}

```

## 3.17 Thermodynamic output options

The `Thermo` class computes and prints thermodynamic information to the screen and log file; see the files `thermo.cpp` and `thermo.h`.

There are four styles defined in `thermo.cpp`: “one”, “multi”, “yaml”, and “custom”. The “custom” style allows the user to explicitly list keywords for individual quantities to print when thermodynamic output is generated. The others have a fixed list of keywords. See the [thermo\\_style](#) command for a list of available quantities. The formatting of the “custom” style defaults to the “one” style, but can be adapted using [thermo\\_modify line](#).

The thermo styles (one, multi, etc) are defined by lists of keywords with associated formats for integer and floating point numbers and identified by an enumerator constant. Adding a new style thus mostly requires defining a new list of keywords and the associated formats and then inserting the required output processing where the enumerators are identified. Search for the word “CUSTOMIZATION” with references to “thermo style” in the `thermo.cpp` file to see the locations where code will need to be added. The member function `Thermo::header()` prints output at the very beginning of a thermodynamic output block and can be used to print column headers or other front matter. The member function `Thermo::footer()` prints output at the end of a thermodynamic output block. The formatting of the output is done by assembling a “line” (which may span multiple lines if the style inserts newline characters (“n” as in the “multi” style).

New thermodynamic keywords can also be added to `thermo.cpp` to compute new quantities for output. Search for the word “CUSTOMIZATION” with references to “keyword” in `thermo.cpp` to see the several locations where code will need to be added. Effectively, you need to define a member function that computes the property, add an if statement in `Thermo::parse_fields()` where the corresponding header string for the keyword and the function pointer is registered by calling the `Thermo::addfield()` method, and add an if statement in `Thermo::evaluate_keyword()` which is called from the `Variable` class when a thermo keyword is encountered.

---

**Note:** The third argument to `Thermo::addfield()` is a flag indicating whether the function for the keyword computes a floating point (FLOAT), regular integer (INT), or big integer (BIGINT) value. This information is used for formatting the thermodynamic output. Inside the function the result must then be stored either in the `dvalue`, `ivalue` or `bvalue` member variable, respectively.

---

Since the [thermo\\_style custom](#) command allows to use output of quantities calculated by [fixes](#), [computes](#), and [variables](#), it may often be simpler to compute what you wish via one of those constructs, rather than by adding a new keyword to the `thermo_style` command.

## 3.18 Variable options

The `Variable` class computes and stores [variable](#) information in LAMMPS; see the file `variable.cpp`. The value associated with a variable can be periodically printed to the screen via the [print](#), [fix print](#), or [thermo\\_style custom](#) commands. Variables of style “equal” can compute complex equations that involve the following types of arguments:

```
thermo keywords = ke, vol, atoms, ...
other variables = v_a, v_myvar, ...
math functions = div(x,y), mult(x,y), add(x,y), ...
group functions = mass(group), xcm(group,x), ...
atom values = x[123], y[3], vx[34], ...
compute values = c_mytemp[0], c_thermo_press[3], ...
```

Adding keywords for the [thermo\\_style custom](#) command (which can then be accessed by variables) is discussed in the [Modify thermo](#) documentation.

Adding a new math function of one or two arguments can be done by editing one section of the `Variable::evaluate()` method. Search for the word “customize” to find the appropriate location.

Adding a new group function can be done by editing one section of the `Variable::evaluate()` method. Search for the word “customize” to find the appropriate location. You may need to add a new method to the Group class as well (see the `group.cpp` file).

Accessing a new atom-based vector can be done by editing one section of the `Variable::evaluate()` method. Search for the word “customize” to find the appropriate location.

Adding new *compute styles* (whose calculated values can then be accessed by variables) is discussed in the *Modify compute* documentation.

## INFORMATION FOR DEVELOPERS

This section describes the internal structure and basic algorithms of the LAMMPS code. This is a work in progress and additional information will be added incrementally depending on availability of time and requests from the LAMMPS user community.

### 4.1 Source files

The source files of the LAMMPS code are found in two directories of the distribution: `src` and `lib`. Most of the code is written in C++ but there are small a number of files in several other languages like C, Fortran, Shell script, or Python.

The core of the code is located in the `src` folder and its subdirectories. A sizable number of these files are in the `src` directory itself, but there are plenty of *packages*, which can be included or excluded when LAMMPS is built. See the *Include packages in build* section of the manual for more information about that part of the build process. LAMMPS currently supports building with *conventional makefiles* and through *CMake*. Those procedures differ in how packages are enabled or disabled for inclusion into a LAMMPS binary, so they cannot be mixed. The source files for each package are in all-uppercase subdirectories of the `src` folder, for example `src/MOLECULE` or `src/EXTRA-MOLECULE`. The `src/STUBS` subdirectory is not a package but contains a dummy MPI library, that is used when building a serial version of the code. The `src/MAKE` directory and its subdirectories contain makefiles with settings and flags for a variety of configuration and machines for the build process with traditional makefiles.

The `lib` directory contains the source code for several supporting libraries or files with configuration settings to use globally installed libraries, that are required by some optional packages. They may include python scripts that can transparently download additional source code on request. Each subdirectory, like `lib/poems` or `lib/gpu`, contains the source files, some of which are in different languages such as Fortran or CUDA. These libraries included in the LAMMPS build, if the corresponding package is installed.

LAMMPS C++ source files almost always come in pairs, such as `src/run.cpp` (implementation file) and `src/run.h` (header file). Each pair of files defines a C++ class, for example the `LAMMPS_NS::Run` class, which contains the code invoked by the *run* command in a LAMMPS input script. As this example illustrates, source file and class names often have a one-to-one correspondence with a command used in a LAMMPS input script. Some source files and classes do not have a corresponding input script command, for example `src/force.cpp` and the `LAMMPS_NS::Force` class. They are discussed in the next section.

The names of all source files are in lower case and may use the underscore character ‘`_`’ to separate words. Apart from bundled, externally maintained libraries, which may have different conventions, all C and C++ header files have a `.h` extension, all C++ files have a `.cpp` extension, and C files a `.c` extension. A few C++ classes and utility functions are implemented with only a `.h` file. Examples are the Pointers and Commands classes or the MathVec functions.

## 4.2 Class topology

Though LAMMPS has a lot of source files and classes, its class topology is not very deep, which can be seen from the *LAMMPS class topology* figure. In that figure, each name refers to a class and has a pair of associated source files in the `src` folder, for example the class `LAMMPS_NS::Memory` corresponds to the files `memory.cpp` and `memory.h`, or the class `LAMMPS_NS::AtomVec` corresponds to the files `atom_vec.cpp` and `atom_vec.h`. Full lines in the figure represent compositing: that is, the class at the base of the arrow holds a pointer to an instance of the class at the tip. Dashed lines instead represent inheritance: the class at the tip of the arrow is derived from the class at the base. Classes with a red boundary are not instantiated directly, but they represent the base classes for “styles”. Those “styles” make up the bulk of the LAMMPS code and only a few representative examples are included in the figure, so it remains readable.

The `LAMMPS_NS::LAMMPS` class is the topmost class and represents what is generally referred to as an “instance of LAMMPS”. It is a composite holding pointers to instances of other core classes providing the core functionality of the MD engine in LAMMPS and through them abstractions of the required operations. The constructor of the LAMMPS class will instantiate those instances, process the command line flags, initialize MPI (if not already done) and set up file pointers for input and output. The destructor will shut everything down and free all associated memory. Thus code for the standalone LAMMPS executable in `main.cpp` simply initializes MPI, instantiates a single instance of LAMMPS while passing it the command line flags and input script. It deletes the LAMMPS instance after the method reading the input returns and shuts down the MPI environment before it exits the executable.

The `LAMMPS_NS::Pointers` class is not shown in the *LAMMPS class topology* figure for clarity. It holds references to many of the members of the `LAMMPS_NS::LAMMPS`, so that all classes derived from `LAMMPS_NS::Pointers` have direct access to those references. From the class topology all classes with blue boundary are referenced in the Pointers class and all classes in the second and third columns, that are not listed as derived classes, are instead derived from `LAMMPS_NS::Pointers`. To initialize the pointer references in Pointers, a pointer to the LAMMPS class instance needs to be passed to the constructor. All constructors for classes derived from it, must do so and thus pass that pointer to the constructor for `LAMMPS_NS::Pointers`. The default constructor for `LAMMPS_NS::Pointers` is disabled to enforce this.

Since all storage is supposed to be encapsulated (there are a few exceptions), the LAMMPS class can also be instantiated multiple times by a calling code. Outside the aforementioned exceptions, those LAMMPS instances can be used alternately. As of the time of this writing (early 2023) LAMMPS is not yet sufficiently thread-safe for concurrent execution. When running in parallel with MPI, care has to be taken, that suitable copies of communicators are used to not create conflicts between different instances.

The LAMMPS class currently holds instances of 19 classes representing the core functionality. There are a handful of virtual parent classes in LAMMPS that define what LAMMPS calls *styles*. These are shaded red in the *LAMMPS class topology* figure. Each of these are parents of a number of child classes that implement the interface defined by the parent class. There are two main categories of these styles: some may only have one instance active at a time (e.g. `atom`, `pair`, `bond`, `angle`, `dihedral`, `improper`, `kpace`, `comm`) and there is a dedicated pointer variable for each of them in the corresponding composite class. Setups that require a mix of different such styles have to use a *hybrid* class instance that acts as a proxy, and manages and forwards calls to the corresponding sub-style class instances for the designated subset of atoms or data. The composite class may also have lists of class instances, e.g. `Modify` handles lists of compute and fix styles, while `Output` handles a list of dump class instances.

The exception to this scheme are the `command` style classes. These implement specific commands that can be invoked before, after, or in between runs. For these an instance of the class is created, its `command()` method called and then, after completion, the class instance deleted. Examples for this are the `create_box`, `create_atoms`, `minimize`, `run`, `set`, or `velocity` command styles.

For all those styles, certain naming conventions are employed: for the `fix nve` command the class is called `FixNVE` and the source files are `fix_nve.h` and `fix_nve.cpp`. Similarly, for `fix ave/time` we have `FixAveTime` and `fix_ave_time.h` and `fix_ave_time.cpp`. Style names are lower case and without spaces or special characters. A suffix or words are appended with a forward slash ‘/’ which denotes a variant of the corresponding class without the suffix. To connect the style name and the class name, LAMMPS uses macros like: `AtomStyle()`, `PairStyle()`,

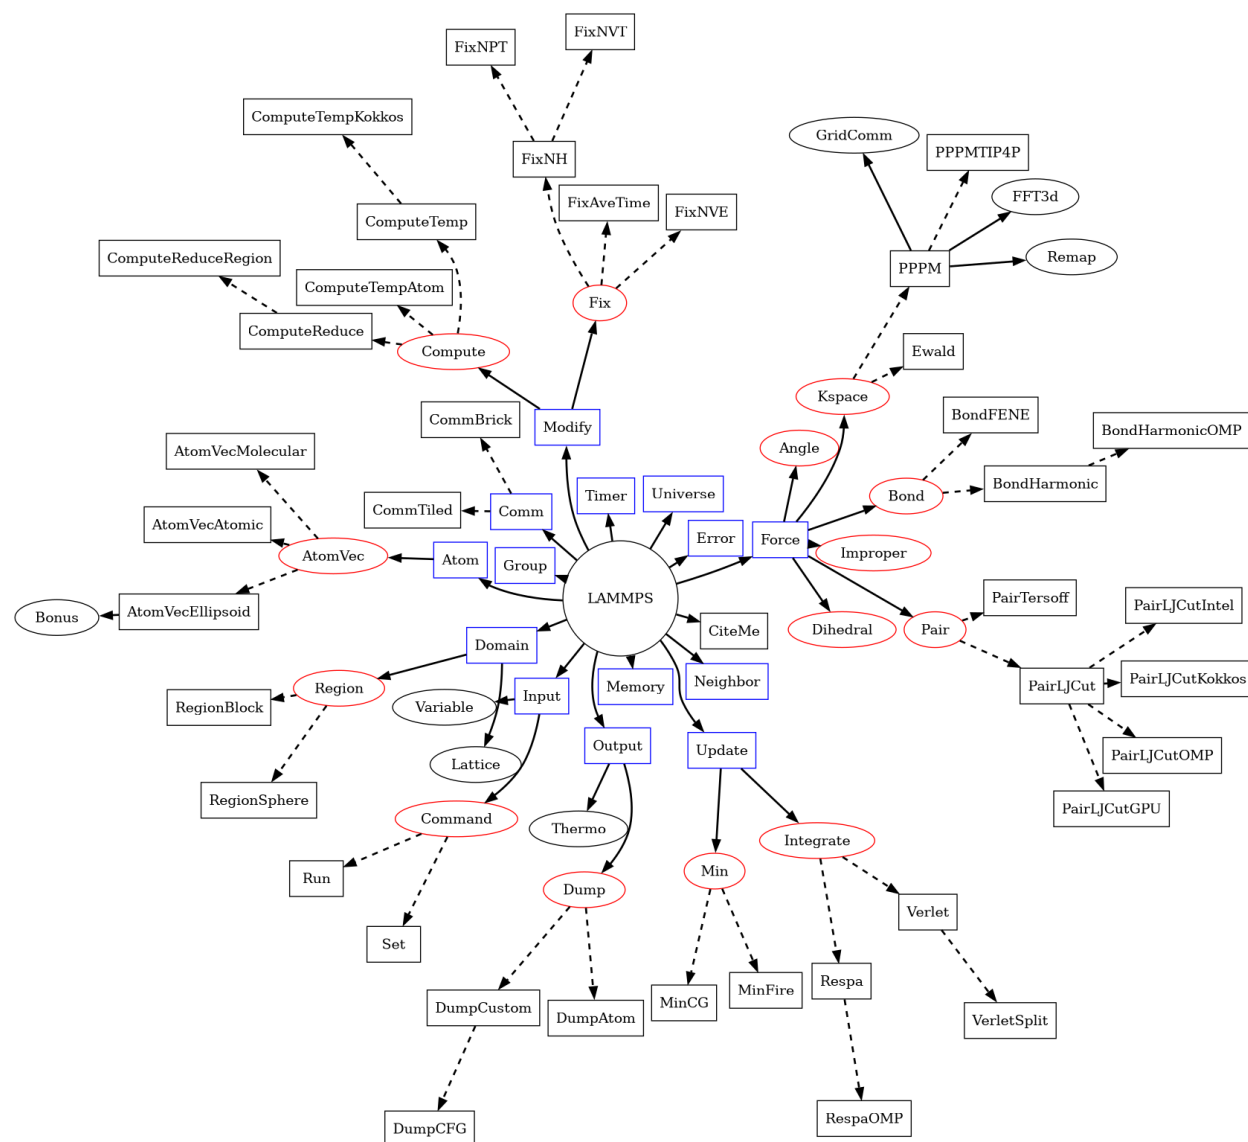

Fig. 1: LAMMPS class topology

BondStyle(), RegionStyle(), and so on in the corresponding header file. During configuration or compilation, files with the pattern `style_<name>.h` are created that consist of a list of include statements including all headers of all styles of a given type that are currently enabled (or “installed”).

More details on individual classes in the *LAMMPS class topology* are as follows:

- The Memory class handles allocation of all large vectors and arrays.
- The Error class prints all (terminal) error and warning messages.
- The Universe class sets up one or more partitions of processors so that one or multiple simulations can be run, on the processors allocated for a run, e.g. by the `mpirun` command.
- The Input class reads and processes input (strings and files), stores variables, and invokes *commands*.
- Command style classes are derived from the Command class. They provide input script commands that perform one-time operations before/after/between simulations or which invoke a simulation. They are usually instantiated from within the Input class, its `command` method invoked, and then immediately destructed.
- The Finish class is instantiated to print statistics to the screen after a simulation is performed, by commands like `run` and `minimize`.
- The Special class walks the bond topology of a molecular system to find first, second, third neighbors of each atom. It is invoked by several commands, like *read\_data*, *read\_restart*, or *replicate*.
- The Atom class stores per-atom properties associated with atom styles. More precisely, they are allocated and managed by a class derived from the AtomVec class, and the Atom class simply stores pointers to them. The classes derived from AtomVec represent the different atom styles, and they are instantiated through the *atom\_style* command.
- The Update class holds instances of an integrator and a minimizer class. The Integrate class is a parent style for the Verlet and r-RESPA time integrators, as defined by the *run\_style* command. The Min class is a parent style for various energy minimizers.
- The Neighbor class builds and stores neighbor lists. The NeighList class stores a single list (for all atoms). A NeighRequest class instance is created by pair, fix, or compute styles when they need a particular kind of neighbor list and use the NeighRequest properties to select the neighbor list settings for the given request. There can be multiple instances of the NeighRequest class. The Neighbor class will try to optimize how the requests are processed. Depending on the NeighRequest properties, neighbor lists are constructed from scratch, aliased, or constructed by post-processing an existing list into sub-lists.
- The Comm class performs inter-processor communication, typically of ghost atom information. This usually involves MPI message exchanges with 6 neighboring processors in the 3d logical grid of processors mapped to the simulation box. There are two *communication styles*, enabling different ways to perform the domain decomposition.
- The Irregular class is used, when atoms may migrate to arbitrary processors.
- The Domain class stores the simulation box geometry, as well as geometric Regions and any user definition of a Lattice. The latter are defined by the *region* and *lattice* commands in an input script.
- The Force class computes various forces between atoms. The Pair parent class is for non-bonded or pairwise forces, which in LAMMPS also includes many-body forces such as the Tersoff 3-body potential if those are computed by walking pairwise neighbor lists. The Bond, Angle, Dihedral, Improper parent classes are styles for bonded interactions within a static molecular topology. The KSpace parent class is for computing long-range Coulombic interactions. One of its child classes, PPPM, uses the FFT3D and Remap classes to redistribute and communicate grid-based information across the parallel processors.
- The Modify class stores lists of class instances derived from the *Fix* and *Compute* base classes.
- The Group class manipulates groups that atoms are assigned to via the *group* command. It also has functions to compute various attributes of groups of atoms.

- The Output class is used to generate 3 kinds of output from a LAMMPS simulation: thermodynamic information printed to the screen and log file, dump file snapshots, and restart files. These correspond to the *Thermo*, *Dump*, and *WriteRestart* classes respectively. The Dump class is a base class, with several derived classes implementing various dump style variants.
- The Timer class logs timing information, output at the end of a run.

## 4.3 Code design

This section explains some code design choices in LAMMPS with the goal of helping developers write new code similar to the existing code. Please see the section on *Requirements for contributed code* for more specific recommendations and guidelines. While that section is organized more in the form of a checklist for code contributors, the focus here is on overall code design strategy, choices made between possible alternatives, and discussing some relevant C++ programming language constructs.

Historically, the basic design philosophy of the LAMMPS C++ code was a “C with classes” style. The motivation was to make it easy to modify LAMMPS for people without significant training in C++ programming. Data structures and code constructs were used that resemble the previous implementation(s) in Fortran. A contributing factor to this choice was that at the time, C++ compilers were often not mature and some advanced features contained bugs or did not function as the standard required. There were also disagreements between compiler vendors as to how to interpret the C++ standard documents.

However, C++ compilers and the C++ programming language have advanced significantly. In 2020, the LAMMPS developers decided to require the C++11 standard as the minimum C++ language standard for LAMMPS. Since then, we have begun to replace C-style constructs with equivalent C++ functionality. This was taken either from the C++ standard library or implemented as custom classes or functions. The goal is to improve readability of the code and to increase code reuse through abstraction of commonly used functionality.

---

**Note:** Please note that as of spring 2023 there is still a sizable chunk of legacy code in LAMMPS that has not yet been refactored to reflect these style conventions in full. LAMMPS has a large code base and many contributors. There is also a hierarchy of precedence in which the code is adapted. Highest priority has been the code in the `src` folder, followed by code in packages in order of their popularity and complexity (simpler code gets adapted sooner), followed by code in the `lib` folder. Source code that is downloaded from external packages or libraries during compilation is not subject to the conventions discussed here.

---

### 4.3.1 Object-oriented code

LAMMPS is designed to be an object-oriented code. Each simulation is represented by an instance of the LAMMPS class. When running in parallel, each MPI process creates such an instance. This can be seen in the `main.cpp` file where the core steps of running a LAMMPS simulation are the following 3 lines of code:

```
LAMMPS *lammps = new LAMMPS(argc, argv, lammps_comm);
lammps->input->file();
delete lammps;
```

The first line creates a LAMMPS class instance and passes the command line arguments and the global communicator to its constructor. The second line triggers the LAMMPS instance to process the input (either from standard input or a provided input file) until the simulation ends. The third line deletes the LAMMPS instance. The remainder of the `main.cpp` file has code for error handling, MPI configuration, and other special features.

The basic LAMMPS class hierarchy which is created by the LAMMPS class constructor is shown in *LAMMPS class topology*. When input commands are processed, additional class instances are created, or deleted, or replaced. Like-

wise, specific member functions of specific classes are called to trigger actions such as creating atoms, computing forces, computing properties, time-propagating the system, or writing output.

## Compositing and Inheritance

LAMMPS makes extensive use of the object-oriented programming (OOP) principles of *compositing* and *inheritance*. Classes like the LAMMPS class are a **composite** containing pointers to instances of other classes like `Atom`, `Comm`, `Force`, `Neighbor`, `Modify`, and so on. Each of these classes implements certain functionality by storing and manipulating data related to the simulation and providing member functions that trigger certain actions. Some of those classes like `Force` are themselves composites, containing instances of classes describing different force interactions. Similarly, the `Modify` class contains a list of `Fix` and `Compute` classes. If the input commands that correspond to these classes include the word *style*, then LAMMPS stores only a single instance of that class. E.g. *atom\_style*, *comm\_style*, *pair\_style*, *bond\_style*. If the input command does **not** include the word *style*, then there may be many instances of that class defined, for example *region*, *fix*, *compute*, *dump*.

**Inheritance** enables creation of *derived* classes that can share common functionality in their base class while providing a consistent interface. The derived classes replace (dummy or pure) functions in the base class. The higher level classes can then call those methods of the instantiated classes without having to know which specific derived class variant was instantiated. In LAMMPS these derived classes are often referred to as “styles”, e.g. pair styles, fix styles, atom styles and so on.

This is the origin of the flexibility of LAMMPS. For example, pair styles implement a variety of different non-bonded interatomic potentials functions. All details for the implementation of a potential are stored and executed in a single class.

As mentioned above, there can be multiple instances of classes derived from the `Fix` or `Compute` base classes. They represent a different facet of LAMMPS’ flexibility, as they provide methods which can be called at different points within a timestep, as explained in the [How a timestep works](#) doc page. This allows the input script to tailor how a specific simulation is run, what diagnostic computations are performed, and how the output of those computations is further processed or output.

Additional code sharing is possible by creating derived classes from the derived classes (e.g., to implement an accelerated version of a pair style) where only a subset of the derived class methods are replaced with accelerated versions.

## Polymorphism

Polymorphism and dynamic dispatch are another OOP feature that play an important role in how LAMMPS selects what code to execute. In a nutshell, this is a mechanism where the decision of which member function to call from a class is determined at runtime and not when the code is compiled. To enable it, the function has to be declared as `virtual` and all corresponding functions in derived classes should use the `override` property. Below is a brief example.

```
class Base {
public:
    virtual ~Base() = default;
    void call();
    void normal();
    virtual void poly();
};

void Base::call() {
    normal();
    poly();
}
```

(continues on next page)

(continued from previous page)

```

class Derived : public Base {
public:
  ~Derived() override = default;
  void normal();
  void poly() override;
};

// [...]

Base *base1 = new Base();
Base *base2 = new Derived();

base1->call();
base2->call();

```

The difference in behavior of the `normal()` and the `poly()` member functions is which of the two member functions is called when executing `base1->call()` versus `base2->call()`. Without polymorphism, a function within the base class can only call member functions within the same scope: that is, `Base::call()` will always call `Base::normal()`. But for the `base2->call()` case, the call of the virtual member function will be dispatched to `Derived::poly()` instead. This mechanism results in calling functions that are within the scope of the class that was used to *create* the instance, even if they are assigned to a pointer for their base class. This is the desired behavior, and this way LAMMPS can even use styles that are loaded at runtime from a shared object file with the *plugin command*.

A special case of virtual functions are so-called pure functions. These are virtual functions that are initialized to 0 in the class declaration (see example below).

```

class Base {
public:
  virtual void pure() = 0;
};

```

This has the effect that an instance of the base class cannot be created and that derived classes **must** implement these functions. Many of the functions listed with the various class styles in the section *Modifying & extending LAMMPS* are pure functions. The motivation for this is to define the interface or API of the functions, but defer their implementation to the derived classes.

However, there are downsides to this. For example, calls to virtual functions from within a constructor, will *not* be in the scope of the derived class, and thus it is good practice to either avoid calling them or to provide an explicit scope such as `Base::poly()` or `Derived::poly()`. Furthermore, any destructors in classes containing virtual functions should be declared virtual too, so they will be processed in the expected order before types are removed from dynamic dispatch.

---

### Important Notes

In order to be able to detect incompatibilities at compile time and to avoid unexpected behavior, it is crucial that all member functions that are intended to replace a virtual or pure function use the `override` property keyword. For the same reason, the use of overloads or default arguments for virtual functions should be avoided, as they lead to confusion over which function is supposed to override which, and which arguments need to be declared.

---

## Style Factories

In order to create class instances for different styles, LAMMPS often uses a programming pattern called *Factory*. Those are functions that create an instance of a specific derived class, say `PairLJCut` and return a pointer to the type of the common base class of that style, `Pair` in this case. To associate the factory function with the style keyword, a `std::map` class is used with function pointers indexed by their keyword (for example “lj/cut” for `PairLJCut` and “morse” for `PairMorse`). A couple of typedefs help keep the code readable, and a template function is used to implement the actual factory functions for the individual classes. Below is an example of such a factory function from the `Force` class as declared in `force.h` and implemented in `force.cpp`. The file `style_pair.h` is generated during compilation and includes all main header files (i.e. those starting with `pair_`) of pair styles and then the macro `PairStyle()` will associate the style name “lj/cut” with a factory function creating an instance of the `PairLJCut` class.

```
// from force.h
typedef Pair *(*PairCreator)(LAMMPS *);
typedef std::map<std::string, PairCreator> PairCreatorMap;
PairCreatorMap *pair_map;

// from force.cpp
template <typename S, typename T> static S *style_creator(LAMMPS *lmp)
{
    return new T(lmp);
}

// [...]

pair_map = new PairCreatorMap();

#define PAIR_CLASS
#define PairStyle(key, Class) (*pair_map)[#key] = &style_creator<Pair, Class>;
#include "style_pair.h"
#undef PairStyle
#undef PAIR_CLASS

// from pair_lj_cut.h

#ifdef PAIR_CLASS
PairStyle(lj/cut, PairLJCut);
#else
// [...]
```

Similar code constructs are present in other files like `modify.cpp` and `modify.h` or `neighbor.cpp` and `neighbor.h`. Those contain similar macros and include `style_*.h` files for creating class instances of styles they manage.

## 4.3.2 I/O and output formatting

### C-style stdio versus C++ style iostreams

LAMMPS uses the “stdio” library of the standard C library for reading from and writing to files and console instead of C++ “iostreams”. This is mainly motivated by better performance, better control over formatting, and less effort to achieve specific formatting.

Since mixing “stdio” and “iostreams” can lead to unexpected behavior, use of the latter is strongly discouraged. Output to the screen should *not* use the predefined `stdout` FILE pointer, but rather the `screen` and `logfile` FILE pointers

managed by the LAMMPS class. Furthermore, output should generally only be done by MPI rank 0 (`comm->me == 0`). Output that is sent to both screen and logfile should use the `utils::logmesg()` convenience function.

We discourage the use of stringstream because the bundled `{fmt}` library and the customized tokenizer classes provide the same functionality in a cleaner way with better performance. This also helps maintain a consistent programming syntax with code from many different contributors.

## Formatting with the `{fmt}` library

The LAMMPS source code includes a copy of the `{fmt}` library, which is preferred over formatting with the “`printf()`” family of functions. The primary reason is that it allows a typesafe default format for any type of supported data. This is particularly useful for formatting integers of a given size (32-bit or 64-bit) which may require different format strings depending on compile time settings or compilers/operating systems. Furthermore, `{fmt}` gives better performance, has more functionality, a familiar formatting syntax that has similarities to `format()` in Python, and provides a facility that can be used to integrate format strings and a variable number of arguments into custom functions in a much simpler way than the varargs mechanism of the C library. Finally, `{fmt}` has been included into the C++20 language standard, so changes to adopt it are future-proof.

Formatted strings are frequently created by calling the `fmt::format()` function, which will return a string as a `std::string` class instance. In contrast to the `%` placeholder in `printf()`, the `{fmt}` library uses `{}` to embed format descriptors. In the simplest case, no additional characters are needed, as `{fmt}` will choose the default format based on the data type of the argument. Otherwise, the `fmt::print()` function may be used instead of `printf()` or `fprintf()`. In addition, several LAMMPS output functions, that originally accepted a single string as argument have been overloaded to accept a format string with optional arguments as well (e.g., `Error::all()`, `Error::one()`, `utils::logmesg()`).

## Summary of the `{fmt}` format syntax

The syntax of the format string is “`{[<argument id>]:<format spec>}`”, where either the argument id or the format spec (separated by a colon ‘:’) is optional. The argument id is usually a number starting from 0 that is the index to the arguments following the format string. By default, these are assigned in order (i.e. 0, 1, 2, 3, 4 etc.). The most common case for using argument id would be to use the same argument in multiple places in the format string without having to provide it as an argument multiple times. The argument id is rarely used in the LAMMPS source code.

More common is the use of a format specifier, which starts with a colon. This may optionally be followed by a fill character (default is ‘ ’). If provided, the fill character **must** be followed by an alignment character (‘<’, ‘^’, ‘>’ for left, centered, or right alignment (default)). The alignment character may be used without a fill character. The next important format parameter would be the minimum width, which may be followed by a dot ‘.’ and a precision for floating point numbers. The final character in the format string would be an indicator for the “presentation”, i.e. ‘d’ for decimal presentation of integers, ‘x’ for hexadecimal, ‘o’ for octal, ‘c’ for character etc. This mostly follows the “`printf()`” scheme, but without requiring an additional length parameter to distinguish between different integer widths. The `{fmt}` library will detect those and adapt the formatting accordingly. For floating point numbers there are correspondingly, ‘g’ for generic presentation, ‘e’ for exponential presentation, and ‘f’ for fixed point presentation.

The format string “`{:8}`” would thus represent *any* type argument and be replaced by at least 8 characters; “`{:<8}`” would do this as left aligned, “`{:^8}`” as centered, “`{:>8}`” as right aligned. If a specific presentation is selected, the argument type must be compatible or else the `{fmt}` formatting code will throw an exception. Some format string examples are given below:

```
auto mesg = fmt::format(" CPU time: {:4d}:{:02d}:{:02d}\n", cpuh, cpum, cpus);
mesg = fmt::format("{:<8s} | {:<10.5g} | {:<10.5g} | {:<10.5g} |{:6.1f} |{:6.2f}\n",
                  label, time_min, time, time_max, time_sq, tmp);
utils::logmesg(lmp, "{:>6} = max # of 1-2 neighbors\n", maxall);
```

(continues on next page)

(continued from previous page)

```
utils::logmesg(lmp, "Lattice spacing in x,y,z = {:.8} {:.8} {:.8}\n",
               xlattice, ylattice, zlattice);
```

which will create the following output lines:

```
CPU time:    0:02:16
Pair      | 2.0133      | 2.0133      | 2.0133      | 0.0 | 84.21
          4 = max # of 1-2 neighbors
Lattice spacing in x,y,z = 1.6795962 1.6795962 1.6795962
```

Finally, a special feature of the `{fmt}` library is that format parameters like the width or the precision may be also provided as arguments. In that case a nested format is used where a pair of curly braces (with an optional argument id) “{ }” are used instead of the value, for example “{: { }d}” will consume two integer arguments, the first will be the value shown and the second the minimum width.

For more details and examples, please consult the [{fmt} syntax documentation](#) website.

### 4.3.3 Memory management

Dynamical allocation of small data and objects can be done with the C++ commands “new” and “delete/delete[]”. Large data should use the member functions of the `Memory` class, most commonly, `Memory::create()`, `Memory::grow()`, and `Memory::destroy()`, which provide variants for vectors, 2d arrays, 3d arrays, etc. These can also be used for small data.

The use of `malloc()`, `calloc()`, `realloc()` and `free()` directly is strongly discouraged. To simplify adapting legacy code into the LAMMPS code base the member functions `Memory::smalloc()`, `Memory::srealloc()`, and `Memory::sfree()` are available, which perform additional error checks for safety.

Use of these custom memory allocation functions is motivated by the following considerations:

- Memory allocation failures on *any* MPI rank during a parallel run will trigger an immediate abort of the entire parallel calculation.
- A failing “new” will trigger an exception, which is also captured by LAMMPS and triggers a global abort.
- Allocation of multidimensional arrays will be done in a C compatible fashion, but such that the storage of the actual data is stored in one large contiguous block. Thus, when MPI communication is needed, the data can be communicated directly (similar to Fortran arrays).
- The “destroy()” and “sfree()” functions may safely be called on NULL pointers.
- The “destroy()” functions will nullify the pointer variables, thus making “use after free” errors easy to detect.
- It is possible to use a larger than default memory alignment (not on all operating systems, since the allocated storage pointers must be compatible with `free()` for technical reasons).

In the practical implementation of code this means, that any pointer variables, that are class members should be initialized to a `nullptr` value in their respective constructors. That way, it is safe to call `Memory::destroy()` or `delete[]` on them before *any* allocation outside the constructor. This helps prevent memory leaks.

## 4.4 Parallel algorithms

LAMMPS is designed to enable running simulations in parallel using the MPI parallel communication standard with distributed data via domain decomposition. The parallelization aims to be efficient, and resulting in good strong scaling (= good speedup for the same system) and good weak scaling (= the computational cost of enlarging the system is proportional to the system size). Additional parallelization using GPUs or OpenMP can also be applied within the subdomain assigned to an MPI process. For clarity, most of the following illustrations show the 2d simulation case. The underlying algorithms in those cases, however, apply to both 2d and 3d cases equally well.

---

**Note:** The text and most of the figures in this chapter were adapted for the manual from the section on parallel algorithms in the *new LAMMPS paper*.

---

### 4.4.1 Partitioning

The underlying spatial decomposition strategy used by LAMMPS for distributed-memory parallelism is set with the *comm\_style* command and can be either “brick” (a regular grid) or “tiled”.

Fig. 2: Domain decomposition schemes

This figure shows the different kinds of domain decomposition used for MPI parallelization: “brick” on the left with an orthogonal (left) and a triclinic (middle) simulation domain, and a “tiled” decomposition (right). The black lines show the division into subdomains, and the contained atoms are “owned” by the corresponding MPI process. The green dashed lines indicate how subdomains are extended with “ghost” atoms up to the communication cutoff distance.

The LAMMPS simulation box is a 3d or 2d volume, which can be of orthogonal or triclinic shape, as illustrated in the *Domain decomposition schemes* figure for the 2d case. Orthogonal means the box edges are aligned with the  $x$ ,  $y$ ,  $z$  Cartesian axes, and the box faces are thus all rectangular. Triclinic allows for a more general parallelepiped shape in which edges are aligned with three arbitrary vectors and the box faces are parallelograms. In each dimension, box faces can be periodic, or non-periodic with fixed or shrink-wrapped boundaries. In the fixed case, atoms which move outside the face are deleted; shrink-wrapped means the position of the box face adjusts continuously to enclose all the atoms.

For distributed-memory MPI parallelism, the simulation box is spatially decomposed (partitioned) into non-overlapping subdomains which fill the box. The default partitioning, “brick”, is most suitable when atom density is roughly uniform, as shown in the left-side images of the *Domain decomposition schemes* figure. The subdomains comprise a regular grid, and all subdomains are identical in size and shape. Both the orthogonal and triclinic boxes can deform continuously during a simulation, e.g. to compress a solid or shear a liquid, in which case the processor subdomains likewise deform.

For models with non-uniform density, the number of particles per processor can be load-imbalanced with the default partitioning. This reduces parallel efficiency, as the overall simulation rate is limited by the slowest processor, i.e. the one with the largest computational load. For such models, LAMMPS supports multiple strategies to reduce the load imbalance:

- The processor grid decomposition is by default based on the simulation cell volume and tries to optimize the volume to surface ratio for the subdomains. This can be changed with the *processors* command.
- The parallel planes defining the size of the subdomains can be shifted with the *balance* command. Which can be done in addition to choosing a more optimal processor grid.
- The recursive bisectioning algorithm in combination with the “tiled” communication style can produce a partitioning with equal numbers of particles in each subdomain.

The pictures above demonstrate different decompositions for a 2d system with 12 MPI ranks. The atom colors indicate the load imbalance of each subdomain, with green being optimal and red the least optimal.

Due to the vacuum in the system, the default decomposition is unbalanced, with several MPI ranks without atoms (left). By forcing a 1x12x1 processor grid, every MPI rank does computations now, but the number of atoms per subdomain is still uneven, and the thin slice shape increases the amount of communication between subdomains (center left). With a 2x6x1 processor grid and shifting the subdomain divisions, the load imbalance is further reduced and the amount of communication required between subdomains is less (center right). And using the recursive bisectioning leads to further improved decomposition (right).

#### 4.4.2 Communication

Following the selected partitioning scheme, all per-atom data is distributed across the MPI processes, which allows LAMMPS to handle very large systems provided it uses a correspondingly large number of MPI processes. To be able to compute the short-range interactions, MPI processes need not only access to the data of atoms they “own” but also information about atoms from neighboring subdomains, in LAMMPS referred to as “ghost” atoms. These are copies of atoms storing required per-atom data for up to the communication cutoff distance. The green dashed-line boxes in the *Domain decomposition schemes* figure illustrate the extended ghost-atom subdomain for one processor.

This approach is also used to implement periodic boundary conditions: atoms that lie within the cutoff distance across a periodic boundary are also stored as ghost atoms and taken from the periodic replication of the subdomain, which may be the same subdomain, e.g. if running in serial. As a consequence of this, force computation in LAMMPS is not subject to minimum image conventions and thus cutoffs may be larger than half the simulation domain.

Efficient communication patterns are needed to update the “ghost” atom data, since that needs to be done at every MD time step or minimization step. The diagrams of the *ghost atom communication* figure illustrate how ghost atom communication is performed in two stages for a 2d simulation (three in 3d) for both a regular and irregular partitioning of the simulation box. For the regular case (left) atoms are exchanged first in the  $x$ -direction, then in  $y$ , with four neighbors in the grid of processor subdomains.

In the  $x$  stage, processor ranks 1 and 2 send owned atoms in their red-shaded regions to rank 0 (and vice versa). Then in the  $y$  stage, ranks 3 and 4 send atoms in their blue-shaded regions to rank 0, which includes ghost atoms they received in the  $x$  stage. Rank 0 thus acquires all its ghost atoms; atoms in the solid blue corner regions are communicated twice before rank 0 receives them.

For the irregular case (right) the two stages are similar, but a processor can have more than one neighbor in each direction. In the  $x$  stage, MPI ranks 1,2,3 send owned atoms in their red-shaded regions to rank 0 (and vice versa). These include only atoms between the lower and upper  $y$ -boundary of rank 0’s subdomain. In the  $y$  stage, ranks 4,5,6

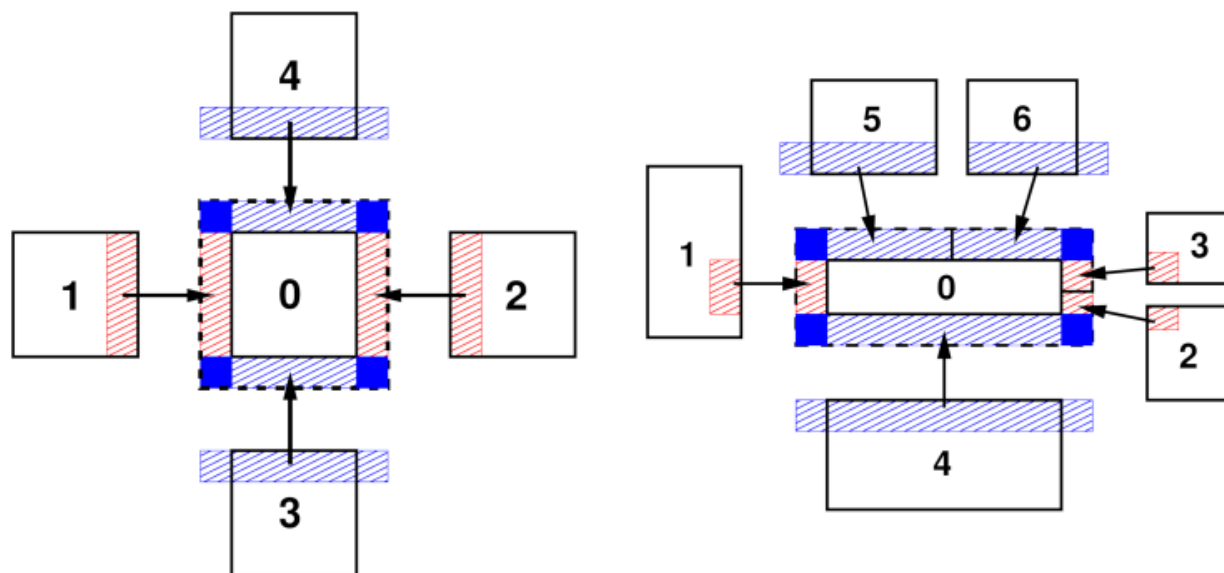

Fig. 3: ghost atom communication

This figure shows the ghost atom communication patterns between subdomains for “brick” (left) and “tiled” communication styles for 2d simulations. The numbers indicate MPI process ranks. Here the subdomains are drawn spatially separated for clarity. The dashed-line box is the extended subdomain of processor 0 which includes its ghost atoms. The red- and blue-shaded boxes are the regions of communicated ghost atoms.

send atoms in their blue-shaded regions to rank 0. This may include ghost atoms they received in the  $x$  stage, but only if they are needed by rank 0 to fill its extended ghost atom regions in the  $\pm y$  directions (blue rectangles). Thus, in this case, ranks 5 and 6 do not include ghost atoms they received from each other (in the  $x$  stage) in the atoms they send to rank 0. The key point is that while the pattern of communication is more complex in the irregular partitioning case, it can still proceed in two stages (three in 3d) via atom exchanges with only neighboring processors.

When attributes of owned atoms are sent to neighboring processors to become attributes of their ghost atoms, LAMMPS calls this a “forward” communication. On timesteps when atoms migrate to new owning processors and neighbor lists are rebuilt, each processor creates a list of its owned atoms which are ghost atoms in each of its neighbor processors. These lists are used to pack per-atom coordinates (for example) into message buffers in subsequent steps until the next reneighboring.

A “reverse” communication is when computed ghost atom attributes are sent back to the processor who owns the atom. This is used (for example) to sum partial forces on ghost atoms to the complete force on owned atoms. The order of the two stages described in the *ghost atom communication* figure is inverted, and the same lists of atoms are used to pack and unpack message buffers with per-atom forces. When a received buffer is unpacked, the ghost forces are summed to owned atom forces. As in forward communication, forces on atoms in the four blue corners of the diagrams are sent, received, and summed twice (once at each stage) before owning processors have the full force.

These two operations are used in many places within LAMMPS aside from exchange of coordinates and forces, for example by manybody potentials to share intermediate per-atom values, or by rigid-body integrators to enable each atom in a body to access body properties. Here are additional details about how these communication operations are performed in LAMMPS:

- When exchanging data with different processors, forward and reverse communication is done using `MPI_Send()` and `MPI_IRecv()` calls. If a processor is “exchanging” atoms with itself, only the pack and unpack operations are performed, e.g. to create ghost atoms across periodic boundaries when running on a single processor.
- For forward communication of owned atom coordinates, periodic box lengths are added and subtracted when the receiving processor is across a periodic boundary from the sender. There is then no need to apply a minimum image convention when calculating distances between atom pairs when building neighbor lists or computing

forces.

- The cutoff distance for exchanging ghost atoms is typically equal to the neighbor cutoff. But it can also be set to a larger value if needed, e.g. half the diameter of a rigid body composed of multiple atoms or over 3x the length of a stretched bond for dihedral interactions. It can also exceed the periodic box size. For the regular communication pattern (left), if the cutoff distance extends beyond a neighbor processor's subdomain, then multiple exchanges are performed in the same direction. Each exchange is with the same neighbor processor, but buffers are packed/unpacked using a different list of atoms. For forward communication, in the first exchange, a processor sends only owned atoms. In subsequent exchanges, it sends ghost atoms received in previous exchanges. For the irregular pattern (right) overlaps of a processor's extended ghost-atom subdomain with all other processors in each dimension are detected.

### 4.4.3 Neighbor lists

To compute forces efficiently, each processor creates a Verlet-style neighbor list which enumerates all pairs of atoms  $i, j$  ( $i$  = owned,  $j$  = owned or ghost) with separation less than the applicable neighbor list cutoff distance. In LAMMPS, the neighbor lists are stored in a multiple-page data structure; each page is a contiguous chunk of memory which stores vectors of neighbor atoms  $j$  for many  $i$  atoms. This allows pages to be incrementally allocated or deallocated in blocks as needed. Neighbor lists typically consume the most memory of any data structure in LAMMPS. The neighbor list is rebuilt (from scratch) once every few timesteps, then used repeatedly each step for force or other computations. The neighbor cutoff distance is  $R_n = R_f + \Delta_s$ , where  $R_f$  is the (largest) force cutoff defined by the interatomic potential for computing short-range pairwise or manybody forces and  $\Delta_s$  is a “skin” distance that allows the list to be used for multiple steps assuming that atoms do not move very far between consecutive time steps. Typically, the code triggers reneighboring when any atom has moved half the skin distance since the last reneighboring; this and other options of the neighbor list rebuild can be adjusted with the `neigh_modify` command.

On steps when reneighboring is performed, atoms which have moved outside their owning processor's subdomain are first migrated to new processors via communication. Periodic boundary conditions are also (only) enforced on these steps to ensure each atom is re-assigned to the correct processor. After migration, the atoms owned by each processor are stored in a contiguous vector. Periodically, each processor spatially sorts owned atoms within its vector to reorder it for improved cache efficiency in force computations and neighbor list building. For that, atoms are spatially binned and then reordered so that atoms in the same bin are adjacent in the vector. Atom sorting can be disabled or its settings modified with the `atom_modify` command.

Fig. 4: neighbor list stencils

A 2d simulation subdomain (thick black line) and the corresponding ghost atom cutoff region (dashed blue line) for both orthogonal (left) and triclinic (right) domains. A regular grid of neighbor bins (thin lines) overlays the entire simulation domain and need not align with subdomain boundaries; only the portion overlapping the augmented subdomain is shown. In the triclinic case, it overlaps the bounding box of the tilted rectangle. The blue- and red-shaded bins represent a stencil of bins searched to find neighbors of a particular atom (black dot).

To build a local neighbor list in linear time, the simulation domain is overlaid (conceptually) with a regular 3d (or

2d) grid of neighbor bins, as shown in the *neighbor list stencils* figure for 2d models and a single MPI processor's subdomain. Each processor stores a set of neighbor bins which overlap its subdomain, extended by the neighbor cutoff distance  $R_n$ . As illustrated, the bins need not align with processor boundaries; an integer number in each dimension is fit to the size of the entire simulation box.

Most often, LAMMPS builds what is called a “half” neighbor list where each  $i,j$  neighbor pair is stored only once, with either atom  $i$  or  $j$  as the central atom. The build can be done efficiently by using a pre-computed “stencil” of bins around a central origin bin which contains the atom whose neighbors are being searched for. A stencil is simply a list of integer offsets in  $x,y,z$  of nearby bins surrounding the origin bin which are close enough to contain any neighbor atom  $j$  within a distance  $R_n$  from any atom  $i$  in the origin bin. Note that for a half neighbor list, the stencil can be asymmetric, since each atom only need store half its nearby neighbors.

These stencils are illustrated in the figure for a half list and a bin size of  $\frac{1}{2}R_n$ . There are 13 red+blue stencil bins in 2d (for the orthogonal case, 15 for triclinic). In 3d there would be 63, 13 in the plane of bins that contain the origin bin and 25 in each of the two planes above it in the  $z$  direction (75 for triclinic). The triclinic stencil has extra bins because the bins tile the bounding box of the entire triclinic domain, and thus are not periodic with respect to the simulation box itself. The stencil and logic for determining which  $i,j$  pairs to include in the neighbor list are altered slightly to account for this.

To build a neighbor list, a processor first loops over its “owned” plus “ghost” atoms and assigns each to a neighbor bin. This uses an integer vector to create a linked list of atom indices within each bin. It then performs a triply-nested loop over its owned atoms  $i$ , the stencil of bins surrounding atom  $i$ 's bin, and the  $j$  atoms in each stencil bin (including ghost atoms). If the distance  $r_{ij} < R_n$ , then atom  $j$  is added to the vector of atom  $i$ 's neighbors.

Here are additional details about neighbor list build options LAMMPS supports:

- The choice of bin size is an option; a size half of  $R_n$  has been found to be optimal for many typical cases. Smaller bins incur additional overhead to loop over; larger bins require more distance calculations. Note that for smaller bin sizes, the 2d stencil in the figure would be of a more semicircular shape (hemispherical in 3d), with bins near the corners of the square eliminated due to their distance from the origin bin.
- Depending on the interatomic potential(s) and other commands used in an input script, multiple neighbor lists and stencils with different attributes may be needed. This includes lists with different cutoff distances, e.g. for force computation versus occasional diagnostic computations such as a radial distribution function, or for the r-RESPA time integrator which can partition pairwise forces by distance into subsets computed at different time intervals. It includes “full” lists (as opposed to half lists) where each  $i,j$  pair appears twice, stored once with  $i$  and  $j$ , and which use a larger symmetric stencil. It also includes lists with partial enumeration of ghost atom neighbors. The full and ghost-atom lists are used by various manybody interatomic potentials. Lists may also use different criteria for inclusion of a pairwise interaction. Typically, this simply depends only on the distance between two atoms and the cutoff distance. But for finite-size coarse-grained particles with individual diameters (e.g. polydisperse granular particles), it can also depend on the diameters of the two particles.
- When using *pair style hybrid* multiple sub-lists of the master neighbor list for the full system need to be generated, one for each sub-style, which contains only the  $i,j$  pairs needed to compute interactions between subsets of atoms for the corresponding potential. This means, not all  $i$  or  $j$  atoms owned by a processor are included in a particular sub-list.
- Some models use different cutoff lengths for pairwise interactions between different kinds of particles, which are stored in a single neighbor list. One example is a solvated colloidal system with large colloidal particles where colloid/colloid, colloid/solvent, and solvent/solvent interaction cutoffs can be dramatically different. Another is a model of polydisperse finite-size granular particles; pairs of particles interact only when they are in contact with each other. Mixtures with particle size ratios as high as 10-100x may be used to model realistic systems. Efficient neighbor list building algorithms for these kinds of systems are available in LAMMPS. They include a method which uses different stencils for different cutoff lengths and trims the stencil to only include bins that straddle the cutoff sphere surface. More recently a method which uses both multiple stencils and multiple bin sizes was developed; it builds neighbor lists efficiently for systems with particles of any size ratio, though other considerations (timestep size, force computations) may limit the ability to model systems with huge polydispersity.

- For small and sparse systems and as a fallback method, LAMMPS also supports neighbor list construction without binning by using a full  $O(N^2)$  loop over all  $i,j$  atom pairs in a subdomain when using the *neighbor nsq* command.
- Dependent on the “pair” setting of the *newton* command, the “half” neighbor lists may contain **all** pairs of atoms where atom  $j$  is a ghost atom (i.e. when the newton pair setting is *off*). For the newton pair *on* setting the atom  $j$  is only added to the list if its  $z$  coordinate is larger, or if equal the  $y$  coordinate is larger, and that is equal, too, the  $x$  coordinate is larger. For homogeneously dense systems, that will result in picking neighbors from a same size sector in always the same direction relative to the “owned” atom, and thus it should lead to similar length neighbor lists and reduce the chance of a load imbalance.

#### 4.4.4 Long-range interactions

For charged systems, LAMMPS can compute long-range Coulombic interactions via the FFT-based particle-particle/particle-mesh (PPPM) method implemented in *k-space style ppm and its variants*. For that Coulombic interactions are partitioned into short- and long-range components. The short-ranged portion is computed in real space as a loop over pairs of charges within a cutoff distance, using neighbor lists. The long-range portion is computed in reciprocal space using a *k-space* style. For the PPPM implementation the simulation cell is overlaid with a regular FFT grid in 3d. It proceeds in several stages:

- a) each atom’s point charge is interpolated to nearby FFT grid points,
- b) a forward 3d FFT is performed,
- c) a convolution operation is performed in reciprocal space,
- d) one or more inverse 3d FFTs are performed, and
- e) electric field values from grid points near each atom are interpolated to compute its forces.

For any of the spatial-decomposition partitioning schemes each processor owns the brick-shaped portion of FFT grid points contained within its subdomain. The two interpolation operations use a stencil of grid points surrounding each atom. To accommodate the stencil size, each processor also stores a few layers of ghost grid points surrounding its brick. Forward and reverse communication of grid point values is performed similar to the corresponding *atom data communication*. In this case, electric field values on owned grid points are sent to neighboring processors to become ghost point values. Likewise charge values on ghost points are sent and summed to values on owned points.

For triclinic simulation boxes, the FFT grid planes are parallel to the box faces, but the mapping of charge and electric field values to/from grid points is done in reduced coordinates where the tilted box is conceptually a unit cube, so that the stencil and FFT operations are unchanged. However the FFT grid size required for a given accuracy is larger for triclinic domains than it is for orthogonal boxes.

Parallel 3d FFTs require substantial communication relative to their computational cost. A 3d FFT is implemented by a series of 1d FFTs along the  $x$ -,  $y$ -, and  $z$ -direction of the FFT grid. Thus, the FFT grid cannot be decomposed like atoms into 3 dimensions for parallel processing of the FFTs but only in 1 (as planes) or 2 (as pencils) dimensions and in between the steps the grid needs to be transposed to have the FFT grid portion “owned” by each MPI process complete in the direction of the 1d FFTs it has to perform. LAMMPS uses the pencil-decomposition algorithm as shown in the *Parallel FFT in PPPM* figure.

Initially (far left), each processor owns a brick of same-color grid cells (actually grid points) contained within in its subdomain. A brick-to-pencil communication operation converts this layout to 1d pencils in the  $x$ -dimension (center left). Again, cells of the same color are owned by the same processor. Each processor can then compute a 1d FFT on each pencil of data it wholly owns using a call to the configured FFT library. A pencil-to-pencil communication then converts this layout to pencils in the  $y$  dimension (center right) which effectively transposes the  $x$  and  $y$  dimensions of the grid, followed by 1d FFTs in  $y$ . A final transpose of pencils from  $y$  to  $z$  (far right) followed by 1d FFTs in  $z$  completes the forward FFT. The data is left in a  $z$ -pencil layout for the convolution operation. One or more inverse FFTs then perform the sequence of 1d FFTs and communication steps in reverse order; the final layout of resulting grid values is the same as the initial brick layout.

Fig. 5: Parallel FFT in PPPM

Stages of a parallel FFT for a simulation domain overlaid with an  $8 \times 8 \times 8$  3d FFT grid, partitioned across 64 processors. Within each of the 4 diagrams, grid cells of the same color are owned by a single processor; for simplicity, only cells owned by 4 or 8 of the 64 processors are colored. The two images on the left illustrate brick-to-pencil communication. The two images on the right illustrate pencil-to-pencil communication, which in this case transposes the  $y$  and  $z$  dimensions of the grid.

Each communication operation within the FFT (brick-to-pencil or pencil-to-pencil or pencil-to-brick) converts one tiling of the 3d grid to another, where a tiling in this context means an assignment of a small brick-shaped subset of grid points to each processor, the union of which comprise the entire grid. The parallel `fftMPI` library written for LAMMPS allows arbitrary definitions of the tiling so that an irregular partitioning of the simulation domain can use it directly. Transforming data from one tiling to another is implemented in `fftMPI` using point-to-point communication, where each processor sends data to a few other processors, since each tile in the initial tiling overlaps with a handful of tiles in the final tiling.

The transformations could also be done using collective communication across all  $P$  processors with a single call to `MPI_Alltoall()`, but this is typically much slower. However, for the specialized brick and pencil tiling illustrated in *Parallel FFT in PPPM* figure, collective communication across the entire MPI communicator is not required. In the example, an  $8^3$  grid with 512 grid cells is partitioned across 64 processors; each processor owns a  $2 \times 2 \times 2$  3d brick of grid cells. The initial brick-to-pencil communication (upper left to upper right) only requires collective communication within subgroups of 4 processors, as illustrated by the 4 colors. More generally, a brick-to-pencil communication can be performed by partitioning  $P$  processors into  $P^{\frac{2}{3}}$  subgroups of  $P^{\frac{1}{3}}$  processors each. Each subgroup performs collective communication only within its subgroup. Similarly, pencil-to-pencil communication can be performed by partitioning  $P$  processors into  $P^{\frac{1}{2}}$  subgroups of  $P^{\frac{1}{2}}$  processors each. This is illustrated in the figure for the  $y \Rightarrow z$  communication (center). An eight-processor subgroup owns the front  $yz$  plane of data and performs collective communication within the subgroup to transpose from a  $y$ -pencil to  $z$ -pencil layout.

LAMMPS invokes point-to-point communication by default, but also provides the option of partitioned collective communication when using a `kpspace_modify collective yes` command to switch to that mode. In the latter case, the code detects the size of the disjoint subgroups and partitions the single  $P$ -size communicator into multiple smaller communicators, each of which invokes collective communication. Testing on a large IBM Blue Gene/Q machine at Argonne National Labs showed a significant improvement in FFT performance for large processor counts; partitioned collective communication was faster than point-to-point communication or global collective communication involving all  $P$  processors.

Here are some additional details about FFTs for long-range and related grid/particle operations that LAMMPS supports:

- The `fftMPI` library allows each grid dimension to be a multiple of small prime factors (2,3,5), and allows any number of processors to perform the FFT. The resulting brick and pencil decompositions are thus not always as well-aligned, but the size of subgroups of processors for the two modes of communication (brick/pencil and pencil/pencil) still scale as  $O(P^{\frac{1}{3}})$  and  $O(P^{\frac{1}{2}})$ .
- For efficiency in performing 1d FFTs, the grid transpose operations illustrated in Figure *Parallel FFT in PPPM* also involve reordering the 3d data so that a different dimension is contiguous in memory. This reordering can

be done during the packing or unpacking of buffers for MPI communication.

- For large systems and particularly many MPI processes, the dominant cost for parallel FFTs is often the communication, not the computation of 1d FFTs, even though the latter scales as  $N \log(N)$  in the number of grid points  $N$  per grid direction. This is due to the fact that only a 2d decomposition into pencils is possible while atom data (and their corresponding short-range force and energy computations) can be decomposed efficiently in 3d.

Reducing the number of MPI processes involved in the MPI communication will reduce this kind of overhead. By using a *hybrid MPI + OpenMP parallelization* it is still possible to use all processes for parallel computation. It will use OpenMP parallelization inside the MPI domains. While that may have a lower parallel efficiency for some part of the computation, that can be less than the communication overhead in the 3d FFTs.

As an alternative, it is also possible to start a *multi-partition* calculation and then use the *verlet/split integrator* to perform the PPPM computation on a dedicated, separate partition of MPI processes. This uses an integer “1: $p$ ” mapping of  $p$  subdomains of the atom decomposition to one subdomain of the FFT grid decomposition and where pairwise non-bonded and bonded forces and energies are computed on the larger partition and the PPPM kspace computation concurrently on the smaller partition.

- LAMMPS also implements PPPM-based solvers for other long-range interactions, dipole and dispersion (Lennard-Jones), which can be used in conjunction with long-range Coulombics for point charges.
- LAMMPS implements a `GridComm` class which overlays the simulation domain with a regular grid, partitions it across processors in a manner consistent with processor subdomains, and provides methods for forward and reverse communication of owned and ghost grid point values. It is used for PPPM as an FFT grid (as outlined above) and also for the MSM algorithm, which uses a cascade of grid sizes from fine to coarse to compute long-range Coulombic forces. The `GridComm` class is also useful for models where continuum fields interact with particles. For example, the two-temperature model (TTM) defines heat transfer between atoms (particles) and electrons (continuum gas) where spatial variations in the electron temperature are computed by finite differences of a discretized heat equation on a regular grid. The *fix ttm/grid* command uses the `GridComm` class internally to perform its grid operations on a distributed grid instead of the original *fix ttm* which uses a replicated grid.

## 4.4.5 OpenMP Parallelism

The styles in the INTEL, KOKKOS, and OPENMP packages offer to use OpenMP thread parallelism to predominantly distribute loops over local data and thus follow an orthogonal parallelization strategy to the decomposition into spatial domains used by the *MPI partitioning*. For clarity, this section discusses only the implementation in the OPENMP package, as it is the simplest. The INTEL and KOKKOS packages offer additional options and are more complex since they support more features and different hardware like co-processors or GPUs.

One of the key decisions when implementing the OPENMP package was to keep the changes to the source code small, so that it would be easier to maintain the code and keep it in sync with the non-threaded standard implementation. This is achieved by a) making the OPENMP version a derived class from the regular version (e.g. `PairLJCutOMP` from `PairLJCut`) and only overriding methods that are multi-threaded or need to be modified to support multi-threading (similar to what was done in the OPT package), b) keeping the structure in the modified code very similar so that side-by-side comparisons are still useful, and c) offloading additional functionality and multi-thread support functions into three separate classes `ThrOMP`, `ThrData`, and `FixOMP`. `ThrOMP` provides additional, multi-thread aware functionality not available in the corresponding base class (e.g. `Pair` for `PairLJCutOMP`) like multi-thread aware variants of the “tally” functions. Those functions are made available through multiple inheritance, so those new functions have to have unique names to avoid ambiguities; typically `_thr` is appended to the name of the function. `ThrData` is a class that manages per-thread data structures. It is used instead of extending the corresponding storage to per-thread arrays to avoid slowdowns due to “false sharing” when multiple threads update adjacent elements in an array and thus force the CPU cache lines to be reset and re-fetched. `FixOMP` finally manages the “multi-thread state” like settings and access to per-thread storage, it is activated by the *package omp* command.

## Avoiding data races

A key problem when implementing thread parallelism in an MD code is to avoid data races when updating accumulated properties like forces, energies, and stresses. When interactions are computed, they always involve multiple atoms and thus there are race conditions when multiple threads want to update per-atom data of the same atoms. Five possible strategies have been considered to avoid this:

1. Restructure the code so that there is no overlapping access possible when computing in parallel, e.g. by breaking lists into multiple parts and synchronizing threads in between.
2. Have each thread be “responsible” for a specific group of atoms and compute these interactions multiple times, once on each thread that is responsible for a given atom, and then have each thread only update the properties of this atom.
3. Use mutexes around functions and regions of code where the data race could happen.
4. Use atomic operations when updating per-atom properties.
5. Use replicated per-thread data structures to accumulate data without conflicts and then use a reduction to combine those results into the data structures used by the regular style.

Option 5 was chosen for the OPENMP package because it would retain the performance for the case of a single thread and the code would be more maintainable. Option 1 would require extensive code changes, particularly to the neighbor list code; option 2 would have incurred a 2x or more performance penalty for the serial case; option 3 causes significant overhead and would enforce serialization of operations in inner loops and thus defeat the purpose of multi-threading; option 4 slows down the serial case although not quite as bad as option 2. The downside of option 5 is that the overhead of the reduction operations grows with the number of threads used, so there would be a crossover point where options 2 or 4 would result in faster executing. That is why option 2 for example is used in the GPU package because a GPU is a processor with a massive number of threads. However, since the MPI parallelization is generally more effective for typical MD systems, the expectation is that thread parallelism is only used for a smaller number of threads (2-8). At the time of its implementation, that number was equivalent to the number of CPU cores per CPU socket on high-end supercomputers.

Thus arrays like the force array are dimensioned to the number of atoms times the number of threads when enabling OpenMP support, and inside the compute functions a pointer to a different chunk is obtained by each thread. Similarly, accumulators like potential energy or virial are kept in per-thread instances of the `ThrData` class and then only reduced and stored in their global counterparts at the end of the force computation.

## Loop scheduling

Multi-thread parallelization is applied by distributing (outer) loops statically across threads. Typically, this would be the loop over local atoms  $i$  when processing  $i,j$  pairs of atoms from a neighbor list. The design of the neighbor list code results in atoms having a similar number of neighbors for homogeneous systems and thus load imbalances across threads are not common and typically happen for systems where also the MPI parallelization would be unbalanced, which would typically have a more pronounced impact on the performance. This same loop scheduling scheme can also be applied to the reduction operations on per-atom data to try and reduce the overhead of the reduction operation.

## Neighbor list parallelization

In addition to the parallelization of force computations, also the generation of the neighbor lists is parallelized. As explained previously, neighbor lists are built by looping over “owned” atoms and storing the neighbors in “pages”. In the OPENMP variants of the neighbor list code, each thread operates on a different chunk of “owned” atoms and allocates and fills its own set of pages with neighbor list data. This is achieved by each thread keeping its own instance of the *MyPage* page allocator class.

## 4.5 Accessing per-atom data

This page discusses how per-atom data is managed in LAMMPS, how it can be accessed, what communication patterns apply, and some of the utility functions that exist for a variety of purposes.

### 4.5.1 Owned and ghost atoms

As described on the *parallel partitioning algorithms* page, LAMMPS uses a domain decomposition of the simulation domain, either in a *brick* or *tiled* manner. Each MPI process *owns* exactly one subdomain and the atoms within it. To compute forces for tuples of atoms that are spread across sub-domain boundaries, also a “halo” of *ghost* atoms are maintained within the communication cutoff distance of its subdomain.

The total number of atoms is stored in *Atom::natoms* (within any typical class this can be referred to at *atom->natoms*). The number of *owned* (or “local” atoms) are stored in *Atom::nlocal*; the number of *ghost* atoms is stored in *Atom::nghost*. The sum of *Atom::nlocal* over all MPI processes should be *Atom::natoms*. This is by default regularly checked by the Thermo class, and if the sum does not match, LAMMPS stops with a “lost atoms” error. For convenience also the property *Atom::nmax* is available, this is the maximum of *Atom::nlocal* + *Atom::nghost* across all MPI processes.

Per-atom properties are either managed by the atom style, individual classes, or as custom arrays by the individual classes. If only access to *owned* atoms is needed, they are usually allocated to be of size *Atom::nlocal*, otherwise of size *Atom::nmax*. Please note that not all per-atom properties are available or updated on *ghost* atoms. For example, per-atom velocities are only updated with *comm\_modify vel yes*.

### 4.5.2 Atom indexing

When referring to individual atoms, they may be indexed by their local *index*, their index in their *Atom::x* array. This is densely populated containing first all *owned* atoms (*index* < *Atom::nlocal*) and then all *ghost* atoms. The order of atoms in these arrays can change due to atoms migrating between subdomains, atoms being added or deleted, or atoms being sorted for better cache efficiency. Atoms are globally uniquely identified by their *atom ID*. There may be multiple atoms with the same atom ID present, but only one of them may be an *owned* atom.

To find the local *index* of an atom, when the *atom ID* is known, the *Atom::map()* function may be used. It will return the local atom index or -1. If the returned value is between 0 (inclusive) and *Atom::nlocal* (exclusive) it is an *owned* or “local” atom; for larger values the atom is present as a ghost atom; for a value of -1, the atom is not present on the current subdomain at all.

If multiple atoms with the same tag exist in the same subdomain, they can be found via the *Atom::sametag* array. It points to the next atom index with the same tag or -1 if there are no more atoms with the same tag. The list will be exhaustive when starting with an index of an *owned* atom, since the atom IDs are unique, so there can only be one such atom. Example code to count atoms with same atom ID in a subdomain:

```

for (int i = 0; i < atom->nlocal; ++i) {
  int count = 0;
  while (sametag[i] >= 0) {
    i = sametag[i];
    ++count;
  }
  printf("Atom ID: %ld is present %d times\n", atom->tag[i], count);
}

```

### 4.5.3 Atom class versus AtomVec classes

The *Atom* class contains all kinds of flags and counters about atoms in the system and that includes pointers to **all** per-atom properties available for atoms. However, only a subset of these pointers are non-NULL and which those are depends on the atom style. For each atom style there is a corresponding *AtomVecXXX* class derived from the *AtomVec* base class, where the XXX indicates the atom style. This *AtomVecXXX* class will update the counters and per-atom pointers if atoms are added or removed to the system or migrate between subdomains.

## 4.6 Communication patterns

This page describes various inter-processor communication operations provided by LAMMPS, mostly in the core *Comm* class. These are operations for common tasks implemented using MPI library calls. They are used by other classes to perform communication of different kinds. These operations are useful to know about when writing new code for LAMMPS that needs to communicate data between processors.

### 4.6.1 Owned and ghost atoms

As described on the [parallel partitioning algorithms](#) page, LAMMPS spatially decomposes the simulation domain, either in a *brick* or *tiled* manner. Each processor (MPI task) owns atoms within its subdomain and additionally stores ghost atoms within a cutoff distance of its subdomain.

#### Forward and reverse communication

As described on the [parallel communication algorithms](#) page, the most common communication operations are first, *forward communication* which sends owned atom information from each processor to nearby processors to store with their ghost atoms. The need to do this communication arises when data from the owned atoms is updated (e.g. their positions) and this updated information needs to be **copied** to the corresponding ghost atoms.

And second, *reverse communication*, which sends ghost atom information from each processor to the owning processor to **accumulate** (sum) the values with the corresponding owned atoms. The need for this arises when data is computed and also stored with ghost atoms (e.g. forces when using a “half” neighbor list) and thus those terms need to be added to their corresponding atoms on the process where they are “owned” atoms. Please note, that with the [newton off](#) setting this does not happen and the neighbor lists are constructed so that these interactions are computed on both MPI processes containing one of the atoms and only the data pertaining to the local atom is stored.

The time-integration classes in LAMMPS invoke these operations each timestep via the *forward\_comm()* and *reverse\_comm()* methods in the *Comm* class. Which per-atom data is communicated depends on the currently used *atom style* and whether *comm\_modify vel* setting is “no” (default) or “yes”.

Similarly, *Pair* style classes can invoke the *forward\_comm(this)* and *reverse\_comm(this)* methods in the *Comm* class to perform the same operations on per-atom data that is generated and stored within the pair style class. Note that this

function requires passing the `this` pointer as the first argument to enable the *Comm* class to call the “pack” and “unpack” functions discussed below. An example of the use of these functions are many-body pair styles like the embedded-atom method (EAM) which compute intermediate values in the first part of the `compute()` function that need to be stored by both owned and ghost atoms for the second part of the force computation. The *Comm* class methods perform the MPI communication for buffers of per-atom data. They “call back” to the *Pair* class, so it can *pack* or *unpack* the buffer with data the *Pair* class owns. There are 4 such methods that the *Pair* class must define, assuming it uses both forward and reverse communication:

- `pack_forward_comm()`
- `unpack_forward_comm()`
- `pack_reverse_comm()`
- `unpack_reverse_comm()`

The arguments to these methods include the buffer and a list of atoms to pack or unpack. The *Pair* class also must set the `comm_forward` and `comm_reverse` variables, which store the number of values stored in the communication buffers for each operation. This means, if desired, it can choose to store multiple per-atom values in the buffer, and they will be communicated together to minimize communication overhead. The communication buffers are defined vectors containing `double` values. To correctly store integers that may be 64-bit (`bigint`, `tagint`, `imageint`) in the buffer, you need to use the *ubuf union* construct.

The *Fix*, *Compute*, and *Dump* classes can also invoke the same kind of forward and reverse communication operations using the same *Comm* class methods. Likewise, the same pack/unpack methods and `comm_forward`/`comm_reverse` variables must be defined by the calling *Fix*, *Compute*, or *Dump* class.

For *Fix* classes, there is an optional second argument to the `forward_comm()` and `reverse_comm()` call which can be used when the fix performs multiple modes of communication, with different numbers of values per atom. The fix should set the `comm_forward` and `comm_reverse` variables to the maximum value, but can invoke the communication for a particular mode with a smaller value. For this to work, the `pack_forward_comm()`, etc methods typically use a class member variable to choose which values to pack/unpack into/from the buffer.

Finally, for reverse communications in *Fix* classes there is also the `reverse_comm_variable()` method that allows the communication to have a different amount of data per-atom. It invokes these corresponding callback methods:

- `pack_reverse_comm_size()`
- `unpack_reverse_comm_size()`

which have extra arguments to specify the amount of data stored in the buffer for each atom.

## 4.6.2 Higher level communication

There are also several higher-level communication operations provided in LAMMPS which work for either *brick* or *tilled* decompositions. They may be useful for a new class to invoke if it requires more sophisticated communication than the *forward* and *reverse* methods provide. The 3 communication operations described here are

- `ring`
- `irregular`
- `rendezvous`

You can invoke these *grep* command in the LAMMPS `src` directory, to see a list of classes that invoke the 3 operations.

- `grep "\->ring" *.cpp */*.cpp`
- `grep "irregular\->" *.cpp`
- `grep "\->rendezvous" *.cpp */*.cpp`

## Ring operation

The *ring* operation is invoked via the *ring()* method in the *Comm* class.

Each processor first creates a buffer with a list of values, typically associated with a subset of the atoms it owns. Now think of the  $P$  processors as connected to each other in a *ring*. Each processor  $M$  sends data to the next  $M+1$  processor. It receives data from the preceding  $M-1$  processor. The ring is periodic so that the last processor sends to the first processor, and the first processor receives from the last processor.

Invoking the *ring()* method passes each processor's buffer in  $P$  steps around the ring. At each step a *callback* method, provided as an argument to *ring()*, in the caller is invoked. This allows each processor to examine the data buffer provided by every other processor. It may extract values needed by its atoms from the buffers, or it may alter placeholder values in the buffer. In the latter case, when the *ring* operation is complete, each processor can examine its original buffer to extract modified values.

Note that the *ring* operation is similar to an *MPI\_Alltoall()* operation, where every processor effectively sends and receives data to every other processor. The difference is that the *ring* operation does it one step at a time, so the total volume of data does not need to be stored by every processor. However, the *ring* operation is also less efficient than *MPI\_Alltoall()* because of the  $P$  stages required. So it is typically only suitable for small data buffers and occasional operations that are not time-critical.

## Irregular operation

The *irregular* operation is provided by the *Irregular* class. What LAMMPS terms irregular communication is when each processor knows what data it needs to send to what processor, but does not know what processors are sending it data. An example is when load-balancing is performed and each processor needs to send some of its atoms to new processors.

The *Irregular* class provides 5 high-level methods useful in this context:

- *create\_data()*
- *exchange\_data()*
- *create\_atom()*
- *exchange\_atom()*
- *migrate\_atoms()*

For the *create\_data()* method, each processor specifies a list of  $N$  datums to send, each to a specified processor. Internally, the method creates efficient data structures for performing the communication. The *exchange\_data()* method triggers the communication to be performed. Each processor provides the vector of  $N$  datums to send, and the size of each datum. All datums must be the same size.

The *create\_atom()* and *exchange\_atom()* methods are similar, except that the size of each datum can be different. Typically, this is used to communicate atoms, each with a variable amount of per-atom data, to other processors.

The *migrate\_atoms()* method is a convenience wrapper on the *create\_atom()* and *exchange\_atom()* methods to simplify communication of all the per-atom data associated with an atom so that the atom can effectively migrate to a new owning processor. It is similar to the *exchange()* method in the *Comm* class invoked when atoms move to neighboring processors (in the regular or tiled decomposition) during timestepping, except that it allows atoms to have moved arbitrarily long distances and still be properly communicated to a new owning processor.

## Rendezvous operation

Finally, the *rendezvous* operation is invoked via the *rendezvous()* method in the *Comm* class. Depending on how much communication is needed and how many processors a LAMMPS simulation is running on, it can be a much more efficient choice than the *ring()* method. It uses the *irregular* operation internally once or twice to do its communication. The rendezvous algorithm is described in detail in (*Plimpton*), including some LAMMPS use cases.

For the *rendezvous()* method, each processor specifies a list of *N* datums to send and which processor to send each of them to. Internally, this communication is performed as an irregular operation. The received datums are returned to the caller via invocation of *callback* function, provided as an argument to *rendezvous()*. The caller can then process the received datums and (optionally) assemble a new list of datums to communicate to a new list of specific processors. When the callback function exits, the *rendezvous()* method performs a second irregular communication on the new list of datums.

Examples in LAMMPS of use of the *rendezvous* operation are the *fix rigid/small* and *fix shake* commands (for one-time identification of the rigid body atom clusters) and the identification of special\_bond 1-2, 1-3 and 1-4 neighbors within molecules. See the *special\_bonds* command for context.

## 4.7 How a timestep works

The first and most fundamental operation within LAMMPS to understand is how a timestep is structured. Timestepping is performed by calling methods of the *Integrate* class instance within the *Update* class. Since *Integrate* is a base class, it will point to an instance of a derived class corresponding to what is selected by the *run\_style* input script command.

In this section, the timestep implemented by the *Verlet* class is described. A similar timestep protocol is implemented by the *Respa* class, for the r-RESPA hierarchical timestepping method.

The *Min* base class performs energy minimization, so does not perform a literal timestep. But it has logic similar to what is described here, to compute forces and invoke fixes at each iteration of a minimization. Differences between time integration and minimization are highlighted at the end of this section.

The *Verlet* class is encoded in the *src/verlet.cpp* and *verlet.h* files. It implements the velocity-Verlet timestepping algorithm. The workhorse method is *Verlet::run()*, but first we highlight several other methods in the class.

- The *init()* method is called at the beginning of each dynamics run. It simply sets some internal flags, based on user settings in other parts of the code.
- The *setup()* or *setup\_minimal()* methods are also called before each run. The velocity-Verlet method requires current forces be calculated before the first timestep, so these routines compute forces due to all atomic interactions, using the same logic that appears in the timestepping described next. A few fixes are also invoked, using the mechanism described in the next section. Various counters are also initialized before the run begins. The *setup\_minimal()* method is a variant that has a flag for performing less setup. This is used when runs are continued and information from the previous run is still valid. For example, if repeated short LAMMPS runs are being invoked, interleaved by other commands, via the *pre no* and *every* options of the run command, the *setup\_minimal()* method is used.
- The *force\_clear()* method initializes force and other arrays to zero before each timestep, so that forces (torques, etc) can be accumulated.

Now for the *Verlet::run()* method. Its basic structure in hi-level pseudocode is shown below. In the actual code in *src/verlet.cpp* some of these operations are conditionally invoked.

```

loop over N timesteps:
  if timeout condition: break
  ev_set()

  fix->initial_integrate()
  fix->post_integrate()

  nflag = neighbor->decide()
  if nflag:
    fix->pre_exchange()
    domain->pbcb()
    domain->reset_box()
    comm->setup()
    neighbor->setup_bins()
    comm->exchange()
    comm->borders()
    fix->pre_neighbor()
    neighbor->build()
    fix->post_neighbor()
  else:
    comm->forward_comm()

  force_clear()
  fix->pre_force()

  pair->compute()
  bond->compute()
  angle->compute()
  dihedral->compute()
  improper->compute()
  kspace->compute()

  fix->pre_reverse()
  comm->reverse_comm()

  fix->post_force()
  fix->final_integrate()
  fix->end_of_step()

  if any output on this step:
    output->write()

# after loop
fix->post_run()

```

The `ev_set()` method (in the parent `Integrate` class), sets two flags (*eflag* and *vflag*) for energy and virial computation. Each flag encodes whether global and/or per-atom energy and virial should be calculated on this timestep, because some fix or variable or output will need it. These flags are passed to the various methods that compute particle interactions, so that they either compute and tally the corresponding data or can skip the extra calculations if the energy and virial are not needed. See the comments for the `Integrate::ev_set()` method, which document the flag values.

At various points of the timestep, fixes are invoked, e.g. `fix->initial_integrate()`. In the code, this is actually done via the `Modify` class, which stores all the `Fix` objects and lists of which should be invoked at what point in the timestep. Fixes are the LAMMPS mechanism for tailoring the operations of a timestep for a particular simula-

tion. As described elsewhere, each fix has one or more methods, each of which is invoked at a specific stage of the timestep, as show in the timestep pseudocode. All the active fixes defined in an input script, that are flagged to have an `initial_integrate()` method, are invoked at the beginning of each timestep. Examples are *fix nve* or *fix nvt* or *fix npt* which perform the start-of-timestep velocity-Verlet integration operations to update velocities by a half-step, and coordinates by a full step. The `post_integrate()` method is next for operations that need to happen immediately after those updates. Only a few fixes use this, e.g. to reflect particles off box boundaries in the *FixWallReflect* class.

The `decide()` method in the Neighbor class determines whether neighbor lists need to be rebuilt on the current timestep (conditions can be changed using the *neigh\_modify every/delay/check* command). If not, coordinates of ghost atoms are acquired by each processor via the `forward_comm()` method of the Comm class. If neighbor lists need to be built, several operations within the inner if clause of the pseudocode are first invoked. The `pre_exchange()` method of any defined fixes is invoked first. Typically, this inserts or deletes particles from the system.

Periodic boundary conditions are then applied by the Domain class via its `pbcb()` method to remap particles that have moved outside the simulation box back into the box. Note that this is not done every timestep, but only when neighbor lists are rebuilt. This is so that each processor's subdomain will have consistent (nearby) atom coordinates for its owned and ghost atoms. It is also why dumped atom coordinates may be slightly outside the simulation box if not dumped on a step where the neighbor lists are rebuilt.

The box boundaries are then reset (if needed) via the `reset_box()` method of the Domain class, e.g. if box boundaries are shrink-wrapped to current particle coordinates. A change in the box size or shape requires internal information for communicating ghost atoms (Comm class) and neighbor list bins (Neighbor class) to be updated. The `setup()` method of the Comm class and `setup_bins()` method of the Neighbor class perform the update.

The code is now ready to migrate atoms that have left a processor's geometric subdomain to new processors. The `exchange()` method of the Comm class performs this operation. The `borders()` method of the Comm class then identifies ghost atoms surrounding each processor's subdomain and communicates ghost atom information to neighboring processors. It does this by looping over all the atoms owned by a processor to make lists of those to send to each neighbor processor. On subsequent timesteps, the lists are used by the `Comm::forward_comm()` method.

Fixes with a `pre_neighbor()` method are then called. These typically re-build some data structure stored by the fix that depends on the current atoms owned by each processor.

Now that each processor has a current list of its owned and ghost atoms, LAMMPS is ready to rebuild neighbor lists via the `build()` method of the Neighbor class. This is typically done by binning all owned and ghost atoms, and scanning a stencil of bins around each owned atom's bin to make a Verlet list of neighboring atoms within the force cutoff plus neighbor skin distance.

In the next portion of the timestep, all interaction forces between particles are computed, after zeroing the per-atom force vector via the `force_clear()` method. If the newton flag is set to *on* by the newton command, forces are added to both owned and ghost atoms, otherwise only to owned (aka local) atoms.

Pairwise forces are calculated first, which enables the global virial (if requested) to be calculated cheaply (at  $O(N)$  cost instead of  $O(N^2)$  at the end of the `Pair::compute()` method), by a dot product of atom coordinates and forces. By including owned and ghost atoms in the dot product, the effect of periodic boundary conditions is correctly accounted for. Molecular topology interactions (bonds, angles, dihedrals, impropers) are calculated next (if supported by the current atom style). The final contribution is from long-range Coulombic interactions, invoked by the KSpace class.

The `pre_reverse()` method in fixes is used for operations that have to be done *before* the upcoming reverse communication (e.g. to perform additional data transfers or reductions for data computed during the force computation and stored with ghost atoms).

If the newton flag is on, forces on ghost atoms are communicated and summed back to their corresponding owned atoms. The `reverse_comm()` method of the Comm class performs this operation, which is essentially the inverse operation of sending copies of owned atom coordinates to other processor's ghost atoms.

At this point in the timestep, the total force on each (local) atom is known. Additional force constraints (external forces, SHAKE, etc) are applied by Fixes that have a `post_force()` method. The second half of the velocity-Verlet

integration, `final_integrate()` is then performed (another half-step update of the velocities) via fixes like `nve`, `nvt`, `npt`.

At the end of the timestep, fixes that contain an `end_of_step()` method are invoked. These typically perform a diagnostic calculation, e.g. the `ave/time` and `ave/spatial` fixes. The final operation of the timestep is to perform any requested output, via the `write()` method of the `Output` class. There are 3 kinds of LAMMPS output: thermodynamic output to the screen and log file, snapshots of atom data to a dump file, and restart files. See the [thermo\\_style](#), [dump](#), and [restart](#) commands for more details.

The flow of control during energy minimization iterations is similar to that of a molecular dynamics timestep. Forces are computed, neighbor lists are built as needed, atoms migrate to new processors, and atom coordinates and forces are communicated to neighboring processors. The only difference is what `Fix` class operations are invoked when. Only a subset of LAMMPS fixes are useful during energy minimization, as explained in their individual doc pages. The relevant `Fix` class methods are `min_pre_exchange()`, `min_pre_force()`, and `min_post_force()`. Each fix is invoked at the appropriate place within the minimization iteration. For example, the `min_post_force()` method is analogous to the `post_force()` method for dynamics; it is used to alter or constrain forces on each atom, which affects the minimization procedure.

After all iterations are completed, there is a `cleanup` step which calls the `post_run()` method of fixes to perform operations only required at the end of a calculation (like freeing temporary storage or creating final outputs).

## 4.8 Writing new styles

The [Modifying & extending LAMMPS](#) section of the manual gives an overview of how LAMMPS can be extended by writing new classes that derive from existing parent classes in LAMMPS. Here, some specific coding details are provided for writing code for LAMMPS.

### 4.8.1 Writing new pair styles

Pair styles are at the core of most simulations with LAMMPS, since they are used to compute the forces (plus energy and virial contributions, if needed) on atoms for pairs or small clusters of atoms within a given cutoff. This is often the dominant computation in LAMMPS, and sometimes even the only one. Pair styles can be grouped into multiple categories:

1. simple pairwise additive interactions of point particles (e.g. [Lennard-Jones](#), [Morse](#), [Buckingham](#))
2. pairwise additive interactions of point particles with added [Coulomb](#) interactions or *only* the Coulomb interactions
3. manybody interactions of point particles (e.g. [EAM](#), [Tersoff](#))
4. complex interactions that include additional per-atom properties (e.g. Discrete Element Models (DEM), Peridynamics, Ellipsoids)
5. special purpose pair styles that may not even compute forces like [pair\\_style zero](#) and [pair\\_style tracker](#), or are a wrapper for multiple kinds of interactions like [pair\\_style hybrid](#), [pair\\_style list](#), and [pair\\_style kim](#)

In the text below, we will discuss aspects of implementing pair styles in LAMMPS by looking at representative case studies. The design of LAMMPS allows developers to focus on the essentials, which is to compute the forces (and energies or virial contributions), enter and manage the global settings as well as the potential parameters, and the pair style specific parts of reading and writing restart and data files. Most of the complex tasks like management of the atom positions, domain decomposition and boundaries, or neighbor list creation are handled transparently by other parts of the LAMMPS code.

As shown on the page for [writing or extending pair styles](#), in order to implement a new pair style, a new class must be written that is either directly or indirectly derived from the `Pair` class. If that class is directly derived from `Pair`,

there are three methods that *must* be re-implemented, since they are “pure” in the base class: `Pair::compute()`, `Pair::settings()`, `Pair::coeff()`. In addition, a custom constructor is needed. All other methods are optional and have default implementations in the base class (most of which do nothing), but they may need to be overridden depending on the requirements of the model.

We are looking at the following cases:

- *Case 1: a pairwise additive model*
- *Case 2: a many-body potential*
- *Case 3: a potential requiring communication*
- *Case 4: potentials without a compute() function*

## 4.8.2 Package and build system considerations

In general, new pair styles should be added to the *EXTRA-PAIR package* unless they are an accelerated pair style and then they should be added to the corresponding accelerator package (*GPU*, *INTEL*, *KOKKOS*, *OPENMP*, *OPT*). If you feel that your contribution should be added to a different package, please consult with the LAMMPS developers first.

The contributed code needs to support the *traditional GNU make build process* **and** the *CMake build process*. For the GNU make process and if the package has an `Install.sh` file, most likely that file needs to be updated to correctly copy the sources when installing the package and properly delete them when uninstalling. This is particularly important when added a new pair style that is a derived class from an existing pair style in a package, so that its installation depends on the the installation status of the package of the derived class. For the CMake process, it is sometimes necessary to make changes to the package specific CMake scripting in `cmake/Modules/Packages`.

---

### 4.8.3 Case 1: a pairwise additive model

In this section, we will describe the procedure of adding a simple pair style to LAMMPS: an empirical model that can be used to model liquid mercury. The pair style shall be called *bond/gauss* and the complete implementation can be found in the files `src/EXTRA-PAIR/pair_born_gauss.cpp` and `src/EXTRA-PAIR/pair_born_gauss.h` of the LAMMPS source code.

#### Model and general considerations

The functional form of the model according to (*Bomont*) consists of a repulsive Born-Mayer exponential term and a temperature dependent, attractive Gaussian term.

$$E = A_0 \exp(-\alpha r) - A_1 \exp[-\beta (r - r_0)^2]$$

For the application to mercury, the following parameters are listed:

- $A_0 = 8.2464 \times 10^{13} \text{ eV}$
- $\alpha = 12.48 \text{ \AA}^{-1}$
- $\beta = 0.44 \text{ \AA}^{-2}$
- $r_0 = 3.56 \text{ \AA}$
- $A_1$  is temperature dependent and can be determined from  $A_1 = a_0 + a_1 T + a_2 T^2$  with:
  - $a_0 = 1.97475 \times 10^{-2} \text{ eV}$

- $a_1 = 8.40841 \times 10^{-5} \text{ eV/K}$
- $a_2 = -2.58717 \times 10^{-8} \text{ eV/K}^{-2}$

With the optional cutoff, this means we have a total of 5 or 6 parameters for each pair of atom types. Additionally, we need to input a default cutoff value as a global setting.

Because of the combination of Born-Mayer with a Gaussian, the pair style shall be named “born/gauss” and thus the class name would be `PairBornGauss` and the source files `pair_born_gauss.h` and `pair_born_gauss.cpp`. Since this is a rather uncommon potential, it shall be added to the *EXTRA-PAIR* package.

## Header file

The first segment of any LAMMPS source should be the copyright and license statement. Note the marker in the first line to indicate to editors like emacs that this file is a C++ source, even though the .h extension suggests a C source (this is a convention inherited from the very beginning of the C++ version of LAMMPS).

```
/* -*- C++ -*- -----
  LAMMPS - Large-scale Atomic/Molecular Massively Parallel Simulator
  https://www.lammps.org/, Sandia National Laboratories
  LAMMPS development team: developers@lammps.org

  Copyright (2003) Sandia Corporation. Under the terms of Contract
  DE-AC04-94AL85000 with Sandia Corporation, the U.S. Government retains
  certain rights in this software. This software is distributed under
  the GNU General Public License.

  See the README file in the top-level LAMMPS directory.
  ----- */
```

Every pair style must be registered in LAMMPS by including the following lines of code in the second part of the header after the copyright message and before the include guards for the class definition:

```
#ifndef PAIR_CLASS
// clang-format off
PairStyle(born/gauss,PairBornGauss);
// clang-format on
#else

/* the definition of the PairBornGauss class (see below) is inserted here */

#endif
```

This block of between `#ifndef PAIR_CLASS` and `#else` will be included by the Force class in `force.cpp` to build a map of “factory functions” that will create an instance of these classes and return a pointer to it. The map connects the name of the pair style, “born/gauss”, to the name of the class, `PairBornGauss`. During compilation, LAMMPS constructs a file `style_pair.h` that contains `#include` statements for all “installed” pair styles. Before including `style_pair.h` into `force.cpp`, the `PAIR_CLASS` define is set and the `PairStyle(name,class)` macro defined. The code of the macro adds the installed pair styles to the “factory map” which enables the *pair\_style command* to create the pair style instance.

The list of header files to include is automatically updated by the build system if there are new files, so the presence of the new header file in the `src/EXTRA-PAIR` folder and the enabling of the *EXTRA-PAIR* package will trigger LAMMPS to include the new pair style when it is (re-)compiled. The “// clang-format” format comments are needed so that running *clang-format* on the file will not insert unwanted blanks between “born”, “/”, and “gauss” which would break the `PairStyle` macro.

The third part of the header file is the actual class definition of the `PairBornGauss` class. This has the prototypes for all member functions that will be implemented by this pair style. This includes *a few required and a number of optional functions*. All functions that were labeled in the base class as “virtual” must be given the “override” property, as it is done in the code shown below.

The “override” property helps to detect unexpected mismatches because compilation will stop with an error in case the signature of a function is changed in the base class without also changing it in all derived classes. For example, if this change added an optional argument with a default value, then all existing source code *calling* the function would not need changes and still compile, but the function in the derived class would no longer override the one in the base class due to the different number of arguments and the behavior of the pair style is thus changed in an unintended way. Using the “override” keyword prevents such issues.

```
#ifndef LMP_PAIR_BORN_GAUSS_H
#define LMP_PAIR_BORN_GAUSS_H

#include "pair.h"

namespace LAMMPS_NS {

class PairBornGauss : public Pair {
public:
  PairBornGauss(class LAMMPS *);
  ~PairBornGauss() override;

  void compute(int, int) override;
  void settings(int, char **) override;
  void coeff(int, char **) override;
  double init_one(int, int) override;

  void write_restart(FILE *) override;
  void read_restart(FILE *) override;
  void write_restart_settings(FILE *) override;
  void read_restart_settings(FILE *) override;
  void write_data(FILE *) override;
  void write_data_all(FILE *) override;

  double single(int, int, int, int, double, double, double, double &) override;
  void *extract(const char *, int &) override;
};

} // namespace LAMMPS_NS
#endif
```

Also, variables and arrays for storing global settings and potential parameters are defined. Since these are internal to the class, they are placed after a “protected:” label.

```
protected:
  double cut_global;
  double **cut;
  double **biga0, **alpha, **biga1, **beta, **r0;
  double **a0, **a1, **a2;
  double **offset;

  virtual void allocate();
};

} // namespace LAMMPS_NS
#endif
```

## Implementation file

We move on to the implementation of the PairBornGauss class in the `pair_born_gauss.cpp` file. This file also starts with a LAMMPS copyright and license header. Below that notice is typically the space where comments may be added with additional information about this specific file, the author(s), affiliation(s), and email address(es). This way the contributing author(s) can be easily contacted, when there are questions about the implementation later. Since the file(s) may be around for a long time, it is beneficial to use some kind of “permanent” email address, if possible.

```

  ----- */

// Contributing author: Axel Kohlmeyer, Temple University, akohlmey@gmail.com

#include "pair_born_gauss.h"

#include "atom.h"
#include "comm.h"
#include "error.h"
#include "fix.h"
#include "force.h"
#include "memory.h"
#include "neigh_list.h"

#include <cmath>
#include <cstring>

using namespace LAMMPS_NS;
```

The second section of the implementation file has various include statements. The include file for the class header has to come first, then a block of LAMMPS classes (sorted alphabetically) followed by a block of system headers and others, if needed. Note the standardized C++ notation for headers of C-library functions (`cmath` instead of `math.h`). The final statement of this segment imports the `LAMMPS_NS::` namespace globally for this file. This way, all LAMMPS specific functions and classes do not have to be prefixed with `LAMMPS_NS::`.

## Constructor and destructor (required)

The first two functions in the implementation source file are typically the constructor and the destructor.

Pair styles are different from most classes in LAMMPS that define a “style”, as their constructor only uses the LAMMPS class instance pointer as an argument, but **not** the command line arguments of the *pair\_style command*. Instead, those arguments are processed in the `Pair::settings()` function (or rather the version in the derived class). The constructor is the place where global defaults are set and specifically flags are set indicating which optional features of a pair style are available.

```
/* ----- */

PairBornGauss::PairBornGauss(LAMMPS *lmp) : Pair(lmp)
{
    writedata = 1;
}
```

The `writedata = 1;` statement indicates that the pair style is capable of writing the current pair coefficient parameters to data files. That is, the class implements specific versions for `Pair::data()` and `Pair::data_all()`. Other statements that could be added here would be `single_enable = 1;` or `respa_enable = 0;` to indicate that the `Pair::single()` function is present and the `Pair::compute_(inner|middle|outer)` functions are not, but those are also the default settings and already set in the base class.

In the destructor, we need to delete all memory that was allocated by the pair style, usually to hold force field parameters that were entered with the *pair\_coeff command*. Most of those array pointers will need to be declared in the derived class header, but some (e.g. `setflag`, `cutsq`) are already declared in the base class.

```
PairBornGauss::~PairBornGauss()
{
    if (allocated) {
        memory->destroy(setflag);
        memory->destroy(cutsq);
        memory->destroy(cut);
        memory->destroy(biga0);
        memory->destroy(alpha);
        memory->destroy(biga1);
        memory->destroy(beta);
        memory->destroy(r0);
        memory->destroy(offset);
    }
}
```

## Settings and coefficients (required)

To enter the global pair style settings and the pair style parameters, the functions `Pair::settings()` and `Pair::coeff()` need to be re-implemented. The arguments to the `settings()` function are the arguments given to the *pair\_style command*. Normally, those would already be processed as part of the constructor, but moving this to a separate function allows users to change global settings like the default cutoff without having to reissue all *pair\_coeff* commands or re-read the `Pair Coeffs` sections from the data file. In the `settings()` function, also the arrays for storing parameters, to define cutoffs, track which pairs of parameters have been explicitly set and allocated and, if needed, initialized. In this case, the memory allocation and initialization are moved to a function `allocate()`.

```
/* -----
    allocate all arrays
```

(continues on next page)

(continued from previous page)

```

----- */
void PairBornGauss::allocate()
{
  allocated = 1;
  int np1 = atom->ntypes + 1;

  memory->create(setflag, np1, np1, "pair:setflag");
  for (int i = 1; i < np1; i++)
    for (int j = i; j < np1; j++) setflag[i][j] = 0;

  memory->create(cutsq, np1, np1, "pair:cutsq");
  memory->create(cut, np1, np1, "pair:cut");
  memory->create(biga0, np1, np1, "pair:biga0");
  memory->create(alpha, np1, np1, "pair:alpha");
  memory->create(biga1, np1, np1, "pair:biga1");
  memory->create(beta, np1, np1, "pair:beta");
  memory->create(r0, np1, np1, "pair:r0");
  memory->create(offset, np1, np1, "pair:offset");
}

/* -----
   global settings
----- */

void PairBornGauss::settings(int narg, char **arg)
{
  if (narg != 1) error->all(FLERR, "Pair style bond/gauss must have exactly one argument
→");
  cut_global = utils::numeric(FLERR, arg[0], false, lmp);

  // reset per-type pair cutoffs that have been explicitly set previously

  if (allocated) {
    for (int i = 1; i <= atom->ntypes; i++)
      for (int j = i; j <= atom->ntypes; j++)
        if (setflag[i][j]) cut[i][j] = cut_global;
  }
}

```

The arguments to the `coeff()` function are the arguments to the *pair\_coeff* command. The function is also called when processing the `Pair Coeffs` or `PairIJ Coeffs` sections of data files. In the case of the `Pair Coeffs` section, there is only one atom type per line and thus the first argument is duplicated. Since the atom type arguments of the *pair\_coeff* command may be a range (e.g. `*3` for atom types 1, 2, and 3), the corresponding arguments are passed to the `utils::bounds()` function which will then return the low and high end of the range. Note that the `setflag` array is set to 1 for all pairs of atom types processed by this call. This information is later used in the `init_one()` function to determine if any coefficients are missing and, if supported by the potential, generate those missing coefficients from the selected mixing rule.

```

/* -----
   set coeffs for one or more type pairs
----- */

```

(continues on next page)

(continued from previous page)

```

void PairBornGauss::coeff(int narg, char **arg)
{
  if (narg < 7 || narg > 8) error->all(FLERR, "Incorrect args for pair coefficients");
  if (!allocated) allocate();

  int ilo, ihi, jlo, jhi;
  utils::bounds(FLERR, arg[0], 1, atom->ntypes, ilo, ihi, error);
  utils::bounds(FLERR, arg[1], 1, atom->ntypes, jlo, jhi, error);

  double biga0_one = utils::numeric(FLERR, arg[2], false, lmp);
  double alpha_one = utils::numeric(FLERR, arg[3], false, lmp);
  double biga1_one = utils::numeric(FLERR, arg[4], false, lmp);
  double beta_one = utils::numeric(FLERR, arg[5], false, lmp);
  double r0_one = utils::numeric(FLERR, arg[6], false, lmp);
  double cut_one = cut_global;
  if (narg == 10) cut_one = utils::numeric(FLERR, arg[7], false, lmp);

  int count = 0;
  for (int i = ilo; i <= ihi; i++) {
    for (int j = MAX(jlo, i); j <= jhi; j++) {
      biga0[i][j] = biga0_one;
      alpha[i][j] = alpha_one;
      biga1[i][j] = biga1_one;
      beta[i][j] = beta_one;
      r0[i][j] = r0_one;
      cut[i][j] = cut_one;
      setflag[i][j] = 1;
      count++;
    }
  }

  if (count == 0) error->all(FLERR, "Incorrect args for pair coefficients");
}

```

## Initialization

The `init_one()` function is called during the “*init*” phase of a simulation. This is where potential parameters are checked for completeness, derived parameters computed (e.g. the “offset” of the potential energy at the cutoff distance for use with the *pair\_modify shift yes* command). If a pair style supports generating “mixed” parameters (i.e. where both atoms of a pair have a different atom type) using a “mixing rule” from the parameters of the type with itself, this is the place to compute and store those mixed values. The *born/gauss* pair style does not support mixing, so we only check for completeness. Another purpose of the `init_one()` function is to symmetrize the potential parameter arrays. The return value of the function is the cutoff for the given pair of atom types. This information is used by the neighbor list code to determine the largest cutoff and then build the neighbor lists accordingly.

```

/* -----
   init for one type pair i,j and corresponding j,i
   ----- */

double PairBornGauss::init_one(int i, int j)

```

(continues on next page)

(continued from previous page)

```

{
  if (setflag[i][j] == 0) error->all(FLERR, "All pair coeffs are not set");

  if (offset_flag) {
    double dr = cut[i][j] - r0[i][j];
    offset[i][j] =
      biga0[i][j] * exp(-alpha[i][j] * cut[i][j]) - biga1[i][j] * exp(-beta[i][j] * dr
→ * dr);
  } else
    offset[i][j] = 0.0;

  biga0[j][i] = biga0[i][j];
  alpha[j][i] = alpha[i][j];
  biga1[j][i] = biga1[i][j];
  beta[j][i] = beta[i][j];
  r0[j][i] = r0[i][j];
  offset[j][i] = offset[i][j];

  return cut[i][j];
}

```

### Computing forces from the neighbor list (required)

The `compute()` function is the “workhorse” of a pair style. This is where we have the nested loops over all pairs of particles from the neighbor list to compute forces and - if needed - energies and virials.

The first part is to define some variables for later use and store cached copies of data or pointers that we need to access frequently. Also, this is a good place to call `Pair::ev_init()`, which initializes several flags derived from the `eflag` and `vflag` parameters signaling whether the energy and virial need to be tallied and whether only globally or also per-atom.

```

/* ----- */

void PairBornGauss::compute(int eflag, int vflag)
{
  int i, j, ii, jj, inum, jnum, itype, jtype;
  double xtmp, ytmp, ztmp, delx, dely, delz, evdwl, fpair;
  double rsq, r, dr, aexp, bexp, factor_lj;
  int *ilist, *jlist, *numneigh, **firstneigh;

  evdwl = 0.0;
  ev_init(eflag, vflag);

  double **x = atom->x;
  double **f = atom->f;
  int *type = atom->type;
  int nlocal = atom->nlocal;
  double *special_lj = force->special_lj;
  int newton_pair = force->newton_pair;

  inum = list->inum;

```

(continues on next page)

(continued from previous page)

```

ilist = list->ilist;
numneigh = list->numneigh;
firstneigh = list->firstneigh;

```

The outer loop (index *i*) is over local atoms of our sub-domain. Typically, the value of *inum* (the number of neighbor lists) is the same as the number of local atoms (= atoms *owned* by this sub-domain). But when the pair style is used as a sub-style of a *hybrid pair style* or neighbor list entries are removed with *neigh\_modify exclude*, this number may be smaller. The array `list->ilist` has the (local) indices of the atoms for which neighbor lists have been created. Then `list->numneigh` is an *inum* sized array with the number of entries of each list of neighbors, and `list->firstneigh` is a list of pointers to those lists.

For efficiency reasons, cached copies of some properties of the outer loop atoms are also initialized.

```
// loop over neighbors of my atoms
```

```

for (ii = 0; ii < inum; ii++) {
  i = ilist[ii];
  xtmp = x[i][0];
  ytmp = x[i][1];
  ztmp = x[i][2];
  itype = type[i];
  jlist = firstneigh[i];
  jnum = numneigh[i];

```

The inner loop (index *j*) processes the neighbor lists. The neighbor list code encodes extra information using the upper 3 bits. The 2 highest bits encode whether a pair is a regular pair of neighbor (= 0) or a pair of 1-2 (= 1), 1-3 (= 2), or 1-4 (= 3) “*special*” neighbor. The next highest bit encodes whether the pair stores data in a `fix neigh/history` instance (an undocumented internal `fix` style). The `sbmask()` inline function extracts those bits and converts them into a number. This number is used to look up the corresponding scaling factor for the non-bonded interaction from the `force->special_lj` array and stores it in the `factor_lj` variable. Due to the additional bits, the value of *j* would be out of range when accessing data from per-atom arrays, so we apply the `NEIGHMASK` constant with a bit-wise and operation to mask them out. This step *must* be done, even if a pair style does not use special bond scaling of forces and energies to avoid segmentation faults.

With the corrected *j* index, it is now possible to compute the distance of the pair. For efficiency reasons, the square root is only taken *after* the check for the cutoff (which has been stored as squared cutoff by the `Pair` base class). For some pair styles, like the 12-6 Lennard-Jones potential, computing the square root can be avoided entirely.

```

for (jj = 0; jj < jnum; jj++) {
  j = jlist[jj];
  factor_lj = special_lj[sbmask(j)];
  j &= NEIGHMASK;

  delx = xtmp - x[j][0];
  dely = ytmp - x[j][1];
  delz = ztmp - x[j][2];
  rsq = delx * delx + dely * dely + delz * delz;
  jtype = type[j];

```

The following block of code is the actual application of the model potential to compute the force. Note, that *fpair* is the pair-wise force divided by the distance, as this simplifies the projection of the x-, y-, and z-components of the force vector by simply multiplying with the respective distances in those directions.

```

if (rsq < cutsq[itype][jtype]) {
  r = sqrt(rsq);
  dr = r - r0[itype][jtype];
  aexp = biga0[itype][jtype] * exp(-alpha[itype][jtype] * r);
  bexp = biga1[itype][jtype] * exp(-beta[itype][jtype] * dr * dr);
  fpair = alpha[itype][jtype] * aexp;
  fpair -= 2.0 * beta[itype][jtype] * dr * bexp;
  fpair *= factor_lj / r;

```

In the next block, the force is added to the per-atom force arrays. This pair style uses a “half” neighbor list (each pair is listed only once) so we take advantage of the fact that  $\vec{F}_{ij} = -\vec{F}_{ji}$ , i.e. apply Newton’s third law. The force is *always* stored when the atom is a “local” atom. Index  $i$  atoms are always “local” (i.e.  $i < nlocal$ ); index  $j$  atoms may be “ghost” atoms ( $j \geq nlocal$ ).

Depending on the settings used with the `newton` command, those pairs are only listed once globally (`newton_pair == 1`), then forces must be stored even with ghost atoms and after all forces are computed a “reverse communication” is performed to add those ghost atom forces to their corresponding local atoms. If the setting is disabled, then the extra communication is skipped, since for pairs straddling sub-domain boundaries, the forces are computed twice and only stored with the local atoms in the domain that *owns* it.

```

f[i][0] += delx * fpair;
f[i][1] += dely * fpair;
f[i][2] += delz * fpair;
if (newton_pair || j < nlocal) {
  f[j][0] -= delx * fpair;
  f[j][1] -= dely * fpair;
  f[j][2] -= delz * fpair;
}

```

The `ev_tally()` function tallies global or per-atom energy and virial. For typical MD simulations, the potential energy is merely a diagnostic and only needed on output. Similarly, the pressure may only be computed for (infrequent) thermodynamic output. For all timesteps where this information is not needed either, `eflag` or `evflag` are zero and the computation and call to the tally function skipped. Note that `evdwl` is initialized to zero at the beginning of the function, so that it still is valid to access it, even if the energy is not computed (e.g. when only the virial is needed).

```

if (eflag) evdwl = factor_lj * (aexp - bexp - offset[itype][jtype]);
if (evflag) ev_tally(i, j, nlocal, newton_pair, evdwl, 0.0, fpair, delx, dely,
→delz);
}
}
}

```

If only the global virial is needed and no energy, then calls to `ev_tally()` can be avoided altogether, and the global virial can be computed more efficiently from the dot product of the total per-atom force vector and the position vector of the corresponding atom,  $\vec{F} \cdot \vec{r}$ . This has to be done *after* all pair-wise forces are computed and *before* the reverse communication to collect data from ghost atoms, since the position has to be the position that was used to compute the force, i.e. *not* the “local” position if that ghost atom is a periodic copy.

```

if (vflag_fdotr) virial_fdotr_compute();
}

```

## Computing force and energy for a single pair

Certain features in LAMMPS only require computing interactions between individual pairs of atoms and the (optional) `single()` function is needed to support those features (e.g. for tabulation of force and energy with *pair\_write*). This is a repetition of the force kernel in the `compute()` function, but only for a single pair of atoms, where the (squared) distance is provided as a parameter (so it may not even be an existing distance between two specific atoms). The energy is returned as the return value of the function and the force as the *fforce* reference. Note, that this is, similar to how *fpair* is used in the `compute()` function, the magnitude of the force along the vector between the two atoms *divided* by the distance.

The `single()` function is optional, but it is expected to be implemented for any true pair-wise additive potential. Many-body potentials and special case potentials do not implement it. In a few special cases (EAM, long-range Coulomb), the `single()` function implements the pairwise additive part of the complete force interaction and depends on either pre-computed properties (derivative of embedding term for EAM) or post-computed non-pair-wise force contributions (KSpace style in case of long-range Coulomb).

The member variable `single_enable` should be set to 0 in the constructor, if it is not implemented (its default value is 1).

```
/* ----- */
double PairBornGauss::single(int /*i*/, int /*j*/, int itype, int jtype, double rsq,
                             double /*factor_coul*/, double factor_lj, double &fforce)
{
    double r, dr, aexp, bexp;

    r = sqrt(rsq);
    dr = r - r0[itype][jtype];
    aexp = biga0[itype][jtype] * exp(-alpha[itype][jtype] * r);
    bexp = biga1[itype][jtype] * exp(-beta[itype][jtype] * dr * dr);

    fforce = factor_lj * (alpha[itype][jtype] * aexp - 2.0 * dr * beta[itype][jtype] *
    ↪ bexp) / r;
    return factor_lj * (aexp - bexp - offset[itype][jtype]);
}
```

## Reading and writing of restart files

Support for writing and reading binary restart files is provided by the following four functions. Writing is only done by MPI processor rank 0. The output of global (not related to atom types) settings is usually delegated to the `write_restart_settings()` function. This restart facility is commonly only used, if there are small number of per-type parameters. For potentials that use per-element parameters or tabulated data and read these from files, those parameters and the name of the potential file are not written to restart files and the *pair\_coeff command* has to re-issued when restarting. For pair styles like “born/gauss” that do support writing to restart files, this is not required.

Implementing the functions to read and write binary restart files is optional. The member variable `restartinfo` should be set to 0 in the constructor, if they are not implemented (its default value is 1).

