
}
```

## CGAL::HalfedgeDS\_default<Traits,HalfedgeDSItems,Alloc>

### Definition

```
template < class Traits,
           class HalfedgeDSItems = CGAL::HalfedgeDS_items_2,
           class Alloc = CGAL_ALLOCATOR(int)>
class HalfedgeDS_default;
```

The class *HalfedgeDS\_default*<Traits,HalfedgeDSItems,Alloc> is a model for the *HalfedgeDS* concept. The second template parameter *HalfedgeDSItems* has a default argument *CGAL::HalfedgeDS\_items\_2*. The third template parameter *Alloc* uses the CGAL default allocator as default setting. *HalfedgeDS\_default*<Traits,HalfedgeDSItems,Alloc> is a list-based representation with bidirectional iterators that supports removal.

```
#include <CGAL/HalfedgeDS_default.h>
```

### Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> ..... page [1545](#)

### Types

```
typedef bidirectional_iterator_tag    iterator_category;
typedef CGAL::Tag_true                Supports_removal;
```

### See Also

*CGAL::HalfedgeDS\_items\_decorator*<HDS> ..... page [1579](#)  
*CGAL::HalfedgeDS\_decorator*<HDS> ..... page [1563](#)  
*CGAL::HalfedgeDS\_const\_decorator*<HDS> ..... page [1561](#)

### Implementation

Currently, *HalfedgeDS\_default*<Traits,HalfedgeDSItems,Alloc> is derived from *CGAL::HalfedgeDS\_list*<Traits>. The copy constructor and the assignment operator need  $O(n)$  time with  $n$  the total number of vertices, halfedges, and faces. The former suboptimal implementation with an  $O(n \log n)$  runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

Due to a workaround for the flag *CGAL\_CFG\_NO\_TMPL\_IN\_TMPL\_PARAM*, a halfedge data structure cannot be instantiated directly. For the *HalfedgeDS\_default*<Traits,HalfedgeDSItems,Alloc> a macro simplifies its direct use. However, when using a halfedge data structure as an argument for another class template, the class template name *HalfedgeDS\_default* must be used, not the macro.

```

// The macro definition.
#ifndef CGAL_CFG_NO_TMPL_IN_TMPL_PARAM
    #define CGAL_HALFEDGEDS_DEFAULT  ::CGAL::HalfedgeDS_default
#else
    #define CGAL_HALFEDGEDS_DEFAULT  ::CGAL::HalfedgeDS_default::HDS
#endif

// The direct instantiation of the default HalfedgeDS given a Traits class.
typedef CGAL_HALFEDGEDS_DEFAULT<Traits> HDS;

```

## CGAL::HalfedgeDS\_face\_base<Refs>

### Definition

The class *HalfedgeDS\_face\_base<Refs>* is a model of the *HalfedgeDSFace* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS\_face\_base<Refs>* has three parameters with some defaults that allow to select various flavors of faces. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

```
template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_face_base;
```

```
template <class Refs, class T, class Plane>
class HalfedgeDS_face_base;
```

*HalfedgeDS\_face\_base<Refs>* defines a face including a reference to an incident halfedge.

*CGAL::HalfedgeDS\_face\_base<Refs,CGAL::Tag\_false>* is a face without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own faces. See also *CGAL::HalfedgeDS\_face\_min\_base<Refs>*.

*CGAL::HalfedgeDS\_face\_base<Refs,CGAL::Tag\_true,Plane>* is a face with a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems\_3* concept.

*CGAL::HalfedgeDS\_face\_base<Refs,CGAL::Tag\_false,Plane>* is a face without a reference to an incident halfedge and it stores a plane equation of type *Plane*. It can be used as a face for a model of the *PolyhedronItems\_3* concept.

```
#include <CGAL/HalfedgeDS_face_base.h>
```

### Is Model for the Concepts

HalfedgeDSFace ..... page [1553](#)

### Types

*HalfedgeDS\_face\_base<Refs>::Plane* plane type for three argument version.

### Creation

*HalfedgeDS\_face\_base<Refs> f;* default constructor.  
*HalfedgeDS\_face\_base<Refs> f(Plane pln);* initialized with plane *pln*.

### Operations

*Plane&* *f.plane()*  
*const Plane&* *f.plane() const*

## CGAL::HalfedgeDS\_halfedge\_base<Refs>

### Definition

The class *HalfedgeDS\_halfedge\_base*<Refs> is a model of the *HalfedgeDSHalfedge* concept. *Refs* is an instantiation of a *HalfedgeDS*. The full declaration states four template parameters:

```
template < class Refs,
           class Tag_prev = CGAL::Tag_true,
           class Tag_vertex = CGAL::Tag_true,
           class Tag_face = CGAL::Tag_true>
class HalfedgeDS_halfedge_base;
```

If *Tag\_prev*  $\equiv$  *CGAL::Tag\_true* a reference to the previous halfedge is supported.

If *Tag\_vertex*  $\equiv$  *CGAL::Tag\_true* an incident vertex is supported.

If *Tag\_face*  $\equiv$  *CGAL::Tag\_true* an incident face is supported.

In all cases, a reference to the next halfedge and to the opposite halfedge is supported.

```
#include <CGAL/HalfedgeDS_halfedge_base.h>
```

## CGAL::HalfedgeDS\_halfedge\_min\_base<Refs>

### Definition

The class *HalfedgeDS\_halfedge\_min\_base<Refs>* is a model of the *HalfedgeDSHalfedge* concept. *Refs* is an instantiation of a *HalfedgeDS*. It is equivalent to *CGAL::HalfedgeDS\_halfedge\_base<Refs, CGAL::Tag\_false, CGAL::Tag\_false, CGAL::Tag\_false>*. The class contains support for the next and the opposite pointer and the required type definitions. It can be used for deriving own halfedges.

```
#include <CGAL/HalfedgeDS_halfedge_min_base.h>
```

## CGAL::HalfedgeDS\_items\_2

### Definition

The class *HalfedgeDS\_items\_2* is a model of the *HalfedgeDSItems* concept. It uses the default types for vertices, halfedges, and faces that declare all incidences supported by a *HalfedgeDS*. The vertex also contains a point of type *Traits::Point\_2*, where *Traits* is the template argument of the corresponding *HalfedgeDS*.

```
#include <CGAL/HalfedgeDS_items_2.h>
```

### Is Model for the Concepts

HalfedgeDSItems.....page [1557](#)

### See Also

*CGAL::HalfedgeDS\_halfedge\_base*<Refs> ..... page [1575](#)  
*CGAL::HalfedgeDS\_face\_base*<Refs> ..... page [1572](#)

### Example

The following example shows the canonical implementation of the *HalfedgeDS\_items\_2* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_items_2 {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef typename Traits::Point_2 Point;
        typedef CGAL::HalfedgeDS_vertex_base< Refs, Tag_true, Point> Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_base< Refs> Face;
    };
};
```

The following example shows a class definition for a new items class derived from the *HalfedgeDS\_items\_2* class. It replaces the *Face\_wrapper* with a new definition of a face that contains a member variable for color. The new face makes use of the face base class provided in the library.

```

// A face type with a color member variable.
template <class Refs>
struct My_face : public CGAL::HalfedgeDS_face_base<Refs> {
    CGAL::Color color;
    My_face() {}
    My_face( CGAL::Color c) : color(c) {}
};

// An items type using my face.
struct My_items : public CGAL::HalfedgeDS_items_2 {
    template <class Refs, class Traits>
    struct Face_wrapper {
        typedef My_face<Refs> Face;
    };
};

```

## CGAL::HalfedgeDS\_items\_decorator<HDS>

### Definition

The classes *CGAL::HalfedgeDS\_items\_decorator<HDS>*, *CGAL::HalfedgeDS\_decorator<HDS>*, and *CGAL::HalfedgeDS\_const\_decorator<HDS>* provide additional functions to examine and to modify a halfedge data structure *HDS*. The class *CGAL::HalfedgeDS\_items\_decorator<HDS>* provides additional functions for vertices, halfedges, and faces of a halfedge data structure without knowing the containing halfedge data structure. The class *CGAL::HalfedgeDS\_decorator<HDS>* stores a reference to the halfedge data structure and provides functions that modify the halfedge data structure, for example Euler-operators. The class *CGAL::HalfedgeDS\_const\_decorator<HDS>* stores a const reference to the halfedge data structure. It contains non-modifying functions, for example the test for validness of the data structure.

All these additional functions take care of the different capabilities a halfedge data structure may have or may not have. The functions evaluate the type tags of the halfedge data structure to decide on the actions. If a particular feature is not supported nothing is done. Note that for example the creation of new halfedges is mandatory for all halfedge data structures and will not appear here again.

```
#include <CGAL/HalfedgeDS_items_decorator.h>
```

### Types

<i>HalfedgeDS_items_decorator&lt;HDS&gt;:: HalfedgeDS</i>	halfedge data structure.
<i>HalfedgeDS_items_decorator&lt;HDS&gt;:: Traits</i>	traits class.
<i>HalfedgeDS_items_decorator&lt;HDS&gt;:: Vertex</i>	vertex type of <i>HalfedgeDS</i> .
<i>HalfedgeDS_items_decorator&lt;HDS&gt;:: Halfedge</i>	halfedge type of <i>HalfedgeDS</i> .
<i>HalfedgeDS_items_decorator&lt;HDS&gt;:: Face</i>	face type of <i>HalfedgeDS</i> .

```
HalfedgeDS_items_decorator<HDS>:: Vertex_handle
HalfedgeDS_items_decorator<HDS>:: Halfedge_handle
HalfedgeDS_items_decorator<HDS>:: Face_handle
HalfedgeDS_items_decorator<HDS>:: Vertex_iterator
HalfedgeDS_items_decorator<HDS>:: Halfedge_iterator
HalfedgeDS_items_decorator<HDS>:: Face_iterator
```

The respective *const\_handle*'s and *const\_iterator*'s are available as well.

```
HalfedgeDS_items_decorator<HDS>:: size_type
HalfedgeDS_items_decorator<HDS>:: difference_type
HalfedgeDS_items_decorator<HDS>:: iterator_category
```

```
HalfedgeDS_items_decorator<HDS>:: Supports_vertex_halfedge
HalfedgeDS_items_decorator<HDS>:: Supports_halfedge_prev
HalfedgeDS_items_decorator<HDS>:: Supports_halfedge_vertex
HalfedgeDS_items_decorator<HDS>:: Supports_halfedge_face
HalfedgeDS_items_decorator<HDS>:: Supports_face_halfedge
HalfedgeDS_items_decorator<HDS>:: Supports_removal
```

## Creation

```
HalfedgeDS_items_decorator<HDS> D;
```

default constructor.

## Access Functions

<i>Halfedge_handle</i>	<i>D.get_vertex_halfedge( Vertex_handle v )</i>	returns the incident halfedge of <i>v</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	---	--

<i>Vertex_handle</i>	<i>D.get_vertex( Halfedge_handle h)</i>	returns the incident vertex of <i>h</i> if supported, <i>Vertex_handle()</i> otherwise.
----------------------	---	--

<i>Halfedge_handle</i>	<i>D.get_prev( Halfedge_handle h )</i>	returns the previous halfedge of <i>h</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	--	---

<i>Halfedge_handle</i> <i>D.find_prev( Halfedge_handle h)</i>	returns the previous halfedge of <i>h</i> . Uses the <i>prev()</i> method if supported or performs a search around the face using <i>next()</i> .
---	---

<i>Halfedge_handle</i>	<i>D.find_prev_around_vertex( Halfedge_handle h)</i>	<p>returns the previous halfedge of <i>h</i>. Uses the <i>prev()</i> method if supported or performs a search around the vertex using <i>next()</i>.</p>
------------------------	--	--

<i>Face_handle</i>	<i>D.get_face( Halfedge_handle h )</i>	returns the incident face of <i>h</i> if supported, <i>Face_handle()</i> otherwise.
--------------------	--	--

<i>Halfedge_handle</i>	<i>D.get_face_halfedge( Face_handle f)</i>	returns the incident halfedge of <i>f</i> if supported, <i>Halfedge_handle()</i> otherwise.
------------------------	--	---

Corresponding member functions for *const\_handle*'s are provided as well.

## Modifying Functions (Composed)

<i>void</i>	<i>D.close_tip( Halfedge_handle h)</i>	makes <i>h-&gt;opposite()</i> the successor of <i>h</i> .
-------------	--	---

void	<i>D.close_tip( Halfedge_handle h, Vertex_handle v)</i>  makes <i>h-&gt;opposite()</i> the successor of <i>h</i> and sets the incident vertex of <i>h</i> to <i>v</i> .
------	--

<code>void</code>	<code>D.insert_tip( Halfedge_handle h, Halfedge_handle v )</code>
	<p>inserts the tip of the edge <math>h</math> into the halfedges around the vertex pointed to by <math>v</math>. Halfedge <math>h \rightarrow \text{opposite}()</math> is the new successor of <math>v</math> and <math>h \rightarrow \text{next}()</math> will be set to <math>v \rightarrow \text{next}()</math>. The vertex of <math>h</math> will be set to the vertex <math>v</math> refers to if vertices are supported.</p>

<i>void</i>	<i>D.remove_tip( Halfedge_handle h)</i>	removes the edge <i>h-&gt;next()-&gt;opposite()</i> from the halfedge circle around the vertex referred to by <i>h</i> . The new successor halfedge of <i>h</i> will be <i>h-&gt;next()-&gt;opposite()-&gt;next()</i> .
-------------	---	---

<i>void</i>	<i>D.insert_halfedge( Halfedge_handle h, Halfedge_handle f)</i>	inserts the halfedge <i>h</i> between <i>f</i> and <i>f-&gt;next()</i> . The face of <i>h</i> will be the one <i>f</i> refers to if faces are supported.
<i>void</i>	<i>D.remove_halfedge( Halfedge_handle h)</i>	removes edge <i>h-&gt;next()</i> from the halfedge circle around the face referred to by <i>h</i> . The new successor of <i>h</i> will be <i>h-&gt;next()-&gt;next()</i> .
<i>void</i>	<i>D.set_vertex_in_vertex_loop( Halfedge_handle h, Vertex_handle v)</i>	loops around the vertex incident to <i>h</i> and sets all vertex pointers to <i>v</i> . <i>Precondition: h != Halfedge_handle().</i>
<i>void</i>	<i>D.set_face_in_face_loop( Halfedge_handle h, Face_handle f)</i>	loops around the face incident to <i>h</i> and sets all face pointers to <i>f</i> . <i>Precondition: h != Halfedge_handle().</i>
<i>Halfedge_handle</i>	<i>D.flip_edge( Halfedge_handle h)</i>	performs an edge flip. It returns <i>h</i> after rotating the edge <i>h</i> one vertex in the direction of the face orientation. <i>Precondition: h != Halfedge_handle() and both incident faces of h are triangles.</i>

### Modifying Functions (Primitives)

<i>void</i>	<i>D.set_vertex_halfedge( Vertex_handle v, Halfedge_handle g)</i>	sets the incident halfedge of <i>v</i> to <i>g</i> .
<i>void</i>	<i>D.set_vertex_halfedge( Halfedge_handle h)</i>	sets the incident halfedge of the vertex incident to <i>h</i> to <i>h</i> .
<i>void</i>	<i>D.set_vertex( Halfedge_handle h, Vertex_handle v)</i>	sets the incident vertex of <i>h</i> to <i>v</i> .
<i>void</i>	<i>D.set_prev( Halfedge_handle h, Halfedge_handle g)</i>	sets the previous link of <i>h</i> to <i>g</i> .
<i>void</i>	<i>D.set_face( Halfedge_handle h, Face_handle f)</i>	sets the incident face of <i>h</i> to <i>f</i> .
<i>void</i>	<i>D.set_face_halfedge( Face_handle f, Halfedge_handle g)</i>	sets the incident halfedge of <i>f</i> to <i>g</i> .
<i>void</i>	<i>D.set_face_halfedge( Halfedge_handle h)</i>	sets the incident halfedge of the face incident to <i>h</i> to <i>h</i> .

### See Also

<i>CGAL::HalfedgeDS_decorator&lt;HDS&gt;</i> .....	page <a href="#">1563</a>
<i>CGAL::HalfedgeDS_const_decorator&lt;HDS&gt;</i> .....	page <a href="#">1561</a>

## Example

The following program fragment illustrates how a refined halfedge class for a polyhedron can make use of the *find\_prev()* member function to implement a *prev()* member function that works regardless of whether the halfedge data structure *HDS* provides a *prev()* member function for its halfedges or not. In the case that not, the implementation given here runs in time proportional to the size of the incident face. For const-correctness a second implementation with signature *Halfedge\_const\_handle prev() const;* is needed.

Note also the use of the static member function *halfedge\_handle()* of the halfedge data structure. It converts a pointer to the halfedge into a halfedge handle. This conversion encapsulates possible adjustments for hidden data members in the true halfedge type, such as linked-list pointers.

```
struct Polyhedron_halfedge {
    // ...
    Halfedge_handle prev() {
        CGAL::HalfedgeDS_items_decorator<HDS> decorator;
        return decorator.find_prev( HDS::halfedge_handle(this));
    }
};
```

## CGAL::HalfedgeDS\_min\_items

### Definition

The class *HalfedgeDS\_min\_items* is a model of the *HalfedgeDSItems* concept. It defines types for vertices, halfedges, and faces that declare the minimal required incidences for a *HalfedgeDS*, which are the *next()* and the *opposite()* member function for halfedges.

```
#include <CGAL/HalfedgeDS_min_items.h>
```

*CGAL::HalfedgeDS\_halfedge\_min\_base<Refs>* ..... page [1576](#)  
*CGAL::HalfedgeDS\_face\_min\_base<Refs>* ..... page [1574](#)

### Example

The following example shows the canonical implementation of the *CGAL::HalfedgeDS\_min\_items* class. It uses the base classes for the item types that are provided in the library.

```
struct HalfedgeDS_min_items {
    template < class Refs, class Traits>
    struct Vertex_wrapper {
        typedef CGAL::HalfedgeDS_vertex_min_base< Refs>    Vertex;
    };
    template < class Refs, class Traits>
    struct Halfedge_wrapper {
        typedef CGAL::HalfedgeDS_halfedge_min_base< Refs> Halfedge;
    };
    template < class Refs, class Traits>
    struct Face_wrapper {
        typedef CGAL::HalfedgeDS_face_min_base< Refs>      Face;
    };
};
```

## CGAL::HalfedgeDS\_list<Traits,HalfedgeDSItems,Alloc>

### Definition

The class *HalfedgeDS\_list*<Traits,HalfedgeDSItems,Alloc> is a model for the *HalfedgeDS* concept. *HalfedgeDS\_list*<Traits,HalfedgeDSItems,Alloc> is a list-based representation with bidirectional iterators that supports removal.

```
#include <CGAL/HalfedgeDS_list.h>
```

### Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> ..... page [1545](#)

### Types

```
typedef bidirectional_iterator_tag    iterator_category;
typedef CGAL::Tag_true               Supports_removal;
```

### Operations

Besides operations required from the concept *HalfedgeDS*<Traits,Items,Alloc>, this class supports additionally:

```
void    hds.vertices_splice( Vertex_iterator target, Self &source, Vertex_iterator first, Vertex_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

*Precondition:* *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

```
void    hds.halfedges_splice( Halfedge_iterator target,
                             Self &source,
                             Halfedge_iterator first,
                             Halfedge_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

*Precondition:* *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

```
void    hds.faces_splice( Face_iterator target, Self &source, Face_iterator first, Face_iterator last)
```

inserts elements in the range *[first, last)* before position *target* and removes the elements from *source*. It takes constant time if *&source == &hds*; otherwise, it takes linear time in the size of the range.

