The class *Kd\_tree*<*Traits*, *Splitter*, *UseExtendedNode*> defines a *k-d* tree.

*#include* <CGAL/Kd\_tree.h>

### Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search\_traits\_2*<*CGAL::Cartesian*<*double*> >.

Expects for the second template argument a model for the concept *Splitter*. It defaults to *Sliding\_midpoint*<*Traits*>.

Expects for the third template argument *CGAL::Tag\_true*, if the tree shall be built with extended nodes, and *CGAL::Tag\_false* otherwise.

### Types

*Traits::Point\_d*            *Point\_d*;            Point class.

*Traits::FT*            *FT*;            Number type.

*Kd\_tree*<*Traits*, *Splitter*, *UseExtendedNode*>::*Splitter*  
Splitter type.

*Kd\_tree*<*Traits*, *Splitter*, *UseExtendedNode*>::*iterator*  
Bidirectional iterator with value type *Point\_d* that allows to enumerate all points in the tree.

— advanced —

*Kd\_tree*<*Traits*, *Splitter*, *UseExtendedNode*>::*Node\_handle*  
A handle with value type *Kd\_tree\_node*<*Traits*,*Splitter*>.

*Kd\_tree*<*Traits*, *Splitter*, *UseExtendedNode*>::*Point\_d\_iterator*  
Random access iterator with value type *Point\_d*\*.

— advanced —

## Creation

```
Kd_tree<Traits, Splitter, UseExtendedNode> tree( Splitter s=Splitter());
```

Constructs an empty  $k$ - $d$  tree.

[illegible]

Constructs a  $k$ - $d$  tree on the elements from the sequence  $[first, beyond)$  using the splitting rule implemented by  $s$ . The value type of the *InputIterator* must be *Point\_d*.

## Operations

```
void tree.insert( Point_d p)
```

Inserts the point  $p$  in the  $k$ - $d$  tree.

```
template <class InputIterator>
void          tree.insert( InputIterator first, InputIterator beyond)
```

Inserts the elements from the sequence  $[first, beyond)$  in the  $k$ -d tree. The value type of the *InputIterator* must be *Point\_d*.

```
template <class OutputIterator, class FuzzyQueryItem>
OutputIterator      tree.search( OutputIterator it, FuzzyQueryItem q)
```

Reports the points that are approximately contained by  $q$ . The types *FuzzyQueryItem::Point\_d* and *Point\_d* must be equivalent.

<i>iterator</i>	<i>tree.begin()</i>	Returns an iterator to the first point in the tree.
-----------------	---------------------	---

<i>iterator</i>	<i>tree.end()</i>	Returns the corresponding past-the-end iterator.
-----------------	-------------------	--

<i>void</i>	<i>tree.clear()</i>	Removes all points from the $k$ -d tree.
-------------	---------------------	--

<i>unsigned int</i>	<code>tree.size()</code>	Returns the number of points that are stored in the tree.
---------------------	--------------------------	---

<hr/> <i>advanced</i> <hr/>		
<i>Node_handle</i>	<i>tree.root()</i>	Returns a handle to the root node of the tree.

*Kd\_tree\_rectangle<Traits>*

*tree.bounding\_box()* returns a const reference to the bounding box of the root node of the tree.

*std::ostream&*      *tree.statistics( std::ostream& s)*

Inserts statistics of the tree into the output stream *s*.

└────────── *advanced* ─────────┘

### See Also

Tree. *CGAL::Kd\_tree\_node<Traits>*,  
*CGAL::Search\_traits\_2<Kernel>*,  
*CGAL::Search\_traits\_3<Kernel>*,  
*CGAL::Search\_traits<FT\_,Point,CartesianIterator,ConstructCartesianIterator>*.

## CGAL::Kd\_tree\_node<Traits, Splitter, UseExtendedNode>

— *advanced* —

### Definition

The class *Kd\_tree\_node*<*Traits*, *Splitter*, *UseExtendedNode*> implements a node class for a *k-d* tree. A node is either a leaf node, an internal node or an extended internal node. A leaf node contains one or more points. An internal node contains a pointer to its lower child, a pointer to its upper child, and a pointer to its separator. An extended internal node is an internal node containing the lower and upper limit of an extended node's rectangle along the node's cutting dimension.

```
#include <CGAL/Kd_tree_node.h>
```

### Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search\_traits\_2*<*CGAL::Cartesian*<*double*> >, or *CGAL::Cartesian\_d*<*double*>.

### Types

```
enum Node_type { LEAF, INTERNAL, EXTENDED_INTERNAL};
```

Denotes type of node.

```
Traits::FT          FT;          Number type.
```

```
Traits::Point_d     Point_d;     Point type.
```

```
Splitter::Separator Separator;   Separator type.
```

```
Kd_tree<Traits,Splitter,UseExtendedNode>::Point_d_iterator
```

```
Point_d_iterator;    Iterator over points.
```

```
Kd_tree<Traits,Splitter,UseExtendedNode>::Node_handle
```

```
Node_handle;         Node handle.
```

### Creation

### Operations

```
template <class OutputIterator, class FuzzyQueryItem>
```

<i>OutputIterator</i>	<i>n.search( OutputIterator it, FuzzyQueryItem q)</i>	Reports the points from the subtree of the node, that are approximately contained by q.
<i>template &lt;class OutputIterator&gt;</i>		
<i>OutputIterator</i>	<i>n.tree_points( OutputIterator it)</i>	Reports all the points contained by the subtree of the node.
<i>bool</i>	<i>n.is_leaf()</i>	Indicates whether a node is a leaf node.
<i>int</i>	<i>n.size()</i>	Returns the number of items stored in a leaf node.
<i>Point_d_iterator</i>	<i>n.begin()</i>	Returns the iterator to the first item in a leaf node.
<i>Point_d_iterator</i>	<i>n.end()</i>	Returns the past-the-end iterator in a leaf node.
<i>Node_handle</i>	<i>n.lower()</i>	Returns a handle to the lower child of an internal node.
<i>Node_handle</i>	<i>n.upper()</i>	Returns a handle to the upper child of an internal node.
<i>Separator&amp;</i>	<i>n.separator()</i>	Returns a reference to the separator.
<i>FT</i>	<i>n.low_val()</i>	Returns the lower limit of an extended node's rectangle along the node's cutting dimension.
<i>FT</i>	<i>n.high_val()</i>	Returns the upper limit of an extended node's rectangle along the node's cutting dimension.

└────────── advanced ─────────┘

## CGAL::Kd\_tree\_rectangle<Traits>

advanced

### Definition

The class *Kd\_tree\_rectangle<Traits>* implements *d*-dimensional iso-rectangles and related operations, e.g., methods to compute bounding boxes of point sets.

```
#include <CGAL/Kd_tree_rectangle.h>
```

### Types

*Traits::FT*                      *FT*;                      Number type.

### Creation

*Kd\_tree\_rectangle<Traits>* *r*( *int d*);                      Constructs a *d*-dimensional rectangle *r* with lower bound and upper bound set to zero in each dimension.

```
template <class PointIter>
Kd_tree_rectangle<Traits> r( int d, PointIter begin, PointIter end);
```

Constructs the bounding box of the points in the range [*begin*,*end*), where the value type of *PointIter* must be *Traits::Point\_d*.

### Operations

*FT*                      *r.min\_coord( int i)*                      Returns the lower bound of the rectangle in dimension *i*.

*FT*                      *r.max\_coord( int i)*                      Returns the upper bound of the rectangle in dimension *i*.

*void*                      *r.set\_upper\_bound( int i, FT x)*  
Sets upper bound in dimension *i* to *x*.

*void*                      *r.set\_lower\_bound( int i, FT x)*  
Sets lower bound in dimension *i* to *x*.

*FT*                      *r.max\_span()*                      Returns the maximal span of the rectangle.

*FT*                      *r.max\_span\_coord()*                      Returns the smallest coordinate for which the rectangle has its maximal span.

*int*                      *r.dimension()*                      Returns the dimension of the rectangle.

*void*                      *r.split( & r, int d, FT value)*

Splits rectangle in dimension *d* at coordinate-value *value* by modifying itself to lower half and by modifying *r* to upper half.

## Output Routines

*template<class FT>*  
*std::ostream&*                      *std::ostream& s << & r*

Inserts rectangle *r* in the output stream *s* and returns *s*.

└────────── *advanced* ─────────┘

## CGAL::Manhattan\_distance\_iso\_box\_point<Traits>

### Definition

The class *Manhattan\_distance\_iso\_box\_point*<Traits> provides an implementation of the *GeneralDistance* concept for the Manhattan distance ( $l_1$  metric) between a  $d$ -dimensional iso-box and a  $d$ -dimensional point and the Manhattan distance between a  $d$ -dimensional iso-box and a  $d$ -dimensional iso-box defined as a  $k$ - $d$  tree rectangle.

```
#include <CGAL/Manhattan_distance_iso_box_point.h>
```

### Parameters

Expects for the template argument a model for the concept *SearchTraits*, for example *CGAL::Search\_traits\_3<CGAL::Cartesian<double>>*.

### Is Model for the Concepts

*GeneralDistance*

### Types

<i>Traits::FT</i>	<i>FT</i> ;	Number type.
<i>Traits::Point_d</i>	<i>Point_d</i> ;	Point type.
<i>Traits::Iso_box_d</i>	<i>Query_item</i> ;	Query item type.

### Creation

```
Manhattan_distance_iso_box_point<Traits> md;
```

Default constructor.

### Operations

<i>FT</i>	<i>md.transformed_distance( Query_item b, Point_d p)</i>	Returns the transformed distance between $b$ and $p$ .
<i>FT</i>	<i>md.transformed_distance( FT d)</i>	Returns the transformed value of $d$ .

*FT* *md.inverse\_of\_transformed\_distance( FT d)*

Returns the value of the inverse of the transform function applied to *d*.

*FT* *md.min\_distance\_to\_rectangle( Query\_item b, Kd\_tree\_rectangle<Traits> r)*

Returns the minimal distance between a point from *b* and a point from *r*.

*FT* *md.max\_distance\_to\_rectangle( Query\_item b, Kd\_tree\_rectangle<Traits> r)*

Returns the maximal distance between the iso-box *b* and a point from *r* furthest to *b*.

**See Also**

*GeneralDistance.*

## CGAL::Median\_of\_max\_spread<Traits, SpatialSeparator>

### Definition

Implements the *median of max spread* splitting rule. The splitting dimension is the dimension of the longest side of the rectangle. The splitting value is defined by the median of the coordinates of the data points along this dimension.

```
#include <CGAL/Splitters.h>
```

### Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example the type `CGAL::Search_traits_3<Cartesian<double>>`.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, `CGAL::Plane_separator<Traits::FT>`.

### Is Model for the Concepts

*Splitter*

### Creation

```
Median_of_max_spread<Traits, SpatialSeparator> s;
```

Default constructor.

```
Median_of_max_spread<Traits, SpatialSeparator> s( unsigned int bucket_size);
```

Constructor.

### Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.
---------------------	------------------------	--

### See Also

*SpatialSeparator*

## CGAL::Midpoint\_of\_max\_spread<Traits, SpatialSeparator>

### Definition

Implements the *midpoint of max spread* splitting rule. A rectangle is cut through  $(Mind + Maxd)/2$  orthogonal to the dimension with the maximum point spread  $[Mind, Maxd]$ .

```
#include <CGAL/Splitters.h>
```

### Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example the type `CGAL::Search_traits_3< Cartesian<double> >`.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, `CGAL::Plane_separator<Traits::FT>`

### Is Model for the Concepts

*Splitter*

### Creation

```
Midpoint_of_max_spread<Traits, SpatialSeparator> s;
```

Default constructor.

```
Midpoint_of_max_spread<Traits, SpatialSeparator> s( unsigned int bucket_size);
```

Constructor.

### Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.
---------------------	------------------------	--

### See Also

*Splitter*,  
*SpatialSeparator*

# CGAL::Midpoint\_of\_rectangle<Traits, SpatialSeparator>

## Definition

Implements the *midpoint of rectangle* splitting rule. A rectangles is cut through its midpoint orthogonal to the longest side.

*#include <CGAL/Splitters.h>*

## Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example the type *CGAL::Search\_traits\_3< Cartesian<double> >*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane\_separator<Traits::FT>*

## Is Model for the Concepts

*Splitter*

## Creation

*Midpoint\_of\_rectangle<Traits, SpatialSeparator> s;*

Default constructor.

*Midpoint\_of\_rectangle<Traits, SpatialSeparator> s( unsigned int bucket\_size);*

Constructor.

## Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.

# OrthogonalDistance

## Definition

Requirements of an orthogonal distance class supporting incremental distance updates. To optimize distance computations transformed distances are used. E.g., for an Euclidean distance the transformed distance is the squared Euclidean distance.

## Refines

*GeneralDistance*

## Has Models

*CGAL::Euclidean\_distance<Traits>*,  
*CGAL::Weighted\_Minkowski\_distance<Traits>*

## Types

<i>OrthogonalDistance:: FT</i>	Number type.
<i>OrthogonalDistance:: Point_d</i>	Point type.
<i>OrthogonalDistance:: Query_item</i>	Query item type.

## Creation

<i>OrthogonalDistance od( int d);</i>	Constructor implementing distance for $d$ -dimensional points.
---------------------------------------	--

## Operations

<i>FT</i>	<i>od.transformed_distance( Query_item q, Point_d r)</i>	Returns the transformed distance between $q$ and $r$ .
<i>FT</i>	<i>od.min_distance_to_rectangle( Query_item q, Kd_tree_rectangle&lt;Traits&gt; r)</i>	Returns the transformed distance between $q$ and the point on the boundary of $r$ closest to $q$ .
<i>FT</i>	<i>od.max_distance_to_rectangle( Query_item q, Kd_tree_rectangle&lt;Traits&gt; r)</i>	Returns the transformed distance between $q$ and the point on the boundary of $r$ farthest to $q$ .

<i>FT</i>	<i>od.transformed_distance( FT d)</i>	Returns the transformed distance.
<i>FT</i>	<i>od.inverse_of_transformed_distance( FT d)</i>	Returns the inverse of the transformed distance.
<i>FT</i>	<i>od.new_distance( FT dist, FT old_off, FT new_off, int cutting_dimension)</i>	Updates <i>dist</i> incrementally and returns the updated distance.

## CGAL::Orthogonal\_incremental\_neighbor\_search<Traits, OrthogonalDistance, Splitter, SpatialTree>

### Definition

The class *Orthogonal\_incremental\_neighbor\_search*<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*> implements incremental nearest and furthest neighbor searching on a tree.

```
#include <CGAL/Orthogonal_incremental_neighbor_search.h>
```

### Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search\_traits\_2*<*CGAL::Cartesian*<*double*>>.

Expects for the second template argument a model of the concept *GeneralDistance*. The default type is *CGAL::Euclidean\_distance*<Traits>.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding\_midpoint*<Traits>.

Expects for fourth template argument a model of the concept *SpatialTree*. The default type is *CGAL::Kd\_tree*<Traits, *Splitter*, *CGAL::Tag\_true*>. The template argument must be *CGAL::Tag\_true* because orthogonal search needs extended kd tree nodes.

### Types

*Traits::Point\_d*      *Point\_d*;      Point type.

*Traits::FT*      *FT*;      Number type.

*OrthogonalDistance::Query\_item*  
                          *Query\_item*;      Query item.

*std::pair*<*Point\_d*,*FT*>  
                          *Point\_with\_transformed\_distance*;  
                          Pair of point and transformed distance.

*Orthogonal\_incremental\_neighbor\_search*<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*>:: *iterator*  
                          Input iterator with value type *Point\_with\_transformed\_distance* for enumerating approximate neighbors.

*SpatialTree*      *Tree*;      The tree type.

## Creation

```
Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree> s(  
    SpatialTree& tree,  
    Query_item query,  
    FT eps=FT(0.0),  
    bool search_nearest=true,  
    OrthogonalDistance d=OrthogonalDistance())
```

Constructor for incremental neighbor searching of the query item *query* in the points stored *tree* using a distance *d* and approximation factor *eps*.

## Operations

<i>iterator</i>	<i>s.begin()</i>	Returns an iterator to the approximate neighbors.
<i>iterator</i>	<i>s.end()</i>	Returns the corresponding past-the-end iterator.

\_\_\_\_\_ *advanced* \_\_\_\_\_  
|

```
std::ostream& s.statistics( std::ostream& s)
```

Inserts statistics of the search process into the output stream *s*.

\_\_\_\_\_ *advanced* \_\_\_\_\_  
|

## See Also

*CGAL::Incremental\_neighbor\_search<Traits, GeneralDistance, SpatialTree>*.

## CGAL::Orthogonal\_k\_neighbor\_search<Traits, OrthogonalDistance, Splitter, SpatialTree>

### Definition

The class *Orthogonal\_k\_neighbor\_search*<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*> implements approximate *k*-nearest and *k*-furthest neighbor searching on a tree using an orthogonal distance class.

```
#include <CGAL/Orthogonal_k_neighbor_search.h>
```

### Parameters

Expects for the first template argument an implementation of the concept *SearchTraits*, for example *CGAL::Search\_traits\_2*<*CGAL::Cartesian*<*double*>>.

Expects for the second template argument a model of the concept *GeneralDistance*. The default type is *CGAL::Euclidean\_distance*<Traits>.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding\_midpoint*<Traits>.

Expects for fourth template argument an implementation of the concept *SpatialTree*. The default type is *CGAL::Kd\_tree*<Traits, *Splitter*, *CGAL::Tag\_true*>. The template argument must be *CGAL::Tag\_true* because orthogonal search needs extended kd tree nodes.

### Types

*Traits::Point\_d*      *Point\_d*;      Point type.

*Traits::FT*      *FT*;      Number type.

*GeneralDistance::Query\_item*  
                          *Query\_item*;      Query item.

*std::pair*<*Point\_d*,*FT*>  
                          *Point\_with\_transformed\_distance*;  
                          Pair of point and transformed distance.

*Orthogonal\_k\_neighbor\_search*<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*>:: *iterator*  
                          Bidirectional iterator with value type *Point\_with\_transformed\_distance* for enumerating approximate neighbors.

*SpatialTree*      *Tree*;      The tree type.

## Operations

```
Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree> s(  
    SpatialTree tree,  
    Query_item query,  
    unsigned int k=1,  
    FT eps=FT(0.0),  
    bool search_nearest=true,  
    OrthogonalDistance d=OrthogonalDistance())
```

Constructor for searching approximately  $k$  neighbors of the query item *query* in the points stored in *tree* using distance  $d$  and approximation factor  $eps$ .

*iterator*                      *s.begin()*                      Returns an iterator to the approximate neighbors.

*iterator*                      *s.end()*                      Past-the-end iterator.

┌────────── *advanced* ─────────┐

*std::ostream&*                      *s.statistics( std::ostream& s )*

Inserts statistics of the search process into the output stream *s*.

└────────── *advanced* ─────────┘

## See Also

*CGAL::K\_neighbor\_search<Traits, GeneralDistance, Splitter, SpatialTree>*.

## CGAL::Plane\_separator<FT>

advanced

### Definition

The class *Plane\_separator*<FT> implements a plane separator, i.e., a hyperplane that is used to separate two half spaces. This hyperplane is defined by a cutting dimension  $d$  and a cutting value  $v$  as  $x_d = v$ , where  $v$  denotes the  $d^{\text{th}}$  coordinate value.

```
#include <CGAL/Plane_separator.h>
```

### Is Model for the Concepts

*SpatialSeparator*

### Creation

```
Plane_separator<FT> s( int d, FT v);
```

Constructs a separator that separates two half spaces by a hyperplane defined by  $x_d = v$ , where  $v$  denotes the  $d^{\text{th}}$  coordinate value.

```
Plane_separator<FT> s( p);
```

Copy constructor.

### Operations

```
void s.set_cutting_dimension( int d)
```

Sets the cutting dimension to  $d$ .

```
void s.set_cutting_value( FT v)
```

Sets the cutting value to  $v$ .

```
int s.cutting_dimension()
```

Returns the number of the cutting dimension.

```
FT s.cutting_value()
```

Returns the cutting value.

```
template <class SpatialPoint>
```

```
bool s.has_on_negative_side( SpatialPoint p)
```

Returns true if and only if the coordinate of  $p$  in the cutting dimension is smaller than the cutting value.

```
Plane_separator<FT>
```

```
s = s2
```

Assignment operator.

## Output Operators

```
template<class FT>  
std::ostream&      std::ostream& os << s
```

Inserts the plane separator *s* in the output stream *os* and returns *os*.

└────────── *advanced* ─────────┘

## SearchTraits

### Definition

The concept *SearchTraits* defines the requirements for the template parameter of the search classes.

### Types

<i>SearchTraits:: Point_d</i>	Point type. <i>CGAL::Kernel_traits</i> has to be specialized for this type.
<i>SearchTraits:: Iso_box_d</i>	Iso box type. It is only needed for range search queries.
<i>SearchTraits:: Sphere_d</i>	Sphere type. It is only needed for range search queries.
<i>SearchTraits:: FT</i>	The number type of the Cartesian coordinates of types <i>Point_d</i>
<i>SearchTraits:: Cartesian_const_iterator</i>	An random access iterator type to enumerate the Cartesian coordinates of a point.
<i>SearchTraits:: Construct_cartesian_const_iterator</i>	Functor with operators to construct iterators on the first and the past-the-end iterator for the Cartesian coordinates of a point.
<i>SearchTraits:: Construct_center_d</i>	Functor with operator to construct the center of an object of type <i>Sphere_d</i> .
<i>SearchTraits:: Construct_squared_radius_d</i>	Functor with operator to compute the squared radius of a an object of type <i>Sphere_d</i> .
<i>SearchTraits:: Construct_min_vertex_d</i>	Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type <i>Iso_box_d</i> .
<i>SearchTraits:: Construct_max_vertex_d</i>	Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type <i>Iso_box_d</i> .

### Has Models

*CGAL::Cartesian\_d<FT>*  
*CGAL::Homogeneous\_d<RT>*  
*CGAL::Search\_traits\_2<Kernel>*  
*CGAL::Search\_traits\_3<Kernel>*,  
*CGAL::Search\_traits<NT,Point, CartesianCoordinateIterator,ConstructCartesianCoordinateIterator,ConstructMinVertex,ConstructMaxVertex>*  
 .

## CGAL::Search\_traits\_2<Kernel>

### Definition

The class *Search\_traits\_2<Kernel>* can be used as a template parameter of the kd tree and the search classes.

```
#include <CGAL/Search_traits_2.h>
```

### Parameters

Expects for the template argument a model of the concept *Kernel*, for example *CGAL::Cartesian<double>* or *CGAL::Simple\_cartesian<CGAL::Gmp\_q>*.

### Is Model for the Concepts

*SearchTraits*.

### Types

*Kernel::FT*                      *FT*;                      Number type.

*Kernel::Point\_2*                *Point\_d*;                      Point type.

*Kernel::Iso\_rectangle\_2*  
    *Iso\_box\_d*;                      Iso box type.

*Kernel::Sphere\_2*                *Sphere\_d*;                      Sphere type.

*Kernel::Cartesian\_const\_iterator\_2*  
    *Cartesian\_const\_iterator\_d*;  
    An iterator over the Cartesian coordinates.

*Kernel::Construct\_cartesian\_const\_iterator\_2*  
    *Construct\_cartesian\_const\_iterator\_d*;  
    A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point\_d*. The functor for the past the end iterator, has as argument a *Point\_d* and an *int*.

*Kernel::Construct\_iso\_rectangle\_2*

*Construct\_iso\_box\_d;*      Functor with operator to construct the iso box from two points.

*Kernel::Construct\_center\_2*

*Construct\_center\_d;*      Functor with operator to construct the center of an object of type *Sphere\_d*.

*Kernel::Compute\_squared\_radius\_2*

*Construct\_squared\_radius\_d;*  
  
Functor with operator to compute the squared radius of a an object of type *Sphere\_d*.

*Kernel::Construct\_min\_vertex\_2*

*Construct\_min\_vertex\_d;*  
  
Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso\_box\_d*.

*Kernel::Construct\_max\_vertex\_2*

*Construct\_max\_vertex\_d;*  
  
Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso\_box\_d*.

## See Also

*Search\_traits\_3<Kernel>*

*Search\_traits<NT\_,Point, CartesianConstIterator, ConstructCartesianConstIterator*

## CGAL::Search\_traits\_3<Kernel>

### Definition

The class *Search\_traits\_3<Kernel>* can be used as a template parameter of the kd tree and the search classes. *Kernel* must be a CGAL kernel.

```
#include <CGAL/Search_traits_3.h>
```

### Parameters

Expects for the template argument a model of the concept *Kernel*, for example *CGAL::Cartesian<double>* or *CGAL::Simple\_cartesian<CGAL::Gmp\_q>*.

### Is Model for the Concepts

*SearchTraits*.

### Types

*Kernel::FT*                      *FT*;                      Number type.

*Kernel::Point\_3*                *Point\_d*;                      Point type.

*Kernel::Iso\_cuboid\_3*  
    *Iso\_box\_d*;                      Iso box type.

*Kernel::Sphere\_3*                *Sphere\_d*;                      Sphere type.

*Kernel::Cartesian\_const\_iterator\_3*  
    *Cartesian\_const\_iterator\_d*;  
    An iterator over the Cartesian coordinates.

*Kernel::Construct\_cartesian\_const\_iterator\_3*  
    *Construct\_cartesian\_const\_iterator\_d*;  
    A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point\_d*. The functor for the past the end iterator, has as argument a *Point\_d* and an *int*.

*Kernel::Construct\_center\_3*

*Construct\_center\_d;*      Functor with operator to construct the center of an object of type *Sphere\_d*.

*Kernel::Compute\_squared\_radius\_3*

*Construct\_squared\_radius\_d;*

Functor with operator to compute the squared radius of a an object of type *Sphere\_d*.

*Kernel::Construct\_min\_vertex\_3*

*Construct\_min\_vertex\_d;*

Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso\_box\_d*.

*Kernel::Construct\_max\_vertex\_3*

*Construct\_max\_vertex\_d;*

Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso\_box\_d*.

## CGAL::Search\_traits\_d<Kernel>

### Definition

The class *Search\_traits\_d<Kernel>* can be used as a template parameter of the kd tree and the search classes. *Kernel* must be a CGAL kernel.

*Kernel* must be a d-dimensional CGAL kernel.

```
#include <CGAL/Search_traits_d.h>
```

### Parameters

Expects for the template argument a model of the concept *Kernel\_d*, for example *CGAL::Cartesian\_d<double>* or *CGAL::Homogeneous\_d<CGAL::Gmp\_z>*.

### Is Model for the Concepts

*SearchTraits*.

### Types

*Kernel::FT*                      *NT*;                      Number type.

*Kernel::Point\_d*                *Point\_d*;                      Point type.

*Kernel::Iso\_box\_d*              *Iso\_box\_d*;                      Iso box type.

*Kernel::Sphere\_d*               *Sphere\_d*;                      Sphere type.

*Kernel::Cartesian\_const\_iterator\_d*

*Cartesian\_const\_iterator*;

An iterator over the Cartesian coordinates.

*Kernel::Construct\_cartesian\_const\_iterator\_d*

*Construct\_cartesian\_const\_iterator*;

A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point\_d*. The functor for the past the end iterator, has as argument a *Point\_d* and an *int*.

*Kernel::Construct\_min\_vertex\_d*

*Construct\_min\_vertex\_d;*

Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso\_box\_d*.

*Kernel::Construct\_max\_vertex\_d*

*Construct\_max\_vertex\_d;*

Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso\_box\_d*.

## CGAL::Sliding\_fair<Traits, SpatialSeparator>

### Definition

Implements the *sliding fair* splitting rule. This splitting rule is a compromise between the *Fair* splitting rule and the *Sliding\_midpoint* rule. Sliding fair-split is based on the theory that there are two types of splits that are good: balanced splits that produce fat rectangles, and unbalanced splits provided the rectangle with fewer points is fat.

Also, this splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among the splits that satisfy this bound, it selects the one one in which the points have the largest spread. It then considers the most extreme cuts that would be allowed by the aspect ratio bound. This is done by dividing the longest side of the rectangle by the aspect ratio bound. If the median cut lies between these extreme cuts, then we use the median cut. If not, then consider the extreme cut that is closer to the median. If all the points lie to one side of this cut, then we slide the cut until it hits the first point. This may violate the aspect ratio bound, but will never generate empty cells.

```
#include <CGAL/Splitters.h>
```

### Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian\_d<double>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane\_separator<Traits::FT>*

### Is Model for the Concepts

*Splitter*

### Types

*Traits::FT*                      *FT*;                      Number type.

### Creation

```
Sliding_fair<Traits, SpatialSeparator> s( unsigned int bucket_size, FT aspect_ratio=FT(3));
```

Constructor.

### Operations

*FT*                      *s.aspect\_ratio()*                      Returns the maximal ratio between the largest and smallest side of a cell allowed for fair splitting.

*unsigned int*                      *s.bucket\_size()*                      Returns the bucket size of the leaf nodes.

**See Also**

*Splitter,*  
*SpatialSeparator*

## CGAL::Sliding\_midpoint<Traits, SpatialSeparator>

### Definition

Implements the *sliding midpoint* splitting rule. This is a modification of the *Midpoint\_of\_rectangle* splitting rule. It first attempts to perform a midpoint of rectangle split as described above. If data points lie on both sides of the separating plane the sliding midpoint rule computes the same separator as the midpoint of rectangle rule. If the data points lie only on one side it avoids this by sliding the separator, computed by the midpoint of rectangle rule, to the nearest data point.

```
#include <CGAL/Splitters.h>
```

### Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian\_d<double>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane\_separator<Traits::FT>*.

### Is Model for the Concepts

*Splitter*

### Creation

```
Sliding_midpoint<Traits, SpatialSeparator> s( unsigned int bucket_size);
```

Constructor.

### Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.

# SpatialSeparator

advanced

## Definition

The concept `SpatialSeparator` defines the requirements for a separator. A separator is a  $(d-1)$ -dimensional subspace that separates a  $d$ -dimensional space into two parts. One part of space is said to be on the negative side of the separator and the other part of space is said to be on the positive side of the separator.

## Has Models

`CGAL::Plane_separator<FT>`.

## Types

`SpatialSeparator::FT`      Number type.

## Creation

`SpatialSeparator s;`      Default constructor.

## Operations

`void`      `s.set_cutting_dimension( int d )`      Sets the cutting dimension to  $d$ .

`void`      `s.set_cutting_value( FT v )`      Sets the cutting value to  $v$ .

`int`      `s.cutting_dimension()`      Returns the number of the cutting dimension.

`FT`      `s.cutting_value()`      Returns the cutting value.

`template <class Point_d>`  
`bool`      `s.has_on_negative_side( Point_d p )`      Returns true if and only if the point  $p$  is on the negative side of the separator.

# SpatialTree

## Definition

The concept `SpatialTree` defines the requirements for a tree supporting both neighbor searching and approximate range searching.

## Types

<code>SpatialTree:: SearchTraits</code>	Search traits.
<code>SpatialTree:: Point_d</code>	Point type.
<code>SpatialTree:: iterator</code>	Bidirectional iterator with value type <code>Point_d</code> that allows to enumerate all points in the tree.
<code>SpatialTree:: Node_handle</code>	Node handle.
<code>SpatialTree:: Point_d_iterator</code>	Iterator with value type <code>Point_d*</code> .
<code>SpatialTree:: Splitter</code>	Splitter.
<code>SpatialTree:: Distance</code>	Distance.

## Creation

```
template <class InputIterator>
SpatialTree tree( InputIterator first, InputIterator beyond, SearchTraits t);
```

Constructs a tree on the elements from the sequence `[first,beyond)`.

## Operations

```
template <class OutputIterator, class FuzzyQueryItem>
OutputIterator tree.search( OutputIterator it, FuzzyQueryItem q)
```

Reports the points that are approximately contained by `q`. The value type of `OutputIterator` must be `Point_d`.

<code>iterator</code>	<code>tree.begin()</code>	Returns an iterator to the first point in the tree.
<code>iterator</code>	<code>tree.end()</code>	Returns the corresponding past-the-end iterator.

<i>Node_handle</i>	<i>tree.root()</i>	Returns a handle to the root node of the tree.
<i>Kd_tree_rectangle&lt;SearchTraits&gt;</i>		
	<i>tree.bounding_box()</i>	returns a const reference to the bounding box of the root node of the tree.
<i>unsigned int</i>	<i>tree.size()</i>	Returns the number of items that are stored in the tree.

## Has Models

*CGAL::Kd\_tree<Traits,Splitter,UseExtendedNode>*.

# Splitter

advanced

## Definition

The concept Splitter defines the requirements for a function object class implementing a splitting rule.

## Has Models

```
CGAL::Fair<Traits, SpatialSeparator>,
CGAL::Median_of_rectangle<Traits, SpatialSeparator>,
CGAL::Median_of_max_spread<Traits, SpatialSeparator>,
CGAL::Midpoint_of_rectangle<Traits, SpatialSeparator>,
CGAL::Midpoint_of_max_spread<Traits, SpatialSeparator>,
CGAL::Sliding_fair<Traits, SpatialSeparator>,
CGAL::Sliding_midpoint<Traits, SpatialSeparator>.
```

## Types

Splitter:: FT

Number type.

Splitter:: Separator

Separator.

The parameters *aspect\_ratio* and *bucket\_size* define the way in which *k-d* tree is constructed.

## Operations

<i>FT</i>	<i>s.aspect_ratio()</i>	Returns the maximal ratio between the largest and smallest side of a cell allowed for fair splitting.
<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.

## CGAL::Weighted\_Minkowski\_distance<Traits>

### Definition

The class *Weighted\_Minkowski\_distance*<Traits> provides an implementation of the concept *OrthogonalDistance*, with a weighted Minkowski metric on  $d$ -dimensional points defined by  $l_p(w)(r, q) = (\sum_{i=1}^d w_i(r_i - q_i)^p)^{1/p}$  for  $0 < p < \infty$  and defined by  $l_\infty(w)(r, q) = \max\{w_i|r_i - q_i| \mid 1 \leq i \leq d\}$ . For the purpose of the distance computations it is more efficient to compute the transformed distance  $\sigma_{i=1}^d w_i(r_i - q_i)^p$  instead of the actual distance.

```
#include <CGAL/Weighted_Minkowski_distance.h>
```

### Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search\_traits\_2*<Kernel>.

### Is Model for the Concepts

*OrthogonalDistance*

### Types

*Traits::FT*                      *FT*;                      Number type.

*Traits::Point\_d*                *Point\_d*;                      Point type.

### Creation

```
Weighted_Minkowski_distance<Traits> wd( int d);
```

Constructor implementing  $l_2$  metric for  $d$ -dimensional points.

```
template <class InputIterator>
```

```
Weighted_Minkowski_distance<Traits> wd( FT power, int dim, InputIterator wb, InputIterator we);
```

Constructor implementing the  $l_{power}(weights)$  metric.  $power \leq 0$  denotes the  $l_\infty(weights)$  metric. The values in the iterator range  $[wb, we)$  are the weight.

### Operations

```
FT                                      wd.transformed_distance( Point_d q, Point_d r)
```

Returns  $d^{power}$ , where  $d$  denotes the distance between  $q$  and  $r$ .

<i>FT</i>	<i>wd.min_distance_to_rectangle( Point_d q, Kd_tree_rectangle&lt;Traits&gt; r;)</i>	Returns $d^{power}$ , where $d$ denotes the distance between the query item $q$ and the point on the boundary of $r$ closest to $q$ .
<i>FT</i>	<i>wd.max_distance_to_rectangle( Point_d q, Kd_tree_rectangle&lt;Traits&gt; r;)</i>	Returns $d^{power}$ , where $d$ denotes the distance between the query item $q$ and the point on the boundary of $r$ farthest to $q$ .
<i>FT</i>	<i>wd.new_distance( FT dist, FT old_off, FT new_off, int cutting_dimension)</i>	Updates <i>dist</i> incrementally and returns the updated distance.
<i>FT</i>	<i>wd.transformed_distance( FT d)</i>	Returns $d^p$ for $0 < p < \infty$ . Returns $d$ for $p = \infty$ .
<i>FT</i>	<i>wd.inverse_of_transformed_distance( FT d)</i>	Returns $d^{1/p}$ for $0 < p < \infty$ . Returns $d$ for $p = \infty$ .

### 52.1 Introduction

This chapter presents the CGAL range tree and segment tree data structures.

### 52.2 Definitions

This section presents  $d$ -dimensional range and segment trees. A one-dimensional range tree is a binary search tree on *one-dimensional point data*. Here we call all one-dimensional data types having a strict ordering (like integer and double) *point data*.  $d$ -dimensional *point data* are  $d$ -tuples of one-dimensional point data.

A one-dimensional segment tree is a binary search tree as well, but with *one-dimensional interval data* as input data. One-dimensional interval data is a pair (i.e., 2-tuple)  $(a, b)$ , where  $a$  and  $b$  are one-dimensional point data of the same type and  $a < b$ . The pair  $(a, b)$  represents a half open interval  $[a, b)$ . Analogously, a  $d$ -dimensional interval is represented by a  $d$ -tuple of one-dimensional intervals.

The *input data type* for a  $d$ -dimensional tree is a container class consisting of a  $d$ -dimensional point data type, interval data type or a mixture of both, and optionally a *value type*, which can be used to store arbitrary data. E.g., the  $d$ -dimensional bounding box of a  $d$ -dimensional polygon may define the interval data of a  $d$ -dimensional segment tree and the polygon itself can be stored as its value. An *input data item* is an instance of an input data type.

The range and segment tree classes are fully generic in the sense that they can be used to define *multilayer trees*. A multilayer tree of dimension (number of layers)  $d$  is a simple tree in the  $d$ -th layer, whereas the  $k$ -th layer,  $1 \leq k \leq d - 1$ , of the tree defines a tree where each (inner) vertex contains a multilayer tree of dimension  $d - k + 1$ . The  $k - 1$ -dimensional tree which is nested in the  $k$ -dimensional tree ( $T$ ) is called the *sublayer tree* (of  $T$ ). For example, a  $d$ -dim tree can be a range tree on the first layer, constructed with respect to the first dimension of  $d$ -dimensional data items. On all the data items in each subtree, a  $(d - 1)$ -dimensional tree is built, either a range or a segment tree, with respect to the second dimension of the data items. And so on. Figures 52.2, 52.3 and 52.5 illustrate the meaning of a sublayer tree graphically.

After creation of the tree, further insertions or deletions of data items are disallowed. The tree class does neither depend on the type of data nor on the concrete physical representation of the data items. E.g., let a multilayer tree be a segment tree for which each vertex defines a range tree. We can choose the data items to consist of intervals of type *double* and the point data of type *integer*. As value type we can choose *string*.

For this generality we have to define what the tree of each dimension looks like and how the input data is organized. For dimension  $k$ ,  $1 \leq k \leq 4$ , CGAL provides ready-to-use range and segment trees that can store  $k$ -dimensional keys (intervals resp.). Examples illustrating the use of these classes are given in Sections 52.5.1 and 52.6.1. The description of the functionality of these classes as well as the definition of higher dimensional trees and mixed multilayer trees is given in the reference manual.

In the following two sections we give short definitions of the version of the range tree and segment tree implemented here together with some examples. The presentation closely follows [dBvKOS97].

## 52.3 Software Design

In order to be able to define a multilayer tree we first designed the range and segment tree to have a template argument defining the type of the sublayer tree. With this sublayer tree type information the sublayers could be created. This approach lead to nested template arguments, since the sublayer tree can again have a template argument defining the sublayer. Therefore, the internal class and function identifiers got longer than a compiler-dependent limit. This happend already for  $d = 2$ .

Therefore, we chose another, object oriented, design. We defined a pure virtual base class called *Tree\_base* from which we derived the classes *Range\_tree\_d* and *Segment\_tree\_d*. The constructor of these classes expects an argument called *sublayer\_prototype* of type *Tree\_base*. Since class *Range\_tree\_d* and class *Segment\_tree\_d* are derived from class *Tree\_base*, one can use an instantiation of class *Range\_tree\_d* or class *Segment\_tree\_d* as constructor argument. This argument defines the sublayer tree of the tree. E.g., you can construct a *Range\_tree\_d* with an instantiation of class *Segment\_tree\_d* as constructor argument. You then have defined a range tree with a segment tree as sublayer tree. Since both classes *Range\_tree\_d* and *Segment\_tree\_d* expect a sublayer tree in their constructor we had to derive a third class called *Tree\_anchor* from class *Tree\_base* which does not expect a constructor argument. An instantiation of this class is used as constructor argument of class *Range\_tree\_d* or *Segment\_tree\_d* in order to stop the recursion.

All classes provide a *clone()* function which returns an instance (a copy) of the same tree type. The *clone()* function of the *sublayer\_prototype* is called in the construction of the tree. In case that the sublayer tree again has a sublayer, it also has a *sublayer\_prototype* which is also cloned and so on. Thus, a call to the *clone()* function generates a sublayer tree which has the complete knowledge about its sublayer tree.

The trees allow to perform window queries, enclosing queries, and inverse range queries on the keys. Clearly, an inverse range query makes only sense in the segment tree. In order to perform an inverse range query, a range query of  $\epsilon$  width has to be performed. We preferred not to offer an extra function for this sort of query, since the inverse range query is a special case of the range query. Furthermore, offering an inverse range query in the segment tree class implies offering this function also in the range tree class and having an extra item in the traits class that accesses the inverse range query point.

The trees are templated with three arguments: *Data*, *Window* and *Traits*. Type *Data* defines the input data type and type *Window* defines the query window type. The tree uses a well defined set of functions in order to access data. These functions have to be provided by class *Traits*.

The design partly follows the *prototype design pattern* in [GHJV95]. In comparison to our first approach using templates we want to note the following: In this approach the sublayer type is defined in use of object oriented programming at run time, while in the approach using templates, the sublayer type is defined at compile time.

The runtime overhead caused in use of virtual member functions in this object oriented design is negligible since all virtual functions are non trivial. The design concept is illustrated in Figure 52.1.

E.g. in order to define a two dimensional multilayer tree, which consists of a range tree in the first dimension and a segment tree in the second dimension we proceed as follows: We construct an object of type *Tree\_anchor* which stops the recursion. Then we construct an object of type *Segment\_tree\_d*, which gets as prototype argument our object of type *Tree\_anchor*. After that, we define an object of type *Range\_tree\_d* which is constructed with the object of type *Segment\_tree\_d* as prototype argument. The following piece of code illustrates the construction of the two-dimensional multilayer tree.

```
int main() {
    Tree_Anchor *anchor=new Tree_Anchor;
    Segment_Tree_d *segment_tree = new Segment_Tree_d(*anchor);
    Range_Tree_d *range_segment_tree = new Range_Tree_d(*segment_tree);
    /* let data_items be a list of Data items */
    range_segment_tree->make_tree(data_items.begin(),data_items.end());
}
```

Here, class *Tree\_Anchor*, *Segment\_Tree\_d*, and *Range\_Tree\_d* are defined by *typedefs*:

```
typedef Tree_anchor<Data,Window> Tree_Anchor;
typedef Segment_tree_d<Data,Window,Interval_traits> Segment_Tree_d;
typedef Range_tree_d<Data,Window,Point_traits> Range_Tree_d;
```

Class *Tree\_base* and class *Tree\_anchor* get two template arguments: a class *Data* which defines the type of data that is stored in the tree, and a class *Window* which defines the type of a query range. The derived classes *Range\_tree\_d* and *Segment\_tree\_d* additionally get an argument called *Tree\_traits* which defines the interface between the *Data* and the tree. Let the *Data* type be a *d*-dimensional tuple, which is either a point data or an interval data in each dimension. Then, the class *Tree\_traits* provides accessors to the point (resp. interval) data of that tree layer and a compare function. Remind our example of the two-dimensional tree which is a range tree in the first dimension and a segment tree in the second dimension. Then, the *Tree\_traits* class template argument of class *Segment\_tree\_d* defines an accessor to the interval data of the *Data*, and the *Tree\_traits* class template argument of class *Range\_tree\_d* defines an accessor to the point data of *Data*. An example implementation for these classes is listed below.

```
struct Data{
```

Figure 52.1: Design of the range and segment tree data structure. The symbol triangle means that the lower class is derived from the upper class.

```

    int min,max; /* interval data */
    double point; /* point data */
};

struct Window{
    int min,max;
    double min_point, max_point;
};

class Point_traits{
public:
    typedef double Key;
    Key get_key(Data& d){return d.point;} /*key accessor */
    Key get_left(Window& w){return w.min_point;}
    Key get_right(Window& w){return w.max_point;}
    bool comp(Key& key1, Key& key2){return (key1 < key2);}
}

class Interval_traits{
public:
    typedef int Key;
    Key get_left(Data& d){return d.min;}
    Key get_right(Data& d){return d.max;}
    Key get_left_win(Window& w){return w.min;}
    Key get_right_win(Window& w){return w.max;}
    bool comp(Key& key1, Key& key2){return (key1 < key2);}
}

```

## 52.4 Creating an Arbitrary Multilayer Tree

Now let us have a closer look on how a multilayer tree is built. In case of creating a  $d$ -dimensional tree, we handle a sequence of arbitrary data items, where each item defines a  $d$ -dimensional interval, point or other object. The tree is constructed with an iterator over this structure. In the  $i$ -th layer, the tree is built with respect to the data slot that defines the  $i$ -th dimension. Therefore, we need to define which data slot corresponds to which dimension. In addition we want our tree to work with arbitrary data items. This requires an adaptor between the algorithm and the data item. This is resolved by the use of traits classes, implemented in form of a traits class using function objects. These classes provide access functions to a specified data slot of a data item. A  $d$ -dimensional tree is then defined separately for each layer by defining a traits class for each layer.

## 52.5 Range Trees

A one-dimensional range tree is a binary search tree on one-dimensional point data. The point data of the tree is stored in the leaves. Each inner vertex stores the highest entry of its left subtree. The version of a range tree implemented here is static, which means that after construction of the tree, no elements be inserted or deleted. A  $d$ -dimensional range tree is a binary leaf search tree according to the first dimension of the  $d$ -dimensional point data, where each vertex contains a  $(d - 1)$ -dimensional search tree of the points in the subtree (sublayer tree) with respect to the second dimension. See [dBvKOS97] and [Sam90] for more detailed information.

A  $d$ -dimensional range tree can be used to determine all  $d$ -dimensional points that lie inside a given  $d$ -dimensional interval (*window\_query*). Figure 52.2 shows a two-dimensional range tree, Figure 52.3 a  $d$ -

dimensional one.

Figure 52.2: A two-dimensional range tree. The tree is a binary search tree on the first dimension. Each sublayer tree of a vertex  $v$  is a binary search tree on the second dimension. The data items in a sublayer tree of  $v$  are all data items of the subtree of  $v$ .

Figure 52.3: A  $d$ -dimensional range tree. For each layer of the tree, one sublayer tree is illustrated.

The tree can be built in  $O(n \log^{d-1} n)$  time and needs  $O(n \log^{d-1} n)$  space. The  $d$ -dimensional points that lie in the  $d$ -dimensional query interval can be reported in  $O(\log^d n + k)$  time, where  $n$  is the total number of points and  $k$  is the number of reported points.

### 52.5.1 Example for Range Tree on Map-like Data

The following example program uses the predefined *Range\_tree\_2* data structure together with the predefined traits class *Range\_tree\_map\_traits\_2* which has two template arguments specifying the type of the point data in each dimension (*CGAL::Cartesian<double>*) and the value type of the 2-dimensional point data (*char*). Therefore the *Range\_tree\_2* is defined on 2-dimensional point data each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_tree_map_traits_2<K, char> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
    typedef Traits::Key Key;
    typedef Traits::Interval Interval;
```

```

std::vector<Key> InputList, OutputList;
InputList.push_back(Key(K::Point_2(8,5.1), 'a'));
InputList.push_back(Key(K::Point_2(1,1.1), 'b'));
InputList.push_back(Key(K::Point_2(3,2.1), 'c'));

Range_tree_2_type Range_tree_2(InputList.begin(),InputList.end());
Interval win(Interval(K::Point_2(4,8.1),K::Point_2(5,8.2)));
std::cout << "\n Window Query:\n ";
Range_tree_2.window_query(win, std::back_inserter(OutputList));
std::vector<Key>::iterator current=OutputList.begin();
while(current!=OutputList.end()){
    std::cout << (*current).first.x() << "," << (*current).first.y()
        << ":" << (*current++).second << std::endl;
}
}

```

## 52.5.2 Example for Range Tree on Set-like Data

This example illustrates the use of the range tree on 2-dimensional point data (no value is associated to a data item). After the definition of the tree, some input data items are created and the tree is constructed according to the input data items. After that, a window query is performed and the query elements are given to standard out.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_segment_tree_set_traits_2<K> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
    typedef Traits::Key Key;
    typedef Traits::Interval Interval;
    std::vector<Key> InputList, OutputList;
    std::vector<Key>::iterator first, last, current;

    InputList.push_back(Key(8,5.1));
    InputList.push_back(Key(1,1.1));
    InputList.push_back(Key(3,2.1));

    Range_tree_2_type Range_tree_2(InputList.begin(),InputList.end());

    Interval win=Interval(Key(4,8.1),Key(5,8.2));
    std::cout << std::endl << "Window Query: lower left point: (4.0,5.0),";
    std::cout << "upper right point: (8.1,8.2)" << std::endl;
    Range_tree_2.window_query(win, std::back_inserter(OutputList));
    current=OutputList.begin();
    while(current!=OutputList.end()){
        std::cout << (*current).x()<< "-" << (*current).y() << std::endl;
        current++;
    }
}

```

```

    }
}

```

## 52.6 Segment Trees

A segment tree is a static binary search tree for a given set of coordinates. The set of coordinates is defined by the endpoints of the input data intervals. Any two adjacent coordinates build an elementary interval. Every leaf corresponds to an elementary interval. Inner vertices correspond to the union of the subtree intervals of the vertex. Each vertex or leaf  $v$  contains a sublayer type (or a list, if it is one-dimensional) that will contain all intervals  $I$ , such that  $I$  contains the interval of vertex  $v$  but not the interval of the parent vertex of  $v$ .

A  $d$ -dimensional segment tree can be used to solve the following problems:

- Determine all  $d$ -dimensional intervals that contain a  $d$ -dimensional point. This query type is called “inverse range query”.
- Determine all  $d$ -dimensional intervals that enclose a given  $d$ -dimensional interval (*enclosing\_query*).
- Determine all  $d$ -dimensional intervals that partially overlap or are contained in a given  $d$ -dimensional interval (*window\_query*).

In Figure 52.4 an example of a one-dimensional segment tree is given. Figure 52.5 shows a two-dimensional segment tree.

The tree can be built in  $O(n \log^d n)$  time and needs  $O(n \log^d n)$  space. The processing time for inverse range queries in an  $d$ -dimensional segment tree is  $O(\log^d n + k)$  time, where  $n$  is the total number of intervals and  $k$  is the number of reported intervals.

One possible application of a two-dimensional segment tree is the following. Given a set of convex polygons in two-dimensional space (CGAL::Polygon\_2), we want to determine all polygons that intersect a given rectangular query window. Therefore, we define a two-dimensional segment tree, where the two-dimensional interval of a data item corresponds to the bounding box of a polygon and the value type corresponds to the polygon itself. The segment tree is created with a sequence of all data items, and a window query is performed. The polygons of the resulting data items are finally tested independently for intersections.

### 52.6.1 Example for Segment Tree on Map-like Data

The following example program uses the predefined *Segment\_tree\_2* data structure together with the predefined traits class *Segment\_tree\_map\_traits\_2* which has two template arguments specifying the type of the point data in each dimension (CGAL::Cartesian<double>) and the value type of the 2-dimensional point data (char). Therefore the *Segment\_tree\_2* is defined on 2-dimensional point data (CGAL::Point\_2<Cartesian<double>>) each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<double> K;

```

Figure 52.4: A one-dimensional segment tree. The segments and the corresponding elementary intervals are shown below the tree. The arcs from the nodes point to their subsets.

Figure 52.5: A two-dimensional segment tree. The first layer of the tree is built according to the elementary intervals of the first dimension. Each sublayer tree of a vertex  $v$  is a segment tree according to the second dimension of all data items of  $v$ .

```

typedef CGAL::Segment_tree_map_traits_2<K, char> Traits;
typedef CGAL::Segment_tree_2<Traits > Segment_tree_2_type;

int main()
{
    typedef Traits::Interval Interval;
    typedef Traits::Pure_interval Pure_interval;
    typedef Traits::Key Key;
    std::list<Interval> InputList, OutputList1, OutputList2;

    InputList.push_back(Interval(Pure_interval(Key(1,5), Key(2,7)), 'a'));
    InputList.push_back(Interval(Pure_interval(Key(2,7), Key(3,8)), 'b'));
    InputList.push_back(Interval(Pure_interval(Key(6,9), Key(9,13)), 'c'));
    InputList.push_back(Interval(Pure_interval(Key(1,3), Key(3,9)), 'd'));

    Segment_tree_2_type Segment_tree_2(InputList.begin(), InputList.end());

    Interval a=Interval(Pure_interval(Key(3,6), Key(7,12)), 'e');
    Segment_tree_2.window_query(a, std::back_inserter(OutputList1));

    std::list<Interval>::iterator j = OutputList1.begin();
    std::cout << "\n window_query (3,6), (7,12)\n";
    while(j!=OutputList1.end()){
        std::cout << (*j).first.first.x() << "-" << (*j).first.second.x() << " "
            << (*j).first.first.y() << "-" << (*j).first.second.y() << std::endl;
        j++;
    }

    Interval b=Interval(Pure_interval(Key(6,10), Key(7,11)), 'f');
    Segment_tree_2.enclosing_query(b, std::back_inserter(OutputList2));
    j = OutputList2.begin();
    std::cout << "\n enclosing_query (6,10), (7,11)\n";
    while(j!=OutputList2.end()){
        std::cout << (*j).first.first.x() << "-" << (*j).first.second.x() << " "
            << (*j).first.first.y() << "-" << (*j).first.second.y() << std::endl;
        j++;
    }
    return 0;
}

```

## 52.6.2 Example for Segment Tree on Set-like Data

This example illustrates the use of the predefined segment tree on 3-dimensional interval data (with no value associated). After the definition of the traits type and tree type, some intervals are constructed and the tree is build according to the intervals. Then, a window query is performed and the query elements are given out.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<int> K;

```

```

typedef CGAL::Range_segment_tree_set_traits_3<K> Traits;
typedef CGAL::Segment_tree_3<Traits > Segment_tree_3_type;

int main()
{
    typedef Traits::Interval Interval;
    typedef Traits::Key Key;
    std::list<Interval> InputList, OutputList;

    InputList.push_back(Interval(Key(1,5,7), Key(2,7,9)));
    InputList.push_back(Interval(Key(2,7,6), Key(3,8,9)));
    InputList.push_back(Interval(Key(6,9,5), Key(9,13,8)));
    InputList.push_back(Interval(Key(1,3,4), Key(3,9,8)));

    Segment_tree_3_type Segment_tree_3(InputList.begin(),InputList.end());

    Interval a(Key(3,6,5), Key(7,12,8));
    Segment_tree_3.window_query(a,std::back_inserter(OutputList));
    std::list<Interval>::iterator j = OutputList1.begin();
    std::cout << "\n window_query (3,6,5), (7,12,8) \n";
    while(j!=OutputList.end()){
        std::cout << (*j).first.x() << "," << (*j).first.y() << ",";
        std::cout << (*j).first.z() <<"," << (*j).second.x() << ",";
        std::cout << (*j).second.y() << "," << (*j).second.z() << std::endl;
        j++;
    }
}

```

# dD Range and Segment Trees

## Reference Manual

*Gabriele Neyer*

This chapter presents the CGAL range tree and segment tree data structures.

The range tree is theoretically superior to the *Kd*-tree, but the latter often seems to perform better. However, the range tree as implemented in CGAL is more flexible than the *Kd*-tree implementation, in that it enables to layer together range trees and segment trees in the same data structure.

## RangeSegmentTreeTraits\_k

### Definition

A tree traits class gives the range tree and segment tree class the necessary type information of the keys and intervals. Further more, they define function objects that allow to access the keys and intervals, and provide comparison functions that are needed for window queries.

### Types

<i>RangeSegmentTreeTraits_k:: Key</i>	The k-dimensional key type.
<i>RangeSegmentTreeTraits_k:: Interval</i>	The k-dimensional interval type.
<i>RangeSegmentTreeTraits_k:: Key_i</i>	The type in dimension $i$ , with $1 \leq i \leq k$ .
<i>RangeSegmentTreeTraits_k:: key_i</i>	function object providing an <i>operator()</i> that takes an argument of type <i>Key</i> and returns a component of type <i>Key_i</i> .
<i>RangeSegmentTreeTraits_k:: low_i</i>	function object providing an <i>operator()</i> that takes an argument of type <i>Interval</i> and returns a component of type <i>Key_i</i> .
<i>RangeSegmentTreeTraits_k:: high_i</i>	function object providing an <i>operator()</i> that takes an argument of type <i>Interval</i> and returns a component of type <i>Key_i</i> .
<i>RangeSegmentTreeTraits_k:: compare_i</i>	function object providing an <i>operator()</i> that takes two arguments argument $a, b$ of type <i>Key_i</i> and returns true if $a < b$ , false otherwise.

### Example

The following piece of code gives an example of how a traits class might look like, if you have keys that are of the type *int* in the first and that are of the type *double* in the second dimension.

```
class Int_double_tree_traits_2{
public:
    typedef std::pair<int, double> Key;
    typedef int Key_1;
    typedef double Key_2;
    typedef std::pair<Key,Key> Interval;

    class C_Key_1{
    public:
        Key_1 operator()(const Key& k)
        { return k.first;}
    };
    class C_Key_2{
```

```

public:
    Key_2 operator()(const Key& k)
    { return k.second;}
};
class C_Low_1{
public:
    Key_1 operator()(const Interval& i)
    { return i.first.first;}
};
class C_High_1{
public:
    Key_1 operator()(const Interval& i)
    { return i.second.first;}
};
class C_Low_2{
public:
    Key_2 operator()(const Interval& i)
    { return i.first.second;}
};
class C_High_2{
public:
    Key_2 operator()(const Interval& i)
    { return i.second.second;}
};
class C_Compare_1{
public:
    bool operator()(Key_1 k1, Key_1 k2)
    { return less<int>()(k1,k2);}
};
class C_Compare_2{
public:
    bool operator()(Key_2 k1, Key_2 k2)
    { return less<double>()(k1,k2);}
};
typedef C_Compare_1 compare_1;
typedef C_Compare_2 compare_2;
typedef C_Low_1 low_1;
typedef C_High_1 high_1;
typedef C_Key_1 key_1;
typedef C_Low_2 low_2;
typedef C_High_2 high_2;
typedef C_Key_2 key_2;
};

```

## CGAL::Range\_segment\_tree\_traits\_set\_2<R>

### Definition

The class is a range and segment tree traits class for the 2-dimensional point class from the CGAL kernel. The class is parameterized with a representation class *R*.

```
#include <CGAL/Range_segment_tree_traits.h>
```

### Types

```
Point_2<R>                      Key;
```

```
std::pair<Key, Key>            Interval;
```

## CGAL::Range\_segment\_tree\_traits\_set\_3<R>

### Definition

The class is a range and segment tree traits class for the 3-dimensional point class from the CGAL kernel. The class is parameterized with a representation class  $R$ .

```
#include <CGAL/Range_segment_tree_traits.h>
```

### Types

```
Point_3<R>                    Key;
```

```
std::pair<Key, Key>          Interval;
```

## CGAL::Range\_tree\_d<Data, Window, Traits>

### Types

*Range\_tree\_d<Data, Window, Traits>::Data*      container *Data*.

*Range\_tree\_d<Data, Window, Traits>::Window*  
container *Window*.

*Range\_tree\_d<Data, Window, Traits>::Traits*      container *Traits*.

## Creation

```
#include <CGAL/Range_tree_d.h>
Range_tree_d<Data, Window, Traits> r( Tree_base<Data, Window> sublayer_tree);
```

A range tree is constructed, such that the subtree of each vertex is of the same type prototype *sublayer\_tree* is.

We assume that the dimension of the tree is  $d$ . This means, that *sublayer\_tree* is a prototype of a  $d - 1$ -dimensional tree. All data items of the  $d$ -dimensional range tree have container type *Data*. The query window of the tree has container type *Window*. *Traits* provides access to the corresponding data slots of container *Data* and *Window* for the  $d$ -th dimension. The traits class *Traits* must at least provide all functions and type definitions as described in, for example, the reference page for *tree\_point\_traits*. The template class described there is fully generic and should fulfill the most requirements one can have. In order to generate a one-dimensional range tree instantiate *Tree\_anchor<Data, Window> sublayer\_tree* with the same template parameters (*Data* and *Window*) *Range\_tree\_d* is defined. In order to construct a two-dimensional range tree, create *Range\_tree\_d* with a one-dimensional *Range\_tree\_d* with the corresponding *Traits* class of the first dimension.

*Precondition:* *Traits::Data==Data* and *Traits::Window==Window*.

## Operations

```
template<class ForwardIterator>
bool r.make_tree( ForwardIterator first, ForwardIterator last)
```

The tree is constructed according to the data items in the sequence between the element pointed by iterator *first* and iterator *last*. The data items of the iterator must have type *Data*.

*Precondition:* This function can only be called once. If it is the first call the tree is build and *true* is returned. Otherwise, nothing is done but a *CGAL warning* is given and *false* returned.

```
template<class OutputIterator>
OutputIterator r.window_query( Window win, OutputIterator result)
```

All elements that lay inside the  $d$ -dimensional interval defined through *win* are placed in the sequence container of *OutputIterator*; the output iterator that points to the last location the function wrote to is returned.

```
bool r.is_valid()
```

The tree structure is checked. For each vertex the subtree is checked on being valid and it is checked whether the value of the *Key\_type* of a vertex corresponds to the highest *Key\_type* value of the left subtree.

## Protected Operations

*bool*                      *r.is\_inside( Window win, Data object)*

returns true, if the data of *object* lies between the start and endpoint of interval *win*. False otherwise.

*bool*                      *r.is\_anchor()*                      returns false.

## Implementation

The construction of a  $d$ -dimensional range tree takes  $O(n \log n^{d-1})$  time. The points in the query window are reported in time  $O(k + \log^d n)$ , where  $k$  is the number of reported points. The tree uses  $O(n \log n^{d-1})$  storage.

## CGAL::Range\_tree\_k<Traits>

### Definition

An object of the class is a  $k$ -dimensional range tree that can store  $k$ -dimensional keys of type *Key*. The class allows to perform window queries on the keys. The class is parameterized with a range tree traits class *Traits* that defines, among other things, the type of the *Key*.

CGAL provides traits class implementations that allow to use the range tree with point classes from the CGAL kernel as keys. These classes are *CGAL::Range\_segment\_tree\_traits\_set\_2<R>*, *CGAL::Range\_segment\_tree\_traits\_set\_3<R>*, *CGAL::Range\_tree\_traits\_map\_2<R>* and *CGAL::Range\_tree\_traits\_map\_3<R>*. The concept *RangeSegmentTreeTraits\_d* defines the requirements that range tree traits classes must fulfill. This allows the advanced user to develop further range tree traits classes.

```
#include <CGAL/Range_tree_k.h>
```

### Types

*Range\_tree\_k<Traits>::Traits* the type of the range tree traits class.

```
typedef Traits::Key Key;
```

```
typedef Traits::Interval  
Interval;
```

### Creation

*Range\_tree\_k<Traits> R;* Introduces an empty range tree *R*.

```
template < class ForwardIterator >  
Range_tree_k<Traits> R( ForwardIterator first, ForwardIterator last);
```

Introduces a range tree *R* and initializes it with the data in the range *[first, last)*.  
*Precondition:* *value\_type(first) == Traits::Key*.

### Operations

```
template < class ForwardIterator >  
void R.make_tree( ForwardIterator first, ForwardIterator last)
```

Introduces a range tree *R* and initializes it with the data in the range *[first, last)*. This function can only be applied once on an empty range tree.  
*Precondition:* *value\_type(first) == Traits::Key*.

```
template < class OutputIterator >
OutputIterator      R.window_query( Interval window, OutputIterator out)
```

writes all data that are in the interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.

*Precondition:* `value_type(out) == Traits::Key`.

## Example

The following example program uses the predefined *Range\_tree\_2* data structure together with the predefined traits class *Range\_tree\_map\_traits\_2* which has two template arguments specifying the type of the point data in each dimension (*CGAL::Cartesian<double>*) and the value type of the 2-dimensional point data (*char*). Therefore the *Range\_tree\_2* is defined on 2-dimensional point data (*CGAL::Point\_2<Cartesian<double> >*) each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_tree_map_traits_2<K, char> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
    typedef Traits::Key Key;
    typedef Traits::Interval Interval;

    std::vector<Key> InputList, OutputList;
    InputList.push_back(Key(K::Point_2(8,5.1), 'a'));
    InputList.push_back(Key(K::Point_2(1,1.1), 'b'));
    InputList.push_back(Key(K::Point_2(3,2.1), 'c'));

    Range_tree_2_type Range_tree_2(InputList.begin(), InputList.end());
    Interval win(Interval(K::Point_2(4,8.1), K::Point_2(5,8.2)));
    std::cout << "\n Window Query:\n ";
    Range_tree_2.window_query(win, std::back_inserter(OutputList));
    std::vector<Key>::iterator current=OutputList.begin();
    while(current!=OutputList.end()) {
        std::cout << (*current).first.x() << "," << (*current).first.y()
            << ":" << (*current++).second << std::endl;
    }
}
```

## CGAL::Range\_tree\_traits\_map\_2<R,T>

### Definition

The class is a range tree traits class for the 2-dimensional point class from the CGAL kernel, where data of type  $T$  is associated to each key. The class is parameterized with a representation class  $R$  and the type of the associated data  $T$ .

```
#include <CGAL/Range_segment_tree_traits.h>
```

### Types

```
std::pair<R::Point_2,T>
```

```
Key;
```

```
std::pair<R::Point_2, R::Point_2 >
```

```
Interval;
```

## CGAL::Range\_tree\_traits\_map\_3<R,T>

### Definition

The class is a range and segment tree traits class for the 3-dimensional point class from the CGAL kernel, where data of type  $T$  is associated to each key. The class is parameterized with a representation class  $R$  and the type of the associated data  $T$ .

```
#include <CGAL/Range_segment_tree_traits.h>
```

### Types

```
std::pair<R::Point_3,T>
```

```
Key;
```

```
std::pair<R::Point_3, R::Point_3>
```

```
Interval;
```

## CGAL::Segment\_tree\_d<Data, Window, Traits>

### Types

*Segment\_tree\_d*<*Data*, *Window*, *Traits*>::*Data*

container *Data*.

*Segment\_tree\_d*<*Data*, *Window*, *Traits*>::*Window*

container *Window*.

*Segment\_tree\_d*<*Data*, *Window*, *Traits*>::*Traits*

class *Traits*.

### Creation

```
#include <CGAL/Segment_tree_d.h>
```

```
Segment_tree_d<Data, Window, Traits> s( Tree_base<Data, Window> sublayer_tree);
```

A segment tree is defined, such that the subtree of each vertex is of the same type prototype *sublayer\_tree* is.

We assume that the dimension of the tree is  $d$ . This means, that *sublayer\_tree* is a prototype of a  $d - 1$ -dimensional tree. All data items of the  $d$ -dimensional segment tree have container type *Data*. The query window of the tree has container type *Window*. *Traits* provides access to the corresponding data slots of container *Data* and *Window* for the  $d$ -th dimension. The traits class *Traits* must at least provide all functions and type definitions described, for example, in the reference page for *tree\_point\_traits*. The template class described there is fully generic and should fulfill the most requirements one can have. In order to generate a one-dimensional segment tree instantiate *Tree\_anchor*<*Data*, *Window*> *sublayer\_tree* with the same template parameters *Data* and *Window* *Segment\_tree\_d* is defined. In order to construct a two-dimensional segment tree, create *Segment\_tree\_d* with a one-dimensional *Segment\_tree\_d* with the corresponding *Traits* of the first dimension.

*Precondition:* *Traits*::*Data*==*Data* and *Traits*::*Window*==*Window*.

## Operations

*bool* *s.make\_tree( In\_it first, In\_it last)*

The tree is constructed according to the data items in the sequence between the element pointed by iterator *first* and iterator *last*.

*Precondition:* This function can only be called once. If it is the first call the tree is build and *true* is returned. Otherwise, nothing is done but a *CGAL warning* is given and *false* returned.

*OutputIterator* *s.window\_query( Window win, OutputIterator result)*

$win = [a_1, b_1), \dots, [a_d, b_d), a_i, b_i \in T_i, 1 \leq i \leq d$ . All elements that intersect the associated  $d$ -dimensional interval of *win* are placed in the associated sequence container of *OutputIterator* and returns an output iterator that points to the last location the function wrote to. In order to perform an inverse range query, a range query of  $\epsilon$  width has to be performed.

*OutputIterator* *s.enclosing\_query( Window win, OutputIterator result)*

All elements that enclose the associated  $d$ -dimensional interval of *win* are placed in the associated sequence container of *OutputIterator* and returns an output iterator that points to the last location the function wrote to.

*bool* *s.is\_valid()*

The tree structure is checked. For each vertex either the sublayer tree is a tree anchor, or it stores a (possibly empty) list of data items. In the first case, the sublayer tree of the vertex is checked on being valid. In the second case, each data item is checked weather it contains the associated interval of the vertex and does not contain the associated interval of the parent vertex or not. True is returned if the tree structure is valid, false otherwise.

## Protected Operations

*bool* *s.is\_inside( Window win, Data object)*

returns true, if the interval of *object* is contained in the interval of *win*. False otherwise.

*bool* *s.is\_anchor()* returns false.

## Implementation

A  $d$ -dimensional segment tree is constructed in  $O(n \log n^d)$  time. An inverse range query is performed in time  $O(k + \log^d n)$ , where  $k$  is the number of reported intervals. The tree uses  $O(n \log n^d)$  storage.

## CGAL::Segment\_tree\_k<Traits>

### Definition

An object of the class is a  $k$ -dimensional segment tree that can store  $k$ -dimensional intervals of type *Interval*. The class allows to perform window queries, enclosing queries, and inverse range queries on the keys. The class is parameterized with a segment tree traits class *Traits* that defines, among other things, the type of the *Interval*. In order to perform an inverse range query, a range query of  $\varepsilon$  width has to be performed. We preferred not to offer an extra function for this sort of query, since the inverse range query is a special case of the range query. Furthermore, offering an inverse range query in the segment tree class implies offering this function also in the range tree class and having an extra item in the traits class that accesses the inverse range query point.

CGAL provides traits class implementations that allow to use the segment tree with point classes from the CGAL kernel as keys. These classes are *CGAL::Range\_segment\_tree\_traits\_set\_2<R>*, *CGAL::Range\_segment\_tree\_traits\_set\_3<R>*, *CGAL::Segment\_tree\_traits\_map\_2<R>* and *CGAL::Segment\_tree\_traits\_map\_3<R>*. The concept *RangeSegmentTreeTraits\_d* defines the requirements that segment tree traits classes must fulfill. This allows the advanced user to develop further segment tree traits classes.

```
#include <CGAL/Segment_tree_k.h>
```

### Types

*Segment\_tree\_k<Traits>::Traits* the type of the segment tree traits class.

```
typedef Traits::Key      Key;
```

```
typedef Traits::Interval  
                        Interval;
```

### Creation

*Segment\_tree\_k<Traits> S;* Introduces an empty segment tree  $S$ .

```
template < class ForwardIterator >  
Segment_tree_k<Traits> S( ForwardIterator first, ForwardIterator last);
```

Introduces a segment tree  $S$  and initializes it with the data in the range  $[first, last)$ .  
*Precondition:*  $value\_type(first) == Traits::Interval$ .

### Operations

```
template < class ForwardIterator >  
void S.make_tree( ForwardIterator first, ForwardIterator last)
```

Introduces a segment tree  $S$  and initializes it with the data in the range  $[first, last)$ . This function can only be applied once on an empty segment tree.  
*Precondition:*  $value\_type(first) == Traits::Interval$ .

```
template < class OutputIterator >
OutputIterator      S.window_query( Interval window, OutputIterator out)
```

writes all intervals that have non empty intersection with interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.

*Precondition:* `value_type(out) == Traits::Interval`.

```
template < class OutputIterator >
OutputIterator      S.enclosing_query( Interval window, OutputIterator out)
```

writes all intervals that enclose in the interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.

*Precondition:* `value_type(out) == Traits::Interval`.

## Example

This example illustrates the use of the predefined segment tree on 3-dimensional interval data (with no value associated). After the definition of the traits type and tree type, some intervals are constructed and the tree is build according to the intervals. Then, a window query is performed and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<int> K;
typedef CGAL::Range_segment_tree_set_traits_3<K> Traits;
typedef CGAL::Segment_tree_3<Traits> Segment_tree_3_type;

int main()
{
    typedef Traits::Interval Interval;
    typedef Traits::Key Key;
    std::list<Interval> InputList, OutputList;

    InputList.push_back(Interval(Key(1,5,7), Key(2,7,9)));
    InputList.push_back(Interval(Key(2,7,6), Key(3,8,9)));
    InputList.push_back(Interval(Key(6,9,5), Key(9,13,8)));
    InputList.push_back(Interval(Key(1,3,4), Key(3,9,8)));

    Segment_tree_3_type Segment_tree_3(InputList.begin(),InputList.end());

    Interval a(Key(3,6,5), Key(7,12,8));
    Segment_tree_3.window_query(a,std::back_inserter(OutputList));
    std::list<Interval>::iterator j = OutputList1.begin();
    std::cout << "\n window_query (3,6,5), (7,12,8) \n";
    while(j!=OutputList.end()){
        std::cout << (*j).first.x() << "," << (*j).first.y() << ",";
        std::cout << (*j).first.z() <<"," << (*j).second.x() << ",";
        std::cout << (*j).second.y() << "," << (*j).second.z() << std::endl;
    }
```

```
        j++;  
    }  
}
```

## CGAL::Segment\_tree\_traits\_map\_2<R,T>

### Definition

The class is a segment tree traits class for the 2-dimensional point class from the CGAL kernel, where data of type  $T$  is associated to each interval. The class is parameterized with a representation class  $R$  and the type of the associated data  $T$ .

```
#include <CGAL/Range_segment_tree_traits.h>
```

### Types

```
R::Point_2          Key;
```

```
std::pair<std::pair<Key,Key>,T>
```

```
Interval;
```

## CGAL::Segment\_tree\_traits\_map\_3<R,T>

### Definition

The class is a segment tree traits class for the 3-dimensional point class from the CGAL kernel, where data of type  $T$  is associated to each interval. The class is parameterized with a representation class  $R$  and the type of the associated data  $T$ .

```
#include <CGAL/Range_segment_tree_traits.h>
```

### Types

```
std::pair<R::Point_3 >
```

```
Key;
```

```
std::pair<std::pair<Key, Key>, T>
```

```
Interval;
```

## Sublayer

### Definition

Defines the requirements that a *Sublayer\_type* of class *Range\_tree\_d* or *Segment\_tree\_d* has to fulfill.

First of all, the class has to be derived from the abstract base class *Tree\_base* and therefore has to provide methods *make\_tree*, *window\_query*, *enclosing\_query* and *is\_inside* with the same parameter types as the instantiated class *Range\_tree\_d* or *Segment\_tree\_d*, respectively. Furthermore a method *bool is\_anchor()* has to be provided. If the *Sublayer\_type* class builds a recursion anchor for class *Segment\_tree\_d*, this function is expected to return *true*, *false* otherwise.

Such a recursion anchor class is provided by the class class. *Tree\_anchor<Data, Window>*.

## CGAL::tree\_interval\_traits

### Definition

*tree\_interval\_traits* is a template class that provides an interface to data items. It is similar to *tree\_point\_traits*, except that it provides access to two data slots of the same type of each container class (*Data*, *Window*) instead of providing access to one data slot of container class *Data* and two data slots of class *Window*.

```
#include <CGAL/Tree_traits.h>
```

### Types

```
typedef
tree_interval_traits<Data, Window, Key, Data_left_func, Data_right_func, Window_left_func, Window_right_
func, Compare> Interval_traits;
```

*tree\_interval\_traits::Data* the container *Data* — the data type. It may consist of several data slots. Two of these data slots have to be of type *Key*.

*tree\_interval\_traits::Window* the container *Window* — the query window type. It may consist of several data slots. Two of these data slots have to be of type *Key*.

*tree\_interval\_traits::Key* the type *Key* of the data slot this traits class provides access to.

*tree\_interval\_traits::Data\_left\_func* *Data\_left\_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a (the left) component of type *Key*.

*tree\_interval\_traits::Data\_right\_func* *Data\_right\_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a (the right) component of type *Key*.

*tree\_interval\_traits::Window\_left\_func* *Window\_left\_func* is a function objects that allow to access the left data slot of container *Window* which has type *Key*

*tree\_interval\_traits::Window\_right\_func* *Window\_right\_func* is a function objects that allow to access the right data slot of container *Window* which has type *Key*

*tree\_interval\_traits::Compare* defines a comparison relation which must define a strict ordering of the objects of type *Key*. If defined, *less<Key>* is sufficient.

### Creation

```
tree_interval_traits<Data, Window, Key, Data_left_func, Data_right_func, Window_left_func, Window_right_
func, Compare> d();
```

Generation of a *tree\_point\_traits* instance. It is a template class that provides an interface to data items.

## Operations

<i>Key</i>	<i>d.get_left( Data d)</i>	The data slot of the data item of <i>d</i> of type <i>Key</i> is accessed by function object <i>Data_left_func</i> .
<i>Key</i>	<i>d.get_right( Data d)</i>	The data slot of the data item of <i>d</i> of type <i>Key</i> is accessed by function object <i>Data_right_func</i> .
<i>Key</i>	<i>d.get_left_win( Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_left_func</i> .
<i>Key</i>	<i>d.get_right_win( Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_right_func</i> .
<i>bool</i>	<i>d.comp( Key&amp; key1, Key&amp; key2)</i>	returns Compare(key1, key2).

## CGAL::tree\_point\_traits

### Definition

*tree\_point\_traits* is a template class that provides an interface to data items.

```
#include <CGAL/Tree_traits.h>
```

### Types

*typedef*

```
tree_point_traits<Data, Window, Key, Data_func, Window_left_func, Window_right_func, Compare> Point_traits;
```

*tree\_point\_traits::Data*

the container *Data* — defines the *Data* type. It may consist of several data slots. One of these data slots has to be of type *Key*.

*tree\_point\_traits::Window*

the container *Window* — defines the type of the query rectangle. It may consist of several data slots. Two of these data slots has to be of type *Key*

*tree\_point\_traits::Key*

the type *Key* of the data slot this traits class provides access to.

*tree\_point\_traits::Data\_func*

*Data\_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a component of type *Key*.

*tree\_point\_traits::Window\_left\_func*

*Window\_left\_func* is a function objects that allow to access the left data slot of container *Window* which has type *Key*

*tree\_point\_traits::Window\_right\_func*

*Window\_right\_func* is a function objects that allow to access the right data slot of container *Window* which has type *Key*

*tree\_point\_traits::Compare*

defines a comparison relation which must define a strict ordering of the objects of type *Key*. If defined, *less*<*Key*> is sufficient.

### Creation

```
tree_point_traits<Data, Window, Key, Data_func, Window_left_func, Window_right_func, Compare> d();
```

Generation of a *tree\_point\_traits* instance. It is a template class that provides an interface to data items.

## Operations

<i>Key</i>	<i>d.get_key( Data d)</i>	The data slot of the data item of <i>d</i> of type <i>Key</i> is accessed by function object <i>Data_func</i> .
<i>Key</i>	<i>d.get_left( Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_left_func</i> .
<i>Key</i>	<i>d.get_right( Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_right_func</i> .
<i>bool</i>	<i>d.comp( Key&amp; key1, Key&amp; key2)</i>	returns <i>Compare(key1, key2)</i> .
<i>bool</i>	<i>d.key_comp( Data&amp; data1, Data&amp; data2)</i>	returns <i>Compare(get_key(data1), get_key(data2))</i> .

### Definition

*Tree\_anchor* is also derived from *Tree\_base*. Therefore, it provides the same methods as *Range\_tree\_d* and *Segment\_tree\_d*, but does nothing; it can be used as a recursion anchor for those classes. Therefore, instantiate *Sublayer\_type* of *Range\_tree\_d* (*Segment\_tree\_d* respectively) with *Tree\_anchor* and the container classes for the data items (*Data* and *Window*).

### Definition

*Tree\_anchor<Data, Window>::Data* container *Data*.

*Tree\_anchor* $\langle$ *Data*, *Window* $\rangle::$  *Window* container *Window*.

## Creation

```
#include <CGAL/Tree_base.h>
```

```
Tree_anchor<Data, Window> a;
```

## Operations

```
template<class OutputIterator>
OutputIterator      a.window_query( Window win, OutputIterator result)
```

```
template<class OutputIterator>
OutputIterator      a.enclosing_query( Window win, OutputIterator result)
```

<i>bool</i>	<i>a.is_valid()</i>	returns true;
-------------	---------------------	---------------

## Protected Operations

*bool* *a.is\_inside( Window win, Data object)*

returns true.

*bool* *a.is\_anchor()* returns true.

### Example

The following figures show a number of rectangles and a 2-dimensional segment tree built on them.

Figure 52.6: Two dimensional interval data.

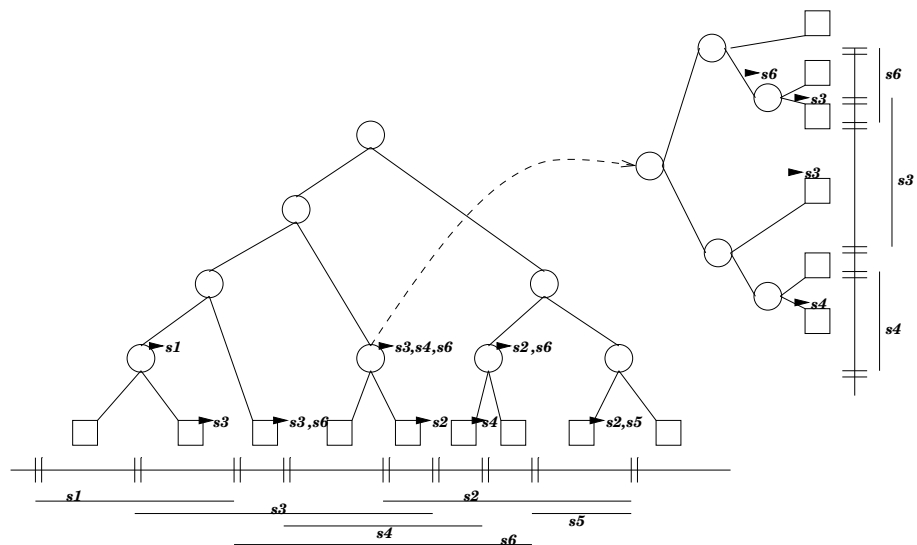

Figure 52.7: Two dimensional segment tree according to the interval data of Figure 52.6.

## 53.1 Introduction

Simple questions on geometric primitives, such as intersection and distance computations, can themselves become quite expensive if the primitives are not so simple anymore, for example, three-dimensional triangles and facets of polyhedral surfaces. Thus algorithms operating on these primitives tend to be slow in practice. A common (heuristic) optimization approximates the geometric primitives with their axis-aligned bounding boxes, runs a suitable modification of the algorithm on the boxes, and whenever a pair of boxes has an interesting interaction<sup>1</sup>, only then the exact answer is computed on the complicated geometric primitives contained in the boxes.

<sup>1</sup>Boxes represent volumes or point-sets. So, *intersection* means intersection of the point-set enclosed by the box and not only intersection of the boundary, of course.

We provide an efficient algorithm [ZE02] for finding all intersecting pairs for large numbers of iso-oriented boxes, i.e., typically these will be such bounding boxes of more complicated geometries. One immediate application of this algorithm is the detection of all intersections (and self-intersections) for polyhedral surfaces, i.e., applying the algorithm on a large set of triangles in space, we give an example program later in this chapter. Not so obvious applications are proximity queries and distance computations among such surfaces, see Section 53.10 for an example and [ZE02] for more details.

## 53.2 Definition

A  $d$ -dimensional iso-oriented box is defined as the Cartesian product of  $d$  intervals. We call the box *half-open* if the  $d$  intervals  $\{[lo_i, hi_i) \mid 0 \leq i < d\}$  are half-open intervals, and we call the box *closed* if the  $d$  intervals  $\{[lo_i, hi_i] \mid 0 \leq i < d\}$  are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed and half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the two possible values for the *topology* parameter:

- `CGAL::Box_intersection_d::HALF_OPEN` and
- `CGAL::Box_intersection_d::CLOSED`.

The number type of the interval boundaries must be one of the built-in types `int`, `unsigned int`, `double` or `float`.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. Note that boxes with equal *id*-number are not reported since they obviously intersect trivially.

The box intersection algorithm comes in two flavors: One algorithm works on a single sequence of boxes and computes all pairwise intersections, which is called the *complete* case, and used, for example, in the self-intersection test. The other algorithm works on two sequences of boxes and computes the pairwise intersections between boxes from the first sequence with boxes from the second sequence, which is called the *bipartite* case. For each pairwise intersection found a callback function is called with two arguments; the first argument is a box from the first sequence and the second argument a box from the second sequence. In the complete case, the second argument is a box from an internal copy of the first sequence.

## 53.3 Software Design

The box intersection algorithm is implemented as a family of generic functions; the functions for the complete case accept one iterator range, and the functions for the bipartite case accept two iterator ranges. The callback function for reporting the intersecting pairs is provided as a template parameter of the *BinaryFunction* concept. The two principle function calls utilizing all default arguments look as follows:

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator, class Callback >
void box_intersection_d( RandomAccessIterator begin, RandomAccessIterator end, Callback callback)
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void    box_intersection_d( RandomAccessIterator1 begin1,
                          RandomAccessIterator1 end1,
                          RandomAccessIterator2 begin2,
                          RandomAccessIterator2 end2,
                          Callback callback)
```

Additional parameters to the functions calls are a *cutoff* value to adjust performance trade-offs, and a *topology* parameter selecting between topologically closed boxes (the default) and topologically half-open boxes.

The algorithm reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value\_type* of the iterator ranges *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type; these choices represent both options from above.

In general, the algorithms treat the box type as opaque type and just assume that they are models of the *Assignable* concept, so that the algorithms can modify the input sequences and reorder the boxes. The access to the box dimension and box coordinates is mediated with a traits class of the *BoxIntersectionTraits\_d* concept. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox\_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type (see the previous paragraph for the value versus pointer nature of the box handle).

Two implementations of iso-oriented boxes are provided; *CGAL::Box\_intersection\_d::Box\_d* as a plain box, and *CGAL::Box\_intersection\_d::Box\_with\_handle\_d* as a box plus a handle that can be used to point to the full geometry that is approximated by the box. Both implementations have template parameters for the number type used for the interval bounds, for the fixed dimension of the box, and for a policy class [Ale01] selecting among several solutions for providing the *id*-number.

The function signatures for the bipartite case look as follows. The signatures for the complete case with the *box\_self\_intersection\_d* function look the same except for the single iterator range.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void    box_intersection_d( RandomAccessIterator1 begin1,
                          RandomAccessIterator1 end1,
                          RandomAccessIterator2 begin2,
                          RandomAccessIterator2 end2,
                          Callback callback,
                          std::ptrdiff_t cutoff = 10,
                          Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
                          Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback, class BoxTraits >
void    box_intersection_d( RandomAccessIterator1 begin1,
                          RandomAccessIterator1 end1,
                          RandomAccessIterator2 begin2,
                          RandomAccessIterator2 end2,
                          Callback callback,
                          BoxTraits box_traits,
                          std::ptrdiff_t cutoff = 10,
                          Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
                          Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)
```

## 53.4 Minimal Example for Intersecting Boxes

The box implementation provided with `CGAL::Box_intersection_d::Box_d<double,2>` has a dedicated constructor for the CGAL bounding box type `CGAL::Bbox_2` (similar for dimension 3). We use this in our minimal example to create easily nine two-dimensional *boxes* in a grid layout of  $3 \times 3$  boxes. Additionally we pick the center box and the box in the upper-right corner as our second box sequence *query*.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works, but it costs space that could potentially be avoided, see the example in the next section. We use the *id*-number in our callback function to report the result of the intersection algorithm. The result will be that the first *query* box intersects all nine *boxes* and the second *query* box intersects the four boxes in the upper-right quadrant. See Section 53.7 for the change of the *topology* parameter and its effect.

```
#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2 Bbox;

// 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), // middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)}; // upper
// 2 selected boxes as query; center and upper right
Box query[2] = { Bbox( 1,1,2,2), Bbox( 2,2,3,3)};

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() << std::endl;
}

int main() {
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2, callback);
    return 0;
}
```

**File:** examples/Box\_intersection\_d/minimal.cpp

## 53.5 Example for Finding Intersecting 3D Triangles

The conventional application of the axis-aligned box intersection algorithm will start from complex geometry, here 3D triangles, approximate them with their bounding box, compute the intersecting pairs of boxes, and check only for those if the original triangles intersect as well.

We start in the *main* function and create ten triangles with endpoints chosen randomly in a cube  $[-1, +1]^3$ . We store the triangles in a vector called *triangles*.

Next we create a vector for the bounding boxes of the triangles called *boxes*. For the boxes we choose the type `Box_with_handle_d<double,3,Iterator>` that works nicely together with the CGAL bounding boxes of type `CGAL::Bbox_3`. In addition, each box stores the iterator to the corresponding triangle.

The default policy of this box type uses for the *id*-number the address of the value of the iterator, i.e., the address of the triangle. This is a good choice that works correctly iff the boxes have unique iterators, i.e., there is a one-

to-one mapping between boxes and approximated geometry, which is the case here. It saves us the extra space that was needed for the explicit *id*-number in the previous example.

We run the self intersection algorithm with the *report\_inters* function as callback. This callback reports the intersecting boxes. It uses the *handle* and the global *triangles* vector to calculate the triangle numbers. Then it checks the triangles themselves for intersection and reports if not only the boxes but also the triangles intersect. We take some precautions before the intersection test in order to avoid problems, although unlikely, with degenerate triangles that we might have created with the random process.

This example can be easily extended to test polyhedral surfaces of the *Polyhedron\_3* class for (self-) intersections. The main difference are the numerous cases of incidences between triangles in the polyhedral surface that should not be reported as intersections, see the examples/Polyhedron/polyhedron\_self\_intersection.cpp example program in the CGAL distribution.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Bbox_3.h>
#include <CGAL/box_intersection_d.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/algorithm.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel    Kernel;
typedef Kernel::Point_3                                         Point_3;
typedef Kernel::Triangle_3                                       Triangle_3;
typedef std::vector<Triangle_3>                                  Triangles;
typedef Triangles::iterator                                       Iterator;
typedef CGAL::Box_intersection_d::Box_with_handle_d<double,3,Iterator> Box;

Triangles triangles; // global vector of all triangles

// callback function that reports all truly intersecting triangles
void report_inters( const Box& a, const Box& b) {
    std::cout << "Box " << (a.handle() - triangles.begin()) << " and "
               << (b.handle() - triangles.begin()) << " intersect";
    if ( ! a.handle()->is_degenerate() && ! b.handle()->is_degenerate()
        && CGAL::do_intersect( *(a.handle()), *(b.handle()) ) ) {
        std::cout << ", and the triangles intersect also";
    }
    std::cout << ' ' << std::endl;
}

int main() {
    // Create 10 random triangles
    typedef CGAL::Random_points_in_cube_3<Point_3>              Pts;
    typedef CGAL::Creator_uniform_3< Point_3, Triangle_3>        Creator;
    typedef CGAL::Join_input_iterator_3<Pts,Pts,Pts,Creator>    Triangle_gen;
    Pts    points( 1); // in centered cube [-1,1]^3
    Triangle_gen triangle_gen( points, points, points);
    CGAL::copy_n( triangle_gen, 10, std::back_inserter(triangles));
```

```

// Create the corresponding vector of bounding boxes
std::vector<Box> boxes;
for ( Iterator i = triangles.begin(); i != triangles.end(); ++i)
    boxes.push_back( Box( i->bbox(), i));

// Run the self intersection algorithm with all defaults
CGAL::box_self_intersection_d( boxes.begin(), boxes.end(), report_inters);
return 0;
}

```

**File:** examples/Box\_intersection\_d/triangle\_self\_intersect.cpp

## 53.6 Example for Using Pointers to Boxes

We modify the previous example, finding intersecting 3D triangles, and add an additional vector *ptr* that stores pointers to the bounding boxes, so that the intersection algorithm will work on a sequence of pointers and not on a sequence of boxes. The change just affects the preparation of the additional vector and the call of the box intersection function. The box intersection function (actually its default traits class) detects automatically that the value type of the iterators is a pointer type and not a class type.

```

// Create the corresponding vector of pointers to bounding boxes
std::vector<Box *> ptr;
for ( std::vector<Box>::iterator i = boxes.begin(); i != boxes.end(); ++i)
    ptr.push_back( &*i);

// Run the self intersection algorithm with all defaults on the
// indirect pointers to bounding boxes. Avoids copying the boxes.
CGAL::box_self_intersection_d( ptr.begin(), ptr.end(), report_inters);

```

In addition, the callback function *report\_inters* needs to be changed to work with pointers to boxes. The full example program looks as follows:

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Bbox_3.h>
#include <CGAL/box_intersection_d.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/algorithm.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel    Kernel;
typedef Kernel::Point_3                                         Point_3;
typedef Kernel::Triangle_3                                       Triangle_3;
typedef std::vector<Triangle_3>                                  Triangles;
typedef Triangles::iterator                                       Iterator;
typedef CGAL::Box_intersection_d::Box_with_handle_d<double,3,Iterator> Box;

```

```

Triangles triangles; // global vector of all triangles

// callback function that reports all truly intersecting triangles
void report_inters( const Box* a, const Box* b) {
    std::cout << "Box " << (a->handle() - triangles.begin()) << " and "
        << (b->handle() - triangles.begin()) << " intersect";
    if ( ! a->handle()->is_degenerate() && ! b->handle()->is_degenerate()
        && CGAL::do_intersect( *(a->handle()), *(b->handle())) {
        std::cout << ", and the triangles intersect also";
    }
    std::cout << ' ' << std::endl;
}

int main() {
    // Create 10 random triangles
    typedef CGAL::Random_points_in_cube_3<Point_3>          Pts;
    typedef CGAL::Creator_uniform_3< Point_3, Triangle_3>    Creator;
    typedef CGAL::Join_input_iterator_3<Pts,Pts,Pts,Creator> Triangle_gen;
    Pts    points( 1); // in centered cube [-1,1]^3
    Triangle_gen triangle_gen( points, points, points);
    CGAL::copy_n( triangle_gen, 10, std::back_inserter(triangles));

    // Create the corresponding vector of bounding boxes
    std::vector<Box> boxes;
    for ( Iterator i = triangles.begin(); i != triangles.end(); ++i)
        boxes.push_back( Box( i->bbox(), i));

    // Create the corresponding vector of pointers to bounding boxes
    std::vector<Box *> ptr;
    for ( std::vector<Box>::iterator i = boxes.begin(); i != boxes.end(); ++i)
        ptr.push_back( &*i);

    // Run the self intersection algorithm with all defaults on the
    // indirect pointers to bounding boxes. Avoids copying the boxes.
    CGAL::box_self_intersection_d( ptr.begin(), ptr.end(), report_inters);
    return 0;
}

```

**File:** examples/Box\_intersection\_d/triangle\_self\_intersect\_pointers.cpp

A note on performance: The algorithm sorts and partitions the input sequences. It is clearly costly to copy a large box compared to a simple pointer. However, the algorithm benefits from memory locality in the later stages when it copies the boxes, while the pointers would refer to boxes that become wildly scattered in memory. These two effects, copying costs and memory locality, counteract each other. For small box sizes, i.e., small dimension, memory locality wins and one should work with boxes, while for larger box sizes one should work with pointers. The exact threshold depends on the memory hierarchy (caching) of the hardware platform and the size of the boxes, most notably the type used to represent the box coordinates. A concrete example; on a laptop with an Intel Mobile Pentium4 running at 1.80GHz with 512KB cache and 254MB main memory under Linux this version with pointers was 20% faster than the version above that copies the boxes for 10000 boxes, but the picture reversed for 100000 boxes, where the version above that copies the boxes becomes 300% faster.

Note that switching to the built-in type *float* is supported by the box intersection algorithm, but the interfacing with the CGAL bounding box *CGAL::Bbox\_3* would not be that easy. In particular, just converting from the

*double* to the *float* representation incurs rounding that needs to be controlled properly, otherwise the box might shrink and one might miss intersections.

## 53.7 Example Using the *topology* and the *cutoff* Parameters

Boxes can be interpreted by the box intersection algorithm as closed or as half-open boxes, see also Section 53.2. Closed boxes support zero-width boxes and they can intersect at their boundaries, while half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The choice between closed or half-open boxes is selected with the *topology* parameter and its two values:

- `CGAL::Box_intersection_d::HALF_OPEN` and
- `CGAL::Box_intersection_d::CLOSED`.

The example program uses a two-dimensional box with *int* coordinates and *id*-numbers that are by default explicitly stored. We create the same boxes as in the minimal example in Section 53.4. We create a  $3 \times 3$  grid of *boxes*, and two boxes for the *query* sequence, namely the box at the center and the box from the upper-right corner of the grid.

We write a more involved callback function object *Report* that stores an output iterator and writes the *id*-number of the box in the first argument to the output iterator. We also provide a small helper function *report* that simplifies the use of the function object.

We call the box intersection algorithm twice; once for the default *topology*, which is the closed box topology, and once for the half-open box topology. We sort the resulting output for better readability and verify its correctness with the *check1* and *check2* data. For the closed box topology, the center box in *query* intersects all *boxes*, and the upper-right box in *query* intersects the four boxes of the upper-right quadrant in *boxes*. Almost all intersections are with the box boundaries, thus, for the half-open topology only one intersection remains per *query* box, namely its corresponding box in *boxes*. So, the output of the algorithm will be:

```
0 1 2 3 4 4 5 5 6 7 7 8 8
4 8
```

For the second box intersection function call we have to specify the *cutoff* parameter explicitly. See the Section 53.8 below for a detailed discussion.

```
#include <CGAL/box_intersection_d.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <cassert>

typedef CGAL::Box_intersection_d::Box_d<int,2> Box;

// coordinates for 9 boxes of a grid
int p[9*4] = { 0,0,1,1, 1,0,2,1, 2,0,3,1, // lower
               0,1,1,2, 1,1,2,2, 2,1,3,2, // middle
               0,2,1,3, 1,2,2,3, 2,2,3,3}; // upper

// 9 boxes
```

```

Box boxes[9] = { Box( p,    p+ 2),  Box( p+ 4, p+ 6),  Box( p+ 8, p+10),
                Box( p+12, p+14),  Box( p+16, p+18),  Box( p+20, p+22),
                Box( p+24, p+26),  Box( p+28, p+30),  Box( p+32, p+34)};
// 2 selected boxes as query; center and upper right
Box query[2] = { Box( p+16, p+18),  Box( p+32, p+34)};

// callback function object writing results to an output iterator
template <class OutputIterator>
struct Report {
    OutputIterator it;
    Report( OutputIterator i) : it(i) {} // store iterator in object
    // We write the id-number of box a to the output iterator assuming
    // that box b (the query box) is not interesting in the result.
    void operator()( const Box& a, const Box&) { *it++ = a.id(); }
};

template <class Iter> // helper function to create the function object
Report<Iter> report( Iter it) { return Report<Iter>(it); }

int main() {
    // run the intersection algorithm and store results in a vector
    std::vector<std::size_t> result;
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2,
                             report( std::back_inserter( result)));
    // sort, check, and show result
    std::sort( result.begin(), result.end());
    std::size_t check1[13] = {0,1,2,3,4,4,5,5,6,7,7,8,8};
    assert(result.size() == 13 && std::equal(check1,check1+13,result.begin()));
    std::copy( result.begin(), result.end(),
               std::ostream_iterator<std::size_t>( std::cout, " "));
    std::cout << std::endl;

    // run it again but for different cutoff value and half-open boxes
    result.clear();
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2,
                             report( std::back_inserter( result)),
                             std::ptrdiff_t(1),
                             CGAL::Box_intersection_d::HALF_OPEN);
    // sort, check, and show result
    std::sort( result.begin(), result.end());
    std::size_t check2[2] = {4,8};
    assert(result.size() == 2 && std::equal(check2, check2+2, result.begin()));
    std::copy( result.begin(), result.end(),
               std::ostream_iterator<std::size_t>( std::cout, " "));
    std::cout << std::endl;
    return 0;
}

```

**File:** examples/Box\_intersection\_d/box\_grid.cpp

## 53.8 Runtime Performance

The implemented algorithm is described in [ZE02] as version two. Its performance depends on a *cutoff* parameter. When the size of both iterator ranges drops below the *cutoff* parameter the function switches from the streamed segment-tree algorithm to the two-way-scan algorithm, see [ZE02] for the details.

The streamed segment-tree algorithm needs  $O(n \log^d(n) + k)$  worst-case running time and  $O(n)$  space, where  $n$  is the number of boxes in both input sequences,  $d$  the (constant) dimension of the boxes, and  $k$  the output complexity, i.e., the number of pairwise intersections of the boxes. The two-way-scan algorithm needs  $O(n \log(n) + l)$  worst-case running time and  $O(n)$  space, where  $l$  is the number of pairwise overlapping intervals in one dimensions (the dimension where the algorithm is used instead of the segment tree). Note that  $l$  is not necessarily related to  $k$  and using the two-way-scan algorithm is a heuristic.

Unfortunately, we have no general method to automatically determine an optimal cutoff parameter, since it depends on the used hardware, the runtime ratio between callback runtime and segment-tree runtime, and of course the number of boxes to be checked and their distribution. In cases where the callback runtime is dominant, it may be best to make the threshold parameter small. Otherwise a *cutoff* =  $\sqrt{n}$  can lead to acceptable results. For well distributed boxes the original paper [ZE02] gives optimal cutoffs in the thousands. Anyway, for optimal runtime some experiments to compare different cutoff parameters are recommended.

To demonstrate that box intersection can be done quite fast, different box sequences are intersected in the range between 4 and 800000 boxes total. We use three-dimensional default boxes of closed topology with *float* coordinates and without additional data fields. The algorithm works directly on the boxes, not on pointer to boxes. Each box intersection is reported to an empty dummy callback.

For each box set, a near-optimal cutoff parameter is determined using an adaptive approximation. The runtime required for streaming is compared against usual scanning. Results on a Xeon 2.4GHz with 4GB main memory can be seen in Figure 53.1. For a small number of boxes, pure scanning is still faster than streaming with optimal cutoff, which would just delegate the box sets to the scanning algorithm. As there are more and more boxes, the overhead becomes less important.

Figure 53.1: Runtime comparison between the scanning and the streaming algorithm.

## 53.9 Example Using a Custom Box Implementation

The example in the previous Section [53.7](#) uses an array to provide the coordinates and then creates another array for the boxes. In the following example we write our own box class *Box* that we can initialize directly with the four coordinates and create the array of boxes directly. We also omit the explicitly stored *id*-number and use the address of the box itself as *id*-number. This works only if the boxes do not change their position, i.e., we work with pointers to the boxes in the intersection algorithm.

We follow with our own box class *Box* the *BoxIntersectionBox\_d* concept, which allows us to reuse the default traits implementation, i.e., we can use the same default function call to compute all intersections. See the example in the next section for a self-written traits class. So, in principle, the remainder of the example stays the same and we omit the part from the previous example for brevity that illustrates the half-open box topology.

The requirements for the box implementation are best studied on page [2981](#) in the Reference Manual. In a nutshell, we have to define the type *NT* for the box coordinates and the type *ID* for the *id*-number. Member functions give access to the coordinates and the *id*-number. A static member function returns the dimension.

```
#include <CGAL/box_intersection_d.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <cassert>

struct Box {
    typedef int NT;
    typedef std::ptrdiff_t ID;
    int x[2], y[2];
    Box( int x0, int x1, int y0, int y1) { x[0]=x0; x[1]=x1; y[0]=y0; y[1]=y1; }
    static int dimension() { return 2; }
    int min_coord(int dim) const { return x[dim]; }
    int max_coord(int dim) const { return y[dim]; }
    // id-function using address of current box,
    // requires to work with pointers to boxes later
    std::ptrdiff_t id() const { return (std::ptrdiff_t)(this); }
};

// 9 boxes of a grid
Box boxes[9] = { Box( 0,0,1,1), Box( 1,0,2,1), Box( 2,0,3,1), // low
                 Box( 0,1,1,2), Box( 1,1,2,2), Box( 2,1,3,2), // middle
                 Box( 0,2,1,3), Box( 1,2,2,3), Box( 2,2,3,3)}; // upper

// 2 selected boxes as query; center and upper right
Box query[2] = { Box( 1,1,2,2), Box( 2,2,3,3)};

// With the special id-function we need to work on box pointers
Box* b_ptr[9] = { boxes, boxes+1, boxes+2, boxes+3, boxes+4, boxes+5,
                 boxes+6, boxes+7, boxes+8};
Box* q_ptr[2] = { query, query+1};

// callback function object writing results to an output iterator
template <class OutputIterator>
struct Report {
    OutputIterator it;
    Report( OutputIterator i) : it(i) {} // store iterator in object
```

```

// We write the position with respect to 'boxes' to the output iterator
// assuming that box b (the query box) is not interesting in the result.
void operator()( const Box* a, const Box*) {
    *it++ = ( reinterpret_cast<Box*>(a->id()) - boxes);
}
};
template <class Iter> // helper function to create the function object
Report<Iter> report( Iter it) { return Report<Iter>(it); }

int main() {
    // run the intersection algorithm and store results in a vector
    std::vector<std::size_t> result;
    CGAL::box_intersection_d( b_ptr, b_ptr+9, q_ptr, q_ptr+2,
                             report( std::back_inserter( result)),
                             std::ptrdiff_t(0));
    // sort and check result
    std::sort( result.begin(), result.end());
    std::size_t chk[13] = {0,1,2,3,4,4,5,5,6,7,7,8,8};
    assert( result.size()==13 && std::equal(chk,chk+13,result.begin()));
    return 0;
}

```

**File:** examples/Box\_intersection\_d/custom\_box\_grid.cpp

## 53.10 Example for Point Proximity Search with a Custom Traits Class

Given a set of 3D points, we want to find all pairs of points that are less than a certain distance apart. We use the box intersection algorithm to find good candidates, namely those that are less than this specified distance apart in the  $L_\infty$  norm, which is a good approximation of the Euclidean norm.

We use an unusual representation for the box, namely pointers to the 3D points themselves. We implement a special box traits class that interprets the point as a box of the dimensions  $[-eps, +eps]^3$  centered at this point. The value for  $eps$  is half the specified distance from above, i.e., points are reported if their distance is smaller than  $2*eps$ .

The requirements for the box traits class are best studied on page 2982 in the Reference Manual. In a nutshell, we have to define the type *NT* for the box coordinates, the type *ID* for the *id*-number, and the type *Box\_parameter* similar to the box handle, here *Point\_3\** since we work with the pointers. All member functions in the traits class are static. Two functions give access to the max and min coordinates that we compute from the point coordinates plus or minus the  $eps$  value, respectively. For the *id*-number function the address of the point itself is sufficient, since the points stay stable. Another function returns the dimension.

The *report* callback function computes than the Euclidean distance and prints a message for points that are close enough.

Note that we need to reserve sufficient space in the *points* vector to avoid reallocations while we create the *points* vector and the *boxes* vector in parallel, since otherwise the *points* vector might reallocate and invalidate all pointers stored in the *boxes* so far.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/box_intersection_d.h>

```

```

#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <cmath>

typedef CGAL::Simple_cartesian<float>          Kernel;
typedef Kernel::Point_3                        Point_3;
typedef CGAL::Random_points_on_sphere_3<Point_3> Points_on_sphere;

std::vector<Point_3> points;
std::vector<Point_3*> boxes;    // boxes are just pointers to points
const float          eps = 0.1f; // finds point pairs of distance < 2*eps

// Boxes are just pointers to 3d points. The traits class adds the
// +- eps size to each interval around the point, effectively building
// on the fly a box of size 2*eps centered at the point.
struct Traits {
    typedef float          NT;
    typedef Point_3*       Box_parameter;
    typedef std::ptrdiff_t ID;

    static int    dimension() { return 3; }
    static float coord( Box_parameter b, int d) {
        return (d == 0) ? b->x() : ((d == 1) ? b->y() : b->z());
    }
    static float min_coord( Box_parameter b, int d) { return coord(b,d)-eps;}
    static float max_coord( Box_parameter b, int d) { return coord(b,d)+eps;}
    // id-function using address of current box,
    // requires to work with pointers to boxes later
    static std::ptrdiff_t id(Box_parameter b) { return (std::ptrdiff_t)(b); }
};

// callback function reports pairs in close proximity
void report( const Point_3* a, const Point_3* b) {
    float dist = std::sqrt( CGAL::squared_distance( *a, *b));
    if ( dist < 2*eps) {
        std::cout << "Point " << (a - &(points.front())) << " and Point "
                   << (b - &(points.front())) << " have distance " << dist
                   << "." << std::endl;
    }
}

int main() {
    // create some random points on the sphere of radius 1.0
    Points_on_sphere generator( 1.0);
    points.reserve( 50);
    for ( int i = 0; i != 50; ++i) {
        points.push_back( *generator++);
        boxes.push_back( & points.back());
    }

    // run the intersection algorithm and report proximity pairs

```

```
CGAL::box_self_intersection_d( boxes.begin(), boxes.end(),  
                               report, Traits());  
return 0;  
}
```

## 53.11 Design and Implementation History

Lutz Kettner and Andreas Meyer implemented the algorithms starting from the publication [ZE02]. We had access to the original C implementation of Afra Zomorodian, which helped clarifying some questions, and we are grateful to the help of Afra Zomorodian in answering our questions during his visit. We thank Steve Robbins for an excellent review for this package. Steve Robbins provided an independent and earlier implementation of this algorithm, however, we learned too late about this implementation.

# Intersecting Sequences of dD Iso-oriented Boxes

## Reference Manual

*Lutz Kettner, Andreas Meyer, and Afra Zomorodian*

We provide an efficient algorithm [ZE02] for finding all intersecting<sup>2</sup> pairs for large numbers of iso-oriented boxes, i.e., typically these will be bounding boxes of more complicated geometries. For comparison and as a base case for other methods, we also offer the simple all-pairs test as a generic function.

## CGAL::box\_intersection\_d

### Definition

The function `box_intersection_d` computes the pairwise intersecting boxes between two sequences of iso-oriented boxes in arbitrary dimension. The sequences of boxes are given with two random-access iterator ranges and will be reordered in the course of the algorithm. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the first sequence, the second argument a box from the second sequence. The performance of the algorithm can be tuned with a *cutoff* parameter, see the implementation section below for more details.

The algorithm reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value\_type* of the iterators *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type.

A  $d$ -dimensional iso-oriented box is defined as the Cartesian product of  $d$  intervals. We call the box *half-open* if the  $d$  intervals  $\{[lo_i, hi_i) \mid 0 \leq i < d\}$  are half-open intervals, and we call the box *closed* if the  $d$  intervals  $\{[lo_i, hi_i] \mid 0 \leq i < d\}$  are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, `CGAL::Box_intersection_d::HALF_OPEN` and `CGAL::Box_intersection_d::CLOSED`.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. Boxes with equal *id*-number are not reported since they obviously intersect trivially.

The algorithm uses a traits class of the `BoxIntersectionTraits_d` concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the `BoxIntersectionBox_d` concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

An important special application of this algorithm is the test for self-intersections where the second box sequence is an identical copy of the first sequence including the preserved *id*-number. Note that this implies that the address of the box is not sufficient for the *id*-number if boxes are copied by value. To ease the use of this special case we offer a simplified version of this function with one iterator range only, which then creates internally the second copy of the boxes, under the name `CGAL::box_self_intersection_d`.

In the general case, we distinguish between the bipartite case (the boxes are from different sequences) and the complete case (the boxes are from the same sequence, i.e., the self intersection case). The default is the bipartite case, since the complete case is typically handled with the simplified function call mentioned above. However, the general function call offers the *setting* parameter with the values `CGAL::Box_intersection_d::COMPLETE` and `CGAL::Box_intersection_d::BIPARTITE`.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void box_intersection_d( RandomAccessIterator1 begin1,
```

```

RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

```

Invocation of box intersection with default box traits *CGAL::Box\_intersection\_d::Box\_traits\_d*<*Box\_handle*>, where *Box\_handle* corresponds to the iterator value type of *RandomAccessIterator1*.

```

template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback, class BoxTraits >
void box_intersection_d( RandomAccessIterator1 begin1,
                        RandomAccessIterator1 end1,
                        RandomAccessIterator2 begin2,
                        RandomAccessIterator2 end2,
                        Callback callback,
                        BoxTraits box_traits,
                        std::ptrdiff_t cutoff = 10,
                        Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
                        Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

```

Invocation with custom box traits.

## Requirements

- *RandomAccessIterator1*, and ...2, must be mutable random-access iterators and both value types must be the same. We call this value type *Box\_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box\_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box\_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box\_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox\_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits\_d* concept.

## Implementation

The implemented algorithm is described in [ZE02] as version two. Its performance depends on a *cutoff* parameter. When the size of both iterator ranges drops below the *cutoff* parameter the function switches from the streamed segment-tree algorithm to the two-way-scan algorithm, see [ZE02] for the details.

The streamed segment-tree algorithm needs  $O(n \log^d(n) + k)$  worst-case running time and  $O(n)$  space, where  $n$  is the number of boxes in both input sequences,  $d$  the (constant) dimension of the boxes, and  $k$  the output complexity, i.e., the number of pairwise intersections of the boxes. The two-way-scan algorithm needs  $O(n \log(n) + l)$  worst-case running time and  $O(n)$  space, where  $l$  is the number of pairwise overlapping intervals in one dimensions (the dimension where the algorithm is used instead of the segment tree). Note that  $l$  is not necessarily related to  $k$  and using the two-way-scan algorithm is a heuristic.

Unfortunately, we have no general method to automatically determine an optimal cutoff parameter, since it depends on the used hardware, the runtime ratio between callback runtime and segment-tree runtime, and of course the number of boxes to be checked and their distribution. In cases where the callback runtime is dominant, it may be best to make the threshold parameter small. Otherwise a *cutoff* =  $\sqrt{n}$  can lead to acceptable results. For well distributed boxes the original paper [ZE02] gives optimal cutoffs in the thousands. Anyway, for optimal runtime some experiments to compare different cutoff parameters are recommended. See also Section 53.8.

## Example

The box implementation provided with `CGAL::Box_intersection_d::Box_d<double,2>` has a special constructor for the CGAL bounding box type `CGAL::Bbox_2` (and similar for dimension 3). We use this in the example to create  $3 \times 3$  boxes in a grid layout. Additionally we pick the center box and the box in the upper-right corner as our second box sequence *query*.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works. We use the *id*-number in our callback function to report the result of the intersection algorithm call. The result will be that the first *query* box intersects all nine boxes and the second *query* box intersects the four boxes in the upper-right quadrant.

```
#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2 Bbox;
// 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), // middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)}; // upper
// 2 selected boxes as query; center and upper right
Box query[2] = { Bbox( 1,1,2,2), Bbox( 2,2,3,3)};

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() << std::endl;
}

int main() {
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2, callback);
    return 0;
}
```

## CGAL::box\_intersection\_all\_pairs\_d

### Definition

The function `box_intersection_all_pairs_d` computes the pairwise intersecting boxes between two sequences of iso-oriented boxes in arbitrary dimension. It does so by comparing all possible pairs of boxes and is thus inferior to the fast `CGAL::box_intersection_d` algorithm on page 2971.

The sequences of boxes are given with two forward iterator ranges. The sequences are not modified. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the first sequence, the second argument a box from the second sequence.

The algorithm is interface compatible with the `CGAL::box_intersection_d` function. Similarly, we call the *value\_type* of the iterators the *box handle*, which is either our box type or a pointer type to our box type.

A  $d$ -dimensional iso-oriented box is defined as the Cartesian product of  $d$  intervals. We call the box *half-open* if the  $d$  intervals  $\{[lo_i, hi_i) \mid 0 \leq i < d\}$  are half-open intervals, and we call the box *closed* if the  $d$  intervals  $\{[lo_i, hi_i] \mid 0 \leq i < d\}$  are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, `CGAL::Box_intersection_d::HALF_OPEN` and `CGAL::Box_intersection_d::CLOSED`.

In addition, a box has an unique *id*-number. Boxes with equal *id*-number are not reported since they obviously intersect trivially.

The algorithm uses a traits class of the `BoxIntersectionTraits_d` concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the `BoxIntersectionBox_d` concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

An important special application of this algorithm is the test for self-intersections where the second box sequence is an identical copy of the first sequence including the preserved *id*-number. We offer a specialized implementation `CGAL::box_self_intersection_all_pairs` for this application.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class ForwardIterator1, class ForwardIterator2, class Callback >
void    box_intersection_all_pairs_d( ForwardIterator1 begin1,
                                     ForwardIterator1 end1,
                                     ForwardIterator2 begin2,
                                     ForwardIterator2 end2,
                                     Callback callback,
                                     Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits `CGAL::Box_intersection_d::Box_traits_d<Box_handle>`, where *Box\_handle* corresponds to the iterator value type of *ForwardIterator1*.

```
template< class ForwardIterator1, class ForwardIterator2, class Callback, class BoxTraits >
void    box_intersection_all_pairs_d( ForwardIterator1 begin1,
```

```

ForwardIterator1 end1,
ForwardIterator2 begin2,
ForwardIterator2 end2,
Callback callback,
BoxTraits box_traits,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)

```

Invocation with custom box traits.

## Requirements

- *ForwardIterator1*, and ...2, must be forward iterators and both value types must be the same. We call this value type *Box\_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box\_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box\_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box\_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox\_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits\_d* concept.

## Implementation

The algorithm is trivially testing all pairs and runs therefore in time  $O(nm)$  where  $n$  is the size of the first sequence and  $m$  is the size of the second sequence.

## CGAL::box\_self\_intersection\_d

### Definition

The function *box\_self\_intersection\_d* computes the pairwise intersecting boxes in a sequence of iso-oriented boxes in arbitrary dimension. The sequence of boxes is given with as a random-access iterator range and will be reordered in the course of the algorithm. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the sequence, the second argument is a copy of a box from the sequence. The performance of the algorithm can be tuned with a *cutoff* parameter, see the implementation section of the *CGAL::box\_intersection\_d* function on page 2971.

The algorithm creates a second copy of the boxes and reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value\_type* of the iterators *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type.