```
/* -----
   proc 0 writes to restart file
   ----- */

void PairBornGauss::write_restart(FILE *fp)
{
```

(continues on next page)

(continued from previous page)

```

write_restart_settings(fp);

int i, j;
for (i = 1; i <= atom->ntypes; i++) {
  for (j = i; j <= atom->ntypes; j++) {
    fwrite(&setflag[i][j], sizeof(int), 1, fp);
    if (setflag[i][j]) {
      fwrite(&biga0[i][j], sizeof(double), 1, fp);
      fwrite(&alpha[i][j], sizeof(double), 1, fp);
      fwrite(&biga1[i][j], sizeof(double), 1, fp);
      fwrite(&beta[i][j], sizeof(double), 1, fp);
      fwrite(&r0[i][j], sizeof(double), 1, fp);
      fwrite(&cut[i][j], sizeof(double), 1, fp);
    }
  }
}

/* -----
   proc 0 writes to restart file
   ----- */

void PairBornGauss::write_restart_settings(FILE *fp)
{
  fwrite(&cut_global, sizeof(double), 1, fp);
  fwrite(&offset_flag, sizeof(int), 1, fp);
  fwrite(&mix_flag, sizeof(int), 1, fp);
}

```

Similarly, on reading, only MPI processor rank 0 has opened the restart file and will read the data. The data is then distributed across all parallel processes using calls to `MPI_Bcast()`. Before reading atom type specific data, the corresponding storage needs to be allocated. Order and number or storage size of items read must be exactly the same as when writing, or else the data will be read incorrectly.

Reading uses the `utils::sfread` utility function to detect read errors and short reads, so that LAMMPS can abort if that happens, e.g. when the restart file is corrupted.

```

/* -----
   proc 0 reads from restart file, bcasts
   ----- */

void PairBornGauss::read_restart(FILE *fp)
{
  read_restart_settings(fp);

  allocate();

  int i, j;
  int me = comm->me;
  for (i = 1; i <= atom->ntypes; i++) {
    for (j = i; j <= atom->ntypes; j++) {
      if (me == 0) utils::sfread(FLError, &setflag[i][j], sizeof(int), 1, fp, nullptr,
→error);
    }
  }
}

```

(continues on next page)

(continued from previous page)

```

MPI_Bcast(&setflag[i][j], 1, MPI_INT, 0, world);
if (setflag[i][j]) {
    if (me == 0) {
        utils::sfsread(FLError, &biga0[i][j], sizeof(double), 1, fp, nullptr, error);
        utils::sfsread(FLError, &alpha[i][j], sizeof(double), 1, fp, nullptr, error);
        utils::sfsread(FLError, &biga1[i][j], sizeof(double), 1, fp, nullptr, error);
        utils::sfsread(FLError, &beta[i][j], sizeof(double), 1, fp, nullptr, error);
        utils::sfsread(FLError, &r0[i][j], sizeof(double), 1, fp, nullptr, error);
        utils::sfsread(FLError, &cut[i][j], sizeof(double), 1, fp, nullptr, error);
    }
    MPI_Bcast(&biga0[i][j], 1, MPI_DOUBLE, 0, world);
    MPI_Bcast(&alpha[i][j], 1, MPI_DOUBLE, 0, world);
    MPI_Bcast(&biga1[i][j], 1, MPI_DOUBLE, 0, world);
    MPI_Bcast(&beta[i][j], 1, MPI_DOUBLE, 0, world);
    MPI_Bcast(&r0[i][j], 1, MPI_DOUBLE, 0, world);
    MPI_Bcast(&cut[i][j], 1, MPI_DOUBLE, 0, world);
}
}
}

/* -----
   proc 0 reads from restart file, bcasts
   ----- */

void PairBornGauss::read_restart_settings(FILE *fp)
{
    if (comm->me == 0) {
        utils::sfsread(FLError, &cut_global, sizeof(double), 1, fp, nullptr, error);
        utils::sfsread(FLError, &offset_flag, sizeof(int), 1, fp, nullptr, error);
        utils::sfsread(FLError, &mix_flag, sizeof(int), 1, fp, nullptr, error);
    }
    MPI_Bcast(&cut_global, 1, MPI_DOUBLE, 0, world);
    MPI_Bcast(&offset_flag, 1, MPI_INT, 0, world);
    MPI_Bcast(&mix_flag, 1, MPI_INT, 0, world);
}

```

## Writing coefficients to data files

The `write_data()` and `write_data_all()` functions are optional and write out the current state of the *pair\_coeff settings* as “Pair Coeffs” or “PairIJ Coeffs” sections to a data file when using the *write\_data command*. The `write_data()` only writes out the diagonal elements of the pair coefficient matrix, as that is required for the format of the “Pair Coeffs” section. It is called when the “pair” option of the *write\_data command* is “ii” (the default). This is suitable for force fields where *all* off-diagonal terms of the pair coefficient matrix are generated from mixing. If explicit settings for off-diagonal elements were made, LAMMPS will print a warning, as those would be lost. To avoid this, the “pair ij” option of *write\_data* can be used which will trigger calling the `write_data_all()` function instead, which will write out all settings of the pair coefficient matrix (regardless of whether they were originally created from mixing or not).

These data file output functions are only useful for true pair-wise additive potentials, where the potential parameters can be entered through *multiple pair\_coeff commands*. Pair styles that require a single “pair\_coeff \*” command line are not compatible with reading their parameters from data files. For pair styles like *born/gauss* that do support writing to data files, the potential parameters will be read from the data file, if present, and *pair\_coeff commands* may not be

needed.

The member variable `writedata` should be set to 1 in the constructor, if these functions are implemented (the default value is 0).

```
/* -----
   proc 0 writes to data file
   ----- */

void PairBornGauss::write_data(FILE *fp)
{
  for (int i = 1; i <= atom->ntypes; i++)
    fprintf(fp, "%d %g %g %g %g %g\n", i, biga0[i][i], alpha[i][i], biga1[i][i],
    beta[i][i],
    r0[i][i]);
}

/* -----
   proc 0 writes all pairs to data file
   ----- */

void PairBornGauss::write_data_all(FILE *fp)
{
  for (int i = 1; i <= atom->ntypes; i++)
    for (int j = i; j <= atom->ntypes; j++)
      fprintf(fp, "%d %d %g %g %g %g %g %g\n", i, j, biga0[i][j], alpha[i][j],
      biga1[i][j],
      beta[i][j], r0[i][j], cut[i][j]);
}
```

### Give access to internal data

The purpose of the `extract()` function is to facilitate access to internal data of the pair style by other parts of LAMMPS. One possible application is to use *fix adapt* to gradually change potential parameters during a run. Here, we implement access to the pair coefficient matrix parameters.

```
/* ----- */

void *PairBornGauss::extract(const char *str, int &dim)
{
  dim = 2;
  if (strcmp(str, "biga0") == 0) return (void *) biga0;
  if (strcmp(str, "biga1") == 0) return (void *) biga1;
  if (strcmp(str, "r0") == 0) return (void *) r0;
  return nullptr;
}
```

Since the mercury potential, for which we have implemented the born/gauss pair style, has a temperature dependent parameter “biga1”, we can automatically adapt the potential based on the Taylor-MacLaurin expansion for “biga1” when performing a simulation with a temperature ramp. LAMMPS commands for that application are given below:

```
variable tlo index 300.0
variable thi index 600.0
```

(continues on next page)

(continued from previous page)

```

variable temp equal ramp(v_tlo,v_thi)
variable bigal equal (-2.58717e-8*v_temp+8.40841e-5)*v_temp+1.97475e-2

fix          1 all nvt temp ${tlo} ${thi} 0.1
fix          2 all adapt 1 pair born/gauss bigal * * v_bigal

```

## 4.8.4 Case 2: a many-body potential

Since there is a detailed description of the purpose and general layout of a pair style in the previous case, we will focus on where the implementation of a typical many-body potential *differs* from a pair-wise additive potential. We will use the implementation of the Tersoff potential as *pair\_style tersoff* as an example. The complete implementation can be found in the files `src/MANYBODY/pair_tersoff.cpp` and `src/MANYBODY/pair_tersoff.h` of the LAMMPS source code.

### Constructor

In the constructor, several *pair style flags* must be set differently for many-body potentials:

- the potential is not pair-wise additive, so the `single()` function cannot be used. This is indicated by setting the `single_enable` member variable to 0 (default value is 1)
- many-body potentials are usually not written to *binary restart files*. This is indicated by setting the member variable `restartinfo` to 0 (default is 1)
- many-body potentials typically read *all* parameters from a file which stores parameters indexed with a string (e.g. the element). For this, only a single *pair\_coeff* `**` command is allowed. This requirement is set and checked for, when the member variable `one_coeff` is set to 1 (default value is 0)
- many-body potentials can produce incorrect results if pairs of atoms are excluded from the neighbor list, e.g. explicitly by *neigh\_modify exclude* or implicitly through defining bonds, angles, etc. and having a *special\_bonds setting* that is not “special\_bonds lj/coul 1.0 1.0 1.0”. LAMMPS will check for this and print a suitable warning, when the member variable `manybody_flag` is set to 1 (default value is 0).

```

PairTersoff::PairTersoff(LAMMPS *lmp) : Pair(lmp)
{
    single_enable = 0;
    restartinfo = 0;
    one_coeff = 1;
    manybody_flag = 1;
}

```

### Neighbor list request

For computing the three-body interactions of the Tersoff potential a “full” neighbor list (both atoms of a pair are listed in each other’s neighbor list) is required. By default a “half” neighbor list is requested (each pair is listed only once). The request is made in the `init_style()` function. A more in-depth discussion of neighbor lists in LAMMPS and how to request them is in *this section of the documentation*

Also, additional conditions must be met for some global settings which are checked in the `init_style()` function.

```

/* -----
   init specific to this pair style
   ----- */

```

(continues on next page)

(continued from previous page)

```

void PairTersoff::init_style()
{
  if (atom->tag_enable == 0)
    error->all(FLERR,"Pair style Tersoff requires atom IDs");
  if (force->newton_pair == 0)
    error->all(FLERR,"Pair style Tersoff requires newton pair on");

  // need a full neighbor list

  neighbor->add_request(this,NeighConst::REQ_FULL);
}

```

### Computing forces from the neighbor list

Computing forces for a many-body potential is usually more complex than for a pair-wise additive potential and there are multiple components. For Tersoff, there is a pair-wise additive two-body term (two nested loops over indices  $i$  and  $j$ ) and a three-body term (three nested loops over indices  $i$ ,  $j$ , and  $k$ ). Since the neighbor list has all neighbors up to the maximum cutoff (for the two-body term), but the three-body interactions have a significantly shorter cutoff, a “short neighbor list” is also constructed at the same time while computing the two-body term and looping over the neighbor list for the first time.

```

if (rsq < cutshortsq) {
  neighshort[numshort++] = j;
  if (numshort >= maxshort) {
    maxshort += maxshort/2;
    memory->grow(neighshort,maxshort,"pair:neighshort");
  }
}

```

For the two-body term, only a half neighbor list would be needed, even though we have requested a full list (for the three-body loops). Rather than computing all interactions twice, we skip over half of the entries. This is done in a slightly complex way to make certain the same choice is made across all subdomains and so that there is no load imbalance introduced.

```

jtag = tag[j];
if (itag > jtag) {
  if ((itag+jtag) % 2 == 0) continue;
} else if (itag < jtag) {
  if ((itag+jtag) % 2 == 1) continue;
} else {
  if (x[j][2] < x[i][2]) continue;
  if (x[j][2] == ztmp && x[j][1] < ytmp) continue;
  if (x[j][2] == ztmp && x[j][1] == ytmp && x[j][0] < xtmp) continue;
}

```

For the three-body term, there is one additional nested loop and it uses the “short” neighbor list, accumulated previously.

```

// three-body interactions
// skip immediately if I-J is not within cutoff
double fjxtmp,fjytmp,fjztmp;

```

(continues on next page)

(continued from previous page)

```
for (jj = 0; jj < numshort; jj++) {
  j = neighshort[jj];
  jtype = map[type[j]];

  [...]

  for (kk = 0; kk < numshort; kk++) {
    if (jj == kk) continue;
    k = neighshort[kk];
    ktype = map[type[k]];

    [...]
  }
  [...]
}
```

## Reading potential parameters

For the Tersoff potential, the parameters are listed in a file and associated with triples of elements. Because we have set the `one_coeff` flag to 1 in the constructor, there may only be a single *pair\_coeff* \* \* line in the input for this pair style, and as a consequence the `coeff()` function will only be called once. Thus, the `coeff()` function has to do three tasks, each of which is delegated to a function in the `PairTersoff` class:

1. map elements to atom types. Those follow the potential file name in the command line arguments and are processed by the `map_element2type()` function.
2. read and parse the potential parameter file in the `read_file()` function.
3. Build data structures where the original and derived parameters are indexed by all possible triples of atom types and thus can be looked up quickly in the loops for the force computation

```
void PairTersoff::coeff(int narg, char **arg)
{
  if (!allocated) allocate();

  map_element2type(narg-3, arg+3);

  // read potential file and initialize potential parameters

  read_file(arg[2]);
  setup_params();
}
```

### 4.8.5 Case 3: a potential requiring communication

For some models, the interactions between atoms depends on properties of their environment which have to be computed *before* the the forces can be computed. Since LAMMPS is designed to run in parallel using a *domain decomposition strategy*, not all information of the atoms may be directly available and thus communication steps may be need to collect data from ghost atoms of neighboring subdomains or send data to ghost atoms for application during the pairwise computation.

Specifically, two communication patterns are needed: a “reverse communication” and a “forward communication”. The reverse communication collects data added to “ghost” atoms from neighboring sub-domains and sums it to their corresponding “local” atoms. This communication is only required and thus executed when the `Force::newton_pair` setting is 1 (i.e. *newton on*, the default). The forward communication is used to copy computed per-atom data from “local” atoms to their corresponding “ghost” atoms in neighboring sub-domains.

For this we will look at how the embedding term of the *embedded atom potential EAM* is implemented in LAMMPS. The complete implementation of this pair style can be found in the files `src/MANYBODY/pair_eam.cpp` and `src/MANYBODY/pair_eam.h` of the LAMMPS source code.

#### Allocating additional per-atom storage

First suitable (local) per-atom arrays (*rho*, *fp*, *numforce*) are allocated. These have to be large enough to include ghost atoms, are not used outside the `compute()` function and are re-initialized to zero once per timestep.

```
if (atom->nmax > nmax) {
  memory->destroy(rho);
  memory->destroy(fp);
  memory->destroy(numforce);
  nmax = atom->nmax;
  memory->create(rho,nmax,"pair:rho");
  memory->create(fp,nmax,"pair:fp");
  memory->create(numforce,nmax,"pair:numforce");
}
```

#### Reverse communication

Then a first loop over all pairs (*i* and *j*) is performed, where data is stored in the *rho* array representing the electron density at the site of *i* contributed from all neighbors *j*. Since the EAM pair style uses a half neighbor list (for efficiency reasons), a reverse communication is needed to collect the contributions to *rho* from ghost atoms (only if *newton on* is set for pair styles).

```
if (newton_pair) comm->reverse_comm(this);
```

To support the reverse communication, two functions must be defined: `pack_reverse_comm()` that copies relevant data into a buffer for ghost atoms and `unpack_reverse_comm()` that takes the collected data and adds it to the *rho* array for the corresponding local atoms that match the ghost atoms. In order to allocate sufficiently sized buffers, a flag must be set in the pair style constructor. Since in this case a single double precision number is communicated per atom, the `comm_reverse` member variable is set to 1 (default is 0 = no reverse communication).

```
int PairEAM::pack_reverse_comm(int n, int first, double *buf)
{
  int i,m,last;

  m = 0;
```

(continues on next page)

(continued from previous page)

```

    last = first + n;
    for (i = first; i < last; i++) buf[m++] = rho[i];
    return m;
}

void PairEAM::unpack_reverse_comm(int n, int *list, double *buf)
{
    int i,j,m;

    m = 0;
    for (i = 0; i < n; i++) {
        j = list[i];
        rho[j] += buf[m++];
    }
}

```

### Forward communication

From the density array *rho*, the derivative of the embedding energy *fp* is computed. The computation is only done for “local” atoms, but for the force computation, that property also is needed on ghost atoms. For that a forward communication is needed.

```
comm->forward_comm(this);
```

Similar to the reverse communication, this requires implementing a `pack_forward_comm()` and an `unpack_forward_comm()` function. Since there is one double precision number per atom that needs to be communicated, we must set the `comm_forward` member variable to 1 (default is 0 = no forward communication).

```

int PairEAM::pack_forward_comm(int n, int *list, double *buf, int pbc_flag, int *pbc)
{
    int i,j,m;

    m = 0;
    for (i = 0; i < n; i++) {
        j = list[i];
        buf[m++] = fp[j];
    }
    return m;
}

void PairEAM::unpack_forward_comm(int n, int first, double *buf)
{
    int i,m,last;

    m = 0;
    last = first + n;
    for (i = first; i < last; i++) fp[i] = buf[m++];
}

```

### 4.8.6 Case 4: potentials without a compute() function

A small number of pair style classes do not implement a `compute()` function, but instead use that of a different pair style.

#### Embedded atom variants “eam/fs” and “eam/alloy”

The pair styles *eam/fs* and *eam/alloy* share the same model and potential function as the *eam pair style*. They differ in the format of the potential files. Pair style *eam* supports only potential files for single elements. For multi-element systems, the mixed terms are computed from mixed parameters. The *eam/fs* and *eam/alloy* pair styles, however, **require** the use of a single potential file for all elements where the mixed element potential is included in the tabulation. That enables more accurate models for alloys, since the mixed terms can be adjusted for a better representation of material properties compared to terms created from mixing of per-element terms in the PairEAM class.

We take a closer at the *eam/alloy* pair style. The complete implementation is in the files `src/MANYBODY/pair_eam_alloy.cpp` and `src/MANYBODY/pair_eam_alloy.h`.

The PairEAMAlloy class is derived from PairEAM and not Pair and overrides only a small number of functions:

```
class PairEAMAlloy : virtual public PairEAM {
public:
    PairEAMAlloy(class LAMMPS *);
    void coeff(int, char **) override;

protected:
    void read_file(char *) override;
    void file2array() override;
};
```

All other functionality is inherited from the base classes. In the constructor we set the `one_coeff` flag and the `manybody_flag` to 1 to indicate the different behavior.

```
PairEAMAlloy::PairEAMAlloy(LAMMPS *lmp) : PairEAM(lmp)
{
    one_coeff = 1;
    manybody_flag = 1;
}
```

The `coeff()` function (not shown here) implements the different behavior when processing the *pair\_coeff command*. The `read_file()` and `file2array()` replace the corresponding PairEAM class functions to accommodate the different data and file format.

#### AIREBO and AIREBO-M potentials

The AIREBO-M potential differs from the better known AIREBO potential in that it use a Morse potential instead of a Lennard-Jones potential for non-bonded interactions. Since this difference is very minimal compared to the entire potential, both potentials are implemented in the PairAIREBO class and which non-bonded potential is used is determined by the value of the `morseflag` flag, which would be set to either 0 or 1.

```
class PairAIREBOMorse : public PairAIREBO {
public:
    PairAIREBOMorse(class LAMMPS *);
    void settings(int, char **) override;
};
```

The `morseflag` variable defaults to 0 and is set to 1 in the `PairAIREBOMorse::settings()` function which is called by the `pair_style` command. This function delegates all command line processing and setting of other parameters to the `PairAIREBO::settings()` function of the base class.

```
void PairAIREBOMorse::settings(int narg, char **arg)
{
    PairAIREBO::settings(narg, arg);

    morseflag = 1;
}
```

The complete implementation is in the files `src/MANYBODY/pair_airebo.cpp`, `src/MANYBODY/pair_airebo.h`, `src/MANYBODY/pair_airebo_morse.cpp`, `src/MANYBODY/pair_airebo_morse.h`.

---

(Bomont) Bomont, Bretonnet, J. Chem. Phys. 124, 054504 (2006)

## 4.8.7 Writing a new fix style

Writing fix styles is a flexible way of extending LAMMPS. Users can implement many things using fixes. Some fix styles are only used internally to support compute styles or pair styles:

- change particles attributes (positions, velocities, forces, etc.). Examples: `FixNVE`, `FixFreeze`.
- read or write data. Example: `FixRestart`.
- adding or modifying properties due to geometry. Example: `FixWall`.
- interacting with other subsystems or external code: Examples: `FixTTM`, `FixExternal`, `FixMDI`
- saving information for analysis or future use (previous positions, for instance). Examples: `FixAveTime`, `FixStoreState`.

All fixes are derived from the `Fix` base class and must have a constructor with the signature: `FixPrintVel(class LAMMPS *, int, char **)`.

Every fix must be registered in LAMMPS by writing the following lines of code in the header before include guards:

```
#ifdef FIX_CLASS
// clang-format off
FixStyle(print/vel, FixPrintVel);
// clang-format on
#else
/* the definition of the FixPrintVel class comes here */
...
#endif
```

Where `print/vel` is the style name of your fix in the input script and `FixPrintVel` is the name of the class. The header file would be called `fix_print_vel.h` and the implementation file `fix_print_vel.cpp`. These conventions allow LAMMPS to automatically integrate it into the executable when compiling and associate your new fix class with the designated keyword when it parses the input script.

Let's write a simple fix which will print the average velocity at the end of each timestep. First of all, implement a constructor:

```

FixPrintVel::FixPrintVel(LAMMPS *lmp, int nargs, char **arg)
: Fix(lmp, nargs, arg)
{
  if (nargs < 4) utils::missing_cmd_args(FLERR, "fix print/vel", error);

  nevery = utils::inumeric(FLERR, arg[3], false, lmp);
  if (nevery <= 0)
    error->all(FLERR, "Illegal fix print/vel nevery value: {}", nevery);
}

```

In the constructor you should parse the fix arguments which are specified in the script. All fixes have pretty much the same syntax: `fix <fix-ID> <fix group> <fix name> <fix arguments ...>`. The first 3 parameters are parsed by Fix base class constructor, while `<fix arguments>` should be parsed by you. In our case, we need to specify how often we want to print an average velocity. For instance, once in 50 timesteps: `fix 1 print/vel 50`. There is a special variable in the Fix class called `nevery` which specifies how often the method `end_of_step()` is called. Thus all we need to do is just set it up.

The next method we need to implement is `setmask()`:

```

int FixPrintVel::setmask()
{
  int mask = 0;
  mask |= FixConst::END_OF_STEP;
  return mask;
}

```

Here we specify which methods of the fix should be called during *execution of a timestep*. The constant `END_OF_STEP` corresponds to the `end_of_step()` method.

```

void FixPrintVel::end_of_step()
{
  // for add3, scale3
  using namespace MathExtra;

  double** v = atom->v;
  int nlocal = atom->nlocal;
  double localAvgVel[4]; // 4th element for particles count
  memset(localAvgVel, 0, 4 * sizeof(double));
  for (int particleInd = 0; particleInd < nlocal; ++particleInd) {
    add3(localAvgVel, v[particleInd], localAvgVel);
  }
  localAvgVel[3] = nlocal;
  double globalAvgVel[4];
  memset(globalAvgVel, 0, 4 * sizeof(double));
  MPI_Allreduce(localAvgVel, globalAvgVel, 4, MPI_DOUBLE, MPI_SUM, world);
  scale3(1.0 / globalAvgVel[3], globalAvgVel);
  if ((comm->me == 0) && screen) {
    fmt::print(screen, "{}, {}, {}\n",
               globalAvgVel[0], globalAvgVel[1], globalAvgVel[2]);
  }
}

```

In the code above, we use MathExtra routines defined in `math_extra.h`. There are bunch of math functions to work with arrays of doubles as with math vectors. It is also important to note that LAMMPS code should always assume to

be run in parallel and that atom data is thus distributed across the MPI ranks. Thus you can only process data from local atoms directly and need to use MPI library calls to combine or exchange data. For serial execution, LAMMPS comes bundled with the MPI STUBS library that contains the MPI library function calls in dummy versions that only work for a single MPI rank.

In this code we use an instance of Atom class. This object is stored in the Pointers class (see `pointers.h`) which is the base class of the Fix base class. This object contains references to various class instances (the original instances are created and held by the LAMMPS class) with all global information about the simulation system. Data from the Pointers class is available to all classes inherited from it using protected inheritance. Hence when you write your own class, which is going to use LAMMPS data, don't forget to inherit from Pointers or pass a Pointer to it to all functions that need access. When writing fixes we inherit from class Fix which is inherited from Pointers so there is no need to inherit from it directly.

The code above computes average velocity for all particles in the simulation. Yet you have one unused parameter in fix call from the script: `group_name`. This parameter specifies the group of atoms used in the fix. So we should compute the average for all particles in the simulation only if `group_name == "all"`, but it can be any group. The group membership information of an atom is contained in the `mask` property of an atom and the bit corresponding to a given group is stored in the `groupbit` variable which is defined in Fix base class:

```
for (int i = 0; i < nlocal; ++i) {
  if (atom->mask[i] & groupbit) {
    // Do all job here
  }
}
```

Class Atom encapsulates atoms positions, velocities, forces, etc. Users can access them using the particle index. Note, that particle indexes are usually changed every few timesteps because of neighbor list rebuilds and spatial sorting (to improve cache efficiency).

Let us consider another Fix example: We want to have a fix which stores atoms position from the previous time step in your fix. The local atoms indexes may not be valid on the next iteration. In order to handle this situation there are several methods which should be implemented:

- `double memory_usage()`: return how much memory the fix uses (optional)
- `void grow_arrays(int)`: do reallocation of the per-particle arrays in your fix
- `void copy_arrays(int i, int j, int delflag)`: copy i-th per-particle information to j-th particle position. Used when atom sorting is performed. if `delflag` is set and atom j owns a body, move the body information to atom i.
- `void set_arrays(int i)`: sets i-th particle related information to zero

Note, that if your class implements these methods, it must add calls of `add_callback` and `delete_callback` to the constructor and destructor. Since we want to store positions of atoms from the previous timestep, we need to add `double** xold` to the header file. Then add allocation code to the constructor:

```
FixSavePos::FixSavePos(LAMMPS *lmp, int narg, char **arg), xold(nullptr)
{
  //...
  memory->create(xold, atom->nmax, 3, "FixSavePos:x");
  atom->add_callback(0);
}

FixSavePos::~FixSavePos() {
  atom->delete_callback(id, 0);
  memory->destroy(xold);
}
```

Implement the aforementioned methods:

```
double FixSavePos::memory_usage()
{
    int nmax = atom->nmax;
    double bytes = 0.0;
    bytes += nmax * 3 * sizeof(double);
    return bytes;
}

void FixSavePos::grow_arrays(int nmax)
{
    memory->grow(xold, nmax, 3, "FixSavePos:xold");
}

void FixSavePos::copy_arrays(int i, int j, int delflag)
{
    memcpy(xold[j], xold[i], sizeof(double) * 3);
}

void FixSavePos::set_arrays(int i)
{
    memset(xold[i], 0, sizeof(double) * 3);
}

int FixSavePos::pack_exchange(int i, double *buf)
{
    int m = 0;
    buf[m++] = xold[i][0];
    buf[m++] = xold[i][1];
    buf[m++] = xold[i][2];

    return m;
}

int FixSavePos::unpack_exchange(int nlocal, double *buf)
{
    int m = 0;
    xold[nlocal][0] = buf[m++];
    xold[nlocal][1] = buf[m++];
    xold[nlocal][2] = buf[m++];

    return m;
}
```

Now, a little bit about memory allocation. We use the Memory class which is just a bunch of template functions for allocating 1D and 2D arrays. So you need to add include `memory.h` to have access to them.

Finally, if you need to write/read some global information used in your fix to the restart file, you might do it by setting the flag `restart_global = 1` in the constructor and implementing methods `void write_restart(FILE *fp)` and `void restart(char *buf)`. If, in addition, you want to write the per-atom property to restart files then these additional settings and functions are needed:

- a fix flag indicating this needs to be set `restart_peratom = 1`;
- `atom->add_callback()` and `atom->delete_callback()` must be called a second time with the final argu-

ment set to 1 instead of 0 (indicating restart processing instead of per-atom data memory management).

- the functions `void pack_restart(int i, double *buf)` and `void unpack_restart(int nlocal, int nth)` need to be implemented

## 4.9 Notes for developers and code maintainers

This section documents how some of the code functionality within LAMMPS works at a conceptual level. Comments on code in source files typically document what a variable stores, what a small section of code does, or what a function does and its input/outputs. The topics on this page are intended to document code functionality at a higher level.

Available topics are:

- *Reading and parsing of text and text files*
  - *Requesting and accessing neighbor lists*
  - *Choosing between a custom atom style, fix property/atom, and fix STORE/ATOM*
  - *Fix contributions to instantaneous energy, virial, and cumulative energy*
  - *KSpace PPPM FFT grids*
- 

### 4.9.1 Reading and parsing of text and text files

Classes in LAMMPS frequently need to read in additional data from a file, e.g. potential parameters from a potential file for manybody potentials. LAMMPS provides several custom classes and convenience functions to simplify the process. They offer the following benefits:

- better code reuse and fewer lines of code needed to implement reading and parsing data from a file
- better detection of format errors, incompatible data, and better error messages
- exit with an error message instead of silently converting only part of the text to a number or returning a 0 on unrecognized text and thus reading incorrect values
- re-entrant code through avoiding global static variables (as used by `strtok()`)
- transparent support for translating unsupported UTF-8 characters to their ASCII equivalents (the text-to-value conversion functions **only** accept ASCII characters)

In most cases (e.g. potential files) the same data is needed on all MPI ranks. Then it is best to do the reading and parsing only on MPI rank 0, and communicate the data later with one or more `MPI_Bcast()` calls. For reading generic text and potential parameter files the custom classes [TextFileReader](#) and [PotentialFileReader](#) are available. They allow reading the file as individual lines for which they can return a tokenizer class (see below) for parsing the line. Or they can return blocks of numbers as a vector directly. The documentation on [File reader classes](#) contains an example for a typical case.

When reading per-atom data, the data on each line of the file usually needs to include an atom ID so it can be associated with a particular atom. In that case the data can be read in multi-line chunks and broadcast to all MPI ranks with [utils::read\\_lines\\_from\\_file\(\)](#). Those chunks are then split into lines, parsed, and applied only to atoms the MPI rank “owns”.

For splitting a string (incrementally) into words and optionally converting those to numbers, the [Tokenizer](#) and [ValueTokenizer](#) can be used. Those provide a superset of the functionality of `strtok()` from the C-library and the latter also includes conversion to different types. Any errors while processing the string in those classes will result in an exception, which can be caught and the error processed as needed. Unlike the C-library functions `atoi()`, `atof()`,

`strtol()`, or `strtod()` the conversion will check if the converted text is a valid integer or floating point number and will not silently return an unexpected or incorrect value. For example, `atoi()` will return 12 when converting “12.5”, while the `ValueTokenizer` class will throw an `InvalidIntegerException` if `ValueTokenizer::next_int()` is called on the same string.

## 4.9.2 Requesting and accessing neighbor lists

LAMMPS uses Verlet-style neighbor lists to avoid having to loop over *all* pairs of *all* atoms when computing pairwise properties with a cutoff (e.g. pairwise forces or radial distribution functions). There are three main algorithms that can be selected by the *neighbor command*: *bin* (the default, uses binning to achieve linear scaling with system size), *nsq* (without binning, quadratic scaling), *multi* (with binning, optimized for varying cutoffs or polydisperse granular particles). In addition to how the neighbor lists are constructed a number of different variants of neighbor lists need to be created (e.g. “full” or “half”) for different purposes and styles and those may be required in every time step (“perpetual”) or on some steps (“occasional”).

The neighbor list creation is managed by the `Neighbor` class. Individual classes can obtain a neighbor list by creating an instance of a `NeighRequest` class which is stored in a list inside the `Neighbor` class. The `Neighbor` class will then analyze the various requests and apply optimizations where neighbor lists that have the same settings will be created only once and then copied, or a list may be constructed by processing a neighbor list from a different request that is a superset of the requested list. The neighbor list build is then *processed in parallel*.

The most commonly required neighbor list is a so-called “half” neighbor list, where each pair of atoms is listed only once (except when the *newton command setting* for pair is off; in that case pairs straddling subdomains or periodic boundaries will be listed twice). Thus these are the default settings when a neighbor list request is created in:

```
void Pair::init_style()
{
    neighbor->add_request(this);
}

void Pair::init_list(int /*id*/, NeighList *ptr)
{
    list = ptr;
}
```

The `this` pointer argument is required so the neighbor list code can access the requesting class instance to store the assembled neighbor list with that instance by calling its `init_list()` member function. The optional second argument (omitted here) contains a bitmask of flags that determines the kind of neighbor list requested. The default value used here asks for a perpetual “half” neighbor list.

Non-default values of the second argument need to be used to adjust a neighbor list request to the specific needs of a style. The *tersoff* pair style, for example, needs a “full” neighbor list:

```
void PairTersoff::init_style()
{
    // [...]
    neighbor->add_request(this, NeighConst::REQ_FULL);
}
```

When a pair style supports r-RESPA time integration with different cutoff regions, the request flag may depend on the corresponding r-RESPA settings. Here is an example from pair style `lj/cut`:

```
void PairLJCut::init_style()
{
```

(continues on next page)

(continued from previous page)

```

int list_style = NeighConst::REQ_DEFAULT;

if (update->whichflag == 1 && utils::strmatch(update->integrate_style, "^respa")) {
    auto respa = (Respa *) update->integrate;
    if (respa->level_inner >= 0) list_style = NeighConst::REQ_RESPA_INOUT;
    if (respa->level_middle >= 0) list_style = NeighConst::REQ_RESPA_ALL;
}
neighbor->add_request(this, list_style);
// [...]
}

```

Granular pair styles need neighbor lists based on particle sizes and not cutoff and also may need to store data across timesteps (“history”). For example with:

```

if (use_history) neighbor->add_request(this, NeighConst::REQ_SIZE | NeighConst::REQ_
→HISTORY);
else neighbor->add_request(this, NeighConst::REQ_SIZE);

```

In case a class would need to make multiple neighbor list requests with different settings, each request can set an id which is then used in the corresponding `init_list()` function to assign it to the suitable pointer variable. This is done for example by the *pair style meam*:

```

void PairMEAM::init_style()
{
    // [...]
    neighbor->add_request(this, NeighConst::REQ_FULL)->set_id(1);
    neighbor->add_request(this)->set_id(2);
}
void PairMEAM::init_list(int id, NeighList *ptr)
{
    if (id == 1) listfull = ptr;
    else if (id == 2) listhalf = ptr;
}

```

Fixes may require a neighbor list that is only build occasionally (or just once) and this can also be indicated by a flag. As an example here is the request from the `FixPeriNeigh` class which is created internally by *Peridynamics pair styles*:

```

neighbor->add_request(this, NeighConst::REQ_FULL | NeighConst::REQ_OCCASIONAL);

```

It is also possible to request a neighbor list that uses a different cutoff than what is usually inferred from the pair style settings (largest cutoff of all pair styles plus neighbor list skin). The following is used in the *compute rdf* command implementation:

```

if (cutflag)
    neighbor->add_request(this, NeighConst::REQ_OCCASIONAL)->set_cutoff(mycutneigh);
else
    neighbor->add_request(this, NeighConst::REQ_OCCASIONAL);

```

The neighbor list request function has a slightly different set of arguments when created by a command style. In this case the neighbor list is *always* an occasional neighbor list, so that flag is not needed. However for printing the neighbor list summary the name of the requesting command should be set. Below is the request from the *delete atoms* command:

```

neighbor->add_request(this, "delete_atoms", NeighConst::REQ_FULL);

```

### 4.9.3 Choosing between a custom atom style, fix property/atom, and fix STORE/ATOM

There are multiple ways to manage per-atom data within LAMMPS. Often the per-atom storage is only used locally and managed by the class that uses it. If the data has to persist between multiple time steps and migrate with atoms when they move from sub-domain to sub-domain or across periodic boundaries, then using a custom atom style, or *fix property/atom*, or the internal fix STORE/ATOM are possible options.

- Using the atom style is usually the most programming effort and mostly needed when the per-atom data is an integral part of the model like a per-atom charge or diameter and thus should be part of the Atoms section of a *data file*.
- Fix property/atom is useful if the data is optional or should be entered by the user, or accessed as a (named) custom property. In this case the fix should be entered as part of the input (and not internally) which allows to enter and store its content with data files.
- Fix STORE/ATOM should be used when the data should be accessed internally only and thus the fix can be created internally.

### 4.9.4 Fix contributions to instantaneous energy, virial, and cumulative energy

Fixes can calculate contributions to the instantaneous energy and/or virial of the system, both in a global and peratom sense. Fixes that perform thermostating or barostating can calculate the cumulative energy they add to or subtract from the system, which is accessed by the *ecouple* and *econserve* thermodynamic keywords. This subsection explains how both work and what flags to set in a new fix to enable this functionality.

Let's start with thermostating and barostating fixes. Examples are the *fix langevin* and *fix npt* commands. Here is what the fix needs to do:

- Set the variable *ecouple\_flag* = 1 in the constructor. Also set *scalar\_flag* = 1, *extscalar* = 1, and *global\_freq* to a timestep increment which matches how often the fix is invoked.
- Implement a *compute\_scalar()* method that returns the cumulative energy added or subtracted by the fix, e.g. by rescaling the velocity of atoms. The sign convention is that subtracted energy is positive, added energy is negative. This must be the total energy added to the entire system, i.e. an “extensive” quantity, not a per-atom energy. Cumulative means the summed energy since the fix was instantiated, even across multiple runs. This is because the energy is used by the *econserve* thermodynamic keyword to check that the fix is conserving the total energy of the system, i.e. potential energy + kinetic energy + coupling energy = a constant.

And here is how the code operates:

- The Modify class makes a list of all fixes that set *ecouple\_flag* = 1.
- The *thermo\_style custom* command defines *ecouple* and *econserve* keywords.
- These keywords sum the energy contributions from all the *ecouple\_flag* = 1 fixes by invoking the *energy\_couple()* method in the Modify class, which calls the *compute\_scalar()* method of each fix in the list.

---

Next, here is how a fix contributes to the instantaneous energy and virial of the system. First, it sets any or all of these flags to a value of 1 in their constructor:

- *energy\_global\_flag* to contribute to global energy, example: *fix indent*
- *energy\_peratom\_flag* to contribute to peratom energy, *fix cmap*
- *virial\_global\_flag* to contribute to global virial, example: *fix wall*
- *virial\_peratom\_flag* to contribute to peratom virial, example: *fix wall*

The fix must also do the following:

- For global energy, implement a `compute_scalar()` method that returns the energy added or subtracted on this timestep. Here the sign convention is that added energy is positive, subtracted energy is negative.
- For peratom energy, invoke the `ev_init(eflag,vflag)` function each time the fix is invoked, which initializes peratom energy storage. The value of `eflag` may need to be stored from an earlier call to the fix during the same timestep. See how the [fix cmap](#) command does this in `src/MOLECULE/fix_cmap.cpp`. When an energy for one or more atoms is calculated, invoke the `ev_tally()` function to tally the contribution to each atom. Both the `ev_init()` and `ev_tally()` methods are in the parent Fix class.
- For global and/or peratom virial, invoke the `v_init(vflag)` function each time the fix is invoked, which initializes virial storage. When forces on one or more atoms are calculated, invoke the `v_tally()` function to tally the contribution. Both the `v_init()` and `v_tally()` methods are in the parent Fix class. Note that there are several variants of `v_tally()`; choose the one appropriate to your fix.

---

**Note:** The `ev_init()` and `ev_tally()` methods also account for global and peratom virial contributions. Thus you do not need to invoke the `v_init()` and `v_tally()` methods if the fix also calculates peratom energies.

---

The fix must also specify whether (by default) to include or exclude these contributions to the global/peratom energy/virial of the system. For the fix to include the contributions, set either or both of these variables in the constructor:

- `thermo_energy = 1`, for global and peratom energy
- `thermo_virial = 1`, for global and peratom virial

Note that these variables are zeroed in `fix.cpp`. Thus if you don't set the variables, the contributions will be excluded (by default).

However, the user has ultimate control over whether to include or exclude the contributions of the fix via the [fix modify](#) command:

- `fix modify energy yes` to include global and peratom energy contributions
- `fix modify virial yes` to include global and peratom virial contributions

If the fix contributes to any of the global/peratom energy/virial values for the system, it should be explained on the fix doc page, along with the default values for the *energy yes/no* and *virial yes/no* settings of the [fix modify](#) command.

Finally, these 4 contributions are included in the output of 4 computes:

- global energy in [compute pe](#)
- peratom energy in [compute pe/atom](#)
- global virial in [compute pressure](#)
- peratom virial in [compute stress/atom](#)

These computes invoke a method of the Modify class to include contributions from fixes that have the corresponding flags set, e.g. `energy_peratom_flag` and `thermo_energy` for [compute pe/atom](#).

Note that each compute has an optional keyword to either include or exclude all contributions from fixes. Also note that [compute pe](#) and [compute pressure](#) are what is used (by default) by [thermodynamic output](#) to calculate values for its *pe* and *press* keywords.

### 4.9.5 KSpace PPPM FFT grids

The various *KSpace PPPM* styles in LAMMPS use FFTs to solve Poisson's equation. This subsection describes:

- how FFT grids are defined
- how they are decomposed across processors
- how they are indexed by each processor
- how particle charge and electric field values are mapped to/from the grid

An FFT grid cell is a 3d volume; grid points are corners of a grid cell and the code stores values assigned to grid points in vectors or 3d arrays. A global 3d FFT grid has points indexed 0 to N-1 inclusive in each dimension.

Each processor owns two subsets of the grid, each subset is brick-shaped. Depending on how it is used, these subsets are allocated as a 1d vector or 3d array. Either way, the ordering of values within contiguous memory x fastest, then y, z slowest.

For the 3d decomposition of the grid, the global grid is partitioned into bricks that correspond to the subdomains of the simulation box that each processor owns. Often, this is a regular 3d array ( $P_x$  by  $P_y$  by  $P_z$ ) of bricks, where  $P$  = number of processors =  $P_x * P_y * P_z$ . More generally it can be a tiled decomposition, where each processor owns a brick and the union of all the bricks is the global grid. Tiled decompositions are produced by load balancing with the RCB algorithm; see the *balance rcb* command.

For the FFT decomposition of the grid, each processor owns a brick that spans the entire x dimension of the grid while the y and z dimensions are partitioned as a regular 2d array ( $P_1$  by  $P_2$ ), where  $P = P_1 * P_2$ .

The following indices store the inclusive bounds of the brick a processor owns, within the global grid:

```
nF00_in = 3d decomposition brick
nF00_fft = FFT decomposition brick
nF00_out = 3d decomposition brick + ghost cells
```

where F00 corresponds to xlo, xhi, ylo, yhi, zlo, or zhi.

The in and fft indices are from 0 to N-1 inclusive in each dimension, where N is the grid size.

The out indices index an array which stores the in subset of the grid plus ghost cells that surround it. These indices can thus be < 0 or >= N.

The number of ghost cells a processor owns in each of the 6 directions is a function of:

```
neighbor skin distance (since atoms can move outside a proc subdomain)
qdist = offset or charge from atom due to TIP4P fictitious charge
order = mapping stencil size
shift = factor used when order is an even number (see below)
```

Here is an explanation of how the PPPM variables order, nlower / nupper, shift, and OFFSET work. They are the relevant variables that determine how atom charge is mapped to grid points and how field values are mapped from grid points to atoms:

```
order = # of nearby grid points in each dim that atom charge/field are mapped to/from
nlower, nupper = extent of stencil around the grid point an atom is assigned to
OFFSET = large integer added/subtracted when mapping to avoid int(-0.75) = 0 when -1 is
→ the desired result
```

The `particle_map()` method assigns each atom to a grid point.

If order is even, say 4:

```
atom is assigned to grid point to its left (in each dim)
shift = OFFSET
nlower = -1, nupper = 2, which are offsets from assigned grid point
window of mapping grid pts is thus 2 grid points to left of atom, 2 to right
```

If order is odd, say 5:

```
atom is assigned to left/right grid pt it is closest to (in each dim)
shift = OFFSET + 0.5
nlower = 2, nupper = 2
if point is in left half of cell, then window of affected grid pts is 3 grid points to
↳ left of atom, 2 to right
if point is in right half of cell, then window of affected grid pts is 2 grid points to
↳ left of atom, 3 to right
```

These settings apply to each dimension, so that if order = 5, an atom's charge is mapped to 125 grid points that surround the atom.

## 4.10 Notes for updating code written for older LAMMPS versions

This section documents how C++ source files that are available *outside of the LAMMPS source distribution* (e.g. in external USER packages or as source files provided as a supplement to a publication) that are written for an older version of LAMMPS and thus need to be updated to be compatible with the current version of LAMMPS. Due to the active development of LAMMPS it is likely to always be incomplete. Please contact [developers@lammps.org](mailto:developers@lammps.org) in case you run across an issue that is not (yet) listed here. Please also review the latest information about the LAMMPS [programming style conventions](#), especially if you are considering to submit the updated version for inclusion into the LAMMPS distribution.

Available topics in mostly chronological order are:

- *Setting flags in the constructor*
- *Rename of `pack/unpack_comm()` to `pack/unpack_forward_comm()`*
- *Use `ev_init()` to initialize variables derived from `eflag` and `vflag`*
- *Use `utils::count_words()` functions instead of `atom->count_words()`*
- *Use `utils::numeric()` functions instead of `force->numeric()`*
- *Use `utils::open_potential()` function to open potential files*
- *Use symbolic `Atom` and `AtomVec` constants instead of numerical values*
- *Simplify customized error messages*
- *Use of “override” instead of “virtual”*
- *Simplified and more compact neighbor list requests*
- *Split of fix `STORE` into fix `STORE/GLOBAL` and fix `STORE/PERATOM`*
- *Rename of fix `STORE/PERATOM` to fix `STORE/ATOM` and change of arguments*
- *Use `Output::get_dump_by_id()` instead of `Output::find_dump()`*
- *Refactored grid communication using `Grid3d/Grid2d` classes instead of `GridComm`*

### 4.10.1 Setting flags in the constructor

As LAMMPS gains additional functionality, new flags may need to be set in the constructor or a class to signal compatibility with such features. Most of the time the defaults are chosen conservatively, but sometimes the conservative choice is the uncommon choice, and then those settings need to be made when updating code.

Pair styles:

- `manybody_flag`: set to 1 if your pair style is not pair-wise additive
- `restartinfo`: set to 0 if your pair style does not store data in restart files

### 4.10.2 Rename of `pack/unpack_comm()` to `pack/unpack_forward_comm()`

Changed in version 8Aug2014.

In this change set, the functions to pack/unpack data into communication buffers for *forward communications* were renamed from `pack_comm()` and `unpack_comm()` to `pack_forward_comm()` and `unpack_forward_comm()`, respectively. Also the meaning of the return value of these functions was changed: rather than returning the number of items per atom stored in the buffer, now the total number of items added (or unpacked) needs to be returned. Here is an example from the *PairEAM* class. Of course the member function declaration in corresponding header file needs to be updated accordingly.

Old:

```
int PairEAM::pack_comm(int n, int *list, double *buf, int pbc_flag, int *pbc)
{
    int m = 0;
    for (int i = 0; i < n; i++) {
        int j = list[i];
        buf[m++] = fp[j];
    }
    return 1;
}
```

New:

```
int PairEAM::pack_forward_comm(int n, int *list, double *buf, int pbc_flag, int *pbc)
{
    int m = 0;
    for (int i = 0; i < n; i++) {
        int j = list[i];
        buf[m++] = fp[j];
    }
    return m;
}
```

**Note:** Because the various “pack” and “unpack” functions are defined in the respective base classes as dummy functions doing nothing, and because of the the name mismatch the custom versions in the derived class will no longer be called, there will be no compilation error when this change is not applied. Only calculations will suddenly produce incorrect results because the required forward communication calls will cease to function correctly.

### 4.10.3 Use `ev_init()` to initialize variables derived from `eflag` and `vflag`

Changed in version 29Mar2019.

There are several variables that need to be initialized based on the values of the “`eflag`” and “`vflag`” variables and since sometimes there are new bits added and new variables need to be set to 1 or 0. To make this consistent across all styles, there is now an inline function `ev_init(eflag, vflag)` that makes those settings consistently and calls either `ev_setup()` or `ev_unset()`. Example from a pair style:

Old:

```
if (eflag || vflag) ev_setup(eflag, vflag);
else evflag = vflag_fdotr = eflag_global = eflag_atom = 0;
```

New:

```
ev_init(eflag, vflag);
```

Not applying this change will not cause a compilation error, but can lead to inconsistent behavior and incorrect tallying of energy or virial.

### 4.10.4 Use `utils::count_words()` functions instead of `atom->count_words()`

Changed in version 2Jun2020.

The “`count_words()`” functions for parsing text have been moved from the `Atom` class to the *`utils namespace`*. The “`count_words()`” function in “`utils`” uses the `Tokenizer` class internally to split a line into words and count them, thus it will not modify the argument string as the function in the `Atoms` class did and thus had a variant using a copy buffer. Unlike the old version, the new version does not remove comments. For that you can use the *`utils::trim_comment()` function* as shown in the example below.

Old:

```
nwords = atom->count_words(line);
int nwords = atom->count_words(buf);
```

New:

```
nwords = utils::count_words(line);
int nwords = utils::count_words(utils::trim_comment(buf));
```

See also:

*`utils::count_words()`, `utils::trim_comments()`*

### 4.10.5 Use `utils::numeric()` functions instead of `force->numeric()`

Changed in version 18Sep2020.

The “`numeric()`” conversion functions (including “`inumeric()`”, “`bnumeric()`”, and “`tnumeric()`”) have been moved from the `Force` class to the *`utils namespace`*. Also they take an additional argument that selects whether the `Error::all()` or `Error::one()` function should be called in case of an error. The former should be used when *all* MPI processes call the conversion function and the latter *must* be used when they are called from only one or a subset of the MPI processes.

Old:

```
val = force->numeric(FLERR, arg[1]);
num = force->inumeric(FLERR, arg[2]);
```

New:

```
val = utils::numeric(FLERR, true, arg[1], lmp);
num = utils::inumeric(FLERR, false, arg[2], lmp);
```

See also:

`utils::numeric()`, `utils::inumeric()`, `utils::bnumeric()`, `utils::tnumeric()`

#### 4.10.6 Use `utils::open_potential()` function to open potential files

Changed in version 18Sep2020.

The `utils::open_potential()` function must be used to replace calls to `force->open_potential()` and should be used to replace `fopen()` for opening potential files for reading. The custom function does three additional steps compared to `fopen()`: 1) it will try to parse the `UNITS:` and `DATE:` metadata and will stop with an error on a units mismatch and will print the date info, if present, in the log file; 2) for pair styles that support it, it will set up possible automatic unit conversions based on the embedded unit information and LAMMPS' current units setting; 3) it will not only try to open a potential file at the given path, but will also search in the folders listed in the `LAMMPS_POTENTIALS` environment variable. This allows potential files to reside in a common location instead of having to copy them around for simulations.

Old:

```
fp = force->open_potential(filename);
fp = fopen(filename, "r");
```

New:

```
fp = utils::open_potential(filename, lmp);
```

#### 4.10.7 Use symbolic `Atom` and `AtomVec` constants instead of numerical values

Changed in version 18Sep2020.

Properties in LAMMPS that were represented by integer values (0, 1, 2, 3) to indicate settings in the `Atom` and `AtomVec` classes (or classes derived from it) (and its derived classes) have been converted to use scoped enumerators instead.

Symbolic Constant	Value	Symbolic Constant	Value	Symbolic Constant	Value
<code>Atom::GROW</code>	0	<code>Atom::ATOMIC</code>	0	<code>Atom::MAP_NONE</code>	0
<code>Atom::RESTART</code>	1	<code>Atom::MOLECULAR</code>	1	<code>Atom::MAP_ARRAY</code>	1
<code>Atom::BORDER</code>	2	<code>Atom::TEMPLATE</code>	2	<code>Atom::MAP_HASH</code>	2
<code>AtomVec::PER_ATOM</code>	0	<code>AtomVec::PER_TYPE</code>	1	<code>Atom::MAP_YES</code>	3

Old:

```
molecular = 0;
mass_type = 1;
if (atom->molecular == 2)
```

(continues on next page)

(continued from previous page)

```
if (atom->map_style == 2)
atom->add_callback(0);
atom->delete_callback(id,1);
```

New:

```
molecular = Atom::ATOMIC;
mass_type = AtomVec::PER_TYPE;
if (atom->molecular == Atom::TEMPLATE)
if (atom->map_style == Atom::MAP_HASH)
atom->add_callback(Atom::GROW);
atom->delete_callback(id,Atom::RESTART);
```

### 4.10.8 Simplify customized error messages

Changed in version 14May2021.

Aided by features of the bundled {fmt} library, error messages now can have a variable number of arguments and the string will be interpreted as a {fmt} style format string so that error messages can be easily customized without having to use temporary buffers and `sprintf()`. Example:

Old:

```
if (fptr == NULL) {
    char str[128];
    sprintf(str,"Cannot open AEAM potential file %s",filename);
    error->one(FLERR,str);
}
```

New:

```
if (fptr == nullptr)
    error->one(FLERR, "Cannot open AEAM potential file {}: {}", filename,
↳utils::getsyserror());
```

### 4.10.9 Use of “override” instead of “virtual”

Changed in version 17Feb2022.

Since LAMMPS requires C++11, we switched to use the “override” keyword instead of “virtual” to indicate polymorphism in derived classes. This allows the C++ compiler to better detect inconsistencies when an override is intended or not. Please note that “override” has to be added to **all** polymorph functions in derived classes and “virtual” *only* to the function in the base class (or the destructor). Here is an example from the `FixWallReflect` class:

Old:

```
FixWallReflect(class LAMMPS *, int, char **);
virtual ~FixWallReflect();
int setmask();
void init();
void post_integrate();
```

New:

```
FixWallReflect(class LAMMPS *, int, char **);
~FixWallReflect() override;
int setmask() override;
void init() override;
void post_integrate() override;
```

This change set will neither cause a compilation failure, nor will it change functionality, but if you plan to submit the updated code for inclusion into the LAMMPS distribution, it will be requested for achieve a consistent *programming style*.

#### 4.10.10 Simplified function names for forward and reverse communication

Changed in version 24Mar2022.

Rather than using the function name to distinguish between the different forward and reverse communication functions for styles, LAMMPS now uses the type of the “this” pointer argument.

Old:

```
comm->forward_comm_pair(this);
comm->forward_comm_fix(this);
comm->forward_comm_compute(this);
comm->forward_comm_dump(this);
comm->reverse_comm_pair(this);
comm->reverse_comm_fix(this);
comm->reverse_comm_compute(this);
comm->reverse_comm_dump(this);
```

New:

```
comm->forward_comm(this);
comm->reverse_comm(this);
```

This change is **required** or else the code will not compile.

#### 4.10.11 Simplified and more compact neighbor list requests

Changed in version 24Mar2022.

This change set reduces the amount of code required to request a neighbor list. It enforces consistency and no longer requires to change internal data of the request. More information on neighbor list requests can be [found here](#). Example from the ComputeRDF class:

Old:

```
int irequest = neighbor->request(this, instance_me);
neighbor->requests[irequest]->pair = 0;
neighbor->requests[irequest]->compute = 1;
neighbor->requests[irequest]->occasional = 1;
if (cutflag) {
    neighbor->requests[irequest]->cut = 1;
    neighbor->requests[irequest]->cutoff = mycutneigh;
}
```

New:

```
auto req = neighbor->add_request(this, NeighConst::REQ_OCCASIONAL);  
if (cutflag) req->set_cutoff(mycutneigh);
```

Public access to the NeighRequest class data members has been removed so this update is **required** to avoid compilation failure.

#### 4.10.12 Split of fix STORE into fix STORE/GLOBAL and fix STORE/PERATOM

Changed in version 15Sep2022.

This change splits the GLOBAL and PERATOM modes of fix STORE into two separate fixes STORE/GLOBAL and STORE/PERATOM. There was very little shared code between the two fix STORE modes and the two different code paths had to be prefixed with if statements. Furthermore, some flags were used differently in the two modes leading to confusion. Splitting the code into two fix styles, makes it more easily maintainable. Since these are internal fixes, there is no user visible change.

Old:

```
#include "fix_store.h"  
  
FixStore *fix = dynamic_cast<FixStore *>(  
    modify->add_fix(fmt::format("{} {} STORE peratom 1 13", id_pole, group->names[0]));  
  
FixStore *fix = dynamic_cast<FixStore *>(modify->get_fix_by_id(id_pole));
```

New:

```
#include "fix_store_peratom.h"  
  
FixStorePeratom *fix = dynamic_cast<FixStorePeratom *>(  
    modify->add_fix(fmt::format("{} {} STORE/PERATOM 1 13", id_pole, group->names[0]));  
  
FixStorePeratom *fix = dynamic_cast<FixStorePeratom *>(modify->get_fix_by_id(id_pole));
```

Old:

```
#include "fix_store.h"  
  
FixStore *fix = dynamic_cast<FixStore *>(  
    modify->add_fix(fmt::format("{} {} STORE global 1 1", id_fix, group->names[igroup]));  
  
FixStore *fix = dynamic_cast<FixStore *>(modify->get_fix_by_id(id_fix));
```

New:

```
#include "fix_store_global.h"  
  
FixStoreGlobal *fix = dynamic_cast<FixStoreGlobal *>(  
    modify->add_fix(fmt::format("{} {} STORE/GLOBAL 1 1", id_fix, group->names[igroup]));  
  
FixStoreGlobal *fix = dynamic_cast<FixStoreGlobal *>(modify->get_fix_by_id(id_fix));
```

This change is **required** or else the code will not compile.

### 4.10.13 Rename of fix STORE/PERATOM to fix STORE/ATOM and change of arguments

Changed in version 28Mar2023.

The available functionality of the internal fix to store per-atom properties was expanded to enable storing data with ghost atoms and to support binary restart files. With those changes, the fix was renamed to fix STORE/ATOM and the number and order of (required) arguments has changed.

Old syntax: ID group-ID STORE/PERATOM rflag n1 n2 [n3]

- *rflag* = 0/1, *no/yes* store per-atom values in restart file
- *n1* = 1, *n2* = 1, no *n3* → per-atom vector, single value per atom
- *n1* = 1, *n2* > 1, no *n3* → per-atom array, *n2* values per atom
- *n1* = 1, *n2* > 0, *n3* > 0 → per-atom tensor, *n2* x *n3* values per atom

New syntax: ID group-ID STORE/ATOM n1 n2 gflag rflag

- *n1* = 1, *n2* = 0 → per-atom vector, single value per atom
- *n1* > 1, *n2* = 0 → per-atom array, *n1* values per atom
- *n1* > 0, *n2* > 0 → per-atom tensor, *n1* x *n2* values per atom
- *gflag* = 0/1, *no/yes* communicate per-atom values with ghost atoms
- *rflag* = 0/1, *no/yes* store per-atom values in restart file

Since this is an internal fix, there is no user visible change.

### 4.10.14 Use Output::get\_dump\_by\_id() instead of Output::find\_dump()

Changed in version 15Sep2022.

The accessor function to individual dump style instances has been changed from Output::find\_dump() returning the index of the dump instance in the list of dumps to Output::get\_dump\_by\_id() returning a pointer to the dump directly. Example:

Old:

```
int idump = output->find_dump(arg[iarg+1]);
if (idump < 0)
    error->all(FLERR, "Dump ID in hyper command does not exist");
memory->grow(dumplist, ndump+1, "hyper:dumplist");
dumplist[ndump++] = idump;

[...]

if (dumpflag)
    for (int idump = 0; idump < ndump; idump++)
        output->dump[dumplist[idump]]->write();
```

New:

```
auto idump = output->get_dump_by_id(arg[iarg+1]);
if (!idump) error->all(FLERR, "Dump ID {} in hyper command does not exist", arg[iarg+1]);
dumplist.emplace_back(idump);
```

(continues on next page)

(continued from previous page)

```
[...]  
if (dumpflag) for (auto idump : dumplist) idump->write();
```

This change is **required** or else the code will not compile.

#### 4.10.15 Refactored grid communication using Grid3d/Grid2d classes instead of GridComm

Changed in version 22Dec2022.

The `GridComm` class was for creating and communicating distributed grids was replaced by the `Grid3d` class with added functionality. A `Grid2d` class was also added for additional flexibility.

The new functionality and commands using the two grid classes are discussed on the following documentation pages:

- [\*Using distributed grids\*](#)
- [\*Use of distributed grids within style classes\*](#)

If you have custom LAMMPS code, which uses the `GridComm` class, here are some notes on how to adapt it for using the `Grid3d` class.

- (1) The constructor has changed to allow the `Grid3d` / `Grid2d` classes to partition the global grid across processors, both for owned and ghost grid cells. Previously any class which called `GridComm` performed the partitioning itself and that information was passed in the `GridComm::GridComm()` constructor. There are several “set” functions which can be called to alter how `Grid3d` / `Grid2d` perform the partitioning. They should be sufficient for most use cases of the grid classes.
- (2) The partitioning is triggered by the `setup_grid()` method.
- (3) The `setup()` method of the `GridComm` class has been replaced by the `setup_comm()` method in the new grid classes. The syntax for the `forward_comm()` and `reverse_comm()` methods is slightly altered as is the syntax of the associated pack/unpack callback methods. But the functionality of these operations is the same as before.
- (4) The new `Grid3d` / `Grid2d` classes have additional functionality for dynamic load-balancing of grids and their associated data across processors. This did not exist in the `GridComm` class.

This and more is explained in detail on the [\*Use of distributed grids within style classes\*](#) page. The following LAMMPS source files can be used as illustrative examples for how the new grid classes are used by computes, fixes, and various KSpace solvers which use distributed FFT grids:

- `src/fix_ave_grid.cpp`
- `src/compute_property_grid.cpp`
- `src/EXTRA-FIX/fix_ttm_grid.cpp`
- `src/KSPACE/pppm.cpp`

This change is **required** or else the code will not compile.

## 4.11 Writing plugins

Plugins provide a mechanism to add functionality to a LAMMPS executable without recompiling LAMMPS. The functionality for this and the *plugin command* are implemented in the *PLUGIN package* which must be installed to use plugins.

Plugins use the operating system's capability to load dynamic shared object (DSO) files in a way similar shared libraries and then reference specific functions in those DSOs. Any DSO file with plugins has to include an initialization function with a specific name, "lammplugin\_init", that has to follow specific rules described below. When loading the DSO with the "plugin" command, this function is looked up and called and will then register the contained plugin(s) with LAMMPS.

When the environment variable LAMMPS\_PLUGIN\_PATH is set, then LAMMPS will search the directory (or directories) listed in this path for files with names that end in `plugin.so` (e.g. `helloplugin.so`) and will try to load the contained plugins automatically at start-up. For plugins that are loaded this way, the behavior of LAMMPS should be identical to a binary where the corresponding code was compiled in statically as a package.

From the programmer perspective this can work because of the object oriented design of LAMMPS where all pair style commands are derived from the class `Pair`, all fix style commands from the class `Fix` and so on and usually only functions present in those base classes are called directly. When a *pair\_style command* or *fix command* is issued a new instance of such a derived class is created. This is done by a so-called factory function which is mapped to the style name. Thus when, for example, the LAMMPS processes the command `pair_style lj/cut 2.5`, LAMMPS will look up the factory function for creating the `PairLJCut` class and then execute it. The return value of that function is a `Pair *` pointer and the pointer will be assigned to the location for the currently active pair style.

A DSO file with a plugin thus has to implement such a factory function and register it with LAMMPS so that it gets added to the map of available styles of the given category. To register a plugin with LAMMPS an initialization function has to be present in the DSO file called `lammplugin_init` which is called with three `void *` arguments: a pointer to the current LAMMPS instance, a pointer to the opened DSO handle, and a pointer to the registration function. The registration function takes two arguments: a pointer to a `lammplugin_t` struct with information about the plugin and a pointer to the current LAMMPS instance. Please see below for an example of how the registration is done.

### 4.11.1 Members of `lammplugin_t`

Member	Description
<code>version</code>	LAMMPS Version string the plugin was compiled for
<code>style</code>	Style of the plugin (pair, bond, fix, command, etc.)
<code>name</code>	Name of the plugin style
<code>info</code>	String with information about the plugin
<code>author</code>	String with the name and email of the author
<code>creator.v1</code>	Pointer to factory function for pair, bond, angle, dihedral, improper, kspace, or command styles
<code>creator.v2</code>	Pointer to factory function for compute, fix, or region styles
<code>handle</code>	Pointer to the open DSO file handle

Only one of the two alternate creator entries can be used at a time and which of those is determined by the style of plugin. The "creator.v1" element is for factory functions of supported styles computing forces (i.e. pair, bond, angle, dihedral, or improper styles) or command styles and the function takes as single argument the pointer to the LAMMPS instance. The factory function is cast to the `lammplugin_factory1` type before assignment. The "creator.v2" element is for factory functions creating an instance of a fix, compute, or region style and takes three arguments: a pointer to the LAMMPS instance, an integer with the length of the argument list and a `char **` pointer to the list of arguments. The factory function pointer needs to be cast to the `lammplugin_factory2` type before assignment.

### 4.11.2 Pair style example

As an example, a hypothetical pair style plugin “morse2” implemented in a class PairMorse2 in the files pair\_morse2.h and pair\_morse2.cpp with the factory function and initialization function would look like this:

```
#include "lammplugin.h"
#include "version.h"
#include "pair_morse2.h"

using namespace LAMMPS_NS;

static Pair *morse2creator(LAMMPS *lmp)
{
    return new PairMorse2(lmp);
}

extern "C" void lammplugin_init(void *lmp, void *handle, void *regfunc)
{
    lammplugin_regfunc register_plugin = (lammplugin_regfunc) regfunc;
    lammplugin_t plugin;

    plugin.version = LAMMPS_VERSION;
    plugin.style   = "pair";
    plugin.name    = "morse2";
    plugin.info    = "Morse2 variant pair style v1.0";
    plugin.author  = "Axel Kohlmeyer (akohlmey@gmail.com)";
    plugin.creator.v1 = (lammplugin_factory1 *) &morse2creator;
    plugin.handle  = handle;
    (*register_plugin)(&plugin, lmp);
}
```

The factory function in this example is called morse2creator(). It receives a pointer to the LAMMPS class as only argument and thus has to be assigned to the creator.v1 member of the plugin struct and cast to the lammplugin\_factory1 function pointer type. It returns a pointer to the allocated class instance derived from the Pair class. This function may be declared static to avoid clashes with other plugins. The name of the derived class, PairMorse2, however must be unique inside the entire LAMMPS executable.

### 4.11.3 Fix style example

If the factory function is for a fix or compute, which take three arguments (a pointer to the LAMMPS class, the number of arguments and the list of argument strings), then the pointer type is lammplugin\_factory2 and it must be assigned to the creator.v2 member of the plugin struct. Below is an example for that:

```
#include "lammplugin.h"
#include "version.h"
#include "fix_nve2.h"

using namespace LAMMPS_NS;

static Fix *nve2creator(LAMMPS *lmp, int argc, char **argv)
{
    return new FixNVE2(lmp, argc, argv);
}
```

(continues on next page)

(continued from previous page)

```
extern "C" void lammpsplugin_init(void *lmp, void *handle, void *regfunc)
{
    lammpsplugin_regfunc register_plugin = (lammpsplugin_regfunc) regfunc;
    lammpsplugin_t plugin;

    plugin.version = LAMMPS_VERSION;
    plugin.style   = "fix";
    plugin.name    = "nve2";
    plugin.info    = "NVE2 variant fix style v1.0";
    plugin.author  = "Axel Kohlmeyer (akohlmey@gmail.com)";
    plugin.creator.v2 = (lammpsplugin_factory2 *) &nve2creator;
    plugin.handle  = handle;
    (*register_plugin>(&plugin,lmp);
}
```

#### 4.11.4 Command style example

Command styles also use the first variant of factory function as demonstrated in the following example, which also shows that the implementation of the plugin class may be within the same source file as the plugin interface code:

```
#include "lammpsplugin.h"

#include "comm.h"
#include "error.h"
#include "command.h"
#include "version.h"

#include <cstring>

namespace LAMMPS_NS {
    class Hello : public Command {
    public:
        Hello(class LAMMPS *lmp) : Command(lmp) {};
        void command(int, char **);
    };
}

using namespace LAMMPS_NS;

void Hello::command(int argc, char **argv)
{
    if (argc != 1) error->all(FLERR,"Illegal hello command");
    if (comm->me == 0)
        utils::logmesg(lmp,fmt::format("Hello, {}!\n",argv[0]));
}

static void hellocreator(LAMMPS *lmp)
{
    return new Hello(lmp);
}
```

(continues on next page)

(continued from previous page)

```
extern "C" void lammpsplugin_init(void *lmp, void *handle, void *regfunc)
{
    lammpsplugin_t plugin;
    lammpsplugin_regfunc register_plugin = (lammpsplugin_regfunc) regfunc;

    plugin.version = LAMMPS_VERSION;
    plugin.style    = "command";
    plugin.name     = "hello";
    plugin.info     = "Hello world command v1.1";
    plugin.author   = "Axel Kohlmeyer (akohlmey@gmail.com)";
    plugin.creator.v1 = (lammpsplugin_factory1 *) &hellocreator;
    plugin.handle   = handle;
    (*register_plugin)(&plugin, lmp);
}
```

### 4.11.5 Additional Details

The initialization function **must** be called `lammpsplugin_init`, it **must** have C bindings and it takes three void pointers as arguments. The first is a pointer to the LAMMPS class that calls it and it needs to be passed to the registration function. The second argument is a pointer to the internal handle of the DSO file, this needs to be added to the plugin info struct, so that the DSO can be closed and unloaded when all its contained plugins are unloaded. The third argument is a function pointer to the registration function and needs to be stored in a variable of `lammpsplugin_regfunc` type and then called with a pointer to the `lammpsplugin_t` struct and the pointer to the LAMMPS instance as arguments to register a single plugin. There may be multiple calls to multiple plugins in the same initialization function.

To register a plugin a struct of the `lammpsplugin_t` needs to be filled with relevant info: current LAMMPS version string, kind of style, name of style, info string, author string, pointer to factory function, and the DSO handle. The registration function is called with a pointer to the address of this struct and the pointer of the LAMMPS class. The registration function will then add the factory function of the plugin style to the respective style map under the provided name. It will also make a copy of the struct in a list of all loaded plugins and update the reference counter for loaded plugins from this specific DSO file.

The pair style itself (i.e. the `PairMorse2` class in this example) can be written just like any other pair style that is included in LAMMPS. For a plugin, the use of the `PairStyle` macro in the section encapsulated by `#ifdef PAIR_CLASS` is not needed, since the mapping of the class name to the style name is done by the plugin registration function with the information from the `lammpsplugin_t` struct. It may be included in case the new code is intended to be later included in LAMMPS directly.

A plugin may be registered under an existing style name. In that case the plugin will override the existing code. This can be used to modify the behavior of existing styles or to debug new versions of them without having to re-compile or re-install all of LAMMPS.

### 4.11.6 Compiling plugins

Plugins need to be compiled with the same compilers and libraries (e.g. MPI) and compilation settings (MPI on/off, OpenMP, integer sizes) as the LAMMPS executable and library. Otherwise the plugin will likely not load due to mismatches in the function signatures (LAMMPS is C++ so scope, type, and number of arguments are encoded into the symbol names and thus differences in them will lead to failed plugin load commands). Compilation of the plugin can be managed via both, CMake or traditional GNU makefiles. Some examples that can be used as a template are in the `examples/plugins` folder. The CMake script code has some small adjustments to allow building the plugins for running unit tests with them.

Another example that converts the KIM package into a plugin can be found in the `examples/kim/plugin` folder. No changes to the sources of the KIM package themselves are needed; only the plugin interface and loader code needs to be added. This example only supports building with CMake, but is probably a more typical example. To compile you need to run CMake with `-DLAMMPS_SOURCE_DIR=<path/to/lammps/src/folder>`. Other configuration setting are identical to those for compiling LAMMPS.

A second example for a plugin from a package is in the `examples/PACKAGES/pace/plugin` folder that will create a plugin from the ML-PACE package. In this case the bulk of the code is in a static external library that is being downloaded and compiled first and then combined with the pair style wrapper and the plugin loader. This example also contains a NSIS script that can be used to create an Installer package for Windows (the mutual licensing terms of the external library and LAMMPS conflict when distributing binaries, so the ML-PACE package cannot be linked statically, but the LAMMPS headers required to build the plugin are also available under a less restrictive license). This will automatically set the required environment variable and launching a (compatible) LAMMPS binary will load and register the plugin and the ML-PACE package can then be used as it was linked into LAMMPS.

## 4.12 Adding tests for unit testing

This section discusses adding or expanding tests for the unit test infrastructure included into the LAMMPS source code distribution. Unlike example inputs, unit tests focus on testing the “local” behavior of individual features, tend to run fast, and should be set up to cover as much of the added code as possible. When contributing code to the distribution, the LAMMPS developers will appreciate if additions to the integrated unit test facility are included.

Given the complex nature of MD simulations where many operations can only be performed when suitable “real” simulation environment has been set up, not all tests will be unit tests in the strict definition of the term. They are rather executed on a more abstract level by issuing LAMMPS script commands and then inspecting the changes to the internal data. For some classes of tests, generic test programs have been written that can be applied to parts of LAMMPS that use the same interface (via polymorphism) and those are driven by input files, so tests can be added by simply adding more of those input files. Those tests should be seen more as a hybrid between unit and regression tests.

When adding tests it is recommended to also *enable support for code coverage reporting*, and study the coverage reports so that it is possible to monitor which parts of the code of a given file are executed during the tests and which tests would need to be added to increase the coverage.

The tests are grouped into categories and corresponding folders. The following sections describe how the tests are implemented and executed in those categories with increasing complexity of tests and implementation.

### 4.12.1 Tests for utility functions

These tests are driven by programs in the `unittest/utils` folder and most closely resemble conventional unit tests. There is one test program for each namespace or group of classes or file. The naming convention for the sources and executables is that they start with `test_`. The following sources and groups of tests are currently available:

File name:	Test name:	Description:
<code>test_argutils.cpp</code>	ArgInfo	Tests for <code>ArgInfo</code> class used by LAMMPS
<code>test_fmtlib.cpp</code>	FmtLib	Tests for <code>fmtlib::</code> functions used by LAMMPS
<code>test_math_eigen_impl.cpp</code>	MathEigen	Tests for <code>MathEigen::</code> classes and functions
<code>test_mempool.cpp</code>	MemPool	Tests for <i>MyPage</i> and <i>MyPoolChunk</i>
<code>test_tokenizer.cpp</code>	Tokenizer	Tests for <i>Tokenizer</i> and <i>ValueTokenizer</i>
<code>test_utils.cpp</code>	Utils	Tests for <code>utils::</code> <i>functions</i>

To add tests either an existing source file needs to be modified or a new source file needs to be added to the distribution and enabled for testing. To add a new file suitable CMake script code needs to be added to the `CMakeLists.txt` file in the `unittest/utils` folder. Example:

```
add_executable(test_tokenizer test_tokenizer.cpp)
target_link_libraries(test_tokenizer PRIVATE lammps GTest::GMockMain GTest::GMock_
→GTest::GTest)
add_test(Tokenizer test_tokenizer)
```

This adds instructions to build the `test_tokenizer` executable from `test_tokenizer.cpp` and links it with the GoogleTest libraries and the LAMMPS library as well as it uses the `main()` function from the GoogleMock library of GoogleTest. The third line registers the executable as a test program to be run from `ctest` under the name `Tokenizer`.

The test executable itself will execute multiple individual tests through the GoogleTest framework. In this case each test consists of creating a tokenizer class instance with a given string and explicit or default separator choice, and then executing member functions of the class and comparing their results with expected values. A few examples:

```
TEST(Tokenizer, empty_string)
{
    Tokenizer t("", " ");
    ASSERT_EQ(t.count(), 0);
}

TEST(Tokenizer, two_words)
{
    Tokenizer t("test word", " ");
    ASSERT_EQ(t.count(), 2);
}

TEST(Tokenizer, default_separators)
{
    Tokenizer t(" \r\n test \t word \f");
    ASSERT_THAT(t.next(), Eq("test"));
    ASSERT_THAT(t.next(), Eq("word"));
    ASSERT_EQ(t.count(), 2);
}
```

Each of these `TEST` functions will become an individual test run by the test program. When using the `ctest` command as a front end to run the tests, their output will be suppressed and only a summary printed, but adding the `-V` option will then produce output from the tests above like the following:

```
[...]
1: [ RUN      ] Tokenizer.empty_string
1: [         OK ] Tokenizer.empty_string (0 ms)
1: [ RUN      ] Tokenizer.two_words
1: [         OK ] Tokenizer.two_words (0 ms)
1: [ RUN      ] Tokenizer.default_separators
1: [         OK ] Tokenizer.default_separators (0 ms)
[...]
```

The MathEigen test collection has been adapted from a standalone test and does not use the GoogleTest framework and thus not representative. The other test sources, however, can serve as guiding examples for additional tests.

### 4.12.2 Tests for individual LAMMPS commands

The tests `unittest/commands` are a bit more complex as they require to first create a [LAMMPS](#) class instance and then use the [C++ API](#) to pass individual commands to that LAMMPS instance. For that reason these tests use a GoogleTest “test fixture”, i.e. a class derived from `testing::Test` that will create (and delete) the required LAMMPS class instance for each set of tests in a `TEST_F()` function. Please see the individual source files for different examples of setting up suitable test fixtures. Here is an example for implementing a test using a fixture by first checking the default value and then issuing LAMMPS commands and checking whether they have the desired effect:

```
TEST_F(SimpleCommandsTest, ResetTimestep)
{
    ASSERT_EQ(lmp->update->ntimestep, 0);

    BEGIN_HIDE_OUTPUT();
    command("reset_timestep 10");
    END_HIDE_OUTPUT();
    ASSERT_EQ(lmp->update->ntimestep, 10);

    BEGIN_HIDE_OUTPUT();
    command("reset_timestep 0");
    END_HIDE_OUTPUT();
    ASSERT_EQ(lmp->update->ntimestep, 0);

    TEST_FAILURE(".*ERROR: Timestep must be >= 0.*", command("reset_timestep -10"));
    TEST_FAILURE(".*ERROR: Illegal reset_timestep .*", command("reset_timestep"));
    TEST_FAILURE(".*ERROR: Illegal reset_timestep .*", command("reset_timestep 10 10"));
    TEST_FAILURE(".*ERROR: Expected integer .*", command("reset_timestep xxx"));
}
```

Please note the use of the `BEGIN_HIDE_OUTPUT` and `END_HIDE_OUTPUT` functions that will capture output from running LAMMPS. This is normally discarded but by setting the verbose flag (via setting the `TEST_ARGS` environment variable, `TEST_ARGS=-v`) it can be printed and used to understand why tests fail unexpectedly.

The specifics of so-called “death tests”, i.e. conditions where LAMMPS should fail and throw an exception, are implemented in the `TEST_FAILURE()` macro. These tests operate by capturing the screen output when executing the failing command and then comparing that with a provided regular expression string pattern. Example:

```
TEST_F(SimpleCommandsTest, UnknownCommand)
{
    TEST_FAILURE(".*ERROR: Unknown command.*", lmp->input->one("XXX one two"));
}
```

The following test programs are currently available:

File name:	Test name:	Description:
test_simple_commands.cpp	SimpleCommands	Tests for LAMMPS commands that do not require a box
test_lattice_region.cpp	LatticeRegion	Tests to validate the <i>lattice</i> and <i>region</i> commands
test_groups.cpp	GroupTest	Tests to validate the <i>group</i> command
test_variables.cpp	VariableTest	Tests to validate the <i>variable</i> command
test_kim_commands.cpp	KimCommands	Tests for several commands from the <i>KIM package</i>
test_reset_atoms.cpp	ResetAtoms	Tests to validate the <i>reset_atoms</i> sub-commands

### 4.12.3 Tests for the C-style library interface

Tests for validating the LAMMPS C-style library interface are in the `unittest/c-library` folder. They are implemented either to be used for utility functions or for LAMMPS commands, but use the functions implemented in the `src/library.cpp` file as much as possible. There may be some overlap with other tests, but only in as much as is required to test the C-style library API. The tests are distributed over multiple test programs which try to match the grouping of the functions in the source code and *in the manual*.

This group of tests also includes tests invoking LAMMPS in parallel through the library interface, provided that LAMMPS was compiled with MPI support. These include tests where LAMMPS is run in multi-partition mode or only on a subset of the MPI world communicator. The CMake script code for adding this kind of test looks like this:

```
if (BUILD_MPI)
  add_executable(test_library_mpi test_library_mpi.cpp)
  target_link_libraries(test_library_mpi PRIVATE lammps GTest::GTest GTest::GMock)
  target_compile_definitions(test_library_mpi PRIVATE ${TEST_CONFIG_DEFS})
  add_mpi_test(NAME LibraryMPI NUM_PROCS 4 COMMAND $<TARGET_FILE:test_library_mpi>)
endif()
```

Note the custom function `add_mpi_test()` which adapts how `ctest` will execute the test so it is launched in parallel (with 4 MPI ranks).

### 4.12.4 Tests for the Python module and package

The `unittest/python` folder contains primarily tests for classes and functions in the LAMMPS python module but also for commands in the PYTHON package. These tests are only enabled if the necessary prerequisites are detected or enabled during configuration and compilation of LAMMPS (shared library build enabled, Python interpreter found, Python development files found).

The Python tests are implemented using the `unittest` standard Python module and split into multiple files with similar categories as the tests for the C-style library interface.

### 4.12.5 Tests for the Fortran interface

Tests for using the Fortran module are in the `unittest/fortran` folder. Since they are also using the GoogleTest library, they require implementing test wrappers in C++ that will call fortran functions which provide a C function interface through `ISO_C_BINDINGS` that will in turn call the functions in the LAMMPS Fortran module.

### 4.12.6 Tests for the C++-style library interface

The tests in the `unittest/cplusplus` folder are somewhat similar to the tests for the C-style library interface, but do not need to test the several convenience and utility functions that are only available through the C-style interface. Instead it can focus on the more generic features that are used internally. This part of the unit tests is currently still mostly in the planning stage.

### 4.12.7 Tests for reading and writing file formats

The `unittest/formats` folder contains test programs for reading and writing files like data files, restart files, potential files or dump files. This covers simple things like the file i/o convenience functions in the `utils::` namespace to complex tests of atom styles where creating and deleting atoms with different properties is tested in different ways and through script commands or reading and writing of data or restart files.

### 4.12.8 Tests for styles computing or modifying forces

These are tests common configurations for pair styles, bond styles, angle styles, kspace styles and certain fix styles. Those are tests driven by some test executables build from sources in the `unittest/force-styles` folder and use LAMMPS input template and data files as well as input files in YAML format from the `unittest/force-styles/tests` folder. The YAML file names have to follow some naming conventions so they get associated with the test programs and categorized and listed with canonical names in the list of tests as displayed by `ctest -N`. If you add a new YAML file, you need to re-run CMake to update the corresponding list of tests.

A minimal YAML file for a (molecular) pair style test will look something like the following (see `mol-pair-zero.yaml`):

```
---
lammps_version: 24 Aug 2020
date_generated: Tue Sep 15 09:44:21 202
epsilon: 1e-14
prerequisites: ! |
  atom full
  pair zero
pre_commands: ! ""
post_commands: ! ""
input_file: in.fourmol
pair_style: zero 8.0
pair_coeff: ! |
  * *
extract: ! ""
natoms: 29
init_vdwl: 0
init_coul: 0

[...]
```

The following table describes the available keys and their purpose for testing pair styles:

Key:	Description:
lammmps_version	LAMMPS version used to last update the reference data
date_generated	date when the file was last updated
epsilon	base value for the relative precision required for tests to pass
prerequisites	list of style kind / style name pairs required to run the test
pre_commands	LAMMPS commands to be executed before the input template file is read
post_commands	LAMMPS commands to be executed right before the actual tests
input_file	LAMMPS input file template based on pair style zero
pair_style	arguments to the pair_style command to be tested
pair_coeff	list of pair_coeff arguments to set parameters for the input template
extract	list of keywords supported by <code>Pair::extract()</code> and their dimension
natoms	number of atoms in the input file template
init_vdwl	non-Coulomb pair energy after “run 0”
init_coul	Coulomb pair energy after “run 0”
init_stress	stress tensor after “run 0”
init_forces	forces on atoms after “run 0”
run_vdwl	non-Coulomb pair energy after “run 4”
run_coul	Coulomb pair energy after “run 4”
run_stress	stress tensor after “run 4”
run_forces	forces on atoms after “run 4”

The test program will read all this data from the YAML file and then create a LAMMPS instance, apply the settings/commands from the YAML file as needed and then issue a “run 0” command, write out a restart file, a data file and a coeff file. The actual test will then compare computed energies, stresses, and forces with the reference data, issue a “run 4” command and compare to the second set of reference data. This will be run with both the newton\_pair setting enabled and disabled and is expected to generate the same results (allowing for some numerical noise). Then it will restart from the previously generated restart and compare with the reference and also start from the data file. A final check will use multi-cutoff r-RESPA (if supported by the pair style) at a 1:1 split and compare to the Verlet results. These sets of tests are run with multiple test fixtures for accelerated styles (OPT, OPENMP, INTEL, KOKKOS (OpenMP only)) and for the latter three with 4 OpenMP threads enabled. For these tests the relative error (epsilon) is lowered by a common factor due to the additional numerical noise, but the tests are still comparing to the same reference data.

Additional tests will check whether all listed extract keywords are supported and have the correct dimensionality and the final set of tests will set up a few pairs of atoms explicitly and in such a fashion that the forces on the atoms computed from `Pair::compute()` will match individually with the results from `Pair::single()`, if the pair style does support that functionality.

With this scheme a large fraction of the code of any tested pair style will be executed and consistent results are required for different settings and between different accelerated pair style variants and the base class, as well as for computing individual pairs through the `Pair::single()` method where supported.

The `test_pair_style` tester is used with 4 categories of test inputs:

- pair styles compatible with molecular systems using bonded interactions and exclusions. For pair styles requiring a KSpace style the KSpace computations are disabled. The YAML files match the pattern “mol-pair-\*.yaml” and the tests are correspondingly labeled with “MolPairStyle:”
- pair styles not compatible with the previous input template. The YAML files match the pattern “atomic-pair-\*.yaml” and the tests are correspondingly labeled with “AtomicPairStyle:”
- manybody pair styles. The YAML files match the pattern “atomic-pair-\*.yaml” and the tests are correspondingly labeled with “AtomicPairStyle:”

- kspace styles. The YAML files match the pattern “kspace-\*.yaml” and the tests are correspondingly labeled with “KSpaceStyle:\*”. In these cases a compatible pair style is defined, but the computation of the pair style contributions is disabled.

The `test_bond_style`, `test_angle_style`, `test_dihedral_style`, and `test_improper_style` tester programs are set up in a similar fashion and share support functions with the pair style tester. The final group of tests in this section is for fix styles that add/manipulate forces and velocities, e.g. for time integration, thermostats and more.

Adding a new test is easiest done by copying and modifying an existing YAML file for a style that is similar to one to be tested. The file name should follow the naming conventions described above and after copying the file, the first step is to replace the style names where needed. The coefficient values do not have to be meaningful, just in a reasonable range for the given system. It does not matter if some forces are large, as long as they do not diverge.

The template input files define a large number of index variables at the top that can be modified inside the YAML file to control the behavior. For example, if a pair style requires a “newton on” setting, the following can be used in as the “pre\_commands” section:

```
pre_commands: ! |
  variable newton_pair delete
  variable newton_pair index on
```

And for a pair style requiring a kspace solver the following would be used as the “post\_commands” section:

```
post_commands: ! |
  pair_modify table 0
  kspace_style pppm/tip4p 1.0e-6
  kspace_modify gewald 0.3
  kspace_modify compute no
```

Note that this disables computing the kspace contribution, but still will run the setup. The “gewald” parameter should be set explicitly to speed up the run. For styles with long-range electrostatics, typically two tests are added one using the (slower) analytic approximation of the `erfc()` function and the other using the tabulated coulomb, to test both code paths. The reference results in the YAML files then should be compared manually, if they agree well enough within the limits of those two approximations.

The `test_pair_style` and equivalent programs have special command line options to update the YAML files. Running a command like

```
test_pair_style mol-pair-lennard_mdf.yaml -g new.yaml
```

will read the settings from the `mol-pair-lennard_mdf.yaml` file and then compute the reference data and write a new file with to `new.yaml`. If this step fails, there are likely some (LAMMPS or YAML) syntax issues in the YAML file that need to be resolved and then one can compare the two files to see if the output is as expected.

It is also possible to do an update in place with:

```
test_pair_style mol-pair-lennard_mdf.yaml -u
```

And one can finally run the full set of tests with:

```
test_pair_style mol-pair-lennard_mdf.yaml
```

This will just print a summary of the groups of tests. When using the “-v” flag the test will also keep any LAMMPS output and when using the “-s” flag, there will be some statistics reported on the relative errors for the individual checks which can help to figure out what would be a good choice of the epsilon parameter. It should be as small as possible to catch any unintended side effects from changes elsewhere, but large enough to accommodate the numerical noise due to the implementation of the potentials and differences in compilers.

**Note:** These kinds of tests can be very sensitive to compiler optimization and thus the expectation is that they pass with compiler optimization turned off. When compiler optimization is enabled, there may be some failures, but one has to carefully check whether those are acceptable due to the enhanced numerical noise from reordering floating-point math operations or due to the compiler mis-compiling the code. That is not always obvious.

---

### 4.12.9 Tests for programs in the tools folder

The `unittest/tools` folder contains tests for programs in the `tools` folder. This currently only contains tests for the LAMMPS shell, which are implemented as a python scripts using the `unittest` Python module and launching the tool commands through the `subprocess` Python module.

### 4.12.10 Troubleshooting failed unit tests

There are by default no unit tests for newly added features (e.g. pair, fix, or compute styles) unless your pull request also includes tests for the added features. If you are modifying some features, you may see failures for existing tests, if your modifications have some unexpected side effects or your changes render the existing test invalid. If you are adding an accelerated version of an existing style, then only tests for INTEL, KOKKOS (with OpenMP only), OPENMP, and OPT will be run automatically. Tests for the GPU package are time consuming and thus are only run *after* a merge, or when a special label, `gpu_unit_tests` is added to the pull request. After the test has started, it is often best to remove the label since every PR activity will re-trigger the test (that is a limitation of triggering a test with a label). Support for unit tests when using KOKKOS with GPU acceleration is currently not supported.

When you see a failed build on GitHub, click on **Details** to be taken to the corresponding LAMMPS Jenkins CI web page. Click on the “Exit” symbol near the Logout button on the top right of that page to go to the “classic view”. In the classic view, there is a list of the individual runs that make up this test run (they are shown but cannot be inspected in the default view). You can click on any of those. Clicking on **Test Result** will display the list of failed tests. Click on the “Status” column to sort the tests based on their Failed or Passed status. Then click on the failed test to expand its output.

For example, the following output snippet shows the failed unit test

```
[ RUN      ] PairStyle.gpu
/home/builder/workspace/dev/pull_requests/ubuntu_gpu/unit_tests/cmake_gpu_opengl_mixed_
→smallbig_clang_static/unittest/force-styles/test_main.cpp:63: Failure
Expected: (err) <= (epsilon)
Actual: 0.00018957912910606503 vs 0.0001
Google Test trace:
/home/builder/workspace/dev/pull_requests/ubuntu_gpu/unit_tests/cmake_gpu_opengl_mixed_
→smallbig_clang_static/unittest/force-styles/test_main.cpp:56: EXPECT_FORCES: init_
→forces (newton off)
/home/builder/workspace/dev/pull_requests/ubuntu_gpu/unit_tests/cmake_gpu_opengl_mixed_
→smallbig_clang_static/unittest/force-styles/test_main.cpp:64: Failure
Expected: (err) <= (epsilon)
Actual: 0.00022892713393549854 vs 0.0001
```

The failed assertions provide line numbers in the test source (e.g. `test_main.cpp:56`), from which one can understand what specific assertion failed.

Note that the force style engine runs one of a small number of systems in a rather off-equilibrium configuration with a few atoms for a few steps, writes data and restart files, uses *the clear command* to reset LAMMPS, and then runs from those files with different settings (e.g. newton on/off) and integrators (e.g. verlet vs. respa). Beyond potential issues/bugs in the source code, the mismatch between the expected and actual values could be that force arrays are not

properly cleared between multiple run commands or that class members are not correctly initialized or written to or read from a data or restart file.

While the epsilon (relative precision) for a single, [IEEE 754 compliant](#), double precision floating point operation is at about  $2.2\text{e-}16$ , the achievable precision for the tests is lower due to most numbers being sums over intermediate results and the non-associativity of floating point math leading to larger errors. As a rule of thumb, the test epsilon can often be in the range  $5.0\text{e-}14$  to  $1.0\text{e-}13$ . But for “noisy” force kernels, e.g. those a larger amount of arithmetic operations involving  $\exp()$ ,  $\log()$  or  $\sin()$  functions, and also due to the effect of compiler optimization or differences between compilers or platforms, epsilon may need to be further relaxed, sometimes epsilon can be relaxed to  $1.0\text{e-}12$ . If interpolation or lookup tables are used, epsilon may need to be set to  $1.0\text{e-}10$  or even higher. For tests of accelerated styles, the per-test epsilon is multiplied by empirical factors that take into account the differences in the order of floating point operations or that some or most intermediate operations may be done using approximations or with single precision floating point math.

To rerun the failed unit test individually, change to the build directory and run the test with verbose output. For example,

```
env TEST_ARGS=-v ctest -R ^MolPairStyle:lj_cut_coul_long -V
```

ctest with the `-V` flag also shows the exact command line of the test. One can then use `gdb --args` to further debug and catch exceptions with the test command, for example,

```
gdb --args /path/to/lammps/build/test_pair_style /path/to/lammps/unittest/force-styles/  
→tests/mol-pair-lj_cut_coul_long.yaml
```

It is recommended to configure the build with `-D BUILD_SHARED_LIBS=on` and use a custom linker to shorten the build time during recompilation. Installing *ccache* in your development environment helps speed up recompilation by caching previous compilations and detecting when the same compilation is being done again. Please see [Development build options](#) for further details.

## 4.13 C++ base classes

LAMMPS is designed to be used as a C++ class library where one can set up and drive a simulation through creating a class instance and then calling some abstract operations or commands on that class or its member class instances. These are interfaced to the [C library API](#), which providing an additional level of abstraction simplification for common operations. The C API is also the basis for calling LAMMPS from Python or Fortran.

When used from a C++ program, most of the symbols and functions in LAMMPS are wrapped into the `LAMMPS_NS` namespace so they will not collide with your own classes or other libraries. This, however, does not extend to the additional libraries bundled with LAMMPS in the `lib` folder and some of the low-level code of some packages.

Behind the scenes this is implemented through inheritance and polymorphism where base classes define the abstract interface and derived classes provide the specialized implementation for specific models or optimizations or ports to accelerator platforms. This document will provide an outline of the fundamental class hierarchy and some selected examples for derived classes of specific models.

---

**Note:** Please see the [note about thread-safety](#) in the library Howto doc page.

---

### 4.13.1 LAMMPS Class

The LAMMPS class is encapsulating an MD simulation state and thus it is the class that needs to be created when starting a new simulation system state. The LAMMPS executable essentially creates one instance of this class and passes the command line flags and tells it to process the provided input (a file or `stdin`). It shuts the class down when control is returned to it and then exits. When using LAMMPS as a library from another code it is required to create an instance of this class, either directly from C++ with `new LAMMPS()` or through one of the library interface functions like `lammps_open()` of the C-library interface, or the `lammps.lammps` class constructor of the Python module, or the `lammps()` constructor of the Fortran module.

In order to avoid clashes of function names, all of the core code in LAMMPS is placed into the `LAMMPS_NS` namespace. Functions or variables outside of that namespace must be “static”, i.e. visible only to the scope of the file/object they are defined in. Code in packages or the libraries in the `lib` folder may not adhere to this as some of them are adapted from legacy code or consist of external libraries with their own requirements and policies.

---

class **LAMMPS**

*LAMMPS* simulation instance.

The *LAMMPS* class contains pointers of all constituent class instances and global variables that are used by a *LAMMPS* simulation. Its contents represent the entire state of the simulation.

The *LAMMPS* class manages the components of an MD simulation by creating, deleting, and initializing instances of the classes it is composed of, processing command line flags, and providing access to some global properties. The specifics of setting up and running a simulation are handled by the individual component class instances.

#### Public Functions

const char \***non\_pair\_suffix**() const

Return suffix for non-pair styles depending on `pair_only_flag`.

##### Returns

suffix or null pointer

const char \***match\_style**(const char \*style, const char \*name)

Return name of package that a specific style belongs to.

This function checks the given name against all list of styles for all types of styles and if the name and the style match, it returns which package this style belongs to.

##### Parameters

- **style** – Type of style (e.g. atom, pair, fix, etc.)
- **name** – Name of style

##### Returns

Name of the package this style is part of

**LAMMPS**(argv &args, MPI\_Comm)

Create a *LAMMPS* simulation instance

##### Parameters

- **args** – list of arguments
- **communicator** – MPI communicator used by this *LAMMPS* instance

**LAMMPS**(int, char\*\*, MPI\_Comm)

Create a *LAMMPS* simulation instance

The *LAMMPS* constructor starts up a simulation by allocating all fundamental classes in the necessary order, parses input switches and their arguments, initializes communicators, screen and logfile output FILE pointers.

#### Parameters

- **narg** – number of arguments
- **arg** – list of arguments
- **communicator** – MPI communicator used by this *LAMMPS* instance

**~LAMMPS**() noexcept(false)

Shut down a *LAMMPS* simulation instance

The *LAMMPS* destructor shuts down the simulation by deleting top-level class instances, closing screen and log files for the global instance (aka “world”) and files and MPI communicators in sub-partitions (“universes”). Then it deletes the fundamental class instances and copies of data inside the class.

### Public Static Functions

static bool **is\_installed\_pkg**(const char \*pkg)

Return true if a *LAMMPS* package is enabled in this binary

#### Parameters

**pkg** – name of package

#### Returns

true if yes, else false

static std::vector<char\*> **argv\_pointers**(argv &args)

Create vector of argv string pointers including terminating nullptr element

#### Parameters

**args** – list of arguments

class **Pointers**

Base class for *LAMMPS* features.

The *Pointers* class contains references to many of the pointers and members of the *LAMMPS\_NS::LAMMPS* class. Derived classes thus gain access to the constituent class instances in the *LAMMPS* composite class and thus to the core functionality of *LAMMPS*.

This kind of construct is needed, since the *LAMMPS* constructor should only be run once per *LAMMPS* instance and thus classes cannot be derived from *LAMMPS* itself. The *Pointers* class constructor instead only initializes C++ references to component pointer in the *LAMMPS* class.

Subclassed by *Atom*, *Input*, *PotentialFileReader*

### 4.13.2 LAMMPS Atom and AtomVec Base Classes

class **Atom** : protected *Pointers*

Class to provide access to atom data.

The Atom class provides access to atom style related global settings and per-atom data that is stored with atoms and migrates with them from sub-domain to sub-domain as atoms move around. This includes topology data, which is stored with either one specific atom or all atoms involved depending on the settings of the *newton command*.

The actual per-atom data is allocated and managed by one of the various classes derived from the AtomVec class as determined by the *atom\_style command*. The pointers in the Atom class are updated by the AtomVec class as needed.

#### Public Functions

**Atom**(class *LAMMPS*\*)

*Atom* class constructor

This resets and initializes all kinds of settings, parameters, and pointer variables for per-atom arrays. This also initializes the factory for creating instances of classes derived from the AtomVec base class, which correspond to the selected atom style.

##### Parameters

**\_lmp** – pointer to the base *LAMMPS* class

int **find\_custom**(const char\*, int&, int&)

Find a custom per-atom property with given name.

This function returns the list index of a custom per-atom property with the name “name”, also returning by reference its data type and number of values per atom.

##### Parameters

- **name** – Name of the property (w/o a “i\_” or “d\_” or “i2\_” or “d2\_” prefix)
- **&flag** – Returns data type of property: 0 for int, 1 for double
- **&cols** – Returns number of values: 0 for a single value, 1 or more for a vector of values

##### Returns

index of property in the respective list of properties

int **find\_custom\_ghost**(const char\*, int&, int&, int&)

Find a custom per-atom property with given name and retrieve ghost property.

This function returns the list index of a custom per-atom property with the name “name”, also returning by reference its data type, number of values per atom, and if it is communicated to ghost particles. Classes rarely need to check on ghost communication and so *find\_custom* is typically preferred to this function. See *pair amoeba* for an example where checking ghost communication is necessary.

##### Parameters

- **name** – Name of the property (w/o a “i\_” or “d\_” or “i2\_” or “d2\_” prefix)
- **&flag** – Returns data type of property: 0 for int, 1 for double
- **&cols** – Returns number of values: 0 for a single value, 1 or more for a vector of values
- **&ghost** – Returns whether property is communicated to ghost atoms: 0 for no, 1 for yes

**Returns**

index of property in the respective list of properties

```
virtual int add_custom(const char*, int, int, int ghost = 0)
```

Add a custom per-atom property with the given name and type and size.

This function will add a custom per-atom property with one or more values with the name “name” to the list of custom properties. This function is called, e.g. from *fix property/atom*.

**Parameters**

- **name** – Name of the property (w/o a “i\_” or “d\_” or “i2\_” or “d2\_” prefix)
- **flag** – Data type of property: 0 for int, 1 for double
- **cols** – Number of values: 0 for a single value, 1 or more for a vector of values
- **ghost** – Whether property is communicated to ghost atoms: 0 for no, 1 for yes

**Returns**

index of property in the respective list of properties

```
virtual void remove_custom(int, int, int)
```

Remove a custom per-atom property of a given type and size.

This will remove a property that was requested, e.g. by the *fix property/atom* command. It frees the allocated memory and sets the pointer to `nullptr` for the entry in the list so it can be reused. The lists of these pointers are never compacted or shrunk, so that indices to name mappings remain valid.

**Parameters**

- **index** – Index of property in the respective list of properties
- **flag** – Data type of property: 0 for int, 1 for double
- **cols** – Number of values: 0 for a single value, 1 or more for a vector of values