*Precondition:* *[first, last)* is a valid range in *source*. *target* is not in the range *[first, last)*.

<i>CGAL::HalfedgeDS_const_decorator&lt;HDS&gt;</i> .....	page <a href="#">1561</a>

## Implementation

*HalfedgeDS\_list<Traits,HalfedgeDSItems,Alloc>* uses internally the *CGAL::In\_place\_list* container class. The copy constructor and the assignment operator need  $O(n)$  time with  $n$  the total number of vertices, halfedges, and faces. The former suboptimal implementation with an  $O(n \log n)$  runtime has been replaced with a faster implementation based on hashing for the pointer lookup.

*CGAL\_ALLOCATOR(int)* is used as default argument for the *Alloc* template parameter.

## CGAL::HalfedgeDS\_vector<Traits,HalfedgeDSItems,Alloc>

### Definition

The class *HalfedgeDS\_vector<Traits,HalfedgeDSItems,Alloc>* is a model for the *HalfedgeDS* concept. *HalfedgeDS\_vector<Traits,HalfedgeDSItems,Alloc>* is a vector-based representation with random access iterators that does not support removal.

```
#include <CGAL/HalfedgeDS_vector.h>
```

### Is Model for the Concepts

HalfedgeDS<Traits,Items,Alloc> ..... page [1545](#)

### Types

```
typedef random_access_iterator_tag    iterator_category;
typedef CGAL::Tag_false               Supports_removal;
```

### See Also

*CGAL::HalfedgeDS\_decorator<HDS>* ..... page [1563](#)  
*CGAL::HalfedgeDS\_const\_decorator<HDS>* ..... page [1561](#)

### Implementation

*HalfedgeDS\_vector<Traits,HalfedgeDSItems,Alloc>* uses internally the STL *std::vector* container class. We require that we can create a *std::vector::iterator* from a pointer. If this will not be true any longer for any major STL distribution we might switch to an internal implementation of a vector.

The capacity is restricted to the reserved size. Allocations are not possible beyond the capacity without calling *reserve* again. All handles and iterators are invalidated upon a *reserve* call that increases the capacity.

*CGAL\_ALLOCATOR(int)* is used as default argument for the *Alloc* template parameter.

## CGAL::HalfedgeDS\_vertex\_base<Refs>

### Definition

The class *HalfedgeDS\_vertex\_base<Refs>* is a model of the *HalfedgeDSVertex* concept. *Refs* is an instantiation of a *HalfedgeDS*. The template declaration of *HalfedgeDS\_vertex\_base<Refs>* has three parameters with some defaults that allow to select various flavors of vertices. The declaration is best explained with the two following declarations, essentially hiding an implementation dependent default setting:

```
template <class Refs, class T = CGAL::Tag_true>
class HalfedgeDS_vertex_base;
```

```
template <class Refs, class T, class Point>
class HalfedgeDS_vertex_base;
```

*HalfedgeDS\_vertex\_base<Refs>* defines a vertex including a reference to an incident halfedge.

*CGAL::HalfedgeDS\_vertex\_base<Refs,CGAL::Tag\_false>* is a vertex without a reference to an incident halfedge. It is empty besides the required type definitions. It can be used for deriving own vertex implementations. See also *CGAL::HalfedgeDS\_vertex\_min\_base<Refs>*.

*CGAL::HalfedgeDS\_vertex\_base<Refs,CGAL::Tag\_true,Point>* is a vertex with a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems\_3* concept.

*CGAL::HalfedgeDS\_vertex\_base<Refs,CGAL::Tag\_false,Point>* is a vertex without a reference to an incident halfedge and it stores a point of type *Point*. It can be used as a vertex for a model of the *PolyhedronItems\_3* concept.

```
#include <CGAL/HalfedgeDS_vertex_base.h>
```

### 23.1 Introduction

In solid modeling, two major representation schemes are used: *constructive solid geometry* (CSG) and *boundary representations* (B-rep). Both have inherent strengths and weaknesses, see [Hof89c] for a discussion.

In CSG a solid is represented as a set-theoretic boolean combination of primitive solid objects, such as blocks, prisms, cylinders, or toruses. The boolean operations are not evaluated, instead, objects are represented implicitly with a tree structure; leaves represent primitive objects and interior nodes represent boolean operations or rigid motions, e.g., translation and rotation. Algorithms on such a CSG-tree first evaluate properties on the primitive objects and propagate the results using the tree structure.

A B-rep describes the incidence structure and the geometric properties of all lower-dimensional features of the boundary of a solid. Surfaces are oriented to decide between the interior and exterior of a solid.

The class of representable objects in a CSG is usually limited by the choice of the primitive solids. A B-rep is usually limited by the choice for the geometry of the supporting curves for edges and the supporting surfaces for surface patches, and, in addition, the connectivity structure that is allowed. In particular, a B-rep is not always closed under boolean set operations. As an example, the class of orientable 2-manifold objects is a popular and well understood class of surfaces commonly used for B-reps. They can be represented and manipulated efficiently, the data structures are compact in storage size, and many algorithms are simple. On the other side, this object class is not closed under boolean set operations, as many examples can illustrate, such as the Figure shown above that can be generated using boolean set operations on cubes. The vertices bounding the tunnel, or the edge connecting the “roof” with the cube are non-manifold situations.

In our implementation of Nef polyhedra in 3D, we offer a B-rep data structure that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations (see Section 23.4 for an explanation of regularized set operations). In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) transformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL-based visualizer for debugging and illustrations.

## 23.2 Definition

The theory of Nef polyhedra has been developed for arbitrary dimensions. The class `CGAL::Nef_polyhedron_3` implements a boundary representation for the 3-dimensional case.

**Definition:** A *Nef-polyhedron* in dimension  $d$  is a point set  $P \subseteq \mathbb{R}^d$  generated from a finite number of open halfspaces by set complement and set intersection operations.

Set union, difference and symmetric difference can be reduced to intersection and complement. Set complement changes between open and closed halfspaces, thus the topological operations *boundary*, *interior*, *exterior*, *closure* and *regularization* are also in the modeling space of Nef polyhedra.

A face of a Nef polyhedron is defined as an equivalence class of *local pyramids* that are a characterization of the local space around a point.

**Definition:** A point set  $K \subseteq \mathbb{R}^d$  is called a *cone with apex 0*, if  $K = \mathbb{R}^+ K$  (i.e.,  $\forall p \in K, \forall \lambda > 0 : \lambda p \in K$ ) and

it is called a *cone with apex*  $x$ ,  $x \in \mathbb{R}^d$ , if  $K = x + \mathbb{R}^+(K - x)$ . A cone  $K$  is called a *pyramid* if  $K$  is a polyhedron.

Now let  $P \in \mathbb{R}^d$  be a polyhedron and  $x \in \mathbb{R}^d$ . There is a neighborhood  $U_0(x)$  of  $x$  such that the pyramid  $Q := x + \mathbb{R}^+((P \cap U(x)) - x)$  is the same for all neighborhoods  $U(x) \subseteq U_0(x)$ .  $Q$  is called the *local pyramid* of  $P$  in  $x$  and denoted  $\text{Pyr}_P(x)$ .

**Definition:** Let  $P \in \mathbb{R}^d$  be a polyhedron and  $x, y \in \mathbb{R}^d$  be two points. We define an equivalence relation  $x \sim y$  iff  $\text{Pyr}_P(x) = \text{Pyr}_P(y)$ . The equivalence classes of  $\sim$  are the *faces* of  $P$ . The dimension of a face  $s$  is the dimension of its affine hull,  $\dim s := \dim \text{aff } s$ .

In other words, a *face*  $s$  of  $P$  is a maximal non-empty subset of  $\mathbb{R}^d$  such that all of its points have the same local pyramid  $Q$  denoted  $\text{Pyr}_P(s)$ . This definition of a face partitions  $\mathbb{R}^d$  into faces of different dimension. A face  $s$  is either a subset of  $P$ , or disjoint from  $P$ . We use this later in our data structure and store a selection mark in each face indicating its set membership.

Faces do not have to be connected. There are only two full-dimensional faces possible, one whose local pyramid is the space  $\mathbb{R}^d$  itself and the other with the empty set as a local pyramid. All lower-dimensional faces form the *boundary* of the polyhedron. As usual, we call zero-dimensional faces *vertices* and one-dimensional faces *edges*. In the case of polyhedra in space we call two-dimensional faces *facets* and the full-dimensional faces *volumes*. Faces are *relative open* sets, e.g., an edge does not contain its end-vertices.

We illustrate the definitions with an example in the plane. Given the closed halfspaces

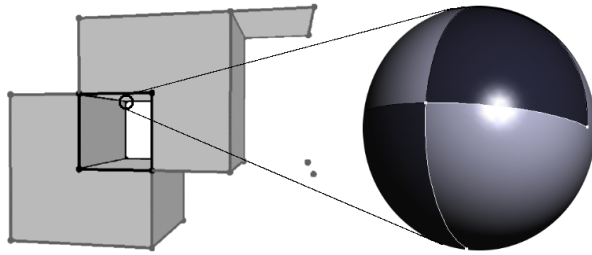

$$h_1 : y \geq 0, \quad h_2 : x - y \geq 0, \quad h_3 : x + y \leq 3, \quad h_4 : x - y \geq 1, \quad h_5 : x + y \leq 2,$$

we define our polyhedron  $P := (h_1 \cap h_2 \cap h_3) - (h_4 \cap h_5)$ .

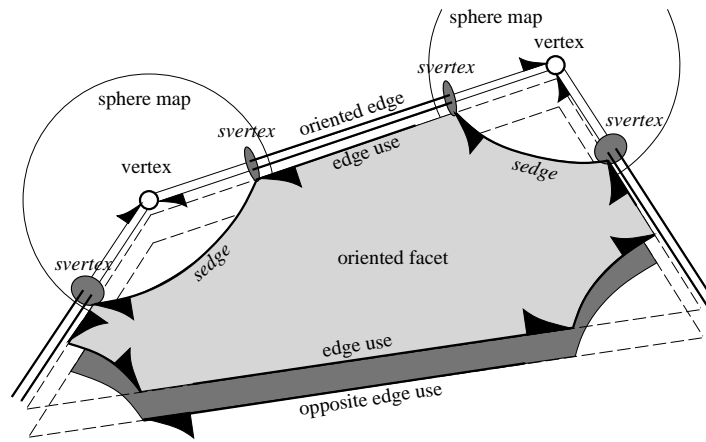

The left figure illustrates the polyhedron with its partially closed and partially open boundary, i.e., vertex  $v_4, v_5, v_6$ , and edges  $e_4$  and  $e_5$  are not part of  $P$ . The local pyramids for the faces are  $\text{Pyr}_P(f_1) = \emptyset$  and  $\text{Pyr}_P(f_2) = \mathbb{R}^2$ . Examples for the local pyramids of edges are the closed halfspace  $h_2$  for the edge  $e_1$ ,  $\text{Pyr}_P(e_1) = h_2$ , and the open halfspace that is the complement of  $h_4$  for the edge  $e_5$ ,  $\text{Pyr}_P(e_5) = \{(x, y) | x - y < 1\}$ . The edge  $e_3$  consists actually of two disconnected parts, both with the same local pyramid  $\text{Pyr}_P(e_3) = h_1$ . In our data structure, we will represent the two connected components of the edge  $e_3$  separately. The figure on the right lists all local pyramids for this example.

The local pyramids of each vertex are represented by conceptually intersecting the local neighborhood with a small  $\epsilon$ -sphere. This intersection forms a planar map on the sphere (see next two figures), which together with the set-selection mark for each item (i.e. vertices, edges, loops and faces) forms a two-dimensional Nef polyhedron embedded in the sphere. We add the set-selection mark for the vertex and call the resulting structure the *sphere map* of the vertex. We use the prefix  $s$  to distinguish the elements of the sphere map from the three-dimensional elements. See Chapter 17 for further details.

Having sphere maps for all vertices of our polyhedron is a sufficient but not easily accessible representation of the polyhedron. We enrich the data structure with more explicit representations of all the faces and incidences between them.

We depart slightly from the definition of faces in a Nef polyhedron; we represent the connected components of a face individually and do not implement additional bookkeeping to recover the original faces (e.g., all edges on a common supporting line with the same local pyramid) as this is not needed in our algorithms. We discuss features in the increasing order of dimension.

**edges:** We store two oppositely oriented edges for each edge and have a pointer from one oriented edge to its opposite edge. Such an oriented edge can be identified with an *svertex* in a sphere map; it remains to link one *svertex* with the corresponding opposite *svertex* in the other sphere map.

**edge uses:** An edge can have many incident facets (non-manifold situation). We introduce two oppositely oriented edge-uses for each incident facet; one for each orientation of the facet. An edge-use points to its corresponding oriented edge and to its oriented facet. We can identify an edge-use with an oriented *sedge* in the sphere map, or, in the special case also with an *sloop*. Without mentioning it explicitly in the remainder, all references to *sedge* can also refer to *sloop*.

**facets:** We store oriented facets as boundary cycles of oriented edge-uses. We have a distinguished outer boundary cycle and several (or maybe none) inner boundary cycles representing holes in the facet. Boundary cycles are linked in one direction. We can access the other traversal direction when we switch to the oppositely oriented facet, i.e., by using the opposite edge-use.

**shells:** The volume boundary decomposes into different connected components, the *shells*. A shell consists of a connected set of facets, edges, and vertices incident to this volume. Facets around an edge form a radial order that is captured in the radial order of *sedges* around an *svertex* in the sphere map. Using this information, we can trace a shell from one entry element with a graph search. We offer this graph traversal (to the user) in a visitor design pattern.

**volumes:** A volume is defined by a set of shells, one outer shell containing the volume and several (or maybe none) inner shells separating voids which are excluded from the volume.

For each face we store a label, e.g., a set-selection mark, which indicates whether the face is part of the solid or if it is excluded. We call the resulting data structure *Selective Nef Complex*, *SNC* for short [GHH<sup>+</sup>03]. However, in CGAL we identify the names and call the *SNC* data structure *CGAL::Nef\_polyhedron\_3*.

### 23.3 Infimaximal Box

We call a Nef polyhedron *bounded* if its boundary is bounded, i.e., finite, and *unbounded* otherwise. Note that unbounded point sets can have a bounded boundary, for example, the complement of a cube has an unbounded outer volume, but its boundary remains bounded.

Using a boundary representation, it is convenient (conceptually and in our implementation) to consider bounded Nef polyhedra only. Bounded Nef polyhedra are also closed under boolean set operations. However, one needs to start with bounded primitives; the conceptually nice halfspaces cannot be used. Instead, we offer a construction from oriented 2-manifolds represented in a *CGAL::Polyhedron\_3*, see Section 23.5.4 below.

In order to handle unbounded Nef polyhedra conceptually in the same way as we handle bounded Nef polyhedra, we intersect them with a bounding cubical volume of size  $[-R, R]^3$ , where  $R$  is a symbolical unspecified value, which is finite but larger than all coordinate values that may occur in the bounded part of the polyhedron. As a result, each Nef polyhedron becomes bounded. We call the boundary of the bounding volume the *infimaximal box* [SM00].

We clip lines and rays at the infimaximal box. The intersection points with the infimaximal box are called *non-standard points*, which are points whose coordinates are  $-R$  or  $R$  in at least one dimension, and linear functions  $f(R)$  for the other dimensions. Such extended points (and developed from there also extended segments etc) are provided in CGAL with extended kernels—*CGAL::Extended\_cartesian* and *CGAL::Extended\_homogeneous*. They are regular CGAL kernels with a polynomial type as coordinate number type.

As long as an extended kernel is used, the full functionality provided by the *CGAL::Nef\_polyhedron\_3* class is available. If a kernel that does not use polynomials to represent coordinates is used, it is not possible to create or load unbounded Nef polyhedra, but all other operations work as expected. We provided both possibilities, since the restriction to bounded Nef polyhedra improves considerably space requirements (plain number type instead of polynomial), and runtime performance.

### 23.4 Regularized Set Operations

Since manifolds are not closed under boolean operations, Requicha proposes to use *regularized set operations* [KM76, Req80]. A set is *regular*, if it equals the closure of its interior. A regularized set operation is defined as the standard set operation followed by a regularization of the result. Regularized sets are closed under regularized set operations.

Regularized set operations are important since they simplify the class of solids to exclude lower dimensional features and the boundary belongs to the point set. These properties are considered to reflect the nature of physical solids more closely.

Regularized polyhedral sets are a subclass of Nef polyhedra. We provide the *regularization* operation as a shortcut for the consecutive execution of the *interior* and the *closure* operations.

## 23.5 Example Programs

The following example gives a first impression of how to instantiate and use *Nef\_polyhedron\_3*. We use the *CGAL::Cartesian* kernel. All Cartesian and homogeneous kernels of CGAL are suitable if the number type parameter follows the usual requirements of being a model of the *CGAL::FieldNumberType* concept for the Cartesian kernels, or the *CGAL::RingNumberType* concept for the homogeneous kernels, respectively. Note however, that in the current state, the Nef polyhedron works only with CGAL kernels. The implementation makes use of CGAL specific functions in kernel objects, and does not yet offer a designed interface to a clean kernel concept that could be offered by an external kernel as well.