A  $d$ -dimensional iso-oriented box is defined as the Cartesian product of  $d$  intervals. We call the box *half-open* if the  $d$  intervals  $\{[lo_i, hi_i) \mid 0 \leq i < d\}$  are half-open intervals, and we call the box *closed* if the  $d$  intervals  $\{[lo_i, hi_i] \mid 0 \leq i < d\}$  are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, *CGAL::Box\_intersection\_d::HALF\_OPEN* and *CGAL::Box\_intersection\_d::CLOSED*.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. This self-intersection function creates internally a second copy of the box sequence. The copying has to preserve the *id*-number of boxes. Note that this implies that the address of the box is not sufficient for the *id*-number if boxes are copied by value. Boxes of equal *id*-number are not reported as intersecting pairs since they are always intersecting trivially.

The algorithm uses a traits class of the *BoxIntersectionTraits\_d* concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox\_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator, class Callback >
void    box_self_intersection_d( RandomAccessIterator begin,
                               RandomAccessIterator end,
                               Callback callback,
                               std::ptrdiff_t cutoff = 10,
                               Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits *CGAL::Box\_intersection\_d::Box\_traits\_d<Box\_handle>*, where *Box\_handle* corresponds to the iterator value type of *RandomAccessIterator*.

```
template< class RandomAccessIterator, class Callback, class BoxTraits >
void    box_self_intersection_d( RandomAccessIterator begin,
```

```

RandomAccessIterator end,
Callback callback,
BoxTraits box_traits,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)

```

Invocation with custom box traits.

## Requirements

- *RandomAccessIterator* must be a mutable random-access iterator. We call its value type *Box\_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box\_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box\_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box\_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox\_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits\_d* concept.

## Implementation

See the implementation section of the *CGAL::box\_intersection\_d* function on page [2971](#).

## Example

The box implementation provided with *CGAL::Box\_intersection\_d::Box\_d<double,2>* has a special constructor for the CGAL bounding box type *CGAL::Bbox\_2* (and similar for dimension 3). We use this in the example to create  $3 \times 3$  boxes in a grid layout.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works. We use the *id*-number in our callback function to report the result of the intersection algorithm call. The result will be 20 pairwise intersections, but the order in which they are reported is non-intuitive.

```

#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2 Bbox;

// 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), // middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)}; // upper

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() << std::endl;
}

int main() {
    CGAL::box_self_intersection_d( boxes, boxes+9, callback);
    return 0;
}

```

## CGAL::box\_self\_intersection\_all\_pairs\_d

### Definition

The function `box_self_intersection_all_pairs_d` computes the pairwise intersecting boxes in a sequence of iso-oriented boxes in arbitrary dimension. It does so by comparing all possible pairs of boxes and is thus inferior to the fast `CGAL::box_self_intersection_d` algorithm on page 2976.

The sequence of boxes is given with a forward iterator range. The sequences are not modified. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument.

The algorithm is interface compatible with the `CGAL::box_self_intersection_d` function. Similarly, we call the *value\_type* of the iterators the *box handle*, which is either our box type or a pointer type to our box type.

A  $d$ -dimensional iso-oriented box is defined as the Cartesian product of  $d$  intervals. We call the box *half-open* if the  $d$  intervals  $\{[lo_i, hi_i) \mid 0 \leq i < d\}$  are half-open intervals, and we call the box *closed* if the  $d$  intervals  $\{[lo_i, hi_i] \mid 0 \leq i < d\}$  are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, `CGAL::Box_intersection_d::HALF_OPEN` and `CGAL::Box_intersection_d::CLOSED`.

The algorithm uses a traits class of the `BoxIntersectionTraits_d` concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the `BoxIntersectionBox_d` concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class ForwardIterator, class Callback >
void    box_self_intersection_all_pairs_d(
        ForwardIterator begin,
        ForwardIterator end,
        Callback callback,
        Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits `CGAL::Box_intersection_d::Box_traits_d<Box_handle>`, where *Box\_handle* corresponds to the iterator value type of *ForwardIterator*.

```
template< class ForwardIterator, class Callback, class BoxTraits >
void    box_self_intersection_all_pairs_d(
        ForwardIterator begin,
        ForwardIterator end,
        Callback callback,
        BoxTraits box_traits,
        Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation with custom box traits.

### Requirements

- *ForwardIterator* must be a forward iterator. We call its value type *Box\_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box\_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box\_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box\_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox\_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits\_d* concept.

## Implementation

The algorithm is trivially testing all pairs and runs therefore in time  $O(n^2)$  where  $n$  is the size of the input sequence. This algorithm does not use the id-number of the boxes.

## BoxIntersectionBox\_d

### Definition

The `BoxIntersectionBox_d` concept is used in the context of the intersection algorithms for sequences of iso-oriented boxes. These algorithms come with a default traits class that assumes that the boxes are a model of this `BoxIntersectionBox_d` concept. This concept defines the access functions to the dimension, the *id*-number, and the boundaries of the box.

### Refines

*Assignable.*

### Has Models

`CGAL::Box_intersection_d::Box_d<NT,int D,IdPolicy>` ..... page 2984  
`CGAL::Box_intersection_d::Box_with_handle_d<NT, int D, Handle, IdPolicy>` ..... page 2988

### Types

`BoxIntersectionBox_d::NT`                      number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

`BoxIntersectionBox_d::ID`                      type for the box *id*-number, must be a model of the *LessThanComparable* concept.

### Access Functions

<i>int</i>	<code>BoxIntersectionBox_d::dimension()</code>	returns the dimension of the box.
<i>ID</i>	<code>box.id()</code>	returns the unique <i>id</i> -number for the <i>box</i> .
<i>NT</i>	<code>box.min_coord( int d)</code>	returns the lower boundary in dimension <i>d</i> , $0 \leq d < \text{dimension}()$ .
<i>NT</i>	<code>box.max_coord( int d)</code>	returns the upper boundary in dimension <i>d</i> , $0 \leq d < \text{dimension}()$ .

## BoxIntersectionTraits\_d

### Definition

The `BoxIntersectionTraits_d` concept is used for the intersection algorithms for sequences of iso-oriented boxes. This concept defines the access functions to the dimension, the *id*-number, and the boundaries of the boxes manipulated in these algorithms.

### Refines

*Assignable*.

### Has Models

`CGAL::Box_intersection_d::Box_traits_d<BoxHandle> .....` page [2987](#)

### Types

`BoxIntersectionTraits_d::Box_parameter`

type used for passing box parameters in the functions below. Since we support in our algorithms passing the boxes by value as well as passing them as pointers, this type can be either *const B&*, *B\**, or *const B\** respectively, where *B* is the actual box type. The difference to the box handle type lies in the first case where the box handle would be *B* where this type is *const B&*.

`BoxIntersectionTraits_d::NT` number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

`BoxIntersectionTraits_d::ID` type for the *id*-number, model of the *LessThanComparable* concept.

### Access Functions

*int*    `BoxIntersectionTraits_d::dimension()`                      returns the dimension of the box.

*ID*    `BoxIntersectionTraits_d::id( Box_parameter box)`           returns the unique *id*-number for the *box*.

*NT*    `BoxIntersectionTraits_d::min_coord( Box_parameter box, int d)`  
          returns the lower boundary of the *box* in dimension *d*,  $0 \leq d < \text{dimension}()$ .

*NT*    `BoxIntersectionTraits_d::max_coord( Box_parameter box, int d)`  
          returns the upper boundary of the *box* in dimension *d*,  $0 \leq d < \text{dimension}()$ .

## CGAL::Box\_intersection\_d::Box\_d<NT,int D,IdPolicy>

### Definition

*Box\_d*<*NT*,*int D*,*IdPolicy*> is a generic iso-oriented bounding box in dimension *D*. It provides in each dimension an interval with lower and upper endpoints represented with the number type *NT*. This class is designed to work smoothly with the algorithms for intersecting sequences of iso-oriented boxes. For degeneracy handling, the boxes need to provide a unique *id*-number. The policy parameter *IdPolicy* offers several choices. The template parameters have to comply with the following requirements:

- *NT*: number type for the box boundaries, needs to be a model of the *Assignable* and the *LessThanComparable* concept.
- *int D*: the dimension of the box.
- *IdPolicy*: specifies how the *id*-number will be provided. Can be one of the following types, where *ID\_EXPLICIT* is the default for this parameter:
  - *ID\_NONE*: no *id*-number is provided. Can be useful if *Box\_d* is used as a base class for a different implementation of *id*-numbers than the ones provided here.
  - *ID\_EXPLICIT*: the *id*-number is stored explicitly in the box and automatically created and assigned at construction time of the box. Note that copying a box (copy-constructor and assignment) does not create a new *id*-number but keeps the old one, which is the behavior needed by the *CGAL::box\_self\_intersection* algorithm. This is therefore the safe default implementation.
  - *ID\_FROM\_BOX\_ADDRESS*: casts the address of the box into a *std::ptrdiff\_t* to create the *id*-number. Works fine if the intersection algorithms work effectively with pointers to boxes, but not in the case where the algorithms work with box values, because the algorithms modify the order of the boxes, and the *CGAL::box\_self\_intersection* algorithm creates copies of the boxes that would not have identical *id*-numbers.

```
#include <CGAL/Box_intersection_d/Box_d.h>
and also automatically with
#include <CGAL/box_intersection_d.h>
```

### Is Model for the Concepts

BoxIntersectionBox\_d.....page [2981](#)

### Types

*Box\_d*<*NT*,*int D*,*IdPolicy*>:: *NT*                      number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

*typedef std::size\_t*            *ID*;                      type for the box *id*-number.

## Creation

<code>Box_d&lt;NT,int D,IdPolicy&gt; box;</code>	Default constructor. No particular initialization.
<code>Box_d&lt;NT,int D,IdPolicy&gt; box( bool complete);</code>	initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.
<code>Box_d&lt;NT,int D,IdPolicy&gt; box( NT lo[D], NT hi[D]);</code>	initializes the box intervals to $[lo[i],hi[i]]$ , $0 \leq i < D$ . <i>Precondition:</i> $lo[i] < hi[i]$ for $0 \leq i < D$ .
<code>Box_d&lt;NT,int D,IdPolicy&gt; box( Bbox_2 bbox);</code>	constructs from bbox <i>Requirement:</i> $D = 2$ and $NT \equiv double$ .
<code>Box_d&lt;NT,int D,IdPolicy&gt; box( Bbox_3 bbox);</code>	constructs from bbox <i>Requirement:</i> $D = 3$ and $NT \equiv double$ .

## Modifiers

<code>void box.init( bool complete = false)</code>	initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.
<code>void box.extend( NT point[D])</code>	extend <i>box</i> to contain the old <i>box</i> and <i>point</i> .

## Access Functions

<code>int Box_d::dimension()</code>	returns $D$ , the dimension of the box.
<code>std::size_t box.id()</code>	returns a unique box id, see the <i>IdPolicy</i> template parameter above for the different choices. <i>Requirement:</i> $IdPolicy \neq ID\_NONE$
<code>NT box.min_coord( int d)</code>	returns the lower boundary in dimension $d$ <i>Precondition:</i> $0 \leq d < D$
<code>NT box.max_coord( int d)</code>	returns the upper boundary in dimension $d$ <i>Precondition:</i> $0 \leq d < D$
<code>Bbox_2 box.bbox()</code>	returns the bounding box <i>Requirement:</i> $D = 2$ and $NT \equiv double$
<code>Bbox_3 box.bbox()</code>	returns the bounding box <i>Requirement:</i> $D = 3$ and $NT \equiv double$
<code>void box.extend( NT p[N])</code>	extends <i>box</i> to the smallest box that additionally contains the point represented by coordinates in $p$ .

*void*            *box.extend( std::pair<NT,NT> p[N])*

extends *box* to the smallest box that additionally contains  
the point represented by coordinate intervals in *p*.

## CGAL::Box\_intersection\_d::Box\_traits\_d<BoxHandle>

### Definition

This is the default traits class for the intersection algorithms for iso-oriented boxes. There are actually three versions depending on the type of *BoxHandle*; there is one if *BoxHandle* is a class type and there are two if *BoxHandle* is a pointer type, one for a mutable and one for a const pointer, respectively.

This class implements the mapping from its *BoxHandle* argument to the *Box\_parameter* type required in the *BoxIntersectionTraits\_d* concept. In particular in the case where *BoxHandle* is a class type *B*, it defines *Box\_parameter* to be of type *const B&*, while for the other cases it just uses the pointer type.

- *BoxHandle*: either a class type *B*, a pointer *B\**, or a const-pointer *const B\**, where *B* is a model of the *BoxIntersectionBox\_d* concept.

`#include <CGAL/Box_intersection_d/Box_traits_d.h>` and also automatically with

## CGAL::Box\_intersection\_d::Box\_with\_handle\_d<NT, int D, Handle, IdPolicy>

### Definition

*Box\_with\_handle\_d*<*NT*, *int D*, *Handle*, *IdPolicy*> is a generic iso-oriented bounding box in dimension *D* that stores additionally a handle to some underlying geometric object. It provides in each dimension an interval with lower and upper endpoints represented with the number type *NT*. This class is designed to work smoothly with the algorithms for intersecting sequences of iso-oriented boxes. For degeneracy handling, the boxes need to provide a unique *id*-number. The policy parameter *IdPolicy* offers several choices. The template parameters have to comply with the following requirements:

- *NT*: number type for the box boundaries, needs to be a model of the *Assignable* and the *LessThanComparable* concept.
- *int D*: the dimension of the box.
- *Handle* concept, e.g., a pointer, an iterator, or a circulator.
- *IdPolicy*: specifies how the *id*-number will be provided. Can be one of the following types, where *ID\_EXPLICIT* is the default for this parameter:
  - *ID\_NONE*: no *id*-number is provided. Can be useful to have this class as a base class for different implementations of *id*-numbers than the ones provided here.
  - *ID\_EXPLICIT*: the *id*-number is stored explicitly in the box and automatically created and assigned at construction time of the box. Note that copying a box (copy-constructor and assignment) does not create a new *id*-number but keeps the old one, which is the behavior needed by the *CGAL::box\_self\_intersection* algorithm. This is therefore the safe default implementation.
  - *ID\_FROM\_BOX\_ADDRESS*: casts the address of the box into a *std::ptrdiff\_t* to create the *id*-number. Works fine if the intersection algorithms work effectively with pointers to boxes, but not in the case where the algorithms work with box values, because the algorithms modify the order of the boxes, and the *CGAL::box\_self\_intersection* algorithm creates copies of the boxes that would not have identical *id*-numbers.
  - *ID\_FROM\_HANDLE*: casts the address of the value of the handle into a *std::ptrdiff\_t* to create the *id*-number. Works in many conceivable settings, e.g., it works with boxes copied by value or by pointer, and the self intersection test. It will not work if there is no one-to-one mapping between boxes and the geometry that is referred to with the handles, i.e., this *id*-number scheme fails if a geometric object creates several boxes with the same handle value. Note that this option is not available for the *CGAL::Box\_intersection\_d::Box\_d* type that does not store a handle.

```
#include <CGAL/Box_intersection_d/Box_with_handle_d.h>
and also automatically with
#include <CGAL/box_intersection_d.h>
```

### Is Model for the Concepts

BoxIntersectionBox\_d.....page 2981

## Types

*Box\_with\_handle\_d*<*NT*, *int D*, *Handle*, *IdPolicy*>::*NT*

number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

*typedef std::size\_t ID;*

type for the box *id*-number.

## Creation

*Box\_with\_handle\_d*<*NT*, *int D*, *Handle*, *IdPolicy*> *box*;

Default constructor. No particular initialization.

*Box\_with\_handle\_d*<*NT*, *int D*, *Handle*, *IdPolicy*> *box*( *bool complete*, *Handle h*);

initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity, sets handle to *h*.

*Box\_with\_handle\_d*<*NT*, *int D*, *Handle*, *IdPolicy*> *box*( *NT lo*[*D*], *NT hi*[*D*], *Handle h*);

initializes the box intervals to [*lo*[*i*],*hi*[*i*]],  $0 \leq i < D$  and sets the handle to *h*.

*Precondition*: *lo*[*i*] < *hi*[*i*] for  $0 \leq i < D$ .

*Box\_with\_handle\_d*<*NT*, *int D*, *Handle*, *IdPolicy*> *box*( *Bbox\_2 bbox*, *Handle h*);

constructs from *bbox* and sets the handle to *h*, exists iff  $D = 2$  and  $NT \equiv double$ .

*Box\_with\_handle\_d*<*NT*, *int D*, *Handle*, *IdPolicy*> *box*( *Bbox\_3 bbox*, *Handle h*);

constructs from *bbox* and sets the handle to *h*, exists iff  $D = 3$  and  $NT \equiv double$ .

## Modifiers

*void box.init*( *bool complete = false*)

initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.

*void box.extend*( *NT point*[*D*])

extend *box* to contain the old *box* and *point*.

## Access Functions

<i>Handle</i>	<i>box.handle()</i>	returns the handle stored in <i>box</i> .
<i>int</i>	<i>Box_with_handle_d::dimension()</i>	returns <i>D</i> , the dimension of the box.
<i>std::size_t</i>	<i>box.id()</i>	returns a unique box id, see the <i>IdPolicy</i> template parameter above for the different choices. Does not exist if <i>ID_NONE</i> has been chosen for the <i>IdPolicy</i> .
<i>NT</i>	<i>box.min_coord( int d)</i>	returns the lower boundary in dimension <i>d</i> , $0 \leq d < D$ .
<i>NT</i>	<i>box.max_coord( int d)</i>	returns the upper boundary in dimension <i>d</i> , $0 \leq d < D$ .
<i>Bbox_2</i>	<i>box.bbox()</i>	returns the bounding box iff $D = 2$ and $NT \equiv \text{double}$ .
<i>Bbox_3</i>	<i>box.bbox()</i>	returns the bounding box iff $D = 3$ and $NT \equiv \text{double}$ .

## **Part XIII**

# **Geometric Optimization**

# Chapter 54

## Bounding Volumes

*Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr*

This chapter describes algorithms which for a given point set compute the “best” circumscribing object from a specific class. If the class consists of all spheres in  $d$ -dimensional Euclidean space and “best” is defined as having smallest radius, then we obtain the smallest enclosing sphere problem already mentioned above.

In the following example a smallest enclosing circle (*CGAL::Min\_circle\_2<Traits>*) is constructed from points on a line and written to standard output. The example shows that it is advisable to switch on random shuffling in order to deal with a ‘bad’ order of the input points.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Min_circle_2.h>
#include <CGAL/Min_circle_2_traits_2.h>
#include <iostream>

// typedefs
typedef CGAL::Exact_predicates_exact_constructions_kernel K;
typedef CGAL::Min_circle_2_traits_2<K> Traits;
typedef CGAL::Min_circle_2<Traits> Min_circle;

typedef K::Point_2 Point;

int
main( int, char**)
{
    const int n = 100;
```

```

Point P[n];

for ( int i = 0; i < n; ++i)
P[ i] = Point( (i%2 == 0 ? i : -i), 0);
// (0,0), (-1,0), (2,0), (-3,0), ...

Min_circle mc1( P, P+n, false);    // very slow
Min_circle mc2( P, P+n, true);     // fast

CGAL::set_pretty_mode( std::cout);
std::cout << mc2;

return 0;
}

```

**File:** examples/Min\_circle\_2/min\_circle\_2.cpp

Other classes for which we provide solutions are ellipses (*CGAL::Min\_ellipse\_2<Traits>*), rectangles (*CGAL::min\_rectangle\_2*), parallelograms (*CGAL::min\_parallelogram\_2*) and strips (*CGAL::min\_strip\_2*) in the plane, with appropriate optimality criteria. For arbitrary dimensions we provide smallest enclosing spheres for points (*CGAL::Min\_sphere\_d<Traits>*) and spheres for spheres (*CGAL::Min\_sphere\_of\_spheres\_d<Traits>*), smallest enclosing annuli (*CGAL::Min\_annulus\_d<Traits>*), and approximate minimum-volume enclosing ellipsoid with user-specified approximation ratio (*CGAL::Approximate\_min\_ellipsoid\_d<Traits>*).

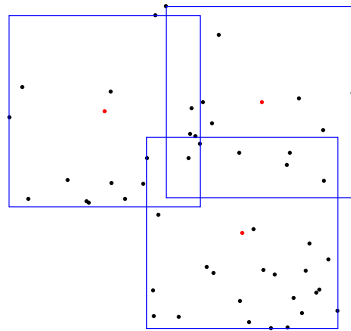

Bounding volumes can be used to obtain simple approximations of complicated objects. For example, consider the problem of deciding whether two moving polygons currently intersect. An obvious solution is to discretize time and perform a full intersection test for any time step. If the polygons are far apart most of the time, this is unnecessary. Instead, simple bounding volumes (for examples, circles) are computed for both polygons at their initial positions. At subsequent time steps, an intersection test between the moving bounding circles replaces the actual intersection test; only if the circles do intersect, the expensive intersection test between the polygons is performed. In practice, bounding volume hierarchies are often used on top of simple bounding volumes to approximate complicated objects more accurately.

Bounding volumes are also frequently applied to extract geometric properties of objects. For example, the smallest enclosing annulus of a point set can be used to test whether a set of points is approximately cospherical. Here, the width of the annulus (or its area, or still another criterion that we use) is a good measure for this property. The largest area triangle is for example used in heuristics for matching archaeological aerial photographs. Largest perimeter triangles are used in scoring cross country soaring flights, where the goal is basically to fly as far as possible, but still return to the departure airfield. To score simply based on the total distance flown is not a good measure, since circling in thermals allows to increase it easily.

Bounding volumes also define geometric “center points” of objects. For example, if two objects are to be matched (approximately), one approach is to first apply the translation that maps the centers of their smallest

enclosing spheres onto each other. Simpler centers are possible, of course (center of gravity, center of bounding box), but more advanced bounding volumes might give better results in some cases. It can also make sense to consider several center points instead of just one. For example, we provide algorithms to cover a planar point set with between two and four minimal boxes (*CGAL::rectangular\_p\_center\_2*). Below is an example covering with three boxes; the center points are shown in red.

# Bounded Volumes

## Reference Manual

*Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr*

This chapter describes concepts, classes, and functions for bounding areas and volumes.

These are Smallest enclosing circle and ellipse (2D), smallest enclosing rectangle, parallelogram, and strip (2D), rectangular  $p$ -center (2D), smallest enclosing sphere and annulus (dD), approximate minimum-volume enclosing ellipsoid with user-specified approximation ratio (dD).

### Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL\_OPTIMISATION\_NO\_PRECONDITIONS* switches precondition checking off, cf. Section 2.10.

## CGAL::Min\_circle\_2<Traits>

### Definition

An object of the class *Min\_circle\_2<Traits>* is the unique circle of smallest area enclosing a finite (multi)set of points in two-dimensional Euclidean space  $\mathbb{E}_2$ . For a point set  $P$  we denote by  $mc(P)$  the smallest circle that contains all points of  $P$ . Note that  $mc(P)$  can be degenerate, i.e.  $mc(P) = \emptyset$  if  $P = \emptyset$  and  $mc(P) = \{p\}$  if  $P = \{p\}$ .

An inclusion-minimal subset  $S$  of  $P$  with  $mc(S) = mc(P)$  is called a *support set*, the points in  $S$  are the *support points*. A support set has size at most three, and all its points lie on the boundary of  $mc(P)$ . In general, neither the support set nor its size are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g.  $P$  may be empty or points may occur more than once. The algorithm computes a support set  $S$  which remains fixed until the next insert or clear operation.

**Please note:** This class is (almost) obsolete. The class *CGAL::Min\_sphere\_of\_spheres\_d<Traits>* solves a more general problem and is faster than *Min\_circle\_2<Traits>* even if used only for points in two dimensions as input. Most importantly, *CGAL::Min\_sphere\_of\_spheres\_d<Traits>* has a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). In contrast, *Min\_circle\_2<Traits>* is not tuned for floating-point computations. The only advantage of *Min\_circle\_2<Traits>* over *CGAL::Min\_sphere\_of\_spheres\_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *Min\_circle\_2<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

```
#include <CGAL/Min_circle_2.h>
```

### Requirements

The template parameter *Traits* is a model for *MinCircle2Traits*.

We provide the model *CGAL::Min\_circle\_2\_traits\_2* using the two-dimensional CGAL kernel.

### Types

*Min\_circle\_2<Traits>::Point*    typedef to *Traits::Point*.

*Min\_circle\_2<Traits>::Circle*    typedef to *Traits::Circle*.

*Min\_circle\_2<Traits>::Point\_iterator*

non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points of the smallest enclosing circle.

*Min\_circle\_2<Traits>::Support\_point\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing circle.

## Creation

A *Min\_circle\_2*<*Traits*> object can be created from an arbitrary point set  $P$  and by specialized construction methods expecting no, one, two or three points as arguments. The latter methods can be useful for reconstructing  $mc(P)$  from a given support set  $S$  of  $P$ .

```
template < class InputIterator >
Min_circle_2<Traits> min_circle( InputIterator first,
                                InputIterator last,
                                bool randomize,
                                Random& random = CGAL::default_random,
                                Traits traits = Traits())
```

initializes *min\_circle* to  $mc(P)$  with  $P$  being the set of points in the range  $[first, last)$ . If *randomize* is *true*, a random permutation of  $P$  is computed in advance, using the random numbers generator *random*. Usually, this will not be necessary, however, the algorithm's efficiency depends on the order in which the points are processed, and a bad order might lead to extremely poor performance (see example below).

*Requirement:* The value type of *first* and *last* is *Point*.

```
Min_circle_2<Traits> min_circle( Traits traits = Traits());
```

initializes *min\_circle* to  $mc(\emptyset)$ , the empty set.  
*Postcondition:* *min\_circle.is\_empty()* = *true*.

```
Min_circle_2<Traits> min_circle( Point p, Traits traits = Traits());
```

initializes *min\_circle* to  $mc(\{p\})$ , the set  $\{p\}$ .  
*Postcondition:* *min\_circle.is\_degenerate()* = *true*.

```
Min_circle_2<Traits> min_circle( Point p1, Point p2, Traits traits = Traits());
```

initializes *min\_circle* to  $mc(\{p1, p2\})$ , the circle with diameter equal to the segment connecting  $p1$  and  $p2$ .

```
Min_circle_2<Traits> min_circle( Point p1, Point p2, Point p3, Traits traits = Traits());
```

initializes *min\_circle* to  $mc(\{p1, p2, p3\})$ .

## Access Functions

*int*      *min\_circle.number\_of\_points()*    returns the number of points of *min\_circle*, i.e.  $|P|$ .

*int*      *min\_circle.number\_of\_support\_points()*

returns the number of support points of *min\_circle*, i.e.  $|S|$ .

*Point\_iterator*     *min\_circle.points\_begin()*     returns an iterator referring to the first point of *min\_circle*.

*Point\_iterator*     *min\_circle.points\_end()*     returns the corresponding past-the-end iterator.

*Support\_point\_iterator*     *min\_circle.support\_points\_begin()*     returns an iterator referring to the first support point of *min\_circle*.

*Support\_point\_iterator*     *min\_circle.support\_points\_end()*     returns the corresponding past-the-end iterator.

*Point*     *min\_circle.support\_point( int i)*     returns the *i*-th support point of *min\_circle*. Between two modifying operations (see below) any call to *min\_circle.support\_point(i)* with the same *i* returns the same point.  
*Precondition:*  $0 \leq i < \text{min\_circle.number\_of\_support\_points}()$ .

*Circle*     *min\_circle.circle()*     returns the current circle of *min\_circle*.

## Predicates

By definition, an empty *Min\_circle\_2<Traits>* has no boundary and no bounded side, i.e. its unbounded side equals the whole space  $\mathbb{E}_2$ .

*CGAL::Bounded\_side*

*min\_circle.bounded\_side( Point p)*     returns *CGAL::ON\_BOUNDED\_SIDE*, *CGAL::ON\_BOUNDARY*, or *CGAL::ON\_UNBOUNDED\_SIDE* iff *p* lies properly inside, on the boundary of, or properly outside of *min\_circle*, resp.

*bool*     *min\_circle.has\_on\_bounded\_side( Point p)*     returns *true*, iff *p* lies properly inside *min\_circle*.

*bool*     *min\_circle.has\_on\_boundary( Point p)*     returns *true*, iff *p* lies on the boundary of *min\_circle*.

*bool*     *min\_circle.has\_on\_unbounded\_side( Point p)*     returns *true*, iff *p* lies properly outside of *min\_circle*.

*bool*     *min\_circle.is\_empty()*     returns *true*, iff *min\_circle* is empty (this implies degeneracy).

*bool min\_circle.is\_degenerate()* returns *true*, iff *min\_circle* is degenerate, i.e. if *min\_circle* is empty or equal to a single point, equivalently if the number of support points is less than 2.

## Modifiers

New points can be added to an existing *min\_circle*, allowing to build  $mc(P)$  incrementally, e.g. if  $P$  is not known in advance. Compared to the direct creation of  $mc(P)$ , this is not much slower, because the construction method is incremental itself.

*void min\_circle.insert( Point p)* inserts  $p$  into *min\_circle* and recomputes the smallest enclosing circle.

*template < class InputIterator >*

*void min\_circle.insert( InputIterator first, InputIterator last)*

inserts the points in the range  $[first, last)$  into *min\_circle* and recomputes the smallest enclosing circle by calling *insert(p)* for each point  $p$  in  $[first, last)$ .

*Requirement:* The value type of *first* and *last* is *Point*.

*void min\_circle.clear()* deletes all points in *min\_circle* and sets *min\_circle* to the empty set.  
*Postcondition:* *min\_circle.is\_empty() = true*.

## Validity Check

An object *min\_circle* is valid, iff

- *min\_circle* contains all points of its defining set  $P$ ,
- *min\_circle* is the smallest circle spanned by its support set  $S$ , and
- $S$  is minimal, i.e. no support point is redundant.

*bool min\_circle.is\_valid( bool verbose = false, int level = 0)*

returns *true*, iff *min\_circle* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

## Miscellaneous

*const Traits&*

*min\_circle.traits()* returns a const reference to the traits class object.

## I/O

*std::ostream&*

*std::ostream& os << min\_circle*

writes *min\_circle* to output stream *os*.

*Requirement:* The output operator is defined for *Point* (and for *Circle*, if pretty printing is used).

*std::istream&*

*std::istream& is >> min\_circle&*

reads *min\_circle* from input stream *is*.

*Requirement:* The input operator is defined for *Point*.

## Implementation

We implement the incremental algorithm of Welzl, with move-to-front heuristic [We191]. The whole implementation is described in [GS98a].

If randomization is chosen, the creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing circle from scratch. The clear operation and the check for validity each takes linear time.

## Example

To illustrate the creation of *Min\_circle\_2<Traits>* and to show that randomization can be useful in certain cases, we give an example.

```
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/Min_circle_2.h>
#include <CGAL/Min_circle_2_traits_2.h>
#include <iostream>

// typedefs
typedef CGAL::Exact_predicates_exact_constructions_kernel K;
typedef CGAL::Min_circle_2_traits_2<K> Traits;
typedef CGAL::Min_circle_2<Traits> Min_circle;
```

```

typedef K::Point_2                                Point;

int
main( int, char**)
{
    const int n = 100;
    Point P[n];

    for ( int i = 0; i < n; ++i)
P[ i] = Point( (i%2 == 0 ? i : -i), 0);
    // (0,0), (-1,0), (2,0), (-3,0), ...

    Min_circle mc1( P, P+n, false);    // very slow
    Min_circle mc2( P, P+n, true);     // fast

    CGAL::set_pretty_mode( std::cout);
    std::cout << mc2;

    return 0;
}

```

**File:** examples/Min\_circle\_2/min\_circle\_2.cpp

The class *Min\_circle\_2\_traits\_2<K>* is a traits class for *Min\_circle\_2<Traits>* using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_circle_2_traits_2.h>
```

The template parameter  $K$  is a model for *Kernel*.

## MinCircle2Traits ..... page 3007

MinCircle2Traits ..... page 3007

# MinCircle2Traits

## Definition

This concept defines the requirements for traits classes of *CGAL::Min\_circle\_2<Traits>*.

## Types

<i>MinCircle2Traits:: Point</i>	The point type must provide default and copy constructor, assignment and equality test.
<i>MinCircle2Traits:: Circle</i>	The circle type must fulfill the requirements listed below in the next section.

## Variables

<i>Circle</i>	<i>circle;</i>	The current circle. This variable is maintained by the algorithm, the user should neither access nor modify it directly.
---------------	----------------	--

## Creation

Only default and copy constructor are required.

*MinCircle2Traits traits;*  
*MinCircle2Traits traits( MinCircle2Traits);*

## Operations

The following predicate is only needed, if the member function *is\_valid* of *Min\_circle\_2* is used.

*CGAL::Orientation*      *traits.orientation( Point p, Point q, Point r)*  
returns                    constants                    *CGAL::LEFT\_TURN*,  
*CGAL::COLLINEAR*, or *CGAL::RIGHT\_TURN* iff *r*  
lies properly to the left of, on, or properly to the right of the  
oriented line through *p* and *q*, resp.

## Has Models

*CGAL::Min\_circle\_2\_traits\_2<K>* ..... page [3006](#)

## See Also

*CGAL::Min\_circle\_2<Traits>* ..... page [3000](#)

### Circle Type (*Circle*)

### Definition

An object of the class *Circle* is a circle in two-dimensional Euclidean plane  $\mathbb{E}_2$ . Its boundary splits the plane into a bounded and an unbounded side. By definition, an empty *Circle* has no boundary and no bounded side, i.e. its unbounded side equals the whole plane  $\mathbb{E}_2$ . A *Circle* containing exactly one point  $p$  has no bounded side, its boundary is  $\{p\}$ , and its unbounded side equals  $\mathbb{E}_2 \setminus \{p\}$ .

## Types

*Circle::Point* Point type.

The following type is only needed, if the member function *is\_valid* of *Min\_circle\_2* is used.

<i>Circle::Distance</i>	Distance type. The function <i>squared_radius</i> (see below) returns an object of this type.
-------------------------	---

## Creation

<i>void</i>	<i>circle.set()</i>	sets <i>circle</i> to the empty circle.
-------------	---------------------	---

<i>void</i>	<i>circle.set( Point p)</i>	sets <i>circle</i> to the circle containing exactly $\{p\}$ .
-------------	-----------------------------	---

<i>void</i>	<i>circle.set( Point p, Point q)</i>	sets <i>circle</i> to the circle with diameter equal to the segment connecting <i>p</i> and <i>q</i> . The algorithm guarantees that <i>set</i> is never called with two equal points.
-------------	--------------------------------------	--

*void circle.set( Point p, Point q, Point r )*

sets *circle* to the circle through *p,q,r*. The algorithm guarantees that *set* is never called with three collinear points.

## Predicates

*bool circle.has\_on\_unbounded\_side( Point p )*  
returns *true*, iff *p* lies properly outside of *circle*.

Each of the following predicates is only needed, if the corresponding predicate of *Min\_circle\_2* is used.

CGAL::Bounded\_side

*circle.bounded\_side*( *Point p*)

returns *CGAL::ON\_BOUNDED\_SIDE*, *CGAL::ON\_BOUNDARY*,  
or *CGAL::ON\_UNBOUNDED\_SIDE* iff *p* lies properly inside, on  
the boundary, or properly outside of *circle*, resp.

*bool*      *circle.has\_on\_bounded\_side( Point p)*

returns *true*, iff *p* lies properly inside *circle*.

*bool*      *circle.has\_on\_boundary( Point p)*

returns *true*, iff *p* lies on the boundary of *circle*.

*bool*      *circle.is\_empty()*

returns *true*, iff *circle* is empty (this implies degeneracy).

*bool*      *circle.is\_degenerate()*

returns *true*, iff *circle* is degenerate, i.e. if *circle* is empty or equal to a single point.

### **Additional Operations for Checking**

The following operations are only needed, if the member function *is\_valid* of *Min\_circle\_2* is used.

*bool*      *circle == circle2*

returns *true*, iff *circle* and *circle2* are equal.

*Point*    *circle.center()*

returns the center of *circle*.

*Distance*    *circle.squared\_radius()*

returns the squared radius of *circle*.

### **I/O**

The following I/O operator is only needed, if the corresponding I/O operator of *Min\_circle\_2* is used.

*std::ostream&*

*std::ostream& os << circle*    writes *circle* to output stream *os*.

## CGAL::Min\_ellipse\_2<Traits>

### Definition

An object of the class *Min\_ellipse\_2<Traits>* is the unique ellipse of smallest area enclosing a finite (multi)set of points in two-dimensional euclidean space  $\mathbb{E}_2$ . For a point set  $P$  we denote by  $me(P)$  the smallest ellipse that contains all points of  $P$ . Note that  $me(P)$  can be degenerate, i.e.  $me(P) = \emptyset$  if  $P = \emptyset$ ,  $me(P) = \{p\}$  if  $P = \{p\}$ , and  $me(P) = \{(1-\lambda)p + \lambda q \mid 0 \leq \lambda \leq 1\}$  if  $P = \{p, q\}$ .

An inclusion-minimal subset  $S$  of  $P$  with  $me(S) = me(P)$  is called a *support set*, the points in  $S$  are the *support points*. A support set has size at most five, and all its points lie on the boundary of  $me(P)$ . In general, neither the support set nor its size are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g.  $P$  may be empty or points may occur more than once. The algorithm computes a support set  $S$  which remains fixed until the next insert or clear operation.

```
#include <CGAL/Min_ellipse_2.h>
```

### Requirements

The template parameter *Traits* is a model for *MinEllipse2Traits*.

We provide the model *CGAL::Min\_ellipse\_2\_traits\_2<K>* using the two-dimensional CGAL kernel.

### Types

*Min\_ellipse\_2<Traits>::Point*      Typedef to *Traits::Point*.

*Min\_ellipse\_2<Traits>::Ellipse*      Typedef to *Traits::Ellipse*. If you are using the predefined traits class *CGAL::Min\_ellipse\_2\_traits\_2<K>*, you can access the coefficients of the ellipse, see the documentation of *CGAL::Min\_ellipse\_2\_traits\_2<K>* and the example below.

*Min\_ellipse\_2<Traits>::Point\_iterator*

Non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points of the smallest enclosing ellipse.

*Min\_ellipse\_2<Traits>::Support\_point\_iterator*

Non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing ellipse.

### Creation

A *Min\_ellipse\_2*<*Traits*> object can be created from an arbitrary point set  $P$  and by specialized construction methods expecting no, one, two, three, four or five points as arguments. The latter methods can be useful for reconstructing  $me(P)$  from a given support set  $S$  of  $P$ .

*template < class InputIterator >*

*Min\_ellipse\_2*<*Traits*> *min\_ellipse*( *InputIterator* *first*,  
*InputIterator* *last*,  
*bool* *randomize*,  
*Random*& *random* = *default\_random*,  
*Traits* *traits* = *Traits*())

initializes *min\_ellipse* to  $me(P)$  with  $P$  being the set of points in the range  $[first, last)$ . If *randomize* is *true*, a random permutation of  $P$  is computed in advance, using the random numbers generator *random*. Usually, this will not be necessary, however, the algorithm's efficiency depends on the order in which the points are processed, and a bad order might lead to extremely poor performance (see example below).

*Requirement:* The value type of *first* and *last* is *Point*.

*Min\_ellipse\_2*<*Traits*> *min\_ellipse*( *Traits* *traits* = *Traits*());

creates a variable *min\_ellipse* of type *Min\_ellipse\_2*<*Traits*>. It is initialized to  $me(\emptyset)$ , the empty set.

*Postcondition:* *min\_ellipse.is\_empty()* = *true*.

*Min\_ellipse\_2*<*Traits*> *min\_ellipse*( *Point* *p*, *Traits* *traits* = *Traits*());

initializes *min\_ellipse* to  $me(\{p\})$ , the set  $\{p\}$ .

*Postcondition:* *min\_ellipse.is\_degenerate()* = *true*.

*Min\_ellipse\_2*<*Traits*> *min\_ellipse*( *Point* *p*, *Point* *q*, *Traits* *traits* = *Traits*());

initializes *min\_ellipse* to  $me(\{p, q\})$ ,

the set  $\{(1 - \lambda)p + \lambda q \mid 0 \leq \lambda \leq 1\}$ .

*Postcondition:* *min\_ellipse.is\_degenerate()* = *true*.

*Min\_ellipse\_2*<*Traits*> *min\_ellipse*( *Point* *p1*, *Point* *p2*, *Point* *p3*, *Traits* *traits* = *Traits*());

initializes *min\_ellipse* to  $me(\{p1, p2, p3\})$ .

*Min\_ellipse\_2*<*Traits*> *min\_ellipse*( *Point* *p1*, *Point* *p2*, *Point* *p3*, *Point* *p4*, *Traits* *traits* = *Traits*());

initializes *min\_ellipse* to  $me(\{p1, p2, p3, p4\})$ .

*Min\_ellipse\_2*<*Traits*> *min\_ellipse*( *Point* *p1*, *Point* *p2*, *Point* *p3*, *Point* *p4*, *Point* *p5*, *Traits* *traits* = *Traits*());

initializes *min\_ellipse* to  $me(\{p1, p2, p3, p4, p5\})$ .

## Access Functions

*int*      *min\_ellipse.number\_of\_points()*

returns the number of points of *min\_ellipse*, i.e.  $|P|$ .

*int*      *min\_ellipse.number\_of\_support\_points()*

returns the number of support points of *min\_ellipse*, i.e.  $|S|$ .

*Point\_iterator*

*min\_ellipse.points\_begin()*

returns an iterator referring to the first point of *min\_ellipse*.

*Point\_iterator*

*min\_ellipse.points\_end()*

returns the corresponding past-the-end iterator.

*Support\_point\_iterator*

*min\_ellipse.support\_points\_begin()*

returns an iterator referring to the first support point of *min\_ellipse*.

*Support\_point\_iterator*

*min\_ellipse.support\_points\_end()*

returns the corresponding past-the-end iterator.

*Point*      *min\_ellipse.support\_point( int i )*

returns the *i*-th support point of *min\_ellipse*. Between two modifying operations (see below) any call to *min\_ellipse.support\_point(i)* with the same *i* returns the same point.

*Precondition:*  $0 \leq i < \text{min\_ellipse.number\_of\_support\_points}()$ .

*Ellipse*      *min\_ellipse.ellipse()*

returns the current ellipse of *min\_ellipse*.

## Predicates

By definition, an empty *Min\_ellipse\_2<Traits>* has no boundary and no bounded side, i.e. its unbounded side equals the whole space  $\mathbb{E}_2$ .

*CGAL::Bounded\_side*

*min\_ellipse.bounded\_side( Point p )*

returns *CGAL::ON\_BOUNDED\_SIDE*, *CGAL::ON\_BOUNDARY*, or *CGAL::ON\_UNBOUNDED\_SIDE* iff *p* lies properly inside, on the boundary of, or properly outside of *min\_ellipse*, resp.

*bool*      *min\_ellipse.has\_on\_bounded\_side( Point p )*

returns *true*, iff *p* lies properly inside *min\_ellipse*.

*bool min\_ellipse.has\_on\_boundary( Point p)*

returns *true*, iff *p* lies on the boundary of *min\_ellipse*.

*bool min\_ellipse.has\_on\_unbounded\_side( Point p)*

returns *true*, iff *p* lies properly outside of *min\_ellipse*.

*bool min\_ellipse.is\_empty()*

returns *true*, iff *min\_ellipse* is empty (this implies degeneracy).

*bool min\_ellipse.is\_degenerate()*

returns *true*, iff *min\_ellipse* is degenerate, i.e. if *min\_ellipse* is empty, equal to a single point or equal to a segment, equivalently if the number of support points is less than 3.

## Modifiers

New points can be added to an existing *min\_ellipse*, allowing to build  $me(P)$  incrementally, e.g. if  $P$  is not known in advance. Compared to the direct creation of  $me(P)$ , this is not much slower, because the construction method is incremental itself.

*void min\_ellipse.insert( Point p)*

inserts *p* into *min\_ellipse* and recomputes the smallest enclosing ellipse.

*template < class InputIterator >*

*void min\_ellipse.insert( InputIterator first, InputIterator last)*

inserts the points in the range  $[first, last)$  into *min\_ellipse* and recomputes the smallest enclosing ellipse by calling *insert(p)* for each point *p* in  $[first, last)$ .

*Requirement:* The value type of *first* and *last* is *Point*.

*void min\_ellipse.clear()*

deletes all points in *min\_ellipse* and sets *min\_ellipse* to the empty set.

*Postcondition:* *min\_ellipse.is\_empty() = true*.

## Validity Check

An object *min\_ellipse* is valid, iff

- *min\_ellipse* contains all points of its defining set  $P$ ,
- *min\_ellipse* is the smallest ellipse spanned by its support set  $S$ , and
- $S$  is minimal, i.e. no support point is redundant.

*Note:* In this release only the first item is considered by the validity check.

*bool min\_ellipse.is\_valid( bool verbose = false, int level = 0)*

returns *true*, iff *min\_ellipse* contains all points of its defining set *P*. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

## Miscellaneous

*const Traits&*

*min\_ellipse.traits()* returns a const reference to the traits class object.

## I/O

*std::ostream&*

*std::ostream& os << min\_ellipse*

writes *min\_ellipse* to output stream *os*.

*Requirement:* The output operator is defined for *Point* (and for *Ellipse*, if pretty printing is used).

*std::istream&*

*std::istream& is >> min\_ellipse&*

reads *min\_ellipse* from input stream *is*.

*Requirement:* The input operator is defined for *Point*.

## See Also

*CGAL::Min\_ellipse\_2\_traits\_2<K>* ..... page [3017](#)  
*MinEllipse2Traits* ..... page [3019](#)

## Implementation

We implement the incremental algorithm of Welzl, with move-to-front heuristic [[WeI91](#)], using the primitives as described in [[GS97a](#), [GS97b](#)]. The whole implementation is described in [[GS98b](#)].

If randomization is chosen, the creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing ellipse from scratch. The clear operation and the check for validity each takes linear time.

## Example

To illustrate the usage of *Min\_ellipse\_2*<Traits> and to show that randomization can be useful in certain cases, we give an example. The example also shows how the coefficients of the constructed ellipse can be accessed.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Min_ellipse_2.h>
#include <CGAL/Min_ellipse_2_traits_2.h>
#include <CGAL/Gmpq.h>

#include <cassert>

typedef CGAL::Gmpq          NT;
typedef CGAL::Cartesian<NT> K;
typedef CGAL::Point_2<K>    Point;
typedef CGAL::Min_ellipse_2_traits_2<K> Traits;
typedef CGAL::Min_ellipse_2<Traits>    Min_ellipse;

int
main( int, char**)
{
    const int n = 200;
    Point    P[n];

    for ( int i = 0; i < n; ++i)
        P[ i] = Point( i % 2 ? i : -i , 0);
    // (0,0), (-1,0), (2,0), (-3,0)

    std::cout << "Computing ellipse (without randomization)...";
    std::cout.flush();
    Min_ellipse me1( P, P+n, false);    // very slow
    std::cout << "done." << std::endl;

    std::cout << "Computing ellipse (with randomization)...";
    std::cout.flush();
    Min_ellipse me2( P, P+n, true);     // fast
    std::cout << "done." << std::endl;

    // because all input points are collinear, the ellipse is
    // degenerate and equals a line segment; the ellipse has
    // two support points
    assert(me2.is_degenerate());
    assert(me2.number_of_support_points()==2);

    // prettyprinting
    CGAL::set_pretty_mode( std::cout);
    std::cout << me2;

    // in general, the ellipse is not explicitly representable
    // over the input number type NT; when you use the default
    // traits class CGAL::Min_ellipse_2_traits_2<K>, you can
    // get double approximations for the coefficients of the
    // underlying conic curve. NOTE: this curve only exists
```

```

// in the nondegenerate case!

me2.insert(Point(0,1)); // resolves the degeneracy
assert(!me2.is_degenerate());

// get the coefficients
double r,s,t,u,v,w;
me2.ellipse().double_coefficients( r, s, t, u, v, w);
std::cout << "ellipse has the equation " <<
  r << " x^2 + " <<
  s << " y^2 + " <<
  t << " xy + " <<
  u << " x + " <<
  v << " y + " <<
  w << " = 0." << std::endl;

return 0;
}

```

## CGAL::Min\_ellipse\_2\_traits\_2&lt;K&gt;

### Definition

The class `Min_ellipse_2_traits_2<K>` is a traits class for `CGAL::Min_ellipse_2<Traits>` using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_ellipse_2_traits_2.h>
```

## Requirements

The template parameter  $K$  is a model for *Kernel*.

## Is Model for the Concepts

MinEllipse2Traits ..... page 3019

## Types

$$Min\_ellipse\_2\_traits\_2<K>:: Point \quad \text{typedef to } K::Point\_2.$$

*Min\_ellipse\_2\_traits\_2<K>:: Ellipse* internal type.

The `Ellipse` type provides the following access methods not required by the concept `MinEllipse2Traits`.

<i>bool</i>	<i>ellipse.is_circle()</i>	tests whether the ellipse is a circle.
-------------	----------------------------	--

```
void ellipse.double_coefficients( double &r,
                                double &s,
                                double &t,
                                double &u,
                                double &v,
                                double &w)
```

gives a double approximation of the ellipse's conic equation. If  $K$  is a Cartesian kernel, the ellipse is the set of all points  $(x, y)$  satisfying  $rx^2 + sy^2 + txy + ux + vy + w = 0$ . In the Homogeneous case, the ellipse is the set of points  $(hx, hy, hw)$  satisfying  $r(hx)^2 + s(hy)^2 + t(hx)(hy) + u(hx)(hw) + v(hy)(hw) + w(hw)^2 = 0$ .

## Creation

*Min\_ellipse\_2\_traits\_2*<*K*> *traits*;      default constructor.

*Min\_ellipse\_2\_traits\_2*<*K*> traits( *Min\_ellipse\_2\_traits\_2*<*K*>);

copy constructor.

# MinEllipse2Traits

## Definition

This concept defines the requirements for traits classes of *CGAL::Min\_ellipse\_2<Traits>*.

## Types

<i>MinEllipse2Traits:: Point</i>	The point type must provide default and copy constructor, assignment and equality test.
<i>MinEllipse2Traits:: Ellipse</i>	The ellipse type must fulfill the requirements listed below in the next section.

## Variables

<i>Ellipse</i>	<i>ellipse;</i>	The current ellipse. This variable is maintained by the algorithm, the user should neither access nor modify it directly.
----------------	-----------------	---

## Creation

Only default and copy constructor are required.

```
MinEllipse2Traits traits;

MinEllipse2Traits traits( Traits);
```

## Has Models

*CGAL::Min\_ellipse\_2\_traits\_2<K>* ..... page [3017](#)

## See Also

*CGAL::Min\_ellipse\_2<Traits>* ..... page [3010](#)

### Ellipse Type (*Ellipse*)

### Definition

An object of the class *Ellipse* is an ellipse in two-dimensional Euclidean plane  $\mathbb{E}_2$ . Its boundary splits the plane into a bounded and an unbounded side. By definition, an empty *Ellipse* has no boundary and no bounded side, i.e. its unbounded side equals the whole plane  $\mathbb{E}_2$ .

## Types

*Ellipse::Point* Point type.

## Creation

<code>void</code>	<code>ellipse.set()</code>	sets <i>ellipse</i> to the empty ellipse.
-------------------	----------------------------	---

<i>void</i>	<i>ellipse.set( Point p)</i>	sets <i>ellipse</i> to the ellipse containing exactly $\{p\}$ .
-------------	------------------------------	---

*void ellipse.set( Point p, Point q)*

sets *ellipse* to the ellipse containing exactly the segment connecting *p* and *q*. The algorithm guarantees that *set* is never called with two equal points.

*void ellipse.set( Point p, Point q, Point r )*

sets *ellipse* to the smallest ellipse through *p,q,r*. The algorithm guarantees that *set* is never called with three collinear points.

void *ellipse.set( Point p, Point q, Point r, Point s )*

sets *ellipse* to the smallest ellipse through  $p, q, r, s$ . The algorithm guarantees that this ellipse exists.

void *ellipse.set*( Point *p*, Point *q*, Point *r*, Point *s*, Point *t*)

sets *ellipse* to the unique conic through *p,q,r,s,t*. The algorithm guarantees that this conic is an ellipse.

## Predicates

*bool ellipse.has\_on\_unbounded\_side( Point p)*

returns *true*, iff *p* lies properly outside of *ellipse*.

Each of the following predicates is only needed, if the corresponding predicate of *Min\_ellipse\_2* is used.

*CGAL::Bounded\_side*

*ellipse.bounded\_side( Point p)*

returns *CGAL::ON\_BOUNDED\_SIDE*, *CGAL::ON\_BOUNDARY*, or *CGAL::ON\_UNBOUNDED\_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *ellipse*, resp.

*bool*

*ellipse.has\_on\_bounded\_side( Point p)*

returns *true*, iff *p* lies properly inside *ellipse*.

*bool*

*ellipse.has\_on\_boundary( Point p)*

returns *true*, iff *p* lies on the boundary of *ellipse*.

*bool*

*ellipse.is\_empty()*

returns *true*, iff *ellipse* is empty (this implies degeneracy).

*bool*

*ellipse.is\_degenerate()*

returns *true*, iff *ellipse* is degenerate, i.e. if *ellipse* is empty or equal to a single point.

## **I/O**

The following I/O operator is only needed, if the corresponding I/O operator of *Min\_ellipse\_2* is used.

*ostream&*

*ostream& os << ellipse*

writes *ellipse* to output stream *os*.

## CGAL::min\_rectangle\_2

### Definition

The function computes a minimum area enclosing rectangle  $R(P)$  of a given convex point set  $P$ . Note that  $R(P)$  is not necessarily axis-parallel, and it is in general not unique. The focus on convex sets is no restriction, since any rectangle enclosing  $P$  – as a convex set – contains the convex hull of  $P$ . For general point sets one has to compute the convex hull as a preprocessing step.

```
#include <CGAL/min_quadrilateral_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator      min_rectangle_2(
                    ForwardIterator points_begin,
                    ForwardIterator points_end,
                    OutputIterator o,
                    Traits& t = Default_traits)
```

computes a minimum area enclosing rectangle of the point set described by  $[points\_begin, points\_end)$ , writes its vertices (counterclockwise) to  $o$ , and returns the past-the-end iterator of this sequence.

If the input range is empty,  $o$  remains unchanged.

If the input range consists of one element only, this point is written to  $o$  four times.

*Precondition:* The points denoted by the range  $[points\_begin, points\_end)$  form the boundary of a simple convex polygon  $P$  in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter  $t$ . The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one of the CGAL kernels. In this case, a default traits class (*Min\_quadrilateral\_default\_traits\_2<K>*) is used.

*Requirement:*

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits\_2* and the value type *VT* of *ForwardIterator* is *Traits::Point\_2*. Otherwise *VT* is *CGAL::Point\_2<K>* for some kernel  $K$ .
2. *OutputIterator* accepts *VT* as value type.

### See Also

*MinQuadrilateralTraits\_2* ..... page [3032](#)  
*CGAL::Min\_quadrilateral\_default\_traits\_2<K>* ..... page [3028](#)

### Implementation

We use a rotating caliper algorithm [[Tou83](#)] with worst case running time linear in the number of input points.

## Example

The following code generates a random convex polygon  $P$  with 20 vertices and computes the minimum enclosing rectangle of  $P$ .

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/min_quadrilateral_2.h>
#include <iostream>

struct Kernel : public CGAL::Cartesian<double> {};

typedef Kernel::Point_2          Point_2;
typedef Kernel::Line_2           Line_2;
typedef CGAL::Polygon_2<Kernel>  Polygon_2;
typedef CGAL::Random_points_in_square_2<Point_2> Generator;

int main()
{
    // build a random convex 20-gon p
    Polygon_2 p;
    CGAL::random_convex_set_2(20, std::back_inserter(p), Generator(1.0));
    std::cout << p << std::endl;

    // compute the minimal enclosing rectangle p_m of p
    Polygon_2 p_m;
    CGAL::min_rectangle_2(
        p.vertices_begin(), p.vertices_end(), std::back_inserter(p_m));
    std::cout << p_m << std::endl;

    return 0;
}
```

## CGAL::min\_parallelgram\_2

### Definition

The function computes a minimum area enclosing parallelogram  $A(P)$  of a given convex point set  $P$ . Note that  $R(P)$  is not necessarily axis-parallel, and it is in general not unique. The focus on convex sets is no restriction, since any parallelogram enclosing  $P$  – as a convex set – contains the convex hull of  $P$ . For general point sets one has to compute the convex hull as a preprocessing step.

```
#include <CGAL/min_quadrilateral_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator      min_parallelgram_2(
                    ForwardIterator points_begin,
                    ForwardIterator points_end,
                    OutputIterator o,
                    Traits& t = Default_traits)
```

computes a minimum area enclosing parallelogram of the point set described by  $[points\_begin, points\_end)$ , writes its vertices (counterclockwise) to  $o$  and returns the past-the-end iterator of this sequence. If the input range is empty,  $o$  remains unchanged.

If the input range consists of one element only, this point is written to  $o$  four times.

*Precondition:* The points denoted by the range  $[points\_begin, points\_end)$  form the boundary of a simple convex polygon  $P$  in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter  $t$ . The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one the CGAL kernels. In this case, a default traits class (*Min\_quadrilateral\_default\_traits\_2*< $K$ >) is used.

*Requirement:*

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits\_2* and the value type *VT* of *ForwardIterator* is *Traits::Point\_2*. Otherwise *VT* is *CGAL::Point\_2*< $K$ > for some kernel  $K$ .
2. *OutputIterator* accepts *VT* as value type.

### Implementation

We use a rotating caliper algorithm [[STV<sup>+</sup>95](#), [Vai90](#)] with worst case running time linear in the number of input points.

## Example

The following code generates a random convex polygon  $P$  with 20 vertices and computes the minimum enclosing parallelogram of  $P$ .

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/min_quadrilateral_2.h>
#include <iostream>

struct Kernel : public CGAL::Cartesian<double> {};

typedef Kernel::Point_2          Point_2;
typedef Kernel::Line_2           Line_2;
typedef CGAL::Polygon_2<Kernel>  Polygon_2;
typedef CGAL::Random_points_in_square_2<Point_2>  Generator;

int main()
{
    // build a random convex 20-gon p
    Polygon_2 p;
    CGAL::random_convex_set_2(20, std::back_inserter(p), Generator(1.0));
    std::cout << p << std::endl;

    // compute the minimal enclosing parallelogram p_m of p
    Polygon_2 p_m;
    CGAL::min_parallelogram_2(
        p.vertices_begin(), p.vertices_end(), std::back_inserter(p_m));
    std::cout << p_m << std::endl;

    return 0;
}
```

**File:** examples/Min\_quadrilateral\_2/minimum\_enclosing\_parallelogram\_2.cpp

## CGAL::min\_strip\_2

### Definition

The function computes a minimum width enclosing strip  $S(P)$  of a given convex point set  $P$ . A strip is the closed region bounded by two parallel lines in the plane. Note that  $S(P)$  is not unique in general. The focus on convex sets is no restriction, since any parallelogram enclosing  $P$  – as a convex set – contains the convex hull of  $P$ . For general point sets one has to compute the convex hull as a preprocessing step.

```
#include <CGAL/min_quadrilateral_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator      min_strip_2(
                    ForwardIterator points_begin,
                    ForwardIterator points_end,
                    OutputIterator o,
                    Traits& t = Default_traits)
```

computes a minimum enclosing strip of the point set described by  $[points\_begin, points\_end)$ , writes its two bounding lines to  $o$  and returns the past-the-end iterator of this sequence.

If the input range is empty or consists of one element only,  $o$  remains unchanged.

*Precondition:* The points denoted by the range  $[points\_begin, points\_end)$  form the boundary of a simple convex polygon  $P$  in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter  $t$ . The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one the CGAL kernels. In this case, a default traits class (*Min\_quadrilateral\_default\_traits\_2*< $K$ >) is used.

*Requirement:*

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits\_2* and the value type *VT* of *ForwardIterator* is *Traits::Point\_2*. Otherwise *VT* is *CGAL::Point\_2*< $K$ > for some kernel  $K$ .
2. *OutputIterator* accepts *Traits::Line\_2* as value type.

*Min\_quadrilateral\_default\_traits\_2<K>:: Construct\_opposite\_direction\_2*

Kernel::Construct\_opposite\_direction\_2 . . . . . page ??.

*Min\_quadrilateral\_default\_traits\_2<K>:: Construct\_line\_2*

Kernel::Construct\_line\_2 . . . . . page ??.

*Min\_quadrilateral\_default\_traits\_2<K>:: Construct\_rectangle\_2*

Function class

*op: Point\_2  $\times$  Direction\_2  $\times$  Point\_2  $\times$  Point\_2  $\times$  Point\_2  $\rightarrow$  Rectangle\_2.*

If the points  $p1, p2, p3, p4$  form the boundary of a convex polygon (oriented counterclockwise), *op*( $p1, d, p2, p3, p4$ ) returns the rectangle with one of the points on each side and one sides parallel to  $d$ .

*Min\_quadrilateral\_default\_traits\_2<K>:: Construct\_parallelogram\_2*

Function class

*op: Point\_2  $\times$  Direction\_2  $\times$  Point\_2  $\times$  Direction\_2  $\times$  Point\_2  $\times$  Point\_2  $\rightarrow$  Rectangle\_2.*

If the points  $p1, p2, p3, p4$  form the boundary of a convex polygon (oriented counterclockwise), *op*( $p1, d1, p2, d2, p3, p4$ ) returns the parallelogram with one of the points on each side and one side parallel to each of  $d1$  and  $d2$ .

*Min\_quadrilateral\_default\_traits\_2<K>:: Construct\_strip\_2*

Function class

*op: Point\_2  $\times$  Direction\_2  $\times$  Point\_2  $\rightarrow$  Strip\_2.*

*op*( $p1, d, p2$ ) returns the strip bounded by the lines through  $p1$  resp.  $p2$  with direction  $d$ .

## Operations

*template < class OutputIterator >*

*OutputIterator*    *t.copy\_rectangle\_vertices\_2( const Rectangle\_2& r, OutputIterator o) const*

copies the four vertices of *r* in counterclockwise order to *o*.

*template < class OutputIterator >*

*OutputIterator*    *t.copy\_parallelogram\_vertices\_2( const Parallelogram\_2& p, OutputIterator o) const*

copies the four vertices of *p* in counterclockwise order to *o*.

*template < class OutputIterator >*

*OutputIterator*    *t.copy\_strip\_lines\_2( const Strip\_2& s, OutputIterator o) const*

copies the two lines bounding *s* to *o*.

Additionally, for each of the predicate and construction functor types listed above, there is a member function that requires no arguments and returns an instance of that functor type. The name of the member function is the uncapitalized name of the type returned with the suffix *\_object* appended. For example, for the functor type *Construct\_vector\_2* the following member function exists:

*Construct\_vector\_2*

*t.construct\_vector\_2\_object() const*

## MinQuadrilateralTraits\_2

### Definition

The concept `MinQuadrilateralTraits_2` defines types and operations needed to compute minimum enclosing quadrilaterals of a planar point set using the functions `min_rectangle_2`, `min_parallelogram_2` and `min_strip_2`.

### Types

<code>MinQuadrilateralTraits_2:: Point_2</code>	type for representing points.
<code>MinQuadrilateralTraits_2:: Vector_2</code>	type for representing vectors.
<code>MinQuadrilateralTraits_2:: Direction_2</code>	type for representing directions.
<code>MinQuadrilateralTraits_2:: Line_2</code>	type for representing lines.
<code>MinQuadrilateralTraits_2:: Rectangle_2</code>	type for representing (not necessarily axis-parallel) rectangles.
<code>MinQuadrilateralTraits_2:: Parallelogram_2</code>	type for representing parallelograms.
<code>MinQuadrilateralTraits_2:: Strip_2</code>	type for representing strips, that is the closed region bounded by two parallel lines.

### Predicates

<code>MinQuadrilateralTraits_2:: Equal_2</code>	a model for <code>Kernel::Equal_2</code> ..... page <a href="#">734</a> .
<code>MinQuadrilateralTraits_2:: Less_xy_2</code>	a model for <code>Kernel::Less_xy_2</code> ..... page ??.
<code>MinQuadrilateralTraits_2:: Less_yx_2</code>	a model for <code>Kernel::Less_yx_2</code> ..... page ??.
<code>MinQuadrilateralTraits_2:: Has_on_negative_side_2</code>	a model for <code>Kernel::Has_on_negative_side_2</code> ..... page ??.
<code>MinQuadrilateralTraits_2:: Compare_angle_with_x_axis_2</code>	a model for <code>Kernel::Compare_angle_with_x_axis_2</code> page ??.
<code>MinQuadrilateralTraits_2:: Area_less_rectangle_2</code>	<p>AdaptableFunctor</p> <p><math>op: Rectangle_2 \times Rectangle_2 \rightarrow bool</math>.</p> <p><math>op(r1,r2)</math> returns true, iff the area of <math>r1</math> is strictly less than the area of <math>r2</math>.</p>

*MinQuadrilateralTraits\_2:: Area\_less\_parallelogram\_2*

AdaptableFunctor

*op: Parallelogram\_2  $\times$  Parallelogram\_2  $\rightarrow$  bool.*

*op(p1,p2)* returns true, iff the area of *p1* is strictly less than the area of *p2*.

*MinQuadrilateralTraits\_2:: Width\_less\_strip\_2*

AdaptableFunctor

*op: Strip\_2  $\times$  Strip\_2  $\rightarrow$  bool.*

*op(s1,s2)* returns true, iff the width of *s1* is strictly less than the width of *s2*.

The following type is used for expensive precondition checking only.

*MinQuadrilateralTraits\_2:: Orientation\_2*

a model for Kernel::Orientation\_2 . . . . . page 771.

## Constructions

page ??.

*MinQuadrilateralTraits\_2:: Construct\_line\_2*

a model for Kernel::Construct\_line\_2 . . . . . page ??.

*MinQuadrilateralTraits\_2:: Construct\_rectangle\_2*

Function class

*op*:  $Point\_2 \times Direction\_2 \times Point\_2 \times Point\_2 \times Point\_2 \rightarrow Rectangle\_2$ .

If the points  $p1, p2, p3, p4$  form the boundary of a convex polygon (oriented counterclockwise), *op*( $p1, d, p2, p3, p4$ ) returns the rectangle with one of the points on each side and one sides parallel to  $d$ .

*MinQuadrilateralTraits\_2:: Construct\_parallelogram\_2*

Function class

*op*:  $Point\_2 \times Direction\_2 \times Point\_2 \times Direction\_2 \times Point\_2 \times Point\_2 \rightarrow Rectangle\_2$ .

If the points  $p1, p2, p3, p4$  form the boundary of a convex polygon (oriented counterclockwise), *op*( $p1, d1, p2, d2, p3, p4$ ) returns the parallelogram with one of the points on each side and one side parallel to each of  $d1$  and  $d2$ .

*MinQuadrilateralTraits\_2:: Construct\_strip\_2*

Function class

*op*:  $Point\_2 \times Direction\_2 \times Point\_2 \rightarrow Strip\_2$ .

*op*( $p1, d, p2$ ) returns the strip bounded by the lines through  $p1$  resp.  $p2$  with direction  $d$ .

## Operations

*template < class OutputIterator >*

*OutputIterator t.copy\_rectangle\_vertices\_2( const Rectangle\_2& r, OutputIterator o) const*

copies the four vertices of  $r$  in counterclockwise order to  $o$ .

*template < class OutputIterator >*

*OutputIterator t.copy\_parallelogram\_vertices\_2( const Parallelogram\_2& p, OutputIterator o) const*

copies the four vertices of  $p$  in counterclockwise order to  $o$ .

*template < class OutputIterator >*

*OutputIterator t.copy\_strip\_lines\_2( const Strip\_2& s, OutputIterator o) const*

copies the two lines bounding  $s$  to  $o$ .

Additionally, for each of the predicate and construction functor types listed above, there must exist a member function that requires no arguments and returns an instance of that functor type. The name of the member function is the uncapitalized name of the type returned with the suffix *\_object* appended. For example, for the functor type *Construct\_vector\_2* the following member function must exist:

*Construct\_vector\_2*

*t.construct\_vector\_2\_object() const*

## CGAL::rectangular\_p\_center\_2

### Definition

The function *rectangular\_p\_center\_2* computes rectilinear  $p$ -centers of a planar point set, i.e. a set of  $p$  points such that the maximum minimal  $L_\infty$ -distance between both sets is minimized.

More formally the problem can be defined as follows.

Given a finite set  $\mathcal{P}$  of points, compute a point set  $\mathcal{C}$  with  $|\mathcal{C}| \leq p$  such that the  $p$ -radius of  $\mathcal{P}$ ,

$$\text{rad}_p(\mathcal{P}) := \max_{P \in \mathcal{P}} \min_{Q \in \mathcal{C}} \|P - Q\|_\infty$$

is minimized. We can interpret  $\mathcal{C}$  as the best approximation (with respect to the given metric) for  $\mathcal{P}$  with at most  $p$  points.

```
#include <CGAL/rectangular_p_center_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class FT, class Traits >
OutputIterator rectangular_p_center_2(
    ForwardIterator f,
    ForwardIterator l,
    OutputIterator o,
    FT& r,
    int p,
    Traits t = Default_traits)
```

computes rectilinear  $p$ -centers for the point set described by the range  $[f, l)$ , sets  $r$  to the corresponding  $p$ -radius, writes the at most  $p$  center points to  $o$  and returns the past-the-end iterator of this sequence.

*Precondition:*

1. The range  $[f, l)$  is not empty.
2.  $2 \leq p \leq 4$ .

The geometric types and operations to be used for the computation are specified by the traits class parameter  $t$ . This parameter can be omitted if *ForwardIterator* refers to a point type from the 2D-Kernel. In this case, a default traits class (*Rectangular\_p\_center\_default\_traits\_2*< $K$ >) is used.

*Requirement:*

1. *Either:* (if no traits parameter is given) Value type of *ForwardIterator* is *CGAL::Point\_2*< $K$ > for some representation class  $K$  and  $FT$  is equivalent to  $K::FT$ ,
2. *Or:* (if a traits parameter is specified) *Traits* is a model for *RectangularPCenterTraits\_2*.
3. *OutputIterator* accepts the value type of *ForwardIterator* as value type.

## See Also

RectangularPCenterTraits\_2 ..... page 3042  
CGAL::Rectangular\_p\_center\_default\_traits\_2<K> ..... page 3039  
CGAL::sorted\_matrix\_search ..... page 3557

## Implementation

The runtime is linear for  $p \in \{2, 3\}$  and  $O(n \cdot \log n)$  for  $p = 4$  where  $n$  is the number of input points. These runtimes are worst case optimal. The 3-center algorithm uses a prune-and-search technique described in [Hof99]. The 4-center implementation uses sorted matrix search [FJ83, FJ84] and fast algorithms for piercing rectangles [SW96].

## Example

The following code generates a random set of ten points and computes its two-centers.

```
#include <CGAL/Cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/rectangular_p_center_2.h>
#include <CGAL/IO/Ostream_iterator.h>
#include <CGAL/algorithm.h>
#include <iostream>
#include <algorithm>
#include <vector>

typedef double FT;

struct Kernel : public CGAL::Cartesian<FT> {};

typedef Kernel::Point_2 Point;
typedef std::vector<Point> Cont;
typedef CGAL::Random_points_in_square_2<Point> Generator;
typedef CGAL::Ostream_iterator<Point, std::ostream> OIterator;

int main()
{
    int n = 10;
    int p = 2;
    OIterator cout_ip(std::cout);
    CGAL::set_pretty_mode(std::cout);

    Cont points;
    CGAL::copy_n(Generator(1), n, std::back_inserter(points));
    std::cout << "Generated Point Set:\n";
    std::copy(points.begin(), points.end(), cout_ip);

    FT p_radius;
    std::cout << "\n\n" << p << "-centers:\n";
    CGAL::rectangular_p_center_2(
        points.begin(), points.end(), cout_ip, p_radius, 3);
    std::cout << "\n\n" << p << "-radius = " << p_radius << std::endl;
```

```
    return 0;
}
// -----
// ** EOF
// -----
```

## CGAL::Rectangular\_p\_center\_default\_traits\_2<K>

### Definition

The class *Rectangular\_p\_center\_default\_traits\_2<K>* defines types and operations needed to compute rectilinear *p*-centers of a planar point set using the function *rectangular\_p\_center\_2*.

### Requirements

The template parameter *K* is a model for *Kernel*.

### Is Model for the Concepts

RectangularPCenterTraits\_2 ..... page [3042](#)

### Types

*Rectangular\_p\_center\_default\_traits\_2<K>:: FT*

typedef to *K::FT*.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Point\_2*

typedef to *K::Point\_2*.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Iso\_rectangle\_2*

typedef to *K::Iso\_rectangle\_2*.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Less\_x\_2*

typedef to *K::Less\_x\_2*.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Less\_y\_2*

typedef to *K::Less\_y\_2*.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Construct\_vertex\_2*

typedef to *K::Construct\_vertex\_2*.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Construct\_iso\_rectangle\_2*

typedef to *K::Construct\_iso\_rectangle\_2*.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Signed\_x\_distance\_2*

adaptable binary function class:  $Point_2 \times Point_2 \rightarrow FT$   
returns the signed distance of two points' x-coordinates.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Signed\_y\_distance\_2*

adaptable binary function class:  $Point_2 \times Point_2 \rightarrow FT$   
returns the signed distance of two points' y-coordinates.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Infinity\_distance\_2*

adaptable binary function class:  $Point_2 \times Point_2 \rightarrow FT$   
returns the  $\|\cdot\|_\infty$  distance of two points.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Signed\_infinity\_distance\_2*

adaptable binary function class:  $Point_2 \times Point_2 \rightarrow FT$   
returns the signed  $\|\cdot\|_\infty$  distance of two points.

*Rectangular\_p\_center\_default\_traits\_2<K>:: Construct\_point\_2\_below\_left\_implicit\_point\_2*

3-argument function class:  $Point_2 \times Point_2 \times FT \rightarrow Point_2$ . For arguments  $(p, q, r)$  it returns the lower-left corner of the iso-oriented square with sidelength  $r$  and upper-right corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

*Rectangular\_p\_center\_default\_traits\_2<K>:: Construct\_point\_2\_below\_right\_implicit\_point\_2*

3-argument function class:  $Point_2 \times Point_2 \times FT \rightarrow Point_2$ . For arguments  $(p, q, r)$  it returns the lower-right corner of the iso-oriented square with sidelength  $r$  and upper-left corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

*Rectangular\_p\_center\_default\_traits\_2<K>:: Construct\_point\_2\_above\_right\_implicit\_point\_2*

3-argument function class:  $Point_2 \times Point_2 \times FT \rightarrow Point_2$ . For arguments  $(p, q, r)$  it returns the upper-right corner of the iso-oriented square with sidelength  $r$  and lower-left corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

*Rectangular\_p\_center\_default\_traits\_2<K>:: Construct\_point\_2\_above\_left\_implicit\_point\_2*

3-argument function class:  $Point_2 \times Point_2 \times FT \rightarrow Point_2$ . For arguments  $(p, q, r)$  it returns the upper-left corner of the iso-oriented square with sidelength  $r$  and lower-right corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

## Operations

For every function class listed above there is a member function to fetch the corresponding function object.

*Inf\_distance\_2* *t.inf\_distance\_2\_object() const*

*Signed\_inf\_distance\_2*

*t.signed\_inf\_distance\_2\_object() const*

*Construct\_vertex\_2* *t.construct\_vertex\_2\_object() const*

*Construct\_iso\_rectangle\_2*

*t.construct\_iso\_rectangle\_2\_object() const*

*Construct\_iso\_rectangle\_2\_below\_left\_point\_2*

*t.construct\_iso\_rectangle\_2\_below\_left\_point\_2\_object() const*

*Construct\_iso\_rectangle\_2\_above\_left\_point\_2*

*t.construct\_iso\_rectangle\_2\_above\_left\_point\_2\_object() const*

*Construct\_iso\_rectangle\_2\_below\_right\_point\_2*

*t.construct\_iso\_rectangle\_2\_below\_right\_point\_2\_object() const*

*Construct\_iso\_rectangle\_2\_above\_right\_point\_2*

*t.construct\_iso\_rectangle\_2\_above\_right\_point\_2\_object() const*

model for Kernel::Construct\_vertex\_2 ..... page ??.

*RectangularPCenterTraits\_2:: Construct\_iso\_rectangle\_2*  
model for Kernel::Construct\_iso\_rectangle\_2 ..... page ??.

*RectangularPCenterTraits\_2:: Signed\_x\_distance\_2*  
adaptable binary function class:  $Point_2 \times Point_2 \rightarrow FT$   
returns the signed distance of two points'  $x$ -coordinates.

*RectangularPCenterTraits\_2:: Signed\_y\_distance\_2*  
adaptable binary function class:  $Point_2 \times Point_2 \rightarrow FT$   
returns the signed distance of two points'  $y$ -coordinates.

*RectangularPCenterTraits\_2:: Infinity\_distance\_2*  
adaptable binary function class:  $Point_2 \times Point_2 \rightarrow FT$   
returns the  $|| \cdot ||_{\infty}$  distance of two points.

*RectangularPCenterTraits\_2:: Signed\_infinity\_distance\_2*

adaptable binary function class:  $Point\_2 \times Point\_2 \rightarrow FT$   
returns the signed  $\| \cdot \|_\infty$  distance of two points.

*RectangularPCenterTraits\_2:: Construct\_point\_2\_below\_left\_implicit\_point\_2*

3-argument function class:  $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$ . For arguments  $(p, q, r)$  it returns the lower-left corner of the iso-oriented square with sidelength  $r$  and upper-right corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

*RectangularPCenterTraits\_2:: Construct\_point\_2\_below\_right\_implicit\_point\_2*

3-argument function class:  $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$ . For arguments  $(p, q, r)$  it returns the lower-right corner of the iso-oriented square with sidelength  $r$  and upper-left corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

*RectangularPCenterTraits\_2:: Construct\_point\_2\_above\_right\_implicit\_point\_2*

3-argument function class:  $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$ . For arguments  $(p, q, r)$  it returns the upper-right corner of the iso-oriented square with sidelength  $r$  and lower-left corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

*RectangularPCenterTraits\_2:: Construct\_point\_2\_above\_left\_implicit\_point\_2*

3-argument function class:  $Point\_2 \times Point\_2 \times FT \rightarrow Point\_2$ . For arguments  $(p, q, r)$  it returns the upper-left corner of the iso-oriented square with sidelength  $r$  and lower-right corner at the intersection of the vertical line through  $p$  and the horizontal line through  $q$ .

## Operations

For every function class listed above there is a member function to fetch the corresponding function object.

```
Inf_distance_2          t.inf_distance_2_object() const
Signed_inf_distance_2
Construct_vertex_2      t.signed_inf_distance_2_object() const
Construct_iso_rectangle_2 t.construct_vertex_2_object() const
                        t.construct_iso_rectangle_2_object() const
```

*Construct\_iso\_rectangle\_2\_below\_left\_point\_2*

*t.construct\_iso\_rectangle\_2\_below\_left\_point\_2\_object() const*

*Construct\_iso\_rectangle\_2\_above\_left\_point\_2*

*t.construct\_iso\_rectangle\_2\_above\_left\_point\_2\_object() const*

*Construct\_iso\_rectangle\_2\_below\_right\_point\_2*

*t.construct\_iso\_rectangle\_2\_below\_right\_point\_2\_object() const*

*Construct\_iso\_rectangle\_2\_above\_right\_point\_2*

*t.construct\_iso\_rectangle\_2\_above\_right\_point\_2\_object() const*

## CGAL::Min\_sphere\_d<Traits>

### Definition

An object of the class *Min\_sphere\_d<Traits>* is the unique sphere of smallest volume enclosing a finite (multi)set of points in  $d$ -dimensional Euclidean space  $\mathbb{E}_d$ . For a set  $P$  we denote by  $ms(P)$  the smallest sphere that contains all points of  $P$ .  $ms(P)$  can be degenerate, i.e.  $ms(P) = \emptyset$  if  $P = \emptyset$  and  $ms(P) = \{p\}$  if  $P = \{p\}$ .

An inclusion-minimal subset  $S$  of  $P$  with  $ms(S) = ms(P)$  is called a *support set*, the points in  $S$  are the *support points*. A support set has size at most  $d + 1$ , and all its points lie on the boundary of  $ms(P)$ . In general, neither the support set nor its size are unique.

The algorithm computes a support set  $S$  which remains fixed until the next insert or clear operation.

**Please note:** This class is (almost) obsolete. The class *CGAL::Min\_sphere\_of\_spheres\_d<Traits>* solves a more general problem and is faster than *Min\_sphere\_d<Traits>* even if used only for points as input. Most importantly, *CGAL::Min\_sphere\_of\_spheres\_d<Traits>* has a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). In contrast, *Min\_sphere\_d<Traits>* is not reliable under floating-point computations. The only advantage of *Min\_sphere\_d<Traits>* over *CGAL::Min\_sphere\_of\_spheres\_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *Min\_sphere\_d<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

```
#include <CGAL/Min_sphere_d.h>
```

### Requirements

The class *Min\_sphere\_d<Traits>* expects a model of the concept *OptimisationDTraits* as its template argument. We provide the models *CGAL::Optimisation\_d\_traits\_2*, *CGAL::Optimisation\_d\_traits\_3* and *CGAL::Optimisation\_d\_traits\_d* for two-, three-, and  $d$ -dimensional points respectively.

### Types

*Min\_sphere\_d<Traits>:: Traits*

*Min\_sphere\_d<Traits>:: FT*                      typedef to *Traits::FT*.

*Min\_sphere\_d<Traits>:: Point*                      typedef to *Traits::Point*.

*Min\_sphere\_d<Traits>:: Point\_iterator*                      non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points used to build the smallest enclosing sphere.

*Min\_sphere\_d<Traits>:: Support\_point\_iterator*                      non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the support points defining the smallest enclosing sphere.

### Creation

*Min\_sphere\_d*<Traits> *min\_sphere*( Traits traits = Traits());

creates a variable of type *Min\_sphere\_d*<Traits> and initializes it to *ms*(  $\emptyset$ ). If the traits parameter is not supplied, the class *Traits* must provide a default constructor.

template < class InputIterator >

*Min\_sphere\_d*<Traits> *min\_sphere*( InputIterator first, InputIterator last, Traits traits = Traits());

creates a variable *min\_sphere* of type *Min\_sphere\_d*<Traits>. It is initialized to *ms*(*P*) with *P* being the set of points in the range [*first*,*last*).

*Requirement:* The value type of *first* and *last* is *Point*. If the traits parameter is not supplied, the class *Traits* must provide a default constructor.

*Precondition:* All points have the same dimension.

int *min\_sphere.number\_of\_points*()

returns the number of points of *min\_sphere*, i.e.  $|P|$ .

int *min\_sphere.number\_of\_support\_points*()

returns the number of support points of *min\_sphere*, i.e.  $|S|$ .

Point\_iterator *min\_sphere.points\_begin*()

returns an iterator referring to the first point of *min\_sphere*.

Point\_iterator *min\_sphere.points\_end*()

returns the corresponding past-the-end iterator.

Support\_point\_iterator *min\_sphere.support\_points\_begin*()

returns an iterator referring to the first support point of *min\_sphere*.

Support\_point\_iterator *min\_sphere.support\_points\_end*()

returns the corresponding past-the-end iterator.

int *min\_sphere.ambient\_dimension*()

returns the dimension of the points in *P*. If *min\_sphere* is empty, the ambient dimension is  $-1$ .

Point *min\_sphere.center*()

returns the center of *min\_sphere*.

*Precondition:* *min\_sphere* is not empty.

FT *min\_sphere.squared\_radius*()

returns the squared radius of *min\_sphere*.

*Precondition:* *min\_sphere* is not empty.

## Predicates

By definition, an empty *Min\_sphere.d*<Traits> has no boundary and no bounded side, i.e. its unbounded side equals the whole space  $\mathbb{E}_d$ .

*Bounded\_side*                      *min\_sphere.bounded\_side( Point p)*

returns *CGAL::ON\_BOUNDED\_SIDE*, *CGAL::ON\_BOUNDARY*, or *CGAL::ON\_UNBOUNDED\_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *min\_sphere*, resp.  
*Precondition*: if *min\_sphere* is not empty, the dimension of *p* equals *ambient\_dimension()*.

*bool*                                  *min\_sphere.has\_on\_bounded\_side( Point p)*

returns *true*, iff *p* lies properly inside *min\_sphere*.  
*Precondition*: if *min\_sphere* is not empty, the dimension of *p* equals *ambient\_dimension()*.

*bool*                                  *min\_sphere.has\_on\_boundary( Point p)*

returns *true*, iff *p* lies on the boundary of *min\_sphere*.  
*Precondition*: if *min\_sphere* is not empty, the dimension of *p* equals *ambient\_dimension()*.

*bool*                                  *min\_sphere.has\_on\_unbounded\_side( Point p)*

returns *true*, iff *p* lies properly outside of *min\_sphere*.  
*Precondition*: if *min\_sphere* is not empty, the dimension of *p* equals *ambient\_dimension()*.

*bool*                                  *min\_sphere.is\_empty()*

returns *true*, iff *min\_sphere* is empty (this implies degeneracy).

*bool*                                  *min\_sphere.is\_degenerate()*

returns *true*, iff *min\_sphere* is degenerate, i.e. if *min\_sphere* is empty or equal to a single point, equivalently if the number of support points is less than 2.

## Modifiers

*void*                                  *min\_sphere.clear()*

resets *min\_sphere* to *ms( 0)*.

*template < class InputIterator >*

*void* *min\_sphere.set( InputIterator first, InputIterator last)*

sets *min\_sphere* to the  $ms(P)$ , where  $P$  is the set of points in the range  $[first, last)$ .  
*Requirement:* The value type of *first* and *last* is *Point*.  
*Precondition:* All points have the same dimension.

*void* *min\_sphere.insert( Point p)*

inserts  $p$  into *min\_sphere*. If  $p$  lies inside the current sphere, this is a constant-time operation, otherwise it might take longer, but usually substantially less than recomputing the smallest enclosing sphere from scratch.  
*Precondition:* The dimension of  $p$  equals *ambient\_dimension()* if *min\_sphere* is not empty.

*template < class InputIterator >*  
*void* *min\_sphere.insert( InputIterator first, InputIterator last)*

inserts the points in the range  $[first, last)$  into *min\_sphere* and recomputes the smallest enclosing sphere, by calling *insert* for all points in the range.  
*Requirement:* The value type of *first* and *last* is *Point*.  
*Precondition:* All points have the same dimension. If *min\_sphere* is not empty, this dimension must be equal to *ambient\_dimension()*.

## Validity Check

An object *min\_sphere* is valid, iff

- *min\_sphere* contains all points of its defining set  $P$ ,
- *min\_sphere* is the smallest sphere containing its support set  $S$ , and
- $S$  is minimal, i.e. no support point is redundant.

*Note:* Under inexact arithmetic, the result of the validation is not reliable, because the checker itself can suffer from numerical problems.

*bool* *min\_sphere.is\_valid( bool verbose = false, int level = 0)*

returns *true*, iff *min\_sphere* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

## Miscellaneous

`const Traits& min_sphere.traits()`

returns a const reference to the traits class object.

## I/O

`std::ostream& os << min_sphere`

writes *min\_sphere* to output stream *os*.

*Requirement:* The output operator is defined for *Point*.

`std::istream& is >> min_sphere&`

reads *min\_sphere* from input stream *is*.

*Requirement:* The input operator is defined for *Point*.

[CGAL::Min\\_annulus\\_d<Traits>](#) ..... page [3059](#)

## Implementation

We implement the algorithm of Welzl with move-to-front heuristic [\[Wel91\]](#) for small point sets, combined with a new efficient method for large sets, which is particularly tuned for moderately large dimension ( $d \leq 20$ ) [\[Gär99\]](#). The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing sphere from scratch. The clear operation and the check for validity each take linear time.

## Example

```
#include <CGAL/Cartesian_d.h>
#include <iostream>
#include <cstdlib>
#include <CGAL/Random.h>
#include <CGAL/Min_sphere_annulus_d_traits_d.h>
#include <CGAL/Min_sphere_d.h>

typedef CGAL::Cartesian_d<double>          K;
typedef CGAL::Min_sphere_annulus_d_traits_d<K> Traits;
typedef CGAL::Min_sphere_d<Traits>         Min_sphere;
typedef K::Point_d                          Point;
```

```

const int n = 10;                // number of points
const int d = 5;                // dimension of points

int main ()
{
    Point      P[n];            // n points
    double     coord[d];        // d coordinates
    CGAL::Random r;             // random number generator

    for (int i=0; i<n; ++i) {
        for (int j=0; j<d; ++j)
            coord[j] = r.get_double();
        P[i] = Point(d, coord, coord+d); // random point
    }

    Min_sphere ms (P, P+n);      // smallest enclosing sphere

    CGAL::set_pretty_mode (std::cout);
    std::cout << ms;            // output the sphere

    return 0;
}

```

## MinSphereAnnulusDTraits

### Definition

This concept defines the requirements for traits classes of  $d$ -dimensional min sphere and min annulus algorithms.

### Types

<i>MinSphereAnnulusDTraits:: Point_d</i>	point type used to represent the input points.
<i>MinSphereAnnulusDTraits:: Rep_tag</i>	compile time tag to distinguish between Cartesian and homogeneous representation of the input points. <i>Rep_tag</i> has to be either <i>CGAL::Cartesian_tag</i> or <i>CGAL::Homogeneous_tag</i> .
<i>MinSphereAnnulusDTraits:: RT</i>	number type used to represent the coordinates of the input points. It has to be a model for <i>RingNumberType</i> .
<i>MinSphereAnnulusDTraits:: FT</i>	number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. <i>FT</i> has to be either <i>RT</i> or <i>CGAL::Quotient&lt;RT&gt;</i> if the input points have Cartesian or homogeneous representation, respectively (cf. <i>Rep_tag</i> ).
<i>MinSphereAnnulusDTraits:: Access_dimension_d</i>	data accessor object used to access the dimension of the input points.
<i>MinSphereAnnulusDTraits:: Access_coordinates_begin_d</i>	data accessor object used to access the coordinates of the input points.
<i>MinSphereAnnulusDTraits:: Construct_point_d</i>	constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.
The following two number types are only needed for <i>CGAL::Min_annulus_d&lt;Traits&gt;</i> and <i>CGAL::Polytope_distance_d&lt;Traits&gt;</i> .	
<i>MinSphereAnnulusDTraits:: ET</i>	exact number type used to do the exact computations in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be an implicit conversion from <i>RT</i> to <i>ET</i> available.
<i>MinSphereAnnulusDTraits:: NT</i>	fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be implicit conversions from <i>RT</i> to <i>NT</i> and from <i>NT</i> to <i>ET</i> available.

## Creation

Only default and copy constructor are required.

```
MinSphereAnnulusDTraits traits;
```

```
MinSphereAnnulusDTraits traits( MinSphereAnnulusDTraits);
```

## Operations

The following functions just return the corresponding function class object.

```
Access_dimension_d traits.access_dimension_d_object()
```

```
Access_coordinates_begin_d traits.access_coordinates_begin_d_object()
```

```
Construct_point_d traits.construct_point_d_object()
```

## Has Models

## CGAL::Min\_sphere\_annulus\_d\_traits\_2&lt;K,ET,NT&gt;

### Definition

The class `Min_sphere_annulus_d_traits_2<K,ET,NT>` is a traits class for the  $d$ -dimensional optimisation algorithms using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_sphere_annulus_d_traits_2.h>
```

## Requirements

The template parameter  $K$  is a model for *Kernel*. Template parameters  $ET$  and  $NT$  are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

## Is Model for the Concepts

MinSphereAnnulusDTraits ..... page 3099

## Types

```
Min_sphere_annulus_d_traits_2<K,ET,NT>::Point_d typedef to K::Point_2.
```

$$Min\_sphere\_annulus\_d\_traits\_2<K,ET,NT>::Rep\_tag \quad \text{typedef to } K::Rep\_tag.$$
$$Min\_sphere\_annulus\_d\_traits\_2\langle K, ET, NT \rangle :: RT \quad \text{typedef to } K :: RT.$$
$$Min\_sphere\_annulus\_d\_traits\_2<K,ET,NT>::FT \quad \text{typedef to } K::FT.$$
$$\text{Min\_sphere\_annulus\_d\_traits\_2} \langle K, ET, NT \rangle :: \text{Access\_dimension\_d}$$

$$\text{typedef to } K :: \text{Access\_dimension\_2.}$$

```
Min_sphere_annulus_d_traits_2<K,ET,NT>::Access_coordinates_begin_d  
typedef to K::Access_coordinates_begin_2.
```

$$\text{Min\_sphere\_annulus\_d\_traits\_2}\langle K, ET, NT \rangle:: \text{Construct\_point\_d}$$

$$\text{typedef to } K::\text{Construct\_point\_2}.$$

*Min\_sphere\_annulus\_d\_traits\_2*<*K*,*ET*,*NT*>::*ET*      second template parameter (default is *K*::*RT*).

*Min\_sphere\_annulus\_d\_traits\_2*<*K*,*ET*,*NT*>::*NT*      third template parameter (default is *K*::*RT*).

## Creation

*Min\_sphere\_annulus\_d\_traits\_2*<*K,ET,NT*> traits;      default constructor.

*Min\_sphere\_annulus\_d\_traits\_2*<*K,ET,NT*> traits( *Min\_sphere\_annulus\_d\_traits\_2*<*K,ET,NT*>);  
copy constructor.

## Operations

The following functions just return the corresponding function class object.

*Access\_dimension\_d*      *traits.access\_dimension\_d\_object()*

*Access\_coordinates\_begin\_d*      *traits.access\_coordinates\_begin\_d\_object()*

*Construct\_point\_d*      *traits.construct\_point\_d\_object()*

## CGAL::Min\_annulus\_d<Traits>

### Definition

An object of the class *Min\_annulus\_d<Traits>* is the unique annulus (region between two concentric spheres with radii  $r$  and  $R$ ,  $r \leq R$ ) enclosing a finite set of points in  $d$ -dimensional Euclidean space  $\mathbb{E}_d$ , where the difference  $R^2 - r^2$  is minimal. For a point set  $P$  we denote by  $ma(P)$  the smallest annulus that contains all points of  $P$ . Note that  $ma(P)$  can be degenerate, i.e.  $ma(P) = \emptyset$  if  $P = \emptyset$  and  $ma(P) = \{p\}$  if  $P = \{p\}$ .

An inclusion-minimal subset  $S$  of  $P$  with  $ma(S) = ma(P)$  is called a *support set*, the points in  $S$  are the *support points*. A support set has size at most  $d + 2$ , and all its points lie on the boundary of  $ma(P)$ . In general, the support set is not necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g.  $P$  may be empty or points may occur more than once. The algorithm computes a support set  $S$  which remains fixed until the next set, insert, or clear operation.

```
#include <CGAL/Min_annulus_d.h>
```

### Requirements

The template parameter *Traits* is a model for *OptimisationDTraits*.

We provide the models *Optimisation\_d\_traits\_2*, *Optimisation\_d\_traits\_3*, and *Optimisation\_d\_traits\_d* using the two-, three-, and  $d$ -dimensional CGAL kernel, respectively.

### Types

*Min\_annulus\_d<Traits>::Point*    typedef to *Traits::Point\_d*. Point type used to represent the input points.

*Min\_annulus\_d<Traits>::FT*    typedef to *Traits::FT*. Number type used to return the squared radii of the smallest enclosing annulus.

*Min\_annulus\_d<Traits>::ET*    typedef to *Traits::ET*. Number type used to do the exact computations in the underlying solver for quadratic programs (cf. **Implementation**).

*Min\_annulus\_d<Traits>::Point\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the points of the smallest enclosing annulus.

*Min\_annulus\_d<Traits>::Support\_point\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing annulus.

*Min\_annulus\_d<Traits>::Inner\_support\_point\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the inner support points of the smallest enclosing annulus.

*Min\_annulus\_d<Traits>:: Outer\_support\_point\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the outer support points of the smallest enclosing annulus.

*Min\_annulus\_d<Traits>:: Coordinate\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *ET*. Used to access the coordinates of the center of the smallest enclosing annulus.

## Creation

```
Min_annulus_d<Traits> min_annulus( Traits traits = Traits(),  
    int verbose = 0,  
    std::ostream& stream = std::cout)  
  
    initializes min_annulus to ma( $\emptyset$ ).
```

```
template < class InputIterator >  
Min_annulus_d<Traits> min_annulus( InputIterator first,  
    InputIterator last,  
    Traits traits = Traits(),  
    int verbose = 0,  
    std::ostream& stream = std::cout)  
  
    initializes min_annulus to ma(P) with P being the set of points in  
    the range [first,last).  
Requirement: The value type of InputIterator is Point.  
Precondition: All points have the same dimension.
```

## Access Functions

```
int min_annulus.ambient_dimension()  
  
    returns the dimension of the points in P. If min_annulus is empty,  
    the ambient dimension is  $-1$ .
```

```
int min_annulus.number_of_points()  
  
    returns the number of points of min_annulus, i.e.  $|P|$ .
```

```
int min_annulus.number_of_support_points()  
  
    returns the number of support points of min_annulus, i.e.  $|S|$ .
```

<i>int</i>	<i>min_annulus.number_of_inner_support_points()</i>	returns the number of support points of <i>min_annulus</i> which lie on the inner sphere.
<i>int</i>	<i>min_annulus.number_of_outer_support_points()</i>	returns the number of support points of <i>min_annulus</i> which lie on the outer sphere.
<i>Point_iterator</i>	<i>min_annulus.points_begin()</i>	returns an iterator referring to the first point of <i>min_annulus</i> .
<i>Point_iterator</i>	<i>min_annulus.points_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_iterator</i>	<i>min_annulus.support_points_begin()</i>	returns an iterator referring to the first support point of <i>min_annulus</i> . <i>Precondition:</i> <i>ma(P)</i> is not degenerate, i.e., <i>number_of_support_points()</i> is at least one.
<i>Support_point_iterator</i>	<i>min_annulus.support_points_end()</i>	returns the corresponding past-the-end iterator. <i>Precondition:</i> <i>ma(P)</i> is not degenerate, i.e., <i>number_of_support_points()</i> is at least one.
<i>Inner_support_point_iterator</i>	<i>min_annulus.inner_support_points_begin()</i>	returns an iterator referring to the first inner support point of <i>min_annulus</i> .
<i>Inner_support_point_iterator</i>	<i>min_annulus.inner_support_points_end()</i>	returns the corresponding past-the-end iterator.
<i>Outer_support_point_iterator</i>	<i>min_annulus.outer_support_points_begin()</i>	returns an iterator referring to the first outer support point of <i>min_annulus</i> .
<i>Outer_support_point_iterator</i>	<i>min_annulus.outer_support_points_end()</i>	returns the corresponding past-the-end iterator.
<i>Point</i>	<i>min_annulus.center()</i>	returns the center of <i>min_annulus</i> . <i>Requirement:</i> An implicit conversion from <i>ET</i> to <i>RT</i> is available. <i>Precondition:</i> <i>min_annulus</i> is not empty.
<i>FT</i>	<i>min_annulus.squared_inner_radius()</i>	returns the squared inner radius of <i>min_annulus</i> . <i>Requirement:</i> An implicit conversion from <i>ET</i> to <i>RT</i> is available. <i>Precondition:</i> <i>min_annulus</i> is not empty.

*FT*      *min\_annulus.squared\_outer\_radius()*

returns the squared outer radius of *min\_annulus*.  
*Requirement:* An implicit conversion from *ET* to *RT* is available.  
*Precondition:* *min\_annulus* is not empty.

*Coordinate\_iterator*  
*min\_annulus.center\_coordinates\_begin()*

returns an iterator referring to the first coordinate of the center of *min\_annulus*.  
*Note:* The coordinates have a rational representation, i.e. the first  $d$  elements of the iterator range are the numerators and the  $(d+1)$ -st element is the common denominator.

*Coordinate\_iterator*  
*min\_annulus.center\_coordinates\_end()*

returns the corresponding past-the-end iterator.

*ET*      *min\_annulus.squared\_inner\_radius\_numerator()*

returns the numerator of the squared inner radius of *min\_annulus*.

*ET*      *min\_annulus.squared\_outer\_radius\_numerator()*

returns the numerator of the squared outer radius of *min\_annulus*.

*ET*      *min\_annulus.squared\_radii\_denominator()*

returns the denominator of the squared radii of *min\_annulus*.

## Predicates

The bounded area of the smallest enclosing annulus lies between the inner and the outer sphere. The boundary is the union of both spheres. By definition, an empty annulus has no boundary and no bounded side, i.e. its unbounded side equals the whole space  $\mathbb{E}_d$ .

*CGAL::Bounded\_side*

*min\_annulus.bounded\_side( Point p)*

returns *CGAL::ON\_BOUNDED\_SIDE*, *CGAL::ON\_BOUNDARY*, or *CGAL::ON\_UNBOUNDED\_SIDE* iff  $p$  lies properly inside, on the boundary, or properly outside of *min\_annulus*, resp.  
*Precondition:* The dimension of  $p$  equals *min\_annulus.ambient\_dimension()* if *min\_annulus* is not empty.

*bool*      *min\_annulus.has\_on\_bounded\_side( Point p)*

returns *true*, iff  $p$  lies properly inside *min\_annulus*.  
*Precondition:* The dimension of  $p$  equals *min\_annulus.ambient\_dimension()* if *min\_annulus* is not empty.

*bool*            *min\_annulus.has\_on\_boundary( Point p)*

returns *true*, iff *p* lies on the boundary of *min\_annulus*.  
*Precondition:* The dimension of *p* equals *min\_annulus.ambient\_dimension()* if *min\_annulus* is not empty.

*bool*            *min\_annulus.has\_on\_unbounded\_side( Point p)*

returns *true*, iff *p* lies properly outside of *min\_annulus*.  
*Precondition:* The dimension of *p* equals *min\_annulus.ambient\_dimension()* if *min\_annulus* is not empty.

*bool*            *min\_annulus.is\_empty()*            returns *true*, iff *min\_annulus* is empty (this implies degeneracy).

*bool*            *min\_annulus.is\_degenerate()*

returns *true*, iff *min\_annulus* is degenerate, i.e. if *min\_annulus* is empty or equal to a single point.

## Modifiers

*void*            *min\_annulus.clear()*            resets *min\_annulus* to *ma(∅)*.

*template < class InputIterator >*  
*void*            *min\_annulus.set( InputIterator first, InputIterator last)*

sets *min\_annulus* to *ma(P)*, where *P* is the set of points in the range *[first,last)*.  
*Requirement:* The value type of *InputIterator* is *Point*.  
*Precondition:* All points have the same dimension.

*void*            *min\_annulus.insert( Point p)*

inserts *p* into *min\_annulus*.  
*Precondition:* The dimension of *p* equals *min\_annulus.ambient\_dimension()* if *min\_annulus* is not empty.

*template < class InputIterator >*  
*void*            *min\_annulus.insert( InputIterator first, InputIterator last)*

inserts the points in the range *[first,last)* into *min\_annulus* and re-computes the smallest enclosing annulus.  
*Requirement:* The value type of *InputIterator* is *Point*.  
*Precondition:* All points have the same dimension. If *min\_annulus* is not empty, this dimension must be equal to *min\_annulus.ambient\_dimension()*.

## Validity Check

An object *min\_annulus* is valid, iff

- *min\_annulus* contains all points of its defining set *P*,
- *min\_annulus* is the smallest annulus containing its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

*Note:* In this release only the first item is considered by the validity check.

*bool min\_annulus.is\_valid( bool verbose = false, int level = 0)*

returns *true*, iff *min\_annulus* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

## Miscellaneous

*const Traits&*

*min\_annulus.traits()* returns a const reference to the traits class object.

## I/O

*std::ostream&*

*std::ostream& os << min\_annulus*

writes *min\_annulus* to output stream *os*.  
*Requirement:* The output operator is defined for *Point*.

*std::istream&*

*std::istream& is >> min\_annulus&*

reads *min\_annulus* from input stream *is*.  
*Requirement:* The input operator is defined for *Point*.

## Implementation

The problem of finding the smallest enclosing annulus of a finite point set can be formulated as an optimization problem with linear constraints and a linear objective function. The solution is obtained using our exact solver for linear and quadratic programs [GS00].

The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point takes almost always linear time. The clear operation and the check for validity each take linear time.

## CGAL::Min\_sphere\_of\_spheres\_d<Traits>

### Definition

An object of the class *Min\_sphere\_of\_spheres\_d<Traits>* is a data structure that represents the unique sphere of smallest volume enclosing a finite set of spheres in  $d$ -dimensional Euclidean space  $\mathbb{E}_d$ . For a set  $S$  of spheres we denote by  $ms(S)$  the smallest sphere that contains all spheres of  $S$ ; we call  $ms(S)$  the *minsphere* of  $S$ .  $ms(S)$  can be degenerate, i.e.,  $ms(S) = \emptyset$ , if  $S = \emptyset$  and  $ms(S) = \{s\}$ , if  $S = \{s\}$ . Any sphere in  $S$  may be degenerate, too, i.e., any sphere from  $S$  may be a point. Also,  $S$  may contain several copies of the same sphere.

An inclusion-minimal subset  $R$  of  $S$  with  $ms(R) = ms(S)$  is called a *support set* for  $ms(S)$ ; the spheres in  $R$  are the *support spheres*. A support set has size at most  $d + 1$ , and all its spheres lie on the boundary of  $ms(S)$ . (A sphere  $s'$  is said to *lie on the boundary* of a sphere  $s$ , if  $s'$  is contained in  $s$  and if their boundaries intersect.) In general, the support set is not unique.

The algorithm computes the center and the radius of  $ms(S)$ , and finds a support set  $R$  (which remains fixed until the next *insert()*, *clear()* or *set()* operation). We also provide a specialization of the algorithm for the case when the center coordinates and radii of the input spheres are floating-point numbers. This specialized algorithm uses floating-point arithmetic only, is very fast and especially tuned for stability and robustness. Still, its output may be incorrect in some (rare) cases; termination is guaranteed.

When default constructed, an instance of type *Min\_sphere\_of\_spheres\_d<Traits>* represents the set  $S = \emptyset$ , together with its minsphere  $ms(S) = \emptyset$ . You can add spheres to the set  $S$  by calling *insert()*. Querying the minsphere is done by calling the routines *is\_empty()*, *radius()* and *center\_cartesian\_begin()*, among others.

In general, the radius and the Euclidean center coordinates of  $ms(S)$  need not be rational. Consequently, the algorithm computing the exact minsphere will have to deal with algebraic numbers. Fortunately, both the radius and the coordinates of the minsphere are numbers of the form  $a_i + b_i\sqrt{t}$ , where  $a_i, b_i, t \in \mathbb{Q}$  and where  $t \geq 0$  is the same for all coordinates and the radius. Thus, the exact minsphere can be described by the number  $t$ , which is called the sphere's *discriminant*, and by  $d + 1$  pairs  $(a_i, b_i) \in \mathbb{Q}^2$  (one for the radius and  $d$  for the center coordinates).

```
#include <CGAL/Min_sphere_of_spheres_d.h>
```

**Note:** This class (almost) replaces *CGAL::Min\_sphere\_d<Traits>*, which solves the less general problem of finding the smallest enclosing ball of a set of *points*. *Min\_sphere\_of\_spheres\_d<Traits>* is faster than *CGAL::Min\_sphere\_d<Traits>*, and in contrast to the latter provides a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). The only advantage of *CGAL::Min\_sphere\_d<Traits>* over *Min\_sphere\_of\_spheres\_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *CGAL::Min\_sphere\_d<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

### Requirements

The class *Min\_sphere\_of\_spheres\_d<Traits>* expects a model of the concept *MinSphereOfSpheresTraits* as its template argument.

### Types

*Min\_sphere\_of\_spheres\_d<Traits>::Sphere* is a typedef to *Traits::Sphere*.

<i>Min_sphere_of_spheres_d&lt;Traits&gt;:: FT</i>	is a typedef to <i>Traits::FT</i> .
<i>Min_sphere_of_spheres_d&lt;Traits&gt;:: Result</i>	is the type of the radius and of the center coordinates of the computed minsphere: When <i>FT</i> is an inexact number type ( <i>double</i> , for instance), then <i>Result</i> is simply <i>FT</i> . However, when <i>FT</i> is an exact number type, then <i>Result</i> is a typedef to a derived class of <i>std::pair&lt;FT,FT&gt;</i> ; an instance of this type represents the number $a + b\sqrt{t}$ , where <i>a</i> is the first and <i>b</i> the second element of the pair and where the number <i>t</i> is accessed using the member function <i>discriminant()</i> of class <i>Min_sphere_of_spheres_d&lt;Traits&gt;</i> .
<i>Min_sphere_of_spheres_d&lt;Traits&gt;:: Algorithm</i>	is either <i>CGAL::LP_algorithm</i> or <i>CGAL::Farthest_first_heuristic</i> . As is described in the documentation of concept <i>MinSphereOfSpheresTraits</i> , the type <i>Algorithm</i> reflects the method which is used to compute the minsphere. (Normally, <i>Algorithm</i> coincides with <i>Traits::Algorithm</i> . However, if the method <i>Traits::Algorithm</i> should not be supported anymore in a future release, then <i>Algorithm</i> will have another type.)
<i>Min_sphere_of_spheres_d&lt;Traits&gt;:: Support_iterator</i>	non-mutable model of the STL concept <i>BidirectionalIterator</i> with value type <i>Sphere</i> . Used to access the support spheres defining the smallest enclosing sphere.
<i>Min_sphere_of_spheres_d&lt;Traits&gt;:: Cartesian_const_iterator</i>	non-mutable model of the STL concept <i>BidirectionalIterator</i> to access the center coordinates of the minsphere.

## Creation

<i>Min_sphere_of_spheres_d&lt;Traits&gt; minsphere( Traits traits = Traits());</i>	creates a variable of type <i>Min_sphere_of_spheres_d&lt;Traits&gt;</i> and initializes it to <i>ms( 0)</i> . If the traits parameter is not supplied, the class <i>Traits</i> must provide a default constructor.
<i>template &lt; typename InputIterator &gt;</i> <i>Min_sphere_of_spheres_d&lt;Traits&gt; minsphere( InputIterator first, InputIterator last, Traits traits = Traits());</i>	creates a variable <i>minsphere</i> of type <i>Min_sphere_of_spheres_d&lt;Traits&gt;</i> and inserts (cf. <i>insert()</i> ) the spheres from the range <i>[first,last)</i> . <i>Requirement:</i> The value type of <i>first</i> and <i>last</i> is <i>Sphere</i> . If the traits parameter is not supplied, the class <i>Traits</i> must provide a default constructor.

## Access Functions

<i>Support_iterator</i>	<i>minsphere.support_begin()</i>	returns an iterator referring to the first support sphere of <i>minsphere</i> .
<i>Support_iterator</i>	<i>minsphere.support_end()</i>	returns the corresponding past-the-end iterator.
<i>FT</i>	<i>minsphere.discriminant()</i>	<p>returns the discriminant of <i>minsphere</i>. This number is undefined when <i>FT</i> is an inexact number type. When <i>FT</i> is exact, the center coordinates and the radius of the minsphere are numbers of the form <math>a + b\sqrt{t}</math>, where <math>t</math> is the discriminant of the minsphere as returned by this function.</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty, and <i>FT</i> is an exact number type.</p>
<i>Result</i>	<i>minsphere.radius()</i>	<p>returns the radius of <i>minsphere</i>. If <i>FT</i> is an exact number type then the radius of the minsphere is the real number <math>a + b\sqrt{t}</math>, where <math>t</math> is the minsphere's discriminant, <math>a</math> is the first and <math>b</math> the second component of the pair returned by <i>radius()</i>.</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty.</p>
<i>Cartesian_const_iterator</i>	<i>minsphere.center_cartesian_begin()</i>	<p>returns a const-iterator to the first of the <i>Traits::D</i> center coordinates of <i>minsphere</i>. The iterator returns objects of type <i>Result</i>. If <i>FT</i> is an exact number type, then a center coordinate is represented by a pair <math>(a, b)</math> describing the real number <math>a + b\sqrt{t}</math>, where <math>t</math> is the minsphere's discriminant (cf. <i>discriminant()</i>).</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty.</p>
<i>Cartesian_const_iterator</i>	<i>minsphere.center_cartesian_end()</i>	<p>returns the corresponding past-the-end iterator, i.e. <i>center_cartesian_begin()+Traits::D</i>.</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty.</p>

## Predicates

<i>bool</i>	<i>minsphere.is_empty()</i>	returns <i>true</i> , iff <i>minsphere</i> is empty, i.e. iff $ms(S) = \emptyset$ .
-------------	-----------------------------	---

## Modifiers

*void*                      *minsphere.clear()*              resets *minsphere* to  $ms(\emptyset)$ , with  $S := \emptyset$ .

*template* < class *InputIterator* >

*void*                      *minsphere.set( InputIterator first, InputIterator last)*

sets *minsphere* to the  $ms(S)$ , where  $S$  is the set of spheres in the range  $[first, last)$ .

*Requirement:* The value type of *first* and *last* is *Sphere*.

*void*                      *minsphere.insert( Sphere s)*

inserts the sphere  $s$  into the set  $S$  of instance *minsphere*.

*template* < class *InputIterator* >

*void*                      *minsphere.insert( InputIterator first, InputIterator last)*

inserts the spheres in the range  $[first, last)$  into the set  $S$  of instance *minsphere*.

*Requirement:* The value type of *first* and *last* is *Sphere*.

## Validity Check

An object *minsphere* is valid, iff

- *minsphere* contains all spheres of its defining set  $S$ ,
- *minsphere* is the smallest sphere containing its support set  $R$ , and
- $R$  is minimal, i.e., no support sphere is redundant.

*bool*                      *minsphere.is\_valid()*              returns *true*, iff *minsphere* is valid. When *FT* is inexact, this routine always returns *true*.

## Miscellaneous

*const Traits&*              *minsphere.traits()*              returns a const reference to the traits class object.

## Implementation

We implement two algorithms, the LP-algorithm and a heuristic [MSW92]. As described in the documentation of concept *MinSphereOfSpheresTraits*, each has its advantages and disadvantages: Our implementation of the LP-algorithm has maximal expected running time  $O(2^d n)$ , while the heuristic comes without any complexity guarantee. In particular, the LP-algorithm runs in linear time for fixed dimension  $d$ . (These running times hold for the arithmetic model, so they count the number of operations on the number type  $FT$ .)

On the other hand, the LP-algorithm is, for inexact number types  $FT$ , much worse at handling degeneracies and should therefore not be used in such a case. (For exact number types  $FT$ , both methods handle all kinds of degeneracies.)

Currently, we require *Traits::FT* to be either an exact number type or *double* or *float*; other inexact number types are not supported at this time. Also, the current implementation only handles spheres with Cartesian coordinates; homogenous representation is not supported yet.