```
void *extract(const char*)
```

Provide access to internal data of the *Atom* class by keyword

This function is a way to access internal per-atom data. This data is distributed across MPI ranks and thus only the data for “local” atoms are expected to be available. Whether also data for “ghost” atoms is stored and up-to-date depends on various simulation settings.

This table lists a large part of the supported names, their data types, length of the data area, and a short description.

Name	Type	Items per atom	Description
mass	double	1	per-type mass. This array is <b>NOT</b> a per-atom array but of length <code>ntypes+1</code> , element 0 is ignored.
id	tagint	1	atom ID of the particles
type	int	1	atom type of the particles
mask	int	1	bitmask for mapping to groups. Individual bits are set to 0 or 1 for each group.
image	imageint	1	3 image flags encoded into a single integer. See <a href="#">lammps_encode_image_flags()</a> .
x	double	3	x-, y-, and z-coordinate of the particles
v	double	3	x-, y-, and z-component of the velocity of the particles
f	double	3	x-, y-, and z-component of the force on the particles
molecule	int	1	molecule ID of the particles
q	double	1	charge of the particles
mu	double	3	dipole moment of the particles
omega	double	3	x-, y-, and z-component of rotational velocity of the particles
angmom	double	3	x-, y-, and z-component of angular momentum of the particles
torque	double	3	x-, y-, and z-component of the torque on the particles
radius	double	1	radius of the (extended) particles
rmass	double	1	per-atom mass of the particles. <code>nullptr</code> if per-type masses are used. See the <a href="#">rmass_flag</a> setting.
ellipsoid	int	1	1 if the particle is an ellipsoidal particle, 0 if not
line	int	1	1 if the particle is a line particle, 0 if not
tri	int	1	1 if the particle is a triangulated particle, 0 if not
body	int	1	1 if the particle is a body particle, 0 if not
quat	double	4	four quaternion components of the particles
temperature	double	1	temperature of the particles
heatflow	double	1	heatflow of the particles
i_name	int	1	single integer value defined by fix property/atom vector name
d_name	double	1	single double value defined by fix property/atom vector name
i2_name	int	N	N integer values defined by fix property/atom array name
d2_name	double	N	N double values defined by fix property/atom array name

See also

[lammps\\_extract\\_atom\(\)](#)

**See also:**

*extract\_datatype*

**Parameters**

**name** – string with the keyword of the desired property. Typically the name of the pointer variable returned

**Returns**

pointer to the requested data cast to void \* or nullptr

int **extract\_datatype**(const char\*)

Provide data type info about internal data of the *Atom* class

New in version 18Sep2020.

**See also:**

*extract*

**Parameters**

**name** – string with the keyword of the desired property.

**Returns**

data type constant for desired property or -1

struct **PerAtom**

### 4.13.3 LAMMPS Input Base Class

class **Input** : protected *Pointers*

Class for processing commands and input files.

The Input class contains methods for reading, pre-processing and parsing LAMMPS commands and input files and will dispatch commands to the respective class instances or contain the code to execute the commands directly. It also contains the instance of the Variable class which performs computations and text substitutions.

#### Public Functions

**Input**(class *LAMMPS*\*, int, char\*\*)

*Input* class constructor

This sets up the input processing, processes the *-var* and *-echo* command line flags, holds the factory of commands and creates and initializes an instance of the Variable class.

To execute a command, a specific class instance, derived from *Command*, is created, then its *command()* member function executed, and finally the class instance is deleted.

**Parameters**

- **lmp** – pointer to the base *LAMMPS* class
- **argc** – number of entries in *argv*
- **argv** – argument vector

void **file()**

Process all input from the FILE \* pointer *infile*

This will read lines from *infile*, parse and execute them until the end of the file is reached. The *infile* pointer will usually point to *stdin* or the input file given with the *-in* command line flag.

void **file**(const char\*)

Process all input from the file *filename*

This function opens the file at the path *filename*, puts the current file pointer stored in *infile* on a stack and instead assigns *infile* with the newly opened file pointer. Then it will call the *Input::file()* function to read, parse and execute the contents of that file. When the end of the file is reached, it is closed and the previous file pointer from the *infile* file pointer stack restored to *infile*.

**Parameters**

**filename** – name of file with *LAMMPS* commands

char \***one**(const std::string&)

Process a single command from a string in *single*

This function takes the text in *single*, makes a copy, parses that, executes the command and returns the name of the command (without the arguments). If there was no command in *single* it will return *nullptr*.

**Parameters**

**single** – string with *LAMMPS* command

**Returns**

string with name of the parsed command w/o arguments

## 4.14 Platform abstraction functions

The *platform* sub-namespace inside the *LAMMPS\_NS* namespace provides a collection of wrapper and convenience functions and utilities that perform common tasks for which platform specific code would be required or for which a more high-level abstraction would be convenient and reduce duplicated code. This reduces redundant implementations and encourages consistent behavior and thus has some overlap with the “*utils*” sub-namespace.

### 4.14.1 Time functions

double *LAMMPS\_NS::platform::cputime*()

Return the consumed CPU time for the current process in seconds

This is a wrapper around the POSIX function *getrusage()* and its Windows equivalent. It is to be used in a similar fashion as *MPI\_Wtime()*. Its resolution may be rather low so it can only be trusted when observing processes consuming CPU time of at least a few seconds.

**Returns**

used CPU time in seconds

double LAMMPS\_NS::platform::walltime()

Return the wall clock state for the current process in seconds

This clock is counting continuous time and is initialized during load of the executable/library. Its absolute value must be considered arbitrary and thus elapsed wall times are measured in taking differences. It is therefore to be used in a similar fashion as MPI\_Wtime() but has a different offset, usually leading to better resolution.

**Returns**

wall clock time in seconds

void LAMMPS\_NS::platform::usleep(int usec)

Suspend execution for a microsecond interval

This emulates the usleep(3) BSD function call also mentioned in POSIX.1-2001. This is not a precise delay; it may be longer, but not shorter.

**Parameters**

**usec** – length of delay in microseconds

## 4.14.2 Platform information functions

std::string LAMMPS\_NS::platform::os\_info()

Return string with the operating system version and architecture info

**Returns**

string with info about the OS and the platform is is running on

std::string LAMMPS\_NS::platform::compiler\_info()

Return string with compiler version info

This function uses predefined compiler macros to identify Compilers and their version and configuration info.

**Returns**

string with the compiler information text

std::string LAMMPS\_NS::platform::cxx\_standard()

Return string with C++ standard version used to compile *LAMMPS*.

This function uses predefined compiler macros to identify the C++ standard version used to compile *LAMMPS* with.

**Returns**

string with the C++ standard version or “unknown”

std::string LAMMPS\_NS::platform::openmp\_standard()

Return string with OpenMP standard version info

This function uses predefined compiler macros to identify OpenMP support and the supported version of the standard.

**Returns**

string with the openmp information text

std::string LAMMPS\_NS::platform::mpi\_vendor()

Return string with MPI vendor info

This function uses predefined macros to identify the vendor of the MPI library used.

**Returns**

string with the MPI vendor information text

`std::string LAMMPS_NS::platform::mpi_info(int &major, int &minor)`

Return string with MPI version info

This function uses predefined macros and MPI function calls to identify the version of the MPI library used.

#### Parameters

- **major** – major version of the MPI standard (set on exit)
- **minor** – minor version of the MPI standard (set on exit)

#### Returns

string with the MPI version information text

`std::string LAMMPS_NS::platform::compress_info()`

Return string with list of available compression types and executables

This function tests which of the supported compression executables are available for reading or writing compressed files where supported.

#### Returns

string with list of available compression tools

### 4.14.3 File and path functions and global constants

`constexpr char LAMMPS_NS::platform::filepathsep[] = "/"`

Platform specific file path component separator

This is a string with the character that separates directories and filename in paths on a platform. If multiple are characters are provided, the first is the preferred one.

`constexpr char LAMMPS_NS::platform::pathvarsep = ':'`

Platform specific path environment variable component separator

This is the character that separates entries in “PATH”-style environment variables.

`const char *LAMMPS_NS::platform::guesspath(FILE *fp, char *buf, int len)`

Try to detect pathname from FILE pointer

Currently only supported on Linux, MacOS, and Windows. Otherwise will report “(unknown)”.

On Linux the folder `/proc/self/fd` holds symbolic links to the actual pathnames associated with each open file descriptor of the current process. On MacOS the same kind of information can be obtained using `fcntl(fd, F_GETPATH, buf)`. On Windows we use `GetFinalPathNameByHandleA()` which is available with Windows Vista and later. If the buffer is too small (`< 16` bytes) a null pointer is returned.

This function is used to provide a filename with error messages in functions where the filename is not passed as an argument, but the FILE \* pointer.

#### Parameters

- **fp** – FILE pointer struct from STDIO library for which we want to detect the name
- **buf** – storage buffer for pathname. output will be truncated if not large enough
- **len** – size of storage buffer. output will be truncated to this length - 1

**Returns**

pointer to the storage buffer with path or a NULL pointer if buf is invalid or the buffer size is too small

`std::string LAMMPS_NS::platform::path_basename(const std::string &path)`

Strip off leading part of path, return just the filename

**Parameters**

**path** – file path

**Returns**

file name

`std::string LAMMPS_NS::platform::path_join(const std::string &a, const std::string &b)`

Join two pathname segments

This uses the forward slash ‘/’ character unless *LAMMPS* is compiled for Windows where it uses the backward slash ‘\’

**Parameters**

- **a** – first path
- **b** – second path

**Returns**

combined path

`bool LAMMPS_NS::platform::file_is_readable(const std::string &path)`

Check if file exists and is readable

**Parameters**

**path** – file path

**Returns**

true if file exists and is readable

`bool LAMMPS_NS::platform::is_console(FILE *fp)`

Check if a file pointer may be connected to a console

**Parameters**

**fp** – file pointer

**Returns**

true if the file pointer is flagged as a TTY

`double LAMMPS_NS::platform::disk_free(const std::string &path)`

Return free disk space in bytes of file system pointed to by path

Returns -1.0 if the path is invalid or free space reporting not supported.

**Parameters**

**path** – file or folder path in file system

**Returns**

`bool LAMMPS_NS::platform::path_is_directory(const std::string &path)`

Check if a path is a directory

**Parameters**

**path** – directory path

**Returns**

true if the directory exists

`std::string LAMMPS_NS::platform::current_directory()`

Get string with path to the current directory

**Returns**

path to the current directory or empty string

`std::vector<std::string> LAMMPS_NS::platform::list_directory(const std::string &dir)`

Get list of entries in a directory

This provides a list of strings of the entries in the directory without the leading path name while also skipping over “.” and “..”.

**Parameters**

**dir** – path to directory

**Returns**

vector with strings of all directory entries

`int LAMMPS_NS::platform::chdir(const std::string &path)`

Change current directory

**Parameters**

**path** – new current working directory path

**Returns**

-1 if unsuccessful, otherwise  $\geq 0$

`int LAMMPS_NS::platform::mkdir(const std::string &path)`

Create a directory

Unlike the the `mkdir()` or `_mkdir()` functions of the C library, this function will also try to create non-existing sub-directories in case they don't exist, and thus behaves like the `mkdir -p` command rather than plain `mkdir` or ``md`.

**Parameters**

**path** – directory path

**Returns**

-1 if unsuccessful, otherwise  $\geq 0$

`int LAMMPS_NS::platform::rmdir(const std::string &path)`

Delete a directory

Unlike the the `rmdir()` or `_rmdir()` functions of the C library, this function will check for the contents of the folder and recurse into any sub-folders, if necessary, and delete all contained folders and their contents before deleting the folder *path*.

**Parameters**

**path** – directory path

**Returns**

-1 if unsuccessful, otherwise  $\geq 0$

`int LAMMPS_NS::platform::unlink(const std::string &path)`

Delete a file

**Parameters**

**path** – path to file to be deleted

**Returns**

0 on success, -1 on error

#### 4.14.4 Standard I/O function wrappers

constexpr bigint LAMMPS\_NS::platform::END\_OF\_FILE = -1

constant to seek to the end of the file

bigint LAMMPS\_NS::platform::ftell(FILE \*fp)

Get current file position

##### Parameters

**fp** – FILE pointer of the given file

##### Returns

current FILE pointer position cast to a bigint

int LAMMPS\_NS::platform::fseek(FILE \*fp, bigint pos)

Set absolute file position

If the absolute position is END\_OF\_FILE, then position at the end of the file.

##### Parameters

- **fp** – FILE pointer of the given file
- **pos** – new position of the FILE pointer

##### Returns

0 if successful, otherwise -1

int LAMMPS\_NS::platform::ftruncate(FILE \*fp, bigint length)

Truncate file to a given length and re-position file pointer

##### Parameters

- **fp** – FILE pointer of the given file
- **length** – length to which the file is being truncated to

##### Returns

0 if successful, otherwise -1

FILE \*LAMMPS\_NS::platform::popen(const std::string &cmd, const std::string &mode)

Open a pipe to a command for reading or writing

##### Parameters

- **cmd** – command for the pipe
- **mode** – “r” for reading from *cmd* or “w” for writing to *cmd*

##### Returns

file pointer to the pipe if successful or null

int LAMMPS\_NS::platform::pclose(FILE \*fp)

Close a previously opened pipe

##### Parameters

**fp** – FILE pointer for the pipe

##### Returns

exit status of the pipe command or -1 in case of errors

### 4.14.5 Environment variable functions

`int LAMMPS_NS::platform::putenv(const std::string &vardef)`

Add variable to the environment

**Parameters**

**vardef** – variable name or variable definition (NAME=value)

**Returns**

-1 if failure otherwise 0

`int LAMMPS_NS::platform::unsetenv(const std::string &variable)`

Delete variable from the environment

**Parameters**

**variable** – variable name

**Returns**

-1 if failure otherwise 0

`std::vector<std::string> LAMMPS_NS::platform::list_pathenv(const std::string &var)`

Get list of entries in a path environment variable

This provides a list of strings of the entries in an environment variable that is containing a “path” like “PATH” or “LD\_LIBRARY\_PATH”.

**Parameters**

**var** – name of the environment variable

**Returns**

vector with strings of all entries in that path variable

`std::string LAMMPS_NS::platform::find_exe_path(const std::string &cmd)`

Find pathname of an executable in the standard search path

This function will traverse the list of directories in the PATH environment variable and look for the executable *cmd*. If the file exists and is executable the full path is returned as string, otherwise an empty string is returned.

On Windows the *cmd* string must not include an extension as this function will automatically append the extensions “.exe”, “.com” and “.bat” and look for those paths. On Windows also the current directory is checked (and first), but otherwise is not checked unless “.” exists in the PATH environment variable.

Because of the nature of the check, this will not detect shell functions built-in command or aliases.

**Parameters**

**cmd** – name of command

**Returns**

vector with strings of all directory entries

### 4.14.6 Dynamically loaded object or library functions

`void *LAMMPS_NS::platform::dlopen(const std::string &fname)`

Open a shared object file or library

**Parameters**

**fname** – name or path of the shared object

**Returns**

handle to the shared object or null

`int LAMMPS_NS::platform::dlclose(void *handle)`

Close a shared object

This releases the object corresponding to the provided handle. Resolved symbols associated with this handle may not be used after this call

**Parameters**

**handle** – handle to an opened shared object

**Returns**

0 if successful, non-zero of not

`void *LAMMPS_NS::platform::dlsym(void *handle, const std::string &symbol)`

Resolve a symbol in shared object

**Parameters**

- **handle** – handle to an opened shared object
- **symbol** – name of the symbol to extract

**Returns**

pointer to the resolved symbol or null

`std::string LAMMPS_NS::platform::dlerror()`

Obtain error diagnostic info after dynamic linking function calls

Return a human-readable string describing the most recent error that occurred when using one of the functions for dynamic loading objects the last call to this function. If there was no error, the string is empty.

**Returns**

string with error message or empty

### 4.14.7 Compressed file I/O functions

`bool LAMMPS_NS::platform::has_compress_extension(const std::string &file)`

Check if a file name ends in a known extension for a compressed file format

Currently supported file extensions are: .gz, .bz2, .zst, .xz, .lzma, lz4

**Parameters**

**file** – name of the file to check

**Returns**

true if the file has a known extension, otherwise false

`FILE *LAMMPS_NS::platform::compressed_read(const std::string &file)`

Open pipe to compressed text file for reading

**Parameters**

**file** – name of the file to open

**Returns**

FILE pointer to pipe using for reading the compressed file.

FILE \*LAMMPS\_NS::platform::compressed\_write(const std::string &file)

Open pipe to compressed text file for writing

**Parameters**

**file** – name of the file to open

**Returns**

FILE pointer to pipe using for reading the compressed file.

## 4.15 Utility functions

The `utils` sub-namespace inside the `LAMMPS_NS` namespace provides a collection of convenience functions and utilities that perform common tasks that are required repeatedly throughout the LAMMPS code like reading or writing to files with error checking or translation of strings into specific types of numbers with checking for validity. This reduces redundant implementations and encourages consistent behavior and thus has some overlap with the “*platform*” sub-namespace.

### 4.15.1 I/O with status check and similar functions

The the first two functions are wrappers around the corresponding C library calls `fgets()` or `fread()`. They will check if there were errors on reading or an unexpected end-of-file state was reached. In that case, the functions will stop with an error message, indicating the name of the problematic file, if possible unless the *error* argument is a NULL pointer.

The `utils::fgets_trunc()` function will work similar for `fgets()` but it will read in a whole line (i.e. until the end of line or end of file), but store only as many characters as will fit into the buffer including a final newline character and the terminating NULL byte. If the line in the file is longer it will thus be truncated in the buffer. This function is used by `utils::read_lines_from_file()` to read individual lines but make certain they follow the size constraints.

The `utils::read_lines_from_file()` function will read the requested number of lines of a maximum length into a buffer and will return 0 if successful or 1 if not. It also guarantees that all lines are terminated with a newline character and the entire buffer with a NULL character.

---

```
void LAMMPS_NS::utils::sfgets(const char *srcname, int srcline, char *s, int size, FILE *fp, const char
                             *filename, Error *error)
```

Safe wrapper around `fgets()` which aborts on errors or EOF and prints a suitable error message to help debugging.

Use nullptr as the error parameter to avoid the abort on EOF or error.

**Parameters**

- **srcname** – name of the calling source file (from FLERR macro)
- **srcline** – line in the calling source file (from FLERR macro)
- **s** – buffer for storing the result of `fgets()`
- **size** – size of buffer `s` (max number of bytes read by `fgets()`)
- **fp** – file pointer used by `fgets()`

- **filename** – file name associated with fp (may be a null pointer; then *LAMMPS* will try to detect)
- **error** – pointer to Error class instance (for abort) or nullptr

```
void LAMMPS_NS::utils::sfread(const char *srcname, int srcline, void *s, size_t size, size_t num, FILE *fp,
                             const char *filename, Error *error)
```

Safe wrapper around fread() which aborts on errors or EOF and prints a suitable error message to help debugging.

Use nullptr as the error parameter to avoid the abort on EOF or error.

#### Parameters

- **srcname** – name of the calling source file (from FLERR macro)
- **srcline** – line in the calling source file (from FLERR macro)
- **s** – buffer for storing the result of fread()
- **size** – size of data elements read by fread()
- **num** – number of data elements read by fread()
- **fp** – file pointer used by fread()
- **filename** – file name associated with fp (may be a null pointer; then *LAMMPS* will try to detect)
- **error** – pointer to Error class instance (for abort) or nullptr

```
char *LAMMPS_NS::utils::fgets_trunc(char *s, int size, FILE *fp)
```

Wrapper around fgets() which reads whole lines but truncates the data to the buffer size and ensures a newline char at the end.

This function is useful for reading line based text files with possible comments that should be parsed later. This applies to data files, potential files, atomfile variable files and so on. It is used instead of fgets() by utils::read\_lines\_from\_file().

#### Parameters

- **s** – buffer for storing the result of fgets()
- **size** – size of buffer s (max number of bytes returned)
- **fp** – file pointer used by fgets()

```
int LAMMPS_NS::utils::read_lines_from_file(FILE *fp, int nlines, int nmax, char *buffer, int me,
                                           MPI_Comm comm)
```

Read N lines of text from file into buffer and broadcast them

This function uses repeated calls to fread() to fill a buffer with newline terminated text. If a line does not end in a newline (e.g. at the end of a file), it is added. The caller has to allocate an nlines by nmax sized buffer for storing the text data. Reading is done by MPI rank 0 of the given communicator only, and thus only MPI rank 0 needs to provide a valid file pointer.

#### Parameters

- **fp** – file pointer used by fread
- **nlines** – number of lines to be read
- **nmax** – maximum length of a single line
- **buffer** – buffer for storing the data.
- **me** – MPI rank of calling process in MPI communicator

- **comm** – MPI communicator for broadcast

**Returns**

1 if the read was short, 0 if read was successful

---

### 4.15.2 String to number conversions with validity check

These functions should be used to convert strings to numbers. They are strongly preferred over C library calls like `atoi()` or `atof()` since they check if the **entire** string is a valid (floating-point or integer) number, and will error out instead of silently returning the result of a partial conversion or zero in cases where the string is not a valid number. This behavior improves detecting typos or issues when processing input files.

Similarly the `utils::logical()` function will convert a string into a boolean and will only accept certain words.

The `do_abort` flag should be set to `true` in case this function is called only on a single MPI rank, as that will then trigger the a call to `Error::one()` for errors instead of `Error::all()` and avoids a “hanging” calculation when run in parallel.

Please also see `utils::is_integer()` and `utils::is_double()` for testing strings for compliance without conversion.

---

```
double LAMMPS_NS::utils::numeric(const char *file, int line, const std::string &str, bool do_abort, LAMMPS
                                *lmp)
```

Convert a string to a floating point number while checking if it is a valid floating point or integer number

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do\_abort** – determines whether to call `Error::one()` or `Error::all()`
- **lmp** – pointer to top-level *LAMMPS* class instance

**Returns**

double precision floating point number

```
double LAMMPS_NS::utils::numeric(const char *file, int line, const char *str, bool do_abort, LAMMPS *lmp)
```

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do\_abort** – determines whether to call `Error::one()` or `Error::all()`
- **lmp** – pointer to top-level *LAMMPS* class instance

**Returns**

double precision floating point number

int LAMMPS\_NS::utils::inumeric(const char \*file, int line, const std::string &str, bool do\_abort, *LAMMPS* \*Imp)

Convert a string to an integer number while checking if it is a valid integer number (regular int)

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do\_abort** – determines whether to call Error::one() or Error::all()
- **Imp** – pointer to top-level *LAMMPS* class instance

**Returns**

integer number (regular int)

int LAMMPS\_NS::utils::inumeric(const char \*file, int line, const char \*str, bool do\_abort, *LAMMPS* \*Imp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do\_abort** – determines whether to call Error::one() or Error::all()
- **Imp** – pointer to top-level *LAMMPS* class instance

**Returns**

double precision floating point number

bigint LAMMPS\_NS::utils::bnumeric(const char \*file, int line, const std::string &str, bool do\_abort, *LAMMPS* \*Imp)

Convert a string to an integer number while checking if it is a valid integer number (bigint)

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do\_abort** – determines whether to call Error::one() or Error::all()
- **Imp** – pointer to top-level *LAMMPS* class instance

**Returns**

integer number (bigint)

bigint LAMMPS\_NS::utils::bnumeric(const char \*file, int line, const char \*str, bool do\_abort, *LAMMPS* \*Imp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number

- **do\_abort** – determines whether to call `Error::one()` or `Error::all()`
- **lmp** – pointer to top-level *LAMMPS* class instance

**Returns**

double precision floating point number

tagint LAMMPS\_NS::utils::tnumeric(const char \*file, int line, const std::string &str, bool do\_abort, *LAMMPS* \*lmp)

Convert a string to an integer number while checking if it is a valid integer number (tagint)

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do\_abort** – determines whether to call `Error::one()` or `Error::all()`
- **lmp** – pointer to top-level *LAMMPS* class instance

**Returns**

integer number (tagint)

tagint LAMMPS\_NS::utils::tnumeric(const char \*file, int line, const char \*str, bool do\_abort, *LAMMPS* \*lmp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to number
- **do\_abort** – determines whether to call `Error::one()` or `Error::all()`
- **lmp** – pointer to top-level *LAMMPS* class instance

**Returns**

double precision floating point number

int LAMMPS\_NS::utils::logical(const char \*file, int line, const std::string &str, bool do\_abort, *LAMMPS* \*lmp)

Convert a string to a boolean while checking whether it is a valid boolean term. Valid terms are ‘yes’, ‘no’, ‘true’, ‘false’, ‘on’, ‘off’, and ‘1’, ‘0’. Only lower case is accepted.

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to logical
- **do\_abort** – determines whether to call `Error::one()` or `Error::all()`
- **lmp** – pointer to top-level *LAMMPS* class instance

**Returns**

1 if string resolves to “true”, otherwise 0

int LAMMPS\_NS::utils::logical(const char \*file, int line, const char \*str, bool do\_abort, *LAMMPS* \*Imp)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be converted to logical
- **do\_abort** – determines whether to call Error::one() or Error::all()
- **Imp** – pointer to top-level *LAMMPS* class instance

**Returns**

1 if string resolves to “true”, otherwise 0

### 4.15.3 String processing

The following are functions to help with processing strings and parsing files or arguments.

---

char \*LAMMPS\_NS::utils::strdup(const std::string &text)

Make C-style copy of string in new storage

This allocates a storage buffer and copies the C-style or C++ style string into it. The buffer is allocated with “new” and thus needs to be deallocated with “delete[]”.

**Parameters**

**text** – string that should be copied

**Returns**

new buffer with copy of string

std::string LAMMPS\_NS::utils::lowercase(const std::string &line)

Convert string to lowercase

**Parameters**

**line** – string that should be converted

**Returns**

new string with all lowercase characters

std::string LAMMPS\_NS::utils::uppercase(const std::string &line)

Convert string to uppercase

**Parameters**

**line** – string that should be converted

**Returns**

new string with all uppercase characters

std::string LAMMPS\_NS::utils::trim(const std::string &line)

Trim leading and trailing whitespace. Like TRIM() in Fortran.

**Parameters**

**line** – string that should be trimmed

**Returns**

new string without whitespace (string)

`std::string LAMMPS_NS::utils::trim_comment(const std::string &line)`

Return string with anything from the first '#' character onward removed

**Parameters**

**line** – string that should be trimmed

**Returns**

new string without comment (string)

`std::string LAMMPS_NS::utils::strip_style_suffix(const std::string &style, LAMMPS *Imp)`

Remove style suffix from string if suffix flag is active

This will try to undo the effect from using the *suffix command* or the *-suffix/-sf* command line flag and return correspondingly modified string.

```
\param style  string of style name
\param Imp    pointer to the LAMMPS class (has suffix_flag and suffix strings)
\return      processed string
```

`std::string LAMMPS_NS::utils::star_subst(const std::string &name, bigint step, int pad)`

Replace first '\*' character in a string with a number, optionally zero-padded

If there is no '\*' character in the string, return the original string. If the number requires more characters than the value of the *pad* argument, do not add zeros; otherwise add as many zeroes as needed to the left to make the the number representation *pad* characters wide.

**Parameters**

- **name** – string with file containing a '\*' (or not)
- **step** – step number to replace the (first) '\*'
- **pad** – zero-padding (may be zero)

**Returns**

processed string

`inline bool LAMMPS_NS::utils::has_utf8(const std::string &line)`

Check if a string will likely have UTF-8 encoded characters

UTF-8 uses the 7-bit standard ASCII table for the first 127 characters and all other characters are encoded as multiple bytes. For the multi-byte characters the first byte has either the highest two, three, or four bits set followed by a zero bit and followed by one, two, or three more bytes, respectively, where the highest bit is set and the second highest bit set to 0. The remaining bits combined are the character code, which is thus limited to 21-bits.

For the sake of efficiency this test only checks if a character in the string has the highest bit set and thus is very likely an UTF-8 character. It will not be able to tell this this is a valid UTF-8 character or whether it is a 2-byte, 3-byte, or 4-byte character.

*See also*

*utils::utf8\_subst()*

**Parameters**

**line** – string that should be checked

**Returns**

true if string contains UTF-8 encoded characters (bool)

std::string LAMMPS\_NS::utils::utf8\_subst(const std::string &line)

Replace known UTF-8 characters with ASCII equivalents

*See also*

[\*utils::has\\_utf8\(\)\*](#)

**Parameters**

**line** – string that should be converted

**Returns**

new string with ascii replacements (string)

size\_t LAMMPS\_NS::utils::count\_words(const char \*text)

Count words in C-string, ignore any whitespace matching “\t\r\n\f”

**Parameters**

**text** – string that should be searched

**Returns**

number of words found

size\_t LAMMPS\_NS::utils::count\_words(const std::string &text)

Count words in string, ignore any whitespace matching “\t\r\n\f”

**Parameters**

**text** – string that should be searched

**Returns**

number of words found

size\_t LAMMPS\_NS::utils::count\_words(const std::string &text, const std::string &separators)

Count words in string with custom choice of separating characters

**Parameters**

- **text** – string that should be searched
- **separators** – string containing characters that will be treated as whitespace

**Returns**

number of words found

size\_t LAMMPS\_NS::utils::trim\_and\_count\_words(const std::string &text, const std::string &separators = "  
\\t\\r\\n\\f")

Count words in a single line, trim anything from ‘#’ onward

**Parameters**

- **text** – string that should be trimmed and searched
- **separators** – string containing characters that will be treated as whitespace

**Returns**

number of words found

```
std::string LAMMPS_NS::utils::join_words(const std::vector<std::string> &words, const std::string &sep)
```

Take list of words and join them with a given separator text.

This is the inverse operation of what the `split_words()` function `Tokenizer` classes do.

**Parameters**

- **words** – STL vector with strings
- **sep** – separator string (may be empty)

**Returns**

string with the concatenated words and separators

```
std::vector<std::string> LAMMPS_NS::utils::split_words(const std::string &text)
```

Take text and split into non-whitespace words.

This can handle strings with single and double quotes, escaped quotes, and escaped codes within quotes, but due to using an STL container and STL strings is rather slow because of making copies. Designed for parsing command lines and similar text and not for time critical processing. Use a tokenizer class if performance matters.

*See also*

[\*Tokenizer\*](#), [\*ValueTokenizer\*](#)

**Parameters**

**text** – string that should be split

**Returns**

STL vector with the words

```
std::vector<std::string> LAMMPS_NS::utils::split_lines(const std::string &text)
```

Take multi-line text and split into lines

**Parameters**

**text** – string that should be split

**Returns**

STL vector with the lines

```
bool LAMMPS_NS::utils::strmatch(const std::string &text, const std::string &pattern)
```

Match text against a simplified regex pattern

More flexible and specific matching of a string against a pattern. This function is supposed to be a more safe, more specific and simple to use API to find pattern matches. The purpose is to replace uses of either `strncmp()` or `strstr()` in the code base to find sub-strings safely. With `strncmp()` finding prefixes, the number of characters to match must be counted, which can lead to errors, while using “^pattern” will do the same with less problems. Matching for suffixes using `strstr()` is not as specific as “pattern\$”, and complex matches, e.g. “^rigid.\*Vsmall.\*”, to match all small body optimized rigid fixes require only one test.

The use of `std::string` arguments allows for simple concatenation even with `char *` type variables. Example: `utils::strmatch(text, std::string("^") + charptr)`

**Parameters**

- **text** – the text to be matched against the pattern
- **pattern** – the search pattern, which may contain regexp markers

**Returns**

true if the pattern matches, false if not

```
std::string LAMMPS_NS::utils::strfind(const std::string &text, const std::string &pattern)
```

Find sub-string that matches a simplified regex pattern

This function is a companion function to `utils::strmatch()`. Arguments and logic is the same, but instead of a boolean, it returns the sub-string that matches the regex pattern. There can be only one match. This can be used as a more flexible alternative to `strstr()`.

**Parameters**

- **text** – the text to be matched against the pattern
- **pattern** – the search pattern, which may contain regexp markers

**Returns**

the string that matches the pattern or an empty one

```
bool LAMMPS_NS::utils::is_integer(const std::string &str)
```

Check if string can be converted to valid integer

**Parameters**

**str** – string that should be checked

**Returns**

true, if string contains valid a integer, false otherwise

```
bool LAMMPS_NS::utils::is_double(const std::string &str)
```

Check if string can be converted to valid floating-point number

**Parameters**

**str** – string that should be checked

**Returns**

true, if string contains valid number, false otherwise

```
bool LAMMPS_NS::utils::is_id(const std::string &str)
```

Check if string is a valid ID ID strings may contain only letters, numbers, and underscores.

**Parameters**

**str** – string that should be checked

**Returns**

true, if string contains valid id, false otherwise

```
int LAMMPS_NS::utils::is_type(const std::string &str)
```

Check if string is a valid type label, or numeric type, or numeric type range. Numeric type or type range may only contain digits or the '\*' character. Type label strings may not contain a digit, or a '\*', or a '#' character as the first character to distinguish them from comments and numeric types or type ranges. They also may not contain any whitespace. If the string is a valid numeric type or type range the function returns 0, if it is a valid type label the function returns 1, otherwise it returns -1.

**Parameters**

**str** – string that should be checked

**Returns**

0, 1, or -1, depending on whether the string is valid numeric type, valid type label or neither, respectively

#### 4.15.4 Potential file functions

`std::string LAMMPS_NS::utils::get_potential_file_path(const std::string &path)`

Determine full path of potential file. If file is not found in current directory, search directories listed in LAMMPS\_POTENTIALS environment variable

**Parameters**

**path** – file path

**Returns**

full path to potential file

`std::string LAMMPS_NS::utils::get_potential_date(const std::string &path, const std::string &potential_name)`

Read potential file and return DATE field if it is present

**Parameters**

- **path** – file path
- **potential\_name** – name of potential that is being read

**Returns**

DATE field if present

`std::string LAMMPS_NS::utils::get_potential_units(const std::string &path, const std::string &potential_name)`

Read potential file and return UNITS field if it is present

**Parameters**

- **path** – file path
- **potential\_name** – name of potential that is being read

**Returns**

UNITS field if present

`int LAMMPS_NS::utils::get_supported_conversions(const int property)`

Return bitmask of available conversion factors for a given property

**Parameters**

**property** – property to be converted

**Returns**

bitmask indicating available conversions

`double LAMMPS_NS::utils::get_conversion_factor(const int property, const int conversion)`

Return unit conversion factor for given property and selected from/to units

**Parameters**

- **property** – property to be converted
- **conversion** – constant indicating the conversion

**Returns**

conversion factor

FILE \*LAMMPS\_NS::utils::open\_potential(const std::string &name, *LAMMPS* \*lmp, int \*auto\_convert)

Open a potential file as specified by *name*

If opening the file directly fails, the function will search for it in the list of folder pointed to by the environment variable LAMMPS\_POTENTIALS (if it is set).

If the potential file has a UNITS tag in the first line, the tag's value is compared to the current unit style setting. The behavior of the function then depends on the value of the *auto\_convert* parameter. If it is a null pointer, then the unit values must match or else the open will fail with an error. Otherwise the bitmask that *auto\_convert* points to is used check for compatibility with possible automatic conversions by the calling function. If compatible, the bitmask is set to the required conversion or `utils::NOCONVERT`.

#### Parameters

- **name** – file- or pathname of the potential file
- **lmp** – pointer to top-level *LAMMPS* class instance
- **auto\_convert** – pointer to unit conversion bitmask or `nullptr`

#### Returns

FILE pointer of the opened potential file or `nullptr`

### 4.15.5 Argument processing

template<typename **TYPE**>

void LAMMPS\_NS::utils::bounds(const char \*file, int line, const std::string &str, bigint nmin, bigint nmax, *TYPE* &nlo, *TYPE* &nhi, Error \*error)

Compute index bounds derived from a string with a possible wildcard

This functions processes the string in *str* and set the values of *nlo* and *nhi* according to the following five cases:

- a single number, *i*: *nlo* = *i*; *nhi* = *i*;
- a single asterisk, *\**: *nlo* = *nmin*; *nhi* = *nmax*;
- a single number followed by an asterisk, *i\**: *nlo* = *i*; *nhi* = *nmax*;
- a single asterisk followed by a number, *\*i*: *nlo* = *nmin*; *nhi* = *i*;
- two numbers with an asterisk in between. *i\*j*: *nlo* = *i*; *nhi* = *j*;

#### Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – string to be processed
- **nmin** – smallest possible lower bound
- **nmax** – largest allowed upper bound
- **nlo** – lower bound
- **nhi** – upper bound
- **error** – pointer to Error class for out-of-bounds messages

template<typename **TYPE**>

```
void LAMMPS_NS::utils::bounds_typelabel(const char *file, int line, const std::string &str, bigint nmin, bigint
                                         nmax, TYPE &nlo, TYPE &nhi, LAMMPS *lmp, int mode)
```

Same as `utils::bounds()`, but string may be a typelabel

New in version 27June2024.

This functions adds the following case to `utils::bounds()`:

- a single type label, `typestr: nlo = nhi = label2type(typestr)`

<code>\param file</code>	name of source file for error message
<code>\param line</code>	line number in source file for error message
<code>\param str</code>	string to be processed
<code>\param nmin</code>	smallest possible lower bound
<code>\param nmax</code>	largest allowed upper bound
<code>\param nlo</code>	lower bound
<code>\param nhi</code>	upper bound
<code>\param lmp</code>	pointer to top-level LAMMPS class instance
<code>\param mode</code>	select labelmap using constants from Atom class

```
int LAMMPS_NS::utils::expand_args(const char *file, int line, int nargs, char **arg, int mode, char **&earg,
                                   LAMMPS *lmp)
```

Expand list of arguments when containing fix/compute wildcards

This function searches the list of arguments in *arg* for strings of the kind `c_ID[*]`, `f_ID[*]`, `v_ID[*]`, `i2_ID[*]`, `d2_ID[*]`, or `c_ID:gname:dname[*]` referring to computes, fixes, vector style variables, custom per-atom arrays, or grids, respectively. Any such strings are replaced by one or more strings with the '\*' character replaced by the corresponding possible numbers as determined from the fix, compute, variable, property, or grid instance. Unrecognized strings are just copied. If the *mode* parameter is set to 0, expand global vectors, but not global arrays; if it is set to 1, expand global arrays (by column) but not global vectors.

If any expansion happens, the *earg* list and all its strings are new allocations and must be freed explicitly by the caller. Otherwise *arg* and *earg* will point to the same address and no explicit de-allocation is needed by the caller.

#### Parameters

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **nargs** – number of arguments in current list
- **arg** – argument list, possibly containing wildcards
- **mode** – select between global vectors(=0) and arrays (=1)
- **earg** – new argument list with wildcards expanded
- **lmp** – pointer to top-level *LAMMPS* class instance

#### Returns

number of arguments in expanded list

```
std::vector<std::string> LAMMPS_NS::utils::parse_grid_id(const char *file, int line, const std::string &name,
                                                         Error *error)
```

Parse grid reference into 3 sub-strings

Format of grid ID reference = `id:gname:dname`. Return vector with the 3 sub-strings.

**Parameters**

**name** – = complete grid ID

**Returns**

std::vector<std::string> containing the 3 sub-strings

char \*LAMMPS\_NS::utils::expand\_type(const char \*file, int line, const std::string &str, int mode, *LAMMPS* \*lmp)

Expand type label string into its equivalent numeric type

This function checks if a given string may be a type label and then searches the labelmap type indicated by the *mode* argument for the corresponding numeric type. If this is found, a copy of the numeric type string is made and returned. Otherwise a null pointer is returned. If a string is returned, the calling code must free it with delete[].

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **str** – type string to be expanded
- **mode** – select labelmap using constants from *Atom* class
- **lmp** – pointer to top-level *LAMMPS* class instance

**Returns**

pointer to expanded string or null pointer

## 4.15.6 Convenience functions

template<typename ...**Args**>

void LAMMPS\_NS::utils::logmesg(*LAMMPS* \*lmp, const std::string &format, *Args*&&... args)

Send formatted message to screen and logfile, if available

This function simplifies the repetitive task of outputting some message to both the screen and/or the log file. The template wrapper with fmtlib format and argument processing allows this function to work similar to `fmt::print()`.

**Parameters**

- **lmp** – pointer to *LAMMPS* class instance
- **format** – format string of message to be printed
- **args** – arguments to format string

void LAMMPS\_NS::utils::logmesg(*LAMMPS* \*lmp, const std::string &mesg)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

**Parameters**

- **lmp** – pointer to *LAMMPS* class instance
- **mesg** – string with message to be printed

std::string LAMMPS\_NS::utils::errorurl(int errorcode)

Return text redirecting the user to a specific paragraph in the manual

The *LAMMPS* manual contains detailed explanations for errors and warnings where a simple error message may not be sufficient. These can be reached through URLs with a numeric code. This function creates the corresponding text to be included into the error message that redirects the user to that URL.

**Parameters**

**errorcode** – number pointing to a paragraph in the manual

void LAMMPS\_NS::utils::missing\_cmd\_args(const std::string &file, int line, const std::string &cmd, Error \*error)

Print error message about missing arguments for command

This function simplifies the repetitive reporting missing arguments to a command.

**Parameters**

- **file** – name of source file for error message
- **line** – line number in source file for error message
- **cmd** – name of the failing command
- **error** – pointer to Error class instance (for abort) or nullptr

void LAMMPS\_NS::utils::flush\_buffers(*LAMMPS* \*Imp)

Flush output buffers

This function calls fflush() on screen and logfile FILE pointers if available and thus tells the operating system to output all currently buffered data. This is local operation and independent from buffering by a file system or an MPI library.

std::string LAMMPS\_NS::utils::getsyserror()

Return a string representing the current system error status

This is a wrapper around calling strerror(errno).

**Returns**

error string

std::string LAMMPS\_NS::utils::check\_packages\_for\_style(const std::string &style, const std::string &name, *LAMMPS* \*Imp)

Report if a requested style is in a package or may have a typo

**Parameters**

- **style** – type of style that is to be checked for
- **name** – name of style that was not found
- **Imp** – pointer to top-level *LAMMPS* class instance

**Returns**

string usable for error messages

double LAMMPS\_NS::utils::timespec2seconds(const std::string &timespec)

Convert a time string to seconds

The strings “off” and “unlimited” result in -1

**Parameters**

**timespec** – a string in the following format: ([HH:]MM:]SS)

**Returns**

total in seconds

int LAMMPS\_NS::utils::**date2num**(const std::string &date)

Convert a *LAMMPS* version date to a number

This will generate a number YYYYMMDD from a date string (with or without blanks) that is suitable for numerical comparisons, i.e. later dates will generate a larger number.

The day may or may not have a leading zero, the month is identified by the first 3 letters (so there may be more) and the year may be 2 or 4 digits (the missing 2 digits will be assumed as 20. That is 04 corresponds to 2004).

No check is made whether the date is valid.

**Parameters**

**date** – string in the format (Day Month Year)

**Returns**

date code

std::string LAMMPS\_NS::utils::**current\_date**()

Return current date as string

This will generate a string containing the current date in YYYY-MM-DD format.

**Returns**

string with current date

## 4.15.7 Customized standard functions

int LAMMPS\_NS::utils::**binary\_search**(const double needle, const int n, const double \*haystack)

Binary search in a vector of ascending doubles of length N

If the value is smaller than the smallest value in the vector, 0 is returned. If the value is larger or equal than the largest value in the vector, N-1 is returned. Otherwise the index that satisfies the condition

haystack[index] <= value < haystack[index+1]

is returned, i.e. a value from 1 to N-2. Note that if there are tied values in the haystack, always the larger index is returned as only that satisfied the condition.

**Parameters**

- **needle** – search value for which are are looking for the closest index
- **n** – size of the haystack array
- **haystack** – array with data in ascending order.

**Returns**

index of value in the haystack array smaller or equal to needle

void LAMMPS\_NS::utils::**merge\_sort**(int \*index, int num, void \*ptr, int (\*comp)(int, int, void\*))

Custom merge sort implementation

This function provides a custom upward hybrid merge sort implementation with support to pass an opaque pointer to the comparison function, e.g. for access to class members. This avoids having to use global variables. For improved performance, it uses an in-place insertion sort on initial chunks of up to 64 elements and switches to merge sort from then on.

**Parameters**

- **index** – Array with indices to be sorted
  - **num** – Length of the index array
  - **ptr** – Pointer to opaque object passed to comparison function
  - **comp** – Pointer to comparison function
- 

## 4.16 Special Math functions

The `MathSpecial` namespace implements a selection of custom and optimized mathematical functions for a variety of applications.

`double LAMMPS_NS::MathSpecial::factorial(const int n)`

Fast tabulated factorial function

This function looks up pre-computed factorial values for arguments of  $n = 0$  to a maximum of 167, which is the maximal value representable by a double precision floating point number. For other values of  $n$  a NaN value is returned.

### Parameters

**n** – argument (valid:  $0 \leq n \leq 167$ )

### Returns

value of  $n!$  as double precision number or NaN

`double LAMMPS_NS::MathSpecial::exp2_x86(double x)`

Fast implementation of  $2^x$  without argument checks for little endian CPUs

This function implements an optimized version of `pow(2.0, x)` that does not check for valid arguments and thus may only be used where arguments are well behaved. The implementation makes assumptions about the layout of double precision floating point numbers in memory and thus will only work on little endian CPUs. If little endian cannot be safely detected, the result of calling `pow(2.0, x)` will be returned. This function also is the basis for the fast exponential `fm_exp(x)`.

### Parameters

**x** – argument

### Returns

value of  $2^x$  as double precision number

`double LAMMPS_NS::MathSpecial::fm_exp(double x)`

Fast implementation of `exp(x)` for little endian CPUs

This function implements an optimized version of `exp(x)` for little endian CPUs. It calls the `exp2_x86(x)` function with a suitable prefactor to  $x$  to return `exp(x)`. The implementation makes assumptions about the layout of double precision floating point numbers in memory and thus will only work on little endian CPUs. If little endian cannot be safely detected, the result of calling the `exp(x)` implementation in the standard math library will be returned.

### Parameters

**x** – argument

### Returns

value of  $e^x$  as double precision number

static inline double LAMMPS\_NS::MathSpecial::my\_erfcx(const double x)

Fast scaled error function complement  $\exp(x*x)*\text{erfc}(x)$  for coul/long styles

This is a portable fast implementation of  $\exp(x*x)*\text{erfc}(x)$  that can be used in coul/long pair styles as a replacement for the polynomial expansion that is/was widely used. Unlike the polynomial expansion, that is only accurate at the level of single precision floating point it provides full double precision accuracy, but at comparable speed (unlike the `erfc()` implementation shipped with GNU standard math library).

**Parameters**

**x** – argument

**Returns**

value of  $e^{(x*x)}*\text{erfc}(x)$

static inline double LAMMPS\_NS::MathSpecial::expmsq(double x)

Fast implementation of  $\exp(-x*x)$  for little endian CPUs for coul/long styles

This function implements an optimized version of  $\exp(-x*x)$  based on `exp2_x86()` for use with little endian CPUs. If little endian cannot be safely detected, the result of calling the  $\exp(-x*x)$  implementation in the standard math library will be returned.

**Parameters**

**x** – argument

**Returns**

value of  $e^{(-x*x)}$  as double precision number

static inline double LAMMPS\_NS::MathSpecial::square(const double &x)

Fast inline version of  $\text{pow}(x, 2.0)$

**Parameters**

**x** – argument

**Returns**

$x*x$

static inline double LAMMPS\_NS::MathSpecial::cube(const double &x)

Fast inline version of  $\text{pow}(x, 3.0)$

**Parameters**

**x** – argument

**Returns**

$x*x*x$

static inline double LAMMPS\_NS::MathSpecial::powsign(const int n)

static inline double LAMMPS\_NS::MathSpecial::powint(const double &x, const int n)

static inline double LAMMPS\_NS::MathSpecial::powsinxx(const double &x, int n)

## 4.17 Tokenizer classes

The purpose of the tokenizer classes is to simplify the recurring task of breaking lines of text down into words and/or numbers. Traditionally, LAMMPS code would be using the `strtok()` function from the C library for that purpose, but that function has two significant disadvantages: 1) it cannot be used concurrently from different LAMMPS instances since it stores its status in a global variable and 2) it modifies the string that it is processing. These classes were implemented to avoid both of these issues and also to reduce the amount of code that needs to be written.

The basic procedure is to create an instance of the tokenizer class with the string to be processed as an argument and then do a loop until all available tokens are read. The constructor has a default set of separator characters, but that can be overridden. The default separators are all “whitespace” characters, i.e. the space character, the tabulator character, the carriage return character, the linefeed character, and the form feed character.

Listing 1: Tokenizer class example listing entries of the PATH environment variable

```
#include "tokenizer.h"
#include <cstdlib>
#include <string>
#include <iostream>

using namespace LAMMPS_NS;

int main(int, char **)
{
    const char *path = getenv("PATH");

    if (path != nullptr) {
        Tokenizer p(path, ":");
        while (p.has_next())
            std::cout << "Entry: " << p.next() << "\n";
    }
    return 0;
}
```

Most tokenizer operations cannot fail except for `LAMMPS_NS::Tokenizer::next()` (when used without first checking with `LAMMPS_NS::Tokenizer::has_next()`) and `LAMMPS_NS::Tokenizer::skip()`. In case of failure, the class will throw an exception, so you may need to wrap the code using the tokenizer into a `try / catch` block to handle errors. The `LAMMPS_NS::ValueTokenizer` class may also throw an exception when a (type of) number is requested as next token that is not compatible with the string representing the next word.

Listing 2: ValueTokenizer class example with exception handling

```
#include "tokenizer.h"
#include <cstdlib>
#include <string>
#include <iostream>

using namespace LAMMPS_NS;

int main(int, char **)
{
    const char *text = "1 2 3 4 5 20.0 21 twentytwo 2.3";
    double num1(0), num2(0), num3(0), num4(0);
```

(continues on next page)

(continued from previous page)

```

ValueTokenizer t(text);
// read 4 doubles after skipping over 5 numbers
try {
    t.skip(5);
    num1 = t.next_double();
    num2 = t.next_double();
    num3 = t.next_double();
    num4 = t.next_double();
} catch (TokenizerException &e) {
    std::cout << "Reading numbers failed: " << e.what() << "\n";
}
std::cout << "Values: " << num1 << " " << num2 << " " << num3 << " " << num4 << "\n";
return 0;
}

```

This code example should produce the following output:

```

Reading numbers failed: Not a valid floating-point number: 'twentytwo'
Values: 20 21 0 0

```

class **Tokenizer**

### Public Functions

**Tokenizer**(std::string str, std::string separators = TOKENIZER\_DEFAULT\_SEPARATORS)

Class for splitting text into words

This tokenizer will break down a string into sub-strings (i.e words) separated by the given separator characters. If the string contains certain known UTF-8 characters they will be replaced by their ASCII equivalents processing the string.

*See also*

[\*ValueTokenizer\*](#), [\*utils::split\\_words\(\)\*](#), [\*utils::utf8\\_subst\(\)\*](#)

#### Parameters

- **str** – string to be processed
- **\_separators** – string with separator characters (default: “\t\r\n\f”)

void **reset**()

Re-position the tokenizer state to the first word, i.e. the first non-separator character

void **skip**(int n = 1)

Skip over a given number of tokens

#### Parameters

**n** – number of tokens to skip over

bool **has\_next**() const

Indicate whether more tokens are available

**Returns**

true if there are more tokens, false if not

bool **contains**(const std::string &str) const

Search the text to be processed for a sub-string.

This method does a generic sub-string match.

**Parameters**

**str** – string to be searched for

**Returns**

true if string was found, false if not

bool **matches**(const std::string &str) const

Search the text to be processed for regular expression match.

This method matches the current string against a regular expression using the [\*utils::strmatch\(\)\*](#) function.

**Parameters**

**str** – regular expression to be matched against

**Returns**

true if string was found, false if not

std::string **next**()

Retrieve next token.

**Returns**

string with the next token

size\_t **count**()

Count number of tokens in text.

**Returns**

number of counted tokens

std::vector<std::string> **as\_vector**()

Retrieve the entire text converted to an STL vector of tokens.

**Returns**

The STL vector

class **TokenizerException** : public exception

General Tokenizer exception class

Subclassed by [\*InvalidFloatException\*](#), [\*InvalidIntegerException\*](#)

## Public Functions

explicit **TokenizerException**(const std::string &msg, const std::string &token)

Thrown during retrieving or skipping tokens

### Parameters

- **msg** – String with error message
- **token** – String of the token/word that caused the error

inline const char \***what**() const noexcept override

Retrieve message describing the thrown exception

### Returns

string with error message

class **ValueTokenizer**

## Public Functions

**ValueTokenizer**(const std::string &str, const std::string &separators =  
TOKENIZER\_DEFAULT\_SEPARATORS)

Class for reading text with numbers

*See also*

[\*Tokenizer\*](#)

**See also:**

Tokenizer [\*InvalidIntegerException\*](#) [\*InvalidFloatException\*](#)

### Parameters

- **str** – String to be processed
- **separators** – String with separator characters (default: “\t\r\n\f”)

std::string **next\_string**()

Retrieve next token

### Returns

string with next token

tagint **next\_tagint**()

Retrieve next token and convert to tagint

### Returns

value of next token

bigint **next\_bigint**()

Retrieve next token and convert to bigint

### Returns

value of next token

int **next\_int**()

Retrieve next token and convert to int

**Returns**

value of next token

double **next\_double**()

Retrieve next token and convert to double

**Returns**

value of next token

bool **has\_next**() const

Indicate whether more tokens are available

**Returns**

true if there are more tokens, false if not

bool **contains**(const std::string &value) const

Search the text to be processed for a sub-string.

This method does a generic sub-string match.

**Parameters**

**value** – string with value to be searched for

**Returns**

true if string was found, false if not

bool **matches**(const std::string &str) const

Search the text to be processed for regular expression match.

This method matches the current string against a regular expression using the *utils::strmatch()* function.

**Parameters**

**str** – regular expression to be matched against

**Returns**

true if string was found, false if not

void **skip**(int ntokens = 1)

Skip over a given number of tokens

**Parameters**

**n** – number of tokens to skip over

size\_t **count**()

Count number of tokens in text.

**Returns**

number of counted tokens

class **InvalidIntegerException** : public *TokenizerException*

Exception thrown by ValueTokenizer when trying to convert an invalid integer string

## Public Functions

inline explicit **InvalidIntegerException**(const std::string &token)

Thrown during converting string to integer number

### Parameters

**token** – String of the token/word that caused the error

class **InvalidFloatException** : public *TokenizerException*

Exception thrown by ValueTokenizer when trying to convert an floating point string

## Public Functions

inline explicit **InvalidFloatException**(const std::string &token)

Thrown during converting string to floating point number

### Parameters

**token** – String of the token/word that caused the error

## 4.18 Argument parsing classes

The purpose of argument parsing classes it to simplify and unify how arguments of commands in LAMMPS are parsed and to make abstractions of repetitive tasks.

The *LAMMPS\_NS::ArgInfo* class provides an abstraction for parsing references to compute or fix styles, variables or custom integer or double properties handled by *fix property/atom*. These would start with a “c\_”, “f\_”, “v\_”, “d\_”, “d2\_”, “i\_”, or “i2\_” followed by the ID or name of than instance and may be postfixed with one or two array indices “[<number>]” with numbers > 0.

A typical code segment would look like this:

Listing 3: Usage example for ArgInfo class

```
int nvalues = 0;
for (iarg = 0; iarg < nargnew; iarg++) {
    ArgInfo argi(arg[iarg]);

    which[nvalues] = argi.get_type();
    argindex[nvalues] = argi.get_index1();
    ids[nvalues] = argi.copy_name();

    if ((which[nvalues] == ArgInfo::UNKNOWN)
        || (which[nvalues] == ArgInfo::NONE)
        || (argi.get_dim() > 1))
        error->all(FLError, "Illegal compute XXX command");

    nvalues++;
}
```

class **ArgInfo**

## Public Types

enum **ArgTypes**

constants for argument types

*Values:*

enumerator **ERROR**

enumerator **UNKNOWN**

enumerator **NONE**

enumerator **X**

enumerator **V**

enumerator **F**

enumerator **COMPUTE**

enumerator **FIX**

enumerator **VARIABLE**

enumerator **KEYWORD**

enumerator **TYPE**

enumerator **MOLECULE**

enumerator **DNAME**

enumerator **INAME**

enumerator **DENSITY\_NUMBER**

enumerator **DENSITY\_MASS**

enumerator **MASS**

enumerator **TEMPERATURE**

enumerator **BIN1D**

enumerator **BIN2D**

enumerator **BIN3D**

enumerator **BINSPHERE**

enumerator **BINCYLINDER**

## Public Functions

**ArgInfo**(const std::string &arg, int allowed = COMPUTE | FIX | VARIABLE)

Class for processing references to fixes, computes and variables

This class provides an abstraction for the repetitive task of parsing arguments that may contain references to fixes, computes, variables, or custom per-atom properties. It will identify the name and the index value in the first and second dimension, if present.

### Parameters

- **arg** – string with possible reference
- **allowed** – integer with bitmap of allowed types of references

inline int **get\_type**() const

get type of reference

Return a type constant for the reference. This may be either COMPUTE, FIX, VARIABLE (if not restricted to a subset of those by the “allowed” argument of the constructor) or NONE, if it is not a recognized or allowed reference, or UNKNOWN, in case some error happened identifying or parsing the values of the indices

### Returns

integer with a constant from ArgTypes enumerator

inline int **get\_dim**() const

get dimension of reference

This will return either 0, 1, 2 depending on whether the reference has no, one or two “[{number}]” postfixes.

### Returns

integer with the dimensionality of the reference

inline int **get\_index1**() const

get index of first dimension

This will return the number in the first “[{number}]” postfix or 0 if there is no postfix.

### Returns

integer with index or the postfix or 0

inline int **get\_index2**() const

get index of second dimension

This will return the number in the second “[{number}]” postfix or -1 if there is no second postfix.

**Returns**

integer with index of the postfix or -1

inline const char \***get\_name**() const

return reference to the ID or name of the reference

This string is pointing to an internal storage element and is only valid to use while the ArgInfo class instance is in scope. If you need a long-lived string make a copy with `copy_name()`.

**Returns**

C-style char \* string

char \***copy\_name**()

make copy of the ID of the reference as C-style string

The ID is copied into a buffer allocated with “new” and thus must be later deleted with “delete []” to avoid a memory leak. Because it is a full copy in a newly allocated buffer, the lifetime of this string extends beyond the the time the ArgInfo class is in scope.

**Returns**

copy of string as char \*

---

## 4.19 File reader classes

The purpose of the file reader classes is to simplify the recurring task of reading and parsing files. They can use the [ValueTokenizer](#) class to process the read in text. The [TextFileReader](#) is a more general version while [PotentialFileReader](#) is specialized to implement the behavior expected for looking up and reading/parsing files with potential parameters in LAMMPS. The potential file reader class requires a LAMMPS instance, requires to be run on MPI rank 0 only, will use the [utils::get\\_potential\\_file\\_path](#) function to look up and open the file, and will call the `LAMMPS_NS::Error` class in case of failures to read or to convert numbers, so that LAMMPS will be aborted.

Listing 4: Use of PotentialFileReader class in pair style coul/streitz

```
PotentialFileReader reader(lmp, file, "coul/streitz");
char * line;

while((line = reader.next_line(NPARAMS_PER_LINE))) {
    try {
        ValueTokenizer values(line);
        std::string iname = values.next_string();

        int ielement;
        for (ielement = 0; ielement < nelements; ielement++)
            if (iname == elements[ielement]) break;

        if (nparams == maxparam) {
            maxparam += DELTA;
            params = (Param *) memory->srealloc(params,maxparam*sizeof(Param),
                                                "pair:params");
        }

        params[nparams].ielement = ielement;
        params[nparams].chi = values.next_double();
    }
```

(continues on next page)

(continued from previous page)

```

    params[nparams].eta = values.next_double();
    params[nparams].gamma = values.next_double();
    params[nparams].zeta = values.next_double();
    params[nparams].zcore = values.next_double();

    } catch (TokenizerException & e) {
        error->one(FLERR, e.what());
    }
    nparams++;
}

```

A file that would be parsed by the reader code fragment looks like this:

```

# DATE: 2015-02-19 UNITS: metal CONTRIBUTOR: Ray Shan CITATION: Streitz and Mintmire,
↪ Phys Rev B, 50, 11996-12003 (1994)
#

```

class **TextFileReader**

## Public Functions

**TextFileReader**(const std::string &filename, const std::string &filetype)

Class for reading and parsing text files

The value of the class member variable *ignore\_comments* controls whether any text following the pound sign (#) should be ignored (true) or not (false). Default: true, i.e. ignore.

*See also*

[\*TextFileReader\*](#)

### Parameters

- **filename** – Name of file to be read
- **filetype** – Description of file type for error messages

**TextFileReader**(FILE \*fp, std::string filetype)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

This function is useful in combination with [\*utils::open\\_potential\(\)\*](#).

---

**Note:** The FILE pointer is not closed in the destructor, but will be advanced when reading from it.

---

### Parameters

- **fp** – File descriptor of the already opened file
- **filetype** – Description of file type for error messages

virtual **~TextFileReader()**

Closes the file

void **set\_bufsize**(int)

adjust line buffer size

void **rewind**()

Reset file to the beginning

void **skip\_line**()

Read the next line and ignore it

char **\*next\_line**(int nparams = 0)

Read the next line(s) until *nparams* words have been read.

This reads a line and counts the words in it, if the number is less than the requested number, it will read the next line, as well. Output will be a string with all read lines combined. The purpose is to somewhat replicate the reading behavior of formatted files in Fortran.

If the *ignore\_comments* class member has the value *true*, then any text read in is truncated at the first '#' character.

#### Parameters

**nparams** – Number of words that must be read. Default: 0

#### Returns

String with the concatenated text

void **next\_dvector**(double \*list, int n)

Read lines until *n* doubles have been read and stored in array *list*

This reads lines from the file using the *next\_line()* function, and splits them into floating-point numbers using the ValueTokenizer class and stores the number in the provided list.

#### Parameters

- **list** – Pointer to array with suitable storage for *n* doubles
- **n** – Number of doubles to be read

*ValueTokenizer* **next\_values**(int nparams, const std::string &separators =  
TOKENIZER\_DEFAULT\_SEPARATORS)

Read text until *nparams* words are read and passed to a tokenizer object for custom parsing.

This reads lines from the file using the *next\_line()* function, and splits them into floating-point numbers using the ValueTokenizer class and stores the number in the provided list.

#### Parameters

- **nparams** – Number of words to be read
- **separators** – String with list of separators.

#### Returns

ValueTokenizer object for read in text

## Public Members

bool **ignore\_comments**

Controls whether comments are ignored.

class **PotentialFileReader** : protected *Pointers*

## Public Functions

**PotentialFileReader**(class *LAMMPS* \*lmp, const std::string &filename, const std::string &potential\_name, const std::string &name\_suffix, const int auto\_convert = 0)

Class for reading and parsing *LAMMPS* potential files

The value of the class member variable *ignore\_comments* controls whether any text following the pound sign (#) should be ignored (true) or not (false). Default: true, i.e. ignore.

*See also*

*TextFileReader*

### Parameters

- **lmp** – Pointer to *LAMMPS* instance
- **filename** – Name of file to be read
- **potential\_name** – Name of potential style for error messages
- **name\_suffix** – Suffix added to potential name in error messages
- **auto\_convert** – Bitmask of supported unit conversions

**~PotentialFileReader()** override

Closes the file

void **ignore\_comments**(bool value)

Set comment (= text after '#') handling preference for the file to be read

### Parameters

**value** – Comment text is ignored if true, or not if false

void **rewind()**

Reset file to the beginning

void **skip\_line()**

Read a line but ignore its content

char \***next\_line**(int nparams = 0)

Read the next line(s) until *nparams* words have been read.

This reads a line and counts the words in it, if the number is less than the requested number, it will read the next line, as well. Output will be a string with all read lines combined. The purpose is to somewhat replicate the reading behavior of formatted files in Fortran.

### Parameters

**nparams** – Number of words that must be read. Default: 0

### Returns

String with the concatenated text

void **next\_dvector**(double \*list, int n)

Read lines until  $n$  doubles have been read and stored in array *list*

This reads lines from the file using the `next_line()` function, and splits them into floating-point numbers using the `ValueTokenizer` class and stores the number in the provided list.

**Parameters**

- **list** – Pointer to array with suitable storage for  $n$  doubles
- **n** – Number of doubles to be read

*ValueTokenizer* **next\_values**(int nparams, const std::string &separators =  
TOKENIZER\_DEFAULT\_SEPARATORS)

Read text until *nparams* words are read and passed to a tokenizer object for custom parsing.

This reads lines from the file using the `next_line()` function, and splits them into floating-point numbers using the `ValueTokenizer` class and stores the number in the provided list.

**Parameters**

- **nparams** – Number of words to be read
- **separators** – String with list of separators.

**Returns**

`ValueTokenizer` object for read in text

double **next\_double**()

Read next line and convert first word to a double

**Returns**

Value of first word in line as double

int **next\_int**()

Read next line and convert first word to an int

**Returns**

Value of first word in line as int

tagint **next\_tagint**()

Read next line and convert first word to a tagint

**Returns**

Value of first word in line as tagint

bigint **next\_bigint**()

Read next line and convert first word to a bigint

**Returns**

Value of first word in line as bigint

std::string **next\_string**()

Read next line and return first word

**Returns**

First word of read in line

## 4.20 Memory pool classes

The memory pool classes are used for cases where otherwise many small memory allocations would be needed and where the data would be either all used or all freed. One example for that is the storage of neighbor lists. The memory management strategy is based on the assumption that allocations will be in chunks of similar sizes. The allocation is then not done per individual call for a reserved chunk of memory, but for a “page” that can hold multiple chunks of data. A parameter for the maximum chunk size must be provided, as that is used to determine whether a new page of memory must be used.

The `MyPage` class offers two ways to reserve a chunk: 1) with `MyPage::get()` the chunk size needs to be known in advance, 2) with `MyPage::vget()` a pointer to the next chunk is returned, but its size is registered later with `MyPage::vgot()`.

Listing 5: Example of using `MyPage`

```
#include "my_page.h"
using namespace LAMMPS_NS;

MyPage<double> *dpage = new MyPage<double>;
// max size of chunk: 256, size of page: 10240 doubles (=81920 bytes)
dpage->init(256,10240);

double **build_some_lists(int num)
{
    dpage->reset();
    double **dlist = new double*[num];
    for (int i=0; i < num; ++i) {
        double *dptr = dpage.vget();
        int jnum = 0;
        for (int j=0; j < jmax; ++j) {
            // compute some dvalue for eligible loop index j
            dptr[j] = dvalue;
            ++jnum;
        }
        if (dpage.status() != 0) {
            // handle out of memory or jnum too large errors
        }
        dpage.vgot(jnum);
        dlist[i] = dptr;
    }
    return dlist;
}
```

```
template<class T>
```

```
class MyPage
```

Templated class for storing chunks of datums in pages.

The size of the chunk may vary from call to call, but must be less or equal than the `maxchunk` setting. The chunks are not returnable like with `malloc()` (i.e. you cannot call `free()` on them individually). One can only reset and start over. The purpose of this class is to replace many small memory allocations via `malloc()` with a few large ones. Since the pages are never freed until the class is re-initialized, they can be re-used without having to re-allocate them by calling the `reset()` method.

The settings *maxchunk*, *pagesize*, and *pagedelta* control the memory allocation strategy. The *maxchunk* value represents the expected largest number of items per chunk. If there is less space left on the current page, a new page is allocated for the next chunk. The *pagesize* value represents how many items can fit on a single page. It should have space for multiple chunks of size *maxchunk*. The combination of these two parameters determines how much memory is wasted by either switching to the next page too soon or allocating too large pages that never get properly used. An error is issued if a requested chunk is larger than *maxchunk*. The *pagedelta* parameter determines how many pages are allocated in one go. In combination with the *pagesize* setting, this determines how often blocks of memory get allocated (fewer allocations will result in faster execution).

---

**Note:** This is a template class with explicit instantiation. If the class is used with a new data type, a new explicit instantiation may need to be added at the end of the file `src/my_page.cpp` to avoid symbol lookup errors.

---

## Public Functions

### MyPage()

Create a class instance

Need to call *init()* before use to define allocation settings

int **init**(int user\_maxchunk = 1, int user\_pagesize = 1024, int user\_pagedelta = 1)

(Re-)initialize the set of pages and allocation parameters.

This also frees all previously allocated storage and allocates the first page(s).

#### Parameters

- **user\_maxchunk** – Expected maximum number of items for one chunk
- **user\_pagesize** – Number of items on a single memory page
- **user\_pagedelta** – Number of pages to allocate with one malloc

#### Returns

1 if there were invalid parameters, 2 if there was an allocation error or 0 if successful

*T* \***get**(int n = 1)

Pointer to location that can store N items.

This will allocate more pages as needed. If the parameter *N* is larger than the *maxchunk* setting, an error is flagged.

#### Parameters

**n** – number of items for which storage is requested

#### Returns

memory location or null pointer, if error or allocation failed

inline *T* \***vget**()

Get pointer to location that can store *maxchunk* items.

This will return the same pointer as the previous call to this function unless *vgot()* is called afterwards to record how many items of the chunk were actually used.

#### Returns

pointer to chunk of memory or null pointer if run out of memory

inline void **vgot**(int n)

Mark  $N$  items as used of the chunk reserved with a preceding call to *vget()*.

This will advance the internal pointer inside the current memory page. It is not necessary to call this function for  $N = 0$ , implying the reserved storage was not used. A following call to *vget()* will then reserve the same location again. It is an error if  $N > \text{maxchunk}$ .

**Parameters**

**n** – Number of items used in previously reserved chunk

void **reset**()

Reset state of memory pool without freeing any memory

inline double **size**() const

Return total size of allocated pages

**Returns**

total storage used in bytes

inline int **status**() const

Return error status

**Returns**

0 if no error, 1 requested chunk size > maxchunk, 2 if malloc failed

template<class T>

class **MyPoolChunk**

Templated class for storing chunks of datums in pages.

The size of the chunk may vary from call to call between the *minchunk* and *maxchunk* setting. Chunks may be returned to the pool for re-use. Chunks can be reserved in *nbin* different sizes between *minchunk* and *maxchunk*. The *chunksperpage* setting specifies how many chunks are stored on any page and the *pagedelta* setting determines how many pages are allocated in one go. Pages are never freed, so they can be re-used without re-allocation.

---

**Note:** This is a template class with explicit instantiation. If the class is used with a new data type, a new explicit instantiation may need to be added at the end of the file `src/my_pool_chunk.cpp` to avoid symbol lookup errors.

---

## Public Functions

**MyPoolChunk**(int user\_minchunk = 1, int user\_maxchunk = 1, int user\_nbin = 1, int user\_chunkperpage = 1024, int user\_pagedelta = 1)

Create a class instance and set memory pool parameters

**Parameters**

- **user\_minchunk** – Minimal chunk size
- **user\_maxchunk** – Maximal chunk size
- **user\_nbin** – Number of bins of different chunk sizes
- **user\_chunkperpage** – Number of chunks per page
- **user\_pagedelta** – Number of pages to allocate in one go

**~MyPoolChunk()**

Destroy class instance and free all allocated memory

**T \*get(int &index)**

Return pointer/index of unused chunk of size maxchunk

**Parameters**

**index** – Index of chunk in memory pool

**Returns**

Pointer to requested chunk of storage

**T \*get(int n, int &index)**

Return pointer/index of unused chunk of size N

**Parameters**

- **n** – Size of chunk
- **index** – Index of chunk in memory pool

**Returns**

Pointer to requested chunk of storage

**void put(int index)**

Put indexed chunk back into memory pool via free list

**Parameters**

**index** – Memory chunk index returned by call to *get()*

**double size() const**

Return total size of allocated pages

**Returns**

total storage used in bytes

**inline int status() const**

Return error status

**Returns**

0 if no error, 1 if invalid input, 2 if malloc() failed, 3 if chunk > maxchunk

---

## 4.21 Eigensolver functions

The `MathEigen` sub-namespace of the `LAMMPS_NS` namespace contains functions and classes for eigensolvers. Currently only the *[jacobi3 function](#)* is used in various places in LAMMPS. That function is built on top of a group of more generic eigensolvers that are maintained in the `math_eigen_impl.h` header file. This header contains the implementation of three template classes:

1. “Jacobi” calculates all of the eigenvalues and eigenvectors of a dense, symmetric, real matrix.
2. The “PEigenDense” class only calculates the principal eigenvalue (i.e. the largest or smallest eigenvalue), and its corresponding eigenvector. However it is much more efficient than “Jacobi” when applied to large matrices (larger than 13x13). PEigenDense also can understand complex-valued Hermitian matrices.
3. The “LambdaLanczos” class is a generalization of “PEigenDense” which can be applied to arbitrary sparse matrices.

The “`math_eigen_impl.h`” code is an amalgamation of `jacobi_pd` by Andrew Jewett at Scripps Research (under CC0-1.0 license) and `Lambda Lanczos` by Yuya Kurebayashi at Tohoku University (under MIT license)

---

`int MathEigen::jacobi3(double const *const *mat, double *eval, double **evec, int sort = -1)`

A specialized function which finds the eigenvalues and eigenvectors of a 3x3 matrix (in double \*\* format).

#### Parameters

- **mat** – the 3x3 matrix you wish to diagonalize
- **eval** – store the eigenvalues here
- **evec** – store the eigenvectors here...
- **sort** – order eigenvalues and -vectors (-1 decreasing (default), 1 increasing, 0 unsorted)

#### Returns

0 if eigenvalue calculation converged, 1 if it failed

`int MathEigen::jacobi3(double const mat[3][3], double *eval, double evec[3][3], int sort = -1)`

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

---

## 4.22 Communication buffer coding with *ubuf*

LAMMPS uses communication buffers where it collects data from various class instances and then exchanges the data with neighboring subdomains. For simplicity those buffers are defined as `double` buffers and used for doubles and integer numbers. This presents a unique problem when 64-bit integers are used. While the storage needed for a `double` is also 64-bit, it cannot be used by a simple assignment. To get around that limitation, LAMMPS uses the *ubuf* union. It is used in the various “pack” and “unpack” functions in the LAMMPS classes to store and retrieve integers that may be 64-bit from the communication buffers.

---

### union *ubuf*

`#include <lmptype.h>` Data structure for packing 32-bit and 64-bit integers into double (communication) buffers

Using this union avoids aliasing issues by having member types (`double`, `int`) referencing the same buffer memory location.

The explicit constructor for 32-bit integers prevents compilers from (incorrectly) calling the double constructor when storing an `int` into a double buffer.

#### Usage:

Listing 6: To copy an integer into a double buffer:

```
double buf[2];
int    foo = 1;
tagint bar = 2<<40;
buf[1] = ubuf(foo).d;
buf[2] = ubuf(bar).d;
```

Listing 7: To copy from a double buffer back to an int:

```
foo = (int)    ubuf(buf[1]).i;  
bar = (tagint) ubuf(buf[2]).i;
```

The typecasts prevent compiler warnings about possible truncation issues.

## Public Functions

```
inline ubuf(const double &arg)
```

```
inline ubuf(const int64_t &arg)
```

```
inline ubuf(const int &arg)
```

## Public Members

```
double d
```

```
int64_t i
```

## 4.23 Use of distributed grids within style classes

New in version 22Dec2022.

The LAMMPS source code includes two classes which facilitate the creation and use of distributed grids. These are the Grid2d and Grid3d classes in the `src/grid2d.cpp.h` and `src/grid3d.cpp.h` files respectively. As the names imply, they are used for 2d or 3d simulations, as defined by the *dimension* command.

The *Howto\_grid* page gives an overview of how distributed grids are defined from a user perspective, lists LAMMPS commands which use them, and explains how grid cell data is referenced from an input script. Please read that page first as it motivates the coding details discussed here.

This doc page is for users who wish to write new styles (input script commands) which use distributed grids. There are a variety of material models and analysis methods which use atoms (or coarse-grained particles) and grids in tandem.

A *distributed* grid means each processor owns a subset of the grid cells. In LAMMPS, the subset for each processor will be a sub-block of grid cells with low and high index bounds in each dimension of the grid. The union of the sub-blocks across all processors is the global grid.

More specifically, a grid point is defined for each cell (by default the center point), and a processor owns a grid cell if its point is within the processor's spatial subdomain. The union of processor subdomains is the global simulation box. If a grid point is on the boundary of two subdomains, the lower processor owns the grid cell. A processor may also store copies of ghost cells which surround its owned cells.

### 4.23.1 Style commands

Style commands which can define and use distributed grids include the *compute*, *fix*, *pair*, and *kpace* styles. If you wish grid cell data to persist across timesteps, then use a *fix*. If you wish grid cell data to be accessible by other commands, then use a *fix* or *compute*. Currently in LAMMPS, the *pair\_style amoeba*, *kpace\_style ppm*, and *kpace\_style msm* commands use distributed grids but do not require either of these capabilities; they thus create and use distributed grids internally. Note that a *pair* style which needs grid cell data to persist could be coded to work in tandem with a *fix* style which provides that capability.

The *size* of a grid is specified by the number of grid cells in each dimension of the simulation domain. In any dimension the size can be any value  $\geq 1$ . Thus a 10x10x1 grid for a 3d simulation is effectively a 2d grid, where each grid cell spans the entire z-dimension. A 1x100x1 grid for a 3d simulation is effectively a 1d grid, where grid cells are a series of thin xz slabs in the y-dimension. It is even possible to define a 1x1x1 3d grid, though it may be inefficient to use it in a computational sense.

Note that the choice of grid size is independent of the number of processors or their layout in a grid of processor subdomains which overlays the simulations domain. Depending on the distributed grid size, a single processor may own many 1000s or no grid cells.

A command can define multiple grids, each of a different size. Each grid is an instantiation of the Grid2d or Grid3d class.

The command also defines what data it will store for each grid it creates and it allocates the multidimensional array(s) needed to store the data. No grid cell data is stored within the Grid2d or Grid3d classes.

If a single value per grid cell is needed, the data array will have the same dimension as the grid, i.e. a 2d array for a 2d grid, likewise for 3d. If multiple values per grid cell are needed, the data array will have one more dimension than the grid, i.e. a 3d array for a 2d grid, or 4d array for a 3d grid. A command can choose to define multiple data arrays for each grid it defines.

### 4.23.2 Grid data allocation and access

The simplest way for a command to allocate and access grid cell data is to use the *create\_offset()* methods provided by the Memory class. Arguments for these methods can be values returned by the *setup\_grid()* method (described below), which define the extent of the grid cells (owned+ghost) the processor owns. These 4 methods allocate memory for 2d (first two) and 3d (second two) grid data. The two methods that end in “\_offset” allocate an array which stores a single value per grid cell. The two that end in “\_last” allocate an array which stores *Nvalues* per grid cell.

```
// single value per cell for a 2d grid = 2d array
memory->create2d_offset(data2d_one, nylo_out, nyhi_out,
                        nxlo_out, nxhi_out, "data2d_one");

// nvalues per cell for a 2d grid = 3d array
memory->create3d_offset_last(data2d_multi, nylo_out, nyhi_out,
                            nxlo_out, nxhi_out, nvalues, "data2d_multi");

// single value per cell for a 3d grid = 3d array
memory->create3d_offset(data3d_one, nzlo_out, nzhi_out, nylo_out,
                        nyhi_out, nxlo_out, nxhi_out, "data3d_one");

// nvalues per cell for a 3d grid = 4d array
memory->create4d_offset_last(data3d_multi, nzlo_out, nzhi_out, nylo_out,
                            nyhi_out, nxlo_out, nxhi_out, nvalues,
                            "data3d_multi");
```

Note that these multidimensional arrays are allocated as contiguous chunks of memory where the x-index of the grid varies fastest, then y, and the z-index slowest. For multiple values per grid cell, the Nvalues are contiguous, so their index varies even faster than the x-index.

The key point is that the “offset” methods create arrays which are indexed by the range of indices which are the bounds of the sub-block of the global grid owned by this processor. This means loops like these can be written in the caller code to loop over owned grid cells, where the “i” loop bounds are the range of owned grid cells for the processor. These are the bounds returned by the `setup_grid()` method:

```
for (int iy = iylo; iy <= iyhi; iy++)
  for (int ix = ixlo; ix <= ixhi; ix++)
    data2d_one[iy][ix] = 0.0;

for (int iy = iylo; iy <= iyhi; iy++)
  for (int ix = ixlo; ix <= ixhi; ix++)
    for (int m = 0; m < nvalues; m++)
      data2d_multi[iy][ix][m] = 0.0;

for (int iz = izlo; iz <= izhi; iz++)
  for (int iy = iylo; iy <= iyhi; iy++)
    for (int ix = ixlo; ix <= ixhi; ix++)
      data3d_one[iz][iy][ix] = 0.0;

for (int iz = izlo; iz <= izhi; iz++)
  for (int iy = iylo; iy <= iyhi; iy++)
    for (int ix = ixlo; ix <= ixhi; ix++)
      for (int m = 0; m < nvalues; m++)
        data3d_multi[iz][iy][ix][m] = 0.0;
```

Simply replacing the “i” bounds with “o” bounds, also returned by the `setup_grid()` method, would alter this code to loop over owned+ghost cells (the entire allocated grid).

---

### 4.23.3 Grid class constructors

The following subsections describe the public methods of the Grid3d class which a style command can invoke. The Grid2d methods are similar; simply remove arguments which refer to the z-dimension.

There are 2 constructors which can be used. They differ in the extra i/o xyz lo/hi arguments:

```
Grid3d(class LAMMPS *lmp, MPI_Comm gcomm, int gn timer, int gny, int gn timer)
Grid3d(class LAMMPS *lmp, MPI_Comm gcomm, int gn timer, int gny, int gn timer,
      int ixlo, int ixhi, int iylo, int iyhi, int izlo, int izhi,
      int oxlo, int oxhi, int oylo, int oyhi, int ozlo, int ozhi)
```

Both constructors take the LAMMPS instance pointer and a communicator over which the grid will be distributed. Typically this is the *world* communicator the LAMMPS instance is using. The *kspace\_style msm* command creates a series of grids, each of different size, which are partitioned across different sub-communicators of processors. Both constructors are also passed the global grid size: *gnx* by *gny* by *gnz*.

The first constructor is used when the caller wants the Grid class to partition the global grid across processors; the Grid class defines which grid cells each processor owns and also which it stores as ghost cells. A subsequent call to `setup_grid()`, discussed below, returns this info to the caller.

The second constructor allows the caller to define the extent of owned and ghost cells, and pass them to the Grid class. The 6 arguments which start with “i” are the inclusive lower and upper index bounds of the owned (inner) grid cells this processor owns in each of the 3 dimensions within the global grid. Owned grid cells are indexed from 0 to N-1 in each dimension.

The 6 arguments which start with “o” are the inclusive bounds of the owned+ghost (outer) grid cells it stores. If the ghost cells are on the other side of a periodic boundary, then these indices may be  $< 0$  or  $\geq N$  in any dimension, so that  $oxlo \leq ixlo$  and  $ixhi \geq oxhi$  is always the case.

For example, if  $N_x = 100$ , then a processor might pass  $ixlo=50$ ,  $ixhi=60$ ,  $oxlo=48$ ,  $oxhi=62$  to the Grid class. Or  $ixlo=0$ ,  $ixhi=10$ ,  $oxlo=-2$ ,  $oxhi=13$ . If a processor owns no grid cells in a dimension, then the  $ixhi$  value should be specified as one less than the  $ixlo$  value.

Note that the only reason to use the second constructor is if the logic for assigning ghost cells is too complex for the Grid class to compute, using the various `set()` methods described next. Currently only the `kpace_style ppm/electrode` and `kpace_style msm` commands use the second constructor.

#### 4.23.4 Grid class set methods

The following methods affect how the Grid class computes which owned and ghost cells are assigned to each processor. `Set_shift_grid()` is the only method which influences owned cell assignment; all the rest influence ghost cell assignment. These methods are only used with the first constructor; they are ignored if the second constructor is used. These methods must be called before the `setup_grid()` method is invoked, because they influence its operation.

```
void set_shift_grid(double shift);
void set_distance(double distance);
void set_stencil_atom(int lo, int hi);
void set_shift_atom(double shift_lo, double shift_hi);
void set_stencil_grid(int lo, int hi);
void set_zfactor(double factor);
```

Processors own a grid cell if a point within the grid cell is inside the processor’s subdomain. By default this is the center point of the grid cell. The `set_shift_grid()` method can change this. The *shift* argument is a value from 0.0 to 1.0 (inclusive) which is the offset of the point within the grid cell in each dimension. The default is 0.5 for the center of the cell. A value of 0.0 is the lower left corner point; a value of 1.0 is the upper right corner point. There is typically no need to change the default as it is optimal for minimizing the number of ghost cells needed.

If a processor maps its particles to grid cells, it needs to allow for its particles being outside its subdomain between reneighboring. The *distance* argument of the `set_distance()` method sets the furthest distance outside a processor’s subdomain which a particle can move. Typically this is half the neighbor skin distance, assuming reneighboring is done appropriately. This distance is used in determining how many ghost cells a processor needs to store to enable its particles to be mapped to grid cells. The default value is 0.0.

Some commands, like the `kpace_style ppm` command, map values (charge in the case of PPPM) to a stencil of grid cells beyond the grid cell the particle is in. The stencil extent may be different in the low and high directions. The `set_stencil_atom()` method defines the maximum values of those 2 extents, assumed to be the same in each of the 3 dimensions. Both the *lo* and *hi* values are specified as positive integers. The default values are both 0.

Some commands, like the `kpace_style ppm` command, shift the position of an atom when mapping it to a grid cell, based on the size of the stencil used to map values to the grid (charge in the case of PPPM). The *lo* and *hi* arguments of the `set_shift_atom()` method are the minimum shift in the low direction and the maximum shift in the high direction, assumed to be the same in each of the 3 dimensions. The shifts should be fractions of a grid cell size with values between 0.0 and 1.0 inclusive. The default values are both 0.0. See the `src/ppm.cpp` file for examples of these *lo/hi* values for regular and staggered grids.

Some methods like the *fix ttm/grid* command, perform finite difference kinds of operations on the grid, to diffuse electron heat in the case of the two-temperature model (TTM). This operation uses ghost grid values beyond the owned grid values the processor updates. The *set\_stencil\_grid()* method defines the extent of this stencil in both directions, assumed to be the same in each of the 3 dimensions. Both the lo and hi values are specified as positive integers. The default values are both 0.

The *kspace\_style* *pppm* commands allow a grid to be defined which overlays a volume which extends beyond the simulation box in the z dimension. This is for the purpose of modeling a 2d-periodic slab (non-periodic in z) as if it were a larger 3d periodic system, extended (with empty space) in the z dimension. The *kspace\_modify slab* command is used to specify the ratio of the larger volume to the simulation volume; a volume ratio of ~3 is typical. For this kind of model, the PPPM caller sets the global grid size *gnz* ~3x larger than it would be otherwise. This same ratio is passed by the PPPM caller as the *factor* argument to the Grid class via the *set\_zfactor()* method (*set\_yfactor()* for 2d grids). The Grid class will then assign ownership of the 1/3 of grid cells that overlay the simulation box to the processors which also overlay the simulation box. The remaining 2/3 of the grid cells are assigned to processors whose subdomains are adjacent to the upper z boundary of the simulation box.

---

#### 4.23.5 Grid class *setup\_grid* method

The *setup\_grid()* method is called after the first constructor (above) to partition the grid across processors, which determines which grid cells each processor owns. It also calculates how many ghost grid cells in each dimension and each direction each processor needs to store.

Note that this method is NOT called if the second constructor above is used. In that case, the caller assigns owned and ghost cells to each processor.

Also note that this method must be invoked after any *set\_\**() methods have been used, since they can influence the assignment of owned and ghost cells.

```
void setup_grid(int &ixlo, int &ixhi, int &iylo, int &iyhi, int &izlo, int &izhi,  
               int &oxlo, int &oxhi, int &oylo, int &oyhi, int &ozlo, int &ozhi)
```

The 6 return arguments which start with “i” are the inclusive lower and upper index bounds of the owned (inner) grid cells this processor owns in each of the 3 dimensions within the global grid. Owned grid cells are indexed from 0 to N-1 in each dimension.

The 6 return arguments which start with “o” are the inclusive bounds of the owned+ghost cells it owns. If the ghost cells are on the other side of a periodic boundary, then these indices may be < 0 or >= N in any dimension, so that *oxlo* <= *ixlo* and *ixhi* >= *ixhi* is always the case.

---

#### 4.23.6 More grid class set methods

The following 2 methods can be used to override settings made by the constructors above. If used, they must be called before the *setup\_comm()* method is invoked, since it uses the settings that these methods override. In LAMMPS these methods are called by the *kspace\_style msm* command for the grids it instantiates using the 2nd constructor above.

```
void set_proc_neighs(int pxlo, int pxhi, int pylo, int pyhi, int pzlo, int pzhi)  
void set_caller_grid(int fxlo, int fxhi, int fylo, int fyhi, int fzlo, int fzhi)
```

The `set_proc_neighs()` method sets the processor IDs of the 6 neighboring processors for each processor. Normally these would match the processor grid neighbors which LAMMPS creates to overlay the simulation box (the default). However, MSM excludes non-participating processors from coarse grid communication when less processors are used. This method allows MSM to override the default values.

The `set_caller_grid()` method species the size of the data arrays the caller allocates. Normally these would match the extent of the ghost grid cells (the default). However the MSM caller allocates a larger data array (more ghost cells) for its finest-level grid, for use in other operations besides owned/ghost cell communication. This method allows MSM to override the default values.

### 4.23.7 Grid class get methods

The following methods allow the caller to query the settings for a specific grid, whether it created the grid or another command created it.

```
void get_size(int &nxgrid, int &nygrid, int &nzgrid);
void get_bounds_owned(int &xlo, int &xhi, int &ylo, int &yhi, int &zlo, int &zhi)
void get_bounds_ghost(int &xlo, int &xhi, int &ylo, int &yhi, int &zlo, int &zhi)
```

The `get_size()` method returns the size of the global grid in each dimension.

The `get_bounds_owned()` method return the inclusive index bounds of the grid cells this processor owns. The values range from 0 to N-1 in each dimension. These values are the same as the “i” values returned by `setup_grid()`.

The `get_bounds_ghost()` method return the inclusive index bounds of the owned+ghost grid cells this processor stores. The owned cell indices range from 0 to N-1, so these indices may be less than 0 or greater than or equal to N in each dimension. These values are the same as the “o” values returned by `setup_grid()`.

### 4.23.8 Grid class owned/ghost communication

If needed by the command, the following methods setup and perform communication of grid data to/from neighboring processors. The `forward_comm()` method sends owned grid cell data to the corresponding ghost grid cells on other processors. The `reverse_comm()` method sends ghost grid cell data to the corresponding owned grid cells on another processor. The caller can choose to sum ghost grid cell data to the owned grid cell or simply copy it.

```
void setup_comm(int &nbuf1, int &nbuf2)
void forward_comm(int caller, void *ptr, int which, int nper, int nbyte,
                  void *buf1, void *buf2, MPI_Datatype datatype);
void reverse_comm(int caller, void *ptr, int which, int nper, int nbyte,
                  void *buf1, void *buf2, MPI_Datatype datatype)
int ghost_adjacent();
```

The `setup_comm()` method must be called one time before performing *forward* or *reverse* communication (multiple times if needed). It returns two integers, which should be used to allocate two buffers. The `nbuf1` and `nbuf2` values are the number of grid cells whose data will be stored in two buffers by the Grid class when *forward* or *reverse* communication is performed. The caller should thus allocate them to a size large enough to hold all the data used in any single forward or reverse communication operation it performs. Note that the caller may allocate and communicate multiple data arrays for a grid it instantiates. This size includes the bytes needed for the data type of the grid data it stores, e.g. double precision values.

The `forward_comm()` and `reverse_comm()` methods send grid cell data from owned to ghost cells, or ghost to owned cells, respectively, as described above. The `caller` argument should be one of these values – Grid3d::COMPUTE,

Grid3d::FIX, Grid3d::KSPACE, Grid3d::PAIR – depending on the style of the caller class. The *ptr* argument is the “this” pointer to the caller class. These two arguments are used to call back to pack()/unpack() functions in the caller class, as explained below.

The *which* argument is a flag the caller can set which is passed to the caller’s pack()/unpack() methods. This allows a single callback method to pack/unpack data for several different flavors of forward/reverse communication, e.g. operating on different grids or grid data.

The *nper* argument is the number of values per grid cell to be communicated. The *nbyte* argument is the number of bytes per value, e.g. 8 for double-precision values. The *buf1* and *buf2* arguments are the two allocated buffers described above. So long as they are allocated for the maximum size communication, they can be re-used for any *forward\_comm()/reverse\_comm()* call. The *datatype* argument is the MPI\_Datatype setting, which should match the buffer allocation and the *nbyte* argument. E.g. MPI\_DOUBLE for buffers storing double precision values.

To use the *forward\_grid()* method, the caller must provide two callback functions; likewise for use of the *reverse\_grid()* methods. These are the 4 functions, their arguments are all the same.

```
void pack_forward_grid(int which, void *vbuf, int nlist, int *list);
void unpack_forward_grid(int which, void *vbuf, int nlist, int *list);
void pack_reverse_grid(int which, void *vbuf, int nlist, int *list);
void unpack_reverse_grid(int which, void *vbuf, int nlist, int *list);
```

The *which* argument is set to the *which* value of the *forward\_comm()* or *reverse\_comm()* calls. It allows the pack/unpack function to select what data values to pack/unpack. *Vbuf* is the buffer to pack/unpack the data to/from. It is a void pointer so that the caller can cast it to whatever data type it chooses, e.g. double precision values. *Nlist* is the number of grid cells to pack/unpack and *list* is a vector (*nlist* in length) of offsets to where the data for each grid cell resides in the caller’s data arrays, which is best illustrated with an example from the src/EXTRA-FIX/fix\_ttm\_grid.cpp class which stores the scalar electron temperature for 3d system in a 3d grid (one value per grid cell):

```
void FixTTMGrid::pack_forward_grid(int /*which*/, void *vbuf, int nlist, int *list)
{
    auto buf = (double *) vbuf;
    double *src = &T_electron[nzlo_out][nylo_out][nxlo_out];
    for (int i = 0; i < nlist; i++) buf[i] = src[list[i]];
}
```

In this case, the *which* argument is not used, *vbuf* points to a buffer of doubles, and the electron temperature is stored by the FixTTMGrid class in a 3d array of owned+ghost cells called T\_electron. That array is allocated by the *memory->create\_3d\_offset()* method described above so that the first grid cell it stores is indexed as T\_electron[nzlo\_out][nylo\_out][nxlo\_out]. The *nlist* values in *list* are integer offsets from that first grid cell. Setting *src* to the address of the first cell allows those offsets to be used to access the temperatures to pack into the buffer.

Here is a similar portion of code from the src/fix\_ave\_grid.cpp class which can store two kinds of data, a scalar count of atoms in a grid cell, and one or more grid-cell-averaged atom properties. The code from its *unpack\_reverse\_grid()* function for 2d grids and multiple per-atom properties per grid cell (*nvalues*) is shown here:

```
void FixAveGrid::unpack_reverse_grid(int /*which*/, void *vbuf, int nlist, int *list)
{
    auto buf = (double *) vbuf;
    double *count,*data,*values;
    count = &count2d[nylo_out][nxlo_out];
    data = &array2d[nylo_out][nxlo_out][0];
    m = 0;
    for (i = 0; i < nlist; i++) {
        count[list[i]] += buf[m++];
        values = &data[nvalues*list[i]];
    }
}
```

(continues on next page)

(continued from previous page)

```

    for (j = 0; j < nvalues; j++)
        values[j] += buf[m++];
    }
}

```

Both the count and the multiple values per grid cell are communicated in *vbuf*. Note that *data* is now a pointer to the first value in the first grid cell. And *values* points to where the first value in *data* is for an offset of grid cells, calculated by multiplying *nvalues* by *list[i]*. Finally, because this is reverse communication, the communicated buffer values are summed to the caller values.

The *ghost\_adjacent()* method returns a 1 if every processor can perform the necessary owned/ghost communication with only its nearest neighbor processors (4 in 2d, 6 in 3d). It returns a 0 if any processor's ghost cells extend further than nearest neighbor processors.

This can be checked by callers who have the option to change the global grid size to ensure more efficient nearest-neighbor-only communication if they wish. In this case, they instantiate a grid of a given size (resolution), then invoke *setup\_comm()* followed by *ghost\_adjacent()*. If the ghost cells are not adjacent, they destroy the grid instance and start over with a higher-resolution grid. Several of the *kpace\_style ppm* command variants have this option.

#### 4.23.9 Grid class remap methods for load balancing

The following methods are used when a load-balancing operation, triggered by the *balance* or *fix balance* commands, changes the partitioning of the simulation domain into processor subdomains.

In order to work with load-balancing, any style command (compute, fix, pair, or kspace style) which allocates a grid and stores per-grid data should define a *reset\_grid()* method; it takes no arguments. It will be called by the two balance commands after they have reset processor subdomains and migrated atoms (particles) to new owning processors. The *reset\_grid()* method will typically perform some or all of the following operations. See the *src/fix\_ave\_grid.cpp* and *src/EXTRA\_FIX/fix\_ttm\_grid.cpp* files for examples of *reset\_grid()* methods, as well as the *pack\_remap\_grid()* and *unpack\_remap\_grid()* functions.

First, the *reset\_grid()* method can instantiate new grid(s) of the same global size, then call *setup\_grid()* to partition them via the new processor subdomains. At this point, it can invoke the *identical()* method which compares the owned and ghost grid cell index bounds between two grids, the old grid passed as a pointer argument, and the new grid whose *identical()* method is being called. It returns 1 if the indices match on all processors, otherwise 0. If they all match, then the new grids can be deleted; the command can continue to use the old grids.

If not, then the command should allocate new grid data array(s) which depend on the new partitioning. If the command does not need to persist its grid data from the old partitioning to the new one, then the command can simply delete the old data array(s) and grid instance(s). It can then return.

If the grid data does need to persist, then the data for each grid needs to be “remapped” from the old grid partitioning to the new grid partitioning. The *setup\_remap()* and *remap()* methods are used for that purpose.

```

int identical(Grid3d *old);
void setup_remap(Grid3d *old, int &nremap_buf1, int &nremap_buf2)
void remap(int caller, void *ptr, int which, int nper, int nbyte,
           void *buf1, void *buf2, MPI_Datatype datatype)

```

The arguments to these methods are identical to those for the *setup\_comm()* and *forward\_comm()* or *reverse\_comm()* methods. However the returned *nremap\_buf1* and *nremap2\_buf* values will be different than the *nbuf1* and *nbuf2* values. They should be used to allocate two different remap buffers, separate from the owned/ghost communication buffers.

To use the *remap()* method, the caller must provide two callback functions:

```
void pack_remap_grid(int which, void *vbuf, int nlist, int *list);  
void unpack_remap_grid(int which, void *vbuf, int list, int *list);
```

Their arguments are identical to those for the *pack\_forward\_grid()* and *unpack\_forward\_grid()* callback functions (or the reverse variants) discussed above. Normally, both these methods pack/unpack all the data arrays for a given grid. The *which* argument of the *remap()* method sets the *which* value for the pack/unpack functions. If the command instantiates multiple grids (of different sizes), it can be used within the pack/unpack methods to select which grid's data is being remapped.

Note that the *pack\_remap\_grid()* function must copy values from the OLD grid data arrays into the *vbuf* buffer. The *unpack\_remap\_grid()* function must copy values from the *vbuf* buffer into the NEW grid data arrays.

After the remap operation for grid cell data has been performed, the *reset\_grid()* method can deallocate the two remap buffers it created, and can then exit.

---

#### 4.23.10 Grid class I/O methods

There are two I/O methods in the Grid classes which can be used to read and write grid cell data to files. The caller can decide on the precise format of each file, e.g. whether header lines are prepended or comment lines are allowed. Fundamentally, the file should contain one line per grid cell for the entire global grid. Each line should contain identifying info as to which grid cell it is, e.g. a unique grid cell ID or the ix,iy,iz indices of the cell within a 3d grid. The line should also contain one or more data values which are stored within the grid data arrays created by the command

For grid cell IDs, the LAMMPS convention is that the IDs run from 1 to N, where  $N = N_x * N_y$  for 2d grids and  $N = N_x * N_y * N_z$  for 3d grids. The x-index of the grid cell varies fastest, then y, and the z-index varies slowest. So for a 10x10x10 grid the cell IDs from 901-1000 would be in the top xy layer of the z dimension.

The *read\_file()* method does something simple. It reads a chunk of consecutive lines from the file and passes them back to the caller to process. The caller provides a *unpack\_read\_grid()* function for this purpose. The function checks the grid cell ID or indices and only stores grid cell data for the grid cells it owns.

The *write\_file()* method does something slightly more complex. Each processor packs the data for its owned grid cells into a buffer. The caller provides a *pack\_write\_grid()* function for this purpose. The *write\_file()* method then loops over all processors and each sends its buffer one at a time to processor 0, along with the 3d (or 2d) index bounds of its grid cell data within the global grid. Processor 0 calls back to the *unpack\_write\_grid()* function provided by the caller with the buffer. The function writes one line per grid cell to the file.

See the `src/EXTRA_FIX/fix_ttm_grid.cpp` file for examples of how both these methods are used to read/write electron temperature values from/to a file, as well as for implementations of the the pack/unpack functions described below.

Here are the details of the two I/O methods and the 3 callback functions. See the `src/fix_ave_grid.cpp` file for examples of all of them.

```
void read_file(int caller, void *ptr, FILE *fp, int nchunk, int maxline)  
void write_file(int caller, void *ptr, int which,  
               int nper, int nbyte, MPI_Datatype datatype)
```

The *caller* argument in both methods should be one of these values – `Grid3d::COMPUTE`, `Grid3d::FIX`, `Grid3d::KSPACE`, `Grid3d::PAIR` – depending on the style of the caller class. The *ptr* argument in both methods is the “this” pointer to the caller class. These 2 arguments are used to call back to pack()/unpack() functions in the caller class, as explained below.

For the `read_file()` method, the `fp` argument is a file pointer to the file to be read from, opened on processor 0 by the caller. `Nchunk` is the number of lines to read per chunk, and `maxline` is the maximum number of characters per line. The Grid class will allocate a buffer for storing chunks of lines based on these values.

For the `write_file()` method, the `which` argument is a flag the caller can set which is passed back to the caller's `pack()/unpack()` methods. If the command instantiates multiple grids (of different sizes), this flag can be used within the `pack/unpack` methods to select which grid's data is being written out (presumably to different files). the `nper` argument is the number of values per grid cell to be written out. The `nbyte` argument is the number of bytes per value, e.g. 8 for double-precision values. The `datatype` argument is the `MPI_Datatype` setting, which should match the `nbyte` argument. E.g. `MPI_DOUBLE` for double precision values.

To use the `read_grid()` method, the caller must provide one callback function. To use the `write_grid()` method, it provides two callback functions:

```
int unpack_read_grid(int nlines, char *buffer)
void pack_write_grid(int which, void *vbuf)
void unpack_write_grid(int which, void *vbuf, int *bounds)
```

For `unpack_read_grid()` the `nlines` argument is the number of lines of character data read from the file and contained in `buffer`. The lines each include a newline character at the end. When the function processes the lines, it may choose to skip some of them (header or comment lines). It returns an integer count of the number of grid cell lines it processed. This enables the Grid class `read_file()` method to know when it has read the correct number of lines.

For `pack_write_grid()` and `unpack_write_grid()`, the `vbuf` argument is the buffer to pack/unpack data to/from. It is a void pointer so that the caller can cast it to whatever data type it chooses, e.g. double precision values. the `which` argument is set to the `which` value of the `write_file()` method. It allows the caller to choose which grid data to operate on.

For `unpack_write_grid()`, the `bounds` argument is a vector of 4 or 6 integer grid indices (4 for 2d, 6 for 3d). They are the `xlo,xhi,ylo,yhi,zlo,zhi` index bounds of the portion of the global grid which the `vbuf` holds owned grid cell data values for. The caller should loop over the values in `vbuf` with a double loop (2d) or triple loop (3d), similar to the code snippets listed above. The x-index varies fastest, then y, and the z-index slowest. If there are multiple values per grid cell, the index for those values varies fastest of all. The caller can add the x,y,z indices of the grid cell (or the corresponding grid cell ID) to the data value(s) written as one line to the output file.

#### 4.23.11 Style class grid access methods

A style command can enable its grid cell data to be accessible from other commands. For example `fix ave/grid` or `dump grid` or `dump grid/vtk`. Those commands access the grid cell data by using a *grid reference* in their input script syntax, as described on the [Howto\\_grid](#) doc page. They look like this:

- `c_ID:gname:dname`
- `c_ID:gname:dname[I]`
- `f_ID:gname:dname`
- `f_ID:gname:dname[I]`

Each grid command instantiates has a unique *gname*, defined by the command. Likewise each grid cell data structure (scalar or vector) associated with a grid has a unique *dname*, also defined by the command.

To provide access to its grid cell data, a style command needs to implement the following 4 methods:

```
int get_grid_by_name(const std::string &name, int &dim);
void *get_grid_by_index(int index);
int get_griddata_by_name(int igrd, const std::string &name, int &ncol);
void *get_griddata_by_index(int index);
```

Currently only computes and fixes can implement these methods. If it does so, the compute or fix should also set the variable *pergrid\_flag* to 1. See any of the compute or fix commands which set “pergrid\_flag = 1” for examples of how these 4 functions can be implemented.

The *get\_grid\_by\_name()* method takes a grid name as input and returns two values. The *dim* argument is returned as 2 or 3 for the dimensionality of the grid. The function return is a grid index from 0 to *G*-1 where *G* is the number of grids the command instantiates. A value of -1 is returned if the grid name is not recognized.

The *get\_grid\_by\_index()* method is called after the *get\_grid\_by\_name()* method, using the grid index it returned as its argument. This method will return a pointer to the Grid2d or Grid3d class. The caller can use this to query grid attributes, such as the global size of the grid, to ensure it is of the expected size.

The *get\_griddata\_by\_name()* method takes a grid index *igrd* and a data name as input. It returns two values. The *ncol* argument is returned as a 0 if the grid data is a single value (scalar) per grid cell, or an integer *M* > 0 if there are *M* values (vector) per grid cell. Note that even if *M* = 1, it is still a 1-length vector, not a scalar. The function return is a data index from 0 to *D*-1 where *D* is the number of data sets associated with that grid by the command. A value of -1 is returned if the data name is not recognized.

The *get\_griddata\_by\_index()* method is called after the *get\_griddata\_by\_name()* method, using the data index it returned as its argument. This method will return a pointer to the multidimensional array which stores the requested data.

As in the discussion above of the Memory class *create\_offset()* methods, the dimensionality of the array associated with the returned pointer depends on whether it is a 2d or 3d grid and whether there is a single or multiple values stored for each grid cell:

- single value per cell for a 2d grid = 2d array pointer
- multiple values per cell for a 2d grid = 3d array pointer
- single value per cell for a 3d grid = 3d array pointer
- multiple values per cell for a 3d grid = 4d array pointer

The caller will typically access the data by casting the void pointer to the corresponding array pointer and using nested loops in x,y,z between owned or ghost index bounds returned by the *get\_bounds\_owned()* or *get\_bounds\_ghost()* methods to index into the array. Example code snippets with this logic were listed above,

---

#### 4.23.12 Final notes

Finally, here are some additional issues to pay attention to for writing any style command which uses distributed grids via the Grid2d or Grid3d class.

The command destructor should delete all instances of the Grid class, any buffers it allocated for forward/reverse or remap communication, and any data arrays it allocated to store grid cell data.

If a command is intended to work for either 2d or 3d simulations, then it should have logic to instantiate either 2d or 3d grids and their associated data arrays, depending on the dimension of the simulation box. The *fix ave/grid* command is an example of such a command.

When a command maps its particles to the grid and updates grid cell values, it should check that it is not updating or accessing a grid cell value outside the range of its owned+ghost cells, and generate an error message if that is the

case. This could happen, for example, if a particle has moved further than half the neighbor skin distance, because the neighbor list update criterion are not adequate to prevent it from happening. See the `src/KSPACE/pppm.cpp` file and its `particle_map()` method for an example of this kind of error check.

# **Part III**

## **Command Reference**

## COMMANDS

### 1.1 `angle_coeff` command

#### 1.1.1 Syntax

```
angle_coeff N args
```

- `N` = numeric angle type (see asterisk form below), or type label
- `args` = coefficients for one or more angle types

#### 1.1.2 Examples

```
angle_coeff 1 300.0 107.0
angle_coeff * 5.0
angle_coeff 2*10 5.0

labelmap angle 1 hydroxyl
angle_coeff hydroxyl 300.0 107.0
```

#### 1.1.3 Description

Specify the angle force field coefficients for one or more angle types. The number and meaning of the coefficients depends on the angle style. Angle coefficients can also be set in the data file read by the [read\\_data](#) command or in a restart file.

`N` can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or `N` can be a type label, which is an alphanumeric string defined by the [labelmap](#) command or in a section of a data file read by the [read\\_data](#) command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple angle types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If `N` is the number of angle types, then an asterisk with no numeric values means all types from 1 to `N`. A leading asterisk means all types from 1 to `n` (inclusive). A trailing asterisk means all types from `n` to `N` (inclusive). A middle asterisk means all types from `m` to `n` (inclusive).

Note that using an [angle\\_coeff](#) command can override a previous setting for the same angle type. For example, these commands set the coeffs for all angle types, then overwrite the coeffs for just angle type 2:

```
angle_coeff * 200.0 107.0 1.2
angle_coeff 2 50.0 107.0
```

A line in a data file that specifies angle coefficients uses the exact same format as the arguments of the [angle\\_coeff](#) command in an input script, except that wild-card asterisks should not be used since coefficients for all  $N$  types must be listed in the file. For example, under the “Angle Coeffs” section of a data file, the line that corresponds to the first example above would be listed as

```
1 300.0 107.0
```

The [angle\\_style class2](#) is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

---

The list of all angle styles defined in LAMMPS is given on the [angle\\_style](#) doc page. They are also listed in more compact form on the [Commands angle](#) doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated [angle\\_coeff](#) command.

---

### 1.1.4 Restrictions

This command must come after the simulation box is defined by a [read\\_data](#), [read\\_restart](#), or [create\\_box](#) command.

An angle style must be defined before any angle coefficients are set, either in the input script or in a data file.

### 1.1.5 Related commands

## 1.2 angle\_style command

### 1.2.1 Syntax

```
angle_style style
```

- style = *none* or *zero* or *hybrid* or *amoeba* or *charmm* or *class2* or *class2/p6* or *cosine* or *cosine/buck6d* or *cosine/delta* or *cosine/periodic* or *cosine/shift* or *cosine/shift/exp* or *cosine/squared* or *cosine/squared/restricted* or *cross* or *dipole* or *fourier* or *fourier/simple* or *gaussian* or *harmonic* or *lepton* or *mm3* or *quartic* or *spica* or *table*

## 1.2.2 Examples

```
angle_style harmonic
angle_style charmm
angle_style hybrid harmonic cosine
```

## 1.2.3 Description

Set the formula(s) LAMMPS uses to compute angle interactions between triplets of atoms, which remain in force for the duration of the simulation. The list of angle triplets is read in by a [read\\_data](#) or [read\\_restart](#) command from a data or restart file.

Hybrid models where angles are computed using different angle potentials can be setup using the *hybrid* angle style.

The coefficients associated with a angle style can be specified in a data or restart file or via the [angle\\_coeff](#) command.

All angle potentials store their coefficient data in binary restart files which means `angle_style` and [angle\\_coeff](#) commands do not need to be re-specified in an input script that restarts a simulation. See the [read\\_restart](#) command for details on how to do this. The one exception is that `angle_style hybrid` only stores the list of sub-styles in the restart file; angle coefficients need to be re-specified.

---

**Note:** When both an angle and pair style is defined, the [special\\_bonds](#) command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between 3 bonded atoms.

---

In the formulas listed for each angle style, *theta* is the angle between the three atoms in the angle.

---

Here is an alphabetic list of angle styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [angle\\_coeff](#) command.

Click on the style to display the formula it computes, any additional arguments specified in the `angle_style` command, and coefficients specified by the associated [angle\\_coeff](#) command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the [Commands angle](#) page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- [none](#) - turn off angle interactions
- [zero](#) - topology but no interactions
- [hybrid](#) - define multiple styles of angle interactions
- [amoeba](#) - AMOEBA angle
- [charmm](#) - CHARMM angle
- [class2](#) - COMPASS (class 2) angle
- [class2/p6](#) - COMPASS (class 2) angle expanded to 6th order
- [cosine](#) - angle with cosine term
- [cosine/buck6d](#) - same as cosine with Buckingham term between 1-3 atoms
- [cosine/delta](#) - angle with difference of cosines
- [cosine/periodic](#) - DREIDING angle
- [cosine/shift](#) - angle cosine with a shift

- *cosine/shift/exp* - cosine with shift and exponential term in spring constant
  - *cosine/squared* - angle with cosine squared term
  - *cosine/squared/restricted* - angle with restricted cosine squared term
  - *cross* - cross term coupling angle and bond lengths
  - *dipole* - angle that controls orientation of a point dipole
  - *fourier* - angle with multiple cosine terms
  - *fourier/simple* - angle with a single cosine term
  - *gaussian* - multi-centered Gaussian-based angle potential
  - *harmonic* - harmonic angle
  - *lepton* - angle potential from evaluating a string
  - *mesocnt* - piecewise harmonic and linear angle for bending-buckling of nanotubes
  - *mm3* - anharmonic angle
  - *quartic* - angle with cubic and quartic terms
  - *spica* - harmonic angle with repulsive SPICA pair style between 1-3 atoms
  - *table* - tabulated by angle
- 

## 1.2.4 Restrictions

Angle styles can only be set for atom\_styles that allow angles to be defined.

Most angle styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual bond potentials tell if it is part of a package.

## 1.2.5 Related commands

*angle\_coeff*

```
angle_style none
```

# 1.3 angle\_write command

## 1.3.1 Syntax

```
angle_write atype N file keyword
```

- atype = angle type
- N = # of values

- file = name of file to write values to
- keyword = section name in file for this set of tabulated values

### 1.3.2 Examples

```
angle_write 1 500 table.txt Harmonic_1
angle_write 3 1000 table.txt Harmonic_3
```

### 1.3.3 Description

New in version 8Feb2023.

Write energy and force values to a file as a function of angle for the currently defined angle potential. Force in this context means the force with respect to the angle, not the force on individual atoms. This is useful for plotting the potential function or otherwise debugging its values. The resulting file can also be used as input for use with *angle style table*.

If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. The individual sections may be identified by the *keyword*.

The energy and force values are computed for angles ranging from 0 degrees to 180 degrees for 3 interacting atoms forming an angle type atype, using the appropriate *angle\_coeff* coefficients. N evenly spaced angles are used.

For example, for N = 6, values are computed at  $\theta = 0, 36, 72, 108, 144, 180$ .

The file is written in the format used as input for the *angle\_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), an angle (in degrees), an energy (in energy units), and a force (in force units per radians<sup>2</sup>). In case a new file is created, the first line will be a comment with a “DATE:” and “UNITS:” tag with the current date and *units* settings. For subsequent invocations of the *angle\_write* command for the same file, data will be appended and the current units settings will be compared to the data from the header, if present. The *angle\_write* will refuse to add a table to an existing file if the units are not the same.

### 1.3.4 Restrictions

All force field coefficients for angle and other kinds of interactions must be set before this command can be invoked.

The table of the angle energy and force data is created by using a separate, internally created, new LAMMPS instance with a dummy system of 3 atoms for which the angle potential energy is computed after transferring the angle style and coefficients and arranging the three atoms into the corresponding geometries. The angle force is then determined from the potential energies through numerical differentiation. As a consequence of this approach, not all angle styles are compatible. The following conditions must be met:

- The angle style must be able to write its coefficients to a data file. This condition excludes for example *angle style hybrid* and *angle style table*.
- The potential function must not have any terms that depend on geometry properties other than the angle. This condition excludes for example *angle style class2* all angle types for *angle style charmm* that have non-zero Urey-Bradley terms. Please note that the *write\_angle* command has no way of checking for this condition, so the resulting tables may be bogus if the requirement is not met. It is thus recommended to make careful tests for any created tables.

### 1.3.5 Related commands

*angle\_style table, bond\_write, dihedral\_write, angle\_style, angle\_coeff*

### 1.3.6 Default

none

## 1.4 atom\_modify command

### 1.4.1 Syntax

```
atom_modify keyword values ...
```

- one or more keyword/value pairs may be appended
- keyword = *id* or *map* or *first* or *sort*
  - id* value = *yes* or *no*
  - map* value = *yes* or *array* or *hash*
  - first* value = group-ID = group whose atoms will appear first in internal atom lists
  - sort* values = Nfreq binsize
    - Nfreq = sort atoms spatially every this many time steps
    - binsize = bin size for spatial sorting (distance units)

### 1.4.2 Examples