The example creates two Nef polyhedra—*N0* is the empty set, while *N1* represents the full space, i.e., the set of all points in the 3-dimensional space. The assertion assures that the empty set is the complement of the full space.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {
    Nef_polyhedron N0(Nef_polyhedron::EMPTY);
    Nef_polyhedron N1(Nef_polyhedron::COMPLETE);

    CGAL_assertion (N0 == N1.complement());
    return 0;
}
```

**File:** examples/Nef\_3/nef\_3\_simple.cpp

### 23.5.1 Construction and Comparison

This example shows the various constructors. We can create the empty set, which is also the default constructor, and the full space, i.e. all points of  $\mathbb{R}^3$  belong to the polyhedron. We can create a halfspace defined by a plane bounding it. It is only available if an extended kernel is used. The halfspace constructor has a second parameter that specifies whether the defining plane belongs to the point set (*Nef\_polyhedron::INCLUDED*) or not (*Nef\_polyhedron::EXCLUDED*). The default value is *Nef\_polyhedron::INCLUDED*. Additionally, we can create a *Nef\_polyhedron\_3* from a *Polyhedron\_3*, see the Section 23.5.4 below.

We can compute the point sets of two Nef polyhedra for equality and proper subset relationships. We offer the usual comparison operators `==`, `!=`, `<=`, `>=`, `<` and `>`.

Nef polyhedra have the important feature that a representation that is called the *reduced Würzburg structure* is unique, i.e., two point sets of Nef polyhedra are equal if and only if the representations are equal. The proof for the reduced Würzburg structure carries over to our representation and the comparison operators are therefore trivial to implement.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
```

```

#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Plane_3 Plane_3;

int main() {
    Nef_polyhedron N0;
    Nef_polyhedron N1(Nef_polyhedron::EMPTY);
    Nef_polyhedron N2(Nef_polyhedron::COMPLETE);
    Nef_polyhedron N3(Plane_3( 1, 2, 5,-1));
    Nef_polyhedron N4(Plane_3( 1, 2, 5,-1), Nef_polyhedron::INCLUDED);
    Nef_polyhedron N5(Plane_3( 1, 2, 5,-1), Nef_polyhedron::EXCLUDED);

    CGAL_assertion(N0 == N1);
    CGAL_assertion(N3 == N4);
    CGAL_assertion(N0 != N2);
    CGAL_assertion(N3 != N5);

    CGAL_assertion(N4 >= N5);
    CGAL_assertion(N5 <= N4);
    CGAL_assertion(N4 > N5);
    CGAL_assertion(N5 < N4);

    N5 = N5.closure();
    CGAL_assertion(N4 >= N5);
    CGAL_assertion(N4 <= N5);

    return 0;
}

```

**File:** examples/Nef\_3/nef\_3\_construction.cpp

### 23.5.2 Point Set Operations

As explained in the introduction, Nef polyhedra are closed under all boolean set operations. The class *Nef\_polyhedron\_3* provides functions and operators for the most common ones: complement (*operator!*), union (*operator+*), difference (*operator-*), intersection (*operator\**) and symmetric difference (*operator^*). Additionally, the operators *\*=*, *-=*, *\*=* and *^=* are defined.

*Nef\_polyhedron\_3* also provides the topological operations *interior()*, *closure()* and *boundary()*. With *interior()* one deselects all boundary items, with *boundary()* one deselects all volumes, and with *closure()* one selects all boundary items.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>

typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Plane_3 Plane_3;

```

```

int main() {

    Nef_polyhedron N1(Plane_3( 1, 0, 0,-1));
    Nef_polyhedron N2(Plane_3(-1, 0, 0,-1));
    Nef_polyhedron N3(Plane_3( 0, 1, 0,-1));
    Nef_polyhedron N4(Plane_3( 0,-1, 0,-1));
    Nef_polyhedron N5(Plane_3( 0, 0, 1,-1));
    Nef_polyhedron N6(Plane_3( 0, 0,-1,-1));

    Nef_polyhedron I1(!N1 + !N2); // open slice in yz-plane
    Nef_polyhedron I2(N3 - !N4); // closed slice in xz-plane
    Nef_polyhedron I3(N5 ^ N6); // open slice in yz-plane
    Nef_polyhedron Cube1(I2 * !I1);
    Cube1 *= !I3;
    Nef_polyhedron Cube2 = N1 * N2 * N3 * N4 * N5 * N6;

    CGAL_assertion(Cube1 == Cube2); // both are closed cube
    CGAL_assertion(Cube1 == Cube1.closure());
    CGAL_assertion(Cube1 == Cube1.regularization());
    CGAL_assertion((N1 - N1.boundary()) == N1.interior());
    CGAL_assertion(I1.closure() == I1.complement().interior().complement());
    CGAL_assertion(I1.regularization() == I1.interior().closure());
    return 0;
}

```

**File:** examples/Nef\_3/point\_set\_operations.cpp

### 23.5.3 Transformation

Using the `std::transform` function, a Nef polyhedron can be translated, rotated and scaled. The usage is shown in the following example:

```

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

//instead of
//typedef CGAL::Extended_homogeneous<CGAL::Gmpz> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Extended_homogeneous<CGAL::Gmpz> {};

typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Plane_3 Plane_3;
typedef Nef_polyhedron::Vector_3 Vector_3;
typedef Nef_polyhedron::Aff_transformation_3 Aff_transformation_3;

int main() {

    Nef_polyhedron N(Plane_3(0,1,0,0));

```

```

Aff_transformation_3 transl(CGAL::TRANSLATION, Vector_3(5, 7, 9));
Aff_transformation_3 rotx90(1,0,0,
    0,0,-1,
    0,1,0,
    1);
Aff_transformation_3 scale(3,0,0,
    0,3,0,
    0,0,3,
    2);

N.transform(transl);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0,1,0,-7)));
N.transform(rotx90);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0,0,1,-7)));
N.transform(scale);
CGAL_assertion(N == Nef_polyhedron(Plane_3(0,0,2,-21)));

return 0;
}

```

**File:** examples/Nef\_3/transformation.cpp

### 23.5.4 The Interface between Polyhedron\_3 and Nef\_polyhedron\_3

*Nef\_polyhedron\_3* provides an interface for the conversion between polyhedral surfaces represented with the *CGAL::Polyhedron\_3* class and *Nef\_polyhedron\_3*. *Polyhedron\_3* represents orientable 2-manifold objects with boundaries. However, we exclude surfaces with boundaries from the conversion to *Nef\_polyhedron\_3* since they have no properly defined volume.

Both conversion directions can only be performed if the boundary of the point set is an oriented closed 2-manifold. *Nef\_polyhedron\_3* provides the function *is\_simple()* and *Polyhedron\_3* provides the function *is\_closed()* to test for this property. The usage is illustrated by the example program below.

The conversion gives us the possibility to use several file formats. *Polyhedron\_3* can read the (.off) file format and can write the (.off), OpenInventor (.iv), VRML 1.0 and 2.0 (.wrl) and Wavefront Advanced Visualizer object format (.obj), see Section 21.4.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <iostream>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Vector_3 Vector_3;
typedef Kernel::Aff_transformation_3 Aff_transformation_3;

int main() {

```

```

Polyhedron P;
std::cin >> P;
if(P.is_closed()) {
    Nef_polyhedron N1(P);
    Nef_polyhedron N2(N1);
    Aff_transformation_3 aff(CGAL::TRANSLATION, Vector_3(2,2,0,1));
    N2.transform(aff);
    N1 += N2;

    if(N1.is_simple()) {
        N1.convert_to_Polyhedron(P);
        std::cout << P;
    }
    else
        std::cerr << "N1 is not a 2-manifold." << std::endl;
}
}

```

**File:** examples/Nef\_3/interface\_polyhedron.cpp

### 23.5.5 Using an Extended Kernel

The provided extended kernels are used the same way as any other CGAL kernel. The essential difference is, that coordinates are not represented by the number type that was used to parameterize the kernel type, but by a *Nef\_polynomial* parametrized by that number type.

The example iterates all vertices of a given Nef polyhedron and decides whether it is an standard vertex or a vertex on the infimal box. Furthermore, it tests whether any of the vertices is at  $(R, R, R)$ . Recall that  $R$  was the symbolical value, large but finite, for the size of the infimal box.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Gmpz NT;
//instead of
//typedef CGAL::Extended_homogeneous<NT> Kernel;
// workaround for VC++
struct Kernel : public CGAL::Extended_homogeneous<NT> {};

typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::RT RT;
typedef Nef_polyhedron::Point_3 Point_3;
typedef Nef_polyhedron::Plane_3 Plane_3;
typedef Nef_polyhedron::Vertex_const_iterator Vertex_const_iterator;

int main() {

    Nef_polyhedron N;
    std::cin >> N;

```

```

Vertex_const_iterator v;
for(v = N.vertices_begin(); v != N.vertices_end(); ++v) {
    Point_3 p(v->point());
    if(p.hx().degree() > 0 || p.hy().degree() > 0 || p.hz().degree() > 0)
        std::cout << "extended vertex at " << p << std::endl;
    else
        std::cout << "standard vertex at " << p << std::endl;

    if(p == Point_3(RT(0,1), RT(0,1), RT(0,1)))
        std::cout << " found vertex (right,back,top) of the infimaximal box"
            << std::endl;
}

return 0;
}

```

**File:** examples/Nef\_3/extended\_kernel.cpp

## 23.6 File I/O

*Nef\_polyhedron\_3* provides an input and an output operator for a proprietary file format. It includes the complete incidence structure, the geometric data, and the marks of each item. The output depends on the output operators of the geometric primitives provided by the traits class, and on the output operators of the used number type. Therefore, it is necessary to use the same kernel and the same number type for input and output operations.

We recommend the use of the CGAL kernels *Homogeneous*, *Exact\_predicates\_exact\_constructions\_kernel*, or *Extended\_homogeneous*. The Homogeneous kernel provides reliable fast performance. In combination with *leda\_integer* it is the fastest kernel for *Nef\_polyhedron\_3*. The *Exact\_predicates\_exact\_constructions\_kernel* uses filtering. In non-degenerate scenarios it's faster than the *Homogeneous* kernel. The most important advantage of the filtered kernel is that it is a Cartesian kernel, which allows the proper handling of OFF files using floating-point coordinates.

For effective filtering we had to change some concepts. The new concepts must be activated by using the *SNC\_indexed\_items*, because they don't apply for the extended kernels, yet. The new concepts also speed up *Nef\_polyhedron\_3* also in combination with all other standard kernels. The following example illustrates their usage.

```

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;

int main() {

    Polyhedron P;
    std::cin >> P;

```

```

Nef_polyhedron N(P);

std::cout << "Exact_predicates_exact_constructions_kernel + SNC_indexed_items"
    << std::endl
    << "  allows efficient handling of input "
"using floating point coordinates"
    << std::endl;

if(N.is_simple()) {
    N.convert_to_Polyhedron(P);
    std::cout << P;
}
else {
    std::cout << N;
}
}

```

**File:** examples/Nef\_3/handling\_double\_coordinates.cpp

We provide compatibility between the input and output of various kernels. For most of the CGAL kernels it is possible to write a file constructed with one kernel and reread it with another. Also, it is possible to write a bounded Nef polyhedron using the *Extended\_homogeneous* kernel and to read it afterwards using a standard kernel.

```

#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Extended_homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <fstream>

typedef CGAL::Gmpz NT;
typedef CGAL::Homogeneous<NT> SK;
typedef CGAL::Extended_homogeneous<NT> EK;
typedef CGAL::Nef_polyhedron_3<SK> Nef_polyhedron_S;
typedef CGAL::Nef_polyhedron_3<EK> Nef_polyhedron_E;

int main() {
    Nef_polyhedron_E E;
    Nef_polyhedron_S S;

    std::cin >> E;

    if(E.is_bounded()) {
        std::ofstream out("temp.nef3");
        out << E;
        std::ifstream in("temp.nef3");
        in >> S;
    }
}

```

**File:** examples/Nef\_3/nefIO.cpp

## 23.7 Further Example Programs

### 23.7.1 Exploring a Sphere Map

A sphere map is explored by using the function *get\_sphere\_map*, which returns the sphere map of the specified vertex as a *Nef\_polyhedron\_S2*. *Nef\_polyhedron\_S2* provides the functionality necessary for the exploration. Note, that one has to use the type *Nef\_polyhedron\_S2* as specified in *Nef\_polyhedron\_3* as is shown in the following example.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main() {

    // We've put the typedefs here as VC7 gives us an ICE if they are global typedefs
    typedef Nef_polyhedron_3::Vertex_const_iterator Vertex_const_iterator;
    typedef Nef_polyhedron_3::Nef_polyhedron_S2 Nef_polyhedron_S2;
    typedef Nef_polyhedron_S2::SVertex_const_handle SVertex_const_handle;
    typedef Nef_polyhedron_S2::SHalfedge_const_handle SHalfedge_const_handle;
    typedef Nef_polyhedron_S2::SHalfloop_const_handle SHalfloop_const_handle;
    typedef Nef_polyhedron_S2::SFace_const_iterator SFace_const_iterator;
    typedef Nef_polyhedron_S2::SFace_cycle_const_iterator
        SFace_cycle_const_iterator;

    Nef_polyhedron_3 N;
    std::cin >> N;

    Vertex_const_iterator v = N.vertices_begin();
    Nef_polyhedron_S2 S(N.get_sphere_map(v));

    int i=0;
    SFace_const_iterator sf;
    for(sf = S.sfaces_begin(); sf != S.sfaces_end(); sf++) {
        SFace_cycle_const_iterator it;
        std::cout << "the sface cycles of sface " << i++ << " start with an\n";
        for(it = sf->sface_cycles_begin(); it != sf->sface_cycles_end(); it++) {
            if (it.is_svertex())
                std::cout << " svertex at position "
                    << SVertex_const_handle(it)->point() << std::endl;
            else if (it.is_shalfedge())
                std::cout << " shalfedge from "
                    << SHalfedge_const_handle(it)->source()->point() << " to "
                    << SHalfedge_const_handle(it)->target()->point() << std::endl;
            else if (it.is_shalfloop())
                std::cout << " shalfloop lying in the plane "
                    << SHalfloop_const_handle(it)->circle() << std::endl;
            // other cases can not occur.
        }
    }
}
```

```

    }
}

return 0;
}

```

### 23.7.2 Exploring Shells

A *shell* of a Nef polyhedron is the connected part of the surface incident to a certain volume. Each halffacet, sface and shalfedge belongs to a single shell. The figure below illustrates the notion of a shell. It shows a Nef polyhedron with two volumes and three shells.

The first volume is the outer volume and the second volume is the interior of the cube. The first shell is the whole surface of the left object. The second shell is the outer surface of the right object, and the third shell is the inner surface of the right object.

In detail, the first shell consists of two halffacets, eight halfedges and four vertices. The second shell consists of the eight vertices of the cube plus the two endpoints of the antenna, all halffacets oriented outwards, and all halfedges. The third shell consists of the same eight vertices of the cube, plus the endpoint of the antenna that is in contact with the cube, all halffacets oriented inwards, and all halfedges (the same as for the second shell).

We discuss how sfaces, shalfedges, and sloops belong to the shells with a closeup view of the situation at the antenna foot. As you can see, there are three items on the sphere map - a shalfloop for each halffacet which intersects the sphere, and an svertex where the antenna intersects the sphere. The upper shalfloop lies on the

halfacet which is oriented outwards and is therefore also oriented outwards. This shalfloop and the svertex belong to the second shell. The other shalfloop lies on the inwards oriented halfacet and is oriented inwards, too. This shalfloop belongs to the third shell.

*Nef\_polyhedron\_3* offers a visitor interface to explore a shell following the well-known visitor pattern [GHJV95]. The interface is illustrated by the following example.

```
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Nef_polyhedron::Vertex_const_handle Vertex_const_handle;
typedef Nef_polyhedron::Halfedge_const_handle Halfedge_const_handle;
typedef Nef_polyhedron::Halfacet_const_handle Halfacet_const_handle;
typedef Nef_polyhedron::SHalfedge_const_handle SHalfedge_const_handle;
typedef Nef_polyhedron::SHalfloop_const_handle SHalfloop_const_handle;
typedef Nef_polyhedron::SFace_const_handle SFace_const_handle;
typedef Nef_polyhedron::Volume_const_iterator Volume_const_iterator;
typedef Nef_polyhedron::Shell_entry_const_iterator Shell_entry_const_iterator;
typedef Kernel::Point_3 Point_3;

class Shell_explorer {
    bool first;
    const Nef_polyhedron& N;
    Vertex_const_handle v_min;

public:
    Shell_explorer(const Nef_polyhedron& N_)
        : first(true), N(N_) {}

    void visit(Vertex_const_handle v) {
        if(first || CGAL::lexicographically_xyz_smaller(v->point(), v_min->point())) {
            v_min = v;
            first=false;
        }
    }

    void visit(Halfedge_const_handle ) {}
    void visit(Halfacet_const_handle ) {}
    void visit(SHalfedge_const_handle ) {}
    void visit(SHalfloop_const_handle ) {}
    void visit(SFace_const_handle ) {}

    Vertex_const_handle& minimal_vertex() { return v_min; }
    void reset_minimal_vertex() { first = true; }
};

int main() {
    Nef_polyhedron N;
    std::cin >> N;
```

```

int ic = 0;
Volume_const_iterator c;
Shell_explorer SE(N);
CGAL_forall_volumes(c,N) {
    std::cout << "Volume " << ic++ << std::endl;
    int is = 0;
    Shell_entry_const_iterator it;
    CGAL_forall_shells_of(it,c) {
        SE.reset_minimal_vertex();
        N.visit_shell_objects(SFace_const_handle(it),SE);
        Point_3 p(SE.minimal_vertex()->point());
        std::cout << "    minimal vertex of shell " << is++
                    << " is at " << p << std::endl;
    }
}
}

```

**File:** examples/Nef\_3/shell\_exploration.cpp

The function *visit\_shell\_objects(SFace\_const\_handle sf, Visitor& V)* explores a shell starting at the *sf*. The second argument expects any class providing the (possibly empty) functions *visit(Vertex\_const\_handle)*, *visit(Halfedge\_const\_handle)* (remember that Halfedge is the same type as SVertex), *visit(Halffacet\_const\_handle)*, *visit(SHalfedge\_const\_handle)*, *visit(SHalfloop\_const\_handle)* and *visit(SFace\_const\_handle)*. The *visit\_shell\_objects* function will call *visit* for each item belonging to the shell once. There are no further requirements on that class.

In the example, the class *Shell\_explorer* is passed as second argument to *visit\_shell\_objects*. Its task is to find the lexicographically smallest vertex of a shell. Its internal state consists of three variables. The first one is a reference to the explored Nef polyhedron. This reference is often necessary to retrieve information from the Nef polyhedron. The second variable *v\_min* stores the smallest vertex found so far, and the third variable *first* is initialized to *false* to signal that no vertex has been visited so far. After the first vertex has been visited *first* is changed to *true*.

*Shell\_explorer* provides further member functions. After the exploration of a shell the *minimal\_vertex* function retrieves the smallest vertex. The *reset\_minimal\_vertex* function allows one to use the same instance of *Shell\_explorer* on multiple shells. In this case, the *reset\_minimal\_vertex* function has to be called between the exploration of two shells.