## Example

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/Random.h>
#include <CGAL/Gmpq.h>
#include <CGAL/Min_sphere_of_spheres_d.h>
#include <vector>

const int N = 1000;           // number of spheres
const int D = 3;             // dimension of points
const int LOW = 0, HIGH = 10000; // range of coordinates and radii

typedef CGAL::Gmpq            FT;
//typedef double              FT;
typedef CGAL::Cartesian_d<FT> K;
typedef CGAL::Min_sphere_of_spheres_d_traits_d<K,FT,D> Traits;
typedef CGAL::Min_sphere_of_spheres_d<Traits> Min_sphere;
typedef K::Point_d            Point;
typedef Traits::Sphere        Sphere;

int main () {
    std::vector<Sphere> S;           // n spheres
    FT coord[D];                   // d coordinates
    CGAL::Random r;                 // random number generator

    for (int i=0; i<N; ++i) {
        for (int j=0; j<D; ++j)
            coord[j] = r.get_int(LOW,HIGH);
        Point p(D,coord,coord+D); // random center...
        S.push_back(Sphere(p,r.get_int(LOW,HIGH))); // ...and random radius
    }

    Min_sphere ms(S.begin(),S.end()); // check in the spheres
    CGAL_assertion(ms.is_valid());
}
```

# MinSphereOfSpheresTraits

## Definition

A model of concept *MinSphereOfSpheresTraits* must provide the following constants, types, predicates and operations.

## Has Models

*CGAL::Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>  
*CGAL::Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>  
*CGAL::Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>

## Constants

*MinSphereOfSpheresTraits:: D* specifies the dimension of the spheres you want to compute the minsphere of.

## Types

*MinSphereOfSpheresTraits:: Sphere* is a typedef to to some class representing a sphere. (The package will compute the minsphere of spheres of type *Sphere*.) The type *Sphere* must provide a copy constructor.

*MinSphereOfSpheresTraits:: FT* is a (exact or inexact) field number type.  
*Requirement:* Currently, *FT* must either be *double* or *float*, or an exact field number type. (An *exact* number type is one which evaluates arithmetic expressions involving the four basic operations and comparisons with infinite precision, that is, like in  $\mathbb{R}$ .)

*MinSphereOfSpheresTraits:: Cartesian\_const\_iterator* non-mutable model of the STL concept *ForwardIterator* with value type *FT*. Used to access the center coordinates of a sphere.

*MinSphereOfSpheresTraits:: Use\_square\_roots*

must typedef to either *CGAL::Tag\_true* or *CGAL::Tag\_false*. The algorithm uses (depending on the type *MinSphereOfSpheresTraits::Algorithm*) floating-point arithmetic internally for some intermediate computations. The type *Use\_square\_roots* affects how these calculations are done: When *Use\_square\_roots* is *Tag\_true*, the algorithm computing the minsphere will perform square-root operations on *doubles* and *floats* where appropriate. On the other hand, if *Use\_square\_roots* is *CGAL::Tag\_false*, the algorithm will work without doing square-roots.

*Note:* On some platforms the algorithm is much faster when square-roots are disabled (due to lacking hardware support).

*MinSphereOfSpheresTraits:: Algorithm*

selects the method to compute the minsphere with. It must typedef to either *CGAL::Default\_algorithm*, *CGAL::LP\_algorithm* or *CGAL::Farthest\_first\_heuristic*. The recommended choice is the first, which is a synonym to the one of the other two methods which we consider “the best in practice.” In case of *CGAL::LP\_algorithm*, the minsphere will be computed using the LP-algorithm [MSW92], which in our implementation has maximal expected running time  $O(2^d n)$  (in the number of operations on the number type *FT*). In case of *CGAL::Farthest\_first\_heuristic*, a simple heuristic will be used instead which seems to work fine in practice, but comes without a guarantee on the running time. For an inexact number type *FT* we strongly recommend *CGAL::Default\_algorithm*, or, if you want, *CGAL::Farthest\_first\_heuristic*, since these handle most degeneracies in a satisfying manner. Notice that this compile-time flag is taken as a hint only. Should one of the methods not be available anymore in a future release, then the default algorithm will be chosen.

## Access Functions

*FT*                      *traits.radius( Sphere s)*

returns the radius of sphere *s*.

*Postcondition:* The returned number is greater or equal to 0.

*Cartesian\_const\_iterator*

*traits.center\_cartesian\_begin( Sphere s)*

returns an iterator referring to the first of the *D* Cartesian coordinates of the center of *s*.

## CGAL::Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>

### Definition

The class *Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point\_2* to represent circles.

### Is Model for the Concepts

*MinSphereOfSpheresTraits*

### Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag\_false* and *CGAL::Default\_algorithm*, respectively.

The template parameters of class *Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

*Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>:: K*

is a model for *Kernel*.

*Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>:: FT*

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

*Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>:: UseSqrt*

fulfills the requirements of type *Use\_square\_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag\_true* or *Tag\_false*.

*Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>:: Algorithm*

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default\_algorithm*, *LP\_algorithm* or *Farthest\_first\_heuristic*.

### Constants

*Min\_sphere\_of\_spheres\_d\_traits\_2<K,FT,UseSqrt,Algorithm>:: D*

is the constant 2, i.e. the dimension of  $\mathbb{R}^2$ .

## Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

*Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*FT*

*Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Use\_square\_roots*

*Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Algorithm*

*Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Radius*

is a typedef to the template parameter *FT*

*Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Point*

is a typedef to *K::Point\_2*.

*Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Sphere*

is a typedef to *std::pair<Point,Radius>*.

*Min\_sphere\_of\_spheres\_d\_traits\_2*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Cartesian\_const\_iterator*

is a typedef to *K::Cartesian\_const\_iterator\_2*.

## Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point\_2*:

*FT*                      *traits.radius( Sphere s)*

maps to *s.second*.

*Cartesian\_const\_iterator*

*traits.center\_cartesian\_begin( Sphere s)*

maps to *s.first.cartesian\_begin()*.

## CGAL::Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>

### Definition

The class *Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point\_3* to represent circles.

### Is Model for the Concepts

*MinSphereOfSpheresTraits*

### Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag\_false* and *CGAL::Default\_algorithm*, respectively.

The template parameters of class *Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

*Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>:: K*

is a model for *Kernel*.

*Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>:: FT*

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

*Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>:: UseSqrt*

fulfills the requirements of type *Use\_square\_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag\_true* or *Tag\_false*.

*Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>:: Algorithm*

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default\_algorithm*, *LP\_algorithm* or *Farthest\_first\_heuristic*.

### Constants

*Min\_sphere\_of\_spheres\_d\_traits\_3<K,FT,UseSqrt,Algorithm>:: D*

is the constant 3, i.e. the dimension of  $\mathbb{R}^3$ .

## Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

*Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*FT*

*Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Use\_square\_roots*

*Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Algorithm*

*Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Radius*

is a typedef to the template parameter *FT*

*Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Point*

is a typedef to *K::Point\_3*.

*Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Sphere*

is a typedef to *std::pair<Point,Radius>*.

*Min\_sphere\_of\_spheres\_d\_traits\_3*<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Cartesian\_const\_iterator*

is a typedef to *K::Cartesian\_const\_iterator\_2*.

## Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point\_3*:

*FT*                      *traits.radius( Sphere s)*

maps to *s.second*.

*Cartesian\_const\_iterator*

*traits.center\_cartesian\_begin( Sphere s)*

maps to *s.first.cartesian\_begin()*.

## CGAL::Min\_sphere\_of\_spheres\_d\_traits\_d<K,FT,Dim,UseSqrt,Algorithm>

### Definition

The class *Min\_sphere\_of\_spheres\_d\_traits\_d*<K,FT,Dim,UseSqrt,Algorithm> is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point\_d* to represent circles.

### Is Model for the Concepts

*MinSphereOfSpheresTraits*

### Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag\_false* and *CGAL::Default\_algorithm*, respectively.

The template parameters of class *Min\_sphere\_of\_spheres\_d\_traits\_d*<K,FT,UseSqrt,Algorithm> must fulfill the following requirements:

*Min\_sphere\_of\_spheres\_d\_traits\_d*<K,FT,Dim,UseSqrt,Algorithm>:: *K*

is a model for *Kernel*.

*Min\_sphere\_of\_spheres\_d\_traits\_d*<K,FT,Dim,UseSqrt,Algorithm>:: *FT*

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

*Min\_sphere\_of\_spheres\_d\_traits\_d*<K,FT,Dim,UseSqrt,Algorithm>:: *UseSqrt*

fulfills the requirements of type *Use\_square\_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag\_true* or *Tag\_false*.

*Min\_sphere\_of\_spheres\_d\_traits\_d*<K,FT,Dim,UseSqrt,Algorithm>:: *Algorithm*

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default\_algorithm*, *LP\_algorithm* or *Farthest\_first\_heuristic*.

## Constants

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*D*

is the constant *Dim*.

## Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*FT*

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Use\_square\_roots*

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Algorithm*

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Radius*

is a typedef to the template parameter *FT*

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Point*

is a typedef to *K::Point\_d*.

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Sphere*

is a typedef to *std::pair<Point,Radius>*.

*Min\_sphere\_of\_spheres\_d\_traits\_d*<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Cartesian\_const\_iterator*

is a typedef to *K::Cartesian\_const\_iterator\_d*.

## Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point\_d*:

*FT*                      *traits.radius( Sphere s)*

maps to *s.second*.

*Cartesian\_const\_iterator*

*traits.center\_cartesian\_begin( Sphere s)*

maps to *s.first.cartesian\_begin()*.

## CGAL::Approximate\_min\_ellipsoid\_d<Traits>

### Definition

An object of class *Approximate\_min\_ellipsoid\_d<Traits>* is an approximation to the ellipsoid of smallest volume enclosing a finite multiset of points in  $d$ -dimensional Euclidean space  $\mathbb{E}^d$ ,  $d \geq 2$ .

An *ellipsoid* in  $\mathbb{E}^d$  is a Cartesian pointset of the form  $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ , where  $E$  is some positive definite matrix from the set  $\mathbb{R}^{d \times d}$ ,  $e$  is some real  $d$ -vector, and  $\eta \in \mathbb{R}$ . A pointset  $P \subseteq \mathbb{E}^d$  is called *full-dimensional* if its affine hull has dimension  $d$ . For a finite, full-dimensional pointset  $P$  we denote by  $\text{MEL}(P)$  the smallest ellipsoid that contains all points of  $P$ ; this ellipsoid exists and is unique.

For a given finite and full-dimensional pointset  $P \subset \mathbb{E}^d$  and a real number  $\varepsilon \geq 0$ , we say that an ellipsoid  $\mathcal{E} \subset \mathbb{E}^d$  is an  $(1 + \varepsilon)$ -approximation to  $\text{MEL}(P)$  if  $P \subset \mathcal{E}$  and  $\text{VOL}(\mathcal{E}) \leq (1 + \varepsilon) \text{VOL}(\text{MEL}(P))$ . In other words, an  $(1 + \varepsilon)$ -approximation to  $\text{MEL}(P)$  is an enclosing ellipsoid whose volume is by at most a factor of  $1 + \varepsilon$  larger than the volume of the smallest enclosing ellipsoid of  $P$ .

Given this notation, an object of class *Approximate\_min\_ellipsoid\_d<Traits>* represents an  $(1 + \varepsilon)$ -approximation to  $\text{MEL}(P)$  for a given finite and full-dimensional multiset of points  $P \subset \mathbb{E}^d$  and a real constant  $\varepsilon > 0$ .<sup>1</sup> When an *Approximate\_min\_ellipsoid\_d<Traits>* object is constructed, an iterator over the points  $P$  and the number  $\varepsilon$  have to be specified; the number  $\varepsilon$  defines the *desired approximation ratio*  $1 + \varepsilon$ . The underlying algorithm will then try to compute an  $(1 + \varepsilon)$ -approximation to  $\text{MEL}(P)$ , and one of the following two cases takes place.

- The algorithm determines that  $P$  is not full-dimensional (see *is\_full\_dimensional()* below).

*Important note:* due to rounding errors, the algorithm cannot in all cases decide correctly whether  $P$  is full-dimensional or not. If *is\_full\_dimensional()* returns *false*, the points lie in such a “thin” subspace of  $\mathbb{E}^d$  that the algorithm is incapable of computing an approximation to  $\text{MEL}(P)$ . More precisely, if *is\_full\_dimensional()* returns *false*, there exist two parallel hyperplanes in  $\mathbb{E}^d$  with the points  $P$  in between so that the distance  $\delta$  between the hyperplanes is very small, possibly zero. (If  $\delta = 0$  then  $P$  is not full-dimensional.)

If  $P$  is not full-dimensional, linear algebra techniques should be used to determine an affine subspace  $S$  of  $\mathbb{E}^d$  that contains the points  $P$  as a (w.r.t.  $S$ ) full-dimensional pointset; once  $S$  is determined, the algorithm can be invoked again to compute an approximation to (the lower-dimensional)  $\text{MEL}(P)$  in  $S$ . Since *is\_full\_dimensional()* might (due to rounding errors, see above) return *false* even though  $P$  is full-dimensional, the lower-dimensional subspace  $S$  containing  $P$  need not exist. Therefore, it might be more advisable to fit a hyperplane  $H$  through the pointset  $P$ , project  $P$  onto this affine subspace  $H$ , and compute an approximation to the minimum-volume enclosing ellipsoid of the projected points within  $H$ ; the fitting can be done for instance using the *linear\_least\_squares\_fitting()* function from the CGAL package *Principal\_component\_analysis*.

- The algorithm determines that  $P$  is full-dimensional. In this case, it provides an approximation  $\mathcal{E}$  to  $\text{MEL}(P)$ , but depending on the input problem (i.e., on the pair  $(P, \varepsilon)$ ), it may not have achieved the desired approximation ratio but merely some *worse* approximation ratio  $1 + \varepsilon' > 1 + \varepsilon$ . The achieved approximation ratio  $1 + \varepsilon'$  can be queried using *achieved\_epsilon()*, which returns  $\varepsilon'$ . The ellipsoid  $\mathcal{E}$  itself can be queried via the methods *defining\_matrix()*, *defining\_vector()*, and *defining\_scalar()*.

The ellipsoid  $\mathcal{E}$  computed by the algorithm satisfies the inclusions

$$\frac{1}{(1 + \varepsilon')^d} \mathcal{E} \subseteq \text{conv}(P) \subseteq \mathcal{E} \quad (54.1)$$

<sup>1</sup>A *multiset* is a set where elements may have multiplicity greater than 1.

where  $f\mathcal{E}$  denotes the ellipsoid  $\mathcal{E}$  scaled by the factor  $f \in \mathbb{R}^+$  with respect to its center, and where  $\text{conv}(A)$  denotes the *convex hull* of a pointset  $A \subset \mathbb{E}^d$ .

The underlying algorithm can cope with all kinds of inputs (multisets  $P$ ,  $\varepsilon \in [0, \infty)$ ) and terminates in all cases. There is, however, no guarantee that any desired approximation ratio is actually achieved; the performance of the algorithm in this respect highly depends on the input pointset. Values of at least 0.01 for  $\varepsilon$  are usually handled without problems.

Internally, the algorithm represents the input points' Cartesian coordinates as *double*'s. For this conversion to work, the input point coordinates must be convertible to *double*. Also, in order to compute the achieved epsilon  $\varepsilon'$  mentioned above, the algorithm requires a number type *ET* that provides *exact* arithmetic. (Both these aspects are discussed in the documentation of the concept *ApproximateMinEllipsoid\_d\_Traits\_d*.)

```
#include <CGAL/Approximate_min_ellipsoid_d.h>
```

## Requirements

The template parameter *Traits* is a model for *ApproximateMinEllipsoid\_d\_Traits\_d*.

We provide the model *CGAL::Approximate\_min\_ellipsoid\_d\_traits\_d<K>* using the  $d$ -dimensional CGAL kernel; the models *CGAL::Approximate\_min\_ellipsoid\_d\_traits\_2<K>* and *CGAL::Approximate\_min\_ellipsoid\_d\_traits\_3<K>* are for use with the 2- and 3-dimensional CGAL kernel, respectively.

## Types

*Approximate\_min\_ellipsoid\_d<Traits>:: FT*

*typedef Traits::FT FT* (which is always a typedef to *double*).

*Approximate\_min\_ellipsoid\_d<Traits>:: ET*

*typedef Traits::ET ET* (which is an exact number type used for exact computation like for example in *achieved\_epsilon()*).

*Approximate\_min\_ellipsoid\_d<Traits>:: Point*

*typedef Traits::Point Point*

*Approximate\_min\_ellipsoid\_d<Traits>:: Cartesian\_const\_iterator*

*typedef Traits::Cartesian\_const\_iterator Cartesian\_const\_iterator*

*Approximate\_min\_ellipsoid\_d<Traits>:: Center\_coordinate\_iterator*

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the Cartesian center coordinates of the computed ellipsoid, see *center\_cartesian\_begin()*.

*Approximate\_min\_ellipsoid\_d<Traits>::Axes\_lengths\_iterator*

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the lengths of the semiaxes of the computed ellipsoid, see *axes\_lengths\_begin()*.

*Approximate\_min\_ellipsoid\_d<Traits>::Axis\_direction\_iterator*

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the Cartesian coordinates of the direction of a fixed axis of the computed ellipsoid, see *axis\_direction\_cartesian\_begin()*.

## Creation

An object of type *Approximate\_min\_ellipsoid\_d<Traits>* can be created from an arbitrary point set  $P$  and some nonnegative *double* value *eps*.

*template < class Iterator >*

*Approximate\_min\_ellipsoid\_d<Traits> ame( double eps, Iterator first, Iterator last, Traits traits = Traits());*

initializes *ame* to an  $(1 + \epsilon)$ -approximation of  $\text{MEL}(P)$  with  $P$  being the set of points in the range  $[first, last)$ . The number  $\epsilon$  in this will be at most *eps*, if possible. However, due to the limited precision in the algorithm's underlying arithmetic, it can happen that the computed approximation ellipsoid has a worse approximation ratio (and  $\epsilon$  can thus be larger than *eps* in general). In any case, the number  $\epsilon$  (and with this, the achieved approximation  $1 + \epsilon$ ) can be queried by calling the routine *achieved\_epsilon()* discussed below.

*Requirement:* *Iterator* must be a model for concept *InputIterator* with value type *Point*.

*Precondition:* The dimension  $d$  of the input points must be at least 2, and  $\epsilon > 0$ .

## Access Functions

The following methods can be used to query the achieved approximation ratio  $1 + \epsilon'$  and the computed ellipsoid  $\mathcal{E} = \{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ . The methods *defining\_matrix()*, *defining\_vector()*, and *defining\_scalar()* do not return  $E$ ,  $e$ , and  $\eta$  directly but yield multiples of these quantities that are exactly representable using the *double* type. (This is necessary because the parameters  $E$ ,  $e$ , and  $\eta$  of the computed approximation ellipsoid  $\mathcal{E}$  might not be exactly representable as *double* numbers.)

*unsigned int ame.number\_of\_points()*

returns the number of points of *ame*, i.e.,  $|P|$ .

<i>double</i>	<i>ame.achieved_epsilon()</i>	<p>returns a number <math>\epsilon'</math> such that the computed approximation is (under exact arithmetic) guaranteed to be an <math>(1 + \epsilon')</math>-approximation to <math>\text{MEL}(P)</math>.</p> <p><i>Precondition:</i> <i>ame.is_full_dimensional()</i> == <i>true</i>.</p> <p><i>Postcondition:</i> <math>\epsilon' &gt; 0</math>.</p>
<i>double</i>	<i>ame.defining_matrix( int i, int j)</i>	<p>gives access to the <math>(i, j)</math>th entry of the matrix <math>E</math> in the representation <math>\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}</math> of the computed approximation ellipsoid <math>\mathcal{E}</math>. The number returned by this routine is <math>(1 + \epsilon')(d + 1) E_{ij}</math>, where <math>\epsilon'</math> is the number returned by <i>achieved_epsilon()</i>.</p> <p><i>Precondition:</i> <math>0 \leq i, j \leq d</math>, where <math>d</math> is the dimension of the points <math>P</math>, and <i>ame.is_full_dimensional()</i> == <i>true</i>.</p>
<i>double</i>	<i>ame.defining_vector( int i)</i>	<p>gives access to the <math>i</math>th entry of the vector <math>e</math> in the representation <math>\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}</math> of the computed approximation ellipsoid <math>\mathcal{E}</math>. The number returned by this routine is <math>(1 + \epsilon')(d + 1) e_i</math>, where <math>\epsilon'</math> is the number returned by <i>achieved_epsilon()</i>.</p> <p><i>Precondition:</i> <math>0 \leq i \leq d</math>, where <math>d</math> is the dimension of the points <math>P</math>, and <i>ame.is_full_dimensional()</i> == <i>true</i>.</p>
<i>double</i>	<i>ame.defining_scalar()</i>	<p>gives access to the scalar <math>\eta</math> from the representation <math>\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}</math> of the computed approximation ellipsoid <math>\mathcal{E}</math>. The number returned by this routine is <math>(1 + \epsilon')(d + 1)(\eta + 1)</math>, where <math>\epsilon'</math> is the number returned by <i>achieved_epsilon()</i>.</p> <p><i>Precondition:</i> <i>ame.is_full_dimensional()</i> == <i>true</i>.</p>
<i>Traits</i>	<i>ame.traits()</i>	returns a const reference to the traits class object.
<i>int</i>	<i>ame.dimension()</i>	returns the dimension of the ambient space, i.e., the dimension of the points $P$ .

In order to access the center and semiaxes of the computed approximation ellipsoid, the functions *center\_cartesian\_begin()*, *axes\_lengths\_begin()*, and *axis\_direction\_cartesian\_begin()* can be used. In contrast to the above access functions *achieved\_epsilon()*, *defining\_matrix()*, *defining\_vector()*, and *defining\_scalar()*, which return the described quantities exactly, the routines below return *numerical approximations* to the real center and real semiaxes of the computed ellipsoid; the comprised relative error may be larger than zero, and there are no guarantees for the returned quantities.

*Center\_coordinate\_iterator*

*ame.center\_cartesian\_begin()*

returns an iterator pointing to the first of the  $d$  Cartesian coordinates of the computed ellipsoid's center.

The returned point is a floating-point approximation to the ellipsoid's exact center; no guarantee is given w.r.t. the involved relative error.

*Precondition:* *ame.is\_full\_dimensional()* == *true*.

*Center\_coordinate\_iterator*

*ame.center\_cartesian\_end()*

returns the past-the-end iterator corresponding to *center\_cartesian\_begin()*.

*Precondition:* *ame.is\_full\_dimensional()* == *true*.

*Axes\_lengths\_iterator*

*ame.axes\_lengths\_begin()*

returns an iterator pointing to the first of the  $d$  descendantly sorted lengths of the computed ellipsoid's axes. The  $d$  returned numbers are floating-point approximations to the exact axes-lengths of the computed ellipsoid; no guarantee is given w.r.t. the involved relative error. (See also method *axes\_direction\_cartesian\_begin()*.)

*Precondition:* *ame.is\_full\_dimensional()* == *true*, and  $d \in \{2, 3\}$ .

*Axes\_lengths\_iterator*

*ame.axes\_lengths\_end()*

returns the past-the-end iterator corresponding to *axes\_lengths\_begin()*.

*Precondition:* *ame.is\_full\_dimensional()* == *true*, and  $d \in \{2, 3\}$ .

*Axes\_direction\_coordinate\_iterator*

*ame.axis\_direction\_cartesian\_begin( int i )*

returns an iterator pointing to the first of the  $d$  Cartesian coordinates of the computed ellipsoid's  $i$ th axis direction (i.e., unit vector in direction of the ellipsoid's  $i$ th axis). The direction described by this iterator is a floating-point approximation to the exact axis direction of the computed ellipsoid; no guarantee is given w.r.t. the involved relative error. An approximation to the length of axis  $i$  is given by the  $i$ th entry of *axes\_lengths\_begin()*.

*Precondition:* *ame.is\_full\_dimensional()* == *true*, and  $d \in \{2, 3\}$ , and  $0 \leq i < d$ .

*Axes\_direction\_coordinate\_iterator*

*ame.axis\_direction\_cartesian\_end( int i )*

returns the past-the-end iterator corresponding to *axis\_direction\_cartesian\_begin()*.

*Precondition:* *ame.is\_full\_dimensional()* == *true*, and  $d \in \{2, 3\}$ , and  $0 \leq i < d$ .

## Predicates

*bool*

*ame.is\_full\_dimensional()*

returns whether  $P$  is full-dimensional or not, i.e., returns *true* if and only if  $P$  is full-dimensional.

*Note:* due to the limited precision in the algorithm's underlying arithmetic, the result of this method is not always correct. Rather, a return value of *false* means that the points  $P$  are contained in a “very thin” linear subspace of  $\mathbb{E}^d$ , and as a consequence, the algorithm cannot compute an approximation. More precisely, a return value of *false* means that the points  $P$  are contained between two parallel hyperplanes in  $\mathbb{E}^d$  that are very close to each other (possibly at distance zero) — so close, that the algorithm could not compute an approximation ellipsoid. Similarly, a return value of *true* does not guarantee  $P$  to be full-dimensional; but there exists an input pointset  $P'$  such that the points  $P'$  and  $P$  have almost identical coordinates and  $P'$  is full-dimensional.

## Validity Check

An object *ame* is valid iff

- *ame* contains all points of its defining set  $P$ ,
- *ame* is an  $(1 + \varepsilon')$ -approximation to the smallest ellipsoid  $\text{MEL}(P)$  of  $P$ ,
- The ellipsoid represented by *ame* fulfills the inclusion (54.1).

*bool*                      *ame.is\_valid( bool verbose = false)*

returns *true* iff *ame* is valid according to the above definition.  
If *verbose* is *true*, some messages concerning the performed checks are written to the standard error stream.

## Miscellaneous

*void*                      *ame.write\_eps( const std::string& name)*

Writes the points  $P$  and the computed approximation to  $\text{MEL}(P)$  as an EPS-file under pathname *name*.

*Precondition:* The dimension of points  $P$  must be 2.

*Note:* this routine is provided as a debugging routine; future version of CGAL might not provide it anymore.

*Precondition:* *ame.is\_full\_dimensional() == true*.

## Implementation

We implement Khachyan's algorithm for rounding polytopes [Kha96]. Internally, we use *double*-arithmetic and (initially a single) Cholesky-decomposition. The algorithm's running time is  $O(nd^2(\varepsilon^{-1} + \ln d + \ln \ln(n)))$ , where  $n = |P|$  and  $1 + \varepsilon$  is the desired approximation ratio.

## Example

To illustrate the usage of *Approximate\_min\_ellipsoid\_d<Traits>* we give two examples in 2D. The first program generates a random set  $P \subset \mathbb{E}^2$  and outputs the points and a 1.01-approximation of  $\text{MEL}(P)$  as an EPS-file, which you can view using *gv*, for instance. (In both examples you can change the variables  $n$  and  $d$  to experiment with the code.)

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include <CGAL/point_generators_d.h>
```

```

#include <CGAL/Approximate_min_ellipsoid_d.h>
#include <CGAL/Approximate_min_ellipsoid_d_traits_d.h>

#include <vector>
#include <iostream>

typedef CGAL::Cartesian_d<double> Kernel;
typedef CGAL::MP_Float ET;
typedef CGAL::Approximate_min_ellipsoid_d_traits_d<Kernel, ET> Traits;
typedef Traits::Point Point;
typedef std::vector<Point> Point_list;
typedef CGAL::Approximate_min_ellipsoid_d<Traits> AME;

int main()
{
    const int      n = 1000;          // number of points
    const int      d = 2;             // dimension
    const double eps = 0.01;          // approximation ratio is (1+eps)

    // create a set of random points:
    Point_list P;
    CGAL::Random_points_in_iso_box_d<Point> rpg(d,100.0);
    for (int i = 0; i < n; ++i) {
        P.push_back(*rpg);
        ++rpg;
    }

    // compute approximation:
    Traits traits;
    AME ame(eps, P.begin(), P.end(), traits);

    // write EPS file:
    if (ame.is_full_dimensional() && d == 2)
        ame.write_eps("example.eps");

    // output center coordinates:
    std::cout << "Cartesian center coordinates: ";
    for (AME::Center_coordinate_iterator c_it = ame.center_cartesian_begin();
         c_it != ame.center_cartesian_end();
         ++c_it)
        std::cout << *c_it << ' ';
    std::cout << ".\n";

    if (d == 2 || d == 3) {
        // output axes:
        AME::Axes_lengths_iterator axes = ame.axes_lengths_begin();
        for (int i = 0; i < d; ++i) {
            std::cout << "Semiaxis " << i << " has length " << *axes++ << "\n"
                      << "and Cartesian coordinates ";
            for (AME::Axes_direction_coordinate_iterator
                 d_it = ame.axis_direction_cartesian_begin(i);
                 d_it != ame.axis_direction_cartesian_end(i); ++d_it)
                std::cout << *d_it << ' ';
            std::cout << ".\n";
        }
    }
}

```

```

    }
}
}

```

## ApproximateMinEllipsoid\_d\_Traits\_d

### Definition

This concept defines the requirements for traits classes of *CGAL::Approximate\_min\_ellipsoid\_d<Traits>*.

### Refines

*DefaultConstructible*

*CopyConstructible*

*Assignable*

### Types

*ApproximateMinEllipsoid\_d\_Traits\_d:: FT*      *typedef double FT*

*ApproximateMinEllipsoid\_d\_Traits\_d:: ET*      Some model of concept *RingNumberType* that provides exact arithmetic, meaning that *CGAL::Number\_type\_traits<ET>::Has\_exact\_ring\_operations* must be *CGAL::Tag\_true*. In addition, *ET* must be able to exactly represent any finite *double* value. (An example for such a type is *CGAL::MP\_Float*.)  
The type *ET* is to be used by the *Approximate\_min\_ellipsoid\_d<Traits>* class for internal, exact computations.

*ApproximateMinEllipsoid\_d\_Traits\_d:: Point*      Type of the input points. *Point* must provide the default and copy constructor, and must be a model of *DefaultConstructible*, *CopyConstructible*, and *Assignable*.

*ApproximateMinEllipsoid\_d\_Traits\_d:: Cartesian\_const\_iterator*      Model for the STL concept *RandomAccessIterator* whose value type must be convertible to *double*. This type is used to iterate over the Cartesian coordinates of an instance of type *Point*, see *cartesian\_begin()* below.

### Access Functions

*int*      *traits.dimension( Point p)*  
returns the dimension of a point *p*.

*Cartesian\_const\_iterator*      *traits.cartesian\_begin( Point p)*  
returns an input iterator over the Euclidean coordinates of the point *p*. The range of the iterator must have size *dimension(p)*.

## CGAL::Approximate\_min\_ellipsoid\_d\_traits\_2<K,ET>

### Definition

The class *Approximate\_min\_ellipsoid\_d\_traits\_2<K,ET>* is a traits class for *CGAL::Approximate\_min\_ellipsoid\_d<Traits>* using the 2-dimensional CGAL kernel. In order to use this class, an exact number-type *ET* has to be provided which *Approximate\_min\_ellipsoid\_d<Traits>* will use for its internal exact computations.

```
#include <CGAL/Approximate_min_ellipsoid_d_traits_2.h>
```

### Requirements

The template parameter *K* must be a model for concept *Kernel*. The template parameter *ET* must be a model for concept *RingNumberType* with exact arithmetic operations, i.e., the type *CGAL::Number\_type\_traits<ET>::Has\_exact\_ring\_operations* must be *CGAL::Tag\_true*. In addition, *ET* must be able to exactly represent any finite *double* value. (Examples of such a number-type are *CGAL::MP\_Float*, *CORE::Expr*, and *CGAL::Gmpq*.)

### Is Model for the Concepts

*ApproximateMinEllipsoid\_d\_Traits\_d*

### Types

*Approximate\_min\_ellipsoid\_d\_traits\_2<K,ET>:: FT*      *typedef double FT*. The kernel's number type *K::RT* must be convertible to *double*.

*Approximate\_min\_ellipsoid\_d\_traits\_2<K,ET>:: ET*      *typedef* to the second template argument, *ET*.

*Approximate\_min\_ellipsoid\_d\_traits\_2<K,ET>:: Point*

*typedef K::Point\_2 Point*

*Approximate\_min\_ellipsoid\_d\_traits\_2<K,ET>:: Cartesian\_const\_iterator*

*typedef K::Cartesian\_const\_iterator\_2 Cartesian\_const\_iterator*

## CGAL::Min\_sphere\_annulus\_d\_traits\_2&lt;K,ET,NT&gt;

### Definition

The class *Min\_sphere\_annulus\_d\_traits\_2<K,ET,NT>* is a traits class for the  $d$ -dimensional optimisation algorithms using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_sphere_annulus_d_traits_2.h>
```

## Requirements

The template parameter  $K$  is a model for *Kernel*. Template parameters  $ET$  and  $NT$  are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

## Is Model for the Concepts

MinSphereAnnulusDTraits ..... page 3099

## Types

```
Min_sphere_annulus_d_traits_2<K,ET,NT>::Point_d typedef to K::Point_2.
```

$$Min\_sphere\_annulus\_d\_traits\_2<K,ET,NT>::Rep\_tag \quad \text{typedef to } K::Rep\_tag.$$
$$Min\_sphere\_annulus\_d\_traits\_2\langle K, ET, NT \rangle :: RT \quad \text{typedef to } K :: RT.$$
$$Min\_sphere\_annulus\_d\_traits\_2<K,ET,NT>::FT \quad \text{typedef to } K::FT.$$
$$\text{Min\_sphere\_annulus\_d\_traits\_2} \langle K, ET, NT \rangle :: \text{Access\_dimension\_d}$$

$$\text{typedef to } K :: \text{Access\_dimension\_2.}$$

```
Min_sphere_annulus_d_traits_2<K,ET,NT>::Access_coordinates_begin_d  
typedef to K::Access_coordinates_begin_2.
```

$$\text{Min\_sphere\_annulus\_d\_traits\_2}\langle K, ET, NT \rangle:: \text{Construct\_point\_d}$$

$$\text{typedef to } K::\text{Construct\_point\_2}.$$

*Min\_sphere\_annulus\_d\_traits\_2*<*K*,*ET*,*NT*>::*ET*      second template parameter (default is *K*::*RT*).

*Min\_sphere\_annulus\_d\_traits\_2*<*K*,*ET*,*NT*>::*NT*      third template parameter (default is *K*::*RT*).

## Creation

*Min\_sphere\_annulus\_d\_traits\_2*<*K,ET,NT*> traits;      default constructor.

## CGAL::Min\_sphere\_annulus\_d\_traits\_3&lt;K,ET,NT&gt;

### Definition

The class *Min\_sphere\_annulus\_d\_traits\_3<K,ET,NT>* is a traits class for the  $d$ -dimensional optimisation algorithms using the three-dimensional CGAL kernel.

```
#include <CGAL/Min_sphere_annulus_d_traits_3.h>
```

## Requirements

The template parameter  $K$  is a model for *Kernel*. Template parameters  $ET$  and  $NT$  are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

## Is Model for the Concepts

MinSphereAnnulusDTraits ..... page 3099

## Types

$$Min\_sphere\_annulus\_d\_traits\_3<K,ET,NT>::Point\_d \quad \text{typedef to } K::Point\_3.$$
$$Min\_sphere\_annulus\_d\_traits\_3<K,ET,NT>::Rep\_tag \quad \text{typedef to } K::Rep\_tag.$$

## MinSphereAnnulusDTraits

### Definition

This concept defines the requirements for traits classes of  $d$ -dimensional min sphere and min annulus algorithms.

### Types

<i>MinSphereAnnulusDTraits:: Point_d</i>	point type used to represent the input points.
<i>MinSphereAnnulusDTraits:: Rep_tag</i>	compile time tag to distinguish between Cartesian and homogeneous representation of the input points. <i>Rep_tag</i> has to be either <i>CGAL::Cartesian_tag</i> or <i>CGAL::Homogeneous_tag</i> .
<i>MinSphereAnnulusDTraits:: RT</i>	number type used to represent the coordinates of the input points. It has to be a model for <i>RingNumberType</i> .
<i>MinSphereAnnulusDTraits:: FT</i>	number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. <i>FT</i> has to be either <i>RT</i> or <i>CGAL::Quotient&lt;RT&gt;</i> if the input points have Cartesian or homogeneous representation, respectively (cf. <i>Rep_tag</i> ).
<i>MinSphereAnnulusDTraits:: Access_dimension_d</i>	data accessor object used to access the dimension of the input points.
<i>MinSphereAnnulusDTraits:: Access_coordinates_begin_d</i>	data accessor object used to access the coordinates of the input points.
<i>MinSphereAnnulusDTraits:: Construct_point_d</i>	constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.
The following two number types are only needed for <i>CGAL::Min_annulus_d&lt;Traits&gt;</i> and <i>CGAL::Polytope_distance_d&lt;Traits&gt;</i> .	
<i>MinSphereAnnulusDTraits:: ET</i>	exact number type used to do the exact computations in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be an implicit conversion from <i>RT</i> to <i>ET</i> available.
<i>MinSphereAnnulusDTraits:: NT</i>	fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be implicit conversions from <i>RT</i> to <i>NT</i> and from <i>NT</i> to <i>ET</i> available.

## Creation

Only default and copy constructor are required.

```
MinSphereAnnulusDTraits traits;
```

```
MinSphereAnnulusDTraits traits( MinSphereAnnulusDTraits);
```

## Operations

The following functions just return the corresponding function class object.

```
Access_dimension_d traits.access_dimension_d_object()
```

```
Access_coordinates_begin_d traits.access_coordinates_begin_d_object()
```

```
Construct_point_d traits.construct_point_d_object()
```

## Chapter 55

# Inscribed Areas

*Michael Hoffmann and Eli Packer*

This chapter describes algorithms which for a given point set compute the “best” inscribed object from a specific class. We provide algorithms for computing maximal inscribed  $k$ -gons (triangles, quadrilaterals, ...) of a planar point set  $P$ . Maximal  $k$ -gons are convex, and it is known that their vertices can be chosen to be vertices of the convex hull of  $P$ . Hence, the functions `CGAL::maximum_area_inscribed_k_gon_2` and `CGAL::maximum_perimeter_inscribed_k_gon_2` operate on convex polygons only. The example below shows that the largest area triangle (green) and the largest perimeter triangle (orange, containing the top point) of a point set are different in general.

We further provide an algorithm for computing the maximal area inscribed axis parallel rectangle

Given a set of points in the plane, the class `CGAL::Largest_empty_iso_rectangle_2<T>` is a data structure that maintains an iso-rectangle with the largest area among all iso-rectangles that are inside a given iso-rectangles, and that do not contain any point of the point set.

Inscribed volumes are also frequently applied to extract geometric properties of objects. The largest area triangle is for example used in heuristics for matching archaeological aerial photographs. Largest perimeter triangles are used in scoring cross country soaring flights, where the goal is basically to fly as far as possible, but still return to the departure airfield. To score simply based on the total distance flown is not a good measure, since circling in thermals allows to increase it easily.

# Inscribed Areas

## Reference Manual

*Michael Hoffmann and Eli Packer*

This chapter describes concepts, classes, and functions for maximum area and perimeter inscribed  $k$ -gon (2D), extremal inscribed  $k$ -gon (2D), largest empty isorectangle (2D).

### Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL\_OPTIMISATION\_NO\_PRECONDITIONS* switches precondition checking off, cf. Section 2.10.

## CGAL::maximum\_area\_inscribed\_k\_gon\_2

### Definition

The function *maximum\_area\_inscribed\_k\_gon\_2* computes a maximum area  $k$ -gon  $P_k$  that can be inscribed into a given convex polygon  $P$ . Note that

- $P_k$  is not unique in general, but it can be chosen in such a way that its vertices form a subset of the vertex set of  $P$  and
- the vertices of a maximum area  $k$ -gon, where the  $k$  vertices are to be drawn from a planar point set  $S$ , lie on the convex hull of  $S$  i.e. a convex polygon.

```
#include <CGAL/extremal_polygon_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      maximum_area_inscribed_k_gon_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    int k,
                    OutputIterator o)
```

computes a maximum area inscribed  $k$ -gon of the convex polygon described by  $[points\_begin, points\_end)$ , writes its vertices to  $o$  and returns the past-the-end iterator of this sequence.

*Precondition:*

1. the – at least three – points denoted by the range  $[points\_begin, points\_end)$  form the boundary of a convex polygon (oriented clock- or counterclockwise).
2.  $k \geq 3$ .

*Requirement:*

1. Value type of *RandomAccessIterator* is  $K::Point\_2$  where  $K$  is a model for *Kernel*.
2. *OutputIterator* accepts the value type of *RandomAccessIterator* as value type.

## Implementation

The implementation uses monotone matrix search [AKM<sup>+</sup>87] and has a worst case running time of  $O(k \cdot n + n \cdot \log n)$ , where  $n$  is the number of vertices in  $P$ .

## Example

The following code generates a random convex polygon  $p$  with ten vertices and computes the maximum area inscribed five-gon of  $p$ .

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/extremal_polygon_2.h>
#include <iostream>
#include <vector>

typedef double FT;

struct Kernel : public CGAL::Cartesian<FT> {};

typedef Kernel::Point_2 Point;
typedef std::vector<int> Index_cont;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Random_points_in_square_2<Point> Generator;

int main() {

    int n = 10;
    int k = 5;

    // generate random convex polygon:
    Polygon_2 p;
    CGAL::random_convex_set_2(n, std::back_inserter(p), Generator(1));
    std::cout << "Generated Polygon:\n" << p << std::endl;

    // compute maximum area inscribed k-gon of p:
    Polygon_2 k_gon;
    CGAL::maximum_area_inscribed_k_gon_2(
        p.vertices_begin(), p.vertices_end(), k, std::back_inserter(k_gon));
    std::cout << "Maximum area " << k << "-gon:\n"
        << k_gon << std::endl;

    return 0;
}
```

## CGAL::maximum\_perimeter\_inscribed\_k\_gon\_2

### Definition

The function *maximum\_perimeter\_inscribed\_k\_gon\_2* computes a maximum perimeter  $k$ -gon  $P_k$  that can be inscribed into a given convex polygon  $P$ . Note that

- $P_k$  is not unique in general, but it can be chosen in such a way that its vertices form a subset of the vertex set of  $P$  and
- the vertices of a maximum perimeter  $k$ -gon, where the  $k$  vertices are to be drawn from a planar point set  $S$ , lie on the convex hull of  $S$  i.e. a convex polygon.

```
#include <CGAL/extremal_polygon_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      maximum_perimeter_inscribed_k_gon_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    int k,
                    OutputIterator o)
```

computes a maximum perimeter inscribed  $k$ -gon of the convex polygon described by  $[points\_begin, points\_end)$ , writes its vertices to  $o$  and returns the past-the-end iterator of this sequence.

*Precondition:*

1. the – at least three – points denoted by the range  $[points\_begin, points\_end)$  form the boundary of a convex polygon (oriented clock- or counterclockwise).
2.  $k \geq 2$ .

*Requirement:*

1. Value type of *RandomAccessIterator* is  $K::Point_2$  where  $K$  is a model for *Kernel*.
2. There is a global function  $K::FT$   $CGAL::sqrt(K::FT)$  defined that computes the squareroot of a number.
3. *OutputIterator* accepts the value type of *RandomAccessIterator* as value type.

        << k_gon << std::endl;

    return 0;
}
```

**File:** examples/Matrix\_search/extremal\_polygon\_2\_perimeter.cpp

## CGAL::extremal\_polygon\_2

— advanced —

### Definition

The function *extremal\_polygon\_2* computes a maximal  $k$ -gon that can be inscribed into a given convex polygon. The criterion for maximality and some basic operations have to be specified in an appropriate traits class parameter.

```
#include <CGAL/extremal_polygon_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator, class Traits >
OutputIterator      extremal_polygon_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    int k,
                    OutputIterator o,
                    Traits t)
```

computes a maximal (as specified by  $t$ ) inscribed  $k$ -gon of the convex polygon described by  $[points\_begin, points\_end)$ , writes its vertices to  $o$  and returns the past-the-end iterator of this sequence.

*Precondition:*

1. the – at least three – points denoted by the range  $[points\_begin, points\_end)$  form the boundary of a convex polygon (oriented clock- or counterclockwise).
2.  $k \geq t.min\_k()$ .

*Requirement:*

1. *Traits* is a model for *ExtremalPolygonTraits\_2*.
2. Value type of *RandomAccessIterator* is *Traits::Point\_2*.
3. *OutputIterator* accepts *Traits::Point\_2* as value type.

### Definition

## Requirements

## Is Model for the Concepts

## Types

*Extremal\_polygon\_area\_traits\_2<K>:: Operation*

AdaptableBinaryFunction class *op*:  $Point\_2 \times Point\_2 \rightarrow FT$ . For a fixed *Point\_2* *root*, *op*(*p*, *q*) returns twice the area of the triangle (*root*, *q*, *p*).

```

FT      t.init( const Point_2& p, const Point_2& q) const
                                returns FT(0).

```

*Operation*                      *t.operation( const Point\_2& p) const*

returns *Operation* where *p* is the fixed *root* point.

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      t.compute_min_k_gon( RandomAccessIterator points_begin,
                                         RandomAccessIterator points_end,
                                         FT& max_area,
                                         OutputIterator o) const
```

writes the vertices of [*points\_begin*, *points\_end*) forming a maximum area triangle rooted at *points\_begin*[0] to *o* and returns the past-the-end iterator for that sequence ( $= o + 3$ ).

advanced

## Definition

The class provides the types and operations needed to compute a maximum perimeter  $k$ -gon  $P_k$  that can be inscribed into a given convex polygon  $P$  using the function *extremal\_polygon\_2*.

## Requirements

The template parameter  $K$  is a model for *Kernel*.

## Is Model for the Concepts

ExtremalPolygonTraits\_2.....page [3113](#)

## Types

*Extremal\_polygon\_perimeter\_traits\_2<K>:: FT*

typedef to  $K::FT$ .

*Extremal\_polygon\_perimeter\_traits\_2<K>:: Point\_2*

typedef to  $K::Point_2$ .

*Extremal\_polygon\_perimeter\_traits\_2<K>:: Less\_xy\_2*

typedef to  $K::Less_{xy\_2}$ .

*Extremal\_polygon\_perimeter\_traits\_2<K>:: Orientation\_2*

typedef to  $K::Orientation_2$ .

*Extremal\_polygon\_perimeter\_traits\_2<K>:: Operation*

AdaptableBinaryFunction class *op*:  $Point_2 \times Point_2 \rightarrow FT$ . For a fixed *Point\_2* *root*, *op*(*p*, *q*) returns  $d(r, p) + d(p, q) - d(r, q)$  where *d* denotes the Euclidean distance.

## Operations

*int*                      *t.min\_k()* *const*                      returns 2.

*FT*  $t.\text{init}(\text{const Point\_2}\& p, \text{const Point\_2}\& q) \text{ const}$

returns twice the Euclidean distance between  $p$  and  $q$ .

*Operation*                      *t.operation( const Point\_2& p) const*

returns *Operation* where *p* is the fixed *root* point.

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      t.compute_min_k_gon( RandomAccessIterator points_begin,
                                         RandomAccessIterator points_end,
                                         FT& max_area,
                                         OutputIterator o) const
```

writes the pair  $(points\_begin[0], p)$  where  $p$  is drawn from  $[points\_begin, points\_end)$  such that the Euclidean distance between both points is maximized (maximum perimeter 2-gon rooted at  $points\_begin[0]$  to  $o$  and returns the past-the-end iterator for that sequence ( $= o + 2$ )).

<i>Less_xy_2</i>	<i>t.less_xy_2_object()</i>
<i>Orientation_2</i>	<i>t.orientation_2_object()</i>

# ExtremalPolygonTraits\_2

advanced

## Definition

The concept `ExtremalPolygonTraits_2` provides the types and operations needed to compute a maximal  $k$ -gon that can be inscribed into a given convex polygon.

## Types

<code>ExtremalPolygonTraits_2:: FT</code>	model for <code>FieldNumberType</code> ..... page <a href="#">121</a> .
<code>ExtremalPolygonTraits_2:: Point_2</code>	model for <code>Kernel::Point_2</code> ..... page <a href="#">533</a> .
<code>ExtremalPolygonTraits_2:: Less_xy_2</code>	model for <code>Kernel::Less_xy_2</code> ..... page <a href="#">??</a> .
<code>ExtremalPolygonTraits_2:: Orientation_2</code>	model for <code>Kernel::Orientation_2</code> ..... page <a href="#">771</a> .
<code>ExtremalPolygonTraits_2:: Operation</code>	AdaptableBinaryFunction class <code>op</code> : $Point_2 \times Point_2 \rightarrow FT$ . Together with <code>init</code> this operation recursively defines the objective function to maximize. Let $p$ and $q$ be two vertices of a polygon $P$ such that $q$ precedes $p$ in the oriented vertex chain of $P$ starting with vertex <code>root</code> . Then <code>op(p,q)</code> returns the value by which an arbitrary sub-polygon of $P$ with vertices from $[root, q]$ increases when $p$ is added to it. E.g. in the maximum area case this is the area of the triangle $(root, q, p)$ .

## Operations

<code>int</code>	<code>t.min_k() const</code>	returns the minimal $k$ for which a maximal $k$ -gon can be computed. (e.g. in the maximum area case this is three.)
<code>FT</code>	<code>t.init( const Point_2&amp; p, const Point_2&amp; q) const</code>	returns the value of the objective function for a polygon consisting of the two points $p$ and $q$ . (e.g. in the maximum area case this is <code>FT( 0)</code> .)
<code>Operation</code>	<code>t.operation( const Point_2&amp; p) const</code>	return <code>Operation</code> where $p$ is the fixed <code>root</code> point.

`template < class RandomAccessIterator, class OutputIterator >`

writes the points of  $[points\_begin, points\_end)$  forming a  $min\_k()$ -gon rooted at  $points\_begin[0]$  of maximal value to  $o$  and returns the past-the-end iterator for that sequence ( $= o + min\_k()$ ).

## Notes

- `::Less_xy_2` and `::Orientation_2` are used for (expensive) precondition checking only. Therefore, they need not to be specified, in case that precondition checking is disabled.

## CGAL::Largest\_empty\_iso\_rectangle\_2<T>

### Definition

Given a set of points in the plane, the class *Largest\_empty\_iso\_rectangle\_2<T>* is a data structure that maintains an iso-rectangle with the largest area among all iso-rectangles that are inside a given bounding box( iso-rectangle), and that do not contain any point of the point set.

The class *Largest\_empty\_iso\_rectangle\_2<T>* expects a model of the concept *LargestEmptyIsoRectangleTraits\_2* as its template argument.

```
#include <CGAL/Largest_empty_iso_rectangle_2.h>
```

### Types

The class *Largest\_empty\_iso\_rectangle\_2<T>* defines the following types:

```
typedef T Traits;
```

```
typedef Traits::Point_2
```

```
Point_2;
```

```
typedef Traits::Iso_rectangle_2
```

```
Iso_rectangle_2;
```

The following iterator allows to enumerate the points. It is non mutable, bidirectional and its value type is *Point\_2*. It is invalidated by any insertion or removal of a point.

```
Largest_empty_iso_rectangle_2<T>::const_iterator
```

Iterator over the points.

### Creation

```
Largest_empty_iso_rectangle_2<T> l( Iso_rectangle_2 b);
```

Constructor. The iso-rectangle *b* is the bounding rectangle.

```
Largest_empty_iso_rectangle_2<T> l( const Point_2 p, const Point_2 q);
```

Constructor. The iso-rectangle whose lower left and upper right points are *p* and *q* respectively is the bounding rectangle.

```
Largest_empty_iso_rectangle_2<T> l;
```

Constructor. The iso-rectangle whose lower left point and upper right points are (0,0) and (1,1) respectively is the bounding rectangle.

*Largest\_empty\_iso\_rectangle\_2*<*T*> *l*( *const Largest\_empty\_iso\_rectangle\_2*<*Traits*> *tr*);

Copy constructor.

## Operations

### Assignment

*Largest\_empty\_iso\_rectangle\_2*<*T*>

*l* = *tr*

### Access Functions

<i>Traits</i>	<i>l.traits()</i>	Returns a const reference to the traits object.
<i>const_iterator</i>	<i>l.begin()</i>	Returns an iterator to the beginning of the point set.
<i>const_iterator</i>	<i>l.end()</i>	Returns a past-the-end iterator for the point set.

### Queries

*Quadruple*<*Point\_2*, *Point\_2*, *Point\_2*, *Point\_2*>

*l.get\_left\_bottom\_right\_top()*

Returns the four points that define the largest empty iso-rectangle. (Note that these points are not necessarily on a corner of an iso-rectangle.)

*Iso\_rectangle\_2*

*l.get\_largest\_empty\_iso\_rectangle()*

Returns the largest empty iso-rectangle. (Note that the two points defining the iso-rectangle are not necessarily part of the point set.)

*Iso\_rectangle\_2*

*l.get\_bounding\_box()* Returns the iso-rectangle passed in the constructor.

### Insertion

*void* *l.insert( Point\_2 p )* Inserts point *p* in the point set, if it is not already in the set.

*void* *l.push\_back( Point\_2 p )* Inserts point *p* in the point set, if it is not already in the set.

*template < class InputIterator >*

*int*                    *l.insert( InputIterator first, InputIterator last)*

Inserts the points in the range  $[first, last)$ . Returns the number of inserted points.

### Requirements

The *value\_type* of *first* and *last* is *Point*.

### Removal

*bool*                    *l.remove( Point\_2 p)*                    Removes point *p*. Returns false iff *p* is not in the point set.

*void*                    *l.clear()*                    Removes all points of *l*.

### Implementation

The algorithm is an implementation of [Ori90]. The runtime of an insertion or a removal is  $O(\log n)$ . A query takes  $O(n^2)$  worst case time and  $O(n \log n)$  expected time. The working storage is  $O(n)$ .

## LargestEmptyIsoRectangleTraits\_2

### Definition

The concept `LargestEmptyIsoRectangleTraits_2` describes the set of requirements to be fulfilled by any class used to instantiate the template parameter of the class `Largest_empty_iso_rectangle_2<T>`. This concept provides the types of the geometric primitives used in this class and some function object types for the required predicates on those primitives.

### Types

`LargestEmptyIsoRectangleTraits_2::Point_2`      The point type.

`LargestEmptyIsoRectangleTraits_2::Iso_rectangle_2`

The iso rectangle type.

`LargestEmptyIsoRectangleTraits_2::Compare_x_2`

Predicate object. Must provide the operator `Comparison_result operator()(Point_2 p, Point_2 q)` which returns `SMALLER`, `EQUAL` or `LARGER` according to the *x*-ordering of points *p* and *q*.

`LargestEmptyIsoRectangleTraits_2::Compare_y_2`

Predicate object. Must provide the operator `Comparison_result operator()(Point_2 p, Point_2 q)` which returns `SMALLER`, `EQUAL` or `LARGER` according to the *y*-ordering of points *p* and *q*.

`LargestEmptyIsoRectangleTraits_2::Less_x_2`

Predicate object. Must provide the operator `bool operator()(Point_2 p, Point_2 q)` which returns whether *p* is less than *q* according to their *x*-ordering.

`LargestEmptyIsoRectangleTraits_2::Less_y_2`

Predicate object. Must provide the operator `bool operator()(Point_2 p, Point_2 q)` which returns whether *p* is less than *q* according to their *y*-ordering.

### Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.

`LargestEmptyIsoRectangleTraits_2 traits;`      Default constructor.

`LargestEmptyIsoRectangleTraits_2 traits( LargestEmptyIsoRectangleTraits_2);`

Copy constructor

`LargestEmptyIsoRectangleTraits_2`

`traits = gtr`

Assignment operator.

## Predicate functions

The following functions give access to the predicate and constructor objects.

<i>Compare_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Compare_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Less_x_2</i>	<i>traits.less_x_2_object()</i>
<i>Less_y_2</i>	<i>traits.less_y_2_object()</i>

## Has Models

## Chapter 56

# Optimal Distances

*Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr*

This chapter describes how to compute the distance between the convex hulls of two given point sets in  $d$ -dimensional Euclidean space (*CGAL::Polytope\_distance\_d<Traits>*). Moreover, it is possible to compute the width of a point set in three dimensions (*CGAL::Width\_3<Traits>*).

The obvious application is collision detection between convex bodies in space. In the spirit of the bounding volume application above, it also makes sense for nonconvex objects: a full intersection test between complicated objects could in a first stage be approximated with the test between the convex hulls of the objects. Only if the hulls intersect, a full intersection test is necessary.

To dampen fears concerning the performance of the distance computation, we want to mention that the convex hulls of the input point sets are not explicitly computed. This avoids a runtime which grows exponentially in  $d$ . In fact, the runtime is almost always linear in the size of the two point sets.

# Optimal Distances

## Reference Manual

*Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr*

This chapter describes concepts, classes, and functions for 2D all furthest neighbors, 3D width of a point set, and dD polytope distance.

### Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL\_OPTIMISATION\_NO\_PRECONDITIONS* switches precondition checking off, cf. Section 2.10.

## CGAL::all\_furthest\_neighbors\_2

### Definition

The function *all\_furthest\_neighbors\_2* computes all furthest neighbors for the vertices of a convex polygon  $P$ , i.e. for each vertex  $v$  of  $P$  a vertex  $f_v$  of  $P$  such that the distance between  $v$  and  $f_v$  is maximized.

```
#include <CGAL/all_furthest_neighbors_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator, class Traits >
OutputIterator      all_furthest_neighbors_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    OutputIterator o,
                    Traits t = Default_traits)
```

computes all furthest neighbors for the vertices of the convex polygon described by the range  $[points\_begin, points\_end)$ , writes their indices (relative to  $points\_begin$ ) to  $o$ <sup>1</sup> and returns the past-the-end iterator of this sequence.

*Precondition:* The points denoted by the non-empty range  $[points\_begin, points\_end)$  form the boundary of a convex polygon  $P$  (oriented clock- or counterclockwise).

The geometric types and operations to be used for the computation are specified by the traits class parameter  $t$ . This parameter can be omitted if *RandomAccessIterator* refers to a point type from a *Kernel*. In this case, the kernel is used as default traits class.

*Requirement:*

1. If  $t$  is specified explicitly, *Traits* is a model for *AllFurthestNeighborsTraits\_2*.
2. Value type of *RandomAccessIterator* is *Traits::Point\_2* or – if  $t$  is not specified explicitly – *K::Point\_2* where  $K$  is a model for *Kernel*.
3. *OutputIterator* accepts *int* as value type.

### See Also

*AllFurthestNeighborsTraits\_2* ..... page [3127](#)  
*CGAL::monotone\_matrix\_search* ..... page [3550](#)

### Implementation

The implementation uses monotone matrix search[AKM<sup>+</sup>87]. Its runtime complexity is linear in the number of vertices of  $P$ .

<sup>1</sup>i.e. the furthest neighbor of  $points\_begin[i]$  is  $points\_begin[i]$ -th number written to  $o$

## Example

The following code generates a random convex polygon  $p$  with ten vertices, computes all furthest neighbors and writes the sequence of their indices (relative to *points\_begin*) to *cout* (e.g. a sequence of 4788911224 means the furthest neighbor of *points\_begin*[0] is *points\_begin*[4], the furthest neighbor of *points\_begin*[1] is *points\_begin*[7] etc.).

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/all_furthest_neighbors_2.h>
#include <CGAL/IO/Ostream_iterator.h>
#include <iostream>
#include <vector>

typedef double FT;

struct Kernel : public CGAL::Cartesian<FT> {};

typedef Kernel::Point_2 Point;
typedef std::vector<int> Index_cont;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Random_points_in_square_2<Point> Generator;
typedef CGAL::Ostream_iterator<int, std::ostream> Oiterator;

int main()
{
    // generate random convex polygon:
    Polygon_2 p;
    CGAL::random_convex_set_2(10, std::back_inserter(p), Generator(1));

    // compute all furthest neighbors:
    CGAL::all_furthest_neighbors_2(p.vertices_begin(), p.vertices_end(),
                                   Oiterator(std::cout));

    std::cout << std::endl;

    return 0;
}
// -----
// ** EOF
// -----
```

## AllFurthestNeighborsTraits\_2

### Definition

The concept AllFurthestNeighborsTraits\_2 defines types and operations needed to compute all furthest neighbors for the vertices of a convex polygon using the function *all\_furthest\_neighbors\_2*.

### Types

<i>AllFurthestNeighborsTraits_2:: FT</i>	model for FieldNumberType . . . . .	page <a href="#">121</a> .
<i>AllFurthestNeighborsTraits_2:: Point_2</i>	model for Kernel::Point_2 . . . . .	page <a href="#">533</a> .
<i>AllFurthestNeighborsTraits_2:: Compute_squared_distance_2</i>	model for Kernel::Compute_squared_distance_2 . . . . .	page ??.
<i>AllFurthestNeighborsTraits_2:: Less_xy_2</i>	model for Kernel::Less_xy_2 . . . . .	page ??.
<i>AllFurthestNeighborsTraits_2:: Orientation_2</i>	model for Kernel::Orientation_2 . . . . .	page <a href="#">771</a> .

### Operations

The following member functions return function objects of the types listed above.  
*Compute\_squared\_distance\_2*

	<i>t.compute_squared_distance_2_object()</i>
<i>Less_xy_2</i>	<i>t.less_xy_2_object()</i>
<i>Orientation_2</i>	<i>t.orientation_2_object()</i>

### Has Models

*Cartesian<FieldNumberType>* . . . . . page ??, *Homogeneous<RingNumberType>* . . . . . page ??,  
*Simple\_cartesian<FieldNumberType>* . . . . . page ??, *Simple\_homogeneous<RingNumberType>* . . . . . page ??.

### See Also

*CGAL::all\_furthest\_neighbors\_2* . . . . . page [3125](#)

### Notes

- *::Less\_xy\_2* and *::Orientation\_2* are used for (expensive) precondition checking only. Therefore, they need not to be specified, in case that precondition checking is disabled.

## CGAL::Width\_3<Traits>

### Definition

Given a set of points  $\mathcal{S} = \{p_1, \dots, p_n\}$  in  $\mathbb{R}^3$ . The width of  $\mathcal{S}$ , denoted as  $\mathcal{W}(\mathcal{S})$ , is defined as the minimum distance between two parallel planes of support of  $\text{conv}(\mathcal{S})$ ; where  $\text{conv}(\mathcal{S})$  denotes the convex hull of  $\mathcal{S}$ . The width in direction  $\mathbf{d}$ , denoted as  $\mathcal{W}_{\mathbf{d}}(\mathcal{S})$ , is the distance between two parallel planes of support of  $\text{conv}(\mathcal{S})$ , which are orthogonal to  $\mathbf{d}$ .

Subject to the applications of the width algorithm, several objects might be interesting:

1. The two parallel planes of support such that the distance between them is as small as possible. These planes are called width-planes in further considerations.
2. The width  $\mathcal{W}(\mathcal{S})$ , i.e., the distance between the width-planes.
3. The direction  $\mathbf{d}_{opt}$  such that  $\mathcal{W}(\mathcal{S}) = \mathcal{W}_{\mathbf{d}_{opt}}(\mathcal{S})$

*Note:* There might be several optimal build directions. Hence neither the width-planes nor the direction  $\mathbf{d}_{opt}$  are unique – only the width is.

```
#include <CGAL/Width_3.h>
```

### Requirements

The template parameter *Traits* is a model for *WidthTraits\_3*. We provide the model *Width\_default\_traits\_3<Kernel>* based on a three-dimensional CGAL kernel.

### Types

<i>Width_3&lt;Traits&gt;::Traits</i>		traits class.
<i>typedef typename Traits::Point_3</i>	<i>Point_3;</i>	point type.
<i>typedef typename Traits::Plane_3</i>	<i>Plane_3;</i>	plane type.
<i>typedef typename Traits::Vector_3</i>	<i>Vector_3;</i>	vector type.
<i>typedef typename Traits::RT</i>	<i>RT;</i>	algebraic ring type.
<i>typedef typename Traits::ChullTraits</i>	<i>ChullTraits;</i>	traits class for the 3D convex hull algorithm.

### Creation

```
template < class InputIterator >
Width_3<Traits> width( InputIterator first, InputIterator beyond);
```

creates a variable *width* initialized to the width of  $\mathcal{S}$  – with  $\mathcal{S}$  being the set of points in the range  $[first, beyond)$ .

*Requirement:* The value type of *InputIterator* is *Point\_3*.

```
template < class Polyhedron >
Width_3<Traits> width( Polyhedron& P);
```

creates a variable *width* initialized to the width of the polyhedron *P*. Note that the vertex point coordinates are altered!

*Precondition:* *P* is a convex polyhedron.

*Requirement:* *Polyhedron* is a *CGAL::Polyhedron\_3* with facets supporting plane equations where *Polyhedron::Point\_3*  $\equiv$  *Point\_3* and *Polyhedron::Plane\_3*  $\equiv$  *Plane\_3*.

## Access Functions

```
void          width.get_squared_width( RT& width_num, RT& width_denom)
```

returns the squared width. For the reason of exact computation not the width itself is stored, but the *squared* width as a fraction: The numerator in *width\_num* and the denominator in *width\_denom*. The width of the point set  $\mathcal{S}$  is  $\sqrt{\frac{width\_num}{width\_denom}}$ .

```
void          width.get_width_planes( Plane_3& e1, Plane_3& e2)
```

The planes *e1* and *e2* are the two parallel supporting planes, which distance is minimal (among all such planes).

```
void          width.get_width_coefficients( RT& A, RT& B, RT& C, RT& D, RT& K)
```

The returned coefficients *A,B,C,D,K* have the property that width-plane *e1* is given by the equation  $Ax + By + Cz + D = 0$  and width-plane *e2* by  $Ax + By + Cz + K = 0$ .

```
Vector_3      width.get_build_direction()
```

returns a direction  $\mathbf{d}_{opt}$  such that the width-planes *e1* and *e2* are perpendicular to  $\mathbf{d}_{opt}$ . The width of the point set is minimal in this direction.

```
void          width.get_all_build_directions( std::vector<Vector_3>& dir)
```

All the build directions are stored in the vector *dir*. It might happen that a certain body has several different build directions, but it is also possible to have only one build direction.

```
int           width.get_number_of_optimal_solutions()
```

returns the number of optimal solutions, i.e., the number of optimal build directions.

## See Also

*CGAL::Width\_default\_traits\_3<K>* ..... page 3132  
*WidthTraits\_3* ..... page 3134

## Implementation

Since the width of the point set  $S$  and the width of the convex hull of  $S$  ( $\text{conv}(S)$ ) is the same, the algorithm uses the 3D convex hull algorithm CGAL provides.

The width-algorithm is not incremental and therefore inserting and erasing points cause not an ‘automatic’ update of the width. Instead you have to run the width-algorithm again even if the point set is extended by only one new point.

————— *advanced* —————

**Large Numbers.** Because there is no need for dividing values during the algorithm, the numbers can get really huge (all the computations are made using a lot of multiplications). Therefore it is strongly recommended to use a number type that can handle numbers of arbitrary length (e.g., *leda\_integer* in combination with the homogeneous representation of the points). But these large numbers have a disadvantage: Operations on them are slower as greater the number gets. Therefore it is possible to shorten the numbers by using the compiler flag `-DSIMPLIFY`. For using this option it is required that the underlying number type provides the ‘modulo’ operation.

**Information Output during the Computations.** If during the algorithm the program should output some information (e.g., during the debugging phase) you can turn on the output information by giving the compiler flag `DEBUG`. In the file `width_assertions.h` you can turn on/off the output of some functions and additional informations by changing the defined values from 0 (no output) to 1 (output available). But then it is required that the `<<-operator` has to been overloaded for *Point\_3*, *Plane\_3*, *Vector\_3* and *RT*.

————— *advanced* —————

## Example

```
#include <CGAL/Homogeneous.h>
#include <CGAL/Width_default_traits_3.h>
#include <CGAL/Width_3.h>
#include <iostream>
#include <vector>

#if defined(CGAL_USE_GMP)
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#elif defined (CGAL_USE_LEDA)
#include <CGAL/leda_integer.h>
typedef leda_integer RT;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float RT;
#endif
```

```

typedef CGAL::Homogeneous<RT>           Kernel;
typedef Kernel::Point_3                 Point_3;
typedef Kernel::Plane_3                 Plane_3;
typedef CGAL::Width_default_traits_3<Kernel> Width_traits;
typedef CGAL::Width_3<Width_traits>     Width;

int main() {
    // Create a simplex using homogeneous integer coordinates
    std::vector<Point_3> points;
    points.push_back( Point_3(2,0,0,1));
    points.push_back( Point_3(0,1,0,1));
    points.push_back( Point_3(0,0,1,1));
    points.push_back( Point_3(0,0,0,1));

    // Compute width of simplex
    Width simplex( points.begin(), points.end());

    // Output of squared width, width-planes, and optimal direction
    RT wnum, wdenom;
    simplex.get_squared_width( wnum, wdenom);
    std::cout << "Squared Width: " << wnum << "/" << wdenom << std::endl;

    std::cout << "Direction: " << simplex.get_build_direction() << std::endl;

    Plane_3 e1, e2;
    std::cout << "Planes: E1: " << e1 << ". E2: " << e2 <<std::endl;

    std::cout << "Number of optimal solutions: "
                << simplex.get_number_of_optimal_solutions() << std::endl;
    return(0);
}

```

## CGAL::Width\_default\_traits\_3<K>

### Definition

The class *Width\_default\_traits\_3<K>* is a traits class for *Width\_3<Traits>* using the three-dimensional CGAL kernel.

```
#include <CGAL/Width_default_traits_3.h>
```

### Requirements

The template parameter *K* is a model for *Kernel*

### Is Model for the Concepts

WidthTraits\_3 ..... page [3134](#)

### Types

```
typedef typename K::Point_3      Point_3;
typedef typename K::Plane_3     Plane_3;
typedef typename K::Vector_3    Vector_3;
typedef typename K::RT          RT;
typedef Convex_hull_traits_3<K>  ChullTraits;
```

### Creation

*Width\_default\_traits\_3<K>* traits;      default constructor.

### Operations

<i>RT</i>	<i>traits.get_hx( Point_3 p)</i>	returns the homogeneous <i>x</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>traits.get_hy( Point_3 p)</i>	returns the homogeneous <i>y</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>traits.get_hz( Point_3 p)</i>	returns the homogeneous <i>z</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>traits.get_hw( Point_3 p)</i>	returns the homogenizing coordinate of point <i>p</i> .
<i>void</i>	<i>traits.get_point_coordinates( Point_3 p, RT&amp; px, RT&amp; py, RT&amp; pz, RT&amp; ph)</i>	returns all homogeneous coordinates of point <i>p</i> at once.
<i>RT</i>	<i>traits.get_a( Plane_3 f)</i>	returns the first coefficient of plane <i>f</i> .
<i>RT</i>	<i>traits.get_b( Plane_3 f)</i>	returns the second coefficient of plane <i>f</i> .
<i>RT</i>	<i>traits.get_c( Plane_3 f)</i>	returns the third coefficient of plane <i>f</i> .
<i>RT</i>	<i>traits.get_d( Plane_3 f)</i>	returns the fourth coefficient of plane <i>f</i> .
<i>void</i>	<i>traits.get_plane_coefficients( Plane_3 f, RT&amp; a, RT&amp; b, RT&amp; c, RT&amp; d)</i>	returns all four plane coefficients of <i>f</i> at once.

## WidthTraits\_3

### Definition

This concept defines the requirements for traits classes of *Width\_3<Traits>*.

### Types

<i>WidthTraits_3:: Point_3</i>	The point type. The (in)equality tests must be available. Access to the point coordinates is done via the <i>get_..()</i> functions. Constructing a point is done with the <i>make_point()</i> operation.
<i>WidthTraits_3:: Plane_3</i>	The plane type. Access to the coefficients of the plane is made via the <i>get_..()</i> functions. Constructing a plane is done with the <i>make_plane()</i> operation.
<i>WidthTraits_3:: Vector_3</i>	The vector type. There is no need to access the coefficients of a vector; only constructing is required and is done with the <i>make_vector</i> operation.
<i>WidthTraits_3:: ChullTraits</i>	The traits class for using the convex hull algorithm. It must be a model of the concept <i>ConvexHullTraits_3</i> . This class is used only if the width is computed from a set of points.
<i>WidthTraits_3:: RT</i>	Ring type numbers. Internally all numbers are treated as ring type numbers, i.e., neither $/$ -operator nor $\sqrt{\phantom{x}}$ nor other inexact operations are used. But because the algorithm does not use any divisions, but multiplication instead, the numbers can get really big. Therefore it is recommended to use a ring type number, that provides values of arbitrary length. Furthermore it is assumed that the underlying number type of <i>Point_3</i> , <i>Plane_3</i> and <i>Vector_3</i> equals <i>RT</i> .

*Notes:* If you want to compute the width of a *polyhedron* then you have to make sure that the point type in the traits class and the point type in the polyhedron class are the same! The same holds for *Traits::Plane\_3* and *Polyhedron::Plane\_3*.

### Creation

Only a default constructor is required.

```
WidthTraits_3 traits;
```

### Operations

Whatever the coordinates of the points are, it is required for the width-algorithm to have access to the homogeneous representation of points.

<i>RT</i>	<i>get_hx( Point_3 p)</i>	returns the homogeneous <i>x</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>get_hy( Point_3 p)</i>	returns the homogeneous <i>y</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>get_hz( Point_3 p)</i>	returns the homogeneous <i>z</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>get_hw( Point_3 p)</i>	returns the homogenizing coordinate of point <i>p</i> .
<i>void</i>	<i>get_point_coordinates( Point_3 p, RT&amp; px, RT&amp; py, RT&amp; pz, RT&amp; ph)</i>	returns all homogeneous coordinates of point <i>p</i> at once.
<i>RT</i>	<i>get_a( Plane_3 f)</i>	returns the first coefficient of plane <i>f</i> .
<i>RT</i>	<i>get_b( Plane_3 f)</i>	returns the second coefficient of plane <i>f</i> .

<i>RT</i>	<i>get_c( Plane_3 f)</i>	returns the third coefficient of plane <i>f</i> .
<i>RT</i>	<i>get_d( Plane_3 f)</i>	returns the fourth coefficient of plane <i>f</i> .
<i>void</i>	<i>get_plane_coefficients( Plane_3 f, RT&amp; a, RT&amp; b, RT&amp; c, RT&amp; d)</i>	returns all four plane coefficients of <i>f</i> at once.
<i>Point_3</i>	<i>make_point( RT hx, RT hy, RT hz, RT hw)</i>	returns a point of type <i>Point_3</i> with homogeneous coordinates <i>hx</i> , <i>hy</i> , <i>hz</i> and <i>hw</i> .
<i>Plane_3</i>	<i>make_plane( RT a, RT b, RT c, RT d)</i>	returns a plane of type <i>Plane_3</i> with coefficients <i>a</i> , <i>b</i> , <i>c</i> and <i>d</i> .
<i>Vector_3</i>	<i>make_vector( RT a, RT b, RT c)</i>	returns a vector of type <i>Vector_3</i> with the four homogeneous coefficients <i>a</i> , <i>b</i> , <i>c</i> and 1.

## CGAL::Polytope\_distance\_d<Traits>

### Definition

An object of the class *Polytope\_distance\_d<Traits>* represents the (squared) distance between two convex polytopes, given as the convex hulls of two finite point sets in  $d$ -dimensional Euclidean space  $\mathbb{E}_d$ . For point sets  $P$  and  $Q$  we denote by  $pd(P, Q)$  the distance between the convex hulls of  $P$  and  $Q$ . Note that  $pd(P, Q)$  can be degenerate, i.e.  $pd(P, Q) = \infty$  if  $P$  or  $Q$  is empty.

Two inclusion-minimal subsets  $S_P$  of  $P$  and  $S_Q$  of  $Q$  with  $pd(S_P, S_Q) = pd(P, Q)$  are called *pair of support sets*, the points in  $S_P$  and  $S_Q$  are the *support points*. A pair of support sets has size at most  $d + 2$  (by size we mean  $|S_P| + |S_Q|$ ). The distance between the two polytopes is *realized* by a pair of points  $p$  and  $q$  lying in the convex hull of  $S_P$  and  $S_Q$ , respectively, i.e.  $\sqrt{\|p - q\|} = pd(P, Q)$ . In general, neither the support sets nor the realizing points are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g.  $P$  and  $Q$  may be in non-convex position or points may occur more than once. The algorithm computes a pair of support sets  $S_P$  and  $S_Q$  with realizing points  $p$  and  $q$  which remain fixed until the next set, insert, or clear operation.

```
#include <CGAL/Polytope_distance_d.h>
```

### Requirements

The template parameter *Traits* is a model for *OptimisationDTraits*.

We provide the models *Optimisation\_d\_traits\_2*, *Optimisation\_d\_traits\_3*, and *Optimisation\_d\_traits\_d* using the two-, three-, and  $d$ -dimensional CGAL kernel, respectively.

### Types

*Polytope\_distance\_d<Traits>::Point*    typedef to *Traits::Point\_d*. Point type used to represent the input points.

*Polytope\_distance\_d<Traits>::FT*    typedef to *Traits::FT*. Number type used to return the squared distance between the two polytopes.

*Polytope\_distance\_d<Traits>::ET*    typedef to *Traits::ET*. Number type used to do the exact computations in the underlying solver for quadratic programs (cf. **Implementation**).

*Polytope\_distance\_d<Traits>::Point\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the points of the two polytopes.

*Polytope\_distance\_d<Traits>::Support\_point\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points.

*Polytope\_distance\_d*<Traits>:: *Support\_point\_index\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *int*. Used to access the indices of the support points in the provided input order (starting from 0 in both point sets).

*Polytope\_distance\_d*<Traits>:: *Coordinate\_iterator*

non-mutable model of the STL concept *RandomAccessIterator* with value type *ET*. Used to access the coordinates of the realizing points.

## Creation

```
Polytope_distance_d<Traits> poly_dist( Traits traits = Traits(),
                                     int verbose = 0,
                                     std::ostream& stream = std::cout)

                                     initializes poly_dist to pd( $\emptyset, \emptyset$ ).
```

```
template < class InputIterator1, class InputIterator2 >
Polytope_distance_d<Traits> poly_dist( InputIterator1 p_first,
                                     InputIterator1 p_last,
                                     InputIterator2 q_first,
                                     InputIterator2 q_last,
                                     Traits traits = Traits(),
                                     int verbose = 0,
                                     std::ostream& stream = std::cout)
```

initializes *poly\_dist* to *pd*( $P, Q$ ) with  $P$  and  $Q$  being the sets of points in the range  $[p\_first, p\_last)$  and  $[q\_first, q\_last)$ , respectively.

*Requirement:* The value type of *InputIterator1* and *InputIterator2* is *Point*.

*Precondition:* All points have the same dimension.

— advanced —

If *verbose* is set to 1, 2, or 3 then some, more, or full verbose output of the underlying solver for quadratic programs is written to *stream*, resp.

— advanced —

## Access Functions

*int* *poly\_dist.ambient\_dimension*()

returns the dimension of the points in  $P$  and  $Q$ . If *poly\_dist* is *pd*( $\emptyset, \emptyset$ ), the ambient dimension is  $-1$ .

<i>int</i>	<i>poly_dist.number_of_points()</i>	returns the number of all points of <i>poly_dist</i> , i.e. $ P  +  Q $ .
<i>int</i>	<i>poly_dist.number_of_points_p()</i>	returns the number of points in <i>P</i> .
<i>int</i>	<i>poly_dist.number_of_points_q()</i>	returns the number of points in <i>Q</i> .
<i>int</i>	<i>poly_dist.number_of_support_points()</i>	returns the number of support points of <i>poly_dist</i> , i.e. $ S_P  +  S_Q $ .
<i>int</i>	<i>poly_dist.number_of_support_points_p()</i>	returns the number of support points in <i>S<sub>P</sub></i> .
<i>int</i>	<i>poly_dist.number_of_support_points_q()</i>	returns the number of support points in <i>S<sub>Q</sub></i> .
<i>Point_iterator</i>	<i>poly_dist.points_p_begin()</i>	returns an iterator referring to the first point in <i>P</i> .
<i>Point_iterator</i>	<i>poly_dist.points_p_end()</i>	returns the corresponding past-the-end iterator.
<i>Point_iterator</i>	<i>poly_dist.points_q_begin()</i>	returns an iterator referring to the first point in <i>Q</i> .
<i>Point_iterator</i>	<i>poly_dist.points_q_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_iterator</i>	<i>poly_dist.support_points_p_begin()</i>	returns an iterator referring to the first support point in <i>S<sub>P</sub></i> .
<i>Support_point_iterator</i>	<i>poly_dist.support_points_p_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_iterator</i>	<i>poly_dist.support_points_q_begin()</i>	returns an iterator referring to the first support point in <i>S<sub>Q</sub></i> .
<i>Support_point_iterator</i>	<i>poly_dist.support_points_q_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_p_indices_begin()</i>	returns an iterator referring to the index of the first support point in <i>P</i> .
<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_p_indices_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_q_indices_begin()</i>	returns an iterator referring to the index of the first support point in <i>Q</i> .

<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_q_indices_end()</i> returns the corresponding past-the-end iterator.
<i>Point</i>	<i>poly_dist.realizing_point_p()</i>  returns the realizing point of $P$ . <i>Requirement:</i> An implicit conversion from $ET$ to $RT$ is available. <i>Precondition:</i> $pd(P, Q)$ is finite.
<i>Point</i>	<i>poly_dist.realizing_point_q()</i>  returns the realizing point of $Q$ . <i>Requirement:</i> An implicit conversion from $ET$ to $RT$ is available. <i>Precondition:</i> $pd(P, Q)$ is finite.
<i>ET</i>	<i>poly_dist.squared_distance()</i>  returns the squared distance of <i>poly_dist</i> , i.e. $(pd(P, Q))^2$ . <i>Requirement:</i> An implicit conversion from $ET$ to $RT$ is available. <i>Precondition:</i> $pd(P, Q)$ is finite.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_p_coordinates_begin()</i> returns an iterator referring to the first coordinate of the realizing point of $P$ . <i>Note:</i> The coordinates have a rational representation, i.e. the first $d$ elements of the iterator range are the numerators and the $(d+1)$ -st element is the common denominator.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_p_coordinates_end()</i> returns the corresponding past-the-end iterator.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_q_coordinates_begin()</i> returns an iterator referring to the first coordinate of the realizing point of $Q$ . <i>Note:</i> The coordinates have a rational representation, i.e. the first $d$ elements of the iterator range are the numerators and the $(d+1)$ -st element is the common denominator.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_q_coordinates_end()</i> returns the corresponding past-the-end iterator.
<i>ET</i>	<i>poly_dist.squared_distance_numerator()</i>  returns the numerator of the squared distance of <i>poly_dist</i> .
<i>ET</i>	<i>poly_dist.squared_distance_denominator()</i>  returns the denominator of the squared distance of <i>poly_dist</i> .

## Predicates

<i>bool</i>	<i>poly_dist.is_finite()</i>	returns <i>true</i> , if $pd(P, Q)$ is finite, i.e. none of the two polytopes is empty.
<i>bool</i>	<i>poly_dist.is_zero()</i>	returns <i>true</i> , if $pd(P, Q)$ is zero, i.e. the two polytopes intersect (this implies degeneracy).
<i>bool</i>	<i>poly_dist.is_degenerate()</i>	returns <i>true</i> , iff $pd(P, Q)$ is degenerate, i.e. $pd(P, Q)$ is not finite.

## Modifiers

<i>void</i>	<i>poly_dist.clear()</i>	resets <i>poly_dist</i> to $pd(\emptyset, \emptyset)$ .
<i>template &lt; class InputIterator1, class InputIterator2 &gt;</i> <i>void</i>	<i>poly_dist.set( InputIterator1 p_first,</i> <i>                  InputIterator1 p_last,</i> <i>                  InputIterator2 q_first,</i> <i>                  InputIterator2 q_last)</i>	sets <i>poly_dist</i> to $pd(P, Q)$ with $P$ and $Q$ being the sets of points in the ranges $[p\_first, p\_last)$ and $[q\_first, q\_last)$ , respectively. <i>Requirement:</i> The value type of <i>InputIterator1</i> and <i>InputIterator2</i> is <i>Point</i> . <i>Precondition:</i> All points have the same dimension.

<i>template &lt; class InputIterator &gt;</i> <i>void</i>	<i>poly_dist.set_p( InputIterator p_first, InputIterator p_last)</i>	sets <i>poly_dist</i> to $pd(P, Q)$ with $P$ being the set of points in the range $[p\_first, p\_last)$ ( $Q$ remains unchanged). <i>Requirement:</i> The value type of <i>InputIterator</i> is <i>Point</i> . <i>Precondition:</i> All points in $P$ have dimension <i>poly_dist.ambient_dimension()</i> if $Q$ is not empty.
--	--	--

<i>template &lt; class InputIterator &gt;</i> <i>void</i>	<i>poly_dist.set_q( InputIterator q_first, InputIterator q_last)</i>	sets <i>poly_dist</i> to $pd(P, Q)$ with $Q$ being the set of points in the range $[q\_first, q\_last)$ ( $P$ remains unchanged). <i>Requirement:</i> The value type of <i>InputIterator</i> is <i>Point</i> . <i>Precondition:</i> All points in $Q$ have dimension <i>poly_dist.ambient_dimension()</i> if $P$ is not empty.
--	--	--

void *poly\_dist.insert\_p( Point p)*

inserts  $p$  into  $P$ .

*Precondition:* The dimension of  $p$  equals *poly\_dist.ambient\_dimension()* if *poly\_dist* is not *pd(0,0)*.

void *poly\_dist.insert\_q( Point q)*

inserts  $q$  into  $Q$ .

*Precondition:* The dimension of  $q$  equals *poly\_dist.ambient\_dimension()* if *poly\_dist* is not *pd(0,0)*.

template < class *InputIterator1*, class *InputIterator2* >  
void *poly\_dist.insert( InputIterator1 p\_first,*  
*InputIterator1 p\_last,*  
*InputIterator2 q\_first,*  
*InputIterator2 q\_last)*

inserts the points in the range  $[p\_first, p\_last)$  and  $[q\_first, q\_last)$  into  $P$  and  $Q$ , respectively, and recomputes the (squared) distance.

*Requirement:* The value type of *InputIterator1* and *InputIterator2* is *Point*.

*Precondition:* All points have the same dimension. If *poly\_dist* is not *pd(0,0)*, this dimension must be equal to *poly\_dist.ambient\_dimension()*.

template < class *InputIterator* >  
void *poly\_dist.insert\_p( InputIterator p\_first, InputIterator p\_last)*

inserts the points in the range  $[p\_first, p\_last)$  into  $P$  and recomputes the (squared) distance ( $Q$  remains unchanged).

*Requirement:* The value type of *InputIterator* is *Point*.

*Precondition:* All points have the same dimension. If *poly\_dist* is not empty, this dimension must be equal to *poly\_dist.ambient\_dimension()*.

template < class *InputIterator* >  
void *poly\_dist.insert\_q( InputIterator q\_first, InputIterator q\_last)*

inserts the points in the range  $[q\_first, q\_last)$  into  $Q$  and recomputes the (squared) distance ( $P$  remains unchanged).

*Requirement:* The value type of *InputIterator* is *Point*.

*Precondition:* All points have the same dimension. If *poly\_dist* is not empty, this dimension must be equal to *poly\_dist.ambient\_dimension()*.

## Validity Check

An object *poly\_dist* is valid, iff ...

- *poly\_dist* contains all points of its defining set *P*,
- *poly\_dist* is the smallest sphere containing its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

*bool*                      *poly\_dist.is\_valid( bool verbose = false, int level = 0)*

returns *true*, iff *poly\_dist* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

## Miscellaneous

*const Traits&*              *poly\_dist.traits()*              returns a const reference to the traits class object.

## I/O

*std::ostream&*              *std::ostream& os << poly\_dist*

writes *poly\_dist* to output stream *os*.  
*Requirement:* The output operator is defined for *Point\_d*.

*std::istream&*              *std::istream& is >> poly\_dist&*

reads *poly\_dist* from input stream *is*.  
*Requirement:* The input operator is defined for *Point\_d*.

## Implementation

The problem of finding the distance between two convex polytopes given as the convex hulls of two finite point sets can be formulated as an optimization problem with linear constraints and a convex quadratic objective function. The solution is obtained using our exact solver for quadratic programs [GS00].

The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time. The clear operation and the check for validity each take linear time.

## PolytopeDistanceDTraits

### Definition

This concept defines the requirements for traits classes of  $d$ -dimensional optimisation algorithms.

### Types

<i>PolytopeDistanceDTraits:: Point_d</i>	point type used to represent the input points.
<i>PolytopeDistanceDTraits:: Rep_tag</i>	compile time tag to distinguish between Cartesian and homogeneous representation of the input points. <i>Rep_tag</i> has to be either <i>CGAL::Cartesian_tag</i> or <i>CGAL::Homogeneous_tag</i> .
<i>PolytopeDistanceDTraits:: RT</i>	number type used to represent the coordinates of the input points. It has to be a model for <i>RingNumberType</i> .
<i>PolytopeDistanceDTraits:: FT</i>	number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. <i>FT</i> has to be either <i>RT</i> or <i>CGAL::Quotient&lt;RT&gt;</i> if the input points have Cartesian or homogeneous representation, respectively (cf. <i>Rep_tag</i> ).
<i>PolytopeDistanceDTraits:: Access_dimension_d</i>	data accessor object used to access the dimension of the input points.
<i>PolytopeDistanceDTraits:: Access_coordinates_begin_d</i>	data accessor object used to access the coordinates of the input points.
<i>PolytopeDistanceDTraits:: Construct_point_d</i>	constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.

The following two number types are only needed for *CGAL::Min\_annulus\_d<Traits>* and *CGAL::Polytope\_distance\_d<Traits>*.

<i>PolytopeDistanceDTraits:: ET</i>	exact number type used to do the exact computations in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be an implicit conversion from <i>RT</i> to <i>ET</i> available.
<i>PolytopeDistanceDTraits:: NT</i>	fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be implicit conversions from <i>RT</i> to <i>NT</i> and from <i>NT</i> to <i>ET</i> available.

## Creation

Only default and copy constructor are required.

```
PolytopeDistanceDTraits traits;
```

```
PolytopeDistanceDTraits traits( PolytopeDistanceDTraits);
```

## Operations

The following functions just return the corresponding function class object.

```
Access_dimension_d traits.access_dimension_d_object()
```

```
Access_coordinates_begin_d traits.access_coordinates_begin_d_object()
```

```
Construct_point_d traits.construct_point_d_object()
```

## CGAL::Polytope\_distance\_d\_traits\_3&lt;K,ET,NT&gt;

### Definition

The class *Polytope\_distance\_d\_traits\_3<K,ET,NT>* is a traits class for the  $d$ -dimensional optimisation algorithms using the three-dimensional CGAL kernel.

```
#include <CGAL/Polytope_distance_d_traits_3.h>
```

## Requirements

The template parameter  $K$  is a model for *Kernel*. Template parameters  $ET$  and  $NT$  are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

## Is Model for the Concepts

PolytopeDistanceDTraits ..... page 3143

## Types

*Polytope\_distance\_d\_traits\_3<K,ET,NT>::Point\_d* typedef to *K::Point\_3*.

*Polytope\_distance\_d\_traits\_3*<K,ET,NT>::Rep\_tag typedef to K::Rep\_tag.

*Polytope\_distance\_d\_traits\_3*<*K*,*ET*,*NT*>::*RT*      typedef to *K*::*RT*.

*Polytope\_distance\_d\_traits\_3*<*K*,*ET*,*NT*>::*FT*      typedef to *K*::*FT*.

```
Polytope_distance_d_traits_3<K,ET,NT>>:: Access_dimension_d
```

```
typedef to K::Access_dimension_3.
```

*Polytope\_distance\_d\_traits\_3<K,ET,NT>::Access\_coordinates\_begin\_d*  
 typedef to *K::Access\_coordinates\_begin\_3*.

```
Polytope_distance_d_traits_3<K,ET,NT>>:: Construct_point_d
```

```
typedef to K::Construct_point_3.
```

*Polytope\_distance\_d\_traits\_3*<*K*,*ET*,*NT*>::*ET*      second template parameter (default is *K*::*RT*).

*Polytope\_distance\_d\_traits\_3*<*K*,*ET*,*NT*>::*NT*      third template parameter (default is *K*::*RT*).

## Creation

*Polytope\_distance\_d\_traits\_3*<*K,ET,NT*> *traits*;      default constructor.

*Polytope\_distance\_d\_traits\_3*<*K,ET,NT*> *traits*( *Polytope\_distance\_d\_traits\_3*<*K,ET,NT*>);  
copy constructor.

## Operations

The following functions just return the corresponding function class object.

*Access\_dimension\_d*      *traits.access\_dimension\_d\_object()*

*Access\_coordinates\_begin\_d*      *traits.access\_coordinates\_begin\_d\_object()*

*Construct\_point\_d*      *traits.construct\_point\_d\_object()*

---

This package provides functions to analyze sets of objects in 2D and 3D. It provides the computation of axis-aligned bounding boxes, centers of mass and principal component analysis for all bounded objects, as well as barycenters for sets of weighted points. Note that unlike most of the CGAL packages, this package uses approximation methods (in particular for linear least squares fitting) and is not intended to provide an exact canonical result in any sense.

### 57.1 Definitions

A *bounding box* for a set of objects is a cuboid that contains the set. An *axis-aligned bounding box* is an expression of the maximum extents of all objects from the set within their coordinate system, i.e., a bounding box aligned with the axes of the coordinate system. Axis-aligned bounding boxes are frequently used in geometric algorithms as an indication of the general position of a data set, for either display, first-approximation spatial query, or spatial indexing purposes.

A *centroid* of a set of objects is their center of mass, i.e., the point whose coordinates are computed by means of coordinates of all points composing the objects. Note that although the general definition of center of mass incorporates a density function (and hence weighted means), the current implementation assumes a uniform density (see barycenter below defined for weighted points). For a point set  $\{X_1, X_2, \dots, X_N\}$  the centroid  $\bar{X}$  is

computed as

$$\bar{X} = \frac{1}{N} \sum_{i=1}^N X_i.$$

For a set of segments  $\{S_1, S_2, \dots, S_N\}$  the centroid  $\bar{X}$  is computed as

$$\bar{X} = \frac{1}{\sum_{i=1}^N |S_i|} \sum_{i=1}^N |S_i| \bar{S}_i,$$

where  $|S_i|$  stands for the length of a segment and  $\bar{S}_i$  stands for its uniform barycenter (midpoint). For a set of triangles  $\{T_1, T_2, \dots, T_N\}$  the centroid  $\bar{X}$  is computed as

$$\bar{X} = \frac{1}{\sum_{i=1}^N |T_i|} \sum_{i=1}^N |T_i| \bar{T}_i,$$

where  $|T_i|$  stands for the area of a triangle and  $\bar{T}_i$  stands for its uniform barycenter. Such definition still holds for more general objects where the Lebesgue measure (length in 1D, area in 2D, volume in 3D) is used for weighting the object barycenters. Centers of mass are used to summarize data sets for either approximation, spatial query or spatial indexing purposes.

A *barycenter* of a set of weighted points is the point whose coordinates are computed by means of weighted coordinates of all weighted points from the set. When all weights are equal the barycenter coincides with the centroid.

Given a set of objects, *linear least squares fitting* amounts to finding the linear sub-space which minimizes the sum of squared distances from all points composing the objects of the set, to their projection onto this linear sub-space. Such linear sub-space is obtained by so-called principal component analysis (PCA). PCA is defined as a transformation that transforms the objects to a new coordinate system such that the greatest variance by orthogonal projection of the objects comes to lie on the first coordinate (called the first principal component), the second greatest variance on the second coordinate, and so on. PCA is often used in geometric applications to reduce data sets to lower dimensions for analysis or approximation. Figure below illustrates (least squares) fitting of a line to a 2D point set, fitting of a line and a plane to a 3D point set and fitting of a plane to a set of 3D triangles.

Figure 57.1: Left: fitting a line to a 2D point set (centroid dotted in red). Middle: fitting a line and a plane to a 3D point set. Right: fitting a plane to a set of 3D triangles.

## 57.2 Examples

### 57.2.1 Bounding Box of 2D and 3D Point Sets

In the following example we use STL containers of 2D points and 3D points, and compute their axis-aligned bounding box. The kernel from which the input points originate is automatically deduced by the function.

```
#include <CGAL/Cartesian.h>
#include <CGAL/bounding_box.h>

#include <list>
#include <iostream>

typedef double          FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Point_2      Point_2;
typedef K::Point_3      Point_3;

int main()
{
    // axis-aligned bounding box of 2D points
    std::list<Point_2> points_2;
    points_2.push_back(Point_2(1.0, 0.0));
    points_2.push_back(Point_2(2.0, 2.0));
    points_2.push_back(Point_2(3.0, 5.0));

    K::Iso_rectangle_2 c2 = CGAL::bounding_box(points_2.begin(), points_2.end());
    std::cout << c2 << std::endl;

    // axis-aligned bounding box of 3D points
    std::list<Point_3> points_3;
    points_3.push_back(Point_3(1.0, 0.0, 0.5));
    points_3.push_back(Point_3(2.0, 2.0, 1.2));
    points_3.push_back(Point_3(3.0, 5.0, 4.5));

    K::Iso_cuboid_3 c3 = CGAL::bounding_box(points_3.begin(), points_3.end());
    std::cout << c3 << std::endl;

    return 0;
}
```

**File:** examples/Principal\_component\_analysis/bounding\_box.cpp

### 57.2.2 Centroid of 2D and 3D Objects

In the following example we use STL containers of 2D, 3D points and 3D triangles, and compute their centroid. The kernel from which the input objects originate is automatically deduced by the function. The dimension tag indicates the dimension of the objects being fitted (0 for points, 2 for triangles). Note that it is also possible to compute the centroid of the triangle edges (3D segments) by specifying 1 as dimension tag, and to compute the centroid of the triangle vertices (3D points) by specifying 0 as dimension tag.

```

#include <CGAL/Cartesian.h>
#include <CGAL/centroid.h>

#include <list>
#include <iostream>

typedef double          FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Point_2      Point_2;
typedef K::Point_3      Point_3;
typedef K::Triangle_3    Triangle_3;

int main()
{
    // centroid of 2D points
    std::list<Point_2> points_2;
    points_2.push_back(Point_2(1.0, 0.0));
    points_2.push_back(Point_2(2.0, 2.0));
    points_2.push_back(Point_2(3.0, 5.0));
    Point_2 c2 = CGAL::centroid(points_2.begin(), points_2.end(), CGAL::Dimension_tag<0>());
    std::cout << c2 << std::endl;

    // centroid of 3D points
    std::list<Point_3> points_3;
    points_3.push_back(Point_3(1.0, 0.0, 0.5));
    points_3.push_back(Point_3(2.0, 2.0, 1.2));
    points_3.push_back(Point_3(3.0, 5.0, 4.5));
    Point_3 c3 = CGAL::centroid(points_3.begin(), points_3.end(), CGAL::Dimension_tag<0>());
    std::cout << c3 << std::endl;

    // centroid of 3D triangles
    std::list<Triangle_3> triangles_3;
    Point_3 p(1.0, 0.0, 0.0);
    Point_3 q(1.0, 2.0, 0.0);
    Point_3 r(0.0, 1.0, 3.0);
    Point_3 s(0.0, 2.0, 5.0);
    triangles_3.push_back(Triangle_3(p,q,r));
    triangles_3.push_back(Triangle_3(p,q,s));
    c3 = CGAL::centroid(triangles_3.begin(), triangles_3.end(), CGAL::Dimension_tag<2>());
    std::cout << c3 << std::endl;

    return 0;
}

```

**File:** examples/Principal\_component\_analysis/centroid.cpp

### 57.2.3 Barycenter of a Set of Weighted Points

In the following example we use STL containers of 2D and 3D weighted points, and compute their barycenter. The kernel from which the input weighted points originate is automatically deduced by the function.

```

#include <CGAL/Cartesian.h>

```

```

#include <CGAL/barycenter.h>

#include <list>
#include <iostream>
#include <utility>

typedef double          FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Point_2      Point_2;
typedef K::Point_3      Point_3;

int main()
{
    // barycenter of 2D weighted points
    std::list<std::pair<Point_2, FT> > points_2;
    points_2.push_back(std::make_pair(Point_2(1.0, 0.0), 1.0));
    points_2.push_back(std::make_pair(Point_2(2.0, 2.0), 2.0));
    points_2.push_back(std::make_pair(Point_2(3.0, 5.0), -2.0));

    Point_2 c2 = CGAL::barycenter(points_2.begin(), points_2.end());
    std::cout << c2 << std::endl;

    // barycenter of 3D weighted points
    std::list<std::pair<Point_3, FT> > points_3;
    points_3.push_back(std::make_pair(Point_3(1.0, 0.0, 0.5), 1.0));
    points_3.push_back(std::make_pair(Point_3(2.0, 2.0, 1.2), 2.0));
    points_3.push_back(std::make_pair(Point_3(3.0, 5.0, 4.5), -5.0));

    Point_3 c3 = CGAL::barycenter(points_3.begin(), points_3.end());
    std::cout << c3 << std::endl;

    return 0;
}

```

**File:** examples/Principal\_component\_analysis/barycenter.cpp

## 57.2.4 Least Squares Fitting of a Line to a 2D Point Set

In the following example we use a STL container of 2D points, and compute the best fitting line in the least squares sense. The kernel from which the input points originate is automatically deduced by the function.

```

#include <CGAL/Cartesian.h>
#include <CGAL/linear_least_squares_fitting_2.h>
#include <list>

typedef double          FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Line_2       Line;
typedef K::Point_2      Point;

int main()
{

```

```

std::list<Point> points;
points.push_back(Point(1.0,2.0));
points.push_back(Point(3.0,4.0));
points.push_back(Point(5.0,6.0));

// fit line
Line line;
linear_least_squares_fitting_2(points.begin(),points.end(),line,CGAL::Dimension_tag<0>());

return 0;
}

```

**File:** examples/Principal\_component\_analysis/linear\_least\_squares\_fitting\_points\_2.cpp

### 57.2.5 Least Squares Fitting of a Line and a Plane to a 3D Triangle Set

In the following example we use a STL container of 3D triangles, and compute the best fitting line and plane in the least squares sense. The kernel from which the input triangles originate is automatically deduced by the function. Note that we can fit either the whole triangles, the triangle edges or the triangle vertices.

```

#include <CGAL/Cartesian.h>
#include <CGAL/linear_least_squares_fitting_3.h>
#include <list>

typedef double FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Line_3 Line;
typedef K::Plane_3 Plane;
typedef K::Point_3 Point;
typedef K::Triangle_3 Triangle;

int main(void)
{
    std::list<Triangle> triangles;
    Point a(1.0,2.0,3.0);
    Point b(4.0,0.0,6.0);
    Point c(7.0,8.0,9.0);
    Point d(8.0,7.0,6.0);
    Point e(5.0,3.0,4.0);
    triangles.push_back(Triangle(a,b,c));
    triangles.push_back(Triangle(a,b,d));
    triangles.push_back(Triangle(d,e,c));

    Line line;
    Plane plane;

    // fit plane to whole triangles
    linear_least_squares_fitting_3(triangles.begin(),triangles.end(),plane,CGAL::Dimension_tag<2>());

    // fit line to triangle vertices
    linear_least_squares_fitting_3(triangles.begin(),triangles.end(),line, CGAL::Dimension_tag<0>());
}

```

```
    return 0;  
}
```

**File:** examples/Principal\_component\_analysis/linear\_least\_squares\_fitting\_triangles\_3.cpp

# Principal Component Analysis Reference Manual

*Pierre Alliez, Sylvain Pion and Ankit Gupta*

This CGAL package provides functions to compute global information about the shape of a set of 2D or 3D objects. It provides the computation of axis-aligned bounding boxes for point sets, and barycenters of weighted point sets. In addition, it provides computation of centroids (center of mass) and linear least squares fitting for point sets as well as for sets of other bounded objects. More specifically, it is possible to fit 2D lines to 2D segments, circles, disks, iso rectangles and triangles, as well as to fit 3D lines or 3D planes to 3D segments, triangles, iso cuboids, tetrahedra, spheres and balls. The common interface to these functions takes an iterator range of objects.

## CGAL::bounding\_box

### Definition

The function *bounding\_box* computes the axis-aligned bounding box of a set of 2D or 3D points. The bounding box is returned either as an iso rectangle in 2D or as an iso cuboid in 3D, the type being deduced automatically from the value type of the iterator range.

```
#include <CGAL/bounding_box.h>
```

There is a set of overloaded *bounding\_box* functions for 2D and 3D points. The user can also optionally pass an explicit kernel, in case the default, based on *Kernel\_traits* is not sufficient. The dimension is also deduced automatically.

```
template < typename InputIterator >
K::Iso_rectangle_2    bounding_box( InputIterator first, InputIterator beyond)
```

computes the bounding box of a non-empty set of 2D points. *K* is *Kernel\_traits*<*std::iterator\_traits*<*InputIterator*>::value\_type>::Kernel. The value type must be *K::Point\_2*.  
*Precondition*: first != beyond.

```
template < typename InputIterator, typename K >
K::Iso_rectangle_2    bounding_box( InputIterator first, InputIterator beyond, K k)
```

computes the bounding box of a non-empty set of 2D points. The value type must be *K::Point\_2*.  
*Precondition*: first != beyond.

```
template < typename InputIterator >
K::Iso_cuboid_3       bounding_box( InputIterator first, InputIterator beyond)
```

computes the bounding box of a non-empty set of 3D points. *K* is *Kernel\_traits*<*std::iterator\_traits*<*InputIterator*>::value\_type>::Kernel. The value type must be *K::Point\_3*.  
*Precondition*: first != beyond.

```
template < typename InputIterator, typename K >
K::Iso_cuboid_3       bounding_box( InputIterator first, InputIterator beyond, K k)
```

computes the bounding box of a non-empty set of 3D points. The value type must be *K::Point\_3*.  
*Precondition*: first != beyond.

## CGAL::centroid

### Definition

The function *centroid* computes the (uniform) center of mass of a set of 2D or 3D bounded objects. In 2D these objects include points, segments, triangles, iso rectangles, circles and disks. In 3D these objects include points, segments, triangles, iso cuboids, spheres, balls and tetrahedra.

```
#include <CGAL/centroid.h>
```

There is a set of overloaded *centroid* functions for 2D and 3D objects. The user can also optionally pass an explicit kernel, in case the default based on *Kernel\_traits* is not sufficient. The default dimension tag is deduced automatically, although the user can pass a *tag* specifying the dimension of the objects to be considered for the centroid computation. For example, the default dimension of a tetrahedron is 3, but specifying a dimension 0 computes the centroid of the tetrahedron vertices (3D points), specifying a dimension 1 computes the centroid of the tetrahedron edges (3D segments) and specifying a dimension 2 computes the centroid of the tetrahedron facets (3D triangles).

```
template < typename InputIterator, typename Tag >
K::Point_2 centroid( InputIterator first, InputIterator beyond, Tag t)
```

computes the centroid of a non-empty set of 2D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel\_traits*<*std::iterator\_traits*<*InputIterator*>::value\_type>::Kernel. The value type must be either *K::Point\_2*, *K::Segment\_2*, *K::Triangle\_2*, *K::Rectangle\_2* or *K::Circle\_2*. To fit a set of disks the user must call the function with value type *K::Circle\_2* and with dimension tag of 2. The tag must range between *CGAL::Dimension\_tag*<0> and *CGAL::Dimension\_tag*<2>. *Precondition*: first != beyond.

```
template < typename InputIterator, typename K, typename Tag >
K::Point_2 centroid( InputIterator first, InputIterator beyond, K k, Tag t)
```

computes the centroid of a non-empty set of 2D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel\_traits*<*std::iterator\_traits*<*InputIterator*>::value\_type>::Kernel. The value type must be either *K::Point\_2*, *K::Segment\_2*, *K::Triangle\_2*, *K::Rectangle\_2* or *K::Circle\_2*. To fit a set of disks the user must call the function with value type *K::Circle\_2* and with dimension tag of 2. The tag must range between *CGAL::Dimension\_tag*<0> and *CGAL::Dimension\_tag*<2>. *Precondition*: first != beyond.

```
template < typename InputIterator, typename Tag >
```

*K::Point\_3*

*centroid( InputIterator first, InputIterator beyond, Tag t)*

computes the centroid of a non-empty set of 3D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel\_traits<std::iterator\_traits<InputIterator>::value\_type>::Kernel*. The value type must be either *K::Point\_3*, *K::Segment\_3*, *Triangle\_3*, *Cuboid\_3*, *Sphere\_3* or *Tetrahedron\_3*. To fit a set of balls the user must call the function with value type *K::Sphere\_3* and with dimension tag of 3. The tag must range between *CGAL::Dimension\_tag<0>* and *CGAL::Dimension\_tag<3>*.  
*Precondition:* first != beyond.

*template < typename InputIterator, typename K, typename Tag >*

*K::Point\_3*

*centroid( InputIterator first, InputIterator beyond, K k, Tag t)*

computes the centroid of a non-empty set of 3D objects. The tag is used to specify the dimension to be considered from the objects. *K* is *Kernel\_traits<std::iterator\_traits<InputIterator>::value\_type>::Kernel*. The value type must be either *K::Point\_3*, *K::Segment\_3*, *Triangle\_3*, *Cuboid\_3*, *Sphere\_3* or *Tetrahedron\_3*. To fit a set of balls the user must call the function with value type *K::Sphere\_3* and with dimension tag of 3. The tag must range between *CGAL::Dimension\_tag<0>* and *CGAL::Dimension\_tag<3>*.  
*Precondition:* first != beyond.

## CGAL::barycenter

### Definition

The function *barycenter* computes the barycenter (weighted center of mass) of a set of 2D or 3D weighted points. The weight associated to each point is specified using a *std::pair* storing the point and its weight.

```
#include <CGAL/barycenter.h>
```

There is a set of overloaded *barycenter* functions for 2D and 3D weighted points. The user can also optionally pass an explicit kernel, in case the default, based on *Kernel\_traits* is not sufficient. The dimension is also deduced automatically.

```
template < typename InputIterator >
```

```
K::Point_2          barycenter( InputIterator first, InputIterator beyond)
```

computes the barycenter of a non-empty set of 2D weighted points. *K* is *Kernel\_traits<std::iterator\_traits<InputIterator>::value\_type::first\_type>::Kernel*. The value type must be *std::pair<K::Point\_2, K::FT>*.

*Precondition:* first != beyond, and the sum of the weights is non-zero.

```
template < typename InputIterator, typename K >
```

```
K::Point_2          barycenter( InputIterator first, InputIterator beyond, K k)
```

computes the barycenter of a non-empty set of 2D weighted points. The value type must be *std::pair<K::Point\_2, K::FT>*.

*Precondition:* first != beyond, and the sum of the weights is non-zero.

```
template < typename InputIterator >
```

```
K::Point_3          barycenter( InputIterator first, InputIterator beyond)
```

computes the barycenter of a non-empty set of 3D weighted points. *K* is *Kernel\_traits<std::iterator\_traits<InputIterator>::value\_type::first\_type>::Kernel*. The value type must be *std::pair<K::Point\_3, K::FT>*.

*Precondition:* first != beyond, and the sum of the weights is non-zero.

```
template < typename InputIterator, typename K >
```

```
K::Point_3          barycenter( InputIterator first, InputIterator beyond, K k)
```

computes the barycenter of a non-empty set of 3D weighted points. The value type must be *std::pair<K::Point\_3, K::FT>*.

*Precondition:* first != beyond, and the sum of the weights is non-zero.

## CGAL::linear\_least\_squares\_fitting\_2

### Definition

The function *linear\_least\_squares\_fitting\_2* computes the 2D best fitting line (in the least squares sense) of a set of 2D objects such as points, segments, triangles, iso rectangles, circles or disks.

The best fitting line minimizes the sum of squared distances from all points comprising these objects to their orthogonal projections onto the line. It can be shown that this line goes through the centroid of the set. This problem is equivalent to search for the linear sub-space which maximizes the variance of projected points (sum of squared distances to the centroid). Internally we solve this problem by eigen decomposition of the covariance matrix of the whole set. Note that the  $2 \times 2$  covariance matrix is computed internally in closed form and not by point sampling the objects. Eigenvectors corresponding to large eigenvalues are the directions in which the data has strong component, or equivalently large variance. If one eigenvalue is null the fit is perfect as the sum of squared distance from all points to their projection onto the best line is null. If the two eigenvalues are the same there is no preferable sub-space and all lines going through the centroid share the same fitting property.

```
#include <CGAL/linear_least_squares_fitting_2.h>
```

```
template < typename InputIterator, typename K, typename Tag >
typename K::FT      linear_least_squares_fitting_2( InputIterator first,
                                                    InputIterator beyond,
                                                    typename K::Line_2 & line,
                                                    typename K::Point_2 & centroid,
                                                    K k,
                                                    Tag tag)
```

computes the best fitting 2D line of a 2D object set in the range *[first,beyond)*. The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any line (a horizontal line going through the centroid is output by default), and 1 means that the variance is null orthogonally to the best fitting line (hence the fit is perfect).

*Precondition:* first != beyond.

The class *K* is the kernel in which the type *InputIterator::value\_type* is defined. It can be omitted and deduced automatically from the value type.

The tag *tag* identifies the dimension to be considered from the objects. For point sets it should be 0. For segments it can be 1 or 0 according to whether one wants to fit the whole segment or just their end points. For triangles it can range from 0 to 2 according to whether one wants to fit either the triangle points, the segments or the whole triangles. For rectangles it can range from 0 to 2 according to whether one wants to fit either the corner points, the segments, or the whole rectangles. For circles it can be 1 or 2 according to whether one wants to fit either the circles or the whole discs. For triangles it ranges from 0 to 2 according to whether one wants to fit either the points, the segments or the whole triangles.

### Requirements

1. *InputIterator::value\_type* is equivalent to *K::Point\_2* or *K::Segment\_2* or *K::Triangle\_2* or *K::Rectangle\_2* or *K::Circle\_2*.
2. *line* is the best fitting line computed.
3. *centroid* is the centroid computed. This parameter is optional and can be omitted.
4. *t* is the tag identifying the dimension to be considered from the objects. It should be one of *Dimension\_tag<0>*, *Dimension\_tag<1>* or *Dimension\_tag<2>*. Also, it should not be of dimension greater than the geometry of the object. For example, a *Segment* can not have a *Dimension\_tag<2>* tag.

## CGAL::linear\_least\_squares\_fitting\_3

### Definition

The function *linear\_least\_squares\_fitting\_3* computes the best fitting 3D line or plane (in the least squares sense) of a set of 3D objects such as points, segments, triangles, spheres, balls, cuboids or tetrahedra.

The best fitting linear sub-space (line or plane) minimizes the sum of squared distances from all points comprising these objects to their orthogonal projections onto this linear subspace. It can be shown that the best line or plane goes through the centroid of the set. This problem is equivalent to search for the linear sub-space which maximizes the variance of projected points (sum of squared distances to the centroid). Internally we solve this problem by eigen decomposition of the covariance matrix of the whole set. Note that the  $3 \times 3$  covariance matrix is computed internally in closed form and not by point sampling the objects. Eigenvectors corresponding to large eigenvalues are the directions in which the data has strong component, or equivalently large variance.

The fitting quality property is characterized by the values of the three eigenvalues. When all three values are distinct the best linear subspace is uniquely determined, be it a line or a plane. When all three eigenvalues are equal there is no preferable sub-space and any line or plane going through the centroid share the same fitting property. A best fitting line is uniquely determined as soon as the largest eigenvalue is different from the two others, otherwise all lines contained in the best fitting plane share the same fitting property. A best fitting plane is uniquely determined as soon as the smallest eigenvalue is different from the two others, otherwise all planes going through the best fitting line share the same fitting property.

```
#include <CGAL/linear_least_squares_fitting_3.h>
```

```
template < typename InputIterator, typename K, typename Tag >
typename K::FT      linear_least_squares_fitting_3( InputIterator first,
                                                    InputIterator beyond,
                                                    typename K::Line_3& line,
                                                    typename K::Point_3& centroid,
                                                    K k,
                                                    Tag tag)
```

computes the best fitting 3D line of a 3D object set in the range *[first,beyond)*. The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any line (a horizontal line going through the centroid is output by default), and 1 means that the variance is null orthogonally to the best fitting line (hence the fit is perfect).

The class *K* is the kernel in which the type *InputIterator::value\_type* is defined. It can be omitted and deduced automatically from the value type.

The tag *tag* identifies the dimension to be considered from the objects. For point sets it should be 0. For segment sets it could be 1 or 0 according to whether one wants to fit the entire segments or just the end points. For triangle sets it can range from 0 to 2 according to whether one wants to fit either the corner points, the segments or the whole triangles. For cuboid sets it can range from 0 to 3 according to whether one wants to fit either the corners, the segments, the faces or the whole solid cuboids. For sphere sets it can be 2 or 3 according to whether one

wants to fit either the surface of the spheres or the whole solid balls. For tetrahedron sets it can range from 0 to 3 according to whether one wants to fit either the points, the segments, the surface triangles or the whole solid tetrahedra.

## Requirements

1. *InputIterator::value\_type* can be either *K::Point\_3*, *K::Segment\_3*, *Triangle\_3*, *Cuboid\_3*, *Sphere\_3* or *Tetrahedron\_3*.
2. *line* is the best fitting line computed.
3. *centroid* is the centroid computed. This parameter is optional and can be omitted.
4. *tag* is the tag identifying the dimension to be considered from the objects. It should range from *Dimension\_tag<0>* to *Dimension\_tag<3>*. Also, it should not be of a dimension greater nor smaller than the geometry of the object. For example, a *Triangle* can not have a *Dimension\_tag<3>* tag. A *Segment* can not have a *Dimension\_tag<2>* nor a *Dimension\_tag<3>* tag. A *Sphere* can not have a *Dimension\_tag<0>* nor a *Dimension\_tag<1>* tag.

```
template < typename InputIterator, typename K, typename Tag >
typename K::FT      linear_least_squares_fitting_3( InputIterator first,
                                                    InputIterator beyond,
                                                    typename K::Plane_3& plane,
                                                    typename K::Point_3& centroid,
                                                    K k,
                                                    Tag tag)
```

computes the best fitting 3D plane of a 3D object set in the range [*first*,*beyond*). The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any plane (a horizontal plane going through the centroid is output by default), and 1 means that the variance is null orthogonally to the best fitting plane (hence the fit is perfect).

The class *K* is the kernel in which the type *InputIterator::value\_type* is defined. It can be omitted and deduced automatically from the value type. The tag *tag* identifies the dimension to be considered from the objects (see above).

## Requirements

1. *InputIterator::value\_type* can either be *K::Point\_3*, *K::Segment\_3*, *Triangle\_3*, *Cuboid\_3*, *Sphere\_3* or *Tetrahedron\_3*.
2. *plane* is the best fitting plane computed.
3. *centroid* is the centroid computed. This parameter is optional and can be omitted.
4. *tag* is the tag identifying the dimension to be considered from the objects. It should range from *Dimension\_tag<0>* to *Dimension\_tag<3>*. Also, it should not be of a dimension greater nor smaller than the geometry of the object. For example, a *Triangle* can not have a *Dimension\_tag<3>* tag. A *Segment* can not have a *Dimension\_tag<2>* nor a *Dimension\_tag<3>* tag. A *Sphere* can not have a *Dimension\_tag<0>* nor a *Dimension\_tag<1>* tag.

This chapter describes CGAL's interpolation package which implements natural neighbor coordinate functions as well as different methods for scattered data interpolation most of which are based on natural neighbor coordinates. The functions for computing natural neighbor coordinates in Euclidean space are described in Section 58.1, the functions concerning the coordinate and neighbor computation on surfaces are discussed in Section 58.2. In Section 58.3, we describe the different interpolation functions.

Scattered data interpolation solves the following problem: given measures of a function on a set of discrete data points, the task is to interpolate this function on an arbitrary query point. More formally, let  $\mathcal{P} = \{\mathbf{p}_1, \dots, \mathbf{p}_n\}$  be a set of  $n$  points in  $\mathbb{R}^2$  or  $\mathbb{R}^3$  and  $\Phi$  be a scalar function defined on the convex hull of  $\mathcal{P}$ . We assume that the function values are known at the points of  $\mathcal{P}$ , i.e. to each  $\mathbf{p}_i \in \mathcal{P}$ , we associate  $z_i = \Phi(\mathbf{p}_i)$ . Sometimes, the gradient of  $\Phi$  is also known at  $\mathbf{p}_i$ . It is denoted  $\mathbf{g}_i = \nabla\Phi(\mathbf{p}_i)$ . The interpolation is carried out for an arbitrary query point  $\mathbf{x}$  on the convex hull of  $\mathcal{P}$ .

## 58.1 Natural Neighbor Coordinates

### 58.1.1 Introduction

Natural neighbor interpolation has been introduced by Sibson [Sib81] to interpolate multivariate scattered data. Given a set of data points  $\mathcal{P}$ , the natural neighbor coordinates associated to  $\mathcal{P}$  are defined from the Voronoi diagram of  $\mathcal{P}$ . When simulating the insertion of a query point  $\mathbf{x}$  into the Voronoi diagram of  $\mathcal{P}$ , the potential Voronoi cell of  $\mathbf{x}$  “steals” some parts from the existing cells.

Figure 58.1: 2D example:  $\mathbf{x}$  has five natural neighbors  $\mathbf{p}_1, \dots, \mathbf{p}_5$ . The natural neighbor coordinate  $\lambda_3(\mathbf{x})$  is the ratio of the area of the pink polygon,  $\pi_3(\mathbf{x})$ , over the area of the total highlighted zone.

Let  $\pi(\mathbf{x})$  denote the volume of the potential Voronoi cell of  $\mathbf{x}$  and  $\pi_i(\mathbf{x})$  denote the volume of the sub-cell that would be stolen from the cell of  $\mathbf{p}_i$  by the cell of  $\mathbf{x}$ . The natural neighbor coordinate of  $\mathbf{x}$  with respect to the data point  $\mathbf{p}_i \in \mathcal{P}$  is defined by

$$\lambda_i(\mathbf{x}) = \frac{\pi_i(\mathbf{x})}{\pi(\mathbf{x})}.$$

A two-dimensional example is depicted in Figure 58.1.

Various papers ([Sib80], [Far90], [Pip93], [Bro97], [HS00]) show that the natural neighbor coordinates have the following properties:

- (i)  $\mathbf{x} = \sum_{i=1}^n \lambda_i(\mathbf{x}) \mathbf{p}_i$  (barycentric coordinate property).
- (ii) For any  $i, j \leq n$ ,  $\lambda_i(\mathbf{p}_j) = \delta_{ij}$ , where  $\delta_{ij}$  is the Kronecker symbol.
- (iii)  $\sum_{i=1}^n \lambda_i(\mathbf{x}) = 1$  (partition of unity property).

For the case where the query point  $\mathbf{x}$  is located on the envelope of the convex hull of  $\mathcal{P}$ , the potential Voronoi cell of  $\mathbf{x}$  becomes infinite and :

$$\pi(\mathbf{x}) = \infty$$

$\lambda_i(\mathbf{x}) = 0$  for all data point  $\mathbf{p}_i$  of  $\mathcal{P}$  except for the two endpoints, let's say  $\mathbf{p}$  and  $\mathbf{q}$ , of the edge where  $\mathbf{x}$  lies.