```
atom_modify map yes
atom_modify map hash sort 10000 2.0
atom_modify first colloid
```

### 1.4.3 Description

Modify certain attributes of atoms defined and stored within LAMMPS, in addition to what is specified by the *atom\_style* command. The *id* and *map* keywords must be specified before a simulation box is defined; other keywords can be specified any time.

The *id* keyword determines whether non-zero atom IDs can be assigned to each atom. If the value is *yes*, which is the default, IDs are assigned, whether you use the *create\_atoms* or *read\_data* or *read\_restart* commands to initialize atoms. If the value is *no* the IDs for all atoms are assumed to be 0.

If atom IDs are used, they must all be positive integers. They should also be unique, though LAMMPS does not check for this. Typically they should also be consecutively numbered (from 1 to Natoms), though this is not required. Molecular *atom styles* are those that store bond topology information (styles bond, angle, molecular, full). These styles require atom IDs since the IDs are used to encode the topology. Some other LAMMPS commands also require the use of atom IDs. E.g. some many-body pair styles use them to avoid double computation of the I-J interaction between two atoms.

The only reason not to use atom IDs is if you are running an atomic simulation so large that IDs cannot be uniquely assigned. For a default LAMMPS build this limit is  $2^{31}$  or about 2 billion atoms. However, even in this case, you can use 64-bit atom IDs, allowing  $2^{63}$  or about  $9e18$  atoms, if you build LAMMPS with the -DLAMMPS\_BIGBIG

switch. This is described on the [Build\\_settings](#) doc page. If atom IDs are not used, they must be specified as 0 for all atoms, e.g. in a data or restart file.

---

**Note:** If a [triclinic simulation box](#) is used, atom IDs are required, due to how neighbor lists are built.

---

The *map* keyword determines how atoms with specific IDs are found when required. For example, the bond (angle, etc) methods need to find the local index of an atom with a specific global ID which is a bond (angle, etc) partner. LAMMPS performs this operation efficiently by creating a “map”, which is either an *array* or *hash* table, as described below.

When the *map* keyword is not specified in your input script, LAMMPS only creates a map for [atom\\_styles](#) for molecular systems which have permanent bonds (angles, etc). No map is created for atomic systems, since it is normally not needed. However some LAMMPS commands require a map, even for atomic systems, and will generate an error if one does not exist. The *map* keyword thus allows you to force the creation of a map.

Specifying a value of *yes* will create either an array-style or hash-style map, depending on the size of the system. If no atom ID is larger than 1 million, then an array-style map is used, otherwise a hash-style map is used. Specifying a value of *array* or *hash* creates an array-style or hash-style map respectively, regardless of the size of the system.

For an array-style map, each processor stores a lookup table of length N, where N is the largest atom ID in the system. This is a fast, simple method for many simulations, but requires too much memory for large simulations. For a hash-style map, a hash table is created on each processor, which finds an atom ID in constant time (independent of the global number of atom IDs). It can be slightly slower than the *array* map, but its memory cost is proportional to the number of atoms owned by a processor, i.e. N/P when N is the total number of atoms in the system and P is the number of processors.

The *first* keyword allows a [group](#) to be specified whose atoms will be maintained as the first atoms in each processor’s list of owned atoms. This is only useful when the specified group is a small fraction of all the atoms, and there are other operations LAMMPS is performing that will be sped-up significantly by being able to loop over the smaller set of atoms. Otherwise the reordering required by this option will be a net slow-down. The [neigh\\_modify include](#) and [comm\\_modify group](#) commands are two examples of commands that require this setting to work efficiently. Several [fixes](#), most notably time integration fixes like [fix nve](#), also take advantage of this setting if the group they operate on is the group specified by this command. Note that specifying “all” as the group-ID effectively turns off the *first* option.

It is OK to use the *first* keyword with a group that has not yet been defined, e.g. to use the [atom\\_modify first](#) command at the beginning of your input script. LAMMPS does not use the group until a simulation is run.

The *sort* keyword turns on a spatial sorting or reordering of atoms within each processor’s subdomain every *Nfreq* timesteps. If *Nfreq* is set to 0, then sorting is turned off. Sorting can improve cache performance and thus speed-up a LAMMPS simulation, as discussed in a paper by ([Meloni](#)). Its efficacy depends on the problem size (atoms/processor), how quickly the system becomes disordered, and various other factors. As a general rule, sorting is typically more effective at speeding up simulations of liquids as opposed to solids. In tests we have done, the speed-up can range from zero to 3-4x.

Reordering is performed every *Nfreq* timesteps during a dynamics run or iterations during a minimization. More precisely, reordering occurs at the first reneighboring that occurs after the target timestep. The reordering is performed locally by each processor, using bins of the specified *binsize*. If *binsize* is set to 0.0, then a binsize equal to half the [neighbor](#) cutoff distance (force cutoff plus skin distance) is used, which is a reasonable value. After the atoms have been binned, they are reordered so that atoms in the same bin are adjacent to each other in the processor’s 1d list of atoms.

The goal of this procedure is for atoms to put atoms close to each other in the processor’s one-dimensional list of atoms that are also near to each other spatially. This can improve cache performance when pairwise interactions and neighbor lists are computed. Note that if bins are too small, there will be few atoms/bin. Likewise if bins are too large, there will be many atoms/bin. In both cases, the goal of cache locality will be undermined.

---

**Note:** Running a simulation with sorting on versus off should not change the simulation results in a statistical sense. However, a different ordering will induce round-off differences, which will lead to diverging trajectories over time when comparing two simulations. Various commands, particularly those which use random numbers (e.g. *velocity create*, and *fix langevin*), may generate (statistically identical) results which depend on the order in which atoms are processed. The order of atoms in a *dump* file will also typically change if sorting is enabled.

---

---

**Note:** When running simple pair-wise potentials like Lennard Jones on GPUs with the KOKKOS package, using a larger binsize (e.g. 2x larger than default) and a more frequent reordering than default (e.g. every 100 time steps) may improve performance.

---

### 1.4.4 Restrictions

The *first* and *sort* options cannot be used together. Since sorting is on by default, it will be turned off if the *first* keyword is used with a group-ID that is not “all”.

### 1.4.5 Related commands

none

### 1.4.6 Default

By default, *id* is yes. By default, atomic systems (no bond topology info) do not use a map. For molecular systems (with bond topology info), the default is to use a map of either *array* or *hash* style depending on the size of the system, as explained above for the *map yes* keyword/value option. By default, a *first* group is not defined. By default, sorting is enabled with a frequency of 1000 and a binsize of 0.0, which means the neighbor cutoff will be used to set the bin size. If no neighbor cutoff is defined, sorting will be turned off.

---

## 1.5 atom\_style command

### 1.5.1 Syntax

**atom\_style** style args

- style = *amoeba* or *angle* or *atomic* or *body* or *bond* or *charge* or *dielectric* or *dipole* or *dpd* or *edpd* or *electron* or *ellipsoid* or *full* or *line* or *mdpd* or *molecular* or *oxdna* or *peri* or *smd* or *sph* or *sphere* or *bpm/sphere* or *spin* or *tdpd* or *tri* or *template* or *wavepacket* or *hybrid*

args = none for any style except the following

*body* args = bstyle bstyle-args

bstyle = style of body particles

bstyle-args = additional arguments specific to the bstyle

see the *Howto body* doc

page for details

*sphere* arg = 0/1 (optional) for static/dynamic particle radii  
*bpm/sphere* arg = 0/1 (optional) for static/dynamic particle radii  
*tdpd* arg = Nspecies  
     Nspecies = # of chemical species  
*template* arg = template-ID  
     template-ID = ID of molecule template specified in a separate *molecule* command  
*hybrid* args = list of one or more sub-styles, each with their args

- accelerated styles (with same args) = *angle/kk* or *atomic/kk* or *bond/kk* or *charge/kk* or *full/kk* or *molecular/kk* or *spin/kk*

## 1.5.2 Examples

```

atom_style atomic
atom_style bond
atom_style full
atom_style body nparticle 2 10
atom_style hybrid charge bond
atom_style hybrid charge body nparticle 2 5
atom_style spin
atom_style template myMols
atom_style hybrid template twomols charge
atom_style tdpd 2
  
```

## 1.5.3 Description

The *atom\_style* command selects which per-atom attributes are associated with atoms in a LAMMPS simulation and thus stored and communicated with those atoms as well as read from and stored in data and restart files. Different models (e.g. *pair styles*) require access to specific per-atom attributes and thus require a specific atom style. For example, to compute Coulomb interactions, the atom must have a “charge” (aka “q”) attribute.

A number of distinct atom styles exist that combine attributes. Some atom styles are a superset of other atom styles. Further attributes may be added to atoms either via using a hybrid style which provides a union of the attributes of the sub-styles, or via the *fix property/atom* command. The *atom\_style* command must be used before a simulation is setup via a *read\_data*, *read\_restart*, or *create\_box* command.

---

**Note:** Many of the atom styles discussed here are only enabled if LAMMPS was built with a specific package, as listed below in the Restrictions section.

---

Once a style is selected and the simulation box defined, it cannot be changed but only augmented with the *fix property/atom* command. So one should select an atom style general enough to encompass all attributes required. E.g. with atom style *bond*, it is not possible to define angles and use angle styles.

It is OK to use a style more general than needed, though it may be slightly inefficient because it will allocate and communicate additional unused data.

### 1.5.4 Atom style attributes

The atom style *atomic* has the minimum subset of per-atom attributes and is also the default setting. It encompasses the following per-atom attributes (name of the vector or array in the *Atom class* is given in parenthesis): atom-ID (tag), type (type), position (x), velocities (v), forces (f), image flags (image), group membership (mask). Since all atom styles are a superset of atom style *atomic*, they all include these attributes.

This table lists all the available atom styles, which attributes they provide, which *package* is required to use them, and what the typical applications are that use them. See the *read\_data*, *create\_atoms*, and *set* commands for details on how to set these various quantities. More information about many of the styles is provided in the Additional Information section below.

Atom style	Attributes	Required package	Applications
<i>amoeba</i>	<i>full</i> + “1-5 special neighbor data”	<i>AMOEBA</i>	AMOEBA/HIPPO force fields
<i>angle</i>	<i>bond</i> + “angle data”	<i>MOLECULE</i>	bead-spring polymers with stiffness
<i>atomic</i>	tag, type, x, v, f, image, mask		atomic liquids, solids, metals
<i>body</i>	<i>atomic</i> + radius, rmass, angmom, torque, body	<i>BODY</i>	arbitrary bodies, see <i>body howto</i>
<i>bond</i>	<i>atomic</i> + molecule, nspecial, special + “bond data”	<i>MOLECULE</i>	bead-spring polymers
<i>bpm/sphere</i>	<i>bond</i> + radius, rmass, omega, torque, quat	<i>BPM</i>	granular bonded particle models, see <i>BPM howto</i>
<i>charge</i>	<i>atomic</i> + q		atomic systems with charges
<i>dielectric</i>	<i>full</i> + mu, area, ed, em, epsilon, curvature, q_scaled	<i>DIELECTRIC</i>	systems with surface polarization
<i>dipole</i>	<i>charge</i> + mu	<i>DIPOLE</i>	atomic systems with charges and point dipoles
<i>dpd</i>	<i>atomic</i> + rho + “reactive DPD data”	<i>DPD-REACT</i>	reactive DPD
<i>edpd</i>	<i>atomic</i> + “eDPD data”	<i>DPD-MESO</i>	Energy conservative DPD (eDPD)
<i>electron</i>	<i>charge</i> + espin, eradius, ervel, erforce	<i>EFF</i>	Electron force field systems
<i>ellipsoid</i>	<i>atomic</i> + rmass, angmom, torque, ellipsoid		aspherical particles
<i>full</i>	<i>molecular</i> + q	<i>MOLECULE</i>	molecular force fields
<i>line</i>	<i>atomic</i> + molecule, radius, rmass, omega, torque, line		2-d rigid body particles
<i>mdpd</i>	<i>atomic</i> + rho, drho, vest	<i>DPD-MESO</i>	Many-body DPD (mDPD)
<i>molecular</i>	<i>angle</i> + “dihedral and improper data”	<i>MOLECULE</i>	apolar and uncharged molecules
<i>oxdna</i>	<i>atomic</i> + id5p	<i>CG-DNA</i>	coarse-grained DNA and RNA models
<i>peri</i>	<i>atomic</i> + rmass, vfrac, s0, x0	<i>PERI</i>	mesoscopic Peridynamics models
<i>smd</i>	<i>atomic</i> + molecule, radius, rmass + “smd data”	<i>MACHDYN</i>	Smooth Mach Dynamics models
<i>rheo</i>	<i>atomic</i> + rho, status	<i>RHEO</i>	solid and fluid RHEO particles
<i>rheo/thermal</i>	<i>atomic</i> + rho, status, energy, temperature	<i>RHEO</i>	RHEO particles with temperature
<i>sph</i>	<i>atomic</i> + “sph data”	<i>SPH</i>	Smoothed particle hydrodynamics models
<i>sphere</i>	<i>atomic</i> + radius, rmass, omega, torque		finite size spherical particles, e.g. granular models
<i>spin</i>	<i>atomic</i> + “magnetic moment data”	<i>SPIN</i>	magnetic particles
<i>tdpd</i>	<i>atomic</i> + cc, cc_flux, vest	<i>DPD-MESO</i>	Transport DPD (tDPD)
<i>template</i>	<i>atomic</i> + molecule, molindex, molatom	<i>MOLECULE</i>	molecular systems where attributes are taken from <i>molecule files</i>
<i>tri</i>	<i>sphere</i> + molecule, angmom, tri		3-d triangulated rigid body LJ particles
<i>wavepacket</i>	<i>charge</i> + “wavepacket data”	<i>AWPMD</i>	Antisymmetrized wave packet MD

**Note:** It is possible to add some attributes, such as a molecule ID and charge, to atom styles that do not have them built in using the *fix property/atom* command. This command also allows new custom-named attributes consisting of extra integer or floating-point values or vectors to be added to atoms. See the *fix property/atom* page for examples of

cases where this is useful and details on how to initialize, access, and output these custom values.

---

### 1.5.5 Particle size and mass

All of the atom styles define point particles unless they (1) define finite-size spherical particles via the *radius* attribute, or (2) define finite-size aspherical particles (e.g. the *body*, *ellipsoid*, *line*, and *tri* styles). Most of these styles can also be used with mixtures of point and finite-size particles.

Note that the *radius* property may need to be provided as a *diameter* (e.g. in *molecule files* or *data files*). See the *Howto spherical* page for an overview of using finite-size spherical and aspherical particle models with LAMMPS.

Unless an atom style defines the per-atom *rmass* attribute, particle masses are defined on a per-type basis, using the *mass* command. This means each particle's mass is indexed by its atom *type*.

A few styles define the per-atom *rmass* attribute which can also be added using the *fix property/atom* command. In this case each particle stores its own mass. Atom styles that have a per-atom *rmass* may define it indirectly through setting particle diameter and density on a per-particle basis. If both per-type mass and per-atom *rmass* are defined (e.g. in a hybrid style), the per-atom mass will take precedence in any operation which works with both flavors of mass.

---

### 1.5.6 Additional information about specific atom styles

For the *body* style, the particles are arbitrary bodies with internal attributes defined by the “style” of the bodies, which is specified by the *bstyle* argument. Body particles can represent complex entities, such as surface meshes of discrete points, collections of sub-particles, deformable objects, etc.

The *Howto body* page describes the body styles LAMMPS currently supports, and provides more details as to the kind of body particles they represent. For all styles, each body particle stores moments of inertia and a quaternion 4-vector, so that its orientation and position can be time integrated due to forces and torques.

Note that there may be additional arguments required along with the *bstyle* specification, in the *atom\_style body* command. These arguments are described on the *Howto body* doc page.

For the *dielectric* style, each particle can be either a physical particle (e.g. an ion), or an interface particle representing a boundary element between two regions of different dielectric constant. For interface particles, in addition to the properties associated with *atom\_style full*, each particle also should be assigned a unit dipole vector (*mu*) representing the direction of the induced dipole moment at each interface particle, an area (*area/patch*), the difference and mean of the dielectric constants of two sides of the interface along the direction of the normal vector (*ed* and *em*), the local dielectric constant at the boundary element (*epsilon*), and a mean local curvature (*curv*). Physical particles must be assigned these values, as well, but only their local dielectric constants will be used; see documentation for associated *pair styles* and *fixes*. The distinction between the physical and interface particles is only meaningful when *fix polarize* commands are applied to the interface particles. This style is part of the DIELECTRIC package.

For the *dipole* style, a point dipole vector *mu* is defined for each point particle. Note that if you wish the particles to be finite-size spheres as in a Stockmayer potential for a dipolar fluid, so that the particles can rotate due to dipole-dipole interactions, then you need to use the command *atom\_style hybrid sphere dipole*, which will assign both a diameter and dipole moment to each particle. This also requires using an integrator with a “/sphere” suffix like *fix nve/sphere* or *fix nvt/sphere* and the “update dipole” or “update dlm” parameters to the *fix* commands.

The *dpd* style is for reactive dissipative particle dynamics (DPD) particles. Note that it is part of the DPD-REACT package, and is not required for use with the *pair\_style dpd* or *dpd/stat* commands, which only require the attributes from *atom\_style atomic*. *Atom\_style dpd* extends DPD particle properties with internal temperature (*dpdTheta*), internal conductive energy (*uCond*), internal mechanical energy (*uMech*), and internal chemical energy (*uChem*).

The *edpd* style is for energy-conserving dissipative particle dynamics (eDPD) particles which store a temperature (*edpd\_temp*), and heat capacity (*edpd\_cv*).

For the *electron* style, the particles representing electrons are 3d Gaussians with a specified position and bandwidth or uncertainty in position, which is represented by the *eradius* = electron size.

For the *ellipsoid* style, particles can be ellipsoids which each stores a shape vector with the 3 diameters of the ellipsoid and a quaternion 4-vector with its orientation. Each particle stores a flag in the ellipsoid vector which indicates whether it is an ellipsoid (1) or a point particle (0).

For the *line* style, particles can be idealized line segments which store a per-particle mass and length and orientation (i.e. the end points of the line segment). Each particle stores a flag in the line vector which indicates whether it is a line segment (1) or a point particle (0).

The *mdpd* style is for many-body dissipative particle dynamics (mDPD) particles which store a density (*rho*) for considering density-dependent many-body interactions.

The *oxdna* style is for coarse-grained nucleotides and stores the 3'-to-5' polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3'-end (5'-end) of the strand.

For the *peri* style, the particles are spherical and each stores a per-particle mass and volume.

The *smd* style is for Smooth Particle Mach dynamics. Both fluids and solids can be modeled. Particles store the mass and volume of an integration point, a kernel diameter used for calculating the field variables (e.g. stress and deformation) and a contact radius for calculating repulsive forces which prevent individual physical bodies from penetrating each other.

The *sph* style is for smoothed particle hydrodynamics (SPH) particles which store a density (*rho*), energy (*esph*), and heat capacity (*cv*).

For the *spin* style, a magnetic spin is associated with each atom. Those spins have a norm (their magnetic moment) and a direction.

The *tdpd* style is for transport dissipative particle dynamics (tDPD) particles which store a set of chemical concentration. An integer “*cc\_species*” is required to specify the number of chemical species involved in a tDPD system.

The *wavepacket* style is similar to the *electron* style, but the electrons may consist of several Gaussian wave packets, summed up with coefficients *cs*= (*cs\_re*,*cs\_im*). Each of the wave packets is treated as a separate particle in LAMMPS, wave packets belonging to the same electron must have identical *etag* values.

The *sphere* and *bpm/sphere* styles allow particles to be either point particles or finite-size particles. If the *radius* attribute is > 0.0, the particle is a finite-size sphere. If the *diameter* = 0.0, it is a point particle. Note that by using the *disc* keyword with the *fix nve/sphere*, *fix nvt/sphere*, *fix nph/sphere*, *fix npt/sphere* commands for the *sphere* style, spheres can be effectively treated as 2d discs for a 2d simulation if desired. See also the *set density/disc* command. These styles also take an optional 0 or 1 argument. A value of 0 means the radius of each sphere is constant for the duration of the simulation (this is the default). A value of 1 means the radii may vary dynamically during the simulation, e.g. due to use of the *fix adapt* command.

The *template* style allows molecular topology (bonds,angles,etc) to be defined via a molecule template using the *molecule* command. The template stores one or more molecules with a single copy of the topology info (bonds,angles,etc) of each. Individual atoms only store a template index and template atom to identify which molecule and which atom-within-the-molecule they represent. Using the *template* style instead of the *bond*, *angle*, *molecular* styles can save memory for systems comprised of a large number of small molecules, all of a single type (or small number of types). See the paper by Grime and Voth, in (*Grime*), for examples of how this can be advantageous for large-scale coarse-grained systems. The *examples/template* directory has a few demo inputs and examples showing the use of the *template* atom style versus *molecular*.

---

**Note:** When using the *template* style with a *molecule template* that contains multiple molecules, you should ensure the atom types, bond types, angle\_types, etc in all the molecules are consistent. E.g. if one molecule represents H2O

and another CO<sub>2</sub>, then you probably do not want each molecule file to define two atom types and a single bond type, because they will conflict with each other when a mixture system of H<sub>2</sub>O and CO<sub>2</sub> molecules is defined, e.g. by the [read\\_data](#) command. Rather the H<sub>2</sub>O molecule should define atom types 1 and 2, and bond type 1. And the CO<sub>2</sub> molecule should define atom types 3 and 4 (or atom types 3 and 2 if a single oxygen type is desired), and bond type 2.

---

For the *tri* style, particles can be planar triangles which each stores a per-particle mass and size and orientation (i.e. the corner points of the triangle). Each particle stores a flag in the tri vector which indicates whether it is a triangle (1) or a point particle (0).

---

Typically, simulations require only a single (non-hybrid) atom style. If some atoms in the simulation do not have all the properties defined by a particular style, use the simplest style that defines all the needed properties by any atom. For example, if some atoms in a simulation are charged, but others are not, use the *charge* style. If some atoms have bonds, but others do not, use the *bond* style.

The only scenario where the *hybrid* style is needed is if there is no single style which defines all needed properties of all atoms. For example, as mentioned above, if you want dipolar particles which will rotate due to torque, you need to use “atom\_style hybrid sphere dipole”. When a hybrid style is used, atoms store and communicate the union of all quantities implied by the individual styles.

When using the *hybrid* style, you cannot combine the *template* style with another molecular style that stores bond, angle, etc info on a per-atom basis.

LAMMPS can be extended with new atom styles as well as new body styles; see the corresponding manual page on [modifying & extending LAMMPS](#).

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 1.5.7 Restrictions

This command cannot be used after the simulation box is defined by a [read\\_data](#) or [create\\_box](#) command.

Many of the styles listed above are only enabled if LAMMPS was built with a specific package, as listed below. See the [Build package](#) page for more info. The table above lists which package is required for individual atom styles.

## 1.5.8 Related commands

*read\_data*, *pair\_style*, *fix property/atom*, *set*

## 1.5.9 Default

The default atom style is *atomic*. If atom\_style *sphere* or *bpm/sphere* is used, its default argument is 0.

(Grime) Grime and Voth, to appear in J Chem Theory & Computation (2014).

## 1.6 balance command

### 1.6.1 Syntax

```
balance thresh style args ... keyword args ...
```

- thresh = imbalance threshold that must be exceeded to perform a re-balance
- one style/arg pair can be used (or multiple for x,y,z)
- style = *x* or *y* or *z* or *shift* or *rcb*
  - x* args = *uniform* or Px-1 numbers between 0 and 1
    - uniform* = evenly spaced cuts between processors in x dimension
    - numbers = Px-1 ascending values between 0 and 1, Px - # of processors in x dimension
    - x* can be specified together with *y* or *z*
  - y* args = *uniform* or Py-1 numbers between 0 and 1
    - uniform* = evenly spaced cuts between processors in y dimension
    - numbers = Py-1 ascending values between 0 and 1, Py - # of processors in y dimension
    - y* can be specified together with *x* or *z*
  - z* args = *uniform* or Pz-1 numbers between 0 and 1
    - uniform* = evenly spaced cuts between processors in z dimension
    - numbers = Pz-1 ascending values between 0 and 1, Pz - # of processors in z dimension
    - z* can be specified together with *x* or *y*
  - shift* args = dimstr Niter stopthresh
    - dimstr = sequence of letters containing "x" or "y" or "z", each not more than once
    - Niter = # of times to iterate within each dimension of dimstr sequence
    - stopthresh = stop balancing when this imbalance threshold is reached
  - rcb* args = none
- zero or more keyword/arg pairs may be appended
- keyword = *weight* or *out*
  - weight* style args = use weighted particle counts for the balancing
    - style = *group* or *neigh* or *time* or *var* or *store*
    - group args = Ngroup group1 weight1 group2 weight2 ...
      - Ngroup = number of groups with assigned weights
      - group1, group2, ... = group IDs
      - weight1, weight2, ... = corresponding weight factors

```
neigh factor = compute weight based on number of neighbors
factor = scaling factor (> 0)
time factor = compute weight based on time spend computing
factor = scaling factor (> 0)
var name = take weight from atom-style variable
name = name of the atom-style variable
store name = store weight in custom atom property defined by fix property/atom
→command
name = atom property name (without d_ prefix)
sort arg = no or yes
out arg = filename
filename = write each processor's subdomain to a file
```

## 1.6.2 Examples

```
balance 0.9 x uniform y 0.4 0.5 0.6
balance 1.2 shift xz 5 1.1
balance 1.0 shift xz 5 1.1
balance 1.1 rcb
balance 1.0 shift x 10 1.1 weight group 2 fast 0.5 slow 2.0
balance 1.0 shift x 10 1.1 weight time 0.8 weight neigh 0.5 weight store balance
balance 1.0 shift x 20 1.0 out tmp.balance
```

## 1.6.3 Description

This command adjusts the size and shape of processor subdomains within the simulation box, to attempt to balance the number of atoms or particles and thus indirectly the computational cost (load) more evenly across processors. The load balancing is “static” in the sense that this command performs the balancing once, before or between simulations. The processor subdomains will then remain static during the subsequent run. To perform “dynamic” balancing, see the *fix balance* command, which can adjust processor subdomain sizes and shapes on-the-fly during a *run*.

Load-balancing is typically most useful if the particles in the simulation box have a spatially-varying density distribution or when the computational cost varies significantly between different particles. E.g. a model of a vapor/liquid interface, or a solid with an irregular-shaped geometry containing void regions, or *hybrid pair style simulations* which combine pair styles with different computational cost. In these cases, the LAMMPS default of dividing the simulation box volume into a regular-spaced grid of 3d bricks, with one equal-volume subdomain per processor, may assign numbers of particles per processor in a way that the computational effort varies significantly. This can lead to poor performance when the simulation is run in parallel.

The balancing can be performed with or without per-particle weighting. With no weighting, the balancing attempts to assign an equal number of particles to each processor. With weighting, the balancing attempts to assign an equal aggregate computational weight to each processor, which typically induces a different number of atoms assigned to each processor. Details on the various weighting options and examples for how they can be used are *given below*.

Note that the *processors* command allows some control over how the box volume is split across processors. Specifically, for a  $P_x$  by  $P_y$  by  $P_z$  grid of processors, it allows choice of  $P_x$ ,  $P_y$ , and  $P_z$ , subject to the constraint that  $P_x * P_y * P_z = P$ , the total number of processors. This is sufficient to achieve good load-balance for some problems on some processor counts. However, all the processor subdomains will still have the same shape and same volume.

The requested load-balancing operation is only performed if the current “imbalance factor” in particles owned by each processor exceeds the specified *thresh* parameter. The imbalance factor is defined as the maximum number of particles (or weight) owned by any processor, divided by the average number of particles (or weight) per processor. Thus an imbalance factor of 1.0 is perfect balance.

As an example, for 10000 particles running on 10 processors, if the most heavily loaded processor has 1200 particles, then the factor is 1.2, meaning there is a 20% imbalance. Note that a re-balance can be forced even if the current balance is perfect (1.0) by specifying a *thresh* < 1.0.

---

**Note:** Balancing is performed even if the imbalance factor does not exceed the *thresh* parameter if a “grid” style is specified when the current partitioning is “tiled”. The meaning of “grid” vs “tiled” is explained below. This is to allow forcing of the partitioning to “grid” so that the *comm\_style brick* command can then be used to replace a current *comm\_style tiled* setting.

---

When the balance command completes, it prints statistics about the result, including the change in the imbalance factor and the change in the maximum number of particles on any processor. For “grid” methods (defined below) that create a logical 3d grid of processors, the positions of all cutting planes in each of the 3 dimensions (as fractions of the box length) are also printed.

---

**Note:** This command attempts to minimize the imbalance factor, as defined above. But depending on the method a perfect balance (1.0) may not be achieved. For example, “grid” methods (defined below) that create a logical 3d grid cannot achieve perfect balance for many irregular distributions of particles. Likewise, if a portion of the system is a perfect lattice, e.g. the initial system is generated by the *create\_atoms* command, then “grid” methods may be unable to achieve exact balance. This is because entire lattice planes will be owned or not owned by a single processor.

---

---

**Note:** The imbalance factor is also an estimate of the maximum speed-up you can hope to achieve by running a perfectly balanced simulation versus an imbalanced one. In the example above, the 10000 particle simulation could run up to 20% faster if it were perfectly balanced, versus when imbalanced. However, computational cost is not strictly proportional to particle count, and changing the relative size and shape of processor subdomains may lead to additional computational and communication overheads, e.g. in the PPPM solver used via the *kpspace\_style* command. Thus you should benchmark the run times of a simulation before and after balancing.

---

The method used to perform a load balance is specified by one of the listed styles (or more in the case of *x,y,z*), which are described in detail below. There are 2 kinds of styles.

The *x*, *y*, *z*, and *shift* styles are “grid” methods which produce a logical 3d grid of processors. They operate by changing the cutting planes (or lines) between processors in 3d (or 2d), to adjust the volume (area in 2d) assigned to each processor, as in the following 2d diagram where processor subdomains are shown and particles are colored by the processor that owns them.

The leftmost diagram is the default partitioning of the simulation box across processors (one sub-box for each of 16 processors); the middle diagram is after a “grid” method has been applied. The *rcb* style is a “tiling” method which

does not produce a logical 3d grid of processors. Rather it tiles the simulation domain with rectangular sub-boxes of varying size and shape in an irregular fashion so as to have equal numbers of particles (or weight) in each sub-box, as in the rightmost diagram above.

The “grid” methods can be used with either of the *comm\_style* command options, *brick* or *tiled*. The “tiling” methods can only be used with *comm\_style tiled*. Note that it can be useful to use a “grid” method with *comm\_style tiled* to return the domain partitioning to a logical 3d grid of processors so that “comm\_style brick” can afterwards be specified for subsequent *run* commands.

When a “grid” method is specified, the current domain partitioning can be either a logical 3d grid or a tiled partitioning. In the former case, the current logical 3d grid is used as a starting point and changes are made to improve the imbalance factor. In the latter case, the tiled partitioning is discarded and a logical 3d grid is created with uniform spacing in all dimensions. This becomes the starting point for the balancing operation.

When a “tiling” method is specified, the current domain partitioning (“grid” or “tiled”) is ignored, and a new partitioning is computed from scratch.

---

The *x*, *y*, and *z* styles invoke a “grid” method for balancing, as described above. Note that any or all of these 3 styles can be specified together, one after the other, but they cannot be used with any other style. This style adjusts the position of cutting planes between processor subdomains in specific dimensions. Only the specified dimensions are altered.

The *uniform* argument spaces the planes evenly, as in the left diagrams above. The *numeric* argument requires listing Ps-1 numbers that specify the position of the cutting planes. This requires knowing  $P_s = P_x$  or  $P_y$  or  $P_z$  = the number of processors assigned by LAMMPS to the relevant dimension. This assignment is made (and the  $P_x$ ,  $P_y$ ,  $P_z$  values printed out) when the simulation box is created by the “create\_box” or “read\_data” or “read\_restart” command and is influenced by the settings of the *processors* command.

Each of the numeric values must be between 0 and 1, and they must be listed in ascending order. They represent the fractional position of the cutting place. The left (or lower) edge of the box is 0.0, and the right (or upper) edge is 1.0. Neither of these values is specified. Only the interior Ps-1 positions are specified. Thus if there are 2 processors in the *x* dimension, you specify a single value such as 0.75, which would make the left processor’s subdomain 3x larger than the right processor’s subdomain.

---

The *shift* style invokes a “grid” method for balancing, as described above. It changes the positions of cutting planes between processors in an iterative fashion, seeking to reduce the imbalance factor, similar to how the *fix balance shift* command operates.

The *dimstr* argument is a string of characters, each of which must be an “x” or “y” or “z”. Each character can appear zero or one time, since there is no advantage to balancing on a dimension more than once. You should normally only list dimensions where you expect there to be a density variation in the particles.

Balancing proceeds by adjusting the cutting planes in each of the dimensions listed in *dimstr*, one dimension at a time. For a single dimension, the balancing operation (described below) is iterated on up to *Niter* times. After each dimension finishes, the imbalance factor is re-computed, and the balancing operation halts if the *stopthresh* criterion is met.

A re-balance operation in a single dimension is performed using a recursive multisectioning algorithm, where the position of each cutting plane (line in 2d) in the dimension is adjusted independently. This is similar to a recursive bisectioning for a single value, except that the bounds used for each bisectioning take advantage of information from neighboring cuts if possible. At each iteration, the count of particles on either side of each plane is tallied. If the counts do not match the target value for the plane, the position of the cut is adjusted to be halfway between a low and high bound. The low and high bounds are adjusted on each iteration, using new count information, so that they become closer together over time. Thus as the recursion progresses, the count of particles on either side of the plane gets closer to the target value.

After the balanced plane positions are determined, if any pair of adjacent planes are closer together than the neighbor skin distance (as specified by the *neigh\_modify* command), then the plane positions are shifted to separate them by at

least this amount. This is to prevent particles being lost when dynamics are run with processor subdomains that are too narrow in one or more dimensions.

Once the re-balancing is complete and final processor subdomains assigned, particles are migrated to their new owning processor, and the balance procedure ends.

---

**Note:** At each re-balance operation, the bisectioning for each cutting plane (line in 2d) typically starts with low and high bounds separated by the extent of a processor's subdomain in one dimension. The size of this bracketing region shrinks by 1/2 every iteration. Thus if *Niter* is specified as 10, the cutting plane will typically be positioned to 1 part in 1000 accuracy (relative to the perfect target position). For *Niter* = 20, it will be accurate to 1 part in a million. Thus there is no need to set *Niter* to a large value. LAMMPS will check if the threshold accuracy is reached (in a dimension) is less iterations than *Niter* and exit early. However, *Niter* should also not be set too small, since it will take roughly the same number of iterations to converge even if the cutting plane is initially close to the target value.

---

The *rcb* style invokes a “tiled” method for balancing, as described above. It performs a recursive coordinate bisectioning (RCB) of the simulation domain. The basic idea is as follows.

The simulation domain is cut into 2 boxes by an axis-aligned cut in one of the dimensions, leaving one new sub-box on either side of the cut. Which dimension is chosen for the cut depends on the particle (weight) distribution within the parent box. Normally the longest dimension of the box is cut, but if all (or most) of the particles are at one end of the box, a cut may be performed in another dimension to induce sub-boxes that are more cube-ish (3d) or square-ish (2d) in shape.

After the cut is made, all the processors are also partitioned into 2 groups, half assigned to the box on the lower side of the cut, and half to the box on the upper side. (If the processor count is odd, one side gets an extra processor.) The cut is positioned so that the number of (weighted) particles in the lower box is exactly the number that the processors assigned to that box should own for load balance to be perfect. This also makes load balance for the upper box perfect. The positioning of the cut is done iteratively, by a bisectioning method (median search). Note that counting particles on either side of the cut requires communication between all processors at each iteration.

That is the procedure for the first cut. Subsequent cuts are made recursively, in exactly the same manner. The subset of processors assigned to each box make a new cut in one dimension of that box, splitting the box, the subset of processors, and the particles in the box in two. The recursion continues until every processor is assigned a sub-box of the entire simulation domain, and owns the (weighted) particles in that sub-box.

---

This subsection describes how to perform weighted load balancing using the *weight* keyword.

By default, all particles have a weight of 1.0, which means each particle is assumed to require the same amount of computation during a timestep. There are, however, scenarios where this is not a good assumption. Measuring the computational cost for each particle accurately would be impractical and slow down the computation. Instead the *weight* keyword implements several ways to influence the per-particle weights empirically by properties readily available or using the user's knowledge of the system. Note that the absolute value of the weights are not important; only their relative ratios affect which particle is assigned to which processor. A particle with a weight of 2.5 is assumed to require 5x more computational than a particle with a weight of 0.5. For all the options below the weight assigned to a particle must be a positive value; an error will be generated if a weight is  $\leq 0.0$ .

Below is a list of possible weight options with a short description of their usage and some example scenarios where they might be applicable. It is possible to apply multiple weight flags and the weightings they induce will be combined through multiplication. Most of the time, however, it is sufficient to use just one method.

The *group* weight style assigns weight factors to specified *groups* of particles. The *group* style keyword is followed by the number of groups, then pairs of group IDs and the corresponding weight factor. If a particle belongs to none of the specified groups, its weight is not changed. If it belongs to multiple groups, its weight is the product of the weight factors.

This weight style is useful in combination with pair style *hybrid*, e.g. when combining a more costly many-body potential with a fast pairwise potential. It is also useful when using *run\_style respa* where some portions of the system have many bonded interactions and others none. It assumes that the computational cost for each group remains constant over time. This is a purely empirical weighting, so a series test runs to tune the assigned weight factors for optimal performance is recommended.

The *neigh* weight style assigns the same weight to each particle owned by a processor based on the total count of neighbors in the neighbor list owned by that processor. The motivation is that more neighbors means a higher computational cost. The style does not use neighbors per atom to assign a unique weight to each atom, because that value can vary depending on how the neighbor list is built.

The *factor* setting is applied as an overall scale factor to the *neigh* weights which allows adjustment of their impact on the balancing operation. The specified *factor* value must be positive. A value  $> 1.0$  will increase the weights so that the ratio of max weight to min weight increases by *factor*. A value  $< 1.0$  will decrease the weights so that the ratio of max weight to min weight decreases by *factor*. In both cases the intermediate weight values increase/decrease proportionally as well. A value  $= 1.0$  has no effect on the *neigh* weights. As a rule of thumb, we have found a *factor* of about 0.8 often results in the best performance, since the number of neighbors is likely to overestimate the ideal weight.

This weight style is useful for systems where there are different cutoffs used for different pairs of interactions, or the density fluctuates, or a large number of particles are in the vicinity of a wall, or a combination of these effects. If a simulation uses multiple neighbor lists, this weight style will use the first suitable neighbor list it finds. It will not request or compute a new list. A warning will be issued if there is no suitable neighbor list available or if it is not current, e.g. if the *balance* command is used before a *run* or *minimize* command is used, in which case the neighbor list may not yet have been built. In this case no weights are computed. Inserting a *run 0 post no* command before issuing the *balance* command, may be a workaround for this case, as it will induce the neighbor list to be built.

The *time* weight style uses *timer data* to estimate weights. It assigns the same weight to each particle owned by a processor based on the total computational time spent by that processor. See details below on what time window is used. It uses the same timing information as is used for the *MPI task timing breakdown*, namely, for sections *Pair*, *Bond*, *Kspace*, and *Neigh*. The time spent in those portions of the timestep are measured for each MPI rank, summed, then divided by the number of particles owned by that processor. I.e. the weight is an effective CPU time/particle averaged over the particles on that processor.

The *factor* setting is applied as an overall scale factor to the *time* weights which allows adjustment of their impact on the balancing operation. The specified *factor* value must be positive. A value  $> 1.0$  will increase the weights so that the ratio of max weight to min weight increases by *factor*. A value  $< 1.0$  will decrease the weights so that the ratio of max weight to min weight decreases by *factor*. In both cases the intermediate weight values increase/decrease proportionally as well. A value  $= 1.0$  has no effect on the *time* weights. As a rule of thumb, effective values to use are typically between 0.5 and 1.2. Note that the timer quantities mentioned above can be affected by communication which occurs in the middle of the operations, e.g. pair styles with intermediate exchange of data within the force computation, and likewise for KSpace solves.

When using the *time* weight style with the *balance* command, the timing data is taken from the preceding run command, i.e. the timings are for the entire previous run. For the *fix balance* command the timing data is for only the timesteps since the last balancing operation was performed. If timing information for the required sections is not available, e.g. at the beginning of a run, or when the *timer* command is set to either *loop* or *off*, a warning is issued. In this case no weights are computed.

---

**Note:** The *time* weight style is the most generic option, and should be tried first, unless the *group* style is easily applicable. However, since the computed cost function is averaged over all particles on a processor, the weights may not be highly accurate. This style can also be effective as a secondary weight in combination with either *group* or *neigh* to offset some of inaccuracies in either of those heuristics.

---

The *var* weight style assigns per-particle weights by evaluating an *atom-style variable* specified by *name*. This is provided as a more flexible alternative to the *group* weight style, allowing definition of a more complex heuristics based

on information (global and per atom) available inside of LAMMPS. For example, atom-style variables can reference the position of a particle, its velocity, the volume of its Voronoi cell, etc.

The *store* weight style does not compute a weight factor. Instead it stores the current accumulated weights in a custom per-atom vector specified by *name*. This must be a vector defined as *d\_name* via the *fix property/atom* command. This means the values in the vector can be read as part of a data file with the *read\_data* command or specified with the *set* command. These weights can also be output in a *dump* file, so this is a way to examine, debug, or visualize the per-particle weights used during the load-balancing operation.

Note that the name of the custom per-atom vector is specified just as *name*, not as *d\_name* as it is for other commands that use different kinds of custom atom vectors or arrays as arguments.

The *sort* keyword determines whether the communication of per-atom data to other processors during load-balancing will be random or deterministic. Random is generally faster; deterministic will ensure the new ordering of atoms on each processor is the same each time the same simulation is run. This can be useful for debugging purposes. Since the *balance* command is a one-time operation, the default is *yes* to perform sorting.

The *out* keyword writes a text file to the specified *filename* with the results of the balancing operation. The file contains the bounds of the subdomain for each processor after the balancing operation completes. The format of the file is compatible with the *Pizza.py mdump* tool which has support for manipulating and visualizing mesh files. An example is shown here for a balancing by 4 processors for a 2d problem:

```
ITEM: TIMESTEP
0
ITEM: NUMBER OF NODES
16
ITEM: BOX BOUNDS
0 10
0 10
0 10
ITEM: NODES
1 1 0 0 0
2 1 5 0 0
3 1 5 5 0
4 1 0 5 0
5 1 5 0 0
6 1 10 0 0
7 1 10 5 0
8 1 5 5 0
9 1 0 5 0
10 1 5 5 0
11 1 5 10 0
12 1 10 5 0
13 1 5 5 0
14 1 10 5 0
15 1 10 10 0
16 1 5 10 0
ITEM: TIMESTEP
0
ITEM: NUMBER OF SQUARES
4
ITEM: SQUARES
1 1 1 2 3 4
2 1 5 6 7 8
```

(continues on next page)

(continued from previous page)

```
3 1 9 10 11 12
4 1 13 14 15 16
```

The coordinates of all the vertices are listed in the `NODES` section, 5 per processor. Note that the 4 subdomains share vertices, so there will be duplicate nodes in the list.

The “`SQUARES`” section lists the node IDs of the 4 vertices in a rectangle for each processor (1 to 4).

For a 3d problem, the syntax is similar with 8 vertices listed for each processor, instead of 4, and “`SQUARES`” replaced by “`CUBES`”.

---

## 1.6.4 Restrictions

For 2d simulations, the `z` style cannot be used. Nor can a “`z`” appear in *dimstr* for the *shift* style.

Balancing through recursive bisectioning (*rcb* style) requires *comm\_style tiled*

## 1.6.5 Related commands

*group, processors, fix balance, comm\_style*

## 1.6.6 Default

The default setting is `sort = yes`.

# 1.7 bond\_coeff command

## 1.7.1 Syntax

```
bond_coeff N args
```

- `N` = numeric bond type (see asterisk form below), or type label
- `args` = coefficients for one or more bond types

## 1.7.2 Examples

```
bond_coeff 5 80.0 1.2
bond_coeff * 30.0 1.5 1.0 1.0
bond_coeff 1*4 30.0 1.5 1.0 1.0
bond_coeff 1 harmonic 200.0 1.0 # (for bond_style hybrid)

labelmap bond 5 carbonyl
bond_coeff carbonyl 80.0 1.2
```

### 1.7.3 Description

Specify the bond force field coefficients for one or more bond types. The number and meaning of the coefficients depends on the bond style. Bond coefficients can also be set in the data file read by the [read\\_data](#) command or in a restart file.

$N$  can be specified in one of several ways. An explicit numeric value can be used, as in the first example above. Or  $N$  can be a type label, which is an alphanumeric string defined by the [labelmap](#) command or in a section of a data file read by the [read\\_data](#) command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple bond types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If  $N$  is the number of bond types, then an asterisk with no numeric values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $n$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive).

Note that using a `bond_coeff` command can override a previous setting for the same bond type. For example, these commands set the coeffs for all bond types, then overwrite the coeffs for just bond type 2:

```
bond_coeff * 100.0 1.2
bond_coeff 2 200.0 1.2
```

A line in a data file that specifies bond coefficients uses the exact same format as the arguments of the `bond_coeff` command in an input script, except that wild-card asterisks should not be used since coefficients for all  $N$  types must be listed in the file. For example, under the “Bond Coeffs” section of a data file, the line that corresponds to the first example above would be listed as

```
5 80.0 1.2
```

---

The list of all bond styles defined in LAMMPS is given on the [bond\\_style](#) doc page. They are also listed in more compact form on the [Commands bond](#) doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated `bond_coeff` command.

---

### 1.7.4 Restrictions

This command must come after the simulation box is defined by a [read\\_data](#), [read\\_restart](#), or [create\\_box](#) command.

A bond style must be defined before any bond coefficients are set, either in the input script or in a data file.

### 1.7.5 Related commands

- args = none for any style except *hybrid*
  - *hybrid* args = list of one or more styles

### 1.8.2 Examples

```
bond_style harmonic  
bond_style fene  
bond_style hybrid harmonic fene
```

### 1.8.3 Description

Set the formula(s) LAMMPS uses to compute bond interactions between pairs of atoms. In LAMMPS, a bond differs from a pairwise interaction, which are set via the [pair\\_style](#) command. Bonds are defined between specified pairs of atoms and remain in force for the duration of the simulation (unless new bonds are created or existing bonds break, which is possible in some fixes and bond potentials). The list of bonded atoms is read in by a [read\\_data](#) or [read\\_restart](#) command from a data or restart file. By contrast, pair potentials are typically defined between all pairs of atoms within a cutoff distance and the set of active interactions changes over time.

Hybrid models where bonds are computed using different bond potentials can be setup using the *hybrid* bond style.

The coefficients associated with a bond style can be specified in a data or restart file or via the [bond\\_coeff](#) command.

All bond potentials store their coefficient data in binary restart files which means `bond_style` and [bond\\_coeff](#) commands do not need to be re-specified in an input script that restarts a simulation. See the [read\\_restart](#) command for details on how to do this. The one exception is that `bond_style hybrid` only stores the list of sub-styles in the restart file; bond coefficients need to be re-specified.

---

**Note:** When both a bond and pair style is defined, the [special\\_bonds](#) command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between two bonded atoms.

---

In the formulas listed for each bond style,  $r$  is the distance between the two atoms in the bond.

---

Here is an alphabetic list of bond styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated [bond\\_coeff](#) command.

Click on the style to display the formula it computes, any additional arguments specified in the `bond_style` command, and coefficients specified by the associated `bond_coeff` command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the [Commands bond](#) doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *none* - turn off bonded interactions
  - *zero* - topology but no interactions
  - *hybrid* - define multiple styles of bond interactions
  - *bpm/rotational* - breakable bond with forces and torques based on deviation from reference state
  - *bpm/spring* - breakable bond with forces based on deviation from reference length
  - *class2* - COMPASS (class 2) bond
  - *fene* - FENE (finite-extensible non-linear elastic) bond
  - *fene/expand* - FENE bonds with variable size particles
  - *fene/nm* - FENE bonds with a generalized Lennard-Jones potential
  - *gaussian* - multicentered Gaussian-based bond potential
  - *gromos* - GROMOS force field bond
  - *harmonic* - harmonic bond
  - *harmonic/restrain* - harmonic bond to restrain to original bond distance
  - *harmonic/shift* - shifted harmonic bond
  - *harmonic/shift/cut* - shifted harmonic bond with a cutoff
  - *lepton* - bond potential from evaluating a string
  - *mesocnt* - Harmonic bond wrapper with parameterization presets for nanotubes
  - *mm3* - MM3 anharmonic bond
  - *morse* - Morse bond
  - *nonlinear* - nonlinear bond
  - *oxdna/fene* - modified FENE bond suitable for DNA modeling
  - *oxdna2/fene* - same as oxdna but used with different pair styles
  - *oxrna2/fene* - modified FENE bond suitable for RNA modeling
  - *quartic* - breakable quartic bond
  - *rheo/shell* - shell bond for oxidation modeling in RHEO
  - *special* - enable special bond exclusions for 1-5 pairs and beyond
  - *table* - tabulated by bond length
-

## 1.8.4 Restrictions

Bond styles can only be set for atom styles that allow bonds to be defined.

Most bond styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info. The doc pages for individual bond potentials tell if it is part of a package.

## 1.8.5 Related commands

*bond\_coeff*, *delete\_bonds*

## 1.8.6 Default

bond_style none
```

# 1.9 bond\_write command

## 1.9.1 Syntax

```
bond_write btype N inner outer file keyword itype jtype
```

- btype = bond type
- N = # of values
- inner,outer = inner and outer bond length (distance units)
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values
- itype,jtype = two atom types (optional)

## 1.9.2 Examples

```
bond_write 1 500 0.5 3.5 table.txt Harmonic_1
bond_write 3 1000 0.1 6.0 table.txt Morse
```

## 1.9.3 Description

Write energy and force values to a file as a function of distance for the currently defined *bond style* for a selected bond type. This is useful for plotting the potential function or otherwise debugging its values. The resulting file can also be used as input for use with *bond style table*.

If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. The individual sections may be identified by the *keyword*.

The energy and force values are computed at distances from *inner* to *outer* for two interacting atoms forming a bond of type *btype*, using the appropriate *bond\_coeff* coefficients. N evenly spaced distances are used.

For example, for N = 7, inner = 1.0, and outer = 4.0, values are computed at r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0.

The file is written in the format used as input for the *bond\_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), a distance (in distance units), an energy (in energy units), and a force (in force units). In case a new file is created, the first line will be a comment with a “DATE:” and “UNITS:” tag with the current date and *units* settings. For subsequent invocations of the *bond\_write* command for the same file, data will be appended and the current units settings will be compared to the data from the header, if present. The *bond\_write* command will refuse to add a table to an existing file if the units are not the same.

## 1.9.4 Restrictions

All force field coefficients for bond and other kinds of interactions must be set before this command can be invoked.

Due to how the bond force is computed, an inner value  $> 0.0$  must be specified even if the potential has a finite value at  $r = 0.0$ .

# 1.10 boundary command

## 1.10.1 Syntax

```
boundary x y z
```

- $x, y, z = p$  or  $s$  or  $f$  or  $m$ , one or two letters
  - $p$  is periodic
  - $f$  is non-periodic and fixed
  - $s$  is non-periodic and shrink-wrapped
  - $m$  is non-periodic and shrink-wrapped with a minimum value

## 1.10.2 Examples

```
boundary p p f
boundary p fs p
boundary s f fm
```

### 1.10.3 Description

Set the style of boundaries for the global simulation box in each dimension. A single letter assigns the same style to both the lower and upper face of the box. Two letters assigns the first style to the lower face and the second style to the upper face. The initial size of the simulation box is set by the *read\_data*, *read\_restart*, or *create\_box* commands.

The style *p* means the box is periodic, so that particles interact across the boundary, and they can exit one end of the box and re-enter the other end. A periodic dimension can change in size due to constant pressure boundary conditions or box deformation (see the *fix npt* and *fix deform* commands). The *p* style must be applied to both faces of a dimension. For 2d simulations the z dimension must be periodic (which is the default).

The styles *f*, *s*, and *m* mean the box is non-periodic, so that particles do not interact across the boundary and do not move from one side of the box to the other.

For style *f*, the position of the face is fixed. If an atom moves outside the face it will be deleted on the next timestep that reneighboring occurs. This will typically generate an error unless you have set the *thermo\_modify lost* option to allow for lost atoms.

For style *s*, the position of the face is set so as to encompass the atoms in that dimension (shrink-wrapping), no matter how far they move. Note that when the difference between the current box dimensions and the shrink-wrap box dimensions is large, this can lead to lost atoms at the beginning of a run when running in parallel. This is due to the large change in the (global) box dimensions also causing significant changes in the individual subdomain sizes. If these changes are farther than the communication cutoff, atoms will be lost. This is best addressed by setting initial box dimensions to match the shrink-wrapped dimensions more closely, by using *m* style boundaries (see below).

For style *m*, shrink-wrapping occurs, but is bounded by the value specified in the data or restart file or set by the *create\_box* command. For example, if the upper z face has a value of 50.0 in the data file, the face will always be positioned at 50.0 or above, even if the maximum z-extent of all the atoms becomes less than 50.0. This can be useful if you start a simulation with an empty box or if you wish to leave room on one side of the box, e.g. for atoms to evaporate from a surface.

LAMMPS also allows use of triclinic (non-orthogonal) simulation boxes. See the *Howto triclinic* page for a description of both general and restricted triclinic boxes and how to define them. General triclinic boxes (arbitrary edge vectors **A**, **B**, and **C**) are converted internally to restricted triclinic boxes with tilt factors (xy,xz,yz) which skew an otherwise orthogonal box.

The boundary <boundary> command settings explained above for the 6 faces of an orthogonal box also apply in similar manner to the 6 faces of a restricted triclinic box (and thus to the corresponding 6 faces of a general triclinic box), with the following context.

if the second dimension of a tilt factor (e.g. y for xy) is periodic, then the periodicity is enforced with the tilt factor offset. This means that for y periodicity a particle which exits the lower y boundary is displaced in the x-direction by xy before it re-enters the upper y boundary. And vice versa if a particle exits the upper y boundary. Likewise the ghost atoms surrounding a particle near the lower y boundary include images of particles near the upper y-boundary which are displaced in the x-direction by xy. Similar rules apply for z-periodicity and the xz and/or yz tilt factors.

If the first dimension of a tilt factor is shrink-wrapped, then the shrink wrapping is applied to the tilted box face, to encompass the atoms. E.g. for a positive xy tilt, the xlo and xhi faces of the box are planes tilting in the +y direction as y increases. The position of these tilted planes are adjusted dynamically to shrink-wrap around the atoms to determine the xlo and xhi extents of the box.

### 1.10.4 Restrictions

This command cannot be used after the simulation box is defined by a *read\_data* or *create\_box* command or *read\_restart* command. See the *change\_box* command for how to change the simulation box boundaries after it has been defined.

For 2d simulations, the z dimension must be periodic.

### 1.10.5 Related commands

See the *thermo\_modify* command for a discussion of lost atoms.

### 1.10.6 Default

```
boundary p p p
```

## 1.11 change\_box command

### 1.11.1 Syntax

```
change_box group-ID parameter args ... keyword args ...
```

- group-ID = ID of group of atoms to (optionally) displace
- one or more parameter/arg pairs may be appended

parameter = x or y or z or xy or xz or yz or *boundary* or *ortho* or *triclinic* or *set* or *remap*

x, y, z args = style value(s)

style = *final* or *delta* or *scale* or *volume*

*final* values = lo hi

lo hi = box boundaries after displacement (distance units)

*delta* values = dlo dhi

dlo dhi = change in box boundaries after displacement (distance units)

*scale* values = factor

factor = multiplicative factor for change in box length after displacement

*volume* value = none = adjust this dim to preserve volume of system

xy, xz, yz args = style value

style = *final* or *delta*

*final* value = tilt

tilt = tilt factor after displacement (distance units)

*delta* value = dtilt

dtilt = change in tilt factor after displacement (distance units)

*boundary* args = x y z

x,y,z = p or s or f or m, one or two letters

p is periodic

f is non-periodic and fixed

s is non-periodic and shrink-wrapped

m is non-periodic and shrink-wrapped with a minimum value

*ortho* args = none = change box to orthogonal

*triclinic* args = none = change box to triclinic

```
set args = none = store state of current box
remap args = none = remap atom coords from last saved state to current box
```

- zero or more keyword/value pairs may be appended
- keyword = *units*

```
units value = lattice or box
lattice = distances are defined in lattice units
box = distances are defined in simulation box units
```

### 1.11.2 Examples

```
change_box all xy final -2.0 z final 0.0 5.0 boundary p p f remap units box
change_box all x scale 1.1 y volume z volume remap
```

### 1.11.3 Description

Change the volume and/or shape and/or boundary conditions for the simulation box. Orthogonal simulation boxes have 3 adjustable size parameters (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable size/shape parameters (x,y,z,xy,xz,yz). Any or all of them can be adjusted independently by this command. Thus it can be used to expand or contract a box, or to apply a shear strain to a non-orthogonal box. It can also be used to change the boundary conditions for the simulation box, similar to the *boundary* command.

The size and shape of the initial simulation box are specified by the *create\_box* or *read\_data* or *read\_restart* command used to setup the simulation. The size and shape may be altered by subsequent runs, e.g. by use of the *fix npt* or *fix deform* commands. The *create\_box*, *read\_data*, and *read\_restart* commands also determine whether the simulation box is orthogonal or triclinic and their doc pages explain the meaning of the xy,xz,yz tilt factors.

See the *Howto triclinic* page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

The keywords used in this command are applied sequentially to the simulation box and the atoms in it, in the order specified.

Before the sequence of keywords are invoked, the current box size/shape is stored, in case a *remap* keyword is used to map the atom coordinates from a previously stored box size/shape to the current one.

After all the keywords have been processed, any shrink-wrap boundary conditions are invoked (see the *boundary* command) which may change simulation box boundaries, and atoms are migrated to new owning processors.

---

**Note:** This means that you cannot use the *change\_box* command to enlarge a shrink-wrapped box, e.g. to make room to insert more atoms via the *create\_atoms* command, because the simulation box will be re-shrink-wrapped before the *change\_box* command completes. Instead you could do something like this, assuming the simulation box is non-periodic and atoms extend from 0 to 20 in all dimensions:

---

```
change_box all x final -10 20
create_atoms 1 single -5 5 5          # this will fail to insert an atom

change_box all x final -10 20 boundary f s s
create_atoms 1 single -5 5 5
change_box all boundary s s s        # this will work
```

---

**Note:** Unlike the earlier “displace\_box” version of this command, atom remapping is NOT performed by default. This command allows remapping to be done in a more general way, exactly when you specify it (zero or more times) in the sequence of transformations. Thus if you do not use the *remap* keyword, atom coordinates will not be changed even if the box size/shape changes. If a uniformly strained state is desired, the *remap* keyword should be specified.

---

---

**Note:** It is possible to lose atoms with this command. E.g. by changing the box without remapping the atoms, and having atoms end up outside of non-periodic boundaries. It is also possible to alter bonds between atoms straddling a boundary in bad ways. E.g. by converting a boundary from periodic to non-periodic. It is also possible when remapping atoms to put them (nearly) on top of each other. E.g. by converting a boundary from non-periodic to periodic. All of these will typically lead to bad dynamics and/or generate error messages.

---

---

**Note:** The simulation box size/shape can be changed by arbitrarily large amounts by this command. This is not a problem, except that the mapping of processors to the simulation box is not changed from its initial 3d configuration; see the *processors* command. Thus, if the box size/shape changes dramatically, the mapping of processors to the simulation box may not end up as optimal as the initial mapping attempted to be. You may wish to re-balance the atoms by using the *balance* command if that is the case.

---

---

**Note:** You cannot use this command after reading a restart file (and before a run is performed) if the restart file stored per-atom information from a fix and any of the specified keywords change the box size or shape or boundary conditions. This is because atoms may be moved to new processors and the restart info will not migrate with them. LAMMPS will generate an error if this could happen. Only the *ortho* and *triclinic* keywords do not trigger this error. One solution is to perform a “run 0” command before using the *change\_box* command. This clears the per-atom restart data, whether it has been re-assigned to a new fix or not.

---

---

**Note:** Because the keywords used in this command are applied one at a time to the simulation box and the atoms in it, care must be taken with triclinic cells to avoid exceeding the limits on skew after each transformation in the sequence. If skew is exceeded before the final transformation this can be avoided by changing the order of the sequence, or breaking the transformation into two or more smaller transformations. For more information on the allowed limits for box skew see the discussion on triclinic boxes on [Howto triclinic](#) doc page.

---

---

For the *x*, *y*, and *z* parameters, this is the meaning of their styles and values.

For style *final*, the final lo and hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *delta*, plus or minus changes in the lo/hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *scale*, a multiplicative factor to apply to the box length of a dimension is specified. For example, if the initial box length is 10, and the factor is 1.1, then the final box length will be 11. A factor less than 1.0 means compression.

The *volume* style changes the specified dimension in such a way that the overall box volume remains constant with respect to the operation performed by the preceding keyword. The *volume* style can only be used following a keyword that changed the volume, which is any of the *x*, *y*, *z* keywords. If the preceding keyword “key” had a *volume* style, then both it and the current keyword apply to the keyword preceding “key”. I.e. this sequence of keywords is allowed:

```
change_box all x scale 1.1 y volume z volume
```

The *volume* style changes the associated dimension so that the overall box volume is unchanged relative to its value before the preceding keyword was invoked.

If the following command is used, then the z box length will shrink by the same 1.1 factor the x box length was increased by:

```
change_box all x scale 1.1 z volume
```

If the following command is used, then the y,z box lengths will each shrink by  $\sqrt{1.1}$  to keep the volume constant. In this case, the y,z box lengths shrink so as to keep their relative aspect ratio constant:

```
change_box all x scale 1.1 y volume z volume
```

If the following command is used, then the final box will be a factor of 10% larger in x and y, and a factor of 21% smaller in z, so as to keep the volume constant:

```
change_box all x scale 1.1 z volume y scale 1.1 z volume
```

---

**Note:** For solids or liquids, when one dimension of the box is expanded, it may be physically undesirable to hold the other 2 box lengths constant since that implies a density change. For solids, adjusting the other dimensions via the *volume* style may make physical sense (just as for a liquid), but may not be correct for materials and potentials whose Poisson ratio is not 0.5.

---

For the *scale* and *volume* styles, the box length is expanded or compressed around its mid point.

---

For the *xy*, *xz*, and *yz* parameters, this is the meaning of their styles and values. Note that changing the tilt factors of a triclinic box does not change its volume.

For style *final*, the final tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

For style *delta*, a plus or minus change in the tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

All of these styles change the *xy*, *xz*, *yz* tilt factors. In LAMMPS, tilt factors (*xy*,*xz*,*yz*) for triclinic boxes are required to be no more than half the distance of the parallel box length. For example, if *xlo* = 2 and *xhi* = 12, then the x box length is 10 and the *xy* tilt factor must be between -5 and 5. Similarly, both *xz* and *yz* must be between  $-(xhi-xlo)/2$  and  $+(yhi-ylo)/2$ . Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all equivalent. Any tilt factor specified by this command must be within these limits.

---

The *boundary* keyword takes arguments that have exactly the same meaning as they do for the *boundary* command. In each dimension, a single letter assigns the same style to both the lower and upper face of the box. Two letters assigns the first style to the lower face and the second style to the upper face.

The style *p* means the box is periodic; the other styles mean non-periodic. For style *f*, the position of the face is fixed. For style *s*, the position of the face is set so as to encompass the atoms in that dimension (shrink-wrapping), no matter how far they move. For style *m*, shrink-wrapping occurs, but is bounded by the current box edge in that dimension, so that the box will become no smaller. See the *boundary* command for more explanation of these style options.

Note that the “boundary” command itself can only be used before the simulation box is defined via a *read\_data* or *create\_box* or *read\_restart* command. This command allows the boundary conditions to be changed later in your input

script. Also note that the *read\_restart* will change boundary conditions to match what is stored in the restart file. So if you wish to change them, you should use the *change\_box* command after the *read\_restart* command.

---

**Note:** Changing a periodic boundary to a non-periodic one will also cause the image flag for that dimension of all atoms to be reset to 0. LAMMPS will print a warning message, if that happens. Please note that this reset can lead to undesired changes when atoms are involved in bonded interactions that straddle periodic boundaries and thus the values of the image flag differs for those atoms.

---

The *ortho* and *triclinic* keywords convert the simulation box to be orthogonal or triclinic (non-orthogonal).

The simulation box is defined as either orthogonal or triclinic when it is created via the *create\_box*, *read\_data*, or *read\_restart* commands.

These keywords allow you to toggle the existing simulation box from orthogonal to triclinic and vice versa. For example, an initial equilibration simulation can be run in an orthogonal box, the box can be toggled to triclinic, and then a *non-equilibrium MD (NEMD) simulation* can be run with deformation via the *fix deform* command.

If the simulation box is currently triclinic and has non-zero tilt in *xy*, *yz*, or *xz*, then it cannot be converted to an orthogonal box.

---

The *set* keyword saves the current box size/shape. This can be useful if you wish to use the *remap* keyword more than once or if you wish it to be applied to an intermediate box size/shape in a sequence of keyword operations. Note that the box size/shape is saved before any of the keywords are processed, i.e. the box size/shape at the time the *create\_box* command is encountered in the input script.

The *remap* keyword remaps atom coordinates from the last saved box size/shape to the current box state. For example, if you stretch the box in the *x* dimension or tilt it in the *xy* plane via the *x* and *xy* keywords, then the *remap* command will dilate or tilt the atoms to conform to the new box size/shape, as if the atoms moved with the box as it deformed.

Note that this operation is performed without regard to periodic boundaries. Also, any shrink-wrapping of non-periodic boundaries (see the *boundary* command) occurs after all keywords, including this one, have been processed.

Only atoms in the specified group are remapped.

---

The *units* keyword determines the meaning of the distance units used to define various arguments. A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for *units = real* or *metal*. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing.

---

### 1.11.4 Restrictions

If you use the *ortho* or *triclinic* keywords, then at the point in the input script when this command is issued, no *dumps* can be active, nor can a *fix deform* be active. This is because these commands test whether the simulation box is orthogonal when they are first issued. Note that these commands can be used in your script before a *change\_box* command is issued, so long as an *undump* or *unfix* command is also used to turn them off.

### 1.11.5 Related commands

*fix deform*, *boundary*

### 1.11.6 Default

The option default is units = lattice.

## 1.12 clear command

### 1.12.1 Syntax

```
clear
```

### 1.12.2 Examples

```
# (commands for 1st simulation)
clear
# (commands for 2nd simulation)
```

### 1.12.3 Description

This command deletes all atoms, restores all settings to their default values, and frees all memory allocated by LAMMPS. Once a clear command has been executed, it is almost as if LAMMPS were starting over, with only the exceptions noted below. This command enables multiple jobs to be run sequentially from one input script.

These settings are not affected by a clear command: the working directory (*shell* command), log file status (*log* command), echo status (*echo* command), and input script variables except for *atomfile* style variables (*variable* command).

### 1.12.4 Restrictions

none

### 1.12.5 Related commands

none

### 1.12.6 Default

none

## 1.13 comm\_modify command

### 1.13.1 Syntax

```
comm_modify keyword value ...
```

- one or more keyword/value pairs may be appended
- keyword = *mode* or *cutoff* or *cutoff/multi* or *group* or *reduce/multi* or *vel*  
*mode* value = *single*, *multi*, or *multi/old* = communicate atoms within a single or   
→ multiple distances  
*cutoff* value = Rcut (distance units) = communicate atoms from this far away  
*cutoff/multi* collection value  
collection = atom collection or collection range (supports asterisk notation)  
value = Rcut (distance units) = communicate atoms for selected types from this   
→ far away  
*reduce/multi* arg = none = reduce number of communicated ghost atoms for multi style  
*cutoff/multi/old* type value  
type = atom type or type range (supports asterisk notation)  
value = Rcut (distance units) = communicate atoms for selected types from this   
→ far away  
*group* value = group-ID = only communicate atoms in the group  
*vel* value = yes or no = do or do not communicate velocity info with ghost atoms

### 1.13.2 Examples

```
comm_modify mode multi reduce/multi
comm_modify mode multi group solvent
comm_modify mode multi cutoff/multi 1 10.0 cutoff/multi 2*4 15.0
comm_modify vel yes
comm_modify mode single cutoff 5.0 vel yes
comm_modify cutoff/multi * 0.0
```

### 1.13.3 Description

This command sets parameters that affect the inter-processor communication of atom information that occurs each timestep as coordinates and other properties are exchanged between neighboring processors and stored as properties of ghost atoms.

**Note:** These options apply to the currently defined comm style. When you specify a *comm\_style* or *read\_restart* command, all communication settings are restored to their default or stored values, including those previously reset by a *comm\_modify* command. Thus if your input script specifies a *comm\_style* or *read\_restart* command, you should use the *comm\_modify* command after it.

The *mode* keyword determines whether a single or multiple cutoff distances are used to determine which atoms to communicate.

The default mode is *single* which means each processor acquires information for ghost atoms that are within a single distance from its subdomain. The distance is by default the maximum of the neighbor cutoff across all atom type pairs.

For many systems this is an efficient algorithm, but for systems with widely varying cutoffs for different type pairs, the *multi* or *multi/old* mode can be faster. In *multi*, each atom is assigned to a collection which should correspond to a set of atoms with similar interaction cutoffs. See the *neighbor* command for a detailed description of collections. In this case, each atom collection is assigned its own distance cutoff for communication purposes, and fewer atoms will be communicated. In *multi/old*, a similar technique is used but atoms are grouped by atom type. See the *neighbor multi* and *neighbor multi/old* commands for neighbor list construction options that may also be beneficial for simulations of this kind. The *multi* communication mode is only compatible with the *multi* neighbor style. The *multi/old* communication mode is comparable with both the *multi* and *multi/old* neighbor styles.

The *cutoff* keyword allows you to extend the ghost cutoff distance for communication mode *single*, which is the distance from the borders of a processor's subdomain at which ghost atoms are acquired from other processors. By default the ghost cutoff = neighbor cutoff = pairwise force cutoff + neighbor skin. See the *neighbor* command for more information about the skin distance. If the specified *Rcut* is greater than the neighbor cutoff, then extra ghost atoms will be acquired. If the provided cutoff is smaller, the provided value will be ignored, the ghost cutoff is set to the neighbor cutoff and a warning will be printed. Specifying a cutoff value of 0.0 will reset any previous value to the default. If bonded interactions exist and equilibrium bond length information is available, then also a heuristic based on that bond length is computed. It is used as communication cutoff, if there is no pair style present and no *comm\_modify cutoff* command used. Otherwise a warning is printed, if this bond based estimate is larger than the communication cutoff used.

The *cutoff/multi* option is equivalent to *cutoff*, but applies to communication mode *multi* instead. Since the communication cutoffs are determined per atom collections, a collection specifier is needed and cutoff for one or multiple collections can be extended. Also ranges of collections using the usual asterisk notation can be given. Collections are indexed from 1 to N where N is the total number of collections. Note that the arguments for *cutoff/multi* are parsed right before each simulation to account for potential changes in the number of collections. Custom cutoffs are preserved between runs but if collections are redefined, one may want to re-specify the communication cutoffs. For granular pair styles, the default cutoff is set to the sum of the current maximum atomic radii for each collection. The *cutoff/multi/old* option is similar to *cutoff/multi* except it operates on atom types as opposed to collections.

The *reduce/multi* option applies to *multi* and sets the communication cutoff for a particle equal to the maximum interaction distance between particles in the same collection. This reduces the number of ghost atoms that need to be communicated. This method is only compatible with the *multi* neighbor style and requires a half neighbor list and Newton on. See the *neighbor multi* command for more information.

These are simulation scenarios in which it may be useful or even necessary to set a ghost cutoff > neighbor cutoff:

- a single polymer chain with bond interactions, but no pairwise interactions
- bonded interactions (e.g. dihedrals) extend further than the pairwise cutoff
- ghost atoms beyond the pairwise cutoff are needed for some computation

In the first scenario, a pairwise potential is not defined. Thus the pairwise neighbor cutoff will be 0.0. But ghost atoms are still needed for computing bond, angle, etc interactions between atoms on different processors, or when the interaction straddles a periodic boundary.

The appropriate ghost cutoff depends on the *newton bond* setting. For newton bond *off*, the distance needs to be the furthest distance between any two atoms in the bond, angle, etc. E.g. the distance between 1-4 atoms in a dihedral. For newton bond *on*, the distance between the central atom in the bond, angle, etc and any other atom is sufficient. E.g. the distance between 2-4 atoms in a dihedral.

In the second scenario, a pairwise potential is defined, but its neighbor cutoff is not sufficiently long enough to enable bond, angle, etc terms to be computed. As in the previous scenario, an appropriate ghost cutoff should be set.

In the last scenario, a *fix* or *compute* or *pairwise potential* needs to calculate with ghost atoms beyond the normal

pairwise cutoff for some computation it performs (e.g. locate neighbors of ghost atoms in a manybody pair potential). Setting the ghost cutoff appropriately can ensure it will find the needed atoms.

---

**Note:** In these scenarios, if you do not set the ghost cutoff long enough, and if there is only one processor in a periodic dimension (e.g. you are running in serial), then LAMMPS may “find” the atom it is looking for (e.g. the partner atom in a bond), that is on the far side of the simulation box, across a periodic boundary. This will typically lead to bad dynamics (i.e. the bond length is now the simulation box length). To detect if this is happening, see the [neigh\\_modify cluster](#) command.

---

The *group* keyword will limit communication to atoms in the specified group. This can be useful for models where no ghost atoms are needed for some kinds of particles. All atoms (not just those in the specified group) will still migrate to new processors as they move. The group specified with this option must also be specified via the [atom\\_modify first](#) command.

The *vel* keyword enables velocity information to be communicated with ghost particles. Depending on the [atom\\_style](#), velocity info includes the translational velocity, angular velocity, and angular momentum of a particle. If the *vel* option is set to *yes*, then ghost atoms store these quantities; if *no* then they do not. The *yes* setting is needed by some pair styles which require the velocity state of both the I and J particles to compute a pairwise I,J interaction, as well as by some compute and fix commands.

Note that if the [fix deform](#) command is being used with its “remap v” option enabled, then the velocities for ghost atoms (in the fix deform group) mirrored across a periodic boundary will also include components due to any velocity shift that occurs across that boundary (e.g. due to dilation or shear).

### 1.13.4 Restrictions

Communication mode *multi* is currently only available for [comm\\_style brick](#).

### 1.13.5 Related commands

[comm\\_style](#), [neighbor](#)

### 1.13.6 Default

The option defaults are mode = single, group = all, cutoff = 0.0, vel = no. The cutoff default of 0.0 means that ghost cutoff = neighbor cutoff = pairwise force cutoff + neighbor skin.

## 1.14 comm\_style command

### 1.14.1 Syntax

`comm_style style`

- style = *brick* or *tiled*

### 1.14.2 Examples

```
comm_style brick
comm_style tiled
```

### 1.14.3 Description

This command sets the style of inter-processor communication of atom information that occurs each timestep as coordinates and other properties are exchanged between neighboring processors and stored as properties of ghost atoms.

For the default *brick* style, the domain decomposition used by LAMMPS to partition the simulation box must be a regular 3d grid of bricks, one per processor. Each processor communicates with its 6 Cartesian neighbors in the grid to acquire information for nearby atoms.

For the *tiled* style, a more general domain decomposition can be used, as triggered by the *balance* or *fix balance* commands. The simulation box can be partitioned into non-overlapping rectangular-shaped “tiles” or varying sizes and shapes. Again there is one tile per processor. To acquire information for nearby atoms, communication must now be done with a more complex pattern of neighboring processors.

Note that this command does not actually define a partitioning of the simulation box (a domain decomposition), rather it determines what kinds of decompositions are allowed and the pattern of communication used to enable the decomposition. A decomposition is created when the simulation box is first created, via the *create\_box* or *read\_data* or *read\_restart* commands. For both the *brick* and *tiled* styles, the initial decomposition will be the same, as described by *create\_box* and *processors* commands. The decomposition can be changed via the *balance* or *fix balance* commands.

### 1.14.4 Restrictions

none

### 1.14.5 Related commands

*comm\_modify*, *processors*, *balance*, *fix balance*

### 1.14.6 Default

The default style is brick.

## 1.15 compute command

### 1.15.1 Syntax

```
compute ID group-ID style args
```

- ID = user-assigned name for the computation
- group-ID = ID of the group of atoms to perform the computation on
- style = one of a list of possible style names (see below)
- args = arguments used by a particular style

## 1.15.2 Examples

```
compute 1 all temp
compute newtemp flow temp/partial 1 1 0
compute 3 all ke/atom
```

## 1.15.3 Description

Define a diagnostic computation that will be performed on a group of atoms. Quantities calculated by a compute are instantaneous values, meaning they are calculated from information about atoms on the current timestep or iteration, though internally a compute may store some information about a previous state of the system. Defining a compute does not perform the computation. Instead computes are invoked by other LAMMPS commands as needed (e.g., to calculate a temperature needed for a thermostat fix or to generate thermodynamic or dump file output). See the [Howto output](#) page for a summary of various LAMMPS output options, many of which involve computes.

The ID of a compute can only contain alphanumeric characters and underscores.

Computes calculate and store any of four *styles* of quantities: global, per-atom, local, or per-grid.

A global quantity is one or more system-wide values, e.g. the temperature of the system. A per-atom quantity is one or more values per atom, e.g. the kinetic energy of each atom. Per-atom values are set to 0.0 for atoms not in the specified compute group. Local quantities are calculated by each processor based on the atoms it owns, but there may be zero or more per atom, e.g. a list of bond distances. Per-grid quantities are calculated on a regular 2d or 3d grid which overlays a 2d or 3d simulation domain. The grid points and the data they store are distributed across processors; each processor owns the grid points which fall within its subdomain.

As a general rule of thumb, computes that produce per-atom quantities have the word “atom” at the end of their style, e.g. *ke/atom*. Computes that produce local quantities have the word “local” at the end of their style, e.g. *bond/local*. Computes that produce per-grid quantities have the word “grid” at the end of their style, e.g. *property/grid*. And styles with neither “atom” or “local” or “grid” at the end of their style name produce global quantities.

Global, per-atom, local, and per-grid quantities can also be of three *kinds*: a single scalar value (global only), a vector of values, or a 2d array of values. For per-atom, local, and per-grid quantities, a “vector” means a single value for each atom, each local entity (e.g. bond), or grid cell. Likewise an “array”, means multiple values for each atom, each local entity, or each grid cell.

Note that a single compute can produce any combination of global, per-atom, local, or per-grid values. Likewise it can produce any combination of scalar, vector, or array output for each style. The exception is that for per-atom, local, and per-grid output, either a vector or array can be produced, but not both. The doc page for each compute explains the values it produces.

When a compute output is accessed by another input script command it is referenced via the following bracket notation, where ID is the ID of the compute:

c_ID	entire scalar, vector, or array
c_ID[I]	one element of vector, one column of array
c_ID[I][J]	one element of array

In other words, using one bracket reduces the dimension of the quantity once (vector → scalar, array → vector). Using two brackets reduces the dimension twice (array → scalar). Thus, for example, a command that uses global scalar compute values as input can also process elements of a vector or array. Depending on the command, this can either be done directly using the syntax in the table, or by first defining a *variable* of the appropriate style to store the quantity, then using the variable as an input to the command.

Note that commands and *variables* which take compute outputs as input typically do not allow for all styles and kinds of data (e.g., a command may require global but not per-atom values, or it may require a vector of values, not a scalar). This means there is typically no ambiguity about referring to a compute output as `c_ID` even if it produces, for example, both a scalar and vector. The doc pages for various commands explain the details, including how any ambiguities are resolved.

---

In LAMMPS, the values generated by a compute can be used in several ways:

- The results of computes that calculate a global temperature or pressure can be used by fixes that do thermostating or barostating or when atom velocities are created.
- Global values can be output via the *thermo\_style custom* or *fix ave/time* command. Or the values can be referenced in a *variable equal* or *variable atom* command.
- Per-atom values can be output via the *dump custom* command. Or they can be time-averaged via the *fix ave/atom* command or reduced by the *compute reduce* command. Or the per-atom values can be referenced in an *atom-style variable*.
- Local values can be reduced by the *compute reduce* command, or histogrammed by the *fix ave/histo* command, or output by the *dump local* command.

The results of computes that calculate global quantities can be either “intensive” or “extensive” values. Intensive means the value is independent of the number of atoms in the simulation (e.g., temperature). Extensive means the value scales with the number of atoms in the simulation (e.g., total rotational kinetic energy). *Thermodynamic output* will normalize extensive values by the number of atoms in the system, depending on the “thermo\_modify norm” setting. It will not normalize intensive values. If a compute value is accessed in another way (e.g., by a *variable*), you may want to know whether it is an intensive or extensive value. See the page for individual computes for further info.

---

LAMMPS creates its own computes internally for thermodynamic output. Three computes are always created, named “thermo\_temp”, “thermo\_press”, and “thermo\_pe”, as if these commands had been invoked in the input script:

```
compute thermo_temp all temp
compute thermo_press all pressure thermo_temp
compute thermo_pe all pe
```

Additional computes for other quantities are created if the thermo style requires it. See the documentation for the *thermo\_style* command.

Fixes that calculate temperature or pressure, i.e. for thermostating or barostating, may also create computes. These are discussed in the documentation for specific *fix* commands.

In all these cases, the default computes LAMMPS creates can be replaced by computes defined by the user in the input script, as described by the *thermo\_modify* and *fix modify* commands.

Properties of either a default or user-defined compute can be modified via the *compute\_modify* command.

Computes can be deleted with the *uncompute* command.

Code for new computes can be added to LAMMPS; see the *Modify* page for details. The results of their calculations accessed in the various ways described above.

---

Each compute style has its own page which describes its arguments and what it does. Here is an alphabetic list of compute styles available in LAMMPS. They are also listed in more compact form on the *Commands compute* doc page.

There are also additional accelerated compute styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands compute* page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *ackland/atom* - determines the local lattice structure based on the Ackland formulation
- *adf* - angular distribution function of triples of atoms
- *aggregate/atom* - aggregate ID for each atom
- *angle* - energy of each angle sub-style
- *angle/local* - theta and energy of each angle
- *angmom/chunk* - angular momentum for each chunk
- *ave/sphere/atom* - compute local density and temperature around each atom
- *basal/atom* - calculates the hexagonal close-packed “c” lattice vector of each atom
- *body/local* - attributes of body sub-particles
- *bond* - energy of each bond sub-style
- *bond/local* - distance and energy of each bond
- *born/matrix* - second derivative or potential with respect to strain
- *centro/atom* - centro-symmetry parameter for each atom
- *centroid/stress/atom* - centroid based stress tensor for each atom
- *chunk/atom* - assign chunk IDs to each atom
- *chunk/spread/atom* - spreads chunk values to each atom in chunk
- *cluster/atom* - cluster ID for each atom
- *cna/atom* - common neighbor analysis (CNA) for each atom
- *cnp/atom* - common neighborhood parameter (CNP) for each atom
- *com* - center of mass of group of atoms
- *com/chunk* - center of mass for each chunk
- *contact/atom* - contact count for each spherical particle
- *coord/atom* - coordination number for each atom
- *count/type* - count of atoms or bonds by type
- *damage/atom* - Peridynamic damage for each atom
- *dihedral* - energy of each dihedral sub-style
- *dihedral/local* - angle of each dihedral
- *dilatation/atom* - Peridynamic dilatation for each atom
- *dipole* - dipole vector and total dipole
- *dipole/chunk* - dipole vector and total dipole for each chunk
- *dipole/tip4p* - dipole vector and total dipole with TIP4P pair style
- *dipole/tip4p/chunk* - dipole vector and total dipole for each chunk with TIP4P pair style
- *displace/atom* - displacement of each atom
- *dpd* - total values of internal conductive energy, internal mechanical energy, chemical energy, and harmonic average of internal temperature
- *dpd/atom* - per-particle values of internal conductive energy, internal mechanical energy, chemical energy, and internal temperature

- *edpd/temp/atom* - per-atom temperature for each eDPD particle in a group
- *efield/atom* - electric field at each atom
- *efield/wolf/atom* - electric field at each atom
- *entropy/atom* - pair entropy fingerprint of each atom
- *erotate/asphere* - rotational energy of aspherical particles
- *erotate/rigid* - rotational energy of rigid bodies
- *erotate/sphere* - rotational energy of spherical particles
- *erotate/sphere/atom* - rotational energy for each spherical particle
- *event/displace* - detect event on atom displacement
- *fabric* - calculates fabric tensors from pair interactions
- *fep* - compute free energies for alchemical transformation from perturbation theory
- *fep/ta* - compute free energies for a test area perturbation
- *force/tally* - force between two groups of atoms via the tally callback mechanism
- *fragment/atom* - fragment ID for each atom
- *global/atom* - assign global values to each atom from arrays of global values
- *group/group* - energy/force between two groups of atoms
- *gyration* - radius of gyration of group of atoms
- *gyration/chunk* - radius of gyration for each chunk
- *gyration/shape* - shape parameters from gyration tensor
- *gyration/shape/chunk* - shape parameters from gyration tensor for each chunk
- *heat/flux* - heat flux through a group of atoms
- *heat/flux/tally* - heat flux through a group of atoms via the tally callback mechanism
- *heat/flux/virial/tally* - virial heat flux between two groups via the tally callback mechanism
- *hexorder/atom* - bond orientational order parameter q6
- *hma* - harmonically mapped averaging for atomic crystals
- *improper* - energy of each improper sub-style
- *improper/local* - angle of each improper
- *inertia/chunk* - inertia tensor for each chunk
- *ke* - translational kinetic energy
- *ke/atom* - kinetic energy for each atom
- *ke/atom/eff* - per-atom translational and radial kinetic energy in the electron force field model
- *ke/eff* - kinetic energy of a group of nuclei and electrons in the electron force field model
- *ke/rigid* - translational kinetic energy of rigid bodies
- *composition/atom* - local composition for each atom
- *mliap* - gradients of energy and forces with respect to model parameters and related quantities for training machine learning interatomic potentials

- *momentum* - translational momentum
- *msd* - mean-squared displacement of group of atoms
- *msd/chunk* - mean-squared displacement for each chunk
- *msd/nongauss* - MSD and non-Gaussian parameter of group of atoms
- *nbond/atom* - calculates number of bonds per atom
- *omega/chunk* - angular velocity for each chunk
- *orientorder/atom* - Steinhardt bond orientational order parameters Ql
- *pace* - atomic cluster expansion descriptors and related quantities
- *pair* - values computed by a pair style
- *pair/local* - distance/energy/force of each pairwise interaction
- *pe* - potential energy
- *pe/atom* - potential energy for each atom
- *pe/mol/tally* - potential energy between two groups of atoms separated into intermolecular and intramolecular components via the tally callback mechanism
- *pe/tally* - potential energy between two groups of atoms via the tally callback mechanism
- *plasticity/atom* - Peridynamic plasticity for each atom
- *pod/atom* - POD descriptors for each atom
- *podd/atom* - derivative of POD descriptors for each atom
- *pod/local* - local POD descriptors and their derivatives
- *pod/global* - global POD descriptors and their derivatives
- *pressure* - total pressure and pressure tensor
- *pressure/alchemy* - mixed system total pressure and pressure tensor for *fix alchemy* runs
- *pressure/uef* - pressure tensor in the reference frame of an applied flow field
- *property/atom* - convert atom attributes to per-atom vectors/arrays
- *property/chunk* - extract various per-chunk attributes
- *property/grid* - convert per-grid attributes to per-grid vectors/arrays
- *property/local* - convert local attributes to local vectors/arrays
- *ptm/atom* - determines the local lattice structure based on the Polyhedral Template Matching method
- *rattlers/atom* - identify under-coordinated rattler atoms
- *rdf* - radial distribution function  $g(r)$  histogram of group of atoms
- *reaxff/atom* - extract ReaxFF bond information
- *reduce* - combine per-atom quantities into a single global value
- *reduce/chunk* - reduce per-atom quantities within each chunk
- *reduce/region* - same as compute reduce, within a region
- *rheo/property/atom* - convert atom attributes in RHEO package to per-atom vectors/arrays
- *rigid/local* - extract rigid body attributes

- *saed* - electron diffraction intensity on a mesh of reciprocal lattice nodes
- *slcsa/atom* - perform Supervised Learning Crystal Structure Analysis (SL-CSA)
- *slice* - extract values from global vector or array
- *smd/contact/radius* - contact radius for Smooth Mach Dynamics
- *smd/damage* - damage status of SPH particles in Smooth Mach Dynamics
- *smd/hourglass/error* - error associated with approximated relative separation in Smooth Mach Dynamics
- *smd/internal/energy* - per-particle enthalpy in Smooth Mach Dynamics
- *smd/plastic/strain* - equivalent plastic strain per particle in Smooth Mach Dynamics
- *smd/plastic/strain/rate* - time rate of the equivalent plastic strain in Smooth Mach Dynamics
- *smd/rho* - per-particle mass density in Smooth Mach Dynamics
- *smd/tlsph/defgrad* - deformation gradient in Smooth Mach Dynamics
- *smd/tlsph/dt* - CFL-stable time increment per particle in Smooth Mach Dynamics
- *smd/tlsph/num/neighs* - number of particles inside the smoothing kernel radius for Smooth Mach Dynamics
- *smd/tlsph/shape* - current shape of the volume of a particle for Smooth Mach Dynamics
- *smd/tlsph/strain* - Green–Lagrange strain tensor for Smooth Mach Dynamics
- *smd/tlsph/strain/rate* - rate of strain for Smooth Mach Dynamics
- *smd/tlsph/stress* - per-particle Cauchy stress tensor for SPH particles
- *smd/triangle/vertices* - coordinates of vertices corresponding to the triangle elements of a mesh for Smooth Mach Dynamics
- *smd/ulsph/effm* - per-particle effective shear modulus
- *smd/ulsph/num/neighs* - number of neighbor particles inside the smoothing kernel radius for Smooth Mach Dynamics
- *smd/ulsph/strain* - logarithmic strain tensor for Smooth Mach Dynamics
- *smd/ulsph/strain/rate* - logarithmic strain rate for Smooth Mach Dynamics
- *smd/ulsph/stress* - per-particle Cauchy stress tensor and von Mises equivalent stress in Smooth Mach Dynamics
- *smd/vol* - per-particle volumes and their sum in Smooth Mach Dynamics
- *snap* - gradients of SNAP energy and forces with respect to linear coefficients and related quantities for fitting SNAP potentials
- *sna/atom* - bispectrum components for each atom
- *sna/grid* - global array of bispectrum components on a regular grid
- *sna/grid/local* - local array of bispectrum components on a regular grid
- *snad/atom* - derivative of bispectrum components for each atom
- *snav/atom* - virial contribution from bispectrum components for each atom
- *sph/e/atom* - per-atom internal energy of Smooth-Particle Hydrodynamics atoms
- *sph/rho/atom* - per-atom density of Smooth-Particle Hydrodynamics atoms
- *sph/t/atom* - per-atom internal temperature of Smooth-Particle Hydrodynamics atoms
- *spin* - magnetic quantities for a system of atoms having spins

- *stress/atom* - stress tensor for each atom
- *stress/cartesian* - stress tensor in cartesian coordinates
- *stress/cylinder* - stress tensor in cylindrical coordinates
- *stress/mop* - normal components of the local stress tensor using the method of planes
- *stress/mop/profile* - profile of the normal components of the local stress tensor using the method of planes
- *stress/spherical* - stress tensor in spherical coordinates
- *stress/tally* - stress between two groups of atoms via the tally callback mechanism
- *tdpd/cc/atom* - per-atom chemical concentration of a specified species for each tDPD particle
- *temp* - temperature of group of atoms
- *temp/asphere* - temperature of aspherical particles
- *temp/body* - temperature of body particles
- *temp/chunk* - temperature of each chunk
- *temp/com* - temperature after subtracting center-of-mass velocity
- *temp/cs* - temperature based on the center-of-mass velocity of atom pairs that are bonded to each other
- *temp/deform* - temperature excluding box deformation velocity
- *temp/deform/eff* - temperature excluding box deformation velocity in the electron force field model
- *temp/drude* - temperature of Core-Drude pairs
- *temp/eff* - temperature of a group of nuclei and electrons in the electron force field model
- *temp/partial* - temperature excluding one or more dimensions of velocity
- *temp/profile* - temperature excluding a binned velocity profile
- *temp/ramp* - temperature excluding ramped velocity component
- *temp/region* - temperature of a region of atoms
- *temp/region/eff* - temperature of a region of nuclei and electrons in the electron force field model
- *temp/rotate* - temperature of a group of atoms after subtracting out their center-of-mass and angular velocities
- *temp/sphere* - temperature of spherical particles
- *temp/uef* - kinetic energy tensor in the reference frame of an applied flow field
- *ti* - thermodynamic integration free energy values
- *torque/chunk* - torque applied on each chunk
- *vacf* - velocity auto-correlation function of group of atoms
- *vcm/chunk* - velocity of center-of-mass for each chunk
- *viscosity/cos* - velocity profile under cosine-shaped acceleration
- *voronoi/atom* - Voronoi volume and neighbors for each atom
- *xrd* - X-ray diffraction intensity on a mesh of reciprocal lattice nodes

### 1.15.4 Restrictions

none

### 1.15.5 Related commands

*uncompute*, *compute\_modify*, *fix ave/atom*, *fix ave/time*, *fix ave/histo*

### 1.15.6 Default

none

## 1.16 compute\_modify command

### 1.16.1 Syntax

```
compute_modify compute-ID keyword value ...
```

- compute-ID = ID of the compute to modify
- one or more keyword/value pairs may be listed
- keyword = *extra/dof* or *dynamic/dof*

*extra/dof* value = N

N = # of extra degrees of freedom to subtract

*dynamic/dof* value = yes or no

yes/no = do or do not re-compute the number of degrees of freedom (DOF) 

 contributing to the temperature

### 1.16.2 Examples

```
compute_modify myTemp extra/dof 0
compute_modify newtemp dynamic/dof yes extra/dof 600
```

### 1.16.3 Description

Modify one or more parameters of a previously defined compute. Not all compute styles support all parameters.

The *extra/dof* keyword refers to how many degrees of freedom are subtracted (typically from  $3N$ ) as a normalizing factor in a temperature computation. Only computes that compute a temperature use this option. The default is 2 or 3 for *2d or 3d systems* which is a correction factor for an ensemble of velocities with zero total linear momentum. For compute temp/partial, if one or more velocity components are excluded, the value used for *extra/dof* is scaled accordingly. You can use a negative number for the *extra/dof* parameter if you need to add degrees-of-freedom. See the *compute temp/asphere* command for an example.

The *dynamic/dof* keyword determines whether the number of atoms  $N$  in the compute group and their associated degrees of freedom (DOF) are re-computed each time a temperature is computed. Only compute styles that calculate a temperature use this option. By default,  $N$  and their DOF are assumed to be constant. If you are adding atoms or molecules to the system (see the *fix pour*, *fix deposit*, and *fix gcmc* commands) or expect atoms or molecules to be lost

(e.g. due to exiting the simulation box or via *fix evaporate*), then this option should be used to ensure the temperature is correctly normalized.

## 1.16.4 Restrictions

none

## 1.16.5 Related commands

*compute*

## 1.16.6 Default

The option defaults are extra/dof = 2 or 3 for 2d or 3d systems, respectively, and dynamic/dof = *no*.

# 1.17 create\_atoms command

## 1.17.1 Syntax

```
create_atoms type style args keyword values ...
```

- type = atom type (1-Ntypes or type label) of atoms to create (offset for molecule creation)
- style = *box* or *region* or *single* or *mesh* or *random*
  - box* args = none
  - region* args = region-ID
    - region-ID = particles will only be created if contained in the region
  - single* args = x y z
    - x,y,z = coordinates of a single particle (distance units)
  - mesh* args = STL-file
    - STL-file = file with triangle mesh in STL format
  - random* args = N seed region-ID
    - N = number of particles to create
    - seed = random # seed (positive integer)
    - region-ID = create atoms within this region, use NULL for entire simulation box
- zero or more keyword/value pairs may be appended
- keyword = *mol* or *basis* or *ratio* or *subset* or *remap* or *var* or *set* or *radscale* or *meshmode* or *rotate* or *overlap* or *maxtry* or *units*
  - mol* values = template-ID seed
    - template-ID = ID of molecule template specified in a separate *molecule* command
    - seed = random # seed (positive integer)
  - basis* values = M itype
    - M = which basis atom
    - itype = atom type (1-Ntypes or type label) to assign to this basis atom
  - ratio* values = frac seed
    - frac = fraction of lattice sites (0 to 1) to populate randomly
    - seed = random # seed (positive integer)
  - subset* values = Nsubset seed

Nsubset = # of lattice sites to populate randomly  
seed = random # seed (positive integer)  
remap value = yes or no  
var value = name = variable name to evaluate for test of atom creation  
set values = dim name  
dim = x or y or z  
name = name of variable to set with x, y, or z atom position  
radscale value = factor  
factor = scale factor for setting atom radius  
meshmode values = mode arg  
mode = *bisect* or *grand*  
bisect arg = radthresh  
radthresh = threshold value for *mesh* to determine when to split triangles.  
→(distance units)  
grand arg = density  
density = minimum number density for atoms place on *mesh* triangles (inverse.  
→distance squared units)  
rotate values = theta Rx Ry Rz  
theta = rotation angle for single molecule (degrees)  
Rx,Ry,Rz = rotation vector for single molecule  
overlap value = Doverlap  
Doverlap = only insert if at least this distance from all existing atoms  
maxtry value = Ntry  
Ntry = number of attempts to insert a particle before failure  
units value = *lattice* or *box*  
lattice = the geometry is defined in lattice units  
box = the geometry is defined in simulation box units

## 1.17.2 Examples

```
create_atoms 1 box

labelmap atom 1 Pt
create_atoms Pt box

labelmap atom 1 C 2 Si
create_atoms C region regsphere basis Si C

create_atoms 3 region regsphere basis 2 3
create_atoms 3 region regsphere basis 2 3 ratio 0.5 74637
create_atoms 3 single 0 0 5
create_atoms 1 box var v set x xpos set y ypos
create_atoms 2 random 50 12345 NULL overlap 2.0 maxtry 50
create_atoms 1 mesh open_box.stl meshmode grand 0.1 units box
create_atoms 1 mesh funnel.stl meshmode bisect 4.0 units box radscale 0.9
```

### 1.17.3 Description

This command creates atoms (or molecules) within the simulation box, either on a lattice, or at random points, or on a surface defined by a triangulated mesh. Or it creates a single atom (or molecule) at a specified point. It is an alternative to reading in atom coordinates explicitly via a [read\\_data](#) or [read\\_restart](#) command.

To use this command a simulation box must already exist, which is typically created via the [create\\_box](#) command. Before using this command, a lattice must typically also be defined using the [lattice](#) command, unless you specify the *single* or *mesh* style with units = box or the *random* style. To create atoms on a lattice for general triclinic boxes, see the discussion below.

For the remainder of this doc page, a created atom or molecule is referred to as a “particle”.

If created particles are individual atoms, they are assigned the specified atom *type*, though this can be altered via the *basis* keyword as discussed below. If molecules are being created, the type of each atom in the created molecule is specified in a specified file read by the [molecule](#) command, and those values are added to the specified atom *type* (e.g., if *type* = 2 and the file specifies atom types 1, 2, and 3, then each created molecule will have atom types 3, 4, and 5).

---

**Note:** You cannot use this command to create atoms that are outside the simulation box; they will just be ignored by LAMMPS. This is true even if you are using shrink-wrapped box boundaries, as specified by the [boundary](#) command. However, you can first use the [change\\_box](#) command to temporarily expand the box, then add atoms via [create\\_atoms](#), then finally use [change\\_box](#) command again if needed to re-shrink-wrap the new atoms. See the [change\\_box](#) doc page for an example of how to do this, using the [create\\_atoms](#) *single* style to insert a new atom outside the current simulation box.

---

For the *box* style, the [create\\_atoms](#) command fills the entire simulation box with particles on the lattice. If your simulation box is periodic, you should ensure its size is a multiple of the lattice spacings, to avoid unwanted atom overlaps at the box boundaries. If your box is periodic and a multiple of the lattice spacing in a particular dimension, LAMMPS is careful to put exactly one particle at the boundary (on either side of the box), not zero or two.

For the *region* style, a geometric volume is filled with particles on the lattice. This volume is what is both inside the simulation box and also consistent with the region volume. See the [region](#) command for details. Note that a region can be specified so that its “volume” is either inside or outside its geometric boundary. Also note that if a region is the same size as a periodic simulation box (in some dimension), LAMMPS does NOT implement the same logic described above for the *box* style, to ensure exactly one particle at periodic boundaries. If this is desired, you should either use the *box* style, or tweak the region size to get precisely the particles you want.

---

If the simulation box is formulated as a general triclinic box defined by arbitrary edge vectors **A**, **B**, **C**, then the *box* and *region* styles will create atoms on a lattice commensurate with those edge vectors. See the [Howto\\_triclinic](#) doc page for a detailed explanation of orthogonal, restricted triclinic, and general triclinic simulation boxes. As with the [create\\_box](#) command, the [lattice](#) command used by this command must be of style *custom* and use its *triclinic/general* option. The *a1*, *\*a2*, *a3* settings of the [lattice](#) command define the edge vectors of a unit cell of the general triclinic lattice. The [create\\_box](#) command creates a simulation box which replicates that unit cell along each of the **A**, **B**, **C** edge vectors.

---

**Note:** LAMMPS allows specification of general triclinic simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the [Howto\\_triclinic](#) doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box created by the [create\\_box](#) command as well as the atoms created by this command with their per-atom information (e.g. coordinates, velocities) are converted (rotated) from general to restricted triclinic form when

the two commands are invoked. The [Howto\\_triclinic](#) doc page also discusses other LAMMPS commands which can input/output general triclinic representations of the simulation box and per-atom data.

---

The *box* style will fill the entire general triclinic box with particles on the lattice, as explained above.

---

**Note:** The *region* style also operates as explained above, but the check for particles inside the region is performed *after* the particle coordinates have been converted to the restricted triclinic box. This means the region must also be defined with respect to the restricted triclinic box, not the general triclinic box.

---

If the simulation box is general triclinic, the *single*, *random*, and *mesh* styles described next operate on the box *after* it has been converted to restricted triclinic. So all the settings for those styles should be made in that context.

---

For the *single* style, a single particle is added to the system at the specified coordinates. This can be useful for debugging purposes or to create a tiny system with a handful of particles at specified positions. For a 2d simulation the specified z coordinate must be 0.0.

Changed in version 2Jun2022.

The *porosity* style has been renamed to *random* with added functionality.

For the *random* style, *N* particles are added to the system at randomly generated coordinates, which can be useful for generating an amorphous system. For 2d simulations, the z coordinates of all added atoms will be 0.0.

The particles are created one by one using the specified random number *seed*, resulting in the same set of particle coordinates, independent of how many processors are being used in the simulation. Unless the *overlap* keyword is specified, particles created by the *random* style will typically be highly overlapped. Various additional criteria can be used to accept or reject a random particle insertion; see the keyword discussion below. Multiple attempts per particle are made (see the *maxtry* keyword) until the insertion is either successful or fails. If this command fails to add all requested *N* particles, a warning will be output.

If the *region-ID* argument is specified as NULL, then the randomly created particles will be anywhere in the simulation box. If a *region-ID* is specified, a geometric volume is filled that is both inside the simulation box and is also consistent with the region volume. See the *region* command for details. Note that a region can be specified so that its “volume” is either inside or outside its geometric boundary.

Note that the *create\_atoms* command adds particles to those that already exist. This means it can be used to add particles to a system previously read in from a data or restart file. Or the *create\_atoms* command can be used multiple times, to add multiple sets of particles to the simulation. For example, grain boundaries can be created, by interleaving the *create\_atoms* command with *lattice* commands specifying different orientations.

When this command is used, care should be taken to ensure the resulting system does not contain particles that are highly overlapped. Such overlaps will cause many interatomic potentials to compute huge energies and forces, leading to bad dynamics. There are several strategies to avoid this problem:

- Use the *delete\_atoms overlap* command after *create\_atoms*. For example, this strategy can be used to overlay and surround a large protein molecule with a volume of water molecules, then delete water molecules that overlap with the protein atoms.
- For the *random* style, use the optional *overlap* keyword to avoid overlaps when each new particle is created.
- Before running dynamics on an overlapped system, perform an *energy minimization*. Or run initial dynamics with *pair\_style soft* or with *fix nve/limit* to un-overlap the particles, before running normal dynamics.

New in version 2Jun2022.

For the *mesh* style, a file with a triangle mesh in [STL format](#) is read and one or more particles are placed into the area of each triangle. The reader supports

both ASCII and binary files conforming to the format on the Wikipedia page. Binary STL files (e.g. as frequently offered for 3d-printing) can also be first converted to ASCII for editing with the *stl\_bin2txt tool*. The use of the *units box* option is required. There are two algorithms available for placing atoms: *bisect* and *grand*. They can be selected via the *meshmode* option; *bisect* is the default. If the atom style allows it, the radius will be set to a value depending on the algorithm and the value of the *radscale* parameter (see below), and the atoms created from the mesh are assigned a new molecule ID.

In *bisect* mode a particle is created at the center of each triangle unless the average distance of the triangle vertices from its center is larger than the *radthresh* value (default is lattice spacing in x-direction). In case the average distance is over the threshold, the triangle is recursively split into two halves along the the longest side until the threshold is reached. There will be at least one sphere per triangle. The value of *radthresh* is set as an argument to *meshmode bisect*. The average distance of the vertices from the center is also used to set the radius.

In *grand* mode a quasi-random sequence is used to distribute particles on mesh triangles using an approach by (Roberts). Particles are added to the triangle until the minimum number density is met or exceeded such that every triangle will have at least one particle. The minimum number density is set as an argument to the *grand* option. The radius will be set so that the sum of the area of the radius of the particles created in place of a triangle will be equal to the area of that triangle.

---

**Note:** The atom placement algorithms in the *mesh* style benefit from meshes where triangles are close to equilateral. It is therefore recommended to pre-process STL files to optimize the mesh accordingly. There are multiple open source and commercial software tools available with the capability to generate optimized meshes.

---

---

**Note:** In most cases the atoms created in *mesh* style will become an immobile or rigid object that would not be time integrated or moved by *fix move* or *fix rigid*. For computational efficiency *and* to avoid undesired contributions to pressure and potential energy due to close contacts, it is usually beneficial to exclude computing interactions between the created particles using *neigh\_modify exclude*.

---

Individual atoms are inserted by this command, unless the *mol* keyword is used. It specifies a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

---

**Note:** If you are using the *mol* keyword in combination with the *atom style template* command, they must use the same molecule template-ID.

---

Using a lattice to add molecules, e.g. via the *box* or *region* or *single* styles, is exactly the same as adding atoms on lattice points, except that entire molecules are added at each point, i.e. on the point defined by each basis atom in the unit cell as it tiles the simulation box or region. This is done by placing the geometric center of the molecule at the lattice point, and (by default) giving the molecule a random orientation about the point. The random *seed* specified with the *mol* keyword is used for this operation, and the random numbers generated by each processor are different. This means the coordinates of individual atoms (in the molecules) will be different when running on different numbers of processors, unlike when atoms are being created in parallel.

Note that with random rotations, it may be important to use a lattice with a large enough spacing that adjacent molecules will not overlap, regardless of their relative orientations. See the description of the *rotate* keyword below, which overrides the default random orientation and inserts all molecules at a specified orientation.

---

**Note:** If the `create_box` command is used to create the simulation box, followed by the `create_atoms` command with its `mol` option for adding molecules, then you typically need to use the optional keywords allowed by the `create_box` command for extra bonds (angles, etc) or extra special neighbors. This is because by default, the `create_box` command sets up a non-molecular system that does not allow molecules to be added.

---

This is the meaning of the other optional keywords.

The `basis` keyword is only used when atoms (not molecules) are being created. It specifies an atom type that will be assigned to specific basis atoms as they are created. See the `lattice` command for specifics on how basis atoms are defined for the unit cell of the lattice. By default, all created atoms are assigned the argument `type` as their atom type.

The `ratio` and `subset` keywords can be used in conjunction with the `box` or `region` styles to limit the total number of particles inserted. The lattice defines a set of  $N_{lattice}$  eligible sites for inserting particles, which may be limited by the `region` style or the `var` and `set` keywords. For the `ratio` keyword, only the specified fraction of them ( $0 \leq f \leq 1$ ) will be assigned particles. For the `subset` keyword only the specified  $N_{subset}$  of them will be assigned particles. In both cases the assigned lattice sites are chosen randomly. An iterative algorithm is used that ensures the correct number of particles are inserted, in a perfectly random fashion. Which lattice sites are selected will change with the number of processors used.

The `remap` keyword only applies to the `single` style. If it is set to `yes`, then if the specified position is outside the simulation box, it will be mapped back into the box, assuming the relevant dimensions are periodic. If it is set to `no`, no remapping is done and no particle is created if its position is outside the box.

The `var` and `set` keywords can be used together to provide a criterion for accepting or rejecting the addition of an individual atom, based on its coordinates. They apply to all styles except `single`. The `name` specified for the `var` keyword is the name of an `equal-style variable` that should evaluate to a zero or non-zero value based on one or two or three variables that will store the  $x$ ,  $y$ , or  $z$  coordinates of an atom (one variable per coordinate). If used, these other variables must be `internal-style variables` defined in the input script; their initial numeric value can be anything. They must be internal-style variables, because this command resets their values directly. The `set` keyword is used to identify the names of these other variables, one variable for the  $x$ -coordinate of a created atom, one for  $y$ , and one for  $z$ .

When an atom is created, its  $(x, y, z)$  coordinates become the values for any `set` variable that is defined. The `var` variable is then evaluated. If the returned value is 0.0, the atom is not created. If it is non-zero, the atom is created.

As an example, these commands can be used in a 2d simulation, to create a sinusoidal surface. Note that the surface is “rough” due to individual lattice points being “above” or “below” the mathematical expression for the sinusoidal curve. If a finer lattice were used, the sinusoid would appear to be “smoother”. Also note the use of the “`xlat`” and “`ylat`” `thermo_style` keywords, which converts lattice spacings to distance.

```
dimension 2
variable x equal 100
variable y equal 25
lattice hex 0.8442
region box block 0 $x 0 $y -0.5 0.5
create_box 1 box

variable xx internal 0.0
variable yy internal 0.0
```

(continues on next page)

(continued from previous page)

```

variable      v equal "(0.2*v_y*ylat * cos(v_xx/xlat * 2.0*PI*4.0/v_x) + 0.5*v_y*ylat - v_
→yy) > 0.0"
create_atoms  1 box var v set x xx set y yy
write_dump    all atom sinusoid.lammpstrj

```

The *rotate* keyword allows specification of the orientation at which molecules are inserted. The axis of rotation is determined by the rotation vector ( $R_x, R_y, R_z$ ) that goes through the insertion point. The specified *theta* determines the angle of rotation around that axis. Note that the direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand's thumb points along  $R$ , then your fingers wrap around the axis in the direction of rotation.

The *radscale* keyword only applies to the *mesh* style and adjusts the radius of created particles (see above), provided this is supported by the atom style. Its value is a prefactor (must be  $> 0.0$ , default is 1.0) that is applied to the atom radius inferred from the size of the individual triangles in the triangle mesh that the particle corresponds to.

New in version 2Jun2022.

The *overlap* keyword only applies to the *random* style. It prevents newly created particles from being created closer than the specified *Doverlap* distance from any other particle. If particles have finite size (see *atom\_style sphere* for example) *Doverlap* should be specified large enough to include the particle size in the non-overlapping criterion. If molecules are being randomly inserted, then an insertion is only accepted if each particle in the molecule meets the overlap criterion with respect to other particles (not including particles in the molecule itself).

**Note:** Checking for overlaps is a costly  $\mathcal{O}(N(N + M))$  operation for inserting  $N$  new particles into a system with  $M$  existing particles. This is because distances to all  $M$  existing particles are computed for each new particle that is added. Thus the intended use of this keyword is to add relatively small numbers of particles to systems that remain at a relatively low density even after the new particles are created. Careful use of the *maxtry* keyword in combination with *overlap* is recommended. See the discussion above about systems with overlapped particles for alternate strategies that allow for overlapped insertions.

New in version 2Jun2022.

The *maxtry* keyword only applies to the *random* style. It limits the number of attempts to generate valid coordinates for a single new particle that satisfy all requirements imposed by the *region*, *var*, and *overlap* keywords. The default is 10 attempts per particle before the loop over the requested  $N$  particles advances to the next particle. Note that if insertion success is unlikely (e.g., inserting new particles into a dense system using the *overlap* keyword), setting the *maxtry* keyword to a large value may result in this command running for a long time.

Here is an example for the *random* style using these commands

```

units          lj
dimension      2
region         box block 0 50 0 50 -0.5 0.5
create_box     1 box
create_atoms   1 random 2000 13487 NULL overlap 1.0 maxtry 50
pair_style     lj/cut 2.5
pair_coeff      1 1 1.0 1.0 2.5

```

to produce a system as shown in the image with 1520 particles (out of 2000 requested) that are moderately dense and which have no overlaps sufficient to prevent the LJ pair\_style from running properly (because the overlap criterion is 1.0). The create\_atoms command ran for 0.3 s on a single CPU core.

The *units* keyword determines the meaning of the distance units used by parameters for various styles. A *box* value selects standard distance units as defined by the *units* command (e.g., Å for units = *real* or *metal*). A *lattice* value means the distance units are in lattice spacings. These are affected settings:

- for *single* style: coordinates of the particle created
- for *random* style: overlap distance *Doverlap* by the *overlap* keyword
- for *mesh* style: *bisect* threshold value for *meshmode* = *bisect*
- for *mesh* style: *radthresh* value for *meshmode* = *bisect*
- for *mesh* style: *density* value for *meshmode* = *grand*

Since *density* represents an area (distance <sup>2</sup>), the lattice spacing factor is also squared.

---

Atom IDs are assigned to created atoms in the following way. The collection of created atoms are assigned consecutive IDs that start immediately following the largest atom ID existing before the *create\_atoms* command was invoked. This is done by the processor's communicating the number of atoms they each own, the first processor numbering its atoms from 1 to  $N_1$ , the second processor from  $N_1 + 1$  to  $N_2$ , and so on, where  $N_1$  is the number of atoms owned by the first processor,  $N_2$  is the number owned by the second processor, and so forth. Thus, when the same simulation is performed on different numbers of processors, there is no guarantee a particular created atom will be assigned the same ID in both simulations. If molecules are being created, molecule IDs are assigned to created molecules in a similar fashion.