The example program uses the *Shell\_explorer* for each shell of the given Nef polyhedron once and reports the smallest vertex of each shell to the standard output.

### 23.7.3 Point Location

The *locate(Point\_3 p)* function locates the point *p* in the Nef polyhedron and returns the item the point belongs to. The *locate* function returns an instance of *Object\_handle*, which is a polymorphic handle type representing any handle type, no matter if it is mutable or const. For further usage of the result, the *Object\_handle* has to be casted to the concrete handle type. The *CGAL::assign* function performs such a cast. It returns a boolean that reports the success or the failure of the cast. Looking at the possible return values of the *locate* function, the *Object\_handle* can represent a *Vertex\_const\_handle*, a *Halfedge\_const\_handle*, a *Halffacet\_handle*, or a *Volume\_const\_handle*. One of the four casts will succeed.

```
#include <CGAL/Gmpz.h>
```

```

#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;
    typedef Kernel::Point_3 Point_3;

int main() {
    //We've put the typedefs here as VC7 gives us an ICE if they are global typedefs
    typedef Nef_polyhedron_3::Vertex_const_handle Vertex_const_handle;
    typedef Nef_polyhedron_3::Halfedge_const_handle Halfedge_const_handle;
    typedef Nef_polyhedron_3::Halffacet_const_handle Halffacet_const_handle;
    typedef Nef_polyhedron_3::Volume_const_handle Volume_const_handle;
    typedef Nef_polyhedron_3::Object_handle Object_handle;

    Nef_polyhedron_3 N;
    std::cin >> N;

    Vertex_const_handle v;
    Halfedge_const_handle e;
    Halffacet_const_handle f;
    Volume_const_handle c;
    Object_handle o = N.locate(Point_3(0,0,0));
    if(CGAL::assign(v,o))
        std::cout << "Locating vertex" << std::endl;
    else if(CGAL::assign(e,o))
        std::cout << "Locating edge" << std::endl;
    else if(CGAL::assign(f,o))
        std::cout << "Locating facet" << std::endl;
    else if(CGAL::assign(c,o))
        std::cout << "Locating volume" << std::endl;
    //other cases can not occur

    return 0;
}

```

**File:** examples/Nef\_3/nef\_3\_point\_location.cpp

## 23.8 Visualization

With the *Qt\_widget\_OpenGL* class an interface to OpenGL visualization via Qt is offered. The class knows how to handle mouse movements and clicks and how to move and scale the 3D object displayed in the widget. *Qt\_widget\_OpenGL* is a basis for writing Qt widgets displaying 3D objects. A user can derive a new class from *Qt\_widget\_OpenGL* which implements the drawing method and configures the context menus.

### 23.8.1 Visualizing a 3D Nef polyhedron

*Qt\_widget\_Nef\_3* implements the drawing methods for displaying instances of *Nef\_polyhedron\_3*. The following example shows how to set up a QApplication with a main widget of type *Qt\_widget\_Nef\_3* and how to start the viewer.

```
#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/IO/Qt_widget_Nef_3.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {
    Nef_polyhedron_3 N;
    std::cin >> N;

    QApplication a(argc, argv);
    CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>* w =
        new CGAL::Qt_widget_Nef_3<Nef_polyhedron_3>(N);
    a.setMainWidget(w);
    w->show();
    return a.exec();
}
```

**File:** demo/Nef\_3/visualization\_SNC.cpp

### 23.8.2 Visualizing a Sphere Map

*Qt\_widget\_Nef\_S2* is a widget implemented on the basis of *Qt\_widget\_OpenGL*. It can be used to visualize the sphere map of a vertex in a *Nef\_polyhedron\_3* using the interface between *Nef\_polyhedron\_S2* and *Nef\_polyhedron\_3*.

```

#include <CGAL/basic.h>
#include <CGAL/Gmpz.h>
#include <CGAL/Homogeneous.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/IO/Qt_widget_Nef_S2.h>
#include <qapplication.h>

typedef CGAL::Homogeneous<CGAL::Gmpz> Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron_3;

int main(int argc, char* argv[]) {

    // We've put the typedefs here as VC7 gives us an ICE if they are global typedefs
    typedef Nef_polyhedron_3::Vertex_const_iterator Vertex_const_iterator;
    typedef Nef_polyhedron_3::Nef_polyhedron_S2 Nef_polyhedron_S2;

    Nef_polyhedron_3 N;
    std::cin >> N;
    Vertex_const_iterator v = N.vertices_begin();
    Nef_polyhedron_S2 S(N.get_sphere_map(v));

    QApplication a(argc, argv);
    CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>* w =
        new CGAL::Qt_widget_Nef_S2<Nef_polyhedron_S2>(S);
    a.setMainWidget(w);
    w->show();
    return a.exec();
}

```

# 3D Boolean Operations on Nef Polyhedra

## Reference Manual

*Peter Hachenberger, Lutz Kettner, and Michael Seel*

A Nef polyhedron is any point set generated from a finite number of open halfspaces by set complement and set intersection operations. In our implementation of Nef polyhedra in 3-dimensional space, we offer a B-rep data structures that is closed under boolean operations and with all their generality. Starting from halfspaces (and also directly from oriented 2-manifolds), we can work with set union, set intersection, set difference, set complement, interior, exterior, boundary, closure, and regularization operations. In essence, we can evaluate a CSG-tree with halfspaces as primitives and convert it into a B-rep representation.

In fact, we work with two data structures; one that represents the local neighborhoods of vertices, which is in itself already a complete description, and a data structure that connects these neighborhoods up to a global data structure with edges, facets, and volumes. We offer a rich interface to investigate these data structures, their different elements and their connectivity. We provide affine (rigid) transformations and a point location query operation. We have a custom file format for storing and reading Nef polyhedra from files. We offer a simple OpenGL visualization for debugging and illustrations.

## CGAL::Nef\_polyhedron\_3<Traits>

### Definition

A 3D Nef polyhedron is a subset of the 3-dimensional space that is the result of forming complements and intersections starting from a finite set  $H$  of 3-dimensional halfspaces. Nef polyhedra are closed under all binary set operations, i.e., intersection, union, difference, complement, and under the topological operations boundary, closure, and interior.

A 3D Nef polyhedron can be represented by the local pyramids of the minimal elements of its incidence structure. Without going into too much detail, a local pyramid essentially reflects the topologic and geometric situation at a certain location in a point set. For finite polyhedra the minimal elements of the incidence structure are vertices only. This means, that it suffices to model the topological and geometric situation of the vertices. For 3D Nef polyhedra, the local pyramid of a vertex is represented by a planar Nef polyhedra embedded on a sphere.

A *Nef\_polyhedron\_3* consists of vertices  $V$ , a sphere map for each vertex in  $V$ , edges  $E$ , facets  $F$ , volumes  $C$ , a mark for every item, and an incidence relation on them. Each edge and each facet is represented by two halfedges or two halffacets, respectively.

```
#include <CGAL/Nef_polyhedron_3.h>
```

### Parameters

```
template < class Nef_polyhedronTraits_3,
            class Nef_polyhedronItems_3 = CGAL::Default_items<Nef_polyhedronTraits_3>,
            class Nef_polyhedronMarks = bool >
class Nef_polyhedron_3;
```

The first parameter requires one of the following exact kernels: *Homogeneous*, *Simple\_homogeneous*, *Extended\_homogeneous* parametrized with *Gmpz*, *leda\_integer* or any other number type modeling  $\mathbb{Z}$ , or *Cartesian*, *Simple\_cartesian*, *Extended\_cartesian* parametrized with *Gmpq*, *leda\_rational*, *Quotient<Gmpz>* or any other number type modeling  $\mathbb{Q}$ .

The second parameter and the third parameter are for future considerations. Neither *Nef\_polyhedronItems\_3* nor *Nef\_polyhedronMarks* is specified, yet. Do not use any other than the default types for these two template parameters.

### Types

<i>Nef_polyhedron_3&lt;Traits&gt;:: Traits</i>	traits class selected for <i>Nef_polyhedronTraits_3</i> .
<i>Nef_polyhedron_3&lt;Traits&gt;:: Mark</i>	All object (vertices, edges, etc.) are attributed by a Mark. Mark equals bool.
<i>Nef_polyhedron_3&lt;Traits&gt;:: size_type</i>	size type of <i>Nef_polyhedron_3</i> .
<i>Nef_polyhedron_3&lt;Traits&gt;:: Vertex_const_handle</i>	non-mutable handle to a vertex.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Halfedge_const_handle</i>	non-mutable handle to a halfedge.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Halffacet_const_handle</i>	non-mutable handle to a halffacet.

<i>Nef_polyhedron_3&lt;Traits&gt;:: Volume_const_handle</i>	non-mutable handle to a volume.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SVertex_const_handle</i>	non-mutable handle to a svertex.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SHalfedge_const_handle</i>	non-mutable handle to a shalfedge.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SHalfloop_const_handle</i>	non-mutable handle to a shalfloop.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SFace_const_handle</i>	non-mutable handle to a sface.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Vertex_const_iterator</i>	non-mutable iterator over all vertices.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Halfedge_const_iterator</i>	non-mutable iterator over all halfedges.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Halffacet_const_iterator</i>	non-mutable iterator over all halffacets.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Volume_const_iterator</i>	non-mutable iterator over all volumes.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SVertex_const_iterator</i>	non-mutable iterator over all svertices.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SHalfedge_const_iterator</i>	non-mutable iterator over all shalfedges.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SHalfloop_const_iterator</i>	non-mutable iterator over all shalfloops.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SFace_const_iterator</i>	non-mutable iterator over all sfaces.
<i>Nef_polyhedron_3&lt;Traits&gt;:: SHalfedge_around_svertex_const_circulator</i>	
	non-mutable circulator of shalfedges around a svertex (cw).
<i>Nef_polyhedron_3&lt;Traits&gt;:: SHalfedge_around_sface_const_circulator</i>	
	non-mutable circulator of shalfedges around a sface (ccw).
<i>Nef_polyhedron_3&lt;Traits&gt;:: SHalfedge_around_facet_const_circulator</i>	
	non-mutable circulator of shalfedges around a halffacet (ccw).
<i>Nef_polyhedron_3&lt;Traits&gt;:: SFace_cycle_const_iterator</i>	
	non-mutable iterator over the cycles of a sface.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Halffacet_cycle_const_iterator</i>	
	non-mutable iterator over the cycles of a halffacet.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Shell_entry_const_iterator</i>	
	non-mutable iterator providing an entry to each shell.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Object_handle</i>	a generic handle to an object. The kind of object ( <i>vertex</i> , <i>halfedge</i> , <i>halffacet</i> , <i>volume</i> , <i>svertex</i> , <i>shalfedge</i> , <i>shalfloop</i> , <i>sface</i> ) can be determined and the object can be assigned to a corresponding constant handle by one of the following functions: <i>bool assign(Vertex_const_handle&amp; h, Object_handle)</i> <i>bool assign(Halfedge_const_handle&amp; h, Object_handle)</i> <i>bool assign(Halffacet_const_handle&amp; h, Object_handle)</i> <i>bool assign(Volume_const_handle&amp; h, Object_handle)</i> <i>bool assign(SVertex_const_handle&amp; h, Object_handle)</i> <i>bool assign(SHalfedge_const_handle&amp; h, Object_handle)</i> <i>bool assign(SHalfloop_const_handle&amp; h, Object_handle)</i> <i>bool assign(SFace_const_handle&amp; h, Object_handle)</i> where each function returns <i>true</i> iff the assignment to <i>h</i> could be accomplished.
<i>Nef_polyhedron_3&lt;Traits&gt;:: Point_3</i>	location of vertices.

*Nef\_polyhedron\_3<Traits>:: Segment\_3*      segment represented by a halfedge.  
*Nef\_polyhedron\_3<Traits>:: Vector\_3*      direction of a halfedge.  
*Nef\_polyhedron\_3<Traits>:: Plane\_3*      plane of a halffacet lies in.  
*Nef\_polyhedron\_3<Traits>:: Aff\_transformation\_3*

affine transformation.

*Nef\_polyhedron\_3<Traits>:: Polylines\_tag*      tag for calling polyline constructor.

*enum Boundary { EXCLUDED, INCLUDED};*

construction selection.

*enum Content { EMPTY, COMPLETE};*

construction selection.

*enum Intersection\_mode { CLOSED\_HALFSPACE, OPEN\_HALFSPACE, PLANE\_ONLY};*

intersection selection.

*Nef\_polyhedron\_3<Traits>:: Nef\_polyhedron\_S2*

a sphere map.

*Nef\_polyhedron\_3<Traits>:: Polyhedron*

a polyhedral surface.

## Creation

*Nef\_polyhedron\_3<Traits> N( Content space = EMPTY);*

creates a Nef polyhedron and initializes it to the empty set if *plane == EMPTY* and to the whole space if *space == COMPLETE*.

*Nef\_polyhedron\_3<Traits> N( Plane\_3 p, Boundary b = INCLUDED);*

creates a Nef polyhedron containing the halfspace on the negative side of *p* including *p* if *b==INCLUDED*, excluding *p* if *b==EXCLUDED*.

*Nef\_polyhedron\_3<Traits> N( Polyhedron& P);*

creates a Nef polyhedron, which represents the same point set as the polyhedral surface *P* does.

*Nef\_polyhedron\_3<Traits> N( Input\_iterator begin, Input\_iterator end);*

creates a Nef polyhedron consisting of a single polygon spanned by the list of points in the iterator range *[begin,end)*. If the points do not on a common supporting plane, the constructor tries to triangulate the polygon into multiple facets.If the construction does not succeed, the empty set is created.

*template <class Forward\_iterator>*

*Nef\_polyhedron\_3<Traits> N( Forward\_iterator it, Forward\_iterator end, Polylines\_tag);*

The iterator range [it, end) defines a set point ranges, each of which defines a polyline.

## Access Member Functions

<i>bool</i>	<i>N.is_simple()</i>	returns true, if <i>N</i> is a 2-manifold.
<i>bool</i>	<i>N.is_valid()</i>	checks the integrity of <i>N</i> .
<i>Size_type</i>	<i>N.number_of_vertices()</i>	returns the number of vertices.
<i>Size_type</i>	<i>N.number_of_halfedges()</i>	return the number of halfedges.
<i>Size_type</i>	<i>N.number_of_edges()</i>	returns the number of halfedge pairs.
<i>Size_type</i>	<i>N.number_of_halffacets()</i>	returns the number of halffacets.
<i>Size_type</i>	<i>N.number_of_facets()</i>	returns the number of halffacet pairs.
<i>Size_type</i>	<i>N.number_of_volumes()</i>	returns the number of volumes.
<i>Vertex_const_iterator</i>	<i>N.vertices_begin()</i>	iterator over all vertices.
<i>Vertex_const_iterator</i>	<i>N.vertices_end()</i>	past-the-end iterator.
<i>Halfedge_const_iterator</i>	<i>N.halfedges_begin()</i>	iterator over all halfedges.
<i>Halfedge_const_iterator</i>	<i>N.halfedges_end()</i>	past-the-end iterator.
<i>Halffacet_const_iterator</i>	<i>N.halffacets_begin()</i>	iterator over all halffacets.
<i>Halffacet_const_iterator</i>	<i>N.halffacets_end()</i>	past-the-end iterator.
<i>Volume_const_iterator</i>	<i>N.volumes_begin()</i>	iterator over all volumes.
<i>Volume_const_iterator</i>	<i>N.volumes_end()</i>	past-the-end iterator.

The following macros are provided: *CGAL\_forall\_vertices(v,N)*, *CGAL\_forall\_halfedges(e,N)*, *CGAL\_forall\_edges(e,N)*, *CGAL\_forall\_halffacets(f,N)*, *CGAL\_forall\_facets(f,N)*, *CGAL\_forall\_volumes(c,N)* where *N* is a *Nef\_polyhedron\_3*.

<i>Object_handle</i>	<i>N.locate( Point_3 p)</i>	returns a generic handle to the object (vertex, edge, facet or volume) which contains the point p in its relative interior.
<i>Nef_polyhedron_S2</i>	<i>N.get_sphere_map( Vertex_const_iterator v)</i>	returns the neighborhood of a vertex modeled by a <i>Nef_polyhedron_S2</i> .

## Point Set Predicates

<i>bool</i>	<i>N.is_empty()</i>	returns true, if <i>N</i> is the empty point set.
<i>bool</i>	<i>N.is_space()</i>	returns true, if <i>N</i> is the complete 3D space.
<i>bool</i>	<i>N == N1</i>	returns true, if <i>N</i> and <i>N1</i> comprise the same point sets.

<i>bool</i>	$N \neq N1$	returns true, if $N$ and $N1$ comprise different point sets.
<i>bool</i>	$N < N1$	returns true, if $N$ is a proper subset of $N1$ .
<i>bool</i>	$N > N1$	returns true, if $N$ is a proper superset of $N1$ .
<i>bool</i>	$N \leq N1$	returns true, if $N$ is a subset of $N1$ .
<i>bool</i>	$N \geq N1$	returns true, if $N$ is a superset of $N1$ .

## Unary Set Operations

<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.complement()$	returns the complement of $N$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.interior()$	returns the interior of $N$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.boundary()$	returns the boundary of $N$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.closure()$	returns the closure of $N$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.regularization()$	returns the regularization, i.e. the closure of the interior, of $N$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$!N$	returns the complement of $N$ .

## Binary Set Operations

<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.intersection( N1)$	return the intersection of $N$ and $N1$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.join( N1)$	return the union of $N$ and $N1$ . (Note that "union" is a C++ keyword and cannot be used for this operation.)
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.difference( N1)$	return the difference between $N$ and $N1$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.symmetric\_difference( N1)$	return the symmetric difference of $N$ and $N1$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N.intersection( Plane\_3 p, Intersection\_mode im)$	returns intersection of $N$ with plane ( $im=PLANE\_ONLY$ ), open halfspace ( $im=OPEN\_HALFSPACE$ ), or closed halfspace ( $im=CLOSED\_HALFSPACE$ ). In the latter two cases, the halfspaces are on the negative side of the plane $p$ . The function is written for the use with standard kernels, where halfspaces are not part of the domain. The function does not work in combination with an extended kernels or with an unbounded polyhedron.
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N * N1$	return the intersection of $N$ and $N1$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N + N1$	return the union of $N$ and $N1$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N - N1$	return the difference between $N$ and $N1$ .
<i>Nef_polyhedron_3&lt;Traits&gt;</i>	$N \wedge N1$	return the symmetric difference of $N$ and $N1$ .
<i>void</i>	$N * = N1$	intersects $N$ and $N1$ .
<i>void</i>	$N + = N1$	unites $N$ with $N1$ .
<i>void</i>	$N - = N1$	subtracts $N1$ from $N$ .
<i>void</i>	$N \wedge = N1$	performs a symmetric intersection of $N$ and $N1$ .