The natural neighbor coordinate of  $\mathbf{x}$  with respect to these endpoints  $\mathbf{p}$  and  $\mathbf{q}$  will be :

$$\lambda_p(\mathbf{x}) = \frac{\|\mathbf{x} - \mathbf{q}\|}{\|\mathbf{q} - \mathbf{p}\|}$$

$$\lambda_q(\mathbf{x}) = \frac{\|\mathbf{x} - \mathbf{p}\|}{\|\mathbf{q} - \mathbf{p}\|}$$

Furthermore, Piper [Pip93] shows that the coordinate functions are continuous in the convex hull of  $\mathcal{P}$  and continuously differentiable except on the data points  $\mathcal{P}$ .

The interpolation package of CGAL provides functions to compute natural neighbor coordinates for 2D and 3D points with respect to Voronoi diagrams as well as with respect to power diagrams (only 2D), i.e. for weighted points. Refer to the reference pages *natural\_neighbor\_coordinates\_2*, *natural\_neighbor\_coordinates\_3* and *regular\_neighbor\_coordinates\_2*.

In addition, the package provides functions to compute natural neighbor coordinates on well sampled point set surfaces. See Section 58.2 and the reference page *surface\_neighbor\_coordinates\_3* for further information.

## 58.1.2 Implementation

Given a Delaunay triangulation or a Regular triangulation, the vertices in conflict with the query point are determined. The areas  $\pi_i(\mathbf{x})$  are computed by triangulating the Voronoi sub-cells. The normalization factor  $\pi(\mathbf{x})$  is also returned. If the query point is already located and/or the boundary edges of the conflict zone are already determined, alternative functions allow to avoid the re-computation.

## 58.1.3 Example for Natural Neighbor Coordinates

The signature of all coordinate computation functions is about the same.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/natural_neighbor_coordinates_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_2<K> Delaunay_triangulation;
typedef std::vector< std::pair< K::Point_2, K::FT > >
    Point_coordinate_vector;

int main()
{
    Delaunay_triangulation dt;

    for (int y=0 ; y<3 ; y++)
        for (int x=0 ; x<3 ; x++)
            dt.insert(K::Point_2(x,y));

    //coordinate computation
    K::Point_2 p(1.2, 0.7);
    Point_coordinate_vector coords;
    CGAL::Triple<
        std::back_insert_iterator<Point_coordinate_vector>,
        K::FT, bool> result =
        CGAL::natural_neighbor_coordinates_2(dt, p,
        std::back_inserter(coords));
    if(!result.third){
        std::cout << "The coordinate computation was not successful."
        << std::endl;
    }
}
```

```

        std::cout << "The point (" <<p << ") lies outside the convex hull."
        << std::endl;
    }
    K::FT norm = result.second;
    std::cout << "Coordinate computation successful." << std::endl;
    std::cout << "Normalization factor: " <<norm << std::endl;
    std::cout << "done" << std::endl;
    return 0;
}

```

**File:** examples/Interpolation/nn\_coordinates\_2.cpp

### 58.1.4 Example for Regular Neighbor Coordinates

For regular neighbor coordinates, it is sufficient to replace the name of the function and the type of triangulation passed as parameter. A special traits class is needed.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_2.h>
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
#include <CGAL/regular_neighbor_coordinates_2.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Regular_triangulation_euclidean_traits_2<K> Gt;
typedef CGAL::Regular_triangulation_2<Gt> Regular_triangulation;
typedef Regular_triangulation::Weighted_point Weighted_point;
typedef std::vector< std::pair< Weighted_point, K::FT > >
    Point_coordinate_vector;

int main()
{
    Regular_triangulation rt;

    for (int y=0 ; y<3 ; y++)
        for (int x=0 ; x<3 ; x++)
            rt.insert(Weighted_point(K::Point_2(x,y), 0));

    //coordinate computation
    Weighted_point wp(K::Point_2(1.2, 0.7),2);
    Point_coordinate_vector coords;
    CGAL::Triple<
        std::back_inserter_iterator<Point_coordinate_vector>,
        K::FT, bool> result =
        CGAL::regular_neighbor_coordinates_2(rt, wp,
std::back_inserter(coords));
    if(!result.third){
        std::cout << "The coordinate computation was not successful."
        << std::endl;
        std::cout << "The point (" <<wp.point() << ") lies outside the convex hull."
        << std::endl;
    }
}

```

```

K::FT norm = result.second;
std::cout << "Coordinate computation successful." << std::endl;
std::cout << "Normalization factor: " << norm << std::endl;

std::cout << "done" << std::endl;
return 0;
}

```

**File:** examples/Interpolation/rn\_coordinates\_2.cpp

For surface neighbor coordinates, the surface normal at the query point must be provided, see Section 58.2.

## 58.2 Surface Natural Neighbor Coordinates and Surface Neighbors

This section introduces the functions to compute natural neighbor coordinates and surface neighbors associated to a set of sample points issued from a surface  $\mathcal{S}$  and given a query point  $\mathbf{x}$  on  $\mathcal{S}$ . We suppose that  $\mathcal{S}$  is a closed and compact surface of  $\mathbb{R}^3$ , and let  $\mathcal{P} = \{\mathbf{p}_1, \dots, \mathbf{p}_n\}$  be an  $\varepsilon$ -sample of  $\mathcal{S}$  (refer to Amenta and Bern [AB99]). The concepts are based on the definition of Boissonnat and Flötotto [BF02], [Flö03b]. Both references contain a thorough description of the requirements and the mathematical properties.

### 58.2.1 Introduction

Two observations lead to the definition of surface neighbors and surface neighbor coordinates: First, it is clear that the tangent plane  $\mathcal{T}_{\mathbf{x}}$  of the surface  $\mathcal{S}$  at the point  $\mathbf{x} \in \mathcal{S}$  approximates  $\mathcal{S}$  in the neighborhood of  $\mathbf{x}$ . It has been shown in [BF02] that, if the surface  $\mathcal{S}$  is well sampled with respect to the curvature and the local thickness of  $\mathcal{S}$ , i.e. it is an  $\varepsilon$ -sample, the intersection of the tangent plane  $\mathcal{T}_{\mathbf{x}}$  with the Voronoi cell of  $\mathbf{x}$  in the Voronoi diagram of  $\mathcal{P} \cup \{\mathbf{x}\}$  has a small diameter. Consequently, inside this Voronoi cell, the tangent plane  $\mathcal{T}_{\mathbf{x}}$  is a reasonable approximation of  $\mathcal{S}$ . Furthermore, the second observation allows to compute this intersection diagram easily: one can show using Pythagoras' Theorem that the intersection of a three-dimensional Voronoi diagram with a plane  $\mathcal{H}$  is a two-dimensional power diagram. The points defining the power diagram are the projections of the points in  $\mathcal{P}$  onto  $\mathcal{H}$ , each point weighted with its negative square distance to  $\mathcal{H}$ . Algorithms for the computation of power diagrams via the dual regular triangulation are well known and for example provided by CGAL in the class *Regular\_triangulation\_2<Gt, Tds>*.

### 58.2.2 Implementation

#### Voronoi Intersection Diagrams

In CGAL, the regular triangulation dual to the intersection of a 3D Voronoi diagram with a plane  $\mathcal{H}$  can be computed by instantiating the *Regular\_triangulation\_2<Gt, Tds>* class with the traits class *Voronoi\_intersection\_2\_traits\_3<K>*. This traits class contains a point and a vector as class member which define the plane  $\mathcal{H}$ . All predicates and constructions used by *Regular\_triangulation\_2<Gt, Tds>* are replaced by the corresponding operators on three-dimensional points. For example, the power test predicate (which takes three weighted 2D points  $p', q', r'$  of the regular triangulation and tests the power distance of a fourth point  $t'$  with respect to the power circle orthogonal to  $p, q, r$ ) is replaced by a *Side\_of\_plane\_centered\_sphere\_2\_3* predicate that tests the position of a 3D point  $t$  with respect to the sphere centered on the plane  $\mathcal{H}$  passing through the 3D points  $p, q, r$ . This approach allows to avoid the explicit constructions of the projected points and the weights which are very prone to rounding errors.

## Natural Neighbor Coordinates on Surfaces

The computation of natural neighbor coordinates on surfaces is based upon the computation of regular neighbor coordinates with respect to the regular triangulation that is dual to  $\text{Vor}(\mathcal{P}) \cap \mathcal{T}_x$ , the intersection of  $\mathcal{T}_x$  and the Voronoi diagram of  $\mathcal{P}$ , via the function *regular\_neighbor\_coordinates\_2*.

Of course, we might introduce all data points  $\mathcal{P}$  into this regular triangulation. However, this is not necessary because we are only interested in the cell of  $\mathbf{x}$ . It is sufficient to guarantee that all surface neighbors of the query point  $\mathbf{x}$  are among the input points that are passed as argument to the function. The sample points  $\mathcal{P}$  can be filtered for example by distance, e.g. using range search or  $k$ -nearest neighbor queries, or with the help of the 3D Delaunay triangulation since the surface neighbors are necessarily a subset of the natural neighbors of the query point in this triangulation. CGAL provides a function that encapsulates the filtering based on the 3D Delaunay triangulation. For input points filtered by distance, functions are provided that indicate whether or not points that lie outside the input range (i.e. points that are further from  $\mathbf{x}$  than the furthest input point) can still influence the result. This allows to iteratively enlarge the set of input points until the range is sufficient to certify the result.

## Surface Neighbors

The surface neighbors of the query point are its neighbors in the regular triangulation that is dual to  $\text{Vor}(\mathcal{P}) \cap \mathcal{T}_x$ , the intersection of  $\mathcal{T}_x$  and the Voronoi diagram of  $\mathcal{P}$ . As for surface neighbor coordinates, this regular triangulation is computed and the same kind of filtering of the data points as well as the certification described above is provided.

### 58.2.3 Example for Surface Neighbor Coordinates

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/point_generators_3.h>
#include <CGAL/algorithm.h>
#include <CGAL/Origin.h>

#include <CGAL/surface_neighbor_coordinates_3.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::FT Coord_type;
typedef K::Point_3 Point_3;
typedef K::Vector_3 Vector_3;
typedef std::vector< std::pair< Point_3, K::FT > >
    Point_coordinate_vector;

int main()
{
    int n=100;
    std::vector< Point_3> points;
    points.reserve(n);

    std::cout << "Generate " << n << " random points on a sphere."
        << std::endl;
    CGAL::Random_points_on_sphere_3<Point_3> g(1);
```

```

CGAL::copy_n( g, n, std::back_inserter(points));

Point_3 p(1, 0,0);
Vector_3 normal(p-CGAL::ORIGIN);
std::cout << "Compute surface neighbor coordinates for "
    << p << std::endl;
Point_coordinate_vector coords;
CGAL::Triple< std::back_insert_iterator<Point_coordinate_vector>,
    K::FT, bool> result =
    CGAL::surface_neighbor_coordinates_3(points.begin(), points.end(),
p, normal,
std::back_inserter(coords),
K());
if(!result.third){
    //Undersampling:
    std::cout << "The coordinate computation was not successful."
        << std::endl;
    return 0;
}
K::FT norm = result.second;

std::cout << "Testing the barycentric property " << std::endl;
Point_3 b(0, 0,0);
for(std::vector< std::pair< Point_3, Coord_type > >::const_iterator
it = coords.begin(); it!=coords.end(); ++it)
    b = b + (it->second/norm)* (it->first - CGAL::ORIGIN);

std::cout <<"    weighted barycenter: " << b <<std::endl;
std::cout << "    squared distance: " <<
    CGAL::squared_distance(p,b) <<std::endl;

std::cout << "done" << std::endl;
return 0;
}

```

**File:** examples/Interpolation/surface\_neighbor\_coordinates\_3.cpp

## 58.3 Interpolation Methods

### 58.3.1 Introduction

#### Linear Precision Interpolation

Sibson [Sib81] defines a very simple interpolant that re-produces linear functions exactly. The interpolation of  $\Phi(\mathbf{x})$  is given as the linear combination of the neighbors' function values weighted by the coordinates:

$$Z^0(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x}) z_i.$$

Indeed, if  $z_i = a + \mathbf{b}' \mathbf{p}_i$  for all natural neighbors of  $\mathbf{x}$ , we have

$$Z^0(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x})(a + \mathbf{b}' \mathbf{p}_i) = a + \mathbf{b}' \mathbf{x}$$

by the barycentric coordinate property. The first example in Subsection 58.3.3 shows how the function is called.

### Sibson's $C^1$ Continuous Interpolant

In [Sib81], Sibson describes a second interpolation method that relies also on the function gradient  $\mathbf{g}_i$  for all  $\mathbf{p}_i \in \mathcal{P}$ . It is  $C^1$  continuous with gradient  $\mathbf{g}_i$  at  $\mathbf{p}_i$ . Spherical quadrics of the form  $\Phi(\mathbf{x}) = a + \mathbf{b}^t \mathbf{x} + \gamma \mathbf{x}^t \mathbf{x}$  are reproduced exactly. The proof relies on the barycentric coordinate property of the natural neighbor coordinates and assumes that the gradient of  $\Phi$  at the data points is known or approximated from the function values as described in [Sib81] (see Section 58.3.2).

Sibson's  $Z^1$  interpolant is a combination of the linear interpolant  $Z^0$  and an interpolant  $\xi$  which is the weighted sum of the first degree functions

$$\xi_i(\mathbf{x}) = z_i + \mathbf{g}_i^t (\mathbf{x} - \mathbf{p}_i), \quad \xi(\mathbf{x}) = \frac{\sum_i \frac{\lambda_i(\mathbf{x})}{\|\mathbf{x} - \mathbf{p}_i\|} \xi_i(\mathbf{x})}{\sum_i \frac{\lambda_i(\mathbf{x})}{\|\mathbf{x} - \mathbf{p}_i\|}}.$$

Sibson observed that the combination of  $Z^0$  and  $\xi$  reconstructs exactly a spherical quadric if they are mixed as follows:

$$Z^1(\mathbf{x}) = \frac{\alpha(\mathbf{x})Z^0(\mathbf{x}) + \beta(\mathbf{x})\xi(\mathbf{x})}{\alpha(\mathbf{x}) + \beta(\mathbf{x})} \text{ where } \alpha(\mathbf{x}) = \frac{\sum_i \lambda_i(\mathbf{x}) \frac{\|\mathbf{x} - \mathbf{p}_i\|^2}{f(\|\mathbf{x} - \mathbf{p}_i\|)}}{\sum_i \frac{\lambda_i(\mathbf{x})}{f(\|\mathbf{x} - \mathbf{p}_i\|)}} \text{ and } \beta(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x}) \|\mathbf{x} - \mathbf{p}_i\|^2,$$

where in Sibson's original work,  $f(\|\mathbf{x} - \mathbf{p}_i\|) = \|\mathbf{x} - \mathbf{p}_i\|$ .

CGAL contains a second implementation with  $f(\|\mathbf{x} - \mathbf{p}_i\|) = \|\mathbf{x} - \mathbf{p}_i\|^2$  which is less demanding on the number type because it avoids the square-root computation needed to compute the distance  $\|\mathbf{x} - \mathbf{p}_i\|$ . The theoretical guarantees are the same (see [Flö03b]). Simply, the smaller the slope of  $f$  around  $f(0)$ , the faster the interpolant approaches  $\xi_i$  as  $\mathbf{x} \rightarrow \mathbf{p}_i$ .

### Farin's $C^1$ Continuous Interpolant

Farin [Far90] extended Sibson's work and realizes a  $C^1$  continuous interpolant by embedding natural neighbor coordinates in the Bernstein-Bézier representation of a cubic simplex. If the gradient of  $\Phi$  at the data points is known, this interpolant reproduces quadratic functions exactly. The function gradient can be approximated from the function values by Sibson's method [Sib81] (see Section 58.3.2) which is exact only for spherical quadrics.

### Quadratic Precision Interpolants

Knowing the gradient  $\mathbf{g}_i$  for all  $\mathbf{p}_i \in \mathcal{P}$ , we formulate a very simple interpolant that reproduces exactly quadratic functions. This interpolant is not  $C^1$  continuous in general. It is defined as follows:

$$I^1(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x}) \left( z_i + \frac{1}{2} \mathbf{g}_i^t (\mathbf{x} - \mathbf{p}_i) \right)$$

## 58.3.2 Gradient Fitting

Sibson describes a method to approximate the gradient of the function  $f$  from the function values on the data sites. For the data point  $\mathbf{p}_i$ , we determine

$$\mathbf{g}_i = \min_{\mathbf{g}} \sum_j \frac{\lambda_j(\mathbf{p}_i)}{\|\mathbf{p}_i - \mathbf{p}_j\|^2} (z_j - (z_i + \mathbf{g}^t (\mathbf{p}_j - \mathbf{p}_i))),$$

where  $\lambda_j(\mathbf{p}_i)$  is the natural neighbor coordinate of  $\mathbf{p}_i$  with respect to  $\mathbf{p}_i$  associated to  $\mathcal{P} \setminus \{\mathbf{p}_i\}$ . For spherical quadrics, the result is exact.

CGAL provides functions to approximate the gradients of all data points that are inside the convex hull. There is one function for each type of natural neighbor coordinate (i.e. *natural\_neighbor\_coordinates\_2*, *regular\_neighbor\_coordinates\_2*).

### 58.3.3 Example for Linear Interpolation

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <CGAL/Interpolation_traits_2.h>
#include <CGAL/natural_neighbor_coordinates_2.h>
#include <CGAL/interpolation_functions.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_2<K>          Delaunay_triangulation;
typedef CGAL::Interpolation_traits_2<K>            Traits;
typedef K::FT                                         Coord_type;
typedef K::Point_2                                    Point;

int main()
{
    Delaunay_triangulation T;
    std::map<Point, Coord_type, K::Less_xy_2> function_values;
    typedef CGAL::Data_access< std::map<Point, Coord_type, K::Less_xy_2 > >
                                   Value_access;

    Coord_type a(0.25), bx(1.3), by(-0.7);

    for (int y=0 ; y<3 ; y++)
        for (int x=0 ; x<3 ; x++){
            K::Point_2 p(x,y);
            T.insert(p);
            function_values.insert(std::make_pair(p,a + bx* x+ by*y));
        }
    //coordinate computation
    K::Point_2 p(1.3,0.34);
    std::vector< std::pair< Point, Coord_type > > coords;
    Coord_type norm =
        CGAL::natural_neighbor_coordinates_2
        (T, p, std::back_inserter(coords)).second;

    Coord_type res = CGAL::linear_interpolation(coords.begin(), coords.end(),
                                                norm,
                                                Value_access(function_values));

    std::cout << "    Tested interpolation on " << p << " interpolation: "
        << res << " exact: " << a + bx* p.x()+ by* p.y()<< std::endl;

    std::cout << "done" << std::endl;
    return 0;
}
```

```
}
```

        << " interpolation: " << res.first << " exact: "
        << a + bx * p.x() + by * p.y() + c*(p.x()*p.x()+p.y()*p.y())
        << std::endl;
else
    std::cout << "C^1 Interpolation not successful." << std::endl
        << " not all function_gradients are provided." << std::endl
        << " You may resort to linear interpolation." << std::endl;

std::cout << "done" << std::endl;
return 0;
}

```

**File:** examples/Interpolation/sibson\_interpolation\_2.cpp

An additional example in the distribution compares numerically the errors of the different interpolation functions with respect to a known function. It is distributed in the examples directory.

# 2D and Surface Function Interpolation Reference Manual

*Julia Flötotto*

Scattered data interpolation solves the following problem: given measures of a function on a set of discrete data points, the task is to interpolate this function on an arbitrary query point.

If the function is a linear function and given barycentric coordinates that allow to express the query point as the convex combination of some data points, the function can be exactly interpolated. If the function gradients are known, we can exactly interpolate quadratic functions given barycentric coordinates. Any further properties of these interpolation functions depend on the properties of the barycentric coordinates. They are provided in this package under the name *linear\_interpolation* and *quadratic\_interpolation*.

## Natural neighbor interpolation

Natural neighbor coordinates are defined by Sibson in 1980 and are based on the Voronoi diagram of the data points. Interpolation methods based on natural neighbor coordinates are particularly interesting because they adapt easily to non-uniform and highly anisotropic data. This package contains Sibson's  $C^1$  continuous interpolation method which interpolates exactly spherical quadrics (of the form  $\Phi(\mathbf{x}) = a + \mathbf{b}'\mathbf{x} + \gamma \mathbf{x}'\mathbf{x}$ ) and Farin's  $C^1$  continuous interpolation method based on Bernstein-Bézier techniques and interpolating exactly quadratic functions – assuming that the function gradient is known. In addition, Sibson defines a method to approximate the function gradients for data points that are in the interior of the convex hull. This method is exact for spherical quadrics.

This CGAL package implements Sibson's and Farin's interpolation functions as well as Sibson's function gradient fitting method. Furthermore, it provides functions to compute the natural neighbor coordinates with respect to a two-dimensional Voronoi diagram (i. e., from the Delaunay triangulation of the data points) and to a two-dimensional power diagram for weighted points (i. e., from their regular triangulation). Natural neighbor coordinates on closed and well-sampled surfaces can also be computed if the normal to the surface at the query point is known. The latter coordinates are only approximately barycentric, see [\[BF02\]](#).

For a more thorough introduction see the user manual.

## CGAL::linear\_interpolation

### Definition

The function *linear\_interpolation* computes the weighted sum of the function values which must be provided via a functor.

```
#include <CGAL/interpolation_functions.h>
```

```
template < class ForwardIterator, class Functor>
typename Functor::result_type
```

```
    linear_interpolation( ForwardIterator first,
                        ForwardIterator beyond,
                        typename          std::iterator_traits<ForwardIterator>::value_
type::second_type norm,
                        Functor function_values)
```

*ForwardIterator::value\_type* is a pair associating a point to a (non-normalized) barycentric coordinate. *norm* is the normalization factor. Given a point, the functor *function\_values* allows to access a pair of a function value and a Boolean. The Boolean indicates whether the function value could be retrieved correctly. This function generates the interpolated function value as the weighted sum of the values corresponding to each point of the point/coordinate pairs in the range *[first, beyond)*.

*Precondition:*  $norm \neq 0$ . *function\_value(p).second == true* for all points *p* of the point/coordinate pairs in the range *[first, beyond)*.

### Requirements

1. *ForwardIterator::value\_type* is a pair of point/coordinate value, thus *ForwardIterator::value\_type::first\_type* is equivalent to a point and *ForwardIterator::value\_type::second\_type* is a field number type.
2. *Functor::argument\_type* must be equivalent to *ForwardIterator::value\_type::first\_type* and *Functor::result\_type* is a pair of the function value type and a Boolean value. The function value type must provide a multiplication and addition operation with the field number type *ForwardIterator::value\_type::second\_type* and a constructor with argument 0. A model of the functor is provided by the struct *Data\_access*. It must be instantiated accordingly with an associative container (e.g. STL *std::map*) having the point type as *key\_type* and the function value type as *mapped\_type*.

## CGAL::sibson\_c1\_interpolation

### Definition

The function *sibson\_c1\_interpolation* interpolates the function values and the gradients that are provided by functors following the method described in [Sib81].

### Parameters

The template parameter *Traits* is to be instantiated with a model of *InterpolationTraits*. *ForwardIterator::value\_type* is a pair associating a point to a (non-normalized) barycentric coordinate. *norm* is the normalization factor. The range  $[first, beyond)$  contains the barycentric coordinates for the query point *p*. The functor *function\_value* allows to access the value of the interpolated function given a point. *function\_gradient* allows to access the function gradient given a point.

```
#include <CGAL/interpolation_functions.h>
```

```
template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
std::pair< typename Functor::result_type, bool>
```

```
    sibson_c1_interpolation( ForwardIterator first,
                             ForwardIterator beyond,
                             typename      std::iterator_traits<ForwardIterator>::value_
type::second_type norm,
                             typename      std::iterator_traits<ForwardIterator>::value_
type::first_type p,
                             Functor function_value,
                             GradFunctor function_gradient,
                             Traits traits)
```

This function generates the interpolated function value at the point *p* using Sibson's  $Z^1$  interpolant [Sib81].

If the functor *function\_gradient* cannot supply the gradient of a point, the function returns a pair where the Boolean is set to *false*. If the interpolation was successful, the pair contains the interpolated function value as first and *true* as second value.

*Precondition:* *norm*  $\neq 0$ . *function\_value(p).second == true* for all points *p* of the point/coordinate pairs in the range  $[first, beyond)$ .

### Requirements

1. *Traits* is a model of the concept *InterpolationTraits*.
2. *ForwardIterator::value\_type* is a point/coordinate pair. Precisely *ForwardIterator::value\_type::first\_type* is equivalent to *Traits::Point\_d* and *ForwardIterator::value\_type::second\_type* is equivalent to *Traits::FT*.

3. *Functor::argument\_type* must be equivalent to *Traits::Point\_d* and *Functor::result\_type* is a pair of the function value type and a Boolean. The function value type must provide a multiplication and addition operation with the type *Traits::FT* as well as a constructor with argument 0.
4. *GradFunctor::argument\_type* must be equivalent to *Traits::Point\_d* and *Functor::result\_type* is a pair of the function's gradient type and a Boolean. The function gradient type must provide a multiplication operation with *Traits::Vector\_d*.
5. A model of the functor types *Functor* (resp. *GradFunctor*) is provided by the struct *Data\_access*. It must be instantiated accordingly with an associative container (e.g. STL *std::map*) having the point type as *key\_type* and the function value type (resp. function gradient type) as *mapped\_type*.
6. The number type *FT* provided by *Traits* must support the square root operation *sqrt()*.

```
template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type
```

```

        sibson_c1_interpolation_square( ForwardIterator first,
                                         ForwardIterator beyond,
                                         typename      std::iterator_traits<ForwardIterator>
::value_type::second_type norm,
                                         Functor function_value,
                                         GradFunctor function_gradient,
                                         Traits traits)

```

The same as above except that no square root operation is needed for *FT*.

## CGAL::farin\_c1\_interpolation

### Definition

The function *farin\_c1\_interpolation* interpolates the function values and the gradients that are provided by functors using the method described in [Far90].

```
#include <CGAL/interpolation_functions.h>
```

### Parameters

*RandomAccessIterator::value\_type* is a pair associating a point to a (non-normalized) barycentric coordinate. See *sibson\_c1\_interpolation* for the other parameters.

```
template < class RandomAccessIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type
```

```
    farin_c1_interpolation( RandomAccessIterator first,
                           RandomAccessIterator beyond,
                           typename std::iterator_traits<RandomAccessIterator>::value_
type::second_type norm,
                           Functor function_value,
                           GradFunctor function_gradient,
                           Traits traits)
```

generates the interpolated function value computed by Farin's interpolant [Far90]. See also *sibson\_c1\_interpolation*.

*Precondition:* *norm*  $\neq 0$ . *function\_value(p).second* == *true* for all points *p* of the point/coordinate pairs in the range [*first*, *beyond*).

*Precondition:* The range [*first*, *beyond*) contains either one or more than three elements.

### Requirements

Same requirements as for *sibson\_c1\_interpolation* only the iterator must provide random access and *Traits::FT* does not need to provide the square root operation.

## CGAL::quadratic\_interpolation

### Definition

The function *quadratic\_interpolation* interpolates the function values and first degree functions defined from the function gradients. Both, function values and gradients, must be provided by functors.

```
#include <CGAL/interpolation_functions.h>
```

### Parameters

See *sibson\_c1\_interpolation*.

```
template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type
```

```
    quadratic_interpolation( ForwardIterator first,
                           ForwardIterator beyond,
                           typename std::iterator_traits<ForwardIterator>:: value_
type::second_type norm,
                           Functor function_value,
                           GradFunctor function_gradient,
                           Traits traits)
```

This function generates the interpolated function value as the weighted sum of the values plus a linear term in the gradient for each point of the point/coordinate pairs in the range  $[first, beyond)$ . See also *sibson\_c1\_interpolation*.

*Precondition:*  $norm \neq 0$   $function\_value(p).second == true$  for all points  $p$  of the point/coordinate pairs in the range  $[first, beyond)$ .

### Requirements

Same requirements as for *sibson\_c1\_interpolation* only that *Traits::FT* does not need to provide the square root operation.

## CGAL::Data\_access<Map>

### Definition

The struct *Data\_access<Map>* implements a functor that allows to retrieve data from an associative container. The functor keeps a reference to the container. Given an instance of the container's key type, it returns a pair of the container's value type and a Boolean indicating whether the retrieval was successful.

This class can be used to provide the values and gradients of the interpolation functions.

```
#include <CGAL/interpolation_functions.h>
```

### Parameters

The class *Data\_access<Map>* has the container type *Map* as template parameter.

### Types

```
typedef Map::mapped_type
                                Data_type;
typedef Map::key_type
                                Key_type;
```

### Creation

*Data\_access<Map>* *data\_access*( *Map* *map*);      Introduces a *Data\_access* to the container *map*.

```
std::pair< Data_type, bool>
```

```
    data_access( Key_type p)
```

If there is an entry for *p* in the container *map*, then the pair of *map.find(p)* and *true* is returned. Otherwise, the Boolean value of the pair is *false*.

## InterpolationTraits

### Definition

Most interpolation functions are parameterized by a traits class that defines the primitives used in the interpolation algorithms. The concept `InterpolationTraits` defines this common set of requirements.

### Types

<i>InterpolationTraits:: FT</i>	The number type must follow the model <i>FieldNumberType</i> .
<i>InterpolationTraits:: Point_d</i>	The point type on which the function is defined and interpolated.
<i>InterpolationTraits:: Vector_d</i>	The corresponding vector type.
<i>InterpolationTraits:: Construct_vector_d</i>	A constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Point_d a, Point_d b)</i> which produces the vector $b - a$ and <i>Vector_d operator() (Null_vector NULL_VECTOR)</i> which introduces the null vector.
<i>InterpolationTraits:: Construct_scaled_vector_d</i>	Constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Vector_d v, FT scale)</i> which produces the vector $v$ scaled by a factor <i>scale</i> .
<i>InterpolationTraits:: Compute_squared_distance_d</i>	Constructor object for <i>FT</i> . Provides the operator: <i>FT operator() (Point_d a, Point_d b)</i> returning the squared distance between $a$ and $b$ .
<i>InterpolationTraits traits;</i>	default constructor.

### Construction objects

The following functions that create instances of the above constructor object types must exist.

*Construct\_vector\_d*     *traits.construct\_vector\_d\_object()*

*Construct\_scaled\_vector\_d*

*traits.construct\_scaled\_vector\_d\_object()*

*Compute\_squared\_distance\_d*

*traits.compute\_squared\_distance\_d\_object()*

## CGAL::Interpolation\_traits\_2<K>

### Definition

*Interpolation\_traits\_2<K>* is a model for the concept *InterpolationTraits* and can be used to instantiate the geometric traits class of interpolation methods applied on a bivariate function over a two-dimensional domain. The traits class is templated by a kernel class *K*.

```
#include <CGAL/Interpolation_traits_2.h>
```

### Is Model for the Concepts

## CGAL::natural\_neighbor\_coordinates\_2

### Definition

The function *natural\_neighbor\_coordinates\_2* computes natural neighbor coordinates, also called Sibson's coordinates, for 2D points provided a two-dimensional triangulation and a query point in the convex hull of the vertices of the triangulation.

```
#include <CGAL/natural_neighbor_coordinates_2.h>
```

```
template < class Dt, class OutputIterator >
```

```
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
    natural_neighbor_coordinates_2( Dt dt,
                                   typename Dt::Geom_traits::Point_2 p,
                                   OutputIterator out,
                                   typename Dt::Face_handle start = typename
Dt::Face_handle())
```

computes the natural neighbor coordinates for  $p$  with respect to the points in the two-dimensional Delaunay triangulation  $dt$ . The template class  $Dt$  should be of type *Delaunay\_triangulation\_2*<*Traits*, *Tds*>. The value type of the *OutputIterator* is a pair of  $Dt::Point_2$  and the coordinate value of type  $Dt::Geom_traits::FT$ . The sequence of point/coordinate pairs that is computed by the function is placed starting at  $out$ . The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful.

```
template <class Dt, class OutputIterator, class EdgeIterator >
```

```
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
    natural_neighbor_coordinates_2( Dt dt,
                                   typename Dt::Geom_traits::Point_2 p,
                                   OutputIterator out,
                                   EdgeIterator hole_begin,
                                   EdgeIterator hole_end)
```

The same as above. *hole\_begin* and *hole\_end* determines the iterator range over the boundary edges of the conflict zone of  $p$  in the triangulation. It is the result of the function *T.get\_boundary\_of\_conflicts*( $p$ , *std::back\_inserter*(*hole*), *start*), see *Delaunay\_triangulation\_2*<*Traits*, *Tds*>.

```
template <class Dt, class OutputIterator>
```

```
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
    natural_neighbor_coordinates_2( Dt dt,
```

```
typename Dt::Vertex_handle vh,
OutputIterator out)
```

This function computes the natural neighbor coordinates of the point *vh->point()* with respect to the vertices of *dt* excluding *vh->point()*. The same as above for the remaining parameters.

## Requirements

1. *Dt* are equivalent to the class *Delaunay\_triangulation\_2<Traits, Tds>*.
2. The traits class *Traits* of *Dt* is a model of the concept *DelaunayTriangulationTraits\_2*. Only the following members of this traits class are used:
  - *Construct\_circumcenter\_2*
  - *FT*
  - *Point\_2*
  - *construct\_circumcenter\_2\_object*

Additionally, *Traits* must meet the requirements for the traits class of the *polygon\_area\_2* function.

3. *OutputIterator::value\_type* is equivalent to *std::pair<Dt::Point\_2, Dt::Geom\_traits::FT>*, i.e. a pair associating a point and its natural neighbor coordinate.

## See Also

*CGAL::surface\_neighbor\_coordinates\_3* ..... [page 3206](#)  
*CGAL::regular\_neighbor\_coordinates\_2* ..... [page 3196](#)

## Implementation

This function computes the area of the sub-cells stolen from the Voronoi cells of the points in *dt* when inserting *p*. The total area of the Voronoi cell of *p* is also computed and returned by the function. If *p* lies outside the convex hull, the coordinate values cannot be computed and the third value of the result triple is set to *false*.

## CGAL::regular\_neighbor\_coordinates\_2

### Definition

The function *regular\_neighbor\_coordinates\_2* computes natural neighbor coordinates, also called Sibson's coordinates, for weighted 2D points provided a two-dimensional regular triangulation and a (weighted) query point inside the convex hull of the vertices of the triangulation. We call these coordinates regular neighbor coordinates.

```
#include <CGAL/regular_neighbor_coordinates_2.h>
```

```
template < class Rt, class OutputIterator >
```

```
CGAL::Triple< OutputIterator, typename Rt::Geom_traits::FT, bool >
```

```
    regular_neighbor_coordinates_2( Rt rt,
                                   typename Rt::Weighted_point p,
                                   OutputIterator out,
                                   typename Rt::Face_handle start = typename
Rt::Face_handle())
```

computes the regular neighbor coordinates for  $p$  with respect to the weighted points in the two-dimensional regular triangulation  $rt$ . The template class  $Rt$  should be of type *Regular\_triangulation\_2*<*Traits*, *Tds*>. The value type of the *OutputIterator* is a pair of  $Rt::Weighted\_point$  and the coordinate value of type  $Rt::Geom\_traits::FT$ . The sequence of point/coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful, i.e. if  $p$  lies inside the convex hull of the points in  $rt$ .

```
template <class Rt, class OutputIterator, class EdgeIterator, class VertexIterator >
```

```
CGAL::Triple< OutputIterator, typename Traits::FT, bool >
```

```
    regular_neighbor_coordinates_2( Rt rt,
                                   typename Traits::Weighted_point p,
                                   OutputIterator out,
                                   EdgeIterator hole_begin,
                                   EdgeIterator hole_end,
                                   VertexIterator hidden_vertices_begin,
```

*VertexIterator hidden\_vertices\_end)*

The same as above. *hole\_begin* and *hole\_end* determines the iterator range over the boundary edges of the conflict zone of *p* in the triangulation *rt*. *hidden\_vertices\_begin* and *hidden\_vertices\_end* determines the iterator range over the hidden vertices of the conflict zone of *p* in *rt*. It is the result of the function *T.get\_boundary\_of\_conflicts(p, std::back\_inserter(hole), std::back\_inserter(hidden\_vertices), start)*, see *Regular\_triangulation\_2<Traits, Tds>*.

```
template <class Rt, class OutputIterator>
CGAL::Triple< OutputIterator, typename Rt::Geom_traits::FT, bool >
```

```
regular_neighbor_coordinates_2( Rt rt,
                               typename Rt::Vertex_handle vh,
                               OutputIterator out)
```

This function computes the regular neighbor coordinates of the point *vh->point()* with respect to the vertices of *rt* excluding *vh->point()*. The same as above for the remaining parameters.

## Requirements

1. *Rt* are equivalent to the class *Regular\_triangulation\_2<Traits, Tds>*.
2. The traits class *Traits* of *Rt* is a model of the concept *RegularTriangulationTraits\_2*. It provides the number type *FT* which is a model for *FieldNumberType* and it must meet the requirements for the traits class of the *polygon\_area\_2* function. A model of this traits class is *Regular\_triangulation\_euclidean\_traits\_2<K, Weight>*.
3. *OutputIterator::value\_type* is equivalent to *std::pair<Rt::Weighted\_point, Rt::Geom\_traits::FT>*, i.e. a pair associating a point and its regular neighbor coordinate.

## Implementation

This function computes the areas stolen from the Voronoi cells of points in *rt* by the insertion of *p*. The total area of the Voronoi cell of *p* is also computed and returned by the function. If *p* lies outside the convex hull, the coordinate values cannot be computed and the third value of the result triple is set to *false*.

## CGAL::sibson\_gradient\_fitting

### Definition

The function *sibson\_gradient\_fitting* approximates the gradient of a function at a point  $p$  given natural neighbor coordinates for  $p$  and its neighbors' function values. The approximation method is described in [Sib81]. Further functions are provided to fit the gradient for all data points that lie inside the convex hull of the data points. One function exists for each type of natural neighbor coordinates.

```
#include <CGAL/sibson_gradient_fitting.h>
```

```
template < class ForwardIterator, class Functor, class Traits>
typename Traits::Vector_d
```

```
        sibson_gradient_fitting( ForwardIterator first,
                                ForwardIterator beyond,
                                typename      std::iterator_traits<ForwardIterator>::value_
type::second_type norm,
                                typename      std::iterator_traits<ForwardIterator>::value_
type::first_type p,
                                Functor f,
                                Traits traits)
```

This function estimates the gradient of a function at the point  $p$  given natural neighbor coordinates of  $p$  in the range  $[first, beyond)$  and the function values of the neighbors provided by the functor  $f$ . *norm* is the normalization factor of the barycentric coordinates.

### Requirements

1. *ForwardIterator::value\_type* is a pair of point/coordinate value, thus *ForwardIterator::value\_type::first\_type* is equivalent to a point and *ForwardIterator::value\_type::second\_type* is a number type.
2. *Functor::argument\_type* must be equivalent to *ForwardIterator::value\_type::first\_type* and *Functor::result\_type* is the function value type. It must provide a multiplication and addition operation with the type *ForwardIterator::value\_type::second\_type*.
3. *Traits* is a model of the concept *GradientFittingTraits*.

```
template < class Dt, class OutputIterator, class Functor, class Traits>
```

*OutputIterator*                      *sibson\_gradient\_fitting\_nn\_2( Dt dt, OutputIterator out, Functor f, Traits traits)*

estimates the function gradients at all vertices of *dt* that lie inside the convex hull using the coordinates computed by the function *natural\_neighbor\_coordinates\_2*. *OutputIterator::value\_type* is a pair associating a point to a vector. The sequence of point/gradient pairs computed by this function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting sequence. The requirements are the same as above. The template class *Dt* must be equivalent to *Delaunay\_triangulation\_2<Gt, Tds>*.

*template < class Rt, class OutputIterator, class Functor, class Traits>*  
*OutputIterator*                      *sibson\_gradient\_fitting\_rn\_2( Rt rt, OutputIterator out, Functor f, Traits traits)*

estimates the function gradients at all vertices of *rt* that lie inside the convex hull using the coordinates computed by the function *regular\_neighbor\_coordinates\_2*. *OutputIterator::value\_type* is a pair associating a point to a vector. The sequence of point/gradient pairs computed by this function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting sequence. The requirements are the same as above. The template class *Rt* must be equivalent to *Regular\_triangulation\_2<Gt, Tds>*.

## Implementation

This function implements Sibson's gradient estimation method based on natural neighbor coordinates [[Sib81](#)].

## GradientFittingTraits

### Definition

The function *sibson\_gradient\_fitting* is parameterized by a traits class that defines the primitives used by the algorithm. The concept *GradientFittingTraits* defines this common set of requirements.

### Types

<i>GradientFittingTraits:: FT</i>	The number type must follow the model <i>FieldNumberType</i> .
<i>GradientFittingTraits:: Point_d</i>	The point type on which the function is defined and interpolated.
<i>GradientFittingTraits:: Vector_d</i>	The corresponding vector type.
<i>GradientFittingTraits:: Aff_transformation_d</i>	defines a matrix type. Must provide the following member functions : <i>Aff_transformation tr.inverse ()</i> which gives the inverse transformation, and <i>Aff_transformation tr.transform( Vector v)</i> which returns the multiplication of <i>tr</i> with <i>v</i> .
<i>GradientFittingTraits:: Construct_vector_d</i>	A constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Point_d a, Point_d b)</i> which produces the vector <i>b - a</i> and <i>Vector_d operator() (Null_vector NULL_VECTOR)</i> which introduces the null vector.
<i>GradientFittingTraits:: Construct_scaled_vector_d</i>	Constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Vector_d v,FT scale)</i> which produces the vector <i>v</i> scaled by a factor <i>scale</i> .
<i>GradientFittingTraits:: Construct_null_matrix_d</i>	Constructor object for <i>Aff_transformation_d</i> . Provides : <i>Aff_transformation_d operator()()</i> which introduces an affine transformation whose matrix has only zero entries.
<i>GradientFittingTraits:: Construct_scaling_matrix_d</i>	Constructor object for <i>Aff_transformation_d</i> . Provides : <i>Aff_transformation_d operator()(FT scale)</i> which introduces a scaling by a scale factor <i>scale</i> .

*GradientFittingTraits:: Construct\_sum\_matrix\_d*

Constructor object for *Aff\_transformation\_d*. Provides :  
*Aff\_transformation\_d operator()(Aff\_transformation\_d tr1, Aff\_transformation\_d tr2)* which returns the sum of the two matrices representing *tr1* and *tr2*.

*GradientFittingTraits:: Construct\_outer\_product\_d*

Constructor object for *Aff\_transformation\_d*. Provides :  
*Aff\_transformation\_d operator()(Vector v)* which returns the outer product, i.e. the quadratic matrix  $v^t v$ .

## Creation

*GradientFittingTraits traits;* default constructor.

## Operations

The following functions that create instances of the above constructor object types must exist.

*Construct\_vector\_d traits.construct\_vector\_d\_object()*

*Construct\_scaled\_vector\_d*

*traits.construct\_scaled\_vector\_d\_object()*

*Construct\_null\_matrix\_d*

*traits.construct\_null\_matrix\_d\_object()*

*Construct\_sum\_matrix\_d*

*traits.construct\_sum\_matrix\_d\_object()*

*Construct\_outer\_product\_d*

*traits.construct\_outer\_product\_d\_object()*

## CGAL::Voronoi\_intersection\_2\_traits\_3<K>

### Definition

*Voronoi\_intersection\_2\_traits\_3<K>* is a model for the concept *RegularTriangulationTraits\_2* and *InterpolationTraits*. It can be used to instantiate the geometric traits class of a two-dimensional regular triangulation. A three-dimensional plane is defined by a point and a vector that are members of the traits class. The triangulation is defined on 3D points. It is the regular triangulation of the input points projected onto the plane and each weighted with the negative squared distance of the input point to the plane. It can be shown that it is dual to the power diagram obtained by intersecting the three-dimensional Voronoi diagram of the input points with the plane. All predicates and constructions used in the computation of the regular triangulation are formulated on the three dimensional points without explicitly constructing the projected points and the weights. This reduces the arithmetic demands. The traits class is templated by a kernel class *K*.

```
#include <CGAL/Voronoi_intersection_2_traits_3.h>
```

### Is Model for the Concepts

RegularTriangulationTraits\_2 ..... page [2076](#)

### Types

```
typedef K::RT          Weight;
```

```
typedef K::FT          FT;
```

```
typedef K::Point_3     Point_2;
```

```
typedef K::Segment_3
```

```
Segment_2;
```

```
typedef K::Triangle_3
```

```
Triangle_2;
```

```
typedef K::Line_3      Line_2;
```

```
typedef K::Ray_3       Ray_2;
```

```
typedef K::Vector_3    Vector_2;

## CGAL::surface\_neighbor\_coordinates\_3

### Definition

The function *surface\_neighbor\_coordinates\_3* computes natural neighbor coordinates for surface points associated to a finite set of sample points issued from the surface. The coordinates are computed from the intersection of the Voronoi cell of the query point  $p$  with the tangent plane to the surface at  $p$ . If the sampling is sufficiently dense, the coordinate system meets the properties described in the manual pages and in [BF02],[Fl603b]. The query point  $p$  needs to lie inside the convex hull of the projection of the sample points onto the tangent plane at  $p$ .

```
#include <CGAL/surface_neighbor_coordinates_3.h>
```

```
template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Triple< OutputIterator, typename Kernel::FT, bool >
```

```
    surface_neighbor_coordinates_3( InputIterator first,
                                   InputIterator beyond,
                                   typename Kernel::Point_3 p,
                                   typename Kernel::Vector_3 normal,
                                   OutputIterator out,
                                   Kernel K)
```

The sample points  $\mathcal{P}$  are provided in the range  $[first, beyond)$ . *InputIterator::value\_type* is the point type *Kernel::Point\_3*. The tangent plane is defined by the point  $p$  and the vector *normal*. The parameter  $K$  determines the kernel type that will instantiate the template parameter of *Voronoi\_intersection\_2\_traits\_3<K>*.

The natural neighbor coordinates for  $p$  are computed in the power diagram that results from the intersection of the 3D Voronoi diagram of  $\mathcal{P}$  with the tangent plane. The sequence of point/coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful, i.e. if  $p$  lies inside the convex hull of the projection of the points  $\mathcal{P}$  onto the tangent plane.

```
template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Triple< OutputIterator, typename ITraits::FT, bool >
```

```
    surface_neighbor_coordinates_3( InputIterator first,
                                   InputIterator beyond,
                                   typename ITraits::Point_2 p,
                                   OutputIterator out,
```

*ITraits traits)*

the same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi\_intersection\_2\_traits\_3<K>*.

The next functions return, in addition, a second Boolean value (the fourth value of the quadruple) that certifies whether or not, the Voronoi cell of  $p$  can be affected by points that lie outside the input range, i.e. outside the ball centered on  $p$  passing through the furthest sample point from  $p$  in the range  $[first, beyond)$ . If the sample points are collected by a  $k$ -nearest neighbor or a range search query, this permits to check whether the neighborhood which has been considered is large enough.

```
template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Quadruple< OutputIterator, typename Kernel::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                           InputIterator beyond,
                                           typename Kernel::Point_3 p,
                                           typename Kernel::Vector_3 normal,
                                           OutputIterator out,
                                           Kernel K)
```

Similar to the first function. The additional fourth return value is *true* if the furthest point in the range  $[first, beyond)$  is further away from  $p$  than twice the distance from  $p$  to the furthest vertex of the intersection of the Voronoi cell of  $p$  with the tangent plane defined by  $(p, normal)$ . It is *false* otherwise.

```
template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Quadruple< OutputIterator, typename Kernel::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                           InputIterator beyond,
                                           typename Kernel::Point_2 p,
                                           typename Kernel::FT max_distance,
                                           OutputIterator out,
                                           Kernel kernel)
```

The same as above except that this function takes the maximal distance from  $p$  to the points in the range  $[first, beyond)$  as additional parameter.

```
template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Quadruple< OutputIterator, typename ITraits::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                           InputIterator beyond,
                                           typename ITraits::Point_2 p,
                                           OutputIterator out,
                                           ITraits traits)
```

The same as above only that the traits class must be instantiated by the user and without the parameter *max\_distance*. *ITraits* must be equivalent to *Voronoi\_intersection\_2\_traits\_3<K>*.

```
template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Quadruple< OutputIterator, typename ITraits::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                          InputIterator beyond,
                                          typename ITraits::Point_2 p,
                                          typename ITraits::FT max_distance,
                                          OutputIterator out,
                                          ITraits traits)
```

The same as above with the parameter *max\_distance*.

The next function allows to filter some potential neighbors of the query point  $p$  from  $\mathcal{P}$  via its three-dimensional Delaunay triangulation. All surface neighbors of  $p$  are necessarily neighbors in the Delaunay triangulation of  $\mathcal{P} \cup \{p\}$ .

```
template < class Dt, class OutputIterator >
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
surface_neighbor_coordinates_3( Dt dt,
                               typename Dt::Geom_traits::Point_2 p,
                               typename Dt::Geom_traits::Vector_3 normal,
                               OutputIterator out,
                               typename Dt::Face_handle start = typename
```

```
Dt::Face_handle())
```

computes the surface neighbor coordinates with respect to the points that are vertices of the Delaunay triangulation  $dt$ . The type  $Dt$  must be equivalent to *Delaunay\_triangulation\_3*< $Gt$ ,  $Tds$ >. The optional parameter *start* is used as a starting place for the search of the conflict zone. It may be the result of the call  $dt.locate(p)$ . This function instantiates the template parameter *ITraits* to be *Voronoi\_intersection\_2\_traits\_3*< $Dt::Geom\_traits$ >.

```
template < class Dt, class OutputIterator, class ITraits>
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
surface_neighbor_coordinates_3( Dt dt,
                               typename Dt::Geom_traits::Point_2 p,
                               OutputIterator out,
                               ITraits traits,
                               typename Dt::Face_handle start = typename
```

```
Dt::Face_handle())
```

The same as above only that the parameter *traits* instantiates the geometric traits class. Its type *ITraits* must be equivalent to *Voronoi\_intersection\_2\_traits\_3*< $K$ >.

## Requirements

1.  $Dt$  is equivalent to the class *Delaunay\_triangulation\_3*.

2. *OutputIterator::value\_type* is equivalent to *std::pair<Dt::Point\_3, Dt::Geom\_traits::FT>*, i.e. a pair associating a point and its natural neighbor coordinate.
3. *ITraits* is equivalent to the class *Voronoi\_intersection\_2\_traits\_3<K>*.

## Implementation

This functions construct the regular triangulation of the input points instantiated with *Voronoi\_intersection\_2\_traits\_3<Kernel>* or *ITraits* if provided. They return the result of the function call *regular\_neighbor\_coordinates\_2* with the regular triangulation and *p* as arguments.

## CGAL::surface\_neighbors\_3

### Definition

Given a set of sample points issued from a surface and a query point  $p$ , the function *surface\_neighbors\_3* computes the neighbors of  $p$  on the surface within the sample points. If the sampling is sufficiently dense, the neighbors are provably close to the point  $p$  on the surface (cf. the manual pages and [BF02],[Flö03b]). They are defined to be the neighbors of  $p$  in the regular triangulation dual to the power diagram which is equivalent to the intersection of the Voronoi cell of the query point  $p$  with the tangent plane to the surface at  $p$ .

```
#include <CGAL/surface_neighbors_3.h>
```

```
template <class OutputIterator, class InputIterator, class Kernel>
OutputIterator      surface_neighbors_3( InputIterator first,
                                         InputIterator beyond,
                                         typename Kernel::Point_3 p,
                                         typename Kernel::Vector_3 normal,
                                         OutputIterator out,
                                         Kernel K)
```

The sample points  $\mathcal{P}$  are provided in the range  $[first, beyond)$ . *InputIterator::value\_type* is the point type *Kernel::Point\_3*. The tangent plane is defined by the point  $p$  and the vector *normal*. The parameter  $K$  determines the kernel type that will instantiate the template parameter of *Voronoi\_intersection\_2\_traits\_3<K>*.

The surface neighbors of  $p$  are computed which are the neighbors of  $p$  in the regular triangulation that is dual to the intersection of the 3D Voronoi diagram of  $\mathcal{P}$  with the tangent plane. The point sequence that is computed by the function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting point sequence.

```
template <class OutputIterator, class InputIterator, class ITraits>
OutputIterator      surface_neighbors_3( InputIterator first,
                                         InputIterator beyond,
                                         typename ITraits::Point_2 p,
                                         OutputIterator out,
                                         ITraits traits)
```

the same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi\_intersection\_2\_traits\_3<K>*.

The next functions return, in addition, a Boolean value that certifies whether or not, the Voronoi cell of  $p$  can be affected by points that lie outside the input range, i.e. outside the ball centered on  $p$  passing through the furthest sample point from  $p$  in the range  $[first, beyond)$ . If the sample points are collected by a  $k$ -nearest neighbor or a range search query, this permits to verify that a large enough neighborhood has been considered.

```
template <class OutputIterator, class InputIterator, class Kernel>
```

*std::pair< OutputIterator, bool >*

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename Kernel::Point_3 p,
                               typename Kernel::Vector_3 normal,
                               OutputIterator out,
                               Kernel K)
```

Similar to the first function. The additional third return value is *true* if the furthest point in the range  $[first, beyond)$  is further away from  $p$  than twice the distance from  $p$  to the furthest vertex of the intersection of the Voronoi cell of  $p$  with the tangent plane defined by  $(p, normal)$ . It is *false* otherwise.

```
template <class OutputIterator, class InputIterator, class Kernel>
std::pair< OutputIterator, bool >
```

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename Kernel::Point_2 p,
                               typename Kernel::FT max_distance,
                               OutputIterator out,
                               Kernel kernel)
```

The same as above except that this function takes the maximal distance from  $p$  to the points in the range  $[first, beyond)$  as additional parameter.

```
template <class OutputIterator, class InputIterator, class ITraits>
std::pair< OutputIterator, bool >
```

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename ITraits::Point_2 p,
                               OutputIterator out,
                               ITraits traits)
```

The same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi\_intersection\_2\_traits\_3<K>*. There is no parameter *max\_distance*.

```
template <class OutputIterator, class InputIterator, class ITraits>
std::pair< OutputIterator, bool >
```

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename ITraits::Point_2 p,
                               typename ITraits::FT max_distance,
                               OutputIterator out,
                               ITraits traits)
```

The same as above with the parameter *max\_distance*.

The next function allows to filter some potential neighbors of the query point  $p$  from  $\mathcal{P}$  via its three-dimensional Delaunay triangulation. All surface neighbors of  $p$  are necessarily neighbors in the Delaunay triangulation of  $\mathcal{P} \cup \{p\}$ .

```
template < class Dt, class OutputIterator >
OutputIterator      surface_neighbors_3( Dt dt,
                                     typename Dt::Geom_traits::Point_2 p,
                                     typename Dt::Geom_traits::Vector_3 normal,
                                     OutputIterator out,
                                     typename Dt::Face_handle start = typename Dt::Face_
handle())
```

computes the surface neighbor coordinates with respect to the points that are vertices of the Delaunay triangulation  $dt$ . The type  $Dt$  must be equivalent to *Delaunay\_triangulation\_3*< $Gt$ ,  $Tds$ >. The optional parameter *start* is used for the used as a starting place for the search of the conflict zone. It may be the result of the call  $dt.locate(p)$ . This function instantiates the template parameter *ITraits* to be *Voronoi\_intersection\_2\_traits\_3*< $Dt::Geom\_traits$ >.

```
template < class Dt, class OutputIterator, class ITraits >
OutputIterator      surface_neighbors_3( Dt dt,
                                     typename Dt::Geom_traits::Point_2 p,
                                     OutputIterator out,
                                     ITraits traits,
                                     typename Dt::Face_handle start = typename Dt::Face_
handle())
```

The same as above only that the parameter *traits* instantiates the geometric traits class. Its type *ITraits* must be equivalent to *Voronoi\_intersection\_2\_traits\_3*< $K$ >.

## Requirements

1.  $Dt$  is equivalent to the class *Delaunay\_triangulation\_3*.
2. *OutputIterator::value\_type* is equivalent to  $Dt::Point_3$ , i.e. a point type.
3. *ITraits* is equivalent to the class *Voronoi\_intersection\_2\_traits\_3*< $K$ >.

## See Also

*CGAL::Voronoi\_intersection\_2\_traits\_3*< $K$ > ..... page [3204](#)

## Implementation

These functions compute the regular triangulation of the sample points and the point  $p$  using a traits class equivalent to *Voronoi\_intersection\_2\_traits\_3*< $K$ >. They determine the neighbors of  $p$  in this triangulation. The functions which certify the result need to compute, in addition, the Voronoi vertices of the cell of  $p$  in this diagram.

Lets say you want to maintain a sorted list of items (each item is associate with a real number key). You can imagine placing each of the items on the point on the real line corresponding to its key. Now, let the key for each item change continuously (i.e. no jumps are allowed). As long as no two (consecutive) items cross, the sorted order is intact. When two items cross, they need to be exchanged in the list and then the sorted order is once again correct. This is a trivial example of a kinetic data structure. The key observation is that the combinatorial structure which is maintained changes at discrete times (events) even though the basic building blocks are changing continuously.

This chapter describes a number of such kinetic data structures implemented using the Kinetic framework described in Chapter 60. We first, in Section 59.2 introduce kinetic data structures and sweepline algorithms. This section can be skipped if the reader is already familiar with the area. The next sections, Section 59.2.1 and Section 59.3 introduce the terms and give an overview of the framework. They are recommended reading for all readers, even if you are just using provided kinetic data structures. We then present kinetic data structures for Delaunay triangulations in two and three dimensions in Section 59.4.

If you are already familiar with kinetic data structures and know what you want to do, you might want to first take a look at the next section Section 59.1 which covers quick hints.

## 59.1 Quick Hints

This section gives quick answers to some questions people might have. It presumes knowledge of kinetic data structures and this framework.

### How do I store extra information along with, for example, a kinetic Point\_2?

See the example *Kinetic\_framework/defining\_a\_simulation\_traits.cpp* to see how to define a new *Simulation-Traits* class where the *ActiveObjectsTable* contains extra data along with the point.

### Where is the best place to look if I want to write my own kinetic data structure?

We provide two simple kinetic data structures, first most trivial is *Kinetic\_framework/trivial\_kds.cpp* and a slightly more complicated one is:

```
#include <CGAL/Kinetic/Sort.h>
```

### How can I use kinetic data structures to update Delaunay triangulations?

We are working on that one, but you will have to wait.

## 59.2 An Overview of Kinetic Data Structures and Sweep Algorithms

Kinetic data structures were first introduced in by Basch et. al. in 1997 [BGH97]. The idea stems from the observation that most, if not all, computational geometry structures are built using *predicates* — functions on quantities defining the geometric input (e.g. point coordinates), which return a discrete set of values. Many predicates reduce to determining the sign of a polynomial on the defining parameters of the primitive objects. For example, to test whether a point lies above or below a plane we compute the dot product of the point with the normal of the plane and subtract the plane's offset along the normal. If the result is positive, the point is above the plane, zero on the plane, negative below. The validity of many combinatorial structures built on top of geometric primitives can be verified by checking a finite number of predicates of the geometric primitives. These predicates, which collectively certify the correctness of the structure, are called *certificates*. For a Delaunay triangulation in three dimensions, for example, the certificates are one *InCircle* test per facet of the triangulation, plus a point plane orientation test for each facet or edge of the convex hull.

The kinetic data structures approach is built on top of this view of computational geometry. Let the geometric primitives move by replacing each of their defining quantities with a function of time (generally a polynomial). As time advances, the primitives trace out paths in space called *trajectories*. The values of the polynomial functions of the defining quantities used to evaluate the predicates now also become functions of time. We call these functions *certificate functions*. Typically, a geometric structure is valid when all predicates have a specific non-zero sign. In the kinetic setting, as long as the certificate functions maintain the correct sign as time varies, the corresponding predicates do not change values, and the original data structure remains correct. However, if one of the certificate functions changes sign, the original structure must be updated, as well as the set of certificate functions that verify it. We call such occurrences *events*.

Maintaining a kinetic data structure is then a matter of determining which certificate function changes sign next, i.e. determining which certificate function has the first real root that is greater than the current time, and then

updating the structure and the set of certificate functions. In addition, the trajectories of primitives are allowed to change at any time, although  $C^0$ -continuity of the trajectories must be maintained. When a trajectory update occurs for a geometric primitive, all certificates involving that primitive must be updated. We call the collection of kinetic data structures, primitives, event queue and other support structures a *simulation*.

Sweep-line algorithms for computing arrangements in  $d$  dimensions easily map on to kinetic data structures by taking one of the coordinates of the ambient space as the time variable. The kinetic data structure then maintains the arrangement of a set of objects defined by the intersection of a hyperplane of dimension  $d - 1$  with the objects whose arrangement is being computed.

Time is one of the central concepts in a kinetic simulation. Just as static geometric data structures divide the continuous space of all possible inputs (as defined by sets of coordinates) into a discrete set of combinatorial structures, kinetic data structures divide the continuous time domain into a set of disjoint intervals. In each interval the combinatorial structure does not change, so, in terms of the combinatorial structure, all times in the interval are equivalent. We capitalize on this equivalence in the framework in order to simplify computations. If the primitives move on polynomial trajectories and the certificates are polynomials in the coordinates, then events occur at real roots of polynomials of time. Real numbers, which define the endpoints of the interval, are more expensive to compute with than rational numbers, so performing computations at a rational number inside the interval is preferable whenever possible. See Section 60.1.4 for an example of where this equivalence is exploited.

### 59.2.1 Terms Used

**primitive** The basic geometric types, e.g., the points of a triangulation. A primitive has a set of *coordinates*.

**combinatorial structure** A structure built on top of the primitives. The structure does not depend directly on the coordinates of the primitives, only on relationships between them.

**trajectory** The path traced out by a primitive as time passes. In other words how the coordinates of a primitive change with time.

**snapshot** The position of all the primitives at a particular moment in time.

**static** Having to do with geometric data structures on non-moving primitives.

**predicate** A function which takes the coordinates of several primitives from a snapshot as input and produces one of a discrete set of outputs.

**certificate** One of a set of predicates which, when all having the correct values, ensure that the combinatorial structure is correct.

**certificate function** A function of time which is positive when the corresponding certificate has the correct value. When the certificate function changes sign, the combinatorial structure needs to be updated.

**event** When a certificate function changes sign and the combinatorial structure needs to be updated.

## 59.3 An Overview of the Kinetic Framework

The provided kinetic data structures are implemented on top of the Kinetic framework presented in Chapter 60. It is not necessary to know the details of the framework, but some familiarity is useful. Here we presented a quick overview of the framework.

The framework is structured around five main concepts. See Figure 59.1 for a schematic of how a kinetic data structure interacts with the various parts. The main concepts are

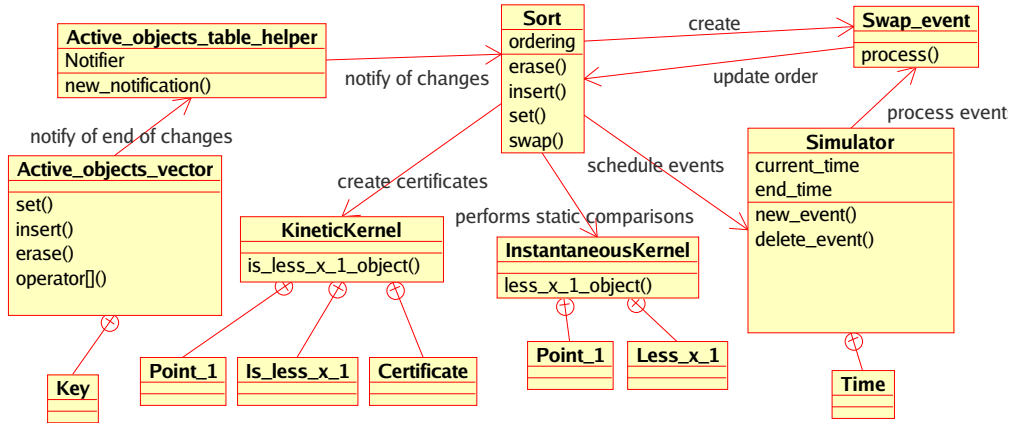

Figure 59.1: The figure shows the interaction between the *Kinetic::Sort<Traits, Visitor>* kinetic data structure and the various pieces of our package. Other, more complicated, kinetic data structures will also use the *Kinetic::InstantaneousKernel* in order to insert/remove geometric primitives and audit themselves. *Kinetic::Sort<Traits, Visitor>* uses the sorting functionality in the STL instead.

- the *Kinetic::Simulator*. Models of this concept process events in the correct order and audit kinetic data structures. There should be one instance of a model of this concept per simulation.
- the *Kinetic::Kernel*. The structure of a *Kinetic::Kernel* is analogous to the static CGAL (i.e., non-kinetic) kernels in that it defines a set of primitives and functors which generate certificates from the primitives.
- the *Kinetic::ActiveObjectsTable*. Models of this concept hold a collection of kinetic primitives in a centralized manner. This structure centralizes management of the primitives in order to properly disseminate notifications when trajectories change, new primitives are added or primitives are deleted. There is generally one instance of a model of this concept per simulation.
- the *Kinetic::InstantaneousKernel*. Models of this concept allow existing non-kinetic CGAL data structures to be used on a snapshot of kinetic data. As a result, pre-existing static structures can be used to initialize and audit kinetic data structures.
- the *Kinetic::FunctionKernel*. This concept is the computational kernel of our framework. Models of this concept are responsible for representing, generating and manipulating the motional and certificate functions and their roots. It is this concept that provides the kinetic data structures framework with the necessary algebraic operations for manipulating event times. The *Kinetic::FunctionKernel* is discussed in detail in Section 60.2.

For simplicity, we added an additional concept, that of *Kinetic::SimulationTraits*, which wraps together a particular set of choices for the above concepts and is responsible for creating instances of each of the models. As a user of existing kinetic data structures, this is the only framework object you will have to create. The addition of this concept reduces the choices the user has to make to picking the dimension of the ambient space and choosing between exact and inexact computations. The model of *Kinetic::SimulationTraits* creates an instance each of the *Kinetic::Simulator* and *Kinetic::ActiveObjectsTable*. Handles for these instances as well as instances of the *Kinetic::Kernel* and *Kinetic::InstantaneousKernel* can be requested from the simulation traits class. Both the *Kinetic::Kernel* and the *Kinetic::Simulator* use the *Kinetic::FunctionKernel*, the former to find certificate failure times and the later to operate on them. For technical reasons, each supplied model of *Kinetic::SimulationTraits* also picks out a particular type of kinetic primitive which will be used by the kinetic data structures.

## 59.4 Using Kinetic Data Structures

There are five provided kinetic data structures. They are

*Kinetic::Sort<Traits, Visitor>* maintain a list of points sorted by x-coordinate.

*Kinetic::Delaunay\_triangulation\_2<Traits, Visitor, Triangulation>* maintain the Delaunay triangulation of a set of two dimensional points

*Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>* maintain the Delaunay triangulation of a set of three dimensional points.

*Kinetic::Regular\_triangulation\_3<Traits, Visitor, Triangulation>* maintain the regular triangulation of a set of waiting three dimensional points.

*Kinetic::Enclosing\_box\_2<Traits>*, *Kinetic::Enclosing\_box\_3<Traits>* restrict points to stay within a box by bouncing them off the walls.

### 59.4.1 A Simple Example

Using a kinetic data structure can be as simple as the following:

```
#include <CGAL/Kinetic/basic.h>

#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Insert_event.h>
#include <CGAL/Kinetic/Sort.h>

int main(int, char *[])
{

    typedef CGAL::Kinetic::Exact_simulation_traits Traits;

    typedef CGAL::Kinetic::Insert_event<Traits::Active_points_1_table> Insert_event;
    typedef Traits::Active_points_1_table::Data Moving_point;
    typedef CGAL::Kinetic::Sort<Traits> Sort;
    typedef Traits::Simulator::Time Time;

    Traits tr(0,100000);
    Sort sort(tr);
    Traits::Simulator::Handle sp= tr.simulator_handle();

    std::ifstream in("data/points_1");
    in >> *tr.active_points_1_table_handle();

    while (sp->next_event_time() != sp->end_time()) {
        sp->set_current_event_number(sp->current_event_number()+1);
    }

    return EXIT_SUCCESS;
};
```

**File:** examples/Kinetic\_data\_structures/Kinetic\_sort.cpp

Using the other kinetic data structures is substantially identical. Please see the appropriate files in the demo/Kinetic\_data\_structures directory.

In the example, first the *Kinetic::SimulationTraits* object is chosen (in this case one that supports exact computations). Then the kinetic data structure is defined using the chosen traits object and a visitor class which logs changes to the sorted list. Next, instances of the two are created and a set of points is read from a file. Then, the simulator is instructed to process all the events until the end of the simulation. Finally, a record of what happened is printed to the terminal.

Several important things happen behind the scenes in this example. First, the *Kinetic::ActiveObjectsTable* which holds the moving points notifies the kinetic data structure that new points have been added to the simulation. Second, the *Kinetic::Sort<Traits,Visitor>* kinetic data structure registers its events with the *Kinetic::Simulator* by providing a time and a proxy object for each event. When a particular event occurs, the *Kinetic::Simulator* calls a function on the proxy object which in turn updates the kinetic data structure.

The example illustrates how to monitor the supplied data structures as they evolve by using a *Kinetic::SortVisitor* object—a small class whose methods are called whenever the kinetic data structure changes. Hooks for such visitor concepts are provided for all of the shipped kinetic data structures. In the case of kinetic sorting, the visitor's methods are called every time a new point is inserted in the sorted list, when one is removed, or when two points are swapped in the sorted order.

The visitor concept is quite powerful, allowing us, for example, to implement a data structure for computing and storing two-dimensional arrangements of *x*-monotone curves on top of the *Kinetic::Sort<Traits, Visitor>* data structure using about 60 lines of code. This sweepline code is presented in Section 59.4.4.

## 59.4.2 Creating Kinetic Primitives

One key part of the framework not shown is how to create kinetic primitives (rather than just reading them in from a file). There are two ways to construction the necessary motion functions (which are models of *Kinetic::FunctionKernel::Function*). The first is to create an array of polynomial coefficients and simply call the constructor as in:

```
typedef Traits::Kinetic_kernel::Motion_function F;
std::vector<F::NT> coefs;
coefs.push_back(F::NT(1.0));
coefs.push_back(F::NT(2.0));
F x(coefs.begin(), coefs.end());
```

A slightly more flexible way is to use a *Kinetic::FunctionKernel::ConstructFunction* object. To do this do the following:

```
typedef Traits::Kinetic_kernel::Function_kernel::Construct_function
CF; typedef Traits::Kinetic_kernel::Motion_function F; CF cf; F
x=cf(F::NT(1.0), F::NT(2.0));
```

The *Kinetic::FunctionKernel::ConstructFunction* can be passed (almost) an number of arguments and will construct a polynomial with those arguments are coefficients.

Once the motion functions are constructed, constructing the primitive is just like constructing the corresponding static object.

```
typedef Traits::Kinetic_kernel::Point_1 Point_1;
Point_1 p(x);
```

### 59.4.3 Visualization of Kinetic Data Structures

The framework includes Qt widgets for displaying kinetic data structures in two and three dimensions. The following example shows using the two dimensional widget with a Delaunay triangulation:

```
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Delaunay_triangulation_2.h>
#include <CGAL/Kinetic/Enclosing_box_2.h>
#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>
#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>
#include <CGAL/Kinetic/IO/Qt_widget_2.h>

int main(int argc, char *argv[]) {
    using namespace CGAL::Kinetic;
    typedef Exact_simulation_traits Traits;
    typedef Delaunay_triangulation_2<Traits> Del_2;
    typedef Enclosing_box_2<Traits> Box_2;
    typedef Qt_widget_2<Traits::Simulator> Qt_widget;
    typedef Qt_moving_points_2<Traits, Qt_gui> Qt_mps;
    typedef Qt_triangulation_2<Del_2, Qt_widget, Qt_mps> Qt_dt2;

    // create a simulation traits and add two KDSs:
    // a kinetic Delaunay triangulation and an enclosing box;
    // the moving points bounce against the walls of the enclosing box
    Traits tr;
    Box_2::Handle box = new Box_2(tr);
    Del_2::Handle kdel = new Del_2(tr);

    // register the simulator, set of moving points and
    // Delaunay triangulation with the kinetic Qt widget
    Qt_widget::Handle qt_w = new Qt_widget(argc, argv, tr.simulator_handle());
    Qt_mps::Handle qt_mps = new Qt_mps(qt_w, tr);
    Qt_dt2::Handle qt_dt2 = new Qt_dt2(kdel, qt_w, qt_mps);

    // read the trajectories of the moving points
    // the simulation traits automatically inserts them in the two KDSs
    // and schedules the appropriate kinetic events; as in the kinetic
    // sorting example this is done with appropriate notifications
    std::ifstream in("data/points_2");
    in >> *tr.active_points_2_table_handle();

    // run the interactive kinetic simulation
    return qt_w->begin_event_loop();
};
```

The example shows how to use a number of additional features of the framework. First, it shows that two kinetic data structures (*Kinetic::Delaunay\_triangulation\_2<Traits, Triangulation>* and *Kinetic::Enclosing\_box\_2<Traits>*) can coexist on the same set of points without any extra effort. Both interact with the moving points

through the active objects table, and never need to directly interact with one another. Second, objects (like `qt_w`, `qt_mps` and `qt_dt2`) are all stored by using reference counted handles (`Object::Handle`). This allows them to share references to one another without the user having to worry about memory management and order of deletion. For example, the `Kinetic::Qt_triangulation_2<KineticDelaunay_2, QtWidget_2, Qt_moving_points_2>` object needs a handle to the kinetic triangulation, in order to get the structure to display, and a handle to the `Active_points_1_table` to get the coordinates of the points.

Finally, the example shows how to use the graphical interface elements provided, see Figure 59.3. Our package includes Qt widgets for displaying kinetic geometry in two and three dimensions. In addition to being able to play and pause the simulation, the user can step through events one at a time and reverse the simulation to retrace what had happened. The three-dimensional visualization support is based on the Coin library <http://www.coin3d.org>.

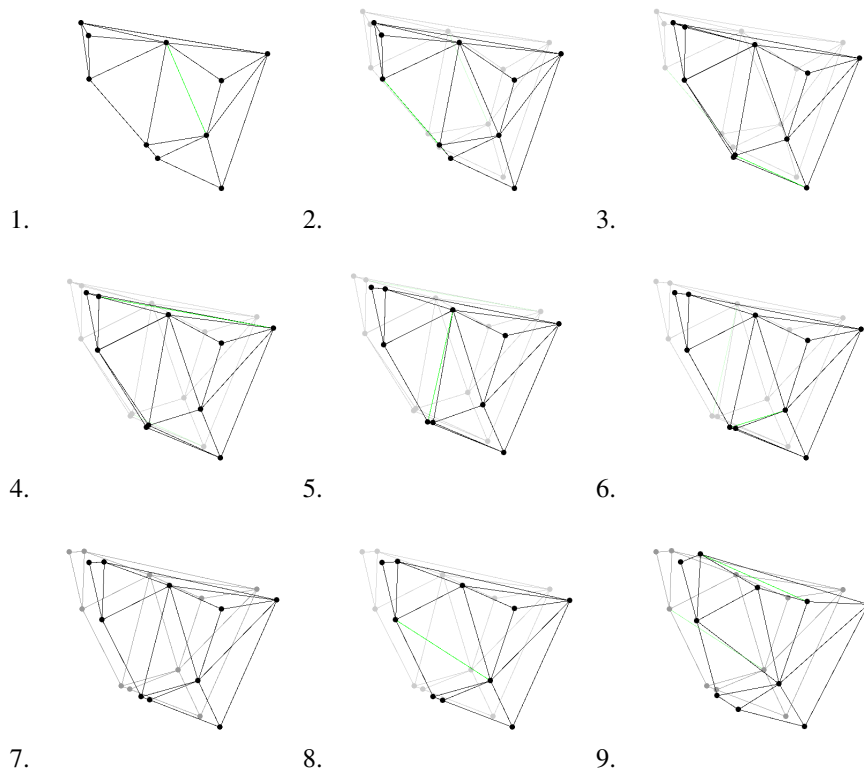

Figure 59.2: *Some events from a Delaunay triangulation kinetic data structure:* The state of the two dimensional Delaunay triangulation immediately following the first events is shown. Green edges are ones which were just created. The pictures are screen shots from `demo/Kinetic_data_structures/Kinetic_Delaunay_triangulation_2.cpp`.

#### 59.4.4 Extending Kinetic Data Structures

Here we present a simple example that uses the `Kinetic::Sort<Traits, Visitor>` kinetic data structure to compute an arrangement of algebraic functions. It wraps the sorting data structure and uses a visitor to monitor changes and map them to corresponding features in the arrangement. To see an example using this kinetic data structure read the example at `examples/Kinetic_data_structures/Kinetic_sweepline.cpp`.

First we define the visitor class. An object of this type is passed to the `Kinetic::Sort<Traits, Visitor>` data

Figure 59.3: The figure shows the graphical user interface for controlling two-dimensional kinetic data structures. It is built on top of the *Qt\_widget* and adds buttons to play, pause, step through and run the simulation backwards.

structure and turns events into calls on the arrangement structure. This class has to be defined externally since the arrangement will inherit from the sorting structure.

```
template <class Arrangement>
struct Arrangement_visitor: public Kinetic::Sort_visitor_base
{
    Arrangement_visitor(Arrangement *a):p_(a){}
    template <class Vertex_handle>
    void remove_vertex(Vertex_handle a) {
        p_->erase(a);
    }
    template <class Vertex_handle>
    void create_vertex(Vertex_handle a) {
        p_->insert(a);
    }
    template <class Vertex_handle>
    void after_swap(Vertex_handle a, Vertex_handle b) {
        p_->swap(a, b);
    }
    Arrangement *p_;
};
```

Now we define the actual arrangement data structure.

```
template <class TraitsT>
class Planar_arrangement:
    public Kinetic::Sort<TraitsT,
        Arrangement_visitor<Planar_arrangement<TraitsT> > > {
    typedef TraitsT Traits;
    typedef Planar_arrangement<TraitsT> This;
    typedef typename Kinetic::Sort<TraitsT,
```

```

Arrangement_visitor<This> > Sort;
typedef Arrangement_visitor<This> Visitor;
typedef typename Traits::Active_objects_table::Key Key;

public:
    typedef CGAL::Exact_predicates_inexact_constructions_kernel::Point_2 Approximate_point;
    typedef std::pair<int,int> Edge;
    typedef typename Sort::Vertex_handle Vertex_handle;

    // Register this KDS with the MovingObjectTable and the Simulator
    Planar_arrangement(Traits tr): Sort(tr, Visitor(this)) {}

    Approximate_point vertex(int i) const
    {
        return approx_coords_[i];
    }

    size_t vertices_size() const
    {
        return approx_coords_.size();
    }

    typedef std::vector<Edge >::const_iterator Edges_iterator;
    Edges_iterator edges_begin() const
    {
        return edges_.begin();
    }
    Edges_iterator edges_end() const
    {
        return edges_.end();
    }

    void insert(Vertex_handle k) {
        last_points_[*k]=new_point(*k);
    }

    void swap(Vertex_handle a, Vertex_handle b) {
        int swap_point= new_point(*a);
        edges_.push_back(Edge(swap_point, last_points_[*a]));
        edges_.push_back(Edge(swap_point, last_points_[*b]));
        last_points_[*a]= swap_point;
        last_points_[*b]= swap_point;
    }

    void erase(Vertex_handle a) {
        edges_.push_back(Edge(last_points_[*a], new_point(*a)));
    }

    int new_point(typename Traits::Active_objects_table::Key k) {
        double tv= CGAL::to_double(Sort::traits().simulator_handle()->current_time());
        double dv= CGAL::to_double(Sort::traits().active_objects_table_handle()->at(k).x()(tv));
        approx_coords_.push_back(Approximate_point(tv, dv));
        return approx_coords_.size()-1;
    }

```

```

std::vector<Approximate_point > approx_coords_;
std::map<Key, int> last_points_;
std::vector<Edge> edges_;

};

```

Finally, we have to set everything up. To do this we use some special event classes: *Kinetic::Insert\_event<ActiveObjectsTable>* and *Kinetic::Erase\_event<ActiveObjectsTable>*. These are events which can be put in the event queue which either insert a primitive into the set of active objects or remove it. Using these, we can allow curves in the arrangement to begin or end in arbitrary places.

```

typedef CGAL::Kinetic::Insert_event<Traits::Active_points_1_table> Insert_event;
typedef CGAL::Kinetic::Erase_event<Traits::Active_points_1_table> Erase_event;
do {
    NT begin, end;
    Point function;
    // initialize the function and the beginning and end somewhere
    tr.simulator_handle()->new_event(Time(begin),
        Insert_event(function, tr.active_points_1_table_handle()));
    tr.simulator_handle()->new_event(Time(end),
        Erase_event(Traits::Active_points_1_table::Key(num),
            tr.active_points_1_table_handle()));
    ++num;
} while (true);

```

# Kinetic Data Structures

## Reference Manual

*Daniel Russel*

### 59.5 Classified Reference Pages

Kinetic data structures are a way of adding motion to classical geometric data structures. CGAL provides several prepackaged kinetic data structures. Here we present those kinetic data structures and the helper classes that allow their activity to be monitored.

## CGAL::Kinetic::Delaunay\_triangulation\_2<Traits, Visitor, Triangulation>

### Definition

The class *Kinetic::Delaunay\_triangulation\_2<Traits, Visitor, Triangulation>* maintains a Delaunay triangulation on top of the points contained in a *Kinetic::ActiveObjectsTable*. It has one main method of interest, *triangulation()*, which returns the triangulation it is maintaining.

Note that the Delaunay triangulation is fully dynamic as it tracks points added to and removed from the *Kinetic::ActiveObjectsTable*.

The class *Kinetic::Qt\_triangulation\_2<KineticTriangulation\_2, QtWidget\_2, QtMovingPoints\_2>* displays a kinetic Delaunay triangulation using the Qt widget.

This class is a good example of a simple, but non-trivial, kinetic data structure.

The *Triangulation* template parameter must be a model of *CGAL::Delaunay\_triangulation\_2<Traits, Tds>* which uses *Traits::Default\_instantaneous\_kernel* as its geometric traits and a *Tds* whose face inherits from *Kinetic::Delaunay\_triangulation\_face\_base\_2<Traits, Base>*.

The optional *Visitor* parameter takes a model of *Kinetic::DelaunayTriangulationVisitor\_2*. Methods on this object will be called whenever the triangulation changes.

```
#include <CGAL/Kinetic/Delaunay_triangulation_2.h>
```

### Is Model for the Concepts

```
Ref_counted<T>
```

### Types

```
Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>:: Triangulation
```

The template argument triangulation.

```
Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>:: Visitor
```

The template argument for the visitor.

### Creation

```
Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation> dt( Traits tr);
```

Maintain the Delaunay triangulation of the points in *tr.active\_points\_2\_handle()*.

## Operations

*Triangulation*            *dt.triangulation()*            Access the triangulation that is maintained.

*Visitor&*                *dt.visitor()*                Access the visitor.

*Vertex\_handle*            *dt.insert( Point\_key k)*  
  
Insert the point.

*void*                    *dt.erase( Vertex\_handle h)*  
  
Erase the vertex.

## CGAL::Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>

### Definition

The class *Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>* maintains a Delaunay triangulation on top of the points contained in a *Kinetic::ActiveObjectsTable*. It has one main method of interest. *triangulation()* which returns the triangulation it is maintaining. In addition, as an optimisation, you can turn on and off whether it is currently maintaining its certificates. This allows a large number of changes to the underlying points to be made at one time without recomputing the certificates each time a single point changes.

Note that the Delaunay triangulation is fully dynamic as it tracks points added to and removed from the *Kinetic::ActiveObjectsTable*.

The class *Kinetic::Qt\_triangulation\_3<Traits>*, included as part of the demo code, displays a kinetic Delaunay triangulation in three dimensions using the Coin library.

The optional *Visitor* template argument is a model of *Kinetic::DelaunayTriangulationVisitor\_3* and can be used to monitor changes in the kinetic data structure.

The optional *Triangulation* template argument must be a model of a *CGAL::DelaunayTriangulation\_3* which uses *Traits::Default\_instantaneous\_kernel* as its geometric traits and has *Kinetic::Delaunay\_triangulation\_cell\_base\_3<Traits, Base>* as the cell type.

```
#include <CGAL/Kinetic/Delaunay_triangulation_3.h>
```

### Types

*Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>:: Triangulation*

The template argument.

*Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>:: Visitor*

The template argument.

### Creation

*Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>* *dt*( *Traits tr*);

Maintain the Delaunay triangulation of the points in *tr.active\_points\_3\_handle()*.

### Operations

*const Triangulation\** *dt.triangulation()* Access the triangulation that is maintained.

<i>bool</i>	<i>dt.has_certificates()</i>	This method returns true if the <i>Kinetic::Delaunay_triangulation_3&lt;Traits, Visitor, Triangulation&gt;</i> is currently maintaining certificates for a Delaunay triangulation.
<i>void</i>	<i>dt.set_has_certificates( bool tf)</i>	This method allows you to control whether the triangulation is maintaining certificates.
<i>Visitor&amp;</i>	<i>dt.visitor()</i>	Access the visitor.

### See Also

*Kinetic::Delaunay\_triangulation\_3*<*Traits*, *Triangulation*, *Visitor*>

## CGAL::Kinetic::Delaunay\_triangulation\_face\_base\_2<Traits, Base>

### Definition

This is the base class for faces used by the triangulation used in *Kinetic::Delaunay\_triangulation\_2<Traits, Triangulation, Visitor>*.

```
#include <CGAL/Kinetic/Delaunay_triangulation_face_base_2.h>
```

### See Also

*Kinetic::Delaunay\_triangulation\_2<Traits, Triangulation, Visitor>*

## CGAL::Kinetic::Delaunay\_triangulation\_recent\_edges\_visitor\_2<Triangulation>

### Definition

The concept *Kinetic::Delaunay\_triangulation\_recent\_edges\_visitor\_2<Triangulation>* provides a model of *Kinetic::DelaunayTriangulationVisitor\_2* which tracks which edges were created in the most recent change.

### Is Model for the Concepts

*Kinetic::DelaunayTriangulationVisitor\_2*

### Creation

*Kinetic::Delaunay\_triangulation\_recent\_edges\_visitor\_2<Triangulation>* *a*;  
 default constructor.

*Kinetic::Delaunay\_triangulation\_recent\_edges\_visitor\_2<Triangulation>::iterator*  
 The iterator through the recently created edges.

### Operations

<i>iterator</i>	<i>a.begin()</i>	Begin iteration through the recent edges.
<i>iterator</i>	<i>a.end()</i>	End iteration through the recent edges.
<i>bool</i>	<i>a.contains( Triangulation::Edge )</i>	Returns true if this edge exists in the set.

### See Also

*Kinetic::Delaunay\_triangulation\_2<Traits, Triangulation, Visitor>*

## Kinetic::DelaunayTriangulationVisitor\_2

### Definition

This concept is for proxy objects which get notified when a kinetic Delaunay triangulation changes.

### Operations

<i>void</i>	<i>v.pre_remove_vertex( Vertex_handle)</i>	The vertex is about to be deleted.
<i>void</i>	<i>v.post_remove_vertex( Point_key)</i>	The vertex was just removed.
<i>void</i>	<i>v.pre_insert_vertex( Point_key)</i>	The vertex is about to be inserted into the cell (although the <i>Cell_handle</i> might be <i>NULL</i> ).
<i>void</i>	<i>v.post_insert_vertex( Vertex_handle)</i>	The vertex was just inserted.
<i>void</i>	<i>v.change_vertex( Vertex_handle)</i>	The trajectory of the point at the vertex changed.
<i>void</i>	<i>v.create_face( Face_handle f)</i>	The face has just been made.
<i>void</i>	<i>v.destroy_face( Face_handle f)</i>	The face is about to be destroyed.
<i>void</i>	<i>v.pre_flip( Edge)</i>	The edge is about to be flipped.
<i>void</i>	<i>v.post_flip( Edge)</i>	The edge was just created with a flip.

### Has Models

*Kinetic::Delaunay\_triangulation\_visitor\_base\_2*, *Kinetic::Delaunay\_triangulation\_recent\_edges\_visitor\_2*<  
*Triangulation*>, *Kinetic::Delaunay\_triangulation\_event\_log\_visitor\_2*

## Kinetic::DelaunayTriangulationVisitor\_3

### Definition

This concept is for proxy objects which get notified when a kinetic Delaunay triangulation changes.

### Operations

*void* *v.pre\_remove\_vertex( Vertex\_handle )*

The vertex is about to be deleted.

*void* *v.post\_remove\_vertex( Point\_key, Cell\_handle )*

The vertex was just removed.

*void* *v.pre\_insert\_vertex( Point\_key, Cell\_handle )*

The vertex is about to be inserted into the cell (although the *Cell\_handle* might be *NULL*).

*void* *v.post\_insert\_vertex( Vertex\_handle )*

The vertex was just inserted.

*void* *v.change\_vertex( Vertex\_handle )*

The trajectory of the point at the vertex changed.

*void* *v.create\_cell( Cell\_handle )*

The cell was just created and initialized.

*void* *v.destroy\_cell( Cell\_handle )*

The cell is about to be removed.

*void* *v.pre\_edge\_flip( Edge )*

The edge is about to be flipped.

*void* *v.post\_edge\_flip( Facet )*

The facet was just created with a flip.

*void* *v.pre\_facet\_flip( Facet)*

The facet is about to be flipped.

*void* *v.post\_facet\_flip( Edge)*

The edge was just created with a flip.

### **Has Models**

*Kinetic::Delaunay\_triangulation\_visitor\_base\_3, Kinetic::Delaunay\_triangulation\_recent\_edges\_visitor\_3< Triangulation>, Kinetic::Delaunay\_triangulation\_event\_log\_visitor\_3*

## CGAL::Kinetic::Delaunay\_triangulation\_visitor\_base\_2

### Definition

The concept *Kinetic::Delaunay\_triangulation\_visitor\_base\_2* provides a model of *Kinetic::DelaunayTriangulationVisitor\_2*. You can extend this class if you only want to implement a few methods from *Kinetic::DelaunayTriangulationVisitor\_2*.

### Is Model for the Concepts

*Kinetic::DelaunayTriangulationVisitor\_2*

### Creation

*Kinetic::Delaunay\_triangulation\_visitor\_base\_2* a;

default constructor.

### See Also

*Kinetic::Delaunay\_triangulation\_2*<Traits, Triangulation, Visitor>

## CGAL::Kinetic::Delaunay\_triangulation\_visitor\_base\_3

### Definition

The concept *Kinetic::Delaunay\_triangulation\_visitor\_base\_3* provides a model of *Kinetic::DelaunayTriangulationVisitor\_3*. You can extend this class if you only want to implement a few methods from *Kinetic::DelaunayTriangulationVisitor\_3*.

### Is Model for the Concepts

*Kinetic::DelaunayTriangulationVisitor\_3*

*Kinetic::Delaunay\_triangulation\_visitor\_base\_3* a;

default constructor.

### See Also

*Kinetic::Delaunay\_triangulation\_3*<Traits, Triangulation, Visitor>

## CGAL::Kinetic::Enclosing\_box\_2<Traits>

### Definition

The class *Kinetic::Enclosing\_box\_2<Traits>* keeps the points in the simulation inside of a box. Whenever the points come close to the wall of the box they bounce off of the wall.

Note that, in general, points hit the wall of the box at times which are not easily represented by standard (rational) number types. The resulting trajectories would also have non-rational coefficients, complicating and slowing the simulation. In order to handle this, the *Kinetic::Enclosing\_box\_2<Traits>* bounces the points at the nearest easily representable time before the point would leave the box.

```
#include <CGAL/Kinetic/Enclosing_box_2.h>
```

### Types

<i>Kinetic::Enclosing_box_2&lt;Traits&gt;:: NT</i>	The number type used to represent the walls of the box and perform calculations. Generally this is <i>Traits::NT</i> .
--	--

### Creation

```
Kinetic::Enclosing_box_2<Traits> eb( Traits, NT xmin, NT xmax, NT ymin, NT ymax);
```

This constructs a bounding box with the dimensions specified by the last 4 arguments. They are optional and will take the values  $\pm 10$  if omitted.

## CGAL::Kinetic::Enclosing\_box\_3<Traits>

### Definition

The class *Kinetic::Enclosing\_box\_3<Traits>* keeps the points in the simulation inside of a box. Whenever the points come close to the wall of the box they bounce off of the wall.

Note that, in general, points hit the wall of the box at times which are not easily represented by standard (rational) number types. The resulting trajectories would also have non-rational coefficients, complicating and slowing the simulation. In order to handle this, the *Kinetic::Enclosing\_box\_3<Traits>* bounces the points at the nearest easily representable time before the point would leave the box.

```
#include <CGAL/Kinetic/Enclosing_box_3.h>
```

### Types

*Kinetic::Enclosing\_box\_3<Traits>::NT*      The number type used to represent the walls of the box and perform calculations. Generally this is *Traits::NT*.

### Creation

```
Kinetic::Enclosing_box_3<Traits> eb( Traits, NT xmin, NT xmax, NT ymin, NT ymax, NT zmin, NT zmax);
```

This constructs a bounding box with the dimensions specified by the last 6 arguments. They are optional and will take the values  $\pm 10$  if omitted.

## CGAL::Kinetic::Erase\_event<ActiveObjectsTable>

### Definition

This event erases a point from the *ActiveObjectsTable* when it is processed.

```
#include <CGAL/Kinetic/Erase_event.h>
```

### Is Model for the Concepts

*Kinetic::Simulator::Event*

### Creation

```
Kinetic::Erase_event<ActiveObjectsTable> i( ActiveObjectsTable::Key k, ActiveObjectsTable::Handle t);
```

Erase the object *k* from the table *t* when processed.

### See Also

*Kinetic::ActiveObjectsTable*, *Kinetic::Active\_objects\_vector<MovingObject>*.

### Example

```
typedef CGAL::Kinetic::Exact_simulation_traits Simulation_traits;
typedef Simulation_traits::Kinetic_kernel::Point_2 Moving_point_2;
typedef CGAL::Kinetic::Insert_event<Simulation_traits::Active_points_2_table> Insert_event;
typedef CGAL::Kinetic::Delaunay_triangulation_2<Simulation_traits> KDel;

Simulation_traits tr;

KDel kdel(tr);

Moving_point_2 mp(Moving_point_2::NT(0),
                  Moving_point_2::NT(0));
tr.simulator_handle()->new_event(Simulation_traits::Simulator::Time(3),
                                Erase_event(*tr.active_objects_table_handle()->keys_begin(),
                                             tr.active_points_2_table_handle()));
```

## Kinetic::EventLogVisitor

### Definition

This concept is for visitors which maintain a text log of events.

### Types

*Kinetic::EventLogVisitor:: Event\_iterator*      An iterator through strings defining the events that occurred.  
Each event is represented by a *std::string*.

### Operations

*Event\_iterator*      *v.events\_begin()*      Begin iterating through the events.

*Event\_iterator*      *v.events\_end()*

### Has Models

*Kinetic::Delaunay\_triangulation\_event\_log\_visitor\_3*,    *Kinetic::Delaunay\_triangulation\_event\_log\_visitor\_2*,  
*Kinetic::Regular\_triangulation\_event\_log\_visitor\_3*, *Kinetic::Sort\_event\_log\_visitor*

## CGAL::Kinetic::Insert\_event<ActiveObjectsTable>

### Definition

This event inserts a point into the *ActiveObjectsTable* when it is processed.

```
#include <CGAL/Kinetic/Insert_event.h>
```

### Is Model for the Concepts

*Kinetic::Simulator::Event*

### Creation

```
Kinetic::Insert_event<ActiveObjectsTable> i( ActiveObjectsTable::Data o, ActiveObjectsTable::Handle t);
```

Insert the object o, into the table t when processed.

### See Also

*Kinetic::ActiveObjectsTable*, *Kinetic::Active\_objects\_vector<MovingObject>*.

### Example

```
typedef CGAL::Kinetic::Exact_simulation_traits Simulation_traits;
typedef Simulation_traits::Kinetic_kernel::Point_2 Moving_point_2;
typedef CGAL::Kinetic::Insert_event<Simulation_traits::Active_points_2_table> Insert_event;
typedef CGAL::Kinetic::Delaunay_triangulation_2<Simulation_traits> KDel;

Simulation_traits tr;

KDel kdel(tr);

Moving_point_2 mp(Moving_point_2::Coordinate(0),
                  Moving_point_2::Coordinate(0));
tr.simulator_handle()->new_event(Simulation_traits::Simulator::Time(3),
                                Insert_event(mp,
                                tr.active_points_2_table_handle()));
```

## CGAL::Kinetic::Qt\_moving\_points\_2<Traits, QWidget\_2>

### Definition

The class *Kinetic::Qt\_moving\_points\_2<Traits, QWidget\_2>* displays a set of moving points in 2D.

See Section [59.4.3](#) for an example using this class.

```
#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>
```

### Creation

```
Kinetic::Qt_moving_points_2<Traits, QWidget_2> a( QtGui::Handle,  
                                                Traits::Active_points_2_table::Handle)
```

default constructor.

### See Also

*Kinetic::Qt\_widget\_2<Simulator>*.

## CGAL::Kinetic::Qt\_triangulation\_2<KineticTriangulation\_2, QtWidget\_2, QtMovingPoints\_2>

### Definition

The class draws a triangulation into a *CGAL::Qt\_widget\_2*. This class is very simple and a good one to look at if you want to see how to draw your own two dimensional kinetic data structure.

See Section [59.4.3](#) for an example using this class.

```
#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>
```

### Creation

```
Kinetic::Qt_triangulation_2<KineticTriangulation_2,      QtWidget_2,      QtMovingPoints_2>      a(
KineticTriangulation_2::Handle,
                                                                    QtWidget_
2::Handle,
                                                                    QtMovingPoints_
2::Handle)
```

Construct the object and make all the connections with the appropriate other objects.

### See Also

*Kinetic::Qt\_widget\_2<Simulator>*

## CGAL::Kinetic::Qt\_widget\_2<Simulator>

### Definition

The class *Kinetic::Qt\_widget\_2<Simulator>* implements a graphical interface for 2D kinetic data structures.

*#include <CGAL/Kinetic/IO/Qt\_widget\_2.h>*

### Types

*Kinetic::Qt\_widget\_2<Simulator>::Listener*      The listener base to listen for when to update the picture. This class includes an extra method *Qt\_widget widget()* which returns the *Qt\_widget* object which can be used for drawing.

### Creation

*Kinetic::Qt\_widget\_2<Simulator> a( int argc, char \*argv[], Simulator::Handle);*

default constructor.

```
#include <CGAL/basic.h>
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Delaunay_triangulation_2.h>
#include <CGAL/Kinetic/Delaunay_triangulation_vertex_base_2.h>
#include <CGAL/Kinetic/Delaunay_triangulation_recent_edges_visitor_2.h>
#include <CGAL/Kinetic/Enclosing_box_2.h>
#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>
#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>
#include <CGAL/Kinetic/IO/Qt_widget_2.h>
#include <CGAL/Kinetic/Insert_event.h>

int main(int argc, char *argv[])
{
    typedef CGAL::Kinetic::Exact_simulation_traits Traits;

    typedef CGAL::Triangulation_data_structure_2<
        CGAL::Kinetic::Delaunay_triangulation_vertex_base_2<Traits::Instantaneous_kernel>,
        CGAL::Kinetic::Delaunay_triangulation_face_base_2<Traits> > TDS;
    typedef CGAL::Delaunay_triangulation_2<Traits::Instantaneous_kernel, TDS > Del;
    // Color edges based on how recently they were created
    typedef CGAL::Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Del> Visitor;
    typedef CGAL::Kinetic::Delaunay_triangulation_2<Traits, Visitor, Del> KDel;
    typedef CGAL::Kinetic::Qt_widget_2<Traits::Simulator> Qt_gui;
    typedef CGAL::Kinetic::Qt_moving_points_2<Traits, Qt_gui> Qt_mps;
    typedef CGAL::Kinetic::Qt_triangulation_2<KDel, Traits::Instantaneous_kernel, Qt_gui> Qt_triangulation;
    // Keeps the points confined
    typedef CGAL::Kinetic::Enclosing_box_2<Traits> Box;
```

```

CGAL_SET_LOG_LEVEL(CGAL::Log::LOTS);

// Run from time 0 until a really large value of time
Traits tr(0, 10000000);
Box::Handle box= new Box(tr);
KDel::Handle kdel= new KDel(tr);

Qt_gui::Handle qtsim= new Qt_gui(argc, argv, tr.simulator_handle());

Qt_mps::Handle qtmps= new Qt_mps(qtsim, tr);
Qt_triangulation::Handle qtdel= new Qt_triangulation(kdel, tr.instantaneous_kernel_object(), qtsim);
Traits::Kinetic_kernel::Point_2 p;
std::cin >> p;
tr.active_points_2_table_handle()->insert(p);
return qtsim->begin_event_loop();
}

```

## CGAL::Kinetic::Regular\_triangulation\_3<Traits, Visitor, Triangulation>

### Definition

The class *Kinetic::Regular\_triangulation\_3<Traits, Visitor, Triangulation>* maintains a triangulation of set of moving weighted points. Its interface is the same as *Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>*.

Note that the regular triangulation tracks as points are added to the *Kinetic::ActiveObjectsTable*, but not removed from it.

The optional *Triangulation* template argument must be a model of *CGAL::RegularTriangulation\_3* which has *Kinetic::Regular\_triangulation\_cell\_base\_3<Traits, Base>* as a cell base and *Kinetic::Regular\_triangulation\_vertex\_base\_3<Traits, Base>* as a vertex base.

```
#include <CGAL/Kinetic/Regular_triangulation_3.h>
```

### See Also

*Kinetic::Delaunay\_triangulation\_3<Traits, Visitor, Triangulation>*. *Kinetic::RegularTriangulationVisitor\_3*.

### Example

```
#define CGAL_CHECK_EXACTNESS
#define CGAL_CHECK_EXPENSIVE

#include <CGAL/Kinetic/Regular_triangulation_exact_simulation_traits.h>
#include <CGAL/Kinetic/Regular_triangulation_3.h>

int main(int, char *[]) {
    typedef CGAL::Kinetic::Regular_triangulation_exact_simulation_traits Traits;
    typedef CGAL::Kinetic::Regular_triangulation_3<Traits> KDel;

    Traits tr(0,100000.0);
    KDel kdel(tr);

    Traits::Simulator::Handle sp= tr.simulator_handle();

    std::ifstream in("data/weighted_points_3");
    CGAL_assertion(in);
    in >> *tr.active_points_3_table_handle();

    std::cout << *tr.active_points_3_table_handle();

    std::cout << *tr.active_points_3_table_handle() << std::endl;

    kdel.set_has_certificates(true);
```

```
    sp->set_current_event_number(10000);  
    return EXIT_SUCCESS;  
};
```

## CGAL::Kinetic::Regular\_triangulation\_cell\_base\_3<Traits, Base>

### Definition

This is the base class for faces used by *Kinetic::Regular\_triangulation\_3<Traits, Triangulation, Visitor>*.

```
#include <CGAL/Kinetic/Regular_triangulation_cell_base_3.h>
```

## CGAL::Kinetic::Regular\_triangulation\_event\_log\_visitor\_3

### Definition

The concept *Kinetic::Regular\_triangulation\_event\_log\_visitor\_3* provides a model of *Kinetic::RegularTriangulationVisitor\_3* and *EventLogVisitor* which logs edge flip events.

### Is Model for the Concepts

*Kinetic::RegularTriangulationVisitor\_3*, *Kinetic::EventLogVisitor*

### See Also

*Kinetic::Regular\_triangulation\_3*<*Traits*, *Triangulation*, *Visitor*>

## CGAL::Kinetic::Regular\_triangulation\_instantaneous\_kernel<ActiveObjectsTable, StaticKernel>

### Definition

The class *Kinetic::Regular\_triangulation\_instantaneous\_kernel*<*ActiveObjectsTable*, *StaticKernel*> is an instantaneous kernel for use with a regular triangulation data structure. There is not currently a reason for the user to call this directly unless the user wants created their own simulation traits as it is included as part of the *Kinetic::Regular\_triangulation\_exact\_simulation\_traits*.

```
#include <CGAL/Kinetic/Regular_triangulation_instantaneous_kernel.h>
```

### Is Model for the Concepts

*CGAL::RegularTriangulationTraits\_3*, *Kinetic::InstantaneousKernel*

### See Also

*Kinetic::Regular\_triangulation\_3*<*Traits*, *Visitor*, *Triangulation*>.

## CGAL::Kinetic::Regular\_triangulation\_vertex\_base\_3<Traits, Base>

### Definition

This is the base class for the vertices of the triangulation class used by *Kinetic::Regular\_triangulation\_3<Traits, Triangulation, Visitor>*.

```
#include <CGAL/Kinetic/Regular_triangulation_vertex_base_3.h>
```

## Kinetic::RegularTriangulationVisitor\_3

### Definition

This concept is for proxy objects which get notified when a kinetic regular triangulation changes. It inherits all the methods of *DelaunayTriangulationVisitor\_3*.

### Is Model for the Concepts

*Kinetic::DelaunayTriangulationVisitor\_3*

### Operations

*void* *v.pre\_move( Key, Cell)*

The point defined by *Key* is about to move from the cell.

*void* *v.post\_move( Key, Cell)*

The point defined by *Key* just moved to the cell.

### Has Models

*Kinetic::Regular\_triangulation\_visitor\_base\_3*, *Kinetic::Regular\_triangulation\_event\_log\_visitor\_3*

## CGAL::Kinetic::Regular\_triangulation\_visitor\_base\_3

### Definition

The concept *Kinetic::Regular\_triangulation\_visitor\_base\_3* provides a model of *Kinetic::RegularTriangulationVisitor\_3*. You can extend this class if you only want to implement a few methods from *Kinetic::RegularTriangulationVisitor\_3*.

### Is Model for the Concepts

*Kinetic::RegularTriangulationVisitor\_3*

### Creation

*Kinetic::Regular\_triangulation\_visitor\_base\_3* *a*;  
default constructor.

### See Also

*Kinetic::Regular\_triangulation\_3*<*Traits*, *Triangulation*, *Visitor*>

## CGAL::Kinetic::Sort\_event\_log\_visitor

### Definition

The concept *Kinetic::Sort\_event\_log\_visitor* provides a model of *SortVisitor* and *EventLogVisitor* which logs changes to the structure.

### Is Model for the Concepts

*Kinetic::SortVisitor*, *Kinetic::EventLogVisitor*

### See Also

*Kinetic::Sort*<*Traits*, *Visitor*>

## CGAL::Kinetic::Sort<Traits, Visitor>

### Definition

The class *Kinetic::Sort<Traits, Visitor>* maintains a sorted list of objects. It is the simplest kinetic data structure provided and is a good place to start when looking at the basics of implementing a kinetic data structure.

The *Kinetic::SortVisitor* can be used to monitor what is happening.

```
#include <CGAL/Kinetic/Sort.h>
```

### Creation

*Kinetic::Sort<Traits, Visitor>* *s*( *Traits tr*);      The basic constructor.

### Types

*Kinetic::Sort<Traits, Visitor>:: Visitor*      The type of the visitor.

*Kinetic::Sort<Traits, Visitor>:: Traits*      The traits type.

*Kinetic::Sort<Traits, Visitor>:: Vertex\_handle*      The handle used to refer to vertex in the sorted list. Dereferencing this returns a *Key* into the *ActiveObjectsTable*.

*Kinetic::Sort<Traits, Visitor>:: Handle*      A reference counted pointer to be used for storing references to the object.

*Kinetic::Sort<Traits, Visitor>:: Const\_handle*      A reference counted pointer to be used for storing references to the object.

### Operations

*Visitor*&      *s.visitor()*      Access the visitor.

*Traits*&      *s.traits()*      Access the traits.

*Vertex\_handle*      *s.insert( Point\_key k)*      Insert the point.

*void*      *s.erase( Vertex\_handle k)*  
Erase the point.

*Iterator*      *s.begin()*      Begin iterating through the ordered *Vertex\_handles* (the iterator is convertible to *Vertex\_handle*).

*Iterator*      *s.end()*      End iterating through the ordered *Vertex\_handles* (the iterator is convertible to *Vertex\_handle*).

## CGAL::Kinetic::Sort\_visitor\_base

### Definition

The concept *Kinetic::Sort\_visitor\_base* provides a model of *Kinetic::SortVisitor*. You can extend this class if you only want to implement a few methods from *Kinetic::SortVisitor*.

### Is Model for the Concepts

*Kinetic::SortVisitor*.

### Creation

*Kinetic::Sort\_visitor\_base* *a*;                      default constructor.

### See Also

*Kinetic::Sort*<*Traits*, *Visitor*>

## Kinetic::SortVisitor

### Definition

This concept is for proxy objects which have functions called on them when a *Kinetic::Sort<Traits, Visitor>*.

### Operations

*void* *v.pre\_remove\_vertex( Vertex\_handle )*

The vertex is about to be deleted.

*void* *v.post\_remove\_vertex( Point\_key )*

The vertex was just removed.

*void* *v.pre\_insert\_vertex( Point\_key )*

The vertex is about to be inserted into the cell (although the *Cell\_handle* might be *NULL*).

*void* *v.post\_insert\_vertex( Vertex\_handle )*

The vertex was just inserted.

*void* *v.change\_vertex( Vertex\_handle )*

Something changed at the vertex.

*void* *v.pre\_swap( Vertex\_handle, Vertex\_handle )*

The pair of vertices is about to be exchanged.

*void* *v.post\_swap( Vertex\_handle, Vertex\_handle )*

The pair of vertices was just swapped.

### Has Models

*Kinetic::Sort\_visitor\_base, Kinetic::Sort\_event\_log\_visitor*

This chapter describes a framework for implementing kinetic data structures and sweepline algorithms. If you just would like to use existing kinetic data structures, please read Chapter 59 instead. Readers wishing to brush up on their familiarity with kinetic data structures or better understand the terminology we use should read Section 59.2 of that chapter. A brief overview of the framework can be found in Section 59.3 (also of that chapter) and it too is recommended reading. Here we dive right in to discussing the architecture of the framework in Section 60.1 and finally we give several examples of using the framework to implement a kinetic data structure in Section 60.3. The framework makes heavy use of our *Polynomial\_kernel* package to provide models of the *Kinetic::FunctionKernel* concept.

The framework was first presented at ALENEX [GKR04].

### 60.1 Architecture

This package provides a framework to allow exact implementation of kinetic data structures and sweepline algorithms. Below we discuss in detail each one of the first four major concepts which help in implementing

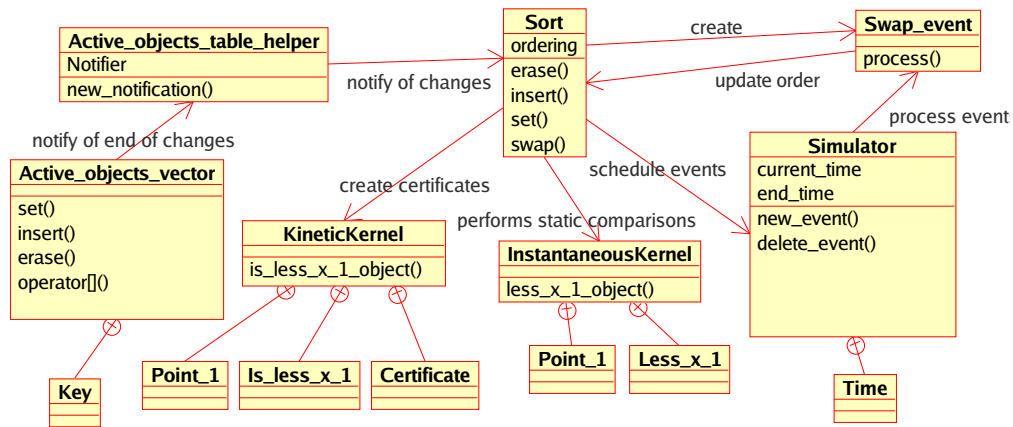

Figure 60.1: The figure, identical to the one in the overview of the previous chapter, shows the interaction between the *Kinetic::Sort*<Traits, Visitor> kinetic data structure and the various pieces of our framework. Other, more complicated, kinetic data structures will also use the *Kinetic::InstantaneousKernel* in order to insert/remove geometric primitives and audit themselves. *Kinetic::Sort*<Traits, Visitor> uses the sorting functionality in STL instead.

kinetic data structures: the *Kinetic::Simulator*, the *Kinetic::Kernel*, the *Kinetic::ActiveObjectsTable* and the *Kinetic::InstantaneousKernel*. The *Kinetic::FunctionKernel* concept is discussed separately in Section 60.2.

### 60.1.1 The *Kinetic::Simulator*

The *Kinetic::Simulator* is the central repository of all active events. It maintains the event queue and can use its knowledge of the events in the queue to find times for the kinetic data structures to easily check their own correctness (this will be discussed in more detail later in this section). Kinetic data structures call methods of the *Kinetic::Simulator* to schedule new events, deschedule old ones and access and change data contained in already scheduled events (the operations on existing events are performed using a key which was returned when the event was scheduled). For controlling the simulation, methods in the *Kinetic::Simulator* allow stepping through events, advancing time and even running the simulation backwards (that is we run the simulation with the time running in the opposite direction).

The kinetic sorting example in Figure 59.4.1 shows the basic usage of the *Kinetic::Simulator*. First, the *Simulator* is created by the *Kinetic::SimulationTraits*. The kinetic data structure gets a handle to the simulator from the traits class and uses the handle to add its events to the simulation. The *Kinetic::Simulator* is then told to advance time up until the end of the simulation, processing all events along the way.

Each event is represented by a *Kinetic::Simulator::Time* and an instance of a model of the *Kinetic::Simulator::Event* concept. Models of the *Kinetic::Simulator::Event* concept are responsible for taking the appropriate action in order to handle the kinetic event they represent. Specifically, the *Kinetic::Simulator::Event* concept specifies one method, *Kinetic::Simulator::Event::process()*, that is called when the event occurs. The body of the *Kinetic::Simulator::Event::process()* method typically simply calls a method of the kinetic data structure that created the event; for example in our kinetic sorting example, processing an event means calling the *Kinetic::Sort*<Traits, Visitor>::*swap*(Iterator) method of the kinetic sorting data structure.

In the model of the *Kinetic::Simulator* concept that we provide, *Kinetic::Default\_simulator*<FunctionKernel, EventQueue>, any model of the *Kinetic::Simulator::Event* concept can be inserted as an event. This ability

implies that events can be mixed at run time, which is essential when we want to support multiple kinetic data structures operating on the same set of moving geometric primitives.

The *Kinetic::Simulator::Time* concept is defined by the simulator, typically to be some representation of a root of a polynomial, taken from the *Kinetic::FunctionKernel* (details of the algebraic side of the package will be discussed in Section 60.2). For most kinetic data structures *Kinetic::Simulator::Time* only needs to support comparisons (we need to compare events, in order to process them in the correct order) and a few other non-arithmetic operations.

When the failure times of certificates are sorted exactly (as opposed to when we numerically approximate the roots of the certificate polynomials) the correctness of kinetic data structures can be easily verified. Let  $I$  be an open interval between the last event processed and the next event to be processed. As was mentioned in the introduction kinetic data structures do not change combinatorially in  $I$ . In addition, although the static data structures can be degenerate at the roots defining the two ends of the interval, they are not, in general, degenerate in the interior. An independent check of the integrity of kinetic data structures can be provided by, for example, using an *Kinetic::InstantaneousKernel* (cf. Subsection 60.1.4) to rebuild the static version of the structure from scratch at some time interior to  $I$  and compare it to the kinetic version. This auditing can typically catch algorithmic or programming errors much closer to the time they arise in the simulation than, for example, using visual inspection. Such easy auditing is one of the powerful advantages of having an exact computational framework since, as with static data structures, when using inexact computations differentiating between errors of implementation and numeric errors is quite tricky.

Kinetic data structures receive alerts of appropriate times to audit themselves using a notification framework. The same framework is also used by the *Kinetic::ActiveObjectsTable* to alert kinetic data structures when the set of primitives changes (see Subsection 60.1.3). To use the notification framework, the kinetic data structure creates a proxy object which implements a standard *Listener* interface. It then registers this proxy with the *Kinetic::Simulator*. When the *Kinetic::Simulator* finds an appropriate time for the kinetic data structures to audit themselves it calls the function *Listener::new\_notification(Type)* on each of the registered proxy objects. A helper for creating such proxy objects, called *Kinetic::Simulator\_kds\_listener<Listener, KDS>*, is provided by the framework. It translates the notification into a function call (*audit()*) on the kinetic data structure. Pointers in the notification framework are reference counted appropriately to avoid issues caused by the creation and destruction order of kinetic data structures and the simulator. See Section 60.1.5 for a more complete discussion of this part of the framework.

Internally the *Kinetic::Simulator* maintains a priority queue containing the scheduled events. The type of the priority queue is a template argument to our *Kinetic::Simulator* model and, as such, it can be replaced by the user. In our package, we provide two different types of priority queues, a heap and a two-list priority queue. A two-list queue is a queue in which there is a sorted front list, containing all events before some time and an unsorted back list. The queue tries to maintain a small number of elements in the front list, leaving most of them in the unsorted main pool. The two-list queue, although an unconventional choice, is our default queue when using exact computation because it minimizes comparisons involving events that are far in the future. These events are likely to be deleted before they are processed, so extra work done structuring them is wasted. Our experiments have shown that, for example, the two-list queue causes a 20% reduction in running time relative to a binary heap for Delaunay triangulations with degree 3 polynomial motions and 20 points.

## 60.1.2 The Kinetic::Kernel

The *Kinetic::Kernel* is structured very much like static CGAL kernels. It defines a number of primitives, which in the model provided are *Kinetic::Kernel::Point\_1*, *Kinetic::Kernel::Point\_2*, *Kinetic::Kernel::Point\_3* and *Kinetic::Kernel::Weighted\_point\_3*. The primitives are defined by a set of Cartesian coordinates each of which is a function of time, a *Kernel::MotionFunction*. In addition it defines constructions and certificate generators which act on the primitives. The certificate generators are the direct analog of the non-kinetic predicates. Each certificate generator take a number of primitives as arguments, but instead of producing an element from a

discrete set they produce a set of discrete failure times for the certificate. These failure times are wrapped in a model of *Kinetic::Certificate*.

A *Kinetic::Certificate* is a simple object whose primary function is to produce a *Kinetic::Simulator::Time* object representing the failure time of the certificate. Since, the handling of most certificate failures involves creating a new certificate whose certificate function is the negation of the old certificate function, a *Kinetic::Certificate* object caches any work that could be useful to isolate future roots of the certificate function (such as the Sturm sequence of the certificate function). To illustrate this further, if you have two one-dimensional points with coordinate functions  $p_0(t)$  and  $p_1(t)$ , the certificate that the first moving point is after the second corresponds to the inequality  $p_0(t) - p_1(t) > 0$ . When the certificate fails and the two points cross, the new certificate is  $p_1(t) - p_0(t) > 0$ , which is the negated version of the certificate just processed and which has the same roots.