Aside from their ID, atom type, and xyz position, other properties of created atoms are set to default values, depending on which quantities are defined by the chosen *atom style*. See the *atom style* command for more details. See the *set* and *velocity* commands for info on how to change these values.

- charge = 0.0
- dipole moment magnitude = 0.0
- diameter = 1.0
- shape = 0.0 0.0 0.0
- density = 1.0
- volume = 1.0
- velocity = 0.0 0.0 0.0
- angular velocity = 0.0 0.0 0.0
- angular momentum = 0.0 0.0 0.0
- quaternion = (1,0,0,0)
- bonds, angles, dihedrals, impropers = none

If molecules are being created, these defaults can be overridden by values specified in the file read by the *molecule* command. That is, the file typically defines bonds (angles, etc.) between atoms in the molecule, and can optionally define charges on each atom.

Note that the *sphere* atom style sets the default particle diameter to 1.0 as well as the density. This means the mass for the particle is not 1.0, but is  $\frac{\pi}{6}d^3 = 0.5236$ , where  $d$  is the diameter. When using the *mesh* style, the particle diameter is adjusted from the size of the individual triangles in the triangle mesh.

Note that the *ellipsoid* atom style sets the default particle shape to (0.0 0.0 0.0) and the density to 1.0, which means it is a point particle, not an ellipsoid, and has a mass of 1.0.

Note that the *peri* style sets the default volume and density to 1.0 and thus also set the mass for the particle to 1.0.

The *set* command can be used to override many of these default settings.

### 1.17.4 Restrictions

An *atom\_style* must be previously defined to use this command.

A rotation vector specified for a single molecule must be in the z-direction for a 2d model.

For *molecule templates* that are created from multiple files, i.e. contain multiple molecule *sets*, only the first set is used. To create multiple molecules the files currently need to be merged and different molecule IDs assigned with a Molecules section.

### 1.17.5 Related commands

*lattice*, *region*, *create\_box*, *read\_data*, *read\_restart*

### 1.17.6 Default

The default for the *basis* keyword is that all created atoms are assigned the argument *type* as their atom type (when single atoms are being created). The other defaults are *remap* = no, *rotate* = random, *radscale* = 1.0, *radthresh* = x-lattice spacing, *overlap* not checked, *maxtry* = 10, and *units* = lattice.

## 1.18 create\_bonds command

### 1.18.1 Syntax

```
create_bonds style args ... keyword value ...
```

- style = *many* or *single/bond* or *single/angle* or *single/dihedral* or *single/improper*

*many* args = group-ID group2-ID btype rmin rmax

group-ID = ID of first group

group2-ID = ID of second group, bonds will be between atoms in the 2 groups

btype = bond type of created bonds

rmin = minimum distance between pair of atoms to bond together

rmax = maximum distance between pair of atoms to bond together

*single/bond* args = btype batom1 batom2

btype = bond type of new bond

batom1, batom2 = atom IDs for two atoms in bond

*single/angle* args = atype aatom1 aatom2 aatom3

atype = angle type of new angle

aatom1, aatom2, aatom3 = atom IDs for three atoms in angle

*single/dihedral* args = dtype datom1 datom2 datom3 datom4

dtype = dihedral type of new dihedral

datom1, datom2, datom3, datom4 = atom IDs for four atoms in dihedral

*single/improper* args = itype iatom1 iatom2 iatom3 iatom4

itype = improper type of new improper  
iatom1,iatom2,iatom3,iatom4 = atom IDs for four atoms in improper

- zero or more keyword/value pairs may be appended
- keyword = *special*

*special* value = *yes* or *no*

## 1.18.2 Examples

```
create_bonds many all all 1 1.0 1.2
create_bonds many surf solvent 3 2.0 2.4
create_bonds single/bond 1 1 2
create_bonds single/angle 5 52 98 107 special no
create_bonds single/dihedral 2 4 19 27 101
create_bonds single/improper 3 23 26 31 57
```

## 1.18.3 Description

Create bonds between pairs of atoms that meet a specified distance criteria. Or create a single bond, angle, dihedral or improper between 2, 3, or 4 specified atoms.

The new bond (angle, dihedral, improper) interactions will then be computed during a simulation by the bond (angle, dihedral, improper) potential defined by the *bond\_style*, *bond\_coeff*, *angle\_style*, *angle\_coeff*, *dihedral\_style*, *dihedral\_coeff*, *improper\_style*, *improper\_coeff* commands.

The *many* style is useful for adding bonds to a system (e.g., between nearest neighbors in a lattice of atoms) without having to enumerate all the bonds in the data file read by the *read\_data* command.

The *single* styles are useful for adding bonds, angles, dihedrals, and impropers to a system incrementally, then continuing a simulation.

Note that this command does not auto-create any angle, dihedral, or improper interactions when a bond is added, nor does it auto-create any bonds when an angle, dihedral, or improper is added. It also will not auto-create any angles when a dihedral or improper is added. Thus, the flexibility of this command is limited. It can be used several times to create different types of bond at different distances, but it cannot typically auto-create all the bonds or angles or dihedrals or impropers that would normally be defined in a data file for a complex system of molecules.

---

**Note:** If the system has no bonds (angles, dihedrals, impropers) to begin with, or if more bonds per atom are being added than currently exist, then you must ensure that the number of bond types and the maximum number of bonds per atom are set to large enough values, and similarly for angles, dihedrals, impropers, and special neighbors, otherwise an error may occur when too many bonds (angles, dihedrals, impropers) are added to an atom. If the *read\_data* command is used to define the system, these parameters can be set via its optional *extra/bond/types*, *extra/bond/per/atom*, and similar keywords to the command. If the *create\_box* command is used to define the system, these two parameters can be set via its optional *bond/types* and *extra/bond/per/atom* arguments, and similarly for angles, dihedrals, and impropers. See the corresponding documentation pages for these two commands for details.

---

The *many* style will create bonds between pairs of atoms  $I, J$ , where  $I$  is in one of the two specified groups and  $J$  is in the other. The two groups can be the same (e.g., group “all”). The created bonds will be of bond type *btype*, where *btype* must be a value between 1 and the number of bond types defined.

For a bond to be created, an  $I, J$  pair of atoms must be a distance  $D$  apart such that  $r_{\min} \leq D \leq r_{\max}$ .

The following settings must have been made in an input script before the *many* style is used:

- `special_bonds` weight for 1–2 interactions must be 0.0
- a *pair\_style* must be defined
- no *kpace\_style* defined
- minimum *pair\_style* cutoff + *neighbor* skin  $\geq r_{\max}$

These settings are required so that a neighbor list can be created to search for nearby atoms. Pairs of atoms that are already bonded cannot appear in the neighbor list, to avoid creation of duplicate bonds. The neighbor list for all atom type pairs must also extend to a distance that encompasses the *rmax* for new bonds to create. When using periodic boundary conditions, the box length in each periodic dimension must be larger than *rmax*, so that no bonds are created between the system and its own periodic image.

---

**Note:** If you want to create bonds between pairs of 1–3 or 1–4 atoms in the current bond topology, then you need to use *special\_bonds lj 0 1 1* to ensure those pairs appear in the neighbor list. They will not appear with the default `special_bonds` settings, which are zero for 1–2, 1–3, and 1–4 atoms. 1–3 or 1–4 atoms are those which are two hops or three hops apart in the bond topology.

---

An additional requirement for this style is that your system must be ready to perform a simulation. This means, for example, that all *pair\_style* coefficients be set via the *pair\_coeff* command. A *bond\_style* command and all bond coefficients must also be set, even if no bonds exist before this command is invoked. This is because the building of neighbor list requires initialization and setup of a simulation, similar to what a *run* command would require.

Note that you can change any of these settings after this command executes (e.g., if you wish to use long-range Coulombic interactions) via the *kpace\_style* command for your subsequent simulation.

---

The *single/bond* style creates a single bond of type *btype* between two atoms with IDs *batom1* and *batom2*. *Btype* must be a value between 1 and the number of bond types defined.

The *single/angle* style creates a single angle of type *atype* between three atoms with IDs *aatom1*, *aatom2*, and *aatom3*. The ordering of the atoms is the same as in the *Angles* section of a data file read by the *read\_data* command (i.e., the three atoms are ordered linearly within the angle; the central atom is *aatom2*). *Atype* must be a value between 1 and the number of angle types defined.

The *single/dihedral* style creates a single dihedral of type *dtype* between four atoms with IDs *datom1*, *datom2*, *datom3*, and *datom4*. The ordering of the atoms is the same as in the *Dihedrals* section of a data file read by the *read\_data* command. I.e. the 4 atoms are ordered linearly within the dihedral. *dtype* must be a value between 1 and the number of dihedral types defined.

The *single/improper* style creates a single improper of type *itype* between four atoms with IDs *iatom1*, *iatom2*, *iatom3*, and *iatom4*. The ordering of the atoms is the same as in the *Impropers* section of a data file read by the *read\_data* command. I.e. the 4 atoms are ordered linearly within the improper. *itype* must be a value between 1 and the number of improper types defined.

---

The keyword *special* controls whether an internal list of special bonds is created after one or more bonds, or a single angle, dihedral, or improper is added to the system.

The default value is *yes*. A value of *no* cannot be used with the *many* style.

This is an expensive operation since the bond topology for the system must be walked to find all 1–2, 1–3, and 1–4 interactions to store in an internal list, which is used when pairwise interactions are weighted; see the *special\_bonds* command for details.

Thus if you are adding a few bonds or a large list of angles all at the same time, by using this command repeatedly, it is more efficient to only trigger the internal list to be created once, after the last bond (or angle, or dihedral, or improper) is added:

```
create_bonds single/bond 5 52 98 special no
create_bonds single/bond 5 73 74 special no
...
create_bonds single/bond 5 17 386 special no
create_bonds single/bond 4 112 183 special yes
```

Note that you **must** ensure the internal list is rebuilt after the last bond (angle, dihedral, improper) is added, *before* performing a simulation. Otherwise, pairwise interactions will not be properly excluded or weighted. LAMMPS does **not** check that you have done this correctly.

---

## 1.18.4 Restrictions

This command cannot be used with molecular systems defined using molecule template files via the *molecule* and *atom\_style template* commands.

For style *many*, no *kpace style* must be defined. Also, the *rmax* value must be smaller than any periodic box length and the neighbor list cutoff (largest pair cutoff plus neighbor skin).

## 1.18.5 Related commands

## 1.19.3 Description

This command creates a simulation box. It also partitions the box into a regular 3d grid of smaller sub-boxes, one per processor (MPI task). The geometry of the partitioning is based on the size and shape of the simulation box, the number of processors being used and the settings of the *processors* command. The partitioning can later be changed by the *balance* or *fix balance* commands.

Simulation boxes in LAMMPS can be either orthogonal or triclinic in shape. Orthogonal boxes are a brick in 3d (rectangle in 2d) with 6 faces that are each perpendicular to one of the standard xyz coordinate axes. Triclinic boxes are a parallelepiped in 3d (parallelogram in 2d) with opposite pairs of faces parallel to each other. LAMMPS supports two forms of triclinic boxes, restricted and general, which differ in how the box is oriented with respect to the xyz coordinate axes. See the *Howto triclinic* for a detailed description of all 3 kinds of simulation boxes.

The argument *N* is the number of atom types that will be used in the simulation.

Orthogonal and restricted triclinic boxes are created by specifying a region ID previously defined by the *region* command. General triclinic boxes are discussed below.

If the region is not of style *prism*, then LAMMPS encloses the region (block, sphere, etc.) with an axis-aligned orthogonal bounding box which becomes the simulation domain. For a 2d simulation, the *zlo* and *zhi* values of the simulation box must straddle zero.

If the region is of style *prism*, LAMMPS creates a non-orthogonal simulation domain shaped as a parallelepiped with triclinic symmetry. As defined by the *region prism* command, the parallelepiped has an “origin” at (*xlo*, *ylo*, *zlo*) and three edge vectors starting from the origin given by  $\vec{a} = (x_{hi} - x_{lo}, 0, 0)$ ;  $\vec{b} = (xy, y_{hi} - y_{lo}, 0)$ ; and  $\vec{c} = (xz, yz, z_{hi} - z_{lo})$ . In LAMMPS lingo, this is a restricted triclinic box because the three edge vectors cannot be defined in arbitrary (general) directions. The parameters *xy*, *xz*, and *yz* can be 0.0 or positive or negative values and are called “tilt factors”

because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped. For a 2d simulation, the *zlo* and *zhi* values of the simulation box must straddle zero.

Typically a *prism* region used with the *create\_box* command should have tilt factors (*xy*, *xz*, *yz*) that do not skew the box more than half the distance of the parallel box length. For example, if  $x_{lo} = 2$  and  $x_{hi} = 12$ , then the *x* box length is 10 and the *xy* tilt factor must be between  $-5$  and  $5$ . Similarly, both *xz* and *yz* must be between  $-(x_{hi} - x_{lo})/2$  and  $+(y_{hi} - y_{lo})/2$ . Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt =  $\dots, -15, -5, 5, 15, 25, \dots$  are all geometrically equivalent.

LAMMPS will issue a warning if the tilt factors of the created box do not meet this criterion. This is because simulations with large tilt factors may run inefficiently, since they require more ghost atoms and thus more communication. With very large tilt factors, LAMMPS may eventually produce incorrect trajectories and stop with errors due to lost atoms or similar issues.

See the [Howto triclinic](#) page for geometric descriptions of triclinic boxes and tilt factors, as well as how to transform the restricted triclinic parameters to and from other commonly used triclinic representations.

When a prism region is used, the simulation domain should normally be periodic in the dimension that the tilt is applied to, which is given by the second dimension of the tilt factor (e.g., *y* for *xy* tilt). This is so that pairs of atoms interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the *boundary* command. For example, if the *xy* tilt factor is non-zero, then the *y* dimension should be periodic. Similarly, the *z* dimension should be periodic if *xz* or *yz* is non-zero. LAMMPS does not require this periodicity, but you may lose atoms if this is not the case.

Note that if your simulation will tilt the box (e.g., via the *fix deform* command), the simulation box must be created as triclinic, even if the tilt factors are initially 0.0. You can also change an orthogonal box to a triclinic box or vice versa by using the *change box* command with its *ortho* and *triclinic* options.

---

**Note:** If the system is non-periodic (in a dimension), then you should not make the lo/hi box dimensions (as defined in your *region* command) radically smaller/larger than the extent of the atoms you eventually plan to create (e.g., via the *create\_atoms* command). For example, if your atoms extend from 0 to 50, you should not specify the box bounds as  $-10000$  and  $10000$ . This is because as described above, LAMMPS uses the specified box size to lay out the 3d grid of processors. A huge (mostly empty) box will be sub-optimal for performance when using “fixed” boundary conditions (see the *boundary* command). When using “shrink-wrap” boundary conditions (see the *boundary* command), a huge (mostly empty) box may cause a parallel simulation to lose atoms the first time that LAMMPS shrink-wraps the box around the atoms.

---

As noted above, general triclinic boxes in LAMMPS allow the box to have arbitrary edge vectors **A**, **B**, **C**. The only restrictions are that the three vectors be distinct, non-zero, and not co-planar. They must also define a right-handed system such that  $(\mathbf{A} \times \mathbf{B})$  points in the direction of **C**. Note that a left-handed system can be converted to a right-handed system by simply swapping the order of any pair of the **A**, **B**, **C** vectors.

To create a general triclinic boxes, the region is specified as *NULL* and the next 6 parameters (*alo*, *ahi*, *blo*, *bhi*, *clo*, *chi*) define the three edge vectors **A**, **B**, **C** using additional information previously defined by the *lattice* command.

The lattice must be of style *custom* and use its *triclinic/general* option. This insures the lattice satisfies the restrictions listed above. The *a1*, *\*a2*, *a3* settings of the *lattice* command define the edge vectors of a unit cell of the general triclinic lattice. This command uses them to define the three edge vectors and origin of the general triclinic box as:

- $\mathbf{A} = (\text{ahi} - \text{alo}) * a1$
- $\mathbf{B} = (\text{bhi} - \text{blo}) * a2$
- $\mathbf{C} = (\text{chi} - \text{clo}) * a3$
- $\text{origin} = (\text{alo} * a1 + \text{blo} * a2 + \text{clo} * a3)$

For 2d general triclinic boxes,  $\text{clo} = -0.5$  and  $\text{chi} = 0.5$  is required.

---

**Note:** LAMMPS allows specification of general triclinic simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the [Howto\\_triclinic](#) doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box defined by this command and per-atom information (e.g. coordinates, velocities) defined by the [create\\_atoms](#) command are converted (rotated) from general to restricted triclinic form when the two commands are invoked. The [Howto\\_triclinic](#) doc page also discusses other LAMMPS commands which can input/output general triclinic representations of the simulation box and per-atom data.

---

The optional keywords can be used to create a system that allows for bond (angle, dihedral, improper) interactions, or for molecules with special 1–2, 1–3, or 1–4 neighbors to be added later. These optional keywords serve the same purpose as the analogous keywords that can be used in a data file which are recognized by the [read\\_data](#) command when it sets up a system.

Note that if these keywords are not used, then the `create_box` command creates an atomic (non-molecular) simulation that does not allow bonds between pairs of atoms to be defined, or a [bond potential](#) to be specified, or for molecules with special neighbors to be added to the system by commands such as [create\\_atoms mol](#), [fix deposit](#) or [fix pour](#).

As an example, see the `examples/deposit/in.deposit.molecule` script, which deposits molecules onto a substrate. Initially there are no molecules in the system, but they are added later by the [fix deposit](#) command. The `create_box` command in the script uses the `bond/types` and `extra/bond/per/atom` keywords to allow this. If the added molecule contained more than one special bond (allowed by default), an `extra/special/per/atom` keyword would also need to be specified.

---

## 1.19.4 Restrictions

An [atom\\_style](#) and [region](#) must have been previously defined to use this command.

# 1.20 delete\_atoms command

## 1.20.1 Syntax

`delete_atoms style args keyword value ...`

- `style` = *group* or *region* or *overlap* or *random* or *variable*

```
group args = group-ID
region args = region-ID
overlap args = cutoff group1-ID group2-ID
  cutoff = delete one atom from pairs of atoms within the cutoff (distance units)
  group1-ID = one atom in pair must be in this group
  group2-ID = other atom in pair must be in this group
random args = ranstyle value eflag group-ID region-ID seed
  ranstyle = fraction or count
  for fraction:
    value = fraction (0.0 to 1.0) of eligible atoms to delete
    eflag = no for fast approximate deletion, yes for exact deletion
  for count:
    value = number of atoms to delete
    eflag = no for warning if count > eligible atoms, yes for error
group-ID = group within which to perform deletions
region-ID = region within which to perform deletions
             or NULL to only impose the group criterion
seed = random number seed (positive integer)
variable args = variable-name
```

- zero or more keyword/value pairs may be appended
- keyword = *compress* or *bond* or *mol*

```
compress value = no or yes
bond value = no or yes
mol value = no or yes
```

## 1.20.2 Examples

```

delete_atoms region sphere compress no
delete_atoms overlap 0.3 all all
delete_atoms overlap 0.5 solvent colloid
delete_atoms random fraction 0.1 yes all cube 482793 bond yes
delete_atoms random fraction 0.3 no polymer NULL 482793 bond yes
delete_atoms random count 500 no ions NULL 482793
delete_atoms variable checkers
```

## 1.20.3 Description

Delete the specified atoms. This command can be used, for example, to carve out voids from a block of material or to delete created atoms that are too close to each other (e.g., at a grain boundary).

For style *group*, all atoms belonging to the group are deleted.

For style *region*, all atoms in the region volume are deleted. Additional atoms can be deleted if they are in a molecule for which one or more atoms were deleted within the region; see the *mol* keyword discussion below.

For style *overlap* pairs of atoms whose distance of separation is within the specified cutoff distance are searched for, and one of the two atoms is deleted. Only pairs where one of the two atoms is in the first group specified and the other atom is in the second group are considered. The atom that is in the first group is the one that is deleted.

Note that it is OK for the two group IDs to be the same (e.g., group *all*), or for some atoms to be members of both groups. In these cases, either atom in the pair may be deleted. Also note that if there are atoms which are members of both

groups, the only guarantee is that at the end of the deletion operation, enough deletions will have occurred that no atom pairs within the cutoff will remain (subject to the group restriction). There is no guarantee that the minimum number of atoms will be deleted, or that the same atoms will be deleted when running on different numbers of processors.

For style *random* a subset of eligible atoms are deleted. Which atoms to delete are chosen randomly using the specified random number *seed*. Which atoms are deleted may vary when running on different numbers of processors.

For *ranstyle = fraction*, the specified fractional *value* (0.0 to 1.0) of eligible atoms are deleted. If *eflag* is set to *no*, then the number of deleted atoms will be approximate, but the operation will be fast. If *eflag* is set to *yes*, then the number deleted will match the requested fraction, but for large systems the selection of deleted atoms may take additional time to determine.

For *ranstyle = count*, the specified integer *value* is the number of eligible atoms are deleted. If *eflag* is set to *no*, then if the requested number is larger then the number of eligible atoms, a warning is issued and only the eligible atoms are deleted instead of the requested *value*. If *eflag* is set to *yes*, an error is triggered instead and LAMMPS will exit. For large systems the selection of atoms to delete may take additional time to determine, the same as for requesting an exact fraction with *pstyle = fraction*.

Which atoms are eligible for deletion for style *random* is determined by the specified *group-ID* and *region-ID*. To be eligible, an atom must be in both the specified group and region. If *group-ID = all*, there is effectively no group criterion. If *region-ID* is specified as NULL, no region criterion is imposed.

New in version 4May2022.

For style *variable*, all atoms for which the atom-style variable with the given name evaluates to non-zero will be deleted. Additional atoms can be deleted if they are in a molecule for which one or more atoms were deleted within the region; see the *mol* keyword discussion below. This option allows complex selections of atoms not covered by the other options listed above.

---

Here is the meaning of the optional keywords.

If the *compress* keyword is set to *yes*, then after atoms are deleted, then atom IDs are re-assigned so that they run from 1 to the number of atoms in the system. Note that this is not done for molecular systems (see the *atom\_style* command), regardless of the *compress* setting, since it would foul up the bond connectivity that has already been assigned. However, the *reset\_atoms id* command can be used after this command to accomplish the same thing.

Note that the re-assignment of IDs is not really a compression, where gaps in atom IDs are removed by decrementing atom IDs that are larger. Instead the IDs for all atoms are erased, and new IDs are assigned so that the atoms owned by individual processors have consecutive IDs, as the *create\_atoms* command explains.

A molecular system with fixed bonds, angles, dihedrals, or improper interactions, is one where the topology of the interactions is typically defined in the data file read by the *read\_data* command, and where the interactions themselves are defined with the *bond\_style*, *angle\_style*, etc. commands. If you delete atoms from such a system, you must be careful not to end up with bonded interactions that are stored by remaining atoms but which include deleted atoms. This will cause LAMMPS to generate a “missing atoms” error when the bonded interaction is computed. The *bond* and *mol* keywords offer two ways to do that.

If the *bond* keyword is set to *yes* then any bond or angle or dihedral or improper interaction that includes a deleted atom is also removed from the lists of such interactions stored by non-deleted atoms. Note that simply deleting interactions due to dangling bonds (e.g., at a surface) may result in an inaccurate or invalid model for the remaining atoms.

If the *mol* keyword is set to *yes*, then for every atom that is deleted, all other atoms in the same molecule (with the same molecule ID) will also be deleted. This is not done for atoms with molecule ID = 0, since such an ID is assumed to flag isolated atoms that are not part of molecules.

---

**Note:** The molecule deletion operation is invoked after all individual atoms have been deleted using the rules described above for each style. This means additional atoms may be deleted that are not in the group or region, that are not required

by the overlap cutoff criterion, or that will create a higher fraction of porosity than was requested.

---

## 1.20.4 Restrictions

The *overlap* styles requires inter-processor communication to acquire ghost atoms and build a neighbor list. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses set, etc.). Since a neighbor list is used to find overlapping atom pairs, it also means that you must define a *pair style* with the minimum force cutoff distance between any pair of atoms types (plus the *neighbor* skin)  $\geq$  the specified overlap cutoff.

If the *special\_bonds* command is used with a setting of 0, then a pair of bonded atoms (1-2, 1-3, or 1-4) will not appear in the neighbor list, and thus will not be considered for deletion by the *overlap* styles. You probably do not want to delete one atom in a bonded pair anyway.

The *bond yes* option cannot be used with molecular systems defined using molecule template files via the *molecule* and *atom\_style template* commands.

## 1.20.5 Related commands

*create\_atoms*, *reset\_atoms id*

## 1.20.6 Default

The option defaults are compress = yes, bond = no, mol = no.

# 1.21 delete\_bonds command

## 1.21.1 Syntax

**delete\_bonds** group-ID style arg keyword ...

- group-ID = group ID
- style = *multi* or *atom* or *bond* or *angle* or *dihedral* or *improper* or *stats*

*multi* arg = none

*atom* arg = an atom type or range of types (see below)

*bond* arg = a bond type or range of types (see below)

*angle* arg = an angle type or range of types (see below)

*dihedral* arg = a dihedral type or range of types (see below)

*improper* arg = an improper type or range of types (see below)

*stats* arg = none

- zero or more keywords may be appended
- keyword = *any* or *undo* or *remove* or *special*

*any* arg = none = turn off interactions if any atoms are in the group (or on if *undo* ↪ is also used)

*undo* arg = none = turn specified bonds on instead of off

*remove* arg = permanently remove bonds that have been turned off

*special* arg = recompute pairwise 1-2, 1-3, and 1-4 lists

## 1.21.2 Examples

```
delete_bonds frozen multi remove
delete_bonds all atom 4 special
delete_bonds all bond 0*3 special
delete_bonds all stats

labelmap atom 4 hc
delete_bonds all atom hc special
```

## 1.21.3 Description

Turn off (or on) molecular topology interactions (i.e., bonds, angles, dihedrals, and/or impropers). This command is useful for deleting interactions that have been previously turned off by bond-breaking potentials. It is also useful for turning off topology interactions between frozen or rigid atoms. Pairwise interactions can be turned off via the *neigh\_modify exclude* command. The *fix shake* command also effectively turns off certain bond and angle interactions.

For all styles, by default, an interaction is only turned off (or on) if all the atoms involved are in the specified group. See the *any* keyword to change the behavior.

Several of the styles (*atom*, *bond*, *angle*, *dihedral*, *improper*) take a *type* as an argument. The specified *type* can be a *type label*. Otherwise, the type should be an integer from 0 to  $N$ , where  $N$  is the number of relevant types (atom types, bond types, etc.). A value of 0 is only relevant for style *bond*; see details below. For numeric types, a wildcard asterisk can be used in place of or in conjunction with the *type* argument to specify a range of types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the number of types, then an asterisk with no numeric values means all types from 0 to  $N$ . A leading asterisk means all types from 0 to  $n$  (inclusive). A trailing asterisk means all types from  $m$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive). Note that it is fine to include a type of 0 for non-bond styles; it will simply be ignored.

For style *multi* all bond, angle, dihedral, and improper interactions of any type, involving atoms in the group, are turned off.

Style *atom* is the same as style *multi* except that in addition, one or more of the atoms involved in the bond, angle, dihedral, or improper interaction must also be of the specified atom type.

For style *bond*, only bonds are candidates for turn-off, and the bond must also be of the specified type. Styles *angle*, *dihedral*, and *improper* are treated similarly.

For style *bond*, you can set the type to 0 to delete bonds that have been previously broken by a bond-breaking potential (which sets the bond type to 0 when a bond is broken); for example, see the *bond\_style quartic* command.

For style *stats* no interactions are turned off (or on); the status of all interactions in the specified group is simply reported. This is useful for diagnostic purposes if bonds have been turned off by a bond-breaking potential during a previous run.

The default behavior of the *delete\_bonds* command is to turn off interactions by toggling their type to a negative value, but not to permanently remove the interaction. For example, a *bond\_type* of 2 is set to  $-2$ . The neighbor list creation routines will not include such an interaction in their interaction lists. The default is also to not alter the list of 1–2, 1–3, or 1–4 neighbors computed by the *special\_bonds* command and used to weight pairwise force and energy calculations. This means that pairwise computations will proceed as if the bond (or angle, etc.) were still turned on.

Several keywords can be appended to the argument list to alter the default behaviors.

The *any* keyword changes the requirement that all atoms in the bond (angle, etc.) must be in the specified group in order to turn off the interaction. Instead, if any of the atoms in the interaction are in the specified group, it will be turned off (or on if the *undo* keyword is used).

The *undo* keyword inverts the *delete\_bonds* command so that the specified bonds, angles, etc. are turned on if they are currently turned off. This means a negative value is toggled to positive. For example, for style *angle*, if *type* is specified

as 2, then all angles with current type = -2 are reset to type = 2. Note that the *fix shake* command also sets bond and angle types negative, so this option should not be used on those interactions.

The *remove* keyword is invoked at the end of the `delete_bonds` operation. It causes turned-off bonds (angles, etc.) to be removed from each atom's data structure and then adjusts the global bond (angle, etc.) counts accordingly. Removal is a permanent change; removed bonds cannot be turned back on via the *undo* keyword. Removal does not alter the pairwise 1-2, 1-3, or 1-4 weighting list.

The *special* keyword is invoked at the end of the `delete_bonds` operation, after (optional) removal. It re-computes the pairwise 1-2, 1-3, 1-4 weighting list. The weighting list computation treats turned-off bonds the same as turned-on. Thus, turned-off bonds must be removed if you wish to change the weighting list.

Note that the choice of *remove* and *special* options affects how 1-2, 1-3, 1-4 pairwise interactions will be computed across bonds that have been modified by the `delete_bonds` command.

### 1.21.4 Restrictions

This command requires inter-processor communication to acquire ghost atoms, to coordinate the deleting of bonds, angles, etc. between atoms shared by multiple processors. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses set, etc.). Just as would be needed to run dynamics, the force field you define should define a cutoff (e.g., through a *pair\_style* command) which is long enough for a processor to acquire the ghost atoms its needs to compute bond, angle, etc. interactions.

If deleted bonds (or angles, etc.) are removed but the 1-2, 1-3, and 1-4 weighting list is not recomputed, this can cause a later *fix shake* command to fail due to an atom's bonds being inconsistent with the weighting list. This should only happen if the group used in the *fix* command includes both atoms in the bond, in which case you probably should be recomputing the weighting list.

## 1.22 dielectric command

### 1.22.1 Syntax

**dielectric** value

- value = dielectric constant

## 1.22.2 Examples

```
dielectric 2.0
```

## 1.22.3 Description

Set the dielectric constant for Coulombic interactions (pairwise and long-range) to this value. The constant is unitless, since it is used to reduce the strength of the interactions. The value is used in the denominator of the formulas for Coulombic interactions (e.g., a value of 4.0 reduces the Coulombic interactions to 25% of their default strength). See the *pair\_style* command for more details.

## 1.22.4 Restrictions

none

## 1.22.5 Related commands

*pair\_style*

## 1.22.6 Default

```
dielectric 1.0
```

# 1.23 dihedral\_coeff command

## 1.23.1 Syntax

```
dihedral_coeff N args
```

- N = numeric dihedral type (see asterisk form below) or alphanumeric type label
- args = coefficients for one or more dihedral types

## 1.23.2 Examples

```
dihedral_coeff 1 80.0 1 3
dihedral_coeff * 80.0 1 3 0.5
dihedral_coeff 2* 80.0 1 3 0.5

labelmap dihedral 1 backbone
dihedral_coeff backbone 80.0 1 3
```

### 1.23.3 Description

Specify the dihedral force field coefficients for one or more dihedral types. The number and meaning of the coefficients depends on the dihedral style. Dihedral coefficients can also be set in the data file read by the [read\\_data](#) command or in a restart file.

$N$  can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or  $N$  can be an alphanumeric type label, which is a string defined by the [labelmap](#) command or in a corresponding section of a data file read by the [read\\_data](#) command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple dihedral types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If  $N$  is the number of dihedral types, then an asterisk with no numeric values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $n$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive).

Note that using a `dihedral_coeff` command can override a previous setting for the same dihedral type. For example, these commands set the coeffs for all dihedral types, then overwrite the coeffs for just dihedral type 2:

```
dihedral_coeff * 80.0 1 3
dihedral_coeff 2 200.0 1 3
```

A line in a data file that specifies dihedral coefficients uses the exact same format as the arguments of the `dihedral_coeff` command in an input script, except that wild-card asterisks should not be used since coefficients for all  $N$  types must be listed in the file. For example, under the “Dihedral Coeffs” section of a data file, the line that corresponds to the first example above would be listed as

```
1 80.0 1 3
```

The [dihedral\\_style class2](#) is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

---

**Note:** When comparing the formulas and coefficients for various LAMMPS dihedral styles with dihedral equations defined by other force fields, note that some force field implementations divide/multiply the energy prefactor  $K$  by the multiple number of torsions that contain the  $J$ – $K$  bond in an  $I$ – $J$ – $K$ – $L$  torsion. LAMMPS does not do this (i.e., the listed dihedral equation applies to each individual dihedral). Thus, you need to define  $K$  appropriately to account for this difference, if necessary.

---

The list of all dihedral styles defined in LAMMPS is given on the [dihedral\\_style](#) doc page. They are also listed in more compact form on the [Commands dihedral](#) doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated `dihedral_coeff` command.

---

### 1.23.4 Restrictions

This command must come after the simulation box is defined by a *read\_data*, *read\_restart*, or *create\_box* command. A dihedral style must be defined before any dihedral coefficients are set, either in the input script or in a data file.

### 1.23.5 Related commands

*dihedral\_style*

### 1.23.6 Default

none

## 1.24 dihedral\_style command

### 1.24.1 Syntax

```
dihedral_style style
```

- style = *none* or *zero* or *hybrid* or *charmm* or *charmmfsw* or *class2* or *cosine/shift/exp* or *cosine/squared/restricted* or *fourier* or *harmonic* or *helix* or *lepton* or *multi/harmonic* or *nharmonic* or *opls* or *spherical* or *table* or *table/cut*

### 1.24.2 Examples

```
dihedral_style harmonic
dihedral_style multi/harmonic
dihedral_style hybrid harmonic charmm
```

### 1.24.3 Description

Set the formula(s) LAMMPS uses to compute dihedral interactions between quadruplets of atoms, which remain in force for the duration of the simulation. The list of dihedral quadruplets is read in by a *read\_data* or *read\_restart* command from a data or restart file.

Hybrid models where dihedrals are computed using different dihedral potentials can be setup using the *hybrid* dihedral style.

The coefficients associated with a dihedral style can be specified in a data or restart file or via the *dihedral\_coeff* command.

All dihedral potentials store their coefficient data in binary restart files which means *dihedral\_style* and *dihedral\_coeff* commands do not need to be re-specified in an input script that restarts a simulation. See the *read\_restart* command for details on how to do this. The one exception is that *dihedral\_style hybrid* only stores the list of sub-styles in the restart file; dihedral coefficients need to be re-specified.

---

**Note:** When both a dihedral and pair style is defined, the *special\_bonds* command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between four bonded atoms.

---

In the formulas listed for each dihedral style,  $\phi$  is the torsional angle defined by the quadruplet of atoms. This angle has a sign convention as shown in this diagram:

where the  $I, J, K, L$  ordering of the four atoms that define the dihedral is from left to right.

This sign convention effects several of the dihedral styles listed below (e.g., charmm, helix) in the sense that the energy formula depends on the sign of  $\phi$ , which may be reflected in the value of the coefficients you specify.

---

**Note:** When comparing the formulas and coefficients for various LAMMPS dihedral styles with dihedral equations defined by other force fields, note that some force field implementations divide/multiply the energy prefactor  $K$  by the multiple number of torsions that contain the  $J$ - $K$  bond in an  $I$ - $J$ - $K$ - $L$  torsion. LAMMPS does not do this (i.e., the listed dihedral equation applies to each individual dihedral). Thus, you need to define  $K$  appropriately via the `dihedral_coeff` command to account for this difference if necessary.

---

Here is an alphabetic list of dihedral styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated `dihedral_coeff` command.

Click on the style to display the formula it computes, any additional arguments specified in the `dihedral_style` command, and coefficients specified by the associated `dihedral_coeff` command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the [Commands dihedral](#) page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- [none](#) - turn off dihedral interactions
- [zero](#) - topology but no interactions
- [hybrid](#) - define multiple styles of dihedral interactions
- [charmm](#) - CHARMM dihedral
- [charmmfsw](#) - CHARMM dihedral with force switching
- [class2](#) - COMPASS (class 2) dihedral
- [cosine/shift/exp](#) - dihedral with exponential in spring constant
- [cosine/squared/restricted](#) - squared cosine dihedral with restricted term
- [fourier](#) - dihedral with multiple cosine terms
- [harmonic](#) - harmonic dihedral
- [helix](#) - helix dihedral
- [lepton](#) - dihedral potential from evaluating a string
- [multi/harmonic](#) - dihedral with 5 harmonic terms
- [nharmonic](#) - same as multi-harmonic with N terms
- [opls](#) - OPLS dihedral

- *quadratic* - dihedral with quadratic term in angle
  - *spherical* - dihedral which includes angle terms to avoid singularities
  - *table* - tabulated dihedral
  - *table/cut* - tabulated dihedral with analytic cutoff
- 

### 1.24.4 Restrictions

Dihedral styles can only be set for atom styles that allow dihedrals to be defined.

Most dihedral styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info. The doc pages for individual dihedral potentials tell if it is part of a package.

### 1.24.5 Related commands

*dihedral\_coeff*

### 1.24.6 Default

dihedral\_style none

## 1.25 dihedral\_write command

### 1.25.1 Syntax

```
dihedral_write dtype N file keyword
```

- dtype = dihedral type
- N = # of values
- file = name of file to write values to
- keyword = section name in file for this set of tabulated values

### 1.25.2 Examples

```
dihedral_write 1 500 table.txt Harmonic_1
dihedral_write 3 1000 table.txt Harmonic_3
```

### 1.25.3 Description

New in version 8Feb2023.

Write energy and force values to a file as a function of the dihedral angle for the currently defined dihedral potential. Force in this context means the force with respect to the dihedral angle, not the force on individual atoms. This is useful for plotting the potential function or otherwise debugging its values. The resulting file can also be used as input for use with *dihedral style table*.

If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. The individual sections may be identified by the *keyword*.

The energy and force values are computed for dihedrals ranging from 0 degrees to 360 degrees for 4 interacting atoms forming an dihedral type dtype, using the appropriate *dihedral\_coeff* coefficients. N evenly spaced dihedrals are used. Since 0 and 360 degrees are the same dihedral angle, the latter entry is skipped.

For example, for N = 6, values would be computed at  $\phi = 0, 60, 120, 180, 240, 300$ .

The file is written in the format used as input for the *dihedral\_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), an dihedral angle (in degrees), an energy (in energy units), and a force (in force units per radians<sup>2</sup>). In case a new file is created, the first line will be a comment with a “DATE:” and “UNITS:” tag with the current date and *units* settings. For subsequent invocations of the *dihedral\_write* command for the same file, data will be appended and the current units settings will be compared to the data from the header, if present. The *dihedral\_write* will refuse to add a table to an existing file if the units are not the same.

### 1.25.4 Restrictions

All force field coefficients for dihedrals and other kinds of interactions must be set before this command can be invoked.

The table of the dihedral energy and force data is created by using a separate, internally created, new LAMMPS instance with a dummy system of 4 atoms for which the dihedral potential energy is computed after transferring the dihedral style and coefficients and arranging the 4 atoms into the corresponding geometries. The dihedral force is then determined from the potential energies through numerical differentiation. As a consequence of this approach, not all dihedral styles are compatible. The following conditions must be met:

- The dihedral style must be able to write its coefficients to a data file. This condition excludes for example *dihedral style hybrid* and *dihedral style table*.
- The potential function must not have any terms that depend on geometry properties other than the dihedral. This condition excludes for example *dihedral style class2*. Please note that the *write\_dihedral* command has no way of checking for this condition. It will check the style name against an internal list of known to be incompatible styles. The resulting tables may be bogus for unlisted dihedral styles if the requirement is not met. It is thus recommended to make careful tests for any created tables.

### 1.25.5 Related commands

*dihedral\_style table*, *bond\_write*, *angle\_write*, *dihedral\_style*, *dihedral\_coeff*

### 1.25.6 Default

none

## 1.26 dimension command

### 1.26.1 Syntax

```
dimension N
```

- N = 2 or 3

### 1.26.2 Examples

```
dimension 2
```

### 1.26.3 Description

Set the dimensionality of the simulation. By default LAMMPS runs 3d simulations. To run a 2d simulation, this command should be used prior to setting up a simulation box via the [create\\_box](#) or [read\\_data](#) commands. Restart files also store this setting.

See the discussion on the [Howto 2d](#) page for additional instructions on how to run 2d simulations.

---

**Note:** Some models in LAMMPS treat particles as finite-size spheres or ellipsoids, as opposed to point particles. In 2d, the particles will still be spheres or ellipsoids, not circular disks or ellipses, meaning their moment of inertia will be the same as in 3d.

---

### 1.26.4 Restrictions

This command must be used before the simulation box is defined by a [read\\_data](#) or [create\\_box](#) command.

### 1.26.5 Related commands

*fix enforce2d*

### 1.26.6 Default

```
dimension 3
```

## 1.27 displace\_atoms command

### 1.27.1 Syntax

```
displace_atoms group-ID style args keyword value ...
```

- group-ID = ID of group of atoms to displace
- style = *move* or *ramp* or *random* or *rotate*
  - move* args = delx dely delz  
delx,dely,delz = distance to displace in each dimension (distance units)  
any of delx,dely,delz can be a variable (see below)
  - ramp* args = ddim dlo dhi dim clo chi  
ddim = x or y or z  
dlo,dhi = displacement distance between dlo and dhi (distance units)  
dim = x or y or z  
clo,chi = lower and upper bound of domain to displace (distance units)
  - random* args = dx dy dz seed  
dx,dy,dz = random displacement magnitude in each dimension (distance units)  
seed = random # seed (positive integer)
  - rotate* args = Px Py Pz Rx Ry Rz theta  
Px,Py,Pz = origin point of axis of rotation (distance units)  
Rx,Ry,Rz = axis of rotation vector  
theta = angle of rotation (degrees)
- zero or more keyword/value pairs may be appended
  - keyword = *units*  
units value = *box* or *lattice*

### 1.27.2 Examples

```
displace_atoms top move 0 -5 0 units box
displace_atoms flow ramp x 0.0 5.0 y 2.0 20.5
```

### 1.27.3 Description

Displace a group of atoms. This can be used to move atoms a large distance before beginning a simulation or to randomize atoms initially on a lattice. For example, in a shear simulation, an initial strain can be imposed on the system. Or two groups of atoms can be brought into closer proximity.

The *move* style displaces the group of atoms by the specified 3d displacement vector. Any of the three quantities defining the vector components can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v\_name, where name is the variable name. In this case, the variable will be evaluated, and its value(s) used for the displacement(s). The scale factor implied by the *units* keyword will also be applied to the variable result.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates or per-atom values read from a file. Note that if the variable references other *compute* or *fix* commands, those values must be up-to-date for the current timestep. See the “Variable Accuracy” section of the *variable* doc page for more details.

The *ramp* style displaces atoms a variable amount in one dimension depending on the atom's coordinate in a (possibly) different dimension. For example, the second example command displaces atoms in the  $x$ -direction an amount between 0.0 and 5.0 distance units. Each atom's displacement depends on the fractional distance its  $y$  coordinate is between 2.0 and 20.5. Atoms with  $y$ -coordinates outside those bounds will be moved the minimum (0.0) or maximum (5.0) amount.

The *random* style independently moves each atom in the group by a random displacement, uniformly sampled from a value between  $-dx$  and  $+dx$  in the  $x$  dimension, and similarly for  $y$  and  $z$ . Random numbers are used in such a way that the displacement of a particular atom is the same, regardless of how many processors are being used.

The *rotate* style rotates each atom in the group by the angle *theta* around a rotation axis  $R = (R_x, R_y, R_z)$  that goes through a point  $P = (P_x, P_y, P_z)$ . The direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along  $R$ , then your fingers wrap around the axis in the direction of positive *theta*.

If the defined *atom\_style* assigns an orientation to each atom (*atom styles* ellipsoid, line, tri, body), then that property is also updated appropriately to correspond to the atom's rotation.

Distance units for displacements and the origin point of the *rotate* style are determined by the setting of *box* or *lattice* for the *units* keyword. *Box* means distance units as defined by the *units* command (e.g., Å for *real* or *metal* units). *Lattice* means distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing.

---

**Note:** Care should be taken not to move atoms on top of other atoms. After the move, atoms are remapped into the periodic simulation box if needed, and any shrink-wrap boundary conditions (see the *boundary* command) are enforced which may change the box size. Other than this effect, this command does not change the size or shape of the simulation box. See the *change\_box* command if that effect is desired.

---

---

**Note:** Atoms can be moved arbitrarily long distances by this command. If the simulation box is non-periodic and shrink-wrapped (see the *boundary* command), this can change its size or shape. This is not a problem, except that the mapping of processors to the simulation box is not changed by this command from its initial 3d configuration; see the *processors* command. Thus, if the box size/shape changes dramatically, the mapping of processors to the simulation box may not end up as optimal as the initial mapping attempted to be.

---

## 1.27.4 Restrictions

For a 2d simulation, only rotations around the a vector parallel to the  $z$ -axis are allowed.

## 1.27.5 Related commands

*lattice*, *change\_box*, *fix move*

## 1.27.6 Default

The option defaults are units = lattice.

## 1.28 dynamical\_matrix command

Accelerator Variant: dynamical\_matrix/kk

### 1.28.1 Syntax

```
dynamical_matrix group-ID style gamma args keyword value ...
```

- group-ID = ID of group of atoms to displace
- style = *regular* or *eskm*
- gamma = finite different displacement length (distance units)
- one or more keyword/arg pairs may be appended

keyword = *file* or *binary*

*file* name = name of output file for the dynamical matrix

*binary* arg = *yes* or *no* or *gzip*

### 1.28.2 Examples

```
dynamical_matrix 1 regular 0.000001  
dynamical_matrix 1 eskm 0.000001  
dynamical_matrix 3 regular 0.00004 file dynmat.dat  
dynamical_matrix 5 eskm 0.00000001 file dynamical.dat binary yes
```

### 1.28.3 Description

Calculate the dynamical matrix by finite difference of the selected group,

$$D = \frac{\Phi_{ij}^{\alpha\beta}}{\sqrt{M_i M_j}}$$

where D is the dynamical matrix and  $\Phi$  is the force constant matrix defined by

$$\Phi_{ij}^{\alpha\beta} = \frac{\partial^2 U}{\partial x_{i,\alpha} \partial x_{j,\beta}}$$

The output for the dynamical matrix is printed three elements at a time. The three elements are the three  $\beta$  elements for a respective  $i/\alpha/j$  combination. Each line is printed in order of  $j$  increasing first,  $\alpha$  second, and  $i$  last.

If the style *eskm* is selected, the dynamical matrix will be in units of inverse squared femtoseconds. These units will then conveniently leave frequencies in THz.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#)

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 1.28.4 Restrictions

The command collects an array of nine times the number of atoms in a group on every single MPI rank, so the memory requirements can be very significant for large systems.

This command is part of the PHONON package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 1.28.5 Related commands

*fix phonon*, *fix numdiff*,

*compute hma* uses an analytic formulation of the Hessian provided by a pair\_style's Pair::single\_hessian() function, if implemented.

## 1.28.6 Default

The default settings are file = "dynmat.dyn", binary = no

# 1.29 echo command

## 1.29.1 Syntax

```
echo style
```

- style = *none* or *screen* or *log* or *both*

## 1.29.2 Examples

```
echo both
echo log
```

### 1.29.3 Description

This command determines whether LAMMPS echoes each input script command to the screen and/or log file as it is read and processed. If an input script has errors, it can be useful to look at echoed output to see the last command processed.

The *command-line switch* `-echo` can be used in place of this command.

### 1.29.4 Restrictions

none

### 1.29.5 Related commands

none

### 1.29.6 Default

```
echo log
```

## 1.30 fix command

### 1.30.1 Syntax

```
fix ID group-ID style args
```

- ID = user-assigned name for the fix
- group-ID = ID of the group of atoms to apply the fix to
- style = one of a long list of possible style names (see below)
- args = arguments used by a particular style

### 1.30.2 Examples

```
fix 1 all nve  
fix 3 all nvt temp 300.0 300.0 0.01  
fix mine top setforce 0.0 NULL 0.0
```

### 1.30.3 Description

Set a fix that will be applied to a group of atoms. In LAMMPS, a “fix” is any operation that is applied to the system during timestepping or minimization. Examples include updating of atom positions and velocities due to time integration, controlling temperature, applying constraint forces to atoms, enforcing boundary conditions, computing diagnostics, etc. There are hundreds of fixes defined in LAMMPS and new ones can be added; see the [Modify](#) page for details.

Fixes perform their operations at different stages of the timestep. If two or more fixes operate at the same stage of the timestep, they are invoked in the order they were specified in the input script.

The ID of a fix can only contain alphanumeric characters and underscores.

Fixes can be deleted with the [unfix](#) command.

---

**Note:** The [unfix](#) command is the only way to turn off a fix; simply specifying a new fix with a similar style will not turn off the first one. This is especially important to realize for integration fixes. For example, using a [fix nve](#) command for a second run after using a [fix nvt](#) command for the first run will not cancel out the NVT time integration invoked by the “fix nvt” command. Thus, two time integrators would be in place!

---

If you specify a new fix with the same ID and style as an existing fix, the old fix is deleted and the new one is created (presumably with new settings). This is the same as if an “unfix” command were first performed on the old fix, except that the new fix is kept in the same order relative to the existing fixes as the old one originally was. Note that this operation also wipes out any additional changes made to the old fix via the [fix\\_modify](#) command.

The [fix\\_modify](#) command allows settings for some fixes to be reset. See the page for individual fixes for details.

Some fixes store an internal “state” which is written to binary restart files via the [restart](#) or [write\\_restart](#) commands. This allows the fix to continue on with its calculations in a restarted simulation. See the [read\\_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file. See the doc pages for individual fixes for info on which ones can be restarted.

---

Some fixes calculate and store any of four *styles* of quantities: global, per-atom, local, or per-grid.

A global quantity is one or more system-wide values, e.g. the energy of a wall interacting with particles. A per-atom quantity is one or more values per atom, e.g. the original coordinates of each atom at time 0. Per-atom values are set to 0.0 for atoms not in the specified fix group. Local quantities are calculated by each processor based on the atoms it owns, but there may be zero or more per atom, e.g. values for each bond. Per-grid quantities are calculated on a regular 2d or 3d grid which overlays a 2d or 3d simulation domain. The grid points and the data they store are distributed across processors; each processor owns the grid points which fall within its subdomain.

As a general rule of thumb, fixes that produce per-atom quantities have the word “atom” at the end of their style, e.g. [ave/atom](#). Fixes that produce local quantities have the word “local” at the end of their style, e.g. [store/local](#). Fixes that produce per-grid quantities have the word “grid” at the end of their style, e.g. [ave/grid](#).

Global, per-atom, local, and per-grid quantities can also be of three *kinds*: a single scalar value (global only), a vector of values, or a 2d array of values. For per-atom, local, and per-grid quantities, a “vector” means a single value for each atom, each local entity (e.g. bond), or grid cell. Likewise an “array”, means multiple values for each atom, each local entity, or each grid cell.

Note that a single fix can produce any combination of global, per-atom, local, or per-grid values. Likewise it can produce any combination of scalar, vector, or array output for each style. The exception is that for per-atom, local, and per-grid output, either a vector or array can be produced, but not both. The doc page for each fix explains the values it produces, if any.

When a fix output is accessed by another input script command it is referenced via the following bracket notation, where ID is the ID of the fix:

f_ID	entire scalar, vector, or array
f_ID[I]	one element of vector, one column of array
f_ID[I][J]	one element of array

In other words, using one bracket reduces the dimension of the quantity once (vector  $\rightarrow$  scalar, array  $\rightarrow$  vector). Using two brackets reduces the dimension twice (array  $\rightarrow$  scalar). Thus, for example, a command that uses global scalar fix values as input can also process elements of a vector or array. Depending on the command, this can either be done directly using the syntax in the table, or by first defining a *variable* of the appropriate style to store the quantity, then using the variable as an input to the command.

Note that commands and *variables* which take fix outputs as input typically do not allow for all styles and kinds of data (e.g., a command may require global but not per-atom values, or it may require a vector of values, not a scalar). This means there is typically no ambiguity about referring to a fix output as c\_ID even if it produces, for example, both a scalar and vector. The doc pages for various commands explain the details, including how any ambiguities are resolved.

---

In LAMMPS, the values generated by a fix can be used in several ways:

- Global values can be output via the *thermo\_style custom* or *fix ave/time* command. Alternatively, the values can be referenced in an *equal-style variable* command.
- Per-atom values can be output via the *dump custom* command, or they can be time-averaged via the *fix ave/atom* command or reduced by the *compute reduce* command. Alternatively, per-atom values can be referenced in an *atom-style variable*.
- Local values can be reduced by the *compute reduce* command or histogrammed by the *fix ave/histo* command. They can also be output by the *dump local* command.

See the *Howto output* page for a summary of various LAMMPS output options, many of which involve fixes.

The results of fixes that calculate global quantities can be either “intensive” or “extensive” values. Intensive means the value is independent of the number of atoms in the simulation (e.g., temperature). Extensive means the value scales with the number of atoms in the simulation (e.g., total rotational kinetic energy). *Thermodynamic output* will normalize extensive values by the number of atoms in the system, depending on the “thermo\_modify norm” setting. It will not normalize intensive values. If a fix value is accessed in another way (e.g., by a *variable*), you may want to know whether it is an intensive or extensive value. See the page for individual fix styles for further info.

---

Each fix style has its own page that describes its arguments and what it does, as listed below. Here is an alphabetical list of fix styles available in LAMMPS. They are also listed in more compact form on the *Commands fix* doc page.

There are also additional accelerated fix styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the *Commands fix* doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- *accelerate/cos* - apply cosine-shaped acceleration to atoms
- *acks2/reaxff* - apply ACKS2 charge equilibration
- *adapt* - change a simulation parameter over time
- *adapt/fep* - enhanced version of fix adapt
- *addforce* - add a force to each atom
- *add/heat* - add a heat flux to each atom
- *addtorque* - add a torque to a group of atoms
- *alchemy* - perform an “alchemical transformation” between two partitions

- *amoeba/bitorsion* - torsion/torsion terms in AMOEBA force field
- *amoeba/pitorsion* - 6-body terms in AMOEBA force field
- *append/atoms* - append atoms to a running simulation
- *atc* - initiates a coupled MD/FE simulation
- *atom/swap* - Monte Carlo atom type swapping
- *ave/atom* - compute per-atom time-averaged quantities
- *ave/chunk* - compute per-chunk time-averaged quantities
- *ave/correlate* - compute/output time correlations
- *ave/correlate/long* - alternative to *ave/correlate* that allows efficient calculation over long time windows
- *ave/grid* - compute per-grid time-averaged quantities
- *ave/histo* - compute/output time-averaged histograms
- *ave/histo/weight* - weighted version of fix ave/histo
- *ave/time* - compute/output global time-averaged quantities
- *aveforce* - add an averaged force to each atom
- *balance* - perform dynamic load-balancing
- *brownian* - overdamped translational brownian motion
- *brownian/asphere* - overdamped translational and rotational brownian motion for ellipsoids
- *brownian/sphere* - overdamped translational and rotational brownian motion for spheres
- *bocs* - NPT style time integration with pressure correction
- *bond/break* - break bonds on the fly
- *bond/create* - create bonds on the fly
- *bond/create/angle* - create bonds on the fly with angle constraints
- *bond/react* - apply topology changes to model reactions
- *bond/swap* - Monte Carlo bond swapping
- *box/relax* - relax box size during energy minimization
- *charge/regulation* - Monte Carlo sampling of charge regulation
- *cmap* - CMAP torsion/torsion terms in CHARMM force field
- *colvars* - interface to the collective variables “Colvars” library
- *controller* - apply control loop feedback mechanism
- *damping/cundall* - Cundall non-viscous damping for granular simulations
- *deform* - change the simulation box size/shape
- *deform/pressure* - change the simulation box size/shape with additional loading conditions
- *deposit* - add new atoms above a surface
- *dpd/energy* - constant energy dissipative particle dynamics
- *drag* - drag atoms towards a defined coordinate
- *drude* - part of Drude oscillator polarization model

- *drude/transform/direct* - part of Drude oscillator polarization model
- *drude/transform/inverse* - part of Drude oscillator polarization model
- *dt/reset* - reset the timestep based on velocity, forces
- *edpd/source* - add heat source to eDPD simulations
- *efield* - impose electric field on system
- *efield/tip4p* - impose electric field on system with TIP4P molecules
- *ehex* - enhanced heat exchange algorithm
- *electrode/conp* - impose electric potential
- *electrode/conq* - impose total electric charge
- *electrode/thermo* - apply thermo-potentiostat
- *electron/stopping* - electronic stopping power as a friction force
- *electron/stopping/fit* - electronic stopping power as a friction force
- *enforce2d* - zero out z-dimension velocity and force
- *eos/cv* - applies a mesoparticle equation of state to relate the particle internal energy to the particle internal temperature
- *eos/table* - applies a tabulated mesoparticle equation of state to relate the particle internal energy to the particle internal temperature
- *eos/table/rx* - applies a tabulated mesoparticle equation of state to relate the concentration-dependent particle internal energy to the particle internal temperature
- *evaporate* - remove atoms from simulation periodically
- *external* - callback to an external driver program
- *ffl* - apply a Fast-Forward Langevin equation thermostat
- *filter/corotate* - implement corotation filter to allow larger timesteps with r-RESPA
- *flow/gauss* - Gaussian dynamics for constant mass flux
- *freeze* - freeze atoms in a granular simulation
- *gcmc* - grand canonical insertions/deletions
- *gld* - generalized Langevin dynamics integrator
- *gle* - generalized Langevin equation thermostat
- *gravity* - add gravity to atoms in a granular simulation
- *grem* - implements the generalized replica exchange method
- *halt* - terminate a dynamics run or minimization
- *heat* - add/subtract momentum-conserving heat
- *heat/flow* - plain time integration of heat flow with per-atom temperature updates
- *hyper/global* - global hyperdynamics
- *hyper/local* - local hyperdynamics
- *imd* - implements the “Interactive MD” (IMD) protocol
- *indent* - impose force due to an indenter

- *ipi* - enable LAMMPS to run as a client for i-PI path-integral simulations
- *langevin* - Langevin temperature control
- *langevin/drude* - Langevin temperature control of Drude oscillators
- *langevin/eff* - Langevin temperature control for the electron force field model
- *langevin/spin* - Langevin temperature control for a spin or spin-lattice system
- *lb/fluid* - lattice-Boltzmann fluid on a uniform mesh
- *lb/momentum* - *fix momentum* replacement for use with a lattice-Boltzmann fluid
- *lb/viscous* - *fix viscous* replacement for use with a lattice-Boltzmann fluid
- *lineforce* - constrain atoms to move in a line
- *manifoldforce* - restrain atoms to a manifold during minimization
- *mdi/qm* - LAMMPS operates as a client for a quantum code via the MolSSI Driver Interface (MDI)
- *mdi/qmmm* - LAMMPS operates as client for QM/MM simulation with a quantum code via the MolSSI Driver Interface (MDI)
- *meso/move* - move mesoscopic SPH/SDPD particles in a prescribed fashion
- *mol/swap* - Monte Carlo atom type swapping with a molecule
- *momentum* - zero the linear and/or angular momentum of a group of atoms
- *momentum/chunk* - zero the linear and/or angular momentum of a chunk of atoms
- *move* - move atoms in a prescribed fashion
- *msst* - multi-scale shock technique (MSST) integration
- *mvv/dpd* - DPD using the modified velocity-Verlet integration algorithm
- *mvv/edpd* - constant energy DPD using the modified velocity-Verlet algorithm
- *mvv/tdpd* - constant temperature DPD using the modified velocity-Verlet algorithm
- *neb* - nudged elastic band (NEB) spring forces
- *neb/spin* - nudged elastic band (NEB) spring forces for spins
- *nonaffine/displacement* - calculate nonaffine displacement of atoms
- *nph* - constant NPH time integration via Nose/Hoover
- *nph/asphere* - NPH for aspherical particles
- *nph/body* - NPH for body particles
- *nph/eff* - NPH for nuclei and electrons in the electron force field model
- *nph/sphere* - NPH for spherical particles
- *nphug* - constant-stress Hugoniotat integration
- *npt* - constant NPT time integration via Nose/Hoover
- *npt/asphere* - NPT for aspherical particles
- *npt/body* - NPT for body particles
- *npt/cauchy* - NPT with Cauchy stress
- *npt/eff* - NPT for nuclei and electrons in the electron force field model

- *npt/sphere* - NPT for spherical particles
- *npt/uef* - NPT style time integration with diagonal flow
- *numdiff* - numerically approximate atomic forces using finite energy differences
- *numdiff/virial* - numerically approximate virial stress tensor using finite energy differences
- *nve* - constant NVE time integration
- *nve/asphere* - NVE for aspherical particles
- *nve/asphere/noforce* - NVE for aspherical particles without forces
- *nve/awpmd* - NVE for the Antisymmetrized Wave Packet Molecular Dynamics model
- *nve/body* - NVE for body particles
- *nve/dot* - rigid body constant energy time integrator for coarse grain models
- *nve/dotc/langevin* - Langevin style rigid body time integrator for coarse grain models
- *nve/eff* - NVE for nuclei and electrons in the electron force field model
- *nve/limit* - NVE with limited step length
- *nve/line* - NVE for line segments
- *nve/manifold/rattle* - NVE time integration for atoms constrained to a curved surface (manifold)
- *nve/noforce* - NVE without forces (update positions only)
- *nve/sphere* - NVE for spherical particles
- *nve/bpm/sphere* - NVE for spherical particles used in the BPM package
- *nve/spin* - NVE for a spin or spin-lattice system
- *nve/tri* - NVE for triangles
- *nvk* - constant kinetic energy time integration
- *nvt* - NVT time integration via Nose/Hoover
- *nvt/asphere* - NVT for aspherical particles
- *nvt/body* - NVT for body particles
- *nvt/eff* - NVE for nuclei and electrons in the electron force field model
- *nvt/manifold/rattle* - NVT time integration for atoms constrained to a curved surface (manifold)
- *nvt/sllod* - NVT for NEMD with SLLOD equations
- *nvt/sllod/eff* - NVT for NEMD with SLLOD equations for the electron force field model
- *nvt/sphere* - NVT for spherical particles
- *nvt/uef* - NVT style time integration with diagonal flow
- *oneway* - constrain particles on move in one direction
- *orient/bcc* - add grain boundary migration force for BCC
- *orient/fcc* - add grain boundary migration force for FCC
- *orient/eco* - add generalized grain boundary migration force
- *pafi* - constrained force averages on hyper-planes to compute free energies (PAFI)
- *pair* - access per-atom info from pair styles

- *phonon* - calculate dynamical matrix from MD simulations
- *pimd/langevin* - Feynman path-integral molecular dynamics with stochastic thermostat
- *pimd/nvt* - Feynman path-integral molecular dynamics with Nose-Hoover thermostat
- *planeforce* - constrain atoms to move in a plane
- *plumed* - wrapper on PLUMED free energy library
- *poems* - constrain clusters of atoms to move as coupled rigid bodies
- *polarize/bem/gmres* - compute induced charges at the interface between impermeable media with different dielectric constants with generalized minimum residual (GMRES)
- *polarize/bem/icc* - compute induced charges at the interface between impermeable media with different dielectric constants with the successive over-relaxation algorithm
- *polarize/functional* - compute induced charges at the interface between impermeable media with different dielectric constants with the energy variational approach
- *pour* - pour new atoms/molecules into a granular simulation domain
- *precession/spin* - apply a precession torque to each magnetic spin
- *press/berendsen* - pressure control by Berendsen barostat
- *press/langevin* - pressure control by Langevin barostat
- *print* - print text and variables during a simulation
- *propel/self* - model self-propelled particles
- *property/atom* - add customized per-atom values
- *python/invoke* - call a Python function during a simulation
- *python/move* - move particles using a Python function during a simulation run
- *qbmsst* - quantum bath multi-scale shock technique time integrator
- *qeq/comb* - charge equilibration for COMB potential
- *qeq/dynamic* - charge equilibration via dynamic method
- *qeq/fire* - charge equilibration via FIRE minimizer
- *qeq/point* - charge equilibration via point method
- *qeq/reaxff* - charge equilibration for ReaxFF potential
- *qeq/shielded* - charge equilibration via shielded method
- *qeq/slater* - charge equilibration via Slater method
- *qmmm* - functionality to enable a quantum mechanics/molecular mechanics coupling
- *qtb* - implement quantum thermal bath scheme
- *rattle* - RATTLE constraints on bonds and/or angles
- *reaxff/bonds* - write out ReaxFF bond information
- *reaxff/species* - write out ReaxFF molecule information
- *recenter* - constrain the center-of-mass position of a group of atoms
- *restrain* - constrain a bond, angle, dihedral
- *rheo* - integrator for the RHEO package

- *rheo/thermal* - thermal integrator for the RHEO package
- *rheo/oxidation* - create oxidation bonds for the RHEO package
- *rheo/pressure* - pressure calculation for the RHEO package
- *rheo/viscosity* - viscosity calculation for the RHEO package
- *rhok* - add bias potential for long-range ordered systems
- *rigid* - constrain one or more clusters of atoms to move as a rigid body with NVE integration
- *rigid/meso* - constrain clusters of mesoscopic SPH/SDPD particles to move as a rigid body
- *rigid/nph* - constrain one or more clusters of atoms to move as a rigid body with NPH integration
- *rigid/nph/small* - constrain many small clusters of atoms to move as a rigid body with NPH integration
- *rigid/npt* - constrain one or more clusters of atoms to move as a rigid body with NPT integration
- *rigid/npt/small* - constrain many small clusters of atoms to move as a rigid body with NPT integration
- *rigid/nve* - constrain one or more clusters of atoms to move as a rigid body with alternate NVE integration
- *rigid/nve/small* - constrain many small clusters of atoms to move as a rigid body with alternate NVE integration
- *rigid/nvt* - constrain one or more clusters of atoms to move as a rigid body with NVT integration
- *rigid/nvt/small* - constrain many small clusters of atoms to move as a rigid body with NVT integration
- *rigid/small* - constrain many small clusters of atoms to move as a rigid body with NVE integration
- *rx* - solve reaction kinetic ODEs for a defined reaction set
- *saed/vtk* - time-average the intensities from *compute saed*
- *setforce* - set the force on each atom
- *setforce/spin* - set magnetic precession vectors on each atom
- *sgcmc* - fix for hybrid semi-grand canonical MD/MC simulations
- *shake* - SHAKE constraints on bonds and/or angles
- *shardlow* - integration of DPD equations of motion using the Shardlow splitting
- *smd* - applied a steered MD force to a group
- *smd/adjust\_dt* - calculate a new stable time increment for use with SMD integrators
- *smd/integrate\_tlsph* - explicit time integration with total Lagrangian SPH pair style
- *smd/integrate\_ulsph* - explicit time integration with updated Lagrangian SPH pair style
- *smd/move\_tri\_surf* - update position and velocity near rigid surfaces using SPH integrators
- *smd/setvel* - sets each velocity component, ignoring forces, for Smooth Mach Dynamics
- *smd/wall\_surface* - create a rigid wall with a triangulated surface for use in Smooth Mach Dynamics
- *sph* - time integration for SPH/DPDE particles
- *sph/stationary* - update energy and density but not position or velocity in Smooth Particle Hydrodynamics
- *spring* - apply harmonic spring force to group of atoms
- *spring/chunk* - apply harmonic spring force to each chunk of atoms
- *spring/rg* - spring on radius of gyration of group of atoms
- *spring/self* - spring from each atom to its origin

- *srd* - stochastic rotation dynamics (SRD)
- *store/force* - store force on each atom
- *store/state* - store attributes for each atom
- *tdpd/source* - add external concentration source
- *temp/berendsen* - temperature control by Berendsen thermostat
- *temp/csld* - canonical sampling thermostat with Langevin dynamics
- *temp/csvr* - canonical sampling thermostat with Hamiltonian dynamics
- *temp/rescale* - temperature control by velocity rescaling
- *temp/rescale/eff* - temperature control by velocity rescaling in the electron force field model
- *tfmc* - perform force-bias Monte Carlo with time-stamped method
- *tgntv/drude* - NVT time integration for Drude polarizable model via temperature-grouped Nose-Hoover
- *tgntp/drude* - NPT time integration for Drude polarizable model via temperature-grouped Nose-Hoover
- *thermal/conductivity* - Mueller-Plathe kinetic energy exchange for thermal conductivity calculation
- *ti/spring* - perform thermodynamic integration between a solid and an Einstein crystal
- *tmd* - guide a group of atoms to a new configuration
- *ttm* - two-temperature model for electronic/atomic coupling (replicated grid)
- *ttm/grid* - two-temperature model for electronic/atomic coupling (distributed grid)
- *ttm/mod* - enhanced two-temperature model with additional options
- *tune/kpace* - auto-tune *k*-space parameters
- *vector* - accumulate a global vector every *N* timesteps
- *viscosity* - Mueller-Plathe momentum exchange for viscosity calculation
- *viscous* - viscous damping for granular simulations
- *viscous/sphere* - viscous damping on angular velocity for granular simulations
- *wall/body/polygon* - time integration for body particles of style *rounded/polygon*
- *wall/body/polyhedron* - time integration for body particles of style *rounded/polyhedron*
- *wall/colloid* - Lennard-Jones wall interacting with finite-size particles
- *wall/ees* - wall for ellipsoidal particles
- *wall/flow* - flow boundary conditions
- *wall/gran* - frictional wall(s) for granular simulations
- *wall/gran/region* - *fix wall/region* equivalent for use with granular particles
- *wall/harmonic* - harmonic spring wall
- *wall/lj1043* - Lennard-Jones 10–4–3 wall
- *wall/lj126* - Lennard-Jones 12–6 wall
- *wall/lj93* - Lennard-Jones 9–3 wall
- *wall/lepton* - Custom Lepton expression wall
- *wall/morse* - Morse potential wall

- *wall/piston* - moving reflective piston wall
- *wall/reflect* - reflecting wall(s)
- *wall/reflect/stochastic* - reflecting wall(s) with finite temperature
- *wall/region* - use region surface as wall
- *wall/region/ees* - use region surface as wall for ellipsoidal particles
- *wall/srd* - slip/no-slip wall for SRD particles
- *wall/table* - Tabulated potential wall wall
- *widom* - Widom insertions of atoms or molecules

### 1.30.4 Restrictions

Some fix styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual fixes tell if it is part of a package.

### 1.30.5 Related commands

*unfix*, *fix\_modify*

### 1.30.6 Default

none

## 1.31 fix\_modify command

### 1.31.1 Syntax

```
fix_modify fix-ID keyword value ...
```

- fix-ID = ID of the fix to modify
- one or more keyword/value pairs may be appended
- keyword = *bodyforces* or *colname* or *dynamic/dof* or *energy* or *press* or *respa* or *temp* or *virial*
  - bodyforces* value = *early* or *late*  
early/late = compute rigid-body forces/torques early or late in the timestep
  - colname* values = ID string  
string = new column header name  
ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities.  
→being output  
or a fix output property keyword or reference to compute, fix, property or  
→variable.
  - dynamic/dof* value = *yes* or *no*  
yes/no = do or do not re-compute the number of degrees of freedom (DOF).  
→contributing to the temperature
  - energy* value = *yes* or *no*
  - press* value = compute ID that calculates a pressure

*respa* value = 1 to *max respa level* or 0 (for outermost level)  
*temp* value = compute ID that calculates a temperature  
*virial* value = *yes* or *no*

### 1.31.2 Examples

```

fix_modify 3 temp myTemp press myPress
fix_modify 1 energy yes
fix_modify tether respa 2
fix_modify ave colname c_thermo_press Pressure colname 1 Temperature

```

### 1.31.3 Description

Modify one or more parameters of a previously defined fix. Only specific fix styles support specific parameters. See the doc pages for individual fix commands for info on which ones support which `fix_modify` parameters.

The *temp* keyword is used to determine how a fix computes temperature. The specified compute ID must have been previously defined by the user via the `compute` command and it must be a style of compute that calculates a temperature. All fixes that compute temperatures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing T.

The *press* keyword is used to determine how a fix computes pressure. The specified compute ID must have been previously defined by the user via the `compute` command and it must be a style of compute that calculates a pressure. All fixes that compute pressures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing P.

The *energy* keyword can be used with fixes that support it, which is explained at the bottom of their doc page. *Energy yes* will add a contribution to the potential energy of the system. More specifically, the fix's global or per-atom energy is included in the calculation performed by the `compute pe` or `compute pe/atom` commands. The former is what is used the `thermo_style` command for output of any quantity that includes the global potential energy of the system. Note that the `compute pe` and `compute pe/atom` commands also have an option to include or exclude the contribution from fixes. For fixes that tally a global energy, it can also be printed with thermodynamic output by using the keyword `f_ID` in the `thermo_style` custom command, where ID is the fix-ID of the appropriate fix.

---

**Note:** If you are performing an *energy minimization* with one of these fixes and want the energy and forces it produces to be part of the optimization criteria, you must specify the *energy yes* setting.

---

---

**Note:** For most fixes that support the *energy* keyword, the default setting is *no*. For a few it is *yes*, when a user would expect that to be the case. The page of each fix gives the default.

---

The *virial* keyword can be used with fixes that support it, which is explained at the bottom of their doc page. *Virial yes* will add a contribution to the virial of the system. More specifically, the fix's global or per-atom virial is included in the calculation performed by the `compute pressure` or `compute stress/atom` commands. The former is what is used the `thermo_style` command for output of any quantity that includes the global pressure of the system. Note that the `compute pressure` and `compute stress/atom` commands also have an option to include or exclude the contribution from fixes.

---

**Note:** If you are performing an *energy minimization* with *box relaxation* and one of these fixes and want the virial contribution of the fix to be part of the optimization criteria, you must specify the *virial yes* setting.

---

---

**Note:** For most fixes that support the *virial* keyword, the default setting is *no*. For a few it is *yes*, when a user would expect that to be the case. The page of each fix gives the default.

---

For fixes that set or modify forces, it may be possible to select at which *r-RESPA* level the fix operates via the *respa* keyword. The RESPA level at which the fix is active can be selected. This is a number ranging from 1 to the number of levels. If the RESPA level is larger than the current maximum, the outermost level will be used, which is also the default setting. This default can be restored using a value of 0 for the RESPA level. The affected fix has to be enabled to support this feature; if not, *fix\_modify* will report an error. Active fixes with a custom RESPA level setting are reported with their specified level at the beginning of a r-RESPA run.

The *dynamic/dof* keyword determines whether the number of atoms N in the fix group and their associated degrees of freedom are re-computed each time a temperature is computed. Only fix styles that calculate their own internal temperature use this option. Currently this is only the *fix rigid/nvt/small* and *fix rigid/npt/small* commands for the purpose of thermostating rigid body translation and rotation. By default, N and their DOF are assumed to be constant. If you are adding atoms or molecules to the system (see the *fix pour*, *fix deposit*, and *fix gcmc* commands) or expect atoms or molecules to be lost (e.g. due to exiting the simulation box or via *fix evaporate*), then this option should be used to ensure the temperature is correctly normalized.

---

**Note:** Other thermostating fixes, such as *fix nvt*, do not use the *dynamic/dof* keyword because they use a temperature compute to calculate temperature. See the *compute\_modify dynamic/dof* command for a similar way to ensure correct temperature normalization for those thermostats.

---

The *bodyforces* keyword determines whether the forces and torques acting on rigid bodies are computed *early* at the post-force stage of each timestep (right after per-atom forces have been computed and communicated among processors), or *late* at the final-integrate stage of each timestep (after any other fixes have finished their post-force tasks). Only the rigid-body integration fixes use this option, which includes *fix rigid* and *fix rigid/small*, and their variants, and also *fix poems*.

The default is *late*. If there are other fixes that add forces to individual atoms, then the rigid-body constraints will include these forces when time-integrating the rigid bodies. If *early* is specified, then new fixes can be written that use or modify the per-body force and torque, before time-integration of the rigid bodies occurs. Note however this has the side effect, that fixes such as *fix addforce*, *fix setforce*, *fix spring*, which add forces to individual atoms will have no effect on the motion of the rigid bodies if they are specified in the input script after the *fix rigid* command. LAMMPS will give a warning if that is the case.

The *colname* keyword can be used to change the default header keywords in output files of fix styles that support it: currently only *fix ave/time* is supported. The setting for *ID string* replaces the default text with the provided string. *ID* can be a positive integer when it represents the column number counting from the left, a negative integer when it represents the column number from the right (i.e. -1 is the last column/keyword), or a custom fix output keyword (or compute, fix, property, or variable reference) and then it replaces the string for that specific keyword. The *colname* keyword can be used multiple times. If multiple *colname* settings refer to the same keyword, the last setting has precedence.

### 1.31.4 Restrictions

none

### 1.31.5 Related commands

*fix*, *compute temp*, *compute pressure*, *thermo\_style*

### 1.31.6 Default

The option defaults are temp = ID defined by fix, press = ID defined by fix, energy = no, virial = different for each fix style, respa = 0, bodyforce = late.

## 1.32 fitpod command

### 1.32.1 Syntax

```
fitpod Ta_param.pod Ta_data.pod Ta_coefficients.pod
```

- fitpod = style name of this command
- Ta\_param.pod = an input file that describes proper orthogonal descriptors (PODs)
- Ta\_data.pod = an input file that specifies DFT data used to fit a POD potential
- Ta\_coefficients.pod (optional) = an input file that specifies trainable coefficients of a POD potential

### 1.32.2 Examples

```
fitpod Ta_param.pod Ta_data.pod
fitpod Ta_param.pod Ta_data.pod Ta_coefficients.pod
```

### 1.32.3 Description

New in version 22Dec2022.

Fit a machine-learning interatomic potential (ML-IAP) based on proper orthogonal descriptors (POD); please see (*Nguyen and Rohskopf*), (*Nguyen2023*), (*Nguyen2024*), and (*Nguyen and Sema*) for details. The fitted POD potential can be used to run MD simulations via *pair\_style pod*.

Two input files are required for this command. The first input file describes a POD potential parameter settings, while the second input file specifies the DFT data used for the fitting procedure. All keywords except *species* have default values. If a keyword is not set in the input file, its default value is used. The table below has one-line descriptions of all the keywords that can be used in the first input file (i.e. Ta\_param.pod)

Keyword	De- fault	Type	Description
species	(none)	STRING	Chemical symbols for all elements in the system and have to match XYZ training files.
pbc	1 1 1	INT	three integer constants specify boundary conditions
rin	0.5	REAL	a real number specifies the inner cut-off radius
rcut	5.0	REAL	a real number specifies the outer cut-off radius
bessel_polynomial_degree	4	INT	the maximum degree of Bessel polynomials
inverse_polynomial_degree	8	INT	the maximum degree of inverse radial basis functions
number_of_environment_clusters	1	INT	the number of clusters for environment-adaptive potentials
number_of_principal_components	2	INT	the number of principal components for dimensionality reduction
onebody	1	BOOL	turns on/off one-body potential
twobody_number_radial_basis_functions	8	INT	number of radial basis functions for two-body potential
threebody_number_radial_basis_functions	6	INT	number of radial basis functions for three-body potential
threebody_angular_degree	5	INT	angular degree for three-body potential
fourbody_number_radial_basis_functions	4	INT	number of radial basis functions for four-body potential
fourbody_angular_degree	3	INT	angular degree for four-body potential
fivebody_number_radial_basis_functions	0	INT	number of radial basis functions for five-body potential
fivebody_angular_degree	0	INT	angular degree for five-body potential
sixbody_number_radial_basis_functions	0	INT	number of radial basis functions for six-body potential
sixbody_angular_degree	0	INT	angular degree for six-body potential
sevenbody_number_radial_basis_functions	0	INT	number of radial basis functions for seven-body potential
sevenbody_angular_degree	0	INT	angular degree for seven-body potential

Note that both the number of radial basis functions and angular degree must decrease as the body order increases. The next table describes all keywords that can be used in the second input file (i.e. `Ta_data.pod` in the example above):

Keyword	De- fault	Type	Description
file_format	extxyz	STRING	only the extended xyz format (extxyz) is currently supported
file_extension	xyz	STRING	extension of the data files
path_to_training_data_set	(none)	STRING	specifies the path to training data files in double quotes
path_to_test_data_set	""	STRING	specifies the path to test data files in double quotes
path_to_environment_configuration_set	""	STRING	specifies the path to environment configuration files in double quotes
fraction_training_data_set	1.0	REAL	a real number ( $\leq 1.0$ ) specifies the fraction of the training set used to fit POD
randomize_training_data_set	0	BOOL	turns on/off randomization of the training set
fraction_test_data_set	1.0	REAL	a real number ( $\leq 1.0$ ) specifies the fraction of the test set used to validate POD
randomize_test_data_set	0	BOOL	turns on/off randomization of the test set
fitting_weight_energy	100.0	REAL	a real constant specifies the weight for energy in the least-squares fit
fitting_weight_force	1.0	REAL	a real constant specifies the weight for force in the least-squares fit
fitting_regularization_parameter	1.0e-10	REAL	a real constant specifies the regularization parameter in the least-squares fit
error_analysis_for_training_data_set	0	BOOL	turns on/off error analysis for the training data set
error_analysis_for_test_data_set	0	BOOL	turns on/off error analysis for the test data set
basename_for_output_files	pod	STRING	a basename string added to the output files
precision_for_pod_coefficients	8	INT	number of digits after the decimal points for numbers in the coefficient file
group_weights	global	STRING	table uses group weights defined for each group named by filename

All keywords except *path\_to\_training\_data\_set* have default values. If a keyword is not set in the input file, its default value is used. After successful training, a number of output files are produced, if enabled:

- *<basename>\_training\_errors.pod* reports the errors in energy and forces for the training data set
- *<basename>\_training\_analysis.pod* reports detailed errors for all training configurations
- *<basename>\_test\_errors.pod* reports errors for the test data set
- *<basename>\_test\_analysis.pod* reports detailed errors for all test configurations
- *<basename>\_coefficients.pod* contains the coefficients of the POD potential

After training the POD potential, *Ta\_param.pod* and *<basename>\_coefficients.pod* are the two files needed to use the POD potential in LAMMPS. See *pair\_style pod* for using the POD potential. Examples about training and using POD potentials are found in the directory *lammps/examples/PACKAGES/pod* and the Github repo <https://github.com/cesm-mit/pod-examples>.

## Loss Function Group Weights

The `group_weights` keyword in the `data.pod` file is responsible for weighting certain groups of configurations in the loss function. For example:

```
group_weights table
Displaced_A15 100.0 1.0
Displaced_BCC 100.0 1.0
Displaced_FCC 100.0 1.0
Elastic_BCC   100.0 1.0
Elastic_FCC   100.0 1.0
GSF_110       100.0 1.0
GSF_112       100.0 1.0
Liquid        100.0 1.0
Surface       100.0 1.0
Volume_A15    100.0 1.0
Volume_BCC    100.0 1.0
Volume_FCC    100.0 1.0
```

This will apply an energy weight of `100.0` and a force weight of `1.0` for all groups in the Ta example. The groups are named by their respective filename. If certain groups are left out of this table, then the globally defined weights from the `fitting_weight_energy` and `fitting_weight_force` keywords will be used.

### 1.32.4 POD Potential

We consider a multi-element system of  $N$  atoms with  $N_e$  unique elements. We denote by  $r_n$  and  $Z_n$  position vector and type of an atom  $n$  in the system, respectively. Note that we have  $Z_n \in \{1, \dots, N_e\}$ ,  $R = (r_1, r_2, \dots, r_N) \in \mathbb{R}^{3N}$ , and  $Z = (Z_1, Z_2, \dots, Z_N) \in \mathbb{N}^N$ . The total energy of the POD potential is expressed as  $E(R, Z) = \sum_{i=1}^N E_i(R_i, Z_i)$ , where

$$E_i(R_i, Z_i) = \sum_{m=1}^M c_m \mathcal{D}_{im}(R_i, Z_i)$$

Here  $c_m$  are trainable coefficients and  $\mathcal{D}_{im}(R_i, Z_i)$  are per-atom POD descriptors. Summing the per-atom descriptors over  $i$  yields the global descriptors  $d_m(R, Z) = \sum_{i=1}^N \mathcal{D}_{im}(R_i, Z_i)$ . It thus follows that  $E(R, Z) = \sum_{m=1}^M c_m d_m(R, Z)$ .

The per-atom POD descriptors include one, two, three, four, five, six, and seven-body descriptors, which can be specified in the first input file. Furthermore, the per-atom POD descriptors also depend on the number of environment clusters specified in the first input file. Please see (Nguyen2024) and (Nguyen and Sema) for the detailed description of the per-atom POD descriptors.

### 1.32.5 Training

A POD potential is trained using the least-squares regression against density functional theory (DFT) data. Let  $J$  be the number of training configurations, with  $N_j$  being the number of atoms in the  $j$ -th configuration. The training configurations are extracted from the extended XYZ files located in a directory (i.e., `path_to_training_data_set` in the second input file). Let  $\{E_j^*\}_{j=1}^J$  and  $\{F_j^*\}_{j=1}^J$  be the DFT energies and forces for  $J$  configurations. Next, we calculate the global descriptors and their derivatives for all training configurations. Let  $d_{jm}$ ,  $1 \leq m \leq M$ , be the global descriptors associated with the  $j$ -th configuration, where  $M$  is the number of global descriptors. We then form a matrix  $A \in \mathbb{R}^{J \times M}$  with entries  $A_{jm} = d_{jm}/N_j$  for  $j = 1, \dots, J$  and  $m = 1, \dots, M$ . Moreover, we form a matrix  $B \in \mathbb{R}^{\mathcal{N} \times M}$  by stacking the derivatives of the global descriptors for all training configurations from top to bottom, where  $\mathcal{N} = 3 \sum_{j=1}^J N_j$ .

The coefficient vector  $c$  of the POD potential is found by solving the following least-squares problem

$$\min_{c \in \mathbb{R}^M} w_E \|Ac - \bar{E}^*\|^2 + w_F \|Bc + F^*\|^2 + w_R \|c\|^2,$$

where  $w_E$  and  $w_F$  are weights for the energy (*fitting\_weight\_energy*) and force (*fitting\_weight\_force*), respectively; and  $w_R$  is the regularization parameter (*fitting\_regularization\_parameter*). Here  $\bar{E}^* \in \mathbb{R}^J$  is a vector of with entries  $\bar{E}_j^* = E_j^*/N_j$  and  $F^*$  is a vector of  $\mathcal{N}$  entries obtained by stacking  $\{F_j^*\}_{j=1}^J$  from top to bottom.

### 1.32.6 Validation

POD potential can be validated on a test dataset in a directory specified by setting *path\_to\_test\_data\_set* in the second input file. It is possible to validate the POD potential after the training is complete. This is done by providing the coefficient file as an input to *fitpod*, for example,

```
fitpod Ta_param.pod Ta_data.pod Ta_coefficients.pod
```

### 1.32.7 Restrictions

This command is part of the ML-POD package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 1.32.8 Related commands

*pair\_style pod*, *compute pod/atom*, *compute podd/atom*, *compute pod/local*, *compute pod/global*

### 1.32.9 Default

The keyword defaults are also given in the description of the input files.

## 1.33 geturl command

### 1.33.1 Syntax

```
geturl url keyword args ...
```

- url = URL of the file to download
- zero or more keyword argument pairs may be provided
- keyword = *output* or *verify* or *overwrite* or *verbose*

*output* filename = write to *filename* instead of inferring the name from the URL

*verify* yes/no = verify SSL certificate and hostname if yes, do not if *no*

*overwrite* yes/no = if yes overwrite the output file in case it exists, do not if *no*

*verbose* yes/no = if yes write verbose debug output from libcurl to screen, do not. ↪if *no*

### 1.33.2 Examples

```
geturl https://www.ctcms.nist.gov/potentials/Download/1990--Ackland-G-J-Vitek-V--Cu/2/
→Cu2.eam.fs
geturl https://github.com/lammps/lammps/blob/develop/bench/in.lj output in.bench-lj
```

### 1.33.3 Description

New in version 29Aug2024.

Download a file from an URL to the local disk. This is implemented with the `libcurl` library which supports a large variety of protocols including “http”, “https”, “ftp”, “scp”, “sftp”, “file”. The transfer will only be performed on MPI rank 0.

The *output* keyword can be used to set the filename. By default, the last part of the URL is used.

The *verify* keyword determines whether `libcurl` will validate the SSL certificate and hostname for encrypted connections. Turning this off may be required when using a proxy or connecting to a server with a self-signed SSL certificate.

The *overwrite* keyword determines whether a file should be overwritten if it already exists. If the argument is *no*, then the download will be skipped if the file exists.

The *verbose* keyword determines whether a detailed protocol of the steps performed by `libcurl` is written to the screen. Using the argument *yes* can be used to debug connection issues when the *geturl* command does not behave as expected. If the argument is *no*, *geturl* will operate silently and only report the error status number provided by `libcurl`, in case of a failure.

---

### 1.33.4 Restrictions

This command is part of the EXTRA-COMMAND package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info. It also requires that LAMMPS was built with support for the `libcurl` library. See the page about *Compiling LAMMPS with libcurl support* for further info. If support for `libcurl` is not included, using *geturl* will trigger an error.

### 1.33.5 Related commands

*shell*

### 1.33.6 Default

*verify* = yes, *overwrite* = yes

## 1.34 group command

### 1.34.1 Syntax

```
group ID style args
```

- ID = user-defined name of the group
- style = *delete* or *clear* or *empty* or *region* or *type* or *id* or *molecule* or *variable* or *include* or *subtract* or *union* or *intersect* or *dynamic* or *static*

*delete* = no args

*clear* = no args

*empty* = no args

*region* args = region-ID

*type* or *id* or *molecule*

args = list of one or more atom types (1-Ntypes or type label), atom IDs, or molecule IDs

any numeric entry in list can be a sequence formatted as A:B or A:B:C where

A = starting index, B = ending index,

C = increment between indices, 1 if not specified

args = logical value

logical = "<" or "<=" or ">" or ">=" or "==" or "!="

value = an atom type (1-Ntypes or type label) or atom ID or molecule ID

(depending on style)

args = logical value1 value2

logical = "<>"

value1,value2 = atom types or atom IDs or molecule IDs (depending on style)

*variable* args = variable-name

*include* args = molecule

molecule = add atoms to group with same molecule ID as atoms already in group

*subtract* args = two or more group IDs

*union* args = one or more group IDs

*intersect* args = two or more group IDs

*dynamic* args = parent-ID keyword value ...

one or more keyword/value pairs may be appended

keyword = *region* or *var* or *property* or *every*

*region* value = region-ID

*var* value = name of variable

*property* value = name of custom integer or floating point vector

*every* value = N = update group every this many timesteps

*static* = no args

### 1.34.2 Examples

```
group edge region regstrip
group water type 3 4
group water type OW HT
group sub id 10 25 50
group sub id 10 25 50 500:1000
group sub id 100:10000:10
group sub id <= 150
```

(continues on next page)

(continued from previous page)

```

group polyA molecule <> 50 250
group hienergy variable eng
group hienergy include molecule
group boundary subtract all a2 a3
group boundary union lower upper
group boundary intersect upper flow
group boundary delete
group mine dynamic all region myRegion every 100

```

### 1.34.3 Description

Identify a collection of atoms as belonging to a group. The group ID can then be used in other commands such as *fix*, *compute*, *dump*, or *velocity* to act on those atoms together.

If the group ID already exists, the group command adds the specified atoms to the group.

---

**Note:** By default groups are static, meaning the atoms are permanently assigned to the group. For example, if the *region* style is used to assign atoms to a group, the atoms will remain in the group even if they later move out of the region. As explained below, the *dynamic* style can be used to make a group dynamic so that a periodic determination is made as to which atoms are in the group. Since many LAMMPS commands operate on groups of atoms, you should think carefully about whether making a group dynamic makes sense for your model.

---

A group with the ID *all* is predefined. All atoms belong to this group. This group cannot be deleted, or made dynamic.

The *delete* style removes the named group and un-assigns all atoms that were assigned to that group. Since there is a restriction (see below) that no more than 32 groups can be defined at any time, the *delete* style allows you to remove groups that are no longer needed, so that more can be specified. You cannot delete a group if it has been used to define a current *fix* or *compute* or *dump*.

The *clear* style un-assigns all atoms that were assigned to that group. This may be dangerous to do during a simulation run (e.g., using the *run every* command if a *fix* or *compute* or other operation expects the atoms in the group to remain constant), but LAMMPS does not check for this.

The *empty* style creates an empty group, which is useful for commands like *fix gcmc* or with complex scripts that add atoms to a group.

The *region* style puts all atoms in the region volume into the group. Note that this is a static one-time assignment. The atoms remain assigned (or not assigned) to the group even in they later move out of the region volume.

The *type*, *id*, and *molecule* styles put all atoms with the specified atom types, atom IDs, or molecule IDs into the group. These three styles can use arguments specified in one of two formats.

The first format is a list of values (types or IDs). For example, the second command in the examples above puts all atoms of type 3 or 4 into the group named *water*. Each numeric entry in the list can be a colon-separated sequence A:B or A:B:C, as in two of the examples above. A “sequence” generates a sequence of values (types or IDs), with an optional increment. The first example with 500:1000 has the default increment of 1 and would add all atom IDs from 500 to 1000 (inclusive) to the group *sub*, along with 10, 25, and 50 since they also appear in the list of values. The second example with 100:10000:10 uses an increment of 10 and would thus would add atoms IDs 100, 110, 120, ..., 9990, 10000 to the group *sub*.

The second format is a *logical* followed by one or two values (type or ID). The 7 valid logicals are listed above. All the logicals except <> take a single argument. The third example above adds all atoms with IDs from 1 to 150 to the group named *sub*. The logical <> means “between” and takes 2 arguments. The fourth example above adds all atoms

belonging to molecules with IDs from 50 to 250 (inclusive) to the group named polyA. For the *type* style, type labels are converted into numeric types before being evaluated.

The *variable* style evaluates a variable to determine which atoms to add to the group. It must be an *atom-style variable* previously defined in the input script. If the variable evaluates to a non-zero value for a particular atom, then that atom is added to the specified group.

Atom-style variables can specify formulas that include thermodynamic quantities, per-atom values such as atom coordinates, or per-atom quantities calculated by computes, fixes, or other variables. They can also include Boolean logic where two numeric values are compared to yield a 1 or 0 (effectively a true or false). Thus, using the *variable* style is a general way to flag specific atoms to include or exclude from a group.

For example, these lines define a variable “eatom” that calculates the potential energy of each atom and includes it in the group if its potential energy is above the threshold value  $-3.0$ .

```
compute      1 all pe/atom
compute      2 all reduce sum c_1
thermo_style  custom step temp pe c_2
run          0

variable      eatom atom "c_1 > -3.0"
group         hienergy variable eatom
```

Note that these lines

```
compute      2 all reduce sum c_1
thermo_style  custom step temp pe c_2
run          0
```

are necessary to ensure that the “eatom” variable is current when the group command invokes it. Because the eatom variable computes the per-atom energy via the pe/atom compute, it will only be current if a run has been performed which evaluated pairwise energies, and the pe/atom compute was actually invoked during the run. Printing the thermodynamic info for compute 2 ensures that this is the case, since it sums the pe/atom compute values (in the reduce compute) to output them to the screen. See the “Variable Accuracy” section of the *variable* page for more details on ensuring that variables are current when they are evaluated between runs.

The *include* style with its arg *molecule* adds atoms to a group that have the same molecule ID as atoms already in the group. The molecule ID = 0 is ignored in this operation, since it is assumed to flag isolated atoms that are not part of molecules. An example of where this operation is useful is if the *region* style has been used previously to add atoms to a group that are within a geometric region. If molecules straddle the region boundary, then atoms outside the region that are part of molecules with atoms inside the region will not be in the group. Using the group command a second time with *include molecule* will add those atoms that are outside the region to the group.

---

**Note:** The *include molecule* operation is relatively expensive in a parallel sense. This is because it requires communication of relevant molecule IDs between all the processors and each processor to loop over its atoms once per processor, to compare its atoms to the list of molecule IDs from every other processor. Hence it scales as  $N$ , rather than  $N/P$  as most of the group operations do, where  $N$  is the number of atoms, and  $P$  is the number of processors.

---

The *subtract* style takes a list of two or more existing group names as arguments. All atoms that belong to the first group, but not to any of the other groups are added to the specified group.

The *union* style takes a list of one or more existing group names as arguments. All atoms that belong to any of the listed groups are added to the specified group.

The *intersect* style takes a list of two or more existing group names as arguments. Atoms that belong to every one of the listed groups are added to the specified group.

The *dynamic* style flags an existing or new group as dynamic. This means atoms will be (re)assigned to the group periodically as a simulation runs. This is in contrast to static groups where atoms are permanently assigned to the group. The way the assignment occurs is as follows. Only atoms in the group specified as the parent group via the parent-ID are assigned to the dynamic group before the following conditions are applied.

If the *region* keyword is used, atoms not in the specified region are removed from the dynamic group.

If the *var* keyword is used, the variable name must be an atom-style or atomfile-style variable. The variable is evaluated and atoms whose per-atom values are 0.0, are removed from the dynamic group.

If the *property* keyword is used, the name refers to a custom integer or floating point per-atom vector defined via the *fix property/atom* command. This means the values in the vector can be read as part of a data file with the *read\_data* command or specified with the *set* command. Or accessed and changed via the *library interface to LAMMPS*, or by styles you add to LAMMPS (pair, fix, compute, etc) which access the custom vector and modify its values. Which means the values can be modified between or during simulations. Atoms whose values in the custom vector are zero are removed from the dynamic group. Note that the name of the custom per-atom vector is specified just as *name*, not as *i\_name* or *d\_name* as it is for other commands that use different kinds of custom atom vectors or arrays as arguments.

The assignment of atoms to a dynamic group is done at the beginning of each run and on every timestep that is a multiple of *N*, which is the argument for the *every* keyword (*N* = 1 is the default). For an energy minimization, via the *minimize* command, an assignment is made at the beginning of the minimization, but not during the iterations of the minimizer.

The point in the timestep at which atoms are assigned to a dynamic group is after interatomic forces have been computed, but before any fixes which alter forces or otherwise update the system have been invoked. This means that atom positions have been updated, neighbor lists and ghost atoms are current, and both intermolecular and intramolecular forces have been calculated based on the new coordinates. Thus the region criterion, if applied, should be accurate. Also, any computes invoked by an atom-style variable should use updated information for that timestep (e.g., potential energy/atom or coordination number/atom). Similarly, fixes or computes which are invoked after that point in the timestep, should operate on the new group of atoms.

---

**Note:** If the *region* keyword is used to determine what atoms are in the dynamic group, atoms can move outside of the simulation box between reneighboring events. Thus if you want to include all atoms on the left side of the simulation box, you probably want to set the left boundary of the region to be outside the simulation box by some reasonable amount (e.g., up to the cutoff of the potential), else they may be excluded from the dynamic region.

---

Here is an example of using a dynamic group to shrink the set of atoms being integrated by using a spherical region with a variable radius (shrinking from 18 to 5 over the course of the run). This could be used to model a quench of the system, freezing atoms outside the shrinking sphere, then converting the remaining atoms to a static group and running further.

```
variable      nsteps equal 5000
variable      rad equal 18-(step/v_nsteps)*(18-5)
region        ss sphere 20 20 0 v_rad
group         mobile dynamic all region ss
fix           1 mobile nve
run           ${nsteps}
group         mobile static
run           ${nsteps}
```

---

**Note:** All fixes and computes take a group ID as an argument, but they do not all allow for use of a dynamic group. If you get an error message that this is not allowed, but feel that it should be for the fix or compute in question, then

please post your reasoning to the [LAMMPS forum at MatSci](#) and we can look into changing it. The same applies if you come across inconsistent behavior when dynamic groups are allowed.

---

The *static* style removes the setting for a dynamic group, converting it to a static group (the default). The atoms in the static group are those currently in the dynamic group.

---

### 1.34.4 Restrictions

There can be no more than 32 groups defined at one time, including “all”.

The parent group of a dynamic group cannot itself be a dynamic group.

### 1.34.5 Related commands

*dump, fix, region, velocity*

### 1.34.6 Default

All atoms belong to the “all” group.

## 1.35 group2ndx command

## 1.36 ndx2group command

### 1.36.1 Syntax

```
group2ndx file args
ndx2group file args
```

- file = name of index file to write out or read in
- args = zero or more group IDs may be appended

### 1.36.2 Examples

```
group2ndx allindex.ndx
group2ndx someindex.ndx upper lower mobile
ndx2group someindex.ndx
ndx2group someindex.ndx mobile
```

### 1.36.3 Description

Write or read a Gromacs style index file in text format that associates atom IDs with the corresponding group definitions. This index file can be used with in combination with Gromacs analysis tools or to import group definitions into the *fix colvars* input file.

It can also be used to save and restore group definitions for static groups using the individual atom IDs. This may be important if the original group definition depends on a region or otherwise on the geometry and thus cannot be easily recreated.

Another application would be to import atom groups defined for Gromacs simulation into LAMMPS. When translating Gromacs topology and geometry data to LAMMPS.

The *group2ndx* command will write group definitions to an index file. Without specifying any group IDs, all groups will be written to the index file. When specifying group IDs, only those groups will be written to the index file. In order to follow the Gromacs conventions, the group *all* will be renamed to *System* in the index file.

The *ndx2group* command will create or update group definitions from those stored in an index file. Without specifying any group IDs, all groups except *System* will be read from the index file and the corresponding groups recreated. If a group of the same name already exists, it will be completely reset. When specifying group IDs, those groups, if present, will be read from the index file and restored.

### 1.36.4 File Format

The file format is equivalent and compatible with what is produced by the Gromacs *make\_ndx* command. and follows the Gromacs definition of an *ndx* file

Each group definition begins with the group name in square brackets with blanks, e.g. [ water ] and is then followed by the list of atom indices, which may be spread over multiple lines. Here is a small example file:

```
[ Oxygen ]
1 4 7
[ Hydrogen ]
2 3 5 6
8 9
[ Water ]
1 2 3 4 5 6 7 8 9
```

The index file defines 3 groups: Oxygen, Hydrogen, and Water and the latter happens to be the union of the first two.

---

### 1.36.5 Restrictions

These commands require that atoms have atom IDs, since this is the information that is written to the index file.

These commands are part of the EXTRA-COMMAND package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 1.36.6 Related commands

*group, dump, fix colvars*

### 1.36.7 Default

none

## 1.37 hyper command

### 1.37.1 Syntax

```
hyper N Nevent fix-ID compute-ID keyword values ...
```

- N = # of timesteps to run
- Nevent = check for events every this many steps
- fix-ID = ID of a fix that applies a global or local bias potential, can be NULL
- compute-ID = ID of a compute that identifies when an event has occurred
- zero or more keyword/value pairs may be appended
- keyword = *min* or *dump* or *rebond*

*min* values = etol ftol maxiter maxeval

etol = stopping tolerance for energy, used in quenching

ftol = stopping tolerance for force, used in quenching

maxiter = max iterations of minimize, used in quenching

maxeval = max number of force/energy evaluations, used in quenching

*dump* value = dump-ID

dump-ID = ID of dump to trigger whenever an event takes place

*rebond* value = Nrebond

Nrebond = frequency at which to reset bonds, even if no event has occurred

### 1.37.2 Examples

```
compute event all event/displace 1.0
fix HG mobile hyper/global 3.0 0.3 0.4 800.0
hyper 5000 100 HG event min 1.0e-6 1.0e-6 100 100 dump 1 dump 5
```

### 1.37.3 Description

Run a bond-boost hyperdynamics (HD) simulation where time is accelerated by application of a bias potential to one or more pairs of nearby atoms in the system. This command can be used to run both global and local hyperdynamics. In global HD a single bond within the system is biased on each timestep. In local HD multiple bonds (separated by a sufficient distance) can be biased simultaneously at each timestep. In the bond-boost hyperdynamics context, a “bond” is not a covalent bond between a pair of atoms in a molecule. Rather it is simply a pair of nearby atoms as discussed below.

Both global and local HD are described in ([Voter2013](#)) by Art Voter and collaborators. Similar to parallel replica dynamics (PRD), global and local HD are methods for performing accelerated dynamics that are suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods (AMD) for such systems is given in ([Voter2002](#)) from the same group. To quote from the review paper: “The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by  $p(t) = k \cdot \exp(-kt)$  where  $k$  is the rate constant.”

Both HD and PRD produce a time-accurate trajectory that effectively extends the timescale over which a system can be simulated, but they do it differently. HD uses a single replica of the system and accelerates time by biasing the interaction potential in a manner such that each timestep is effectively longer. PRD creates  $N_r$  replicas of the system and runs dynamics on each independently with a normal unbiased potential until an event occurs in one of the replicas. The time between events is reduced by a factor of  $N_r$  replicas. For both methods, per CPU second, more physical time elapses and more events occur. See the [prd](#) page for more info about PRD.

An HD run has several stages, which are repeated each time an event occurs, as explained below. The logic for an HD run is as follows:

```
quench
create initial list of bonds

while (time remains):
  run dynamics for Nevent steps
  quench
  check for an event
  if event occurred: reset list of bonds
  restore pre-quench state
```

The list of bonds is the list of atom pairs of atoms that are within a short cutoff distance of each other after the system energy is minimized (quenched). This list is created and reset by a [fix hyper/global](#) or [fix hyper/local](#) command specified as *fix-ID*. At every dynamics timestep, the same fix selects one of more bonds to apply a bias potential to.

---

**Note:** The style of fix associated with the specified *fix-ID* determines whether you are running the global versus local hyperdynamics algorithm.

---

Dynamics (with the bias potential) is run continuously, stopping every *Nevent* steps to check if a transition event has occurred. The specified  $N$  for total steps must be a multiple of *Nevent*. check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the [min\\_style](#) command. Minimization parameters may be set via the [min\\_modify](#) command and by the *min* keyword of the hyper command. The latter are the settings that would be used with the [minimize](#) command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event, though you may need to in order to prevent a set of atoms in the system from relaxing to a saddle point.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the hyper command, which is the [compute event/displace](#) command. Other event-checking computes may

be added. *Compute event/displace* checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an event has occurred.

If this happens, the list of bonds is reset, since some bond pairs are likely now too far apart, and new pairs are likely close enough to be considered a bond. The pre-quenched state of the system (coordinates and velocities) is restored, and dynamics continue.

At the end of the hyper run, a variety of statistics are output to the screen and logfile. These include info relevant to both global and local hyperdynamics, such as the number of events and the elapsed hyper time (accelerated time). And it includes info specific to one or the other, depending on which style of fix was specified by *fix-ID*.

---

The optional keywords operate as follows.

As explained above, the *min* keyword can be used to specify parameters for the quench. Their meaning is the same as for the *minimize* command

The *dump* keyword can be used to trigger a specific dump command with the specified *dump-ID* to output a snapshot each time an event is detected. It can be specified multiple times with different *dump-ID* values, as in the example above. These snapshots will be for the quenched state of the system on a timestep that is a multiple of *Nevent*, i.e. a timestep after the event has occurred. Note that any dump command in the input script will also output snapshots at whatever timestep interval it defines via its *N* argument; see the *dump* command for details. This means if you only want a particular dump to output snapshots when events are detected, you should specify its *N* as a value larger than the length of the hyperdynamics run.

As in the code logic above, the bond list is normally only reset when an event occurs. The *rebond* keyword will force a reset of the bond list every *Nrebond* steps, even if an event has not occurred. *Nrebond* must be a multiple of *Nevent*. This can be useful to check if more frequent resets alter event statistics, perhaps because the parameters chosen for defining what is a bond and what is an event are producing bad dynamics in the presence of the bias potential.

---

### 1.37.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

### 1.37.5 Related commands

*fix hyper/global*, *fix hyper/local*, *compute event/displace*, *prd*

### 1.37.6 Default

The option defaults are *min* = 0.1 0.1 40 50 and *time* = steps.

(Voter2013) S. Y. Kim, D. Perez, A. F. Voter, J Chem Phys, 139, 144110 (2013).

(Voter2002) Voter, Montalenti, Germann, Annual Review of Materials Research 32, 321 (2002).

## 1.38 if command

### 1.38.1 Syntax

```
if boolean then t1 t2 ... elif boolean f1 f2 ... elif boolean f1 f2 ... else e1 e2 ...
```

- boolean = a Boolean expression evaluated as TRUE or FALSE (see below)
- then = required word
- t1,t2,...,tN = one or more LAMMPS commands to execute if condition is met, each enclosed in quotes
- elif = optional word, can appear multiple times
- f1,f2,...,fN = one or more LAMMPS commands to execute if elif condition is met, each enclosed in quotes (optional arguments)
- else = optional argument
- e1,e2,...,eN = one or more LAMMPS commands to execute if no condition is met, each enclosed in quotes (optional arguments)

### 1.38.2 Examples

```
if "${steps} > 1000" then quit
if "${myString} == a10" then quit
if "$x <= $y" then "print 'X is smaller = $x'" else "print 'Y is smaller = $y'"
if "({eng} > 0.0) || ($n < 1000)" then &
    "timestep 0.005" &
elif $n<10000 &
    "timestep 0.01" &
else &
    "timestep 0.02" &
    "print 'Max step reached'"
if "${eng} > ${eng_previous}" then "jump file1" else "jump file2"
```

### 1.38.3 Description

This command provides an if-then-else capability within an input script. A Boolean expression is evaluated and the result is TRUE or FALSE. Note that as in the examples above, the expression can contain variables, as defined by the *variable* command, which will be evaluated as part of the expression. Thus a user-defined formula that reflects the current state of the simulation can be used to issue one or more new commands.

If the result of the Boolean expression is TRUE, then one or more commands (t1, t2, ..., tN) are executed. If it is FALSE, then Boolean expressions associated with successive elif keywords are evaluated until one is found to be true, in which case its commands (f1, f2, ..., fN) are executed. If no Boolean expression is TRUE, then the commands associated with the else keyword, namely (e1, e2, ..., eN), are executed. The elif and else keywords and their associated commands are optional. If they are not specified and the initial Boolean expression is FALSE, then no commands are executed.

The syntax for Boolean expressions is described below.

Each command (t1, f1, e1, etc.) can be any valid LAMMPS input script command. If the command is more than one word, it must be enclosed in quotes, so it will be treated as a single argument, as in the examples above.

**Note:** If a command itself requires a quoted argument (e.g., a *print* command), then double and single quotes can be used and nested in the usual manner, as in the examples above and below. The *Commands parse* page has more details on using quotes in arguments. Only one of level of nesting is allowed, but that should be sufficient for most use cases.

Note that by using the line continuation character “&”, the if command can be spread across many lines, though it is still a single command:

```
if "$a < $b" then &
  "print 'Minimum value = $a'" &
  "run 1000" &
else &
  'print "Minimum value = $b"' &
  "minimize 0.001 0.001 1000 10000"
```

Note that if one of the commands to execute is *quit*, as in the first example above, then executing the command will cause LAMMPS to halt.

Note that by jumping to a label in the same input script, the if command can be used to break out of a loop. See the *variable delete* command for info on how to delete the associated loop variable, so that it can be re-used later in the input script.