## Operations

*void* *N.clear( Content space = EMPTY)*

make *N* the empty set if *space == EMPTY* and the complete 3D space if *space == COMPLETE*.

*void* *N.transform( Aff\_transformation\_3 aff)*

applies an affine transformation to *N* .

*void* *N.convert\_to\_Polyhedron( Polyhedron& P)*

converts *N* into a Polyhedron.

*Precondition:* *N* is simple.

*void* *N.visit\_shell\_objects( SFace\_const\_handle f, Visitor& V)*

calls the visit function of *V* for every item which belongs to the same shell as *sf*.

# CGAL::Nef\_polyhedron\_3<Traits>::Vertex

## Definition

A vertex is a point in the 3-dimensional space. Its incidence structure can be accessed creating a sphere map of the vertex. This is done by the member function *get\_sphere\_map* of the class *Nef\_polyhedron\_3*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

## Types

The following types are the same as in *Nef\_polyhedron\_3<Traits>*.

*Vertex::Mark* type of mark.

*Vertex::Point\_3* point type stored in Vertex.

## Creation

There is no need for a user to create a *Vertex* explicitly. The class *Nef\_polyhedron\_3<Traits>* manages the needed vertices internally.

## Operations

*Mark* *v.mark()* the mark of *v* .

*Point\_3* *v.point()* the point of *v* .

*CGAL::Nef\_polyhedron\_3<Traits>* ..... page [1613](#)

*CGAL::Nef\_polyhedron\_S2<Traits>* ..... page [1303](#)

## CGAL::Nef\_polyhedron\_3<Traits>::Halfedge

### Definition

A Halfedge has a double meaning. In the global incidence structure of a *Nef\_polyhedron\_3* it is an oriented edge going from one vertex to another. A halfedge also coincides with an svertex of the sphere map of its source vertex. Because of this, we offer the types *Halfedge* and *SVertex* which are the same. Furthermore, the redundant functions *center\_vertex()* and *source()* are provided. The reason is, that we get the same vertex either if we want to have the source vertex of a halfedge, or if we want to have the vertex in the center of the sphere map a svertex lies on. Figure 23.9 on page 1625 and figure 23.9 on page 1622 illustrate the incidence of a svertex on a sphere map and of a halfedge in the global structure.

As part of the global incidence structure, the member functions *source* and *target* return the source and target vertex of an edge. The member function *twin()* returns the opposite halfedge.

Looking at the incidence structure on a sphere map, the member function *out\_sedge* returns the first outgoing halfedge, and *incident\_sface* returns the incident sface.

```
#include <CGAL/Nef_polyhedron_3.h>
```

### Types

The following types are the same as in *Nef\_polyhedron\_3<Traits>*.

<i>Halfedge::Mark</i>	type of mark.
<i>Halfedge::Sphere_point</i>	sphere point type stored in Halfedge.
<i>Halfedge::Vertex_const_handle</i>	const handle to vertex.
<i>Halfedge::Halfedge_const_handle</i>	const handle to halfedge.
<i>Halfedge::SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>Halfedge::SFace_const_handle</i>	const handle to SFace.

### Creation

There is no need for a user to create a *Halfedge* explicitly. The class *Nef\_polyhedron\_3<Traits>* manages the needed halfedges internally.

### Operations

<i>Mark</i>	<i>e.mark()</i>	the mark of <i>e</i> .
<i>Sphere_point</i>	<i>e.point()</i>	the sphere point of <i>e</i> .
<i>bool</i>	<i>e.is_isolated()</i>	returns —true— if <i>e</i> has no adjacent sedges.
<i>Vertex_const_handle</i>	<i>e.center_vertex()</i>	the center vertex of the sphere map <i>e</i> belongs to.

<i>Vertex_const_handle</i>	<i>e.source()</i>	the source vertex of <i>e</i> .
<i>Vertex_const_handle</i>	<i>e.target()</i>	the target vertex <i>e</i> .
<i>Halfedge_const_handle</i>	<i>e.twin()</i>	the twin of <i>e</i> .
<i>SHalfedge_const_handle</i>		
	<i>e.out_sedge()</i>	the first out sedege of <i>e</i> .
<i>SFace_const_handle</i>	<i>e.incident_sface()</i>	the incident sface of <i>e</i> .

## CGAL::Nef\_polyhedron\_3<Traits>::Halffacet

### Definition

A halffacet is an oriented, rectilinear bounded part of a plane. The following figure depicts the incidences to halfedges, vertices and the notion of facet cycles.

The member function *twin* returns the opposite halffacet, *incident\_volume* returns the incident volume. A Halffacet cycle either consists of consecutive halfedges along the border (or a hole) of the halffacet, or of a single halfloop on the sphere map of a vertex isolated on the halffacet. The iterator range (*halffacet\_cycles\_begin()/halffacet\_cycles\_end()*) provides an entry element for each halffacet cycle of a halffacet.

```
#include <CGAL/Nef_polyhedron_3.h>
```

### Types

The following types are the same as in *Nef\_polyhedron\_3<Traits>*.

<i>Halffacet:: Mark</i>	type of mark.
<i>Halffacet:: Plane_3</i>	plane type stored in Halffacet.
<i>Halffacet:: Object_list</i>	list of Object handles.
<i>Halffacet:: Halffacet_const_handle</i>	const handle to Halffacet.
<i>Halffacet:: Volume_const_handle</i>	const handle to volume.
<i>Halffacet:: Halffacet_cycle_const_iterator</i>	const iterator over the entries to all halffacet cycles of a halffacet.

### Creation

There is no need for a user to create a *Halffacet* explicitly. The class *Nef\_polyhedron\_3<Traits>* manages the needed halffacets internally.

## Operations

<i>Mark</i>	<i>f.mark()</i>	the mark of <i>f</i> .
<i>Plane_3</i>	<i>f.plane()</i>	the supporting plane of <i>f</i> .
<i>Halffacet_const_handle</i>	<i>f.twin()</i>	the twin of <i>f</i> .
<i>Volume_const_handle</i>	<i>f.incident_volume()</i>	the incident volume of <i>f</i> .
<i>Halffacet_cycle_const_iterator</i>	<i>f.facet_cycle_begin()</i>	iterator over the entries to all halffacet cycles of <i>f</i> .
<i>Halffacet_cycle_const_iterator</i>	<i>f.facet_cycle_end()</i>	past-the-end iterator.

# CGAL::Nef\_polyhedron\_3<Traits>::Volume

## Definition

A volume is a full-dimensional connected point set in  $\mathbb{R}^3$ . It is bounded by several shells, i.e. a connected part of the boundary incident to a single volume. An entry element to each shell is provided by the iterator range (*shells\_begin()/shells\_end()*). A *Shell\_entry\_iterator* is assignable to *SFace\_handle*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

## Types

The following types are the same as in *Nef\_polyhedron\_3<Traits>*.

<i>Volume:: Mark</i>	type of mark.
<i>Volume:: Object_list</i>	list of Object handles.
<i>Volume:: Volume_const_handle</i>	const handle to Volume.
<i>Volume:: Shell_entry_const_iterator</i>	const iterator over the entries to all shells adjacent to a volume.

## Creation

There is no need for a user to create a *Volume* explicitly. The class *Nef\_polyhedron\_3<Traits>* manages the needed volumes internally.

## Operations

<i>Mark</i>	<i>c.mark()</i>	the mark of <i>c</i> .
<i>Shell_entry_const_iterator</i>	<i>c.shells_begin()</i>	const iterator over the entries to all shells adjacent to <i>c</i> .
<i>Shell_entry_const_iterator</i>	<i>c.shells_end()</i>	past-the-end iterator.

## CGAL::Nef\_polyhedron\_3<Traits>::SHalfedge

### Definition

A shalfedge is a great arc on a sphere map. Figure 23.9 on page 1625 depicts the relationship between a shalfedge and its incident shalfedges, svertices, and sfaces on a sphere map. A shalfedge is an oriented sedge between two svertices. It is always paired with a shalfedge pointing in the opposite direction. The *twin()* member function returns this shalfedge of opposite orientation.

The *snext()* member function points to the successor shalfedge around this sface while the *sprev()* member function points to the preceding shalfedge. An successive assignments of the form *se = se->snext()* cycles counterclockwise around the sface (or hole).

Similarly, the successive assignments of the form *se = se->snext()->twin()* cycle clockwise around the svertex and traverse all halfedges incident to this svertex. The assignment *se = se->cyclic\_adj\_succ()* can be used as a shortcut.

The role of shalfedges in a facet is illustrated in Figure 23.9 on page 1622. The *facet()* member function returns the facet in which the shalfedge is part of one of the facet cycles. The successive assignment of the form *se = se->next()* cycles counterclockwise around the facet (or a hole of the facet).

A const circulators is provided for each of the three circular orders. The circulators are bidirectional and assignable to *SHalfedge\_const\_handle*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

### Types

The following types are the same as in *Nef\_polyhedron\_3<Traits>*.

<i>SHalfedge:: Mark</i>	type of mark.
<i>SHalfedge:: Sphere_circle</i>	sphere circle type stored in SHalfedge.
<i>SHalfedge:: Halffacet_const_handle</i>	const handle to Halffacet.
<i>SHalfedge:: SVertex_const_handle</i>	const handle to SVertex.
<i>SHalfedge:: SHalfedge_const_handle</i>	const handle to SHalfedge.
<i>SHalfedge:: SFace_const_handle</i>	const handle to SFace.

## Creation

There is no need for a user to create a *SHalfedge* explicitly. The class *Nef\_polyhedron\_3<Traits>* manages the needed shalfedges internally.

## Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .
<i>SHalfedge_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.source()</i>	the source svertex of <i>se</i> .
<i>SVertex_const_handle</i>	<i>se.target()</i>	equals <i>twin()-&gt;source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.prev()</i>	the SHalfedge previous to <i>se</i> in a facet cycle.
<i>SHalfedge_const_handle</i>	<i>se.next()</i>	the next SHalfedge of <i>se</i> in a facet cycle.
<i>SHalfedge_const_handle</i>	<i>se.sprev()</i>	the SHalfedge previous to <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.snext()</i>	the next SHalfedge of <i>se</i> in a sface cycle.
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_pred()</i>	the edge before <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>SHalfedge_const_handle</i>	<i>se.cyclic_adj_succ()</i>	the edge after <i>se</i> in the cyclic ordered adjacency list of <i>source()</i> .
<i>Halffacet_const_handle</i>	<i>se.facet()</i>	the facet that corresponds to <i>se</i> in the 3D incidence structure.
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .
<i>bool</i>	<i>se.in_outer_sface_cycle()</i>	determines whether <i>se</i> is in an outer sface cycle.
<i>bool</i>	<i>se.in_inner_sface_cycle()</i>	determines whether <i>se</i> is in an inner sface cycle.
<i>bool</i>	<i>se.in_outer_facet_cycle()</i>	determines whether <i>se</i> is in an outer facet cycle.

```
se.in_inner_facet_cycle()
```

determines whether  $se$  is in an inner facet cycle.

# CGAL::Nef\_polyhedron\_3<Traits>::SHalfloop

## Definition

A shalfloop is a great circle on a sphere map. Figure 23.9 on page 1628 depicts the relationship between a shalfloop and its incident shalfloops, and sfaces on a sphere map. A shalfloop is an oriented sloop. It is always paired with a shalfloop whose supporting *Sphere\_circle* is pointing in the opposite direction. The *twin()* member function returns this shalfloop of opposite orientation.

A sphere map having a shalfloop models the neighborhood of a vertex which is isolated on a facet. That facet is returned by the member function *facet*.

```
#include <CGAL/Nef_polyhedron_3.h>
```

## Types

The following types are the same as in *Nef\_polyhedron\_3<Traits>*.

<i>SHalfloop:: Mark</i>	type of mark.
<i>SHalfloop:: Sphere_circle</i>	sphere circle type stored in SHalfloop.
<i>SHalfloop:: Halffacet_const_handle</i>	const handle to Halffacet.
<i>SHalfloop:: SHalfloop_const_handle</i>	const handle to SHalfloop.
<i>SHalfloop:: SFace_const_handle</i>	const handle to SFace.

## Creation

There is no need for a user to create a *SHalfloop* explicitly. The class *Nef\_polyhedron\_3<Traits>* manages the needed shalfloops internally.

## Operations

<i>Mark</i>	<i>se.mark()</i>	the mark of <i>se</i> .
<i>Sphere_circle</i>	<i>se.circle()</i>	the sphere circle of <i>se</i> .

<i>SHalfloop_const_handle</i>	<i>se.twin()</i>	the twin of <i>se</i> .
<i>Halffacet_const_handle</i>	<i>se.facet()</i>	the facet that corresponds to <i>se</i> in the 3D incidence structure.
<i>SFace_const_handle</i>	<i>se.incident_sface()</i>	the incident sface of <i>se</i> .

## CGAL::Nef\_polyhedron\_3<Traits>::SFace

### Definition

Figure 23.9 on page 1625 and figure 23.9 on page 1628 illustrate the incidences of an sface. An sface is described by its boundaries. An entry item to each boundary cycle can be accessed using the iterator range (*sface\_cycles\_begin()/sface\_cycles\_end()*). Additionally, *Nef\_polyhedron\_S2* provides the macro *CGAL\_forall\_sface\_cycles\_of*. The iterators are of type *SFace\_cycle\_const\_iterator* and represent either a shalfedge, a shalfloop, or a svertex.

```
#include <CGAL/Nef_polyhedron_3.h>
```

### Types

The following types are the same as in *Nef\_polyhedron\_3<Traits>*.

<i>SFace:: Mark</i>	type of mark.
<i>SFace:: Object_list</i>	list of Object handles.
<i>SFace:: Vertex_const_handle</i>	const handle to Vertex.
<i>SFace:: Volume_const_handle</i>	const handle to Volume.
<i>SFace:: SFace_const_handle</i>	const handle to SFace.
<i>SFace:: SFace_cycle_const_iterator</i>	const iterator over the entries to all sface cycles of a sface.

### Creation

There is no need for a user to create a *SFace* explicitly. The class *Nef\_polyhedron\_3<Traits>* manages the needed sfaces internally.

### Operations

<i>Mark</i>	<i>sf.mark()</i>	the mark of <i>sf</i> .
<i>Vertex_const_handle</i>	<i>sf.center_vertex()</i>	the center vertex of the sphere map <i>sf</i> belongs to.
<i>Volume_const_handle</i>	<i>sf.volume()</i>	the volume that corresponds to <i>sf</i> in the 3D incidence structure.
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_begin()</i>	iterator over the entries to all sface cycles of <i>sf</i> .
<i>SFace_cycle_const_iterator</i>	<i>sf.sface_cycle_end()</i>	past-the-end iterator.

# CGAL::Nef\_polyhedron\_3<Traits>::Halfacet\_cycle\_iterator

## Definition

The type *Halfacet\_cycle\_iterator* iterates over a list of *Object\_handles*. Each item of that list can either be assigned to *SHalfedge\_handle* or *SHalfloop\_handle*. To find out which of these assignment works out, the member functions *is\_shalfedge()* and *is\_shalfloop()* are provided.

```
#include <CGAL/Nef_polyhedron_3.h>
```

## Types

<i>Halfacet_cycle_iterator::SHalfedge_handle</i>	const handle to <i>SHalfedge</i> .
<i>Halfacet_cycle_iterator::SHalfloop_handle</i>	const handle to <i>SHalfloop</i> .

## Creation

<i>Halfacet_cycle_iterator hfc;</i>	default constructor.
-------------------------------------	----------------------

## Operations

<i>bool</i>	<i>hfc.is_shalfedge()</i>	returns true if <i>hfc</i> represents a <i>SHalfedge_handle</i> .
<i>bool</i>	<i>hfc.is_shalfloop()</i>	returns true if <i>hfc</i> represents a <i>SHalfloop_handle</i> .
<i>SHalfedge_handle</i>	<i>SHalfedge_handle(hfc)</i>	casts <i>hfc</i> to <i>SHalfedge_handle</i> .
<i>SHalfloop_handle</i>	<i>SHalfloop_handle(hfc)</i>	casts <i>hfc</i> to <i>SHalfloop_handle</i> .

## CGAL::OFF\_to\_nef\_3

### Definition

This constructor creates a 3D Nef polyhedron from OFF file. OFF file is read from input stream *in*. The purpose of *OFF\_to\_nef\_3* is to create a Nef polyhedron from an OFF file that cannot be handled by the *Nef\_polyhedron\_3* constructors. It handles double coordinates while using a homogenous kernel, non-coplanar facets, surfaces with boundaries, self-intersecting surfaces, and single facets. Every closed volume gets marked. The function returns the number of facets it could not handle.

```
template<class Nef_polyhedron_3>
std::size_t      OFF_to_nef_3( std::istream& in, Nef_polyhedron_3& N)
```

## CGAL::Nef\_nary\_union\_3<Nef\_polyhedron\_3>

### Definition

This class helps to perform the union of a set of 3D Nef polyhedra efficiently. It successively applies the binary union operation of *Nef\_polyhedron\_3*, but schedules these union operations in an opportune way. The class is most efficient, if the polyhedra are added in sorted order. Any order that reflects proximity in the three-dimensional space is helpful. To allow saving memory space, the sorting is left to the user. This way the user can generate the polyhedra in a sorted way and add them one by one to *Nef\_nary\_union\_3*.

```
#include <CGAL/Nef_nary_union_3.h>
```

### Parameters

```
template < class Nef_polyhedron_3,
class Nef_nary_union_3;
```

As a template parameter an instantiation of the template class Nef polyhedra is needed.

### Creation

```
Nef_nary_union_3<Nef_polyhedron_3> U;      initialization only.
```

### Member Functions

<i>Nef_polyhedron_3</i>	<i>U.get_union()</i>
	returns the union of the polyhedra previously added to the class.

<i>void</i>	<i>U.add_polyhedron( Nef_polyhedron_3 N)</i>
	adds a polyhedron.

*CGAL::Nef\_polyhedron\_3<Traits>* ..... page [1613](#)

## CGAL::operator<<

### Definition

This operator writes The Nef polyhedron  $N$  to the output stream *out* using a propriatary file format. It includes the complete incidence structure, the geometric data, and the marks of each item.

Using CGAL stream modifiers the following output formats can be chosen: ASCII(*set\_ascii\_mode*), binary(*set\_binary\_mode*) or pretty(*set\_pretty\_mode*). The mandatory format is the ASCII format. It is recommended to use this format for file input and output.

As the output depends on the output operators of the geometric primitives provided by the traits class, it might not be possible that the input operator and output operators of different traits classes are not compatible. We recommend to use the CGAL kernels *Homogeneous*, *Simple\_homogeneous*, or *Extended\_homogeneous* parametrized with any exact number type that models  $\mathbb{Z}$  (e.g. *Gmpz* or *leda\_integer*).