The model of *Kinetic::Kernel* provided includes the certificate generators necessary for Delaunay triangulations (in one, two and three dimensions) and regular triangulations (in 3D). New certificates can be fairly easily added. An example is included in the distributed code.

### 60.1.3 The *Kinetic::ActiveObjectsTable*

The *Kinetic::ActiveObjectsTable* stores a set of kinetic primitives. Its purpose is to notify kinetic data structures when new primitives are added, when primitives are removed or when a trajectories change. Each primitive is uniquely identified by a Key, assigned by the table when the primitive is added, that can be used to change or remove it. We provide one model of the *Kinetic::ActiveObjectsTable* concept, called *Kinetic::Active\_objects\_vector<MovingObject>* which stores all the moving primitives in an *std::vector<D>*.

Notifications of changes to the set of active objects are handled using a setup similar to the *Kinetic::Simulator* audit time notification. We provide a helper class, *Kinetic::Active\_objects\_listener\_helper<ActiveObjectsTable, KDS>*, which translates the notifications into *insert(Key)*, *erase(Key)* or *set(Key)* function calls on the kinetic data structure.

### 60.1.4 The *Kinetic::InstantaneousKernel*

The *Kinetic::InstantaneousKernel* allows existing CGAL data structures to be used on moving data as it appears at some instant of time. Models of this concept are, by definition, models of a CGAL Kernel or a traits class, and, therefore, can then be used as the traits class of CGAL's algorithms and data structures.

Consider for example the kinetic Delaunay data structure in either two or three dimensions. Internally, it uses a *Delaunay\_triangulation\_2<Traits, Tds>* or *Delaunay\_triangulation\_3<Traits, Tds>* to represent the triangulation, instantiated with a model of the *Kinetic::InstantaneousKernel* concept as its traits class. At initialization, as well as at times during the simulation when we want to insert a point to the kinetic Delaunay triangulation, a static version of the Delaunay triangulation is conceptually instantiated. More precisely, the time for the copy of the model of the *Kinetic::InstantaneousKernel* stored in the CGAL triangulation is set to be the current time (or rather, as discussed in the introduction, a more convenient time determined by the *Kinetic::Simulator* combinatorially equivalent to the current time). The kinetic data structure then calls the *Delaunay\_triangulation\_3<Traits, Tds>::insert(Point)* insert method to insert the point. The static insert method called uses various predicate functors on the moving points which evaluate to the values that the predicates have at that instant in time. Removal is handled in an analogous manner. Auditing of the geometric structure is easily handled in a similar manner (in the case of Delaunay triangulations by simply calling the *verify()* method after setting the time).

## 60.1.5 Miscellaneous: notification and reference management

We describe some coding conventions used, graphical display, notification and reference management support in the framework in the following sections.

### Reference management

A number of objects need to maintain pointers to other independent objects. For example, each kinetic data structure must have access to the *Kinetic::Simulator* so that it can schedule and deschedule events. These pointers are all reference counted in order to guarantee that they are always valid. We provide a standard reference counting pointer and object base to facilitate this, namely *Ref.counted<Object>*.

Each shared object in the framework defines a type *Handle* which is the type for a reference counter pointer pointing to it. These should be used for storing pointers to the objects in order to avoid dangling pointers. In addition, many of the objects expect such pointers as arguments.

### Runtime event passing

Runtime events must be passed from *notifiers*, namely the *Kinetic::ActiveObjectsTable* and the *Kinetic::Simulator* to *listeners*, typically the kinetic data structures. For example, kinetic data structures are notified when new primitives are added to the *Kinetic::ActiveObjectsTable*. On receiving the notification, it will add the new primitive to the combinatorial structure it is maintaining. The events are passed using a simple, standardized notification interface. To receive notifications, the listener first defines a small proxy class which inherits from a *Listener* base type provided by the notifier. On creation, the *Listener* base class registers itself with the notifier on construction (and unregisters itself on destruction).

When the some state of the notifier changes, it calls the *new\_notification* method on the listener proxy object provided and passes it a label corresponding to the name of the field that changed. The proxy object can then call an appropriate method on the kinetic data structure or whatever the listening class is.

In order to unregister on destruction, the *Listener* must store a (reference counted) pointer to the object providing notifications. This pointer can be accessed through the *notifier()* field. The *Listener* object stores a reference counted pointer to the notifying object, while the notifying object stores a plain pointer to the *Listener*. It can do this since the *Listener* is guaranteed to unregister itself when it is destroyed. This avoids circular reference counted pointers as well as dangling pointers.

## 60.2 Algebraic Kernel

The interface between the algebraic kernel and the kinetic data structures package was kept quite minimal in order to ease the implementation of various underlying computation models. The interface is detailed in the reference page (*Kinetic::FunctionKernel*).

We provide models of the algebraic kernel that handle polynomial *Kinetic::Function* objects. The provided models perform

- exact computations using Sturm sequences to isolate roots
- exact computations using Descartes rule of sign in order to isolate roots (Sturm sequences are also used in order to properly handle even multiplicity roots)

- filtered exact computations using Descartes rule of sign
- numeric (inexact) root approximations
- numeric root approximations which take advantage of certain assumptions that can be made about the types of polynomials solved in the process of evaluating kinetic data structures
- a wrapper for `CORE::Expr` which implements the required concepts.

The exact models, which we implement the numerics for, handle non-square-free polynomials and polynomials with arbitrary field number type coefficients and are quite robust.

### 60.2.1 `Kinetic::FunctionKernel` customized for kinetic data structures

There are several modifications we can make to how the roots are handled to optimize for the case of kinetic data structures. The first are motivated by the question of how to handle degeneracies (certificate functions which have roots at the same time). Naively, there is no way to differentiate between a certificate which fails immediately when it is created and one whose function is momentarily 0, but will be valid immediately in the future. In order to handle such degeneracies we ensure that all the certificate function generators produce certificate functions which are positive when the corresponding certificates are valid. Then, if we have a degeneracy we can differentiate between a certificate which fails immediately and one which is simply degenerate by looking at the sign of the certificate function immediately following the root (equivalently, by looking at the derivative). In addition, this allows us, under the assumption that computations are performed exactly, to check that all certificates are not invalid upon creation.

The assumption that certificates are positive when valid is particular useful when using numeric solvers. Without it there is no reliable way to tell whether a root near the current time is the certificate having become valid just before the current time, or failing shortly in the future. Testing the sign of the function immediately after the root reliably disambiguates the two cases.

In addition, we have to specially handle even roots of functions. For the most part these can just be discarded as dropping an even root is equivalent to perturbing the simulation to remove the degeneracy. However, when we are using the *Kinetic::Simulator* to audit the kinetic data structures, they must be broken up in to two, equal, roots to avoid auditing at the degeneracy.

## 60.3 Examples

We provide a number of examples of different levels of usage of the kinetic data structures framework, both for kinetic data structures as well as sweepline algorithms.

To see how to use existing kinetic data structures, look at the examples in the previous chapter such as Section [59.4.1](#).

Here we cover implementing kinetic data structures. The examples explained are

- A trivial kinetic data structure which has all the parts of a full kinetic data structure but doesn't do much in Section [60.3.2](#).
- Adding a new type of certificate to a kernel in Section [60.3.3](#).

In order to see more detail about how to implement a kinetic data structure, the best place to start is the source code for the kinetic sorting data structure, *Kinetic::Sort<Traits, Visitor>*. Once you are familiar with that, *Kinetic::Delaunay\_2<Traits, Triangulation, Visitor>* is the next step in complexity.

We will first explain in detail how a typical kinetic data structure uses the various pieces of the framework, then move on to showing the actual code for a simpler data structure.

### 60.3.1 Using the Pieces of the Package

Here we will explain how the kinetic sorting data structure uses the various pieces of the package. A schematic of its relationship to the various components is shown in the UML diagram in Figure 60.1. In this subsection we abuse, for reasons of simplicity of presentation, the concept/model semantics: when we refer to concepts we actually refer to an instance of a model of them.

As with most kinetic data structures, *Kinetic::Sort<Traits, Visitor>* maintains some sort of combinatorial structure (in this case a sorted doubly linked list), each element of which has a corresponding certificate in the event queue maintained by the simulator. In the case of sorting, there is one certificate maintained for each “edge” between two consecutive elements in the list.

On creation, the data structure is passed a copy of the *Kinetic::SimulationTraits* for this simulation, which it saves for future use. It gets a handle to the *Kinetic::ActiveObjectsTable* by calling the *Kinetic::SimulationTraits::active\_points\_1\_table\_handle()* method and registers a proxy with the table in order to receive notifications of changes to the point set. The *Kinetic::SimulationTraits* method returns a handle to, rather than a copy of, the *Kinetic::ActiveObjectsTable*, since the table must be shared between all the kinetic data structures using these points. The handles are reference counted pointers, thus saving the user from worrying about cleaning things up properly.

When new points are added to the model of the *Kinetic::ActiveObjectsTable*, the table calls the *new\_notification()* method on the proxy of the kinetic data structure, which in turn calls the *insert(Point\_key)* method of the kinetic data structure. The *Point\_key* here is the key which uniquely identifies the newly inserted point in the table. The data structure then requests an instance of a model of the *Kinetic::InstantaneousKernel* from the *Kinetic::SimulationTraits*. It sets the time on the instantaneous kernel to the time value gotten from the *Kinetic::Simulator::current\_time\_nt()* method. This method returns a field number type that is between the previous and next event, as discussed in the introduction. An instance of the *Kinetic::InstantaneousKernel::Compare\_x\_1* predicate (wrapped in order to make it return less) and the STL function *std::upper\_bound()* are then used to insert the new point in the sorted list. For each inserted object, the kinetic data structure removes the no longer relevant certificate from the event queue by calling the *Kinetic::Simulator::delete\_event(Key)* function and creates two new certificates using a *Kinetic::Kernel::Compare\_x\_1* certificate functor. The new certificates are inserted in the event queue by calling the *Kinetic::Simulator::new\_event(Time, Event)* method where *Kinetic::Simulator::Event* is a proxy object which instructs the sort kinetic data structure to swap two points when its *process()* method is called.

Now that the kinetic data structure has been initialized, the simulator is instructed to process all events. Each time an event occurs, the simulator calls the *process()* method on the corresponding proxy object. The proxy, in turn, tells the sort kinetic data structure to swap the two points whose order has changed.

The *Kinetic::Simulator* can periodically instruct the kinetic data structures to audit themselves. As is explained in Section 60.1.1, a proxy object maps the notification on to an *audit()* function call in the kinetic data structure. To audit itself the kinetic data structure builds a list of all the current points and uses *std::sort* to sort this list using a comparison function gotten from the *Kinetic::InstantaneousKernel*. This sorted list is compared to the maintained one to verify correctness. This auditing could also have been done by evaluating the *Kinetic::InstantaneousKernel* predicate for each sorted pair. Since auditing a kinetic data structure typically requires at least linear time in the size of the combinatorial structure, the auditing procedure in between events is

deactivated by default. The user can however easily switch it on by defining the *CGAL\_CHECK\_EXACTNESS* and *CGAL\_CHECK\_EXPENSIVE* CGAL macros.

This general structure of the interaction between the kinetic data structure and the framework is shared by all of the provided kinetic data structures and has proved itself to go quite far.

### 60.3.2 The Trivial Kinetic Data Structure

To show how to implement such things, instead of presenting a full kinetic data structure, we present a trivial one which maintains one event in the queue which maintains one event in the queue, scheduled to occur one time unit after the last change was made to the set of active primitives. Two classes are defined, the *Trivial\_event*, and the *Trivial\_kds*. The event classes must be declared outside of the kinetic data structure so that the *operator<<* can be defined for them.

The kinetic data structure maintains the invariant that it was one event in the queue at all times. This event occurs one time unit after the last event or change in the set of objects occurs. As a result, the kinetic data structure has the main parts of a real one—it responds to changes in trajectories of the objects and certificate failures (when the event expires).

The public methods can be grouped into three sets which are shared with almost all other kinetic data structures:

- *has\_certificates* and *set\_has\_certificates* which checks/sets whether the kinetic data structure is currently maintaining certificates.
- *insert*, *set*, *erase* which are called by the *Kinetic::Active\_objects\_listener\_helper* in response to the addition, modification, or deletion of an object to, in or from the simulation.
- *audit* which is called periodically by the *Kinetic::Simulator\_kds\_listener* when kinetic data structures can easily audit themselves.

In addition, it has one method which is called when a certificate fails. The name/existence of such methods depend on the nature of the kinetic data structure in question.

Like many kinetic data structures, it takes a *Kinetic::SimulationTraits* as a template argument. This traits class defines the types needed for the simulation and is responsible for instantiating them.

```
#include <CGAL/Kinetic/Ref_counted.h>
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Active_objects_listener_helper.h>
#include <CGAL/Kinetic/Simulator_kds_listener.h>
...

// This must be external since operator<< has to be defined
template <class KDS>
struct Trivial_event
{
    Trivial_event() {}
    Trivial_event(KDS* kds): kds_(kds) {}
}
void process() const
{
    kds_>process();
}
```

```

    }
    KDS* kds_;
};

template <class KDS>
std::ostream &operator<<(std::ostream &out,
const Trivial_event<KDS> &) {
    out << "\"An event\"";
    return out;
}

template <class Traits>
struct Trivial_kds: CGAL::Kinetic::Ref_counted<Trivial_kds<Traits> >
{
    typedef Trivial_kds<Traits> This;
    typedef typename Traits::Active_points_1_table::Data Point;
    typedef typename Traits::Simulator::Time Time;
    typedef typename Traits::Active_objects_table::Key Point_key;
    typedef typename Traits::Simulator::Event_key Event_key;
    typedef CGAL::Kinetic::Active_objects_listener_helper<
        typename Traits::Active_points_1_table::Listener, This> Active_objects_helper;
    typedef CGAL::Kinetic::Simulator_kds_listener<
        typename Traits::Simulator::Listener, This> Simulator_helper;

    typedef Trivial_event<This> Event;

    Trivial_kds(Traits tr): has_certificates_(true),
        tr_(tr),
        nth_(tr.active_points_1_table_handle(), this),
        sh_(tr.simulator_handle(), this){}

    // this method is called with the value true when the event is processed
    void process(bool tf) {
        event_ = Event_key();
        set_has_certificates(false);
        set_has_certificates(true);
    }

    void audit() const
    {
        ...
    }

    void set_has_certificates(bool tf) {
        typename Traits::Simulator::Handle sp= tr_.simulator_handle();
        if (has_certificates_ != tf) {
            has_certificates_=tf;
            if (has_certificates_) {
bool ev= event_;
CGAL_assertion(!ev);
Time t= CGAL::to_interval(sp->current_time()).second+1;
event_= sp->new_event(t, Event(this));
            } else if (event_) {

```

```

sp->delete_event(event_);
event_=Event_key();
    }
}

bool has_certificates() const {
    return has_certificates_;
}

void insert(Point_key k) {
    if (has_certificates_) {
        set_has_certificates(false);
        set_has_certificates(true);
    }
}

void set(Point_key k) {
    if (has_certificates_) {
        set_has_certificates(false);
        set_has_certificates(true);
    }
}

void erase(Point_key k) {
    if (has_certificates_) {
        set_has_certificates(false);
        set_has_certificates(true);
    }
}

~Trivial_kds() {
    set_has_certificates(false);
}

protected:
    bool has_certificates_;
    Event_key event_;
    Traits tr_;
    Active_objects_helper nth_;
    Simulator_helper sh_;
};

```

### 60.3.3 Adding a New Certificate Type

The following example shows how to add a new type of certificate to a simulation.

First we code the actual certificate function generator. It must take some sort (or sorts) of kinetic primitives, compute some function from their coordinates.

```

template <class KineticKernel>

```

```

struct Positive_x_f_2 {
    typedef typename KineticKernel::Certificate_function result_type;
    typedef typename KineticKernel::Point_2 argument_type;
    result_type operator()(const argument_type &p){
        return result_type(p.x()- result_type(0));
    }
};

```

Then we define a kinetic kernel which includes this predicate. To do this we wrap the function generator generator in a *Kinetic::Certificate\_generator<Kernel, Generator>*. This wrapper uses the generator to create the certificate function and then the *Kinetic::FunctionKernel* to solve the certificate function. The result is wrapped in a *Kinetic::Certificate* object.

```

template <class FunctionKernel>
class My_kinetic_kernel:
    public CGAL::Kinetic::Cartesian<FunctionKernel> {
    typedef CGAL::Kinetic::Cartesian<FunctionKernel> P;
    typedef My_kinetic_kernel<FunctionKernel> This;
public:
    typedef CGAL::Kinetic::internal::Certificate_generator<This, Positive_x_f_2<This> > Positive_x_2;
    Positive_x_2 positive_x_2_object() const
    {
        return Positive_x_2(P::function_kernel_object());
    }
};

```

Now we have the unfortunately rather messy part of assembling a new *Kinetic::SimulationTraits* model. This is done in two steps for convenience.

```

struct My_simulation_traits {
    typedef My_simulation_traits This;

    typedef CGAL::Exact_predicates_exact_constructions_kernel Static_kernel;
    //typedef CGAL::Regular_triangulation_euclidean_traits_3<Static_kernel_base> Static_kernel;
    typedef CGAL::POLYNOMIAL::Polynomial<Static_kernel::FT> Function;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function> Root_stack_traits;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits> Root_stack;
    typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;

    typedef CGAL::Kinetic::Handle_degeneracy_function_kernel<Function_kernel, false> Simulator_function_ke
    struct Simulator_function_kernel: public Simulator_function_kernel_base{};

    typedef My_kinetic_kernel<Simulator_function_kernel> Kinetic_kernel;
    typedef CGAL::Kinetic::Two_list_pointer_event_queue<Function_kernel> Event_queue;
    typedef CGAL::Kinetic::Default_simulator<Simulator_function_kernel, Event_queue > Simulator;

    typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_1> Active_points_1_table;
    typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_2> Active_points_2_table;
    typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_3> Active_points_3_table;
    // typedef Active_objects_vector<Kinetic_kernel::Weighted_point_3> Active_weighted_points_3_table;

    typedef CGAL::Kinetic::Default_instantaneous_kernel<This> Instantaneous_kernel;

```

```

Active_points_1_table* active_points_1_table_handle() const { return ap1_.get();}
Active_points_2_table* active_points_2_table_handle() const {return ap2_.get();}
Active_points_3_table* active_points_3_table_handle() const {return ap3_.get();}
//Active_weighted_points_3_table* active_weighted_points_3_table_handle() const {return awp3_.get();}

Simulator* simulator_handle() const { return sim_.get();}
const Static_kernel& static_kernel_object() const {return k_;}
const Kinetic_kernel& kinetic_kernel_object() const {return kk_;}

Instantaneous_kernel instantaneous_kernel_object() const {
    return Instantaneous_kernel(*this);
}

My_simulation_traits(const Simulator::Time &lb,
    const Simulator::Time &ub): sim_(new Simulator(lb, ub)),
    ap1_(new Active_points_1_table()),
    ap2_(new Active_points_2_table()),
    ap3_(new Active_points_3_table())
{}

bool is_exact() const {
    return true;
}
protected:
    Simulator::Handle sim_;
    Active_points_1_table::Handle ap1_;
    Active_points_2_table::Handle ap2_;
    Active_points_3_table::Handle ap3_;
    //Active_weighted_points_3_table::Handle awp3_;
    Static_kernel k_;
    Kinetic_kernel kk_;
    Function_kernel fk_;
};

```

Now the simulation traits can be used by a kinetic data structure. Note that we define active point table for all dimensions. This is needed by the *Kinetic::InstantaneousKernel*, even if they are not used.

# Kinetic Framework Reference Manual

*Daniel Russel*

## 60.4 Classified Reference Pages

### Definition

Kinetic data structures are a way of adding motion to classical geometric data structures. CGAL provides a number of classes to aid implementation of kinetic data structures.

There are three levels at which the user can interact with the package. The user can use an existing kinetic data structure, write a new kinetic data structure, or replace parts of the framework. The first level is covered in the Chapter 60.

### Main Support Classes and Concepts

## CGAL::Kinetic::Active\_objects\_listener<ActiveObjectsTable, KDS>

### Definition

The class *Kinetic::Active\_objects\_listener<ActiveObjectsTable, KDS>* acts as an intermediate between a moving object table and a KDS. It translates the *ActiveObjectsTable::Listener::IS\_EDITING* notification events into appropriate calls to *KDS::insert(Key)*, *KDS::set(Key)*, *KDS::erase(Key)*.

Kinetic data structures can still take advantage of the batch editing if they are careful. The methods (such as *KDS::set(Key)*) are called in lexicographical order in the *Keys*. So, when a KDS is preparing to update some certificate involving a recently set object, it can first check if the certificate involves another changed object which is lexicographically prior. If so, then the certificate has already been updated and can be skipped.

```
#include <CGAL/Kinetic/listeners.h>
```

### See Also

*Kinetic::Active\_objects\_vector<MovingObject>*, *Kinetic::ActiveObjectsTable*.

## Kinetic::ActiveObjectsTable

### Definition

This container holds a set of objects of a particular type. It creates notifications using the standard *Multi\_listener<Interface>* interface when a primitive changes or is added or deleted. Objects which are listening for events can then ask which primitives changed.

For speed, modifications to the *Kinetic::ActiveObjectsTable* can be grouped into editing sessions. A session is begun by calling *set\_is\_editing(true)* and ended by calling *set\_is\_editing(false)*. There is one type of notification, namely, *Listener::IS\_EDITING* which occurs when the editing mode is set to false, signaling that a batch of changes is completed.

As an convenience, the change methods can be called without setting the editing state to true, this acts as if it were set to true for that one function call.

### Types

<i>Kinetic::ActiveObjectsTable:: Key</i>	A key identifying an object in the table.
<i>Kinetic::ActiveObjectsTable:: Data</i>	The type being stored in the table.
<i>Kinetic::ActiveObjectsTable:: Listener</i>	The base class to derive from for listening for runtime events.

The following types are iterators. Each type, *Foo\_iterator* has two corresponding methods *foo\_begin* and *foo\_end* which allow you to iterate through the objects in the set *Foo*.

<i>Kinetic::ActiveObjectsTable:: Key_iterator</i>	An iterator through all the valid keys in the table.
<i>Kinetic::ActiveObjectsTable:: Changed_iterator</i>	An iterator through all the objects which have been changed in the last editing session. The iterator iterates through the objects in lexicographical order.
<i>Kinetic::ActiveObjectsTable:: Inserted_iterator</i>	An iterator through all the objects which were added in the last editing session.
<i>Kinetic::ActiveObjectsTable:: Erased_iterator</i>	An iterator through all the objects which were deleted in the last editing session.

### Creation

## Operations

<i>Data</i>	<i>mot[ Key key]</i>	Access the object referenced by the key.
<i>Data</i>	<i>mot.at( Key key)</i>	Access the object referenced by the key.
<i>void</i>	<i>mot.set_is_editing( bool is_editing)</i>	Set the editing state of the object. A notification is sent when the editing state is set to false after it has been true, i.e. the editing session is finished. This allows changes to be batched together.
<i>bool</i>	<i>mot.is_editing()</i>	Access the editing state.
<i>void</i>	<i>mot.set( Key key, Data object)</i>	This method changes the motion of one moving object. The position at the current time should not be different from the previous current position. However, at the moment I do not check this as there is no reference to time in the Kinetic::ActiveObjectsTable. If <i>is_editing()</i> is not true, then it is as if the calls <i>set_is_editing(true)</i> , <i>set(key, value)</i> and finally <i>set_is_editing(false)</i> were made. If it is true, then no notifications are created.
<i>Key</i>	<i>mot.insert_object( Data ob)</i>	Insert a new object into the table and return a <i>Key</i> which can be used to refer to it. See <i>set(Key, Data)</i> for a description of editing modes.
<i>void</i>	<i>mot.erase( Key key)</i>	Delete an object from the table. The object with <i>Key key</i> must already be in the table. This does not necessarily decrease the amount of storage used at all. In fact, it is unlikely to do so. See <i>set(Key,Data)</i> for an explaining of how the editing modes are used.
<i>void</i>	<i>mot.clear()</i>	Remove all objects from the table and free all storage.
<i>void</i>	<i>mot.is_set( Key)</i>	Returns true if the object has been set in the currently notified editing session. Note that this method can only be safely called when processing an <i>IS_EDITING</i> notification.
<i>void</i>	<i>mot.is_new( Key)</i>	Returns true if the object has been set in the currently notified editing session.
<i>void</i>	<i>mot.clear( Key)</i>	Returns true if the object has been set in the currently notified editing session.

## Has Models

*Kinetic::Active\_objects\_vector<MovingObject>*

## See Also

*Multi\_listener<Interface>, Kinetic::Active\_objects\_listener\_helper<ActiveObjectsTable, KDS>*

## CGAL::Kinetic::Active\_objects\_vector<MovingObject>

### Definition

MovingObjects are stored in a vector. This means that access is constant time, but storage is not generally freed. The only way to be sure is to remove all reference counts for the table or to call *clear()*.

*#include <CGAL/Kinetic/Active\_objects\_vector.h>*

### Is Model for the Concepts

*Kinetic::ActiveObjectsTable*

## CGAL::Kinetic::Cartesian<FunctionKernel>

### Definition

This class provides a model of *Kinetic::Kernel* for use with general Cartesian geometry.

The IO format for points is currently  $p_0, p_1, \dots, w$ .  $p_i$  and  $w$  are instances of *Function*. There IO format is typically  $c_0 + c_1t + c_2t^2 + \dots$ . Beware of issues with CGAL IO of the coefficients as exact number types often require that the coefficients be expressed as  $a/b$  even when  $b$  is 1.

```
#include <CGAL/Kinetic/Cartesian.h>
```

### Types

*Kinetic::Cartesian<FunctionKernel>::Certificate*

This is a model of *Kinetic::Certificate*.

*Kinetic::Cartesian<FunctionKernel>::Point\_1*

*Kinetic::Cartesian<FunctionKernel>::Point\_2*

*Kinetic::Cartesian<FunctionKernel>::Point\_3*

*Kinetic::Cartesian<FunctionKernel>::Weighted\_point\_3*

The following are functors which generate *Certificate* objects. Each has a corresponding *\_object* method which creates the functor. They are models of *Kinetic::CertificateGenerator*.

*Kinetic::Cartesian<FunctionKernel>::Orientation\_2*

*Kinetic::Cartesian<FunctionKernel>::Orientation\_3*

*Kinetic::Cartesian<FunctionKernel>::Side\_of\_oriented\_circle\_2*

*Kinetic::Cartesian<FunctionKernel>::Side\_of\_oriented\_sphere\_3*

*Kinetic::Cartesian<FunctionKernel>::Power\_test\_3*

*Kinetic::Cartesian<FunctionKernel>::Weighted\_orientation\_3*

*Kinetic::Cartesian<FunctionKernel>::Compare\_x\_1*

*Kinetic::Cartesian<FunctionKernel>::Compare\_x\_2*

*Kinetic::Cartesian<FunctionKernel>:: Compare\_y\_2*

*Kinetic::Cartesian<FunctionKernel>:: Compare\_x\_3*

*Kinetic::Cartesian<FunctionKernel>:: Compare\_y\_3*

*Kinetic::Cartesian<FunctionKernel>:: Compare\_z\_3*

*Kinetic::Cartesian<FunctionKernel>:: Compare\_distance\_2*

*Kinetic::Cartesian<FunctionKernel>:: Compare\_distance\_3*

### **Is Model for the Concepts**

*Kinetic::Kernel.*

## Kinetic::Certificate

### Definition

The `concept` represents certificate. Its main purpose is to provide a way of creating *Time* objects corresponding to when the certificate fails and to cache any useful work done in find the *Time* for later.

### Operations

<i>Time</i>	<i>c.failure_time()</i>	Returns the next failure time.
<i>bool</i>	<i>c.will_fail()</i>	Returns true if the certificate will ever fail.
<i>void</i>	<i>c.pop_failure_time()</i>	Advances to the next failure time (the next root of the certificate functions).

### See Also

*Kinetic::Kernel*.

## Kinetic::CertificateGenerator

### Definition

This functor allows you to create certificate objects of some type. The models of this “concept” take some set of arguments which depend on the certificate being computed (for example three points for a two dimensional orientation) followed by either one or two instances of the *Kinetic::Simulator::Time* concept. The functions either return a *Certificate* or the corresponding value at the current time (if only a time value rather than an interval is passed).

### Operations

<i>Certificate</i>	<i>a( Args, Time begin, Time end)</i>	Return a <i>Certifate</i> object for the corresponding certificate.
<i>CGAL::Sign</i>	<i>a( Args, Time t)</i>	Compute the sign of the function at $\lim_{\delta \rightarrow 0} t + \delta$ . This can be used to evaluate predicates at the current moment.

### Has Models

All over the place.

### See Also

*Kinetic::KineticKernel*

### Example

Here you see how to use both functions on an orientation predicate.

```
KineticKernel::Point_2 a,b,c;
Simulator::Handle sh;
KineticKernekkk;

KineticKernel::Orientation_2 o2= kk.orientation_2_object();

KineticKernel::Certificate c= o2(a,b,c, sh->current_time(), sh->end_time());
if (c.will_fail()) {
    std::cout << "Certificate will fail" << std::endl;
}
// Compute the sign immediately following the current time
CGAL::Sign sn= o2(a,c,b, sh->current_time());
CGAL_postcondition(sn==CGAL::NEGATIVE);
```

## Kinetic::FunctionKernel::ConstructFunction

### Definition

The concept `is` used to construct functions.

### Operations

<i>Function</i>	<i>a( NT a, ...)</i>	This family of methods takes a list of coefficients and returns a function. There can be any number of coefficients passed as arguments (up to about 25 in the current implementations).
-----------------	----------------------	--

### See Also

*FunctionKernel*

### Example

```
Function_kernel fk;
Function_kernel::Construct_function cf= fk.construct_function_object();
Function_kernel::Function f= cf(0,1,2,3,4,5);
```

# Kinetic::EventQueue

## Definition

The for priority queues used by the *Simulator*. The concept basically defines a priority queue which supports deletions and changes of items in the queue (but not their priorities). Items in the queue must implement the *Event* concept.

## Types

*Kinetic::EventQueue::Key* The type used to access items in the queue in order to change or delete them.

*Kinetic::EventQueue::Priority* The priority type for items in the queue. This is typically the same as *Kinetic::Simulator::Time*

.

## Creation

*Kinetic::EventQueue* *q*( *Priority start*, *Priority end*, *int size\_hint*);

Construct a queue which will start at time *start* and run until time *end*.

## Operations

*template <class Event>*

*Key* *q.insert( Priority, Event)*

Insert an event into the event queue. A *Key* which can be used to manipulated the event is returned.

*void* *q.erase( Key)*

Erase an event from the queue.

*template <class Event>*

*void* *q.set( Key, Event)*

Change the data in the event referred to by the key.

*template <class Event>*

*Event&* *q.get( Key)*

Access the event referred to by the passed key.

*Priority* *q.priority( Key)*

Return the priority of the event.

*bool* *q.empty()*

Return true if the queue is empty.

*Priority* *q.next\_priority()*

Return the priority of the next event in the queue.

<i>void</i>	<i>q.process_next()</i>	Process the next <i>Event</i> by calling its process method with its <i>Priority</i> .
<i>void</i>	<i>q.set_end_priority()</i>	Set the priority beyond which to ignore events.
<i>bool</i>	<i>q.contains( Key)</i>	Return true if the queue contains the event and false if it does not. This is used for auditing events and can be slow if needed.

## Has Models

*Kinetic::Two\_list\_pointer\_event\_queue<FunctionKernel>*,  
*FunctionKernel>*.

*Kinetic::Heap\_pointer\_event\_queue<*

## Kinetic::Simulator::Event

### Definition

The concept represents a single event. Models of should be passed to the *Kinetic::Simulator* when scheduling events which will in turn pass them to the *EventQueue*.

### Operations

<i>void</i>	<i>a.process()</i>	This method is called when the event occurs. This method will only be called once per time this event is scheduled and the event will be removed from the queue immediately afterwards.
-------------	--------------------	---

<i>void*</i>	<i>a.kds()</i>	Return a <i>void *</i> which represents the KDS which this event belongs to. The pointer is used solely to tell if two events come from the same KDS for the purposes of handling degeneracy.
--------------	----------------	---

*CGAL::Comparison\_result*

*a.compare\_concurrent( Key a, Key b)*

The two events *a* and *b* occur at the same time (*this* has key *a*). This method returns a *CGAL::Comparison\_result* which is used to order the two equal events. If *CGAL::EQUAL* is returned then *merge* will be called.

<i>bool</i>	<i>a.merge_concurrent( Key a, Key b)</i>
-------------	--

The two events *a* and *b* occur at the same time (*this* has key *a*) and cannot be perturbed to be unequal. This event allows the KDS to merge event *b* with *a*. If it returns *true* then *b* is dropped from the event queue.

<i>void</i>	<i>a.audit( Key this_key)</i>	Audit that this is a valid event. To use this, kinetic data structure can check that this event is indeed pointed to by the correct part of the combinatorial structure.
-------------	-------------------------------	--

<i>std::ostream&amp;</i>	<i>a.write( std::ostream&amp;)</i>
--------------------------	------------------------------------

Write the event to a stream.

### Has Models

All over the place. *Kinetic::Event\_base*.

## See Also

*Kinetic::EventQueue*

## Example

All of the kinetic data structures provided have models of Event. Here is the code implementing a swap event from the sorting kinetic data structure. Events occurring at equal times are perturbed so that the one that occurs first in the list is processed first (just to illustrate the idea).

```
template <class Certificate, class Id, class Root_enumerator>
class Swap_event {
    typedef Swap_event<class Certificate, class Id, class Root_enumerator> This;
public:
    Swap_event(Id o, Sort* sorter,
               const Certificate &s): left_object_(o),
                                   sorter_(sorter),
                                   s_(s) {}

    void process() {
        sorter_>swap(left_object_, s_);
    }
    void *kds() const {return sorter_;}
    CGAL::Comparison_result perturb_comparison(typename Sort::Event_key a, typename Sort::Event_key b) const {
        return CGAL::compare(std::distance(sorter_>objects_begin(), left_object_),
                             std::distance(sorter_>objects_begin(),
                                             sorter_>simulator_handle()->get_event<This>(b).left_object_));
    }
    bool merge(typename Sort::Event_key a, typename Sort::Event_key b) {
        return false;
    }
    Id left_object_;
    Sort* sorter_;
    Certificate s_;
};
```

## Kinetic::FunctionKernel

### Definition

The concept `Kinetic::FunctionKernel` encapsulates all the methods for representing and handling functions. The set is kept deliberately small to easy use of new `Kinetic::FunctionKernels`, but together these operations are sufficient to allow the correct processing of events, handling of degeneracies, usage of static data structures, run-time error checking as well as run-time verification of the correctness of kinetic data structures. The computation of a polynomial with the variable negated is used for reversing time in kinetic data structures and can be omitted if that capability is not needed.

### Types

<code>Kinetic::FunctionKernel:: Function</code>	The type of function being handled.
<code>Kinetic::FunctionKernel:: NT</code>	The basic representational number type.
<code>Kinetic::FunctionKernel:: Root</code>	A type representing the roots of a <i>Function</i> .
<code>Kinetic::FunctionKernel:: Root_stack</code>	A model of <i>RootStack</i> . These objects can be created by calling the <i>root_stack_object</i> method with a <i>Function</i> and two (optional) <i>Root</i> objects. The enumerator then enumerates all roots of the function in the open interval defined by the two root arguments. They optional arguments default to positive and negative infinity.
<code>Kinetic::FunctionKernel:: Root_enumerator_traits</code>	The traits for the <i>Root_enumerator</i> class.
Each of the following types has a corresponding <i>type_object</i> method (not explicitly documented) which takes a <i>Function</i> as an argument.	
<code>Kinetic::FunctionKernel:: Sign_at</code>	A functor which returns the sign of a <i>Function</i> at a <i>NT</i> or <i>Root</i> .
<code>Kinetic::FunctionKernel:: Sign_after</code>	A functor which returns sign of a function immediately after a root.
The following type is used to construct functions from a list of coefficients. To get an instance use the <i>construct_function_object()</i> method.	
<code>Kinetic::FunctionKernel:: Construct_function</code>	This functor can be used create instances of <i>Function</i> . See its reference page <i>FunctionKernel::ConstructFunction</i> for more details.

The following functor likewise have a *type\_object* method, but these take arguments other than a *Function*. The arguments are given below.

*Kinetic::FunctionKernel:: Sign\_between\_roots* This functor, creation of which requires two *Roots*, returns the sign of a passed function between the pair of roots.

*Kinetic::FunctionKernel:: Differentiate* This functor computes the derivative of a *Function*. Construction takes no arguments.

The following methods do not require any arguments to get the functor and take one *Function* as a functor argument.

*Kinetic::FunctionKernel:: Negate\_variable* Map  $f(x)$  to  $f(-x)$ .

## Has Models

*POLYNOMIAL::Kernel<RootStack>, POLYNOMIAL::Filtered\_kernel<RootStack>.*

## See Also

*Kinetic::RootEnumerator.*

## Example

We provide several models of the concept, which are not documented separately. The models of *Kinetic::SimulationTraits* all choose appropriate models. However, if more control is desired, we here provide examples of how to create the various supported *Kinetic::FunctionKernel*.

A Sturm sequence based kernel which supports exact comparisons of roots of polynomials (certificate failure times):

```
typedef CGAL::POLYNOMIAL::Polynomial<CGAL::Gmpq> Function;
typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function> Root_stack_traits;
typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits> Root_stack;
typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;
```

A wrapper for *CORE::Expr* which implements the necessary operations:

```
typedef CGAL::POLYNOMIAL::CORE_kernel Function_kernel;
```

A function kernel which computes approximations to the roots of the polynomials:

```
typedef CGAL::POLYNOMIAL::Polynomial<double> Function;
typedef CGAL::POLYNOMIAL::Root_stack_default_traits<Function> Root_stack_traits;
typedef CGAL::POLYNOMIAL::Numeric_root_stack<Root_stack_traits> Root_stack;
typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;
```

When using the function kernel in kinetic data structures, especially one that is in exact, it is useful to wrap the root stack. The wrapper checks the sign of the certificate function being solved and uses that to handle degeneracies. This is done by, for the inexact solvers

```
typedef Kinetic::Derivative_filter_function_kernel<Function_kernel> KDS_function_kernel;
```

and for exact solvers

```
typedef Kinetic::Handle_degeneracy_function_kernel<Function_kernel> KDS_function_kernel;
```

For exact computations, the primary representation for roots is the now standard choice of a polynomial with an associated isolating interval (and interval containing exactly one distinct root of a polynomial) along with whether the root has odd or even multiplicity and, if needed, the Sturm sequence of the polynomial. Two intervals can be compared by first seeing if the isolating intervals are disjoint. If they are, then we know the ordering of the respective roots. If not we can subdivide each of the intervals (using the endpoints of the other interval) and repeat. In order to avoid subdividing endlessly when comparing equal roots, once we subdivide a constant number of times, we use the Sturm sequence of  $p$  and  $p'q$  (where  $p$  and  $q$  are the two polynomials and  $p'$  is the derivative of  $p$ ) to evaluate the sign of the second at the root of the first one directly (note that this Sturm sequence is applied to a common isolating interval of the roots of interest of both polynomials).

## Kinetic::FunctionKernel::Function

### Definition

The concept represents a function.

### Types

*Function::NT* The number type used in describing the function.

*Function a(NT);* Construct a constant function from a number.

### Operations

*NT*                      *a(NT)*                      Evaluate the function at an *NT*.

### See Also

*FunctionKernel*, *FunctionKernel::ConstructFunction*

### Example

Several ways to create functions:

Using *Kinetic::ConstructFunction*:

```
Traits::Function_kernel::Construct_function cf= traits.function_kernel_object().construct_function_object();
Traits::Kinetic_kernel::Motion_function x= cf(0.0,1.0,2.0);
Traits::Kinetic_kernel::Motion_function y= cf(0.0,1.0,2.0);
Traits::Kinetic_kernel::Point_2 pt(x,y);
```

Using the constructor:

```
double coefs[]={1.0, 2.0, 3.0};
Traits::Kinetic_kernel::Motion_function z(coefs, coefs+3);
```

Using ring operations:

```
Traits::Kinetic_kernel::Motion_function z= x*z+y;
```

## CGAL::Kinetic::Default\_instantaneous\_kernel<SimulationTraits>

### Definition

This class provides a model of the *Kinetic::InstantaneousKernel* for use with general Cartesian Geometry. It provides all the predicates needed for Delaunay triangulations and regular triangulations.

```
#include <CGAL/Kinetic/Default_instantaneous_kernel.h>
```

### Types

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Orientation\_2*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Orientation\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Side\_of\_oriented\_circle\_2*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Side\_of\_oriented\_sphere\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Power\_test\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Weighted\_orientation\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_x\_1*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_x\_2*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_y\_2*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_x\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_y\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_z\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_distance\_2*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Compare\_distance\_3*

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Coplanar\_orientation\_3*

Note that this one does not work if the current time is not a *NT*.

*Kinetic::Default\_instantaneous\_kernel<SimulationTraits>:: Coplanar\_side\_of\_bounded\_circle\_3*

Note that this one does not work if the current time is not a *NT*.

### **Is Model for the Concepts**

*Kinetic::InstantaneousKernel*

## Kinetic::InstantaneousKernel

### Definition

The concept `Kinetic::InstantaneousKernel` covers models that act as adaptors allowing CGAL static data structures to act on snapshots of kinetic data. Different methods for evaluating predicates are used depending on whether time is set using an *NT* or a *Time* object. Evaluating predicates when time is the former is much cheaper.

### Types

<i>Kinetic::InstantaneousKernel:: NT</i>	A number type which can be used to represent the current time. This must be a ring or field type.
<i>Kinetic::InstantaneousKernel:: Time</i>	The type used to represent the current time. This type must be comparable.

### Operations

<i>Time</i>	<i>a.time()</i>	Return the current time.
<i>NT</i>	<i>a.time_as_nt()</i>	Return the current time as an <i>NT</i> . As a precondition, <i>time_is_nt</i> must be true.
<i>bool</i>	<i>a.time_is_nt()</i>	Return true if the last time time was set, it was using an object of type <i>NT</i> .
<i>void</i>	<i>a.set_time( Time )</i>	Set the current time to have a certain value. All existing predicates are updated automatically.
<i>void</i>	<i>a.set_time( NT )</i>	Set the current time to be an instance of <i>NT</i> . With this more efficient techniques can be used. <i>time_is_nt()</i> must be true.
<i>Static_object</i>	<i>a.static_object( Key )</i>	Return a static object corresponding to the kinetic object at this instant in time. <i>time_is_nt()</i> must be true.

### Has Models

*Kinetic::Default\_instantaneous\_kernel*

# Key

## Definition

The concept Key is a unique identifier for something in some sort of table. In general, they can be only created by the table and are returned when a appropriate *new\_foo()* method is called on the table. There are two classes of values for a Key, valid and invalid. The latter cannot refer to something in a table. Use the method *is\_valid()* to differentiate.

*Key a;*

The default constructor is guaranteed to construct an invalid key (i.e. one which is false when cast to a bool).

## Operations

*bool*

*a.is\_valid()*

This method returns false if the key was created using the default constructor or was otherwise created to be invalid.

*std::ostream&*

*std::ostream& << Event*

Write a text description of the key to a standard stream.

## Has Models

*Kinetic::Simulator::Event\_key, Kinetic::Active\_objects\_vector<Object>::Key.*

## Kinetic::Kernel

### Definition

The concept `Kinetic::Kernel` acts as the kinetic analog of a CGAL kernel. It provides some set of primitives and predicates acting on them. The predicates are instances of `Kinetic::CertificateGenerator` and can be used to either create *Certificates* or to evaluate instantaneous predicates.

### Types

<i>Kinetic::Kernel:: Motion_function</i>	The type which is used to represent coordinates of moving primitives. It is a model of the concept <i>FunctionKernel::Function</i> . This is the analog of the CGAL kernel <i>RT</i> .
<i>Kinetic::Kernel:: Certificate</i>	The type representing the results of predicates. See <i>Kinetic::Certificate</i> .
<i>Kinetic::Kernel:: Function_kernel</i>	The type of the function kernel used. See <i>Kinetic::FunctionKernel</i> .

### Operations

<i>Function_kernel</i>	<i>kk.function_kernel_object()</i>	Gets a copy of the function kernel.
------------------------	------------------------------------	-------------------------------------

### Has Models

*Kinetic::Cartesian<FunctionKernel>*.

## CGAL::Listener<Interface>

### Definition

The *Listener<Interface>* class provides the core of the run time notification system used by the kinetic data structures package. In short, notifications are handled through proxy objects called listeners. In order to listen for notifications from an object, called the notifier, you make define a small class called a listener proxy, which inherits from the Listener interface defined by the notifier. When constructing your listener proxy, you pass a reference counted pointer to the notifier, which is used to register the proxy for notifications. When a notification occurs, the notifier calls the *new\_notification* method on the proxy, passing the type of the notification. The proxy stores a reference counted pointer to the notifier, ensuring that there are never any dangling pointers in the system.

The class *Listener<Interface>* provides base class for listener proxy objects. A notifier should provide a class which inherits from this base. To use this base class, implement a class, here called *Interface*, which defines a type *Interface::Notification\_type* and a type *Interface::Notifier\_handle*.

The *Notification\_type* is generally an enum with one value for each type of notification which can be used.

The *Notifier\_handle* is the type of a (ref counted) pointer to the object providing the notifications. The ref counter pointer must provide a nested type *Pointer* which is the type of a raw pointer.

The *Listener<Interface>* maintains a ref counted pointer to the object performing notifications. It is registered for notifications on construction and unregistered on destruction using the function *set\_listener(Listener<Interface>\*)* on the object providing the notifications. The use of ref counted pointers means that as long as the notification object exists, the object providing the notifications must exist, ensuring that the object providing the notifications is not prematurely destroyed.

These objects cannot be copied since the notifier only support one listener. If copying and more than one listener are desired, the *Multi\_listener<Interface>* base class should be used instead.

As a side note, Boost provides a similar functionality in the Boost.Signal package. However, it is quite a bit more complex (and flexible). This complexity add significantly to compile time and (although I did not test this directly), I suspect it is much slower at runtime due to the overhead of worrying about signal orders and not supporting single signals. In addition, it does not get on well with Qt due to collisions with the Qt moc keywords.

There is also the TinyTL library which implements signals. As of writing it did not have any easy support for making sure all pointers are valid, so it did not seem to offer significant code saving over writing my own.

```
#include <CGAL/Kinetic/Listener.h>
```

### Types

*Listener<Interface>::Notifier\_handle*

This type is inherited from the *Interface* template argument. It is a reference counted pointer type for the object providing notifications.

*Listener<Interface>::Notification\_type*

The type (usually an enum) used to distinguish different types of notifications. This is inherited from the *Interface* template argument.

## Creation

*Listener<Interface> l( Notifier\_handle np);*      The *Listener<Interface>* subscribes to events coming from the notifier and stores a pointer to the notifier.

## Operations

*Notifier\_handle*      *l.notifier()*      Return a pointer to the notifier.

*virtual void*      *l.new\_notification( Notification\_type)*

This method is pure virtual. A class which wishes to receive events must inherit from this class and implement this method. The method will then be called whenever there is a notification.

## See Also

*Multi\_listener<Interface>.*

## Example

Here is a simpler class that provides notifications:

```
struct Notifier: public CGAL::Kinetic::Ref_counted<Notifier>
{
public:
    Notifier(): data_(0), listener_(NULL){}

    struct Listener_interface
    {
    public:
        typedef enum Notification_type {DATA_CHANGED} Notification_type;
        typedef Notifier::Handle Notifier_handle;
    };

    typedef CGAL::Kinetic::Listener<Listener_interface> Listener;
    friend class CGAL::Kinetic::Listener<Listener_interface>;

    void set_data(int d) {
        data_=d;
        if (listener_ != NULL) listener_>new_notification(Listener_interface::DATA_CHANGED);
    }

protected:
    void set_listener(Listener *l) {
        listener_= l;
    }
    Listener* listener() const {return listener_;}
```

```

    int data_;
    Listener *listener_;
};

```

Now the listener:

```

struct My_listener: public Notifier::Listener, public CGAL::Kinetic::Ref_counted<My_listener>
{
    typedef Notifier::Listener::Notifier_handle PP;
    My_listener(PP p): P(p){}

    void new_notification(P::Notification_type nt) {
        ...
    }
};

```

## CGAL::Multi\_listener<Interface>

### Definition

The class *Multi\_listener<Interface>* implements a base class for listeners where more than one listener is allowed to subscribe to a notifier. See *Listener* for full documentation. This uses the function calls *new\_listener()* and *delete\_listener()* to register and unregister the listener (instead of *set\_listener()*).

```
#include <CGAL/Kinetic/Multi_listener.h>
```

### See Also

*Listener<Interface>*.

## CGAL::Ref\_counted<T>

### Definition

The class *Ref\_counted*<T> implements a base class for objects which are reference counted. To use it simply inherit from *Ref\_counted*<T> (passing the type to be reference counted as the template argument) and then access the object through *Handle* objects rather than bare C++ pointers.

```
#include <CGAL/Kinetic/Ref_counted.h>
```

### Types

*Ref\_counted*<T>:: *Handle*                      A reference counted pointer to an Object.

*Ref\_counted*<T>:: *Const\_handle*              A const reference counted pointer to an Object.

### Creation

*Ref\_counted*<T> *rc*;                          default constructor.

### Operations

There are no methods which should be called by users of this class.

## Kinetic::RootStack

### Definition

The concept `Kinetic::RootStack` enumerates through roots of a function contained in a half open interval  $[lb \dots ub)$ .

### Types

*Kinetic::RootStack::Root*                      The root of a function.

*Kinetic::RootStack::Traits*                      The traits class for this concept.

### Creation

*Kinetic::RootStack* *re*;                      default constructor.

*Kinetic::RootStack* *re*( *Function* *f*, *Root* *lb*, *Root* *ub*, *Traits* *tr*);

Construct a `Kinetic::RootStack` over the roots of *f* in the half open interval  $[lb$  to  $ub)$ .

### Operations

*void*                      *re.pop()*                      Advance to the next root. As a precondition, `empty()` must be false.

*Root*                      *re.top()*                      Return the current root. As a precondition, `empty()` must be false. Note that the *Root* returned might not actually be in the interval (since the solver has not yet proved that there are no more roots).

*bool*                      *re.empty()*                      Return true if there are known to be no more roots left. There might not actually be any roots of the polynomial left in the interval, but the work necessary to prove this has been delayed.

### See Also

*Kinetic::FunctionKernel*, *Kinetic::Certificate*.

## Kinetic::SimulationTraits

### Definition

This concept ties together the parts needed in order to run a kinetic data structure. We provide several models of this concept:

- *Kinetic::Exact\_simulation\_traits*
- *Kinetic::Inexact\_simulation\_traits*
- *Kinetic::Regular\_triangulation\_exact\_simulation\_traits*
- *Kinetic::Regular\_triangulation\_inexact\_simulation\_traits*

All support trajectories defined by polynomial coordinates. The *Exact* vs *Inexact* picks whether the roots of the certificate functions are compared exactly or approximated numerically. The regular triangulation models have weighted points of the appropriate dimension as the primitive used in the *Kinetic::InstantaneousKernel* and the *Kinetic::ActiveObjectsTable*.

### Types

<i>Kinetic::SimulationTraits:: NT</i>	The number type used for representation.
<i>Kinetic::SimulationTraits:: Instantaneous_kernel</i>	A model of <i>Kinetic::InstantaneousKernel</i> which can be used to apply static CGAL data structures to snapshots of moving data.
<i>Kinetic::SimulationTraits:: Kinetic_kernel</i>	A model of <i>Kinetic::Kernel</i> .
<i>Kinetic::SimulationTraits:: Function_kernel</i>	A model of <i>Kinetic::FunctionKernel</i> .
<i>Kinetic::SimulationTraits:: Active_points_[123]_table</i>	A model of <i>Kinetic::ActiveObjectsTable</i> which holds the relevant kinetic primitives.
<i>Kinetic::SimulationTraits:: Simulator</i>	A model of <i>Kinetic::Simulator</i> which will be used by all the kinetic data structures.

### Operations

*Instantaneous\_kernel*    *st.instantaneous\_kernel\_object()*

Get a new instantaneous kernel.

*Kinetic\_kernel*            *st.kinetic\_kernel\_object()*

Get a new kinetic kernel.

*Function\_kernel*            *st.function\_kernel\_object()*

Get a new function kernel.

*Simulator::Handle*        *st.simulator\_handle()*    Return a pointer to the *Kinetic::Simulator* which is to be used in the simulation.

*Active\_points\_[123]\_table::Handle*

*st.active\_points\_[123]\_table\_handle()*

Return a pointer to the *Kinetic::ActiveObjectsTable* which is to be used in the simulation.

## **Has Models**

*Kinetic::Exact\_simulation\_traits*, *Kinetic::Inexact\_simulation\_traits*, *Kinetic::Regular\_triangulation\_exact\_simulation\_traits*, *Kinetic::Regular\_triangulation\_inexact\_simulation\_traits*

## Example

The simulation traits class is simply there for convenience in order to bundle a set of related typedefs and create a few objects. As a result, creating your own requires little thought, and just copying and changing a few lines. An example is below which sets up to use the CORE Sturm sequences to solve polynomials rather than our own (faster) solvers. It can be found in `examples/Kinetic.framework/defining_a_simulation_traits.cpp`.

```
#include <CGAL/Polynomial/Sturm_root_stack_traits.h>
#include <CGAL/Polynomial/Sturm_root_stack.h>
#include <CGAL/Kinetic/Active_objects_vector.h>
#include <CGAL/Kinetic/Default_instantaneous_kernel.h>
#include <CGAL/Kinetic/Cartesian.h>
#include <CGAL/Kinetic/Handle_degeneracy_function_kernel.h>
#include <CGAL/Kinetic/Default_simulator.h>
#include <CGAL/Kinetic/Two_list_pointer_event_queue.h>
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>

using namespace CGAL::Kinetic;

struct My_simulation_traits {
    typedef My_simulation_traits This;

    typedef CGAL::Exact_predicates_exact_constructions_kernel Static_kernel;
    //typedef CGAL::Regular_triangulation_euclidean_traits_3<Static_kernel_base> Static_kernel;
    typedef CGAL::POLYNOMIAL::Polynomial<Static_kernel::FT> Function;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function> Root_stack_traits;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits> Root_stack;
    typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;

    typedef CGAL::Kinetic::Handle_degeneracy_function_kernel<Function_kernel, false> Simulator_function_kernel;
    struct Simulator_function_kernel: public Simulator_function_kernel_base{};

    typedef Cartesian<Simulator_function_kernel> Kinetic_kernel;

    const Kinetic_kernel& kinetic_kernel_object() const {return kk_;}

    Instantaneous_kernel instantaneous_kernel_object() const {
```

```

        return Instantaneous_kernel(*this);
    }

My_simulation_traits(const Simulator::Time &lb,
const Simulator::Time &ub): sim_(new Simulator(lb, ub)),
    ap1_(new Active_points_1_table()),
    ap2_(new Active_points_2_table()),
    ap3_(new Active_points_3_table())
    //awp3_(new Active_weighted_points_3_table())
{}

bool is_exact() const {
    return true;
}
protected:
    Simulator::Handle sim_;
    Active_points_1_table::Handle ap1_;
    Active_points_2_table::Handle ap2_;
    Active_points_3_table::Handle ap3_;
    //Active_weighted_points_3_table::Handle awp3_;
    Static_kernel k_;
    Kinetic_kernel kk_;
    Function_kernel fk_;
};

#endif

```

## CGAL::Kinetic::Default\_simulator<FunctionKernel, EventQueue>

### Definition

The class *Kinetic::Default\_simulator<FunctionKernel, EventQueue>* controls kinetic data structures by maintaining a concept of time and ensuring that events are processed when necessary.

```
#include <CGAL/Kinetic/Default_simulator.h>
```

### Is Model for the Concepts

*Kinetic::Simulator*.

### Creation

```
Kinetic::Default_simulator<FunctionKernel, EventQueue> sim( const Time start=Time(0),  
                                                         const Time end= Time::infinity())
```

Construct a *Kinetic::Default\_simulator<FunctionKernel, EventQueue>* which will process events between times start and end (events outside this window will be discarded).

## CGAL::Kinetic::Simulator\_listener<Listener, KDS>

### Definition

The class *Kinetic::Simulator\_listener<Listener, KDS>* acts as a helper class for kinetic data structures which want to respond to *Simulator::Listener::HAS\_AUDIT\_TIME* notifications. When kinetic data structures can audit themselves, the *Kinetic::Simulator\_listener<Listener, KDS>* calls the *audit()* method on the kinetic data structure.

```
#include <CGAL/Kinetic/listeners.h>
```

### Creation

```
Kinetic::Simulator_listener<Listener, KDS> a( Simulator::Handle, KDS *kds);
```

default constructor.

### See Also

*Kinetic::Simulator*, *Listener<Interface>*.

## CGAL::Kinetic::Simulator\_objects\_listener<Simulator\_listener, KDS>

### Definition

The class *Kinetic::Simulator\_objects\_listener<Simulator\_listener, KDS>* is a helper for classes which wish to react to *Simulator::Listener::DIRECTION\_OF\_TIME* notifications. The helper object translates such notifications *reverse\_time* function calls on the responder. See *Kinetic::Qt\_moving\_points\_2* for a simple example of using this helper function.

```
#include <CGAL/Kinetic/Simulator_objects_listener.h>
```

### Creation

```
Kinetic::Simulator_objects_listener<Simulator_listener, KDS> a( Simulator::Handle, KDS*);
```

default constructor.

### See Also

*Kinetic::Listener*.

# Kinetic::Simulator

## Definition

The class `Kinetic::Simulator` controls kinetic data structures by maintaining a the current time and ensuring that events are processed when necessary.

In addition, the `Kinetic::Simulator` can call on the kinetic data structures to audit themselves at appropriate times. When the last event processed and the next to be processed have different times, then there is a rational value of time at which all kinetic data structures should be non-degenerate (since there are no events at that time). At such a time, kinetic data structures can easily verify their correctness by checking that all the certificate predicates have the correct value. When exactness checks are enabled, whenever the last event processed and the next event to be processed have different times, a `Kinetic::Simulator::Listener::HAS_AUDIT_TIME` notification is made. Kinetic data structures can listen for that event, and when it is made, they can call `Kinetic::Simulator::audit_time()` to get the time value and then verify that their structure is correct.

In addition, at such a time, the `Event::audit(Key)` is called on each event. This allows kinetic data structures to check that the event should be in the queue.

Typically, the simulator is created by the `Kinetic::SimulationTraits` class and kinetic data structures request a handle to it from there.

Events that occur at or after `Kinetic::Simulator::end_time()` will may not be processed. The exception are events which are scheduled using the `new_final_event(Event)` call which are guaranteed to occur after all other events (but have no particular order amongst themselves).

## Types

<code>Kinetic::Simulator::Function_kernel</code>	The type of the function kernel used to instantiate this <code>Kinetic::Simulator</code> .
<code>Kinetic::Simulator::Listener</code>	Extend this base class to listen to notifications from this <code>Kinetic::Simulator</code> . There are two types of notifications: <code>HAS_AUDIT_TIME</code> and <code>DIRECTION_OF_TIME</code> . The first is made when kinetic data structures can perform an audit. The second is made when the direction of time is changed.
<code>Kinetic::Simulator::Time</code>	The representation type for times in the simulator. It is <code>Function_kernel::Root_enumerator::Root</code> .
<code>Kinetic::Simulator::Event_key</code>	The key to access scheduled <code>Event</code> in order to inspect or delete them.
<code>Kinetic::Simulator::NT</code>	The basic number type used in computations.
<code>Kinetic::Simulator::Handle</code>	A reference counted pointer to be used for storing references to the object.
<code>Kinetic::Simulator::Const_handle</code>	A reference counted pointer to be used for storing references to the object.

## Creation

*Kinetic::Simulator* *sim*( *const Time start=Time(0), const Time end= Time::infinity()*);

Construct a *Kinetic::Simulator* which will process events between times start and end (events outside this window will be discarded).

## Operations

*Function\_kernel*      *sim.function\_kernel\_object()*

Access the *Function\_kernel* object used by the *Kinetic::Simulator*.

*Time*      *sim.current\_time()*      Return the current time.

*void*      *sim.set\_current\_time( Time t )*

Set the current time to *t*, which cannot be less than *current\_time*. Any events in the queue before time *t* are processed.

*NT*      *sim.next\_time\_representable\_as\_nt()*

This function returns a time which can be represented using an instance of type *NT* which is shortly after the current time. You can then advance the current time to this one and act on the data structure using the return *nt*.

*bool*      *sim.has\_current\_time\_as\_nt()*

Return true if there is a rational number which is equivalent to the current time. Equivalent means that it has the same ordering relation to all previous and scheduled events.

*bool*      *sim.has\_audit\_time()*      Returns true if the current time is a rational number and there are no events at the current time. This means that the simulation can be audited at this time.

*Time*      *sim.next\_event\_time()*      Return the time of the next event in the queue.

*Time*      *sim.end\_time()*      Return the time the simulation will end. If time is running backwards, then this returns *Time::infinity()*.

*void*      *sim.set\_interval( Time t\_cur, Time t\_end )*

Set the current time to *t<sub>cur</sub>* and the end time to *t<sub>end</sub>*. The event queue must be empty. Use this method if you want to reset or extend the simulation.

<i>template &lt;class Event&gt;</i> <i>Event_key</i>	<i>sim.new_event( Time t, const Event event)</i>	Schedule a new event at time <i>t</i> . The object <i>event</i> must implement the concept <i>Event</i> . The <i>Event_key</i> returned can be used to access or deschedule the event.
<i>template &lt;class Event&gt;</i> <i>Event_key</i>	<i>sim.new_final_event( const Event event)</i>	Schedule a new event that will occur at the end of the simulation. This type of event is useful if, for example, you want to run for a while, change all motions, and then run some more.
<i>Event_key</i>	<i>sim.null_event()</i>	This method returns an <i>Event_key</i> which is guaranteed never to be assigned to any real event. This is a very useful placeholder for events which are known never to occur (and allows data structures to differentiate between uninitialized and never failing).
<i>void</i>	<i>sim.audit_event( Event_key)</i>	Performs some checks as to whether the key corresponds to a valid event. Generally, a event is valid if it is not defaultly constructed and either is in the queue or is the <i>null_event()</i> .
<i>bool</i>	<i>sim.empty()</i>	Return true if there are no more events.
<i>void</i>	<i>sim.delete_event( const Event_key k)</i>	Remove the event referenced by <i>k</i> from the event queue.
<i>template &lt;class Ev&gt;</i> <i>typename Queue::Event_handle&lt;Ev&gt;::Handle</i>	<i>sim.event( const Event_key k, const Ev e)</i>	This method returns a pointer to an event, which can be used for recoving data, such as cached solvers, from that event. The second argument really shouldn't be there, but gcc seems to sometimes have issues if you try to specify the template value directly.
<i>Time</i>	<i>sim.event_time( Event_key k)</i>	Return the time at which the event referenced by <i>k</i> occurs.
<i>template &lt;class Ev&gt;</i>		

<i>Event_key</i>	<i>sim.set_event( Event_key k, const Ev ev)</i>	Set the event referenced by key <i>k</i> to <i>ev</i> , for example if you want to change what happens when that event occurs. A new event key is returned.
<i>Sign</i>	<i>sim.direction_of_time()</i>	Return <i>POSITIVE</i> if time is running forwards or <i>NEGATIVE</i> if it is running backwards.
<i>void</i>	<i>sim.set_direction_of_time( Sign dir)</i>	Set which direction time is running.
<i>unsigned int</i>	<i>sim.current_event_number()</i>	Return the number of events which have been processed.
<i>void</i>	<i>sim.set_current_event_number( unsigned int i)</i>	Process all events up to the <i>i</i> th event. <i>i</i> cannot be less than <i>current_event_number</i> .

## Has Models

*Kinetic::Default\_simulator<FunctionKernel, EventQueue>*

## Kinetic::Simulator::Time

### Definition

The concept `Time` represents time in the simulator.

*Time* *a*( *NT*);

Construct an instance of time from a number type, where *NT* is the number type used in the simulation.

### Operations

*std::ostream&* *std::ostream&* << *Time*

Write it to a stream.

*double* *to\_double*( *Time*)

Return a double approximation of the time value.

*std::pair<double, double>*

*to\_interval*( *Time*)

Return an interval containing the time value.

Comparisons with other *Kinetic::Simulator::Time* objects are supported.

### Has Models

*double*, *Kinetic::FunctionKernel::Root*

CGAL is designed in the spirit of the generic programming paradigm to work together with the Standard Template Library (STL) [C++98, Aus98]. This chapter documents non-geometric STL-like components that are not provided in the STL standard but in CGAL: a doubly-connected list managing items in place (where inserted items are not copied), a compact container, a multi-set class that uses three-valued comparisons and offers additional functionality, generic algorithms, iterators, functor adaptors for binding and swapping arguments and for composition, functors for projection and creation and adaptor classes around iterators and circulators. See also circulators in Chapter 63. A class storing polymorphic objects is also provided, as well as a class to manage the uncertainty of some values.

### 61.1 Doubly-Connected List Managing Items in Place

The class `In_place_list<T,bool>` manages a sequence of items in place in a doubly-connected list. Its goals are the flexible handling of memory management and performance optimization. The item type has to provide the two necessary pointers `&T::next_link` and `&T::prev_link`. One possibility to obtain these pointers is to inherit them from the base class `In_place_list_base<T>`.

The class `In_place_list<T,bool>` is a container quite similar to STL containers, with the advantage that it is able to handle the stored elements by reference instead of copying them. It is possible to delete an element only knowing its address and no iterator to it. This used to simplify mutually pointed data structures like a halfedge data structure for planar maps or polyhedral surfaces (the current design does not need this anymore). The usual iterators are also available.

## 61.2 Compact Container

The class *Compact\_container*<*T*, *Allocator*> is an STL like container which provides a very compact storage for its elements. It achieves this goal by requiring *T* to provide access to a pointer in it, which is going to be used by *Compact\_container*<*T*, *Allocator*> for its internal management. The traits class *Compact\_container\_traits*<*T*> specifies the way to access that pointer. The class *Compact\_container\_base* can be used as a base class to provide the pointer, although in this case you do not get the most compact representation. The values that this pointer can have during valid use of the object are valid pointer values to 4 bytes aligned objects (i.e., the two least significant bits of the pointer need to be zero when the object is constructed). Another interesting property of this container is that iterators are not invalidated during *insert* or *erase* operations.

The main deviation from the STL container concept is that the ++ and -- operators of the iterator do not have a constant time complexity in all cases. The actual complexity is related to the maximum size that the container has had during its life time compared to its current size, because the iterator has to go over the "erased" elements as well, so the bad case is when the container used to contain lots of elements, but now has far less. In this case, we suggest to do a copy of the container in order to "defragment" the internal representation.

This container has been developed in order to efficiently handle large data structures like the triangulation and halfedge data structures. It can probably be useful for other kinds of graphs as well.

## 61.3 Multiset with Extended Functionality

The class *Multiset*<*Type*, *Compare*, *Allocator*> represents a multi-set of elements of type *Type*, represented as a red-black tree (see [CLRS01, Chapter 13] for an excellent introduction to red-black trees). It differs from the STL's *multiset* class-template mainly due to the fact that it is parameterized by a comparison functor *Compare* that returns the three-valued *Comparison\_result* (namely it returns either *SMALLER*, *EQUAL*, or *LARGER*), rather than a *less* functor returning *bool*. Thus, it is possible to maintain the underlying red-black tree with less invocations of the comparison functor, which can considerably decrease running times, especially when comparing elements of type *Type* is an expensive operation.

*Multiset*<*Type*, *Compare*, *Allocator*> also guarantees that the order of elements sent to the comparison functor is fixed. For example, if we insert a new element *x* into the set (or erase an element from the set), then we always invoke *Compare*() (*x*, *y*) (and never *Compare*() (*y*, *x*)), where *y* is an element already stored in the set. This behavior, not supported by *std::multiset*, is sometimes crucial for designing more efficient comparison predicates.

The interface of *Multiset*<*Type*, *Compare*, *Allocator*> is in general derived from *std::multiset*. However, it extends the interface by offering some additional operations, such as: inserting of an element into the set given its *exact* position (and not just using an insertion hint); looking up keys whose type may differ from *Type*, as long as users supply a comparison functor *CompareKey*, between the keys and set elements; and catenating and splitting sets.

## 61.4 Polymorphic Object

The class *Object* can store an object of whatever other type. It can be used by a function to return objects of different types. A mechanism to extract the stored object based on its type is also provided. This class is similar to *boost::any*.

## 61.5 Uncertainty Management

The class *Uncertain*<*T*> represents a range of values of type *T*. *T* is allowed to stand for *bool*, or CGAL's enumeration types *Sign*, *Comparison\_result*, *Orientation*, *Oriented\_side*, *Bounded\_side* and *Angle*.

The idea is that sometimes you are not sure of the result of a function, and you would like to communicate that to the caller. *Uncertain*<*T*> allows just that. It also provides functions to naturally extend the Boolean operations for *Uncertain*<*bool*> for example.

*Uncertain*<*T*> is used in CGAL as the return type of geometric predicates when the number type used is interval arithmetic like *Interval\_nt*. End users typically do not see it as it is hidden in the implementation of the filtered predicates provided by the various filtered kernels, but it is important that providers of predicates that are meant to be filtered by *Filtered\_predicate*, know about it.

It can also be used in other contexts as well, as it is a general tool.

## CGAL::In\_place\_list\_base<T>

### Definition

The node base classes provides pointers to build linked lists. The class *In\_place\_sl\_list\_base*<*T*> provides a pointer *next\_link* for a single linked list. The class *In\_place\_list\_base*<*T*> provides an additional pointer *prev\_link* for doubly linked lists. These names conform to the default parameters used in the template argument lists of the container classes. The pointers are public members.

```
#include <CGAL/In_place_list.h>
```

### Variables

<i>T</i> *	<i>next_link</i> ;	forward pointer
<i>T</i> *	<i>prev_link</i> ;	backward pointer

## CGAL::In\_place\_list<T,bool>

### Definition

An object of the class *In\_place\_list*<*T*,*bool*> represents a sequence of items of type *T* that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence. The functionality is similar to the *list*<*T*> in the STL.

The *In\_place\_list*<*T*,*bool*> manages the items in place, i.e., inserted items are not copied. Two pointers of type *T\** are expected to be reserved in *T* for the list management. The base class *In\_place\_list\_base*<*T*> can be used to obtain such pointers.

The *In\_place\_list*<*T*,*bool*> does not copy element items during insertion (unless otherwise stated for a function). On removal of an item or destruction of the list the items are not deleted by default. The second template parameter *bool* is set to *false* in this case. If the *In\_place\_list*<*T*,*bool*> should take the responsibility for the stored objects the *bool* parameter could be set to *true*, in which case the list will delete removed items and will delete all remaining items on destruction. In any case, the *destroy()* member function deletes all items. Note that these two possible versions of *In\_place\_list*<*T*,*bool*> are not assignable to each other to avoid confusions between the different storage responsibilities.

```
#include <CGAL/In_place_list.h>
```

### Parameters

The full class name is *In\_place\_list*<*T*, *bool managed* = *false*, *class Alloc* = *CGAL\_ALLOCATOR(T)*>.

The parameter *T* is supposed to have a default constructor, a copy constructor and an assignment operator. The copy constructor and the assignment may copy the pointers in *T* for the list management, but they do not have to. The equality test and the relational order require the operators == and < for *T* respectively. These operators must not compare the pointers in *T*.

### Types

```
In_place_list<T,bool>::iterator  
In_place_list<T,bool>::const_iterator
```

```
In_place_list<T,bool>::value_type  
In_place_list<T,bool>::reference  
In_place_list<T,bool>::const_reference  
In_place_list<T,bool>::size_type  
In_place_list<T,bool>::difference_type
```

```
In_place_list<T,bool>::reverse_iterator  
In_place_list<T,bool>::const_reverse_iterator
```

```
In_place_list<T,bool>::allocator_type
```

## Creation

*In\_place\_list*<*T*,*bool*> *l*;                      introduces an empty list.

*In\_place\_list*<*T*,*bool*> *l*( *list*<*T*> *ll*);              copy constructor. Each item in *ll* is copied.

*In\_place\_list*<*T*,*bool*> *l*( *size\_type* *n*, *T* *t* = *T*() );

introduces a list with *n* items, all initialized with copies of *t*.

*template* <*class InputIterator*>

*In\_place\_list*<*T*,*bool*> *l*( *InputIterator* *first*, *InputIterator* *last* );

a list with copies from the range [*first*,*last*).

*In\_place\_list*<*T*,*bool*> *l*( *const T*\* *first*, *const T*\* *last* );

non-member-template version.

*In\_place\_list*<*T*,*bool*> &    *l* = *ll*              assignment. Each item in *ll* is copied. Each item in *l* is deleted if the *bool* parameter is *true*.

*void*                              *l.swap*( *ll* )              swaps the contents of *l* with *ll*.

*void*                              *l.destroy*()              all items in *l* are deleted regardless of the *bool* parameter.

## Comparison Operations

*bool*                              *l* == *ll*              test for equality: Two lists are equal, iff they have the same size and if their corresponding elements are equal.

*bool*                              *l* < *ll*              compares in lexicographical order.

## Access Member Functions

*iterator*                      *l.begin*()              returns a mutable iterator referring to the first element in *l*.

*const\_iterator*              *l.begin*() *const*              returns a constant iterator referring to the first element in *l*.

*iterator*                      *l.end*()              returns a mutable iterator which is the past-end-value of *l*.

*const\_iterator*              *l.end*() *const*              returns a constant iterator which is the past-end-value of *l*.

*bool*                              *l.empty*()              returns *true* if *l* is empty.

*size\_type*                      *l.size*()              returns the number of items in list *l*.

*size\_type*                      *l.max\_size*()              returns the maximum possible size of the list *l*.

*T*&                              *l.front*()              returns the first item in list *l*.

*T*&                              *l.back*()              returns the last item in list *l*.

*allocator\_type*

*l.get\_allocator()* returns the allocator.

## Insertion

*void l.push\_front( T& )* inserts an item in front of list *l*.  
*void l.push\_back( T& )* inserts an item at the back of list *l*.

*iterator l.insert( iterator pos, T& t )*  
*iterator l.insert( T\* pos, T& t )* inserts *t* in front of *pos*. The return value points to the inserted item.

*void l.insert( iterator pos, size\_type n, T t = T() )*  
*void l.insert( T\* pos, size\_type n, T t = T() )*  
inserts *n* copies of *t* in front of *pos*.

*template <class InputIterator>*  
*void l.insert( iterator pos, InputIterator first, InputIterator last )*

*template <class InputIterator>*  
*void l.insert( T\* pos, InputIterator first, InputIterator last )*  
inserts the range [*first*, *last*) in front of iterator *pos*.

As long as member templates are not supported, member functions using *T\** instead of the general *InputIterator* are provided.

## Removal

*void l.pop\_front()* removes the first item from list *l*.  
*void l.pop\_back()* removes the last item from list *l*.  
*void l.erase( iterator pos )* removes the item from list *l*, where *pos* refers to.  
*void l.erase( T\* pos )* removes the item from list *l*, where *pos* refers to.

*void l.erase( iterator first, iterator last )*  
*void l.erase( T\* first, T\* last )*  
removes the items in the range [*first*, *last*) from *l*.

## Special List Operations

*void l.splice( iterator pos, & x )*  
*void l.splice( T\* pos, & x )* inserts the list *x* before position *pos* and *x* becomes empty. It takes constant time.  
*Precondition: & != &x.*

*void l.splice( iterator pos, & x, iterator i )*

<i>void</i>	<i>l.splice( T* pos, &amp; x, T* i)</i>	inserts an element pointed to by <i>i</i> from list <i>x</i> before position <i>pos</i> and removes the element from <i>x</i> . It takes constant time. <i>i</i> is a valid dereferenceable iterator of <i>x</i> . The result is unchanged if <i>pos</i> == <i>i</i> or <i>pos</i> == ++ <i>i</i> .
<i>void</i> <i>void</i>	<i>l.splice( iterator pos, &amp; x, iterator first, iterator last)</i> <i>l.splice( T* pos, &amp; x, T* first, T* last)</i>	inserts elements in the range [ <i>first</i> , <i>last</i> ) before position <i>pos</i> and removes the elements from <i>x</i> . It takes constant time if & <i>x</i> == & <i>l</i> ; otherwise, it takes linear time. [ <i>first</i> , <i>last</i> ) is a valid range in <i>x</i> . <i>Precondition</i> : <i>pos</i> is not in the range [ <i>first</i> , <i>last</i> ).
<i>void</i>	<i>l.remove( T value)</i>	erases all elements <i>e</i> in the list <i>l</i> for which <i>e</i> == <i>value</i> . It is stable. <i>Precondition</i> : a suitable <i>operator</i> == for the type <i>T</i> .
<i>void</i>	<i>l.unique()</i>	erases all but the first element from every consecutive group of equal elements in the list <i>l</i> . <i>Precondition</i> : a suitable <i>operator</i> == for the type <i>T</i> .
<i>void</i>	<i>l.merge( &amp; x)</i>	merges the list <i>x</i> into the list <i>l</i> and <i>x</i> becomes empty. It is stable. <i>Precondition</i> : Both lists are increasingly sorted. A suitable <i>operator</i> < for the type <i>T</i> .
<i>void</i>	<i>l.reverse()</i>	reverses the order of the elements in <i>l</i> in linear time.
<i>void</i>	<i>l.sort()</i>	sorts the list <i>l</i> according to the <i>operator</i> < in time $O(n \log n)$ where $n = \text{size}()$ . It is stable. <i>Precondition</i> : a suitable <i>operator</i> < for the type <i>T</i> .

## Example

```
#include <CGAL/basic.h>
#include <cassert>
#include <algorithm>
#include <CGAL/In_place_list.h>

using CGAL::In_place_list_base;

struct item : public In_place_list_base<item> {
    int key;
    item() {}
    item( const item& i ) : In_place_list_base<item>(i), key(i.key) {}
    item( int i ) : key(i) {}
    bool operator== (const item& i) const { return key == i.key;}
    bool operator!= (const item& i) const { return ! (*this == i);}
    bool operator== (int i) const          { return key == i;}
    bool operator!= (int i) const          { return ! (*this == i);}
    bool operator<  (const item& i) const { return key < i.key;}
};

int main() {
    typedef CGAL::In_place_list<item,true> List;
    List l;
    item* p = new item(1);
    l.push_back(*p);
    l.push_back(*new item(2));
    l.push_front(*new item(3));
    l.push_front(*new item(4));
    l.push_front(*new item(2));
    List::iterator i = l.begin();
    ++i;
    l.insert(i, *new item(5));
    l.insert(p, *new item(5));
    int a[7] = {2,5,4,3,5,1,2};
    bool ok = std::equal(l.begin(), l.end(), a);
    assert(ok);
    l.sort();
    l.unique();
    assert(l.size() == 5);
    int b[5] = {1,2,3,4,5};
    ok = std::equal(l.begin(), l.end(), b);
    assert(ok);
    return 0;
}
```

**File:** examples/STL\_Extension/in\_place\_list\_prog.cpp

## CGAL::Compact\_container\_base

### Definition

The class *Compact\_container\_base* can be used as a base class for your own type *T*, so that *T* can be used directly within *Compact\_container*<*T*, *Allocator*>. This class stores a *void \** pointer only for this purpose, so it may not be the most memory efficient way to achieve this goal. The other ways are to provide in *T* the necessary member functions so that the template *Compact\_container\_traits*<*T*> works, or to specialize it for the particular type *T* that you want to use.

```
#include <CGAL/Compact_container.h>
```

### Operations

<code>void*</code>	<code>ccb.for_compact_container() const</code>	Returns the pointer necessary for <i>Compact_container_traits</i> < <i>T</i> >.
<code>void*&amp;</code>	<code>ccb.for_compact_container()</code>	Returns a reference to the pointer necessary for <i>Compact_container_traits</i> < <i>T</i> >.

## CGAL::Compact\_container\_traits<T>

### Definition

The traits class *Compact\_container\_traits*<*T*> provides the way to access the internal pointer required for *T* to be used in a *Compact\_container*<*T*, *Allocator*>. Note that this pointer needs to be accessible even when the object is not constructed, which means it has to reside in the same memory place as *T*.

You can specialize this class for your own type *T* if the default template is not suitable.

You can also use *Compact\_container\_base* as base class for your own types *T* to make them usable with the default *Compact\_container\_traits*<*T*>.

```
#include <CGAL/Compact_container.h>
```

### Parameters

*T* is any type providing the following member functions:

```
void *t.for_compact_container() const;
```

```
void *&t.for_compact_container();
```

### Operations

<i>static void*</i>	<i>cct.pointer( const T &amp;t)</i>	Returns the pointer hold by <i>t</i> . The template version defines this function as: <i>return t.for_compact_container();</i>
<i>static void*&amp;</i>	<i>cct.pointer( T &amp;t)</i>	Returns a reference to the pointer hold by <i>t</i> . The template version defines this function as: <i>return t.for_compact_container();</i>

## CGAL::Compact\_container<T, Allocator>

### Definition

An object of the class *Compact\_container*<*T*, *Allocator*> is a container of objects of type *T*. It matches all the standard requirements for reversible containers, except that the complexity of its iterator increment and decrement operations is not always guaranteed to be amortized constant time.

This container is not a standard *sequence* nor *associative* container, which means the elements are stored in no particular order, and it is not possible to specify a particular place in the iterator sequence where to insert new objects. However, all dereferenceable iterators are still valid after calls to *insert()* and *erase()*, except those that have been erased (it behaves similarly to *std::list*).

The main feature of this container is that it is very memory efficient : its memory size is  $N * \text{sizeof}(T) + o(N)$ , where *N* is the maximum size that the container has had in its past history, its *capacity()* (the memory of erased elements is not deallocated until destruction of the container or a call to *clear()*). This container has been developed in order to store large graph-like data structures like the triangulation and the halfedge data structures.

It supports bidirectional iterators and allows a constant time amortized *insert()* operation. You cannot specify where to insert new objects (i.e. you don't know where they will end up in the iterator sequence, although *insert()* returns an iterator pointing to the newly inserted object). You can erase any element with a constant time complexity.

Summary of the differences with *std::list* : it is more compact in memory since it doesn't store two additional pointers for the iterator needs. It doesn't deallocate elements until the destruction or *clear()* of the container. The iterator does not have constant amortized time complexity for the increment and decrement operations in all cases, only when not too many elements have not been freed (i.e. when the *size()* is close to the *capacity()*). Iterating from *begin()* to *end()* takes  $O(\text{capacity}())$  time, not *size()*. In the case where the container has a small *size()* compared to its *capacity()*, we advise to "defragment the memory" by copying the container if the iterator performance is needed.

The iterators themselves can be used as *T*, they provide the necessary functions to be used by *Compact\_container\_traits*<*T*>.

```
#include <CGAL/Compact_container.h>
```

### Parameters

The parameter *T* is required to have a copy constructor and an assignment operator. It also needs to provide access to an internal pointer via *Compact\_container\_traits*<*T*>.

The equality test and the relational order require the operators == and < for *T* respectively.

The parameter *Allocator* has to match the standard allocator requirements, with value type *T*. This parameter has the default value *CGAL\_ALLOCATOR*(*T*).

### Types

*Compact\_container*<*T*, *Allocator*>:: *value\_type*

*Compact\_container*<*T*, *Allocator*>:: *reference*

*Compact\_container<T, Allocator>:: const\_reference*  
*Compact\_container<T, Allocator>:: pointer*  
*Compact\_container<T, Allocator>:: const\_pointer*  
*Compact\_container<T, Allocator>:: size\_type*  
*Compact\_container<T, Allocator>:: difference\_type*

*Compact\_container<T, Allocator>:: iterator*  
*Compact\_container<T, Allocator>:: const\_iterator*  
*Compact\_container<T, Allocator>:: reverse\_iterator*  
*Compact\_container<T, Allocator>:: const\_reverse\_iterator*

*Compact\_container<T, Allocator>:: allocator\_type*

## Creation

*Compact\_container<T, Allocator> c(Allocator a = Allocator());*

introduces an empty container, eventually specifying a particular allocator *a* as well.

*template <class InputIterator>*

*Compact\_container<T, Allocator> c( InputIterator first, InputIterator last, Allocator a = Allocator());*

a container with copies from the range [*first,last*), eventually specifying a particular allocator.

*Compact\_container<T, Allocator> c( cc);*

copy constructor. Each item in *cc* is copied. The allocator is copied. The iterator order is preserved.

*Compact\_container<T, Allocator> & c = cc*

assignment. Each item in *cc* is copied. The allocator is copied. Each item in *c* is deleted. The iterator order is preserved.

*void c.swap( &cc)*

swaps the contents of *c* and *cc* in constant time complexity. No exception is thrown.

## Access Member Functions

*iterator c.begin()* returns a mutable iterator referring to the first element in *c*.

*const\_iterator c.begin() const* returns a constant iterator referring to the first element in *c*.

*iterator c.end()* returns a mutable iterator which is the past-end-value of *c*.

<i>const_iterator</i>	<i>c.end()</i> <i>const</i>	returns a constant iterator which is the past-end-value of <i>c</i> .
<i>reverse_iterator</i>	<i>c.rbegin()</i>	
<i>const_reverse_iterator</i>	<i>c.rbegin()</i> <i>const</i>	
<i>reverse_iterator</i>	<i>c.rend()</i>	
<i>const_reverse_iterator</i>	<i>c.rend()</i> <i>const</i>	
<i>bool</i>	<i>c.empty()</i>	returns <i>true</i> iff <i>c</i> is empty.
<i>size_type</i>	<i>c.size()</i>	returns the number of items in <i>c</i> .
<i>size_type</i>	<i>c.max_size()</i>	returns the maximum possible size of the container <i>c</i> .
<i>size_type</i>	<i>c.capacity()</i>	returns the total number of elements that <i>c</i> can hold without requiring reallocation.
<i>Allocator</i>	<i>c.get_allocator()</i>	returns the allocator.
<b>Insertion</b>		
<i>iterator</i>	<i>c.insert( T t )</i>	inserts a copy of <i>t</i> in <i>c</i> and returns the iterator pointing to it.
<i>template &lt;class InputIterator&gt;</i> <i>void</i>	<i>c.insert( InputIterator first, InputIterator last )</i>	inserts the range [ <i>first</i> , <i>last</i> ) in <i>c</i> .
<i>template &lt;class InputIterator&gt;</i> <i>void</i>	<i>c.assign( InputIterator first, InputIterator last )</i>	erases all the elements of <i>c</i> , then inserts the range [ <i>first</i> , <i>last</i> ) in <i>c</i> .
<i>template &lt; class T1 &gt;</i> <i>iterator</i>	<i>c.emplace( T1 t1 )</i>	constructs an object of type <i>T</i> with the constructor that takes <i>t1</i> as argument, inserts it in <i>c</i> , and returns the iterator pointing to it. Overloads of this member function are defined that take additional arguments, up to 9.

## Removal

<i>void</i>	<i>c.erase( iterator pos)</i>	removes the item pointed by <i>pos</i> from <i>c</i> .
<i>void</i>	<i>c.erase( iterator first, iterator last)</i>	removes the items from the range [ <i>first</i> , <i>last</i> ) from <i>c</i> .
<i>void</i>	<i>c.clear()</i>	all items in <i>c</i> are deleted, and the memory is deallocated. After this call, <i>c</i> is in the same state as if just default constructed.

## Special Operation

<i>void</i>	<i>c.merge( &amp;cc)</i>	adds the items of <i>cc</i> to the end of <i>c</i> and <i>cc</i> becomes empty. The time complexity is $O(c.capacity() - c.size())$ . <i>Precondition:</i> <i>cc</i> must not be the same as <i>c</i> , and the allocators of <i>c</i> and <i>cc</i> need to be compatible : <i>c.get_allocator() == cc.get_allocator()</i> .
-------------	--------------------------	--

## Comparison Operations

<i>bool</i>	<i>c == cc</i>	test for equality: Two containers are equal, iff they have the same size and if their corresponding elements are equal.
<i>bool</i>	<i>c != cc</i>	test for inequality: returns $!(c == cc)$ .
<i>bool</i>	<i>c &lt; cc</i>	compares in lexicographical order.
<i>bool</i>	<i>c &gt; cc</i>	returns $cc < c$ .
<i>bool</i>	<i>c &lt;= cc</i>	returns $!(c > cc)$ .
<i>bool</i>	<i>c &gt;= cc</i>	returns $!(c < cc)$ .

## CGAL::Multiset<Type,Compare,Allocator>

### Definition

An instance  $s$  of the parametrized data type *Multiset*<*Type*,*Compare*,*Allocator*> is a multi-set of elements of type *Type*, represented as a red-black tree (see [CLRS01, Chapter 13] for an excellent introduction to red-black trees). The main difference between *Multiset*<*Type*,*Compare*,*Allocator*> and STL's *multiset* is that the latter uses a less-than functor with a Boolean return type, while our *Multiset*<*Type*,*Compare*,*Allocator*> class is parameterized by a comparison functor *Compare* that returns the three-valued *Comparison\_result* (namely it returns either *SMALLER*, *EQUAL*, or *LARGER*). It is thus possible to maintain the underlying red-black tree with less invocations of the comparison functor. This leads to a speedup of about 5% even if we maintain a set of integers. When each comparison of two elements of type *Type* is an expensive operation (for example, when they are geometric entities represented using exact arithmetic), the usage of a three-valued comparison functor can lead to considerable decrease in the running times.

Moreover, *Multiset*<*Type*,*Compare*,*Allocator*> allows the insertion of an element into the set given its *exact* position, and not just using an insertion hint, as done by *std::multiset*. This can further reduce the running times, as additional comparison operations can be avoided.

In addition, the *Multiset*<*Type*,*Compare*,*Allocator*> guarantees that the order of elements sent to the comparison functor is fixed. For example, if we insert a new element  $x$  into the set (or erase an element from the set), then we always invoke *Compare*() ( $x$ ,  $y$ ) (and never *Compare*() ( $y$ ,  $x$ )), where  $y$  is an element already stored in the set. This behavior, not supported by *std::multiset*, is sometimes crucial for designing more efficient comparison predicates.

*Multiset*<*Type*,*Compare*,*Allocator*> also allows for look-up of keys whose type may differ from *Type*, as long as users supply a comparison functor *CompareKey*, where *CompareKey*() ( $key$ ,  $y$ ) returns the three-valued *Comparison\_result* ( $key$  is the look-up key and  $y$  is an element of type *Type*). Indeed, it is very convenient to look-up equivalent objects in the set given just by their key. We note however that it is also possible to use a key of type *Type* and to employ the default *Compare* functor for the look-up, as done when using the *std::multiset* class.

— advanced —

Finally, *Multiset*<*Type*,*Compare*,*Allocator*> introduces the *catenate*() and *split*() functions. The first function operates on  $s$  and accepts a second set  $s'$ , such that the maximum element in  $s$  is not greater than the minimal element in  $s'$ , and concatenates  $s'$  to  $s$ . The second function splits  $s$  into two sets, one containing all the elements that are less than a given key, and the other contains all elements greater than (or equal to) this key.

— advanced —

### Parameters

The *Multiset* class-template has three parameters:

- *Type* — the type of the stored elements.
- *Compare* — the comparison-functor type. This type should provide the following operator for comparing two *Type* elements, namely:  
`Comparison_result operator() (const Type& t1, const Type& t2) const;`  
 The *CGAL::Compare*<*Type*> functor is used by default. In this case, *Type* must support an equality operator (*operator*==) and a less-than operator (*operator*<).

- *Allocator* — the allocator type.  
*CGAL\_ALLOCATOR* is used by default.

```
#include <CGAL/Multiset.h>
```

## Assertions

The assertion and precondition flags for the *Multiset* class use *MULTISET* in their names (i.e., *CGAL\_MULTISET\_NO\_ASSERTIONS* and *CGAL\_MULTISET\_NO\_PRECONDITIONS*).

## Types

In compliance with STL, the types *value\_type* and *key\_type* (both equivalent to *Type*), *reference* and *const\_reference* (reference to a value-type), *key\_compare* and *value\_compare* (both equivalent to *Compare*), *size\_type* and *difference\_type* are defined as well.

```
Multiset<Type,Compare,Allocator>:: iterator  
Multiset<Type,Compare,Allocator>:: const_iterator
```

bi-directional iterators for the elements stored in the set.

```
Multiset<Type,Compare,Allocator>:: reverse_iterator  
Multiset<Type,Compare,Allocator>:: const_reverse_iterator
```

reverse bi-directional iterators for the elements stored in the set.

## Creation

```
Multiset<Type,Compare,Allocator> s;
```

creates an an empty set *s* that uses a default comparison functor.

```
Multiset<Type,Compare,Allocator> s( Compare comp);
```

creates an an empty set *s* that uses the given comparison functor *comp*.

```
template <class InputIterator>  
Multiset<Type,Compare,Allocator> s( InputIterator first, InputIterator last, Compare comp = Compare());
```

creates a set *s* containing all elements in the range [*first*, *last*), that uses the comparison functor *comp*.

```
Multiset<Type,Compare,Allocator> s( other);
```

copy constructor.

```
Multiset<Type,Compare,Allocator>  
s = other
```

assignment operator.

<i>void</i>	<i>s.swap( &amp; other)</i>	swaps the contents of <i>s</i> with those of the other set.
-------------	-----------------------------	---

### Access Member Functions

<i>Compare</i>	<i>s.key_comp()</i>	the comparison functor used.
<i>Compare</i>	<i>s.value_comp()</i>	the comparison functor used (same as above). Both functions have a non-const version that return a reference to the comparison functor.

<i>bool</i>	<i>s.empty()</i>	returns <i>true</i> if the set is empty, <i>false</i> otherwise.
-------------	------------------	--

<i>size_t</i>	<i>s.size()</i>	returns the number of elements stored in the set.
---------------	-----------------	---

<i>size_t</i>	<i>s.max_size()</i>	returns the maximal number of elements the set can store (same as <i>size()</i> ).
---------------	---------------------	--

<i>iterator</i>	<i>s.begin()</i>	returns an iterator pointing to the first element stored in the set (a <i>const</i> version is also available).
-----------------	------------------	---

<i>iterator</i>	<i>s.end()</i>	returns an iterator pointing beyond the last element stored in the set (a <i>const</i> version is also available).
-----------------	----------------	--

<i>reverse_iterator</i>	<i>s.rbegin()</i>	returns a reverse iterator pointing beyond the last element stored in the set (a <i>const</i> version is also available).
-------------------------	-------------------	---

<i>reverse_iterator</i>	<i>s.rend()</i>	returns a reverse iterator pointing to the first element stored in the set (a <i>const</i> version is also available).
-------------------------	-----------------	--

### Comparison Operations

<i>bool</i>	<i>s == other</i>	returns <i>true</i> if the sequences of elements in the two sets are pairwise equal (using the comparison functor).
-------------	-------------------	---

<i>bool</i>	<i>s &lt; other</i>	returns <i>true</i> if the element sequence in <i>s</i> is lexicographically smaller than the element sequence of <i>other</i> .
-------------	---------------------	--

### Insertion Methods

<i>iterator</i>	<i>s.insert( Type x)</i>	inserts the element <i>x</i> into the set and returns an iterator pointing to the newly inserted element.
-----------------	--------------------------	---

<i>template &lt;class InputIterator&gt;</i>	<i>s.insert( InputIterator first, InputIterator last)</i>	
<i>void</i>		inserts all elements in the range <i>[first, last)</i> into the set.

<i>iterator</i>	<i>s.insert( iterator position, Type x)</i>	inserts the element <i>x</i> with a given iterator used as a hint for the position of the new element. It Returns an iterator pointing to the newly inserted element.
-----------------	---	---

<i>iterator</i>	<i>s.insert_before( iterator position, Type x)</i>	<p>inserts the element <i>x</i> as the predecessor of the element at the given position.</p> <p><i>Precondition:</i> The operation does not violate the set order — that is, <i>x</i> is not greater than the element pointed by <i>position</i> and not less than its current predecessor.</p>
-----------------	--	---

<i>iterator</i>	<i>s.insert_after( iterator position, Type x)</i>	<p>inserts the element <i>x</i> as the successor of the element at the given position.</p> <p><i>Precondition:</i> The operation does not violate the set order — that is, <i>x</i> is not less than the element pointed by <i>position</i> and not greater than its current successor.</p>
-----------------	---	---

## Removal Methods

<i>size_t</i>	<i>s.erase( Type x)</i>	erases all elements equivalent to <i>x</i> from the set and returns the number of erased elements.
---------------	-------------------------	--

<i>void</i>	<i>s.erase( iterator position)</i>	erases the element pointed by <i>position</i> .
-------------	------------------------------------	---

<i>void</i>	<i>s.clear()</i>	clears the set (erases all stored elements).
-------------	------------------	--

## Look-up Methods

All methods listed in this section can also accept a *Type* element as a look-up key. In this case, it is not necessary to supply a *CompareKey* functor, as the *Compare* functor will be used by default.

<i>template &lt;class Key, class CompareKey&gt;</i> <i>iterator</i>	<i>s.find( Key key, CompareKey comp_key)</i>	searches for the an element equivalent to <i>key</i> in the set. If the set contains objects equivalent to <i>key</i> , it returns an iterator pointing to the first one. Otherwise, <i>end()</i> is returned (a <i>const</i> version is also available).
--	--	---

*template <class Key, class CompareKey>*

*size\_t*

*s.count( Key key, CompareKey comp\_key)*

returns the number of elements equivalent to *key* in the set.

*template <class Key, class CompareKey>*

*iterator*

*s.lower\_bound( Key key, CompareKey comp\_key)*

returns an iterator pointing to the first element in the set that is not less than *key*. If all set elements are less than *key*, *end()* is returned (a *const* version is also available).

*template <class Key, class CompareKey>*

*iterator*

*s.upper\_bound( Key key, CompareKey comp\_key)*

returns an iterator pointing to the first element in the set that is greater than *key*. If no set element is greater than *key*, *end()* is returned (a *const* version is also available).

*template <class Key, class CompareKey>*

*std::pair<iterator,iterator>*

*s.equal\_range( Key key, CompareKey comp\_key)*

returns the range of set elements equivalent to the given key, namely (*lower\_bound(key)*, *upper\_bound(key)*) (a *const* version is also available).

*template <class Key, class CompareKey>*

*std::pair<iterator,bool>*

*s.find\_lower( Key key, CompareKey comp\_key)*

returns a pair comprised of *lower\_bound(key)* and a Boolean flag indicating whether this iterator points to an element equivalent to the given key (a *const* version is also available).

---

advanced

## Special Operations

*void*

*s.replace( iterator position, Type x)*

replaces the element stored at the given position with *x*.

*Precondition:* The operation does not violate the set order — that is, *x* is not less than *position*'s predecessor and not greater than its successor.

*void* *s.swap( iterator pos1, iterator pos2)*

swaps places between the two elements given by *pos1* and *pos2*.

*Precondition:* The operation does not violate the set order — that is, *pos1* and *pos2* store equivalent elements.

*void* *s.catenate( Self& s\_prime)*

concatenates all elements in *s\_prime* into *s* and clears *s\_prime*. All iterators to *s* and to *s\_prime* remain valid.

*Precondition:* The maximal element in *s* is not greater than the minimal element in *s\_prime*.

*template <class Key, class CompareKey>*  
*void* *s.split( Key key, CompareKey comp\_key, Self& s\_prime)*

splits *s* such that it contains all elements that are less than the given *key* and such that *s\_prime* contains all other elements.

*Precondition:* *s\_prime* is initially empty.

*void* *s.split( iterator position, Self& s\_prime)*

splits *s* such that it contains all set elements in the range [*begin*, *position*) and such that *s\_prime* contains all elements in the range [*position*, *end*()).

*Precondition:* *s\_prime* is initially empty.

————— *advanced* —————

## Implementation

*Multiset* uses a proprietary implementation of a red-black tree data-structure. The red-black tree invariants guarantee that the height of a tree containing  $n$  elements is  $O(\log n)$  (more precisely, it is bounded by  $2 \log_2 n$ ). As a consequence, all methods that accept an element and need to locate it in the tree (namely *insert*(*x*), *erase*(*x*), *find*(*x*), *count*(*x*), *lower\_bound*(*x*), *upper\_bound*(*x*), *find\_lower*(*x*) and *equal\_range*(*x*)) take  $O(\log n)$  time and perform  $O(\log n)$  comparison operations.

On the other hand, the set operations that accept a position iterator (namely *insert\_before*(*pos*, *x*), *insert\_after*(*pos*, *x*) and *erase*(*pos*)) are much more efficient as they can be performed at a *constant* amortized cost (see [GS78] and [Tar83] for more details). More important, these set operations require *no* comparison operations. Therefore, it is highly recommended to maintain the set via iterators to the stored elements, whenever possible. The function *insert*(*pos*, *x*) is safer to use, but it takes amortized  $O(\min\{d, \log n\})$  time, where  $d$  is the distance between the given position and the true position of *x*. In addition, it always performs at least two comparison operations.

————— *advanced* —————

The *catenate*() and *split*() functions are also very efficient, and can be performed in  $O(\log n)$  time, where  $n$  is the total number of elements in the sets, and without performing any comparison operations (see [Tar83] for the details). Note however that the size of two sets resulting from a split operation is initially unknown, as it is

impossible to compute it in less than linear time. Thus, the first invocation of *size()* on such a set takes linear time, and *not* constant time.

————— *advanced* —————

The design is derived from the STL *multiset* class-template (see, e.g. [MS96]), where the main differences between the two classes are highlighted in the class definition above.

## CGAL::Object

```
#include <CGAL/Object.h>
```

### Definition

Some functions can return different types of objects. A typical C++ solution to this problem is to derive all possible return types from a common base class, to return a pointer to this class and to perform a dynamic cast on this pointer. The class *Object* provides an abstraction. An object *obj* of the class *Object* can represent an arbitrary class. The only operations it provides is to make copies and assignments, so that you can put them in lists or arrays. Note that *Object* is NOT a common base class for the elementary classes. Therefore, there is no automatic conversion from these classes to *Object*. Rather this is done with the global function *make\_object*. This encapsulation mechanism requires the use of *assign* or *object\_cast* to use the functionality of the encapsulated class.

This class is similar in spirit to *boost::any*.

### Creation

*Object obj*; introduces an empty object.

*Object obj( o )*; Copy constructor.

Objects of type *Object* are normally created using the global function *make\_object*.

### Operations

*Object & obj = o* Assignment.

*bool obj.empty()* returns true, if *obj* does not contain an object.

*std::type\_info obj.type()* returns the type information of the contained type, or *typeid(void)* if empty.

Construction of an *Object* storing an object of type *T* can be performed using the *make\_object* global function :

```
template <class T>
Object      make_object( T t)      Creates an object that contains t.
```

Assignment of an object of type *Object* to an object of type *T* can be done using *assign* :

```
template <class T>
bool      assign( T& c, o)          assigns o to c if o was constructed from an object of type T.
                                      Returns true, if the assignment was possible. For efficiency
                                      reasons, we recommend using object_cast instead.
```

Another possibility to access the encapsulated object is to use *object\_cast*, which avoids the default constructor and assignment required by *assign* :

*template <class T>*

*const T\** *object\_cast( const \*o)*

Returns a pointer to the object of type *T* stored by *o*, if any, otherwise returns *NULL*.

*template <class T>*

*T* *object\_cast( o)*

Returns a copy of the object of type *T* stored by *o*, if any, otherwise throws an exception of type *Bad\_object\_cast*.

## Example

In the following example, the object class is used as return value for the intersection computation, as there are possibly different return values.

```
{
    typedef Cartesian<double>    K;
    typedef K::Point_2          Point_2;
    typedef K::Segment_2         Segment_2;

    Point_2 point;
    Segment_2 segment, segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;

    Object obj = intersection(segment_1, segment_2);

    if (assign(point, obj)) {
        /* do something with point */
    } else if (assign(segment, obj)) {
        /* do something with segment*/
    }

    /* there was no intersection */
}
```

A more efficient way to access the object is to use *object\_cast*, which allows to skip a default construction and assignment :

```
{
    typedef Cartesian<double>    K;
    typedef K::Point_2          Point_2;
    typedef K::Segment_2         Segment_2;

    Segment_2 segment_1, segment_2;

    std::cin >> segment_1 >> segment_2;

    Object obj = intersection(segment_1, segment_2);

    if (const Point_2 * point = object_cast<Point_2>(&obj)) {
```

```

        /* do something with *point */
    } else if (const Segment_2 * segment = object_cast<Segment_2>(&obj)) {
        /* do something with *segment */
    }

    /* there was no intersection */
}

```

The intersection routine itself looks roughly as follows:

```

template < class Kernel >
Object intersection(Segment_2<Kernel> s1, Segment_2<Kernel> s2)
{

    if (/* intersection is a point */) {

        Point_2<Kernel> p = ... ;
        return make_object(p);

    } else if (/* intersection is a segment */) {

        Segment_2<Kernel> s = ... ;
        return make_object(s);
    }

    /* empty intersection */
    return Object();
}

```

## CGAL::predecessor

### Definition

The function *predecessor* returns the previous iterator, i.e. the result of *operator--* on a bidirectional iterator.

```
#include <CGAL/algorithm.h>
```

```
template <class BidirectionalIterator>
```

```
BidirectionalIterator predecessor( BidirectionalIterator it)
```

returns *--it*.

### See Also

*CGAL::successor* ..... [page 3356](#)

## CGAL::successor

### Definition

The function *successor* returns the next iterator, i.e. the result of *operator++* on a forward iterator.

```
#include <CGAL/algorithm.h>
```

```
template <class ForwardIterator>
```

```
ForwardIterator    successor( ForwardIterator it)
```

returns  $++it$ .

### See Also

*CGAL::predecessor* ..... page [3355](#)

## CGAL::copy\_n

### Definition

The function *copy\_n* copies *n* items from an input iterator to an output iterator which is useful for possibly infinite sequences of random geometric objects.<sup>1</sup>

```
#include <CGAL/algorithm.h>
```

```
template <class InputIterator, class Size, class OutputIterator>
OutputIterator copy_n( InputIterator first, Size n, OutputIterator result)
```

copies the first *n* items from *first* to *result*. Returns the value of *result* after inserting the *n* items.

### See Also

*CGAL::Counting\_iterator*<*Iterator*, *Value*> ..... page [3363](#)

---

<sup>1</sup>The STL release June 13, 1997, from SGI contains an equivalent function, but it is not part of the ISO standard.

## CGAL::min\_max\_element

### Definition

The function *min\_max\_element* computes the minimal and the maximal element of a range. It is modeled after the STL functions *min\_element* and *max\_element*. The advantage of *min\_max\_element* compared to calling both STL functions is that one only iterates once over the sequence. This is more efficient especially for large and/or complex sequences.

```
#include <CGAL/algorithm.h>
```

```
template < class ForwardIterator >
std::pair< ForwardIterator, ForwardIterator >
```

```
min_max_element( ForwardIterator first, ForwardIterator last)
```

returns a pair of iterators where the first component refers to the minimal and the second component refers to the maximal element in the range  $[first, last)$ . The ordering is defined by *operator<* on the value type of *ForwardIterator*.

```
template < class ForwardIterator, class CompareMin, class CompareMax >
std::pair< ForwardIterator, ForwardIterator >
```

```
min_max_element( ForwardIterator first,
                  ForwardIterator last,
                  CompareMin comp_min,
                  CompareMax comp_max)
```

returns a pair of iterators where the first component refers to the minimal and the second component refers to the maximal element in the range  $[first, last)$ .

*Requirement:* *CompareMin* and *CompareMax* are adaptable binary function objects:  $VT \times VT \rightarrow bool$  where *VT* is the value type of *ForwardIterator*.

### Example

The following example program computes the minimal and maximal element of the sequence (3, 6, 5). Hence the output is *min* = 3, *max* = 6.

```
#include <CGAL/algorithm.h>
#include <vector>
#include <iostream>

using std::vector;
using std::pair;
using std::cout;
```

```

using std::endl;
using CGAL::min_max_element;

int main()
{
    vector< int > v;
    v.push_back(3);
    v.push_back(6);
    v.push_back(5);
    typedef std::vector< int >::iterator iterator;
    pair< iterator, iterator > p = min_max_element(v.begin(), v.end());
    cout << "min = " << *p.first << ", max = " << *p.second << endl;
    return 0;
}

```

**File:** examples/STL\_Extension/min\_max\_element\_example.cpp

## CGAL::Emptyset\_iterator

### Definition

The class defines an *OutputIterator* that ignores everything written to it. One can think of it as being connected to `/dev/null`.

```
#include <CGAL/iterator.h>
```

### Is Model for the Concepts

*OutputIterator*

### Creation

```
Emptyset_iterator i;
```

default constructor.

### See Also

*CGAL::Oneset\_iterator* .....page ??

*CGAL::Const\_oneset\_iterator* .....page ??

## CGAL::Oneset\_iterator<T>

### Definition

The class *Oneset\_iterator*<*T*> defines an *BidirectionalIterator* that always refers to one specific object of type *T*. Internally, *Oneset\_iterator*<*T*> stores a pointer to the referred object.

```
#include <CGAL/iterator.h>
```

### Is Model for the Concepts

*BidirectionalIterator*

### Creation

```
Oneset_iterator<T> i( T& t);
```

creates an iterator referring to *t*.

### See Also

*CGAL::Emptyset\_iterator* ..... page [3360](#)

*CGAL::Const\_oneset\_iterator* ..... page ??

## CGAL::Const\_onese\_iterator<T>

### Definition

The class *Const\_onese\_iterator*<*T*> defines an *RandomAccessIterator* that always refers to a copy of a specific object of type *T*.

```
#include <CGAL/iterator.h>
```

### Is Model for the Concepts

*RandomAccessIterator*

### Creation

```
Const_onese_iterator<T> i( T& t);
```

creates an iterator that always refers to some copy of *t*. The copy is constructed by invoking *T*'s copy constructor and remains constant during *i*'s lifetime.

### See Also

*CGAL::Emptyset\_iterator* ..... page [3360](#)  
*CGAL::Onese\_iterator* ..... page ??

## CGAL::Counting\_iterator<Iterator, Value>

### Definition

The iterator adaptor *Counting\_iterator*<*Iterator*, *Value*> adds a counter to the internal iterator of type *Iterator* and defines equality of two instances in terms of this counter. It can be used to create finite sequences of possibly infinite sequences of values from input iterators.

```
#include <CGAL/iterator.h>
```

### Is Model for the Concepts

*InputIterator*

### Requirements

*Iterator* is a model for *InputIterator*.

### Creation

```
Counting_iterator<Iterator, Value> i( std::size_t n = 0);
```

initializes the internal counter to *n* and *i* has a singular value.

```
Counting_iterator<Iterator, Value> i( Iterator j, std::size_t n = 0);
```

initializes the internal counter to *n* and *i* to *j*.

### See Also

*CGAL::copy\_n* ..... page [3357](#)

## CGAL::Insert\_iterator<Container>

### Definition

The output iterator *Insert\_iterator*<*Container*> is similar to *std::insert\_iterator*, but differs in that it calls the *insert()* function of the container without the iterator additional argument.

```
#include <CGAL/iterator.h>
```

### Is Model for the Concepts

*OutputIterator*

### Requirements

*Container* provides a member function *insert(const Container::const\_reference&)*.

### Creation

```
Insert_iterator<Container> i( Container &c);
```

initializes the internal container reference to *c*.

There is also a global function similar to *std::inserter*:

```
template < class Container >
Insert_iterator<Container>
```

```
inserter( Container &x)
```

Constructs *Insert\_iterator*<*Container*>(x).

## CGAL::N\_step\_adaptor<I,int N>

### Definition

The adaptor *N\_step\_adaptor*<*I*,int *N*> changes the step width of the iterator or circulator class *I* to *N*. It is itself an iterator or circulator respectively. The behavior is undefined if the adaptor is used on a range  $[i, j)$  where  $j - i$  is not a multiple of *n*.

*#include* <CGAL/iterator.h>

### Creation

*N\_step\_adaptor*<*I*,int *N*> *i*( *I* *j*);      down cast.

## CGAL::Filter\_iterator<Iterator, Predicate>

### Definition

The iterator adaptor *Filter\_iterator*<*Iterator*, *Predicate*> acts as a filter on a given range. Whenever the iterator is in- or decremented, it ignores all iterators for which the given *Predicate* is true. The iterator category is the same as for *Iterator*.

Note: Boost also provides the same functionality via the *boost::filter\_iterator* class. Unfortunately, the semantics chosen for accepting or rejecting elements based on the predicate's result are opposite as the semantic chosen here. What is more, the argument of the predicate is different: the predicate used with *boost::filter\_iterator* must take the value type of the iterator, as argument, and not the iterator itself.

```
#include <CGAL/iterator.h>
```

### Requirements

- *Iterator* is a model for *ForwardIterator*.
- *Predicate* is a functor:  $Iterator \rightarrow bool$ .

### Creation

```
Filter_iterator<Iterator, Predicate> i;
```

```
Filter_iterator<Iterator, Predicate> i( Iterator e, Predicate p, Iterator c = e);
```

creates an iterator which filters values according to *p*. Initializes by taking the first valid iterator (according to *p*), starting at *c*, and stopping at *e* if none is found.

There is also a global function to help the use of *Filter\_iterator*<*Iterator*, *Predicate*>:

```
template < class Iterator, class Predicate >
```

```
inline Filter_iterator< Iterator, Predicate >
```

```
filter_iterator( Iterator e, Predicate p, Iterator c = e)
```

Constructs *Filter\_iterator*<*Iterator*, *Predicate*>(e, p, c).

## CGAL::Join\_input\_iterator\_1<Iterator, Creator>

### Definition

The class *Join\_input\_iterator\_1*<*Iterator*, *Creator*> joins an iterator and a creator function object. The result is again an iterator (of the same iterator category type as the original iterator) that reads an object from the stream and applies a creator function object to that object.

```
#include <CGAL/iterator.h>
```

### Is Model for the Concepts

*InputIterator*

### Types

*Join\_input\_iterator\_1*<*Iterator*, *Creator*>::*value\_type*

typedef to *Creator*::*result\_type*.

### Creation

```
Join_input_iterator_1<Iterator, Creator> join( Iterator i, Creator creator);
```

creates a join iterator from the given iterator *i* and the functor *creator*. Applies *creator* to each item read from *i*.

```
Join_input_iterator_1<Iterator, Creator> join( Iterator i);
```

creates a join iterator from the given iterator *i* and a default constructed instance of *Creator*. The latter instance is applied to each item read from *i*.

### See Also

*CGAL::Creator\_1*<*Arg*, *Result*> ..... page [3387](#)

## CGAL::Inverse\_index<IC>

### Definition

The class *Inverse\_index*<IC> constructs an inverse index for a given range  $[i, j)$  of two iterators or circulators of type *IC*. The first element *I* in the range  $[i, j)$  has the index 0. Consecutive elements are numbered incrementally. The inverse index provides a query for a given iterator or circulator *k* to retrieve its index number. *Precondition*: The iterator or circulator must be either of the random access category or the dereference operator must return stable and distinguishable addresses for the values, e.g. proxies or non-modifiable iterator with opaque values will not work.

```
#include <CGAL/iterator.h>
```

### Creation

<i>Inverse_index</i> <IC> <i>inverse</i> ;	invalid index.
<i>Inverse_index</i> <IC> <i>inverse</i> ( <i>IC</i> <i>i</i> );	empty inverse index initialized to start at <i>i</i> .
<i>Inverse_index</i> <IC> <i>inverse</i> ( <i>IC</i> <i>i</i> , <i>IC</i> <i>j</i> );	inverse index initialized with range $[i, j)$ .

### Operations

<i>std::size_t</i> <i>inverse</i> [ <i>IC</i> <i>k</i> ]	returns inverse index of <i>k</i> . <i>Precondition</i> : <i>k</i> has been stored in the inverse index.
<i>void</i> <i>inverse.push_back</i> ( <i>IC</i> <i>k</i> )	adds <i>k</i> at the end of the indices.

### Implementation

For random access iterators or circulators, it is done in constant time by subtracting *i*. For other iterator categories, an STL *map* is used, which results in a  $\log j - i$  query time. The comparisons are done using the operator *operator<* on pointers.

### See Also

<i>CGAL::Random_access_adaptor</i> <IC> .....	page <a href="#">3369</a>
<i>CGAL::Random_access_value_adaptor</i> <IC,T> .....	page <a href="#">3370</a>

## CGAL::compare\_to\_less

### Definition

The function *compare\_to\_less* is used to change a functor returning a *Comparison\_result* to one which returns a *bool*. The returned functor will return *true* iff the original one returns *SMALLER*.

```
#include <CGAL/function_objects.h>
```

```
template < class F >
Compare_to_less< F >          compare_to_less( F f)
```

returns a functor equivalent to *f*, but which returns a *bool* instead of a *Comparison\_result*.

### See Also

*CGAL::Compare\_to\_less<F>* ..... page [3372](#)

The class *Compare\_to\_less* $\langle F \rangle$  is used to convert a functor which returns a *Comparison\_result* to a predicate (returning bool) : it will return true iff the return value of *F* is *SMALLER*. The class is used in conjunction with the *compare\_to\_less* function; see there for an explanation on how exactly the functors are combined.

## Types

<i>Compare_to_less</i> <F>:: Type	type of the composed functor.
-----------------------------------	-------------------------------

## CGAL::compare\_to\_less.....page 3371

# Projection\_object

## Definition

The concept `Projection_object` is modeled after the STL concept *UnaryFunction*, but takes also care of (const) references.

*Projection\_object:: argument\_type*                      argument type.

*Projection\_object:: result\_type*                      result type.

## Creation

*Projection\_object o;*                      default constructor.

## Operations

*result\_type&*                      *o.operator()( argument\_type &) const*  
*const result\_type&*                      *o.operator()( const argument\_type &) const*

## Has Models

## CGAL::Identity<Value>

### Definition

The class *Identity*<*Value*> represents the identity function on *Value*.

*#include* <*CGAL/function\_objects.h*>

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Identity*<*Value*>::*argument\_type*                      typedef to *Value*.

*Identity*<*Value*>::*result\_type*                      typedef to *Value*.

### Creation

*Identity*<*Value*> *o*;                                      default constructor.

### Operations

*result\_type*&                      *o.operator()*( *argument\_type*& *x*) *const*

returns *x*.

*const result\_type*&                      *o.operator()*( *const argument\_type*& *x*) *const*

returns *x*.

## CGAL::Dereference<Value>

### Definition

The class *Dereference*<Value> dereferences a pointer (*operator\**).

*#include* <CGAL/function\_objects.h>

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Dereference*<Value>::*argument\_type*                      typedef to *Value\**.

*Dereference*<Value>::*result\_type*                      typedef to *Value*.

### Creation

*Dereference*<Value> *o*;                                      default constructor.