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the *variable* doc page, this can be ensured by including the variable in thermodynamic output.

```
variable myTemp equal temp
label loop
variable a loop 1000
run 1000
if "${myTemp} < 300.0" then "jump SELF break"
next a
jump SELF loop
label break
print "ALL DONE"
```

Here is an example of a double loop which uses the if and *jump* commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
label      loopa
variable  a loop 5
  label    loopb
  variable b loop 5
    print  "A,B = $a,$b"
    run    10000
    if     "$b > 2" then "jump SELF break"
  next     b
  jump     in.script loopb
  label    break
  variable b delete
next       a
jump      SELF loopa
```

The Boolean expressions for the `if` and `elif` keywords have a C-like syntax. Note that each expression is a single argument within the `if` command. Thus if you want to include spaces in the expression for clarity, you must enclose the entire expression in quotes.

An expression is built out of numbers (which start with a digit or period or minus sign) or strings (which start with a letter and can contain alphanumeric characters, underscores, or forward slashes):

```
0.2, 100, 1.0e20, -15.4, ...  
InP, myString, a123, ab_23_cd, lj/cut, ...
```

and Boolean operators:

```
A == B, A != B, A < B, A <= B, A > B, A >= B, A && B, A || B, A ^ B, !A
```

Each `A` and `B` is a number or string or a variable reference like `$a` or `${abc}`, or `A` or `B` can be another Boolean expression.

Note that all variables used will be substituted for before the Boolean expression is evaluated. A variable can produce a number, like an *equal-style variable*, or it can produce a string, like an *index-style variable*.

The Boolean operators `==` and `!=` can operate on a pair of strings or numbers. They cannot compare a number to a string. All the other Boolean operations can only operate on numbers.

Expressions are evaluated left to right and have the usual C-style precedence: the unary logical NOT operator `!` has the highest precedence, the 4 relational operators `<`, `<=`, `>`, and `>=` are next; the two remaining relational operators `==` and `!=` are next; then the logical AND operator `&&`; and finally the logical OR operator `||` and logical XOR (exclusive or) operator `^` have the lowest precedence. Parenthesis can be used to group one or more portions of an expression and/or enforce a different order of evaluation than what would occur with the default precedence.

When the six relational operators (first six in list above) compare two numbers, they return either a 1.0 or 0.0 depending on whether the relationship between `A` and `B` is TRUE or FALSE.

When the three logical operators (last three in list above) compare two numbers, they also return either a 1.0 or 0.0 depending on whether the relationship between `A` and `B` is TRUE or FALSE (or just `A`). The logical AND operator will return 1.0 if both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments is non-zero, else it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0. The 3 logical operators can only be used to operate on numbers, not on strings.

The overall Boolean expression produces a TRUE result if the numeric result is non-zero. If the result is zero, the expression result is FALSE.

---

**Note:** If the Boolean expression is a single numeric value with no Boolean operators, it will be FALSE if the value = 0.0, otherwise TRUE. If the Boolean expression is a single string, an error message will be issued.

---

### 1.38.4 Restrictions

none

### 1.38.5 Related commands

*variable, print*

### 1.38.6 Default

none

## 1.39 improper\_coeff command

### 1.39.1 Syntax

```
improper_coeff N args
```

- N = numeric improper type (see asterisk form below), or type label
- args = coefficients for one or more improper types

### 1.39.2 Examples

```
improper_coeff 1 300.0 0.0
improper_coeff * 80.2 -1 2
improper_coeff *4 80.2 -1 2

labelmap improper 1 benzene
improper_coeff benzene 300.0 0.0
```

### 1.39.3 Description

Specify the improper force field coefficients for one or more improper types. The number and meaning of the coefficients depends on the improper style. Improper coefficients can also be set in the data file read by the [read\\_data](#) command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or N can be a type label, which is an alphanumeric string defined by the [labelmap](#) command or in a section of a data file read by the [read\\_data](#) command.

For numeric values only, a wild-card asterisk can be used to set the coefficients for multiple improper types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If N = the number of improper types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

Note that using an improper\_coeff command can override a previous setting for the same improper type. For example, these commands set the coeffs for all improper types, then overwrite the coeffs for just improper type 2:

```
improper_coeff * 300.0 0.0
improper_coeff 2 50.0 0.0
```

A line in a data file that specifies improper coefficients uses the exact same format as the arguments of the `improper_coeff` command in an input script, except that wild-card asterisks should not be used since coefficients for all  $N$  types must be listed in the file. For example, under the “Improper Coeffs” section of a data file, the line that corresponds to the first example above would be listed as

```
1 300.0 0.0
```

The *`improper_style class2`* is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

---

The list of all improper styles defined in LAMMPS is given on the *`improper_style`* doc page. They are also listed in more compact form on the *`Commands improper`* doc page.

On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated `improper_coeff` command.

---

### 1.39.4 Restrictions

This command must come after the simulation box is defined by a *`read_data`*, *`read_restart`*, or *`create_box`* command.

An improper style must be defined before any improper coefficients are set, either in the input script or in a data file.

### 1.39.5 Related commands

*`improper_style`*

### 1.39.6 Default

## 1.40 `improper_style` command

### 1.40.1 Syntax

```
improper_style style
```

- `style = none` or *`hybrid`* or *`class2`* or *`cvff`* or *`harmonic`*

### 1.40.2 Examples

```
improper_style harmonic  
improper_style cvff  
improper_style hybrid cvff harmonic
```

### 1.40.3 Description

Set the formula(s) LAMMPS uses to compute improper interactions between quadruplets of atoms, which remain in force for the duration of the simulation. The list of improper quadruplets is read in by a [read\\_data](#) or [read\\_restart](#) command from a data or restart file. Note that the ordering of the 4 atoms in an improper quadruplet determines the definition of the improper angle used in the formula for each style. See the doc pages of individual styles for details.

Hybrid models where impropers are computed using different improper potentials can be setup using the *hybrid* improper style.

The coefficients associated with an improper style can be specified in a data or restart file or via the *improper\_coeff* command.

All improper potentials store their coefficient data in binary restart files which means *improper\_style* and *improper\_coeff* commands do not need to be re-specified in an input script that restarts a simulation. See the [read\\_restart](#) command for details on how to do this. The one exception is that *improper\_style hybrid* only stores the list of sub-styles in the restart file; improper coefficients need to be re-specified.

---

**Note:** When both an improper and pair style is defined, the *special\_bonds* command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between a group of 4 bonded atoms.

---

Here is an alphabetic list of improper styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated *improper\_coeff* command.

Click on the style to display the formula it computes, any additional arguments specified in the *improper\_style* command, and coefficients specified by the associated *improper\_coeff* command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the [Commands improper](#) page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- [none](#) - turn off improper interactions
  - [zero](#) - topology but no interactions
  - [hybrid](#) - define multiple styles of improper interactions
  - [amoeba](#) - AMOEBA out-of-plane improper
  - [class2](#) - COMPASS (class 2) improper
  - [cossq](#) - improper with a cosine squared term
  - [cvff](#) - CVFF improper
  - [distance](#) - improper based on distance between atom planes
  - [distharm](#) - improper that is harmonic in the out-of-plane distance
  - [fourier](#) - improper with multiple cosine terms
  - [harmonic](#) - harmonic improper
  - [inversion/harmonic](#) - harmonic improper with Wilson-Decius out-of-plane definition
  - [ring](#) - improper which prevents planar conformations
  - [umbrella](#) - DREIDING improper
  - [sqdistharm](#) - improper that is harmonic in the square of the out-of-plane distance
-

### 1.40.4 Restrictions

Improper styles can only be set for atom\_style choices that allow impropers to be defined.

Most improper styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info. The doc pages for individual improper potentials tell if it is part of a package.

### 1.40.5 Related commands

*improper\_coeff*

### 1.40.6 Default

```
improper_style none
```

## 1.41 include command

### 1.41.1 Syntax

```
include file
```

- file = filename of new input script to switch to

### 1.41.2 Examples

```
include newfile
include in.run2
```

### 1.41.3 Description

This command opens a new input script file and begins reading LAMMPS commands from that file. When the new file is finished, the original file is returned to. Include files can be nested as deeply as desired. If input script A includes script B, and B includes A, then LAMMPS could run for a long time.

If the filename is a variable (see the [variable](#) command), different processor partitions can run different input scripts.

### 1.41.4 Restrictions

none

### 1.41.5 Related commands

*variable, jump*

### 1.41.6 Default

## 1.42 info command

### 1.42.1 Syntax

```
info args
```

- args = one or more of the following keywords: *out, all, system, memory, communication, computes, dumps, fixes, groups, regions, variables, coeffs, styles, time, accelerator, fft* or *configuration*
- *out* values = *screen, log, append* filename, *overwrite* filename
- *styles* values = *all, angle, atom, bond, compute, command, dump, dihedral, fix, improper, integrate, kspace, minimize, pair, region*

### 1.42.2 Examples

```
info system
info groups computes variables
info all out log
info all out append info.txt
info styles all
info styles atom styles command
```

### 1.42.3 Description

Print out information about the current internal state of the running LAMMPS process. This can be helpful when debugging or validating complex input scripts. Several output categories are available and one or more output categories may be requested. All category keywords take no arguments, only *out* and *styles* take arguments as shown below. The keywords are cumulative, may be abbreviated, and unknown keywords are ignored.

The *out* flag controls where the output is sent. It can only be sent to one target. By default this is the screen, if it is active. The *log* argument selects the log file instead. With the *append* and *overwrite* option, followed by a filename, the output is written to that file, which is either appended to or overwritten, respectively.

The *all* flag activates printing all categories listed below.

The *configuration* category prints some information about the LAMMPS version as well as architecture and OS it is run on.

The *memory* category prints some information about the current memory allocation of MPI rank 0 (this is the amount of dynamically allocated memory reported by LAMMPS classes). Where supported, also some OS specific information about the size of the reserved memory pool size (this is where `malloc()` and the new operator request memory from) and the maximum resident set size is reported (this is the maximum amount of physical memory occupied so far).

The *system* category prints a general system overview listing. This includes the unit style, atom style, number of atoms, bonds, angles, dihedrals, and impropers and the number of the respective types, box dimensions and properties, force computing styles and more.

The *communication* category prints a variety of information about communication and parallelization: the MPI library version level, the number of MPI ranks and OpenMP threads, the communication style and layout, the processor grid dimensions, ghost atom communication mode, cutoff, and related settings.

The *computes* category prints a list of all currently defined computes, their IDs and styles and groups they operate on.

The *dumps* category prints a list of all currently active dumps, their IDs, styles, filenames, groups, and dump frequencies.

The *fixes* category prints a list of all currently defined fixes, their IDs and styles and groups they operate on.

The *groups* category prints a list of all currently defined groups.

The *regions* category prints a list of all currently defined regions, their IDs and styles and whether “inside” or “outside” atoms are selected.

The *variables* category prints a list of all currently defined variables, their names, styles, definition and last computed value, if available.

The *coeffs* category prints a list for each defined force style (pair, bond, angle, dihedral, improper) indicating which of the corresponding coefficients have been set. This can be very helpful to debug error messages like “All pair coeffs are not set”.

The *accelerator* category prints out information about compile time settings of included accelerator support for the GPU, KOKKOS, INTEL, and OPENMP packages.

New in version 7Feb2024.

The *fft* category prints out information about the included 3d-FFT support. This lists the 3d-FFT engine, FFT precision, FFT library used by the FFT engine. If the KOKKOS package is included, the settings used for the KOKKOS package are displayed as well.

The *styles* category prints the list of styles available in the current LAMMPS binary. The *styles* keyword without option is the same as using the “all” option. One of the following options may be used to control which category of styles is printed out. To select multiple categories, the styles keyword needs to be used multiple times with the desired categories:

- all
- angle
- atom
- bond
- compute
- command
- dump
- dihedral
- fix
- improper
- integrate
- kspace
- minimize

- pair
- region

The *time* category prints the accumulated CPU and wall time for the process that writes output (usually MPI rank 0).

### 1.42.4 Restrictions

none

### 1.42.5 Related commands

*print*

### 1.42.6 Default

The *out* option has the default *screen*.

The *styles* option has the default *all*.

## 1.43 jump command

### 1.43.1 Syntax

```
jump file label
```

- file = filename of new input script to switch to
- label = optional label within file to jump to

### 1.43.2 Examples

```
jump newfile
jump in.run2 runloop
jump SELF runloop
```

### 1.43.3 Description

This command closes the current input script file, opens the file with the specified name, and begins reading LAMMPS commands from that file. Unlike the *include* command, the original file is not returned to, although by using multiple jump commands it is possible to chain from file to file or back to the original file.

If the word “SELF” is used for the filename, then the current input script is re-opened and read again.

---

**Note:** The SELF option is not guaranteed to work when the current input script is being read through stdin (standard input), e.g.

---

```
lmp_g++ < in.script
```

since the SELF option invokes the C-library `rewind()` call, which may not be supported for stdin on some systems or by some MPI implementations. This can be worked around by using the *-in command-line switch*, e.g.

```
lmp_g++ -in in.script
```

or by using the *-var command-line switch* to pass the script name as a variable to the input script. In the latter case, a *variable* called “fname” could be used in place of SELF, e.g.

```
lmp_g++ -var fname in.script < in.script
```

The second argument to the jump command is optional. If specified, it is treated as a label and the new file is scanned (without executing commands) until the label is found, and commands are executed from that point forward. This can be used to loop over a portion of the input script, as in this example. These commands perform 10 runs, each of 10000 steps, and create 10 dump files named file.1, file.2, etc. The *next* command is used to exit the loop after 10 iterations. When the “a” variable has been incremented for the tenth time, it will cause the next jump command to be skipped.

```
variable a loop 10
label loop
dump 1 all atom 100 file.$a
run 10000
undump 1
next a
jump in.lj loop
```

If the jump *file* argument is a variable, the jump command can be used to cause different processor partitions to run different input scripts. In this example, LAMMPS is run on 40 processors, with 4 partitions of 10 procs each. An in.file containing the example variable and jump command will cause each partition to run a different simulation.

```
mpirun -np 40 lmp_ibm -partition 4x10 -in in.file

variable f world script.1 script.2 script.3 script.4
jump $f
```

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the *variable* doc page, this can be ensured by including the variable in thermodynamic output.

```
variable myTemp equal temp
label loop
variable a loop 1000
run 1000
if "${myTemp} < 300.0" then "jump SELF break"
next a
jump SELF loop
label break
print "ALL DONE"
```

Here is an example of a double loop which uses the if and *jump* commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```

label      loopa
variable   a loop 5
  label    loopb
  variable b loop 5
    print  "A,B = $a,$b"
    run    10000
    if     "$b > 2" then "jump SELF break"
  next     b
  jump     in.script loopb
  label    break
  variable b delete
next       a
jump       SELF loopa

```

### 1.43.4 Restrictions

If you jump to a file and it does not contain the specified label, LAMMPS will come to the end of the file and exit.

### 1.43.5 Related commands

*variable, include, label, next*

## 1.44 kim command

### 1.44.1 Syntax

```
kim sub-command args
```

- sub-command = *init* or *interactions* or *query* or *param* or *property*
- args = arguments used by a particular sub-command

### 1.44.2 Examples

```

kim init args
kim interactions args
kim query args
kim param args
kim property args

```

### 1.44.3 Description

The *kim command* includes a set of sub-commands that allow LAMMPS users to use interatomic models (IM) (potentials and force fields) and their predictions for various physical properties archived in the [Open Knowledgebase of Interatomic Models \(OpenKIM\)](#) repository.

Using OpenKIM provides LAMMPS users with immediate access to a large number of verified IMs and their predictions. OpenKIM IMs have multiple benefits including [reliability](#), [reproducibility](#) and [convenience](#).

There are two types of IMs archived in OpenKIM:

1. The first type is called a *KIM Portable Model* (PM). A KIM PM is an independent computer implementation of an IM written in one of the languages supported by KIM (C, C++, Fortran) that conforms to the KIM Application Programming Interface ([KIM API](#)) Portable Model Interface (PMI) standard. A KIM PM will work seamlessly with any simulation code that supports the KIM API/PMI standard (including LAMMPS; see [complete list of supported codes](#)).
2. The second type is called a *KIM Simulator Model* (SM). A KIM SM is an IM that is implemented natively within a simulation code (*simulator*) that supports the KIM API Simulator Model Interface (SMI); in this case LAMMPS. A separate SM package is archived in OpenKIM for each parameterization of the IM, which includes all of the necessary parameter files, LAMMPS commands, and metadata (supported species, units, etc.) needed to run the IM in LAMMPS.

With these two IM types, OpenKIM can archive and test almost all IMs that can be used by LAMMPS. (It is easy to contribute new IMs to OpenKIM, see the [upload instructions](#).)

OpenKIM IMs are uniquely identified by a [KIM ID](#). The extended KIM ID consists of a human-readable prefix identifying the type of IM, authors, publication year, and supported species, separated by two underscores from the KIM ID itself, which begins with an IM code (*MO* for a KIM Portable Model, and *SM* for a KIM Simulator Model) followed by a unique 12-digit code and a 3-digit version identifier. By convention SM prefixes begin with *Sim\_* to readily identify them.

```
SW_StillingerWeber_1985_Si__MO_405512056662_005  
Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001
```

Each OpenKIM IM has a dedicated “Model Page” on [OpenKIM](#) providing all the information on the IM including a title, description, authorship and citation information, test and verification check results, visualizations of results, a wiki with documentation and user comments, and access to raw files, and other information. The URL for the Model Page is constructed from the [extended KIM ID](#) of the IM:

```
https://openkim.org/id/extended_KIM_ID
```

For example, for the Stillinger-Weber potential listed above the Model Page is located at:

[https://openkim.org/id/SW\\_StillingerWeber\\_1985\\_Si\\_\\_MO\\_405512056662\\_005](https://openkim.org/id/SW_StillingerWeber_1985_Si__MO_405512056662_005)

See the [current list of KIM PMs and SMs archived in OpenKIM](#). This list is sorted by species and can be filtered to display only IMs for certain species combinations.

See [Obtaining KIM Models](#) to learn how to install a pre-built binary of the OpenKIM Repository of Models.

---

**Note:** It is also possible to locally install IMs not archived in OpenKIM, in which case their names do not have to conform to the KIM ID format.

---

### 1.44.4 Using OpenKIM IMs with LAMMPS (*kim init*, *kim interactions*)

Two sub-commands are employed when using OpenKIM IMs in LAMMPS, one to select the IM and perform necessary initialization (*kim init*), and the second to set up the IM for use by executing any necessary LAMMPS commands (*kim interactions*). Both are required.

#### Syntax

```
kim init model user_units unitarg
kim interactions typeargs
```

- model = name of the KIM interatomic model (the KIM ID for models archived in OpenKIM)
- user\_units = the LAMMPS *units* style assumed in the LAMMPS input script
- unitarg = *unit\_conversion\_mode* (optional)
- typeargs = atom type to species mapping (one entry per atom type) or *fixed\_types* for models with a preset fixed mapping

#### Examples

```
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
kim interactions Si

kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001 real
kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001_
→metal unit_conversion_mode
kim interactions C H O

kim init Sim_LAMMPS_IFF_PCFF_HeinzMishraLinEmami_2015Ver1v5_
→FccmetalsMineralsSolventsPolymers__SM_039297821658_000 real
kim interactions fixed_types
```

See the *examples/kim* directory for example input scripts that use KIM PMs and KIM SMs.

#### OpenKIM IM Initialization (*kim init*)

The *kim* command followed by *init* sub-command must be issued **before** the simulation box is created (normally at the top of the file). This command sets the OpenKIM IM that will be used and may issue additional commands changing LAMMPS default settings that are required for using the selected IM (such as *units* or *atom\_style*). If needed, those settings can be overridden, however, typically a script containing a *kim init* command would not include *units* and *atom\_style* commands.

The required arguments of *kim init* are the *model* name of the IM to be used in the simulation (for an IM archived in OpenKIM this is its *extended KIM ID*), and the *user\_units*, which are the LAMMPS *units style* used in the input script. (Any dimensioned numerical values in the input script and values read in from files are expected to be in the *user\_units* system.)

The selected IM can be either a *KIM PM* or a *KIM SM*. For a KIM SM, the *kim init* command verifies that the SM is designed to work with LAMMPS (and not another simulation code). In addition, the LAMMPS version used for defining the SM and the LAMMPS version being currently run are printed to help diagnose any incompatible changes to input script or command syntax between the two LAMMPS versions.

Based on the selected model *kim init* may modify the *atom\_style*. Some SMs have requirements for this setting. If this is the case, then *atom\_style* will be set to the required style. Otherwise, the value is left unchanged (which in the absence of an *atom\_style* command in the input script is the *default atom\_style value*).

Regarding units, the *kim init* behaves in different ways depending on whether or not *unit conversion mode* is activated as indicated by the optional *unitarg* argument. If unit conversion mode is **not** active, then *user\_units* must either match the required units of the IM or the IM must be able to adjust its units to match. (The latter is only possible with some KIM PMs; SMs can never adjust their units.) If a match is possible, the LAMMPS *units* command is called to set the units to *user\_units*. If the match fails, the simulation is terminated with an error. The *kim init* command also sets the default value for the *skin* (extra distance beyond force cutoff) as 2.0 Angstroms and sets the default value for the *timestep* size as 1.0 femtosecond.

Here is an example of a LAMMPS script to compute the cohesive energy of a face-centered cubic (fcc) lattice for the MEAM potential by Pascuet and Fernandez (2015) for Al.

```
kim      init Sim_LAMMPS_MEAM_PascuetFernandez_2015_Al__SM_811588957187_000 metal
boundary p p p
lattice  fcc 4.049
region   simbox block 0 1 0 1 0 1 units lattice
create_box 1 simbox
create_atoms 1 box
mass      1 26.981539
kim      interactions Al
run       0
variable Ec equal (pe/count(all))
print    "Cohesive Energy = ${Ec} eV"
```

The above script will end with an error in the *kim init* line if the IM is changed to another potential for Al that does not work with *metal* units. To address this, *kim init* offers the *unit\_conversion\_mode* as shown below.

If unit conversion mode *is* active, then *kim init* calls the LAMMPS *units* command to set the units to the IM's required or preferred units. Conversion factors between the IM's units and the *user\_units* are defined for all *physical quantities* (mass, distance, etc.). (Note that converting to or from the "lj" unit style is not supported.) These factors are stored as *internal style variables* with the following standard names:

```
_u_mass
_u_distance
_u_time
_u_energy
_u_velocity
_u_force
_u_torque
_u_temperature
_u_pressure
_u_viscosity
_u_charge
_u_dipole
_u_efield
_u_density
```

If desired, the input script can be designed to work with these conversion factors so that the script will work without change with any OpenKIM IM. (This approach is used in the [OpenKIM Testing Framework](#).)

For example, the script given above for the cohesive energy of fcc Al can be rewritten to work with any IM regardless of units. The following script constructs an fcc lattice with a lattice parameter defined in meters, computes the total energy, and prints the cohesive energy in Joules regardless of the units of the IM.

```

kim      init Sim_LAMMPS_MEAM_PascuetFernandez_2015_Al__SM_811588957187_000 si unit_
→conversion_mode
boundary  p p p
lattice   fcc $(4.049e-10*v__u_distance)
region    simbox block 0 1 0 1 0 1 units lattice
create_box 1 simbox
create_atoms 1 box
mass       1 $(4.480134e-26*v__u_mass)
kim        interactions Al
neighbor   $(2e-10*v__u_distance) bin
run        0
variable   Ec_in_J equal (pe/count(all))/v__u_energy
print      "Cohesive Energy = ${Ec_in_J} J"

```

Note the multiplication by `v__u_distance` and `v__u_mass` to convert from SI units (specified in the `kim init` command) to whatever units the IM uses (metal in this case), and the division by `v__u_energy` to convert from the IM's energy units to SI units (Joule). This script will work correctly for any IM for Al (KIM PM or SM) selected by the `kim init` command.

Care must be taken to apply unit conversion to dimensional variables read in from a file. For example, if a configuration of atoms is read in from a dump file using the `read_dump` command, the following can be done to convert the box and all atomic positions to the correct units:

```

change_box all x scale ${_u_distance} &
              y scale ${_u_distance} &
              z scale ${_u_distance} &
              xy final $(xy*v__u_distance) &
              xz final $(xz*v__u_distance) &
              yz final $(yz*v__u_distance) &
              remap

```

**Note:** Unit conversion will only work if the conversion factors are placed in all appropriate places in the input script. It is up to the user to do this correctly.

## OpenKIM IM Execution (*kim interactions*)

The second and final step in using an OpenKIM IM is to execute the `kim interactions` command. This command must be preceded by a `kim init` command and a command that defines the number of atom types  $N$  (such as `create_box`). The `kim interactions` command has one argument `typeargs`. This argument contains either a list of  $N$  chemical species, which defines a mapping between atom types in LAMMPS to the available species in the OpenKIM IM, or the keyword `fixed_types` for models that have a preset fixed mapping (i.e. the mapping between LAMMPS atom types and chemical species is defined by the model and cannot be changed). In the latter case, the user must consult the model documentation to see how many atom types there are and how they map to the chemical species.

For example, consider an OpenKIM IM that supports Si and C species. If the LAMMPS simulation has four atom types, where the first three are Si, and the fourth is C, the following `kim interactions` command would be used:

```

kim interactions Si Si Si C

```

Alternatively, for a model with a fixed mapping the command would be:

```
kim interactions fixed_types
```

The *kim interactions* command performs all the necessary steps to set up the OpenKIM IM selected in the *kim init* command. The specific actions depend on whether the IM is a KIM PM or a KIM SM. For a KIM PM, a *pair\_style kim* command is executed followed by the appropriate *pair\_coeff* command. For example, for the Ercolessi and Adams (1994) KIM PM for Al set by the following commands:

```
kim init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
...
... box specification lines skipped
...
kim interactions Al
```

the *kim interactions* command executes the following LAMMPS input commands:

```
pair_style kim EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005
pair_coeff * * Al
```

For a KIM SM, the generated input commands may be more complex and require that LAMMPS is built with the required packages included for the type of potential being used. The set of commands to be executed is defined in the SM specification file, which is part of the SM package. For example, for the Strachan et al. (2003) ReaxFF SM set by the following commands:

```
kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_000 real
...
... box specification lines skipped
...
kim interactions C H N O
```

the *kim interactions* command executes the following LAMMPS input commands:

```
pair_style reaxff lmp_control safezone 2.0 mincap 100
pair_coeff * * ffield.reax.rdx C H N O
fix reaxqeq all qeq/reaxff 1 0.0 10.0 1.0e-6 param.qeq
```

---

**Note:** The files *lmp\_control*, *ffield.reax.rdx* and *param.qeq* are specific to the Strachan et al. (2003) ReaxFF parameterization and are archived as part of the SM package in OpenKIM.

---

---

**Note:** Parameters like cutoff radii and charge tolerances, which have an effect on IM predictions, are also included in the SM definition ensuring reproducibility.

---

---

**Note:** When using *kim init* and *kim interactions* to select and set up an OpenKIM IM, other LAMMPS commands for the same functions (such as *pair\_style*, *pair\_coeff*, *bond\_style*, *bond\_coeff*, fixes related to charge equilibration, etc.) should normally not appear in the input script.

---

---

**Note:** *kim interactions* must be called each time after the *change\_box* command to provide the correct settings (it should be called with the same *typeargs* as the first call.) The reason is that changing a periodic boundary to a non-periodic one, or in general, using the *change\_box* command after the interactions are set via *kim interactions* or *pair\_coeff* commands might affect some of the settings. For example, SM models containing Coulombic terms in the interactions

require different settings if a periodic boundary changes to a non-periodic one. In other cases, the second call to *kim interactions* does not affect any other settings.

### 1.44.5 Using OpenKIM Web Queries in LAMMPS (*kim query*)

The *kim query* command performs a web query to retrieve the predictions of an IM set by *kim init* for material properties archived in OpenKIM.

#### Syntax

```
kim query variable formatarg query_function queryargs
```

- *variable(s)* = single name or list of names of (string style) LAMMPS variable(s) where a query result or parameter get result is stored. Variables that do not exist will be created by the command
- *formatarg* = *list* or *split* or *index* (optional)
  - list* = returns a single string with a list of space separated values (e.g. "1.0 2.0 3.0"), which is placed in a LAMMPS variable as defined by the *variable* argument. [default]
  - split* = returns the values separately in new variables with names based on the prefix specified in *variable* and a number appended to indicate which element in the list of values is in the variable
  - index* = returns a variable style index that can be incremented via the *next* command. This enables the construction of simple loops
- *query\_function* = name of the OpenKIM web API query function to be used
- *queryargs* = a series of *keyword=value* pairs that represent the web query; supported keywords depend on the query function

#### Examples

```
kim query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
kim query model index get_available_models species=[Al] potential_type=[eam]
```

The result of the query is stored in one or more *string style variables* as determined by the optional *formatarg* argument. For the “list” setting of *formatarg* (or if *formatarg* is not specified), the result is returned as a space-separated list of values in *variable*. The *formatarg* keyword “split” separates the result values into individual variables of the form *prefix\_I*, where *prefix* is set to the *kim query variable* argument and *I* ranges from 1 to the number of returned values. The number and order of the returned values is determined by the type of query performed. The *formatarg* keyword “index” returns a *variable style index* that can be incremented via the *next* command. This enables the construction of simple loops over the returned values by the type of query performed.

**Note:** *kim query* only supports queries that return a single result or an array of values. More complex queries that return a JSON structure are not currently supported. An attempt to use *kim query* in such cases will generate an error.

The second required argument *query\_function* is the name of the query function to be called (e.g. *get\_lattice\_constant\_cubic*). All following *arguments* are parameters handed over to the web query in the format *keyword=value*, where *value* is always an array of one or more comma-separated items in brackets. The list of supported

keywords and the type and format of their values depend on the query function used. The current list of query functions is available on the OpenKIM webpage at <https://openkim.org/doc/usage/kim-query>.

---

**Note:** All query functions, except *get\_available\_models*, require the *model* keyword, which identifies the IM whose predictions are being queried. *kim query* automatically generates the *model* keyword based on the IM set in by *kim init*, and it can be overwritten if specified as an argument to the *kim query*. Where *kim init* is not specified, the *model* keyword must be provided as an argument to the *kim query*.

---

---

**Note:** Each *query\_function* is associated with a default method (implemented as a [KIM Test](#)) used to compute this property. In cases where there are multiple methods in OpenKIM for computing a property, a *method* keyword can be provided to select the method of choice. See the [query documentation](#) to see which methods are available for a given *query\_function*.

---

### *kim query* Usage Examples and Further Clarifications

The data obtained by *kim query* commands can be used as part of the setup or analysis phases of LAMMPS simulations. Some examples are given below.

#### Define an equilibrium fcc crystal

```
kim      init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
boundary p p p
kim      query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
lattice  fcc ${a0}
...
```

```
units    metal
kim      query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
↳model=[EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005]
lattice  fcc ${a0}
...
```

The *kim query* command retrieves from [OpenKIM](#) the equilibrium lattice constant predicted by the Ercolessi and Adams (1994) potential for the fcc structure and places it in variable *a0*. This variable is then used on the next line to set up the crystal. By using *kim query*, the user is saved the trouble and possible error of tracking this value down, or of having to perform an energy minimization to find the equilibrium lattice constant.

---

**Note:** In *unit\_conversion\_mode* the results obtained from a *kim query* would need to be converted to the appropriate units system. For example, in the above script, the lattice command would need to be changed to: “lattice fcc  $\$(v\_a0*v\_u\_distance)$ ”.

---

#### Define an equilibrium hcp crystal

```
kim      init EAM_Dynamo_MendeleevAckland_2007v3_Zr__MO_004835508849_000 metal
boundary p p p
kim      query latconst split get_lattice_constant_hexagonal crystal=[hcp] species=[Zr]
↳units=[angstrom]
lattice  custom ${latconst_1} a1 0.5 -0.866025 0 a2 0.5 0.866025 0 a3 0 0 $(latconst_2/
↳latconst_1) &
```

(continues on next page)

(continued from previous page)

```
...
basis 0.333333 0.666666 0.25 basis 0.666666 0.333333 0.75
...
```

In this case the *kim query* returns two arguments (since the hexagonal close packed (hcp) structure has two independent lattice constants). The *formatarg* keyword “split” places the two values into the variables *latconst\_1* and *latconst\_2*. (These variables are created if they do not already exist.)

### Define a crystal at finite temperature accounting for thermal expansion

```
kim      init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
boundary p p p
kim      query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
kim      query alpha get_linear_thermal_expansion_coefficient_cubic crystal=[fcc]
→species=[Al] units=[1/K] temperature=[293.15] temperature_units=[K]
variable DeltaT equal 300
lattice fcc $(v_a0*v_alpha*v_DeltaT)
...
```

As in the previous example, the equilibrium lattice constant is obtained for the Ercolessi and Adams (1994) potential. However, in this case the crystal is scaled to the appropriate lattice constant at room temperature (293.15 K) by using the linear thermal expansion constant predicted by the potential.

**Note:** When passing numerical values as arguments (as in the case of the temperature in the above example) it is also possible to pass a tolerance indicating how close to the value is considered a match. If no tolerance is passed a default value is used. If multiple results are returned (indicating that the tolerance is too large), *kim query* will return an error. See the [query documentation](#) to see which numerical arguments and tolerances are available for a given *query\_function*.

### Compute defect formation energy

```
kim      init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
...
... Build fcc crystal containing some defect and compute the total energy
... which is stored in the variable *Etot*
...
kim      query Ec get_cohesive_energy_cubic crystal=[fcc] species=[Al] units=[eV]
variable Eform equal ${Etot} - count(all)*${Ec}
...
```

The defect formation energy *Eform* is computed by subtracting the ideal fcc cohesive energy of the atoms in the system from *Etot*. The ideal fcc cohesive energy of the atoms is obtained from [OpenKIM](#) for the Ercolessi and Adams (1994) potential.

### Retrieve equilibrium fcc crystal of all EAM potentials that support a specific species

```
kim      query model index get_available_models species=[Al] potential_type=[eam]
label model_loop
kim      query latconst get_lattice_constant_cubic crystal=[fcc] species=[Al]
→units=[angstrom] model=${model}
print "FCC lattice constant (${model} potential) = ${latconst}"
...
... do something with current value of latconst
...
```

(continues on next page)

(continued from previous page)

```
next model
jump SELF model_loop
```

In this example, the *index* mode of *formatarg* is used. The first *kim query* returns the list of all available EAM potentials that support the *Al* species and archived in [OpenKIM](#). The result of the query operation is stored in the LAMMPS variable *model* as an index *variable*. This variable is used later to access the values one at a time within a loop as shown in the example. The second *kim query* command retrieves from [OpenKIM](#) the equilibrium lattice constant predicted by each potential for the fcc structure and places it in variable *latconst*.

---

**Note:** *kim query* commands return results archived in [OpenKIM](#). These results are obtained using programs for computing material properties (KIM Tests and KIM Test Drivers) that were contributed to OpenKIM. In order to give credit to Test developers, the number of times results from these programs are queried is tracked. No other information about the nature of the query or its source is recorded.

---

### 1.44.6 Accessing KIM Model Parameters from LAMMPS (*kim param*)

All IMs are functional forms containing a set of parameters. These parameters' values are typically selected to best reproduce a training set of quantum mechanical calculations or available experimental data. For example, a Lennard-Jones potential intended to model argon might have the values of its two parameters, epsilon, and sigma, fit to the dimer dissociation energy or thermodynamic properties at a critical point of the phase diagram.

Normally a user employing an IM should not modify its parameters since, as noted above, these are selected to reproduce material properties. However, there are cases where accessing and modifying IM parameters is desired, such as for assessing uncertainty, fitting an IM, or working with an ensemble of IMs. As explained [above](#), IMs archived in OpenKIM are either Portable Models (PMs) or Simulator Models (SMs). KIM PMs are complete independent implementations of an IM, whereas KIM SMs are wrappers to an IM implemented within LAMMPS. Two different mechanisms are provided for accessing IM parameters in these two cases:

- For a KIM PM, the *kim param* command can be used to *get* and *set* the values of the PM's parameters as explained below.
- For a KIM SM, the user should consult the documentation page for the specific IM and follow instructions there for how to modify its parameters (if possible).

The *kim param get* and *kim param set* commands provide an interface to access and change the parameters of a KIM PM that “publishes” its parameters and makes them publicly available (see the [KIM API documentation](#) for details).

---

**Note:** The *kim param set/get* command must be preceded by a *kim interactions* command (or alternatively by a *pair\_style kim* and *pair\_coeff* commands). The *kim param set* command may be used wherever a *pair\_coeff* command may occur.

---

## Syntax

```
kim param get param_name index_range variable formatarg
kim param set param_name index_range values
```

- `param_name` = name of a KIM portable model parameter (which is published by the PM and available for access). The specific string used to identify a parameter is defined by the PM. For example, for the [Stillinger-Weber \(SW\) potential in OpenKIM](#), the parameter names are *A*, *B*, *p*, *q*, *sigma*, *gamma*, *cutoff*, *lambda*, *costheta0*
- `index_range` = KIM portable model parameter index range (an integer for a single element, or pair of integers separated by a colon for a range of elements)
- `variable(s)` = single name or list of names of (string style) LAMMPS variable(s) where a query result or parameter get result is stored. Variables that do not exist will be created by the command
- `formatarg` = *list* or *split* or *explicit* (optional)
  - list* = returns a single string with a list of space separated values (e.g. "1.0 2.0 3.0"), which is placed in a LAMMPS variable as defined by the *variable* argument
  - split* = returns the values separately in new variables with names based on the prefix specified in *variable* and a number appended to indicate which element in the list of values is in the variable
  - explicit* = returns the values separately in one more more variable names provided as arguments that precede *formatarg* (default)
- `values` = new value(s) to replace the current value(s) of a KIM portable model parameter

**Note:** The list of all the parameters that a PM exposes for access/mutation are automatically written to the lammps log file when *kim init* is called.

Each published parameter of a KIM PM takes the form of an array of numerical values. The array can contain one element for a single-valued parameter, or a set of values. For example, the [multispecies SW potential for the Zn-Cd-Hg-S-Se-Te system](#) has the same parameter names as the [single-species SW potential](#), but each parameter array contains 21 entries that correspond to the parameter values used for each pairwise combination of the model's six supported species (this model does not have parameters specific to individual ternary combinations of its supported species).

The *index\_range* argument may either be an integer referring to a specific element within the array associated with the parameter specified by *param\_name*, or a pair of integers separated by a colon that refer to a slice of this array. In both cases, one-based indexing is used to refer to the entries of the array.

The result of a *get* operation for a specific *index\_range* is stored in one or more [LAMMPS string style variables](#) as determined by the optional *formatarg* argument [documented above](#). If not specified, the default for *formatarg* is "explicit" for the *kim param* command.

For the case where the result is an array with multiple values (i.e. *index\_range* contains a range), the optional "split" or "explicit" *formatarg* keywords can be used to separate the results into multiple variables; see the examples below. Multiple parameters can be retrieved with a single call to *kim param get* by repeating the argument list following *get*.

For a *set* operation, the *values* argument contains the new value(s) for the element(s) of the parameter specified by *index\_range*. For the case where multiple values are being set, *values* contains a set of values separated by spaces. Multiple parameters can be set with a single call to *kim param set* by repeating the argument list following *set*.

## *kim param* Usage Examples and Further Clarifications

Examples of getting and setting KIM PM parameters with further clarifications are provided below.

### Getting a scalar parameter

```
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
...
kim interactions Si
kim param get A 1 VARA
```

or

```
...
pair_style kim SW_StillingerWeber_1985_Si__MO_405512056662_005
pair_coeff * * Si
kim param get A 1 VARA
```

In these cases, the value of the SW *A* parameter is retrieved and placed in the LAMMPS variable *VARA*. The variable *VARA* can be used in the remainder of the input script in the same manner as any other LAMMPS variable.

### Getting multiple scalar parameters with a single call

```
...
kim interactions Si
kim param get A 1 VARA B 1 VARB
```

In this example, it is shown how to retrieve the *A* and *B* parameters of the SW potential and store them in the LAMMPS variables *VARA* and *VARB*.

### Getting a range of values from a parameter

There are several options when getting a range of values from a parameter determined by the *formatarg* argument.

```
kim init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal
...
kim interactions Te Zn Se
kim param get lambda 7:9 LAM_TeTe LAM_TeZn LAM_TeSe
```

In this case, *formatarg* is not specified and therefore the default “explicit” mode is used. (The behavior would be the same if the word *explicit* were added after *LAM\_TeSe*.) Elements 7, 8 and 9 of parameter *lambda* retrieved by the *get* operation are placed in the LAMMPS variables *LAM\_TeTe*, *LAM\_TeZn* and *LAM\_TeSe*, respectively.

---

**Note:** In the above example, elements 7-9 of the *lambda* parameter correspond to Te-Te, Te-Zn and Te-Se interactions. This can be determined by visiting the [model page for the specified potential](#) and looking at its parameter file linked to at the bottom of the page (file with *.param* ending) and consulting the README documentation provided with the driver for the PM being used. A link to the driver is provided at the top of the model page.

---

```
...
kim      interactions Te Zn Se
kim      param get lambda 15:17 LAMS list
variable LAM_VALUE index ${LAMS}
label    loop_on_lambda
...
...      do something with the current value of lambda
```

(continues on next page)

(continued from previous page)

```
...
next      LAM_VALUE
jump      SELF loop_on_lambda
```

In this case, the “list” mode of *formatarg* is used. The result of the *get* operation is stored in the LAMMPS variable *LAM* as a string containing the three retrieved values separated by spaces, e.g. “1.0 2.0 3.0”. This can be used in LAMMPS with an *index* variable to access the values one at a time within a loop as shown in the example. At each iteration of the loop *LAM\_VALUE* contains the current value of lambda.

```
...
kim interactions Te Zn Se
kim param get lambda 15:17 LAM split
```

In this case, the “split” mode of *formatarg* is used. The three values retrieved by the *get* operation are stored in the three LAMMPS variables *LAM\_15*, *LAM\_16* and *LAM\_17*. The provided name “LAM” is used as prefix and the location in the lambda array is appended to create the variable names.

### Setting a scalar parameter

```
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
...
kim interactions Si
kim param set gamma 1 2.6
```

Here, the SW potential’s gamma parameter is set to 2.6. Note that the *get* and *set* commands work together, so that a *get* following a *set* operation will return the new value that was set. For example,

```
...
kim interactions Si
kim param get gamma 1 ORIG_GAMMA
kim param set gamma 1 2.6
kim param get gamma 1 NEW_GAMMA
...
print "original gamma = ${ORIG_GAMMA}, new gamma = ${NEW_GAMMA}"
```

Here, *ORIG\_GAMMA* will contain the original gamma value for the SW potential, while *NEW\_GAMMA* will contain the value 2.6.

### Setting multiple scalar parameters with a single call

```
kim      init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal
...
kim      interactions Cd Te
variable VARG equal 2.6
variable VARS equal 2.0951
kim      param set gamma 1 ${VARG} sigma 3 ${VARS}
```

In this case, the first element of the *gamma* parameter and third element of the *sigma* parameter are set to 2.6 and 2.0951, respectively. This example also shows how LAMMPS variables can be used when setting parameters.

### Setting a range of values of a parameter

```
kim init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal
...
```

(continues on next page)

(continued from previous page)

```
kim interactions Cd Te Zn Se Hg S
kim param set sigma 2:6 2.35214 2.23869 2.04516 2.43269 1.80415
```

In this case, elements 2 through 6 of the parameter *sigma* are set to the values 2.35214, 2.23869, 2.04516, 2.43269 and 1.80415 in order.

### 1.44.7 Writing material properties in standard KIM Property Instance format (*kim property*)

The OpenKIM system includes a collection of Tests (material property calculation codes), Models (interatomic potentials), Predictions, and Reference Data (DFT or experiments). Specifically, a KIM Test is a computation that when coupled with a KIM Model generates the prediction of that model for a specific material property rigorously defined by a KIM Property Definition (see the [KIM Properties Framework](#) for further details). A prediction of a material property for a given model is a specific numerical realization of a property definition, referred to as a “Property Instance.” The objective of the *kim property* command is to make it easy to output material properties in a standardized, machine readable, format that can be easily ingested by other programs. Additionally, it aims to make it as easy as possible to convert a LAMMPS script that computes a material property into a KIM Test that can then be uploaded to [openkim.org](https://openkim.org)

A developer interested in creating a KIM Test using a LAMMPS script should first determine whether a property definition that applies to their calculation already exists in OpenKIM by searching the [properties page](#). If none exists, it is possible to use a locally defined property definition contained in a file until it can be uploaded to the official repository (see below). Once one or more applicable property definitions have been identified, the *kim property create*, *kim property modify*, *kim property remove*, and *kim property destroy*, commands provide an interface to create, set, modify, remove, and destroy instances of them within a LAMMPS script.

#### Syntax

```
kim property create instance_id property_id
kim property modify instance_id key key_name key_name_key key_name_value
kim property remove instance_id key key_name
kim property destroy instance_id
kim property dump file
```

- *instance\_id* = a positive integer identifying the KIM property instance; (note that the results file can contain multiple property instances)
- *property\_id* = identifier of a [KIM Property Definition](#), which can be (1) a property short name, (2) the full unique ID of the property (including the contributor and date), (3) a file name corresponding to a local property definition file
- *key\_name* = one of the keys belonging to the specified KIM property definition
- *key\_name\_key* = a key belonging to a key-value pair (standardized in the [KIM Properties Framework](#))
- *key\_name\_value* = value to be associated with a *key\_name\_key* in a key-value pair
- *file* = name of a file to write the currently defined set of KIM property instances to

Examples of each of the three *property\_id* cases are shown below,

```
kim property create 1 atomic-mass
kim property create 2 cohesive-energy-relation-cubic-crystal
```

```
kim property create 1 tag:brunnels@noreply.openkim.org,2016-05-11:property/atomic-mass
kim property create 2 tag:staff@noreply.openkim.org,2014-04-15:property/cohesive-energy-
→relation-cubic-crystal
```

```
kim property create 1 new-property.edn
kim property create 2 /home/mary/marys-kim-properties/dissociation-energy.edn
```

In the last example, “new-property.edn” and “/home/mary/marys-kim-properties/dissociation-energy.edn” are the names of files that contain user-defined (local) property definitions.

A KIM property instance takes the form of a “map”, i.e. a set of key-value pairs akin to Perl’s hash, Python’s dictionary, or Java’s Hashtable. It consists of a set of property key names, each of which is referred to here by the *key\_name* argument, that are defined as part of the relevant KIM Property Definition and include only lowercase alphanumeric characters and dashes. The value paired with each property key is itself a map whose possible keys are defined as part of the [KIM Properties Framework](#); these keys are referred to by the *key\_name\_key* argument and their associated values by the *key\_name\_value* argument. These values may either be scalars or arrays, as stipulated in the property definition.

**Note:** Each map assigned to a *key\_name* must contain the *key\_name\_key* “source-value” and an associated *key\_name\_value* of the appropriate type (as defined in the relevant KIM Property Definition). For keys that are defined as having physical units, the “source-unit” *key\_name\_key* must also be given a string value recognized by [GNU units](#).

Once a *kim property create* command has been given to instantiate a property instance, maps associated with the property’s keys can be edited using the *kim property modify* command. In using this command, the special keyword “key” should be given, followed by the property key name and the key-value pair in the map associated with the key that is to be set. For example, the [atomic-mass](#) property definition consists of two property keys named “mass” and “species.” An instance of this property could be created like so:

```
kim property create 1 atomic-mass
kim property modify 1 key species source-value Al
kim property modify 1 key mass source-value 26.98154
kim property modify 1 key mass source-unit amu
```

or, equivalently,

```
kim property create 1 atomic-mass
kim property modify 1 key species source-value Al &
                    key mass source-value 26.98154 &
                    source-unit amu
```

## *kim property* Usage Examples and Further Clarifications

### Create

```
kim property create instance_id property_id
```

The *kim property create* command takes as input a property instance ID and the property definition name, and creates an initial empty property instance data structure. For example,

```
kim property create 1 atomic-mass
kim property create 2 cohesive-energy-relation-cubic-crystal
```

creates an empty property instance of the “atomic-mass” property definition with instance ID 1 and an empty instance of the “cohesive-energy-relation-cubic-crystal” property with ID 2. A list of published property definitions in OpenKIM can be found on the [properties page](#).

One can also provide the name of a file in the current working directory or the path of a file containing a valid property definition. For example,

```
kim property create 1 new-property.edn
```

where “new-property.edn” refers to a file name containing a new property definition that does not exist in OpenKIM.

If the *property\_id* given cannot be found in OpenKIM and no file of this name containing a valid property definition can be found, this command will produce an error with an appropriate message. Calling *kim property create* with the same instance ID multiple times will also produce an error.

### Modify

```
kim property modify instance_id key key_name key_name_key key_name_value
```

The *kim property modify* command incrementally builds the property instance by receiving property definition keys along with associated arguments. Each *key\_name* is associated with a map containing one or more key-value pairs (in the form of *key\_name\_key*-*key\_name\_value* pairs). For example,

```
kim property modify 1 key species source-value Al
kim property modify 1 key mass    source-value 26.98154
kim property modify 1 key mass    source-unit  amu
```

where the special keyword “key” is followed by a *key\_name* (“species” or “mass” in the above) and one or more key-value pairs. These key-value pairs may continue until either another “key” keyword is given or the end of the command line is reached. Thus, the above could equivalently be written as

```
kim property modify 1 key species source-value Al      &
                        key mass    source-value 26.98154 &
                        key mass    source-unit  amu
```

As an example of modifying multiple key-value pairs belonging to the map of a single property key, the following command modifies the map of the “cohesive-potential-energy” property key to contain the key “source-unit” which is assigned a value of “eV” and the key “digits” which is assigned a value of 5,

```
kim property modify 2 key cohesive-potential-energy source-unit eV digits 5
```

---

**Note:** The relevant data types of the values in the map are handled automatically based on the specification of the key in the KIM Property Definition. In the example above, this means that the value “eV” will automatically be interpreted as a string while the value 5 will be interpreted as an integer.

---

The values contained in maps can either be scalars, as in all of the examples above, or arrays depending on which is stipulated in the corresponding Property Definition. For one-dimensional arrays, a single one-based index must be supplied that indicates which element of the array is to be modified. For multidimensional arrays, multiple indices must be given depending on the dimensionality of the array.

---

**Note:** All array indexing used by *kim property modify* is one-based, i.e. the indices are enumerated 1, 2, 3, ...

---

---

**Note:** The dimensionality of arrays are defined in the the corresponding Property Definition. The extent of each

---

dimension of an array can either be a specific finite number or indefinite and determined at run time. If an array has a fixed extent, attempting to modify an out-of-range index will fail with an error message.

For example, the “species” property key of the `cohesive-energy-relation-cubic-crystal` property is a one-dimensional array that can contain any number of entries based on the number of atoms in the unit cell of a given cubic crystal. To assign an array containing the string “Al” four times to the “source-value” key of the “species” property key, we can do so by issuing:

```
kim property modify 2 key species source-value 1 Al
kim property modify 2 key species source-value 2 Al
kim property modify 2 key species source-value 3 Al
kim property modify 2 key species source-value 4 Al
```

**Note:** No declaration of the number of elements in this array was given; *kim property modify* will automatically handle memory management to allow an arbitrary number of elements to be added to the array.

**Note:** In the event that *kim property modify* is used to set the value of an array index without having set the values of all lesser indices, they will be assigned default values based on the data type associated with the key in the map:

Data type	Default value
int	0
float	0.0
string	""
file	""

For example, doing the following:

```
kim property create 2 cohesive-energy-relation-cubic-crystal
kim property modify 2 key species source-value 4 Al
```

will result in the “source-value” key in the map for the property key “species” being assigned the array [“,“,“,“,“Al”].

For convenience, the index argument provided may refer to an inclusive range of indices by specifying two integers separated by a colon (the first integer must be less than or equal to the second integer, and no whitespace should be included). Thus, the snippet above could equivalently be written:

```
kim property modify 2 key species source-value 1:4 Al Al Al Al
```

Calling this command with a non-positive index, e.g. `kim property modify 2 key species source-value 0 Al`, or an incorrect number of input arguments, e.g. `kim property modify 2 key species source-value 1:4 Al Al`, will result in an error.

As an example of modifying multidimensional arrays, consider the “basis-atoms” key in the `cohesive-energy-relation-cubic-crystal` property definition. This is a two-dimensional array containing the fractional coordinates of atoms in the unit cell of the cubic crystal. In the case of, e.g. a conventional fcc unit cell, the “source-value” key in the map associated with this key should be assigned the following value:

```
[[0.0, 0.0, 0.0],
 [0.5, 0.5, 0.0],
```

(continues on next page)

(continued from previous page)

```
[0.5, 0.0, 0.5],
[0.0, 0.5, 0.5]]
```

While each of the twelve components could be set individually, we can instead set each row at a time using colon notation:

```
kim property modify 2 key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0
kim property modify 2 key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0
kim property modify 2 key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5
kim property modify 2 key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5
```

Where the first index given refers to a row and the second index refers to a column. We could, instead, choose to set each column at a time like so:

```
kim property modify 2 key basis-atom-coordinates source-value 1:4 1 0.0 0.5 0.5 0.0 &
                    key basis-atom-coordinates source-value 1:4 2 0.0 0.5 0.0 0.5 &
                    key basis-atom-coordinates source-value 1:4 3 0.0 0.0 0.5 0.5
```

**Note:** Multiple calls of *kim property modify* made for the same instance ID can be combined into a single invocation, meaning the following are both valid:

```
kim property modify 2 key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0 &
                    key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0 &
                    key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5 &
                    key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5
```

```
kim property modify 2 key short-name source-value 1 fcc &
                    key species source-value 1:4 Al Al Al Al &
                    key a source-value 1:5 3.9149 4.0000 4.032 4.0817 4.1602 &
                    source-unit angstrom &
                    digits 5 &
                    key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0 &
                    key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0 &
                    key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5 &
                    key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5
```

**Note:** For multidimensional arrays, only one colon-separated range is allowed in the index listing. Therefore,

```
kim property modify 2 key basis-atom-coordinates 1 1:3 0.0 0.0 0.0
```

is valid but

```
kim property modify 2 key basis-atom-coordinates 1:2 1:3 0.0 0.0 0.0 0.0 0.0 0.0
```

is not.

**Note:** After one sets a value in a map with the *kim property modify* command, additional calls will overwrite the previous value.

### Remove

```
kim property remove instance_id key key_name
```

The *kim property remove* command can be used to remove a property key from a property instance. For example,

```
kim property remove 2 key basis-atom-coordinates
```

### Destroy

```
kim property destroy instance_id
```

The *kim property destroy* command deletes a previously created property instance ID. For example,

```
kim property destroy 2
```

---

**Note:** If this command is called with an instance ID that does not exist, no error is raised.

---

### Dump

The *kim property dump* command can be used to write the content of all currently defined property instances to a file:

```
kim property dump file
```

For example,

```
kim property dump results.edn
```

---

**Note:** Issuing the *kim property dump* command clears all existing property instances from memory.

---

## 1.44.8 Citation of OpenKIM IMs

When publishing results obtained using OpenKIM IMs researchers are requested to cite the OpenKIM project (*Tadmor*), KIM API (*Elliott*), and the specific IM codes used in the simulations, in addition to the relevant scientific references for the IM. The citation format for an IM is displayed on its page on [OpenKIM](#) along with the corresponding BibTex file, and is automatically added to the LAMMPS citation reminder.

Citing the IM software (KIM infrastructure and specific PM or SM codes) used in the simulation gives credit to the researchers who developed them and enables open source efforts like OpenKIM to function.

## 1.44.9 Restrictions

The *kim* command is part of the KIM package. It is only enabled if LAMMPS is built with that package. A requirement for the KIM package, is the KIM API library that must be downloaded from the [OpenKIM website](#) and installed before LAMMPS is compiled. When installing LAMMPS from binary, the *kim-api* package is a dependency that is automatically downloaded and installed. The *kim query* command requires the *libcurl* library to be installed. The *kim property* command requires *Python* 3.6 or later and the *kim-property* python package to be installed. See the KIM section of the [Packages details](#) for details.

Furthermore, when using *kim* command to run KIM SMs, any packages required by the native potential being used or other commands or fixes that it invokes must be installed.

## 1.44.10 Related commands

*pair\_style kim*

## 1.45 kspace\_modify command

### 1.45.1 Syntax

**kspace\_modify** keyword value ...

- one or more keyword/value pairs may be listed
- keyword = *collective* or *compute* or *cutoff/adjust* or *diff* or *disp/auto* or *fftbench* or *force/disp/kspace* or *force/disp/real* or *force* or *gewald/disp* or *gewald* or *kmax/ewald* or *mesh* or *minorder* or *mix/disp* or *order/disp* or *order* or *overlap* or *scafacos* or *slab* or *splittol* or *wire*

*collective* value = *yes* or *no*

*compute* value = *yes* or *no*

*cutoff/adjust* value = *yes* or *no*

*diff* value = *ad* or *ik* = 2 or 4 FFTs for PPPM in smoothed or non-smoothed mode

*disp/auto* value = *yes* or *no*

*fftbench* value = *yes* or *no*

*force/disp/real* value = accuracy (force units)

*force/disp/kspace* value = accuracy (force units)

*force* value = accuracy (force units)

*gewald* value = *rinv* (1/distance units)

*rinv* = G-ewald parameter for Coulombics

*gewald/disp* value = *rinv* (1/distance units)

*rinv* = G-ewald parameter for dispersion

*kmax/ewald* value = *kx ky kz*

*kx,ky,kz* = number of Ewald sum kspace vectors in each dimension

*mesh* value = *x y z*

*x,y,z* = grid size in each dimension for long-range Coulombics

*mesh/disp* value = *x y z*

*x,y,z* = grid size in each dimension for 1/r<sup>6</sup> dispersion

*minorder* value = *M*

*M* = min allowed extent of Gaussian when auto-adjusting to minimize grid<sub>↪</sub>

*↪communication*

*mix/disp* value = *pair* or *geom* or *none*

*order* value = *N*

*N* = extent of Gaussian for PPPM or MSM mapping of charge to grid

*order/disp* value = *N*

*N* = extent of Gaussian for PPPM mapping of dispersion term to grid

*overlap* = *yes* or *no* = whether the grid stencil for PPPM is allowed to overlap into<sub>↪</sub>

*↪more than the nearest-neighbor processor*

*pressure/scalar* value = *yes* or *no*

*scafacos* values = option value1 value2 ...

```
option = tolerance
  value = energy or energy_rel or field or field_rel or potential or potential_rel
option = fmn_tuning
  value = 0 or 1
slab value = volfactor or nozforce
  volfactor = ratio of the total extended volume used in the
    2d approximation compared with the volume of the simulation domain
  nozforce turns off kspace forces in the z direction
splittol value = tol
  tol = relative size of two eigenvalues (see discussion below)
wire value = volfactor (available with ELECTRODE package)
  volfactor = ratio of the total extended dimension used in the 1d
    approximation compared with the dimension of the simulation domain
```

## 1.45.2 Examples

```
kspace_modify mesh 24 24 30 order 6
kspace_modify slab 3.0
kspace_modify scafacos tolerance energy
```

## 1.45.3 Description

Set parameters used by the kspace solvers defined by the *kspace\_style* command. Not all parameters are relevant to all kspace styles.

---

The *collective* keyword applies only to PPPM. It is set to *no* by default, except on IBM BlueGene machines. If this option is set to *yes*, LAMMPS will use MPI collective operations to remap data for 3d-FFT operations instead of the default point-to-point communication. This is faster on IBM BlueGene machines, and may also be faster on other machines if they have an efficient implementation of MPI collective operations and adequate hardware.

---

The *compute* keyword allows Kspace computations to be turned off, even though a *kspace\_style* is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for computing only partial forces that do not include the Kspace contribution. You can also do this by simply not defining a *kspace\_style*, but a Kspace-compatible *pair\_style* requires a kspace style to be defined. This keyword gives you that option.

---

The *cutoff/adjust* keyword applies only to MSM. If this option is turned on, the Coulombic cutoff will be automatically adjusted at the beginning of the run to give the desired estimated error. Other cutoffs such as LJ will not be affected. If the grid is not set using the *mesh* command, this command will also attempt to use the optimal grid that minimizes cost using an estimate given by (*Hardy*). Note that this cost estimate is not exact, somewhat experimental, and still may not yield the optimal parameters.

---

The *diff* keyword specifies the differentiation scheme used by the PPPM method to compute forces on particles given electrostatic potentials on the PPPM mesh. The *ik* approach is the default for PPPM and is the original formulation used in (*Hockney*). It performs differentiation in Kspace, and uses 3 FFTs to transfer each component of the computed fields back to real space for total of 4 FFTs per timestep.

The analytic differentiation *ad* approach uses only 1 FFT to transfer information back to real space for a total of 2 FFTs per timestep. It then performs analytic differentiation on the single quantity to generate the 3 components of the electric

field at each grid point. This is sometimes referred to as “smoothed” PPPM. This approach requires a somewhat larger PPPM mesh to achieve the same accuracy as the *ik* method. Currently, only the *ik* method (default) can be used for a triclinic simulation cell with PPPM. The *ad* method is always used for MSM.

---

**Note:** Currently, not all PPPM styles support the *ad* option. Support for those PPPM variants will be added later.

---

The *disp/auto* option controls whether the *pppm/disp* is allowed to generate PPPM parameters automatically. If set to *no*, parameters have to be specified using the *gewald/disp*, *mesh/disp*, *force/disp/real* or *force/disp/kpace* keywords, or the code will stop with an error message. When this option is set to *yes*, the error message will not appear and the simulation will start. For a typical application, using the automatic parameter generation will provide simulations that are either inaccurate or slow. Using this option is thus not recommended. For guidelines on how to obtain good parameters, see the [long-range dispersion howto](#) discussion.

The *ffibench* keyword applies only to PPPM. It is off by default. If this option is turned on, LAMMPS will perform a short FFT benchmark computation and report its timings, and will thus finish some seconds later than it would if this option were off.

The *force/disp/real* and *force/disp/kpace* keywords set the force accuracy for the real and reciprocal space computations for the dispersion part of *pppm/disp*. As shown in ([Isele-Holder](#)), optimal performance and accuracy in the results is obtained when these values are different.

The *force* keyword overrides the relative accuracy parameter set by the *kpace\_style* command with an absolute accuracy. The accuracy determines the RMS error in per-atom forces calculated by the long-range solver and is thus specified in force units. A negative value for the accuracy setting means to use the relative accuracy parameter. The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style *ewald*, the FFT grid size for style *pppm*, or the real space grid size for style *msm*.

The *gewald* keyword sets the value of the Ewald or PPPM G-ewald parameter for charge as *rinv* in reciprocal distance units. Without this setting, LAMMPS chooses the parameter automatically as a function of cutoff, precision, grid spacing, etc. This means it can vary from one simulation to the next which may not be desirable for matching a KSpace solver to a pre-tabulated pairwise potential. This setting can also be useful if Ewald or PPPM fails to choose a good grid spacing and G-ewald parameter automatically. If the value is set to 0.0, LAMMPS will choose the G-ewald parameter automatically. MSM does not use the *gewald* parameter.

The *gewald/disp* keyword sets the value of the Ewald or PPPM G-ewald parameter for dispersion as *rinv* in reciprocal distance units. It has the same meaning as the *gewald* setting for Coulombics.

The *kmax/ewald* keyword sets the number of kspace vectors in each dimension for kspace style *ewald*. The three values must be positive integers, or else (0,0,0), which unsets the option. When this option is not set, the Ewald sum scheme chooses its own kspace vectors, consistent with the user-specified accuracy and pairwise cutoff. In any case, if kspace style *ewald* is invoked, the values used are printed to the screen and the log file at the start of the run.

The *mesh* keyword sets the grid size for kspace style *pppm* or *msm*. In the case of PPPM, this is the FFT mesh, and each dimension must be factorizable into powers of 2, 3, and 5. In the case of MSM, this is the finest scale real-space

mesh, and each dimension must be factorizable into powers of 2. When this option is not set, the PPPM or MSM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

---

The *mesh/disp* keyword sets the grid size for kspace style *pppm/disp*. This is the FFT mesh for long-range dispersion and each dimension must be factorizable into powers of 2, 3, and 5. When this option is not set, the PPPM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

---

The *minorder* keyword allows LAMMPS to reduce the *order* setting if necessary to keep the communication of ghost grid point limited to exchanges between nearest-neighbor processors. See the discussion of the *overlap* keyword for details. If the *overlap* keyword is set to *yes*, which is the default, this is never needed. If it is set to *no* and overlap occurs, then LAMMPS will reduce the order setting, one step at a time, until the ghost grid overlap only extends to nearest neighbor processors. The *minorder* keyword limits how small the *order* setting can become. The minimum allowed value for PPPM is 2, which is the default. If *minorder* is set to the same value as *order* then no reduction is allowed, and LAMMPS will generate an error if the grid communication is non-nearest-neighbor and *overlap* is set to *no*. The *minorder* keyword is not currently supported in MSM.

---

The *mix/disp* keyword selects the mixing rule for the dispersion coefficients. With *pair*, the dispersion coefficients of unlike types are computed as indicated with *pair\_modify*. With *geom*, geometric mixing is enforced on the dispersion coefficients in the kspace coefficients. When using the arithmetic mixing rule, this will speed-up the simulations but introduces some error in the force computations, as shown in (Wennberg). With *none*, it is assumed that no mixing rule is applicable. Splitting of the dispersion coefficients will be performed as described in (Isele-Holder).

This splitting can be influenced with the *splittol* keywords. Only the eigenvalues that are larger than *tol* compared to the largest eigenvalues are included. Using this keywords the original matrix of dispersion coefficients is approximated. This leads to faster computations, but the accuracy in the reciprocal space computations of the dispersion part is decreased.

---

The *order* keyword determines how many grid spacings an atom's charge extends when it is mapped to the grid in kspace style *pppm* or *msm*. The default for this parameter is 5 for PPPM and 8 for MSM, which means each charge spans 5 or 8 grid cells in each dimension, respectively. For the LAMMPS implementation of MSM, the order can range from 4 to 10 and must be even. For PPPM, the minimum allowed setting is 2 and the maximum allowed setting is 7. The larger the value of this parameter, the smaller that LAMMPS will set the grid size, to achieve the requested accuracy. Conversely, the smaller the order value, the larger the grid size will be. Note that there is an inherent trade-off involved: a small grid will lower the cost of FFTs or MSM direct sum, but a larger order parameter will increase the cost of interpolating charge/fields to/from the grid.

The PPPM order parameter may be reset by LAMMPS when it sets up the FFT grid if the implied grid stencil extends beyond the grid cells owned by neighboring processors. Typically this will only occur when small problems are run on large numbers of processors. A warning will be generated indicating the order parameter is being reduced to allow LAMMPS to run the problem. Automatic adjustment of the order parameter is not supported in MSM.

---

The *order/disp* keyword determines how many grid spacings an atom's dispersion term extends when it is mapped to the grid in kspace style *pppm/disp*. It has the same meaning as the *order* setting for Coulombics.

---

The *overlap* keyword can be used in conjunction with the *minorder* keyword with the PPPM styles to adjust the amount of communication that occurs when values on the FFT grid are exchanged between processors. This communication is

distinct from the communication inherent in the parallel FFTs themselves, and is required because processors interpolate charge and field values using grid point values owned by neighboring processors (i.e. ghost point communication). If the *overlap* keyword is set to *yes* then this communication is allowed to extend beyond nearest-neighbor processors, e.g. when using lots of processors on a small problem. If it is set to *no* then the communication will be limited to nearest-neighbor processors and the *order* setting will be reduced if necessary, as explained by the *minorder* keyword discussion. The *overlap* keyword is always set to *yes* in MSM.

---

The *pressure/scalar* keyword applies only to MSM. If this option is turned on, only the scalar pressure (i.e.  $(P_{xx} + P_{yy} + P_{zz})/3.0$ ) will be computed, which can be used, for example, to run an isotropic barostat. Computing the full pressure tensor with MSM is expensive, and this option provides a faster alternative. The scalar pressure is computed using a relationship between the Coulombic energy and pressure (*Hummer*) instead of using the virial equation. This option cannot be used to access individual components of the pressure tensor, to compute per-atom virial, or with suffix *k*space/pair styles of MSM, like OMP or GPU.

---

The *scafacos* keyword is used for settings that are passed to the ScaFaCoS library when using *k*space\_style *scafacos*.

The *tolerance* option affects how the *accuracy* specified with the *k*space\_style command is interpreted by ScaFaCoS. The following values may be used:

- energy = absolute accuracy in total Coulombic energy
- energy\_rel = relative accuracy in total Coulombic energy
- potential = absolute accuracy in total Coulombic potential
- potential\_rel = relative accuracy in total Coulombic potential
- field = absolute accuracy in electric field
- field\_rel = relative accuracy in electric field

The values with suffix *\_rel* indicate the tolerance is a relative tolerance; the other values impose an absolute tolerance on the given quantity. Absolute tolerance in this case means, that for a given quantity *q* and a given absolute tolerance of *t\_a* the result should be between *q-t\_a* and *q+t\_a*. For a relative tolerance *t\_r* the relative error should not be greater than *t\_r*, i.e.  $\text{abs}(1 - (\text{result}/q)) < t_r$ . As a consequence of this, the tolerance type should be checked, when performing computations with a high absolute field / energy. E.g. if the total energy in the system is 1000000.0 an absolute tolerance of 1e-3 would mean that the result has to be between 999999.999 and 1000000.001, which would be equivalent to a relative tolerance of 1e-9.

The energy and energy\_rel values, set a tolerance based on the total Coulombic energy of the system. The potential and potential\_rel set a tolerance based on the per-atom Coulombic energy. The field and field\_rel tolerance types set a tolerance based on the electric field values computed by ScaFaCoS. Since per-atom forces are derived from the per-atom electric field, this effectively sets a tolerance on the forces, similar to other LAMMPS KSpace styles, as explained on the *k*space\_style doc page.

Note that not all ScaFaCoS solvers support all tolerance types. These are the allowed values for each method:

- fmm = energy and energy\_rel
- p2nfft = field (1d-,2d-,3d-periodic systems) or potential (0d-periodic)
- p3m = field
- ewald = field
- direct = has no tolerance tuning

If the tolerance type is not changed, the default values for the tolerance type are the first values in the above list, e.g. energy is the default tolerance type for the fmm solver.

The *fmm\_tuning* option is only relevant when using the FMM method. It activates (value=1) or deactivates (value=0) an internal tuning mechanism for the FMM solver. The tuning operation runs sequentially and can be very time-consuming. Usually it is not needed for systems with a homogeneous charge distribution. The default for this option is therefore 0. The FMM internal tuning is performed once, when the solver is set up.

---

The *slab* keyword allows an Ewald or PPPM solver to be used for a systems that are periodic in x,y but non-periodic in z - a *boundary* setting of “boundary p p f”. This is done by treating the system as if it were periodic in z, but inserting empty volume between atom slabs and removing dipole inter-slab interactions so that slab-slab interactions are effectively turned off. The volfactor value sets the ratio of the extended dimension in z divided by the actual dimension in z. It must be a value  $\geq 1.0$ . A value of 1.0 (the default) means the slab approximation is not used.

The recommended value for volfactor is 3.0. A larger value is inefficient; a smaller value introduces unwanted slab-slab interactions. The use of fixed boundaries in z means that the user must prevent particle migration beyond the initial z-bounds, typically by providing a wall-style fix. The methodology behind the *slab* option is explained in the paper by (Yeh). The *slab* option is also extended to non-neutral systems (Ballenegger).

An alternative slab option can be invoked with the *nozforce* keyword in lieu of the volfactor. This turns off all kspace forces in the z direction. The *nozforce* option is not supported by MSM. For MSM, any combination of periodic, non-periodic, or shrink-wrapped boundaries can be set using *boundary* (the slab approximation is not needed). The *slab* keyword is not currently supported by Ewald or PPPM when using a triclinic simulation cell. The slab correction has also been extended to point dipole interactions (*Klapp*) in *kspace\_style ewald/disp*, *ewald/dipole*, and *pppm/dipole*.

---

**Note:** If you wish to apply an electric field in the Z-direction, in conjunction with the *slab* keyword, you should do it by adding explicit charged particles to the +/- Z surfaces. If you do it via the *fix efield* command, it will not give the correct dielectric constant due to the Yeh/Berkowitz (Yeh) correction not being compatible with how *fix efield* works.

---

The *force/disp/real* and *force/disp/kspace* keywords set the force accuracy for the real and reciprocal space computations for the dispersion part of ppm/disp. As shown in (Isele-Holder), optimal performance and accuracy in the results is obtained when these values are different.

The *disp/auto* option controls whether the ppm/disp is allowed to generate PPPM parameters automatically. If set to *no*, parameters have to be specified using the *gewald/disp*, *mesh/disp*, *force/disp/real* or *force/disp/kspace* keywords, or the code will stop with an error message. When this option is set to *yes*, the error message will not appear and the simulation will start. For a typical application, using the automatic parameter generation will provide simulations that are either inaccurate or slow. Using this option is thus not recommended. For guidelines on how to obtain good parameters, see the *Howto dispersion* doc page.

---

## 1.45.4 Restrictions

none

### 1.45.5 Related commands

*kspace\_style, boundary*

### 1.45.6 Default

The option defaults are as follows:

- compute = yes
- cutoff/adjust = yes (MSM)
- diff = ik (PPPM)
- disp/auto = no
- fftbench = no (PPPM)
- force = -1.0
- force/disp/kspace = -1.0
- force/disp/real = -1.0
- gewald = gewald/disp = 0.0
- mesh = mesh/disp = 0 0 0
- minorder = 2
- mix/disp = pair
- order = 10 (MSM)
- order = order/disp = 5 (PPPM)
- order = order/disp = 7 (PPPM/intel)
- overlap = yes
- pressure/scalar = yes (MSM)
- slab = 1.0
- split = 0
- tol = 1.0e-6

For scafacos settings, the scafacos tolerance option depends on the method chosen, as documented above. The scafacos fmm\_tuning default = 0.

### 1.46.3 Description

Define a long-range solver for LAMMPS to use each timestep to compute long-range Coulombic interactions or long-range  $1/r^6$  interactions. Most of the long-range solvers perform their computation in K-space, hence the name of this command.

When such a solver is used in conjunction with an appropriate pair style, the cutoff for Coulombic or  $1/r^N$  interactions is effectively infinite. If the Coulombic case, this means each charge in the system interacts with charges in an infinite array of periodic images of the simulation domain.

Note that using a long-range solver requires use of a matching *pair style* to perform consistent short-range pairwise calculations. This means that the name of the pair style contains a matching keyword to the name of the KSpace style, as in this table:

Pair style	KSpace style
coul/long	ewald or ppm
coul/msm	msm
lj/long or buck/long	disp (for dispersion)
tip4p/long	tip4p
dipole/long	dipole

The *ewald* style performs a standard Ewald summation as described in any solid-state physics text.

The *ewald/disp* style adds a long-range dispersion sum option for  $1/r^6$  potentials and is useful for simulation of interfaces (*Veld*). It also performs standard Coulombic Ewald summations, but in a more efficient manner than the *ewald* style. The  $1/r^6$  capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials.

The *ewald/disp/dipole* style can also be used with point-dipoles, see (*Toukmaji*).

The *ewald/dipole* style adds long-range standard Ewald summations for dipole-dipole interactions, see (*Toukmaji*).

The *ewald/dipole/spin* style adds long-range standard Ewald summations for magnetic dipole-dipole interactions between magnetic spins.

The *pppm* style invokes a particle-particle particle-mesh solver (*Hockney*) which maps atom charge to a 3d mesh, uses 3d FFTs to solve Poisson's equation on the mesh, then interpolates electric fields on the mesh points back to the atoms. It is closely related to the particle-mesh Ewald technique (PME) (*Darden*) used in AMBER and CHARMM. The cost of traditional Ewald summation scales as  $N^{3/2}$  where  $N$  is the number of atoms in the system. The PPPM solver scales as  $N \log N$  due to the FFTs, so it is almost always a faster choice (*Pollock*).

The *pppm/cg* style is identical to the *pppm* style except that it has an optimization for systems where most particles are uncharged. Similarly the *msm/cg* style implements the same optimization for *msm*. The optional *smallq* argument defines the cutoff for the absolute charge value which determines whether a particle is considered charged or not. Its default value is 1.0e-5.

The *pppm/dipole* style invokes a particle-particle particle-mesh solver for dipole-dipole interactions, following the method of (*Cerda*).

The *pppm/dipole/spin* style invokes a particle-particle particle-mesh solver for magnetic dipole-dipole interactions between magnetic spins.

The *pppm/tip4p* style is identical to the *pppm* style except that it adds a charge at the massless fourth site in each TIP4P water molecule. It should be used with *pair styles* with a *tip4p/long* in their style name.

The *pppm/stagger* style performs calculations using two different meshes, one shifted slightly with respect to the other. This can reduce force aliasing errors and increase the accuracy of the method for a given mesh size. Or a coarser mesh can be used for the same target accuracy, which saves CPU time. However, there is a trade-off since FFTs on two meshes are now performed which increases the computation required. See ([Cerutti](#)), ([Neelov](#)), and ([Hockney](#)) for details of the method.

For high relative accuracy, using staggered PPPM allows the mesh size to be reduced by a factor of 2 in each dimension as compared to regular PPPM (for the same target accuracy). This can give up to a 4x speedup in the KSpace time (8x less mesh points, 2x more expensive). However, for low relative accuracy, the staggered PPPM mesh size may be essentially the same as for regular PPPM, which means the method will be up to 2x slower in the KSpace time (simply 2x more expensive). For more details and timings, see the [Speed tips](#) doc page.

---

**Note:** Using *pppm/stagger* may not give the same increase in the accuracy of energy and pressure as it does in forces, so some caution must be used if energy and/or pressure are quantities of interest, such as when using a barostat.

---

The *pppm/disp* and *pppm/disp/tip4p* styles add a mesh-based long-range dispersion sum option for  $1/r^6$  potentials ([Isele-Holder](#)), similar to the *ewald/disp* style. The  $1/r^6$  capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials.

For these styles, you will possibly want to adjust the default choice of parameters by using the *kpace\_modify* command. This can be done by either choosing the Ewald and grid parameters, or by specifying separate accuracies for the real and kspace calculations. When not making any settings, the simulation will stop with an error message. Further information on the influence of the parameters and how to choose them is described in ([Isele-Holder](#)), ([Isele-Holder2](#)) and the [Howto dispersion](#) doc page.

---

**Note:** All of the PPPM styles can be used with single-precision FFTs by using the compiler switch `-DFFT_SINGLE` for the `FFT_INC` setting in your low-level Makefile. This setting also changes some of the PPPM operations (e.g. mapping charge to mesh and interpolating electric fields to particles) to be performed in single precision. This option can speed-up long-range calculations, particularly in parallel or on GPUs. The use of the `-DFFT_SINGLE` flag is discussed on the [Build settings](#) doc page. MSM does not currently support the `-DFFT_SINGLE` compiler switch.

---

The *electrode* styles add methods that are required for the constant potential method implemented in *fix electrode/\**. The styles *ewald/electrode*, *pppm/electrode* and *pppm/electrode/intel* are available. These styles do not support the *kpace\_modify slab nozforce* command.

---

The *msm* style invokes a multi-level summation method MSM solver, ([Hardy](#)) or ([Hardy2](#)), which maps atom charge to a 3d mesh, and uses a multi-level hierarchy of coarser and coarser meshes on which direct Coulomb solvers are done. This method does not use FFTs and scales as  $N$ . It may therefore be faster than the other K-space solvers for relatively large problems when running on large core counts. MSM can also be used for non-periodic boundary conditions and for mixed periodic and non-periodic boundaries.

MSM is most competitive versus Ewald and PPPM when only relatively low accuracy forces, about  $1e-4$  relative error or less accurate, are needed. Note that use of a larger Coulombic cutoff (i.e. 15 Angstroms instead of 10 Angstroms) provides better MSM accuracy for both the real space and grid computed forces.

Currently calculation of the full pressure tensor in MSM is expensive. Using the *kpace\_modify pressure/scalar yes* command provides a less expensive way to compute the scalar pressure ( $P_{xx} + P_{yy} + P_{zz}$ )/3.0. The scalar pressure can be used, for example, to run an isotropic barostat. If the full pressure tensor is needed, then calculating the pressure at every timestep or using a fixed pressure simulation with MSM will cause the code to run slower.

The *scafacos* style is a wrapper on the [ScaFaCoS Coulomb solver library](#) which provides a variety of solver methods which can be used with LAMMPS. The paper by ([Sutman](#)) gives an overview of ScaFaCoS.

ScaFaCoS was developed by a consortium of German research facilities with a BMBF (German Ministry of Science and Education) funded project in 2009-2012. Participants of the consortium were the Universities of Bonn, Chemnitz, Stuttgart, and Wuppertal as well as the Forschungszentrum Juelich.

The library is available for download at “<http://scafacos.de>” or can be cloned from the git-repository “<https://github.com/scafacos/scafacos.git>”.

In order to use this KSpace style, you must download and build the ScaFaCoS library, then build LAMMPS with the SCAFACOS package installed package which links LAMMPS to the ScaFaCoS library. See details on [this page](#).

---

**Note:** Unlike other KSpace solvers in LAMMPS, ScaFaCoS computes all Coulombic interactions, both short- and long-range. Thus you should NOT use a Coulombic pair style when using `kpace_style scafacos`. This also means the total Coulombic energy (short- and long-range) will be tallied for *thermodynamic output* command as part of the *elong* keyword; the *ecoul* keyword will be zero.

---

---

**Note:** See the current restriction below about use of ScaFaCoS in LAMMPS with molecular charged systems or the TIP4P water model.

---

The specified *method* determines which ScaFaCoS algorithm is used. These are the ScaFaCoS methods currently available from LAMMPS:

- *fmm* = Fast Multi-Pole method
- *p2nfft* = FFT-based Coulomb solver
- *ewald* = Ewald summation
- *direct* = direct  $O(N^2)$  summation
- *p3m* = PPPM

We plan to support additional ScaFaCoS solvers from LAMMPS in the future. For an overview of the included solvers, refer to ([Sutmann](#))

The specified *accuracy* is similar to the accuracy setting for other LAMMPS KSpace styles, but is passed to ScaFaCoS, which can interpret it in different ways for different methods it supports. Within the ScaFaCoS library the *accuracy* is treated as a tolerance level (either absolute or relative) for the chosen quantity, where the quantity can be either the Columic field values, the per-atom Columic energy or the total Columic energy. To select from these options, see the [kpace\\_modify scafacos accuracy](#) doc page.

The *kpace\_modify scafacos* command also explains other ScaFaCoS options currently exposed to LAMMPS.

---

The specified *accuracy* determines the relative RMS error in per-atom forces calculated by the long-range solver. It is set as a dimensionless number, relative to the force that two unit point charges (e.g. 2 monovalent ions) exert on each other at a distance of 1 Angstrom. This reference value was chosen as representative of the magnitude of electrostatic forces in atomic systems. Thus an accuracy value of 1.0e-4 means that the RMS error will be a factor of 10000 smaller than the reference force.

The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style *ewald* or the grid size for style *pppm* or *msm*.

Note that style *pppm* only computes the grid size at the beginning of a simulation, so if the length or triclinic tilt of the simulation cell increases dramatically during the course of the simulation, the accuracy of the simulation may degrade. Likewise, if the *kpspace\_modify slab* option is used with shrink-wrap boundaries in the z-dimension, and the box size changes dramatically in z. For example, for a triclinic system with all three tilt factors set to the maximum limit, the PPPM grid should be increased roughly by a factor of 1.5 in the y direction and 2.0 in the z direction as compared to the same system using a cubic orthogonal simulation cell. One way to handle this issue if you have a long simulation where the box size changes dramatically, is to break it into shorter simulations (multiple *run* commands). This works because the grid size is re-computed at the beginning of each run. Another way to ensure the described accuracy requirement is met is to run a short simulation at the maximum expected tilt or length, note the required grid size, and then use the *kpspace\_modify mesh* command to manually set the PPPM grid size to this value for the long run. The simulation then will be “too accurate” for some portion of the run.

RMS force errors in real space for *ewald* and *pppm* are estimated using equation 18 of (Kolafa), which is also referenced as equation 9 of (Petersen). RMS force errors in K-space for *ewald* are estimated using equation 11 of (Petersen), which is similar to equation 32 of (Kolafa). RMS force errors in K-space for *pppm* are estimated using equation 38 of (Deserno). RMS force errors for *msm* are estimated using ideas from chapter 3 of (Hardy), with equation 3.197 of particular note. When using *msm* with non-periodic boundary conditions, it is expected that the error estimation will be too pessimistic. RMS force errors for dipoles when using *ewald/disp* or *ewald/dipole* are estimated using equations 33 and 46 of (Wang). The RMS force errors for *pppm/dipole* are estimated using the equations in (Cerdea).

See the *kpspace\_modify* command for additional options of the K-space solvers that can be set, including a *force* option for setting an absolute RMS error in forces, as opposed to a relative RMS error.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

**Note:** For the GPU package, the *pppm/gpu* style performs charge assignment and force interpolation calculations on the GPU. These processes are performed either in single or double precision, depending on whether the `-DFFT_SINGLE` setting was specified in your low-level Makefile, as discussed above. The FFTs themselves are still calculated on the CPU. If *pppm/gpu* is used with a GPU-enabled pair style, part of the PPPM calculation can be performed concurrently on the GPU while other calculations for non-bonded and bonded force calculation are performed on the CPU.

---

**Note:** For the KOKKOS package, the *pppm/kk* style performs charge assignment and force interpolation calculations, along with the FFTs themselves, on the GPU or (optionally) threaded on the CPU when using OpenMP and FFTW3. The specific FFT library is selected using the `FFT_KOKKOS` CMake parameter. See the *Build settings* doc page for how to select a 3rd-party FFT library.

---

### 1.46.4 Restrictions

Note that the long-range electrostatic solvers in LAMMPS assume conducting metal (tin foil) boundary conditions for both charge and dipole interactions. Vacuum boundary conditions are not currently supported.

The *ewald/disp*, *ewald*, *pppm*, and *msm* styles support non-orthogonal (triclinic symmetry) simulation boxes. However, triclinic simulation cells may not yet be supported by all suffix versions of these styles.

Most of the base *k*space styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The *msm/dielectric* and *pppm/dielectric* *k*space styles are part of the DIELECTRIC package. They are only enabled if LAMMPS was built with that package **and** the KSPACE package. See the [Build package](#) page for more info.

For MSM, a simulation must be 3d and one can use any combination of periodic, non-periodic, but not shrink-wrapped boundaries (specified using the [boundary](#) command).

For Ewald and PPPM, a simulation must be 3d and periodic in all dimensions. The only exception is if the slab option is set with [kpace\\_modify](#), in which case the xy dimensions must be periodic and the z dimension must be non-periodic.

The *scafacos* KSpace style will only be enabled if LAMMPS is built with the SCAFACOS package. See the [Build package](#) doc page for more info.

The use of ScaFaCos in LAMMPS does not yet support molecular charged systems where the short-range Coulombic interactions between atoms in the same bond/angle/dihedral are weighted by the [special\\_bonds](#) command. Likewise it does not support the “TIP4P water style” where a fictitious charge site is introduced in each water molecule. Finally, the methods *p3m* and *ewald* do not support computing the virial, so this contribution is not included.

## 1.47 label command

### 1.47.1 Syntax

```
label ID
```

- ID = string used as label name

### 1.47.2 Examples

```
label xyz  
label loop
```

### 1.47.3 Description

Label this line of the input script with the chosen ID. Unless a jump command was used previously, this does nothing. But if a *jump* command was used with a label argument to begin invoking this script file, then all command lines in the script prior to this line will be ignored. I.e. execution of the script will begin at this line. This is useful for looping over a section of the input script as discussed in the *jump* command.

### 1.47.4 Restrictions

none

### 1.47.5 Related commands

*jump*, *next*

## 1.47.6 Default

none

## 1.48 labelmap command

### 1.48.1 Syntax

```
labelmap option args
```

- *option* = *atom* or *bond* or *angle* or *dihedral* or *improper* or *clear* or *write*
- clear* = no args  
*write* arg = filename  
*atom* or *bond* or *angle* or *dihedral* or *improper*  
 args = list of one or more numeric-type/type-label pairs

### 1.48.2 Examples

```
labelmap atom 1 c1 2 hc 3 cp 4 nt
labelmap atom 3 carbon 4 'c3' 5 "c1" 6 "c#"
labelmap atom $(label2type(atom,carbon)) C # change type label from 'carbon' to 'C'
labelmap clear
labelmap write mymap.include
labelmap bond 1 carbonyl 2 nitrile 3 "" c1'-c2" ""
```

### 1.48.3 Description

New in version 15Sep2022.

Define alphanumeric type labels to associate with one or more numeric atom, bond, angle, dihedral or improper types. A collection of type labels for all atom types, bond types, etc. is stored as a label map.

The label map can also be defined by the *read\_data* command when it reads these sections in a data file: Atom Type Labels, Bond Type Labels, etc. See the *Howto type labels* doc page for a general discussion of how type labels can be used. See (*Gissinger*) for a discussion of the type label implementation in LAMMPS and its uses.

Valid type labels can contain any alphanumeric character, but must not start with a number, a '#', or a '\*' character. They can contain other standard ASCII characters such as angular or square brackets '<' and '>' or '[' and ']', parenthesis '(' and ')', dash '-', underscore '\_', plus '+' and equals '=' signs and more. They must not contain blanks or any other whitespace. Note that type labels must be put in single or double quotation marks if they contain the '#' character or if they contain a double (") or single quotation mark ('). If the label contains both a single and a double quotation mark, then triple quotation (""") must be used. When enclosing a type label with quotation marks, the LAMMPS input parser may require adding leading or trailing blanks around the type label so it can identify the enclosing quotation marks. Those blanks will be removed when defining the label.

A *labelmap* command can only modify the label map for one type-kind (atom types, bond types, etc). Any number of numeric-type/type-label pairs may follow. If a type label already exists for the same numeric type, it will be overwritten. Type labels must be unique; assigning the same type label to multiple numeric types within the same type-kind is not allowed. When reading and writing data files, it is required that there is a label defined for *every* numeric type within a given type-kind in order to write out the type label section for that type-kind.

The *clear* option resets the label map and thus discards all previous settings.

The *write* option takes a filename as argument and writes the current label mappings to a file as a sequence of *labelmap* commands, so the file can be copied into a new LAMMPS input file or read in using the *include* command.

---

## 1.48.4 Restrictions

This command must come after the simulation box is defined by a *read\_data*, *read\_restart*, or *create\_box* command.

Label maps are currently not supported when using the KOKKOS package.

## 1.48.5 Related commands

*read\_data*, *write\_data*, *molecule*, *fix bond/react*

## 1.48.6 Default

none

---

# 1.49 lattice command

## 1.49.1 Syntax

**lattice** style scale keyword values ...

- style = *none* or *sc* or *bcc* or *fcc* or *hcp* or *diamond* or *sq* or *sq2* or *hex* or *custom*
- scale = scale factor between lattice and simulation box  
scale = reduced density rho\* (for LJ units)  
scale = lattice constant in distance units (for all other units)
- zero or more keyword/value pairs may be appended
- keyword = *origin* or *orient* or *spacing* or *a1* or *a2* or *a3* or *basis* or *triclinic/general*  
*origin* values = x y z  
x,y,z = fractions of a unit cell (0 <= x,y,z < 1)  
*orient* values = dim i j k  
dim = x or y or z  
i,j,k = integer lattice directions  
*spacing* values = dx dy dz  
dx,dy,dz = lattice spacings in the x,y,z box directions  
*a1,a2,a3* values = x y z  
x,y,z = primitive vector components that define unit cell  
*basis* values = x y z  
x,y,z = fractional coords of a basis atom (0 <= x,y,z < 1)  
*triclinic/general* values = no values

## 1.49.2 Examples

```
lattice fcc 3.52
lattice hex 0.85
lattice sq 0.8 origin 0.0 0.5 0.0 orient x 1 1 0 orient y -1 1 0
lattice custom 3.52 a1 1.0 0.0 0.0 a2 0.5 1.0 0.0 a3 0.0 0.0 0.5 &
                basis 0.0 0.0 0.0 basis 0.5 0.5 0.5 triclinic/general
lattice none 2.0
```

## 1.49.3 Description

Define a lattice for use by other commands. In LAMMPS, a lattice is simply a set of points in space, determined by a unit cell with basis atoms, that is replicated infinitely in all dimensions. The arguments of the lattice command can be used to define a wide variety of crystallographic lattices.

A lattice is used by LAMMPS in two ways. First, the `create_atoms` command creates atoms on the lattice points inside the simulation box. Note that the `create_atoms` command allows different atom types to be assigned to different basis atoms of the lattice. Second, the lattice spacing in the x,y,z dimensions implied by the lattice, can be used by other commands as distance units (e.g. `create_box`, `region` and `velocity`), which are often convenient to use when the underlying problem geometry is atoms on a lattice.

The lattice style must be consistent with the dimension of the simulation - see the `dimension` command. Styles *sc* or *bcc* or *fcc* or *hcp* or *diamond* are for 3d problems. Styles *sq* or *sq2* or *hex* are for 2d problems. Style *custom* can be used for either 2d or 3d problems.

A lattice consists of a unit cell, a set of basis atoms within that cell, and a set of transformation parameters (scale, origin, orient) that map the unit cell into the simulation box. The vectors *a1*, *a2*, *a3* are the edge vectors of the unit cell. This is the nomenclature for “primitive” vectors in solid-state crystallography, but in LAMMPS the unit cell they determine does not have to be a “primitive cell” of minimum volume.

Note that the lattice command can be used multiple times in an input script. Each time it is invoked, the lattice attributes are re-defined and are used for all subsequent commands (that use lattice attributes). For example, a sequence of `lattice`, `region`, and `create_atoms` commands can be repeated multiple times to build a poly-crystalline model with different geometric regions populated with atoms in different lattice orientations.

A lattice of style *none* does not define a unit cell and basis set, so it cannot be used with the `create_atoms` command. However it does define a lattice spacing via the specified scale parameter. As explained above the lattice spacings in x,y,z can be used by other commands as distance units. No additional keyword/value pairs can be specified for the *none* style. By default, a “lattice none 1.0” is defined, which means the lattice spacing is the same as one distance unit, as defined by the `units` command.

Lattices of style *sc*, *fcc*, *bcc*, and *diamond* are 3d lattices that define a cubic unit cell with edge length = 1.0. This means *a1* = 1 0 0, *a2* = 0 1 0, and *a3* = 0 0 1. Style *hcp* has *a1* = 1 0 0, *a2* = 0 sqrt(3) 0, and *a3* = 0 0 sqrt(8/3). The placement of the basis atoms within the unit cell are described in any solid-state physics text. A *sc* lattice has 1 basis atom at the lower-left-bottom corner of the cube. A *bcc* lattice has 2 basis atoms, one at the corner and one at the center of the cube. A *fcc* lattice has 4 basis atoms, one at the corner and 3 at the cube face centers. A *hcp* lattice has 4 basis atoms, two in the *z* = 0 plane and 2 in the *z* = 0.5 plane. A *diamond* lattice has 8 basis atoms.

Lattices of style *sq* and *sq2* are 2d lattices that define a square unit cell with edge length = 1.0. This means *a1* = 1 0 0 and *a2* = 0 1 0. A *sq* lattice has 1 basis atom at the lower-left corner of the square. A *sq2* lattice has 2 basis atoms, one at the corner and one at the center of the square. A *hex* style is also a 2d lattice, but the unit cell is rectangular, with *a1* = 1 0 0 and *a2* = 0 sqrt(3) 0. It has 2 basis atoms, one at the corner and one at the center of the rectangle.

A lattice of style *custom* allows you to specify *a1*, *a2*, *a3*, and a list of basis atoms to put in the unit cell. By default, *a1* and *a2* and *a3* are 3 orthogonal unit vectors (edges of a unit cube). But you can specify them to be of any length and

non-orthogonal to each other, so that they describe a tilted parallelepiped. Via the *basis* keyword you add atoms, one at a time, to the unit cell. Its arguments are fractional coordinates ( $0.0 \leq x,y,z < 1.0$ ). For 2d simulations, the fractional z coordinate for any basis atom must be 0.0.

The position vector  $\mathbf{x}$  of a basis atom within the unit cell is a linear combination of the unit cell's 3 edge vectors, i.e.  $\mathbf{x} = b_x \mathbf{a}_1 + b_y \mathbf{a}_2 + b_z \mathbf{a}_3$ , where  $b_x, b_y, b_z$  are the 3 values specified for the *basis* keyword.

---

This subsection discusses the arguments that determine how the idealized unit cell is transformed into a lattice of points within the simulation box.

The *scale* argument determines how the size of the unit cell will be scaled when mapping it into the simulation box. I.e. it determines a multiplicative factor to apply to the unit cell, to convert it to a lattice of the desired size and distance units in the simulation box. The meaning of the *scale* argument depends on the *units* being used in your simulation.

For all unit styles except *lj*, the scale argument is specified in the distance units defined by the unit style. For example, in *real* or *metal* units, if the unit cell is a unit cube with edge length 1.0, specifying *scale* = 3.52 would create a cubic lattice with a spacing of 3.52 Angstroms. In *cgs* units, the spacing would be 3.52 cm.

For unit style *lj*, the scale argument is the Lennard-Jones reduced density, typically written as  $\rho^*$ . LAMMPS converts this value into the multiplicative factor via the formula “ $\text{factor}^{\text{dim}} = \rho / \rho^*$ ”, where  $\rho = N/V$  with  $V$  = the volume of the lattice unit cell and  $N$  = the number of basis atoms in the unit cell (described below), and  $\text{dim} = 2$  or  $3$  for the dimensionality of the simulation. Effectively, this means that if LJ particles of size  $\sigma = 1.0$  are used in the simulation, the lattice of particles will be at the desired reduced density.

The *origin* option specifies how the unit cell will be shifted or translated when mapping it into the simulation box. The  $x,y,z$  values are fractional values ( $0.0 \leq x,y,z < 1.0$ ) meaning shift the lattice by a fraction of the lattice spacing in each dimension. The meaning of “lattice spacing” is discussed below. For 2d simulations, the *origin* z value must be 0.0.

The *orient* option specifies how the unit cell will be rotated when mapping it into the simulation box. The *dim* argument is one of the 3 coordinate axes in the simulation box. The other 3 arguments are the crystallographic direction in the lattice that you want to orient along that axis, specified as integers. E.g. “orient x 2 1 0” means the x-axis in the simulation box will be the [210] lattice direction, and similarly for y and z. The 3 lattice directions you specify do not have to be unit vectors, but they must be mutually orthogonal and obey the right-hand rule, i.e. ( $\mathbf{X} \text{ cross } \mathbf{Y}$ ) points in the Z direction. For 2d simulations, the *orient* x and y vectors must define 0 for their 3rd component. Similarly the *orient* z vector must define 0 for its 1st and 2nd components.

---

**Note:** The preceding paragraph describing lattice directions is only valid for orthogonal cubic unit cells (or square in 2d). If you are using a *hcp* or *hex* lattice or the more general lattice style *custom* with non-orthogonal  $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$  vectors, then you should think of the 3 *orient* vectors as creating a 3x3 rotation matrix which is applied to  $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$  to rotate the original unit cell to a new orientation in the simulation box.

---

The *triclinic/general* option specifies that the defined lattice is for use with a general triclinic simulation box, as opposed to an orthogonal or restricted triclinic box. The [Howto triclinic](#) doc page explains all 3 kinds of simulation boxes LAMMPS supports.

If this option is specified, a *custom* lattice style must be used. The  $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$  vectors should define the edge vectors of a single unit cell of the lattice with one or more basis atoms. They edge vectors can be arbitrary so long as they are non-zero, distinct, and not co-planar. In addition, they must define a right-handed system, such that ( $\mathbf{a}_1 \text{ cross } \mathbf{a}_2$ ) points in the direction of  $\mathbf{a}_3$ . Note that a left-handed system can be converted to a right-handed system by simply swapping the order of any pair of the  $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$  vectors. For 2d simulations, the  $\mathbf{a}_3$  vector must be specified as (0.0,0.0,1.0), which is its default value.

If this option is used, the *origin* and *orient* settings must have their default values. Namely (0.0,0.0,0.0) for the *origin* and (100), (010), (001) for the *orient* vectors.

The `create_box` command can be used to create a general triclinic box that replicates the  $a_1$ ,  $a_2$ ,  $a_3$  unit cell vectors in each direction to create the 3 arbitrary edge vectors of the overall simulation box. It requires a lattice with the *triclinic/general* option.

Likewise, the `create_atoms` command can be used to add atoms (or molecules) to a general triclinic box which lie on the lattice points defined by  $a_1$ ,  $a_2$ ,  $a_3$  and the unit cell basis atoms. To do this, it also requires a lattice with the *triclinic/general* option.

---

**Note:** LAMMPS allows specification of general triclinic lattices and simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the *Howto\_triclinic* doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box and per-atom information (e.g. coordinates, velocities) defined by the `create_box` and `create_atoms` commands are converted from general to restricted triclinic form when the two commands are invoked. It also means that any other commands which use lattice spacings from this command (e.g. the `region` command), will be operating on a restricted triclinic simulation box, even if the *triclinic/general* option was used to define the lattice. See the next section for details.

---

Several LAMMPS commands have the option to use distance units that are inferred from “lattice spacings” in the x,y,z box directions. E.g. the `region` command can create a block of size 10x20x20, where 10 means 10 lattice spacings in the x direction.

---

**Note:** Though they are called lattice spacings, all the commands that have a “units lattice” option, simply use the 3 values as scale factors on the distance units defined by the `units` command. Thus if you do not like the lattice spacings computed by LAMMPS (e.g. for a non-orthogonal or rotated unit cell), you can define the 3 values to be whatever you wish, via the *spacing* option.

---

If the *spacing* option is not specified, the lattice spacings are computed by LAMMPS in the following way. A unit cell of the lattice is mapped into the simulation box (scaled and rotated), so that it now has (perhaps) a modified size and orientation. The lattice spacing in X is defined as the difference between the min/max extent of the x coordinates of the 8 corner points of the modified unit cell (4 in 2d). Similarly, the Y and Z lattice spacings are defined as the difference in the min/max of the y and z coordinates.

---

**Note:** If the *triclinic/general* option is specified, the unit cell defined by  $a_1$ ,  $a_2$ ,  $a_3$  edge vectors is first converted to a restricted triclinic orientation, which is a rotation operation. The min/max extent of the 8 corner points is then determined, as described in the preceding paragraph, to set the lattice spacings. As explained for the *triclinic/general* option above, this is because any use of the lattice spacings by other commands will be for a restricted triclinic simulation box, not a general triclinic box.

---

Note that if the unit cell is orthogonal with axis-aligned edges (no rotation via the *orient* keyword), then the lattice spacings in each dimension are simply the scale factor (described above) multiplied by the length of  $a_1, a_2, a_3$ . Thus a *hex* style lattice with a scale factor of 3.0 Angstroms, would have a lattice spacing of 3.0 in x and  $3*\sqrt{3}$  in y.

---

**Note:** For non-orthogonal unit cells and/or when a rotation is applied via the *orient* keyword, then the lattice spacings computed by LAMMPS are typically less intuitive. In particular, in these cases, there is no guarantee that a particular lattice spacing is an integer multiple of the periodicity of the lattice in that direction. Thus, if you create an orthogonal periodic simulation box whose size in a dimension is a multiple of the lattice spacing, and then fill it with atoms via the `create_atoms` command, you will NOT necessarily create a periodic system. I.e. atoms may overlap incorrectly at the faces of the simulation box.

---

The *spacing* option sets the 3 lattice spacings directly. All must be non-zero (use 1.0 for dz in a 2d simulation). The specified values are multiplied by the multiplicative factor described above that is associated with the scale factor. Thus a spacing of 1.0 means one unit cell edge length independent of the scale factor. As mentioned above, this option can be useful if the spacings LAMMPS computes are inconvenient to use in subsequent commands, which can be the case for non-orthogonal or rotated lattices.

Note that whenever the lattice command is used, the values of the lattice spacings LAMMPS calculates are printed out. Thus their effect in commands that use the spacings should be decipherable.

---

Example commands for generating a Wurtzite crystal. The lattice constants approximate those of CdSe. The  $\sqrt{3} \times 1$  orthorhombic supercell is used with the x, y, and z directions oriented along  $[\bar{1}\bar{2}30]$ ,  $[10\bar{1}0]$ , and  $[0001]$ , respectively.

```
variable a equal 4.34
variable b equal $a*sqrt(3.0)
variable c equal $a*sqrt(8.0/3.0)

variable third equal 1.0/3.0
variable five6 equal 5.0/6.0

lattice custom 1.0 &
  a1 $b 0.0 0.0 &
  a2 0.0 $a 0.0 &
  a3 0.0 0.0 $c &
  basis 0.0 0.0 0.0 &

  basis 7 2 &
  basis 8 2
```

---

### 1.49.4 Restrictions

The *a1*, *a2*, *a3*, *basis* keywords can only be used with style *custom*.

## 1.49.5 Related commands

*dimension, create\_atoms, region*

## 1.49.6 Default

```
lattice none 1.0
```

For other lattice styles, the option defaults are origin = 0.0 0.0 0.0, orient = x 1 0 0, orient = y 0 1 0, orient = z 0 0 1, a1 = 1 0 0, a2 = 0 1 0, and a3 = 0 0 1.

## 1.50 log command

### 1.50.1 Syntax

```
log file keyword
```

- file = name of new logfile
- keyword = *append* if output should be appended to logfile (optional)

### 1.50.2 Examples

```
log log.equil
log log.equil append
```

### 1.50.3 Description

This command closes the current LAMMPS log file, opens a new file with the specified name, and begins logging information to it. If the specified file name is *none*, then no new log file is opened. If the optional keyword *append* is specified, then output will be appended to an existing log file, instead of overwriting it.

If multiple processor partitions are being used, the file name should be a variable, so that different processors do not attempt to write to the same log file.

The file “log.lammps” is the default log file for a LAMMPS run. The name of the initial log file can also be set by the *-log command-line switch*.

### 1.50.4 Restrictions

none

### 1.50.5 Related commands

none

### 1.50.6 Default

The default LAMMPS log file is named log.lammps

## 1.51 mass command

### 1.51.1 Syntax

```
mass I value
```

- I = atom type (see asterisk form below), or type label
- value = mass

### 1.51.2 Examples

```
mass 1 1.0
mass * 62.5
mass 2* 62.5

labelmap atom 1 C
mass C 12.01
```

### 1.51.3 Description

Set the mass for all atoms of one or more atom types. Per-type mass values can also be set in the [read\\_data](#) data file using the “Masses” keyword. See the [units](#) command for what mass units to use.

The I index can be specified in one of several ways. An explicit numeric value can be used, as in the first example above. Or I can be a type label, which is an alphanumeric string defined by the [labelmap](#) command or in a section of a data file read by the [read\\_data](#) command, and which converts internally to a numeric type. Or a wild-card asterisk can be used to set the mass for multiple atom types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”, where m and n are numbers. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

A line in a [data file](#) that follows the “Masses” keyword specifies mass using the same format as the arguments of the mass command in an input script, except that no wild-card asterisk can be used. For example, under the “Masses” section of a data file, the line that corresponds to the first example above would be listed as

```
1 1.0
```

Note that the mass command can only be used if the [atom style](#) requires per-type atom mass to be set. Currently, all but the *sphere* and *ellipsoid* and *peri* styles do. They require mass to be set for individual particles, not types. Per-atom masses are defined in the data file read by the [read\\_data](#) command, or set to default values by the [create\\_atoms](#) command. Per-atom masses can also be set to new values by the [set mass](#) or [set density](#) commands.

Also note that *pair\_style eam* and *pair\_style bop* commands define the masses of atom types in their respective potential files, in which case the mass command is normally not used.

If you define a *hybrid atom style* which includes one (or more) sub-styles which require per-type mass and one (or more) sub-styles which require per-atom mass, then you must define both. However, in this case the per-type mass will be ignored; only the per-atom mass will be used by LAMMPS.

### 1.51.4 Restrictions

This command must come after the simulation box is defined by a *read\_data*, *read\_restart*, or *create\_box* command.

All masses must be defined before a simulation is run. They must also all be defined before a *velocity* or *fix shake* command is used.

The mass assigned to any type or atom must be > 0.0.

### 1.51.5 Related commands

none

### 1.51.6 Default

none

## 1.52 mdi command

### 1.52.1 Syntax

**mdi** option args

- option = *engine* or *plugin* or *connect* or *exit*
  - engine* args = zero or more keyword/args pairs
    - keywords = *elements*
      - elements* args = N\_1 N\_2 ... N\_ntypes
        - N\_1,N\_2,...N\_ntypes = chemical symbol for each of ntypes LAMMPS atom types
    - plugin* args = name keyword value keyword value ...
      - name = name of plugin library (e.g., *lammps* means a liblammps.so library will be loaded)
      - keyword/value pairs in any order, some are required, some are optional
      - keywords = *mdi* or *infile* or *extra* or *command*
        - mdi* value = args passed to MDI for driver to operate with plugins (required)
        - infile* value = filename the engine will read at start-up (optional)
        - extra* value = additional command-line args to pass to engine library when loaded (optional)
        - command* value = a LAMMPS input script command to execute (required)
  - connect* args = none
  - exit* args = none

## 1.52.2 Examples

```
mdi engine
mdi engine elements Al Cu
mdi plugin lammmps mdi "-role ENGINE -name lammmps -method LINK" &
      infile in.aimd.engine extra "-log log.aimd.engine.plugin" &
      command "run 5"
mdi connect
mdi exit
```

## 1.52.3 Description

This command implements operations within LAMMPS to use the *MDI Library* <[https://molssi-mdi.github.io/MDI\\_Library/html/index.html](https://molssi-mdi.github.io/MDI_Library/html/index.html)> for coupling to other codes in a client/server protocol.

See the Howto MDI doc page for a discussion of all the different ways 2 or more codes can interact via MDI.

The examples/mdi directory has examples which use LAMMPS in 4 different modes: as a driver using an engine as either a stand-alone code or as a plugin, and as an engine operating as either a stand-alone code or as a plugin. The README file in that directory shows how to launch and couple codes for all the 4 usage modes, and so they communicate via the MDI library using either MPI or sockets.

The scripts in that directory illustrate the use of all the options for this command.

The *engine* option enables LAMMPS to act as an MDI engine (server), responding to requests from an MDI driver (client) code.

The *plugin* option enables LAMMPS to act as an MDI driver (client), and load the MDI engine (server) code as a library plugin. In this case the MDI engine is a library plugin. An MDI engine can also be a stand-alone code, launched separately from LAMMPS, in which case the mdi plugin command is not used.

The *connect* and *exit* options are only used when LAMMPS is acting as an MDI driver. As explained below, these options are normally not needed, except for a specific kind of use case.

---

The *mdi engine* command is used to make LAMMPS operate as an MDI engine. It is typically used in an input script after LAMMPS has setup the system it is going to model consistent with what the driver code expects. Depending on when the driver code tells the LAMMPS engine to exit, other commands can be executed after this command, but typically it is used at the end of a LAMMPS input script.

To act as an MDI engine operating as an MD code (or surrogate QM code), this is the list of standard MDI commands issued by a driver code which LAMMPS currently recognizes. Using standard commands defined by the MDI library means that a driver code can work interchangeably with LAMMPS or other MD codes or with QM codes which support the MDI standard. See more details about these commands in the [MDI library documentation](#)

These commands are valid at the @DEFAULT node defined by MDI. Commands that start with ">" mean the driver is sending information to LAMMPS. Commands that start with "<" are requests by the driver for LAMMPS to send it information. Commands that start with an alphabetic letter perform actions. Commands that start with "@" are MDI "node" commands, which are described further below.