A bounded *Nef\_polyhedron\_3*<*Extended\_homogeneous*> is automatically written as though *Nef\_polyhedron\_3*<*CGAL::Homogeneous*> or *Nef\_polyhedron\_3*<*CGAL::Simple\_homogeneous*> is used. As a result, the input operator of each of these types can read the output.

```
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
```

```
template <class Traits>
ostream& ostream& out << CGAL::Nef_polyhedron_3<Traits> N
```

*operator*>> ..... page [1636](#)

## CGAL::operator>>

### Definition

This operator reads a Nef polyhedron, which is given in the proprietary file format written by the input operator *in* and assigns it to *N*. It includes the complete incidence structure, the geometric data, and the marks of each item.

It is recommended to use the CGAL kernels *Homogeneous*, *Simple\_homogeneous*, or *Extended\_homogeneous* parametrized with any exact number type that models  $\mathbb{Z}$  (e.g. *Gmpz* or *leda\_integer*). The input and output iterators of Nef polyhedra parametrized with either of these kernels are compatible as long as the Nef polyhedron is bounded. An unbounded Nef polyhedron can only be read by a Nef polyhedron parametrized with an extended kernel. It is also recommended to use the CGAL stream modifier *set\_ascii\_mode*.

```
#include <CGAL/IO/Nef_polyhedron_istream_3.h>
```

```
template <class Traits>
istream&                istream& in >> CGAL::Nef_polyhedron_3<Traits>& N
```

## CGAL::Qt\_widget\_Nef\_3<Nef\_polyhedron\_3>

### Definition

The class *Qt\_widget\_Nef\_3* uses the OpenGL interface of Qt to display a *Nef\_polyhedron\_3*. Its purpose is to provide an easy to use viewer for *Nef\_polyhedron\_3*. There are no means provided to enhance the functionality of the viewer.

In addition to the functions inherited from the Qt class *OpenGLWidget* via, *Qt\_widget\_Nef\_3* only has a single public constructor. For the usage of *Qt\_widget\_Nef\_3* see the example below.

```
#include <CGAL/IO/Qt_widget_Nef_3.h>
```

### Parameters

The template parameter expects an instantiation of *Nef\_polyhedron\_3<Traits>*.

### Creation

```
Qt_widget_Nef_3<Nef_polyhedron_3> W( Nef_polyhedron_3 N);
```

Creates a widget *W* for displaying the 3D Nef polyhedron *N*.

## Chapter 24

# Convex Decomposition of Polyhedra

*Peter Hachenberger*

### 24.1 Introduction

For many applications on non-convex polyhedra, there are efficient solutions that first decompose the polyhedron into convex pieces. As an example, the Minkowski sum of two polyhedra can be computed by decomposing both polyhedra into convex pieces, compute pair-wise Minkowski sums of the convex pieces, and unite the pair-wise sums.

While it is desirable to have a decomposition into a minimum number of pieces, this problem is known to be NP-hard [Cha84]. Our implementation decomposes a Nef polyhedron  $N$  into  $O(r^2)$  convex pieces, where  $r$  is the number of edges, which have two adjacent facets that span an angle of more than 180 degrees with respect to the interior of the polyhedron. Those edges are also called reflex edges. The bound of  $O(r^2)$  convex pieces is worst-case optimal [Cha84].

Figure 24.1: Vertical decomposition based on the insertion of walls (viewed from the top). Left: Non-convex polyhedron. Middle: Non-vertical reflex edges have been resolved. Right: Vertical reflex edges have been resolved. The cells are convex.

Our decomposition runs in two steps. In the first step, each non-vertical reflex edge  $e$  is resolved by insertion of vertical facets  $W(e)$  through  $e$ . In the second step, we do the same with the vertical reflex edges. Figure 24.1 illustrates the two steps.

The worst-case running time of our implementation is  $O(n^2 r^4 \sqrt[3]{nr^2} \log nr)$ , where  $n$  is the complexity of the polyhedron and  $r$  is the number of reflex edges. But this running time is very pessimistic. Assuming that every inserted facet has complexity  $O(n)$  and that ray shooting queries run in logarithmic time, the running time is  $O(nr^2 \log nr)$ .

At the moment our implementation is restricted to the decomposition of bounded polyhedra. An extension to unbounded polyhedra is planned.

## 24.2 Interface and Usage

A *Nef\_polyhedron\_3* represents a subdivision of the three-dimensional space into vertices, edges, facets, and volumes. Each of these items contains set-selection mark, which indicates whether the item belongs to the represented point set or not. The represented polyhedron is the union of the point sets represented by the selected items. As an example, a cube is represented by 8 vertices, 12 edges, 6 facets, and 2 volumes, where one volume represents the interior of the cube and the other the volume outside of the cube. All of these items are selected, except for outer volume. Read the chapter on 3D Boolean operations on Nef polyhedra for more details [23](#).

The function *convex\_decomposition\_3* takes one *Nef\_polyhedron\_3* as input and inserts additional facets into the selected volumes. These additional facets are also selected and therefore redundant for the representation of the polyhedron. If some of these facets split a volume into two parts, each of the two volumes is represented by a separate volume item. The insertion of facets stops when all the selected volumes are convex. The modified polyhedron is the result of the function *convex\_decomposition\_3*. Note that the function *convex\_decomposition\_3* is restricted to standard kernels. The extended kernels, which allow the representation of polyhedra with an infinite boundary (e.g. halfspaces) only add further unbounded polyhedra to the domain of representable polyhedra. Using a standard kernel, unbounded polyhedra can be identified by the selected outer volume. In such a case, we ignore the outer volume in the decomposition process.

The convex pieces of the modified polyhedron can be accessed by traversing *N* [23.7.2](#), or by converting them into separate Nef polyhedra, as illustrated by the example code.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/Nef_3/SNC_indexed_items.h>
#include <CGAL/convex_decomposition_3.h>
#include <list>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron_3;
typedef CGAL::Nef_polyhedron_3<Kernel, CGAL::SNC_indexed_items> Nef_polyhedron_3;
typedef Nef_polyhedron_3::Volume_const_iterator Volume_const_iterator;

int main() {

    Nef_polyhedron_3 N;
    std::cin >> N;

    CGAL::convex_decomposition_3(N);
    std::list<Polyhedron_3> convex_parts;
```

```

// the first volumes is the outer volume, which is
// ignored in the decomposition
Volume_const_iterator ci = ++N.volumes_begin();
for( ; ci != N.volumes_end(); ++ci) {
    if(ci->mark()) {
        Polyhedron_3 P;
        N.convert_inner_shell_to_polyhedron(ci->shells_begin(), P);
        convex_parts.push_back(P);
    }
}
std::cout << "decomposition into " << convex_parts.size() << " convex parts " << std::endl;
}

```

## Chapter 25

# 3D Minkowski Sum of Polyhedra

*Peter Hachenberger*

### 25.1 Introduction

Figure 25.1: The Minkowski sum of a spoon and a star.

The Minkowski sum of two point sets  $P$  and  $Q$  in  $\mathbb{R}^d$ , denoted by  $P \oplus Q$ , is defined as the set  $\{p + q : p \in P, q \in Q\}$ . Minkowski sums are used in a wide range of applications such as robot motion planning [Lat91] and computer-aided design [EK99]. Figure 25.2 shows an example how Minkowski sums can be used to plan the motion of a translational robot. We want to know which are legal positions of the robot, and where can the robot go to from a specified starting position. If we model both, the robot and the obstacles as a polyhedron and compute the Minkowski sum of the inverted robot (robot reflected at the origin) and the obstacles, then this Minkowski sum represents all illegal positions of the robot, i.e., all positions where it intersects the obstacle. Of course, the complement of that polyhedron are all legal positions of the robot, i.e., all positions where it does not intersect an obstacle.

This package provides a function `minkowski_sum_3` that computes the Minkowski sum of two Nef polyhedra. We do not support arbitrary Nef polyhedra, yet. The restrictions are discussed in detail in Section 25.3.

### 25.2 Decomposition Method

The decomposition method for computing the Minkowski sum of non-convex polyhedra makes use of the fact that Minkowski sums of convex polyhedra are rather easy to compute. It decomposes both polyhedra

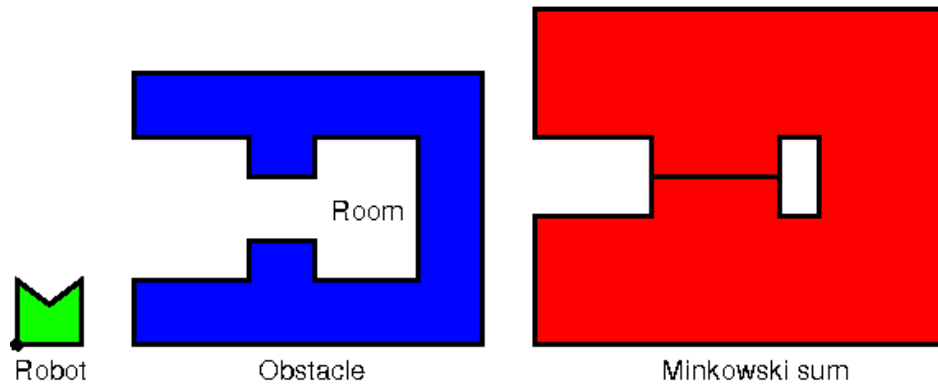

Figure 25.2: Can the robot enter the room? The Minkowski sum of the inverted robot and the obstacle represents all illegal positions of the robot with respect to the obstacle. The boundary of the Minkowski sum are legal positions. Thus, there is a path for the robot between the outer area and the room.

Figure 25.3: The decomposition method decomposes both input polyhedra into convex parts, computes all pairwise Minkowski sums of the convex parts, and merges the pairwise sums.

into convex pieces, computes all pairwise Minkowski sums of the convex pieces, and merges the pairwise sums [dBvKOS97].

The Minkowski sum is an inherent complex method. Using the decomposition method, each polyhedron might be divided into a quadratic number of pieces, which is worst-case optimal. Then up to  $n^2m^2$  pairwise sums have to be computed and merged, where  $n$  and  $m$  is the complexity of the two input polyhedra. In total the operation runs in  $O(n^3m^3)$  time.

Since the computation of the Minkowski sum takes quite some time, we give the running times of some Minkowski sum computations. The were computed with CGAL 3.3 on a machine with a 2.4 GHz AMD Opteron processor and 4 GB RAM. The code was compiled with g++ 3.2 and compiler options -O2. The *Nef\_polyhedron\_3* class was instantiated with the geometric kernel *Homogeneous<leda\_integer>*. The Minkowski sum of the spoon and the star is illustrated in Figure 25.1.

model 1			model 2			running time
name	facets	conv. pcs.	name	facets	conv. pcs.	
mushroom	448	255	cube	6	1	204s
mushrrom	448	255	ball1	128	1	553s
spoon	336	186	star	24	5	882s
cup	1000	774	ball2	1000	1	9851s

Table 25.1: Performance of the function *minkowski\_sum\_3*.

## 25.3 Features and Restrictions

This package was written to allow the computation of Minkowski sums of full-dimensional polyhedra even in so-called tight-passage scenarios. Tight passage scenarios occur in robot motion planning, when a robot is just as wide as a passage it needs to traverse. In these scenarios at least one polyhedron—the obstacles or the robot—must be modeled as an open set. Then the Minkowski sum will also be an open set and tight passages will occur as lower-dimensional exclusions, i.e., as facets, lines, or vertices that are, in contrast to the volume around them, not part of the resulting point set. Figure 25.2 shows such a tight passage scenario.

Our implementation uses *Nef\_polyhedron\_3* to model the input polyhedra and the result polyhedron. A *Nef\_polyhedron\_3* represents a subdivision of the three-dimensional space into vertices, edges, facets, and volumes. Each of these items contains set-selection mark, which indicates whether the item belongs to the represented point set or not. The represented polyhedron is the union of the point sets represented by the selected items. As an example, a cube is represented by 8 vertices, 12 edges, 6 facets, and 2 volumes, where one volume represents the interior of the cube and the other the volume outside of the cube. All of these items are selected, except for outer volume. Read the chapter on 3D Boolean operations on Nef polyhedra for more details 23.

The use of *Nef\_polyhedron\_3* allows many scenarios beyond the Minkowski sum of two solids. First, they can model the input and the result of a tight passage scenario, i.e., they can model open and closed solids for the input, and they can model lower-dimensional exclusions by unselected facets, edges, and vertices. We strive for extending the package to work for arbitrary 3D Nef polyhedra. In addition to the Minkowski sums of two solids, we added several features, but are not complete. At the moment we allow an input polyhedron to consist of:

1. singular vertices
2. singular edges
3. singular convex facets without holes
4. surface with convex facets that have no holes.
5. three-dimensional features, whose coplanar facets have common selection marks (this includes open and closed solids)

Taking a different viewpoint, the implementation is restricted as follows:

1. The input polyhedra must be bounded (selected outer volume is ignored).
2. All sets of coplanar facets of a full-dimensional feature must have the same selection mark (in case of different selection marks, unselected is assumed).
3. All facets of lower-dimensional features need to be convex and must not have holes (non-convex facets and holes are ignored).

## 25.4 Usage

The following example code illustrates the usage of the function *minkowski\_sum\_3*. Note that the two input polyhedra will be destroyed by the function. So, if they are needed further on, they need to be copied, first. The copying is not done by the function itself to keep the memory usage as small as possible.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/minkowski_sum_3.h>
#include <fstream>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;

int main() {

    Nef_polyhedron N0, N1;
    std::ifstream in("cube.nef3");
    in >> N0;
    std::cin >> N1;
    Nef_polyhedron result = CGAL::minkowski_sum_3(N0, N1);
}
```

**File:** examples/Minkowski\_sum\_3/cube\_offset.cpp

## 25.5 Glide

With the function *minkowski\_sum\_3* it is also possible to realize other interesting geometric operations like the glide operation, which computes the point set swept by a polyhedron that moves along a polygonal path. The following example shows how to construct a polygonal path and then compute the glide operation by calling the function *minkowski\_sum\_3*.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Nef_polyhedron_3.h>
#include <CGAL/IO/Nef_polyhedron_iostream_3.h>
#include <CGAL/minkowski_sum_3.h>
#include <iostream>

typedef CGAL::Exact_predicates_exact_constructions_kernel Kernel;
typedef CGAL::Nef_polyhedron_3<Kernel> Nef_polyhedron;
typedef Kernel::Point_3 Point_3;
typedef Point_3* point_iterator;
typedef std::pair<point_iterator, point_iterator>
    point_range;
```

Figure 25.4: The region swept by a star that moves along a polygonal path.

```
typedef std::list<point_range> polyline;

int main(int argc, char* argv[])
{
    Nef_polyhedron N0;
    std::cin >> N0;
    Point_3 pl[6] =
        {Point_3(-100,0,0),
         Point_3(40,-70,0),
         Point_3(40,50,40),
         Point_3(-90,-60,60),
         Point_3(0, 0, -100),
         Point_3(30,0,150)};
    };