### Operations

*result\_type*&                      *o.operator()*( *argument\_type*& *x*) *const*

returns *\*x*.

*const result\_type*&                      *o.operator()*( *const argument\_type*& *x*) *const*

returns *\*x*.

## CGAL::Get\_address<Value>

### Definition

The class *Get\_address<Value>* gets the address of an lvalue (*operator&*).

*#include <CGAL/function\_objects.h>*

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Get\_address<Value>:: argument\_type*                      typedef to *Value*.

*Get\_address<Value>:: result\_type*                      typedef to *Value\**.

### Creation

*Get\_address<Value> o;*                                      default constructor.

### Operations

*result\_type&*                      *o.operator()( argument\_type& x) const*

returns *&x*.

*const result\_type&*                      *o.operator()( const argument\_type& x) const*

returns *&x*.

## CGAL::Cast\_function\_object<Arg, Result>

### Definition

The class *Cast\_function\_object*<Arg, Result> applies a C-style type cast to its argument.

*#include* <CGAL/function\_objects.h>

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Cast\_function\_object*<Arg, Result>::*argument\_type*

typedef to Arg.

*Cast\_function\_object*<Arg, Result>::*result\_type*

typedef to Result.

### Creation

*Cast\_function\_object*<Arg, Result> o;                      default constructor.

### Operations

*result\_type*&                      o.operator()( *argument\_type*& x) const

returns (Result)x.

const *result\_type*&                      o.operator()( const *argument\_type*& x) const

returns (Result)x.

## CGAL::Project\_vertex<Node>

### Definition

The class *Project\_vertex<Node>* calls the member function *vertex()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_vertex<Node>:: argument\_type*                      typedef to *Node*.

*Project\_vertex<Node>:: result\_type*                      typedef to *Node::Vertex*.

### Creation

*Project\_vertex<Node> o;*                                      default constructor.

### Operations

*result\_type&*                      *o.operator()( argument\_type& n) const*

returns *n.vertex()*.

*const result\_type&*                      *o.operator()( const argument\_type& n) const*

returns *n.vertex()*.

## CGAL::Project\_facet<Node>

### Definition

The class *Project\_facet<Node>* calls the member function *facet()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_facet<Node>:: argument\_type*                      typedef to *Node*.

*Project\_facet<Node>:: result\_type*                      typedef to *Node::Facet*.

### Creation

*Project\_facet<Node> o;*                                      default constructor.

### Operations

*result\_type&*                      *o.operator()( argument\_type& n) const*

returns *n.facet()*.

*const result\_type&*                      *o.operator()( const argument\_type& n) const*

returns *n.facet()*.

## CGAL::Project\_point<Node>

### Definition

The class *Project\_point*<*Node*> calls the member function *point()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_point*<*Node*>::*argument\_type*                      typedef to *Node*.

*Project\_point*<*Node*>::*result\_type*                      typedef to *Node*::*Point*.

### Creation

*Project\_point*<*Node*> *o*;                                      default constructor.

### Operations

*result\_type*&                      *o.operator()( argument\_type& n) const*

returns *n.point()*.

*const result\_type*&                      *o.operator()( const argument\_type& n) const*

returns *n.point()*.

## CGAL::Project\_normal<Node>

### Definition

The class *Project\_normal*<Node> calls the member function *normal()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_normal*<Node>::*argument\_type*                      typedef to *Node*.

*Project\_normal*<Node>::*result\_type*                      typedef to *Node*::*Normal*.

### Creation

*Project\_normal*<Node> *o*;                                      default constructor.

### Operations

*result\_type*&                      *o.operator()( argument\_type& n) const*

returns *n.normal()*.

*const result\_type*&                      *o.operator()( const argument\_type& n) const*

returns *n.normal()*.

## CGAL::Project\_plane<Node>

### Definition

The class *Project\_plane<Node>* calls the member function *plane()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_plane<Node>:: argument\_type*                      typedef to *Node*.

*Project\_plane<Node>:: result\_type*                      typedef to *Node::Plane*.

### Creation

*Project\_plane<Node> o;*                                      default constructor.

### Operations

*result\_type&*                      *o.operator()( argument\_type& n) const*

returns *n.plane()*.

*const result\_type&*                      *o.operator()( const argument\_type& n) const*

returns *n.plane()*.

## CGAL::Project\_next<Node>

### Definition

The class *Project\_next<Node>* calls the member function *next()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_next<Node>:: argument\_type*                      typedef to *Node\**.

*Project\_next<Node>:: result\_type*                      typedef to *Node\**.

### Creation

*Project\_next<Node> o;*                      default constructor.

### Operations

*result\_type&*                      *o.operator()( argument\_type& n) const*

returns *n->next()*.

*const result\_type&*                      *o.operator()( const argument\_type& n) const*

returns *n->next()*.

## CGAL::Project\_prev<Node>

### Definition

The class *Project\_prev<Node>* calls the member function *prev()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_prev<Node>:: argument\_type*                      typedef to *Node\**.

*Project\_prev<Node>:: result\_type*                      typedef to *Node\**.

### Creation

*Project\_prev<Node> o;*                      default constructor.

### Operations

*result\_type&*                      *o.operator()( argument\_type& n) const*

returns *n->prev()*.

*const result\_type&*                      *o.operator()( const argument\_type& n) const*

returns *n->prev()*.

## CGAL::Project\_next\_opposite<Node>

### Definition

The class *Project\_next\_opposite<Node>* calls the member functions *next()*->*opposite()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_next\_opposite<Node>:: argument\_type*    typedef to *Node\**.

*Project\_next\_opposite<Node>:: result\_type*        typedef to *Node\**.

### Creation

*Project\_next\_opposite<Node>* *o*;                      default constructor.

### Operations

*result\_type&*                      *o.operator()( argument\_type& n) const*

returns *n->next()*->*opposite()*.

*const result\_type&*                *o.operator()( const argument\_type& n) const*

returns *n->next()*->*opposite()*.

## CGAL::Project\_opposite\_prev<Node>

### Definition

The class *Project\_opposite\_prev*<Node> calls the member functions *opposite()*->*prev()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

### Is Model for the Concepts

Projection\_object ..... page [3373](#)

*Project\_opposite\_prev*<Node>:: *argument\_type*

typedef to *Node*\*.

*Project\_opposite\_prev*<Node>:: *result\_type*

typedef to *Node*\*.

### Creation

*Project\_opposite\_prev*<Node> *o*;

default constructor.

### Operations

*result\_type*&            *o.operator()*( *argument\_type*& *n*) *const*

returns *n*->*opposite()*->*prev()*.

*const result\_type*&    *o.operator()*( *const argument\_type*& *n*) *const*

returns *n*->*opposite()*->*prev()*.

**CGAL::Creator\_1<Arg, Result>**

### Definition

The concept *Creator\_1* $\langle Arg, Result \rangle$  defines types and operations for creating objects from one argument.

```
#include <CGAL/function_objects.h>
```

## Requirements

*Arg* is convertible to *Result*.

*Creator\_1* $\langle Arg, Result \rangle :: argument\_type$       type of argument.

*Creator\_I*<Arg, Result>:: *result\_type*                      type of object to create.

*result\_type*      *c.operator()*( *argument\_type* *a*) *const*

returns *result\_type*(*a*).

## CGAL::Creator\_2<Arg1, Arg2, Result>

### Definition

The concept *Creator\_2<Arg1, Arg2, Result>* defines types and operations for creating objects from two arguments.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a corresponding constructor.

*Creator\_2<Arg1, Arg2, Result>:: argument1\_type*      type of first argument.

*Creator\_2<Arg1, Arg2, Result>:: argument2\_type*      type of second argument.

*Creator\_2<Arg1, Arg2, Result>:: result\_type*      type of object to create.

*result\_type*      *c.operator()( argument\_type1 a1, argument\_type2 a2) const*  
returns *result\_type(a1, a2)*.

## CGAL::Creator\_3<Arg1, Arg2, Arg3, Result>

### Definition

The concept *Creator\_3<Arg1, Arg2, Arg3, Result>* defines types and operations for creating objects from three arguments.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a corresponding constructor.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: argument1_type
```

type of first argument.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: argument2_type
```

type of second argument.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: argument3_type
```

type of third argument.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: result_type
```

type of object to create.

```
result_type    c.operator()( argument_type1 a1, argument_type2 a2, argument_type3 a3) const
```

returns *result\_type(a1, a2, a3)*.

## CGAL::Creator\_4<Arg1, Arg2, Arg3, Arg4, Result>

### Definition

The concept *Creator\_4<Arg1, Arg2, Arg3, Arg4, Result>* defines types and operations for creating objects from four arguments.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a corresponding constructor.

*Creator\_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument1\_type*  
type of first argument.

*Creator\_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument2\_type*  
type of second argument.

*Creator\_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument3\_type*  
type of third argument.

*Creator\_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument4\_type*  
type of 4th argument.

*Creator\_4<Arg1, Arg2, Arg3, Arg4, Result>:: result\_type*  
type of object to create.

```
result_type    c.operator()(
                argument_type1 a1,
                argument_type2 a2,
                argument_type3 a3,
                argument_type4 a4) const
```

returns *result\_type(a1, a2, a3, a4)*.

## CGAL::Creator\_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>

### Definition

The concept *Creator\_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>* defines types and operations for creating objects from five arguments.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a corresponding constructor.

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument1_type  
                                     type of first argument.
```

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument2_type  
                                     type of second argument.
```

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument3_type  
                                     type of third argument.
```

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument4_type  
                                     type of 4th argument.
```

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument5_type  
                                     type of 5th argument.
```

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: result_type  
                                     type of object to create.
```

```
result_type    c.operator()(  
                    argument_type1 a1,  
                    argument_type2 a2,  
                    argument_type3 a3,  
                    argument_type4 a4,  
                    argument_type5 a5) const  
                                     returns result_type(a1, a2, a3, a4, a5).
```

## CGAL::Creator\_uniform\_2<Arg, Result>

### Definition

The concept *Creator\_uniform\_2*<Arg, Result> defines types and operations for creating objects from two arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from two *Arg* arguments.

*Creator\_uniform\_2*<Arg, Result>:: *argument\_type*

type of arguments; typedef to *Arg*.

*Creator\_uniform\_2*<Arg, Result>:: *result\_type*      type of object to create; typedef to *Result*.

*result\_type*      *c.operator()( argument\_type a1, argument\_type a2) const*

returns *result\_type(a1, a2)*.

## CGAL::Creator\_uniform\_3<Arg, Result>

### Definition

The concept *Creator\_uniform\_3*<Arg, Result> defines types and operations for creating objects from three arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from three *Arg* arguments.

*Creator\_uniform\_3*<Arg, Result>:: *argument\_type*

type of arguments; typedef to *Arg*.

*Creator\_uniform\_3*<Arg, Result>:: *result\_type*      type of object to create; typedef to *Result*.

*result\_type*      *c.operator()( argument\_type a1, argument\_type a2, argument\_type a3) const*

returns *result\_type(a1, a2, a3)*.

## CGAL::Creator\_uniform\_4<Arg, Result>

### Definition

The concept *Creator\_uniform\_4<Arg, Result>* defines types and operations for creating objects from four arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from four *Arg* arguments.

*Creator\_uniform\_4<Arg, Result>:: argument\_type*

type of arguments; typedef to *Arg*.

*Creator\_uniform\_4<Arg, Result>:: result\_type*      type of object to create; typedef to *Result*.

```
result_type      c.operator()(
                    argument_type a1,
                    argument_type a2,
                    argument_type a3,
                    argument_type a4) const
```

returns *result\_type(a1, a2, a3, a4)*.

## CGAL::Creator\_uniform\_5<Arg, Result>

### Definition

The concept *Creator\_uniform\_5<Arg, Result>* defines types and operations for creating objects from five arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from five *Arg* arguments.

```
Creator_uniform_5<Arg, Result>:: argument_type
                                type of arguments; typedef to Arg.
```

```
Creator_uniform_5<Arg, Result>:: result_type    type of object to create; typedef to Result.
```

```
result_type    c.operator()(
                argument_type a1,
                argument_type a2,
                argument_type a3,
                argument_type a4,
                argument_type a5) const
                                returns result_type(a1, a2, a3, a4, a5).
```

## CGAL::Creator\_uniform\_6<Arg, Result>

### Definition

The concept *Creator\_uniform\_6<Arg, Result>* defines types and operations for creating objects from six arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from six *Arg* arguments.

*Creator\_uniform\_6<Arg, Result>:: argument\_type*

type of arguments; typedef to *Arg*.

*Creator\_uniform\_6<Arg, Result>:: result\_type*      type of object to create; typedef to *Result*.

```
result_type      c.operator()(
                    argument_type a1,
                    argument_type a2,
                    argument_type a3,
                    argument_type a4,
                    argument_type a5,
                    argument_type a6) const
```

returns *result\_type(a1, a2, a3, a4, a5, a6)*.

## CGAL::Creator\_uniform\_7<Arg, Result>

### Definition

The concept *Creator\_uniform\_7*<Arg, Result> defines types and operations for creating objects from seven arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from seven *Arg* arguments.

```
Creator_uniform_7<Arg, Result>:: argument_type
                                     type of arguments; typedef to Arg.
```

```
Creator_uniform_7<Arg, Result>:: result_type  type of object to create; typedef to Result.
```

```
result_type  c.operator()(
               argument_type a1,
               argument_type a2,
               argument_type a3,
               argument_type a4,
               argument_type a5,
               argument_type a6,
               argument_type a7) const
                                     returns result_type(a1, a2, a3, a4, a5, a6, a7).
```

## CGAL::Creator\_uniform\_8<Arg, Result>

### Definition

The concept *Creator\_uniform\_8<Arg, Result>* defines types and operations for creating objects from eight arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from eight *Arg* arguments.

*Creator\_uniform\_8<Arg, Result>:: argument\_type*

type of arguments; typedef to *Arg*.

*Creator\_uniform\_8<Arg, Result>:: result\_type*      type of object to create; typedef to *Result*.

```
result_type      c.operator()(
    argument_type a1,
    argument_type a2,
    argument_type a3,
    argument_type a4,
    argument_type a5,
    argument_type a6,
    argument_type a7,
    argument_type a8) const
```

returns *result\_type(a1, a2, a3, a4, a5, a6, a7, a8)*.

## CGAL::Creator\_uniform\_9<Arg, Result>

### Definition

The concept *Creator\_uniform\_9<Arg, Result>* defines types and operations for creating objects from nine arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from nine *Arg* arguments.

*Creator\_uniform\_9<Arg, Result>:: argument\_type*

type of arguments; typedef to *Arg*.

*Creator\_uniform\_9<Arg, Result>:: result\_type*      type of object to create; typedef to *Result*.

```
result_type      c.operator()(
                    argument_type a1,
                    argument_type a2,
                    argument_type a3,
                    argument_type a4,
                    argument_type a5,
                    argument_type a6,
                    argument_type a7,
                    argument_type a8,
                    argument_type a9) const
```

returns *result\_type(a1, a2, a3, a4, a5, a6, a7, a8, a9)*.

## CGAL::Creator\_uniform\_d<Arg, Result>

### Definition

The concept *Creator\_uniform\_d*<*Arg*, *Result*> defines types and operations for creating objects from two arguments of the same type.

```
#include <CGAL/function_objects.h>
```

### Requirements

*Result* defines a constructor from three arguments: one *d* dimension and two *Arg* arguments.

*Creator\_uniform\_d*<*Arg*, *Result*>:: *argument\_type*

type of arguments; typedef to *Arg*.

*Creator\_uniform\_d*<*Arg*, *Result*>:: *result\_type*      type of object to create; typedef to *Result*.

*result\_type*      *c.operator()*( *argument\_type* *a1*, *argument\_type* *a2*) *const*

returns *result\_type*(*d*, *a1*, *a2*).

## CGAL::Twotuple<T>

### Definition

The *Twotuple*<*T*> class stores a homogeneous (same type) pair of objects of type *T*. A *Twotuple*<*T*> is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is DEPRECATED, and will be removed in some future CGAL release. Please use *CGAL::array* instead.

```
#include <CGAL/Twotuple.h>
```

### Requirements

*T* must be *Assignable*.

### Types

```
typedef T      value_type;
```

### Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element

### Creation

<i>Twotuple</i> < <i>T</i> > <i>t</i> ;	introduces a <i>Twotuple</i> < <i>T</i> > using the default constructor of the elements.
---	--

<i>Twotuple</i> < <i>T</i> > <i>t</i> ( <i>T</i> <i>x</i> , <i>T</i> <i>y</i> );	constructs a <i>Twotuple</i> < <i>T</i> > such that <i>e0</i> is constructed from <i>x</i> and <i>e1</i> is constructed from <i>y</i> .
--	---

## CGAL::Threetuple<T>

### Definition

The *Threetuple*<*T*> class stores a homogeneous (same type) triple of objects of type *T*. A *Threetuple*<*T*> is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is DEPRECATED, and will be removed in some future CGAL release. Please use *CGAL::array* instead.

```
#include <CGAL/Threetuple.h>
```

### Requirements

*T* must be *Assignable*.

### Types

```
typedef T      value_type;
```

### Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element
<i>T</i>	<i>e2</i> ;	third element

### Creation

<i>Threetuple</i> < <i>T</i> > <i>t</i> ;	introduces a <i>Threetuple</i> < <i>T</i> > using the default constructor of the elements.
---	--

<i>Threetuple</i> < <i>T</i> > <i>t</i> ( <i>T</i> <i>x</i> , <i>T</i> <i>y</i> , <i>T</i> <i>z</i> );	constructs a <i>Threetuple</i> < <i>T</i> > such that <i>e0</i> is constructed from <i>x</i> , <i>e1</i> is constructed from <i>y</i> and <i>e2</i> is constructed from <i>z</i> .
--	--

## CGAL::Fourtuple<T>

### Definition

The *Fourtuple<T>* class stores a homogeneous (same type) fourtuple of objects of type *T*. A *Fourtuple<T>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is DEPRECATED, and will be removed in some future CGAL release. Please use *CGAL::array* instead.

```
#include <CGAL/Fourtuple.h>
```

### Requirements

*T* must be *Assignable*.

### Types

```
typedef T      value_type;
```

### Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element
<i>T</i>	<i>e2</i> ;	third element
<i>T</i>	<i>e3</i> ;	fourth element

### Creation

<i>Fourtuple&lt;T&gt;</i> <i>t</i> ;	introduces a <i>Fourtuple&lt;T&gt;</i> using the default constructor of the elements.
--------------------------------------	---

<i>Fourtuple&lt;T&gt;</i> <i>t</i> ( <i>T</i> <i>x</i> , <i>T</i> <i>y</i> , <i>T</i> <i>z</i> , <i>T</i> <i>t</i> );	constructs a <i>Fourtuple&lt;T&gt;</i> such that <i>e0</i> is constructed from <i>x</i> , <i>e1</i> from <i>y</i> , <i>e2</i> from <i>z</i> and <i>e3</i> from <i>t</i> .
---	---

## CGAL::Sextuple<T>

### Definition

The *Sextuple*<*T*> class stores a homogeneous (same type) sextuple of objects of type *T*. A *Sextuple*<*T*> is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is DEPRECATED, and will be removed in some future CGAL release. Please use *CGAL::array* instead.

```
#include <CGAL/Sextuple.h>
```

### Requirements

*T* must be *Assignable*.

### Types

```
typedef T      value_type;
```

### Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element
<i>T</i>	<i>e2</i> ;	third element
<i>T</i>	<i>e3</i> ;	fourth element
<i>T</i>	<i>e4</i> ;	fifth element
<i>T</i>	<i>e5</i> ;	sixth element

### Creation

<i>Sextuple</i> < <i>T</i> > <i>t</i> ;	introduces a <i>Sextuple</i> < <i>T</i> > using the default constructor of the elements.
---	--

<i>Sextuple</i> < <i>T</i> > <i>t</i> ( <i>T</i> <i>x</i> , <i>T</i> <i>y</i> , <i>T</i> <i>z</i> , <i>T</i> <i>t</i> , <i>T</i> <i>u</i> , <i>T</i> <i>v</i> );	constructs a <i>Sextuple</i> < <i>T</i> > such that <i>e0</i> is constructed from <i>x</i> , <i>e1</i> from <i>y</i> , <i>e2</i> from <i>z</i> , <i>e3</i> from <i>t</i> , <i>e4</i> from <i>u</i> and <i>e5</i> from <i>v</i> .
--	--

## CGAL::Triple<T1, T2, T3>

### Definition

The Triple class is an extension of *std::pair*. *Triple<T1, T2, T3>* is a heterogeneous triple: it holds one object of type *T1*, one of type *T2*, and one of type *T3*. A *Triple<T1, T2, T3>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is NOT RECOMMENDED anymore. We recommend that you use *boost::tuple* or *CGAL::array* instead for new uses.

```
#include <CGAL/utility.h>
```

### Requirements

*T1*, *T2* and *T3* must be *Assignable*. Additional operations have additional requirements.

### Types

```
typedef T1      first_type;
typedef T2      second_type;
typedef T3      third_type;
```

### Variables

<i>T1</i>	<i>first</i> ;	first element. Please access it using <i>get&lt;0&gt;()</i> .
<i>T2</i>	<i>second</i> ;	second element. Please access it using <i>get&lt;1&gt;()</i> .
<i>T3</i>	<i>third</i> ;	third element. Please access it using <i>get&lt;2&gt;()</i> .

### Creation

*Triple<T1, T2, T3> t*;

introduces a triple using the default constructor of the three elements.

*Triple<T1, T2, T3> t( T1 x, T2 y, T3 z);*

constructs a triple such that *first* is constructed from *x*, *second* is constructed from *y*, and *third* is constructed from *z*.

*template <class U, class V, class W>*  
*Triple<T1, T2, T3> t( U u, V v, W w);*

constructs a triple such that *first* is constructed from *u*, *second* is constructed from *v*, and *third* is constructed from *w*.  
*Requirement:* Proper conversion operators exist from *U* to *T1*, *V* to *T2*, and *W* to *T3*.

*template <int i>*  
*T* *t.get()*

Gives access to *first*, *second* or *third* whenever *i* is 0, 1 or 2, via a, potentially const, reference. Note: *T* stands for *T1*, *T2* or *T3* depending on *i*.

```
template <class T1, class T2, class T3>
bool      x < y
```

The comparison operator. It uses lexicographic comparison: the return value is true if the first element of  $x$  is less than the first element of  $y$ , and false if the first element of  $y$  is less than the first element of  $x$ . If neither of these is the case, then it returns true if the second element of  $x$  is less than the second element of  $y$ , and false if the second element of  $y$  is less than the second element of  $x$ . If neither of these is the case, then it returns the result of comparing the third elements of  $x$  and  $y$ . This operator may only be used if  $T1$ ,  $T2$  and  $T3$  define the comparison operator.

```
template <class T1, class T2, class T3>
bool      x == y
```

The equality operator. The return value is true if and only the first elements of  $x$  and  $y$  are equal, the second elements of  $x$  and  $y$  are equal, and the third elements of  $x$  and  $y$  are equal. This operator may only be used if  $T1$ ,  $T2$  and  $T3$  define the equality operator.

```
template <class T1, class T2, class T3>
Triple<T1, T2, T3>
```

```
make_triple( T1 x, T2 y, T3 z)
```

Equivalent to  $\text{Triple}<T1, T2, T3>(x, y, z)$ .

```
template <class T1, class T2, class T3>
Triple<T1, T2, T3>
```

```
make_tuple( T1 x, T2 y, T3 z)
```

Equivalent to  $\text{Triple}<T1, T2, T3>(x, y, z)$ .

## CGAL::Quadruple<T1, T2, T3, T4>

### Definition

The Quadruple class is an extension of *std::pair*. *Quadruple<T1, T2, T3, T4>* is a heterogeneous quadruple: it holds one object of type *T1*, one of type *T2*, one of type *T3*, and one of type *T4*. A *Quadruple<T1, T2, T3, T4>* is much like a container, in that it “owns” its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

This class is NOT RECOMMENDED anymore. We recommend that you use *boost::tuple* or *CGAL::array* instead for new uses.

```
#include <CGAL/utility.h>
```

### Requirements

*T1*, *T2*, *T3* and *T4* must be *Assignable*. Additional operations have additional requirements.

### Types

```
typedef T1    first_type;
typedef T2    second_type;
typedef T3    third_type;
typedef T4    fourth_type;
```

### Variables

<i>T1</i>	<i>first</i> ;	first element. Please access it using <i>get&lt;0&gt;()</i> .
<i>T2</i>	<i>second</i> ;	second element. Please access it using <i>get&lt;1&gt;()</i> .
<i>T3</i>	<i>third</i> ;	third element. Please access it using <i>get&lt;2&gt;()</i> .
<i>T4</i>	<i>fourth</i> ;	fourth element. Please access it using <i>get&lt;3&gt;()</i> .

### Creation

*Quadruple<T1, T2, T3, T4>* *t*;

introduces a quadruple using the default constructor of the four elements.

*Quadruple<T1, T2, T3, T4>* *t*( *T1* *x*, *T2* *y*, *T3* *z*, *T4* *w*);

constructs a quadruple such that *first* is constructed from *x*, *second* is constructed from *y*, *third* is constructed from *z*, and *fourth* is constructed from *w*.

```
template <class U, class V, class W, class X>
Quadruple<T1, T2, T3, T4> t( U u, V v, W w, X x);
```

constructs a quadruple such that *first* is constructed from *u*, *second* is constructed from *v*, *third* is constructed from *w*, and *fourth* is constructed from *x*.

*Requirement:* Proper conversion operators exist from *U* to *T1*, *V* to *T2*, *W* to *T3*, and *X* to *T4*.

```
template <int i>
T t.get()
```

Gives access to *first*, *second*, *third* or *fourth* whenever *i* is 0, 1, 2 or 3, via a, potentially const, reference. Note: *T* stands for *T1*, *T2*, *T3* or *T4* depending on *i*.

```
template <class T1, class T2, class T3, class T4>
bool x < y
```

The comparison operator. It uses lexicographic comparison: the return value is true if the first element of *x* is less than the first element of *y*, and false if the first element of *y* is less than the first element of *x*. If neither of these is the case, then it returns true if the second element of *x* is less than the second element of *y*, and false if the second element of *y* is less than the second element of *x*. If neither of these is the case, then it returns true if the third element of *x* is less than the third element of *y*, and false if the third element of *y* is less than the third element of *x*. If neither of these is the case, then it returns the result of comparing the fourth elements of *x* and *y*. This operator may only be used if *T1*, *T2*, *T3*, and *T4* define the comparison operator.

```
template <class T1, class T2, class T3, class T4>
bool x == y
```

The equality operator. The return value is true if and only the first elements of *x* and *y* are equal, the second elements of *x* and *y* are equal, the third elements of *x* and *y* are equal, and the fourth elements of *x* and *y* are equal. This operator may only be used if *T1*, *T2*, *T3*, and *T4* define the equality operator.

```
template <class T1, class T2, class T3, class T4>
Quadruple<T1, T2, T3, T4>
```

```
make_quadruple( T1 x, T2 y, T3 z, T4 w)
```

Equivalent to *Quadruple*<*T1*, *T2*, *T3*, *T4*>(*x*, *y*, *z*, *w*).

```
template <class T1, class T2, class T3, class T4>
Quadruple<T1, T2, T3, T4>
```

```
make_tuple( T1 x, T2 y, T3 z, T4 w)
```

Equivalent to *Quadruple*<*T1*, *T2*, *T3*, *T4*>(*x*, *y*, *z*, *w*).

## CGAL::Boolean\_tag<bool value>

### Definition

Depending on *bool value* the class *Boolean\_tag<bool value>* indicates that something is *true* or *false* respectively.

```
#include <CGAL/tags.h>
```

### Constants

```
static const bool      value;
```

### See Also

*CGAL::Tag\_true* ..... [page 3410](#)  
*CGAL::Tag\_false* ..... [page 3411](#)

## CGAL::Tag\_true

### Definition

The typedef *Tag\_true* is *Boolean\_tag<true>*. It is used to indicate, for example, that a certain feature is available in a class.

```
#include <CGAL/tags.h>
```

```
static const bool      value;           is true
```

### See Also

*CGAL::Boolean\_tag<bool value>* ..... page [3409](#)  
*CGAL::Tag\_false* ..... page [3411](#)

## CGAL::Tag\_false

### Definition

The typedef *Tag\_false* is *Boolean\_tag<false>*. It is used to indicate, for example, that a certain feature is not available in a class.

```
#include <CGAL/tags.h>
```

```
static const bool      value;           is false
```

### See Also

*CGAL::Boolean\_tag<bool value>* ..... page [3409](#)  
*CGAL::Tag\_true* ..... page [3410](#)

## CGAL::Null\_functor

### Definition

Class indicating the absence of a functor.

### Is Model for the Concepts

*DefaultConstructible*

## CGAL::Uncertain<T>

### Definition

An object of the class *Uncertain<T>* represents an uncertainty on the value of type *T*. This uncertainty is represented by a non-empty range of values of type *T*.

The idea is that sometimes you are not sure of the result of a function, and you would like to communicate that to the caller. *Uncertain<T>* allows just that.

*Uncertain<T>* is also meant to be used as a drop-in replacement for *T* in some template contexts, as much as possible. This is why it provides overloaded operators and functions to naturally extend the Boolean operations for *Uncertain<bool>* for example, or the operations on enumeration types.

*Uncertain<T>* is used in CGAL as the return type of geometric predicates when the number type used is interval arithmetic like *Interval\_nt*. End users typically do not see it, as it is hidden in the implementation of the filtered predicates provided by the various filtered kernels, but it is important that providers of predicates that are meant to be filtered by *Filtered\_predicate*, know about it.

Note concerning CGAL assertions: assertions checking an expression of type *Uncertain<bool>* will trigger an assertion failure only if the assertion is certainly *false*. In case of an indeterminate value, the assertion is not triggered. This means that we assume, in case of doubt, that there is no error.

It can also be used in other contexts as well, as it is a general tool. This can be seen as support for non-deterministic programming. Finally, note that this class has some common points with *boost::tribool*.

```
#include <CGAL/Uncertain.h>
```

### Parameters

The parameter *T* can either be *bool* or one of the three-valued (-1, 0, 1) enumeration types: *Sign*, *Comparison\_result*, *Orientation*, *Oriented\_side*, *Bounded\_side* or *Angle*.

Some functions are defined only when *T* is *bool* or alternatively when it is one of the enumeration types listed previously.

### Types

*Uncertain<T>::value\_type*                      The type *T*.

*Uncertain<T>::Uncertain\_conversion\_exception*

The type of the exception thrown for uncertain conversions. It is a typedef to the type *CGAL::Uncertain\_conversion\_exception* which derives from *std::range\_error*.

### Creation

*Uncertain<T> u;*                                      introduces a certain object with value *T()*.

<i>Uncertain</i> < <i>T</i> > <i>u</i> ( <i>T t</i> );	introduces a certain object with value <i>t</i> .
<i>Uncertain</i> & <i>u</i> = <i>T t</i>	assigns the certain value <i>t</i> to <i>u</i> .
<i>Uncertain</i> < <i>T</i> > <i>u</i> ( <i>T i</i> , <i>T s</i> );	introduces an object representing the range with lower bound <i>i</i> and upper bound <i>s</i> . <i>Precondition</i> : <i>i</i> <= <i>s</i> .

## Access Functions

The following functions are meant to be used very rarely, they provide ways to inspect the content of an *Uncertain*<*T*> object.

<i>T</i>	<i>u.inf()</i>	returns the lower bound of the range represented by <i>u</i> .
<i>T</i>	<i>u.sup()</i>	returns the upper bound of the range represented by <i>u</i> .
<i>bool</i>	<i>u.is_same( Uncertain u )</i>	returns true whether <i>u</i> and <i>u</i> are the same range (equality as sets).

## Uncertainty testing and conversion

There are several ways to extract the content of an *Uncertain* object. The simplest way is to rely on the implicit conversion from *Uncertain*<*T*> to *T*. In this case, no special code has to be written, apart from an exception handler (anywhere higher in the call stack) to manage the uncertain case. The more involved one is more efficient, but requires manual treatment of the uncertain case, such as:

```
Uncertain<bool> b = ...;
if (is_certain(b))
    bool cert_b = get_certain(b); // Extract the certain bool it contains
...
else
    ... // b is indeterminate
```

Another option is :

```
Uncertain<bool> b = ...;
if (certainly(b))
    ... // b is certainly true
else if (certainly_not(b))
    ... // b is certainly false
else
    ... // b is indeterminate
```

There are many other handy functions which can be used for easier usage depending on the context. They are listed in the sequel.

<i>bool</i>	<i>u.is_certain()</i>	returns <i>true</i> iff the value is certain, that is, it is unique, the range is a singleton. That is, <i>u.inf()</i> == <i>u.sup()</i> .
-------------	-----------------------	--

<i>T</i>	<i>u.make_certain()</i>	if <i>u.is_certain()</i> , then returns the certain value which is represented. Otherwise, throws an exception of type <i>Uncertain_conversion_exception</i> . A profile counter of the number of such exceptions thrown during the execution of the program is available with <i>CGAL_PROFILE</i> .
<i>T</i>	<i>T(u)</i>	conversion operator to <i>T</i> . It does and returns the same thing as <i>u.make_certain()</i> . Note that relying on the automatic conversion can throw exceptions, which defeats the purpose of propagating uncertainty. Nevertheless, in many cases, it is hard to avoid it, for example for the <code>&amp;&amp;</code> and <code>  </code> operators for <i>bool</i> (see below).

### Static member function

*static Uncertain<T>    Uncertain<T>::indeterminate()*  
returns an indeterminate range.

### Free functions

<i>template &lt;class T&gt;</i> <i>T</i>	<i>inf( Uncertain&lt;T&gt; u)</i>	returns <i>u.inf()</i> .
<i>template &lt;class T&gt;</i> <i>T</i>	<i>sup( Uncertain&lt;T&gt; u)</i>	returns <i>u.sup()</i> .
<i>template &lt;class T&gt;</i> <i>bool</i>	<i>is_certain( T t)</i>	returns <i>true</i> .
<i>template &lt;class T&gt;</i> <i>bool</i>	<i>is_certain( Uncertain&lt;T&gt; u)</i>	returns <i>u.is_certain()</i> .
<i>template &lt;class U&gt;</i> <i>U</i>	<i>indeterminate()</i>	returns <i>U::indeterminate()</i> if <i>U</i> is <i>Uncertain&lt;T&gt;</i> , and <i>U()</i> otherwise.
<i>template &lt;class T&gt;</i> <i>bool</i>	<i>is_indeterminate( T u)</i>	returns <i>false</i> .
<i>template &lt;class T&gt;</i> <i>bool</i>	<i>is_indeterminate( Uncertain&lt;T&gt; u)</i>	returns <i>!is_certain(u)</i> .

*template <class T>*

<i>T</i>	<i>get_certain( T t)</i>	returns <i>t</i> .
<i>template &lt;class T&gt;</i> <i>T</i>	<i>get_certain( Uncertain&lt;T&gt; u)</i>	returns <i>u.make_certain()</i> . Precondition: <i>u.is_certain()</i> .
<i>template &lt;class T&gt;</i> <i>T</i>	<i>make_certain( T t)</i>	returns <i>t</i> .
<i>template &lt;class T&gt;</i> <i>T</i>	<i>make_certain( Uncertain&lt;T&gt; u)</i>	returns <i>u.make_certain()</i> .
<i>template &lt;class T&gt;</i> <i>Uncertain&lt;T&gt;</i>	<i>make_uncertain( T t)</i>	returns <i>Uncertain&lt;T&gt;(u)</i> .
<i>template &lt;class T&gt;</i> <i>Uncertain&lt;T&gt;</i>	<i>make_uncertain( Uncertain&lt;T&gt; u)</i>	returns <i>u</i> .

## Overloaded operators

The overloaded operators and functions are defined as preserving the set-inclusion property. Similarly to interval arithmetic, the returned range is guaranteed to contain the result of the operation over all values of the input range(s). In the following documentation we express this as the extension of the corresponding function over the type *T*.

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u == Uncertain&lt;T&gt; v</i>	returns the extension of the equality operator over <i>u</i> and <i>v</i> .
---	---	---

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u == T v</i>	returns <i>u == make_uncertain(v)</i> .
---	------------------------------------	---

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>T u == Uncertain&lt;T&gt; v</i>	returns <i>v == u</i> .
---	------------------------------------	-------------------------

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u != Uncertain&lt;T&gt; v</i>	returns the extension of the inequality operator over <i>u</i> and <i>v</i> .
---	---	---

*template <class T>*

*Uncertain<bool>*      *Uncertain<T> u != T v*      returns *u != make\_uncertain(v)*.

*template <class T>*

*Uncertain<bool>*      *T u != Uncertain<T> v*      returns *v != u*.

### **Overloaded operators for *Uncertain<bool>* only**

*Uncertain<bool>*      *!Uncertain<bool> u*      returns the range containing the negated values of *u*.

*Uncertain<bool>*      *Uncertain<bool> u | Uncertain<bool> v*  
returns the range containing the values computed as logical or from *u* and *v*.

*Uncertain<bool>*      *Uncertain<bool> u | bool v*  
returns *u — make\_uncertain(v)*.

*Uncertain<bool>*      *bool u | Uncertain<bool> v*  
returns *v — u*.

*Uncertain<bool>*      *Uncertain<bool> u & Uncertain<bool> v*  
returns the range containing the values computed as logical and from *u* and *v*.

*Uncertain<bool>*      *Uncertain<bool> u & bool v*  
returns *u & make\_uncertain(v)*.

*Uncertain<bool>*      *bool u & Uncertain<bool> v*  
returns *v & u*.

Note : the logical operators `&&` and `||` are not overloaded on purpose. The reason is that, when *f()* `&&` *g()* is evaluated and they return *bool*, then *g()* is only evaluated when *f()* returns *true*. One could have a dependency so that *g()* has an internal precondition that required that *f()* had returned *true*. The overloaded operators for user-defined types can not provide this short-circuiting property, and so, if the overloaded operators were provided, then *g()* would be evaluated, no matter the result of *f()*, which could lead to an unwanted situation, or a performance loss. The `&` and `|` operators do not have this short-circuiting property, and are therefore overloaded safely.

When translating normal code to use and propagate uncertainty, such as :

```

// Logical AND
if ( (p.x() == 0) && (p.y() == 0) )
    ...
else
    ...

// Logical OR
if ( (q.x() == 0) || (q.y() == 0) )
    ...
else
    ...

```

One can do, for example :

```

// Logical AND
Uncertain<bool> tmp = (p.x() == 0);
Uncertain<bool> res = certainly_not(tmp) ? make_uncertain(false) : tmp & (p.y() == 0);

... // Use res

// Logical OR
Uncertain<bool> tmp = (q.x() == 0);
Uncertain<bool> res = certainly(tmp) ? make_uncertain(true) : tmp | (q.y() == 0);

... // Use res

```

This ensures that the first expression is not evaluated twice, and that the second is evaluated only if needed.

This behavior can also be emulated through the use of macros, but only using non-standard features ("statement expressions", such as provided by GCC). The macros *CGAL\_AND* and *CGAL\_OR* are provided that perform the lazy evaluation of these logical operations. On compilers that do not support statement expressions, the macros simply expand to the *&&* and *||* operators (which will throw an exception instead of propagating the uncertainty).

```

// Logical AND
Uncertain<bool> res = CGAL_AND( p.x() == 0 , p.y() == 0 );

... // Use res

// Logical OR
Uncertain<bool> res = CGAL_OR( q.x() == 0 , q.y() == 0 );

... // Use res

```

For convenience, the macros *CGAL\_AND\_3* and *CGAL\_OR\_3* are also provided to support boolean operations with 3 arguments instead of 2.

### Overloaded operators and functions for *Uncertain<enum T>* only

*template <class T>*

<i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &lt; Uncertain&lt;T&gt; v</i>	
		returns the extension of the less-than operator over <i>u</i> and <i>v</i> .

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &lt; T v</i>	returns <i>u &lt; make_uncertain(v)</i> .
---	--------------------------------------	---

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>T u &lt; Uncertain&lt;T&gt; v</i>	returns <i>make_uncertain(u) &lt; v</i> .
---	--------------------------------------	---

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &gt; Uncertain&lt;T&gt; v</i>	
		returns the extension of the greater-than operator over <i>u</i> and <i>v</i> .

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &gt; T v</i>	returns <i>u &gt; make_uncertain(v)</i> .
---	--------------------------------------	---

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>T u &gt; Uncertain&lt;T&gt; v</i>	returns <i>make_uncertain(u) &gt; v</i> .
---	--------------------------------------	---

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &lt;= Uncertain&lt;T&gt; v</i>	
		returns the extension of the less-than or equal operator over <i>u</i> and <i>v</i> .

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &lt;= T v</i>	returns <i>u &lt;= make_uncertain(v)</i> .
---	---------------------------------------	--

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>T u &lt;= Uncertain&lt;T&gt; v</i>	returns <i>make_uncertain(u) &lt;= v</i> .
---	---------------------------------------	--

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &gt;= Uncertain&lt;T&gt; v</i>	
		returns the extension of the greater-than or equal operator over <i>u</i> and <i>v</i> .

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>Uncertain&lt;T&gt; u &gt;= T v</i>	returns <i>u &gt;= make_uncertain(v)</i> .
---	---------------------------------------	--

<i>template &lt;class T&gt;</i> <i>Uncertain&lt;bool&gt;</i>	<i>T u &gt;= Uncertain&lt;T&gt; v</i>	returns <i>make_uncertain(u) &gt;= v</i> .
---	---------------------------------------	--

*template <class T>*

<i>Uncertain</i> < <i>T</i> >	<i>Uncertain</i> < <i>T</i> > <i>u</i> * <i>Uncertain</i> < <i>T</i> > <i>v</i>	returns the extension of the multiplication operator over <i>u</i> and <i>v</i> . This requires <i>T</i> to have a multiplication operator as well.
<i>template</i> < <i>class T</i> > <i>Uncertain</i> < <i>T</i> >	<i>Uncertain</i> < <i>T</i> > <i>u</i> * <i>T v</i>	returns <i>u</i> * <i>make_uncertain(v)</i> .
<i>template</i> < <i>class T</i> > <i>Uncertain</i> < <i>T</i> >	<i>T u</i> < <i>Uncertain</i> < <i>T</i> > <i>v</i>	returns <i>make_uncertain(u)</i> * <i>v</i> .
<i>template</i> < <i>class T</i> > <i>Uncertain</i> < <i>T</i> >	- <i>Uncertain</i> < <i>T</i> > <i>u</i>	returns the extension of the unary minus operator over <i>u</i> .
<i>template</i> < <i>class T, class U</i> > <i>Uncertain</i> < <i>T</i> >	<i>enum_cast</i> ( <i>Uncertain</i> < <i>U</i> > <i>u</i> )	returns the extension of the <i>enum_cast</i> < <i>T</i> > function over <i>u</i> .

#### Other free functions for *Uncertain*<*bool*>

<i>bool</i>	<i>certainly</i> ( <i>Uncertain</i> < <i>bool</i> > <i>u</i> )	returns <i>true</i> iff <i>u.is_certain()</i> , and the <i>u.make_certain()</i> returns <i>true</i> .
<i>bool</i>	<i>certainly</i> ( <i>bool u</i> )	returns <i>u</i> .
<i>bool</i>	<i>possibly</i> ( <i>Uncertain</i> < <i>bool</i> > <i>u</i> )	returns <i>true</i> iff <i>u.is_certain()</i> returns <i>false</i> , or if <i>u.make_certain()</i> returns <i>true</i> .
<i>bool</i>	<i>possibly</i> ( <i>bool u</i> )	returns <i>u</i> .
<i>bool</i>	<i>certainly_not</i> ( <i>Uncertain</i> < <i>bool</i> > <i>u</i> )	returns <i>true</i> iff <i>u.is_certain()</i> , and the <i>u.make_certain()</i> returns <i>false</i> .
<i>bool</i>	<i>certainly_not</i> ( <i>bool u</i> )	returns <i>!u</i> .
<i>bool</i>	<i>possibly_not</i> ( <i>Uncertain</i> < <i>bool</i> > <i>u</i> )	returns <i>true</i> iff <i>u.is_certain()</i> returns <i>false</i> , or if <i>u.make_certain()</i> returns <i>false</i> .
<i>bool</i>	<i>possibly_not</i> ( <i>bool u</i> )	returns <i>!u</i> .

*CGAL::Interval\_nt<bool>*

## CGAL::array<T, int>

### Definition

An object of the class `array<T, int>` represents an array of elements of type `T`, the number of which is specified by the second template argument.

There is actually no class in CGAL with this name, but a using declaration which imports a class from another namespace. By order of priority: the one in namespace `std` is used (provided by C++0x), if not found, then the one in namespace `std::tr1` is used (provided by TR1), and finally, the fallback solution is taken from Boost.

```
#include <CGAL/array.h>
```

### Parameters

The parameter `T` is the value type. The second parameter is the dimension of the array.

### Construction functions

The array class does not provide a constructor which can be used to initialize data members. CGAL therefore provides a `make_array` function for this purpose, up to a certain number of arguments.

```
template <class T>
array<T, 1>      make_array( T a)      returns an array of dimension 1 whose first element is a.
```

```
template <class T>
array<T, 2>      make_array( T a1, T a2)

returns an array of dimension 2 whose first element is a1 and
second element is a2.
```

---

Many geometric data structures can be interpreted as graphs, as they consist of vertices, edges and faces. This is the case for the halfedge data structure, for the polyhedron, for arrangements and for triangulations. With means of duality one can also interpret faces as vertices and edges between adjacent faces as edges of the dual graph.

As the scope of CGAL is geometry and not graph algorithms, we provide the necessary classes and functions that allow to use the algorithms of the [Boost Graph Library \(BGL\)](#) [SLL02] for CGAL data structures.

### 62.1 A Short Introduction to the Boost Graph Library

The algorithms of the BGL operate on models of the various *graph concepts*. The *traits class* `boost::graph_traits` allows the algorithms to determine the types of vertices and edges. *Free functions* that operator on graphs allow the algorithms to obtain, for example, the source vertex of an edge, or all edges incident to a vertex. The algorithms use *property maps* to associate information to vertices and edges. The algorithms allow *visitors* to register callbacks that will be called during the execution of the algorithms. Finally, the graph algorithms use the *named parameter* mechanism, which allows to pass the arguments in arbitrary order.

## Graph Concepts

The BGL introduces several graph concepts, which have different sets of characteristics and requirements, as for example whether one can enumerate all vertices or all edges, whether one only can get the outgoing edges of a vertex, or also the ingoing edges, or whether one can add and remove vertices and edges or not.

Graph concepts in the BGL manual: [http://www.boost.org/libs/graph/doc/graph\\_concepts.html](http://www.boost.org/libs/graph/doc/graph_concepts.html)

## The Graph Traits Class

The algorithms determine types with the help of the traits class *boost::graph\_traits*. Such types are the *vertex\_descriptor* which is equivalent to a vertex handle in CGAL data structures, the *vertex\_iterator* which is similar to the vertex iterators in CGAL data structures, and the *out\_edge\_iterator* which is similar to edge circulators, which allow to enumerate the edges incident to a vertex. The latter two are similar and not equivalent, because their value type is a *vertex\_descriptor*, whereas in CGAL handles, iterators, and circulators all have the same value type, namely the vertex type. Given a graph type *G* the declaration of a vertex descriptor looks as follows: *boost::graph\_traits<G>::vertex\_descriptor vd;*

The graph traits in the BGL manual: [http://www.boost.org/libs/graph/doc/graph\\_traits.html](http://www.boost.org/libs/graph/doc/graph_traits.html)

## Free Functions for Exploring a Graph

The algorithms obtain incidence information with the help of global functions like *pair<vertex\_iterator,vertex\_iterator> vertices(const Graph& g);* for getting an iterator range which allows to enumerate all vertices, or *int num\_vertices(const Graph&);* for getting the number of vertices of a graph, or *vertex\_descriptor source(edge\_descriptor, const Graph&);* for getting the source vertex of an edge. Note, that the way we have written the types is a simplification, that is in reality the signature of the first of the above functions is *pair<boost::graph\_traits<Graph>::vertex\_iterator,boost::graph\_traits<Graph>::vertex\_iterator> vertices(const Graph& g);*

The free functions required for graph concepts: [http://www.boost.org/libs/graph/doc/graph\\_concepts.html](http://www.boost.org/libs/graph/doc/graph_concepts.html)

## Property Maps

Another feature used heavily in the BGL is the *property map* which is offered by the Boost Property Map Library. Property maps are used to attach information to vertices and edges. It is again a traits class and some free functions for obtaining the property map from a graph, and for getting and putting properties.

The free functions are *get* and *put*. The first one is overloaded. One version allows to obtain a property map for a given property tag. For example *m = get(g, boost::vertex\_index)* gives us a property map that associates an index in the range *[0, num\_vertices(g))* to each vertex descriptor of the graph. The second version of the *get* function allows to read it as follows for a vertex descriptor *vd*: *int vdi = get(m, vd)*. Just as *get* allows to read data, *put* allows to write them. For example, the Dijkstra's shortest path algorithm writes the predecessor of each vertex, as well as the distance to the source in such a property map.

The data themselves may be stored in the vertex or edge, or they may be stored in an external data structure, or they may be computed on the fly. This is an "implementation detail" of the particular property map.

Property maps in the Boost manuals: [http://www.boost.org/libs/property\\_map/property\\_map.html](http://www.boost.org/libs/property_map/property_map.html)

## Visitors

Visitors are objects that provide functions that get called at specified event points by the algorithm they visit. The notion of visitors is a design pattern, and also used in CGAL, e.g., the *Arr\_observer*<Arrangement> in the arrangement package.

The functions as well as the event points are library specific. Event points in graph algorithms are, for example, when a vertex is traversed the first time, or when all outgoing edges of a vertex are traversed.

Visitors in the BGL manual: [http://www.boost.org/libs/graph/doc/visitor\\_concepts.html](http://www.boost.org/libs/graph/doc/visitor_concepts.html)

## Named Parameters

The algorithms of the BGL often have many parameters. Although the default value is most often appropriate, one has to write them explicitly, if one only wants to deviate from the default for the last one. The solution to this problem is to first write a tag and then the parameter, which for Dijkstra's shortest path algorithm, might look as follows:

```
std::vector<vertex_descriptor> p(num_vertices(g));
std::vector<int> d(num_vertices(g));
vertex_descriptor s = vertex(A, g);
dijkstra_shortest_paths(g, s, predecessor_map(&p[0]).distance_map(&d[0]));
```

The named parameters in the example use the tags *predecessor\_map* and *distance\_map* and they are concatenated with the dot operator.

Named parameters in the BGL manual: [http://www.boost.org/libs/graph/doc/bgl\\_named\\_params.html](http://www.boost.org/libs/graph/doc/bgl_named_params.html)

## 62.2 Extensions of the BGL

CGAL provides the partial specializations and free functions such that several data structures become model of some of the BGL graph concepts. Furthermore, we define the new graph concept *HalfedgeGraph*, a traits class *halfedge\_graph\_traits*, and free functions for accessing opposite edges as well as the clockwise and counter-clockwise neighbor of an edge around a given vertex.

These extensions are used by the surface simplification algorithms which follow the design of the BGL as sketched in the previous section.

## 62.3 Header Files, Namespaces, and Naming Conventions

As we interface two libraries we have to explain what resides in which namespace, and what naming conventions we apply to what.

Partial specializations of the *boost::graph\_traits*<Graph> for the CGAL package *Package* are in the namespace *boost* and in the headerfile <CGAL/boost/graph/graph\_traits\_Package.h>.

The *halfedge\_graph\_traits* class is in the namespace *CGAL*, but it is not capitalized as the *boost::graph\_traits* is not. The same holds for the types and enums for vertex and edge properties.

## 62.4 Polyhedral Surfaces as Model of the Boost Graph Concept

The class *Polyhedron\_3* is model of the graph concept. Furthermore this chapter introduces a new graph concept, the *HalfedgeGraph*.

### 62.4.1 Example: Minimum Spanning Tree of a Polyhedral Surface

The example code computes the minimum spanning tree on a polyhedral surface. More examples can be found in Chapter 44 on surface mesh simplification.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
#include <CGAL/boost/graph/properties_Polyhedron_3.h>

#include <iostream>
#include <list>

#include <boost/graph/kruskal_min_spanning_tree.hpp>

typedef CGAL::Cartesian<double>           Kernel;
typedef Kernel::Vector_3                  Vector;
typedef Kernel::Point_3                   Point;
typedef CGAL::Polyhedron_3<Kernel>        Polyhedron;

typedef boost::graph_traits<Polyhedron>::vertex_descriptor vertex_descriptor;
typedef boost::graph_traits<Polyhedron>::vertex_iterator   vertex_iterator;
typedef boost::graph_traits<Polyhedron>::edge_descriptor   edge_descriptor;

// The BGL makes heavy use of indices associated to the vertices
// We use a std::map to store the index

namespace CGAL
{
    // we define operator < for handles as is not predefined
    bool operator< ( vertex_descriptor x, vertex_descriptor y )
    {
        return &*x < &*y ;
    }
} // namespace CGAL

typedef std::map<vertex_descriptor,int> VertexIndexMap;

## 62.4.2 Example: Using Vertices, and Edges with an ID

The following example program shows a call to the BGL Kruskal's minimum spanning tree algorithm accessing the `id()` field stored in a `Polyhedron` vertex.

The main function illustrates the access to the `id()` field.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/Polyhedron_items_with_id_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
#include <CGAL/boost/graph/properties_Polyhedron_3.h>

#include <iostream>
#include <list>

#include <boost/graph/kruskal_min_spanning_tree.hpp>

typedef CGAL::Cartesian<double> Kernel;
typedef Kernel::Point_3 Point;
typedef CGAL::Polyhedron_3<Kernel,CGAL::Polyhedron_items_with_id_3> Polyhedron;

typedef boost::graph_traits<Polyhedron>::vertex_descriptor vertex_descriptor;
typedef boost::graph_traits<Polyhedron>::vertex_iterator vertex_iterator;
typedef boost::graph_traits<Polyhedron>::edge_descriptor edge_descriptor;

```

```

void
kruskal( const Polyhedron& P)
{

    // We use the default edge weight which is the squared length of the edge
    // This property map is defined in graph_traits_Polyhedron_3.h

    // This function call requires a vertex_index_map named parameter which
    // when omitted defaults to "get(vertex_index,graph)".
    // That default works here because the vertex type supports the "id()"
    // field which is used by the vertex_index internal property.
    std::list<edge_descriptor> mst;
    boost::kruskal_minimum_spanning_tree(P, std::back_inserter(mst));

    std::cout << "#VRML V2.0 utf8\n"
        "Shape {\n"
        "  appearance Appearance {\n"
        "    material Material { emissiveColor 1 0 0 }\n"
        "    geometry\n"
        "      IndexedLineSet {\n"
        "        coord Coordinate {\n"
        "          point [ \n";

    vertex_iterator vb, ve;
    for(boost::tie(vb,ve) = boost::vertices(P); vb!=ve; ++vb){
        std::cout << (*vb)->point() << "\n";
    }

## 62.5 Triangulations as Models of the Boost Graph Concept

Triangulations have vertices and faces. Edges are pairs of a face and the index of the edge. Particular care has to be taken with the infinite vertex, and its incident edges. One can either use a *boost::filtered\_graph*, which makes the infinite edges invisible, or one can have a property map that returns an infinite length for these edges.

A classical example for an algorithm that is a combination of computational geometry and graph theory is the *Euclidean Minimum Spanning Tree* for a point set in the plane. It can be computed by running the minimum spanning tree algorithm on a Delaunay triangulation of the point set.

### 62.5.1 Example: Euclidean Minimum Spanning Tree

In the following example we create a Delaunay triangulation and run Kruskal's minimum spanning tree algorithm on it. Because the vertex handles of the triangulation are not indices in an array, we have to provide a property map that maps vertex handles to int's in the range  $[0, t.number\_of\_vertices())$ .

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/boost/graph/graph_traits_Delaunay_triangulation_2.h>

#include <boost/graph/kruskal_min_spanning_tree.hpp>
#include <boost/graph/filtered_graph.hpp>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;

typedef CGAL::Delaunay_triangulation_2<K> Triangulation;

// As we only consider finite vertices and edges
// we need the following filter

```

```

template <typename T>
struct Is_finite {

    const T* t_;

    Is_finite()
        : t_(NULL)
    {}

    Is_finite(const T& t)
        : t_(&t)
    { }

    template <typename VertexOrEdge>
    bool operator()(const VertexOrEdge& voe) const {
        return ! t_->is_infinite(voe);
    }
};

typedef Is_finite<Triangulation> Filter;
typedef boost::filtered_graph<Triangulation,Filter,Filter> Finite_triangulation;
typedef boost::graph_traits<Finite_triangulation>::vertex_descriptor vertex_descriptor;
typedef boost::graph_traits<Finite_triangulation>::vertex_iterator vertex_iterator;
typedef boost::graph_traits<Finite_triangulation>::edge_descriptor edge_descriptor;

// The BGL makes use of indices associated to the vertices
// We use a std::map to store the index
typedef std::map<vertex_descriptor,int> VertexIndexMap;
VertexIndexMap vertex_id_map;

// A std::map is not a property map, because it is not lightweight
typedef boost::associative_property_map<VertexIndexMap> VertexIdPropertyMap;
VertexIdPropertyMap vertex_index_pmap(vertex_id_map);

int
main(int,char*[])
{
    Triangulation t;
    Filter is_finite(t);
    Finite_triangulation ft(t, is_finite, is_finite);

    Point p ;
    while(std::cin >> p){
        t.insert(p);
    }

    vertex_iterator vit, ve;
    // Associate indices to the vertices
    int index = 0;
    // boost::tie assigns the first and second element of the std::pair
    // returned by boost::vertices to the variables vit and ve
    for(boost::tie(vit,ve)=boost::vertices(ft); vit!=ve; ++vit ){
        vertex_descriptor vd = *vit;

```

```

    vertex_id_map[vd]= index++;
}

// We use the default edge weight which is the squared length of the edge
// This property map is defined in graph_traits_Triangulation_2.h

// In the function call you can see a named parameter: vertex_index_map
std::list<edge_descriptor> mst;
boost::kruskal_minimum_spanning_tree(t,
std::back_inserter(mst),
vertex_index_map(vertex_index_pmap));

std::cout << "The edges of the Euclidean mimimum spanning tree:" << std::endl;

for(std::list<edge_descriptor>::iterator it = mst.begin(); it != mst.end(); ++it){
    edge_descriptor ed = *it;
    vertex_descriptor svd = boost::source(ed,t);
    vertex_descriptor tvd = boost::target(ed,t);
    Triangulation::Vertex_handle sv = svd;
    Triangulation::Vertex_handle tv = tvd;
    std::cout << "[ " << sv->point() << " | " << tv->point() << " ] " << std::endl;
}

return 0;
}

```

**File:** examples/BGL\_triangulation\_2/emst.cpp

## 62.5.2 Example: Storing the Vertex ID in the Vertex

The algorithms of the BGL extensively use of the indices of vertices. In the previous example we stored the index in a *std::map* and turned that map in a property map. This property map was then passed as argument to the shortest path function.

If the user does not pass explicitly a property map, the graph algorithms use the property map returned by the call *boost::get(boost::vertex\_index,ft)*. This property map assumes that the vertex has a member function *id()* that returns a reference to an int. Therefore CGAL offers a class *Triangulation\_vertex\_base\_with\_id\_2*. It is in the users responsibility to set the indices properly.

The example further illustrates that the graph traits also works for the Delaunay triangulation.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_vertex_base_with_id_2.h>
#include <CGAL/boost/graph/graph_traits_Delaunay_triangulation_2.h>

#include <climits>
#include <boost/graph/dijkstra_shortest_paths.hpp>
#include <boost/graph/filtered_graph.hpp>

```

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;

typedef CGAL::Triangulation_vertex_base_with_id_2<K> Tvb;
typedef CGAL::Triangulation_face_base_2<K> Tfb;
typedef CGAL::Triangulation_data_structure_2<Tvb,Tfb> Tds;
typedef CGAL::Delaunay_triangulation_2<K, Tds> Triangulation;

// consider finite vertices and edges.

## 62.6 Arrangements as Models of the Boost Graph Concept

For the arrangements CGAL offers the graph traits for the arrangement itself as well as for its dual graph.

### 62.6.1 Example for the Arrangement as Graph

Arrangement instances are adapted to *boost* graphs by specializing the *boost:graph\_traits* template for *Arrangement\_2* instances. The graph-traits states the graph concepts that the arrangement class models (see below) and defines the types required by these concepts.

In this specialization the *Arrangement\_2* vertices correspond to the graph vertices, where two vertices are adjacent if there is at least one halfedge connecting them. More precisely, *Arrangement\_2::Vertex\_handle* is the graph-vertex type, while *Arrangement\_2::Halfedge\_handle* is the graph-edge type. As halfedges are directed, we consider the graph to be directed as well. Moreover, as several interior-disjoint *x*-monotone curves (say circular arcs) may share two common endpoints, inducing an arrangement with two vertices that are connected with several edges, we allow parallel edges in our *boost* graph.

Figure 62.1: An arrangement of 7 line segments, as constructed by *ex\_bgl\_primal\_adapter.cpp* and *ex\_bgl\_dual\_adapter.cpp*. The breadth-first visit times for the arrangement faces, starting from the unbounded face  $f_0$ , are shown in brackets.

Given an *Arrangement\_2* instance, we can efficiently traverse its vertices and halfedges. Thus, the arrangement graph is a model of the concepts *VertexListGraph* and *EdgeListGraph* introduced by the BGL. At the same time, we use an iterator adapter of the circulator over the halfedges incident to a vertex (*Halfedge\_around\_vertex\_circulator* — see Section 26.2.2), so it is possible to go over the ingoing and outgoing edges of a vertex in linear time. Thus, our arrangement graph is a model of the concept *BidirectionalGraph* (this concept refines *IncidenceGraph*, which requires only the traversal of outgoing edges).

It is important to notice that the vertex descriptors we use are *Vertex\_handle* objects and *not* vertex indices. However, in order to gain more efficiency in most BGL algorithm, it is better to have them indexed  $0, 1, \dots, (n - 1)$ , where  $n$  is the number of vertices. We therefore introduce the *Arr\_vertex\_index\_map<Arrangement>* class-template, which maintains a mapping of vertex handles to indices, as required by the BGL. An instance of this class must be attached to a valid arrangement vertex when it is created. It uses the notification mechanism (see Section 26.7) to automatically maintain the mapping of vertices to indices, even when new vertices are inserted into the arrangement or existing vertices are removed.

In most algorithm provided by the BGL, the output is given by *property maps*, such that each map entry corresponds to a vertex. For example, when we compute the shortest paths from a given source vertex  $s$  to all other vertices we can obtain a map of distances and a map of predecessors — namely for each  $v$  vertex we have its distance from  $s$  and a descriptor of the vertex that precedes  $v$  in the shortest path from  $s$ . If the vertex descriptors are simply indices, one can use vectors to efficiently represent the property maps. As this is not the case with the arrangement graph, we offer the *Arr\_vertex\_property\_map<Arrangement, Type>* template allows for an efficient mapping of *Vertex\_handle* objects to properties of type *Type*. Note however that unlike the *Arr\_vertex\_index\_map* class, the vertex property-map class is not kept synchronized with the number of vertices in the arrangement, so it should not be reused in calls to BGL functions in case the arrangement is modified in between these calls.

In the following example we construct an arrangement of 7 line segments, as shown in Figure 62.1, then use Dijkstra's shortest-paths algorithm from the BGL to compute the graph distance of all vertices from the leftmost vertex in the arrangement  $v_0$ . Note the usage of the *Arr\_vertex\_index\_map* and the *Arr\_vertex\_property\_map* classes. The latter one, instantiated by the type *double* is used to map vertices to their distances from  $v_0$ .

## 62.6.2 Example for the Dual of an Arrangement as Graph

It is possible to give a dual graph representation for an arrangement instance, such that each arrangement face corresponds to a graph vertex and two vertices are adjacent iff the corresponding faces share a common edge on their boundaries. This is done by specializing the *boost::graph\_traits* template for *Dual<Arrangement\_2>* instances, where *Dual<Arrangement\_2>* is a template specialization that gives a dual interpretation to an arrangement instance.

In dual representation, *Arrangement\_2::Face\_handle* is the graph-vertex type, while *Arrangement\_2::Halfedge\_handle* is the graph-edge type. We treat the graph edges as directed, such that a halfedge *e* is directed from *f*<sub>1</sub>, which is its incident face, to *f*<sub>2</sub>, which is the incident face of its twin halfedge. As two arrangement faces may share more than a single edge on their boundary, we allow parallel edges in our *boost* graph. As is the case in the primal graph, the dual arrangement graph is also a model of the concepts *VertexListGraph*, *EdgeListGraph* and *BidirectionalGraph* (thus also of *IncidenceGraph*).

Since we use *Face\_handle* objects as the vertex descriptors, we define the *Arr\_face\_index\_map<Arrangement>* class-template, which maintains an efficient mapping of face handles to indices. We also provide the template *Arr\_face\_property\_map<Arrangement,Type>* for associating arbitrary data with the arrangement faces.

In the following example we construct the same arrangement as in example *ex\_bgl\_primal\_adapter.cpp* (see Figure 62.1), and perform breadth-first search on the graph faces, starting from the unbounded face. We extend the DCEL faces with an unsigned integer, marking the discover time of the face and use a breadth-first-search visitor to obtain these times and update the faces accordingly:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>

#include <climits>
#include <boost/graph/dijkstra_shortest_paths.hpp>

#include <CGAL/graph_traits_Dual_Arrangement_2.h>
#include <CGAL/Arr_face_map.h>

#include "arr_print.h"

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>     Traits_2;
typedef Traits_2::Point_2                     Point_2;
typedef Traits_2::X_monotone_curve_2          Segment_2;
typedef CGAL::Arr_face_extended_dcel<Traits_2, unsigned int> Dcel;
typedef CGAL::Arrangement_2<Traits_2, Dcel>     Arrangement_2;
typedef CGAL::Dual<Arrangement_2>             Dual_arrangement_2;

// A BFS visitor class that associates each vertex with its discover time.
// In our case graph vertices represent arrangement faces.
template <class IndexMap>
class Discover_time_bfs_visitor : public boost::default_bfs_visitor
{
private:

    const IndexMap *index_map;      // Mapping vertices to indices.
    unsigned int    time;           // The current time stamp.

public:

    // Constructor.
    Discover_time_bfs_visitor (const IndexMap& imap) :
        index_map (&imap),

# HalfedgeGraph

## Definition

The concept HalfedgeGraph describes the requirements for a graph that is structurally equivalent to a polyhedral surface represented by a halfedge data structure, and it provides an interface for efficient access to the opposite edge of an edge, and to the successor and predecessor of an edge in the iterator range of the incoming edges of a vertex. Each vertex has a geometric position in space. As in a halfedge data structure we define the face adjacent to a halfedge to be to the *left* of the halfedge.

## Requirements

For each *directed edge*  $e = (v, w)$  its opposite edge  $e' = (w, v)$  must be part of the graph.

The incoming edges of a vertex  $v$  have a fixed order, that is all calls of  $in\_edges(v, g)$  must return the same iterator range, modulo a cyclic permutation. The order must be *clockwise*.

As the HalfedgeGraph is equivalent to a polyhedral surface there must exist an embedding for the vertices and edges such that the ordered edges do not intersect.

## Refines

**IncidenceGraph**  
**PropertyGraph**

A model of HalfedgeGraph must have the *interior properties*  $edge\_is\_border$  attached to its edges, and it must have  $vertex\_is\_border$  and  $vertex\_point$  attached to its vertices.

## Associated Types

$HalfedgeGraph::halfedge\_graph\_traits<HalfedgeGraph>::Point$

The type of the geometric location of a vertex.

Because (directed) edges must come in pairs, there is the additional notion of an *undirected edge*<sup>1</sup> for a pair of opposite directed edges. The number of undirected edges is exactly half the number of directed edges.

Note that the notion of directed and undirected edges does not imply the existence of two different types. The type  $edge\_descriptor$  is used for both. An undirected edge must be implicitly handled, and there is no requirement on which of the directed edges of the undirected edge must be used to represent it.

$HalfedgeGraph::halfedge\_graph\_traits<HalfedgeGraph>::undirected\_edge\_iterator$

An iterator that iterates over one and only one of the directed edges in each pair of opposite directed edges. The value type of the iterator is  $boost::graph\_traits<HalfedgeGraph>::edge\_descriptor$ .

<sup>1</sup> The directed edges are not called *halfedges* (as in a *HalfedgeDS*) because from the point of view of this graph, being a refinement of a BGL graph, each directed edge is an edge in itself. In other words, the unqualified term edge refers to one and only one directed edge and not to a pair.

## Valid Expressions

Following the BGL design, the following graph operations are defined as free rather than member functions.

```
template<class Graph>
std::pair<typename halfedge_graph_traits<HalfedgeGraph>::undirected_edge_iterator, typename halfedge_
graph_traits<HalfedgeGraph>::undirected_edge_iterator>
```

`undirected_edges( Graph g)`

Returns the undirected edges of  $g$ .

An edge  $e = (v, w)$  is said to be the *opposite edge* of edge  $e' = (w, v)$ .

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

`opposite_edge( typename boost::graph_traits<Graph const>::edge_descriptor e,
Graph g)`

Returns the opposite edge of  $e$ .

An edge  $e' = (v, w)$  is called the *clockwise neighbor* of edge  $e = (u, w)$ , and  $e$  the *counterclockwise neighbor* of  $e'$ , iff there exist two iterators  $it$  and  $it'$  in the iterator range `in_edges(w, g)` such that `**it == e` and `**it' == e'`, and `it' == it++` or `it` is the last and `it'` the first iterator of the iterator range.

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

`next_edge_cw( typename boost::graph_traits<Graph const>::edge_descriptor e,
Graph g)`

Returns the clockwise neighbor of  $e$ .

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

`next_edge_ccw( typename boost::graph_traits<Graph const>::edge_descriptor e,
Graph g)`

Returns the counterclockwise neighbor of  $e$ .

A composition of these access functions yields an access function for the edge cycle adjacent to the same face. An edge  $e' = (v, w)$  is called the *successor* of edge  $e = (u, v)$ , and  $e$  the *predecessor* of  $e'$ , iff  $e'$  is the clockwise neighbor of the opposite edge of  $e$ .

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

`next_edge( typename boost::graph_traits<Graph const>::edge_descriptor e, Graph g)`

Returns the successor of  $e$ .

*template<class Graph>*  
*typename boost::graph\_traits<Graph const>::edge\_descriptor*

*prev\_edge( typename boost::graph\_traits<Graph const>::edge\_descriptor e,*  
*Graph g)*

Returns the predecessor of *e*.

## **Has Models**

*CGAL::Polyhedron\_3<Traits>* ..... page [1497](#)

## boost::graph\_traits< CGAL::Arrangement\_2<Traits,Dcel> >

### Definition

The class `graph_traits< CGAL::Arrangement_2<Traits,Dcel> >` is a partial specialization of `boost::graph_traits` for the class `Arrangement_2`. It provides the types associated to the `graph` concepts *BidirectionalGraph* and *EdgeAndVertexListGraph*.

```
#include <CGAL/boost/graph/graph_traits_Arrangement_2.h>
```

### Types

```
typename CGAL::Arrangement_2::Vertex_handle
```

`vertex_descriptor;`      The vertex descriptor.

```
typename CGAL::Arrangement_2::Halfedge_handle
```

`edge_descriptor;`      The edge descriptor.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: vertex_iterator
```

An iterator corresponding to `CGAL::Arrangement_2::Vertex_iterator`, with the difference that its value type is a vertex descriptor and not `CGAL::Arrangement_2::Vertex`.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: edge_iterator
```

An iterator corresponding to `CGAL::Arrangement_2::Halfedge_iterator` with the difference that its value type is an edge descriptor and not `CGAL::Arrangement_2::Halfedge`.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: in_edge_iterator
```

An edge iterator which only iterates over the incoming edges around a vertex. It corresponds to a `CGAL::Arrangement_2::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Arrangement_2::Halfedge`.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: out_edge_iterator
```

An edge iterator which only iterates over the outgoing halfedges around a vertex. It corresponds to a `CGAL::Arrangement_2::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Arrangement_2::Halfedge`.

*boost::sallow\_parallel\_edge\_tag*

*edge\_parallel\_category;*

Indicates that this graph does support multiedges.

*boost::bidirectional\_graph\_tag*

*traversal\_category;*

Indicates that this graph is bidirectional.

*typename Arrangement\_2::size\_type*

*vertices\_size\_type;*

The size type of the vertex list.

*typename Arrangement\_2::size\_type*

*edges\_size\_type;*

The size type of the edge list.

*typename Arrangement\_2::size\_type*

*degree\_size\_type;*

The size type of the adjacency list.

The const specialization, *boost::graph\_traits< CGAL::Arrangement\_2< Traits, Dcel> const>* is also defined, using the constant handles in the arrangement.

## boost::graph\_traits< CGAL::Polyhedron\_3<Traits> >

### Definition

The class `graph_traits< CGAL::Polyhedron_3<Traits> >` is a partial specialization of `boost::graph_traits` for the class `Polyhedron_3`. It provides the types associated to the **graph** concepts *BidirectionalGraph* and *EdgeAndVertexListGraph*.

```
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
```

### Types

```
typename CGAL::Polyhedron_3::Vertex_handle
```

`vertex_descriptor;`      The vertex descriptor.

```
typename CGAL::Polyhedron_3::Halfedge_handle
```

`edge_descriptor;`      The edge descriptor.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: vertex_iterator
```

An iterator corresponding to `CGAL::Polyhedron_3::Vertex_iterator`, with the difference that its value type is a vertex descriptor and not `CGAL::Polyhedron_3::Vertex`.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: edge_iterator
```

An iterator corresponding to `CGAL::Polyhedron_3::Halfedge_iterator` with the difference that its value type is an edge descriptor and not `CGAL::Polyhedron_3::Halfedge`.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: in_edge_iterator
```

An edge iterator which only iterates over the incoming edges around a vertex. It corresponds to a `CGAL::Polyhedron_3::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Polyhedron_3::Halfedge`.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: out_edge_iterator
```

An edge iterator which only iterates over the outgoing halfedges around a vertex. It corresponds to a `CGAL::Polyhedron_3::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Polyhedron_3::Halfedge`.

*boost::disallow\_parallel\_edge\_tag*

*edge\_parallel\_category;*

Indicates that this graph does not support multiedges.

*boost::bidirectional\_graph\_tag*

*traversal\_category;*

Indicates that this graph is bidirectional.

*typename Polyhedron\_3::size\_type*

*vertices\_size\_type;*

The size type of the vertex list.

*typename Polyhedron\_3::size\_type*

*edges\_size\_type;*

The size type of the edge list.

*typename Polyhedron\_3::size\_type*

*degree\_size\_type;*

The size type of the adjacency list.

The const specialization, *boost::graph\_traits< CGAL::Polyhedron\_3<Traits> const>* is also defined, using the constant handles in the polyhedron.

## boost::graph\_traits< CGAL::Triangulation\_2<GT, TDS> >

### Definition

The triangulations of CGAL are all models of the concepts *BidirectionalGraph* and *VertexAndEdgeListGraph* of the Boost Graph Library [SLL02].

The class `graph_traits< CGAL::Triangulation_2<GT, TDS> >` is a partial specialization of the class `boost::graph_traits<G>`.

The mapping between vertices and edges of the triangulation and the graph is rather straightforward, but there are some subtleties. The value type of the BGL iterators is the vertex or edge descriptor, whereas in CGAL all iterators and circulators are also handles and hence have as value type *Vertex* or *Edge*.

The graph traits class for triangulations does not distinguish between finite and infinite vertices and edges. As the edge weight computed with the default property map of BGL algorithms (obtained with `boost::get(t, boost::edge_weight)`) is the length of the edge, the edge weight is not well defined for infinite edges. For algorithms that make use of the edge weight the user must therefore define a `boost::filtered_graph` or pass a property map to the algorithm that returns “infinity” for infinite edges.

Note also that when you derive from the class `CGAL::Triangulation_2` you must upcast the object in order to use this partial specialization.

For the user convenience, CGAL provides the partial specializations for all 2D triangulation classes.

```
#include <CGAL/boost/graph/graph_traits_Triangulation_2.h>
```

### Types

```
typedef Triangulation::Vertex_handle
```

`vertex_descriptor;`      The vertex descriptor.

```
graph_traits< CGAL::Triangulation_2<GT, TDS> >:: edge_descriptor
```

The edge descriptor. It is constructible from and convertible to `Triangulation::Edge`. The edge descriptor is not a simple typedef, but a proper class, because in an undirected graph the edges  $(u,v)$  and  $(v,u)$  must be equal. This is not the case for the *Edge* type of the triangulation.

```
graph_traits< CGAL::Triangulation_2<GT, TDS> >:: vertex_iterator
```

The vertex iterator type. Its value type is `vertex_descriptor`.

```
graph_traits< CGAL::Triangulation_2<GT, TDS> >:: edge_iterator
```

The edge iterator type, Its value type is `edge_descriptor`.

*graph\_traits< CGAL::Triangulation\_2<GT, TDS> >:: out\_edge\_iterator*

An iterator for the outgoing edges incident to a vertex. Its value type is *edge\_descriptor*.

*graph\_traits< CGAL::Triangulation\_2<GT, TDS> >:: in\_edge\_iterator*

An iterator for the incoming edges incident to a vertex. Its value type is *edge\_descriptor*.

*graph\_traits< CGAL::Triangulation\_2<GT, TDS> >:: adjacency\_iterator*

An iterator for the vertices adjacent to a vertex. Its value type is *vertex\_descriptor*.

*typedef boost::undirected\_tag*

*directed\_category;*

*typedef boost::disallow\_parallel\_edge\_tag*

*edge\_parallel\_category;*

## CGAL::halfedge\_graph\_traits< CGAL::Polyhedron\_3<Traits> >

### Definition

The class *halfedge\_graph\_traits< CGAL::Polyhedron\_3<Traits> >* is a partial specialization of *CGAL::halfedge\_graph\_traits* for *Polyhedron\_3*. It provides the types associated to the *HalfedgeGraph* concept.

```
#include <CGAL/boost/graph/halfedge_graph_traits_Polyhedron_3.h>
```

### Types

*halfedge\_graph\_traits< CGAL::Polyhedron\_3<Traits> >::undirected\_edge\_iterator*

An edge iterator that iterates over one of the two opposite edges forming an undirected edge.

The value type is *CGAL::Polyhedron\_3::Halfedge\_const\_handle*.

*typename CGAL::Polyhedron\_3<Traits>::Point\_3*

*Point;*

The point type of the vertex.

## CGAL::Triangulation\_vertex\_base\_with\_id\_2<TriangulationTraits\_2, TriangulationVertexBase\_2>

### Definition

The class *Triangulation\_vertex\_base\_with\_id\_2* is a model of the concept *TriangulationVertexBase\_2*, the base vertex of a 2D-triangulation. It provides an integer field that can be used to index vertices for BGL algorithms.

Note that the user is in charge to set the index correctly before running a graph algorithm.

```
#include <CGAL/Triangulation_vertex_base_with_id_2.h>
```

### Parameters

The first template argument is the geometric traits class *TriangulationTraits\_2* which provides the *Point\_2*.

The second template argument is a vertex base class from which *Triangulation\_vertex\_base\_with\_id\_2* derives. It has the default value *Triangulation\_vertex\_base\_2<TriangulationTraits\_2>*.

### Is Model for the Concepts

*TriangulationVertexBase\_2*

### Inherits From

*TriangulationVertexBase\_2*

### Access Functions

<i>int</i>	<i>v.id() const</i>	Returns the index.
<i>int&amp;</i>	<i>v.id()</i>	Returns a reference to the index stored in the vertex.

## CGAL::HalfedgeDS\_vertex\_max\_base\_with\_id<Refs>

### Definition

The class *HalfedgeDS\_vertex\_max\_base\_with\_id<Refs>* is a model of the *HalfedgeDSVertex* concept. *Refs* is an instantiation of a *HalfedgeDS*. It is equivalent to *CGAL::HalfedgeDS\_vertex\_base<Refs, CGAL::Tag\_true>* with an added integer field which can be used to index vertices in BGL algorithms.. The class contains support for the point and the required type definitions. It can be used for deriving own vertices.

Note that the user is in charge to set the index correctly before running a graph algorithm.

```
#include <CGAL/HalfedgeDS_vertex_max_base_with_id.h>
```

### Is Model for the Concepts

HalfedgeDSVertex.....page [1559](#)

### Creation

*HalfedgeDS\_vertex\_max\_base\_with\_id<Refs>* v;                      default constructor.

int                      v.id()                      Returns the index.

int&                      v.id()                      Returns a reference to the index stored in the vertex.

## CGAL::Polyhedron\_items\_with\_id\_3

### Definition

The class *Polyhedron\_items\_with\_id\_3* is a model of the *PolyhedronItems\_3* concept. It provides definitions for vertices with points, halfedges, and faces with plane equations, all of them with an additional integer field which can be used to index the items in a BGL algorithm. The polyhedron traits class must provide the respective types for the point and the plane equation. Vertices and facets both contain a halfedge handle to an incident halfedge.

```
#include <CGAL/Polyhedron_items_with_id_3.h>
```

### Is Model for the Concepts

## **boost::edge\_index\_t**

```
enum edge_index_t { edge_index};
```

The constant *edge\_index* is a **property tag** which identifies the *index* property of an edge of a BGL **Graph**.

## CGAL::edge\_is\_border\_t

```
#include <CGAL/boost/graph/properties.h>
```

```
enum edge_is_border_t { edge_is_border};
```

The constant `edge_is_border` is a **property tag** which refers to the property of an edge of being a border edge.

`edge_is_border` is an **interior property**. That is, a **property map** for `edge_is_border` can be extracted from any model of a *HalfedgeGraph* using the BGL **PropertyGraph** interface:

```
boost::get(edge_is_border, graph)
```

The Boolean flag that indicates if the edge is a border can be directly accessed via:

```
boost::get(edge_is_border, graph, edge).
```

## CGAL::vertex\_is\_border\_t

```
#include <CGAL/boost/graph/properties.h>
```

```
enum vertex_is_border_t { vertex_is_border};
```

The constant `vertex_is_border` is a **property tag** which refers to the property of a vertex of being a border vertex.

`vertex_is_border` is an **interior property**, that is, a **property map** for `vertex_is_border` can be extracted from any model of a *HalfedgeGraph* using the BGL **PropertyGraph** interface:

```
boost::get(vertex_is_border, graph)
```

The Boolean flag that indicates if the vertex is a border can be directly accessed via:

```
boost::get(vertex_is_border, graph, edge)
```

## CGAL::vertex\_point\_t

```
#include <CGAL/boost/graph/properties.h>
```

```
enum vertex_point_t { vertex_point};
```

The constant `vertex_point` is a **property tag** which refers to the geometric embedding property of a vertex of a *HalfedgeGraph*.

A *vertex\_point* is an **interior property**, that is, a **property map** for a *vertex\_point* can be extracted from any model of a *HalfedgeGraph* using the BGL **PropertyGraph** interface:

```
boost::get(vertex_point, graph)
```

A point of a vertex can be directly accessed via:

```
boost::get(vertex_point, graph, vertex)
```

```
boost::put(vertex_point, graph, vertex, newpoint)
```

### 63.1 Handles

Most data structures in CGAL use the concept of *Handle* in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A *Handle* is akin to a pointer to an object providing the dereference operator *operator\**() and member access *operator->*() but no increment or decrement operators like iterators. A *Handle* is intended to be used whenever the referenced object is not part of a logical sequence.

**Model for a handle** A simple pointer  $T^*$ , an iterator or a circulator with value type  $T$ , are also handles.

### 63.2 Circulators

An introduction to the concept of circulators is given here. A couple of adaptors are presented that convert between iterators and circulators. Some useful functions for circulators follow. This chapter concludes with a discussion of the design decisions taken. For the full description of the circulator requirements, the provided

base classes, the circulator tags, and the support for generic algorithms that work for iterators as well as for circulators please refer to the reference pages. Note that circulators are not part of STL, but of CGAL.

### 63.2.1 Introduction

The concept of iterators in STL is tailored for linear sequences [C++98, MS96]. In contrast, circular sequences occur naturally in many combinatorial and geometric structures. Examples are polyhedral surfaces and planar maps, where the edges emanating from a vertex or the edges around a facet form a circular sequence.

Since circular sequences do not allow for efficient iterators, we have introduced the new concept of *circulators*. They share most of the requirements of iterators, while the main difference is the lack of a past-the-end position in the sequence. Appropriate adaptors are provided between iterators and circulators to integrate circulators smoothly into the framework of STL. An example of a generic `contains` function illustrates the use of circulators. As usual for circular structures, a `do-while` loop is preferable, such that for the specific input, `c == d`, all elements in the sequence are reached.

```
template <class Circulator, class T>
bool contains( Circulator c, Circulator d, const T& value) {
    if (c != 0) {
        do {
            if (*c == value)
                return true;
        } while (++c != d);
    }
    return false;
}
```

Three circulator categories are defined: forward, bidirectional and random-access circulators. Given a circulator `c`, the operation `*c` denotes the item the circulator refers to. The operation `++c` advances the circulator by one item and `--c` steps a bidirectional circulator one item backwards. For random-access circulators `c+n` advances the circulator `n` steps. Two circulators can be compared for equality.

Circulators have a different notion of reachability and ranges than iterators. A circulator `d` is called *reachable* from a circulator `c` if `c` can be made equal to `d` with finitely many applications of the operator `++`. Due to the circularity of the sequence this is always true if both circulators refer to items of the same sequence. In particular, `c` is always reachable from `c`. Given two circulators `c` and `d`, the range `[c, d)` denotes all circulators obtained by starting with `c` and advancing `c` until `d` is reached, but does not include `d`, for `d ≠ c`. So far it is the same range definition as for iterators. The difference lies in the use of `[c, c)` to denote all items in the circular sequence, whereas for an iterator `i` the range `[i, i)` denotes the empty range. As long as `c != d` the range `[c, d)` behaves like an iterator range and could be used in STL algorithms. For circulators however, an additional test `c == NULL` is required that returns true if and only if the circular sequence is empty. As for C++, we recommend the use of 0 instead of `NULL`.

Besides the conceptual cleanness, the main reason for inventing a new concept with a similar intent as iterators is efficiency. An iterator is supposed to be a light-weight object – merely a pointer and a single indirection to advance the iterator. Although iterators could be written for circular sequences, we do not know of an efficient solution. The missing past-the-end situation in circular sequences can be solved with an arbitrary sentinel in the cyclic order, but this would destroy the natural symmetry in the structure (which is in itself a bad idea) and additional bookkeeping in the items and checking in the iterator advance method reduces efficiency. Another solution may use more bookkeeping in the iterator, e.g. with a start item, a current item, and a kind of winding-number that is zero for the `begin()`-iterator and one for the past-the-end situation<sup>1</sup>. We have introduced the

---

<sup>1</sup>This is currently implemented as the adaptor class which provides a pair of iterators for a given circulator.

concept of circulators that allows light-weight implementations and the CGAL support library provides adaptor classes that convert between iterators and circulators (with the corresponding penalty in efficiency), so as to integrate this new concept into the framework of STL.

A serious design problem is the slight change of the semantic for circulator ranges as compared to iterator ranges. Since this semantic is defined by the intuitive operators `++` and `==`, which we would like to keep for circulators as well, circulator ranges can be used in STL algorithms. This is in itself a useful feature, if there would not be the definition of a full range  $[c, c)$  that an STL algorithm will treat as an empty range. However, the likelihood of a mistake may be overestimated, since for a container `C` supporting circulators there is no `end()` member function, and an expression such as `std::sort( C.begin(), C.end())` will fail. It is easy to distinguish iterators and circulators at compile time, which allows for generic algorithms supporting both as arguments. It is also possible to protect algorithms against inappropriate arguments using the same technique, see the reference pages for circulators, specifically the *Assert\_iterator* and *is\_empty\_range* functions.

**Warning:** Please note that the definition of a range is different from that of iterators. An interface of a data structure must declare whether it works with iterators, circulators, or both. STL algorithms always specify only iterators in their interfaces. A range  $[c, d)$  of circulators used in an interface for iterators will work as expected as long as  $c \neq d$ . A range  $[c, c)$  will be interpreted as the empty range like for iterators, which is different than the full range that it should denote for circulators.

## 63.2.2 Forward Circulator

A class *Circulator* that satisfies the requirements of a forward circulator with the value type  $T$ , supports the following operations. See the reference pages for the full set of requirements. Note that the stated return values are not required, only a return value that is convertible to the stated type is required. As for C++, we recommend the use of 0 instead of `NULL`.

### Types

<i>Circulator::value_type</i>	the value type $T$ .
<i>Circulator::reference</i>	either reference or const reference to $T$ .
<i>Circulator::pointer</i>	either pointer or const pointer to $T$ .
<i>Circulator::size_type</i>	unsigned integral type that can hold the size of the sequence.
<i>Circulator::difference_type</i>	signed integral type that can hold the distance between two circulators.
<i>Circulator::iterator_category</i>	circulator category <i>Forward_circulator_tag</i> .

### Creation

<i>Circulator</i> $c$ ;	a circulator equal to <i>NULL</i> denoting an empty sequence.
<i>Circulator</i> $c(d)$ ;	a circulator equal to $d$ .

### Operations

<i>Circulator</i> &	$c = d$	Assignment.
<i>bool</i>	$c == \text{NULL}$	Test for emptiness.
<i>bool</i>	$c \neq \text{NULL}$	Test for non-emptiness, i.e. $!(c == \text{NULL})$ .
<i>bool</i>	$c == d$	$c$ is equal to $d$ if they refer to the same item.

<i>bool</i>	$c \neq d$	Test for inequality, i.e. $!(c == d)$ .
<i>reference</i>	$*c$	Returns the value of the circulator. If <i>Circulator</i> is mutable $*c = t$ is valid. <i>Precondition</i> : $c$ is dereferenceable.
<i>pointer</i>	$c \rightarrow$	Returns a pointer to the value of the circulator. <i>Precondition</i> : $c$ is dereferenceable.
<i>Circulator&amp;</i>	$++c$	Prefix increment operation. <i>Precondition</i> : $c$ is dereferenceable. <i>Postcondition</i> : $c$ is dereferenceable.
<i>Circulator</i>	$c++$	Postfix increment operation. The result is the same as that of: <i>Circulator</i> $tmp = c; ++c; return tmp; .$

### 63.2.3 Bidirectional Circulator

A class *Circulator* that satisfies the requirements of a bidirectional circulator with the value type  $T$ , supports the following operations in addition to the operations supported by a forward circulator.

#### Types

*Circulator*:: *iterator\_category*

circulator category *Bidirectional\_circulator\_tag*.

#### Operations

<i>Circulator&amp;</i>	$--c$	Prefix decrement operation. <i>Precondition</i> : $c$ is dereferenceable. <i>Postcondition</i> : $c$ is dereferenceable.
<i>Circulator</i>	$c--$	Postfix decrement operation. The result is the same as that of <i>Circulator</i> $tmp = c; --c; return tmp; .$

### 63.2.4 Random Access Circulator

A class *Circulator* that satisfies the requirements of a random access *Circulator* for the value type  $T$ , supports the following operations in addition to the operations supported by a bidirectional *Circulator*. In contrast to random access iterators, no comparison operators are available for random access circulators.

#### Types

*Circulator*:: *iterator\_category*

circulator category *Random\_access\_circulator\_tag*.

## Operations

<i>Circulator</i> &	$c += \text{difference\_type } n$	The result is the same as if the prefix increment operation was applied $n$ times, but it is computed in constant time.
<i>Circulator</i>	$c + \text{difference\_type } n$	Same as above, but returns a new circulator.
<i>Circulator</i>	$\text{difference\_type } n + c$	Same as above.
<i>Circulator</i> &	$c -= \text{difference\_type } n$	The result is the same as if the prefix decrement operation was applied $n$ times, but it is computed in constant time.
<i>Circulator</i>	$c - \text{difference\_type } n$	Same as above, but returns a new circulator.
<i>reference</i>	$c[\text{difference\_type } n]$	Returns $*(c + n)$ .
<i>difference_type</i>	$c - \text{Circulator } d$	returns the difference between the two circulators. The value will be in the interval $[1 - s, s - 1]$ if $s$ is the size of the total sequence. The difference for a fixed circulator $c$ (or $d$ ) with all other circulators $d$ (or $c$ ) is a consistent ordering of the elements in the data structure. There has to be a minimal circulator $d_{\min}$ for which the difference $c - d_{\min}$ to all other circulators $c$ is non-negative.
<i>Circulator</i>	$c.\text{min\_circulator}()$	Returns the minimal circulator $c_{\min}$ in constant time.

### 63.2.5 Adaptors Between Iterators and Circulators

Algorithms working on iterator ranges can not be applied to circulator ranges in full generality, only to subranges (see the warning in Section 63.2.1). The following adaptors convert circulators to iterators and vice versa (with the unavoidable space and time penalty) to reestablish this generality.

```
#include <CGAL/circulator.h>
```

*Container\_from\_circulator* container-like class with iterators built from a circulator  
*Circulator\_from\_iterator* circulator over a range of two iterators  
*Circulator\_from\_container* circulator for a container

The following example applies the generic `std::reverse()` algorithm from STL to a sequence given by a bidirectional circulator `c`. It uses the *Container\_from\_circulator* adaptor.

```
Circulator c; // c must be at least bidirectional.  
CGAL::Container_from_circulator<Circulator> container(c);  
std::reverse(container.begin(), container.end());
```

Another example defines a circulator  $c$  for a vector of  $int$ 's. However, since there are no elements in the vector, the circulator denotes an empty sequence. If there were elements in the vector, the circulator would implement a random access modulus the size of the sequence.

```
std::vector<int> v;
typedef CGAL::Circulator_from_iterator<
    std::vector<int>::iterator > Circulator;
Circulator c( v.begin(), v.end());
```

### 63.2.6 Functions on Circulators

A few functions deal with circulators and circulator ranges. The type  $C$  denotes a circulator. The type  $IC$  denotes either a circulator or an iterator. More on algorithms that work with circulators as well with iterators can be found in the reference pages.

```
#include <CGAL/circulator.h>
```

<i>circulator_size</i> ( $C\ c$ )	size of the sequence reachable by $c$
<i>circulator_distance</i> ( $C\ c, C\ d$ )	number of elements in the range $[c, d)$
<i>iterator_distance</i> ( $IC\ ic1, IC\ ic2$ )	number of elements in the range $[ic2, ic1)$
<i>is_empty_range</i> ( $IC\ ic1, IC\ ic2$ )	test the range $[ic2, ic1)$ for emptiness

# Handles and Circulators

## Reference Manual

*Olivier Devillers, Lutz Kettner, Michael Seel, and Mariette Yvinec*

Most data structures in CGAL use the concept of *Handle* in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A *Handle* is akin to a pointer to an object providing the dereference operator *operator\**() and member access *operator->*() but no increment or decrement operators like iterators. A *Handle* is intended to be used whenever the referenced object is not part of a logical sequence.

The concept of iterators in STL is tailored for linear sequences. In contrast, circular sequences occur naturally in many combinatorial and geometric structures. Examples are polyhedral surfaces and planar maps, where the edges emanating from a vertex or the edges around a facet form a circular sequence.

We provide several functions, classes and macros to assist in working with circulators: distance computation, adaptor classes converting between circulators and iterators, base classes to ease the implementation of circulators, and support for generic algorithms that work with circulators as well as with iterators.

## CGAL::Assert\_circulator

### Definition

Each of the following assertions, applicable to an iterator or a circulator or both, checks at compile time if its argument is of the kind stated in the assertions name, i.e. a circulator, an iterator, or a particular category of either an iterator or a circulator. Note that neither input nor output circulators exists.

```
#include <CGAL/circulator.h>
```

```
void          Assert_circulator( C c)
void          Assert_iterator( I i)
void          Assert_circulator_or_iterator( IC i)

void          Assert_input_category( I i)
void          Assert_output_category( I i)
void          Assert_forward_category( IC ic)
void          Assert_bidirectional_category( IC ic)
void          Assert_random_access_category( IC ic)
```

### See Also

*Circulator\_tag*, *Circulator\_traits*, *query\_circulator\_or\_iterator*, *Circulator*.

## CGAL::circulator\_distance

### Definition

The distance of a circulator  $c$  to a circulator  $d$  is the number of elements in the range  $[c, d)$ . It is defined to be zero for a circulator on an empty sequence and it returns the size of the data structure when applied to a range of the form  $[c, c)$ .

```
#include <CGAL/circulator.h>
```

```
template <class C>  
C::difference_type      circulator_distance( C c, C d)
```

### See Also

*circulator\_size*, *iterator\_distance*, *is\_empty\_range*, *Circulator*.

## CGAL::circulator\_size

### Definition

The size of a circulator is the size of the data structure it refers to. It is zero for a circulator on an empty sequence. The size can be computed in linear time for forward and bidirectional circulators, and in constant time for random access circulators using the minimal circulator. The function *circulator\_size(c)* returns the circulator size. It uses the *c.min\_circulator()* function if *c* is a random access circulator.

```
#include <CGAL/circulator.h>
```

```
template <class C>  
C::size_type          circulator_size( C c)
```

# Circulator

## Definition

Note: This specification is a revised version based on the C++ Standard [C++98], which is available now. In particular, iterator traits are now assumed and required.

Iterators in the STL were tailored for linear sequences. The specialization for circular data structures leads to slightly different requirements which we will summarize in the *circulators* concept. The main difference is that a circular data structure has no natural past-the-end value. As a consequence, a container supporting circulators will not have an `end()`-member function. The semantic of a circulator range differs from the semantic of an iterator range. For a circulator  $c$  the range  $[c, c)$  denotes the sequence of all elements in the data structure. For iterators, this range defines the empty sequence. A separate test for an empty sequence has been added to the circulator requirements: A comparison  $c == \text{NULL}$  for a circulator  $c$  is true for an empty sequence. As for C++, we recommend the use of 0 instead of `NULL`.

Similar to STL iterators, we distinguish between forward, bidirectional, and random access circulators<sup>2</sup>. Most requirements for circulators are equal to those for iterators. We present the changes, please refer to [MS96, chapter 18] or [C++98] for the iterator requirements.

**Past-the-end value:** There is no past-the-end value for circulators.

**Singular values:** There are no singular values for circulators<sup>3</sup>

**Empty sequence:** The comparison  $c == \text{NULL}$  (or  $c == 0$ ) for a circulator  $c$  is `true` if  $c$  denotes an empty sequence, and `false` otherwise.

**Dereferenceable values:** A circulator that does not denote an empty sequence is dereferenceable.

**Reachability:** Each dereferenceable circulator can reach itself with a finite and non-empty sequence of applications of `operator++`.

**Ranges:** For any circulator  $c$  the range  $[c, c)$  is a valid range. If the circulator refers to an empty sequence, the range  $[c, c)$  denotes the empty range. Otherwise the circulator is dereferenceable and the range  $[c, c)$  denotes the sequence of all elements in the data structure. *Remark:* When a circulator is used in a place of an iterator, as, for example, with an STL algorithm, it will work as expected with the only exception that, in STL algorithms, the range  $[c, c)$  denotes always the empty range. This is not a requirement, but a consequence of the requirements stated here and the fact that the STL requirements for iterator ranges are based on the `operator++` and the `operator==`, which we use for circulators as well. In principle, we face here the difference between a `while` loop and a `do-while` loop.

**Types:** For a circulator of type  $C$  the following local types are required:

<code>C::value_type</code>	value type the circulator refers to.
<code>C::reference</code>	reference type used for the return type of <code>C::operator*()</code> .
<code>C::pointer</code>	pointer type used for the return type of <code>C::operator-&gt;()</code> .
<code>C::size_type</code>	unsigned integral type that can hold the size of a sequence
<code>C::difference_type</code>	signed integral type that can hold the distance between two circulators.
<code>C::iterator_category</code>	circulator category.

<sup>2</sup>Input circulators are a contradiction, since any circulator is supposed to return once to itself. Output circulators are not supported since they would be indistinguishable from output iterators.

<sup>3</sup>Since circulators must be implemented as classes anyway, there is no need to allow singular values for them. An un-initialized circulator does not have a singular value, but is supposed to refer to an empty sequence.

## Forward Circulators

In the following, we assume that  $a$  and  $b$  are circulators of type  $C$ ,  $r$  is of type  $C\&$  (is assignable), and  $T$  denotes the value type of  $C$ . Let  $D$  be the distance type of  $C$ . As for  $C++$ , we recommend the use of  $0$  instead of  $NULL$ .

<code>C()</code>	a circulator equal to <i>NULL</i> denoting an empty sequence.
<code>a == NULL</code>	Returns <i>true</i> if $a$ denotes an empty sequence, <i>false</i> otherwise. For simplicity, <code>NULL == a</code> is not required. The behavior for comparisons with pointer-like values different than <i>NULL</i> is undefined. A runtime assertion is recommended.
<code>a != NULL</code>	Returns <code>!(a == NULL)</code> .
<code>++r</code>	Like for forward iterators, but a dereferenceable circulator $r$ will always be dereferenceable after <code>++r</code> (no past-the-end value). <i>Precondition:</i> $r$ does not denote an empty sequence.
<code>r++</code>	Same as for <code>++r</code> .
<code>C::iterator_category</code>	circulator category <code>CBP_Forward_circulator_tag</code> .

## Bidirectional Circulators

The same requirements as for the forward circulators hold for bidirectional iterators with the following change of the iterator category:

<code>C::iterator_category</code>	circulator category <code>CBP_Bidirectional_circulator_tag</code> .
-----------------------------------	---

## Random Access Circulators

The same requirements as for the bidirectional circulators hold for random access iterators with the following changes and extensions.

The idea of random access extends naturally to circulators using equivalence classes modulus the length of the sequence. With this in mind, the additional requirements for random access iterators hold also for random access circulators. The only exception is that the random access iterator is required to provide a total order on the sequence, which a circulator cannot provide<sup>4</sup>.

The difference of two circulators is not unique as for iterators. A reasonable requirement demands that the result is in a certain range  $[1 - size, size - 1]$ , where *size* is the size of the sequence, and that whenever a circulator  $a$  is fixed that the differences with all other circulators of the sequence form a consistent ordering.

For the adaptor to iterators a minimal circulator  $d_{\min}$  is required for which the difference  $c - d_{\min}$  to all other circulators  $c$  is non negative.

<code>b - a</code>	limited range and consistent ordering as explained above.
<code>a.min_circulator()</code>	returns the minimal circulator from the range $[a, a)$ .
<code>C::iterator_category</code>	circulator category <code>CBP_Random_access_circulator_tag</code> .

---

<sup>4</sup>One might define an order by splitting the circle at a fixed point, e.g. the start circulator provided from the data structure. This is what the adaptor to iterators will do. Nonetheless, we do not require this for circulators.

## Const Circulators

As with iterators, we distinguish between circulators and const circulators. The expression `*a = t` with `t` of type `T` is valid for mutable circulators. It is invalid for const circulators.

## Circulators in Container Classes

For a container `x` of type `X` that supports circulators `c` the following naming convention is recommended:

<code>X::Circulator</code>	the type of the mutable circulator.
<code>X::Const_circulator</code>	the type of the const circulator.
<code>c = x.begin()</code>	the start circulator of the sequence. It is of type <code>X::Circulator</code> for a mutable container or <code>X::Const_circulator</code> for a const container. There must not be an <code>end()</code> member function.

If a container will support iterators and circulators, the member function `circulator_begin()` is proposed. However, the support of iterators and circulators simultaneously is not recommended, since it would lead to fat interfaces. The natural choice should be supported, the other concept will be available through adaptors.

## Example

A generic `contains` function accepts a range of circulators and a value. It returns *true* if the value is contained in the sequence of items denoted by the range of circulators. As usual for circular structures, a do-while loop is preferable, such that for the specific input, `c == d`, all elements in the sequence are reached. Note that the example simplifies if the sequence is known to be non-empty, which is for example the common case in polyhedral surfaces where vertices and facets have at least one incident edge.

```
template <class Circulator, class T>
bool contains( Circulator c, Circulator d, const T& value) {
    if (c != 0) {
        do {
            if (*c == value)
                return true;
        } while (++c != d);
    }
    return false;
}
```

```

#include <CGAL/basic.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/circulator.h>

typedef CGAL::Circulator_from_container< std::vector<int> > Circulator;
typedef CGAL::Container_from_circulator<Circulator> Container;
typedef Container::iterator Iterator;

int main() {
    std::vector<int> v;
    v.push_back(5);
    v.push_back(2);
    v.push_back(9);
    Circulator c( &v);
    Container container( c);
    std::sort( container.begin(), container.end());
    Iterator i = container.begin();
    assert( *i == 2);
    i++;    assert( *i == 5);
    i++;    assert( *i == 9);
    i++;    assert( i == container.end());
    return 0;
}

```

**File:** examples/Circulator/circulator\_prog2.cpp

## CGAL::Circulator\_from\_iterator<I>

### Definition

The adaptor *Circulator\_from\_iterator<I>* converts two iterators of type *I*, a begin and a past-the-end value, to a circulator of equal category. The iterator must be at least of the forward iterator category. The circulator will be mutable or non-mutable according to the iterator. Iterators provide no *size\_type*. This adapter assumes *std::size\_t* instead.

```
#include <CGAL/circulator.h>
```

### Types

```
typedef I          iterator;
```

In addition all types required for circulators are provided.

### Creation

```
Circulator_from_iterator<I> c;          a circulator c on an empty sequence.
```

```
Circulator_from_iterator<I> c( I begin, I end, I cur = begin);
```

a circulator *c* initialized to refer to the element *\*cur* in a range *[begin, end)*. The circulator *c* refers to a empty sequence if *begin==end*.

```
Circulator_from_iterator<I> c( Circulator_from_iterator<I,T,Size,Dist> d, I cur);
```

a copy of circulator *d* referring to the element *\*cur*. The circulator *c* refers to a empty sequence if *d* does so.

### Operations

The adaptor conforms to the requirements of the respective circulator category. An additional member function *current\_iterator()* returns the current iterator pointing to the same position as the circulator does.

### See Also

*Container\_from\_circulator*, *Circulator\_from\_container*, *Circulator*.

### Example

The following program composes two adaptors – from an iterator to a circulator and back to an iterator. It applies an STL sort algorithm on a STL vector containing three elements. The resulting vector will be [2 5 9] as it is checked by the assertions. The program is part of the CGAL distribution.

```

#include <CGAL/basic.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/circulator.h>

typedef std::vector<int>::iterator      I;
typedef CGAL::Circulator_from_iterator<I>      Circulator;
typedef CGAL::Container_from_circulator<Circulator> Container;
typedef Container::iterator      Iterator;

int main() {
    std::vector<int> v;
    v.push_back(5);
    v.push_back(2);
    v.push_back(9);
    Circulator c( v.begin(), v.end());
    Container container( c);
    std::sort( container.begin(), container.end());
    Iterator i = container.begin();
    assert( *i == 2);
    i++;    assert( *i == 5);
    i++;    assert( *i == 9);
    i++;    assert( i == container.end());
    return 0;
}

```

**File:** examples/Circulator/circulator\_prog1.cpp

Another example usage for this adaptor is a random access circulator over the built-in C arrays. Given an array of type  $T^*$  with a begin pointer  $b$  and a past-the-end pointer  $e$  the adaptor *Circulator\_from\_iterator* $\langle T^* \rangle c(b,e)$  is a random access circulator  $c$  over this array.

## CGAL::Circulator\_tag

### Definition

Iterators and circulators as well as different categories of circulators can be distinguished with the use of discriminating functions and the following circulator tags. A couple of base classes simplify the task of writing own circulators. They declare the appropriate tags and the local types needed for circulators. To use the tags or base classes only it is sufficient to include:

```
#include <CGAL/circulator_bases.h>
#include <CGAL/circulator.h>
```

### Compile Time Tags

<code>struct Circulator_tag {};</code>	any circulator.
<code>struct Iterator_tag {};</code>	any iterator.
 <code>struct Forward_circulator_tag {};</code>	 derived from <code>forward_iterator_tag</code> .
<code>struct Bidirectional_circulator_tag {};</code>	derived from <code>bidirectional_iterator_tag</code> .
<code>struct Random_access_circulator_tag {};</code>	derived from <code>random_access_iterator_tag</code> .

### Base Classes

```
template < class Category, class T, class Dist = std::ptrdiff_t, class Size = std::size_t, class Ptr = T*, class Ref
= T& >
struct Circulator_base {};

struct Forward_circulator_base {};
struct Bidirectional_circulator_base {};
struct Random_access_circulator_base {};
```

### See Also

`query_circulator_or_iterator`, `Circulator_traits`, `Assert_circulator`,  
`CGAL_For_all`, `is_empty_range`, `Circulator`.

### Example

The above declarations can be used to distinguish between iterators and circulators and between different circulator categories. The assertions can be used to protect a templated algorithm against instantiations that do not fulfill the requirements. The following example program illustrates both.

```
#include <CGAL/basic.h>
#include <cassert>
#include <list>
#include <CGAL/circulator.h>
```

```

template <class C> inline int foo( C c, std::forward_iterator_tag) {
    CGAL::Assert_circulator( c);
    CGAL::Assert_forward_category( c);
    return 1;
}
template <class C> inline int foo( C c, std::random_access_iterator_tag) {
    CGAL::Assert_circulator( c);
    CGAL::Assert_random_access_category( c);
    return 2;
}
template <class I> inline int foo( I i, CGAL::Iterator_tag) {
    CGAL::Assert_iterator( i);
    return 3;
}

template <class C> inline int foo( C c, CGAL::Circulator_tag) {
    CGAL::Assert_circulator( c);
    typedef std::iterator_traits<C> Traits;
    typedef typename Traits::iterator_category iterator_category;
    return foo( c, iterator_category());
}
template <class IC> inline int foo( IC ic) {
    typedef CGAL::Circulator_traits<IC> Traits;
    typedef typename Traits::category category;
    return foo( ic, category());
}

int main() {
    typedef CGAL::Forward_circulator_base<int> F;
    typedef CGAL::Random_access_circulator_base<int> R;
    F f = F();
    R r = R();
    std::list<int> l;
    assert( foo( f) == 1);
    assert( foo( r) == 2);
    assert( foo( l.begin()) == 3);
    return 0;
}

```

**File:** examples/Circulator/circulator\_prog3.cpp

## Implementation

Since not all current compilers can eliminate the space needed for the compile time tags even when deriving from them, we implement a variant for each base class that contains a protected *void\** data member called *\_ptr*. Here, the allocated space in the derived classes can be reused.

<i>template &lt;class T, class Dist, class Size&gt;</i>	
<i>class Forward_circulator_ptrbase {};</i>	forward circulator.
<i>template &lt;class T, class Dist, class Size&gt;</i>	
<i>class Bidirectional_circulator_ptrbase {};</i>	bidirectional circulator.
<i>template &lt;class T, class Dist, class Size&gt;</i>	

*class Random\_access\_circulator\_ptrbase* {};

random access circulator.

## CGAL::Circulator\_traits<C>

### Definition

The circulator traits class distinguishes between circulators and iterators. It defines a local type *category* that is identical to the type *Circulator\_tag* if the iterator category of the argument *C* is a circulator category. Otherwise it is identical to the type *Iterator\_tag*.

The local type *iterator\_category* gives the corresponding iterator category for circulators, i.e. one of *forward\_iterator\_tag*, *bidirectional\_iterator\_tag*, or *random\_access\_iterator\_tag*.

The local type *circulator\_category* gives the corresponding circulator category for iterators, i.e. one of *Forward\_circulator\_tag*, *Bidirectional\_circulator\_tag*, or *Random\_access\_circulator\_tag*.

```
#include <CGAL/circulator.h>
```

### Types

<i>Circulator_traits&lt;C&gt;::category</i>	either <i>Iterator_tag</i> or <i>Circulator_tag</i> .
<i>Circulator_traits&lt;C&gt;::iterator_category</i>	corresponding iterator category for circulators.
<i>Circulator_traits&lt;C&gt;::circulator_category</i>	corresponding circulator category for iterator

### Example

A generic function *bar* that distinguishes between a call with a circulator range and a call with an iterator range:

```
template <class I>
void bar( I i, I j, CGAL::Iterator_tag) {
    CGAL::Assert_iterator(i);
    // This function is called for iterator ranges [i,j).
}
template <class C>
void bar( C c, C d, CGAL::Circulator_tag) {
    CGAL::Assert_circulator(c);
    // This function is called for circulator ranges [c,d).
}
template <class IC>
void bar( IC i, IC j) { // calls the correct function
    return bar( i, j, typename CGAL::Circulator_traits<IC>::category());
}
```

## CGAL::Container\_from\_circulator<C>

### Definition

The adaptor *Container\_from\_circulator<C>* is a class that converts any circulator type *C* to a kind of container class, i.e. a class that provides an *iterator* and a *const\_iterator* type and two member functions – *begin()* and *end()* – that return the appropriate iterators. By analogy to STL container classes these member functions return a const iterator in the case that the container itself is constant and a mutable iterator otherwise.

```
#include <CGAL/circulator.h>
```

### Types

```
typedef C          Circulator;
Container_from_circulator<C>:: iterator
Container_from_circulator<C>:: const_iterator
Container_from_circulator<C>:: value_type
Container_from_circulator<C>:: reference
Container_from_circulator<C>:: const_reference
Container_from_circulator<C>:: pointer
Container_from_circulator<C>:: const_pointer
Container_from_circulator<C>:: size_type
Container_from_circulator<C>:: difference_type
```

### Creation

```
Container_from_circulator<C> container;
```

any iterator of *container* will have a singular value.

```
Container_from_circulator<C> container( C c);
```

any iterator of *container* will have a singular value if the circulator *c* corresponds to an empty sequence.

### Operations

<i>iterator</i>	<i>container.begin()</i>	the start iterator.
<i>const_iterator</i>	<i>container.begin() const</i>	the start const iterator.
<i>iterator</i>	<i>container.end()</i>	the past-the-end iterator.
<i>const_iterator</i>	<i>container.end() const</i>	the past-the-end const iterator.

The *iterator* and *const\_iterator* types are of the appropriate iterator category. In addition to the operations required for their category, they have a member function *current\_circulator()* that returns a circulator pointing to the same position as the iterator does.

## See Also

*Circulator\_from\_iterator*, *Circulator\_from\_container*, *Circulator*.

## Example

The generic `reverse()` algorithm from the STL can be used with an adaptor if at least a bidirectional circulator `c` is given.

```
Circulator c; // c is assumed to be a bidirectional circulator.
CGAL::Container_from_circulator<Circulator> container(c);
reverse( container.begin(), container.end());
```

## Implementation

The iterator adaptor keeps track of the number of rounds a circulator has done around the ring-like data structure (a kind of winding number). It is used to distinguish between the start position and the end position which will be denoted by the same circulator internally. This winding number is zero for the *begin()*-iterator and one for the *end()*-iterator. It is incremented whenever the internal circulator passes the *begin()* position. Two iterators are equal if their internally used circulators and winding numbers are equal. This is more general than necessary since an iterator equal to *end()*-iterator is not supposed to be incremented any more, which is here still possible in a defined manner.

The implementation is different for random access iterators. The random access iterator has to be able to compute the size of the data structure in constant time. This is for example needed if the difference of the past-the-end iterator and the begin iterator is taken, which is exactly the size of the data structure. Therefore, if the circulator is of the random-access category, the adapter chooses the minimal circulator for the internal anchor position. The minimal circulator is part of the random access circulator requirements, see Page [3478](#). For the random access iterator the adaptor implements a total ordering relation that is currently not required for random access circulators.

## CGAL\_For\_all

### Definition

In order to write algorithms that work with iterator ranges as well as with circulator ranges we have to consider the difference of representing an empty range. For iterators this is the range  $[i, i)$ , while for circulators it would be  $c == \text{NULL}$ , the empty sequence test. The function *is\_empty\_range* provides the necessary generic test which accepts an iterator range or a circulator range and says whether the range is empty or not.

```
#include <CGAL/circulator.h>
```

A macro *CGAL\_For\_all*( *i*, *j*) simplifies the writing of such simple loops as the one in the example of the function *is\_empty\_range*. *i* and *j* can be either iterators or circulators. The macro loops through the range  $[i, j)$ . It increments *i* until it reaches *j*. The implementation looks like:

```
CGAL_For_all(i,j)  ≡  for ( bool _circ_loop_flag = ! ::CGAL::is_empty_range(i, j);
                          _circ_loop_flag;
                          _circ_loop_flag = ((++i) != (j))
                          )
```

Note that the macro behaves like a *for*-loop. It can be used with a single statement or with a statement block. For bidirectional iterators or circulators, a backwards loop macro *CGAL\_For\_all\_backwards*( *i*, *j*) exists that decrements *j* until it reaches *i*.

*Assert\_circulator\_or\_iterator*, *Circulator*.

# Handle

## Definition

Most data structures in CGAL use the concept of Handle in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A Handle is akin to a pointer to an object providing the dereference operator *operator\**() and member access *operator->*() but no increment or decrement operators like iterators. A Handle is intended to be used whenever the referenced object is not part of a logical sequence.

Like iterators, the handle can be passed as template argument to *std::iterators\_traits* in order to extract its *value\_type*, the type of the element pointed to. The *iterator\_category* is *void*.

## Refines

DefaultConstructible, CopyConstructible, Assignable, EqualityComparable

The default constructed object must be unique as far as the equality operator is concerned (this serves the same purpose as NULL for pointers). (Note that this is not a generally supported feature of iterators of standard containers.)

## Creation

## Dereference

<i>value_type</i> &	<i>*h</i>	returns the object pointed to.
<i>value_type</i> *	<i>h</i> $\rightarrow$	returns a pointer to the object pointed to.

## Has Models

pointers  
const pointers  
iterators  
circulators

## CGAL::is\_empty\_range

### Definition

In order to write algorithms that work with iterator ranges as well as with circulator ranges we have to consider the difference of representing an empty range. For iterators this is the range  $[i, i)$ , while for circulators it would be  $c == \text{NULL}$ , the empty sequence test. The function *is\_empty\_range* provides the necessary generic test which accepts an iterator range or a circulator range and says whether the range is empty or not.

```
#include <CGAL/circulator.h>
```

```
template< class IC>
```

```
bool    is_empty_range( IC i, IC j)    is true if the range  $[i, j)$  is empty, false otherwise.  
                                             Precondition: IC is either a circulator or an iterator type. The range  $[i, j)$  is valid.
```

### Example

The following function *process\_all* accepts a range  $[i, j)$  of an iterator or circulator *IC* and processes each element in this range:

```
template <class IC>
void process_all( IC i, IC j) {
    if (! CGAL::is_empty_range( i, j)) {
        do {
            process(*i);
        } while (++i != j);
    }
}
```

## CGAL::query\_circulator\_or\_iterator

### Definition

The following function distinguishes between circulators and iterators. It is based on iterator traits [C++98, Mye95] and *Circulator\_traits*.

```
#include <CGAL/circulator.h>
```

```
template <class I>
Iterator_tag    query_circulator_or_iterator( I i)
```

if the iterator category of *I* belongs to an iterator.

```
template <class C>
Circulator_tag  query_circulator_or_iterator( C c)
```

if the iterator category of *C* belongs to a circulator.