Command name	Action
>CELL or <CELL	Send/request 3 simulation box edge vectors (9 values)
>CELL_DISPL or <CELL_DISPL	Send/request displacement of the simulation box from the origin (3 values)
>CHARGES or <CHARGES	Send/request charge on each atom (N values)
>COORDS or <COORDS	Send/request coordinates of each atom (3N values)
>ELEMENTS	Send elements (atomic numbers) for each atom (N values)
<ENERGY	Request total energy (potential + kinetic) of the system (1 value)
>FORCES or <FORCES	Send/request forces on each atom (3N values)
>+FORCES	Send forces to add to each atom (3N values)
<LABELS	Request string label of each atom (N values)
<MASSES	Request mass of each atom (N values)
MD	Perform an MD simulation for N timesteps (most recent >NSTEPS value)
OPTG	Perform an energy minimization to convergence (most recent >TOLERANCE values)
>NATOMS or <NATOMS	Sends/request number of atoms in the system (1 value)
>NSTEPS	Send number of timesteps for next MD dynamics run via MD command
<PE	Request potential energy of the system (1 value)
<STRESS	Request symmetric stress tensor (virial) of the system (9 values)
>TOLERANCE	Send 4 tolerance parameters for next MD minimization via OPTG command
>TYPES or <TYPES	Send/request the LAMMPS atom type for each atom (N values)
>VELOCITIES or <VELOCITIES	Send/request the velocity of each atom (3N values)
@INIT_MD or @INIT_OPTG	Driver tells LAMMPS to start single-step dynamics or minimization (see below)
EXIT	Driver tells LAMMPS to exit engine mode

**Note:** The <ENERGY, <FORCES, <PE, and <STRESS commands trigger LAMMPS to compute atomic interactions for the current configuration of atoms and size/shape of the simulation box. I.e. LAMMPS invokes its pair, bond, angle, ..., kspace styles. If the driver is updating the atom coordinates and/or box incrementally (as in an MD simulation which the driver is managing), then the LAMMPS engine will do the same, and only occasionally trigger neighbor list builds. If the change in atom positions is large (since the previous >COORDS command), then LAMMPS will do a more expensive operation to migrate atoms to new processors as needed and re-neighbor. If the >NATOMS or >TYPES or >ELEMENTS commands have been sent (since the previous >COORDS command), then LAMMPS assumes the system is new and re-initializes an entirely new simulation.

**Note:** The >TYPES or >ELEMENTS commands are how the MDI driver tells the LAMMPS engine which LAMMPS atom type to assign to each atom. If both the MDI driver and the LAMMPS engine are initialized so that atom type values are consistent in both codes, then the >TYPES command can be used. If not, the optional *elements* keyword can be used to specify what element each LAMMPS atom type corresponds to. This is specified by the chemical symbol of the element, e.g. C or Al or Si. A symbol must be specified for each of the ntypes LAMMPS atom types. Each LAMMPS type must map to a unique element; two or more types cannot map to the same element. Ntypes is typically specified via the *create\_box* command or in the data file read by the *read\_data* command. Once this has been done, the MDI driver can send an >ELEMENTS command to the LAMMPS driver with the atomic number of each atom and the LAMMPS engine will be able to map it to a LAMMPS atom type.

The MD and OPTG commands perform an entire MD simulation or energy minimization (to convergence) with no communication from the driver until the simulation is complete. By contrast, the @INIT\_MD and @INIT\_OPTG commands allow the driver to communicate with the engine at each timestep of a dynamics run or iteration of a minimization; see more info below.

The MD command performs a simulation using the most recent >NSTEPS value. The OPTG command performs a

minimization using the 4 convergence parameters from the most recent >TOLERANCE command. The 4 parameters sent are those used by the *minimize* command in LAMMPS: etol, ftol, maxiter, and maxeval.

The mdi engine command also implements the following custom MDI commands which are LAMMPS-specific. These commands are also valid at the @DEFAULT node defined by MDI:

- – Command name
  - Action
- – >NBYTES
  - Send # of datums in a subsequent command (1 value)
- – >COMMAND
  - Send a LAMMPS input script command as a string (Nbytes in length)
- – >COMMANDS
  - Send multiple LAMMPS input script commands as a newline-separated string (Nbytes in length)
- – >INFILE
  - Send filename of an input script to execute (filename Nbytes in length)
- – <KE
  - Request kinetic energy of the system (1 value)

Note that other custom commands can easily be added if these are not sufficient to support what a user-written driver code needs. Code to support new commands can be added to the MDI package within LAMMPS, specifically to the src/MDI/mdi\_engine.cpp file.

MDI also defines a standard mechanism for the driver to request that an MD engine (LAMMPS) perform a dynamics simulation one step at a time or an energy minimization one iteration at a time. This is so that the driver can (optionally) communicate with LAMMPS at intermediate points of the timestep or iteration by issuing MDI node commands which start with “@”.

To tell LAMMPS to run dynamics in single-step mode, the driver sends as @INIT\_MD command followed by the these commands. The driver can interact with LAMMPS at 3 node locations within each timestep: @COORDS, @FORCES, @ENDSTEP:

- – Command name
  - Action
- – @COORDS
  - Proceed to next @COORDS node = post-integrate location in LAMMPS timestep
- – @FORCES
  - Proceed to next @FORCES node = post-force location in LAMMPS timestep
- – @ENDSTEP
  - Proceed to next @ENDSTEP node = end-of-step location in LAMMPS timestep
- – @DEFAULT
  - Exit MD simulation, return to @DEFAULT node
- – EXIT
  - Driver tells LAMMPS to exit the MD simulation and engine mode

To tell LAMMPS to run an energy minimization in single-iteration mode. The driver can interact with LAMMPS at 2 node locations within each iteration of the minimizer: @COORDS, @FORCES:

- – Command name
- Action
- – @COORDS
- Proceed to next @COORDS node = min-pre-force location in LAMMPS min iteration
- – @FORCES
- Proceed to next @FORCES node = min-post-force location in LAMMPS min iteration
- – @DEFAULT
- Exit minimization, return to @DEFAULT node
- – EXIT
- Driver tells LAMMPS to exit the minimization and engine mode

While LAMMPS is at its @COORDS node, the following standard MDI commands are supported, as documented above: >COORDS or <COORDS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

While LAMMPS is at its @FORCES node, the following standard MDI commands are supported, as documented above: <COORDS, <ENERGY, >FORCES or >+FORCES or <FORCES, <KE, <PE, <STRESS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

While LAMMPS is at its @ENDSTEP node, the following standard MDI commands are supported, as documented above: <ENERGY, <FORCES, <KE, <PE, <STRESS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

---

The *mdi plugin* command is used to make LAMMPS operate as an MDI driver which loads an MDI engine as a plugin library. It is typically used in an input script after LAMMPS has setup the system it is going to model consistent with the engine code.

The *name* argument specifies which plugin library to load. A name like “lammips” is converted to a filename `li-blammips.so`. The path for where this file is located is specified by the `-plugin_path` switch within the `-mdi` command-line switch, which is specified when LAMMPS is launched. See the `examples/mdi/README` files for examples of how this is done.

The *mdi* keyword is required and is used as the `-mdi` argument passed to the library when it is launched. The `-role` and `-method` settings are required. The `-name` setting can be anything you choose. MDI drivers and engines can query their names to verify they are values they expect.

The *infile* keyword is optional. It sets the name of an input script which the engine will open and process. MDI will pass it as a command-line argument to the library when it is launched. The file typically contains settings that an MD or QM code will use for its calculations.

The *extra* keyword is optional. It contains additional command-line arguments which MDI will pass to the library when it is launched.

The *command* keyword is required. It specifies a LAMMPS input script command (as a single argument in quotes if it is multiple words). Once the plugin library is launched, LAMMPS will execute this command. Other previously-defined commands in the input script, such as the *fix mdi/qm* command, should perform MDI communication with the engine, while the specified *command* executes. Note that if *command* is an *include* command, then it could specify a filename with multiple LAMMPS commands.

---

**Note:** When the *command* is complete, LAMMPS will send an MDI EXIT command to the plugin engine and the plugin will be removed. The “mdi plugin” command will then exit and the next command (if any) in the LAMMPS

input script will be processed. A subsequent “mdi plugin” command could then load the same or a different MDI plugin if desired.

---

The *mdi connect* and *mdi exit* commands are only used when LAMMPS is operating as an MDI driver. And when other LAMMPS command(s) which send MDI commands and associated data to/from the MDI engine are not able to initiate and terminate the connection to the engine code.

The only current MDI driver command in LAMMPS is the *fix mdi/qm* command. If it is only used once in an input script then it can initiate and terminate the connection, but if it is being issued multiple times (e.g., in a loop that issues a *clear* command), then it cannot initiate or terminate the connection multiple times. Instead, the *mdi connect* and *mdi exit* commands should be used outside the loop to initiate or terminate the connection.

See the examples/mdi/in.series.driver script for an example of how this is done. The LOOP in that script is reading a series of data file configurations and passing them to an MDI engine (e.g., quantum code) for energy and force evaluation. A *clear* command inside the loop wipes out the current system so a new one can be defined. This operation also destroys all fixes. So the *fix mdi/qm* command is issued once per loop iteration. Note that it includes a “connect no” option which disables the initiate/terminate logic within that fix.

### 1.52.4 Restrictions

This command is part of the MDI package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

To use LAMMPS in conjunction with other MDI-enabled atomistic codes, the *units* command should be used to specify *real* or *metal* units. This will ensure the correct unit conversions between LAMMPS and MDI units, which the other codes will also perform in their preferred units.

LAMMPS can also be used as an MDI engine in other unit choices it supports (e.g., *lj*), but then no unit conversion is performed.

### 1.52.5 Related commands

*fix mdi/qm*

### 1.52.6 Default

## 1.53 min\_modify command

### 1.53.1 Syntax

`min_modify` keyword values ...

- one or more keyword/value pairs may be listed

keyword = *dmax* or *line* or *norm* or *alpha\_damp* or *discrete\_factor* or *integrator* or *→abcfire* or *tmax*

*dmax* value = max

max = maximum distance for line search to move (distance units)

```

line value = backtrack or quadratic or forcezero or spin_cubic or spin_none
  backtrack,quadratic,forcezero,spin_cubic,spin_none = style of linesearch to use
norm value = two or inf or max
  two = Euclidean two-norm (length of 3N vector)
  inf = max force component across all 3-vectors
  max = max force norm across all 3-vectors
alpha_damp value = damping
  damping = fictitious magnetic damping for spin minimization (adim)
discrete_factor value = factor
  factor = discretization factor for adaptive spin timestep (adim)
integrator value = eulerimplicit or verlet or leapfrog or eulerexplicit
  time integration scheme for fire minimization
abcfire value = yes or no (default no)
  yes = use ABC-FIRE variant of fire minimization style
  no  = use default FIRE variant of fire minimization style
tmax value = factor
  factor = maximum adaptive timestep for fire minimization (adim)

```

## 1.53.2 Examples

```

min_modify dmax 0.2
min_modify integrator verlet tmax 4

```

## 1.53.3 Description

This command sets parameters that affect the energy minimization algorithms selected by the `min_style` command. The various settings may affect the convergence rate and overall number of force evaluations required by a minimization, so users can experiment with these parameters to tune their minimizations.

The `cg` and `sd` minimization styles have an outer iteration and an inner iteration which is steps along a one-dimensional line search in a particular search direction. The `dmax` parameter is how far any atom can move in a single line search in any dimension (x, y, or z). For the `quickmin` and `fire` minimization styles, the `dmax` setting is how far any atom can move in a single iteration (timestep). Thus a value of 0.1 in real *units* means no atom will move further than 0.1 Angstroms in a single outer iteration. This prevents highly overlapped atoms from being moved long distances (e.g. through another atom) due to large forces.

The choice of line search algorithm for the `cg` and `sd` minimization styles can be selected via the `line` keyword. The default `quadratic` line search algorithm starts out using the robust backtracking method described below. However, once the system gets close to a local minimum and the linesearch steps get small, so that the energy is approximately quadratic in the step length, it uses the estimated location of zero gradient as the linesearch step, provided the energy change is downhill. This becomes more efficient than backtracking for highly-converged relaxations. The `forcezero` line search algorithm is similar to `quadratic`. It may be more efficient than `quadratic` on some systems.

The backtracking search is robust and should always find a local energy minimum. However, it will “converge” when it can no longer reduce the energy of the system. Individual atom forces may still be larger than desired at this point, because the energy change is measured as the difference of two large values (energy before and energy after) and that difference may be smaller than machine epsilon even if atoms could move in the gradient direction to reduce forces further.

The choice of a norm can be modified for the min styles `cg`, `sd`, `quickmin`, `fire`, `fire/old`, `spin`, `spin/cg` and `spin/lbfgs` using the `norm` keyword. The default `two` norm computes the 2-norm (Euclidean length) of the global force vector:

$$||\vec{F}||_2 = \sqrt{\vec{F}_1^2 + \cdots + \vec{F}_N^2}$$

The *max* norm computes the length of the 3-vector force for each atom (2-norm), and takes the maximum value of those across all atoms

$$||\vec{F}||_{max} = \max \left( ||\vec{F}_1||, \dots, ||\vec{F}_N|| \right)$$

The *inf* norm takes the maximum component across the forces of all atoms in the system:

$$||\vec{F}||_{inf} = \max \left( |F_1^1|, |F_1^2|, |F_1^3| \dots, |F_N^1|, |F_N^2|, |F_N^3| \right)$$

For the min styles *spin*, *spin/cg* and *spin/lbfgs*, the force norm is replaced by the spin-torque norm.

Keywords *alpha\_damp* and *discrete\_factor* only make sense when a *min\_spin* command is declared. Keyword *alpha\_damp* defines an analog of a magnetic damping. It defines a relaxation rate toward an equilibrium for a given magnetic system. Keyword *discrete\_factor* defines a discretization factor for the adaptive timestep used in the *spin* minimization. See *min\_spin* for more information about those quantities.

The choice of a line search algorithm for the *spin/cg* and *spin/lbfgs* styles can be specified via the *line* keyword. The *spin\_cubic* and *spin\_none* keywords only make sense when one of those two minimization styles is declared. The *spin\_cubic* performs the line search based on a cubic interpolation of the energy along the search direction. The *spin\_none* keyword deactivates the line search procedure. The *spin\_none* is a default value for *line* keyword for both *spin/lbfgs* and *spin/cg*. Convergence of *spin/lbfgs* can be more robust if *spin\_cubic* line search is used.

The Newton *integrator* used for *fire* minimization can be selected to be either the symplectic Euler (*eulerimplicit*), velocity Verlet (*verlet*), Leapfrog (*leapfrog*) or non-symplectic forward Euler (*eulerexplicit*). The keyword *tmax* defines the maximum value for the adaptive timestep during a *fire* minimization. It is a multiplication factor applied to the current *timestep* (not in time unit). For example, *tmax* = 4.0 with a *timestep* of 2fs, means that the maximum value the timestep can reach during a *fire* minimization is 4fs. Note that parameter defaults has been chosen to be reliable in most cases, but one should consider adjusting *timestep* and *tmax* to optimize the minimization for large or complex systems. Other parameters of the *fire* minimization can be tuned (*tmin*, *delaystep*, *dtgrow*, *dtshrink*, *alpha0*, and *alphashrink*). Please refer to the references describing the *min\_style fire*. An additional stopping criteria *vdffmax* is used by *fire* in order to avoid unnecessary looping when it is reasonable to think the system will not be relaxed further. Note that in this case the system will NOT have reached your minimization criteria. This could happen when the system comes to be stuck in a local basin of the phase space. *vdffmax* is the maximum number of consecutive iterations with  $P(t) < 0$ .

New in version 8Feb2023.

The *abcfire* keyword allows to activate the ABC-FIRE variant of the *fire* minimization algorithm. ABC-FIRE introduces an additional factor that modifies the bias and scaling of the velocities of the atoms during the mixing step (*Echeverri Restrepo*). This can lead to faster convergence of the minimizer.

The *min\_style fire* is an optimized implementation of *min\_style fire/old*. It can however behave similarly to the *fire/old* style by using the following set of parameters:

```
min_modify integrator eulerexplicit tmax 10.0 tmin 0.0 delaystep 5 &
           dtgrow 1.1 dtshrink 0.5 alpha0 0.1 alphashrink 0.99 &
           vdffmax 1000000 halfstepback no initialdelay no
```

### 1.53.4 Restrictions

For magnetic GNEB calculations, only *spin\_none* value for *line* keyword can be used when minimization styles *spin/cg* and *spin/lbfgs* are employed. See *neb/spin* for more explanation.

### 1.53.5 Related commands

*min\_style*, *minimize*

### 1.53.6 Default

The option defaults are `dmax = 0.1`, `line = quadratic` and `norm = two`.

For the *spin*, *spin/cg* and *spin/lbfgs* styles, the option defaults are `alpha_damp = 1.0`, `discrete_factor = 10.0`, `line = spin_none`, and `norm = euclidean`.

For the *fire* style, the option defaults are `integrator = eulerimplicit`, `tmax = 10.0`, `tmin = 0.02`, `delaystep = 20`, `dtgrow = 1.1`, `dtshrink = 0.5`, `alpha0 = 0.25`, `alphashrink = 0.99`, `vdmax = 2000`, `halfstepback = yes` and `initialdelay = yes`.

## 1.54 min\_style spin command

### 1.55 min\_style spin/cg command

### 1.56 min\_style spin/lbfgs command

#### 1.56.1 Syntax

```
min_style spin
min_style spin/cg
min_style spin/lbfgs
```

#### 1.56.2 Examples

```
min_style spin/lbfgs
min_modify line spin_cubic discrete_factor 10.0
```

#### 1.56.3 Description

Apply a minimization algorithm to use when a *minimize* command is performed.

Style *spin* defines a damped spin dynamics with an adaptive timestep, according to:

$$\frac{d\vec{s}_i}{dt} = \lambda \vec{s}_i \times (\vec{\omega}_i \times \vec{s}_i)$$

with  $\lambda$  a damping coefficient (similar to a magnetic damping).  $\lambda$  can be defined by setting the *alpha\_damp* keyword with the *min\_modify* command.

The minimization procedure solves this equation using an adaptive timestep. The value of this timestep is defined by the largest precession frequency that has to be solved in the system:

$$\Delta t_{\max} = \frac{2\pi}{\kappa |\vec{\omega}_{\max}|}$$

with  $|\vec{\omega}_{\max}|$  the norm of the largest precession frequency in the system (across all processes, and across all replicas if a spin/neb calculation is performed).

$\kappa$  defines a discretization factor *discrete\_factor* for the definition of this timestep. *discrete\_factor* can be defined with the *min\_modify* command.

Style *spin/cg* defines an orthogonal spin optimization (OSO) combined to a conjugate gradient (CG) algorithm. The *min\_modify* command can be used to couple the *spin/cg* to a line search procedure, and to modify the discretization factor *discrete\_factor*. By default, style *spin/cg* does not employ the line search procedure and uses the adaptive time-step technique in the same way as style *spin*.

Style *spin/lbfgs* defines an orthogonal spin optimization (OSO) combined to a limited-memory Broyden-Fletcher-Goldfarb-Shanno (L-BFGS) algorithm. By default, style *spin/lbfgs* does not employ line search procedure. If the line search procedure is not used then the discrete factor defines the maximum root mean squared rotation angle of spins by equation  $\pi/(5*Kappa)$ . The default value for Kappa is 10. The *spin\_cubic* line search option can improve the convergence of the *spin/lbfgs* algorithm.

The *min\_modify* command can be used to activate the line search procedure, and to modify the discretization factor *discrete\_factor*.

For more information about styles *spin/cg* and *spin/lbfgs*, see their implementation reported in (Ivanov).

---

**Note:** All the *spin* styles replace the force tolerance by a torque tolerance. See *minimize* for more explanation.

---

---

**Note:** The *spin/cg* and *spin/lbfgs* styles can be used for magnetic NEB calculations only if the line search procedure is deactivated. See *neb/spin* for more explanation.

---

## 1.56.4 Restrictions

The *spin*, *spin/cg*, and *spin/lbfgs* styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This minimization procedure is only applied to spin degrees of freedom for a frozen lattice configuration.

## 1.56.5 Related commands

*min\_style*, *minimize*, *min\_modify*

## 1.56.6 Default

The option defaults are *alpha\_damp* = 1.0, *discrete\_factor* = 10.0, *line* = *spin\_none* and *norm* = *euclidean*.

*spin/cg* is discussed briefly here and fully on [min\\_style spin](#) doc page

*spin/lbfgs* is discussed briefly here and fully on [min\\_style spin](#) doc page

### 1.64.2 Examples

```
min_style cg
min_style fire
min_style spin
```

### 1.64.3 Description

Choose a minimization algorithm to use when a [minimize](#) command is performed.

Style *cg* is the Polak-Ribiere version of the conjugate gradient (CG) algorithm. At each iteration the force gradient is combined with the previous iteration information to compute a new search direction perpendicular (conjugate) to the previous search direction. The PR variant affects how the direction is chosen and how the CG method is restarted when it ceases to make progress. The PR variant is thought to be the most effective CG choice for most problems.

Style *hftn* is a Hessian-free truncated Newton algorithm. At each iteration a quadratic model of the energy potential is solved by a conjugate gradient inner iteration. The Hessian (second derivatives) of the energy is not formed directly, but approximated in each conjugate search direction by a finite difference directional derivative. When close to an energy minimum, the algorithm behaves like a Newton method and exhibits a quadratic convergence rate to high accuracy. In

most cases the behavior of *hftn* is similar to *cg*, but it offers an alternative if *cg* seems to perform poorly. This style is not affected by the *min\_modify* command.

Style *sd* is a steepest descent algorithm. At each iteration, the search direction is set to the downhill direction corresponding to the force vector (negative gradient of energy). Typically, steepest descent will not converge as quickly as CG, but may be more robust in some situations.

Style *quickmin* is a damped dynamics method described in (*Sheppard*), where the damping parameter is related to the projection of the velocity vector along the current force vector for each atom. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization.

Style *fire* is a damped dynamics method described in (*Bitzek*), which is similar to *quickmin* but adds a variable timestep and alters the projection operation to maintain components of the velocity non-parallel to the current force vector. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization. This style correspond to an optimized version described in (*Guenole*) that include different time integration schemes and default parameters. The default parameters can be modified with the command *min\_modify*.

Style *spin* is a damped spin dynamics with an adaptive timestep.

Style *spin/cg* uses an orthogonal spin optimization (OSO) combined to a conjugate gradient (CG) approach to minimize spin configurations.

Style *spin/lbfgs* uses an orthogonal spin optimization (OSO) combined to a limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) approach to minimize spin configurations.

See the *min/spin* page for more information about the *spin*, *spin/cg* and *spin/lbfgs* styles.

Either the *quickmin* or the *fire* styles are useful in the context of nudged elastic band (NEB) calculations via the *neb* command.

Either the *spin*, *spin/cg*, or *spin/lbfgs* styles are useful in the context of magnetic geodesic nudged elastic band (GNEB) calculations via the *neb/spin* command.

---

**Note:** The damped dynamic minimizers use whatever timestep you have defined via the *timestep* command. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations. For *fire*, the default timestep is recommended to be equal to the one you would normally use for dynamics simulations.

---

---

**Note:** The *quickmin*, *fire*, *hftn*, and *cg/kk* styles do not yet support the use of the *fix box/relax* command or minimizations involving the electron radius in *eFF* models.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 1.64.4 Restrictions

The *spin*, *spin/cg*, and *spin/lbfgs* styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 1.64.5 Related commands

*min\_modify*, *minimize*, *neb*

### 1.64.6 Default

```
min_style cg
```

## 1.65 minimize command

Accelerator Variant: minimize/kk

### 1.65.1 Syntax

```
minimize etol ftol maxiter maxeval
```

- etol = stopping tolerance for energy (unitless)
- ftol = stopping tolerance for force (force units)
- maxiter = max iterations of minimizer
- maxeval = max number of force/energy evaluations

### 1.65.2 Examples

```
minimize 1.0e-4 1.0e-6 100 1000
minimize 0.0 1.0e-8 1000 100000
```

### 1.65.3 Description

Perform an energy minimization of the system, by iteratively adjusting atom coordinates. Iterations are terminated when one of the stopping criteria is satisfied. At that point the configuration will hopefully be in a local potential energy minimum. More precisely, the configuration should approximate a critical point for the objective function (see below), which may or may not be a local minimum.

The minimization algorithm used is set by the *min\_style* command. Other options are set by the *min\_modify* command. Minimize commands can be interspersed with *run* commands to alternate between relaxation and dynamics. The minimizers bound the distance atoms may move in one iteration, so that you can relax systems with highly overlapped atoms (large energies and forces) by pushing the atoms off of each other.

---

#### Neighbor list update settings

The distance that atoms can move during individual minimization steps can be quite large, especially at the beginning of a minimization. Thus *neighbor list settings* of *every = 1* and *delay = 0* are **required**. This may be combined with either *check = no* (always update the neighbor list) or *check = yes* (only update the neighbor list if at least one atom has moved more than half the *neighbor list skin* distance since the last reneighboring). Using *check = yes* is recommended since it avoids unneeded reneighboring steps when the system is closer to the minimum and thus atoms move only small distances. Using *check = no* may be required for debugging or when coupling LAMMPS with external codes that require a predictable sequence of neighbor list updates.

If the settings are **not** *every = 1* and *delay = 0*, LAMMPS will temporarily apply a *neigh\_modify every 1 delay 0 check yes* setting during the minimization and restore the original setting at the end of the minimization. A corresponding message will be printed to the screen and log file, if this happens.

---

Alternate means of relaxing a system are to run dynamics with a small or *limited timestep*. Or dynamics can be run using *fix viscous* to impose a damping force that slowly drains all kinetic energy from the system. The *pair\_style soft* potential can be used to un-overlap atoms while running dynamics.

Note that you can minimize some atoms in the system while holding the coordinates of other atoms fixed by applying *fix setforce 0.0 0.0 0.0* to the other atoms. See a more detailed discussion of *using fixes while minimizing below*.

The *minimization styles* *cg*, *sd*, and *hfn* involves an outer iteration loop which sets the search direction along which atom coordinates are changed. An inner iteration is then performed using a line search algorithm. The line search typically evaluates forces and energies several times to set new coordinates. Currently, a backtracking algorithm is used which may not be optimal in terms of the number of force evaluations performed, but appears to be more robust than previous line searches we have tried. The backtracking method is described in Nocedal and Wright's Numerical Optimization (Procedure 3.1 on p 41).

The *minimization styles* *quickmin*, *fire* and *fire/old* perform damped dynamics using an Euler integration step. Thus they require a *timestep* be defined.

---

**Note:** The damped dynamic minimizer algorithms will use the timestep you have defined via the *timestep* command or its default value. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for regular molecular dynamics simulations.

---

In all cases, the objective function being minimized is the total potential energy of the system as a function of the N atom coordinates:

$$E(r_1, r_2, \dots, r_N) = \sum_{i,j} E_{\text{pair}}(r_i, r_j) + \sum_{ij} E_{\text{bond}}(r_i, r_j) + \sum_{ijk} E_{\text{angle}}(r_i, r_j, r_k) + \\ \sum_{ijkl} E_{\text{dihedral}}(r_i, r_j, r_k, r_l) + \sum_{ijkl} E_{\text{improper}}(r_i, r_j, r_k, r_l) + \sum_i E_{\text{fix}}(r_i)$$

where the first term is the sum of all non-bonded *pairwise interactions* including *long-range Coulombic interactions*, the second through fifth terms are *bond*, *angle*, *dihedral*, and *improper* interactions respectively, and the last term is energy due to *fixes* which can act as constraints or apply force to atoms, such as through interaction with a wall. See the discussion below about how fix commands affect minimization.

The starting point for the minimization is the current configuration of the atoms.

The minimization procedure stops if any of several criteria are met:

- the change in energy between outer iterations is less than *etol*
- the 2-norm (length) of the global force vector is less than the *ftol*
- the line search fails because the step distance backtracks to 0.0
- the number of outer iterations or timesteps exceeds *maxiter*
- the number of total force evaluations exceeds *maxeval*

**Note:** the *minimization style spin*, *spin/cg*, and *spin/lbfgs* replace the force tolerance *ftol* by a torque tolerance. The minimization procedure stops if the 2-norm (length) of the torque vector on atom (defined as the cross product between the atomic spin and its precession vectors omega) is less than *ftol*, or if any of the other criteria are met. Torque have the same units as the energy.

**Note:** You can also use the *fix halt* command to specify a general criterion for exiting a minimization, that is a calculation performed on the state of the current system, as defined by an *equal-style variable*.

For the first criterion, the specified energy tolerance *etol* is unitless; it is met when the energy change between successive iterations divided by the energy magnitude is less than or equal to the tolerance. For example, a setting of 1.0e-4 for *etol* means an energy tolerance of one part in 10<sup>4</sup>. For the damped dynamics minimizers this check is not performed for a few steps after velocities are reset to 0, otherwise the minimizer would prematurely converge.

For the second criterion, the specified force tolerance *ftol* is in force units, since it is the length of the global force vector for all atoms, e.g. a vector of size 3N for N atoms. Since many of the components will be near zero after minimization, you can think of *ftol* as an upper bound on the final force on any component of any atom. For example, a setting of 1.0e-4 for *ftol* means no x, y, or z component of force on any atom will be larger than 1.0e-4 (in force units) after minimization.

Either or both of the *etol* and *ftol* values can be set to 0.0, in which case some other criterion will terminate the minimization.

During a minimization, the outer iteration count is treated as a timestep. Output is triggered by this timestep, e.g. thermodynamic output or dump and restart files.

Using the *thermo\_style custom* command with the *fmax* or *fnorm* keywords can be useful for monitoring the progress of the minimization. Note that these outputs will be calculated only from forces on the atoms, and will not include any extra degrees of freedom, such as from the *fix box/relax* command.

Following minimization, a statistical summary is printed that lists which convergence criterion caused the minimizer to stop, as well as information about the energy, force, final line search, and iteration counts. An example is as follows:

```
Minimization stats:
  Stopping criterion = max iterations
  Energy initial, next-to-last, final =
    -0.626828169302    -2.82642039062    -2.82643549739
```

(continues on next page)

(continued from previous page)

```
Force two-norm initial, final = 2052.1 91.9642
Force max component initial, final = 346.048 9.78056
Final line search alpha, max atom move = 2.23899e-06 2.18986e-05
Iterations, force evaluations = 2000 12724
```

The 3 energy values are for before and after the minimization and on the next-to-last iteration. This is what the *etol* parameter checks.

The two-norm force values are the length of the global force vector before and after minimization. This is what the *ftol* parameter checks.

The max-component force values are the absolute value of the largest component (x,y,z) in the global force vector, i.e. the infinity-norm of the force vector.

The alpha parameter for the line-search, when multiplied by the max force component (on the last iteration), gives the max distance any atom moved during the last iteration. Alpha will be 0.0 if the line search could not reduce the energy. Even if alpha is non-zero, if the “max atom move” distance is tiny compared to typical atom coordinates, then it is possible the last iteration effectively caused no atom movement and thus the evaluated energy did not change and the minimizer terminated. Said another way, even with non-zero forces, it’s possible the effect of those forces is to move atoms a distance less than machine precision, so that the energy cannot be further reduced.

The iterations and force evaluation values are what is checked by the *maxiter* and *maxeval* parameters.

---

**Note:** There are several force fields in LAMMPS which have discontinuities or other approximations which may prevent you from performing an energy minimization to tight tolerances. For example, you should use a *pair style* that goes to 0.0 at the cutoff distance when performing minimization (even if you later change it when running dynamics). If you do not do this, the total energy of the system will have discontinuities when the relative distance between any pair of atoms changes from cutoff *plus* epsilon to cutoff *minus* epsilon and the minimizer may thus behave poorly. Some of the many-body potentials use splines and other internal cutoffs that inherently have this problem. The *long-range Coulombic styles* (PPPM, Ewald) are approximate to within the user-specified tolerance, which means their energy and forces may not agree to a higher precision than the Kspace-specified tolerance. This agreement is further reduced when using tabulation to speed up the computation of the real-space part of the Coulomb interactions, which is enabled by default. In all these cases, the minimizer may give up and stop before finding a minimum to the specified energy or force tolerance.

---

Note that a cutoff Lennard-Jones potential (and others) can be shifted so that its energy is 0.0 at the cutoff via the *pair\_modify* command. See the doc pages for individual *pair styles* for details. Note that most Coulombic potentials have a cutoff, unless versions with a long-range component are used (e.g. *pair\_style lj/cut/coul/long*) or some other damping/smoothing schemes are used. The CHARMM potentials go to 0.0 at the cutoff (e.g. *pair\_style lj/charmm/coul/charmm*), as do the GROMACS potentials (e.g. *pair\_style lj/gromacs*).

If a soft potential (*pair\_style soft*) is used the Astop value is used for the prefactor (no time dependence).

The *fix box/relax* command can be used to apply an external pressure to the simulation box and allow it to shrink/expand during the minimization.

Only a few other fixes (typically those that add forces) are invoked during minimization. See the doc pages for individual *fix* commands to see which ones are relevant. Current examples of fixes that can be used include:

- *fix addforce*
- *fix addtorque*
- *fix efield*
- *fix enforce2d*

- *fix indent*
- *fix lineforce*
- *fix planeforce*
- *fix setforce*
- *fix spring*
- *fix spring/self*
- *fix viscous*
- *fix wall*
- *fix wall/region*

---

**Note:** Some fixes which are invoked during minimization have an associated potential energy. For that energy to be included in the total potential energy of the system (the quantity being minimized), you **MUST** enable the *fix\_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

---

---

**Note:** The minimizers in LAMMPS do not allow for bonds (or angles, etc) to be held fixed while atom coordinates are being relaxed, e.g. via *fix shake* or *fix rigid*. See more info in the Restrictions section below.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 1.65.4 Restrictions

Features that are not yet implemented are listed here, in case someone knows how they could be coded:

It is an error to use *fix shake* with minimization because it turns off bonds that should be included in the potential energy of the system. The effect of a fix shake can be approximated during a minimization by using stiff spring constants for the bonds and/or angles that would normally be constrained by the SHAKE algorithm.

*Fix rigid* is also not supported by minimization. It is not an error to have it defined, but the energy minimization will not keep the defined body(s) rigid during the minimization. Note that if bonds, angles, etc internal to a rigid body have been turned off (e.g. via *neigh\_modify exclude*), they will not contribute to the potential energy which is probably not what is desired.

Pair potentials that produce torque on a particle (e.g. *granular potentials* or the *GayBerne potential* for ellipsoidal particles) are not relaxed by a minimization. More specifically, radial relaxations are induced, but no rotations are induced by a minimization, so such a system will not fully relax.

### 1.65.5 Related commands

*min\_modify*, *min\_style*, *run\_style*

### 1.65.6 Default

none

## 1.66 molecule command

### 1.66.1 Syntax

```
molecule ID file1 keyword values ... file2 keyword values ... fileN ...
```

- ID = user-assigned name for the molecule template
- file1,file2,... = names of files containing molecule descriptions
- zero or more keyword/value pairs may be appended after each file
- keyword = *offset* or *toff* or *boff* or *aoff* or *doff* or *ioff* or *scale*

*offset* values = Toff Boff Aoff Doft Ioff

Toff = offset to add to atom types

Boff = offset to add to bond types

Aoff = offset to add to angle types

Doft = offset to add to dihedral types

Ioff = offset to add to improper types

*toff* value = Toff

Toff = offset to add to atom types

*boff* value = Boff

Boff = offset to add to bond types

*aoff* value = Aoff

Aoff = offset to add to angle types

*doff* value = Doft

Doft = offset to add to dihedral types

*ioff* value = Ioff

Ioff = offset to add to improper types

*scale* value = sfactor

sfactor = scale factor to apply to the size and mass of the molecule

### 1.66.2 Examples

```
molecule 1 mymol.txt
molecule 1 co2.txt h2o.txt
molecule C02 co2.txt boff 3 aoff 2
molecule 1 mymol.txt offset 6 9 18 23 14
molecule objects file.1 scale 1.5 file.1 scale 2.0 file.2 scale 1.3
```

### 1.66.3 Description

Define a molecule template that can be used as part of other LAMMPS commands, typically to define a collection of particles as a bonded molecule or a rigid body. Commands that currently use molecule templates include:

- *fix deposit*
- *fix pour*
- *fix rigid/small*
- *fix shake*
- *fix gcmc*
- *fix bond/react*
- *create\_atoms*
- *atom\_style template*

The ID of a molecule template can only contain alphanumeric characters and underscores.

A single template can contain multiple molecules, listed one per file. Some of the commands listed above currently use only the first molecule in the template, and will issue a warning if the template contains multiple molecules. The *atom\_style template* command allows multiple-molecule templates to define a system with more than one templated molecule.

Each filename can be followed by optional keywords which are applied only to the molecule in the file as used in this template. This is to make it easy to use the same molecule file in different molecule templates or in different simulations. You can specify the same file multiple times with different optional keywords.

The *offset*, *toff*, *boff*, *aoff*, *doff*, *ioff* keywords add the specified offset values to the atom types, bond types, angle types, dihedral types, and/or improper types as they are read from the molecule file. E.g. if *toff* = 2, and the file uses atom types 1,2,3, then each created molecule will have atom types 3,4,5. For the *offset* keyword, all five offset values must be specified, but individual values will be ignored if the molecule template does not use that attribute (e.g. no bonds).

---

**Note:** Offsets are **ignored** on lines using type labels, as the type labels will determine the actual types directly depending on the current *labelmap* settings.

---

The *scale* keyword scales the size of the molecule. This can be useful for modeling polydisperse granular rigid bodies. The scale factor is applied to each of these properties in the molecule file, if they are defined: the individual particle coordinates (Coords section), the individual mass of each particle (Masses section), the individual diameters of each particle (Diameters section), the total mass of the molecule (header keyword = mass), the center-of-mass of the molecule (header keyword = com), and the moments of inertia of the molecule (header keyword = inertia).

---

**Note:** The molecule command can be used to define molecules with bonds, angles, dihedrals, impropers, or special bond lists of neighbors within a molecular topology, so that you can later add the molecules to your simulation, via one or more of the commands listed above. Since this topology-related information requires that suitable storage is reserved when LAMMPS creates the simulation box (e.g. when using the *create\_box* command or the *read\_data* command) suitable space has to be reserved so you do not overflow those pre-allocated data structures when adding molecules later. Both the *create\_box* command and the *read\_data* command have “extra” options which ensure space is allocated for storing topology info for molecules that are added later.

---

### 1.66.4 Format of a molecule file

The format of an individual molecule file looks similar but is different than that of a data file read by the *read\_data* commands. Here is a simple example for a TIP3P water molecule:

```
# Water molecule. TIP3P geometry
# header section:
3 atoms
2 bonds
1 angles

# body section:
Coords

1      0.000000  -0.06556   0.000000
2      0.75695   0.52032   0.000000
3     -0.75695   0.52032   0.000000

Types

1      1      # O
2      2      # H
3      2      # H

Charges

1      -0.834
2      0.417
3      0.417

Bonds

1  1      1      2
2  1      1      3

Angles

1  1      2      1      3
```

A molecule file has a header and a body. The header appears first. The first line of the header and thus of the molecule file is *always* skipped; it typically contains a description of the file or a comment from the software that created the file.

Then lines are read one line at a time. Lines can have a trailing comment starting with '#' that is ignored. There *must* be at least one blank between any valid content and the comment. If the line is blank (i.e. contains only white-space after comments are deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is/are read from the line. A line that is *not* blank and does *not* contains a header keyword begins the body of the file.

The body of the file contains zero or more sections. The first line of a section has only a keyword. The next line is skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used between sections. Sections can appear in any order, with a few exceptions as noted below.

These are the recognized header keywords. Header lines can come in any order. The numeric value(s) are read from the beginning of the line. The keyword should appear at the end of the line. All these settings have default values, as explained below. A line need only appear if the value(s) are different than the default, except when defining a *body* particle, which requires setting the number of *atoms* to 1, and setting the *inertia* in a specific section (see below).

Number(s)	Keyword	Meaning	Default Value
N	atoms	# of atoms N in molecule	0
Nb	bonds	# of bonds Nb in molecule	0
Na	angles	# of angles Na in molecule	0
Nd	dihedrals	# of dihedrals Nd in molecule	0
Ni	impropers	# of impropers Ni in molecule	0
Nf	fragments	# of fragments Nf in molecule	0
Ninteger Ndouble	body	# of integer and floating-point values in body particle	0
Mtotal	mass	total mass of molecule	computed
Xc Yc Zc	com	coordinates of center-of-mass of molecule	computed
Ixx Iyy Izz Ixy Ixz Iyz	inertia	6 components of inertia tensor of molecule	computed

For *mass*, *com*, and *inertia*, the default is for LAMMPS to calculate this quantity itself if needed, assuming the molecules consist of a set of point particles or finite-size particles (with a non-zero diameter) that do **not** overlap. If finite-size particles in the molecule **do** overlap, LAMMPS will not account for the overlap effects when calculating any of these 3 quantities, so you should pre-compute them yourself and list the values in the file.

The mass and center-of-mass coordinates (Xc,Yc,Zc) are self-explanatory. The 6 moments of inertia (ixx,iyy,izz,ixy,ixz,iyz) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

These are the allowed section keywords for the body of the file.

- *Coords, Types, Molecules, Fragments, Charges, Diameters, Dipoles, Masses* = atom-property sections
- *Bonds, Angles, Dihedrals, Improvers* = molecular topology sections
- *Special Bond Counts, Special Bonds* = special neighbor info
- *Shake Flags, Shake Atoms, Shake Bond Types* = SHAKE info
- *Body Integers, Body Doubles* = body-property sections

For the Types, Bonds, Angles, Dihedrals, and Improvers sections, each atom/bond/angle/etc type can be specified either as a number (numeric type) or as an alphanumeric type label. The latter is only allowed if type labels have been defined, either by the [labelmap](#) command or in data files read by the [read\\_data](#) command which have sections for Atom Type Labels, Bond Type Labels, Angle Type Labels, etc. See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used. When using type labels, any values specified as *offset* are ignored.

If a Bonds section is specified then the Special Bond Counts and Special Bonds sections can also be used, if desired, to explicitly list the 1-2, 1-3, 1-4 neighbors within the molecule topology (see details below). This is optional since if these sections are not included, LAMMPS will auto-generate this information. Note that LAMMPS uses this info to properly exclude or weight bonded pairwise interactions between bonded atoms. See the [special\\_bonds](#) command for more details. One reason to list the special bond info explicitly is for the [thermalized Drude oscillator model](#) which treats the bonds between nuclear cores and Drude electrons in a different manner.

**Note:** Whether a section is required depends on how the molecule template is used by other LAMMPS commands. For example, to add a molecule via the [fix deposit](#) command, the Coords and Types sections are required. To add a rigid body via the [fix pour](#) command, the Bonds (Angles, etc) sections are not required, since the molecule will be treated as a rigid body. Some sections are optional. For example, the [fix pour](#) command can be used to add “molecules” which are clusters of finite-size granular particles. If the Diameters section is not specified, each particle in the molecule will have a default diameter of 1.0. See the doc pages for LAMMPS commands that use molecule templates for more details.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for whether it can appear in the data file. For per-atom sections, entries should be numbered from 1 to Natoms (where Natoms is the number of atoms in the template), indicating which atom (or bond, etc) the entry applies to. Per-atom sections need to include a setting for every atom, but the atoms can be listed in any order.

---

*Coords* section:

- one line per atom
  - line syntax: ID x y z
  - x,y,z = coordinate of atom
- 

*Types* section:

- one line per atom
  - line syntax: ID type
  - type = atom type of atom (1-Natomtype, or type label)
- 

*Molecules* section:

- one line per atom
  - line syntax: ID molecule-ID
  - molecule-ID = molecule ID of atom
- 

*Fragments* section:

- one line per fragment
- line syntax: ID a b c d ...
- a,b,c,d,... = IDs of atoms in fragment

The ID of a fragment can only contain alphanumeric characters and underscores. The atom IDs should be values from 1 to Natoms, where Natoms = # of atoms in the molecule.

---

*Charges* section:

- one line per atom
- line syntax: ID q
- q = charge on atom

This section is only allowed for *atom styles* that support charge. If this section is not included, the default charge on each atom in the molecule is 0.0.

---

*Diameters* section:

- one line per atom
  - line syntax: ID diam
-

- diam = diameter of atom

This section is only allowed for *atom styles* that support finite-size spherical particles, e.g. atom\_style sphere. If not listed, the default diameter of each atom in the molecule is 1.0.

---

New in version 7Feb2024.

*Dipoles* section:

- one line per atom
- line syntax: ID mux muy muz
- mux,muy,muz = x-, y-, and z-component of point dipole vector of atom

This section is only allowed for *atom styles* that support particles with point dipoles, e.g. atom\_style dipole. If not listed, the default dipole component of each atom in the molecule is set to 0.0.

---

*Masses* section:

- one line per atom
- line syntax: ID mass
- mass = mass of atom

This section is only allowed for *atom styles* that support per-atom mass, as opposed to per-type mass. See the *mass* command for details. If this section is not included, the default mass for each atom is derived from its volume (see Diameters section) and a default density of 1.0, in *units* of mass/volume.

---

*Bonds* section:

- one line per bond
- line syntax: ID type atom1 atom2
- type = bond type (1-Nbondtype, or type label)
- atom1,atom2 = IDs of atoms in bond

The IDs for the two atoms in each bond should be values from 1 to Natoms, where Natoms = # of atoms in the molecule.

---

*Angles* section:

- one line per angle
- line syntax: ID type atom1 atom2 atom3
- type = angle type (1-Nangletype, or type label)
- atom1,atom2,atom3 = IDs of atoms in angle

The IDs for the three atoms in each angle should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The three atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list.

---

*Dihedrals* section:

- one line per dihedral

- line syntax: ID type atom1 atom2 atom3 atom4
- type = dihedral type (1-Ndihedralttype, or type label)
- atom1,atom2,atom3,atom4 = IDs of atoms in dihedral

The IDs for the four atoms in each dihedral should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The 4 atoms are ordered linearly within the dihedral.

---

*Impropers* section:

- one line per improper
- line syntax: ID type atom1 atom2 atom3 atom4
- type = improper type (1-Nimproptype, or type label)
- atom1,atom2,atom3,atom4 = IDs of atoms in improper

The IDs for the four atoms in each improper should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The ordering of the 4 atoms determines the definition of the improper angle used in the formula for the defined *improper style*. See the doc pages for individual styles for details.

---

*Special Bond Counts* section:

- one line per atom
- line syntax: ID N1 N2 N3
- N1 = # of 1-2 bonds
- N2 = # of 1-3 bonds
- N3 = # of 1-4 bonds

N1, N2, N3 are the number of 1-2, 1-3, 1-4 neighbors respectively of this atom within the topology of the molecule. See the *special\_bonds* page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bonds section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

---

*Special Bonds* section:

- one line per atom
- line syntax: ID a b c d ...
- a,b,c,d,... = IDs of atoms in N1+N2+N3 special bonds

A, b, c, d, etc are the IDs of the n1+n2+n3 atoms that are 1-2, 1-3, 1-4 neighbors of this atom. The IDs should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The first N1 values should be the 1-2 neighbors, the next N2 should be the 1-3 neighbors, the last N3 should be the 1-4 neighbors. No atom ID should appear more than once. See the *special\_bonds* doc page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bond Counts section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

---

*Shake Flags* section:

- one line per atom
- line syntax: ID flag
- flag = 0,1,2,3,4

This section is only needed when molecules created using the template will be constrained by SHAKE via the “fix shake” command. The other two Shake sections must also appear in the file, following this one.

The meaning of the flag for each atom is as follows. See the [fix shake](#) page for a further description of SHAKE clusters.

- 0 = not part of a SHAKE cluster
  - 1 = part of a SHAKE angle cluster (two bonds and the angle they form)
  - 2 = part of a 2-atom SHAKE cluster with a single bond
  - 3 = part of a 3-atom SHAKE cluster with two bonds
  - 4 = part of a 4-atom SHAKE cluster with three bonds
- 

#### *Shake Atoms* section:

- one line per atom
- line syntax: ID a b c d
- a,b,c,d = IDs of atoms in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the “fix shake” command. The other two Shake sections must also appear in the file.

The a,b,c,d values are atom IDs (from 1 to Natoms) for all the atoms in the SHAKE cluster that this atom belongs to. The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c,d values identically.

If flag = 0, no a,b,c,d values are listed on the line, just the (ignored) ID.

If flag = 1, a,b,c are listed, where a = ID of central atom in the angle, and b,c the other two atoms in the angle.

If flag = 2, a,b are listed, where a = ID of atom in bond with the lowest ID, and b = ID of atom in bond with the highest ID.

If flag = 3, a,b,c are listed, where a = ID of central atom, and b,c = IDs of other two atoms bonded to the central atom.

If flag = 4, a,b,c,d are listed, where a = ID of central atom, and b,c,d = IDs of other three atoms bonded to the central atom.

See the [fix shake](#) page for a further description of SHAKE clusters.

---

#### *Shake Bond Types* section:

- one line per atom
- line syntax: ID a b c
- a,b,c = bond types (or angle type) of bonds (or angle) in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the “fix shake” command. The other two Shake sections must also appear in the file.

The a,b,c values are bond types for all bonds in the SHAKE cluster that this atom belongs to. Bond types may be either numbers (from 1 to Nbondtypes) or bond type labels as defined by the [labelmap](#) command or a “Bond Type Labels” section of a data file.

The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c values identically.

If flag = 0, no a,b,c values are listed on the line, just the (ignored) ID.

If flag = 1, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section), and c = the angle type (1 to Nangletypes, or angle type label) of the angle between the three atoms.

If flag = 2, only a is listed, where a = bondtype of the bond between the two atoms in the cluster.

If flag = 3, a,b are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), and b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section).

If flag = 4, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section), and c = bondtype of the bond between the central atom and the third non-central atom (value d in the Shake Atoms section).

See the [fix shake](#) page for a further description of SHAKE clusters.

---

*Body Integers* section:

- one line
- line syntax: N E F
- N = number of sub-particles or number of vertices
- E,F = number of edges and faces

This section is only needed when the molecule is a body particle. the other Body section must also appear in the file.

The total number of values that must appear is determined by the body style, and must be equal to the Ninteger value given in the *body* header.

For *nparticle* and *rounded/polygon*, only the number of sub-particles or vertices N is required, and Ninteger should have a value of 1.

For *rounded/polyhedron*, the number of edges E and faces F is required, and Ninteger should have a value of 3.

See the [Howto body](#) page for a further description of the file format.

---

*Body Doubles* section:

- first line
- line syntax: Ixx Iyy Izz Ixy Ixz Iyz
- Ixx Iyy Izz Ixy Ixz Iyz = 6 components of inertia tensor of body particle
- one line per sub-particle or vertex
- line syntax: x y z
- x, y, z = coordinates of sub-particle or vertex
- one line per edge
- line syntax: N1 N2
- N1, N2 = vertex indices

- one line per face
- line syntax: N1 N2 N3 N4
- N1, N2, N3, N4 = vertex indices
- last line
- line syntax: diam
- diam = rounded diameter that surrounds each vertex

This section is only needed when the molecule is a body particle. the other Body section must also appear in the file.

The total number of values that must appear is determined by the body style, and must be equal to the Ndouble value given in the *body* header. The 6 moments of inertia and the 3N coordinates of the sub-particles or vertices are required for all body styles.

For *rounded/polygon*, the  $E = 6 + 3*N + 1$  edges are automatically determined from the vertices.

For *rounded/polyhedron*, the 2E vertex indices for the end points of the edges and 4F vertex indices defining the faces are required.

See the [Howto body](#) page for a further description of the file format.

### 1.66.7 Default

The default keywords values are offset 0 0 0 0 0 and scale = 1.0.

## 1.67 neb command

### 1.67.1 Syntax

```
neb etol ftol N1 N2 Nevery file-style arg keyword values
```

- etol = stopping tolerance for energy (dimensionless)
- ftol = stopping tolerance for force (force units)
- N1 = max # of iterations (timesteps) to run initial NEB
- N2 = max # of iterations (timesteps) to run barrier-climbing NEB
- Nevery = print replica energies and reaction coordinates every this many timesteps
- file-style = *final* or *each* or *none*

```
final arg = filename
  filename = file with initial coords for final replica
  coords for intermediate replicas are linearly interpolated
  between first and last replica
each arg = filename
  filename = unique filename for each replica (except first)
  with its initial coords
none arg = no argument all replicas assumed to already have
  their initial coords
```

- zero or more keyword/value pairs may be appended
- keyword = *verbosity*

```
verbosity value = verbose or default or terse
  verbose = very detailed per-replica output
  default = some per-replica output
  terse = only global state output
```

### 1.67.2 Examples

```
neb 0.1 0.0 1000 500 50 final coords.final
neb 0.0 0.001 1000 500 50 each coords.initial.$i
neb 0.0 0.001 1000 500 50 none verbose
```

### 1.67.3 Description

Perform a nudged elastic band (NEB) calculation using multiple replicas of a system. Two or more replicas must be used; the first and last are the end points of the transition path.

NEB is a method for finding both the atomic configurations and height of the energy barrier associated with a transition state, e.g. for an atom to perform a diffusive hop from one energy basin to another in a coordinated fashion with its neighbors. The implementation in LAMMPS follows the discussion in these 4 papers: ([HenkelmanA](#)), ([HenkelmanB](#)), ([Nakano](#)) and ([Maras](#)).

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the *partition command-line switch*. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on just one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the *Howto replica* doc page for further discussion.

---

**Note:** As explained below, a NEB calculation performs a damped dynamics minimization across all the replicas. The minimizer uses whatever timestep you have defined in your input script, via the *timestep* command. Often NEB will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

---

When a NEB calculation is performed, it is assumed that each replica is running the same system, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, and the starting configuration when the *neb* command is issued should be the same for every replica.

In a NEB calculation each replica is connected to other replicas by inter-replica nudging forces. These forces are imposed by the *fix neb* command, which must be used in conjunction with the *neb* command. The group used to define the *fix neb* command defines the NEB atoms which are the only ones that inter-replica springs are applied to. If the group does not include all atoms, then non-NEB atoms have no inter-replica springs and the forces they feel and their motion

is computed in the usual way due only to other atoms within their replica. Conceptually, the non-NEB atoms provide a background force field for the NEB atoms. They can be allowed to move during the NEB minimization procedure (which will typically induce different coordinates for non-NEB atoms in different replicas), or held fixed using other LAMMPS commands such as *fix setforce*. Note that the *partition* command can be used to invoke a command on a subset of the replicas, e.g. if you wish to hold NEB or non-NEB atoms fixed in only the end-point replicas.

The initial atomic configuration for each of the replicas can be specified in different manners via the *file-style* setting, as discussed below. Only atoms whose initial coordinates should differ from the current configuration need be specified.

Conceptually, the initial and final configurations for the first replica should be states on either side of an energy barrier.

As explained below, the initial configurations of intermediate replicas can be atomic coordinates interpolated in a linear fashion between the first and last replicas. This is often adequate for simple transitions. For more complex transitions, it may lead to slow convergence or even bad results if the minimum energy path (MEP, see below) of states over the barrier cannot be correctly converged to from such an initial path. In this case, you will want to generate initial states for the intermediate replicas that are geometrically closer to the MEP and read them in.

For a *file-style* setting of *final*, a filename is specified which contains atomic coordinates for zero or more atoms, in the format described below. For each atom that appears in the file, the new coordinates are assigned to that atom in the final replica. Each intermediate replica also assigns a new position to that atom in an interpolated manner. This is done by using the current position of the atom as the starting point and the read-in position as the final point. The distance between them is calculated, and the new position is assigned to be a fraction of the distance. E.g. if there are 10 replicas, the second replica will assign a position that is 10% of the distance along a line between the starting and final point, and the 9th replica will assign a position that is 90% of the distance along the line. Note that for this procedure to produce consistent coordinates across all the replicas, the current coordinates need to be the same in all replicas. LAMMPS does not check for this, but invalid initial configurations will likely result if it is not the case.

**Note:** The “distance” between the starting and final point is calculated in a minimum-image sense for a periodic simulation box. This means that if the two positions are on opposite sides of a box (periodic in that dimension), the distance between them will be small, because the periodic image of one of the atoms is close to the other. Similarly, even if the assigned position resulting from the interpolation is outside the periodic box, the atom will be wrapped back into the box when the NEB calculation begins.

For a *file-style* setting of *each*, a filename is specified which is assumed to be unique to each replica. This can be done by using a variable in the filename, e.g.

```
variable i equal part
neb 0.0 0.001 1000 500 50 each coords.initial.$i
```

which in this case will substitute the partition ID (0 to N-1) for the variable I, which is also effectively the replica ID. See the *variable* command for other options, such as using world-, universe-, or uloop-style variables.

Each replica (except the first replica) will read its file, formatted as described below, and for any atom that appears in the file, assign the specified coordinates to its atom. The various files do not need to contain the same set of atoms.

For a *file-style* setting of *none*, no filename is specified. Each replica is assumed to already be in its initial configuration at the time the neb command is issued. This allows each replica to define its own configuration by reading a replica-specific data or restart or dump file, via the *read\_data*, *read\_restart*, or *read\_dump* commands. The replica-specific names of these files can be specified as in the discussion above for the *each* file-style. Also see the section below for how a NEB calculation can produce restart files, so that a long calculation can be restarted if needed.

**Note:** None of the *file-style* settings change the initial configuration of any atom in the first replica. The first replica must thus be in the correct initial configuration at the time the neb command is issued.

A NEB calculation proceeds in two stages, each of which is a minimization procedure, performed via damped dynamics. To enable this, you must first define a damped dynamics *min\_style*, such as *quickmin* or *fire*. The *cg*, *sd*, and *hfn* styles cannot be used, since they perform iterative line searches in their inner loop, which cannot be easily synchronized across multiple replicas.

The minimizer tolerances for energy and force are set by *etol* and *ftol*, the same as for the *minimize* command.

A non-zero *etol* means that the NEB calculation will terminate if the energy criterion is met by every replica. The energies being compared to *etol* do not include any contribution from the inter-replica nudging forces, since these are non-conservative. A non-zero *ftol* means that the NEB calculation will terminate if the force criterion is met by every replica. The forces being compared to *ftol* include the inter-replica nudging forces.

The maximum number of iterations in each stage is set by *N1* and *N2*. These are effectively timestep counts since each iteration of damped dynamics is like a single timestep in a dynamics *run*. During both stages, the potential energy of each replica and its normalized distance along the reaction path (reaction coordinate RD) will be printed to the screen and log file every *Nevery* timesteps. The RD is 0 and 1 for the first and last replica. For intermediate replicas, it is the cumulative distance (normalized by the total cumulative distance) between adjacent replicas, where “distance” is defined as the length of the 3N-vector of differences in atomic coordinates, where N is the number of NEB atoms involved in the transition. These outputs allow you to monitor NEB’s progress in finding a good energy barrier. *N1* and *N2* must both be multiples of *Nevery*.

In the first stage of NEB, the set of replicas should converge toward a minimum energy path (MEP) of conformational states that transition over a barrier. The MEP for a transition is defined as a sequence of 3N-dimensional states, each of which has a potential energy gradient parallel to the MEP itself. The configuration of highest energy along a MEP corresponds to a saddle point. The replica states will also be roughly equally spaced along the MEP due to the inter-replica nudging force added by the *fix neb* command.

In the second stage of NEB, the replica with the highest energy is selected and the inter-replica forces on it are converted to a force that drives its atom coordinates to the top or saddle point of the barrier, via the barrier-climbing calculation described in (*HenkelmanB*). As before, the other replicas rearrange themselves along the MEP so as to be roughly equally spaced.

When both stages are complete, if the NEB calculation was successful, the configurations of the replicas should be along (close to) the MEP and the replica with the highest energy should be an atomic configuration at (close to) the saddle point of the transition. The potential energies for the set of replicas represents the energy profile of the transition along the MEP.

---

A few other settings in your input script are required or advised to perform a NEB calculation. See the NOTE about the choice of timestep at the beginning of this doc page.

An atom map must be defined which it is not by default for *atom\_style atomic* problems. The *atom\_modify map* command can be used to do this.

The minimizers in LAMMPS operate on all atoms in your system, even non-NEB atoms, as defined above. To prevent non-NEB atoms from moving during the minimization, you should use the *fix setforce* command to set the force on each of those atoms to 0.0. This is not required, and may not even be desired in some cases, but if those atoms move too far (e.g. because the initial state of your system was not well-minimized), it can cause problems for the NEB procedure.

The damped dynamics *minimizers*, such as *quickmin* and *fire*, adjust the position and velocity of the atoms via an Euler integration step. Thus you must define an appropriate *timestep* to use with NEB. As mentioned above, NEB will often converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

---

Each file read by the *neb* command containing atomic coordinates used to initialize one or more replicas must be formatted as follows.

The file can be ASCII text or a gzipped text file (detected by a .gz suffix). The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list  $N$  = the number of lines to follow. The  $N$  successive lines contain the following information:

```
ID1 x1 y1 z1
ID2 x2 y2 z2
...
IDN xN yN zN
```

The fields are the atom ID, followed by the x,y,z coordinates. The lines can be listed in any order. Additional trailing information on the line is OK, such as a comment.

Note that for a typical NEB calculation you do not need to specify initial coordinates for very many atoms to produce differing starting and final replicas whose intermediate replicas will converge to the energy barrier. Typically only new coordinates for atoms geometrically near the barrier need be specified.

Also note there is no requirement that the atoms in the file correspond to the NEB atoms in the group defined by the `fix neb` command. Not every NEB atom need be in the file, and non-NEB atoms can be listed in the file.

Four kinds of output can be generated during a NEB calculation: energy barrier statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file contains a line of output, printed once every *Nevery* timesteps. The amount of information printed in this line can be selected with the *verbosity* keyword. Available options are *terse*, *default*, and *verbose*.

With the *terse* setting, it contains the timestep, the maximum force of a replica, the maximum force per atom (in any replica), potential gradients in the initial, final, and climbing replicas, the forward and backward energy barriers, the total reaction coordinate (RDT).

With the *default* setting, additionally the normalized reaction coordinate and potential energy of each replica are printed.

With the *verbose* setting, additional per-replica properties are printed: the “path angle” (pathangle), the angle between the 3N-length tangent vector and the 3N-length force vector at image  $i$  (angletangrad), the angle between the 3N-length energy gradient vector of replica  $i$  and that of replica  $i+1$  (anglegrad), the norm of the energy gradient (gradV), the two-norm of the 3N-length force vector (RepForce), and the maximum force component of any atom (MaxAtomForce).

The “maximum force per replica” is the two-norm of the 3N-length force vector for the atoms in each replica, maximized across replicas, which is what the *ftol* setting is checking against. In this case,  $N$  is all the atoms in each replica. The “maximum force per atom” is the maximum force component of any atom in any replica. The potential gradients are the two-norm of the 3N-length force vector solely due to the interaction potential i.e. without adding in inter-replica forces.

The “reaction coordinate” (RD) for each replica is the two-norm of the 3N-length vector of distances between its atoms and the preceding replica’s atoms, added to the RD of the preceding replica. The RD of the first replica  $RD1 = 0.0$ ; the RD of the final replica  $RDN = RDT$ , the total reaction coordinate. The normalized RDs are divided by RDT, so that they form a monotonically increasing sequence from zero to one. When computing RD,  $N$  only includes the atoms being operated on by the `fix neb` command.

The forward (reverse) energy barrier is the potential energy of the highest replica minus the energy of the first (last) replica.

The “path angle” (pathangle) for the replica  $i$  which is the angle between the 3N-length vectors  $(R_{i-1} - R_i)$  and  $(R_{i+1} - R_i)$  (where  $R_i$  is the atomic coordinates of replica  $i$ ). A “path angle” of 180 indicates that replicas  $i-1$ ,  $i$  and  $i+1$  are aligned. “angletangrad” is the angle between the 3N-length tangent vector and the 3N-length force vector at image  $i$ . The tangent vector is calculated as in (HenkelmanA) for all intermediate replicas and at  $R2 - R1$  and  $RM - RM-1$  for the first and last replica, respectively. “anglegrad” is the angle between the 3N-length energy gradient vector of replica  $i$  and that of replica  $i+1$ . It is not defined for the final replica and reads nan. gradV is the norm of the energy gradient

of image  $i$  ( $\nabla V$ ). `ReplicaForce` is the two-norm of the  $3N$ -length force vector (including nudging forces) for replica  $i$ . `MaxAtomForce` is the maximum force component of any atom in replica  $i$ .

When a NEB calculation does not converge properly, the supplementary information can help understanding what is going wrong. For instance when the path angle becomes acute, the definition of tangent used in the NEB calculation is questionable and the NEB cannot may diverge ([Maras](#)).

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. `log.lammps.0`, `log.lammps.1`, etc. For a NEB calculation, these contain the thermodynamic output for each replica.

If `dump` commands in the input script define a filename that includes a *universe* or *uloop* style *variable*, then one dump file (per dump command) will be created for each replica. At the end of the NEB calculation, the final snapshot in each file will contain the sequence of snapshots that transition the system over the energy barrier. Earlier snapshots will show the convergence of the replicas to the MEP.

Likewise, `restart` filenames can be specified with a *universe* or *uloop* style *variable*, to generate restart files for each replica. These may be useful if the NEB calculation fails to converge properly to the MEP, and you wish to restart the calculation from an intermediate point with altered parameters.

There are 2 Python scripts provided in the `tools/python` directory, `neb_combine.py` and `neb_final.py`, which are useful in analyzing output from a NEB calculation. Assume a NEB simulation with  $M$  replicas, and the NEB atoms labeled with a specific atom type.

The `neb_combine.py` script extracts atom coords for the NEB atoms from all  $M$  dump files and creates a single dump file where each snapshot contains the NEB atoms from all the replicas and one copy of non-NEB atoms from the first replica (presumed to be identical in other replicas). This can be visualized/animated to see how the NEB atoms relax as the NEB calculation proceeds.

The `neb_final.py` script extracts the final snapshot from each of the  $M$  dump files to create a single dump file with  $M$  snapshots. This can be visualized to watch the system make its transition over the energy barrier.

To illustrate, here are images from the final snapshot produced by the `neb_combine.py` script run on the dump files produced by the two example input scripts in `examples/neb`.

## 1.67.4 Restrictions

```

## 1.68.3 Description

Perform a geodesic nudged elastic band (GNEB) calculation using multiple replicas of a system. Two or more replicas must be used; the first and last are the end points of the transition path.

GNEB is a method for finding both the spin configurations and height of the energy barrier associated with a transition state, e.g. spins to perform a collective rotation from one energy basin to another. The implementation in LAMMPS follows the discussion in the following paper: ([Bessarab](#)).

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the *-partition command-line switch*. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on just one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the [Howto replica](#) doc page for further discussion.

---

**Note:** As explained below, a GNEB calculation performs a minimization across all the replicas. One of the *spin* style minimizers has to be defined in your input script.

---

When a GNEB calculation is performed, it is assumed that each replica is running the same system, though LAMMPS does not check for this. I.e. the simulation domain, the number of magnetic atoms, the interaction potentials, and the starting configuration when the neb command is issued should be the same for every replica.

In a GNEB calculation each replica is connected to other replicas by inter-replica nudging forces. These forces are imposed by the *fix neb/spin* command, which must be used in conjunction with the neb command. The group used to define the fix neb/spin command defines the GNEB magnetic atoms which are the only ones that inter-replica springs are applied to. If the group does not include all magnetic atoms, then non-GNEB magnetic atoms have no inter-replica springs and the torques they feel and their precession motion is computed in the usual way due only to other magnetic atoms within their replica. Conceptually, the non-GNEB atoms provide a background force field for the GNEB atoms. Their magnetic spins can be allowed to evolve during the GNEB minimization procedure.

The initial spin configuration for each of the replicas can be specified in different manners via the *file-style* setting, as discussed below. Only atomic spins whose initial coordinates should differ from the current configuration need to be specified.

Conceptually, the initial and final configurations for the first replica should be states on either side of an energy barrier.

As explained below, the initial configurations of intermediate replicas can be spin coordinates interpolated in a linear fashion between the first and last replicas. This is often adequate for simple transitions. For more complex transitions, it may lead to slow convergence or even bad results if the minimum energy path (MEP, see below) of states over the barrier cannot be correctly converged to from such an initial path. In this case, you will want to generate initial states for the intermediate replicas that are geometrically closer to the MEP and read them in.

---

For a *file-style* setting of *final*, a filename is specified which contains atomic and spin coordinates for zero or more atoms, in the format described below. For each atom that appears in the file, the new coordinates are assigned to that atom in the final replica. Each intermediate replica also assigns a new spin to that atom in an interpolated manner. This is done by using the current direction of the spin at the starting point and the read-in direction as the final point.

The “angular distance” between them is calculated, and the new direction is assigned to be a fraction of the angular distance.

---

**Note:** The “angular distance” between the starting and final point is evaluated in the geodesic sense, as described in ([Bessarab](#)).

---

---

**Note:** The angular interpolation between the starting and final point is achieved using Rodrigues formula:

---

$$\vec{m}_i^v = \vec{m}_i^I \cos(\omega_i^v) + (\vec{k}_i \times \vec{m}_i^I) \sin(\omega_i^v) + (1.0 - \cos(\omega_i^v))\vec{k}_i(\vec{k}_i \cdot \vec{m}_i^I)$$

where  $\vec{m}_i^I$  is the initial spin configuration for spin  $i$ ,  $\omega_i^v$  is a rotation angle defined as:

$$\omega_i^v = (v - 1)\Delta\omega_i \text{ and } \Delta\omega_i = \frac{\omega_i}{Q - 1}$$

with  $v$  the image number,  $Q$  the total number of images, and  $\omega_i$  the total rotation between the initial and final spins.  $\vec{k}_i$  defines a rotation axis such as:

$$\vec{k}_i = \frac{\vec{m}_i^I \times \vec{m}_i^F}{|\vec{m}_i^I \times \vec{m}_i^F|}$$

if the initial and final spins are not aligned. If the initial and final spins are aligned, then their cross product is null, and the expression above does not apply. If they point toward the same direction, the intermediate images conserve the same orientation. If the initial and final spins are aligned, but point toward opposite directions, an arbitrary rotation vector belonging to the plane perpendicular to initial and final spins is chosen. In this case, a warning message is displayed.

For a *file-style* setting of *each*, a filename is specified which is assumed to be unique to each replica. See the [neb](#) documentation page for more information about this option.

For a *file-style* setting of *none*, no filename is specified. Each replica is assumed to already be in its initial configuration at the time the *neb* command is issued. This allows each replica to define its own configuration by reading a replica-specific data or restart or dump file, via the [read\\_data](#), [read\\_restart](#), or [read\\_dump](#) commands. The replica-specific names of these files can be specified as in the discussion above for the *each* file-style. Also see the section below for how a NEB calculation can produce restart files, so that a long calculation can be restarted if needed.

---

**Note:** None of the *file-style* settings change the initial configuration of any atom in the first replica. The first replica must thus be in the correct initial configuration at the time the *neb* command is issued.

---

A NEB calculation proceeds in two stages, each of which is a minimization procedure. To enable this, you must first define a *min\_style*, using either the *spin*, *spin/cg*, or *spin/lbfgs* style (see [min\\_spin](#) for more information). The other styles cannot be used, since they relax the lattice degrees of freedom instead of the spins.

The minimizer tolerances for energy and force are set by *etol* and *ttol*, the same as for the [minimize](#) command.

A non-zero *etol* means that the GNEB calculation will terminate if the energy criterion is met by every replica. The energies being compared to *etol* do not include any contribution from the inter-replica nudging forces, since these are non-conservative. A non-zero *ttol* means that the GNEB calculation will terminate if the torque criterion is met by every replica. The torques being compared to *ttol* include the inter-replica nudging forces.

The maximum number of iterations in each stage is set by *N1* and *N2*. These are effectively timestep counts since each iteration of damped dynamics is like a single timestep in a dynamics [run](#). During both stages, the potential energy of

each replica and its normalized distance along the reaction path (reaction coordinate RD) will be printed to the screen and log file every *Nevery* timesteps. The RD is 0 and 1 for the first and last replica. For intermediate replicas, it is the cumulative angular distance (normalized by the total cumulative angular distance) between adjacent replicas, where “distance” is defined as the length of the 3N-vector of the geodesic distances in spin coordinates, with N the number of GNEB spins involved (see equation (13) in ([Bessarab](#))). These outputs allow you to monitor NEB’s progress in finding a good energy barrier. *N1* and *N2* must both be multiples of *Nevery*.

In the first stage of GNEB, the set of replicas should converge toward a minimum energy path (MEP) of conformational states that transition over a barrier. The MEP for a transition is defined as a sequence of 3N-dimensional spin states, each of which has a potential energy gradient parallel to the MEP itself. The configuration of highest energy along a MEP corresponds to a saddle point. The replica states will also be roughly equally spaced along the MEP due to the inter-replica nudging force added by the *fix neb* command.

In the second stage of GNEB, the replica with the highest energy is selected and the inter-replica forces on it are converted to a force that drives its spin coordinates to the top or saddle point of the barrier, via the barrier-climbing calculation described in ([Bessarab](#)). As before, the other replicas rearrange themselves along the MEP so as to be roughly equally spaced.

When both stages are complete, if the GNEB calculation was successful, the configurations of the replicas should be along (close to) the MEP and the replica with the highest energy should be a spin configuration at (close to) the saddle point of the transition. The potential energies for the set of replicas represents the energy profile of the transition along the MEP.

---

An atom map must be defined which it is not by default for *atom\_style atomic* problems. The *atom\_modify map* command can be used to do this.

An initial value can be defined for the timestep. Although, the *spin* minimization algorithm is an adaptive timestep methodology, so that this timestep is likely to evolve during the calculation.

The minimizers in LAMMPS operate on all spins in your system, even non-GNEB atoms, as defined above.

---

Each file read by the *neb/spin* command containing spin coordinates used to initialize one or more replicas must be formatted as follows.

The file can be ASCII text or a gzipped text file (detected by a .gz suffix). The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 g1 x1 y1 z1 sx1 sy1 sz1
ID2 g2 x2 y2 z2 sx2 sy2 sz2
...
IDN gN yN zN sxN syN szN
```

The fields are the atom ID, the norm of the associated magnetic spin, followed by the x,y,z coordinates and the sx,sy,sz spin coordinates. The lines can be listed in any order. Additional trailing information on the line is OK, such as a comment.

Note that for a typical GNEB calculation you do not need to specify initial spin coordinates for very many atoms to produce differing starting and final replicas whose intermediate replicas will converge to the energy barrier. Typically only new spin coordinates for atoms geometrically near the barrier need be specified.

Also note there is no requirement that the atoms in the file correspond to the GNEB atoms in the group defined by the *fix neb* command. Not every GNEB atom need be in the file, and non-GNEB atoms can be listed in the file.

---

Four kinds of output can be generated during a GNEB calculation: energy barrier statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file contains a line of output, printed once every *Nevery* timesteps. It contains the timestep, the maximum torque per replica, the maximum torque per atom (in any replica), potential gradients in the initial, final, and climbing replicas, the forward and backward energy barriers, the total reaction coordinate (RDT), and the normalized reaction coordinate and potential energy of each replica.

The “maximum torque per replica” is the two-norm of the  $3N$ -length vector given by the cross product of a spin by its precession vector  $\omega$ , in each replica, maximized across replicas, which is what the *ttol* setting is checking against. In this case,  $N$  is all the atoms in each replica. The “maximum torque per atom” is the maximum torque component of any atom in any replica. The potential gradients are the two-norm of the  $3N$ -length magnetic precession vector solely due to the interaction potential i.e. without adding in inter-replica forces, and projected along the path tangent (as detailed in Appendix D of ([Bessarab](#))).

The “reaction coordinate” (RD) for each replica is the two-norm of the  $3N$ -length vector of geodesic distances between its spins and the preceding replica’s spins (see equation (13) of ([Bessarab](#))), added to the RD of the preceding replica. The RD of the first replica  $RD1 = 0.0$ ; the RD of the final replica  $RDN = RDT$ , the total reaction coordinate. The normalized RDs are divided by RDT, so that they form a monotonically increasing sequence from zero to one. When computing RD,  $N$  only includes the spins being operated on by the *fix neb/spin* command.

The forward (reverse) energy barrier is the potential energy of the highest replica minus the energy of the first (last) replica.

Supplementary information for all replicas can be printed out to the screen and master log.lammps file by adding the *verbose* keyword. This information include the following. The “GradVidottan” are the projections of the potential gradient for the replica  $i$  on its tangent vector (as detailed in Appendix D of ([Bessarab](#))). The “ $DN_i$ ” are the non normalized geodesic distances (see equation (13) of ([Bessarab](#))), between a replica  $i$  and the next replica  $i+1$ . For the last replica, this distance is not defined and a “NAN” value is the corresponding output.

When a NEB calculation does not converge properly, the supplementary information can help understanding what is going wrong.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For a GNEB calculation, these contain the thermodynamic output for each replica.

If *dump* commands in the input script define a filename that includes a *universe* or *uloop* style *variable*, then one dump file (per dump command) will be created for each replica. At the end of the GNEB calculation, the final snapshot in each file will contain the sequence of snapshots that transition the system over the energy barrier. Earlier snapshots will show the convergence of the replicas to the MEP.

Likewise, *restart* filenames can be specified with a *universe* or *uloop* style *variable*, to generate restart files for each replica. These may be useful if the GNEB calculation fails to converge properly to the MEP, and you wish to restart the calculation from an intermediate point with altered parameters.

A c file script is provided in the tool/spin/interpolate\_gneb directory, that interpolates the MEP given the information provided by the *verbose* output option (as detailed in Appendix D of ([Bessarab](#))).

---

### 1.68.4 Restrictions

This command can only be used if LAMMPS was built with the SPIN package. See the [Build package](#) doc page for more info.

For magnetic GNEB calculations, only the *spin\_none* value for the *line* keyword can be used when minimization styles *spin/cg* and *spin/lbfgs* are employed.

## 1.68.5 Related commands

*min/spin, fix neb/spin*

## 1.68.6 Default

# 1.69 neigh\_modify command

## 1.69.1 Syntax

`neigh_modify` keyword values ...

- one or more keyword/value pairs may be listed

`keyword` = *delay* or *every* or *check* or *once* or *cluster* or *include* or *exclude* or *page*  
→ or *one* or *binsize* or *collection/type* or *collection/interval*

*delay* value = N

N = delay building neighbor lists until this many steps since last build

*every* value = M

M = consider building neighbor lists every this many steps

*check* value = *yes* or *no*

*yes* = only build if at least one atom has moved half the skin distance or more

*no* = always build on 1st step where *every* and *delay* are conditions are satisfied

*once* value = *yes* or *no*

*yes* = only build neighbor list once at start of run and never rebuild

*no* = rebuild neighbor list according to other settings

*cluster* value = *yes* or *no*

*yes* = check bond,angle,etc neighbor list for nearby clusters

*no* = do not check bond,angle,etc neighbor list for nearby clusters

*include* value = group-ID

group-ID = only build pair neighbor lists for atoms in this group

*exclude* values:

*type* M N

M,N = exclude if one atom in pair is type M, other is type N (M and N may be  
→ type labels)

*group* group1-ID group2-ID

group1-ID,group2-ID = exclude if one atom is in 1st group, other in 2nd

*molecule/intra* group-ID

group-ID = exclude if both atoms are in the same molecule and in group

*molecule/inter* group-ID

group-ID = exclude if both atoms are in different molecules and in group

*none*

delete all exclude settings

*page* value = N

N = number of pairs stored in a single neighbor page

*one* value = N

N = max number of neighbors of one atom  
 binsize value = size  
 size = bin size for neighbor list construction (distance units)  
 collection/type values = N arg1 ... argN  
 N = number of custom collections  
 arg = N separate lists of types (see below)  
 collection/interval values = N arg1 ... argN  
 N = number of custom collections  
 arg = N separate cutoffs for intervals (see below)

## 1.69.2 Examples

```

neigh_modify every 2 delay 10 check yes page 1000000
neigh_modify exclude type 2 3
neigh_modify exclude group frozen frozen check no
neigh_modify exclude group residue1 chain3
neigh_modify exclude molecule/intra rigid
neigh_modify collection/type 2 1*2,5 3*4
neigh_modify collection/interval 2 1.0 10.0
  
```

## 1.69.3 Description

This command sets parameters that affect the building and use of pairwise neighbor lists. Depending on what pair interactions and other commands are defined, a simulation may require one or more neighbor lists.

The *every*, *delay*, *check*, and *once* options affect how often lists are built as a simulation runs. The *delay* setting means never build new lists until at least N steps after the previous build. The *every* setting means attempt to build lists every M steps (after the delay has passed). If the *check* setting is *no*, the lists are built on the first step that satisfies the *delay* and *every* settings. If the *check* setting is *yes*, then the *every* and *delay* settings determine when a build may possibly be performed, but an actual build only occurs if at least one atom has moved more than half the neighbor skin distance (specified in the *neighbor* command) since the last neighbor list build.

### Impact of neighbor list settings

The choice of neighbor list settings can have a significant impact on the (parallel) performance of LAMMPS and the correctness of the simulation results. Since building the neighbor lists is time consuming, doing it less frequently can speed up a calculation. If the lists are rebuilt too infrequently, however, interacting pairs may be missing and thus the resulting pairwise interactions incorrect. The optimal settings depend on many factors like the properties of the simulated system (density, geometry, topology, temperature, pressure), the force field parameters and settings, the size of the timestep, neighbor list skin distance and more. The default settings are chosen to be very conservative to guarantee correctness of the simulation. They depend on the *check* flag heuristics to reduce the number of neighbor list rebuilds at a minor expense for executing the check. Determining the correctness of a specific choice of neighbor list settings is complicated by the fact that a neighbor list rebuild changes the order in which pairwise interactions are computed and thus - due to the limitations of floating-point math - the trajectory.

If the *once* setting is *yes*, then the neighbor list is only built once at the beginning of each run, and never rebuilt, except on steps when a restart file is written, or steps when a fix forces a rebuild to occur (e.g. fixes that create or delete atoms, such as *fix deposit* or *fix evaporate*). This setting should only be made if you are certain atoms will not move far enough that the neighbor list should be rebuilt, e.g. running a simulation of a cold crystal. Note that it is not that expensive to check if neighbor lists should be rebuilt.

When the rRESPA integrator is used (see the [run\\_style](#) command), the *every* and *delay* parameters refer to the longest (outermost) timestep.

The *cluster* option does a sanity test every time neighbor lists are built for bond, angle, dihedral, and improper interactions, to check that each set of 2, 3, or 4 atoms is a cluster of nearby atoms. It does this by computing the distance between pairs of atoms in the interaction and ensuring they are not further apart than half the periodic box length. If they are, an error is generated, since the interaction would be computed between far-away atoms instead of their nearby periodic images. The only way this should happen is if the pairwise cutoff is so short that atoms that are part of the same interaction are not communicated as ghost atoms. This is an unusual model (e.g. no pair interactions at all) and the problem can be fixed by use of the [comm\\_modify cutoff](#) command. Note that to save time, the default *cluster* setting is *no*, so that this check is not performed.

The *include* option limits the building of pairwise neighbor lists to atoms in the specified group. This can be useful for models where a large portion of the simulation is particles that do not interact with other particles or with each other via pairwise interactions. The group specified with this option must also be specified via the [atom\\_modify first](#) command. Note that specifying “all” as the group-ID effectively turns off the *include* option.

The *exclude* option turns off pairwise interactions between certain pairs of atoms, by not including them in the neighbor list. These are sample scenarios where this is useful:

- In crack simulations, pairwise interactions can be shut off between 2 slabs of atoms to effectively create a crack.
- When a large collection of atoms is treated as frozen, interactions between those atoms can be turned off to save needless computation. E.g. Using the [fix setforce](#) command to freeze a wall or portion of a bio-molecule.
- When one or more rigid bodies are specified, interactions within each body can be turned off to save needless computation. See the [fix rigid](#) command for more details.

Changed in version 29Aug2024: Support for type labels was added.

The *exclude type* option turns off the pairwise interaction if one atom is of type M and the other of type N. M can equal N. The *exclude group* option turns off the interaction if one atom is in the first group and the other is the second. Group1-ID can equal group2-ID. The *exclude molecule/intra* option turns off the interaction if both atoms are in the specified group and in the same molecule, as determined by their molecule ID. The *exclude molecule/inter* turns off the interaction between pairs of atoms that have different molecule IDs and are both in the specified group.

Each of the exclude options can be specified multiple times. The *exclude type* option is the most efficient option to use; it requires only a single check, no matter how many times it has been specified. The other exclude options are more expensive if specified multiple times; they require one check for each time they have been specified.

Note that the exclude options only affect pairwise interactions; see the [delete\\_bonds](#) command for information on turning off bond interactions.

---

**Note:** Excluding pairwise interactions will not work correctly when also using a long-range solver via the [kspace\\_style](#) command. LAMMPS will give a warning to this effect. This is because the short-range pairwise interaction needs to subtract off a term from the total energy for pairs whose short-range interaction is excluded, to compensate for how the long-range solver treats the interaction. This is done correctly for pairwise interactions that are excluded (or weighted) via the [special\\_bonds](#) command. But it is not done for interactions that are excluded via these [neigh\\_modify exclude](#) options.

---

The *page* and *one* options affect how memory is allocated for the neighbor lists. For most simulations the default settings for these options are fine, but if a very large problem is being run or a very long cutoff is being used, these parameters can be tuned. The indices of neighboring atoms are stored in “pages”, which are allocated one after another as they fill up. The size of each page is set by the *page* value. A new page is allocated when the next atom’s neighbors could potentially overflow the list. This threshold is set by the *one* value which tells LAMMPS the maximum number of neighbor’s one atom can have.

**Note:** LAMMPS can crash without an error message if the number of neighbors for a single particle is larger than the *page* setting, which means it is much, much larger than the *one* setting. This is because LAMMPS does not error check these limits for every pairwise interaction (too costly), but only after all the particle's neighbors have been found. This problem usually means something is very wrong with the way you have setup your problem (particle spacing, cutoff length, neighbor skin distance, etc). If you really expect that many neighbors per particle, then boost the *one* and *page* settings accordingly.

---

The *binsize* option allows you to specify what size of bins will be used in neighbor list construction to sort and find neighboring atoms. By default, for *neighbor style bin*, LAMMPS uses bins that are 1/2 the size of the maximum pair cutoff. For *neighbor style multi*, the bins are 1/2 the size of the collection interaction cutoff. Typically these are good values for minimizing the time for neighbor list construction. This setting overrides the default. If you make it too big, there is little overhead due to looping over bins, but more atoms are checked. If you make it too small, the optimal number of atoms is checked, but bin overhead goes up. If you set the *binsize* to 0.0, LAMMPS will use the default *binsize* of 1/2 the cutoff.

The *collection/type* option allows you to define collections of atom types, used by the *multi* neighbor mode. By grouping atom types with similar physical size or interaction cutoff lengths, one may be able to improve performance by reducing overhead. You must first specify the number of collections N to be defined followed by N lists of types. Each list consists of a series of type ranges separated by commas. The range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. For example, if M = the number of atom types, then an asterisk with no numeric values means all types from 1 to M. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to M (inclusive). A middle asterisk means all types from m to n (inclusive). Note that all atom types must be included in exactly one of the N collections.

The *collection/interval* option provides a similar capability. This command allows a user to define collections by specifying a series of cutoff intervals. LAMMPS will automatically sort atoms into these intervals based on their type-dependent cutoffs or their finite size. You must first specify the number of collections N to be defined followed by N values representing the upper cutoff of each interval. This command is particularly useful for granular pair styles where the interaction distance of particles depends on their radius and may not depend on their atom type.

### 1.69.4 Restrictions

If the *delay* setting is non-zero, then it must be a multiple of the *every* setting.

The *molecule/intra* and *molecule/inter* exclusion options can only be used with atom styles that define molecule IDs.

The value of the *page* setting must be at least 10x larger than the *one* setting. This ensures neighbor pages are not mostly empty space.

The *exclude group* setting is currently not compatible with dynamic groups.

### 1.69.5 Related commands

*neighbor*, *delete\_bonds*

### 1.69.6 Default

The option defaults are delay = 0, every = 1, check = yes, once = no, cluster = no, include = all (same as no include option defined), exclude = none, page = 100000, one = 2000, and binsize = 0.0.

## 1.70 neighbor command

### 1.70.1 Syntax

```
neighbor skin style
```

- skin = extra distance beyond force cutoff (distance units)
- style = *bin* or *nsq* or *multi* or *multi/old*

### 1.70.2 Examples

```
neighbor 0.3 bin  
neighbor 2.0 nsq
```

### 1.70.3 Description

This command sets parameters that affect the building of pairwise neighbor lists. All atom pairs within a neighbor cutoff distance equal to the their force cutoff plus the *skin* distance are stored in the list. Typically, the larger the skin distance, the less often neighbor lists need to be built, but more pairs must be checked for possible force interactions every timestep. The default value for *skin* depends on the choice of units for the simulation; see the default values below.

The *skin* distance is also used to determine how often atoms migrate to new processors if the *check* option of the *neigh\_modify* command is set to *yes*. Atoms are migrated (communicated) to new processors on the same timestep that neighbor lists are re-built.

The *style* value selects what algorithm is used to build the list. The *bin* style creates the list by binning which is an operation that scales linearly with N/P, the number of atoms per processor where N = total number of atoms and P = number of processors. It is almost always faster than the *nsq* style which scales as (N/P)^2. For unsolvated small molecules in a non-periodic box, the *nsq* choice can sometimes be faster. Either style should give the same answers.

The *multi* style is a modified binning algorithm that is useful for systems with a wide range of cutoff distances, e.g. due to different size particles. For granular pair styles, cutoffs are set to the sum of the maximum atomic radii for each atom type. For the *bin* style, the bin size is set to 1/2 of the largest cutoff distance between any pair of atom types and a single set of bins is defined to search over for all atom types. This can be inefficient if one pair of types has a very long cutoff, but other type pairs have a much shorter cutoff. The *multi* style uses different sized bins for collections of different sized particles, where “size” may mean the physical size of the particle or its cutoff distance for interacting with other particles. Different sets of bins are then used to construct the neighbor lists as as further described by Shire, Hanley, and Stratford (*Shire*) and Monti et al. (*Monti*). This imposes some extra setup overhead, but the searches themselves may be much faster.

For instance in a dense binary system in d-dimensions with a ratio of the size of the largest to smallest collection bin  $\lambda$ , the computational costs of building a default neighbor list grows as  $\lambda^{2d}$  while the costs for *multi* grows as  $\lambda^d$ , equivalent to the cost of force evaluations, as argued in Monti et al. (*Monti*). In other words, the neighboring costs of *multi* are expected to scale the same as force calculations, such that its relative cost is independent of the particle size ratio. This is not the case for the default style which becomes substantially more expensive with increasing size ratios.

By default in *multi*, each atom type defines a separate collection of particles. For systems where two or more atom types have the same size (either physical size or cutoff distance), the definition of collections can be customized, which can result in less overhead and faster performance. See the [neigh\\_modify](#) command for how to define custom collections. Whether the collection definition is customized or not, also see the [comm\\_modify mode multi](#) command for communication options that further improve performance in a manner consistent with neighbor style multi.

An alternate style, *multi/old*, sets the bin size to 1/2 of the shortest cutoff distance and multiple sets of bins are defined to search over for different atom types. This algorithm used to be the default *multi* algorithm in LAMMPS but was found to be significantly slower than the new approach. For the dense binary system, computational costs still grew as  $\lambda^{2d}$  at large enough  $\lambda$ . This is equivalent to the default style, albeit with a smaller prefactor. For now we are keeping the old option in case there are use cases where multi/old outperforms the new multi style.

---

**Note:** If there are multiple sub-styles in a [hybrid/overlay pair style](#) that cover the same atom types, but have significantly different cutoffs, the *multi* style does not apply. Instead, the [pair\\_modify neigh/trim](#) setting applies (which is *yes* by default). Please check the neighbor list summary printed at the beginning of a calculation to verify that the desired set of neighbor list builds is performed.

---

The [neigh\\_modify](#) command has additional options that control how often neighbor lists are built and which pairs are stored in the list.

When a run is finished, counts of the number of neighbors stored in the pairwise list and the number of times neighbor lists were built are printed to the screen and log file. See the [Run output](#) page for details.

## 1.70.4 Restrictions

## 1.71 newton command

### 1.71.1 Syntax

```
newton flag  
newton flag1 flag2
```

- flag = *on* or *off* for both pairwise and bonded interactions
- flag1 = *on* or *off* for pairwise interactions
- flag2 = *on* or *off* for bonded interactions

### 1.71.2 Examples

```
newton off  
newton on off
```

### 1.71.3 Description

This command turns Newton's third law *on* or *off* for pairwise and bonded interactions. For most problems, setting Newton's third law to *on* means a modest savings in computation at the cost of two times more communication. Whether this is faster depends on problem size, force cutoff lengths, a machine's compute/communication ratio, and how many processors are being used.

Setting the pairwise newton flag to *off* means that if two interacting atoms are on different processors, both processors compute their interaction and the resulting force information is not communicated. Similarly, for bonded interactions, newton *off* means that if a bond, angle, dihedral, or improper interaction contains atoms on 2 or more processors, the interaction is computed by each processor.

LAMMPS should produce the same answers for any newton flag settings, except for round-off issues.

With *run\_style respa* and only bonded interactions (bond, angle, etc) computed in the innermost timestep, it may be faster to turn newton *off* for bonded interactions, to avoid extra communication in the innermost loop.

### 1.71.4 Restrictions

The newton bond setting cannot be changed after the simulation box is defined by a *read\_data* or *create\_box* command.

### 1.71.5 Related commands

*run\_style respa*

## 1.71.6 Default

```
newton on
```

## 1.72 next command

### 1.72.1 Syntax

```
next variables
```

- variables = one or more variable names

### 1.72.2 Examples

```
next x
next a t x myTemp
```

### 1.72.3 Description

This command is used with variables defined by the *variable* command. It assigns the next value to the variable from the list of values defined for that variable by the *variable* command. Thus when that variable is subsequently substituted for in an input script command, the new value is used.

See the *variable* command for info on how to define and use different kinds of variables in LAMMPS input scripts. If a variable name is a single lower-case character from “a” to “z”, it can be used in an input script command as \$a or \$z. If it is multiple letters, it can be used as \${myTemp}.

If multiple variables are used as arguments to the *next* command, then all must be of the same variable style: *index*, *loop*, *file*, *universe*, or *uloop*. An exception is that *universe*- and *uloop*-style variables can be mixed in the same *next* command.

All the variables specified with the *next* command are incremented by one value from their respective list of values. A *file*-style variable reads the next line from its associated file. An *atomfile*-style variable reads the next set of lines (one per atom) from its associated file. *String*- or *atom*- or *equal*- or *world*-style variables cannot be used with the *next* command, since they only store a single value.

When any of the variables in the *next* command has no more values, a flag is set that causes the input script to skip the next *jump* command encountered. This enables a loop containing a *next* command to exit. As explained in the *variable* command, the variable that has exhausted its values is also deleted. This allows it to be used and re-defined later in the input script. *File*-style and *atomfile*-style variables are exhausted when the end-of-file is reached.

When the *next* command is used with *index*- or *loop*-style variables, the next value is assigned to the variable for all processors. When the *next* command is used with *file*-style variables, the next line is read from its file and the string assigned to the variable. When the *next* command is used with *atomfile*-style variables, the next set of per-atom values is read from its file and assigned to the variable.

When the *next* command is used with *universe*- or *uloop*-style variables, all *universe*- or *uloop*-style variables must be listed in the *next* command. This is because of the manner in which the incrementing is done, using a single lock file for all variables. The next value (for each variable) is assigned to whichever processor partition executes the command first. All processors in the partition are assigned the same value(s). Running LAMMPS on multiple partitions of processors via the *-partition command-line switch*. *Universe*- and *uloop*-style variables are incremented using the files

“tmp.lammps.variable” and “tmp.lammps.variable.lock” which you will see in your directory during and after such a LAMMPS run.

Here is an example of running a series of simulations using the next command with an *index*-style variable. If this input script is named in.polymer, 8 simulations would be run using data files from directories run1 through run8.

```
variable d index run1 run2 run3 run4 run5 run6 run7 run8
shell cd $d
read_data data.polymer
run 10000
shell cd ..
clear
next d
jump in.polymer
```

If the variable “d” were of style *universe*, and the same in.polymer input script were run on 3 partitions of processors, then the first 3 simulations would begin, one on each set of processors. Whichever partition finished first, it would assign variable “d” the fourth value and run another simulation, and so forth until all 8 simulations were finished.

Jump and next commands can also be nested to enable multi-level loops. For example, this script will run 15 simulations in a double loop.

```
variable i loop 3
variable j loop 5
clear
...
read_data data.polymer.$i$j
print Running simulation $i.$j
run 10000
next j
jump in.script
next i
jump in.script
```

Here is an example of a double loop which uses the *if* and *jump* commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
label      loopa
variable a loop 5
label      loopb
variable b loop 5
print      "A,B = $a,$b"
run        10000
if         $b > 2 then "jump in.script break"
next       b
jump       in.script loopb
label      break
variable b delete

next       a
jump       in.script loopa
```

## 1.72.4 Restrictions

As described above.

## 1.72.5 Related commands

package intel 2 omp 4 mode mixed balance 0.5

```

### 1.73.3 Description

This command invokes package-specific settings for the various accelerator packages available in LAMMPS. Currently the following packages use settings from this command: GPU, INTEL, KOKKOS, and OPENMP.

If this command is specified in an input script, it must be near the top of the script, before the simulation box has been defined. This is because it specifies settings that the accelerator packages use in their initialization, before a simulation is defined.

This command can also be specified from the command-line when launching LAMMPS, using the “-pk” *command-line switch*. The syntax is exactly the same as when used in an input script.

Note that all of the accelerator packages require the package command to be specified (except the OPT package), if the package is to be used in a simulation (LAMMPS can be built with an accelerator package without using it in a particular simulation). However, in all cases, a default version of the command is typically invoked by other accelerator settings.

The KOKKOS package requires a “-k on” *command-line switch* respectively, which invokes a “package kokkos” command with default settings.

For the GPU, INTEL, and OPENMP packages, if a “-sf gpu” or “-sf intel” or “-sf omp” *command-line switch* is used to auto-append accelerator suffixes to various styles in the input script, then those switches also invoke a “package gpu”, “package intel”, or “package omp” command with default settings.

---

**Note:** A package command for a particular style can be invoked multiple times when a simulation is setup, e.g. by the *-c on*, *-k on*, *-sf*, and *-pk command-line switches*, and by using this command in an input script. Each time it is used all of the style options are set, either to default values or to specified settings. I.e. settings from previous invocations do not persist across multiple invocations.

---

See the *Accelerator packages* page for more details about using the various accelerator packages for speeding up LAMMPS simulations.

---

The *gpu* style invokes settings associated with the use of the GPU package.

The *Ngpu* argument sets the number of GPUs per node. If *Ngpu* is 0 and no other keywords are specified, GPU or accelerator devices are auto-selected. In this process, all platforms are searched for accelerator devices and GPUs are chosen if available. The device with the highest number of compute cores is selected. The number of devices is increased to be the number of matching accelerators with the same number of compute cores. If there are more devices than MPI tasks, the additional devices will be unused. The auto-selection of GPUs/ accelerator devices and platforms can be restricted by specifying a non-zero value for *Ngpu* and / or using the *gpuID*, *platform*, and *device\_type* keywords as described below. If there are more MPI tasks (per node) than GPUs, multiple MPI tasks will share each GPU.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *neigh* keyword specifies where neighbor lists for pair style computation will be built. If *neigh* is *yes*, which is the default, neighbor list building is performed on the GPU. If *neigh* is *no*, neighbor list building is performed on the CPU. GPU neighbor list building currently cannot be used with a triclinic box. GPU neighbor lists are not compatible with commands that are not GPU-enabled. When a non-GPU enabled command requires a neighbor list, it will also be built on the CPU. In these cases, it will typically be more efficient to only use CPU neighbor list builds.

The *newton* keyword sets the Newton flags for pairwise (not bonded) interactions to *off* or *on*, the same as the *newton* command allows. Currently, only an *off* value is allowed, since all the GPU package pair styles require this setting. This means more computation is done, but less communication. In the future a value of *on* may be allowed, so the *newton* keyword is included as an option for compatibility with the package command for other accelerator styles. Note that the *newton* setting for bonded interactions is not affected by this keyword.

The *pair/only* keyword can change how any “gpu” suffix is applied. By default a suffix is applied to all styles for which an accelerated variant is available. However, that is not always the most effective way to use an accelerator. With

*pair/only* set to *on* the suffix will only be applied to supported pair styles, which tend to be the most effective in using an accelerator and their operation can be overlapped with all other computations on the CPU.

The *binsize* keyword sets the size of bins used to bin atoms in neighbor list builds performed on the GPU, if *neigh = yes* is set. If *binsize* is set to 0.0 (the default), then the binsize is set automatically using heuristics in the GPU package.

The *split* keyword can be used for load balancing force calculations between CPU and GPU cores in GPU-enabled pair styles. If  $0 < \textit{split} < 1.0$ , a fixed fraction of particles is offloaded to the GPU while force calculation for the other particles occurs simultaneously on the CPU. If *split* < 0.0, the optimal fraction (based on CPU and GPU timings) is calculated every 25 timesteps, i.e. dynamic load-balancing across the CPU and GPU is performed. If *split* = 1.0, all force calculations for GPU accelerated pair styles are performed on the GPU. In this case, other *hybrid* pair interactions, *bond*, *angle*, *dihedral*, *improper*, and *long-range* calculations can be performed on the CPU while the GPU is performing force calculations for the GPU-enabled pair style. If all CPU force computations complete before the GPU completes, LAMMPS will block until the GPU has finished before continuing the timestep.

As an example, if you have two GPUs per node and 8 CPU cores per node, and would like to run on 4 nodes (32 cores) with dynamic balancing of force calculation across CPU and GPU cores, you could specify

```
mpirun -np 32 -sf gpu -in in.script      # launch command
package gpu 2 split -1                   # input script command
```

In this case, all CPU cores and GPU devices on the nodes would be utilized. Each GPU device would be shared by 4 CPU cores. The CPU cores would perform force calculations for some fraction of the particles at the same time the GPUs performed force calculation for the other particles.

The *gpuID* keyword is used to specify the first ID for the GPU or other accelerator that LAMMPS will use. For example, if the ID is 1 and *Ngpu* is 3, GPUs 1-3 will be used. Device IDs should be determined from the output of *nvc\_get\_devices*, *ocl\_get\_devices*, or *hip\_get\_devices* as provided in the *lib/gpu* directory. When using OpenCL with accelerators that have main memory NUMA, the accelerators can be split into smaller virtual accelerators for more efficient use with MPI.

The *tpa* keyword sets the number of GPU vector lanes per atom used to perform force calculations. With a default value of 1, the number of lanes will be chosen based on the pair style, however, the value can be set explicitly with this keyword to fine-tune performance. For large cutoffs or with a small number of particles per GPU, increasing the value can improve performance. The number of lanes per atom must be a power of 2 and currently cannot be greater than the SIMD width for the GPU / accelerator. In the case it exceeds the SIMD width, it will automatically be decreased to meet the restriction.

The *blocksize* keyword allows you to tweak the number of threads used per thread block. This number should be a multiple of 32 (for GPUs) and its maximum depends on the specific GPU hardware. Typical choices are 64, 128, or 256. A larger block size increases occupancy of individual GPU cores, but reduces the total number of thread blocks, thus may lead to load imbalance. On modern hardware, the sensitivity to the blocksize is typically low.

The *Nthreads* value for the *omp* keyword sets the number of OpenMP threads allocated for each MPI task. This setting controls OpenMP parallelism only for routines run on the CPUs. For more details on setting the number of OpenMP threads, see the discussion of the *Nthreads* setting on this page for the “package omp” command. The meaning of *Nthreads* is exactly the same for the GPU, INTEL, and GPU packages.

The *platform* keyword is only used with OpenCL to specify the ID for an OpenCL platform. See the output from *ocl\_get\_devices* in the *lib/gpu* directory. In LAMMPS only one platform can be active at a time and by default (*id=-1*) the platform is auto-selected to find the GPU with the most compute cores. When *Ngpu* or other keywords are specified, the auto-selection is appropriately restricted. For example, if *Ngpu* is 3, only platforms with at least 3 accelerators are considered. Similar restrictions can be enforced by the *gpuID* and *device\_type* keywords.

The *device\_type* keyword can be used for OpenCL to specify the type of GPU to use or specify a custom configuration for an accelerator. In most cases this selection will be automatic and there is no need to use the keyword. The *applegpu* type is not specific to a particular GPU vendor, but is separate due to the more restrictive Apple OpenCL implementation. For expert users, to specify a custom configuration, the *custom* keyword followed by the next parameters can be specified:

CONFIG\_ID, SIMD\_SIZE, MEM\_THREADS, SHUFFLE\_AVAIL, FAST\_MATH, THREADS\_PER\_ATOM, THREADS\_PER\_CHARGE, THREADS\_PER\_THREE, BLOCK\_PAIR, BLOCK\_BIO\_PAIR, BLOCK\_ELLIPSE, PPPM\_BLOCK\_ID, BLOCK\_NBOR\_BUILD, BLOCK\_CELL\_2D, BLOCK\_CELL\_ID, MAX\_SHARED\_TYPES, MAX\_BIO\_SHARED\_TYPES, PPPM\_MAX\_SPLINE, NBOR\_PREFETCH.

CONFIG\_ID can be 0. SHUFFLE\_AVAIL in {0,1} indicates that inline-PTX (NVIDIA) or OpenCL extensions (Intel) should be used for horizontal vector operations. FAST\_MATH in {0,1} indicates that OpenCL fast math optimizations are used during the build and hardware-accelerated transcendental functions are used when available. THREADS\_PER\_\* give the default *tpa* values for ellipsoidal models, styles using charge, and any other styles. The BLOCK\_\* parameters specify the block sizes for various kernel calls and the MAX\_\*SHARED\*\_ parameters are used to determine the amount of local shared memory to use for storing model parameters.

For OpenCL, the routines are compiled at runtime for the specified GPU or accelerator architecture. The *ocl\_args* keyword can be used to specify additional flags for the runtime build.

---

The *intel* style invokes settings associated with the use of the INTEL package. The keywords *balance*, *ghost*, *tpc*, and *tptask* are **only** applicable if LAMMPS was built with Xeon Phi co-processor support and are otherwise ignored.

The *Nphi* argument sets the number of co-processors per node. This can be set to any value, including 0, if LAMMPS was not built with co-processor support.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *Nthreads* value for the *omp* keyword sets the number of OpenMP threads allocated for each MPI task. This setting controls OpenMP parallelism only for routines run on the CPUs. For more details on setting the number of OpenMP threads, see the discussion of the *Nthreads* setting on this page for the “package omp” command. The meaning of *Nthreads* is exactly the same for the GPU, INTEL, and GPU packages.

The *mode* keyword determines the precision mode to use for computing pair style forces, either on the CPU or on the co-processor, when using a INTEL supported *pair style*. It can take a value of *single*, *mixed* which is the default, or *double*. *Single* means single precision is used for the entire force calculation. *Mixed* means forces between a pair of atoms are computed in single precision, but accumulated and stored in double precision, including storage of forces, torques, energies, and virial quantities. *Double* means double precision is used for the entire force calculation.

The *lrt* keyword can be used to enable “Long Range Thread (LRT)” mode. It can take a value of *yes* to enable and *no* to disable. LRT mode generates an extra thread (in addition to any OpenMP threads specified with the OMP\_NUM\_THREADS environment variable or the *omp* keyword). The extra thread is dedicated for performing part of the *PPPM solver* computations and communications. This can improve parallel performance on processors supporting Simultaneous Multithreading (SMT) such as Hyper-Threading (HT) on Intel processors. In this mode, one additional thread is generated per MPI process. LAMMPS will generate a warning in the case that more threads are used than available in SMT hardware on a node. If the PPPM solver from the INTEL package is not used, then the LRT setting is ignored and no extra threads are generated. Enabling LRT will replace the *run\_style* with the *verlet/lrt/intel* style that is identical to the default *verlet* style aside from supporting the LRT feature. This feature requires setting the pre-processor flag -DLMP\_INTEL\_USELRT in the makefile when compiling LAMMPS.

The *balance* keyword sets the fraction of *pair style* work offloaded to the co-processor for split values between 0.0 and 1.0 inclusive. While this fraction of work is running on the co-processor, other calculations will run on the host, including neighbor and pair calculations that are not offloaded, as well as angle, bond, dihedral, kspace, and some MPI communications. If *split* is set to -1, the fraction of work is dynamically adjusted automatically throughout the run. This typically give performance within 5 to 10 percent of the optimal fixed fraction.

The *ghost* keyword determines whether or not ghost atoms, i.e. atoms at the boundaries of processor subdomains, are offloaded for neighbor and force calculations. When the value = “no”, ghost atoms are not offloaded. This option can reduce the amount of data transfer with the co-processor and can also overlap MPI communication of forces with computation on the co-processor when the *newton pair* setting is “on”. When the value = “yes”, ghost atoms are offloaded. In some cases this can provide better performance, especially if the *balance* fraction is high.

The *tpc* keyword sets the max # of co-processor threads *Ntpc* that will run on each core of the co-processor. The default value = 4, which is the number of hardware threads per core supported by the current generation Xeon Phi chips.

The *tptask* keyword sets the max # of co-processor threads (*Ntptask*\* assigned to each MPI task. The default value = 240, which is the total # of threads an entire current generation Xeon Phi chip can run (240 = 60 cores \* 4 threads/core). This means each MPI task assigned to the Phi will enough threads for the chip to run the max allowed, even if only 1 MPI task is assigned. If 8 MPI tasks are assigned to the Phi, each will run with 30 threads. If you wish to limit the number of threads per MPI task, set *tptask* to a smaller value. E.g. for *tptask* = 16, if 8 MPI tasks are assigned, each will run with 16 threads, for a total of 128.

Note that the default settings for *tpc* and *tptask* are fine for most problems, regardless of how many MPI tasks you assign to a Phi.

New in version 15Jun2023.

The *pppm\_table* keyword with the argument *yes* allows to use a pre-computed table to efficiently spread the charge to the PPPM grid. This feature is enabled by default but can be turned off using the keyword with the argument *no*.

The *no\_affinity* keyword will turn off automatic setting of core affinity for MPI tasks and OpenMP threads on the host when using offload to a co-processor. Affinity settings are used when possible to prevent MPI tasks and OpenMP threads from being on separate NUMA domains and to prevent offload threads from interfering with other processes/threads used for LAMMPS.

---

The *kokkos* style invokes settings associated with the use of the KOKKOS package.

All of the settings are optional keyword/value pairs. Each has a default value as listed below.

The *neigh* keyword determines how neighbor lists are built. A value of *half* uses a thread-safe variant of half-neighbor lists, the same as used by most pair styles in LAMMPS, which is the default when running on CPUs (i.e. the Kokkos CUDA back end is not enabled).

A value of *full* uses a full neighbor lists and is the default when running on GPUs. This performs twice as much computation as the *half* option, however that is often a win because it is thread-safe and does not require atomic operations in the calculation of pair forces. For that reason, *full* is the default setting for GPUs. However, when running on CPUs, a *half* neighbor list is the default because it are often faster, just as it is for non-accelerated pair styles. Similarly, the *neigh/req* keyword determines how neighbor lists are built for *fix req/reaxff/kk*.