    polyline poly;
    poly.push_back(point_range(pl,pl+6));
    Nef_polyhedron N1(poly.begin(), poly.end(), Nef_polyhedron::Polylines_tag());
    Nef_polyhedron result = CGAL::minkowski_sum_3(N0, N1);
}
```

**File:** examples/Minkowski\_sum\_3/glide.cpp

# 3D Minkowski sum of Polyhedra

## Reference Manual

*Peter Hachenberger*

The function *minkowski\_sum\_3* computes the Minkowski sum of the two 3D Nef polyhedra *N0* and *N1*. If either of the input polyhedra is non-convex, it is modified during the computation, i.e., they are decomposed into convex pieces.

## 26.1 Introduction

Given a set  $C$  of planar curves, the *arrangement*  $\mathcal{A}(C)$  is the subdivision of the plane into zero-dimensional, one-dimensional and two-dimensional cells, called *vertices*, *edges* and *faces*, respectively induced by the curves in  $C$ . Arrangements are ubiquitous in the computational-geometry literature and have many applications; see, e.g., [AS00, Hal04].

The curves in  $C$  can intersect each other (a single curve may also be self-intersecting or may be comprised of several disconnected branches) and are not necessarily  $x$ -monotone.<sup>1</sup> We construct a collection  $C''$  of  $x$ -monotone subcurves that are pairwise disjoint in their interiors in two steps as follows. First, we decompose each curve in  $C$  into maximal  $x$ -monotone subcurves (and possibly isolated points), obtaining the collection  $C'$ . Note that an  $x$ -monotone curve cannot be self-intersecting. Then, we decompose each curve in  $C'$  into maximal connected subcurves not intersecting any other curve (or point) in  $C'$ . The collection  $C''$  may also contain isolated points, if the curves of  $C$  contain such points. The arrangement induced by the collection  $C''$  can be conveniently embedded as a planar graph, whose vertices are associated with curve endpoints or with isolated points, and whose edges are associated with subcurves. It is easy to see that  $\mathcal{A}(C) = \mathcal{A}(C'')$ . This graph can be represented using a *doubly-connected edge list* data-structure (DCEL for short), which consists of containers of vertices, edges and faces and maintains the incidence relations among these objects.

The main idea behind the DCEL data-structure is to represent each edge using a pair of directed *halfedges*, one going from the  $xy$ -lexicographically smaller (left) endpoint of the curve toward its the  $xy$ -lexicographically larger (right) endpoint, and the other, known as its *twin* halfedge, going in the opposite direction. As each halfedge is directed, we say it has a *source* vertex and a *target* vertex. Halfedges are used to separate faces, and to connect vertices (with the exception of *isolated vertices*, which are unconnected).

If a vertex  $v$  is the target of a halfedge  $e$ , we say that  $v$  and  $e$  are *incident* to each other. The halfedges incident to a vertex  $v$  form a circular list oriented in a clockwise order around this vertex. (An isolated vertex has no incident halfedges.)

---

<sup>1</sup>A continuous planar curve  $C$  is *x-monotone* if every vertical line intersects it at most once. For example, a non-vertical line segment is always  $x$ -monotone and so is the graph of any continuous function  $y = f(x)$ . For convenience, we treat vertical line segments as *weakly x-monotone*, as there exists a single vertical line that overlaps them. A circle of radius  $r$  centered at  $(x_0, y_0)$  is not  $x$ -monotone, as the vertical line  $x = x_0$  intersects it at  $(x_0, y_0 - r)$  and at  $(x_0, y_0 + r)$ .

Figure 26.1: An arrangement of interior-disjoint line segments with some of the DCEL records that represent it. The unbounded face  $f_0$  has a single connected component that forms a hole inside it, and this hole is comprised of several faces. The half-edge  $e$  is directed from its source vertex  $v_1$  to its target vertex  $v_2$ . This edge, together with its twin  $e'$ , correspond to a line segment that connects the points associated with  $v_1$  and  $v_2$  and separates the face  $f_1$  from  $f_2$ . The predecessor  $e_{\text{prev}}$  and successor  $e_{\text{next}}$  of  $e$  are part of the chain that form the outer boundary of the face  $f_2$ . The face  $f_1$  has a more complicated structure as it contains two holes in its interior: One hole consists of two adjacent faces  $f_3$  and  $f_4$ , while the other hole is comprised of two edges.  $f_1$  also contains two isolated vertices  $u_1$  and  $u_2$  in its interior.

Each halfedge  $e$  stores a pointer to its *incident face*, which is the face lying to its left. Moreover, every halfedge is followed by another halfedge sharing the same incident face, such that the target vertex of the halfedge is the same as the source vertex of the next halfedge. The halfedges are therefore connected in circular lists, and form chains, such that all edges of a chain are incident to the same face and wind along its boundary. We call such a chain a *connected component of the boundary* (or *CCB* for short).

The unique CCB of halfedges winding in a counterclockwise orientation along a face boundary is referred to as the *outer CCB* of the face. For the time being let us consider only arrangements of bounded curves, such that exactly one unbounded face exists in every arrangement. The unbounded face does not have an outer boundary. Any other connected component of the boundary of the face is called a *hole* (or *inner CCB*), and can be represented as a circular chain of halfedges winding in a clockwise orientation around it. Note that a hole does not necessarily correspond to a single face, as it may have no area, or alternatively it may consist of several connected faces. Every face can have several holes contained in its interior (or no holes at all). In addition, every face may contain isolated vertices in its interior. See Figure 26.1 for an illustration of the various DCEL features. For more details on the DCEL data structure see [dBvKOS00, Chapter 2].

The rest of this chapter is organized as follows: In Section 26.2 we review in detail the interface of the *Arrangement\_2* class-template, which is the central component in the arrangement package. In Section 26.3 we show how queries on an arrangement can be issued. In Section 26.4 we review some important free (global) functions that operate on arrangements, the most important ones being the free insertion-functions. Section 26.6 contains detailed descriptions of the various geometric traits classes included in the arrangement package. Using these traits classes it is possible to construct arrangements of different families of curves. In Section 26.7 we review the notification mechanism that allows external classes to keep track of the changes that an arrangement instance goes through. Section 26.8 explains how to extend the DCEL records, to store extra data with them, and to efficiently update this data. In Section 26.9 we introduce the fundamental operation of overlaying two arrangements. Section 26.10 describes the *Arrangement\_with\_history\_2* class-template that extends the arrange-

ment by storing additional history records with its curves. Finally, in Section 26.11 we review the arrangement input/output functions.

## 26.2 The Main Arrangement Class

The class `Arrangement_2<Traits,Dcel>` is the main class in the arrangement package. It is used to represent planar arrangements and provides the interface needed to construct them, traverse them, and maintain them. An arrangement is defined by a geometric *traits* class that determines the family of planar curves that form the arrangement, and a DCEL class, which represents the *topological structure* of the planar subdivision. It supplies a minimal set of geometric operations (predicates and constructions) required to construct and maintain the arrangement and to operate on it.

The design of the arrangement package is guided by the need to separate between the representation of the arrangements and the various geometric algorithms that operate on them, and by the need to separate between the topological and geometric aspects of the planar subdivision. The separation is exhibited by the two template parameters of the `Arrangement_2` template:

- The *Traits* template-parameter should be instantiated with a model of the *ArrangementBasicTraits\_2* concept. The traits class defines the types of *x-monotone* curves and two-dimensional points, *X\_monotone\_curve\_2* and *Point\_2* respectively, and supports basic geometric predicates on them.

In the first sections of this chapter we always use `Arr_segment_traits_2` as our traits class, to construct arrangements of line segments. However, the arrangement package contains several other traits classes that can handle also polylines (continuous piecewise-linear curves), conic arcs, and arcs of rational functions. We exemplify the usage of these traits classes in Section 26.6.

- The *Dcel* template-parameter should be instantiated with a class that is a model of the *ArrangementDcel* concept. The value of this parameter is `Arr_default_dcel<Traits>` by default. However, in many applications it is necessary to extend the DCEL features; see Section 26.8 for further explanations and examples.

### 26.2.1 A Simple Program

The simple program listed below constructs a planar map of three line segments forming a triangle. The constructed arrangement is instantiated with the `Arr_segment_traits_2` traits class to handle segments only. The resulting arrangement consists of two faces, a bounded triangular face and the unbounded face. The program is not very useful as it is, since it ends immediately after the arrangement is constructed. We give more enhanced examples in the rest of this chapter.

```
#include <CGAL/Cartesian.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Quotient.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>      Number_type;
typedef CGAL::Cartesian<Number_type>        Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel> Traits_2;
typedef Traits_2::Point_2                   Point_2;
typedef Traits_2::X_monotone_curve_2        Segment_2;
```

```

typedef CGAL::Arrangement_2<Traits_2> Arrangement_2;

int main()
{
    Arrangement_2 arr;
    Segment_2      cv[3];
    Point_2        p1 (0, 0), p2 (0, 4), p3 (4, 0);

    cv[0] = Segment_2 (p1, p2);
    cv[1] = Segment_2 (p2, p3);
    cv[2] = Segment_2 (p3, p1);
    CGAL::insert (arr, &cv[0], &cv[3]);

    return (0);
}

```

## 26.2.2 Traversing the Arrangement

The simplest and most fundamental arrangement operations are the various traversal methods, which allow users to systematically go over the relevant features of the arrangement at hand.

As mentioned above, the arrangement is represented as a DCEL, which stores three containers of vertices, halfedges and faces. Thus, the *Arrangement\_2* class supplies iterators for these containers. For example, the methods *vertices\_begin()* and *vertices\_end()* return *Arrangement\_2::Vertex\_iterator* objects that define the valid range of arrangement vertices. The value type of this iterator is *Arrangement\_2::Vertex*. Moreover, the vertex-iterator type is equivalent to *Arrangement\_2::Vertex\_handle*, which serves as a pointer to a vertex. As we show next, all functions related to arrangement features accept handle types as input parameters and return handle types as their output.

In addition to the iterators for arrangement vertices, halfedges and faces, the arrangement class also provides *edges\_begin()* and *edges\_end()* that return *Arrangement\_2::Edge\_iterator* objects for traversing the arrangement edges. Note that the value type of this iterator is *Arrangement\_2::Halfedge*, representing one of the twin halfedges that represent the edge.

All iterator, circulator<sup>2</sup> and handle types also have non-mutable (*const*) counterparts. These non-mutable iterators are useful to traverse an arrangement without changing it. For example, the arrangement has a non-constant member function called *vertices\_begin()* that returns a *Vertex\_iterator* object and another *const* member function that returns a *Vertex\_const\_iterator* object. In fact, all methods listed in this section that return an iterator, a circulator or a handle have non-mutable counterparts. It should be noted that, for example, *Vertex\_handle* can be readily converted into a *Vertex\_const\_handle*, but not vice-verse.

Conversion of a non-mutable handle to a corresponding mutable handle are nevertheless possible, and can be performed using the static function *Arrangement\_2::non\_const\_handle()* (see, e.g., Section 26.3.1). There are three variant of this function, one for each type of handle.

### Traversal Methods for an Arrangement Vertex

A vertex is always associated with a geometric entity, namely with a *Point\_2* object, which can be obtained by the *point()* method of the *Vertex* class nested within *Arrangement\_2*.

---

<sup>2</sup>A *circulator* is used to traverse a circular list, such as the list of halfedges incident to a vertex — see below.

The *is\_isolated()* method determines whether a vertex is isolated or not. Recall that the halfedges incident to a non-isolated vertex, namely the halfedges that share a common target vertex, form a circular list around this vertex. The *incident\_halfedges()* method returns a circulator of type *Arrangement\_2::Halfedge\_around\_vertex\_circulator* that enables the traversal of this circular list in a clockwise direction. The value type of this circulator is *Halfedge*.

The following function prints all the neighbors of a given arrangement vertex (assuming that the *Point\_2* type can be inserted into the standard output using the << operator). The arrangement type is the same as in the simple example above.

```
void print_neighboring_vertices (Arrangement_2::Vertex_const_handle v)
{
    if (v->is_isolated()) {
        std::cout << "The vertex (" << v->point() << ") is isolated" << std::endl;
        return;
    }

    Arrangement_2::Halfedge_around_vertex_const_circulator first, curr;
    first = curr = v->incident_halfedges();

    std::cout << "The neighbors of the vertex (" << v->point() << ") are:";
    do {
        // Note that the current halfedge is directed from u to v:
        Arrangement_2::Vertex_const_handle u = curr->source();
        std::cout << " (" << u->point() << ")";
    } while (++curr != first);
    std::cout << std::endl;
}
```

In case of an isolated vertex, it is possible to obtain the face that contains this vertex using the *face()* method.

## Traversal Methods for an Arrangement Halfedge

Each arrangement edge, realized as a pair of twin halfedges, is associated with an *X\_monotone\_curve\_2* object, which can be obtained by the *curve()* method of the *Halfedge* class nested in the *Arrangement\_2* class.

The *source()* and *target()* methods return handles to the halfedge source and target vertices respectively. We can obtain a handle to the twin halfedge using the *twin()* method. From the definition of halfedges, it follows that if *he* is a halfedge handle, then:

- *he->curve()* is equivalent to *he->twin()->curve()*,
- *he->source()* is equivalent to *he->twin()->target()*, and
- *he->target()* is equivalent to *he->twin()->source()*.

Every halfedge has an incident face that lies to its left, which can be obtained by the *face()* method. Recall that a halfedge is always one link in a connected chain of halfedges that share the same incident face, known as a *CCB*. The *prev()* and *next()* methods return handles to the previous and next halfedges in the *CCB* respectively.

As the *CCB* is a circular list of halfedges, it is only natural to traverse it using a circulator. The *ccb()* method returns a *Arrangement\_2::Ccb\_halfedge\_circulator* object for the halfedges along the *CCB*.

The function *print\_ccb()* listed below prints all *x*-monotone curves along a given CCB (assuming that the *Point\_2* and the *X\_monotone\_curve\_2* types can be inserted into the standard output using the `<<` operator).

```
void print_ccb (Arrangement_2::Ccb_halfedge_const_circulator circ)
{
    Ccb_halfedge_const_circulator curr = circ;
    std::cout << "(" << curr->source()->point() << ")";
    do {
        Arrangement_2::Halfedge_const_handle he = curr->handle();
        std::cout << "    [" << he->curve() << "]" << "    "
            << "(" << he->target()->point() << ")";
    } while (++curr != circ);
    std::cout << std::endl;
}
```

### Traversal Methods for an Arrangement Face

An arrangement of bounded curves always has a single unbounded face. The function *unbounded\_face()* returns a handle to this face. (Note that an empty arrangement contains nothing *but* the unbounded face.)

Given a *Face* object, we can use the *is\_unbounded()* method to determine whether it is unbounded. Bounded faces have an outer CCB, and the *outer\_ccb()* method returns a circulator for the halfedges along this CCB. Note that the halfedges along this CCB wind in a counterclockwise orientation around the outer boundary of the face.

A face can also contain disconnected components in its interior, namely holes and isolated vertices:

- The *holes\_begin()* and *holes\_end()* methods return *Arrangement\_2::Hole\_iterator* iterators that define the range of holes inside the face. The value type of this iterator is *Ccb\_halfedge\_circulator*, defining the CCB that winds in a clockwise orientation around a hole.
- The *isolated\_vertices\_begin()* and *isolated\_vertices\_end()* methods return *Arrangement\_2::Isolated\_vertex\_iterator* iterators that define the range of isolated vertices inside the face. The value type of this iterator is *Vertex*.

The function *print\_face()* listed below prints the outer and inner boundaries of a given face, using the function *print\_ccb()*, which was introduced in the previous subsection.

```
void print_face (Arrangement_2::Face_const_handle f)
{
    // Print the outer boundary.
    if (f->is_unbounded())
        std::cout << "Unbounded face. " << std::endl;
    else {
        std::cout << "Outer boundary: ";
        print_ccb (f->outer_ccb());
    }

    // Print the boundary of each of the holes.
    Arrangement_2::Hole_const_iterator hi;
    int index = 1;
    for (hi = f->holes_begin(); hi != f->holes_end(); ++hi, ++index) {
```

```

        std::cout << "        Hole #" << index << ": ";
        print_ccb (*hi);
    }

    // Print the isolated vertices.
    Arrangement_2::Isolated_vertex_const_iterator iv;
    for (iv = f->isolated_vertices_begin(), index = 1;
         iv != f->isolated_vertices_end(); ++iv, ++index)
    {
        std::cout << "        Isolated vertex #" << index << ": "
                  << "(" << iv->point() << ")" << std::endl;
    }
}

```

### Additional Example

The function listed below prints the current setting of a given arrangement. This concludes the preview of the various traversal methods.<sup>3</sup>

```

void print_arrangement (const Arrangement_2& arr)
{
    // Print the arrangement vertices.
    Vertex_const_iterator vit;
    std::cout << arr.number_of_vertices() << " vertices:" << std::endl;
    for (vit = arr.vertices_begin(); vit != arr.vertices_end(); ++vit) {
        std::cout << "(" << vit->point() << ")";
        if (vit->is_isolated())
            std::cout << " - Isolated." << std::endl;
        else
            std::cout << " - degree " << vit->degree() << std::endl;
    }

    // Print the arrangement edges.
    Edge_const_iterator eit;
    std::cout << arr.number_of_edges() << " edges:" << std::endl;
    for (eit = arr.edges_begin(); eit != arr.edges_end(); ++eit)
        std::cout << "[" << eit->curve() << "]" << std::endl;

    // Print the arrangement faces.
    Face_const_iterator fit;
    std::cout << arr.number_of_faces() << " faces:" << std::endl;
    for (fit = arr.faces_begin(); fit != arr.faces_end(); ++fit)
        print_face (fit);
}

```

---

<sup>3</sup>The file *arr\_print.h*, which can be found under the examples folder, includes this function and the rest of the functions listed in this section. Over there they are written in a more generic fashion, where the arrangement type serves as a template parameter for these functions, so different instantiations of the *Arrangement\_2<Traits,Dcel>* template can be provided to the same function templates.

Figure 26.2: The various specialized insertion procedures. The inserted  $x$ -monotone curve is drawn with a light dashed line, surrounded by two solid arrows that represent the pair of twin half-edges added to the DCEL. Existing vertices are shown as black dots while new vertices are shown as light dots. Existing half-edges that are affected by the insertion operations are drawn as dashed arrows. (a) Inserting a curve as a new hole inside the face  $f$ . (b) Inserting a curve from an existing vertex  $u$  that corresponds to one of its endpoints. (c) Inserting an  $x$ -monotone curve whose endpoints are the already existing vertices  $u_1$  and  $u_2$ . In our case, the new pair of half-edges close a new face  $f'$ , where the hole  $h_1$ , which used to belong to  $f$ , now becomes an enclave in this new face.

### 26.2.3 Modifying the Arrangement

In this section we review the various member functions of the *Arrangement\_2* class that allow users to modify the topological structure of the arrangement by introducing new edges or vertices, modifying them, or removing them.

The arrangement member-functions that insert new curves into the arrangement, thus enabling the construction of a planar subdivision, are rather specialized, as they require a-priori knowledge on the location of the inserted curve. Indeed, for most purposes it is more convenient to construct an arrangement using the free (global) insertion-functions.

#### Inserting Non-Intersecting $x$ -Monotone Curves

The most important functions that allow users to modify the arrangement, and perhaps the most frequently used ones, are the specialized insertion functions of  $x$ -monotone curves whose interior is disjoint from any other curve in the existing arrangement and do not contain any vertex of the arrangement. In addition, these function require that the location of the curve in the arrangement is known.

The motivation behind these rather harsh restrictions on the nature of the inserted curves is the decoupling of the topological arrangement representation from the various algorithms that operate on it. While the insertion of an  $x$ -monotone curve whose interior is disjoint from all existing arrangement features is quite straightforward (as we show next), inserting curves that intersect with the curves already inserted into the arrangement is much more complicated and requires the application of non-trivial geometric algorithms. These insertion operations are therefore implemented as free functions that operate on the arrangement and the inserted curve(s); see Section 26.4 for more details and examples.<sup>4</sup>

When an  $x$ -monotone curve is inserted into an existing arrangement, such that the interior of this curve is disjoint from any arrangement feature, only the following three scenarios are possible, depending on the status of the endpoints of the inserted subcurve:

1. In case both curve endpoints do not correspond to any existing arrangement vertex we have to create two new vertices corresponding to the curve endpoints and connect them using a pair of twin halfedges. This halfedge pair initiates a new hole inside the face that contains the curve in its interior.

<sup>4</sup>You may skip to Section 26.4, and return to this subsection at a later point in time.

Figure 26.3: The arrangement of the line segments  $s_1, \dots, s_5$  constructed in *edge\_insertion.cpp*. The arrows mark the direction of the halfedges returned from the various insertion functions.

2. If exactly one endpoint corresponds to an existing arrangement vertex (we distinguish between a vertex that corresponds to the left endpoint of the inserted curve and a vertex corresponding to its right endpoint), we have to create a new vertex that corresponds to the other endpoint of the curve and to connect the two vertices by a pair of twin halfedges that form an “antenna” emanating from the boundary of an existing connected component (note that if the existing vertex used to be isolated, this operation is actually equivalent to forming a new hole inside the face that contains this vertex).
3. If both endpoints correspond to existing arrangement vertices, we connect these vertices using a pair of twin halfedges. (If one or both vertices are isolated this case reduces to one of the two previous cases respectively.) The two following subcases may occur:

- Two disconnected components are merged into a single connected component (as is the case with the segment  $s_1$  in the figure to the left).
- A new face is created, a face that splits from an existing arrangement face. In this case we also have to examine the holes and isolated vertices in the existing face and move the relevant ones inside the new face (as is the case with the segment  $s_2$  in the figure to the left).

The *Arrangement\_2* class offers insertion functions named *insert\_in\_face\_interior()*, *insert\_from\_left\_vertex()*, *insert\_from\_right\_vertex()* and *insert\_at\_vertices()* that perform the special insertion procedures listed above. The first function accepts an  $x$ -monotone curve  $c$  and an arrangement face  $f$  that contains this curve in its interior. The other functions accept an  $x$ -monotone curve  $c$  and handles to the existing vertices that correspond to the curve endpoint(s). Each of the four functions returns a handle to one of the twin halfedges that have been created, where:

- *insert\_in\_face\_interior(c, f)* returns a halfedge directed from the vertex corresponding to the left endpoint of  $c$  toward the vertex corresponding to its right endpoint.
- *insert\_from\_left\_vertex(c, v)* and *insert\_from\_right\_vertex(c, v)* returns a halfedge whose source is the vertex  $v$  that and whose target is the new vertex that has just been created.
- *insert\_at\_vertices(c, v1, v2)* returns a halfedge directed from  $v_1$  to  $v_2$ .

The following program demonstrates the usage of the four insertion functions. It creates an arrangement of five line segments, as depicted in Figure 26.3.<sup>5</sup> As the arrangement is very simple, we use the simple Cartesian kernel of CGAL with integer coordinates for the segment endpoints. We also use the *Arr\_segment\_traits\_2* class that enables the efficient maintenance of arrangements of line segments; see more details on this traits class in Section 26.6. This example, as many others in this chapter, uses some print-utility functions from the file *print\_arr.h*; these functions are also listed in Section 26.2.2.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef Traits_2::Point_2                     Point_2;
typedef Traits_2::X_monotone_curve_2          Segment_2;
typedef CGAL::Arrangement_2<Traits_2>         Arrangement_2;
typedef Arrangement_2::Vertex_handle           Vertex_handle;
typedef Arrangement_2::Halfedge_handle         Halfedge_handle;

int main ()
{
    Arrangement_2    arr;

    Segment_2        s1 (Point_2 (1, 3), Point_2 (3, 5));
    Segment_2        s2 (Point_2 (3, 5), Point_2 (5, 3));
    Segment_2        s3 (Point_2 (5, 3), Point_2 (3, 1));
    Segment_2        s4 (Point_2 (3, 1), Point_2 (1, 3));
    Segment_2        s5 (Point_2 (1, 3), Point_2 (5, 3));

    Halfedge_handle e1 = arr.insert_in_face_interior (s1, arr.unbounded_face());
    Vertex_handle   v1 = e1->source();
    Vertex_handle   v2 = e1->target();
    Halfedge_handle e2 = arr.insert_from_left_vertex (s2, v2);
    Vertex_handle   v3 = e2->target();
    Halfedge_handle e3 = arr.insert_from_right_vertex (s3, v3);
    Vertex_handle   v4 = e3->target();
    Halfedge_handle e4 = arr.insert_at_vertices (s4, v4, v1);
    Halfedge_handle e5 = arr.insert_at_vertices (s5, v1, v3);

    print_arrangement (arr);
    return 0;
}
```

**File:** examples/Arrangement\_on\_surface\_2/edge\_insertion.cpp

Observe that the first line segment is inserted in the interior of the unbounded face. The other line segments are inserted using the vertices created by the insertion of previous segments. The resulting arrangement consists of three faces, where the two bounded faces form together a hole in the unbounded face.