### 64.1 Introduction

A variety of generators for geometric objects are provided in CGAL. They are useful as synthetic test data sets, e.g. for testing algorithms on degenerate object sets and for performance analysis.

Two kinds of point generators are provided: first, random point generators and second deterministic point generators. Most random point generators and a few deterministic point generators are provided as input iterators. The input iterators model an infinite sequence of points. The function `CGAL::copy_n()` can be used to copy a finite sequence; see Section 61.6. The iterator adaptor `Counting_iterator` can be used to create finite iterator ranges; see Section 61.6. Other generators are provided as functions that write to output iterators. Further functions add degeneracies or random perturbations.

In 2D, we provide input iterators to generate random points in a disc (`Random_points_in_disc_2`), in a square (`Random_points_in_square_2`), on a circle (`Random_points_on_circle_2`), on a segment (`Random_points_on_segment`), and on a square (`Random_points_on_square_2`). For generating grid points we provide three functions, `points_on_segment_2`, `points_on_square_grid_2` that write to output iterators and an input iterator `Points_on_segment_2`.

For 3D points, input iterators are provided for random points uniformly distributed in a sphere (`Random_points_in_sphere_3`) or cube (`Random_points_in_cube_3`) or on the boundary of a sphere (`Random_points_on_sphere_3`). For generating 3D grid points, we provide the function `points_on_cube_grid_3` that writes to an output iterator.

We also provide two functions for generating more complex geometric objects. The function *random\_convex\_set\_2* computes a random convex planar point set of a given size where the points are drawn from a specific domain and *random\_polygon\_2* generates a random simple polygon from points drawn from a specific domain.

### 64.1.1 Random Perturbations

Degenerate input sets like grid points can be randomly perturbed by a small amount to produce *quasi*-degenerate test sets. This challenges numerical stability of algorithms using inexact arithmetic and exact predicates to compute the sign of expressions slightly off from zero. For this the function *perturb\_points\_2* is provided.

### 64.1.2 Adding Degeneracies

For a given point set certain kinds of degeneracies can be produced by adding new points. The *random\_selection()* function is useful for generating multiple copies of identical points. The function *random\_collinear\_points\_2()* adds collinearities to a point set.

### 64.1.3 Support Functions and Classes for Generators

The function *random\_selection* chooses  $n$  items at random from a random access iterator range which is useful to produce degenerate input data sets with multiple entries of identical items.

## 64.2 Example Generating Degenerate Point Sets

We want to generate a test set of 1000 points, where 60% are chosen randomly in a small disc, 20% are from a larger grid, 10% are duplicates points, and 10% collinear points. A random shuffle removes the construction order from the test set. See Figure 64.1 for the example output.

```
#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>
#include <CGAL/random_selection.h>

using namespace CGAL;

typedef Simple_cartesian<double>          R;
typedef R::Point_2                        Point;
typedef Creator_uniform_2<double,Point>   Creator;
typedef std::vector<Point>                Vector;

int main() {
    // Create test point set. Prepare a vector for 1000 points.
    Vector points;
    points.reserve(1000);
```

```

// Create 600 points within a disc of radius 150.
Random_points_in_disc_2<Point,Creator> g( 150.0);
CGAL::copy_n( g, 600, std::back_inserter(points));

// Create 200 points from a 15 x 15 grid.
points_on_square_grid_2( 250.0, 200, std::back_inserter(points),Creator());

// Select 100 points randomly and append them at the end of
// the current vector of points.
random_selection( points.begin(), points.end(), 100,
    std::back_inserter(points));

// Create 100 points that are collinear to two randomly chosen
// points and append them to the current vector of points.
random_collinear_points_2( points.begin(), points.end(), 100,
    std::back_inserter( points));

// Check that we have really created 1000 points.
assert( points.size() == 1000);

// Use a random permutation to hide the creation history
// of the point set.
std::random_shuffle( points.begin(), points.end(), default_random);

// Check range of values.
for ( Vector::iterator i = points.begin(); i != points.end(); i++){
assert( i->x() <= 251);
assert( i->x() >= -251);
assert( i->y() <= 251);
assert( i->y() >= -251);
}
return 0;
}

```

**File:** examples/Generator/random\_degenerate\_point\_set.cpp

## 64.3 Example Generating Grid Points

The second example demonstrates the point generators with integer points. Arithmetic with *doubles* is sufficient to produce regular integer grids. See Figure 64.2 for the example output.

```

#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>

using namespace CGAL;

```

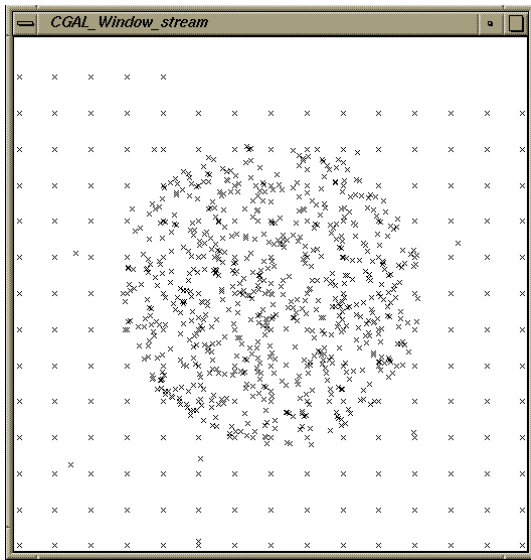

Figure 64.1: Output of example program for point generators.

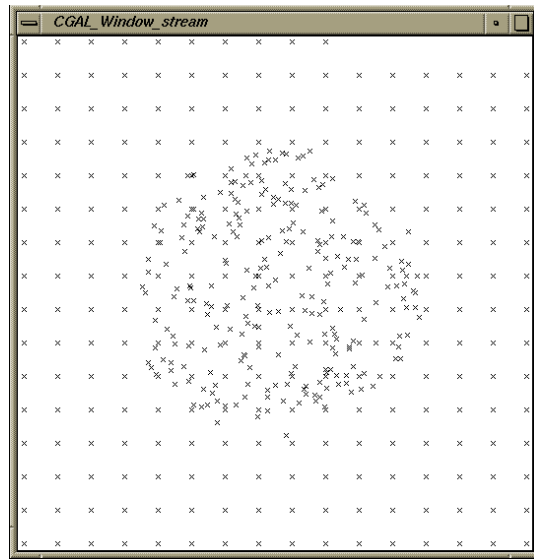

Figure 64.2: Output of example program for point generators working on integer points.

```
typedef Simple_cartesian<int>      R;
typedef R::Point_2                 Point;
typedef Creator_uniform_2<int,Point> Creator;

int main() {
    // Create test point set. Prepare a vector for 400 points.
    std::vector<Point> points;
    points.reserve(400);

    // Create 250 points from a 16 x 16 grid. Note that the double
    // arithmetic is sufficient to produce exact integer grid points.
    // The distance between neighbors is 34 pixel = 510 / 15.
    points_on_square_grid_2( 255.0, 250, std::back_inserter(points),Creator());

    // Lower, left corner.
    assert( points[0].x() == -255);
    assert( points[0].y() == -255);

    // Upper, right corner. Note that 6 points are missing to fill the grid.
    assert( points[249].x() == 255 - 6 * 34);
    assert( points[249].y() == 255);

    // Create 250 points within a disc of radius 150.
    Random_points_in_disc_2<Point,Creator> g( 150.0);
    CGAL::copy_n( g, 250, std::back_inserter(points));

    // Check that we have really created 500 points.
    assert( points.size() == 500);
    return 0;
}
```

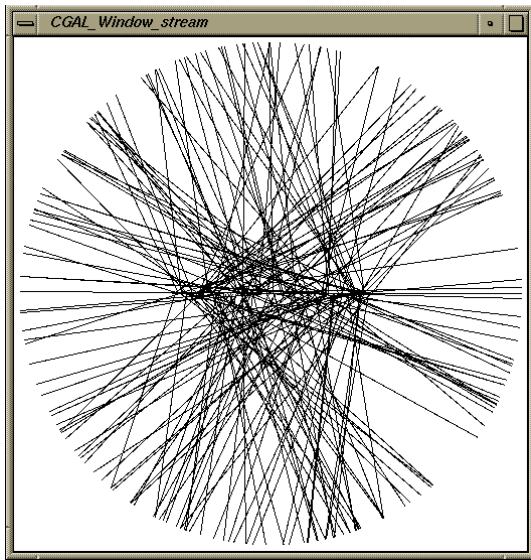

Figure 64.3: Output of the first example program for the generic generator.

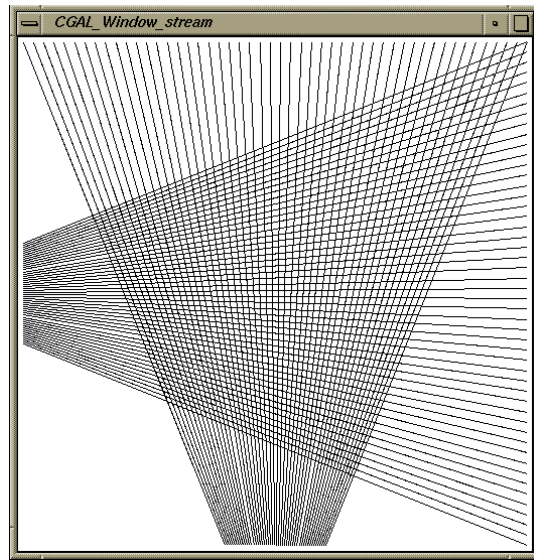

Figure 64.4: Output of the second example program for the generic generator without using intermediate storage.

**File:** examples/Generator/random\_grid.cpp

## 64.4 Examples Generating Segments

The following two examples illustrate the use of the generic functions from Section 61.6 like *Join\_input\_iterator\_2* to generate composed objects from other generators – here two-dimensional segments from two point generators.

We want to generate a test set of 200 segments, where one endpoint is chosen randomly from a horizontal segment of length 200, and the other endpoint is chosen randomly from a circle of radius 250. See Figure 64.3 for the example output.

```
#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/Point_2.h>
#include <CGAL/Segment_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/algorithm.h>

using namespace CGAL;

typedef Simple_cartesian<double>          R;
typedef R::Point_2                        Point;
typedef Creator_uniform_2<double, Point> Pt_creator;
```

```

typedef R::Segment_2          Segment;
typedef std::vector<Segment>   Vector;

int main() {
    // Create test segment set. Prepare a vector for 200 segments.
    Vector segs;
    segs.reserve(200);

    // Prepare point generator for the horizontal segment, length 200.
    typedef Random_points_on_segment_2<Point,Pt_creator> P1;
    P1 p1( Point(-100,0), Point(100,0));

    // Prepare point generator for random points on circle, radius 250.
    typedef Random_points_on_circle_2<Point,Pt_creator> P2;
    P2 p2( 250);

    // Create 200 segments.
    typedef Creator_uniform_2< Point, Segment> Seg_creator;
    typedef Join_input_iterator_2< P1, P2, Seg_creator> Seg_iterator;
    Seg_iterator g( p1, p2);
    CGAL::copy_n( g, 200, std::back_inserter(segs));

    assert( segs.size() == 200);
    for ( Vector::iterator i = segs.begin(); i != segs.end(); i++){
        assert( i->source().x() <= 100);
        assert( i->source().x() >= -100);
        assert( i->source().y() == 0);
        assert( i->target().x() * i->target().x() +
                i->target().y() * i->target().y() <= 251*251);
        assert( i->target().x() * i->target().x() +
                i->target().y() * i->target().y() >= 249*249);
    }
    return 0;
}

```

**File:** examples/Generator/random\_segments1.cpp

The second example generates a regular structure of 100 segments; see Figure 64.4 for the example output. It uses the *Points\_on\_segment\_2* iterator, *Join\_input\_iterator\_2* and *Counting\_iterator* to avoid any intermediate storage of the generated objects until they are used, which in this example means copied to a window stream.

```

#include <CGAL/Simple_cartesian.h>
#include <algorithm>
#include <vector>
#include <CGAL/point_generators_2.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/Counting_iterator.h>

using namespace CGAL;

typedef Simple_cartesian<double>          R;

```

```

typedef R::Point_2                               Point;
typedef R::Segment_2                             Segment;
typedef Points_on_segment_2<Point>               PG;
typedef Creator_uniform_2< Point, Segment>       Creator;
typedef Join_input_iterator_2< PG, PG, Creator>   Segm_iterator;
typedef Counting_iterator<Segm_iterator,Segment> Count_iterator;
typedef std::vector<Segment>                     Vector;

int main() {
    // Create test segment set. Prepare a vector for 100 segments.
    Vector segs;
    segs.reserve(100);

    // A horizontal like fan.
    PG p1( Point(-250, -50), Point(-250, 50),50); // Point generator.
    PG p2( Point( 250,-250), Point( 250,250),50);
    Segm_iterator t1( p1, p2); // Segment generator.
    Count_iterator t1_begin( t1); // Finite range.
    Count_iterator t1_end( 50);
    std::copy( t1_begin, t1_end, std::back_inserter(segs));

    // A vertical like fan.
    PG p3( Point( -50,-250), Point( 50,-250),50);
    PG p4( Point(-250, 250), Point( 250, 250),50);
    Segm_iterator t2( p3, p4);
    Count_iterator t2_begin( t2);
    Count_iterator t2_end( 50);
    std::copy( t2_begin, t2_end, std::back_inserter(segs));

    CGAL_assertion( segs.size() == 100);
    for ( Vector::iterator i = segs.begin(); i != segs.end(); i++){
        CGAL_assertion( i->source().x() <= 250);
        CGAL_assertion( i->source().x() >= -250);
        CGAL_assertion( i->source().y() <= 250);
        CGAL_assertion( i->source().y() >= -250);
        CGAL_assertion( i->target().x() <= 250);
        CGAL_assertion( i->target().x() >= -250);
        CGAL_assertion( i->target().y() <= 250);
        CGAL_assertion( i->target().y() >= -250);
    }
    return 0;
}

```

# Geometric Object Generators

## Reference Manual

*Susan Hert, Michael Hoffmann, Lutz Kettner, and Sven Schönherr*

This chapter describes the functions and classes provided in CGAL that are useful for generating synthetic test data sets, *e.g.*, for testing algorithms on degenerate object sets and for performance analysis. These include a class for generating random numbers and function for selecting random items from a set of objects, generators for two-dimensional and three-dimensional points sets, a generator for random convex sets and one for simple polygons. The STL algorithm *std::random\_shuffle* is useful with these functions and classes to to achieve random permutations for otherwise regular generators ( *e.g.*, points on a grid or segment).

## CGAL::default\_random

### Definition

The variable *default\_random* is the default random numbers generator used for the generator functions and classes.

```
#include <CGAL/Random.h>
```

```
Random                default_random;
```

## CGAL::perturb\_points\_2

### Definition

The function *perturb\_points\_2* perturbs each point in a given range of points by a random amount.

```
#include <CGAL/point_generators_2.h>
```

```
template <class ForwardIterator>
void perturb_points_2(
    ForwardIterator first,
    ForwardIterator last,
    double xeps,
    double yeps = xeps,
    Random& rnd = default_random,
    Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)
```

perturbs the points in the range  $[first, last)$  by replacing each point with a random point from the  $xeps \times yeps$  rectangle centered at the original point. Two random numbers are needed from *rnd* for each point.

### Requirements

- *Creator* must be a function object accepting two *double* values *x* and *y* and returning an initialized point (*x*,*y*) of type *P*.  
Predefined implementations for these creators like the default are described in Section 61.6.
- The *value\_type* of the *ForwardIterator* must be assignable to *P*.
- *P* is equal to the *value\_type* of the *ForwardIterator* when using the default initializer.
- The expressions *to\_double((\*first).x())* and *to\_double((\*first).y())* must result in the respective coordinate values.

## CGAL::points\_on\_segment\_2

### Definition

The function *points\_on\_segment\_2* generates a set of points equally spaced on a segment given the endpoints of the segment.

```
#include <CGAL/point_generators_2.h>
```

```
template <class P, class OutputIterator>
OutputIterator points_on_segment_2( P p, P q, std::size_t n, OutputIterator o)
```

creates  $n$  points equally spaced on the segment from  $p$  to  $q$ , i.e.  $\forall i : 0 \leq i < n : o[i] := \frac{n-i-1}{n-1} p + \frac{i}{n-1} q$ . Returns the value of  $o$  after inserting the  $n$  points.

## CGAL::Points\_on\_segment\_2<Point\_2>

### Definition

The class *Points\_on\_segment\_2<Point\_2>* is a generator for points on a segment whose endpoints are specified upon construction. The points are equally spaced

### Is Model for the Concepts

PointGenerator ..... page [3512](#)

### Types

```
typedef std::input_iterator_tag      iterator_category;
typedef Point_2                     value_type;
typedef std::ptrdiff_t              difference_type;
typedef const Point_2*              pointer;
typedef Point_2                     reference;
```

### Creation

*Points\_on\_segment\_2<Point\_2>* *g*( *Point\_2* *p*, *Point\_2* *q*, *std::size\_t* *n*, *std::size\_t* *i* = 0);

*g* is an input iterator creating points of type *P* equally spaced on the segment from *p* to *q*. *n* − *i* points are placed on the segment defined by *p* and *q*. Values of the index parameter *i* larger than 0 indicate starting points for the sequence further from *p*. Point *p* has index value 0 and *q* has index value *n* − 1. *Requirement:* The expressions *to\_double(p.x())* and *to\_double(p.y())* must result in the respective *double* representation of the coordinates of *p*, and similarly for *q*.

### Operations

*double*      *g.range()*      returns the range in which the point coordinates lie, i.e.  $\forall x : |x| \leq range()$  and  $\forall y : |y| \leq range()$

.

*Point\_2*      *g.source()*      returns the source point of the segment.  
*Point\_2*      *g.target()*      returns the target point of the segment.

## CGAL::points\_on\_square\_grid\_2

### Definition

The function *points\_on\_square\_grid\_2* generates a given number of points on a square grid whose size is determined by the number of points to be generated.

```
#include <CGAL/point_generators_2.h>
```

```
template <class OutputIterator, Creator creator>
OutputIterator      points_on_square_grid_2(
                    double a,
                    std::size_t n,
                    OutputIterator o,
                    Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)
```

creates the first  $n$  points on the regular  $\lceil\sqrt{n}\rceil \times \lceil\sqrt{n}\rceil$  grid within the square  $[-a,a] \times [-a,a]$ . Returns the value of  $o$  after inserting the  $n$  points.

### Requirements

- *Creator* must be a function object accepting two *double* values  $x$  and  $y$  and returning an initialized point  $(x,y)$  of type  $P$ . Predefined implementations for these creators like the default can be found in Section 61.6.
- The *OutputIterator* must accept values of type  $P$ . If the *OutputIterator* has a *value\_type* the default initializer of the *creator* can be used.  $P$  is set to the *value\_type* in this case.

## CGAL::points\_on\_cube\_grid\_3

### Definition

The function *points\_on\_cube\_grid\_3* generates a given number of points on a cubic grid whose size is determined by the number of points to be generated.

```
#include <CGAL/point_generators_3.h>
```

```
template <class OutputIterator, Creator creator>
OutputIterator      points_on_cube_grid_3(
    double a,
    std::size_t n,
    OutputIterator o,
    Creator creator = Creator_uniform_3<Kernel_traits<P>::Kernel::RT,P>)
```

creates the first  $n$  points on the regular  $\lceil n^{1/3} \rceil \times \lceil n^{1/3} \rceil \times \lceil n^{1/3} \rceil$  grid within the cube  $[-a, a] \times [-a, a] \times [-a, a]$ . Returns the value of  $o$  after inserting the  $n$  points.

### Requirements

- *Creator* must be a function object accepting three *double* values  $x$ ,  $y$ , and  $z$  and returning an initialized point  $(x, y, z)$  of type  $P$ . Predefined implementations for these creators like the default can be found in Section 61.6.
- The *OutputIterator* must accept values of type  $P$ . If the *OutputIterator* has a *value\_type* the default initializer of the *creator* can be used.  $P$  is set to the *value\_type* in this case.

## Types

`PointGenerator::value_type`                      the type of point being generated.

## Operations

`double`                      `pg.range() const`                      return an absolute bound for the coordinates of all generated points.

## CGAL::random\_collinear\_points\_2

### Definition

```
#include <CGAL/point_generators_2.h>
```

```
template <class RandomAccessIterator, class OutputIterator>
OutputIterator      random_collinear_points_2(
                    RandomAccessIterator first,
                    RandomAccessIterator last,
                    std::size_t n,
                    OutputIterator first2,
                    Random& rnd = default_random,
                    Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)
```

randomly chooses two points from the range  $[first, last)$ , creates a random third point on the segment connecting these two points, writes it to  $first2$ , and repeats this  $n$  times, thus writing  $n$  points to  $first2$  that are collinear with points in the range  $[first, last)$ . Three random numbers are needed from  $rnd$  for each point. Returns the value of  $first2$  after inserting the  $n$  points.

### Requirements

- *Creator* must be a function object accepting two *double* values  $x$  and  $y$  and returning an initialized point  $(x, y)$  of type  $P$ . Predefined implementations for these creators like the default can be found in Section 61.6.
- The *value\_type* of the *RandomAccessIterator* must be assignable to  $P$ .  $P$  is equal to the *value\_type* of the *RandomAccessIterator* when using the default initializer.
- The expressions  $to\_double((*first).x())$  and  $to\_double((*first).y())$  must result in the respective coordinate values.

## CGAL::random\_convex\_set\_2

### Definition

The function *random\_convex\_set\_2* computes a random convex planar point set of given size where the points are drawn from a specific domain.

```
#include <CGAL/random_convex_set_2.h>
```

```
template < class OutputIterator, class PointGenerator, class Traits >
OutputIterator      random_convex_set_2(
                    int n,
                    OutputIterator o,
                    PointGenerator pg,
                    Traits t = Default_traits)
```

computes a random convex  $n$ -gon by writing its vertices (oriented counterclockwise) to  $o$ . The resulting polygon is scaled such that it fits into the bounding box as specified by  $pg$ . Therefore we cannot easily describe the resulting distribution.

*Precondition:*  $n \geq 3$ .

### Requirements

1. *PointGenerator* is a model of the concept *PointGenerator*
2. *Traits* is a model of the concept *RandomConvexSetTraits\_2*
3. *Point\_generator::value\_type* is equivalent to *Traits::Point\_2* and *OutputIterator::value\_type*.
4. if *Traits* is not specified, *Point\_generator::value\_type* must be *Point\_2*<  $R$  > for some representation class  $R$ ,

The default traits class *Default\_traits* is *Random\_convex\_set\_traits\_2*.

### See Also

*CGAL::Random\_points\_in\_square\_2*<*Point\_2*, *Creator*> ..... page [3528](#)  
*CGAL::Random\_points\_in\_disc\_2*<*Point\_2*, *Creator*> ..... page [3526](#)

### Implementation

The implementation uses the centroid method described in [Sch96] and has a worst case running time of  $O(r \cdot n + n \cdot \log n)$ , where  $r$  is the time needed by  $pg$  to generate a random point.

## Example

The following program displays a random convex 500-gon where the points are drawn uniformly from the unit square centered at the origin.

```
#include <CGAL/Cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>

#include <iostream>
#include <iterator>

typedef CGAL::Cartesian< double >    K;
typedef K::Point_2                   Point_2;
typedef CGAL::Random_points_in_square_2<
    Point_2,
    CGAL::Creator_uniform_2< double, Point_2 > >
    Point_generator;

int main() {
    // create 500-gon and write it into a window:
    CGAL::random_convex_set_2(
        500,
        std::ostream_iterator<Point_2>(std::cout, "\n"),
        Point_generator( 0.5));
    return 0;
}
```

**File:** examples/Generator/random\_convex\_set.cpp

## CGAL::random\_polygon\_2

### Definition

The function *random\_polygon\_2* constructs a random simple polygon from points that are drawn from a specific domain. Though each simple polygon defined on this set of points has a non-zero probability of being constructed, some polygons may have higher probabilities than others. The overall distribution of the generated polygons is not known since it depends on the generated points.

```
#include <CGAL/random_polygon_2.h>
```

```
template < class OutputIterator, class PointGenerator, class Traits >
OutputIterator      random_polygon_2( int n,
                                     OutputIterator result,
                                     PointGenerator pg,
                                     Traits t = Default_traits)
```

computes a random simple polygon by writing its vertices (oriented counterclockwise) to *result*. The polygon generated will have a number of vertices equal to the number of unique points in the first *n* points generated by *pg*.

### Requirements

1. *Traits* is a model of the concept `RandomPolygonTraits_2`
2. `PointGenerator::value_type` is equivalent to `Traits::Point_2` and `OutputIterator::value_type`.

The default traits class *Default\_traits* is the kernel in which `Traits::Point_2` is defined.

### See Also

`CGAL::Random_points_in_disc_2<Point_2, Creator>` ..... [page 3526](#)  
`CGAL::Random_points_in_square_2<Point_2, Creator>` ..... [page 3528](#)

### Implementation

The implementation is based on the method of eliminating self-intersections in a polygon by using so-called “2-opt” moves. Such a move eliminates an intersection between two edges by reversing the order of the vertices between the edges. No more than  $O(n^3)$  such moves are required to simplify a polygon defined on *n* points [vLS82]. Intersecting edges are detected using a simple sweep through the vertices and then one intersection is chosen at random to eliminate after each sweep. The worse-case running time is therefore  $O(n^4 \log n)$ .

### Example

The following program displays a random simple polygon with up to 100 vertices, where the vertex coordinates are drawn uniformly from the unit square centered at the origin.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <CGAL/Random.h>
#include <CGAL/algorithm.h>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
// NOTE: the choice of double here for a number type may cause problems
//       for degenerate point sets
#include <CGAL/double.h>
typedef double RT;
#endif

#include <fstream>
#include <list>

typedef CGAL::Cartesian<RT> K;
typedef K::Point_2 Point_2;
typedef std::list<Point_2> Container;
typedef CGAL::Polygon_2<K, Container> Polygon_2;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator> Point_generator;

const double RADIUS = 100;
const int MAX_POLY_SIZE = 100;

int main( )
{
    Polygon_2 polygon;
    std::list<Point_2> point_set;
    CGAL::Random rand;

    int size = rand.get_int(4, MAX_POLY_SIZE);

    // copy size points from the generator, eliminating duplicates, so the
    // polygon will have <= size vertices
    CGAL::copy_n_unique(Point_generator(RADIUS), size,
                        std::back_inserter(point_set));

    std::ostream_iterator< Point_2 > out( std::cout, " " );
    std::cout << "From the following " << point_set.size() << " points "
               << std::endl;
    std::copy(point_set.begin(), point_set.end(), out);
    std::cout << std::endl;

    CGAL::random_polygon_2(point_set.size(), std::back_inserter(polygon),
                          point_set.begin());
    std::cout << "The following simple polygon was made: " << std::endl;
    std::cout << polygon << std::endl;
}

```

```
    return 0;  
}
```

**File:** examples/Generator/random\_polygon.cpp

## CGAL::random\_selection

### Definition

*random\_selection* chooses  $n$  items at random from a random access iterator range which is useful to produce degenerate input data sets with multiple entries of identical items.

```
#include <CGAL/random_selection.h>
```

```
template <class RandomAccessIterator, class Size, class OutputIterator, class Random>
OutputIterator      random_selection( RandomAccessIterator first,
                                     RandomAccessIterator last,
                                     Size n,
                                     OutputIterator result,
                                     Random& rnd = default_random)
```

chooses a random item from the range  $[first, last)$  and writes it to *result*, each item from the range with equal probability, and repeats this  $n$  times, thus writing  $n$  items to *result*. A single random number is needed from *rnd* for each item. Returns the value of *result* after inserting the  $n$  items.

*Precondition:* *Random* is a random number generator type as provided by the STL or by *Random*.

## CGAL::Random

### Definition

The class *Randomis* is a random numbers generator. It generates uniformly distributed random *bools*, *ints* and *doubles*. It can be used as the random number generating function object in the STL algorithm *random\_shuffle*.

Instances of `Stream` can be seen as input streams. Different streams are *independent* of each other, i.e. the sequence of numbers from one stream does *not* depend upon how many numbers were extracted from the other streams. At each time, an instance has a *state* that uniquely determines the subsequent numbers being produced.

It can be very useful, e.g. for debugging, to reproduce a sequence of random numbers. This can be done by either initialising with a fixed seed, or by using the state functions as described below.

```
#include <CGAL/Random.h>
```

## Types

<i>Random::State</i>	The State type.
----------------------	-----------------

## Creation

*Random random;* introduces a variable *random* of type *Random*. The seed is chosen “randomly”, depending on the system time.

*Random* *random*(*unsigned int seed*); introduces a variable *random* of type *Random* and initializes its internal state using *seed*. Equal values for *seed* result in equal sequences of random numbers.

## Operations

<i>bool</i>	<i>random.get_bool()</i>	returns a random <i>bool</i> .
-------------	--------------------------	--------------------------------

<code>template &lt;int b&gt;</code>		
<code>int</code>	<code>random.get_bits()</code>	returns a random <i>int</i> value from the interval $[0, 2^b)$ . This is supposed to be efficient.

*int* *random.get\_int( int lower, int upper)*

returns a random *int* from the interval  $[lower, upper)$ .

*double*                      *random.get\_double( double lower = 0.0, double upper = 1.0)*

returns a random *double* from the interval  $[lower, upper)$ .

*int*                      *random( int upper)*            returns *random.get\_int( 0, upper)*.

## Seed and State Functions

*unsigned int* `random.get_seed()` returns the seed used for initialization.

*void* *random.save\_state( State& state)*

saves the current internal state in *state*.

```
void random.restore_state( State state)
```

restores the internal state from *state*.

### Equality Test

<i>bool</i>	<i>random == random2</i>	returns <i>true</i> , iff <i>random</i> and <i>random2</i> have equal internal states.
-------------	--------------------------	--

## Implementation

We use the C library function *rand* to generate the random numbers, *i.e.*, the sequence of numbers depends on the implementation of *rand* on your specific platform.

## RandomConvexSetTraits\_2

### Definition

The concept `RandomConvexSetTraits_2` describes the requirements of the traits class for the function `random_convex_set_2`.

### Has Models

`CGAL::Random_convex_set_traits_2<Kernel>` ..... page [3524](#)

### Types

<code>RandomConvexSetTraits_2:: Point_2</code>	point class.
<code>RandomConvexSetTraits_2:: FT</code>	class used for doing computations on point and vector coordinates (has to fulfill field type requirements).
<code>RandomConvexSetTraits_2:: Sum</code>	AdaptableBinaryFunction class: $Point_2 \times Point_2 \rightarrow Point_2$ . It returns the point that results from adding the vectors corresponding to both arguments.
<code>RandomConvexSetTraits_2:: Scale</code>	AdaptableBinaryFunction class: $Point_2 \times FT \rightarrow Point_2$ . <code>Scale(p,k)</code> returns the point that results from scaling the vector corresponding to $p$ by a factor of $k$ .
<code>RandomConvexSetTraits_2:: Max_coordinate</code>	AdaptableUnaryFunction class: $Point_2 \rightarrow FT$ . <code>Max_coordinate(p)</code> returns the coordinate of $p$ with largest absolute value.
<code>RandomConvexSetTraits_2:: Angle_less</code>	AdaptableBinaryFunction class: $Point_2 \times Point_2 \rightarrow bool$ . It returns <code>true</code> , iff the angle of the direction corresponding to the first argument with respect to the positive $x$ -axis is less than the angle of the direction corresponding to the second argument.

### Operations

<code>Point_2</code>	<code>t.origin() const</code>	return origin (neutral element for the <code>Sum</code> operation).
----------------------	-------------------------------	---

## RandomPolygonTraits\_2

### Definition

The concept `RandomPolygonTraits_2` describes the requirements for the traits class used by the function `random_polygon_2`.

### Has Models

The CGAL kernels.

### Types

<i>RandomPolygonTraits_2:: FT</i>	The coordinate type of the points of the polygon ( <i>i.e.</i> , a field type)
<i>RandomPolygonTraits_2:: Point_2</i>	The point type of the polygon.
<i>RandomPolygonTraits_2:: Orientation_2</i>	Predicate object type that determines the orientation of three points. It must provide <i>Orientation operator()(Point_2 p, Point_2 q, Point_2 r)</i> that returns <i>LEFT_TURN</i> , if <i>r</i> lies to the left of the oriented line <i>l</i> defined by <i>p</i> and <i>q</i> , returns <i>RIGHT_TURN</i> if <i>r</i> lies to the right of <i>l</i> , and returns <i>COLLINEAR</i> if <i>r</i> lies on <i>l</i> .
<i>RandomPolygonTraits_2:: Less_xy_2</i>	Binary predicate object type comparing <i>Point_2</i> s lexicographically. It must provide <i>bool operator()(Point_2 p, Point_2 q)</i> that returns <i>true</i> iff $p <_{xy} q$ . We have $p <_{xy} q$ , iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$ , where $p_x$ and $p_y$ denote the <i>x</i> and <i>y</i> coordinates of point <i>p</i> , resp.

### Operations

The following two member functions returning instances of the above predicate object types are required.

<i>Less_xy_2</i>	<i>t.less_xy_2_object()</i>
<i>Orienation_2</i>	<i>t.orientation_2_object()</i>

## CGAL::Random\_convex\_set\_traits\_2<Kernel>

### Definition

The class *Random\_convex\_set\_traits\_2<Kernel>* serves as a traits class for the function *random\_convex\_set\_2*.

*#include <CGAL/Random\_convex\_set\_traits\_2.h>*

### Is Model for the Concepts

RandomConvexSetTraits\_2 ..... page [3522](#)

### Types

*typedef Kernel::Point\_2*

*typedef Kernel::FT*      *Point\_2;*  
                                 *FT;*

*Random\_convex\_set\_traits\_2<Kernel>:: Scale*      function object class derived from *std::binary\_function<Point\_2, Point\_2, Point\_2>*

*Random\_convex\_set\_traits\_2<Kernel>:: Max\_coordinate*

function object class derived from *std::unary\_function<Point\_2, FT>*

*Random\_convex\_set\_traits\_2<Kernel>:: Angle\_less*

function object class derived from *std::binary\_function<Point\_2, Point\_2, bool>*

### Creation

*Random\_convex\_set\_traits\_2<Kernel> t;*      default constructor

### Operations

*Point\_2*      *t.origin() const*      returns CGAL::ORIGIN.

## CGAL::Random\_points\_in\_cube\_3<Point\_3, Creator>

### Definition

The class *Random\_points\_in\_cube\_3<Point\_3, Creator>* is an input iterator creating points uniformly distributed in a half-open cube. The default *Creator* is *Creator\_uniform\_3<Kernel\_traits<P>::Kernel::RT,P>*.

### Is Model for the Concepts

InputIterator

PointGenerator ..... page [3512](#)

#include <CGAL/point\_generators\_3.h>

### Types

<code>typedef std::input_iterator_tag</code>	<code>iterator_category;</code>
<code>typedef Point_3</code>	<code>value_type;</code>
<code>typedef std::ptrdiff_t</code>	<code>difference_type;</code>
<code>typedef const Point_3*</code>	<code>pointer;</code>
<code>typedef Point_3</code>	<code>reference;</code>

### Operations

*Random\_points\_in\_cube\_3<Point\_3, Creator>* *g*( *double a*, *Random& rnd* = *default\_random*);

*g* is an input iterator creating points of type *Point\_3* uniformly distributed in the half-open cube with side length  $2a$ , centered at the origin, i.e.  $\forall p = *g : -a \leq p.x(), p.y(), p.z() < a$ . Three random numbers are needed from *rnd* for each point.

## CGAL::Random\_points\_on\_segment\_2<Point\_2, Creator>

### Definition

The class *Random\_points\_on\_segment\_2<Point\_2, Creator>* is an input iterator creating points uniformly distributed on a segment. The default *Creator* is *Creator\_uniform\_2<Kernel\_traits<P>::Kernel::RT,P>*.

### Is Model for the Concepts

InputIterator

PointGenerator ..... page [3512](#)

#include <CGAL/point\_generators\_2.h>

### Types

```
typedef std::input_iterator_tag      iterator_category;
typedef Point_2                     value_type;
typedef std::ptrdiff_t              difference_type;
typedef const Point_2*              pointer;
typedef Point_2                     reference;
```

### Operations

*Random\_points\_on\_segment\_2<Point\_2, Creator>* *g*( *Point\_2* *p*, *Point\_2* *q*, *Random& rnd* = *default\_random*);

*g* is an input iterator creating points of type *Point\_2* uniformly distributed on the segment from *p* to *q* (excluding *q*), i.e.  $*g == (1 - \lambda)p + \lambda q$  where  $0 \leq \lambda < 1$ . A single random number is needed from *rnd* for each point.

*Requirement:* The expressions *to\_double(p.x())* and *to\_double(p.y())* must result in the respective *double* representation of the coordinates of *p*, and similarly for *q*.

### 65.1 Introduction

Many geometric algorithms implemented in CGAL are incremental, and thus their speed is dependent on the order of insertion. This package provides sorting algorithms that may considerably improve running times of such algorithms.

The rationale is to sort objects along a space-filling curve so that two objects close geometrically will be close in the insertion order with high probability. That way, parts of a data structure that will be looked at during an insertion will probably have been looked at in a recent insertion, and thus probably will be in cache memory instead of main memory.

As another side-effect, these sorting functions usually improve memory locality of the data structures produced by incremental algorithms, sometimes leading to speed ups in other algorithm using these data structures.

### 65.2 Spatial Sorting

CGAL provides a small set of sorting algorithms, currently implemented only for 2D and 3D points, although it is easy to extend them to other objects through a traits mechanism.

Given an iterator range of points, the function *hilbert\_sort* sorts them along the space-filling Hilbert curve. Combined with a *std::random\_shuffle*, the function *spatial\_sort* will sort points in a way keeping enough randomness to retain theoretical optimality for some algorithms<sup>1</sup>, and close enough to a space-filling curve to speed-up algorithms.

---

<sup>1</sup>in fact, this has only been proved for Delaunay triangulation

The 2D and 3D triangulation classes of CGAL internally sort points as described above, when the points are passed as an iterator range to a constructor or the *insert* method.

## CGAL::spatial\_sort

### Definition

The function *spatial\_sort* sorts an iterator range of points in a way that improves space locality. Two points close in the order will be close geometrically, and two points close geometrically will have a high probability of being close in the order.

```
#include <CGAL/spatial_sort.h>
```

```
template <class RandomAccessIterator, class Traits>
void      spatial_sort( RandomAccessIterator begin,
                       RandomAccessIterator end,
                       Traits traits = Default_traits)
```

sorts the range  $[begin, end)$  in place.

The default traits class *Default\_traits* is the kernel in which the type *RandomAccessIterator::value\_type* is defined.

### Requirements

1. *RandomAccessIterator::value\_type* is convertible to *Traits::Point\_2* or *Traits::Point\_3*.
2. *Traits* is a model for concept *SpatialSortingTraits\_2* or *SpatialSortingTraits\_3*.

### Implementation

Creates an instance of *Multiscale\_sort<Hilbert\_sort\_2<Traits>>* or *Multiscale\_sort<Hilbert\_sort\_3<Traits>>* and calls its *operator()*.

## CGAL::hilbert\_sort

### Definition

The function *hilbert\_sort* sorts an iterator range of points along a Hilbert curve.

```
#include <CGAL/hilbert_sort.h>
```

```
template <class RandomAccessIterator, class Traits>
void      hilbert_sort( RandomAccessIterator begin,
                       RandomAccessIterator end,
                       Traits traits = Default_traits)
```

sorts the range *[begin,end)* in place.

The default traits class *Default\_traits* is the kernel in which the type *RandomAccessIterator::value\_type* is defined.

### Requirements

1. *RandomAccessIterator::value\_type* is convertible to *Traits::Point\_2* or *Traits::Point\_3*.
2. *Traits* is a model for concept *SpatialSortingTraits\_2* or *SpatialSortingTraits\_3*.

### Implementation

Creates an instance of *Hilbert\_sort\_2*<*Traits*> or *Hilbert\_sort\_3*<*Traits*> and calls its *operator()*.

## SpatialSortingTraits\_2

### Definition

All 2D spatial sorting algorithms provided in CGAL are parameterized by a traits class *Traits*, which defines the primitives (objects and predicates) that the sorting algorithms use. *SpatialSortingTraits\_2* defines the complete set of primitives required in these functions and functors.

### Types

*SpatialSortingTraits\_2:: Point\_2*    The point type on which the sorting algorithms operate.

*SpatialSortingTraits\_2:: Less\_x\_2*

Binary predicate object type comparing *Point\_2*s along the *x* coordinate. Must provide *bool operator()(Point\_2 p, Point\_2 q)* where *true* is returned iff  $p_x < q_x$ , where  $p_x$  and  $q_x$  denote *x* coordinate of point *p* and *q*, respectively.

*SpatialSortingTraits\_2:: Less\_y\_2*

Binary predicate object type comparing *Point\_2*s along the *y* coordinate. Must provide *bool operator()(Point\_2 p, Point\_2 q)* where *true* is returned iff  $p_y < q_y$ , where  $p_y$  and  $q_y$  denote *y* coordinate of point *p* and *q*, respectively.

### Creation

Only a copy constructor is required.

*SpatialSortingTraits\_2 traits( t );*

### Operations

The following member functions to create instances of the above predicate object types must exist.

*Less\_x\_2*                      *traits.less\_x\_2\_object()*

*Less\_y\_2*                      *traits.less\_y\_2\_object()*

### Has Models

Any CGAL kernel.

## CGAL::Hilbert\_sort\_2<Traits>

### Definition

The function object *Hilbert\_sort\_2<Traits>* sorts iterator ranges of *Traits::Point\_2* along a Hilbert curve.

### Requirements

*Traits* is a model for *SpatialSortingTraits*.

### Creation

*Hilbert\_sort\_2<Traits>* *o*( *const Traits &traits = Traits()*);

constructs an instance with *traits* as traits class instance.

### Operations

```
template <class RandomAccessIterator>
void      o.operator()( RandomAccessIterator begin, RandomAccessIterator end) const
```

sorts the range [*begin*, *end*).

*Requirement:* *RandomAccessIterator::value\_type* equals to *Traits::Point\_2*.

## SpatialSortingTraits\_3

### Definition

All 3D spatial sorting algorithms provided in CGAL are parameterized by a traits class *Traits*, which defines the primitives (objects and predicates) that the sorting algorithms use. *SpatialSortingTraits\_3* defines the complete set of primitives required in these functions and functors.

### Types

*SpatialSortingTraits\_3::Point\_3*    The point type on which the sorting algorithms operate.

*SpatialSortingTraits\_3::Less\_x\_3*

Binary predicate object type comparing *Point\_3*s along the *x* coordinate. Must provide *bool operator()(Point\_3 p, Point\_3 q)* where *true* is returned iff  $p_x < q_x$ , where  $p_x$  and  $q_x$  denote *x* coordinate of point *p* and *q*, respectively.

*SpatialSortingTraits\_3::Less\_y\_3*

Binary predicate object type comparing *Point\_3*s along the *y* coordinate. Must provide *bool operator()(Point\_3 p, Point\_3 q)* where *true* is returned iff  $p_y < q_y$ , where  $p_y$  and  $q_y$  denote *y* coordinate of point *p* and *q*, respectively.

*SpatialSortingTraits\_3::Less\_z\_3*

Binary predicate object type comparing *Point\_3*s along the *z* coordinate. Must provide *bool operator()(Point\_3 p, Point\_3 q)* where *true* is returned iff  $p_z < q_z$ , where  $p_z$  and  $q_z$  denote *z* coordinate of point *p* and *q*, respectively.

### Creation

Only a copy constructor is required.

*SpatialSortingTraits\_3 traits( t);*

### Operations

The following member functions to create instances of the above predicate object types must exist.

*Less\_x\_3*  
     *traits.less\_x\_3\_object()*

*Less\_y\_3*  
     *traits.less\_y\_3\_object()*

*Less\_z\_3*  
*traits.less\_z\_3\_object()*

### **Has Models**

Any CGAL kernel.

## CGAL::Hilbert\_sort\_3<Traits>

### Definition

The function object *Hilbert\_sort\_3<Traits>* sorts iterator ranges of *Traits::Point\_3* along a Hilbert curve.

### Requirements

*Traits* is a model for *SpatialSortingTraits\_3*.

### Creation

*Hilbert\_sort\_3<Traits>* *o*( *const Traits &traits* = *Traits*() );

constructs an instance with *traits* as traits class instance.

### Operations

```
template <class RandomAccessIterator>
void      o.operator()( RandomAccessIterator begin, RandomAccessIterator end) const
```

sorts the range [*begin*, *end*).

*Requirement:* *RandomAccessIterator::value\_type* equals to *Traits::Point\_3*.

## CGAL::Multiscale\_sort<Sort>

### Definition

The class *Multiscale\_sort*<*Sort*> represents a sorting algorithm adaptor. Given a range of  $n$  points:

1. it applies *Sort* on the last  $(1 - \text{ratio}) \times n$  points,
2. it recurses on the first  $\text{ratio} \times n$  points, stopping when there are less than *threshold* points.

### Creation

*Multiscale\_sort*<*Sort*> *o*( *const Sort* &*sort* = *Sort*(), *std::ptrdiff\_t* *threshold* = 1, *double* *ratio* = 0.5);

constructs an instance with *traits* as traits class instance.

### Operations

*template* <*class RandomAccessIterator*>

*void* *o.operator()*( *RandomAccessIterator* *begin*, *RandomAccessIterator* *end*) *const*

sorts the range [*begin*, *end*).

*Requirement:* *Sort::operator()*(*RandomAccessIterator* *begin*, *RandomAccessIterator* *end*) is defined.

## Chapter 66

# Monotone and Sorted Matrix Search

*Michael Hoffmann*

*CGAL::monotone\_matrix\_search* and *CGAL::sorted\_matrix\_search* are techniques that deal with the problem of efficiently finding largest entries in matrices with certain structural properties. Many concrete problems can be modelled as matrix search problems, and for some of them we provide explicit solutions that allow you to solve them without knowing about the matrix search technique. Examples are, the computation of all furthest neighbors for the vertices of a convex polygon, maximal  $k$ -gons inscribed into a planar point set, and computing rectangular  $p$ -centers.

# Monotone and Sorted Matrix Search Reference Manual

*Michael Hoffmann*

This chapter describes concepts, classes, and functions for monotone and sorted matrix search.

## Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL\_OPTIMISATION\_NO\_PRECONDITIONS* switches precondition checking off, cf. Section 2.10.

## CGAL::monotone\_matrix\_search

— advanced —

### Definition

The function *monotone\_matrix\_search* computes the maxima for all rows of a totally monotone matrix.

More precisely, monotony for matrices is defined as follows.

Let  $K$  be a totally ordered set,  $M \in K^{(n,m)}$  a matrix over  $K$  and for  $0 \leq i < n$ :

$$rmax_M(i) := \left\{ \min_{0 \leq j < m} j \mid M[i, j] = \max_{0 \leq k < m} M[i, k] \right\}$$

the (leftmost) column containing the maximum entry in row  $i$ .  $M$  is called monotone, iff

$$\forall 0 \leq i_1 < i_2 < n : rmax_M(i_1) \leq rmax_M(i_2) .$$

$M$  is totally monotone, iff all of its submatrices are monotone (or equivalently: iff all  $2 \times 2$  submatrices are monotone).

```
#include <CGAL/monotone_matrix_search.h>
```

```
template < class Matrix, class RandomAccessIC, class Compare_strictly >
void    monotone_matrix_search(
        Matrix m,
        RandomAccessIC t,
        Compare_strictly compare_strictly = less< Matrix::Value >())
```

computes the maximum (as specified by *compare\_strictly*) entry for each row of  $m$  and writes the corresponding column to  $t$ , i.e.  $t[i]$  is set to the index of the column containing the maximum element in row  $i$ . The maximum  $m_r$  of a row  $r$  is the leftmost element for which *compare\_strictly*( $m_r, x$ ) is false for all elements  $x$  in  $r$ .

*Precondition:*  $t$  points to a structure of size at least  $m.number\_of\_rows()$

*Requirement:*

1. *Matrix* is a model for *MonotoneMatrixSearchTraits*.
2. Value type of *RandomAccessIC* is *int*.
3. If *compare\_strictly* is defined, it is an adaptable binary function:  $Matrix::Value \times Matrix::Value \rightarrow bool$  describing a strict (non-reflexive) total ordering on *Matrix::Value*.

# CGAL::Dynamic\_matrix<M>

— *advanced* —

## Definition

The class *Dynamic\_matrix*<*M*> is an adaptor for an arbitrary matrix class *M* to provide the dynamic operations needed for monotone matrix search.

## Requirements

*M* is a model for *BasicMatrix*.

```
#include <CGAL/Dynamic_matrix.h>
```

## Is Model for the Concepts

MonotoneMatrixSearchTraits ..... page [3554](#)

BasicMatrix ..... page [3556](#)

## Creation

*Dynamic\_matrix*<*M*> *d*( *M* *m*); initializes *d* to *m*. *m* is *not* copied, we only store a reference.

## Operations

*int* *d.number\_of\_columns()*  
returns the number of columns.

*int* *d.number\_of\_rows()* returns the number of rows.

*Entry* *d( int row, int column)*  
returns the entry at position (*row*, *column*).  
*Precondition:*  
 $0 \leq \text{row} < \text{number\_of\_rows}()$  and  
 $0 \leq \text{column} < \text{number\_of\_columns}()$ .

*void* *d.replace\_column( int old, int new)*  
replace column *old* with column number *new*.  
*Precondition:*  
 $0 \leq \text{old}, \text{new} < \text{number\_of\_columns}()$ .

*Matrix\** *d.extract\_all\_even\_rows()*

returns a new **Matrix** consisting of all rows of *d* with even index, (i.e. first row is row 0 of *d*, second row is row 2 of *d* etc.).

*Precondition:* *number\_of\_rows()* > 0.

*void* *d.shrink\_to\_quadratic\_size()*

deletes the rightmost columns, such that *d* becomes quadratic.

*Precondition:*

*number\_of\_columns()* ≥ *number\_of\_rows()*.

*Postcondition:*

*number\_of\_rows()* == *number\_of\_columns()*.

## See Also

*CGAL::monotone\_matrix\_search* ..... page [3550](#)

*MonotoneMatrixSearchTraits* ..... page [3554](#)

*BasicMatrix* ..... page [3556](#)

## Implementation

All operations take constant time except for *extract\_all\_even\_rows* which needs time linear in the number of rows.

\_\_\_\_\_ *advanced* \_\_\_\_\_

# MonotoneMatrixSearchTraits

— *advanced* —

## Definition

The concept `MonotoneMatrixSearchTraits` is a refinement of *BasicMatrix* and defines types and operations needed to compute the maxima for all rows of a totally monotone matrix using the function *monotone\_matrix\_search*.

## Types

*MonotoneMatrixSearchTraits::Value*      The type of a matrix entry.

## Operations

*int*      *m.number\_of\_columns() const*  
returns the number of columns.

*int*      *m.number\_of\_rows() const*  
returns the number of rows.

*Entry*      *m.operator()( int row, int column) const*  
returns the entry at position (*row*, *column*).  
*Precondition:*  
 $0 \leq \text{row} < \text{number\_of\_rows}()$  and  
 $0 \leq \text{column} < \text{number\_of\_columns}()$ .

*void*      *m.replace\_column( int old, int new)*  
replace column *old* with column number *new*.  
*Precondition:*  
 $0 \leq \text{old}, \text{new} < \text{number\_of\_columns}()$ .

*Matrix\**      *m.extract\_all\_even\_rows() const*  
returns a new `Matrix` consisting of all rows of *m* with even index, (i.e. first row is row 0 of *m*, second row is row 2 of *m* etc.).  
*Precondition:* *number\_of\_rows()* > 0.

*void* *m.shrink\_to\_quadratic\_size()*

deletes the rightmost columns, such that *m* becomes quadratic.

*Precondition:*

*number\_of\_columns() ≥ number\_of\_rows().*

*Postcondition:*

*number\_of\_rows() == number\_of\_columns().*

## Notes

- For the sake of efficiency (and in order to achieve the time bounds claimed for *monotone\_matrix\_search*), all these operations have to be realized in constant time – except for *extract\_all\_even\_rows* which may take linear time.
- There is an adaptor *Dynamic\_matrix* that can be used to add most of the functionality described above to arbitrary matrix classes.

# BasicMatrix

advanced

## Definition

A class has to provide the following types and operations in order to be a model for *BasicMatrix*.

## Types

*BasicMatrix::Value* The type of a matrix entry. It has to define a copy constructor.

## Operations

*int* *m.number\_of\_columns() const*  
returns the number of columns.

*int* *m.number\_of\_rows() const*  
returns the number of rows.

*Entry* *m.operator()( int row, int column) const*  
returns the entry at position (*row*, *column*).  
*Precondition:*  
 $0 \leq \text{row} < \text{number\_of\_rows}()$  and  
 $0 \leq \text{column} < \text{number\_of\_columns}()$ .

## CGAL::sorted\_matrix\_search

— advanced —

### Definition

The function *sorted\_matrix\_search* selects the smallest entry in a set of sorted matrices that fulfills a certain feasibility criterion.

More exactly, a matrix  $M = (m_{ij}) \in S^{r \times l}$  (over a totally ordered set  $S$ ) is sorted, iff

$$\begin{aligned} \forall 1 \leq i \leq r, 1 \leq j < l : m_{ij} \leq m_{i(j+1)} \text{ and} \\ \forall 1 \leq i < r, 1 \leq j \leq l : m_{ij} \leq m_{(i+1)j} . \end{aligned}$$

Now let  $\mathcal{M}$  be a set of  $n$  sorted matrices over  $S$  and  $f$  be a monotone predicate on  $S$ , i.e.

$$f : S \longrightarrow \text{bool} \quad \text{with} \quad f(r) \implies \forall t \in S, t > r : f(t) .$$

If we assume there is any feasible element in one of the matrices in  $\mathcal{M}$ , there certainly is a smallest such element. This is the one we are searching for.

The feasibility test as well as some other parameters can (and have to) be customized through a traits class.

```
#include <CGAL/sorted_matrix_search.h>
```

```
template < class RandomAccessIterator, class Traits >
Traits::Value sorted_matrix_search( RandomAccessIterator f, RandomAccessIterator l, Traits t)
```

returns the element  $x$  in one of the sorted matrices from the range  $[f, l)$ , for which *t.is\_feasible( x)* is true and *t.compare( x, y)* is true for all other  $y$  values from any matrix for which *t.is\_feasible( y)* is true.

*Precondition:*

1. All matrices in  $[f, l)$  are sorted according to *Traits::compare\_non\_strictly*.
2. There is at least one entry  $x$  in a matrix  $M \in [f, l)$  for which *Traits::is\_feasible(x)* is true.

*Requirement:*

1. *Traits* is a model for *SortedMatrixSearchTraits*.
2. Value type of *RandomAccessIterator* is *Traits::Matrix*.

### See Also

SortedMatrixSearchTraits ..... page [3562](#)

## Implementation

The implementation uses an algorithm by Frederickson and Johnson[FJ83, FJ84] and runs in  $O(n \cdot k + f \cdot \log(n \cdot k))$ , where  $n$  is the number of input matrices,  $k$  denotes the maximal dimension of any input matrix and  $f$  the time needed for one feasibility test.

## Example

In the following program we build a random vector  $a = (a_i)_{i=1, \dots, 5}$  (elements drawn uniformly from  $\{0, \dots, 99\}$ ) and construct a Cartesian matrix  $M$  containing as elements all sums  $a_i + a_j$ ,  $i, j \in \{1, \dots, 5\}$ . If  $a$  is sorted,  $M$  is sorted as well. So we can apply *sorted\_matrix\_search* to compute the upper bound for the maximal entry of  $a$  in  $M$ .

```
#include <CGAL/Random.h>
#include <CGAL/Cartesian_matrix.h>
#include <CGAL/sorted_matrix_search.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <functional>

typedef int Value;
typedef std::vector<Value> Vector;
typedef Vector::iterator Value_iterator;
typedef std::vector<Vector> Vector_cont;
typedef CGAL::Cartesian_matrix<std::plus<int>,
                               Value_iterator,
                               Value_iterator> Matrix;

int main()
{
    // set of vectors the matrices are build from:
    Vector_cont vectors;

    // generate a random vector and sort it:
    Vector a;
    const int n = 5;
    for (int i = 0; i < n; ++i)
        a.push_back(CGAL::default_random(100));
    std::sort(a.begin(), a.end());
    std::cout << "a = ( ";
    std::copy(a.begin(), a.end(), std::ostream_iterator<int>(std::cout, " "));
    std::cout << ")\n";

    // build a Cartesian matrix from a:
    Matrix M(a.begin(), a.end(), a.begin(), a.end());

    // search for an upper bound for max(a):
    Value bound = a[n-1];
    Value upper_bound =
    CGAL::sorted_matrix_search(
        &M, &M + 1,
        CGAL::sorted_matrix_search_traits_adaptor(
```

```

        std::bind2nd(std::greater_equal<Value>(), bound), M));
std::cout << "Upper bound for " << bound << " is "
        << upper_bound << "." << std::endl;

    return 0;
}
// -----
// ** EOF
// -----

## CGAL::Sorted\_matrix\_search\_traits\_adaptor<F,M>

— advanced —

#include <CGAL/Sorted\_matrix\_search\_traits\_adaptor.h>

### Definition

The class *Sorted\_matrix\_search\_traits\_adaptor*<*F*,*M*> can be used as an adaptor to create sorted matrix search traits classes for arbitrary feasibility test and matrix classes *F* resp. *M*.

### Is Model for the Concepts

SortedMatrixSearchTraits ..... page [3562](#)

### Requirements

1. *M* is a model for *BasicMatrix* and
2. *F* defines a copy constructor and a monotone *bool operator()*(*const Value*&).

### Creation

*Sorted\_matrix\_search\_traits\_adaptor*<*F*,*M*> *t*(*const F*& *m*);

initializes *t* to use *m* for feasibility testing.

### Types

*Sorted\_matrix\_search\_traits\_adaptor*<*F*,*M*>::*Matrix*

typedef to *M*.

*Sorted\_matrix\_search\_traits\_adaptor*<*F*,*M*>::*Value*

typedef to *Matrix*::*Value*.

*Sorted\_matrix\_search\_traits\_adaptor*<*F*,*M*>::*Compare\_strictly*

typedef to *std::less*<*Value*>.

*Sorted\_matrix\_search\_traits\_adaptor*<*F*,*M*>::*Compare\_non\_strictly*

typedef to *std::less\_equal*<*Value*>.

## Operations

*Compare\_strictly*      *t.compare\_strictly()* *const*

returns the *Compare\_strictly* object to be used for the search.

*Compare\_non\_strictly*

*t.compare\_non\_strictly()* *const*

returns the *Compare\_non\_strictly* object to be used for the search.

*bool*      *t.is\_feasible( const Value& a)*

uses the feasibility test given during creation.

## SortedMatrixSearchTraits

— *advanced* —

### Definition

The concept `SortedMatrixSearchTraits` defines types and operations needed to compute the smallest entry in a set of sorted matrices that fulfills a certain feasibility criterion using the function `sorted_matrix_search`.

### Types

`SortedMatrixSearchTraits::Matrix`      The class used for representing matrices. It has to be a model for `BasicMatrix`.

`typedef Matrix::Value`

`Value;`      The class used for representing the matrix elements.

`SortedMatrixSearchTraits::Compare_strictly`      An adaptable binary function class:  $Value \times Value \rightarrow bool$  defining a non-reflexive total order on `Value`. This determines the direction of the search.

`SortedMatrixSearchTraits::Compare_non_strictly`

An adaptable binary function class:  $Value \times Value \rightarrow bool$  defining the reflexive total order on `Value` corresponding to `Compare_strictly`.

### Operations

`Compare_strictly`      `t.compare_strictly() const`

returns the `Compare_strictly` object to be used for the search.

`Compare_non_strictly`

`t.compare_non_strictly() const`

returns the `Compare_non_strictly` object to be used for the search.

`bool`      `t.is_feasible( const Value& a)`

The predicate to determine whether an element `a` is feasible. It has to be monotone in the sense that `compare( a, b)` and `is_feasible( a)` imply `is_feasible( b)`.

## 67.1 Which Programs can be Solved?

This package lets you solve *convex quadratic programs* of the general form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $\mathbf{l}$  is an  $n$ -dimensional vector of lower bounds for  $\mathbf{x}$ , where  $l_j \in \mathbb{R} \cup \{-\infty\}$  for all  $j$
- $\mathbf{u}$  is an  $n$ -dimensional vector of upper bounds for  $\mathbf{x}$ , where  $u_j \in \mathbb{R} \cup \{\infty\}$  for all  $j$
- $D$  is a symmetric positive-semidefinite  $n \times n$  matrix (the quadratic objective function),
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

If  $D = 0$ , the program (QP) is actually a *linear program*. Section 67.2.2 on robustness briefly discusses the case of  $D$  not being positive-semidefinite and therefore not defining a convex program.

Solving the program means to find an  $n$ -vector  $\mathbf{x}^*$  such that  $A \mathbf{x}^* \begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \mathbf{l} \leq \mathbf{x}^* \leq \mathbf{u}$  (a *feasible solution*), and with the smallest objective function value  $\mathbf{x}^{*T} D \mathbf{x}^* + \mathbf{c}^T \mathbf{x}^* + c_0$  among all feasible solutions.

There might be no feasible solution at all, in which case the quadratic program is *infeasible*, or there might be feasible solutions of arbitrarily small objective function value, in which case the program is *unbounded*.

## 67.2 Design, Efficiency, and Robustness

The design of the package is quite simple. The linear or quadratic program to be solved is supplied in form of an object of a class that is a model of the concept *QuadraticProgram* (or some specialized other concepts, e.g. for linear programs). CGAL provides a number of easy-to-use and flexible models, see Section 67.3 below. The input data may be of any given number type, such as *double*, *int*, or any exact type.

Then the program is solved using the function *solve\_quadratic\_program* (or some specialized other functions, e.g. for linear programs). For this, you also have to provide a suitable *exact* number type *ET* used in the solution process. In case of input type *double*, solution methods that use floating-point-filtering are chosen by default for certain programs (in some cases, this is not appropriate, and the default should be changed; see Section 67.8 for details).

The output of this is an object of *Quadratic\_program\_solution<ET>* which you can in turn query for various things: what is the status of the program (optimally solved, infeasible, or unbounded?), what are the values of the optimal solution  $\mathbf{x}^*$ , what is the associated objective function value, etc.

You can in particular get *certificates* for the solution. In short, these are proofs that the output is correct. Thus, if you don't believe in the solution (whether it says "optimally solved", "infeasible", or "unbounded"), you can verify it yourself by using the certificates. Section 67.7 says more about this.

### 67.2.1 Efficiency

The concept *QuadraticProgram* (as well as the other specialized ones) require a *dense interface* of the program, in terms of *random-access iterators* over the matrices and vectors of (QP). Zero entries therefore play no special role and are treated like all other entries by the interface.

This has mainly historical reasons: the original motivation behind this package was low-dimensional geometric optimization where a dense representation is appropriate and efficient. In fact, the CGAL packages *Min\_annulus\_d<Traits>* and *Polytope\_distance\_d<Traits>* internally use the linear and quadratic programming solver.

As a user, however, you don't necessarily have to provide a dense *representation* of your program. You do not pass vectors or matrices to the solution functions, but rather specify the vectors and matrices through iterators. The iterator abstraction easily allows to build models that convert a sparse representation into a dense interface. The predefined models *Quadratic\_program<NT>* and *Quadratic\_program\_from\_mps<NT>* do exactly this; in using them, you can forget about the dense interface.

Nevertheless, if you care about efficiency, you cannot completely ignore the issue. If you think about a quadratic program in  $n$  variables and  $m$  constraints, its dense interface has  $\Theta(n^2 + mn)$  entries, even if actually very few of them are nonzero. This has consequences for the complexity of the internal computations. In fact, a single iteration of the solution process has complexity at least  $\Omega(mn)$ , since usually, all entries of the matrix  $A$  are accessed. This implies that problems where  $\min(n, m)$  is large cannot be solved efficiently, even if the number of nonzero entries in the problem description is very small.

We can actually be quite precise about performance, in terms of the following parameters.

- $n$  : the number of variables (or columns of  $A$ ),
- $m$  : the number of constraints (or rows of  $A$ ),
- $e$  : the number of equality constraints,
- $r$  : the rank of the quadratic objective function matrix  $D$ .

The time required to solve the problems is in most cases linear in  $\max(n, m)$ , but with a factor heavily depending on  $\min(n, e) + r$ . Therefore, the solver will be efficient only if  $\min(n, e) + r$  is small.

Here are the scenarios in which this applies:

- Quadratic programs with a small number of variables, but possibly a large number of inequality constraints,
- Linear programs with a small number of equality constraints but possibly a large number of variables,
- Quadratic programs with a small number of equality constraints and  $D$  of small rank, but possibly with a large number of variables.

How small is small? If  $\min(n, e) + r$  is up to 10, the solver will probably be very fast, even if  $\max(n, m)$  goes into the millions. If  $\min(n, m) + r$  is up to a few hundreds, you may still get a solution within reasonable time, depending on the problem characteristics.

If you have a problem where both  $n$  and  $e$  are well above 1,000, say, then chances are high that CGAL cannot solve it within reasonable time.

### 67.2.2 Robustness

Given that you use an *exact number type* in the function *solve\_quadratic\_program* (or in the other, specialized solution functions), the solver will give you *exact rational output*, for every convex quadratic program. It may

fail to compute a solution only if

1. The quadratic program is too large (see the previous subsection on efficiency).
2. The quadratic objective function matrix  $D$  is not positive-semidefinite (see the discussion below).
3. The floating-point filter used by default for certain programs and input type *double* fails due to a *double* exponent overflow. This happens in rare cases only, and it does not pay off to sacrifice the efficiency of the filtered approach in order to cope with these rare cases. There are means, however, to avoid such problems by switching to a slower non-filtered variant, see Section 67.8.1.
4. The solver internally cycles. This also happens in rare cases only. However, if you have a hunch that the solver cycles on your problem, there are means to switch to a slower variant that is guaranteed not to cycle, see Section 67.8.2.

The second item merits special attention. First, you may ask why the solver does not check that  $D$  is positive semidefinite. But recall that  $D$  is given by a dense interface, and it would therefore cost  $\Omega(n^2)$  time already to access all entries of the matrix  $D$ . The solver itself gets away with accessing much less entries of  $D$  in the relevant case where  $r$ , the rank of  $D$ , is small.

Nevertheless, the solver contains some runtime checks that may detect that the matrix  $D$  is not positive-semidefinite. But you may as well get an “optimal solution” in this case, even with valid certificates. The validity of these certificates, however, depends on  $D$  being positive-semidefinite; if this is not the case, the certificates only prove that the solver has found a “critical point” of your (nonconvex) program, but there are no guarantees whatsoever that this is a global optimum, or even a local optimum.

## 67.3 How to Enter and Solve a Program

In this section, we describe how you can supply and solve your problem, using the CGAL program models and solution functions. There are two essentially different ways to proceed, and we will discuss them in turn. In short,

- you can let the model take care of your program data; you start from an empty program and then simply insert the non-zero entries, or read them from a file (more generally, any input stream) in *MPSFormat*. You can also change program entries at any time. This is usually the most convenient way if you don’t want to care about representation issues;
- you can maintain the data yourself and only supply suitable random-access iterators over the matrices and vectors. This is advantageous if you already have the data (explicitly, or implicitly encoded, for example through iterators) and want to avoid copying of data. Typically, this happens if you write generic iterator-based code.

Our running example is the following quadratic program in two variables:

$$\begin{array}{llll} \text{minimize} & x^2 + 4(y - 4)^2 & (= & x^2 + 4y^2 - 32y + 64) \\ \text{subject to} & x + y & \leq & 7 \\ & -x + 2y & \leq & 4 \\ & x & \geq & 0 \\ & y & \geq & 0 \\ & y & \leq & 4 \end{array}$$

Figure 67.1 shows a picture. It depicts the five inequalities of the program, along with the *feasible region* (green), the set of points that satisfy all the five constraints. The dashed elliptic curves represent *contour lines* of the objective function, i.e., along each dashed curve, the objective function value is constant.

The global minimum of the objective function is attained at the point  $(0, 4)$ , and the minimum within the feasible region appears at the point  $(2, 3)$  marked with a black dot. The value of the objective function at this optimal solution is  $2^2 + 4(3 - 4)^2 = 8$ .

Figure 67.1: A quadratic program in two variables

### 67.3.1 Constructing a Program from Data

Here is how this quadratic program can be solved in CGAL according to the first way (letting the model take care of the data). We use *int* as the input type, and *MP\_Float* or *Gmpz* (which is faster and preferable if GMP is installed) as the exact type for the internal computations. In larger examples, it pays off to use *double* as input type in order to profit from the automatic floating-point filtering that takes place then.

For examples how to work with the input type *double*, we refer to Sections 67.5 and 67.8.

**Note:** For the quadratic objective function, the entries of the matrix  $2D$  have to be provided, rather than  $D$ . Although this is common to almost all quadratic programming solvers, it can easily be overlooked by a novice.

```
#include <iostream>
#include <cassert>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
```

```

#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program<int> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    // by default, we have a nonnegative QP with Ax <= b
    Program qp (CGAL::SMALLER, true, 0, false, 0);

    // now set the non-default entries:
    const int X = 0;
    const int Y = 1;
    qp.set_a(X, 0, 1); qp.set_a(Y, 0, 1); qp.set_b(0, 7); // x + y <= 7
    qp.set_a(X, 1, -1); qp.set_a(Y, 1, 2); qp.set_b(1, 4); // -x + 2y <= 4
    qp.set_u(Y, true, 4); // y <= 4
    qp.set_d(X, X, 2); qp.set_d (Y, Y, 8); // !!specify 2D!! x^2 + 4 y^2
    qp.set_c(Y, -32); // -32y
    qp.set_c0(64); // +64

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_quadratic_program(qp, ET());
    assert (s.solves_quadratic_program(qp));

    // output solution
    std::cout << s;
    return 0;
}

```

**File:** examples/QP\_solver/first\_qp.cpp

Assuming that GMP is installed, the output of the of the above program is:

```

status:          OPTIMAL
objective value: 8/1
variable values:
  0: 2/1
  1: 3/1

```

If GMP is not installed, the values are of course the same, but numerator and denominator might have a common divisor that is not factored out.

### 67.3.2 Constructing a Program from a Stream

Here, the program data must be available in *MPSFormat* (the *MPSFormat* page shows how our running example looks like in this format, and it briefly explains the format). Assuming that your working directory contains the file `first_qp.mps`, the following program will read and solve it, with the same output as before.

```
#include <iostream>
#include <fstream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program_from_mps<int> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    std::ifstream in ("first_qp.mps");
    Program qp(in);           // read program from file
    assert (qp.is_valid()); // we should have a valid mps file

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_quadratic_program(qp, ET());

    // output solution
    std::cout << s;
    return 0;
}
```

**File:** `examples/QP_solver/first_qp_from_mps.cpp`

### 67.3.3 Constructing a Program from Iterators

The following program again solves our running example from above, with the same output, but this time with iterators over data stored in suitable containers. You can see that we also store zero entries here (in *D*). For this toy problem, the previous two approaches (program from data/stream) are clearly preferable, but [Section 67.5](#) shows an example where it makes sense to use the iterator-based approach.

```
#include <iostream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
```

```

#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program_from_iterators
<int**,                                // for A
 int*,                                // for b
 CGAL::Const_onset_iterator<CGAL::Comparison_result>, // for r
 bool*,                                // for fl
 int*,                                // for l
 bool*,                                // for fu
 int*,                                // for u
 int**,                                // for D
 int*>                                // for c
Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    int Ax[] = {1, -1};                // column for x
    int Ay[] = {1, 2};                // column for y
    int* A[] = {Ax, Ay};              // A comes columnwise
    int b[] = {7, 4};                 // right-hand side
    CGAL::Const_onset_iterator<CGAL::Comparison_result>
        r( CGAL::SMALLER);            // constraints are "<="
    bool fl[] = {true, true};          // both x, y are lower-bounded
    int l[] = {0, 0};
    bool fu[] = {false, true};        // only y is upper-bounded
    int u[] = {0, 4};                 // x's u-entry is ignored
    int D1[] = {2};                   // 2D_{1,1}
    int D2[] = {0, 8};                // 2D_{2,1}, 2D_{2,2}
    int* D[] = {D1, D2};              // D-entries on/below diagonal
    int c[] = {0, -32};
    int c0 = 64;                      // constant term

    // now construct the quadratic program; the first two parameters are
    // the number of variables and the number of constraints (rows of A)
    Program qp (2, 2, A, b, r, fl, l, fu, u, D, c, c0);

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_quadratic_program(qp, ET());

    // output solution
    std::cout << s;
    return 0;
}

```

**File:** examples/QP\_solver/first\_qp\_from\_iterators.cpp

**Note 1:** The example shows an interesting feature of this approach: not all data need to come from containers. Here, the iterator over the vector of relations can be provided through the class *Const\_oneset\_iterator*<*T*>, since all entries of this vector are equal to *CGAL::SMALLER*. The same could have been done with the vector *fl* for the finiteness of the lower bounds.

**Note 2:** The program type looks a bit scary, with its total of 9 template arguments, one for each iterator type. In Section 67.5.1 we show how the explicit construction of this type can be circumvented.

## 67.4 Solving Linear and Nonnegative Programs

Let us reconsider the general form of (QP) from Section 67.1 above. If  $D = 0$ , the quadratic program is in fact a *linear program*, and in the case that the bound vectors  $l$  is the zero vector and all entries of  $u$  are  $\infty$ , the program is said to be *nonnegative*. The package offers dedicated models and solution methods for these special cases.

From an interface perspective, this is just syntactic sugar: in the model *Quadratic\_program*<*NT*>, we can easily set the default bounds so that a nonnegative program results, and a linear program is obtained by simply not inserting any  $D$ -entries. Even in the iterator-based approach (see *QP\_solver/first\_qp\_from\_iterators.cpp*), linear and nonnegative programs can easily be defined through suitable *Const\_oneset\_iterator*<*T*>-style iterators.

The main reason for having dedicated solution methods for linear and nonnegative programs is efficiency: if the solver knows that the program is linear, it can save some computations compared to the general solver that unknowingly has to fiddle around with a zero  $D$ -matrix. As in Section 67.2.2 above, we can argue that checking in advance whether  $D = 0$  is not an option in general, since this may require  $\Omega(n^2)$  time on the dense interface.

Similarly, if the solver knows that the program is nonnegative, it will be more efficient than under the general bounds  $\mathbf{l} \leq \mathbf{x} \leq \mathbf{u}$ . You can argue that nonnegativity *is* something that could easily be checked in time  $O(n)$  beforehand, but then again nonnegative programs are so frequent that the syntactic sugar aspect becomes somewhat important. After all, we can save four iterators in specifying a nonnegative linear program in terms of the concept *NonnegativeLinearProgram* rather than *LinearProgram*.

Often, there are no bounds at all for the variables, i.e., all entries of  $\mathbf{l}$  are  $-\infty$ , and all entries of  $\mathbf{u}$  are  $\infty$  (this is called a *free* program). There is no dedicated solution method for this case (a free quadratic or linear program is treated like a general quadratic or linear program), but all predefined models make it easy to specify all sorts of default bounds, covering the free case.

### 67.4.1 The Linear Programming Solver

Let's go back to our first quadratic program from above and change it into a linear program by simply removing the quadratic part of the objective function:

$$\begin{array}{ll} \text{minimize} & -32y + 64 \\ \text{subject to} & x + y \leq 7 \\ & -x + 2y \leq 4 \\ & x \geq 0 \\ & y \geq 0 \\ & y \leq 4 \end{array}$$

Figure 67.2 shows how this looks like. We will not visualize a linear objective function with contour lines but with arrows instead. The arrow represents the (direction) of the vector  $-c$ , and we are looking for a feasible solution that is “extreme” in the direction of the arrow. In our small example, this is the unique point “on” the two constraints  $x_1 + x_2 \leq 7$  and  $-x_1 + x_2 \leq 4$ , the point  $(10/3, 11/3)$  marked with a black dot. The optimal objective function value is  $-32(11/3) + 64 = -160/3$ .

Figure 67.2: A linear program in two variables

Here is CGAL code for solving it, using the dedicated LP solver, and according to the three ways for constructing a program that we have already discussed in Section 67.3.

```
QP_solver/first_lp.cpp
QP_solver/first_lp_from_mps.cpp
QP_solver/first_lp_from_iterators.cpp
```

In all cases, the output is

```
status:          OPTIMAL
objective value: -160/3
variable values:
  0: 10/3
  1: 11/3
```

## 67.4.2 The Nonnegative Quadratic Programming Solver

If we go back to our first quadratic program and remove the constraint  $y \leq 4$ , we arrive at a nonnegative quadratic program:

$$\begin{array}{ll} \text{minimize} & x^2 + 4(y - 4)^2 \quad (= x^2 + 4y^2 - 32y + 64) \\ \text{subject to} & x + y \leq 7 \\ & -x + 2y \leq 4 \\ & x, y \geq 0 \end{array}$$

Figure 67.3 contains the illustration; since the constraint  $y \leq 4$  was redundant, the feasible region and the optimal solution do not change.

Figure 67.3: A nonnegative quadratic program in two variables

The following programs (using the dedicated solver for nonnegative quadratic programs) will therefore again output

```
status:          OPTIMAL
objective value: 8/1
variable values:
  0: 2/1
  1: 3/1
```

```
QP_solver/first_nonnegative_qp.cpp
QP_solver/first_nonnegative_qp_from_mps.cpp
QP_solver/first_nonnegative_qp_from_iterators.cpp
```

### 67.4.3 The Nonnegative Linear Programming Solver

Finally, a dedicated model and function is available for nonnegative linear programs as well. Let's take our linear program from above and remove the constraint  $y \leq 4$  to obtain a nonnegative linear program. At the same time we remove the constant objective function term to get a "minimal" input and a "shortest" program; the optimal value is  $-32(11/3) = -352/3$ .

$$\begin{array}{ll}
\text{minimize} & -32y \\
\text{subject to} & x + y \leq 7 \\
& -x + 2y \leq 4 \\
& x, y \geq 0
\end{array}$$

This can be solved by any of the following three programs

```

QP_solver/first_nonnegative_lp.cpp
QP_solver/first_nonnegative_lp_from_mps.cpp
QP_solver/first_nonnegative_lp_from_iterators.cpp

```

The output will always be

```

status:          OPTIMAL
objective value: -352/3
variable values:
  0: 10/3
  1: 11/3

```

## 67.5 Working from Iterators

Here we present a somewhat more advanced example that emphasizes the usefulness of solving linear and quadratic programs from iterators. Let's look at a situation in which a linear program is given implicitly, and access to it is gained through properly constructed iterators.

The problem we are going to solve is the following: given points  $p_1, \dots, p_n$  in  $d$ -dimensional space and another point  $p$ : is  $p$  in the convex hull of  $\{p_1, \dots, p_n\}$ ? In formulas, this is the case if and only if there are real coefficients  $\lambda_1, \dots, \lambda_n$  such that  $p$  is a convex combination of  $p_1, \dots, p_n$ :

$$p = \sum_{j=1}^n \lambda_j p_j, \quad \sum_{j=1}^n \lambda_j = 1, \quad \lambda_j \geq 0 \text{ for all } j.$$

The problem of testing the existence of such  $\lambda_j$  can be expressed as a linear program. It becomes particularly easy when we use the homogeneous representations of the points: if  $q_1, \dots, q_n, q \in \mathbb{R}^{d+1}$  are homogeneous coordinates for  $p_1, \dots, p_n, p$  with positive homogenizing coordinates  $h_1, \dots, h_n, h$ , we have

$$q_j = h_j \cdot (p_j \mid 1) \text{ for all } j, \text{ and } q = h \cdot (p \mid 1).$$

Now, nonnegative  $\lambda_1, \dots, \lambda_n$  are suitable coefficients for a convex combination if and only if

$$\sum_{j=1}^n \lambda_j (p_j \mid 1) = (p \mid 1),$$

equivalently, if there are  $\mu_1, \dots, \mu_n$  (with  $\mu_j = \lambda_j \cdot h/h_j$  for all  $j$ ) such that

$$\sum_{j=1}^n \mu_j q_j = q, \quad \mu_j \geq 0 \text{ for all } j.$$

The linear program now tests for the existence of nonnegative  $\mu_j$  that satisfy the latter equation. Below is the code; it defines a function that solves the linear program, given  $p$  and  $p_1, \dots, p_n$  (through an iterator range). The only (mild) trickery involved is the construction of the nested iterator through a fixed column of the constraint matrix  $A$ . We get this from transforming the iterator through the points using a functor that maps a point to an iterator through its homogeneous coordinates.

```

#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin {
    typedef typename Point_d::Homogeneous_const_iterator result_type;
    result_type operator() (const Point_d& p) const {
        return p.homogeneous_begin();
    }
};

// function to solve the LP that tests whether a point is in the
// convex hull of other points; the type ET is an exact type used
// for the internal computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
    RandomAccessIterator begin,
    RandomAccessIterator end, const ET& dummy)
{
    // Constraint matrix type: A[j][i] is the i-th homogeneous coordinate of p_j
    typedef boost::transform_iterator
        <Homogeneous_begin<Point_d>, RandomAccessIterator> A_it;
    // Right-hand side type: b[i] is the i-th homogeneous coordinate of p
    typedef typename Point_d::Homogeneous_const_iterator B_it;
    // Relation type ("=")
    typedef CGAL::Const_onese_iterator<CGAL::Comparison_result> R_it;
    // input number type
    typedef typename CGAL::Kernel_traits<Point_d>::Kernel::RT RT;
    // Linear objective function type (c=0: we only test feasibility)
    typedef CGAL::Const_onese_iterator<RT> C_it;
    // the nonnegative linear program type
    typedef
        CGAL::Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>
        Program;

    // ok, we are prepared now: construct program and solve it
    Program lp (end-begin, // number of variables
        p.dimension()+1, // number of constraints
        A_it (begin), B_it (p.homogeneous_begin()),
        R_it (CGAL::EQUAL), C_it (0));
    return CGAL::solve_nonnegative_linear_program (lp, dummy);
}

```

**File:** examples/QP\_solver/solve\_convex\_hull\_containment\_lp.h

To see this in action, let us call it with  $p_1 = (0,0)$ ,  $p_2 = (10,0)$ ,  $p_3 = (0,10)$  fixed (they define a triangle) and all integral points  $p$  in  $[0,10]^2$ . We know that  $p$  is in the convex hull of  $\{p_1, p_2, p_3\}$  if and only if its two coordinates sum up to 10 at most. As the exact type, we use *MP\_Float* or *Gmpzf* (which is faster and preferable if GMP is installed).

```

#include <cassert>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include "solve_convex_hull_containment_lp.h"

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;

bool is_in_convex_hull (const Point_d& p,
std::vector<Point_d>::const_iterator begin,
std::vector<Point_d>::const_iterator end)
{
    CGAL::Quadratic_program_solution<ET> s =
        solve_convex_hull_containment_lp (p, begin, end, ET(0));
    return !s.is_infeasible();
}

int main()
{
    std::vector<Point_d> points;
    // convex hull: simplex spanned by {(0,0), (10,0), (0,10)}
    points.push_back (Point_d ( 0.0,  0.0));
    points.push_back (Point_d (10.0,  0.0));
    points.push_back (Point_d ( 0.0, 10.0));
    for (int i=0; i<=10; ++i)
        for (int j=0; j<=10; ++j) {
            // (i,j) is in the simplex iff i+j <= 10
            bool contained = is_in_convex_hull
(Point_d (i, j), points.begin(), points.end());
            assert (contained == (i+j<=10));
        }

    return 0;
}

```

**File:** examples/QP\_solver/convex\_hull\_containment.cpp

### 67.5.1 Using Makers

You already noticed in the previous example that the actual template arguments for *CGAL::Nonnegative\_linear\_program\_from\_iterators*<*A\_it*, *B\_it*, *R\_it*, *C\_it*> can be quite elaborate, and this only gets worse if you plug more iterators into each other. In general, you want to construct a program from given expressions for the iterators,

but the types of these expressions are probably very complicated and difficult to look up.

You can avoid the explicit construction of the type `CGAL::Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>` if you only need an expression of it, e.g. to pass it directly as an argument to the solving function. Here is an alternative version of `QP_solver/solve_convex_hull_containment_lp.h` that shows how this works. In effect, you get shorter and more readable code.

```
#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin {
    typedef typename Point_d::Homogeneous_const_iterator result_type;
    result_type operator() (const Point_d& p) const {
        return p.homogeneous_begin();
    }
};

// function to test whether point is in the convex hull of other points;
// the type ET is an exact type used for the computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
    RandomAccessIterator begin,
    RandomAccessIterator end, const ET& dummy)
{
    // construct program and solve it
    return CGAL::solve_nonnegative_linear_program
        (CGAL::make_nonnegative_linear_program_from_iterators
            (end-begin, // n
            p.dimension()+1, // m
            boost::transform_iterator
                <Homogeneous_begin<Point_d>, RandomAccessIterator>(begin), // A
            typename Point_d::Homogeneous_const_iterator (p.homogeneous_begin()), // b
            CGAL::Const_onset_iterator<CGAL::Comparison_result>(CGAL::EQUAL), // ~
            CGAL::Const_onset_iterator
                <typename CGAL::Kernel_traits<Point_d>::Kernel::RT> (0)), dummy); // c
}
```

**File:** examples/QP\_solver/solve\_convex\_hull\_containment\_lp2.h

## 67.6 Important Variables and Constraints

If you have a solution  $\mathbf{x}^*$  of a linear or quadratic program, the “important” variables are typically the ones that are not on their bounds. In case of a nonnegative program, these are the nonzero variables. Going back to the example of the previous Section 67.5, we can easily interpret their importance: the nonzero variables correspond to points  $p_j$  that actually contribute to the convex combination that yields  $p$ .

The following example shows how we can access the important variables, using the iterators *basic\_variable\_indices\_begin()* and *basic\_variable\_indices\_end()*.

We generate a set of points that form a 4-gon in  $[0,4]^2$ , and then find the ones that contribute to the convex combinations of all 25 lattice points in  $[0,4]^2$ . If the lattice point in question is not in the 4-gon, we simply output this fact.

```
#include <cassert>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include "solve_convex_hull_containment_lp2.h"

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;
typedef CGAL::Quadratic_program_solution<CGAL::MP_Float> Solution;

int main()
{
    std::vector<Point_d> points;
    // convex hull: 4-gon spanned by {(1,0), (4,1), (4,4), (2,3)}
    points.push_back (Point_d (1, 0)); // point 0
    points.push_back (Point_d (4, 1)); // point 1
    points.push_back (Point_d (4, 4)); // point 2
    points.push_back (Point_d (2, 3)); // point 3

    // test all 25 integer points in  $[0,4]^2$ 
    for (int i=0; i<=4; ++i)
        for (int j=0; j<=4; ++j) {
            Point_d p (i, j);
            Solution s = solve_convex_hull_containment_lp
(p, points.begin(), points.end(), CGAL::MP_Float());
            std::cout << p;
            if (s.is_infeasible())
std::cout << " is not in the convex hull\n";
            else {
assert (s.is_optimal());
std::cout << " is a convex combination of the points ";
Solution::Index_iterator it = s.basic_variable_indices_begin();
Solution::Index_iterator end = s.basic_variable_indices_end();
for (; it != end; ++it) std::cout << *it << " ";
std::cout << std::endl;
            }
        }
    return 0;
}
```

**File:** examples/QP\_solver/important\_variables.cpp

It turns out that exactly three of the four points contribute to any convex combination, even though there are lattice points that lie in the convex hull of less than three of the points. This shows that the set of basic variables that we access in the example does not necessarily coincide with the set of important variables as defined above.

In fact, it is only guaranteed that a non-basic variable attains one of its bounds, but there might be basic variables that also have this property. In linear and quadratic programming terms, such a situation is called a *degeneracy*.

There is also the concept of an important constraint: this is typically a constraint in the system  $A\mathbf{x} \leq \mathbf{b}$  that is satisfied with equality at  $\mathbf{x}^*$ . Program *QP\_solver/first\_qp\_basic\_constraints.cpp* shows how these can be accessed, using the iterators *basic\_constraint\_indices\_begin()* and *basic\_constraint\_indices\_end()*.

Again, we have a disagreement between “basic” and “important”: it is guaranteed that all basic constraints are satisfied with equality at  $\mathbf{x}^*$ , but there might be non-basic constraints that are satisfied with equality as well.

## 67.7 Solution Certificates

Suppose the solver tells you that the problem you have entered is infeasible. Why should you believe this? Similarly, you can quite easily verify that a claimed optimal solution is feasible, but why is there no better one?

Certificates are proofs that the solver can give you in order to convince you that what it claims is indeed true. The archetype of such a proof is *Farkas Lemma* [MG06].

**Farkas Lemma:** *Either* the inequality system

$$\begin{array}{rcl} A\mathbf{x} & \leq & \mathbf{b} \\ \mathbf{x} & \geq & 0 \end{array}$$

has a solution  $\mathbf{x}^*$ , *or* there exists a vector  $\mathbf{y}$  such that

$$\begin{array}{rcl} \mathbf{y} & \geq & 0 \\ \mathbf{y}^T A & \geq & 0 \\ \mathbf{y}^T \mathbf{b} & < & 0, \end{array}$$

but not both.

Thus, if someone wants to convince you that the first system in the Farkas Lemma is infeasible, that person can simply give you a vector  $\mathbf{y}$  that solves the second system. Since you can easily verify yourself that the  $\mathbf{y}$  you got satisfies this second system, you now have a certificate for the infeasibility of the first system, assuming that you believe in Farkas Lemma.

Here we show how the solver can convince you. We first set up an infeasible linear program with constraints of the type  $A\mathbf{x} \leq \mathbf{b}, \mathbf{x} \geq 0$ ; then we solve it and ask for a certificate. Finally, we verify the certificate by simply checking the inequalities of the second system in Farkas Lemma.

```
#include <cassert>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif
```

```

// program and solution types
typedef CGAL::Nonnegative_linear_program_from_iterators
<int**,                                // for A
 int*,                                  // for b
 CGAL::Comparison_result*,             // for r
 int*>                                  // for c
Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

// we demonstrate Farkas Lemma: either the system
//      A x <= b
//      x >= 0
// has a solution, or there exists y such that
//      y >= 0
//      y^TA >= 0
//      y^Tb < 0
// In the following instance, the first system has no solution,
// since adding up the two inequalities gives x_2 <= -1:
//      x_1 - 2x_2 <= 1
//      -x_1 + 3x_2 <= -2
//      x_1,   x_2 >= 0

int main() {
    int  Ax1[] = { 1, -1};                // column for x1
    int  Ax2[] = {-2,  3};                // column for x2
    int*  A[] = {Ax1, Ax2};               // A comes columnwise
    int   b[] = {1, -2};                  // right-hand side
    CGAL::Comparison_result
        r[] = {CGAL::SMALLER, CGAL::SMALLER}; // constraints are "<="
    int   c[] = {0, 0};                   // zero objective function

    // now construct the linear program; the first two parameters are
    // the number of variables and the number of constraints (rows of A)
    Program lp (2, 2, A, b, r, c);

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_nonnegative_linear_program(lp, ET());

    // get certificate for infeasibility
    assert (s.is_infeasible());
    Solution::Infeasibility_certificate_iterator y =
        s.infeasibility_certificate_begin();
    // check y >= 0
    assert (y[0] >= 0);
    assert (y[1] >= 0);
    // check y^T A >= 0
    assert (y[0] * A[0][0] + y[1] * A[0][1] >= 0);
    assert (y[0] * A[1][0] + y[1] * A[1][1] >= 0);
    // check y^T b < 0
    assert (y[0] * b[0] + y[1] * b[1] < 0);

    return 0;
}

```

**File:** examples/QP\_solver/infeasibility\_certificate.cpp

There are similar certificates for optimality and unboundedness that you can see in action in the programs *QP\_solver/optimality\_certificate.cpp* and *QP\_solver/unboundedness\_certificate.cpp*. The underlying variants of Farkas Lemma are somewhat more complicated, due to the mixed relations in  $\geq$  and the general bounds. The certificate section of *Quadratic\_program\_solution<ET>* gives the full picture and mathematically proves the correctness of the certificates.

## 67.8 Customizing the Solver

Sometimes it is necessary to alter the default behavior of the solver. This can be done by passing a suitably prepared object of the class *Quadratic\_program\_options* to the solution functions. Most options concern “soft” issues like verbosity, but there are two notable case where it is of critical importance to be able to change the defaults.

### 67.8.1 Exponent Overflow in Double Using Floating-Point Filters

The filtered version of the solver that is used for some problems by default on input type *double* internally constructs double-approximations of exact multiprecision values. If these exact values are extremely large, this may lead to *infinite double* values and incorrect results. In debug mode, the solver will notice this through a certificate cross-check in the end (or even earlier). In this case, it is advisable to explicitly switch to a non-filtered *pricing strategy*, see *Quadratic\_program\_pricing\_strategy*.

**Hint:** If you have a program where the number of variables  $n$  and the number of constraints  $m$  have the same order of magnitude, the filtering will usually have no dramatic effect on the performance, so in that case you might as well switch to *QP\_PARTIAL\_DANTZIG* to be safe from the issue described here (see *QP\_solver/cycling.cpp* for an example that shows how to change the pricing strategy).

### 67.8.2 The Solver Internally Cycles

Consider the following program. It reads a nonnegative linear program from the file *cycling.mps* (which is in the example directory as well), and then solves it in verbose mode, using *Bland’s rule*, see *Quadratic\_program\_pricing\_strategy*.

```
#include <iostream>
#include <fstream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
```

```

#endif

// program and solution types
typedef CGAL::Quadratic_program_from_mps<double> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    std::ifstream in ("cycling.mps");
    Program lp(in);          // read program from file
    assert (lp.is_valid()); // we should have a valid mps file...
    assert (lp.is_linear()); // ... and it should be linear...
    assert (lp.is_nonnegative()); // as well as nonnegative

    // solve the program, using ET as the exact type
    // choose verbose mode and Bland pricing
    CGAL::Quadratic_program_options options;
    options.set_verbosity(1);          // verbose mode
    options.set_pricing_strategy(CGAL::QP_BLAND); // Bland's rule
    options.set_auto_validation(true); // automatic self-check
    Solution s = CGAL::solve_nonnegative_linear_program(lp, ET(), options);
    assert (s.is_valid());             // did the self-check succeed?

    // output solution
    std::cout << s;
    return 0;
}

```

**File:** examples/QP\_solver/cycling.cpp

If you comment the line

```
options.set_pricing_strategy(CGAL::QP_BLAND); // Bland's rule
```

you will see that the solver cycles: the verbose mode outputs the same sequence of six iterations over and over again. By switching to *QP.BLAND*, the solution process typically slows down a bit (it may also speed up in some cases), but now it is guaranteed that no cycling occurs.

In general, the verbose mode can be of use when you are not sure whether the solver “has died”, or whether it simply takes very long to solve your problem. We refer to the class *Quadratic\_program\_options* for further details.

## 67.9 Some Benchmarks for Convex Hull Containment

Here we want to show what you can expect from the solver’s performance in a specific application; we don’t know whether this application is typical in your case, and we make no claims whatsoever about the performance in other applications.

Still, the example shows that the performance can be dramatically affected by switching between pricing strategies, and we give some hints on how to achieve good performance in general.

The application is the one already discussed in Section 67.5 above: testing whether a point is in the convex hull of other points. To be able to switch between pricing strategies, we add another parameter of type *Quadratic\_program\_options* to the function *solve\_convex\_hull\_containment\_lp* that we pass on to the solution function:

```
#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_options.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin {
    typedef typename Point_d::Homogeneous_const_iterator result_type;
    result_type operator() (const Point_d& p) const {
        return p.homogeneous_begin();
    }
};

// function to test whether point is in the convex hull of other points;
// the type ET is an exact type used for the computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
    RandomAccessIterator begin,
    RandomAccessIterator end, const ET& dummy,
    const CGAL::Quadratic_program_options& o)
{
    // construct program and solve it
    return CGAL::solve_nonnegative_linear_program
        (CGAL::make_nonnegative_linear_program_from_iterators
            (end-begin, // n
            p.dimension()+1, // m
            boost::transform_iterator
                <Homogeneous_begin<Point_d>, RandomAccessIterator>(begin), // A
            typename Point_d::Homogeneous_const_iterator (p.homogeneous_begin()), // b
            CGAL::Const_onset_iterator<CGAL::Comparison_result>(CGAL::EQUAL), // ~
            CGAL::Const_onset_iterator
                <typename CGAL::Kernel_traits<Point_d>::Kernel::RT> (0)), // c
            dummy, o);
}
```

**File:** examples/QP\_solver/solve\_convex\_hull\_containment\_lp3.h

Now let us test containment of the origin in the convex hull of  $n$  random points in  $[0, 1]^d$  (it will most likely not be contained, and it turns out that this is the most expensive case). In the program below, we use  $d = 10$  and  $n = 100,000$ , and we comment on some other combinations of  $n$  and  $d$  below (feel free to experiment with still other values).

```
#include <vector>
#include <CGAL/Cartesian_d.h>
```

```

#include <CGAL/MP_Float.h>
#include <CGAL/Random.h>
#include <CGAL/Timer.h>
#include "solve_convex_hull_containment_lp3.h"

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;

int main()
{
    const int d = 10;          // change this in order to experiment
    const int n = 100000;      // change this in order to experiment

    // generate n random d-dimensional points in  $[0,1]^d$ 
    CGAL::Random rd;
    std::vector<Point_d> points;
    for (int j = 0; j < n; ++j) {
        std::vector<double> coords;
        for (int i = 0; i < d; ++i)
            coords.push_back(rd.get_double());
        points.push_back (Point_d (d, coords.begin(), coords.end()));
    }

    // benchmark all pricing strategies in turn
    CGAL::Quadratic_program_pricing_strategy strategy[] = {
        CGAL::QP_CHOOSE_DEFAULT,          // QP_PARTIAL_FILTERED_DANTZIG
        CGAL::QP_DANTZIG,                 // Dantzig's pivot rule...
        CGAL::QP_PARTIAL_DANTZIG,         // ... with partial pricing
        CGAL::QP_BLAND,                   // Bland's pivot rule
        CGAL::QP_FILTERED_DANTZIG,        // Dantzig's filtered pivot rule...
        CGAL::QP_PARTIAL_FILTERED_DANTZIG // ... with partial pricing
    };

    CGAL::Timer t;
    for (int i = 0; i < 6; ++i) {
        // test strategy i
        CGAL::Quadratic_program_options options;
        options.set_pricing_strategy (strategy[i]);
        t.reset(); t.start();
        // is origin in convex hull of the points? (most likely, not)
        solve_convex_hull_containment_lp
            (Point_d (d, CGAL::ORIGIN), points.begin(), points.end(),
             ET(0), options);
        t.stop();
        std::cout << "Time (s) = " << t.time() << std::endl;
    }
}

```

```

    }

    return 0;
}

```

**File:** examples/QP\_solver/convex\_hull\_containment\_benchmarks.cpp

If you compile with the macros `NDEBUG` or `CGAL_QP_NO_ASSERTIONS` set (this is essential for good performance!), you will see runtimes that qualitatively look as follows (on your machine, the actual runtimes will roughly be some fixed multiples of the numbers in the table below, and they might vary with the random choices). The default choice of the pricing strategy in that case is `QP_PARTIAL_FILTERED_DANTZIG`.

strategy	runtime in seconds
<i>CGAL::QP_CHOOSE_DEFAULT</i>	— 0.32
<i>CGAL::QP_DANTZIG</i>	— 10.7
<i>CGAL::QP_PARTIAL_DANTZIG</i>	— 3.72
<i>CGAL::QP_BLAND</i>	— 3.65
<i>CGAL::QP_FILTERED_DANTZIG</i>	— 0.43
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	— 0.32

We clearly see the effect of filtering: we gain a factor of ten, roughly, compared to the next best non-filtered variant.

### 67.9.1 $d = 3, n = 1,000,000$

The filtering effect is amplified if the points/dimension ratio becomes larger. This is what you might see in dimension three, with one million points.

strategy	runtime in seconds
<i>CGAL::QP_CHOOSE_DEFAULT</i>	— 1.34
<i>CGAL::QP_DANTZIG</i>	— 47.6
<i>CGAL::QP_PARTIAL_DANTZIG</i>	— 15.6
<i>CGAL::QP_BLAND</i>	— 16.02
<i>CGAL::QP_FILTERED_DANTZIG</i>	— 1.89
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	— 1.34

In general, if your problem has a high variable/constraint or constraint/variable ratio, then filtering will typically pay off. In such cases, it might be beneficial to encode your problem using input type *double* in order to profit from the filtering (but see the issue discussed in Section 67.8.1).

### 67.9.2 $d = 100, n = 100,000$

Conversely, the filtering effect deteriorates if the points/dimension ratio becomes smaller.

strategy	runtime in seconds
<i>CGAL::QP_CHOOSE_DEFAULT</i>	— 3.05
<i>CGAL::QP_DANTZIG</i>	— 78.4
<i>CGAL::QP_PARTIAL_DANTZIG</i>	— 45.9
<i>CGAL::QP_BLAND</i>	— 33.2
<i>CGAL::QP_FILTERED_DANTZIG</i>	— 3.36
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	— 3.06

### 67.9.3 $d = 500, n = 1,000$

If the points/dimension ratio tends to a constant, filtering is no longer a clear winner. The reason is that in this case, the necessary exact calculations with multiprecision numbers dominate the overall runtime.

strategy		runtime in seconds
<i>CGAL::QP_CHOOSE_DEFAULT</i>	—	2.65
<i>CGAL::QP_DANTZIG</i>	—	5.55
<i>CGAL::QP_PARTIAL_DANTZIG</i>	—	5.6
<i>CGAL::QP_BLAND</i>	—	4.46
<i>CGAL::QP_FILTERED_DANTZIG</i>	—	2.65
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	—	2.61

In general, if you have a program where the number of variables and the number of constraints have the same order of magnitude, then the saving gained from using the filtered approach is typically small. In such a situation, you should consider switching to a non-filtered variant in order to avoid the rare issue discussed in [Section 67.8.1](#) altogether.

# Linear and Quadratic Programming Solver

## Reference Manual

### 67.10 Classified Reference Pages

#### Concepts

QuadraticProgram . . . . .	page 3592
(for quadratic programs with variable bounds $\mathbf{l} \leq \mathbf{x} \leq \mathbf{u}$ )	
LinearProgram . . . . .	page 3598
(for linear programs with variable bounds $\mathbf{l} \leq \mathbf{x} \leq \mathbf{u}$ )	
NonnegativeQuadraticProgram . . . . .	page 3595
(for quadratic programs with variable bounds $\mathbf{x} \geq 0$ )	
NonnegativeLinearProgram . . . . .	page 3601
(for linear programs with variable bounds $\mathbf{x} \geq 0$ )	
MPSFormat . . . . .	page 3603
(the format used for reading and writing linear and quadratic programs)	

#### Classes

There is a class that represents the solution of a linear or quadratic program. An instance of this class is returned by any of the solution functions below.

<i>CGAL::Quadratic_program_solution</i> <ET> . . . . .	page 3606
--	-----------

We offer a number of predefined models for the above program concepts. The following two are simultaneously models for all four concepts and are probably the most convenient models; they allow you to construct linear or quadratic programs entry by entry, or from streams in *MPSFormat*. At any time, you can query these programs for linearity and nonnegativity and thus select the appropriate solution function.

<i>CGAL::Quadratic_program</i> <NT> . . . . .	page 3617
(for linear and quadratic programs that own their data and are built entry-wise)	
<i>CGAL::Quadratic_program_from_mps</i> <NT> . . . . .	page 3620
(for linear and quadratic programs read from an input stream in <i>MPSFormat</i> ; the constructed program can also be manipulate entry-wise)	

Then there are specific models for any of the four program concepts above; these are useful if you want to maintain the program data yourself, since they simply wrap random access iterators over the program data and involve no further copying of data.

*CGAL::Quadratic\_program\_from\_iterators*<A\_it, B\_it, R\_it, FL\_it, L\_it, FU\_it, U\_it, D\_it, C\_it> . . . . page 3624  
(for quadratic programs that wrap given iterators, without copying data)

*CGAL::Linear\_program\_from\_iterators*<A\_it, B\_it, R\_it, FL\_it, L\_it, FU\_it, U\_it, C\_it> . . . . . page 3626  
(for linear programs wrapping given iterators)

*CGAL::Nonnegative\_quadratic\_program\_from\_iterators*<A\_it, B\_it, R\_it, D\_it, C\_it> . . . . . page 3628  
(for nonnegative quadratic programs, wrapping given iterators)

*CGAL::Nonnegative\_linear\_program\_from\_iterators*<A\_it, B\_it, R\_it, C\_it> . . . . . page 3630  
(for nonnegative linear programs, wrapping given iterators) **Functions**

In case you want to construct a program from complicated iterators (whose types you don't know, or simply don't want to bother with), we provide four makers.

*CGAL::make\_quadratic\_program\_from\_iterators* . . . . . page 3632  
*CGAL::make\_linear\_program\_from\_iterators* . . . . . page 3633  
*CGAL::make\_nonnegative\_quadratic\_program\_from\_iterators* . . . . . page 3634  
*CGAL::make\_nonnegative\_linear\_program\_from\_iterators* . . . . . page 3635

There are four functions to solve a program, one for each program concept.

*CGAL::solve\_quadratic\_program* . . . . . page 3636  
*CGAL::solve\_linear\_program* . . . . . page 3637  
*CGAL::solve\_nonnegative\_quadratic\_program* . . . . . page 3638  
*CGAL::solve\_nonnegative\_linear\_program* . . . . . page 3639

The solution process can be customized by passing an object of the class

*Quadratic\_program\_options* . . . . . page ??

Programs can be written to an output stream in *MPSFormat*, using one of the following four functions.

*CGAL::print\_quadratic\_program* . . . . . page 3644  
*CGAL::print\_linear\_program* . . . . . page 3645  
*CGAL::print\_nonnegative\_quadratic\_program* . . . . . page 3646  
*CGAL::print\_nonnegative\_linear\_program* . . . . . page 3647

# QuadraticProgram

## Definition

A model of QuadraticProgram describes a convex quadratic program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $\mathbf{l}$  is an  $n$ -dimensional vector of lower bounds for  $\mathbf{x}$ , where  $l_j \in \mathbb{R} \cup \{-\infty\}$  for all  $j$
- $\mathbf{u}$  is an  $n$ -dimensional vector of upper bounds for  $\mathbf{x}$ , where  $u_j \in \mathbb{R} \cup \{\infty\}$  for all  $j$
- $D$  is a symmetric positive-semidefinite  $n \times n$  matrix (the quadratic objective function),
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

The description is given by appropriate *random-access* iterators over the program data, see below. The program therefore comes in *dense* representation which includes zero entries.

## Has Models

*Quadratic\_program*<NT>

*Quadratic\_program\_from\_mps*<NT>

*Quadratic\_program\_from\_iterators*<*A\_it*, *B\_it*, *R\_it*, *FL\_it*, *L\_it*, *FU\_it*, *U\_it*, *D\_it*, *C\_it*>

## Types

*QuadraticProgram::A\_iterator*

A random access iterator type to go columnwise over the constraint matrix  $A$ . The value type is a random access iterator type for an individual column that goes over the entries in that column.

*QuadraticProgram::B\_iterator*

A random access iterator type to go over the entries of the right-hand side  $\mathbf{b}$ .

*QuadraticProgram::R\_iterator*

A random access iterator type to go over the relations  $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$ . The value type of *R\_iterator* is *CGAL::Comparison\_result*.

<i>QuadraticProgram:: FL_iterator</i>	A random access iterator type to go over the existence (finiteness) of the lower bounds $l_j, j = 0, \dots, n-1$ . The value type of <i>FL_iterator</i> is <i>bool</i> .
<i>QuadraticProgram:: L_iterator</i>	A random access iterator type to go over the entries of the lower bound vector <b>l</b> .
<i>QuadraticProgram:: UL_iterator</i>	A random access iterator type to go over the existence (finiteness) of the upper bounds $u_j, j = 0, \dots, n-1$ . The value type of <i>UL_iterator</i> is <i>bool</i> .
<i>QuadraticProgram:: U_iterator</i>	A random access iterator type to go over the entries of the upper bound vector <b>u</b> .
<i>QuadraticProgram:: D_iterator</i>	A random access iterator type to go rowwise over the matrix $2D$ . The value type is a random access iterator type for an individual row that goes over the entries in that row, up to (and including) the entry on the main diagonal.
<i>QuadraticProgram:: C_iterator</i>	A random access iterator type to go over the entries of the linear objective function vector <i>c</i> .

## Operations

<i>int</i>	<i>qp.get_n()</i>	returns the number <i>n</i> of variables (number of columns of <i>A</i> ) in <i>qp</i> .
<i>int</i>	<i>qp.get_m()</i>	returns the number <i>m</i> of constraints (number of rows of <i>A</i> ) in <i>qp</i> .
<i>A_iterator</i>	<i>qp.get_a()</i>	returns an iterator over the columns of <i>A</i> . The corresponding past-the-end iterator is <i>get_a()+get_n()</i> . For $j = 0, \dots, n-1$ , $*(get\_a() + j)$ is a random access iterator for column <i>j</i> .
<i>B_iterator</i>	<i>qp.get_b()</i>	returns an iterator over the entries of <b>b</b> . The corresponding past-the-end iterator is <i>get_b()+get_m()</i> .
<i>R_iterator</i>	<i>qp.get_r()</i>	returns an iterator over the entries of $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$ . The corresponding past-the-end iterator is <i>get_r()+get_m()</i> . The value <i>CGAL::SMALLER</i> stands for $\leq$ , <i>CGAL::EQUAL</i> stands for $=$ , and <i>CGAL::LARGER</i> stands for $\geq$ .
<i>FL_iterator</i>	<i>qp.get_fl()</i>	returns an iterator over the existence of the lower bounds $l_j, j = 0, \dots, n-1$ . The corresponding past-the-end iterator is <i>get_fl()+get_n()</i> . If $*(get\_fl() + j)$ has value <i>true</i> , the variable $x_j$ has a lower bound given by $*(get\_l() + j)$ , otherwise it has no lower bound.
<i>L_iterator</i>	<i>qp.get_l()</i>	returns an iterator over the entries of <b>l</b> . The corresponding past-the-end iterator is <i>get_l()+get_n()</i> . If $*(get\_fl() + j)$ has value <i>false</i> , the value $*(get\_l() + j)$ is not accessed. <i>Precondition:</i> if both $*(get\_fl() + j)$ and $*(get\_fu() + j)$ have value <i>true</i> , then $*(get\_l() + j) \leq *(get\_u() + j)$

<i>FU_iterator</i>	<i>qp.get_fu()</i>	returns an iterator over the existence of the upper bounds $u_j, j = 0, \dots, n - 1$ . The corresponding past-the-end iterator is <i>get_fu()+get_n()</i> . If <i>*(get_fu()+j)</i> has value <i>true</i> , the variable $x_j$ has an upper bound given by <i>*(get_u()+j)</i> , otherwise it has no upper bound.
<i>L_iterator</i>	<i>qp.get_u()</i>	returns an iterator over the entries of <b>u</b> . The corresponding past-the-end iterator is <i>get_u()+get_n()</i> . If <i>*(get_fu()+j)</i> has value <i>false</i> , the value <i>*(get_u()+j)</i> is not accessed. <i>Precondition:</i> if both <i>*(get_fl()+j)</i> and <i>*(get_fu()+j)</i> have value <i>true</i> , then <i>*(get_l()+j) ≤ *(get_u()+j)</i>
<i>D_iterator</i>	<i>qp.get_d()</i>	returns an iterator over the rows of $2D$ . The corresponding past-the-end iterator is <i>get_d()+get_n()</i> . For $i = 0, \dots, n - 1$ , <i>*(get_d()+i)</i> is a random access iterator for the entries in row $i$ below or on the diagonal. The valid range of this iterator is guaranteed to have length $i + 1$ but not more. Values to the right of the diagonal are deduced from the symmetry requirement on $D$ .
<i>C_iterator</i>	<i>qp.get_c()</i>	returns an iterator over the entries of <b>c</b> . The corresponding past-the-end iterator is <i>get_c()+get_n()</i> .
<i>std::iterator_traits&lt;C_iterator&gt;::value_type</i>		
	<i>qp.get_c0()</i>	returns the constant term $c_0$ of the objective function.

# NonnegativeQuadraticProgram

## Definition

A model of NonnegativeQuadraticProgram describes a convex quadratic program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{smallmatrix} \geq \\ = \\ \leq \end{smallmatrix} \mathbf{b}, \\ & \quad \mathbf{x} \geq 0 \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{smallmatrix} \geq \\ = \\ \leq \end{smallmatrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $D$  is a symmetric positive-semidefinite  $n \times n$  matrix (the quadratic objective function),
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

The description is given by appropriate *random-access* iterators over the program data, see below. The program therefore comes in *dense* representation which includes zero entries.

## Types

<i>NonnegativeQuadraticProgram::A_iterator</i>	A random access iterator type to go columnwise over the constraint matrix $A$ . The value type is a random access iterator type for an individual column that goes over the entries in that column.
<i>NonnegativeQuadraticProgram::B_iterator</i>	A random access iterator type to go over the entries of the right-hand side $\mathbf{b}$ .
<i>NonnegativeQuadraticProgram::R_iterator</i>	A random access iterator type to go over the relations $\begin{smallmatrix} \geq \\ = \\ \leq \end{smallmatrix}$ . The value type of <i>R_iterator</i> is <i>CGAL::Comparison_result</i> .
<i>NonnegativeQuadraticProgram::D_iterator</i>	A random access iterator type to go rowwise over the matrix $2D$ . The value type is a random access iterator type for an individual row that goes over the entries in that row, up to (and including) the entry on the main diagonal.

<i>NonnegativeQuadraticProgram::C_iterator</i>	A random access iterator type to go over the entries of the linear objective function vector <i>c</i> .
--	---

## Operations

<i>int</i>	<i>qp.get_n()</i>	returns the number <i>n</i> of variables (number of columns of <i>A</i> ) in <i>qp</i> .
<i>int</i>	<i>qp.get_m()</i>	returns the number <i>m</i> of constraints (number of rows of <i>A</i> ) in <i>qp</i> .
<i>A_iterator</i>	<i>qp.get_a()</i>	returns an iterator over the columns of <i>A</i> . The corresponding past-the-end iterator is <i>get_a()+get_n()</i> . For $j = 0, \dots, n-1$ , $*(get\_a() + j)$ is a random access iterator for column <i>j</i> .
<i>B_iterator</i>	<i>qp.get_b()</i>	returns an iterator over the entries of <b>b</b> . The corresponding past-the-end iterator is <i>get_b()+get_m()</i> .
<i>R_iterator</i>	<i>qp.get_r()</i>	returns an iterator over the entries of $\geq$ . The corresponding past-the-end iterator is <i>get_r()+get_m()</i> . The value <i>CGAL::SMALLER</i> stands for $\leq$ , <i>CGAL::EQUAL</i> stands for $=$ , and <i>CGAL::LARGER</i> stands for $\geq$ .
<i>D_iterator</i>	<i>qp.get_d()</i>	returns an iterator over the rows of <i>2D</i> . The corresponding past-the-end iterator is <i>get_d()+get_n()</i> . For $i = 0, \dots, n-1$ , $*(get\_d() + i)$ is a random access iterator for the entries in row <i>i</i> below or on the diagonal. The valid range of this iterator is guaranteed to have length $i+1$ but not more. Values to the right of the diagonal are deduced from the symmetry requirement on <i>D</i> .
<i>C_iterator</i>	<i>qp.get_c()</i>	returns an iterator over the entries of <b>c</b> . The corresponding past-the-end iterator is <i>get_c()+get_n()</i> .
<i>std::iterator_traits&lt;C_iterator&gt;::value_type</i>	<i>qp.get_c0()</i>	returns the constant term $c_0$ of the objective function.

## Requirements

# LinearProgram

## Definition

A model of LinearProgram describes a linear program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad \mathbf{A}\mathbf{x} \begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $\mathbf{l}$  is an  $n$ -dimensional vector of lower bounds for  $\mathbf{x}$ , where  $l_j \in \mathbb{R} \cup \{-\infty\}$  for all  $j$
- $\mathbf{u}$  is an  $n$ -dimensional vector of upper bounds for  $\mathbf{x}$ , where  $u_j \in \mathbb{R} \cup \{\infty\}$  for all  $j$
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

The description is given by appropriate *random-access* iterators over the program data, see below. The program therefore comes in *dense* representation which includes zero entries.

## Has Models

*Linear\_program\_from\_iterators*<*A\_it*, *B\_it*, *R\_it*, *FL\_it*, *L\_it*, *FU\_it*, *U\_it*, *D\_it*, *C\_it*>

## Types

*LinearProgram::A\_iterator*

A random access iterator type to go columnwise over the constraint matrix  $A$ . The value type is a random access iterator type for an individual column that goes over the entries in that column.

*LinearProgram::B\_iterator*

A random access iterator type to go over the entries of the right-hand side  $\mathbf{b}$ .

*LinearProgram::R\_iterator*

A random access iterator type to go over the relations  $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$ . The value type of *R\_iterator* is *CGAL::Comparison\_result*.

*LinearProgram::FL\_iterator*

A random access iterator type to go over the existence (finiteness) of the lower bounds  $l_j, j = 0, \dots, n-1$ . The value type of *FL\_iterator* is *bool*.

<i>LinearProgram:: L_iterator</i>	A random access iterator type to go over the entries of the lower bound vector <b>l</b> .
<i>LinearProgram:: UL_iterator</i>	A random access iterator type to go over the existence (finiteness) of the upper bounds $u_j, j = 0, \dots, n-1$ . The value type of <i>UL_iterator</i> is <i>bool</i> .
<i>LinearProgram:: U_iterator</i>	A random access iterator type to go over the entries of the upper bound vector <b>u</b> .
<i>LinearProgram:: C_iterator</i>	A random access iterator type to go over the entries of the linear objective function vector <i>c</i> .