---

<sup>5</sup>Notice that in all figures in the rest of this chapter the coordinate axes are drawn only for illustrative purposes and are *not* part of the arrangement.

Figure 26.4: An arrangement of line segments containing three isolated vertices, as constructed in *isolated\_vertices.cpp*. The vertices  $u_2$  and  $u_3$  are eventually removed from the arrangement.

### Manipulating Isolated Vertices

Isolated points are in general simpler geometric entities than curves and indeed the member functions that manipulate them are easier to understand.

The function *insert\_in\_face\_interior*( $p, f$ ) inserts an isolated point  $p$ , located in the interior of a given face  $f$ , into the arrangement and returns a handle to the arrangement vertex it has created and associated with  $p$ . Naturally, this function has a precondition that  $p$  is really an isolated point, namely it does not coincide with any existing arrangement vertex and does not lie on any edge. As mentioned in Section 26.2.2, it is possible to obtain the face containing an isolated vertex handle  $v$  by calling  $v \rightarrow \text{face}()$ .

The function *remove\_isolated\_vertex*( $v$ ) receives a handle to an isolated vertex and removes it from the arrangement.

The following program demonstrates the usage of the arrangement member-functions for manipulating isolated vertices. It first inserts three isolated vertices located inside the unbounded face, then it inserts four line segments that form a rectangular hole inside the unbounded face (see Figure 26.4 for an illustration). Finally, it traverses the vertices and removes those isolated vertices that are still contained in the unbounded face ( $u_2$  and  $u_3$  in this case):

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"

typedef int
typedef CGAL::Simple_cartesian<Number_type>

typedef Traits_2::Point_2
typedef Traits_2::X_monotone_curve_2
typedef CGAL::Arrangement_2<Traits_2>
typedef Arrangement_2::Vertex_handle
typedef Arrangement_2::Halfedge_handle

Number_type;
Kernel;
Traits_2;
Point_2;
Segment_2;
Arrangement_2;
Vertex_handle;
Halfedge_handle;
```

```

typedef Arrangement_2::Face_handle      Face_handle;

int main ()
{
    Arrangement_2  arr;

    // Insert some isolated points:
    Face_handle    uf = arr.unbounded_face();
    Vertex_handle  u1 = arr.insert_in_face_interior (Point_2 (3, 3), uf);
    Vertex_handle  u2 = arr.insert_in_face_interior (Point_2 (1, 5), uf);
    Vertex_handle  u3 = arr.insert_in_face_interior (Point_2 (5, 5), uf);

    // Insert four segments that form a rectangular face:
    Segment_2      s1 (Point_2 (1, 3), Point_2 (3, 5));
    Segment_2      s2 (Point_2 (3, 5), Point_2 (5, 3));
    Segment_2      s3 (Point_2 (5, 3), Point_2 (3, 1));
    Segment_2      s4 (Point_2 (3, 1), Point_2 (1, 3));

    Halfedge_handle e1 = arr.insert_in_face_interior (s1, uf);
    Vertex_handle   v1 = e1->source();
    Vertex_handle   v2 = e1->target();
    Halfedge_handle e2 = arr.insert_from_left_vertex (s2, v2);
    Vertex_handle   v3 = e2->target();
    Halfedge_handle e3 = arr.insert_from_right_vertex (s3, v3);
    Vertex_handle   v4 = e3->target();
    Halfedge_handle e4 = arr.insert_at_vertices (s4, v4, v1);

    // Remove the isolated vertices located in the unbounded face.
    Arrangement_2::Vertex_iterator      curr_v, next_v;

    for (curr_v = arr.vertices_begin();
         curr_v != arr.vertices_end(); curr_v = next_v)
    {
        // Store an iterator to the next vertex (as we may delete curr_v and
        // invalidate the iterator).
        next_v = curr_v;
        ++next_v;

        if (curr_v->is_isolated() && curr_v->face() == uf)
            arr.remove_isolated_vertex (curr_v);
    }

    print_arrangement (arr);
    return 0;
}

```

## Manipulating Halfedges

In the previous subsection we showed how to introduce new isolated vertices in the arrangement. But how does one create a vertex that lies on an existing arrangement edge (more precisely, on an  $x$ -monotone curve that is associated with an arrangement edge)?

Figure 26.5: An arrangement of line segments as constructed in *edge\_manipulation.cpp*. Note that the edges  $e_7$  and  $e_8$  and the vertices  $w_1$  and  $w_2$ , introduced in step (b) are eventually removed in step (c).

It should be noted that such an operation involves the splitting of a curve at a given point in its interior, while the traits class used by *Arrangement\_2* does not necessarily have the ability to perform such a split operation. However, if users have the ability to split an  $x$ -monotone curve into two at a given point  $p$  (this is usually the case when employing a more sophisticated traits class; see Section 26.6 for more details) they can use the *split\_edge*( $e$ ,  $c_1$ ,  $c_2$ ) function, where  $c_1$  and  $c_2$  are the two subcurves resulting from splitting the  $x$ -monotone curve associated with the halfedge  $e$  at some point (call it  $p$ ) in its interior. The function splits the halfedge pair into two pairs, both incident to a new vertex  $v$  associated with  $p$ , and returns a handle to a halfedge whose source equals  $e$ 's source vertex and whose target is the new vertex  $v$ .

The reverse operation is also possible. Suppose that we have a vertex  $v$  of degree 2, whose two incident halfedges,  $e_1$  and  $e_2$ , are associated with the curves  $c_1$  and  $c_2$ . Suppose further that it is possible to merge these two curves into a single continuous  $x$ -monotone curve  $c$ . Calling *merge\_edge*( $e_1$ ,  $e_2$ ,  $c$ ) will merge the two edges into a single edge associated with the curve  $c$ , essentially removing the vertex  $v$  from the arrangement.

Finally, the function *remove\_edge*( $e$ ) removes the edge  $e$  from the arrangement. Note that this operation is the reverse of an insertion operation, so it may cause a connected component to split into two, or two faces to merge into one, or a hole to disappear. By default, if the removal of  $e$  causes one of its end-vertices to become isolated, we remove this vertex as well. However, users can control this behavior and choose to keep the isolated vertices by supplying additional Boolean flags to *remove\_edge*() indicating whether the source and the target vertices are to be removed should they become isolated.

In the following example program we show how the edge-manipulation functions can be used. The program works in three steps, as demonstrated in Figure 26.5. Note that here we still stick to integer coordinates, but as we work on a larger scale we use an unbounded integer number-type (in this case, the *Gmpz* type taken from the GMP library) instead of the built-in *int* type.<sup>6</sup> In case the GMP library is not installed (as indicated by the *CGAL\_USE\_GMP* flag defined in *CGAL/basic.h*), we use *MP\_Float*, a number-type included in CGAL's support library that is capable of storing floating-point numbers with unbounded mantissa. We also use the standard Cartesian kernel of CGAL as our kernel. This is recommended when the kernel is instantiated with a more complex number type, as we demonstrate in other examples in this chapter.

```
#include <CGAL/basic.h>
```

<sup>6</sup>As a rule of thumb, one can use a bounded integer type for representing line segments whose coordinates are bounded by  $\lfloor \sqrt[3]{M} \rfloor$ , where  $M$  is the maximal representable integer value. This guarantees that no overflows occur in the computations carried out by the traits class, hence all traits-class predicates always return correct results.

```

#ifdef CGAL_USE_GMP
    #include <CGAL/Gmpz.h>
    typedef CGAL::Gmpz                                Number_type;
#else
    #include <CGAL/MP_Float.h>
    typedef CGAL::MP_Float                            Number_type;
#endif

#include <CGAL/Cartesian.h>

                                                    e8->face());

arr.insert_at_vertices (s9, v4, v6);
arr.insert_at_vertices (s10, v5, v6);
arr.insert_at_vertices (s11, v4, v5);

// Step (c) - remove and merge faces to form a single hole in the triangle.
arr.remove_edge (e7);
arr.remove_edge (e8);

e5 = arr.merge_edge (e5, e6, Segment_2 (e5->source()->point(),
                                         e6->target()->point()));
e2 = arr.merge_edge (e4, e5, s2);

print_arrangement (arr);
return 0;
}

```

**File:** examples/Arrangement\_on\_surface\_2/edge\_manipulation.cpp

Note how we use the halfedge handles returned from *split\_edge()* and *merge\_edge()*. Also note the insertion of the isolated vertex  $v_6$  located inside the triangular face (the incident face of  $e_7$ ). This vertex seizes from being isolated, as it is gets connected to other vertices.

In this context, we should mention the two member functions *modify\_vertex( $v, p$ )*, which sets  $p$  to be the point associated with the vertex  $v$ , and *modify\_edge( $e, c$ )*, which sets  $c$  to be the  $x$ -monotone curve associated with the halfedge  $e$ . These functions have preconditions that  $p$  is geometrically equivalent to  $v \rightarrow \text{point}()$  and  $c$  is equivalent to  $e \rightarrow \text{curve}()$  (i.e., the two curves have the same graph), respectively, to avoid the invalidation of the geometric structure of the arrangement. At a first glance it may seem as these two functions are of little use. However, we should keep in mind that there may be extraneous data (probably non-geometric) associated with the point objects or with the curve objects, as defined by the traits class. With these two functions we can modify this data; see more details in Section 26.6.

In addition, we can use these functions to replace a geometric object (a point or a curve) with an equivalent object that has a more compact representation. For example, we can replace the point  $(\frac{20}{40}, \frac{99}{33})$  associated with some vertex  $v$ , by  $(\frac{1}{2}, 3)$ .

Figure 26.6: An arrangement of line segments, as constructed in *special\_edge\_insertion.cpp*. Note that  $p_0$  is initially inserted as an isolated point and later on connected to the other four vertices.

advanced

### Advanced Insertion Functions

Assume that the specialized insertion function *insert\_from\_left\_vertex*( $c, v$ ) is invoked for a curve  $c$ , whose left endpoint is already associated with a non-isolated vertex  $v$ . Namely,  $v$  has already several incident halfedges. It is necessary in this case to locate the exact place for the new halfedge mapped to the inserted new curve  $c$  in the circular list of halfedges incident to  $v$ . More precisely, it is sufficient to locate one of the halfedges *pred* directed toward  $v$  such that  $c$  is located between *pred* and *pred->next()* in clockwise order around  $v$ , in order to complete the insertion (see Figure 26.2 for an illustration). This may take  $O(d)$  time where  $d$  is the degree of the vertex. However, if the halfedge *pred* is known in advance, the insertion can be carried out in constant time.

The *Arrangement\_2* class provides the advanced versions of the specialized insertion functions for a curve  $c$  — namely we have *insert\_from\_left\_vertex*( $c, pred$ ) and *insert\_from\_right\_vertex*( $c, pred$ ) that accept a halfedge *pred* as specified above, instead of a vertex  $v$ . These functions are more efficient, as they take constant time and do not perform any geometric operations. Thus, they should be used when the halfedge *pred* is known. In case that the vertex  $v$  is isolated or that the predecessor halfedge for the new inserted curve is not known, the simpler versions of these insertion functions should be used.

Similarly, there exist two overrides of the *insert\_at\_vertices()* function: One that accept the two predecessor halfedges around the two vertices  $v_1$  and  $v_2$  that correspond to the curve endpoints, and one that accepts a handle for one vertex and a predecessor halfedge around the other vertex.

The following program shows how to construct the arrangement depicted in Figure 26.6 using the specialized insertion functions that accept predecessor halfedges:

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>

#include "arr_print.h"
```

```

typedef int                                     Number_type;
typedef CGAL::Simple_cartesian<Number_type>    Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                     Point_2;
typedef Traits_2::X_monotone_curve_2           Segment_2;
typedef CGAL::Arrangement_2<Traits_2>          Arrangement_2;
typedef Arrangement_2::Vertex_handle           Vertex_handle;
typedef Arrangement_2::Halfedge_handle         Halfedge_handle;

int main ()
{
    Arrangement_2    arr;

    Point_2          p0 (3, 3);
    Point_2          p1 (1, 3), p2 (3, 5), p3 (5, 3), p4 (3, 1);
    Segment_2        s1 (p1, p2);
    Segment_2        s2 (p2, p3);
    Segment_2        s3 (p3, p4);
    Segment_2        s4 (p4, p1);
    Segment_2        s5 (p1, p0);
    Segment_2        s6 (p0, p3);
    Segment_2        s7 (p4, p0);
    Segment_2        s8 (p0, p2);

    Vertex_handle    v0 = arr.insert_in_face_interior (p0, arr.unbounded_face());
    Halfedge_handle  e1 = arr.insert_in_face_interior (s1, arr.unbounded_face());
    Halfedge_handle  e2 = arr.insert_from_left_vertex (s2, e1);
    Halfedge_handle  e3 = arr.insert_from_right_vertex (s3, e2);
    Halfedge_handle  e4 = arr.insert_at_vertices (s4, e3, e1->twin());
    Halfedge_handle  e5 = arr.insert_at_vertices (s5, e1->twin(), v0);
    Halfedge_handle  e6 = arr.insert_at_vertices (s6, e5, e3->twin());
    Halfedge_handle  e7 = arr.insert_at_vertices (s7, e4->twin(), e6->twin());
    Halfedge_handle  e8 = arr.insert_at_vertices (s8, e5, e2->twin());

    print_arrangement (arr);
    return 0;
}

```

**File:** examples/Arrangement\_on\_surface\_2/special\_edge\_insertion.cpp

It is possible to perform even more refined operations on an *Arrangement\_2* instance given specific topological information. As most of these operations are very fragile and perform no precondition testing on their input in order to gain efficiency, they are not included in the public interface of the arrangement class. Instead, the *Arr\_accessor<Arrangement>* class allows access to these internal arrangement operations — see more details in the Reference Manual.

## 26.3 Issuing Queries on an Arrangement

One of the most important query types defined on arrangements is the *point-location* query: Given a point, find the arrangement cell that contains it. Typically, the result of a point-location query is one of the arrangement faces, but in degenerate situations the query point can be located on an edge or coincide with a vertex.

Point-location queries are not only common in many applications, they also play an important role in the free insertion-functions (see Section 26.4). Therefore, it is crucial to have the ability to answer such queries effectively for any arrangement instance.

### 26.3.1 Point-Location Queries

The arrangement package includes several classes (more precisely, class templates parameterized by an arrangement class) that model the *ArrangementPointLocation\_2* concept. Namely, they all have a member function called *locate(q)* that accepts a query point *q* and result with a CGAL *Object* that wraps a handle to the arrangement cell containing the query point. This object can be assigned to either a *Face\_const\_handle*, *Halfedge\_const\_handle* or a *Vertex\_const\_handle*, depending on whether the query point is located inside a face, on an edge or on a vertex.

Note that the handles returned by the *locate()* functions are *const* (non-mutable) handles. If necessary, such handles may be casted to mutable handles using the static functions *Arrangement\_on\_surface\_2::non\_const\_handle()* provided by the arrangement class.

An instance of any point-location class must be attached to an *Arrangement\_on\_surface\_2* instance so we can use it to issue point-location queries. This attachment can be performed when the point-location instance is constructed, or at a later time, using the *init(arr)* method, where *arr* is the attached *Arrangement\_on\_surface\_2* instance. In this chapter we always use the first option.

The following function template, which can be found in the example file *point\_location\_utils.h*, accepts a point-location object (whose type can be any of the models to the *ArrangementPointLocation\_2* concept) and a query point, and prints out the result of the point-location query for the given point. Observe how we use the function *CGAL::assign()* in order to cast the resulting *CGAL::Object* into a handle to an arrangement feature. The point-location object *pl* is assumed to be already associated with an arrangement:

```
template <class PointLocation>
void point_location_query
    (const PointLocation& pl,
     const typename PointLocation::Arrangement_on_surface_2::Point_2& q)
{
    // Perform the point-location query.
    CGAL::Object obj = pl.locate (q);

    // Print the result.
    typedef typename PointLocation::Arrangement_on_surface_2 Arrangement_on_surface_2;

    typename Arrangement_on_surface_2::Vertex_const_handle    v;
    typename Arrangement_on_surface_2::Halfedge_const_handle   e;