## Operations

<i>int</i>	<i>lp.get_n()</i>	returns the number <i>n</i> of variables (number of columns of <i>A</i> ) in <i>lp</i> .
<i>int</i>	<i>lp.get_m()</i>	returns the number <i>m</i> of constraints (number of rows of <i>A</i> ) in <i>lp</i> .
<i>A_iterator</i>	<i>lp.get_a()</i>	returns an iterator over the columns of <i>A</i> . The corresponding past-the-end iterator is <i>get_a()+get_n()</i> . For $j = 0, \dots, n-1$ , $*(get\_a()+j)$ is a random access iterator for column <i>j</i> .
<i>B_iterator</i>	<i>lp.get_b()</i>	returns an iterator over the entries of <b>b</b> . The corresponding past-the-end iterator is <i>get_b()+get_m()</i> .
<i>R_iterator</i>	<i>lp.get_r()</i>	returns an iterator over the entries of $\geq$ . The corresponding past-the-end iterator is <i>get_r()+get_m()</i> . The value <i>CGAL::SMALLER</i> stands for $\leq$ , <i>CGAL::EQUAL</i> stands for $=$ , and <i>CGAL::LARGER</i> stands for $\geq$ .
<i>FL_iterator</i>	<i>lp.get_fl()</i>	returns an iterator over the existence of the lower bounds $l_j, j = 0, \dots, n-1$ . The corresponding past-the-end iterator is <i>get_fl()+get_n()</i> . If $*(get\_fl()+j)$ has value <i>true</i> , the variable $x_j$ has a lower bound given by $*(get\_l()+j)$ , otherwise it has no lower bound.
<i>L_iterator</i>	<i>lp.get_l()</i>	returns an iterator over the entries of <b>l</b> . The corresponding past-the-end iterator is <i>get_l()+get_n()</i> . If $*(get\_fl()+j)$ has value <i>false</i> , the value $*(get\_l()+j)$ is not accessed. <i>Precondition:</i> if both $*(get\_fl()+j)$ and $*(get\_fu()+j)$ have value <i>true</i> , then $*(get\_l()+j) \leq *(get\_u()+j)$
<i>FU_iterator</i>	<i>lp.get_fu()</i>	returns an iterator over the existence of the upper bounds $u_j, j = 0, \dots, n-1$ . The corresponding past-the-end iterator is <i>get_fu()+get_n()</i> . If $*(get\_fu()+j)$ has value <i>true</i> , the variable $x_j$ has an upper bound given by $*(get\_u()+j)$ , otherwise it has no upper bound.

<i>L_iterator</i>	<i>lp.get_u()</i>	returns an iterator over the entries of <b>u</b> . The corresponding past-the-end iterator is <i>get_u()+get_n()</i> . If <i>*(get_fu()+j)</i> has value <i>false</i> , the value <i>*(get_u()+j)</i> is not accessed. <i>Precondition:</i> if both <i>*(get_fl()+j)</i> and <i>*(get_fu()+j)</i> have value <i>true</i> , then $*(get_l()+j) \leq *(get_u()+j)$
<i>C_iterator</i>	<i>lp.get_c()</i>	returns an iterator over the entries of <b>c</b> . The corresponding past-the-end iterator is <i>get_c()+get_n()</i> .
<i>std::iterator_traits&lt;C_iterator&gt;::value_type</i>	<i>lp.get_c0()</i>	returns the constant term $c_0$ of the objective function.

# NonnegativeLinearProgram

## Definition

A model of NonnegativeLinearProgram describes a linear program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad \mathbf{A} \mathbf{x} \begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \\ & \quad \mathbf{x} \geq 0 \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

The description is given by appropriate *random-access* iterators over the program data, see below. The program therefore comes in *dense* representation which includes zero entries.

## MPSFormat

MPS is a commonly used file format for storing linear and quadratic programs according to the concepts *QuadraticProgram*, *LinearProgram*, *NonnegativeQuadraticProgram*, and *NonnegativeLinearProgram*, see also [http://en.wikipedia.org/wiki/MPS\\_\(format\)](http://en.wikipedia.org/wiki/MPS_(format)).

CGAL supports a large subset of this format, but there are MPS files around that we cannot read (for example, files that encode integrality constraints on the variables). Also, there might be some other MPS-based solvers that will not be able to read the MPS files written by CGAL, since we do not strictly adhere to the very rigid layout requirements of the original MPS format.

Let's look at an example first. The quadratic program

$$\begin{array}{ll} \text{minimize} & x^2 + 4(y - 4)^2 \quad (= x^2 + 4y^2 - 32y + 64) \\ \text{subject to} & \begin{array}{ll} x + y & \leq 7 \\ -x + 2y & \leq 4 \\ x & \geq 0 \\ y & \geq 0 \\ y & \leq 4 \end{array} \end{array}$$

has the following description in MPS format.

```
NAME first_qp
ROWS
  N obj
  L c0
  L c1
COLUMNS
  x0 c0 1
  x0 c1 -1
  x1 obj -32
  x1 c0 1
  x1 c1 2
RHS
  rhs obj -64
  rhs c0 7
  rhs c1 4
BOUNDS
  UP BND x1 4
QMATRIX
  x0 x0 2
  x1 x1 8
ENDATA
```

Here comes a semiformal description of the format in general.

## NAME section

This (mandatory) section consists of a single line starting with `NAME`. Everything starting from the first non-whitespace after that until the end of the line constitutes the name of the problem.

## ROWS section

In the (mandatory) `ROW` section, you find one line for every constraint, where the letter `L` indicates relation  $\leq$ , letter `G` stands for  $\geq$ , and `E` for  $=$ . In addition, there is a row for the linear objective function (indicated by letter `N`). In that section, names are assigned to the constraints (here: `c0`, `c1`) and the objective function (here: `obj`). An MPS file may encode several linear objective functions by using several rows starting with `N`, but we ignore all but the first.

## COLUMNS section

The (mandatory) `COLUMNS` section encodes the constraint matrix  $A$  and the linear objective function vector  $c$ . Every line consists of one or two sequences of three tokens *jival*, where  $j$  is the name of a variable (here, we have variables `x0`, `x1`),  $i$  is the name of a constraint or the objective function, and  $val$  is the value  $A_{ij}$  (if  $i$  names a constraint), or  $c_j$  (if  $i$  names the linear objective function). Values for pairs  $(i, j)$  that are not specified in this section default to 0. Otherwise, for every pair  $(i, j)$ , the *last* specified value determines  $A_{ij}$  or  $c_j$ .

## RHS section

This (mandatory) section encodes the right-hand side vector  $b$  and the constant term  $c_0$  in the objective function. The first token in every line is an identifier (here: `rhs`). An MPS file may encode several right-hand sides  $b$  by using several such identifiers, but we ignore all lines having an identifier different from that of the first line.

The right-hand side identifier is succeeded by one or two sequences of tokens *ival*, where  $i$  names a constraint or the linear objective function, and  $val$  specifies the value  $b_i$  (if  $i$  names a constraint), or  $-c_0$  (if  $i$  names the linear objective function). Values that are not specified in this section default to 0. Otherwise, for every  $i$ , the *last* specified value determines  $b_i$  or  $-c_0$ .

## BOUNDS section

This (optional) section encodes the lower and upper bound vectors  $l$  and  $u$  for the variables. The default bounds for any variable  $x_j$  are  $0 \leq x_j \leq \infty$ ; the `BOUNDS` section is used to override these defaults. In particular, if there is no `BOUNDS` section, the program is nonnegative and actually a model of the concept *NonnegativeQuadraticProgram* or *NonnegativeLinearProgram*.

The first token in every line is succeeded by an (optional) identifier (here: `BND`). An MPS file may encode several bound vectors  $l$  and  $u$  by using several such identifiers, but we ignore all lines having an identifier different from that of the first line. The first token  $t$  itself determines the type of the bound, and the token  $j$  after the bound identifier names the variable to which the bound applies. In case of bound types `FX`, `LO`, and `UP`, there is another

token *val* that specifies the bound value. Here is how bound type and value determine a bound for variable  $x_j$ . There may be several bound specifications for a single variable, and they are processed in order of appearance.

bound type	resulting bound
FX	$x_j = val$ ( $x_j$ becomes a fixed variable)
LO	$x_j \geq val$ (upper bound remains unchanged)
UP	$x_j \leq val$ (lower bound remains unchanged, except if $val < 0$ ; then, a zero lower bound is reset to $-\infty$ )
FR	$-\infty \leq x_j \leq \infty$ (previous bounds are discarded)
MI	$x_j \geq -\infty$ (upper bound remains unchanged)
PL	$x_j \leq \infty$ (lower bound remains unchanged)

## QMATRIX / QUADOBJ / DMATRIX section

This (optional) section encodes the quadratic objective function matrix  $D$ . Every line is a sequence *ijval* of three tokens, where both *i* and *j* name variables, and *val* is the value  $2D_{i,j}$  (in case of QMATRIX or QUADOBJ), or  $D_{ij}$  (in case of DMATRIX).

In case of QMATRIX and DMATRIX, *all* nonzero entries must be specified: if there is a line *ijval*, then there must also be a line *jival*, since  $D$  is required to be symmetric. In case of QUADOBJ, only the entries of  $2D$  on or below the diagonal must be specified, entries above the diagonal are deduced from symmetry. It is not allowed to specify two or more *different* nonzero values for an unordered pair  $\{i, j\}$ .

If this section is missing or does not contain nonzero values, the program is a model of the concept *LinearProgram*.

## Miscellaneous

Our MPS format also supports an (optional) RANGES section, but we don't explain this here.

### See Also

*Quadratic\_program\_from\_mps*<NT>

## CGAL::Quadratic\_program\_solution<ET>

#include <CGAL/QP\_solution.h>

### Definition

An object of class *Quadratic\_program\_solution*<ET> represents the solution of a linear or convex quadratic program of the general form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ .

If  $D = 0$ , the program is a linear program; if the variable bounds are  $\mathbf{x} \geq 0$ , we have a nonnegative program. Objects of type *Quadratic\_program\_solution*<ET> are returned by any of the four functions *solve\_quadratic\_program*, *solve\_linear\_program*, *solve\_nonnegative\_quadratic\_program*, and *solve\_nonnegative\_linear\_program*.

### Example

*QP\_solver/first\_qp.cpp*

### Terminology

If there is no  $\mathbf{x}$  that satisfies all the (in)equalities, the program is called *infeasible*, otherwise, it is *feasible*, and any  $\mathbf{x}$  that satisfies all (in)equalities is called a *feasible solution*.

If the objective function value becomes arbitrarily small over the *feasible region* (the set of feasible solutions), the program is called *unbounded*, and *bounded* otherwise.

Any program that is both feasible and bounded has at least one feasible solution  $\mathbf{x}^*$  whose objective function value is not larger than that of any other feasible solution. This is called an *optimal solution*.

Every convex quadratic program (even if it is infeasible or unbounded) has a 'solution' in form of an object of the class *Quadratic\_program\_solution*<ET>.

### Types

*Quadratic\_program\_solution*<ET>:: *ET*                      The exact number type that was used to solve the program.

*Quadratic\_program\_solution*<ET>:: *Variable\_value\_iterator*

An iterator type with value type *Quotient*<ET> to go over the values of the variables in the solution.

*Quadratic\_program\_solution<ET>:: Variable\_numerator\_iterator*

An iterator type with value type *ET* to go over the numerators of the variable values with respect to a common denominator.

*Quadratic\_program\_solution<ET>:: Index\_iterator*

An iterator type with value type *int* to go over the indices of the basic variables and the basic constraints.

*Quadratic\_program\_solution<ET>:: Optimality\_certificate\_iterator*

An iterator type with value type *Quotient<ET>* to go over an *m*-vector  $\lambda$  that proves optimality of the solution.

*Quadratic\_program\_solution<ET>:: Optimality\_certificate\_numerator\_iterator*

An iterator type with value type *ET* to go over the numerators of the vector  $\lambda$  with respect to a common denominator.

*Quadratic\_program\_solution<ET>:: Infeasibility\_certificate\_iterator*

An iterator type with value type *ET* to go over an *m*-vector  $\lambda$  that proves infeasibility of the solution.

*Quadratic\_program\_solution<ET>:: Unboundedness\_certificate\_iterator*

An iterator type with value type *ET* to go over an *n*-vector  $\mathbf{w}$  that proves unboundedness of the solution.

## Creation

*Quadratic\_program\_solution<ET> sol;* constructs a void instance of *Quadratic\_program\_solution<ET>* that is associated to no program.

Objects of type *Quadratic\_program\_solution<ET>* can be copied and assigned.

Objects of type *Quadratic\_program\_solution<ET>* that are associated to an actual program are returned by any of the four functions *solve\_quadratic\_program*, *solve\_linear\_program*, *solve\_nonnegative\_quadratic\_program*, and *solve\_nonnegative\_linear\_program*.

## Example

*QP\_solver/first\_qp.cpp*

## Operations

<i>bool</i>	<i>sol.is_void()</i>	returns <i>true</i> iff <i>sol</i> is not associated to a program. The condition <i>!sol.is_void()</i> is a precondition for all access methods below.
-------------	----------------------	--

## Solution status

Here are the access methods for the status of the solution.

<i>bool</i>	<i>sol.is_optimal()</i>	returns <i>true</i> iff <i>sol</i> is an optimal solution of the associated program.
-------------	-------------------------	--

<i>bool</i>	<i>sol.is_infeasible()</i>	returns <i>true</i> iff the associated program is infeasible.
-------------	----------------------------	---

<i>bool</i>	<i>sol.is_unbounded()</i>	returns <i>true</i> iff the associated program is unbounded.
-------------	---------------------------	--

## Quadratic\_program\_status

	<i>sol.status()</i>	returns the status of the solution; this is one of the values <i>QP_OPTIMAL</i> , <i>QP_INFEASIBLE</i> , and <i>QP_UNBOUNDED</i> , depending on whether the program asociated to <i>sol</i> has an optimal solution, is infeasible, or is unbounded.
--	---------------------	--

<i>int</i>	<i>sol.number_of_iterations()</i>	returns the number of iterations that it took to solve the program asociated to <i>sol</i> .
------------	-----------------------------------	--

## Solution values

The actual solution (variable and objective function values) can be accessed as follows.

<i>Quotient&lt;ET&gt;</i>	<i>sol.objective_value()</i>	returns the objective function value of <i>sol</i> .
---------------------------	------------------------------	--

<i>ET</i>	<i>sol.objective_value_numerator()</i>	returns the numerator of the objective function value of <i>sol</i> .
-----------	--	---

<i>ET</i>	<i>sol.objective_value_denominator()</i>	returns the denominator of the objective function value of <i>sol</i> .
-----------	--	---

## Variable\_value\_iterator

	<i>sol.variable_values_begin()</i>	returns a random-access iterator over the values of the variables in <i>sol</i> . The value type is <i>Quotient&lt;ET&gt;</i> , and the valid iterator range has length <i>n</i> .
--	------------------------------------	--

*Variable\_value\_iterator*

*sol.variable\_values\_end()*

returns the corresponding past-the-end iterator.

*Variable\_numerator\_iterator*

*sol.variable\_numerators\_begin()*

returns a random-access iterator *it* over the values of the variables in *sol*, with respect to a common denominator of all variables. The value type is *ET*, and the valid iterator range has length *n*.

*Variable\_numerator\_iterator*

*sol.variable\_numerators\_end()*

returns the corresponding past-the-end iterator.

*ET*

*sol.variables\_common\_denominator()*

returns the common denominator of the variable values as referred to by the previous two methods.

### Basic variables and constraints

The solution of a linear or quadratic program distinguishes 'important' variables (the ones not attaining one of their bounds), and 'important' constraints (the ones being satisfied with equality). The following methods grant access to them.

*Index\_iterator*

*sol.basic\_variable\_indices\_begin()*

returns a random access iterator over the indices of the basic variables. The value type is *int*. It is guaranteed that any variable that is not basic in *sol* attains one of its bounds. In particular, if the bounds are of type  $x \geq 0$ , all non-basic variables have value 0.

*Index\_iterator*

*sol.basic\_variable\_indices\_end()*

returns the corresponding past-the-end iterator.

*int*

*sol.number\_of\_basic\_variables()*

returns the number of basic variables, equivalently the length of the range determined by the previous two iterators.

## Example

*QP\_solver/important\_variables.cpp*

*Index\_iterator*            *sol.basic\_constraint\_indices\_begin()*

returns a random access iterator over the indices of the basic constraints in the system  $A\mathbf{x} \geq \mathbf{b}$ . The value type is *int*. It is guaranteed that any basic constraint is satisfied with equality. In particular, if the system is of type  $A\mathbf{x} = \mathbf{b}$ , all constraints are basic.

*Index\_iterator*            *sol.basic\_constraint\_indices\_end()*

returns the corresponding past-the-end iterator.

*int*                        *sol.number\_of\_basic\_constraints()*

returns the number of basic constraint, equivalently the length of the range determined by the previous two iterators.

## Example

*QP\_solver/first\_qp\_basic\_constraints.cpp*

## Output

```
template <typename ET>
std::ostream&            std::ostream& out << sol
```

writes the status of *sol* to the stream *out*. In case the status is *QP.OPTIMAL*, the optimal objective value and the values of the variables at the optimal solution are output as well. For more detailed information about the solution (like basic variables/constraints) please use the dedicated methods of *Quadratic\_program\_solution<ET>*.

## Validity

The following four methods allow you to check whether *sol* indeed solves the program that you intended to solve. The methods use the certificates described in the advanced section below and thus save you from validating the certificates yourself (if you believe in the correctness of these methods; otherwise, you can look at their implementation to convince yourself).

By passing a suitable option to the solution function, you can make sure that this check is done automatically after the solution of the program, see *Quadratic\_program\_options*. If the check fails, a logfile is generated that contains the details, and an error message is written to *std::cerr* (see *QP\_solver/cycling.cpp* for an example that uses this option).

```
template <class QuadraticProgram>
```

<i>bool</i>	<i>sol.solves_quadratic_program( QuadraticProgram qp)</i>	returns <i>true</i> iff <i>sol</i> solves the quadratic program <i>qp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .
-------------	---	---

*QP\_solver/first\_qp.cpp*

<i>template &lt;class LinearProgram&gt;</i>		
<i>bool</i>	<i>sol.solves_linear_program( LinearProgram lp)</i>	returns <i>true</i> iff <i>sol</i> solves the linear program <i>lp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .

*QP\_solver/first\_lp.cpp*

<i>template &lt;class NonnegativeQuadraticProgram&gt;</i>		
<i>bool</i>	<i>sol.solves_nonnegative_quadratic_program( NonnegativeQuadraticProgram qp)</i>	returns <i>true</i> iff <i>sol</i> solves the nonnegative quadratic program <i>qp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .

*QP\_solver/first\_nonnegative\_qp.cpp*

<i>template &lt;class NonnegativeLinearProgram&gt;</i>		
<i>bool</i>	<i>sol.solves_nonnegative_linear_program( NonnegativeLinearProgram lp)</i>	returns <i>true</i> iff <i>sol</i> solves the nonnegative linear program <i>lp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .

*QP\_solver/first\_nonnegative\_lp.cpp*

<i>bool</i>	<i>sol.is_valid()</i>	returns <i>false</i> iff the validation through one of the previous four functions has failed.
-------------	-----------------------	--

<i>std::string</i>	<i>sol.get_error()</i>	returns an error message in case any of the previous four validation functions has returned <i>false</i> .
--------------------	------------------------	--

————— advanced —————

## Certificates

A certificate is a vector that admits a simple proof for the correctness of the solution. Any non-void object of *Quadratic\_program\_solution<ET>* comes with such a certificate.

**Lemma 1 (optimality certificate):** A feasible  $n$ -vector  $\mathbf{x}^*$  is an optimal solution of (QP) if an  $m$ -vector  $\lambda$  with the following properties exist.

1. if the  $i$ -th constraint is of type  $\leq$  ( $\geq$ , respectively), then  $\lambda_i \geq 0$  ( $\lambda_i \leq 0$ , respectively).
2.  $\lambda^T (A\mathbf{x}^* - \mathbf{b}) = 0$ .
- 3.

$$(\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)_j \begin{cases} \geq 0, & \text{if } x_j^* = l_j < u_j \\ = 0, & \text{if } l_j < x_j^* < u_j \\ \leq 0, & \text{if } l_j < u_j = x_j^*. \end{cases}$$

**Proof:** Let  $\mathbf{x}$  be any feasible solution. We need to prove that

$$\mathbf{c}^T \mathbf{x} + \mathbf{x}^T D \mathbf{x} \geq \mathbf{c}^T \mathbf{x}^* + \mathbf{x}^{*T} D \mathbf{x}^*.$$

For this, we argue as follows.

$$\begin{aligned} \mathbf{c}^T \mathbf{x} + 2\mathbf{x}^{*T} D \mathbf{x} &\geq \mathbf{c}^T \mathbf{x} + 2\mathbf{x}^{*T} D \mathbf{x} + \lambda^T (A\mathbf{x} - \mathbf{b}) && \text{(by } A\mathbf{x} \preceq \mathbf{b} \text{ and 1.)} \\ &= (\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)\mathbf{x} - \lambda^T \mathbf{b} \\ &\geq (\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)\mathbf{x}^* - \lambda^T \mathbf{b} && \text{(by } \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \text{ and 3.)} \\ &= \mathbf{c}^T \mathbf{x}^* + 2\mathbf{x}^{*T} D \mathbf{x}^* && \text{(by 2.)} \end{aligned}$$

After adding  $\mathbf{x}^T D \mathbf{x} - \mathbf{x}^T D \mathbf{x} - \mathbf{x}^{*T} D \mathbf{x}^* = -\mathbf{x}^{*T} D \mathbf{x}^*$  to both sides of this inequality, we get

$$\mathbf{c}^T \mathbf{x} + \mathbf{x}^T D \mathbf{x} - (\mathbf{x} - \mathbf{x}^*)^T D (\mathbf{x} - \mathbf{x}^*) \geq \mathbf{c}^T \mathbf{x}^* + \mathbf{x}^{*T} D \mathbf{x}^*,$$

and since  $D$  is positive semidefinite, we have  $(\mathbf{x} - \mathbf{x}^*)^T D (\mathbf{x} - \mathbf{x}^*) \geq 0$  and the lemma follows.

*Optimality\_certificate\_iterator*

*sol.optimality\_certificate\_begin()*

returns a random access iterator over the optimality certificate  $\lambda$  as given in Lemma 1, with respect to the solution  $\mathbf{x}^*$  obtained from *sol.variable\_values\_begin()*. The value type is *Quotient<ET>*, and the valid iterator range has length  $m$ .  
Precondition: *sol.is\_optimal()*

*Optimality\_certificate\_iterator*

*sol.optimality\_certificate\_end()*

returns the corresponding past-the-end iterator.

*Optimality\_certificate\_numerator\_iterator*

*sol.optimality\_certificate\_numerators\_begin()*

returns a random access iterator over the numerator values of the optimality certificate  $\lambda$ , with respect to the common denominator returned by *sol.variables\_common\_denominator()*. The value type is *ET*, and the valid iterator range has length  $m$ .

*Optimality\_certificate\_numerator\_iterator*

*sol.optimality\_certificate\_numerators\_end()*

returns the corresponding past-the-end iterator.

### Example

*QP\_solver/optimality\_certificate.cpp*

**Lemma 2 (infeasibility certificate):** The program (QP) is infeasible if an  $m$ -vector  $\lambda$  with the following properties exist.

1. if the  $i$ -th constraint is of type  $\leq$  ( $\geq$ , respectively), then  $\lambda_i \geq 0$  ( $\lambda_i \leq 0$ , respectively).
- 2.

$$\lambda^T A_j \begin{array}{ll} \geq 0 & \text{if } u_j = \infty \\ \leq 0 & \text{if } l_j = -\infty. \end{array}$$

- 3.

$$\lambda^T \mathbf{b} < \sum_{j: \lambda^T A_j < 0} \lambda^T A_j u_j + \sum_{j: \lambda^T A_j > 0} \lambda^T A_j l_j.$$

**Proof:** Let us assume for the purpose of obtaining a contradiction that there is a feasible solution  $\mathbf{x}$ . Then we get

$$\begin{aligned} 0 &\geq \lambda^T (\mathbf{A}\mathbf{x} - \mathbf{b}) && \text{(by } \mathbf{A}\mathbf{x} \geq \mathbf{b} \text{ and 1.)} \\ &= \sum_{j: \lambda^T A_j < 0} \lambda^T A_j x_j + \sum_{j: \lambda^T A_j > 0} \lambda^T A_j x_j - \lambda^T \mathbf{b} \\ &\geq \sum_{j: \lambda^T A_j < 0} \lambda^T A_j u_j + \sum_{j: \lambda^T A_j > 0} \lambda^T A_j l_j - \lambda^T \mathbf{b} && \text{(by } \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \text{ and 2.)} \\ &> 0 && \text{(by 3.),} \end{aligned}$$

and this is the desired contradiction  $0 > 0$ .

*Infeasibility\_certificate\_iterator*

*sol.infeasibility\_certificate\_begin()*

returns a random access iterator over the infeasibility certificate  $\lambda$  as given in Lemma 2. The value type is *ET*, and the valid iterator range has length  $m$ .

*Precondition:* *sol.is\_infeasible()*

*Infeasibility\_certificate\_iterator*

*sol.infeasibility\_certificate\_end()*

returns the corresponding past-the-end iterator.

## Example

*QP\_solver/infeasibility\_certificate.cpp*

**Lemma 3 (unboundedness certificate:)** Let  $\mathbf{x}^*$  be a feasible solution of (QP). The program (QP) is unbounded if an  $n$ -vector  $\mathbf{w}$  with the following properties exist.

1. if the  $i$ -th constraint is of type  $\leq (\geq, =, \text{ respectively})$ , then  $(A\mathbf{w})_i \leq 0 ((A\mathbf{w})_i \geq 0, (A\mathbf{w})_i = 0, \text{ respectively})$ .
- 2.

$$w_j \begin{array}{ll} \geq 0 & \text{if } l_j \text{ is finite} \\ \leq 0 & \text{if } u_j \text{ is finite.} \end{array}$$

3.  $\mathbf{w}^T D\mathbf{w} = 0$  and  $(\mathbf{c}^T + 2\mathbf{x}^{*T} D)\mathbf{w} < 0$ .

The vector  $\mathbf{w}$  is called an *unbounded direction*.

**Proof:** For a real number  $t$ , consider the vector  $\mathbf{x}(t) := \mathbf{x}^* + t\mathbf{w}$ . By 1. and 2.,  $\mathbf{x}(t)$  is feasible for all  $t \geq 0$ . The objective function value of  $\mathbf{x}(t)$  is

$$\begin{aligned} \mathbf{c}^T \mathbf{x}(t) + \mathbf{x}(t)^T D\mathbf{x}(t) &= \mathbf{c}^T \mathbf{x}^* + t\mathbf{c}^T \mathbf{w} + \mathbf{x}^{*T} D\mathbf{x}^* + 2t\mathbf{x}^{*T} D\mathbf{w} + t^2 \mathbf{w}^T D\mathbf{w} \\ &= \mathbf{c}^T \mathbf{x}^* + \mathbf{x}^{*T} D\mathbf{x}^* + t(\mathbf{c}^T + 2\mathbf{x}^{*T} D)\mathbf{w} + t^2 \mathbf{w}^T D\mathbf{w}. \end{aligned}$$

By condition 3., this tends to  $-\infty$  for  $t \rightarrow \infty$ , so the problem is indeed unbounded.

*Unboundedness\_certificate\_iterator*

*sol.unboundedness\_certificate\_begin()*

returns a random access iterator over the unbounded direction  $\mathbf{w}$  as given in Lemma 3, with respect to the solution  $\mathbf{x}^*$  obtained from *sol.variable\_values\_begin()*. The value type is *ET*, and the valid iterator range has length  $n$ .  
*Precondition: sol.is\_unbounded()*

*Unboundedness\_certificate\_iterator*

*sol.unboundedness\_certificate\_end()*

returns the corresponding past-the-end iterator.

## CGAL::Quadratic\_program\_status

*#include* <CGAL/QP\_solution.h>

### Definition

This is an enumeration type containing the values *QP\_OPTIMAL*, *QP\_INFEASIBLE*, and *QP\_UNBOUNDED*. It indicates the status of a linear or quadratic program solution as represented by an object of type *Quadratic\_program\_solution*<ET>.

### See Also

*Quadratic\_program\_solution*<ET>

## CGAL::Quadratic\_program<NT>

#include <CGAL/QP\_models.h>

### Definition

An object of class *Quadratic\_program*<NT> describes a convex quadratic program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{matrix} \geq \\ \leq \end{matrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $\mathbf{l}$  is an  $n$ -dimensional vector of lower bounds for  $\mathbf{x}$ , where  $l_j \in \mathbb{R} \cup \{-\infty\}$  for all  $j$
- $\mathbf{u}$  is an  $n$ -dimensional vector of upper bounds for  $\mathbf{x}$ , where  $u_j \in \mathbb{R} \cup \{\infty\}$  for all  $j$
- $D$  is a symmetric positive-semidefinite  $n \times n$  matrix (the quadratic objective function),
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

If  $D = 0$ , the program is a linear program; if the variable bounds are  $x \geq 0$ , we have a nonnegative program.

This class allows you to build your program entry by entry, using the set-methods below.

If you only need to wrap existing (random-access) iterators over your own data, then you may use any of the four models *Quadratic\_program\_from\_iterators*<A\_it, B\_it, R\_it, FL\_it, L\_it, FU\_it, U\_it, D\_it, C\_it>, *Linear\_program\_from\_iterators*<A\_it, B\_it, R\_it, FL\_it, L\_it, FU\_it, U\_it, C\_it>, *Nonnegative\_quadratic\_program\_from\_iterators*<A\_it, B\_it, R\_it, D\_it, C\_it>, and *Nonnegative\_linear\_program\_from\_iterators*<A\_it, B\_it, R\_it, C\_it>.

If you want to read a quadratic program in *MPSFormat* from a stream, please use the model *Quadratic\_program\_from\_mps*<NT>.

### Is Model for the Concepts

*QuadraticProgram*

*LinearProgram*

*NonnegativeQuadraticProgram*

*NonnegativeLinearProgram*

### Types

*Quadratic\_program*<NT>:: NT

The number type of the program entries.

## Creation

*Quadratic\_program*<NT> *qp*( *CGAL::Comparison\_result* *default\_r* = *CGAL::EQUAL*,  
                                   *bool* *default\_fl* = *true*,  
                                   NT *default\_l* = 0,  
                                   *bool* *default\_fu* = *false*,  
                                   NT *default\_u* = 0)

constructs a quadratic program with no variables and no constraints, ready for data to be added. Unless relations are explicitly set, they will be of type *default\_r*. Unless bounds are explicitly set, they will be as specified by *default\_fl* (finite lower bound?), *default\_l* (lower bound value if lower bound is finite), *default\_fu* (finite upper bound?), and *default\_u* (upper bound value if upper bound is finite). If all parameters take their default values, we thus get equality constraints and bounds  $x \geq 0$  by default. Numerical entries that are not explicitly set will default to 0.

*Precondition:* if *default\_fl* = *default\_fu* = *true*, then  $\text{default\_l} \leq \text{default\_u}$

## Operations

<i>bool</i>	<i>qp.is_linear()</i>	returns <i>true</i> if and only if <i>qp</i> is a linear program.
<i>bool</i>	<i>qp.is_nonnegative()</i>	returns <i>true</i> if and only if <i>qp</i> is a nonnegative program.
<i>void</i>	<i>qp.set_a</i> ( <i>int j</i> , <i>int i</i> , NT <i>val</i> )	sets the entry $A_{ij}$ in column <i>j</i> and row <i>i</i> of the constraint matrix <i>A</i> of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_b</i> ( <i>int i</i> , NT <i>val</i> )	sets the entry $b_i$ of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_r</i> ( <i>int i</i> , <i>CGAL::Comparison_result</i> <i>rel</i> )	sets the entry $\geq_i$ of <i>qp</i> to <i>rel</i> . <i>CGAL::SMALLER</i> means that the <i>i</i> -th constraint is of type “ $\leq$ ”, <i>CGAL::EQUAL</i> means “ $=$ ”, and <i>CGAL::LARGER</i> encodes “ $\geq$ ”. An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_l</i> ( <i>int j</i> , <i>bool is_finite</i> , NT <i>val</i> = NT(0) )	if <i>is_finite</i> , this sets the entry $l_j$ of <i>qp</i> to <i>val</i> , otherwise it sets $l_j$ to $-\infty$ . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.

<i>void</i>	<i>qp.set_u( int j, bool is_finite, NT val = NT(0))</i>	if <i>is_finite</i> , this sets the entry $u_j$ of <i>qp</i> to <i>val</i> , otherwise it sets $u_j$ to $\infty$ . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c( int j, NT val)</i>	sets the entry $c_j$ of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c0( NT val)</i>	sets the entry $c_0$ of <i>qp</i> to <i>val</i> . An existing entry is overwritten.
<i>void</i>	<i>qp.set_d( int i, int j, NT val)</i>	sets the entries $2D_{ij}$ and $2D_{ji}$ of <i>qp</i> to <i>val</i> . Existing entries are overwritten. <i>qp</i> is enlarged if necessary to accomodate these entries. <i>Precondition:</i> $j \leq i$

## CGAL::Quadratic\_program\_from\_mps<NT>

#include <CGAL/QP\_models.h>

### Definition

An object of class *Quadratic\_program\_from\_mps<NT>* describes a convex quadratic program of the general form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{matrix} \geq \\ \leq \end{matrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $\mathbf{l}$  is an  $n$ -dimensional vector of lower bounds for  $\mathbf{x}$ , where  $l_j \in \mathbb{R} \cup \{-\infty\}$  for all  $j$
- $\mathbf{u}$  is an  $n$ -dimensional vector of upper bounds for  $\mathbf{x}$ , where  $u_j \in \mathbb{R} \cup \{\infty\}$  for all  $j$
- $D$  is a symmetric positive-semidefinite  $n \times n$  matrix (the quadratic objective function),
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

If  $D = 0$ , the program is a linear program; if the variable bounds are  $x \geq 0$ , we have a nonnegative program.

The program data are read from an input stream in *MPSFormat*. This is a commonly used format for encoding linear and quadratic programs that is understood by many solvers. All values are expected to be readable into type *NT*. The constructed program can be further manipulated by using the set-methods below.

### Is Model for the Concepts

*QuadraticProgram*

*LinearProgram*

*NonnegativeQuadraticProgram*

*NonnegativeLinearProgram*

### Types

*Quadratic\_program\_from\_mps<NT>::NT*

The number type of the program entries.

## Creation

*Quadratic\_program\_from\_mps*<NT> *qp*( *std::istream& in*);

reads *qp* from the input stream *in*.

## Operations

*bool*                      *qp.is\_valid()*                      returns *true* if and only if an MPS-encoded quadratic program could be extracted from the input stream.

*std::string*              *qp.get\_error()*                      if *!qp.is\_valid()*, this method returns an error message explaining why the input does not conform to the *MPSFormat*.

*std::string*              *qp.variable\_name\_by\_index*( *int j*)

returns the name of the *j*-th variable.  
*Precondition:* *j* must not refer to a variable that has been added later, using one of the set methods below.

*int*                      *qp.variable\_index\_by\_name*( *std::string name*)

returns the index of the variable with name *name*. If there is no variable with this name, the result is  $-1$ .

*std::string*              *qp.constraint\_name\_by\_index*( *int i*)

returns the name of the *i*-th constraint.  
*Precondition:* *i* must not refer to a constraint that has been added later, using one of the set methods below.

*int*                      *qp.constraint\_index\_by\_name*( *std::string name*)

returns the index of the constraint with name *name*. If there is no constraint with this name, the result is  $-1$ .

*bool*                      *qp.is\_linear()*                      returns *true* if and only if *qp* is a linear program.

*bool*                      *qp.is\_nonnegative()*                      returns *true* if and only if *qp* is a nonnegative program.

*void*                      *qp.set\_a*( *int j*, *int i*, *NT val*)

sets the entry  $A_{ij}$  in column *j* and row *i* of the constraint matrix *A* of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

<i>void</i>	<i>qp.set_b( int i, NT val)</i>	sets the entry $b_i$ of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_r( int i, CGAL::Comparison_result rel)</i>	sets the entry $\geq_i$ of <i>qp</i> to <i>rel</i> . <i>CGAL::SMALLER</i> means that the <i>i</i> -th constraint is of type “ $\leq$ ”, <i>CGAL::EQUAL</i> means “ $=$ ”, and <i>CGAL::LARGER</i> encodes “ $\geq$ ”. An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_l( int j, bool is_finite, NT val = NT(0))</i>	if <i>is_finite</i> , this sets the entry $l_j$ of <i>qp</i> to <i>val</i> , otherwise it sets $l_j$ to $-\infty$ . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_u( int j, bool is_finite, NT val = NT(0))</i>	if <i>is_finite</i> , this sets the entry $u_j$ of <i>qp</i> to <i>val</i> , otherwise it sets $u_j$ to $\infty$ . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c( int j, NT val)</i>	sets the entry $c_j$ of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c0( NT val)</i>	sets the entry $c_0$ of <i>qp</i> to <i>val</i> . An existing entry is overwritten.
<i>void</i>	<i>qp.set_d( int i, int j, NT val)</i>	sets the entries $2D_{ij}$ and $2D_{ji}$ of <i>qp</i> to <i>val</i> . Existing entries are overwritten. <i>qp</i> is enlarged if necessary to accomodate these entries. <i>Precondition:</i> $j \leq i$

#include <CGAL/QP_models.h>
```

### Definition

An object of class *Quadratic\_program\_from\_iterators*<A\_it, B\_it, R\_it, FL\_it, L\_it, FU\_it, U\_it, D\_it, C\_it> describes a convex quadratic program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in  $n$  real variables  $\mathbf{x} = (x_0, \dots, x_{n-1})$ . Here,

- $A$  is an  $m \times n$  matrix (the constraint matrix),
- $\mathbf{b}$  is an  $m$ -dimensional vector (the right-hand side),
- $\begin{matrix} \geq \\ \leq \end{matrix}$  is an  $m$ -dimensional vector of relations from  $\{\leq, =, \geq\}$ ,
- $\mathbf{l}$  is an  $n$ -dimensional vector of lower bounds for  $\mathbf{x}$ , where  $l_j \in \mathbb{R} \cup \{-\infty\}$  for all  $j$
- $\mathbf{u}$  is an  $n$ -dimensional vector of upper bounds for  $\mathbf{x}$ , where  $u_j \in \mathbb{R} \cup \{\infty\}$  for all  $j$
- $D$  is a symmetric positive-semidefinite  $n \times n$  matrix (the quadratic objective function),
- $\mathbf{c}$  is an  $n$ -dimensional vector (the linear objective function), and
- $c_0$  is a constant.

This class is simply a wrapper for existing iterators, and it does not copy the program data.

It frequently happens that all values in one of the vectors from above are the same, for example if the system  $Ax \begin{matrix} \geq \\ \leq \end{matrix} b$  is actually a system of equations  $Ax = b$ . To get an iterator over such a vector, it is not necessary to store multiple copies of the value in some container; an instance of the class *Const\_oneseq\_iterator*<T>, constructed from the value in question, does the job more efficiently.

### Is Model for the Concepts

*QuadraticProgram*

### Creation

```

Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it> qp( int n,
                                                                    int m,
                                                                    A_it a,
                                                                    B_it b,
                                                                    R_it r,
                                                                    FL_it fl,
                                                                    L_it l,
                                                                    FU_it fu,
                                                                    U_it u,
                                                                    D_it d,
                                                                    C_it c,
                                                                    std::iterator_
traits<C_it>value_type c0 = 0)

```

constructs *qp* from given random-access iterators and the constant *c0*. The passed iterators are merely stored, no copying of the program data takes place. How these iterators are supposed to encode the quadratic program is described in *QuadraticProgram*.

### Example

*QP\_solver/first\_qp\_from\_iterators.cpp*

The following example for the simpler model *Nonnegative\_linear\_program\_from\_iterators<A\_it, B\_it, R\_it, C\_it>* should give you a flavor of the use of this model in practice.

```

## CGAL::make\_nonnegative\_quadratic\_program\_from\_iterators

```
#include <CGAL/QP_models.h>
```

This template function creates an instance of *Nonnegative\_quadratic\_program\_from\_iterators*<*A\_it*, *B\_it*, *R\_it*, *D\_it*, *C\_it*> from given iterators. This function can be useful if the types of these iterators are too complicated (or of too little interest for you) to write them down explicitly.

```
template < A_it, B_it, R_it, D_it, C_it >
```

```
Nonnegative_quadratic_program_from_iterators <A_it, B_it, R_it, D_it, C_it>
```

```
    make_nonnegative_quadratic_program_from_iterators( int n,
                                                         int m,
                                                         A_it a,
                                                         B_it b,
                                                         R_it r,
                                                         D_it d,
                                                         C_it c,
                                                         std::iterator_traits<C_it>
```

```
::value_type c0 = std::iterator_traits<C_it>::value_type(0))
```

returns an instance of *Nonnegative\_quadratic\_program\_from\_iterators*<*A\_it*, *B\_it*, *R\_it*, *D\_it*, *C\_it*>, constructed from the given iterators.

### Example

The following example demonstrates the typical usage of makers with the simpler function *make\_nonnegative\_linear\_program\_from\_iterators*.

```
QP_solver/solve_convex_hull_containment_lp2.h
QP_solver/convex_hull_containment2.cpp
```

### See Also

```
Nonnegative_quadratic_program_from_iterators<A_it, B_it, R_it, D_it, C_it>
```

## CGAL::make\_nonnegative\_linear\_program\_from\_iterators

```
#include <CGAL/QP_models.h>
```

This template function creates an instance of *Nonnegative\_linear\_program\_from\_iterators*<*A\_it*, *B\_it*, *R\_it*, *C\_it*> from given iterators. This function can be useful if the types of these iterators are too complicated (or of too little interest for you) to write them down explicitly.

```
template < A_it, B_it, R_it, C_it >
```

```
Nonnegative_linear_program_from_iterators <A_it, B_it, R_it, C_it>
```

```
    make_nonnegative_linear_program_from_iterators( int n,
                                                    int m,
                                                    A_it a,
                                                    B_it b,
                                                    R_it r,
                                                    C_it c,
                                                    std::iterator_traits<C_it>::value_
```

```
type c0 = std::iterator_traits<C_it>::value_type(0))
```

returns an instance of *Nonnegative\_linear\_program\_from\_iterators*<*A\_it*, *B\_it*, *R\_it*, *C\_it*>, constructed from the given iterators.

### Example

```
QP_solver/solve_convex_hull_containment_lp2.h
```

```
QP_solver/convex_hull_containment2.cpp
```

```

## CGAL::solve\_quadratic\_program

```
#include <CGAL/QP_functions.h>
```

This function solves a quadratic program, using some exact Integral Domain *ET* for its computations. Various options may be provided, see *Quadratic\_program\_options*.

```
template <QuadraticProgram, ET>
Quadratic_program_solution<ET>
```

```
    solve_quadratic_program( QuadraticProgram qp,
                             ET,
                             Quadratic_program_options options = Quadratic_
program_options())
```

returns the solution of the quadratic program *qp*, solved with exact number type *ET*.

### Requirements

*ET* is a model of the concepts *IntegralDomain* and *RealEmbeddable*; it must be an exact type, and all entries of *qp* are convertible to *ET*.

Here are some recommended combinations of input type (the type of the *qp* entries) and *ET*.

input type	—	<i>ET</i>
<i>double</i>	—	<i>MP_Float</i> , <i>Gmpzf</i> , or <i>Gmpq</i>
<i>int</i>	—	<i>MP_Float</i> , or <i>Gmpz</i>
any exact type <i>NT</i>	—	<i>NT</i>

**Note:** by default, this function performs a large number of runtime-checks to ensure consistency during the solution process. However, these checks slow down the computations by a considerable factor. For maximum efficiency, it is advisable to define the macros `CGAL_QP_NO_ASSERTIONS` or `NDEBUG`.

### Example

*QP\_solver/first\_qp.cpp*

## CGAL::solve\_linear\_program

```
#include <CGAL/QP_functions.h>
```

This function solves a linear program, using some exact Integral Domain *ET* for its computations. Various options may be provided, see *Quadratic\_program\_options*.

```
template <LinearProgram, ET>
Quadratic_program_solution<ET>
```

```
    solve_linear_program( LinearProgram lp,
                          ET,
                          Quadratic_program_options options = Quadratic_program_
options())
```

returns the solution of the linear program *lp*, solved with exact number type *ET*.

### Requirements

*ET* is a model of the concepts *IntegralDomain* and *RealEmbeddable*; it must be an exact type, and all entries of *qp* are convertible to *ET*.

Here are some recommended combinations of input type (the type of the *qp* entries) and *ET*.

input type	—	<i>ET</i>
<i>double</i>	—	<i>MP_Float</i> , <i>Gmpzf</i> , or <i>Gmpq</i>
<i>int</i>	—	<i>MP_Float</i> , or <i>Gmpz</i>
any exact type <i>NT</i>	—	<i>NT</i>

**Note:** by default, this function performs a large number of runtime-checks to ensure consistency during the solution process. However, these checks slow down the computations by a considerable factor. For maximum efficiency, it is advisable to define the macros `CGAL_QP_NO_ASSERTIONS` or `NDEBUG`.

## CGAL::solve\_nonnegative\_quadratic\_program

```
#include <CGAL/QP_functions.h>
```

This function solves a nonnegative quadratic program, using some exact Integral Domain *ET* for its computations. Various options may be provided, see *Quadratic\_program\_options*.

```
template <NonnegativeQuadraticProgram, ET>
Quadratic_program_solution<ET>
```

```
    solve_nonnegative_quadratic_program( NonnegativeQuadraticProgram qp,
                                         ET,
                                         Quadratic_program_options options) =
Quadratic_program_solution<ET>()
```

returns the solution of the nonnegative quadratic program *qp*, solved with exact number type *ET*.

### Requirements

*ET* is a model of the concepts *IntegralDomain* and *RealEmbeddable*; it must be an exact type, and all entries of *qp* are convertible to *ET*.

Here are some recommended combinations of input type (the type of the *qp* entries) and *ET*.

## CGAL::Quadratic\_program\_options

*#include <CGAL/QP\_options.h>*

### Definition

This is a class used for passing options to the linear and quadratic programming solvers. Currently, we support only options referring to

1. the verbosity,
2. the pricing strategy (see *Quadratic\_program\_pricing\_strategy*),
3. the validation mode (see the Validity section of *Quadratic\_program\_solution*)

The idea is that this list grows in the future.

### Creation

*Quadratic\_program\_options options;* constructs an instance of *Quadratic\_program\_options* where all available options are at their defaults.

### Operations

Here we just have set/get pairs for any option type.

### Verbosity

*void options.set\_verbosity( int verbosity)*

sets the verbosity of the solver to the value *verbosity* when *options* is passed to any of the four solution functions. The provided value must be a number between 0 and 5. Verbosity 0 is the default and results in the solver running silently. Verbosity 1 prints a short summary of every iteration. Higher verbosity values print more information about the solution process, but these are mainly for debugging purposes and have no effect if you compile with `CGAL_QP_NO_ASSERTIONS` or `NDEBUG`.

*int options.get\_verbosity()*

returns the verbosity level of *options*.

## Pricing strategy

*void*                      *options.set\_pricing\_strategy( Quadratic\_program\_pricing\_strategy pricing\_strategy)*

sets the pricing strategy of the solver to the value *pricing\_strategy* when *options* is passed to any of the four solution functions. The pricing strategy controls how the solver proceeds from any intermediate solution. For the available strategies and their behavior, see the documentation of the class *Quadratic\_program\_pricing\_strategy*.

*Quadratic\_program\_pricing\_strategy*

*options.get\_pricing\_strategy()*

returns the pricing strategy of *options*.

## Validation mode

*void*                      *options.set\_auto\_validation( bool validate)*

sets the automatic validation mode of the solver to the value *validate*. The default is *false*. By providing value *true* you can tell the solver to automatically check whether the program has correctly been solved, see the Validity section of the class *Quadratic\_program\_solution*.

*bool*                      *options.get\_auto\_validation()*

returns the validation mode of *options*.

## Example

*QP\_solver/cycling.cpp*

## CGAL::Quadratic\_program\_pricing\_strategy

```
#include <CGAL/QP_options.h>
```

### Definition

This is an enumeration type containing the values *QP\_CHOOSE\_DEFAULT*, *QP\_DANTZIG*, *QP\_PARTIAL\_DANTZIG*, *QP\_FILTERED\_DANTZIG*, *QP\_PARTIAL\_FILTERED\_DANTZIG*, and *QP\_BLAND*.

It indicates the pricing strategy to be used in solving a linear or quadratic program. This strategy determines how the solver gets from one intermediate solution to the next during any of its iterations.

Here we briefly describe when to choose which strategy.

#### *QP\_CHOOSE\_DEFAULT*

This is the default value of the pricing strategy in *Quadratic\_program\_options*, and it lets the solver choose the strategy that it thinks is most appropriate for the problem at hand. There are only few reasons to deviate from this default, but you are free to experiment, of course.

#### *QP\_PARTIAL\_DANTZIG*

If the input type is **not** *double*, this is usually the best choice for linear and quadratic programs of medium size.

#### *QP\_DANTZIG*

If the input type is **not** *double*, this can sometimes make a difference (be faster or slower) than *QP\_PARTIAL\_DANTZIG* for problems with a high variable/constraint or constraint/variable ratio.

#### *QP\_PARTIAL\_FILTERED\_DANTZIG*

If the input type **is** *double*, this is usually the best choice for linear and quadratic programs of medium size. If the input type is not *double*, this choice is equivalent to *QP\_PARTIAL\_DANTZIG*.

**Note:** filtered strategies may in rare cases fail due to double exponent overflows, see Section [67.8.1](#). In this case, the slower fallback option is the non-filtered variant *QP\_PARTIAL\_DANTZIG* of this strategy.

#### *QP\_FILTERED\_DANTZIG*

If the input type **is** *double*, this can sometimes make a difference (be faster or slower) than *QP\_PARTIAL\_FILTERED\_DANTZIG* for problems with a high variable/constraint or constraint/variable ratio. If the input type is not *double*, this choice is equivalent to *QP\_DANTZIG*.

**Note:** filtered strategies may in rare cases fail due to double exponent overflows, see Section [67.8.1](#). In this case, the slower fallback option is the non-filtered variant *QP\_DANTZIG* of this strategy.

*QP\_BLAND*

This is hardly ever the most efficient choice, but it is guaranteed to avoid internal cycling of the solution algorithm, see Section [67.8.2](#).

## CGAL::print\_quadratic\_program

```
#include <CGAL/QP_functions.h>
```

This function writes a quadratic program to an output stream (in *MPSFormat*). The time complexity is  $\Theta(n^2 + mn)$ , even if the program is very sparse.

```
template <QuadraticProgram>
void print_quadratic_program( std::ostream& out,
                             QuadraticProgram qp,
                             std::string problem_name = std::string("MY_MPS"))
```

writes the quadratic program *qp* to *out* in *MPSFormat*. The name of the program will be the one provided by *problem\_name*.

### Requirements

Output operators are defined for all entry types of *qp*.

### Example

*QP\_solver/print\_first\_qp.cpp*

### 68.1 Timers

CGAL provides classes for measuring the user process time and the real time. The class *CGAL::Timer* is the version for the user process time and the class *CGAL::Real\_timer* is the version for the real time.

Instantiations of both classes are objects with a state. The state is either *running* or it is *stopped*. The state of an object *t* is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occurs while the timer is running it counts as the first interval.

### 68.2 Memory Size

CGAL provides access to the memory size used by the program with the *CGAL::Memory\_sizer* class. Both the virtual memory size and the resident size are available (the resident size does not account for swapped out memory nor for the memory which is not yet paged-in).

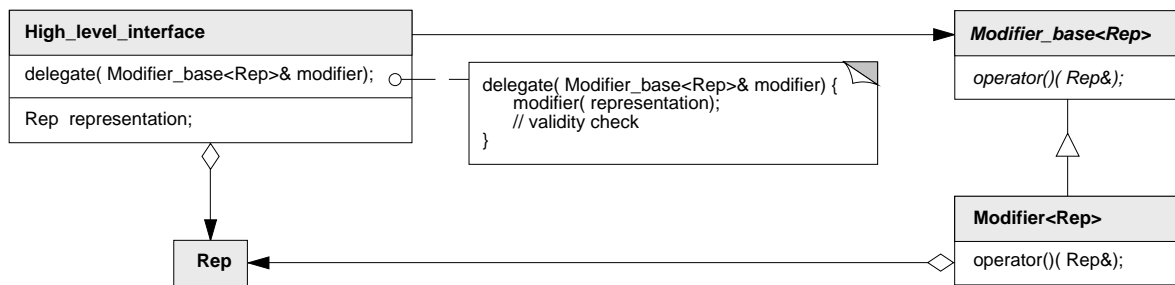

Figure 68.1: Class diagram for the modifier. It illustrates the safe access to an internal representation through an high-level interface.

## 68.3 Profiling

CGAL provides a way to count the number of times a given line of code is executed during the execution of a program. Such *CGAL::Profile\_counter* counters can be added at critical place in the code, and at the end of the execution of a program, the count is printed on *std::cerr*. A macro *CGAL\_PROFILER* can be used to conveniently place these counters anywhere. They are disabled by default and activated by the global macro *CGAL\_PROFILE*.

## 68.4 Unique Hash Map

The class *Unique\_hash\_map* implements an injective mapping between a set of unique keys and a set of data values. This is implemented using a chained hashing scheme and access operations take  $O(1)$  expected time. Such a mapping is useful, for example, when keys are pointers, handles, iterators or circulators that refer to unique memory locations. In this case, the default hash function is *Handle\_hash\_function*.

## 68.5 Union-find

CGAL also provides a class *Union\_find* that implements a partition of values into disjoint sets. This is implemented with union by rank and path compression. The running time for  $m$  set operations on  $n$  elements is  $O(n\alpha(m,n))$  where  $\alpha(m,n)$  is the extremely slowly growing inverse of Ackermann's function.

## 68.6 Protected Access to Internal Representations

High level data structures typically maintain integrity of an internal data representation, which they protect from the user. A minimal while complete interface of the data structure allows manipulations in the domain of valid representations. Additional operations might benefit from being allowed to access the internal data representation directly. An example are intermediate steps within an algorithm where the internal representation would be invalid. We present a general method to accomplish access in a safe manner, such that the high level data structures can guarantee validity after the possibly compromising algorithm has finished its work. An example are polyhedral surfaces in the Basic Library, where a construction process like for a file scanner could be performed more efficiently on the internal halfedge data structure than by using the high-level Euler operators of the polyhedron.

The solution provided here is inspired by the strategy pattern [GHJV95], though it serves a different intent, see Figure 68.1. The abstract base class *Modifier\_base<R>* declares a pure virtual member function *operator()* that accepts a single reference parameter of the internal representation type. The member function *delegate()* of the high-level interface calls this *operator()* with its internal representation. An actual modifier implements this virtual function, thus gaining access to the internal representation. Once, the modifier has finished its work, the member function *delegate()* is back in control and can check the validity of the internal representation. Summarizing, a user can implement and apply arbitrary functions based on the internal representation and keeps the benefit of a protected high-level interface. User provided modifiers must in any case return a valid internal representation or the checker in the high-level interface is allowed (and supposed) to abort the program. The indirection via the virtual function invocation is negligible for operations that consists of more than a pointer update or integer addition.

# Profiling tools, Hash Map, Union-find, Modifiers

## Reference Manual

*Lutz Kettner, Sylvain Pion, and Michael Seel*

This chapter describes classes for measuring user process time and real time as well as the memory size. It also provides a profile counter tool.

A hash map *CGAL::Unique\_hash\_map* is offered that is specialized on unique hash values of type *std::size\_t*, i.e., it is particularly useful for pointers, handles, iterators, and circulators as key values.

Furthermore, a union-find data structure and the modifier base class is documented.

## CGAL::Handle\_hash\_function

### Definition

The class *Handle\_hash\_function* is a model for the *UniqueHasFunction* concept. It is applicable for all key types with pointer-like functionality, such as handles, iterators, and circulators. Specifically, for a *key* value the expression `&*key` must return a unique address.

```
#include <CGAL/Handle_hash_function.h>
```

## Is Model for the Concepts

UniqueHashFunction.....page 3665

## Creation

*Handle\_hash\_function* *hash*; default constructor.

## Operations

<i>template &lt;class Handle&gt;</i>		
<i>std::size_t</i>	<i>hash( Handle key)</i>	returns unique hash value for any <i>Handle</i> type for which &*key gives a unique address.
		<i>Requirement:</i> The type <i>std::iterator_traits&lt;Handle&gt;::value_</i> <i>type</i> has to be defined (which it is already for pointers, han- dles, iterators, and circulators).

## See Also

CGAL::Unique\_hash\_map&lt;Key,Data,UniqueHashFunction&gt; ..... page 3663

## Implementation

Plain type cast of `&*key` to `std::size_t` and divided by the size of the `std::iterator_traits<Handle>::value_type` to avoid correlations with the internal table size, which is a power of two.

## CGAL::Memory\_sizer

### Definition

The class *Memory\_sizer* allows to measure the memory size used by the process. Both the virtual memory size and the resident size are available (the resident size does not account for swapped out memory nor for the memory which is not yet paged-in).

```
#include <CGAL/Memory_sizer.h>
```

### Types

```
typedef std::size_t      size_type;
```

### Creation

```
Memory_sizer m;           Default constructor.
```

### Operations

*size\_type*

```
m.virtual_size()
```

Returns the virtual memory size in bytes.

*size\_type*

```
m.resident_size()
```

Returns the resident memory size in bytes.

### Implementation

Accessing this information requires the use of non-portable code. Currently, there is support for Linux platforms, the Microsoft and Intel compiler on Windows, as well as Mac OS X. If a platform is not supported, the two member functions return 0.

## CGAL::Modifier\_base<R>

### Definition

*Modifier\_base<R>* is an abstract base class providing the interface for any modifier. A modifier is a function object derived from *Modifier\_base<R>* that implements the pure virtual member function *operator()*, which accepts a single reference parameter *R*& on which the modifier is allowed to work. *R* is the type of the internal representation that is to be modified.

```
#include <CGAL/Modifier_base.h>
```

### Types

```
typedef R      Representation;           the internal representation type.
```

### Operations

```
virtual void    modifier.operator()( R& rep)    Postcondition: rep is a valid representation.
```

### Example

The following fragment defines a class *A* with an internal representation *i* of type *int*. It provides a member function *delegate()*, which gives a modifier access to the internal variable and checks validity thereafter. The example modifier sets the internal variable to 42. The example function applies the modifier to an instance of class *A*.

```
class A {
    int i; // protected internal representation
public:
    void delegate( CGAL::Modifier_base<int>& modifier) {
        modifier(i);
        CGAL_postcondition( i > 0); // check validity
    }
};

struct Modifier : public CGAL::Modifier_base<int> {
    void operator()( int& rep) { rep = 42;}
};

void use_it() {
    A a;
    Modifier m;
    a.delegate(m); // a.i == 42 and A has checked that A::i > 0.
}
```

## CGAL::Profile\_counter

### Definition

```
#include <CGAL/Profile_counter.h>
```

The class *Profile\_counter* provides a way to count the number of times a given line of code is executed during the execution of a program, and print this number at the end of the execution of the program. Such counters can be added at critical places in the code, and at the end of the execution of a program, the count is printed on *std::cerr*, together with an identification string passed to the constructor. The macro *CGAL\_PROFILER* can be used to conveniently place these counters anywhere. They are disabled by default and activated by the global macro *CGAL\_PROFILE*.

### Creation

*Profile\_counter pc( std::string s);*      The internal counter is initialized to 0, and the string *s* is stored for further printing by the destructor.

*Profile\_counter pc;*      The value of the counter is printed to *std::cerr* together with the string.

### Operations

*void ++pc*      Increments the internal counter.

*#define CGAL\_PROFILER(MSG)* If *CGAL\_PROFILE* is not defined, then *CGAL\_PROFILER* is defined to an empty statement. Otherwise, it is defined to *static CGAL::Profile\_counter tmp(MSG); ++tmp;*

```
#define CGAL_PROFILE

#include <CGAL/Profile_counter.h>

int main()
{
    for (int i=0; i<10; ++i)
    {
        CGAL_PROFILER("iterations of the for-loop");
    }
    return 0;
}
```

**File:** examples/Profiling\_tools/Profile\_counter.cpp

will print at exit:

```
[CGAL::Profile_counter]      10 iterations of the for-loop
```

## CGAL::Real\_timer

### Definition

```
#include <CGAL/Real_timer.h>
```

The class *Real\_timer* is a timer class for measuring real time. A timer *t* of type *Real\_timer* is an object with a state. It is either *running* or it is *stopped*. The state is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occurs while the timer is running it counts as the first interval.

### Creation

*Real\_timer t;*                      state is *stopped*.

### Operations

<i>void</i>	<i>t.start()</i>	<i>Precondition:</i> state is <i>stopped</i> .
<i>void</i>	<i>t.stop()</i>	<i>Precondition:</i> state is <i>running</i> .
<i>void</i>	<i>t.reset()</i>	reset timer to zero. The state is unaffected.
<i>bool</i>	<i>t.is_running()</i>	<i>true</i> if the current state is running.
<i>double</i>	<i>t.time()</i>	real time in seconds, or 0 if the underlying system call failed.
<i>int</i>	<i>t.intervals()</i>	number of start/stop-intervals since the last reset.
<i>double</i>	<i>t.precision()</i>	smallest possible time step in seconds, or -1 if the system call failed.
<i>double</i>	<i>t.max()</i>	maximal representable time in seconds.

### Implementation

The timer class is based in the C function *gettimeofday()* on POSIX systems and the C function *\_ftime()* on MS Visual C++. The system calls to these timers might fail, in which case a warning message will be issued through the CGAL error handler and the functions return with the error codes indicated above. The *precision* method computes the precision dynamically at runtime at its first invocation.

## CGAL::Timer

### Definition

The class *Timer* is a timer class for measuring user process time. A timer *t* of type *Timer* is an object with a state. It is either *running* or it is *stopped*. The state is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occurs while the timer is running it counts as the first interval.

```
#include <CGAL/Timer.h>
```

### Creation

*Timer t;*                      state is *stopped*.

### Operations

<i>void</i>	<i>t.start()</i>	<i>Precondition:</i> state is <i>stopped</i> .
<i>void</i>	<i>t.stop()</i>	<i>Precondition:</i> state is <i>running</i> .
<i>void</i>	<i>t.reset()</i>	reset timer to zero. The state is unaffected.
<i>bool</i>	<i>t.is_running()</i>	<i>true</i> if the current state is running.
<i>double</i>	<i>t.time()</i>	user process time in seconds, or 0 if the underlying system call failed.
<i>int</i>	<i>t.intervals()</i>	number of start/stop-intervals since the last reset.
<i>double</i>	<i>t.precision()</i>	smallest possible time step in seconds, or -1 if the system call failed.
<i>double</i>	<i>t.max()</i>	maximal representable time in seconds.

### Implementation

The timer class is based in the C function *std::clock()* on PC systems and the C function *getrusage()* on standard POSIX systems. The counter for the *std::clock()* based solution might wrap around (overflow) after only about 36 minutes. This won't happen on POSIX systems. The system calls to these timers might fail, in which case a warning message will be issued through the CGAL error handler and the functions return with the error codes indicated above. The *precision* method computes the precision dynamically at runtime at its first invocation.

## CGAL::Union\_find<T,A>

### Definition

An instance  $P$  of the data type  $Union\_find<T,A>$  is a partition of values of type  $T$  into disjoint sets. The template parameter  $A$  has to be a model of the allocator concept as defined in the C++ standard. It has a default argument  $CGAL\_ALLOCATOR(T)$ .

```
#include <CGAL/Union_find.h>
```

### Types

$Union\_find<T,A>::value\_type$  values stored in items (equal to  $T$ ).

$Union\_find<T,A>::handle$  handle to values.

$Union\_find<T,A>::iterator$  iterator over values.

There are also constant versions  $const\_handle$  and  $const\_iterator$ .

$Union\_find<T,A>::allocator$  allocator.

### Creation

$Union\_find<T,A> P;$  creates an instance  $P$  of type  $Union\_find<T,A>$  and initializes it to the empty partition.

### Operations

$allocator$   $P.get\_allocator()$  the allocator of  $P$ .

$std::size\_t$   $P.number\_of\_sets()$  returns the number of disjoint sets of  $P$ .

$std::size\_t$   $P.size()$  returns the number of values of  $P$ .

$std::size\_t$   $P.bytes()$  returns the memory consumed by  $P$ .

$std::size\_t$   $P.size( const\_handle p)$  returns the size of the set containing  $p$ .

$void$   $P.clear()$  reinitializes  $P$  to an empty partition.

$handle$   $P.make\_set( T x)$  creates a new singleton set containing  $x$  and returns a handle to it.

$handle$   $P.push\_back( T x)$  same as  $make\_set(x)$ .

<i>template</i>	<i>&lt;class Forward_iterator&gt;</i>	
<i>void</i>	<i>P.insert( Forward_iterator first, Forward_iterator beyond)</i>	insert the range of values referenced by <i>[first,beyond)</i> . <i>Requirement:</i> value type of <i>Forward_iterator</i> is <i>T</i> .
<i>handle</i>	<i>P.find( handle p)</i>	returns a canonical handle of the set that contains <i>p</i> , i.e., <i>P.same_set(p,q)</i> iff <i>P.find(p)</i> and <i>P.find(q)</i> return the same handle. <i>Precondition:</i> <i>p</i> is a handle in <i>P</i> .
<i>const_handle</i>	<i>P.find( const_handle p)</i>	
<i>void</i>	<i>P.unify_sets( handle p, handle q)</i>	unites the sets of partition <i>P</i> containing <i>p</i> and <i>q</i> . <i>Precondition:</i> <i>p</i> and <i>q</i> are in <i>P</i> .
<i>bool</i>	<i>P.same_set( const_handle p, const_handle q)</i>	returns true iff <i>p</i> and <i>q</i> belong to the same set of <i>P</i> . <i>Precondition:</i> <i>p</i> and <i>q</i> are in <i>P</i> .
<i>iterator</i>	<i>P.begin()</i>	returns an iterator pointing to the first value of <i>P</i> .
<i>iterator</i>	<i>P.end()</i>	returns an iterator pointing beyond the last value of <i>P</i> .

## Implementation

*Union\_find* $\langle T, A \rangle$  is implemented with union by rank and path compression. The running time for  $m$  set operations on  $n$  elements is  $O(n\alpha(m, n))$  where  $\alpha(m, n)$  is the extremely slow growing inverse of Ackermann's function.

## CGAL::Unique\_hash\_map<Key,Data,UniqueHashFunction>

### Definition

An instance *map* of the parameterized data type *Unique\_hash\_map<Key,Data,UniqueHashFunction>* is an injective mapping from the set of keys of type *Key* to the set of variables of type *Data*. New keys can be inserted at any time, however keys cannot be individually deleted.

An object *hash* of the type *UniqueHashFunction* returns a unique integer index *hash(key)* of type *std::size\_t* for all objects *key* stored in *map*. The template parameter has as default the *Handle\_hash\_function* that hashes all types of pointers, handles, iterators, and circulators.

All variables are initialized to *default\_data*, a value of type *Data* specified in the definition of *map*.

```
#include <CGAL/Unique_hash_map.h>
```

### Types

<i>Unique_hash_map&lt;Key,Data,UniqueHashFunction&gt;::Key</i>	the <i>Key</i> type.
<i>Unique_hash_map&lt;Key,Data,UniqueHashFunction&gt;::Data</i>	the <i>Data</i> type.
<i>Unique_hash_map&lt;Key,Data,UniqueHashFunction&gt;::Hash_function</i>	the unique hash function type.

In compliance with STL, the types *key\_type*, *data\_type*, and *hasher* are defined as well.

### Creation

```
Unique_hash_map<Key,Data,UniqueHashFunction> map( Data default = Data(),
                                                    std::size_t table_size = 1,
                                                    Hash_function fct = Hash_function())
```

creates an injective function *map* from *Key* to the set of unused variables of type *Data*, sets *default\_data* to *default*, passes the *table\_size* as argument to the internal implementation, and initializes the hash function with *fct*.

```
Unique_hash_map<Key,Data,UniqueHashFunction> map( Key first1,
                                                    Key beyond1,
                                                    Data first2,
                                                    Data default = Data(),
                                                    std::size_t table_size = 1,
                                                    Hash_function fct = Hash_function())
```

creates an injective function *map* from *Key* to the set of unused variables of type *Data*, sets *default\_data* to *default*, passes the *table\_size* as argument to the internal implementation, initializes the hash function with *fct*, and inserts all keys from the range *[first1,beyond1)*. The data variable for each inserted *key* is initialized with the corresponding value from the range *[first2,first2 + (beyond1-first1))*.

*Precondition:* The increment operator must be defined for values of type *Key* and for values of type *Data*. *beyond1* must be reachable from *first1* using increments.

## Operations

<i>Data</i>	<i>map.default_value()</i>	the current <i>default_value</i> .
<i>Hash_function</i>	<i>map.hash_function()</i>	the current hash function.
<i>bool</i>	<i>map.is_defined( Key key)</i>	returns true if <i>key</i> is defined in <i>map</i> . Note that there can be keys defined that have not been inserted explicitly. Their variables are initialized to <i>default_value</i> .
<i>void</i>	<i>map.clear()</i>	resets <i>map</i> to the injective function <i>map</i> from <i>Key</i> to the set of unused variables of type <i>Data</i> . The <i>default_data</i> remains unchanged.
<i>void</i>	<i>map.clear( Data default)</i>	resets <i>map</i> to the injective function <i>map</i> from <i>Key</i> to the set of unused variables of type <i>Data</i> and sets <i>default_data</i> to <i>default</i> .
<i>Data&amp;</i>	<i>map.operator[]( const Key&amp; key)</i>	returns a reference to the variable <i>map(key)</i> . If <i>key</i> has not been inserted into <i>map</i> before, <i>key</i> is inserted and initialized with <i>default_value</i> .
<i>const Data&amp;</i>	<i>map.operator[]( const Key&amp; key) const</i>	returns a const reference to the variable <i>map(key)</i> . If <i>key</i> has not been inserted into <i>map</i> before, a const reference to the <i>default_value</i> is returned. However, <i>key</i> is not inserted into <i>map</i> .
<i>Data</i>	<i>map.insert( Key first1, Key beyond1, Data first2)</i>	<p>inserts all keys from the range <math>[first1, beyond1)</math>. The data variable for each inserted <i>key</i> is initialized with the corresponding value from the range <math>[first2, first2 + (beyond1 - first1))</math>. Returns <math>first2 + (beyond1 - first1)</math>.</p> <p><i>Precondition:</i> The increment operator must be defined for values of type <i>Key</i> and for values of type <i>Data</i>. <i>beyond1</i> must be reachable from <i>first1</i> using increments.</p>

 CGAL::Handle\_hash\_function .....page [3655](#)

## Implementation

*Unique\_hash\_map* is implemented via a chained hashing scheme. Access operations *map[i]* take expected time  $O(1)$ . The *table\_size* parameter passed to chained hashing can be used to avoid unnecessary rehashing when set to the number of expected elements in the map. The design is derived from the STL *hash\_map* and the LEDA type *map*. Its specialization on insertion only and unique hash values allow for a more time- and space-efficient implementation, see also [MN00, Chapter 5]. This implementation makes also use of sentinels that lead to defined keys that have not been inserted.

# UniqueHashFunction

## Definition

UniqueHashFunction is a concept for a hash function with unique hash values. An instance *hash* for a model of the UniqueHashFunction concept is a function object. It maps objects of its domain type *Key* to the integral image type *std::size\_t*. The image values have to be unique for all keys in the domain type *Key*.

## Refines

STL concept HashFunction.

## Types

*typedef std::size\_t result\_type;* type of the hash value.

## Creation

*UniqueHashFunction hash( hash2);* copy constructor.

*UniqueHashFunction& hash = hash2* assignment.

## Operations

*std::size\_t hash( Key key)* returns unique hash value for the *key* value.

## Has Models

All classes in the CGAL kernel provide input and output operators for IO streams. Classes external to CGAL are also supported, by means of *offormat* (Section 69.3). The basic task of such an operator is to produce a representation of an object that can be written as a sequence of characters on devices as a console, a file, or a pipe. In CGAL we distinguish between a raw ascii, a raw binary and a pretty printing format.

*enum Mode { ASCII = 0, BINARY, PRETTY};*

In *ASCII* mode, objects are written as a set of numbers, e.g. the coordinates of a point or the coefficients of a line, in a machine independent format. In *BINARY* mode, data are written in a binary format, e.g. a double is represented as a sequence of four byte. The format depends on the machine. The mode *PRETTY* serves mainly for debugging as the type of the geometric object is written, as well as the data defining the object. For example for a point at the origin with Cartesian double coordinates, the output would be *PointC2(0.0, 0.0)*. At the moment CGAL does not provide input operations for pretty printed data. By default a stream is in *ASCII* mode.

CGAL provides the following functions to modify the mode of an IO stream.

*IO::Mode set\_mode( std::ios& s, IO::Mode m)*

*IO::Mode set\_ascii\_mode( std::ios& s)*

*IO::Mode set\_binary\_mode( std::ios& s)*

*IO::Mode*    *set\_pretty\_mode( std::ios& s)*

The following functions allow to test whether a stream is in a certain mode.

*IO::Mode*    *get\_mode( std::ios& s)*

*bool*        *is\_ascii( std::ios& s)*

*bool*        *is\_binary( std::ios& s)*

*bool*        *is\_pretty( std::ios& s)*

## 69.1 Output Operator

CGAL defines output operators for classes that are derived from the class *ostream*. This allows to write to ostreams as *cout* or *cerr*, as well as to strstreams and fstreams. The output operator is defined for all classes in the CGAL kernel and for the class *Color* as well. Let *os* be an output stream.

*ostream&*    *ostream& os << Class c*        Inserts object *c* in the stream *os*. Returns *os*.

### Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >    Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >    Segment;

int main()
{
    Point p(0,1), q(2,2);
    Segment s(p,q);

    CGAL::set_pretty_mode(std::cout);
    std::cout << p << std::endl << q << std::endl;

    std::ofstream f("data.txt");
    CGAL::set_binary_mode(f);
    f << s << p ;

    return 1;
}
```

## 69.2 Input Operator

CGAL defines input operators for classes that are derived from the class *istream*. This allows to read from istreams as *cin*, as well as from strstreams and fstreams. The input operator is defined for all classes in the CGAL kernel. Let *is* be an input stream.

*istream&    istream& is >> Class c*            Extracts object *c* from the stream *is*. Returns *is*.

### Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >    Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >    Segment;

int
main()
{
    Point p, q;
    Segment s;

    CGAL::set_ascii_mode(std::cin);
    std::cin >> p >> q;

    std::ifstream f("data.txt");
    CGAL::set_binary_mode(f);
    f >> s >> p;

    return 1;
}
```

## 69.3 IO for non-CGAL types

### 69.3.1 Using Output Formatting

To ensure that non-CGAL types are formatted correctly (i.e., respecting *IO::Mode*), *offormat* can be used. For types with a *Output\_rep* specialization, the respective output routine of *Output\_rep* will be called by *offormat*. Otherwise, the stream output operator will be called.

### Example

```
std::cout << CGAL::offormat( myobject );
```

Optional, you can provide a second template parameter *F* as a formatting tag:

### Example

```
std::cout << CGAL::oformat( myobject, My_formatting_tag() );
```

For a list of formatting tags supported by the type *T*, please refer to the documentation of the respective type.

## 69.3.2 Customizing Output Formatting

In some situations, you want to control the output formatting for a type *T*. For external types (third party libraries etc.), there might be problems if their stream output operator does not respect *IO::Mode*. The purpose of *Output\_rep* is to provide a way to control output formatting that works independently of the object's stream output operator.

Instead of putting *T* directly into an output stream, *T* is wrapped into an output representation *Output\_rep*. For convenience, a function *oformat* exists which constructs an instance of *Output\_rep*.

If you do not specialize *Output\_rep* for *T*, *T*'s stream output operator is called from within *Output\_rep*, by default. If you want another behaviour for your type *T*, you have to provide a specialization for that type. Furthermore, you can provide specializations with a second template parameter (a formatting tag). The second template parameter defaults to *Null\_tag* and means *default behaviour*.

For example, specializing *Output\_rep* for *CORE::BigRat* (without a formatting tag parameter) could look like this:

### Example

```
template <class F>
class Output_rep< ::CORE::BigRat, F> {
    const ::CORE::BigRat& t;
public:
    Output_rep( const ::CORE::BigRat& tt) : t(tt) {}

    std::ostream& operator()( std::ostream& out) const {
        switch (get_mode(out)) {
            case IO::PRETTY:{
                if(CGAL_CORE_DENOMINATOR(t) == ::CORE::BigRat(1))
                    return out <<CGAL_CORE_NUMERATOR(t);
                else
                    return out << CGAL_CORE_NUMERATOR(t)
                               << "/"
                               << CGAL_CORE_DENOMINATOR(t);
                break;
            }

            default:
                return out << CGAL_CORE_NUMERATOR(t)
                           << "/"

```

```

        << CGAL_CORE_DENOMINATOR(t);
    }
}
};

```

## 69.4 Colors

An object of the class *CGAL::Color* is a color available for drawing operations in many CGAL output streams.

Each color is defined by a triple of integers  $(r, g, b)$  with  $0 \leq r, g, b \leq 255$ , the so-called *rgb-value* of the color. There are a 11 predefined *Color* constants available: *BLACK*, *WHITE*, *GRAY*, *RED*, *GREEN*, *DEEPBLUE*, *BLUE*, *PURPLE*, *VIOLET*, *ORANGE*, and *YELLOW*.

## 69.5 Stream Support

Three classes are provided by CGAL as adaptors to input and output stream iterators. The class *Istream\_iterator* is an input iterator adaptor and is particularly useful for classes that are similar but not compatible to *std::istream*. Similarly, the class *Ostream\_iterator* is an output iterator adaptor. The class *Verbose\_ostream* can be used as an output stream. The stream output operator *<<* is defined for any type. The class stores in an internal state a stream and whether the output is active or not. If the state is active, the stream output operator *<<* uses the internal stream to output its argument. If the state is inactive, nothing happens.

# IO Streams

## Reference Manual

Andreas Fabri, Geert-Jan Giezeman, and Lutz Kettner

All classes in the CGAL kernel provide input and output operators for IO streams. CGAL provides three different printing mode, defined in the enum *Mode*, as well as different functions to set and get the printing mode.

## CGAL::Color

### Definition

An object of the class *Color* is a color available for drawing operations in many CGAL output streams. Each color is defined by a triple of integers  $(r, g, b)$  with  $0 \leq r, g, b \leq 255$ , the so-called *rgb-value* of the color.

```
#include <CGAL/IO/Color.h>
```

## Creation

*Color* *c*; creates a color with rgb-value (0,0,0), i.e. black.

*Color* *c*( *int red*, *int green*, *int blue*);      creates a color with rgb-value (*red,green,blue*).

## Operations

<i>bool</i>	$c == q$	Test for equality: Two colors are equal, iff their rgb-values are equal.
-------------	----------	--

<i>bool</i>	$c \neq q$	Test for inequality.
-------------	------------	----------------------

<i>int</i>	<i>c.red()</i>	returns the red component of <i>c</i> .
<i>int</i>	<i>c.green()</i>	returns the green component of <i>c</i> .
<i>int</i>	<i>c.blue()</i>	returns the blue component of <i>c</i> .

## Constants

The following constants are predefined:

<i>const Color</i>	<b>BLACK</b> = Color(0, 0, 0);	Black.
<i>const Color</i>	<b>WHITE</b> = Color(255, 255, 255);	White.
<i>const Color</i>	<b>RED</b> = Color(255, 0, 0);	Red.
<i>const Color</i>	<b>GREEN</b> = Color(0, 255, 0);	Green.
<i>const Color</i>	<b>BLUE</b> = Color(0, 0, 255);	Blue.
<i>const Color</i>	<b>VIOLET</b> = Color(255, 0, 255);	Violet.
<i>const Color</i>	<b>ORANGE</b> = Color(255, 170, 0);	Orange.

## CGAL::operator>>

### Definition

CGAL defines input operators for classes that are derived from the class *istream*. This allows to read from istreams as *cin*, as well as from strstreams and fstreams. The input operator is defined for all classes in the CGAL kernel.

*istream*&            *istream*& *is* >> *Class c*            Extracts object *c* from the stream *is*. Returns *is*.

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >   Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >   Segment;

int
main()
{
    Point p, q;
    Segment s;

    CGAL::set_ascii_mode(std::cin);
    std::cin >> p >> q;

    std::ifstream f("data.txt");
    CGAL::set_binary_mode(f);
    f >> s >> p;

    return 1;
}
```

## CGAL::is\_ascii

*bool*                    *is\_ascii( std::ios& s )*                    checks if the IO stream *s* is in *ASCII* mode.

## CGAL::Istream\_iterator<T,Stream>

### Definition

The class *Istream\_iterator*<*T*,*Stream*> is an input iterator adaptor for the input stream class *Stream* and value type *T*. It is particularly useful for classes that are similar but not compatible to *std::istream*.

```
#include <CGAL/IO/Istream_iterator.h>
```

### Creation

*Istream\_iterator*<*T*,*Stream*> *i*;  
creates an end-of-stream iterator *i*. This is a past-the-end iterator, and it is useful when constructing a range.

*Istream\_iterator*<*T*,*Stream*> *i*( *Stream*& *s*);  
creates an input iterator *i* reading from *s*. When *s* reaches end of stream, this iterator will compare equal to an end-of-stream iterator created using the default constructor.

### Operations

*i* fulfills the requirements for an input iterator.

## CGAL::Mode

### Definition

All classes in the CGAL kernel provide input and output operators for IOStreams. The basic task of such an operator is to produce a representation of an object that can be written as a sequence of characters on devices as a console, a file, or a pipe. The enum *Mode* distinguish between three different printing formats.

In *ASCII* mode, numbers e.g. the coordinates of a point or the coefficients of a line, are written in a machine independent format. In *BINARY* mode, data are written in a binary format, e.g. a double is represented as a sequence of four byte. The format depends on the machine. The mode *PRETTY* serves mainly for debugging as the type of the geometric object is written, as well as the data defining the object. For example for a point at the origin with Cartesian double coordinates, the output would be *PointC2(0.0, 0.0)*. At the moment CGAL does not provide input operations for pretty printed data. By default a stream is in *ASCII* mode.

```
enum Mode { ASCII = 0, BINARY, PRETTY};
```

## CGAL::Ostream\_iterator<T,Stream>

### Definition

The class *Ostream\_iterator*<*T*,*Stream*> is an output iterator adaptor for the output stream class *Stream* and value type *T*.

```
#include <CGAL/IO/Ostream_iterator.h>
```

### Creation

*Ostream\_iterator*<*T*,*Stream*> *o*( *Stream*& *s*);      creates an output iterator *o* writing to *s*.

### Operations

*o* fulfills the requirements for an output iterator.

### Implementation

The *operator\**() in class *Ostream\_iterator*<*T*,*Stream*> uses a proxy class.

## CGAL::operator<<

### Definition

CGAL defines output operators for classes that are derived from the class *ostream*. This allows to write to ostreams as *cout* or *cerr*, as well as to strstreams and fstreams. The output operator is defined for all classes in the CGAL kernel and for the class *Color* as well. Let *os* be an output stream.

```
ostream&          ostream& os >> Class c
```

Inserts object *c* in the stream *os*. Returns *os*.

### Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >    Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >    Segment;

int main()
{
    Point p(0,1), q(2,2);
    Segment s(p,q);

    CGAL::set_pretty_mode(std::cout);
    std::cout << p << std::endl << q << std::endl;

    std::ofstream f("data.txt");
    CGAL::set_binary_mode(f);
    f << s << p ;

    return 1;
}
```

## CGAL::Input\_rep<T,F>

### Definition

The definition of *Input\_rep* is completely symmetric to *Output\_rep*.

## CGAL::Output\_rep<T,F>

### Definition

The purpose of *Output\_rep* is to provide a way to control output formatting that works independently of the object's stream output operator.

If you don't specialize *Output\_rep* for *T*, *T*'s stream output operator is called from within *Output\_rep*, by default. If you want another behaviour for your type *T*, you have to provide a specialization for that type. Furthermore, you can provide specializations with a second template parameter (a formatting tag). The second template parameter defaults to *Null\_tag* and means DEFAULT BEHAVIOUR.

Specializations of *Output\_rep* should provide the following features:

```
template< class F >
struct Output_rep< Some_type, F > {
    Output_rep( const Some_type& t );
    std::ostream& operator()( std::ostream& out ) const;
};
```

You can also specialize for a formatting tag *F*.

## CGAL::iformat

The definition of the function *iformat* is completely symmetric to *oformat*.

## CGAL::oformat

### Definition

Convenience function to construct an output representation (*Output\_rep*) for type  $T$ .

```
template <class T>  
Output_rep<T>
```

```
oformat( T t)
```

Generic IO for type  $T$ .

```
template <class T, typename F>  
Output_rep<T,F>
```

```
oformat( T t, F)
```

Generic IO for type  $T$  with formatting tag.

# CGAL::set\_ascii\_mode

*Mode*                    *set\_ascii\_mode( std::ios& s)*

sets the mode of the IO stream *s* to be the *ASCII* mode. Returns the previous mode of *s*.

## CGAL::Verbose\_ostream

### Definition

The class *Verbose\_ostream* can be used as an output stream. The stream output operator << is defined for any type. The class *Verbose\_ostream* stores in an internal state a stream and whether the output is active or not. If the state is active, the stream output operator << uses the internal stream to output its argument. If the state is inactive, nothing happens.

```
#include <CGAL/IO/Verbose_ostream.h>
```

### Creation

```
Verbose_ostream verr( bool active = false, std::ostream& out = std::cerr);
```

creates an output stream with state set to *active* that writes to the stream *out*.

### Operations

```
template < class T >
Verbose_ostream&      verr << T t
```

### Example

The class *Verbose\_ostream* can be conveniently used to implement for example the *is\_valid()* member function for triangulations or other complex data structures.

```
bool is_valid( bool verbose = false, int level = 0) {
    Verbose_ostream verr( verbose);
    verr << "Triangulation::is_valid( level = " << level << ' ' << endl;
    verr << "    Number of vertices = " << size_of_vertices() << endl;
    // ...
}
```

### 70.1 Definition

This chapter presents the CGAL interface to Geomview<sup>1</sup>, which is a viewer for three-dimensional objects, originally developed at the Geometry Center in Minneapolis<sup>2</sup>.

**Note:** The functionality described in this chapter is not available on Windows.

An object of the class *Geomview\_stream* is a stream in which geometric objects can be inserted and where geometric objects can be extracted from. The constructor starts Geomview either on the local either on a remote machine.

Not all but most classes of the CGAL kernel have output operators for the *Geomview\_stream*. 2D objects are embedded in the *xy*-plane. Input is only provided for points. Polyhedron and 2D and 3D triangulations have output operators for the *Geomview\_stream*.

### 70.2 Implementation

The constructor forks a process and establishes two pipes between the processes. The forked process is then overlaid with Geomview. The file descriptors *stdin* and *stdout* of Geomview are hooked on the two pipes.

---

<sup>1</sup><http://www.geomview.org/>

<sup>2</sup><http://www.geom.umn.edu/>

All insert operators construct expressions in *gcl*, the Geomview command language, which is a subset of LISP. These expressions are sent to Geomview via the pipe. The extract operators notify *interest* for a certain kind of events. When such an event happens Geomview sends a description of the event in *gcl* and the extract operator has to parse this expression.

In order to implement further insert and extract operators you should take a look at the implementation and at the Geomview manual.

## 70.3 Example

The following program outputs successively a 2D Delaunay triangulation (projected), a 3D Delaunay, and a terrain from the set of points.

```
#include <CGAL/Cartesian.h>
#include <iostream>

#ifndef CGAL_USE_GEOMVIEW
int main()
{
    std::cout << "Geomview doesn't work on Windows, so..." << std::endl;
    return 0;
}
#else

#include <fstream>
#include <unistd.h> // for sleep()

#include <CGAL/Triangulation_euclidean_traits_xy_3.h>

#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_triangulation_3.h>

#include <CGAL/IO/Geomview_stream.h>
#include <CGAL/IO/Triangulation_geomview_ostream_2.h>
#include <CGAL/IO/Triangulation_geomview_ostream_3.h>

#include <CGAL/intersections.h>

typedef CGAL::Cartesian<double> K;

typedef K::Point_2 Point2;
typedef CGAL::Triangulation_euclidean_traits_xy_3<K> Gt3;
typedef Gt3::Point Point3;

typedef CGAL::Delaunay_triangulation_2<K> Delaunay;
typedef CGAL::Delaunay_triangulation_2<Gt3> Terrain;

typedef CGAL::Delaunay_triangulation_3<K> Delaunay3d;

int main()
{
    CGAL::Geomview_stream gv(CGAL::Bbox_3(-100, -100, -100, 600, 600, 600));
```

```

gv.set_line_width(4);
// gv.set_trace(true);
gv.set_bg_color(CGAL::Color(0, 200, 200));
// gv.clear();

Delaunay D;
Delaunay3d D3d;
Terrain T;
std::ifstream iFile("data/points3", std::ios::in);
Point3 p;

while ( iFile >> p )
{
    D.insert( Point2(p.x(), p.y()) );
    D3d.insert( p );
    T.insert( p );
}

// use different colors, and put a few sleeps/clear.

gv << CGAL::BLUE;

# Geomview

## Reference Manual

*Andreas Fabri and Sylvain Pion*

This chapter presents the CGAL interface to Geomview<sup>3</sup>, which is a viewer for three-dimensional objects, originally developed at the Geometry Center in Minneapolis<sup>4</sup>.

Geomview 1.8.1 is required.

### Classes

*CGAL::Geomview\_stream* ..... page [3700](#)

## 70.4 Alphabetical List of Reference Pages

*Geomview\_stream* ..... page [3700](#)

<sup>3</sup><http://www.geomview.org/>

<sup>4</sup><http://www.geom.umn.edu/>

## CGAL::Geomview\_stream

### Definition

An object of the class *Geomview\_stream* is a stream in which geometric objects can be inserted and where geometric objects can be extracted from. The constructor starts Geomview either on the local either on a remote machine.

```
#include <CGAL/IO/Geomview_stream.h>
```

### Creation

```
Geomview_stream gs( Bbox_3 bbox = Bbox_3(0,0,0, 1,1,1),
                   const char *machine = NULL,
                   const char *login = NULL)
```

Introduces a Geomview stream *gs* with a camera that sees the bounding box. The command *geomview* must be in the user's *PATH*. If *machine* and *login* are not *NULL*, Geomview is started on the remote machine using *rsh*.

### Operations

#### Output Operators for CGAL Kernel Classes

At the moment not all classes of the CGAL kernel have output operators. 2D objects are embedded in the *xy*-plane.

```
template <class R>
Geomview_stream&      Geomview_stream& G << Point_2<R> p
```

Inserts the point *p* into the stream *gs*.

```
template <class R>
Geomview_stream& G << Point_3<R> p
```

Inserts the point  $p$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Segment_2<R> s
```

Inserts the segment  $s$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Segment_3<R> s
```

Inserts the segment  $s$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Ray_2<R> r
```

Inserts the ray  $r$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Ray_3<R> r
```

Inserts the ray  $r$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Line_2<R> l
```

Inserts the line  $l$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Line_3<R> l
```

Inserts the line  $l$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Triangle_2<R> t
```

Inserts the triangle  $t$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& G << Triangle_3<R> t
```

Inserts the triangle  $t$  into the stream  $gs$ .

```
template <class R>
```

```
Geomview_stream& Geomview_stream& G << Tetrahedron_3<R> t
```

Inserts the tetrahedron  $t$  into the stream  $gs$ .

```
template <class R>
Geomview_stream& Geomview_stream& G << Sphere_3<R> s
```

Inserts the sphere  $s$  into the stream  $gs$ .

```
Geomview_stream& Geomview_stream& G << Bbox_2 b
```

Inserts the bounding box  $b$  into the stream  $gs$ .

```
Geomview_stream& Geomview_stream& G << Bbox_3 b
```

Inserts the bounding box  $b$  into the stream  $gs$ .

```
template < class InputIterator >
void gs.draw_triangles( InputIterator begin, InputIterator end)
```

$[begin;end)$  is an iterator range with value type  $Triangle_3<R>$ . This method uses the OFF format to draw several triangles at once, which is much faster than drawing them one by one.

## Input Operators for CGAL Kernel Classes

At the moment input is only provided for points. The user has to select a point on the *pick plane* with the right mouse button. The pick plane can be moved anywhere with the left mouse button, before a point is entered.

```
template <class R>
Geomview_stream& Geomview_stream& G >> Point_3<R>& p
```

Extracts the point  $p$  from the stream  $gs$ . The point is echoed by default, and it depends on the stream echo mode status.

## Output Operators for CGAL Basic Library Classes

```
#include <CGAL/IO/Polyhedron_geomview_ostream.h>
```

```
template <class Traits, class HDS>
Geomview_stream& Geomview_stream &G << Polyhedron_3<Traits,HDS> P
```

Inserts the polyhedron  $P$  into the stream  $gs$ .

```
#include <CGAL/IO/Triangulation_geomview_ostream.2.h>
```

```
template <class GT, class TDS>
Geomview_stream&      Geomview_stream &G << Triangulation_2<GT,TDS> T
```

Inserts the 2D triangulation  $T$  into the stream  $gs$ . The actual output depends on whether the stream is in wired mode or not. Also note that in the case of terrains (when  $GT::Point_2$  is  $Point_3<R>$ ), then the 3D terrain is displayed.

```
#include <CGAL/IO/Triangulation_geomview_ostream_3.h>
```

```
template <class GT, class TDS>
Geomview_stream&      Geomview_stream &G << Triangulation_3<GT,TDS> T
```

Inserts the 3D triangulation  $T$  into the stream  $gs$ . The actual output depends on whether the stream is in wired mode or not.

## Colors

Geomview distinguishes between edge and face colors. The edge color is at the same time the color of vertices.

```
Geomview_stream&      gs << Color c
```

Makes  $c$  the color of vertices, edges and faces in subsequent IO operations.

```
Color                  gs.set_bg_color( Color c)
```

Changes the background color. Returns the old value.

```
Color                  gs.set_vertex_color( Color c)
```

Changes the vertex color. Returns the old value.

```
Color                  gs.set_edge_color( Color c)
```

Changes the edge color. Returns the old value.

```
Color                  gs.set_face_color( Color c)
```

Changes the face color. Returns the old value.

## Miscellaneous

```
void                  gs.clear()
```

Deletes all objects.

```
void                  gs.pickplane()
```

Creates a pickplane (useful after a clear).

```
void                  gs.look_recenter()
```

Positions the camera in a way that all objects can be seen.

<i>int</i>	<i>gs.get_line_width()</i>	Returns the line width.
<i>int</i>	<i>gs.set_line_width( int w )</i>	Sets the line width to <i>w</i> . Returns the previous value.
<i>double</i>	<i>gs.get_vertex_radius()</i>	Returns the radius of vertices.
<i>double</i>	<i>gs.set_vertex_radius( double r )</i>	Sets the radius of vertices to <i>d</i> . Returns the previous value.
<i>string</i>	<i>gs.get_new_id( string s )</i>	Used to obtain unique identifier names passed to Geomview. On successive calls with the same <i>s</i> value, it will return a string which is <i>s</i> appended with the numbers 0, then 1, then 2... Note that all counters are reset when <i>clear()</i> is called.
<i>bool</i>	<i>gs.set_wired( bool b )</i>	Sets wired mode. In wired mode, some structures output only there edges, not there surfaces. Returns the previous value. By default, wired mode is off.
<i>bool</i>	<i>gs.get_wired()</i>	Returns <i>true</i> iff wired mode is on.

— *advanced* —

## Advanced and Developers Features

The following functions are helpful if you develop your own insert and extract functions. The following functions allow to pass a string from Geomview and to read data sent back by Geomview.

<i>Geomview_stream&amp;</i>	<i>gs &lt;&lt; string s</i>	Inserts string <i>s</i> into the stream.
<i>Geomview_stream&amp;</i>	<i>gs &gt;&gt; char* s</i>	Extracts a string <i>s</i> from the stream. <i>Precondition:</i> You have to allocate enough memory.
<i>Geomview_stream&amp;</i>	<i>gs &lt;&lt; int i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode.
<i>Geomview_stream&amp;</i>	<i>gs &lt;&lt; unsigned int i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode.
<i>Geomview_stream&amp;</i>	<i>gs &lt;&lt; long i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode. Currently implemented by converting to int, so it can be truncated on 64 bit platforms.

<i>Geomview_stream</i>	<i>gs &lt;&lt; unsigned long i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode. Currently implemented by converting to unsigned int, so it can be truncated on 64 bit platforms.
<i>Geomview_stream</i>	<i>gs &lt;&lt; double d</i>	Inserts double <i>d</i> into the stream. Puts whitespace around if the stream is in ascii mode.
<i>bool</i>	<i>gs.set_trace( bool b)</i>	Sets tracing on. The data that are sent to <i>Geomview</i> are also sent to <i>cerr</i> . Returns the previous value. By default tracing is off.
<i>bool</i>	<i>gs.get_trace()</i>	Returns <i>true</i> iff tracing is on.
<i>bool</i>	<i>gs.set_raw( bool b)</i>	Sets raw mode. In raw mode, kernel points are output without headers and footers, just the coordinates (in binary or ascii mode). This allows the implementation of the stream functions for other objects to re-use the code for points internally, by temporary saving the raw mode to true, and restoring it after. Returns the previous value. By default, raw mode is off.
<i>bool</i>	<i>gs.get_raw()</i>	Returns <i>true</i> iff raw mode is on.
<i>bool</i>	<i>gs.set_echo( bool b)</i>	Sets echo mode. In echo mode, when you select a point in Geomview, the point is actually sent back to Geomview. Returns the previous value. By default, echo mode is on.
<i>bool</i>	<i>gs.get_echo()</i>	Returns <i>true</i> iff echo mode is on.
<i>bool</i>	<i>gs.set_binary_mode( bool b = true)</i>	Sets whether we are in binary mode.
<i>bool</i>	<i>gs.set_ascii_mode( bool b = true)</i>	Sets whether we are in ascii mode.
<i>bool</i>	<i>gs.get_binary_mode()</i>	Returns <i>true</i> iff <i>gs</i> is in binary mode.
<i>bool</i>	<i>gs.get_ascii_mode()</i>	Returns <i>true</i> iff <i>gs</i> is in ascii mode.

\_\_\_\_\_ *advanced* \_\_\_\_\_

## Implementation

The constructor forks a process and establishes two pipes between the processes. The forked process is then overlaid with Geomview. The file descriptors *stdin* and *stdout* of Geomview are hooked on the two pipes.

All insert operators construct expressions in *gcl*, the Geomview command language, which is a subset of LISP. These expressions are sent to Geomview via the pipe. The extract operators notify *interest* for a certain kind of events. When such an event happens Geomview sends a description of the event in *gcl* and the extract operator has to parse this expression.

In order to implement further insert and extract operators you should take a look at the implementation and at the Geomview manual.

# Chapter 71

## CGAL and the Qt Graphics View Framework

*Andreas Fabri and Laurent Rineau*

Qt is a GUI toolkit for cross-platform application development.

### 71.1 Introduction

This chapter describes classes that help to visualize two dimensional CGAL objects with the Qt Graphics View Framework.

This framework uses the model view paradigm. *QGraphicsItems* are stored in a *QGraphicsScene* and are displayed in a *QGraphicsView*. The items have a paint method which is called when an item is in the visible area of a view. The framework is also responsible for dispatching events from the view via the scene to the items. The framework is extensible in the sense that users can add classes derived from *QGraphicsItem*.

Besides visualizing *QGraphicsItems* users want to enter geometric objects. We provide the input generators for all 2D CGAL kernel objects.

The package includes also a class for providing zooming, panning, and scrolling to the graphics view.

The following sections describe the interaction between all these classes, We finally describe the internals of a *QGraphicsItem*.

#### 71.1.1 Naming Conventions

As Qt and CGAL have different naming conventions, and as this package brings them together we adopted the following, hybrid naming conventions.

- All header files are in the directory *CGAL/Qt/*.
- Class names are concatenated capitalized words, and function names are concatenated capitalized word with the first word in lowercase. The rationale is that these classes are related to Qt, and that they sometimes are derived classes that have to override member functions adhering to this naming scheme.

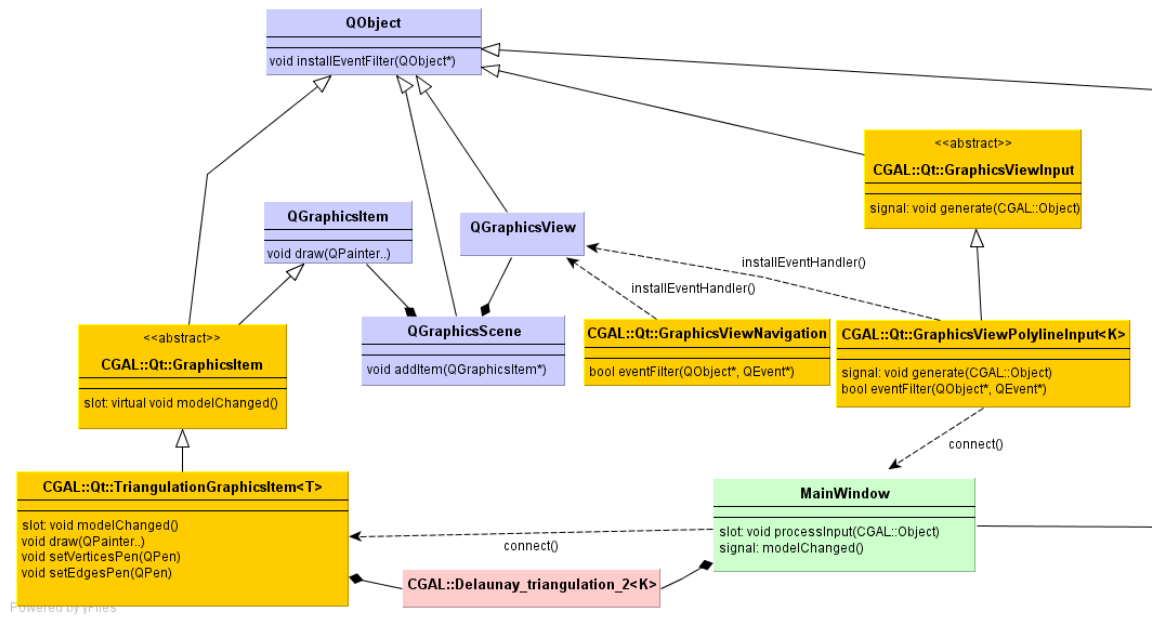

Figure 71.1: UML Class Diagram with the Qt classes (blue), CGAL classes for using the framework (yellow), CGAL data structures (red), and application classes (green).

- All classes are in the nested namespace *CGAL::Qt*.

## 71.2 Overall Design

In Figure 71.1 you see four classes depicted in grey, that come from the Qt Graphics View Framework. The *QGraphicsScene* contains *QGraphicsItems*, which get displayed in any number of *QGraphicsViews*. The views are widgets, that is they take screen space in an application.

The fourth class is the *QObject*. It plays an important role in Qt for event handling and memory management. First, it allows to add **signals and slots**, and to connect them. Second, it allows to install **event filters**.

### 71.2.1 Visualizing CGAL Datastructures

In order to visualize for example a `CGAL::Delaunay_triangulation_2<K>`, we provide the graphics item class `CGAL::Qt::TriangulationGraphicsItem<T>`. It provides a `paint` method that draws the edges and vertices of a triangulation using the drawing primitives of the `QPainter`. The color of vertices and edges, can be chosen by setting a user defined `QPen`.

As this graphics item only stores a pointer to a triangulation, it must be notified about changes like the insertion of points coming from a file, a process or as input generated with the mouse. We use the signal/slot mechanism of Qt for that purpose, that is when the triangulation changes the application emits a signal that can get connected to the *modelChanged()* slot of the graphics item.

### 71.2.2 Navigation

We provide a class *CGAL::Qt::GraphicsViewNavigation* that can be installed as an event filter of a graphics view and its viewport. As for all Qt widgets, the *QGraphicsView* is derived from *QObject*. Events like the mouse buttons pressed or released, the mouse moved, keys pressed, are passed to the view which first hands them over to the event filter. The *CGAL::Qt::GraphicsViewNavigation* event filter allows to zoom, scroll, and recenter. Finally, the class emits a signal with the mouse coordinates. This can be used to display the current mouse position in the status bar of an application.

### 71.2.3 Generation of Input

Input of CGAL kernel objects, polylines, etc. is generated by classes derived from *CGAL::Qt::GraphicsViewInput*. As the navigation class, they are event handler of the graphics view, because they have to know where the mouse is, when the user clicks in order to enter a point.

Once the input generator has assembled the object, which can involve several mouse clicks, it emits a *CGAL::Object* wrapping the input. The emitted input can be connected by the application developer to a slot. In the 2D demos of CGAL, which use the Graphics View Framework we connect it to the slot *Main-Window::processInput(CGAL::Object)*. This method unwraps from the *CGAL::Object* and inserts it in the data structure. It then typically emits a signal *modelChanged()* which can be connected to the graphics item representing the data structure.

All input generators we provide use the left mouse button for entering points. The right click terminates a sequence of entered points. 'Delete' and 'backspace' remove the last entered point. 'Esc' resets the input generator. As the 'Ctrl' key is used by the *CGAL::Qt::GraphicsViewNavigation* this modifier is not used.

# CGAL and the Qt Graphics View Framework

## Reference Manual

*Andreas Fabri and Laurent Rineau*

This package provides some classes which allow to use CGAL classes in *Qt* applications which make use of the [Qt Graphics View Framework](#).

## CGAL::Qt::Converter<K>

### Definition

An object of type *Converter<K>* converts 2D CGAL kernel objects to their equivalent objects in *Qt*, and the other way round. Note that some objects have no equivalent. For example the *CGAL::Circle\_2<K>* cannot be converted to something in *Qt*, and the unbounded objects *CGAL::Ray\_2<K>* and *CGAL::Line\_2<K>* are clipped. Note also that CGAL and *Qt* sometimes also use the same word for different things. For example *line* denotes an unbounded line in CGAL, whereas it denotes a bounded segment in *Qt*.

```
#include <CGAL/Qt/Converter.h>
```

### Creation

*Converter<K>* *c*( *QRectF* *clippingRect*);      The clipping rect is used for unbounded CGAL objects.

### From CGAL to Qt

<i>QRectF</i>	<i>c</i> ( <i>Bbox_2</i> )	Converts a bounding box.
<i>QPointF</i>	<i>c</i> ( <i>K::Point_2</i> )	Converts a point.
<i>QLineF</i>	<i>c</i> ( <i>K::Segment_2</i> )	Converts a segment.
<i>QLineF</i>	<i>c</i> ( <i>K::Ray_2</i> )	Clips the ray and converts the resulting segment.
<i>QLineF</i>	<i>c</i> ( <i>K::Line_2</i> )	Clips the line and converts the resulting segment.
<i>QPolygonF</i>	<i>c</i> ( <i>K::Triangle_2</i> )	Converts a triangle.
<i>QRectF</i>	<i>c</i> ( <i>K::Iso_rectangle_2</i> )	Converts an iso rectangle.
<i>QPolygonF</i>	<i>c</i> ( <i>std::list&lt;K::Point_2&gt;</i> )	Converts a list of points to a polygon.

### From Qt to CGAL

<i>K::Point_2</i>	<i>c</i> ( <i>QPointF</i> )	Converts a point.
<i>K::Segment_2</i>	<i>c</i> ( <i>QLineF</i> )	Converts a segment.
<i>K::Iso_rectangle_2</i>	<i>c</i> ( <i>QRectF</i> )	Converts an iso rectangle.
<i>std::list&lt;K::Point_2&gt;</i>	<i>c</i> ( <i>QPolygonF</i> )	Converts a polygon to a list of points.

## CGAL::Qt::PainterOstream<K>

### Definition

An object of type *PainterOstream<K>* provides output operators for CGAL kernel objects. As CGAL has unbounded objects the *PainterOstream<K>* must be constructed with a clipping rectangle. This is typically the visible area of the widget where the unbounded object is displayed.

```
#include <CGAL/Qt/PainterOstream.h>
```

### Creation

```
PainterOstream<K> os( QPainter* qp, QRectF clippingRect);
```

The clipping rect is used for unbounded CGAL objects.

### Operations

```
PainterOstream<K>    os << K::Point_2    Draws a point.
```

```
PainterOstream<K>    os << K::Segment_2   Draws a segment.
```

```
PainterOstream<K>    os << K::Ray_2       Draws a clipped ray.
```

```
PainterOstream<K>    os << K::Line_2      Draws a clipped line.
```

```
PainterOstream<K>    os << K::Triangle_2  Draws a triangle.
```

```
PainterOstream<K>    os << K::Iso_rectangle_2

                                Draws an iso rectangle.
```

```
PainterOstream<K>    os << K::Circle_2    Draws a circle.
```

```
PainterOstream<K>    os << K::Circular_arc_2

                                Draws a circular arc.
```

```
PainterOstream<K>    os << std::list<K::Point_2>

                                Draws a polyline. In order to close it the first and last point
                                must be equal.
```

<i>PainterOstream</i> <K>	<i>os</i> << <i>Bbox_2</i>	Draws an iso rectangle.
<i>PainterOstream</i> <K>	<i>os</i> << <i>QPen</i>	Sets the pen used in the next paint operations.
<i>PainterOstream</i> <K>	<i>os</i> << <i>QBrush</i>	Sets the brush used in the next paint operations.

## CGAL::Qt::GraphicsViewInput

### Definition

An object of type *GraphicsViewInput* can emit a signal with *CGAL::Object* as argument.

```
#include <CGAL/Qt/GraphicsViewInput.h>
```

### Signals

<i>void</i>	<i>in.generate( Object)</i>	A signal that emits a <i>CGAL::Object</i> .
-------------	-----------------------------	---

## CGAL::Qt::GraphicsViewPolylineInput<K>

### Definition

An object of type *GraphicsViewPolylineInput<K>* creates a list of points. A new vertex is inserted every time the left mouse button is pressed. The list of points is emitted on a right click or when the number of points specified in the constructor is reached. You can use the 'Del' or 'Backspace' key if you want to remove your last entered point in the polygon, and the 'Esc' key if you want to remove all points.

The tool can serve at the same time for entering a single point, a polyline with a given number of points, and for open as well as closed polylines.

```
#include <CGAL/Qt/GraphicsViewPolylineInput.h>
```

### Parameters

The template parameter of *GraphicsViewPolylineInput<K>* must be a CGAL *Kernel*.

### Inherits From

*Qt::GraphicsViewInput*

### Creation

```
GraphicsViewPolylineInput<K> in( QObject *p, QGraphicsScene *s, int n = 0, bool closed = true);
```

*p* is a parent object. *s* is the scene where the polyline is generated. *n* is the number of points of the polyline to be generated. If *c* is equal to 0, the default value, the number of points of the polyline is not limited. When *closed* is *true* the function displays a polygon.

### Signals

```
void in.generate( CGAL::Object o)
```

The object *o* contains a *std::list<K::Point\_2>*.

## CGAL::Qt::GraphicsViewIsoRectangleInput<K>

### Definition

An object of type *GraphicsViewIsoRectangleInput<K>* creates an axis parallel rectangle.

```
#include <CGAL/Qt/GraphicsViewIsoRectangleInput.h>
```

### Parameters

The template parameter of *GraphicsViewIsoRectangleInput<K>* must be a CGAL *Kernel*.

### Inherits From

*GraphicsViewInput*

### Creation

```
GraphicsViewIsoRectangleInput<K> in( QObject *p, QGraphicsScene* s);
```

*p* is a parent object. *s* is the scene where the iso rectangle is generated.

### Signals

```
void in.generate( Object o)
```

The object *o* contains a *K::Iso\_rectangle\_2*.

## CGAL::Qt::GraphicsViewCircleInput<K>

### Definition

An object of type *GraphicsViewCircleInput<K>* creates a circle, defined by either center and radius, or two or three points on the circle. A new vertex is inserted every time the left mouse button is released. The *Del* key removes the last entered point. The *Esc* key removes all entered points.

```
#include <CGAL/Qt/GraphicsViewCircleInput.h>
```

### Parameters

The template parameter of *GraphicsViewCircleInput<K>* must be a CGAL *Kernel*.

### Inherits From

*Qt::GraphicsViewInput*

### Creation

```
GraphicsViewCircleInput<K> in( QObject *p, QGraphicsScene* s, int pointsOnCircle = 1);
```

*p* is a parent object. *s* is the scene where the circle is generated. *pointsOnCircle* is the number of points on the circle to be generated, that is the default value 1 corresponds to the case center/radius.

### Signals

```
void in.generate( Object o)
```

The object *o* contains a *std::pair<K::Point\_2, K::FT>* for center and radius, or a *std::pair<K::Point\_2, K::Point\_2>* for two points defining the circle, or *CGAL::array<K::Point\_2, 3>* for three points defining the circle.

## CGAL::Qt::GraphicsViewCircularArcInput<K>

### Definition

An object of type *GraphicsViewCircularArcInput<K>* creates a circular arc, defined by three points on a circle. A new vertex is inserted every time the left mouse button is released. The *Del* key removes the last entered point. The *Esc* key removes all entered points.

*#include <CGAL/Qt/GraphicsViewCircularArcInput.h>*

### Parameters

The template parameter of *GraphicsViewCircularArcInput<K>* must be a CGAL *CircularKernel*.

### Inherits From

*Qt::GraphicsViewInput*

### Creation

*GraphicsViewCircularArcInput<K>* *in*( *QObject* \**p*, *QGraphicsScene*\* *s*);

*p* is a parent object. *s* is the scene where the circular arc is generated.

### Signals

*void* *in.generate( Object o)*

The object *o* contains a *Circular\_arc\_2<K>*.

## CGAL::Qt::GraphicsItem

### Definition

The CGAL graphics items hold pointers to CGAL datastructures. When a datastructure changes, a signal is emitted. An object derived from type *GraphicsItem* must provide an implementation of the virtual slot *modelChanged()*. This typically triggers redrawing, as well as recomputation of the bounding box which in turn may trigger redrawing of overlapping graphics items.

```
#include <CGAL/Qt/GraphicsItem.h>
```

### Inherits From

*QGraphicsItem*

### Slots

<i>virtual void</i>	<i>gi.modelChanged()</i>	This slot must be provided by derived classes.
---------------------	--------------------------	--

## CGAL::Qt::CircularArcGraphicsItem<CK>

### Definition

An object of type *CircularArcGraphicsItem<CK>* is a graphics item that encapsulates a circular arc.

```
#include <CGAL/Qt/CircularArcGraphicsItem.h>
```

### Parameters

The template parameter of *CircularArcGraphicsItem<CK>* must be a CGAL *CircularKernel*.

### Inherits From

*Qt::GraphicsItem*

### Creation

```
CircularArcGraphicsItem<CK> cagi;
```

Constructs a graphics item for a circular arc.

### Operations

<i>QPen</i>	<i>cagi.edgesPen()</i>	Returns the pen used to draw edges.
-------------	------------------------	-------------------------------------

<i>void</i>	<i>cagi.setEdgesPen()</i>	Sets the pen used to draw edges.
-------------	---------------------------	----------------------------------

<i>void</i>	<i>cagi.setArc( Circular_arc_2&lt;CK&gt; ca2)</i>	Sets the circular arc.
-------------	---	------------------------

## CGAL::Qt::TriangulationGraphicsItem<T>

### Definition

An object of type *TriangulationGraphicsItem<T>* is a graphics item that encapsulates a 2D triangulation.

*#include <CGAL/Qt/TriangulationGraphicsItem.h>*

### Parameters

The template parameter of *TriangulationGraphicsItem<T>* must be a CGAL 2D triangulation class.

### Inherits From

*Qt::GraphicsItem*

### Creation

*TriangulationGraphicsItem<T> tgi( T\* t);*

Constructs a graphics item for a triangulation pointed by *t*.

### Operations

<i>QPen</i>	<i>tgi.verticesPen()</i>	Returns the pen used to draw vertices.
<i>void</i>	<i>tgi.setVerticesPen()</i>	Sets the pen used to draw vertices.
<i>QPen</i>	<i>tgi.edgesPen()</i>	Returns the pen used to draw edges.
<i>void</i>	<i>tgi.setEdgesPen()</i>	Sets the pen used to draw edges.
<i>bool</i>	<i>tgi.visibleVertices()</i>	Returns <i>true</i> , iff vertices are drawn.
<i>void</i>	<i>tgi.setVisibleVertices( bool b)</i>	Sets the property.
<i>bool</i>	<i>tgi.visibleEdges()</i>	Returns <i>true</i> , iff edges are drawn.
<i>void</i>	<i>tgi.setVisibleEdges( bool b)</i>	Sets the property.

## CGAL::Qt::ConstrainedTriangulationGraphicsItem<CT>

### Definition

An object of type *ConstrainedTriangulationGraphicsItem<CT>* is a graphics item that encapsulates a constrained triangulation.

```
#include <CGAL/Qt/ConstrainedTriangulationGraphicsItem.h>
```

### Parameters

The template parameter of *ConstrainedTriangulationGraphicsItem<CT>* must be a CGAL 2D constrained triangulation class.

### Inherits From

*Qt::TriangulationGraphicsItem*

### Creation

```
ConstrainedTriangulationGraphicsItem<CT> ctgi( CT* ct);
```

Constructs a graphics item for triangulation *ct*.

### Operations

<i>QPen</i>	<i>ctgi.constraintsPen()</i>	Returns the pen used to draw constraints.
-------------	------------------------------	---

<i>void</i>	<i>ctgi.setConstraintsPen()</i>	Sets the pen used to draw constraints.
-------------	---------------------------------	--

## CGAL::Qt::VoronoiGraphicsItem<DT>

### Definition

An object of type *VoronoiGraphicsItem<DT>* is a graphics item that encapsulates a Delaunay triangulation in order to draw its dual, the Voronoi diagram.

```
#include <CGAL/Qt/VoronoiGraphicsItem.h>
```

### Parameters

The template parameter *DT* of *VoronoiGraphicsItem<DT>* must be a CGAL 2D Delaunay triangulation class.

### Inherits From

*Qt::GraphicsItem*

### Creation

```
VoronoiGraphicsItem<DT> vgi( DT* dt);
```

Constructs a graphics item for the dual of the Delaunay triangulation *dt*.

### Operations

<i>QPen</i>	<i>vgi.edgesPen()</i>	Returns the pen used to draw edges.
<i>void</i>	<i>vgi.setEdgesPen()</i>	Set the pen used to draw edges.
<i>bool</i>	<i>vgi.visibleEdges()</i>	Returns <i>true</i> , iff edges are drawn.
<i>bool</i>	<i>vgi.setVisibleEdges( bool b)</i>	Set the property.

## CGAL::Qt::GraphicsViewNavigation

### Definition

An object of type *GraphicsViewNavigation* can be added as event filter to a *Qt::QGraphicsView* and its view-port.

Dragging the left mouse button while holding the 'Ctrl' key defines a zoom rectangle. Dragging the right mouse button while holding the 'Ctrl' key translates the scene. 'Ctrl-Shift' and a click of the right mouse button translates what is under the mouse to the center.

```
#include <CGAL/Qt/GraphicsViewNavigation.h>
```

### Operations

```
bool nav.eventFilter( QObject *obj, QEvent *event)
```

The event filter.

### Signals

```
void nav.mouseCoordinates( QPointF p)
```

Emits the real world mouse coordinates.