If the *neigh/thread* keyword is set to *off*, then the KOKKOS package threads only over atoms. However, for small systems, this may not expose enough parallelism to keep a GPU busy. When this keyword is set to *on*, the KOKKOS package threads over both atoms and neighbors of atoms. When using *neigh/thread on*, the *newton pair* setting must be “off”. Using *neigh/thread on* may be slower for large systems, so this this option is turned on by default only when running on one or more GPUs and there are 16k atoms or less owned by an MPI rank. Not all KOKKOS-enabled potentials support this keyword yet, and only thread over atoms. Many simple pairwise potentials such as Lennard-Jones do support threading over both atoms and neighbors.

If the *neigh/transpose* keyword is set to *off*, then the KOKKOS package will use the same memory layout for building the neighbor list on GPUs as used for the pair style. When this keyword is set to *on* it will use a different (transposed) memory layout to build the neighbor list on GPUs. This can be faster in some cases (e.g. ReaxFF HNS benchmark) but slower in others (e.g. Lennard Jones benchmark). The copy between different memory layouts is done out of place and therefore doubles the memory overhead of the neighbor list, which can be significant.

The *newton* keyword sets the Newton flags for pairwise and bonded interactions to *off* or *on*, the same as the *newton* command allows. The default for GPUs is *off* because this will almost always give better performance for the KOKKOS package. This means more computation is done, but less communication. However, when running on CPUs a value of *on* is the default since it can often be faster, just as it is for non-accelerated pair styles

The *binsize* keyword sets the size of bins used to bin atoms during neighbor list builds. The same value can be set by the *neigh\_modify binsize* command. Making it an option in the package kokkos command allows it to be set from the command line. The default value for CPUs is 0.0, which means the LAMMPS default will be used, which is bins = 1/2

the size of the pairwise cutoff + neighbor skin distance. This is fine when neighbor lists are built on the CPU. For GPU builds, a 2x larger binsize equal to the pairwise cutoff + neighbor skin is often faster, which is the default. Note that if you use a longer-than-usual pairwise cutoff, e.g. to allow for a smaller fraction of KSpace work with a [long-range Coulombic solver](#) because the GPU is faster at performing pairwise interactions, then this rule of thumb may give too large a binsize and the default should be overridden with a smaller value.

The *comm* and *comm/exchange* and *comm/forward* and *comm/pair/forward* and *comm/fix/forward* and *comm/reverse* and *comm/pair/reverse* keywords determine whether the host or device performs the packing and unpacking of data when communicating per-atom data between processors. “Exchange” communication happens only on timesteps that neighbor lists are rebuilt. The data is only for atoms that migrate to new processors. “Forward” communication happens every timestep. “Reverse” communication happens every timestep if the *newton* option is on. The data is for atom coordinates and any other atom properties that needs to be updated for ghost atoms owned by each processor. “Pair/comm” controls additional communication in pair styles, such as pair\_style EAM. “Fix/comm” controls additional communication in fixes, such as fix SHAKE.

The *comm* keyword is simply a short-cut to set the same value for all the comm keywords.

The value options for the keywords are *no* or *host* or *device*. A value of *no* means to use the standard non-KOKKOS method of packing/unpacking data for the communication. A value of *host* means to use the host, typically a multicore CPU, and perform the packing/unpacking in parallel with threads. A value of *device* means to use the device, typically a GPU, to perform the packing/unpacking operation.

For the *comm/pair/forward* or *comm/fix/forward* or *comm/pair/reverse* keywords, if a value of *host* is used it will be automatically be changed to *no* since these keywords don’t support *host* mode. The value of *no* will also always be used when running on the CPU, i.e. setting the value to *device* will have no effect if the pair/fix style is running on the CPU. For the *comm/fix/forward* or *comm/pair/reverse* keywords, not all styles support *device* mode and in that case will run in *no* mode instead.

The optimal choice for these keywords depends on the input script and the hardware used. The *no* value is useful for verifying that the Kokkos-based *host* and *device* values are working correctly. It is the default when running on CPUs since it is usually the fastest.

When running on CPUs or Xeon Phi, the *host* and *device* values work identically. When using GPUs, the *device* value is the default since it will typically be optimal if all of your styles used in your input script are supported by the KOKKOS package. In this case data can stay on the GPU for many timesteps without being moved between the host and GPU, if you use the *device* value. If your script uses styles (e.g. fixes) which are not yet supported by the KOKKOS package, then data has to be moved between the host and device anyway, so it is typically faster to let the host handle communication, by using the *host* value. Using *host* instead of *no* will enable use of multiple threads to pack/unpack communicated data. When running small systems on a GPU, performing the exchange pack/unpack on the host CPU can give speedup since it reduces the number of CUDA kernel launches.

The *sort* keyword determines whether the host or device performs atom sorting, see the [atom\\_modify sort](#) command. The value options for the *sort* keyword are *no* or *device* similar to the *comm* keywords above. If a value of *host* is used it will be automatically be changed to *no* since the *sort* keyword does not support *host* mode. Not all fix styles with extra atom data support *device* mode and in that case a warning will be given and atom sorting will run in *no* mode instead.

New in version 17Apr2024.

The *atom/map* keyword determines whether the host or device builds the atom\_map, see the [atom\\_modify map](#) command. The value options for the *atom/map* keyword are identical to the *sort* keyword above.

The *gpu/aware* keyword chooses whether GPU-aware MPI will be used. When this keyword is set to *on*, buffers in GPU memory are passed directly through MPI send/receive calls. This reduces overhead of first copying the data to the host CPU. However GPU-aware MPI is not supported on all systems, which can lead to segmentation faults and would require using a value of *off*. If LAMMPS can safely detect that GPU-aware MPI is not available (currently only possible with OpenMPI v2.0.0 or later), then the *gpu/aware* keyword is automatically set to *off* by default. When the *gpu/aware* keyword is set to *off* while any of the *comm* keywords are set to *device*, the value for these *comm* keywords will be

automatically changed to *no*. This setting has no effect if not running on GPUs or if using only one MPI rank. GPU-aware MPI is available for OpenMPI 1.8 (or later versions), Mvapich2 1.9 (or later) when the “MV2\_USE\_CUDA” environment variable is set to “1”, CrayMPI, and IBM Spectrum MPI when the “-gpu” flag is used.

The *pair/only* keyword can change how the KOKKOS suffix “kk” is applied when using an accelerator device. By default device acceleration is always used for all available styles. With *pair/only* set to *on* the suffix setting will choose device acceleration only for pair styles and run all other force computations on the host CPU. The *comm* flags, along with the *sort* and *atom/map* keywords will also automatically be changed to *no*. This can result in better performance for certain configurations and system sizes.

---

The *omp* style invokes settings associated with the use of the OPENMP package.

The *Nthreads* argument sets the number of OpenMP threads allocated for each MPI task. For example, if your system has nodes with dual quad-core processors, it has a total of 8 cores per node. You could use two MPI tasks per node (e.g. using the *-ppn* option of the *mpirun* command in MPICH or *-npnode* in OpenMPI), and set *Nthreads* = 4. This would use all 8 cores on each node. Note that the product of MPI tasks \* threads/task should not exceed the physical number of cores (on a node), otherwise performance will suffer.

Setting *Nthreads* = 0 instructs LAMMPS to use whatever value is the default for the given OpenMP environment. This is usually determined via the *OMP\_NUM\_THREADS* environment variable or the compiler runtime. Note that in most cases the default for OpenMP capable compilers is to use one thread for each available CPU core when *OMP\_NUM\_THREADS* is not explicitly set, which can lead to poor performance.

Here are examples of how to set the environment variable when launching LAMMPS:

```
env OMP_NUM_THREADS=4 lmp_machine -sf omp -in in.script
env OMP_NUM_THREADS=2 mpirun -np 2 lmp_machine -sf omp -in in.script
mpirun -x OMP_NUM_THREADS=2 -np 2 lmp_machine -sf omp -in in.script
```

or you can set it permanently in your shell’s start-up script. All three of these examples use a total of 4 CPU cores.

Note that different MPI implementations have different ways of passing the *OMP\_NUM\_THREADS* environment variable to all MPI processes. The second example line above is for MPICH; the third example line with *-x* is for OpenMPI. Check your MPI documentation for additional details.

What combination of threads and MPI tasks gives the best performance is difficult to predict and can depend on many components of your input. Not all features of LAMMPS support OpenMP threading via the OPENMP package and the parallel efficiency can be very different, too.

---

**Note:** If you build LAMMPS with the GPU, INTEL, and / or OPENMP packages, be aware these packages all allow setting of the *Nthreads* value via their package commands, but there is only a single global *Nthreads* value used by OpenMP. Thus if multiple package commands are invoked, you should ensure the values are consistent. If they are not, the last one invoked will take precedence, for all packages. Also note that if the *-sf hybrid intel omp command-line switch* is used, it invokes a “package intel” command, followed by a “package omp” command, both with a setting of *Nthreads* = 0. Likewise for a hybrid suffix for gpu and omp. Note that KOKKOS also supports setting the number of OpenMP threads from the command line using the “-k on” *command-line switch*. The default for KOKKOS is 1 thread per MPI task, so any other number of threads should be explicitly set using the “-k on” command-line switch (and this setting should be consistent with settings from any other packages used).

---

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The *neigh* keyword specifies whether neighbor list building will be multi-threaded in addition to force calculations. If *neigh* is set to *no* then neighbor list calculation is performed only by MPI tasks with no OpenMP threading. If *mode* is *yes* (the default), a multi-threaded neighbor list build is used. Using *neigh* = *yes* is almost always faster and should produce identical neighbor lists at the expense of using more memory. Specifically, neighbor list pages are allocated for all threads at the same time and each thread works within its own pages.

### 1.73.4 Restrictions

This command cannot be used after the simulation box is defined by a *read\_data* or *create\_box* command.

The *gpu* style of this command can only be invoked if LAMMPS was built with the GPU package. See the *Build package* doc page for more info.

The *intel* style of this command can only be invoked if LAMMPS was built with the INTEL package. See the *Build package* page for more info.

The *kokkos* style of this command can only be invoked if LAMMPS was built with the KOKKOS package. See the *Build package* doc page for more info.

The *omp* style of this command can only be invoked if LAMMPS was built with the OPENMP package. See the *Build package* doc page for more info.

### 1.73.5 Related commands

*suffix*, *-pk command-line switch*

### 1.73.6 Defaults

For the GPU package, the default parameters and settings are:

```
Ngpu = 0, neigh = yes, newton = off, binsize = 0.0, split = 1.0, gpuID = 0 to Ngpu-1,
→tpa = 1, omp = 0, platform=-1.
```

These settings are made automatically if the “-sf gpu” *command-line switch* is used. If it is not used, you must invoke the package gpu command in your input script or via the “-pk gpu” *command-line switch*.

For the INTEL package, the default parameters and settings are:

```
Nphi = 1, omp = 0, mode = mixed, lrt = no, balance = -1, tpc = 4, tptask = 240, pppm_
→table = yes
```

The default ghost option is determined by the pair style being used. This value is output to the screen in the offload report at the end of each run. Note that all of these settings, except “omp” and “mode”, are ignored if LAMMPS was not built with Xeon Phi co-processor support. These settings are made automatically if the “-sf intel” *command-line switch* is used. If it is not used, you must invoke the package intel command in your input script or via the “-pk intel” *command-line switch*.

For the KOKKOS package when using GPUs, the option defaults are:

```
neigh = full, neigh/req = full, newton = off, binsize = 2x LAMMPS default value, comm =
→device, sort = device, atom/map = device, neigh/transpose = off, gpu/aware = on
```

For GPUs, option neigh/thread = on when there are 16k atoms or less on an MPI rank, otherwise it is “off”. When LAMMPS can safely detect that GPU-aware MPI is not available, the default value of gpu/aware becomes “off”.

For the KOKKOS package when using CPUs or Xeon Phis, the option defaults are:

```
neigh = half, neigh/req = half, newton = on, binsize = 0.0, comm = no, sort = no, atom/
→map = no
```

These settings are made automatically by the required “-k on” *command-line switch*. You can change them by using the package kokkos command in your input script or via the *-pk kokkos command-line switch*.

For the OMP package, the defaults are

```
Nthreads = 0, neigh = yes
```

These settings are made automatically if the “-sf omp” *command-line switch* is used. If it is not used, you must invoke the package omp command in your input script or via the “-pk omp” *command-line switch*.

## 1.74 pair\_coeff command

### 1.74.1 Syntax

```
pair_coeff I J args
```

- I,J = numeric atom types (see asterisk form below), or type labels
- args = coefficients for one or more pairs of atom types

### 1.74.2 Examples

```
pair_coeff 1 2 1.0 1.0 2.5
pair_coeff 2 * 1.0 1.0
pair_coeff 3* 1*2 1.0 1.0 2.5
pair_coeff * * 1.0 1.0
pair_coeff * * nialhjea 1 1 2
pair_coeff * 3 morse.table ENTRY1
pair_coeff 1 2 lj/cut 1.0 1.0 2.5 # (for pair_style hybrid)

labelmap atom 1 C
labelmap atom 2 H
pair_coeff C H 1.0 1.0 2.5
```

### 1.74.3 Description

Specify the pairwise force field coefficients for one or more pairs of atom types. The number and meaning of the coefficients depends on the pair style. Pair coefficients can also be set in the data file read by the *read\_data* command or in a restart file.

I and J can be specified in one of several ways. Explicit numeric values can be used for each, as in the first example above. Or, one or both of the types in the I,J pair can be a type label, which is an alphanumeric string defined by the *labelmap* command or in a section of a data file read by the *read\_data* command, and which converts internally to a numeric type. Internally, LAMMPS will set coefficients for the symmetric J,I interaction to the same values as the I,J interaction.

For numeric values only, a wildcard asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *n* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive). For the asterisk syntax, only type pairs with *I* ≤ *J* are considered; if asterisks imply type pairs

where  $J < I$ , they are ignored. Again internally, LAMMPS will set the coefficients for the symmetric  $J,I$  interactions to the same values as the  $I \leq J$  interactions.

Note that a `pair_coeff` command can override a previous setting for the same  $I,J$  pair. For example, these commands set the coeffs for all  $I,J$  pairs, then overwrite the coeffs for just the  $I,J = 2,3$  pair:

```
pair_coeff * * 1.0 1.0 2.5
pair_coeff 2 3 2.0 1.0 1.12
```

A line in a data file that specifies pair coefficients uses the exact same format as the arguments of the `pair_coeff` command in an input script, with the exception of the  $I,J$  type arguments. In each line of the “Pair Coeffs” section of a data file, only a single type  $I$  is specified, which sets the coefficients for type  $I$  interacting with type  $I$ . This is because the section has exactly  $N$  lines, where  $N$  is the number of atom types. For this reason, the wild-card asterisk should also not be used as part of the  $I$  argument. Thus in a data file, the line corresponding to the first example above would be listed as

```
2 1.0 1.0 2.5
```

For many potentials, if coefficients for type pairs with  $I \neq J$  are not set explicitly by a `pair_coeff` command, the values are inferred from the  $I,I$  and  $J,J$  settings by mixing rules; see the [pair\\_modify](#) command for a discussion. Details on this option as it pertains to individual potentials are described on the page for the potential.

Many pair styles, typically for many-body potentials, use tabulated potential files as input, when specifying the `pair_coeff` command. Potential files provided with LAMMPS are in the potentials directory of the distribution. For some potentials, such as EAM, other archives of suitable files can be found on the Web. They can be used with LAMMPS so long as they are in the format LAMMPS expects, as discussed on the individual doc pages. The first line of potential files may contain metadata with upper case tags followed their value. These may be parsed and used by LAMMPS. Currently supported are the “DATE:” tag and the UNITS: tag. For pair styles that have been programmed to support the metadata, the value of the “DATE:” tag is printed to the screen and logfile so that the version of a potential file can be later identified. The UNITS: tag indicates the [units](#) setting required for this particular potential file. If the potential file was created for a different sets of units, LAMMPS will terminate with an error. If the potential file does not contain the tag, no check will be made and it is the responsibility of the user to determine that the unit style is correct.

In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

When a `pair_coeff` command using a potential file is specified, LAMMPS looks for the potential file in 2 places. First it looks in the location specified. E.g. if the file is specified as “niu3.eam”, it is looked for in the current working directory. If it is specified as “./potentials/niu3.eam”, then it is looked for in the potentials directory, assuming it is a sister directory of the current working directory. If the file is not found, it is then looked for in one of the directories specified by the LAMMPS\_POTENTIALS environment variable. Thus if this is set to the potentials directory in the LAMMPS distribution, then you can use those files from anywhere on your system, without copying them into your working directory. Environment variables are set in different ways for different shells. Here are example settings for

csh, tcsh:

```
setenv LAMMPS_POTENTIALS /path/to/lammps/potentials
```

bash:

```
export LAMMPS_POTENTIALS=/path/to/lammps/potentials
```

Windows:

```
set LAMMPS_POTENTIALS="C:\\Path to LAMMPS\\Potentials"
```

The LAMMPS\_POTENTIALS environment variable may contain paths to multiple folders, if they are separated by “;” on Windows and “:” on all other operating systems, just like the PATH and similar environment variables.

---

The alphabetic list of pair styles defined in LAMMPS is given on the [pair\\_style](#) doc page. They are also listed in more compact form on the [Commands pair](#) doc page.

Click on the style to display the formula it computes and its coefficients as specified by the associated pair\_coeff command.

---

### 1.74.4 Restrictions

This command must come after the simulation box is defined by a [read\\_data](#), [read\\_restart](#), or [create\\_box](#) command.

### 1.74.5 Related commands

[pair\\_style](#), [pair\\_modify](#), [read\\_data](#), [read\\_restart](#), [pair\\_write](#)

### 1.74.6 Default

none

## 1.75 pair\_modify command

### 1.75.1 Syntax

**pair\_modify** keyword values ...

- one or more keyword/value pairs may be listed
- keyword = *pair* or *shift* or *mix* or *table* or *table/disp* or *tabinner* or *tabinner/disp* or *tail* or *compute* or *nofdotr* or *special* or *compute/tally* or *neigh/trim*

*pair* value = sub-style N

sub-style = sub-style of [pair hybrid](#)

N = which instance of sub-style (1 to M), only specify if sub-style is used.

↪multiple times

*mix* value = *geometric* or *arithmetic* or *sixthpower*

*shift* value = *yes* or *no*

*table* value = N

2^N = # of values in table

*table/disp* value = N

2^N = # of values in table

*tabinner* value = cutoff

cutoff = inner cutoff at which to begin table (distance units)

*tabinner/disp* value = cutoff

cutoff = inner cutoff at which to begin table (distance units)

*tail* value = *yes* or *no*

*compute* value = *yes* or *no*

```
nofdotr value = none
special values = which wt1 wt2 wt3
  which = lj/coul or lj or coul
  w1,w2,w3 = 1-2, 1-3, 1-4 weights from 0.0 to 1.0 inclusive
compute/tally value = yes or no
neigh/trim value = yes or no
```

## 1.75.2 Examples

```
pair_modify shift yes mix geometric
pair_modify tail yes
pair_modify table 12
pair_modify pair lj/cut compute no
pair_modify pair tersoff compute/tally no
pair_modify pair lj/cut/coul/long 1 special lj/coul 0.0 0.0 0.0
pair_modify pair lj/cut/coul/long special lj 0.0 0.0 0.5 special coul 0.0 0.0 0.8333333
```

## 1.75.3 Description

Modify the parameters of the currently defined pair style. If the pair style is *hybrid or hybrid/overlay*, then the specified parameters are by default modified for all the hybrid sub-styles.

---

**Note:** The behavior for hybrid pair styles can be changed by using the *pair* keyword, which allows selection of a specific sub-style to apply all remaining keywords to. The *special* and *compute/tally* keywords can **only** be used in conjunction with the *pair* keyword. See further details about these 3 keywords below.

---

The *mix* keyword affects pair coefficients for interactions between atoms of type I and J, when  $I \neq J$  and the coefficients are not explicitly set in the input script. Note that coefficients for  $I = J$  must be set explicitly, either in the input script via the *pair\_coeff* command or in the “Pair Coeffs” or “PairIJ Coeffs” sections of the *data file*. For some pair styles it is not necessary to specify coefficients when  $I \neq J$ , since a “mixing” rule will create them from the I,I and J,J settings. The *pair\_modify mix* value determines what formulas are used to compute the mixed coefficients. In each case, the cutoff distance is mixed the same way as sigma.

Note that not all pair styles support mixing and some mix options are not available for certain pair styles. Also, there are additional restrictions when using *pair style hybrid or hybrid/overlay*. See the page for individual pair styles for those restrictions. Note also that the *pair\_coeff* command also can be used to directly set coefficients for a specific  $I \neq J$  pairing, in which case no mixing is performed. If possible, LAMMPS will print an informational message about how many of the mixed pair coefficients were generated and which mixing rule was applied.

- mix *geometric*

$$\begin{aligned}\epsilon_{ij} &= \sqrt{\epsilon_i \epsilon_j} \\ \sigma_{ij} &= \sqrt{\sigma_i \sigma_j}\end{aligned}$$

- mix *arithmetic*

$$\begin{aligned}\epsilon_{ij} &= \sqrt{\epsilon_i \epsilon_j} \\ \sigma_{ij} &= \frac{1}{2}(\sigma_i + \sigma_j)\end{aligned}$$

- *mix sixthpower*

$$\epsilon_{ij} = \frac{2\sqrt{\epsilon_i \epsilon_j} \sigma_i^3 \sigma_j^3}{\sigma_i^6 + \sigma_j^6}$$

$$\sigma_{ij} = \left( \frac{1}{2} (\sigma_i^6 + \sigma_j^6) \right)^{\frac{1}{6}}$$

The *shift* keyword determines whether a Lennard-Jones potential is shifted at its cutoff to 0.0. If so, this adds an energy term to each pairwise interaction which will be included in the thermodynamic output, but does not affect pair forces or atom trajectories. See the doc page for individual pair styles to see which ones support this option.

The *table* and *table/disp* keywords apply to pair styles with a long-range Coulombic term or long-range dispersion term respectively; see the page for individual styles to see which potentials support these options. If N is non-zero, a table of length 2^N is pre-computed for forces and energies, which can shrink their computational cost by up to a factor of 2. The table is indexed via a bit-mapping technique (*Wolff*) and a linear interpolation is performed between adjacent table values. In our experiments with different table styles (lookup, linear, spline), this method typically gave the best performance in terms of speed and accuracy.

The choice of table length is a tradeoff in accuracy versus speed. A larger N yields more accurate force computations, but requires more memory which can slow down the computation due to cache misses. A reasonable value of N is between 8 and 16. The default value of 12 (table of length 4096) gives approximately the same accuracy as the no-table (N = 0) option. For N = 0, forces and energies are computed directly, using a polynomial fit for the needed erfc() function evaluation, which is what earlier versions of LAMMPS did. Values greater than 16 typically slow down the simulation and will not improve accuracy; values from 1 to 8 give unreliable results.

The *tabinner* and *tabinner/disp* keywords set an inner cutoff above which the pairwise computation is done by table lookup (if tables are invoked), for the corresponding Coulombic and dispersion tables discussed with the *table* and *table/disp* keywords. The smaller the cutoff is set, the less accurate the table becomes (for a given number of table values), which can require use of larger tables. The default cutoff value is sqrt(2.0) distance units which means nearly all pairwise interactions are computed via table lookup for simulations with “real” units, but some close pairs may be computed directly (non-table) for simulations with “lj” units.

When the *tail* keyword is set to *yes*, certain pair styles will add a long-range VanderWaals tail “correction” to the energy and pressure. These corrections are bookkeeping terms which do not affect dynamics, unless a constant-pressure simulation is being performed. See the page for individual styles to see which support this option. These corrections are included in the calculation and printing of thermodynamic quantities (see the *thermo\_style* command). Their effect will also be included in constant NPT or NPH simulations where the pressure influences the simulation box dimensions (e.g. the *fix npt* and *fix nph* commands). The formulas used for the long-range corrections come from equation 5 of (*Sun*).

---

**Note:** The tail correction terms are computed at the beginning of each run, using the current atom counts of each atom type. If atoms are deleted (or lost) or created during a simulation, e.g. via the *fix gcmc* command, the correction factors are not re-computed. If you expect the counts to change dramatically, you can break a run into a series of shorter runs so that the correction factors are re-computed more frequently.

---

Several additional assumptions are inherent in using tail corrections, including the following:

- The simulated system is a 3d bulk homogeneous liquid. This option should not be used for systems that are non-liquid, 2d, have a slab geometry (only 2d periodic), or inhomogeneous.
- G(r), the radial distribution function (rdf), is unity beyond the cutoff, so a fairly large cutoff should be used (i.e. 2.5 sigma for an LJ fluid), and it is probably a good idea to verify this assumption by checking the rdf. The rdf is not exactly unity beyond the cutoff for each pair of interaction types, so the tail correction is necessarily an approximation.

The tail corrections are computed at the beginning of each simulation run. If the number of atoms changes during the run, e.g. due to atoms leaving the simulation domain, or use of the *fix gcmc* command, then the corrections are not updated to reflect the changed atom count. If this is a large effect in your simulation, you should break the long run into several short runs, so that the correction factors are re-computed multiple times.

- Thermophysical properties obtained from calculations with this option enabled will not be thermodynamically consistent with the truncated force-field that was used. In other words, atoms do not feel any LJ pair interactions beyond the cutoff, but the energy and pressure reported by the simulation include an estimated contribution from those interactions.

The *compute* keyword allows pairwise computations to be turned off, even though a *pair\_style* is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for performing a *rerun* simulation, when you only wish to compute partial forces that do not include the pairwise contribution.

Two examples are as follows. First, this option allows you to perform a simulation with *pair\_style hybrid* with only a subset of the hybrid sub-styles enabled. Second, this option allows you to perform a simulation with only long-range interactions but no short-range pairwise interactions. Doing this by simply not defining a pair style will not work, because the *kspace\_style* command requires a Kspace-compatible pair style be defined.

The *nofdotr* keyword allows to disable an optimization that computes the global stress tensor from the total forces and atom positions rather than from summing forces between individual pairs of atoms.

---

The *pair* keyword can only be used with the *hybrid* and *hybrid/overlay* pair styles. If used, it must appear first in the list of keywords.

Its meaning is that all the following parameters will only be modified for the specified sub-style. If the sub-style is defined multiple times, then an additional numeric argument *N* must also be specified, which is a number from 1 to *M* where *M* is the number of times the sub-style was listed in the *pair\_style hybrid* command. The extra number indicates which instance of the sub-style the remaining keywords will be applied to.

The *special* and *compute/tally* keywords can **only** be used in conjunction with the *pair* keyword and they must directly follow it. I.e. any other keyword, must appear after *pair*, *special*, and *compute/tally*.

The *special* keyword overrides the global *special\_bonds* 1-2, 1-3, 1-4 exclusion settings (weights) for the sub-style selected by the *pair* keyword.

Similar to the *special\_bonds* command, it takes 4 arguments. The *which* argument can be *lj* to change only the non-Coulomb weights (e.g. Lennard-Jones or Buckingham), *coul* to change only the Coulombic settings, or *lj/coul* to change both to the same values. The *wt1*, *wt2*, *wt3* values are numeric weights from 0.0 to 1.0 inclusive, for the 1-2, 1-3, and 1-4 bond topology neighbors, respectively. The *special* keyword can be used multiple times, e.g. to set the *lj* and *coul* settings to different values.

---

**Note:** The *special* keyword is not compatible with pair styles from the GPU or the INTEL package and attempting to use it will cause an error.

---

---

**Note:** Weights of exactly 0.0 or 1.0 in the *special\_bonds* command have implications on the neighbor list construction, which means that they cannot be overridden by using the *special* keyword. One workaround for this restriction is to use the *special\_bonds* command with weights like 1.0e-10 or 0.999999999 instead of 0.0 or 1.0, respectively, which enables to reset each them to any value between 0.0 and 1.0 inclusively. Otherwise you can set **all** global weights to an arbitrary number between 0.0 or 1.0, like 0.5, and then you have to override **all** *special* settings for **all** sub-styles which use the 1-2, 1-3, and 1-4 exclusion weights in their force/energy computation.

---

The *compute/tally* keyword disables or enables registering *compute \*/tally* computes for the sub-style specified by the *pair* keyword. Use *no* to disable, or *yes* to enable.

---

**Note:** The “pair\_modify pair compute/tally” command must be issued **before** the corresponding compute style is defined.

---

New in version 3Aug2022.

The *neigh/trim* keyword controls whether an explicit cutoff is set for each neighbor list request issued by individual pair sub-styles when using *pair hybrid/overlay*. When this keyword is set to *no*, then the cutoff of each pair sub-style neighbor list will be set equal to the largest cutoff, even if a shorter cutoff is specified for a particular sub-style. If possible the neighbor list will be copied directly from another list. When this keyword is set to *yes* then the cutoff of the neighbor list will be explicitly set to the value requested by the pair sub-style, and if possible the list will be created by trimming neighbors from another list with a longer cutoff, otherwise a new neighbor list will be created with the specified cutoff. The *yes* option can be faster when there are multiple pair styles with different cutoffs since the number of pair-wise distance checks between neighbors is reduced (but the time required to build the neighbor lists is increased). The *no* option could be faster when two or more neighbor lists have similar (but not exactly the same) cutoffs.

---

**Note:** The “pair\_modify neigh/trim” command *only* applies when there are multiple pair sub-styles for the same atoms with different cutoffs, i.e. when using pair style hybrid/overlay. If you have different cutoffs for different pairs for atoms type, the *neighbor style multi* should be used to create optimized neighbor lists.

---

#### 1.75.4 Restrictions

You cannot use *shift yes* with *tail yes*, since those are conflicting options. You cannot use *tail yes* with 2d simulations. You cannot use *special* with pair styles from the GPU or INTEL package.

#### 1.75.5 Related commands

*pair\_style*, *pair\_style hybrid*, *pair\_coeff*, *thermo\_style*, *compute \*/tally*, *neighbor multi*

#### 1.75.6 Default

The option defaults are mix = geometric, shift = no, table = 12, tabinner = sqrt(2.0), tail = no, compute = yes, and neigh/trim yes.

Note that some pair styles perform mixing, but only a certain style of mixing. See the doc pages for individual pair styles for details.

## 1.76 pair\_style command

### 1.76.1 Syntax

```
pair_style style args
```

- style = one of the styles from the list below
- args = arguments used by a particular style

### 1.76.2 Examples

```
pair_style lj/cut 2.5
pair_style eam/alloy
pair_style hybrid lj/charmm/coul/long 10.0 eam
pair_style table linear 1000
pair_style none
```

### 1.76.3 Description

Set the formula(s) LAMMPS uses to compute pairwise interactions. In LAMMPS, pair potentials are defined between pairs of atoms that are within a cutoff distance and the set of active interactions typically changes over time. See the [bond\\_style](#) command to define potentials between pairs of bonded atoms, which typically remain in place for the duration of a simulation.

In LAMMPS, pairwise force fields encompass a variety of interactions, some of which include many-body effects, e.g. EAM, Stillinger-Weber, Tersoff, REBO potentials. They are still classified as “pairwise” potentials because the set of interacting atoms changes with time (unlike molecular bonds) and thus a neighbor list is used to find nearby interacting atoms.

Hybrid models where specified pairs of atom types interact via different pair potentials can be setup using the *hybrid* pair style.

The coefficients associated with a pair style are typically set for each pair of atom types, and are specified by the [pair\\_coeff](#) command or read from a file by the [read\\_data](#) or [read\\_restart](#) commands.

The [pair\\_modify](#) command sets options for mixing of type I-J interaction coefficients and adding energy offsets or tail corrections to Lennard-Jones potentials. Details on these options as they pertain to individual potentials are described on the doc page for the potential. Likewise, info on whether the potential information is stored in a [restart file](#) is listed on the potential doc page.

In the formulas listed for each pair style,  $E$  is the energy of a pairwise interaction between two atoms separated by a distance  $r$ . The force between the atoms is the negative derivative of this expression.

If the pair\_style command has a cutoff argument, it sets global cutoffs for all pairs of atom types. The distance(s) can be smaller or larger than the dimensions of the simulation box.

In many cases, the global cutoff value can be overridden for a specific pair of atom types by the [pair\\_coeff](#) command.

If a new pair\_style command is specified with a new style, all previous [pair\\_coeff](#) and [pair\\_modify](#) command settings are erased; those commands must be re-specified if necessary.

If a new pair\_style command is specified with the same style, then only the global settings in that command are reset. Any previous doc:pair\_coeff <pair\_coeff> and [pair\\_modify](#) command settings are preserved. The only exception is

that if the global cutoff in the `pair_style` command is changed, it will override the corresponding cutoff in any of the previous `pair_modify` commands.

Two pair styles which do not follow this rule are the `pair_style table` and `hybrid` commands. A new `pair_style` command for these styles will wipe out all previously specified `pair_coeff` and `pair_modify` settings, including for the sub-styles of the `hybrid` command.

---

Here is an alphabetic list of pair styles defined in LAMMPS. They are also listed in more compact form on the [Commands pair](#) doc page.

Click on the style to display the formula it computes, any additional arguments specified in the `pair_style` command, and coefficients specified by the associated `pair_coeff` command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the [Commands pair](#) doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- [none](#) - turn off pairwise interactions
- [hybrid](#) - multiple styles of pairwise interactions
- [hybrid/molecular](#) - different pair styles for intra- and inter-molecular interactions
- [hybrid/overlay](#) - multiple styles of superposed pairwise interactions
- [hybrid/scaled](#) - multiple styles of scaled superposed pairwise interactions
- [zero](#) - neighbor list but no interactions
- [adp](#) - angular dependent potential (ADP) of Mishin
- [agni](#) - AGNI machine-learning potential
- [aip/water/2dm](#) - anisotropic interfacial potential for water in 2d geometries
- [airebo](#) - AIREBO potential of Stuart
- [airebo/morse](#) - AIREBO with Morse instead of LJ
- [amoeba](#) -
- [atm](#) - Axilrod-Teller-Muto potential
- [awpmd/cut](#) - Antisymmetrized Wave Packet MD potential for atoms and electrons
- [beck](#) - Beck potential
- [body/nparticle](#) - interactions between body particles
- [body/rounded/polygon](#) - granular-style 2d polygon potential
- [body/rounded/polyhedron](#) - granular-style 3d polyhedron potential
- [bop](#) - BOP potential of Pettifor
- [born](#) - Born-Mayer-Huggins potential
- [born/coul/dsf](#) - Born with damped-shifted-force model
- [born/coul/dsf/cs](#) - Born with damped-shifted-force and core/shell model
- [born/coul/long](#) - Born with long-range Coulomb
- [born/coul/long/cs](#) - Born with long-range Coulomb and core/shell
- [born/coul/msm](#) - Born with long-range MSM Coulomb

- *born/coul/wolf* - Born with Wolf potential for Coulomb
- *born/coul/wolf/cs* - Born with Wolf potential for Coulomb and core/shell model
- *born/gauss* - Born-Mayer / Gaussian potential
- *bpm/spring* - repulsive harmonic force with damping
- *brownian* - Brownian potential for Fast Lubrication Dynamics
- *brownian/poly* - Brownian potential for Fast Lubrication Dynamics with polydispersity
- *buck* - Buckingham potential
- *buck/coul/cut* - Buckingham with cutoff Coulomb
- *buck/coul/long* - Buckingham with long-range Coulomb
- *buck/coul/long/cs* - Buckingham with long-range Coulomb and core/shell
- *buck/coul/msm* - Buckingham with long-range MSM Coulomb
- *buck/long/coul/long* - long-range Buckingham with long-range Coulomb
- *buck/mdf* - Buckingham with a taper function
- *buck6d/coul/gauss/dsf* - dispersion-damped Buckingham with damped-shift-force model
- *buck6d/coul/gauss/long* - dispersion-damped Buckingham with long-range Coulomb
- *colloid* - integrated colloidal potential
- *comb* - charge-optimized many-body (COMB) potential
- *comb3* - charge-optimized many-body (COMB3) potential
- *cosine/squared* - Cooke-Kremer-Deserno membrane model potential
- *coul/cut* - cutoff Coulomb potential
- *coul/cut/dielectric* -
- *coul/cut/global* - cutoff Coulomb potential
- *coul/cut/soft* - Coulomb potential with a soft core
- *coul/debye* - cutoff Coulomb potential with Debye screening
- *coul/diel* - Coulomb potential with dielectric permittivity
- *coul/dsf* - Coulomb with damped-shifted-force model
- *coul/exclude* - subtract Coulomb potential for excluded pairs
- *coul/long* - long-range Coulomb potential
- *coul/long/cs* - long-range Coulomb potential and core/shell
- *coul/long/dielectric* -
- *coul/long/soft* - long-range Coulomb potential with a soft core
- *coul/msm* - long-range MSM Coulomb
- *coul/slater/cut* - smeared out Coulomb
- *coul/slater/long* - long-range smeared out Coulomb
- *coul/shield* - Coulomb for boron nitride for use with *ilp/graphene/hbn* potential
- *coul/streitz* - Coulomb via Streitz/Mintmire Slater orbitals

- *coul/tt* - damped charge-dipole Coulomb for Drude dipoles
- *coul/wolf* - Coulomb via Wolf potential
- *coul/wolf/cs* - Coulomb via Wolf potential with core/shell adjustments
- *dpd* - dissipative particle dynamics (DPD)
- *dpd/coul/slatter/long* - dissipative particle dynamics (DPD) with electrostatic interactions
- *dpd/ext* - generalized force field for DPD
- *dpd/ext/tstat* - pairwise DPD thermostating with generalized force field
- *dpd/fdt* - DPD for constant temperature and pressure
- *dpd/fdt/energy* - DPD for constant energy and enthalpy
- *dpd/tstat* - pairwise DPD thermostating
- *dsmc* - Direct Simulation Monte Carlo (DSMC)
- *e3b* - Explicit-three body (E3B) water model
- *drip* - Dihedral-angle-corrected registry-dependent interlayer potential (DRIP)
- *eam* - embedded atom method (EAM)
- *eam/alloy* - alloy EAM
- *eam/cd* - concentration-dependent EAM
- *eam/cd/old* - older two-site model for concentration-dependent EAM
- *eam/fs* - Finnis-Sinclair EAM
- *eam/he* - Finnis-Sinclair EAM modified for Helium in metals
- *edip* - three-body EDIP potential
- *edip/multi* - multi-element EDIP potential
- *edpd* - eDPD particle interactions
- *eff/cut* - electron force field with a cutoff
- *eim* - embedded ion method (EIM)
- *exp6/rx* - reactive DPD potential
- *extep* - extended Tersoff potential
- *gauss* - Gaussian potential
- *gauss/cut* - generalized Gaussian potential
- *gayberne* - Gay-Berne ellipsoidal potential
- *granular* - Generalized granular potential
- *gran/hertz/history* - granular potential with Hertzian interactions
- *gran/hooke* - granular potential with history effects
- *gran/hooke/history* - granular potential without history effects
- *gw* - Gao-Weber potential
- *gw/zbl* - Gao-Weber potential with a repulsive ZBL core
- *harmonic/cut* - repulsive-only harmonic potential

- *hbond/dreiding/lj* - DREIDING hydrogen bonding LJ potential
- *hbond/dreiding/morse* - DREIDING hydrogen bonding Morse potential
- *hdnnp* - High-dimensional neural network potential
- *hippo* -
- *ilp/graphene/hbn* - registry-dependent interlayer potential (ILP)
- *ilp/tmd* - interlayer potential (ILP) potential for transition metal dichalcogenides (TMD)
- *kim* - interface to potentials provided by KIM project
- *kolmogorov/crespi/full* - Kolmogorov-Crespi (KC) potential with no simplifications
- *kolmogorov/crespi/z* - Kolmogorov-Crespi (KC) potential with normals along z-axis
- *lcbop* - long-range bond-order potential (LCBOP)
- *lebedeva/z* - Lebedeva interlayer potential for graphene with normals along z-axis
- *lennard/mdf* - LJ potential in A/B form with a taper function
- *lepton* - pair potential from evaluating a string
- *lepton/coul* - pair potential from evaluating a string with support for charges
- *lepton/sphere* - pair potential from evaluating a string with support for radii
- *line/lj* - LJ potential between line segments
- *list* - potential between pairs of atoms explicitly listed in an input file
- *lj/charmm/coul/charmm* - CHARMM potential with cutoff Coulomb
- *lj/charmm/coul/charmm/implicit* - CHARMM for implicit solvent
- *lj/charmm/coul/long* - CHARMM with long-range Coulomb
- *lj/charmm/coul/long/soft* - CHARMM with long-range Coulomb and a soft core
- *lj/charmm/coul/msm* - CHARMM with long-range MSM Coulomb
- *lj/charmmfsw/coul/charmmfsh* - CHARMM with force switching and shifting
- *lj/charmmfsw/coul/long* - CHARMM with force switching and long-range Coulomb
- *lj/class2* - COMPASS (class 2) force field without Coulomb
- *lj/class2/coul/cut* - COMPASS with cutoff Coulomb
- *lj/class2/coul/cut/soft* - COMPASS with cutoff Coulomb with a soft core
- *lj/class2/coul/long* - COMPASS with long-range Coulomb
- *lj/class2/coul/long/cs* - COMPASS with long-range Coulomb with core/shell adjustments
- *lj/class2/coul/long/soft* - COMPASS with long-range Coulomb with a soft core
- *lj/class2/soft* - COMPASS (class 2) force field with no Coulomb with a soft core
- *lj/cubic* - LJ with cubic after inflection point
- *lj/cut* - cutoff Lennard-Jones potential without Coulomb
- *lj/cut/coul/cut* - LJ with cutoff Coulomb
- *lj/cut/coul/cut/dielectric* -
- *lj/cut/coul/cut/soft* - LJ with cutoff Coulomb with a soft core

- *lj/cut/coul/debye* - LJ with Debye screening added to Coulomb
- *lj/cut/coul/debye/dielectric* -
- *lj/cut/coul/dsf* - LJ with Coulomb via damped shifted forces
- *lj/cut/coul/long* - LJ with long-range Coulomb
- *lj/cut/coul/long/cs* - LJ with long-range Coulomb with core/shell adjustments
- *lj/cut/coul/long/dielectric* -
- *lj/cut/coul/long/soft* - LJ with long-range Coulomb with a soft core
- *lj/cut/coul/msm* - LJ with long-range MSM Coulomb
- *lj/cut/coul/msm/dielectric* -
- *lj/cut/coul/wolf* - LJ with Coulomb via Wolf potential
- *lj/cut/dipole/cut* - point dipoles with cutoff
- *lj/cut/dipole/long* - point dipoles with long-range Ewald
- *lj/cut/soft* - LJ with a soft core
- *lj/cut/sphere* - LJ where per-atom radius is used as LJ sigma
- *lj/cut/thole/long* - LJ with Coulomb with thole damping
- *lj/cut/tip4p/cut* - LJ with cutoff Coulomb for TIP4P water
- *lj/cut/tip4p/long* - LJ with long-range Coulomb for TIP4P water
- *lj/cut/tip4p/long/soft* - LJ with cutoff Coulomb for TIP4P water with a soft core
- *lj/expand* - Lennard-Jones for variable size particles
- *lj/expand/coul/long* - Lennard-Jones for variable size particles with long-range Coulomb
- *lj/expand/sphere* - Variable size LJ where per-atom radius is used as delta (size)
- *lj/gromacs* - GROMACS-style Lennard-Jones potential
- *lj/gromacs/coul/gromacs* - GROMACS-style LJ and Coulomb potential
- *lj/long/coul/long* - long-range LJ and long-range Coulomb
- *lj/long/coul/long/dielectric* -
- *lj/long/dipole/long* - long-range LJ and long-range point dipoles
- *lj/long/tip4p/long* - long-range LJ and long-range Coulomb for TIP4P water
- *lj/mdf* - LJ potential with a taper function
- *lj/relres* - LJ using multiscale Relative Resolution (RelRes) methodology ([Chaimovich](#)).
- *lj/spica* - LJ for SPICA coarse-graining
- *lj/spica/coul/long* - LJ for SPICA coarse-graining with long-range Coulomb
- *lj/spica/coul/msm* - LJ for SPICA coarse-graining with long-range Coulomb via MSM
- *lj/sf/dipole/sf* - LJ with dipole interaction with shifted forces
- *lj/smooth* - smoothed Lennard-Jones potential
- *lj/smooth/linear* - linear smoothed LJ potential
- *lj/switch3/coulgauss/long* - smoothed LJ vdW potential with Gaussian electrostatics

- *lj96/cut* - Lennard-Jones 9/6 potential
- *local/density* - Generalized basic local density potential
- *lubricate* - Hydrodynamic lubrication forces
- *lubricate/poly* - Hydrodynamic lubrication forces with polydispersity
- *lubricateU* - Hydrodynamic lubrication forces for Fast Lubrication Dynamics
- *lubricateU/poly* - Hydrodynamic lubrication forces for Fast Lubrication with polydispersity
- *mdpd* - mDPD particle interactions
- *mdpd/rhsum* - mDPD particle interactions for mass density
- *meam* - Modified embedded atom method (MEAM)
- *meam/ms* - Multi-state modified embedded atom method (MS-MEAM)
- *meam/spline* - Splined version of MEAM
- *meam/sw/spline* - Splined version of MEAM with a Stillinger-Weber term
- *mesocnt* - Mesoscopic vdW potential for (carbon) nanotubes
- *mesocnt/viscous* - Mesoscopic vdW potential for (carbon) nanotubes with friction
- *mgpt* - Simplified model generalized pseudopotential theory (MGPT) potential
- *mie/cut* - Mie potential
- *mliap* - Multiple styles of machine-learning potential
- *mm3/switch3/coulgauss/long* - Smoothed MM3 vdW potential with Gaussian electrostatics
- *momb* - Many-Body Metal-Organic (MOMB) force field
- *morse* - Morse potential
- *morse/smooth/linear* - Linear smoothed Morse potential
- *morse/soft* - Morse potential with a soft core
- *multi/lucy* - DPD potential with density-dependent force
- *multi/lucy/rx* - reactive DPD potential with density-dependent force
- *nb3b/harmonic* - Non-bonded 3-body harmonic potential
- *nb3b/screened* - Non-bonded 3-body screened harmonic potential
- *nm/cut* - N-M potential
- *nm/cut/coul/cut* - N-M potential with cutoff Coulomb
- *nm/cut/coul/long* - N-M potential with long-range Coulomb
- *nm/cut/split* - Split 12-6 Lennard-Jones and N-M potential
- *oxdna/coaxstk* -
- *oxdna/excv* -
- *oxdna/hbond* -
- *oxdna/stk* -
- *oxdna/xstk* -
- *oxdna2/coaxstk* -

- *oxdna2/dh* -
- *oxdna2/excv* -
- *oxdna2/hbond* -
- *oxdna2/stk* -
- *oxdna2/xstk* -
- *oxrna2/coaxstk* -
- *oxrna2/dh* -
- *oxrna2/excv* -
- *oxrna2/hbond* -
- *oxrna2/stk* -
- *oxrna2/xstk* -
- *pace* - Atomic Cluster Expansion (ACE) machine-learning potential
- *pace/extrapolation* - Atomic Cluster Expansion (ACE) machine-learning potential with extrapolation grades
- *pedone* - Pedone (PMMCS) potential (non-Coulomb part)
- *pod* - Proper orthogonal decomposition (POD) machine-learning potential
- *peri/eps* - Peridynamic EPS potential
- *peri/lps* - Peridynamic LPS potential
- *peri/pmb* - Peridynamic PMB potential
- *peri/ves* - Peridynamic VES potential
- *polymorphic* - Polymorphic 3-body potential
- *python* -
- *quip* -
- *rann* -
- *reaxff* - ReaxFF potential
- *rebo* - Second generation REBO potential of Brenner
- *rebomos* - REBOMoS potential for MoS2
- *rheo* - fluid interactions in RHEO package
- *rheo/solid* - solid interactions in RHEO package
- *resquared* - Everaers RE-Squared ellipsoidal potential
- *saip/metal* - Interlayer potential for hetero-junctions formed with hexagonal 2D materials and metal surfaces
- *sdpd/taitwater/isothermal* - Smoothed dissipative particle dynamics for water at isothermal conditions
- *smatb* - Second Moment Approximation to the Tight Binding
- *smatb/single* - Second Moment Approximation to the Tight Binding for single-element systems
- *smd/hertz* -
- *smd/tlsph* -
- *smd/tri\_surface* -

- *smd/ulsph* -
- *smtbq* -
- *snap* - SNAP machine-learning potential
- *soft* - Soft (cosine) potential
- *sph/heatconduction* -
- *sph/idealgas* -
- *sph/lj* -
- *sph/rhosum* -
- *sph/taitwater* -
- *sph/taitwater/morris* -
- *spin/dipole/cut* -
- *spin/dipole/long* -
- *spin/dmi* -
- *spin/exchange* -
- *spin/exchange/biquadratic* -
- *spin/magelec* -
- *spin/neel* -
- *srp* -
- *srp/react* -
- *sw* - Stillinger-Weber 3-body potential
- *sw/angle/table* - Stillinger-Weber potential with tabulated angular term
- *sw/mod* - modified Stillinger-Weber 3-body potential
- *table* - tabulated pair potential
- *table/rx* -
- *tdpd* - tDPD particle interactions
- *tersoff* - Tersoff 3-body potential
- *tersoff/mod* - modified Tersoff 3-body potential
- *tersoff/mod/c* -
- *tersoff/table* -
- *tersoff/zbl* - Tersoff/ZBL 3-body potential
- *thole* - Coulomb interactions with thole damping
- *threebody/table* - generic tabulated three-body potential
- *tip4p/cut* - Coulomb for TIP4P water w/out LJ
- *tip4p/long* - long-range Coulomb for TIP4P water w/out LJ
- *tip4p/long/soft* -
- *tracker* - monitor information about pairwise interactions

- *tri/lj* - LJ potential between triangles
- *ufm* -
- *uf3* - UF3 machine-learning potential
- *vashishta* - Vashishta 2-body and 3-body potential
- *vashishta/table* -
- *wf/cut* - Wang-Frenkel Potential for short-ranged interactions
- *ylz* - Yuan-Li-Zhang Potential for anisotropic interactions
- *yukawa* - Yukawa potential
- *yukawa/colloid* - screened Yukawa potential for finite-size particles
- *zbl* - Ziegler-Biersack-Littmark potential

### 1.76.4 Restrictions

This command must be used before any coefficients are set by the *pair\_coeff*, *read\_data*, or *read\_restart* commands.

Some pair styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual pair potentials tell if it is part of a package.

### 1.76.5 Related commands

*pair\_coeff*, *read\_data*, *pair\_modify*, *kpace\_style*, *dielectric*, *pair\_write*

### 1.76.6 Default

```
pair_style none
```

## 1.77 pair\_write command

### 1.77.1 Syntax

```
pair_write itype jtype N style inner outer file keyword Qi Qj
```

- *itype,jtype* = 2 atom types (numeric or type label)
- *N* = # of values
- *style* = *r* or *rsq* or *bitmap*
- *inner,outer* = inner and outer cutoff (distance units)
- *file* = name of file to write values to
- *keyword* = section name in file for this set of tabulated values
- *Qi,Qj* = 2 atom charges (charge units) (optional)

## 1.77.2 Examples

```
pair_write 1 3 500 r 1.0 10.0 table.txt LJ
pair_write 1 1 1000 rsq 2.0 8.0 table.txt Yukawa_1_1 -0.5 0.5

labelmap atom 1 C 2 H
pair_write C H 500 r 1.0 10.0 table.txt LJ
```

## 1.77.3 Description

Write energy and force values to a file as a function of distance for the currently defined pair potential. This is useful for plotting the potential function or otherwise debugging its values. If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. In case a new file is created, the first line will be a comment containing a “DATE:” and “UNITS:” tag with the current date and the current *units* setting as argument. For subsequent invocations of the `pair_write` command, the current units setting is compared against the entry in the file, if present, and `pair_write` will refuse to add a table if the units are not the same.

The energy and force values are computed at distances from inner to outer for 2 interacting atoms of type *itype* and *jtype*, using the appropriate *pair\_coeff* coefficients. If the style is *r*, then N distances are used, evenly spaced in *r*; if the style is *rsq*, N distances are used, evenly spaced in  $r^2$ .

For example, for N = 7, style = *r*, inner = 1.0, and outer = 4.0, values are computed at  $r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0$ .

If the style is *bitmap*, then  $2^N$  values are written to the file in a format and order consistent with how they are read in by the *pair\_coeff* command for pair style *table*. For reasonable accuracy in a bitmapped table, choose  $N \geq 12$ , an *inner* value that is smaller than the distance of closest approach of 2 atoms, and an *outer* value  $\leq$  cutoff of the potential.

If the pair potential is computed between charged atoms, the charges of the pair of interacting atoms can optionally be specified. If not specified, values of  $Q_i = Q_j = 1.0$  are used.

The file is written in the format used as input for the *pair\_style table* option with *keyword* as the section name. Each line written to the file lists an index number (1-N), a distance (in distance units), an energy (in energy units), and a force (in force units).

## 1.77.4 Restrictions

All force field coefficients for pair and other kinds of interactions must be set before this command can be invoked.

Due to how the pairwise force is computed, an inner value  $> 0.0$  must be specified even if the potential has a finite value at  $r = 0.0$ .

The *pair\_write* command can only be used for pairwise additive interactions for which a *Pair::single()* function can be and has been implemented. This excludes for example manybody potentials or TIP4P coulomb styles.

## 1.77.5 Related commands

*pair\_style table*, *pair\_style*, *pair\_coeff*

## 1.77.6 Default

none

## 1.78 partition command

### 1.78.1 Syntax

```
partition style N command ...
```

- style = *yes* or *no*
- N = partition number (see asterisk form below)
- command = any LAMMPS command

### 1.78.2 Examples

```
partition yes 1 processors 4 10 6
partition no 5 print "Active partition"
partition yes *5 fix all nve
partition yes 6* fix all nvt temp 1.0 1.0 0.1
```

### 1.78.3 Description

This command invokes the specified command on a subset of the partitions of processors you have defined via the *-partition command-line switch*.

Normally, every input script command in your script is invoked by every partition. This behavior can be modified by defining world- or universe-style *variables* that have different values for each partition. This mechanism can be used to cause your script to jump to different input script files on different partitions, if such a variable is used in a *jump* command.

The “partition” command is another mechanism for having an input script operate differently on different partitions. It is basically a prefix on any LAMMPS command. The command will only be invoked on the partition(s) specified by the *style* and *N* arguments.

If the *style* is *yes*, the command will be invoked on any partition which matches the *N* argument. If the *style* is *no* the command will be invoked on all the partitions which do not match the *Np* argument.

Partitions are numbered from 1 to *Np*, where *Np* is the number of partitions specified by the *-partition command-line switch*.

*N* can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a wild-card asterisk can be used to span a range of partition numbers. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. An asterisk with no numeric values means all partitions from 1 to *Np*. A leading asterisk means all partitions from 1 to *n* (inclusive). A trailing asterisk means all partitions from *n* to *Np* (inclusive). A middle asterisk means all partitions from *m* to *n* (inclusive).

This command can be useful for the “run\_style verlet/split” command which imposed requirements on how the *processors* command lays out a 3d grid of processors in each of 2 partitions.

## 1.78.4 Restrictions

none

## 1.78.5 Related commands

*run\_style verlet/split*

## 1.78.6 Default

# 1.79 plugin command

## 1.79.1 Syntax

```
plugin command args
```

- command = *load* or *unload* or *list* or *clear*
  - args = list of arguments for a particular plugin command
- load file* = load plugin(s) from shared object in *file*  
*unload style name* = unload plugin *name* of style *style*  
          *style* = *pair* or *bond* or *angle* or *dihedral* or *improper* or *kpace* or *compute* or *fix* or *region* or *command*  
*list* = print a list of currently loaded plugins  
*clear* = unload all currently loaded plugins

## 1.79.2 Examples

```
plugin load morse2plugin.so
plugin unload pair morse2/omp
plugin unload command hello
plugin list
plugin clear
```

## 1.79.3 Description

The plugin command allows to load (and unload) additional styles and commands into a LAMMPS binary from so-called dynamic shared object (DSO) files. This enables to add new functionality to an existing LAMMPS binary without having to recompile and link the entire executable.

The *load* command will load and initialize all plugins contained in the plugin DSO with the given filename. A message with information the plugin style and name and more will be printed. Individual DSO files may contain multiple plugins. More details about how to write and compile the plugin DSO is given in programmer's guide part of the manual under *Writing plugins*.

The *unload* command will remove the given style or the given name from the list of available styles. If the plugin style is currently in use, that style instance will be deleted.

The *list* command will print a list of the loaded plugins and their styles and names.

The *clear* command will unload all currently loaded plugins.

---

### Automatic loading of plugins

New in version 4May2022.

When the environment variable `LAMMPS_PLUGIN_PATH` is set, then LAMMPS will search the directory (or directories) listed in this path for files with names that end in `plugin.so` (e.g. `helloplugin.so`) and will try to load the contained plugins automatically at start-up.

---

## 1.79.4 Restrictions

The *plugin* command is part of the `PLUGIN` package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

If plugins access functions or classes from a package, LAMMPS must have been compiled with that package included.

Plugins are dependent on the LAMMPS binary interface (ABI) and particularly the MPI library used. So they are not guaranteed to work when the plugin was compiled with a different MPI library or different compilation settings or a different LAMMPS version. There are no checks, so if there is a mismatch the plugin object will either not load or data corruption and crashes may happen.

```

## 1.80.3 Description

Run a parallel replica dynamics (PRD) simulation using multiple replicas of a system. One or more replicas can be used. The total number of steps  $N$  to run can be interpreted in one of two ways; see discussion of the *time* keyword below.

PRD is described in ([Voter1998](#)) by Art Voter. Similar to global or local hyperdynamics (HD), PRD is a method for performing accelerated dynamics that is suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods (AMD) for such systems is given in this review paper ([Voter2002](#)) from Art's group. To quote from the paper: "The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by  $p(t) = k \cdot \exp(-kt)$  where  $k$  is the rate constant."

Both PRD and HD produce a time-accurate trajectory that effectively extends the timescale over which a system can be simulated, but they do it differently. PRD creates  $N_r$  replicas of the system and runs dynamics on each independently with a normal unbiased potential until an event occurs in one of the replicas. The time between events is reduced by a factor of  $N_r$  replicas. HD uses a single replica of the system and accelerates time by biasing the interaction potential in a manner such that each timestep is effectively longer. For both methods, per CPU second, more physical time elapses and more events occur. See the [hyper](#) page for more info about HD.

In PRD, each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the [-partition command-line switch](#). Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on one or two processors. However for PRD, this makes little sense, since running a replica on virtual instead of physical processors, offers no effective parallel speed-up in searching for infrequent events. See the [Howto replica](#) doc page for further discussion.

When a PRD simulation is performed, it is assumed that each replica is running the same model, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, etc should be the same for every replica.

A PRD run has several stages, which are repeated each time an "event" occurs in one of the replicas, as explained below. The logic for a PRD run is as follows:

```
while (time remains):
  dephase for n_dephase*t_dephase steps
  until (event occurs on some replica):
    run dynamics for t_event steps
    quench
    check for uncorrelated event on any replica
  until (no correlated event occurs):
    run dynamics for t_correlate steps
    quench
    check for correlated event on this replica
  event replica shares state with all replicas
```

Before this loop begins, the state of the system on replica 0 is shared with all replicas, so that all replicas begin from the same initial state. The first potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

In the first stage, dephasing is performed by each replica independently to eliminate correlations between replicas. This is done by choosing a random set of velocities, based on the *random\_seed* that is specified, and running *t\_dephase* timesteps of dynamics. This is repeated *n\_dephase* times. At each of the *n\_dephase* stages, if an event occurs during the *t\_dephase* steps of dynamics for a particular replica, the replica repeats the stage until no event occurs.

If the *temp* keyword is not specified, the target temperature for velocity randomization for each replica is the current temperature of that replica. Otherwise, it is the specified *Tdephase* temperature. The style of velocity randomization is controlled using the keyword *vel* with arguments that have the same meaning as their counterparts in the *velocity* command.

In the second stage, each replica runs dynamics continuously, stopping every *t\_event* steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin. The first time through the PRD loop, the “previous basin” is the set of quenched coordinates from the initial state of the system.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the *min\_style* command. Minimization parameters may be set via the *min\_modify* command and by the *min* keyword of the PRD command. The latter are the settings that would be used with the *minimize* command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event, though you may need to in order to prevent a set of atoms in the system from relaxing to a saddle point.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the PRD command, which is the *compute event/displace* command. Other event-checking computes may be added. *Compute event/displace* checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an “event” has occurred.

In the third stage, the replica on which the event occurred (event replica) continues to run dynamics to search for correlated events. This is done by running dynamics for *t\_correlate* steps, quenching every *t\_event* steps, and checking if another event has occurred.

The first time no correlated event occurs, the final state of the event replica is shared with all replicas, the new basin reference coordinates are updated with the quenched state, and the outer loop begins again. While the replica event is searching for correlated events, all the other replicas also run dynamics and event checking with the same schedule, but the final states are always overwritten by the state of the event replica.

The outer loop of the pseudocode above continues until *N* steps of dynamics have been performed. Note that *N* only includes the dynamics of stages 2 and 3, not the steps taken during dephasing or the minimization iterations of quenching. The specified *N* is interpreted in one of two ways, depending on the *time* keyword. If the *time* value is *steps*, which is the default, then each replica runs for *N* timesteps. If the *time* value is *clock*, then the simulation runs until *N* aggregate timesteps across all replicas have elapsed. This aggregate time is the “clock” time defined below, which typically advances nearly *M* times faster than the timestepping on a single replica, where *M* is the number of replicas.

Four kinds of output can be generated during a PRD run: event statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file is limited to event statistics. Note that if a PRD run is performed on only a single replica then the event statistics will be intermixed with the usual thermodynamic output discussed below.

The quantities printed each time an event occurs are the timestep, CPU time, clock, event number, a correlation flag, the number of coincident events, and the replica number of the chosen event.

The timestep is the usual LAMMPS timestep, except that time does not advance during dephasing or quenches, but only during dynamics. Note that there are two kinds of dynamics in the PRD loop listed above that contribute to this timestepping. The first is when all replicas are performing independent dynamics, waiting for an event to occur. The second is when correlated events are being searched for, but only one replica is running dynamics.

The CPU time is the total elapsed time on each processor, since the start of the PRD run.

The clock is the same as the timestep except that it advances by  $M$  steps per timestep during the first kind of dynamics when the  $M$  replicas are running independently. The clock advances by only 1 step per timestep during the second kind of dynamics, when only a single replica is checking for a correlated event. Thus “clock” time represents the aggregate time (in steps) that has effectively elapsed during a PRD simulation on  $M$  replicas. If most of the PRD run is spent in the second stage of the loop above, searching for infrequent events, then the clock will advance nearly  $M$  times faster than it would if a single replica was running. Note the clock time between successive events should be drawn from  $p(t)$ .

The event number is a counter that increments with each event, whether it is uncorrelated or correlated.

The correlation flag will be 0 when an uncorrelated event occurs during the second stage of the loop listed above, i.e. when all replicas are running independently. The correlation flag will be 1 when a correlated event occurs during the third stage of the loop listed above, i.e. when only one replica is running dynamics.

When more than one replica detects an event at the end of the same event check (every  $t_{event}$  steps) during the second stage, then one of them is chosen at random. The number of coincident events is the number of replicas that detected an event. Normally, this value should be 1. If it is often greater than 1, then either the number of replicas is too large, or  $t_{event}$  is too large.

The replica number is the ID of the replica (from 0 to  $M-1$ ) in which the event occurred.

---

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For the PRD command, these contain the thermodynamic output for each replica. You will see short runs and minimizations corresponding to the dynamics and quench operations of the loop listed above. The timestep will be reset appropriately depending on whether the operation advances time or not.

After the PRD command completes, timing statistics for the PRD run are printed in each replica’s log file, giving a breakdown of how much CPU time was spent in each stage (dephasing, dynamics, quenching, etc).

---

Any *dump files* defined in the input script, will be written to during a PRD run at timesteps corresponding to both uncorrelated and correlated events. This means the requested dump frequency in the *dump* command is ignored. There will be one dump file (per dump command) created for all partitions.

The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following a transition event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each PRD run.

---

If the *restart* command is used, a single restart file for all the partitions is generated, which allows a PRD run to be continued by a new input script in the usual manner.

The restart file is generated at the end of the loop listed above. If no correlated events are found, this means it contains a snapshot of the system at time  $T + t\_correlate$ , where  $T$  is the time at which the uncorrelated event occurred. If correlated events were found, then it contains a snapshot of the system at time  $T + t\_correlate$ , where  $T$  is the time of the last correlated event.

The restart frequency specified in the `restart` command is interpreted differently when performing a PRD run. It does not mean the timestep interval between restart files. Instead it means an event interval for uncorrelated events. Thus a frequency of 1 means write a restart file every time an uncorrelated event occurs. A frequency of 10 means write a restart file every 10th uncorrelated event.

When an input script reads a restart file from a previous PRD run, the new script can be run on a different number of replicas or processors. However, it is assumed that  $t\_correlate$  in the new PRD command is the same as it was previously. If not, the calculation of the “clock” value for the first event in the new run will be slightly off.

---

## 1.80.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the [Build package](#) doc page for more info.

The  $N$  and  $t\_correlate$  settings must be integer multiples of  $t\_event$ .

Runs restarted from restart file written during a PRD run will not produce identical results due to changes in the random numbers used for dephasing.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the “ave” fixes such as `fix ave/chunk`. Also `fix dt/reset` and `fix deposit`.

## 1.80.5 Related commands

*compute event/displace, min\_modify, min\_style, run\_style, minimize, velocity, temper, neb, tad, hyper*

## 1.80.6 Default

The option defaults are min = 0.1 0.1 40 50, no temp setting, vel = geom gaussian, and time = steps.

---

(Voter1998) Voter, Phys Rev B, 57, 13985 (1998).

(Voter2002) Voter, Montalenti, Germann, Annual Review of Materials Research 32, 321 (2002).

## 1.81 print command

### 1.81.1 Syntax

`print` string keyword value

- string = text string to print, which may contain variables
- zero or more keyword/value pairs may be appended
- keyword = *file* or *append* or *screen* or *universe*

```
file value = filename
append value = filename
screen value = yes or no
universe value = yes or no
```

## 1.81.2 Examples

```
print "Done with equilibration" file info.dat
print Vol=$v append info.dat screen no
print "The system volume is now $v"
print 'The system volume is now $v'
print "NEB calculation 1 complete" screen no universe yes
print ""
System volume = $v
System temperature = $t
""
```

## 1.81.3 Description

Print a text string to the screen and logfile. The text string must be a single argument, so if it is one line but more than one word, it should be enclosed in single or double quotes. To generate multiple lines of output, the string can be enclosed in triple quotes, as in the last example above. If the text string contains variables, they will be evaluated and their current values printed.

New in version 15Jun2023: support for vector style variables

See the [variable](#) command for a description of *equal* and *vector* style variables which are typically the most useful ones to use with the print command. Equal- and vector-style variables can calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a [compute](#) or [fix](#), or references to other [variables](#). Vector-style variables are printed in a bracketed, comma-separated format, e.g. [1,2,3,4] or [12.5,2,4.6,10.1].

---

**Note:** As discussed on the [Commands parse](#) doc page, the text string can use “immediate” variables, specified as \$(formula) with parenthesis, where the numeric formula has the same syntax as equal-style variables described on the [variable](#) doc page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then use that variable in the text string. The formula can include a trailing colon and format string which determines the precision with which the numeric value is output. This is also explained on the [Commands parse](#) doc page.

---

If you want the print command to be executed multiple times (with changing variable values), there are 3 options. First, consider using the [fix print](#) command, which will print a string periodically during a simulation. Second, the print command can be used as an argument to the *every* option of the [run](#) command. Third, the print command could appear in a section of the input script that is looped over (see the [jump](#) and [next](#) commands).

If the *file* or *append* keyword is used, a filename is specified to which the output will be written. If *file* is used, then the filename is overwritten if it already exists. If *append* is used, then the filename is appended to if it already exists, or created if it does not exist.

If the *screen* keyword is used, output to the screen and logfile can be turned on or off as desired.

If the *universe* keyword is used, output to the global screen and logfile can be turned on or off as desired. In multi-partition calculations, the *screen* option and the corresponding output only apply to the screen and logfile of the individual partition.

## 1.81.4 Restrictions

none

## 1.81.5 Related commands

*fix print, variable*

## 1.81.6 Default

The option defaults are no file output, screen = yes, and universe = no.

```

## 1.82.3 Description

Specify how processors are mapped as a regular 3d grid to the global simulation box. The mapping involves 2 steps. First if there are  $P$  processors it means choosing a factorization  $P = P_x$  by  $P_y$  by  $P_z$  so that there are  $P_x$  processors in the  $x$  dimension, and similarly for the  $y$  and  $z$  dimensions. Second, the  $P$  processors are mapped to the regular 3d grid. The arguments to this command control each of these 2 steps.

The  $P_x$ ,  $P_y$ ,  $P_z$  parameters affect the factorization. Any of the 3 parameters can be specified with an asterisk “\*”, which means LAMMPS will choose the number of processors in that dimension of the grid. It will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor’s subdomain.

Choosing explicit values for  $P_x$  or  $P_y$  or  $P_z$  can be used to override the default manner in which LAMMPS will create the regular 3d grid of processors, if it is known to be sub-optimal for a particular problem. E.g. a problem where the extent of atoms will change dramatically in a particular dimension over the course of the simulation.

The product of  $P_x$ ,  $P_y$ ,  $P_z$  must equal  $P$ , the total # of processors LAMMPS is running on. For a *2d simulation*,  $P_z$  must equal 1.

Note that if you run on a prime number of processors  $P$ , then a grid such as  $1 \times P \times 1$  will be required, which may incur extra communication costs due to the high surface area of each processor’s subdomain.

Also note that if multiple partitions are being used then  $P$  is the number of processors in this partition; see the *partition command-line switch* page for details. Also note that you can prefix the processors command with the *partition* command to easily specify different  $P_x, P_y, P_z$  values for different partitions.

You can use the *partition* command to specify different processor grids for different partitions, e.g.

```
partition yes 1 processors 4 4 4
partition yes 2 processors 2 3 2
```

---

**Note:** This command only affects the initial regular 3d grid created when the simulation box is first specified via a *create\_box* or *read\_data* or *read\_restart* command. Or if the simulation box is re-created via the *replicate* command. The same regular grid is initially created, regardless of which *comm\_style* command is in effect.

---

If load-balancing is never invoked via the *balance* or *fix balance* commands, then the initial regular grid will persist for all simulations. If balancing is performed, some of the methods invoked by those commands retain the logical topology of the initial 3d grid, and the mapping of processors to the grid specified by the processors command. However the grid spacings in different dimensions may change, so that processors own subdomains of different sizes. If the *comm\_style tiled* command is used, methods invoked by the balancing commands may discard the 3d grid of processors and tile the simulation domain with subdomains of different sizes and shapes which no longer have a logical 3d connectivity. If that occurs, all the information specified by the processors command is ignored.

---

The *grid* keyword affects the factorization of  $P$  into  $P_x, P_y, P_z$  and it can also affect how the  $P$  processor IDs are mapped to the 3d grid of processors.

The *onelevel* style creates a 3d grid that is compatible with the  $P_x, P_y, P_z$  settings, and which minimizes the surface-to-volume ratio of each processor's subdomain, as described above. The mapping of processors to the grid is determined by the *map* keyword setting.

The *twolevel* style can be used on machines with multicore nodes to minimize off-node communication. It ensures that contiguous subsections of the 3d grid are assigned to all the cores of a node. For example if  $N_c$  is 4, then  $2 \times 2 \times 1$  or  $2 \times 1 \times 2$  or  $1 \times 2 \times 2$  subsections of the 3d grid will correspond to the cores of each node. This affects both the factorization and mapping steps.

The  $C_x, C_y, C_z$  settings are similar to the  $P_x, P_y, P_z$  settings, only their product should equal  $N_c$ . Any of the 3 parameters can be specified with an asterisk "\*", which means LAMMPS will choose the number of cores in that dimension of the node's sub-grid. As with  $P_x, P_y, P_z$ , it will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor's subdomain.

---

**Note:** For the *twolevel* style to work correctly, it assumes the MPI ranks of processors LAMMPS is running on are ordered by core and then by node. E.g. if you are running on 2 quad-core nodes, for a total of 8 processors, then it assumes processors 0,1,2,3 are on node 1, and processors 4,5,6,7 are on node 2. This is the default rank ordering for most MPI implementations, but some MPIs provide options for this ordering, e.g. via environment variable settings.

---

The *numa* style operates similar to the *twolevel* keyword except that it auto-detects which cores are running on which nodes. It will also subdivide the cores into numa domains. Currently, the number of numa domains is not auto-detected and must be specified using the *numa\_nodes* keyword; otherwise, the default value is used. The *numa* style uses a different algorithm than the *twolevel* keyword for doing the two-level factorization of the simulation box into a 3d processor grid to minimize off-node communication and communication across numa domains. It does its own MPI-based mapping of nodes and cores to the regular 3d grid. Thus it may produce a different layout of the processors than the *twolevel* options.

The *numa* style will give an error if the number of MPI processes is not divisible by the number of cores used per node, or any of the  $P_x$  or  $P_y$  or  $P_z$  values is greater than 1.

---

**Note:** Unlike the *twolevel* style, the *numa* style does not require any particular ordering of MPI ranks in order to work correctly. This is because it auto-detects which processes are running on which nodes. However, it assumes that the lowest ranks are in the first numa domain, and so forth. MPI rank orderings that do not preserve this property might result in more intra-node communication between CPUs.

---

The *custom* style uses the file *infile* to define both the 3d factorization and the mapping of processors to the grid.

The file should have the following format. Any number of initial blank or comment lines (starting with a "#" character) can be present. The first non-blank, non-comment line should have 3 values:

```
Px Py Pz
```

These must be compatible with the total number of processors and the  $P_x, P_y, P_z$  settings of the processors command.

This line should be immediately followed by  $P = P_x * P_y * P_z$  lines of the form:

```
ID I J K
```

where ID is a processor ID (from 0 to  $P-1$ ) and I,J,K are the processors location in the 3d grid. I must be a number from 1 to  $P_x$  (inclusive) and similarly for J and K. The  $P$  lines can be listed in any order, but no processor ID should appear more than once.

The *numa\_nodes* keyword is used to specify the number of numa domains per node. It is currently only used by the *numa* style for two-level factorization to reduce the amount of MPI communications between CPUs. A good setting for this will typically be equal to the number of CPU sockets per node.

---

The *map* keyword affects how the P processor IDs (from 0 to P-1) are mapped to the 3d grid of processors. It is only used by the *onelevel* and *twolevel* grid settings.

The *cart* style uses the family of MPI Cartesian functions to perform the mapping, namely `MPI_Cart_create()`, `MPI_Cart_get()`, `MPI_Cart_shift()`, and `MPI_Cart_rank()`. It invokes the `MPI_Cart_create()` function with its reorder flag = 0, so that MPI is not free to reorder the processors.

The *cart/reorder* style does the same thing as the *cart* style except it sets the reorder flag to 1, so that MPI can reorder processors if it desires.

The *xyz*, *xzy*, *yxz*, *yzx*, *zxy*, and *zyx* styles are all similar. If the style is IJK, then it maps the P processors to the grid so that the processor ID in the I direction varies fastest, the processor ID in the J direction varies next fastest, and the processor ID in the K direction varies slowest. For example, if you select style *xyz* and you have a 2x2x2 grid of 8 processors, the assignments of the 8 octants of the simulation domain will be:

```
proc 0 = lo x, lo y, lo z octant
proc 1 = hi x, lo y, lo z octant
proc 2 = lo x, hi y, lo z octant
proc 3 = hi x, hi y, lo z octant
proc 4 = lo x, lo y, hi z octant
proc 5 = hi x, lo y, hi z octant
proc 6 = lo x, hi y, hi z octant
proc 7 = hi x, hi y, hi z octant
```

Note that, in principle, an MPI implementation on a particular machine should be aware of both the machine's network topology and the specific subset of processors and nodes that were assigned to your simulation. Thus its `MPI_Cart` calls can optimize the assignment of MPI processes to the 3d grid to minimize communication costs. In practice, however, few if any MPI implementations actually do this. So it is likely that the *cart* and *cart/reorder* styles simply give the same result as one of the IJK styles.

Also note, that for the *twolevel* grid style, the *map* setting is used to first map the nodes to the 3d grid, then again to the cores within each node. For the latter step, the *cart* and *cart/reorder* styles are not supported, so an *xyz* style is used in their place.

---

The *part* keyword affects the factorization of P into *Px*, *Py*, *Pz*.

It can be useful when running in multi-partition mode, e.g. with the *run\_style verlet/split* command. It specifies a dependency between a sending partition *Psend* and a receiving partition *Precv* which is enforced when each is setting up their own mapping of their processors to the simulation box. Each of *Psend* and *Precv* must be integers from 1 to *Np*, where *Np* is the number of partitions you have defined via the *-partition command-line switch*.

A “dependency” means that the sending partition will create its regular 3d grid as *Px* by *Py* by *Pz* and after it has done this, it will send the *Px*, *Py*, *Pz* values to the receiving partition. The receiving partition will wait to receive these values before creating its own regular 3d grid and will use the sender's *Px*, *Py*, *Pz* values as a constraint. The nature of the constraint is determined by the *cstyle* argument.

For a *cstyle* of *multiple*, each dimension of the sender's processor grid is required to be an integer multiple of the corresponding dimension in the receiver's processor grid. This is a requirement of the *run\_style verlet/split* command.

For example, assume the sending partition creates a 4x6x10 grid = 240 processor grid. If the receiving partition is running on 80 processors, it could create a 4x2x10 grid, but it will not create a 2x4x10 grid, since in the y-dimension, 6 is not an integer multiple of 4.

---

**Note:** If you use the *partition* command to invoke different “processors” commands on different partitions, and you also use the *part* keyword, then you must ensure that both the sending and receiving partitions invoke the “processors” command that connects the 2 partitions via the *part* keyword. LAMMPS cannot easily check for this, but your simulation will likely hang in its setup phase if this error has been made.

---

The *file* keyword writes the mapping of the factorization of P processors and their mapping to the 3d grid to the specified file *outfile*. This is useful to check that you assigned physical processors in the manner you desired, which can be tricky to figure out, especially when running on multiple partitions or on, a multicore machine or when the processor ranks were reordered by use of the *-reorder command-line switch* or due to use of MPI-specific launch options such as a config file.

If you have multiple partitions you should ensure that each one writes to a different file, e.g. using a *world-style variable* for the filename. The file has a self-explanatory header, followed by one-line per processor in this format:

```
world-ID universe-ID original-ID: I J K: name
```

The IDs are the processor’s rank in this simulation (the world), the universe (of multiple simulations), and the original MPI communicator used to instantiate LAMMPS, respectively. The world and universe IDs will only be different if you are running on more than one partition; see the *-partition command-line switch*. The universe and original IDs will only be different if you used the *-reorder command-line switch* to reorder the processors differently than their rank in the original communicator LAMMPS was instantiated with.

I,J,K are the indices of the processor in the regular 3d grid, each from 1 to Nd, where Nd is the number of processors in that dimension of the grid.

The *name* is what is returned by a call to `MPI_Get_processor_name()` and should represent an identifier relevant to the physical processors in your machine. Note that depending on the MPI implementation, multiple cores can have the same *name*.

---

## 1.82.4 Restrictions

This command cannot be used after the simulation box is defined by a *read\_data* or *create\_box* command. It can be used before a restart file is read to change the 3d processor grid from what is specified in the restart file.

The *grid numa* keyword only currently works with the *map cart* option.

The *part* keyword (for the receiving partition) only works with the *grid onelevel* or *grid twolevel* options.

## 1.82.5 Related commands

*partition*, *-reorder command-line switch*

## 1.82.6 Default

The option defaults are Px Py Pz = \* \* \*, grid = onelevel, map = cart, and numa\_nodes = 2.

## 1.83 python command

### 1.83.1 Syntax

```
python mode keyword args ...
```

- mode = *source* or name of Python function

if mode is *source*:

keyword = *here* or name of a *Python file*

*here* arg = inline

inline = one or more lines of Python code which defines func

must be a single argument, typically enclosed between triple quotes

*Python file* = name of a file with Python code which will be executed immediately

- if *mode* is the name of a Python function, one or more keywords with/without arguments must be appended

keyword = *invoke* or *input* or *return* or *format* or *length* or *file* or *here* or *exists*

*invoke* arg = none = invoke the previously defined Python function

*input* args = N i1 i2 ... iN

N = # of inputs to function

i1,...,iN = value, SELF, or LAMMPS variable name

value = integer number, floating point number, or string

SELF = reference to LAMMPS itself which can be accessed by Python function

variable = v\_name, where name = name of LAMMPS variable, e.g. v\_abc

*return* arg = varReturn

varReturn = v\_name = LAMMPS variable name which the return value of the Python\_

→function will be assigned to

*format* arg = fstring with M characters

M = N if no return value, where N = # of inputs

M = N+1 if there is a return value

fstring = each character (i,f,s,p) corresponds in order to an input or return\_

→value

'i' = integer, 'f' = floating point, 's' = string, 'p' = SELF

*length* arg = Nlen

Nlen = max length of string returned from Python function

*file* arg = filename

filename = file of Python code, which defines func

*here* arg = inline

inline = one or more lines of Python code which defines func

must be a single argument, typically enclosed between triple quotes

*exists* arg = none = Python code has been loaded by previous python command

## 1.83.2 Examples

```
python pForce input 2 v_x 20.0 return v_f format fff file force.py
python pForce invoke

python factorial input 1 myN return v_fac format ii here """
def factorial(n):
    if n == 1: return n
    return n * factorial(n-1)
"""

python loop input 1 SELF return v_value format pf here """
def loop(lmp_ptr,N,cut0):
    from lammps import lammps
    lmp = lammps(ptr=lmp_ptr)

    # loop N times, increasing cutoff each time

    for i in range(N):
        cut = cut0 + i*0.1
        lmp.set_variable("cut",cut)                # set a variable in LAMMPS
        lmp.command("pair_style lj/cut ${cut}")      # LAMMPS commands
        lmp.command("pair_coeff * * 1.0 1.0")
        lmp.command("run 100")
    """

python source funcdef.py

python source here "from lammps import lammps"
```

## 1.83.3 Description

The *python* command allows interfacing LAMMPS with an embedded Python interpreter and enables either executing arbitrary python code in that interpreter, registering a Python function for future execution (as a python style variable, from a fix interfaced with python, or for direct invocation), or invoking such a previously registered function.

Arguments, including LAMMPS variables, can be passed to the function from the LAMMPS input script and a value returned by the Python function assigned to a LAMMPS variable. The Python code for the function can be included directly in the input script or in a separate Python file. The function can be standard Python code or it can make “callbacks” to LAMMPS through its library interface to query or set internal values within LAMMPS. This is a powerful mechanism for performing complex operations in a LAMMPS input script that are not possible with the simple input script and variable syntax which LAMMPS defines. Thus your input script can operate more like a true programming language.

Use of this command requires building LAMMPS with the PYTHON package which links to the Python library so that the Python interpreter is embedded in LAMMPS. More details about this process are given below.

There are two ways to invoke a Python function once it has been registered. One is using the *invoke* keyword. The other is to assign the function to a *python-style variable* defined in your input script. Whenever the variable is evaluated, it will execute the Python function to assign a value to the variable. Note that variables can be evaluated in many different ways within LAMMPS. They can be substituted with their result directly in an input script, or they can be passed to various commands as arguments, so that the variable is evaluated during a simulation run.

A broader overview of how Python can be used with LAMMPS is given in the *Use Python with LAMMPS* section of

the documentation. There also is an `examples/python` directory which illustrates use of the `python` command.

---

The first argument of the `python` command is either the `source` keyword or the name of a Python function. This defines the mode of the `python` command.

Changed in version 22Dec2022.

If the `source` keyword is used, it is followed by either a file name or the `here` keyword. No other keywords can be used. The `here` keyword is followed by a string with python commands, either on a single line enclosed in quotes, or as multiple lines enclosed in triple quotes. These Python commands will be passed to the python interpreter and executed immediately without registering a Python function for future execution. The code will be loaded into and run in the “main” module of the Python interpreter. This allows running arbitrary Python code at any time while processing the LAMMPS input file. This can be used to pre-load Python modules, initialize global variables, define functions or classes, or perform operations using the python programming language. The Python code will be executed in parallel on all MPI processes. No arguments can be passed.

In all other cases, the first argument is the name of a Python function that will be registered with LAMMPS for future execution. The function may already be defined (see `exists` keyword) or must be defined using the `file` or `here` keywords as explained below.

If the `invoke` keyword is used, no other keywords can be used, and a previous `python` command must have registered the Python function referenced by this command. This invokes the Python function with the previously defined arguments and the return value is processed as explained below. You can invoke the function as many times as you wish in your input script.

The `input` keyword defines how many arguments  $N$  the Python function expects. If it takes no arguments, then the `input` keyword should not be used. Each argument can be specified directly as a value, e.g. ‘6’ or ‘3.14159’ or ‘abc’ (a string of characters). The type of each argument is specified by the `format` keyword as explained below, so that Python will know how to interpret the value. If the word `SELF` is used for an argument it has a special meaning. A pointer is passed to the Python function which it can convert into a reference to LAMMPS itself using the [LAMMPS Python module](#). This enables the function to call back to LAMMPS through its library interface as explained below. This allows the Python function to query or set values internal to LAMMPS which can affect the subsequent execution of the input script. A LAMMPS variable can also be used as an argument, specified as `v_name`, where “name” is the name of the variable. Any style of LAMMPS variable returning a scalar or a string can be used, as defined by the [variable](#) command. The `format` keyword must be used to set the type of data that is passed to Python. Each time the Python function is invoked, the LAMMPS variable is evaluated and its value is passed to the Python function.

The `return` keyword is only needed if the Python function returns a value. The specified `varReturn` must be of the form `v_name`, where “name” is the name of a python-style LAMMPS variable, defined by the [variable](#) command. The Python function can return a numeric or string value, as specified by the `format` keyword.

As explained on the [variable](#) doc page, the definition of a python-style variable associates a Python function name with the variable. This must match the *Python function name* first argument of the `python` command. For example these two commands would be consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

The two commands can appear in either order in the input script so long as both are specified before the Python function is invoked for the first time. Afterwards, the variable ‘foo’ is associated with the Python function ‘myMultiply’.

The `format` keyword must be used if the `input` or `return` keywords are used. It defines an *fstring* with  $M$  characters, where  $M$  = sum of number of inputs and outputs. The order of characters corresponds to the  $N$  inputs, followed by the return value (if it exists). Each character must be one of the following: “i” for integer, “f” for floating point, “s” for string, or “p” for SELF. Each character defines the type of the corresponding input or output value of the Python function and affects the type conversion that is performed internally as data is passed back and forth between LAMMPS

and Python. Note that it is permissible to use a *python-style variable* in a LAMMPS command that allows for an equal-style variable as an argument, but only if the output of the Python function is flagged as a numeric value (“i” or “f”) via the *format* keyword.

If the *return* keyword is used and the *format* keyword specifies the output as a string, then the default maximum length of that string is 63 characters (64-1 for the string terminator). If you want to return a longer string, the *length* keyword can be specified with its *Nlen* value set to a larger number (the code allocates space for *Nlen*+1 to include the string terminator). If the Python function generates a string longer than the default 63 or the specified *Nlen*, it will be truncated.

---

Either the *file*, *here*, or *exists* keyword must be used, but only one of them. These keywords specify what Python code to load into the Python interpreter. The *file* keyword gives the name of a file containing Python code, which should end with a “.py” suffix. The code will be immediately loaded into and run in the “main” module of the Python interpreter. The Python code will be executed in parallel on all MPI processes. Note that Python code which contains a function definition does not “execute” the function when it is run; it simply defines the function so that it can be invoked later.

The *here* keyword does the same thing, except that the Python code follows as a single argument to the *here* keyword. This can be done using triple quotes as delimiters, as in the examples above. This allows Python code to be listed verbatim in your input script, with proper indentation, blank lines, and comments, as desired. See the [Commands parse](#) doc page, for an explanation of how triple quotes can be used as part of input script syntax.

The *exists* keyword takes no argument. It means that Python code containing the required Python function with the given name has already been executed, for example by a *python source* command or in the same file that was used previously with the *file* keyword.

Note that the Python code that is loaded and run must contain a function with the specified function name. To operate properly when later invoked, the function code must match the *input* and *return* and *format* keywords specified by the python command. Otherwise Python will generate an error.

---

This section describes how Python code can be written to work with LAMMPS.

Whether you load Python code from a file or directly from your input script, via the *file* and *here* keywords, the code can be identical. It must be indented properly as Python requires. It can contain comments or blank lines. If the code is in your input script, it cannot however contain triple-quoted Python strings, since that will conflict with the triple-quote parsing that the LAMMPS input script performs.

All the Python code you specify via one or more python commands is loaded into the Python “main” module, i.e. `__name__ == '__main__'`. The code can define global variables, define global functions, define classes or execute statements that are outside of function definitions. It can contain multiple functions, only one of which matches the *func* setting in the python command. This means you can use the *file* keyword once to load several functions, and the *exists* keyword thereafter in subsequent python commands to register the other functions that were previously loaded with LAMMPS.

A Python function you define (or more generally, the code you load) can import other Python modules or classes, it can make calls to other system functions or functions you define, and it can access or modify global variables (in the “main” module) which will persist between successive function calls. The latter can be useful, for example, to prevent a function from being invoke multiple times per timestep by different commands in a LAMMPS input script that access the returned python-style variable associated with the function. For example, consider this function loaded with two global variables defined outside the function:

```
nsteplast = -1
nvaluelast = 0

def expensive(nstep):
    global nsteplast, nvaluelast
    if nstep == nsteplast: return nvaluelast
```

(continues on next page)

(continued from previous page)

```
nsteplast = nstep
# perform complicated calculation
nvalue = ...
nvaluelast = nvalue
return nvalue
```

The variable ‘nsteplast’ stores the previous timestep the function was invoked (passed as an argument to the function). The variable ‘nvaluelast’ stores the return value computed on the last function invocation. If the function is invoked again on the same timestep, the previous value is simply returned, without re-computing it. The “global” statement inside the Python function allows it to overwrite the global variables from within the local context of the function.

Note that if you load Python code multiple times (via multiple python commands), you can overwrite previously loaded variables and functions if you are not careful. E.g. if the code above were loaded twice, the global variables would be re-initialized, which might not be what you want. Likewise, if a function with the same name exists in two chunks of Python code you load, the function loaded second will override the function loaded first.

It’s important to realize that if you are running LAMMPS in parallel, each MPI task will load the Python interpreter and execute a local copy of the Python function(s) you define. There is no connection between the Python interpreters running on different processors. This implies three important things.

First, if you put a print or other statement creating output to the screen in your Python function, you will see P copies of the output, when running on P processors. If the prints occur at (nearly) the same time, the P copies of the output may be mixed together. When loading the LAMMPS Python module into the embedded Python interpreter, it is possible to pass the pointer to the current LAMMPS class instance and via the Python interface to the LAMMPS library interface, it is possible to determine the MPI rank of the current process and thus adapt the Python code so that output will only appear on MPI rank 0. The following LAMMPS input demonstrates how this could be done. The text ‘Hello, LAMMPS!’ should be printed only once, even when running LAMMPS in parallel.

```
python python_hello input 1 SELF format p here """
def python_hello(handle):
    from lammmps import lammmps
    lmp = lammmps(ptr=handle)
    me = lmp.extract_setting('world_rank')
    if me == 0:
        print('Hello, LAMMPS!')
"""

python python_hello invoke
```

If your Python code loads Python modules that are not pre-loaded by the Python library, then it will load the module from disk. This may be a bottleneck if 1000s of processors try to load a module at the same time. On some large supercomputers, loading of modules from disk by Python may be disabled. In this case you would need to pre-build a Python library that has the required modules pre-loaded and link LAMMPS with that library.

Third, if your Python code calls back to LAMMPS (discussed in the next section) and causes LAMMPS to perform an MPI operation requires global communication (e.g. via MPI\_Allreduce), such as computing the global temperature of the system, then you must ensure all your Python functions (running independently on different processors) call back to LAMMPS. Otherwise the code may hang.

---

Your Python function can “call back” to LAMMPS through its library interface, if you use the SELF input to pass Python a pointer to LAMMPS. The mechanism for doing this in your Python function is as follows:

```
def foo(handle,...):
    from lammps import lammps
    lmp = lammps(ptr=handle)
    lmp.command('print "Hello from inside Python"')
    ...
```

The function definition must include a variable ('handle' in this case) which corresponds to SELF in the *python* command. The first line of the function imports the “*lammps*” Python module. The second line creates a Python object *lmp* which wraps the instance of LAMMPS that called the function. The 'ptr=handle' argument is what makes that happen. The third line invokes the *command()* function in the LAMMPS library interface. It takes a single string argument which is a LAMMPS input script command for LAMMPS to execute, the same as if it appeared in your input script. In this case, LAMMPS should output

```
Hello from inside Python
```

to the screen and log file. Note that since the LAMMPS print command itself takes a string in quotes as its argument, the Python string must be delimited with a different style of quotes.

The *Use Python with LAMMPS* page describes the syntax for how Python wraps the various functions included in the LAMMPS library interface.

A more interesting example is in the *examples/python/in.python* script which loads and runs the following function from *examples/python/funcs.py*:

```
def loop(N,cut0,thresh,lmpptr):
    print("LOOP ARGS", N, cut0, thresh, lmpptr)
    from lammps import lammps
    lmp = lammps(ptr=lmpptr)
    natoms = lmp.get_natoms()

    for i in range(N):
        cut = cut0 + i*0.1

        lmp.set_variable("cut",cut)                # set a variable in LAMMPS
        lmp.command("pair_style lj/cut ${cut}")      # LAMMPS command
        #lmp.command("pair_style lj/cut %d" % cut)   # LAMMPS command option

        lmp.command("pair_coeff * * 1.0 1.0")       # ditto
        lmp.command("run 10")                      # ditto
        pe = lmp.extract_compute("thermo_pe",0,0)   # extract total PE from LAMMPS
        print("PE", pe/natoms, thresh)
        if pe/natoms < thresh: return
```

with these input script commands:

```
python      loop input 4 10 1.0 -4.0 SELF format iffp file funcs.py
python      loop invoke
```

This has the effect of looping over a series of 10 short runs (10 timesteps each) where the pair style cutoff is increased from a value of 1.0 in distance units, in increments of 0.1. The looping stops when the per-atom potential energy falls below a threshold of -4.0 in energy units. More generally, Python can be used to implement a loop with complex logic, much more so than can be created using the LAMMPS *jump* and *if* commands.

Several LAMMPS library functions are called from the loop function. *Get\_natoms()* returns the number of atoms in the simulation, so that it can be used to normalize the potential energy that is returned by *extract\_compute()* for the “thermo\_pe” compute that is defined by default for LAMMPS thermodynamic output. *Set\_variable()* sets the value of

a string variable defined in LAMMPS. This library function is a useful way for a Python function to return multiple values to LAMMPS, more than the single value that can be passed back via a return statement. This cutoff value in the “cut” variable is then substituted (by LAMMPS) in the pair\_style command that is executed next. Alternatively, the “LAMMPS command option” line could be used in place of the 2 preceding lines, to have Python insert the value into the LAMMPS command string.

---

**Note:** When using the callback mechanism just described, recognize that there are some operations you should not attempt because LAMMPS cannot execute them correctly. If the Python function is invoked between runs in the LAMMPS input script, then it should be OK to invoke any LAMMPS input script command via the library interface `command()` or `file()` functions, so long as the command would work if it were executed in the LAMMPS input script directly at the same point.

---

However, a Python function can also be invoked during a run, whenever an associated LAMMPS variable it is assigned to is evaluated. If the variable is an input argument to another LAMMPS command (e.g. *fix setforce*), then the Python function will be invoked inside the class for that command, in one of its methods that is invoked in the middle of a timestep. You cannot execute arbitrary input script commands from the Python function (again, via the `command()` or `file()` functions) at that point in the run and expect it to work. Other library functions such as those that invoke `computes` or other variables may have hidden side effects as well. In these cases, LAMMPS has no simple way to check that something illogical is being attempted.

The same applies to Python functions called during a simulation run at each time step using *fix python/invoke*.

---

If you run Python code directly on your workstation, either interactively or by using Python to launch a Python script stored in a file, and your code has an error, you will typically see informative error messages. That is not the case when you run Python code from LAMMPS using an embedded Python interpreter. The code will typically fail silently. LAMMPS will catch some errors but cannot tell you where in the Python code the problem occurred. For example, if the Python code cannot be loaded and run because it has syntax or other logic errors, you may get an error from Python pointing to the offending line, or you may get one of these generic errors from LAMMPS:

```
Could not process Python file
Could not process Python string
```

When the Python function is invoked, if it does not return properly, you will typically get this generic error from LAMMPS:

```
Python function evaluation failed
```

Here are three suggestions for debugging your Python code while running it under LAMMPS.

First, don’t run it under LAMMPS, at least to start with! Debug it using plain Python. Load and invoke your function, pass it arguments, check return values, etc.

Second, add Python print statements to the function to check how far it gets and intermediate values it calculates. See the discussion above about printing from Python when running in parallel.

Third, use Python exception handling. For example, say this statement in your Python function is failing, because you have not initialized the variable `foo`:

```
foo += 1
```

If you put one (or more) statements inside a “try” statement, like this:

```
import exceptions
print("Inside simple function")
try:
    foo += 1      # one or more statements here
except Exception as e:
    print("FOO error:", e)
```

then you will get this message printed to the screen:

```
FOO error: local variable 'foo' referenced before assignment
```

If there is no error in the try statements, then nothing is printed. Either way the function continues on (unless you put a return or sys.exit() in the except clause).

### 1.83.4 Restrictions

This command is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Building LAMMPS with the PYTHON package will link LAMMPS with the Python library on your system. Settings to enable this are in the lib/python/Makefile.lammps file. See the lib/python/README file for information on those settings.

If you use Python code which calls back to LAMMPS, via the SELF input argument explained above, there is an extra step required when building LAMMPS. LAMMPS must also be built as a shared library and your Python function must be able to load the “*lammps*” *Python module* that wraps the LAMMPS library interface. These are the same steps required to use Python by itself to wrap LAMMPS. Details on these steps are explained on the [Python](#) doc page. Note that it is important that the stand-alone LAMMPS executable and the LAMMPS shared library be consistent (built from the same source code files) in order for this to work. If the two have been built at different times using different source files, problems may occur.

Another limitation of calling back to Python from the LAMMPS module using the *python* command in a LAMMPS input is that both, the Python interpreter and LAMMPS, must be linked to the same Python runtime as a shared library. If the Python interpreter is linked to Python statically (which seems to happen with Conda) then loading the shared LAMMPS library will create a second python “main” module that hides the one from the Python interpreter and all previous defined function and global variables will become invisible.

### 1.83.5 Related commands

*shell, variable, fix python/invoke*

### 1.83.6 Default

none

## 1.84 quit command

### 1.84.1 Syntax

```
quit status
```

status = numerical exit status (optional)

### 1.84.2 Examples

```
quit  
if "$n > 10000" then "quit 1"
```

### 1.84.3 Description

This command causes LAMMPS to exit, after shutting down all output cleanly.

It can be used as a debug statement in an input script, to terminate the script at some intermediate point.

It can also be used as an invoked command inside the “then” or “else” portion of an *if* command.

The optional status argument is an integer which signals the return status to a program calling LAMMPS. A return status of 0 usually indicates success. A status != 0 is failure, where the specified value can be used to distinguish the kind of error, e.g. where in the input script the quit was invoked. If not specified, a status of 0 is returned.

## 1.85 read\_data command

### 1.85.1 Syntax

```
read_data file keyword args ...
```

- file = name of data file to read in
- zero or more keyword/arg pairs may be appended

- keyword = *add* or *offset* or *shift* or *extra/atom/types* or *extra/bond/types* or *extra/angle/types* or *extra/dihedral/types* or *extra/improper/types* or *extra/bond/per/atom* or *extra/angle/per/atom* or *extra/dihedral/per/atom* or *extra/improper/per/atom* or *extra/special/per/atom* or *group* or *nocoeff* or *fix*

*add* arg = *append* or *IDoffset* or *IDoffset MOLOffset* or *merge*

*append* = add new atoms with atom IDs appended to current IDs

*IDoffset* = add new atoms with atom IDs having *IDoffset* added

*MOLOffset* = add new atoms with molecule IDs having *MOLOffset* added (only when *→molecule* IDs are enabled)

*merge* = add new atoms with their atom IDs (and molecule IDs) unchanged

*offset* args = *toff* *boff* *aoff* *doff* *ioff*

*toff* = offset to add to atom types

*boff* = offset to add to bond types

*aoff* = offset to add to angle types

*doff* = offset to add to dihedral types

*ioff* = offset to add to improper types

*shift* args = *Sx* *Sy* *Sz*

*Sx,Sy,Sz* = distance to shift atoms when adding to system (distance units)

*extra/atom/types* arg = # of extra atom types

*extra/bond/types* arg = # of extra bond types

*extra/angle/types* arg = # of extra angle types

*extra/dihedral/types* arg = # of extra dihedral types

*extra/improper/types* arg = # of extra improper types

*extra/bond/per/atom* arg = leave space for this many new bonds per atom

*extra/angle/per/atom* arg = leave space for this many new angles per atom

*extra/dihedral/per/atom* arg = leave space for this many new dihedrals per atom

*extra/improper/per/atom* arg = leave space for this many new impropers per atom

*extra/special/per/atom* arg = leave space for extra 1-2,1-3,1-4 interactions per atom

*group* args = *groupID*

*groupID* = add atoms in data file to this group

*nocoeff* = ignore force field parameters

*fix* args = *fix-ID* *header-string* *section-string*

*fix-ID* = ID of *fix* to process header lines and sections of data file

*header-string* = header lines containing this string will be passed to *fix*

*section-string* = section names with this string will be passed to *fix*

## 1.85.2 Examples

```
read_data data.lj
read_data ../run7/data.polymer.gz
read_data data.protein fix mycmap crossterm CMAP
read_data data.water add append offset 3 1 1 1 1 shift 0.0 0.0 50.0
read_data data.water add merge group solvent
```

### 1.85.3 Description

Read in a data file containing information LAMMPS needs to run a simulation. The file can be ASCII text or a gzipped text file (detected by a .gz suffix).

This is one of 3 ways to specify the simulation box: see the [create\\_box](#) and [read\\_restart](#) and commands for alternative methods. It is also one of 3 ways to specify initial atom coordinates: see the [create\\_atoms](#) and [read\\_restart](#) and commands for alternative methods. Also see the explanation of the [-restart command-line switch](#) which can convert a restart file to a data file.

This command can be used multiple times to add new atoms and their properties to an existing system by using the *add*, *offset*, and *shift* keywords. However, it is important to understand that several system parameters, like the number of types of different kinds and per atom settings are **locked in** after the first *read\_data* command, which means that no type ID (including its offset) may have a larger value when processing additional data files than what is set by the first data file and the corresponding *read\_data* command options. See more details on this situation below, which includes the use case for the *extra* keywords.

The *group* keyword adds all the atoms in the data file to the specified group-ID. The group will be created if it does not already exist. This is useful if you are reading multiple data files and wish to put sets of atoms into different groups so they can be operated on later. E.g. a group of added atoms can be moved to new positions via the [displace\\_atoms](#) command. Note that atoms read from the data file are also always added to the “all” group. The *group* command discusses atom groups, as used in LAMMPS.

The *nocoeff* keyword tells *read\_data* to ignore force field parameters. The various Coeff sections are still read and have to have the correct number of lines, but they are not applied. This also allows to read a data file without having any pair, bond, angle, dihedral or improper styles defined, or to read a data file for a different force field.

The use of the *fix* keyword is discussed below.

---

### 1.85.4 Reading multiple data files

The *read\_data* command can be used multiple times with the same or different data files to build up a complex system from components contained in individual data files. For example one data file could contain fluid in a confined domain; a second could contain wall atoms, and the second file could be read a third time to create a wall on the other side of the fluid. The third set of atoms could be rotated to an opposing direction using the [displace\\_atoms](#) command, after the third *read\_data* command is used.

The *add*, *offset*, *shift*, *extra*, and *group* keywords are useful in this context.

If a simulation box does not yet exist, the *add* keyword cannot be used; the *read\_data* command is being used for the first time. If a simulation box does exist, due to using the [create\\_box](#) command, or a previous *read\_data* command, then the *add* keyword must be used.

---

**Note:** If the first *read\_data* command defined an orthogonal or restricted triclinic or general triclinic simulation box (see the sub-section below on header keywords), then subsequent data files must define the same kind of simulation box. For orthogonal boxes, the new box can be a different size; see the next Note. For a restricted triclinic box, the 3 new tilt factors (“xy xz yz” keyword) must have the same values as in the original data file. For a general triclinic box, the new *avec*, *bvec*, *cvec*, and “abc origin” keywords must have the same values in the original data file. files. Also the *shift* keyword cannot be used in subsequent *read\_data* commands for a general triclinic box.

---

**Note:** For orthogonal boxes, the simulation box size in the new data file will be merged with the existing simulation box to create a large enough box in each dimension to contain both the existing and new atoms. Each box dimension never shrinks due to this merge operation, it only stays the same or grows. Care must be used if you are growing

the existing simulation box in a periodic dimension. If there are existing atoms with bonds that straddle that periodic boundary, then the atoms may become far apart if the box size grows. This will separate the atoms in the bond, which can lead to “lost” bond atoms or bad dynamics.

---

The three choices for the *add* argument affect how the atom IDs and molecule IDs of atoms in the data file are treated.

If *append* is specified, atoms in the data file are added to the current system, with their atom IDs reset so that an atom-ID = *M* in the data file becomes atom-ID = *N*+*M*, where *N* is the largest atom ID in the current system. This rule is applied to all occurrences of atom IDs in the data file, e.g. in the Velocity or Bonds section. This is also done for molecule IDs, if the atom style does support molecule IDs or they are enabled via *fix property/atom*.

If *IDoffset* is specified, then *IDoffset* is a numeric value is given, e.g. 1000, so that an atom-ID = *M* in the data file becomes atom-ID = 1000+*M*. For systems with enabled molecule IDs, another numerical argument *MOLOffset* is required representing the equivalent offset for molecule IDs.

If *merge* is specified, the data file atoms are added to the current system without changing their IDs. They are assumed to merge (without duplication) with the currently defined atoms. It is up to you to ensure there are no multiply defined atom IDs, as LAMMPS only performs an incomplete check that this is the case by ensuring the resulting max atom-ID  $\geq$  the number of atoms. For molecule IDs, there is no check done at all.

The *offset* and *shift* keywords can only be used if the *add* keyword is also specified.

The *offset* keyword adds the specified offset values to the atom types, bond types, angle types, dihedral types, and improper types as they are read from the data file. E.g. if *toff* = 2, and the file uses atom types 1,2,3, then the added atoms will have atom types 3,4,5. These offsets apply to all occurrences of types in the data file, e.g. for the Atoms or Masses or Pair Coeffs or Bond Coeffs sections. This makes it easy to use atoms and molecules and their attributes from a data file in different simulations, where you want their types (atom, bond, angle, etc) to be different depending on what other types already exist. All five offset values must be specified, but individual values will be ignored if the data file does not use that attribute (e.g. no bonds).

---

**Note:** Offsets are **ignored** on lines using type labels, as the type labels will determine the actual types directly depending on the current *labelmap* settings.

---

The *shift* keyword can be used to specify an (*Sx*, *Sy*, *Sz*) displacement applied to the coordinates of each atom. *Sz* must be 0.0 for a 2d simulation. This is a mechanism for adding structured collections of atoms at different locations within the simulation box, to build up a complex geometry. It is up to you to ensure atoms do not end up overlapping unphysically which would lead to bad dynamics. Note that the *displace\_atoms* command can be used to move a subset of atoms after they have been read from a data file. Likewise, the *delete\_atoms* command can be used to remove overlapping atoms. Note that the shift values (*Sx*, *Sy*, *Sz*) are also added to the simulation box information (*xlo*, *xhi*, *ylo*, *yhi*, *zlo*, *zhi*) in the data file to shift its boundaries. E.g. *xlo\_new* = *xlo* + *Sx*, *xhi\_new* = *xhi* + *Sx*.

The *extra* keywords can only be used the first time the *read\_data* command is used. They are useful if you intend to add new atom, bond, angle, etc types later with additional *read\_data* commands. This is because the maximum number of allowed atom, bond, angle, etc types is set by LAMMPS when the system is first initialized. If you do not use the *extra* keywords, then the number of these types will be limited to what appears in the first data file you read. For example, if the first data file is a solid substrate of Si, it will likely specify a single atom type. If you read a second data file with a different material (water molecules) that sit on top of the substrate, you will want to use different atom types for those atoms. You can only do this if you set the *extra/atom/types* keyword to a sufficiently large value when reading the substrate data file. Note that use of the *extra* keywords also allows each data file to contain sections like Masses or Pair Coeffs or Bond Coeffs which are sized appropriately for the number of types in that data file. If the *offset* keyword is used appropriately when each data file is read, the values in those sections will be stored correctly in the larger data structures allocated by the use of the *extra* keywords. E.g. the substrate file can list mass and pair coefficients for type 1 silicon atoms. The water file can list mass and pair coefficients for type 1 and type 2 hydrogen and oxygen atoms. Use of the *extra* and *offset* keywords will store those mass and pair coefficient values appropriately in data structures that allow for 3 atom types (Si, H, O). Of course, you would still need to specify coefficients for H/Si and O/Si interactions

in your input script to have a complete pairwise interaction model.

An alternative to using the *extra* keywords with the `read_data` command, is to use the `create_box` command to initialize the simulation box and all the various type limits you need via its *extra* keywords. Then use the `read_data` command one or more times to populate the system with atoms, bonds, angles, etc, using the *offset* keyword if desired to alter types used in the various data files you read.

---

### 1.85.5 Format of a data file

The structure of the data file is important, though many settings and sections are optional or can come in any order. See the examples directory for sample data files for different problems.

The file will be read line by line, but there is a limit of 254 characters per line and characters beyond that limit will be ignored.

A data file has a header and a body. The header appears first. The first line of the header and thus of the data file is *always* skipped; it typically contains a description of the file or a comment from the software that created the file.

Then lines are read one line at a time. Lines can have a trailing comment starting with '#' that is ignored. There *must* be at least one blank between any valid content and the comment. If a line is blank (i.e. contains only white-space after comments are deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is/are read from the line. A line that is *not* blank and does *not* contain a header keyword begins the body of the file.

The body of the file contains zero or more sections. The first line of a section has only a keyword. This line can have a trailing comment starting with '#' that is either ignored or can be used to check for a style match, as described below. There must be a blank between the keyword and any comment. The *next* line is *always* skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used *between* sections. Sections can appear in any order, with a few exceptions as noted below.

The keyword *fix* can be used one or more times. Each usage specifies a fix that will be used to process a specific portion of the data file. Any header line containing *header-string* and any section that is an exact match to *section-string* will be passed to the specified fix. See the `fix property/atom` command for an example of a fix that operates in this manner. The doc page for the fix defines the syntax of the header line(s) and section that it reads from the data file. Note that the *header-string* can be specified as NULL, in which case no header lines are passed to the fix. This means the fix can infer the length of its Section from standard header settings, such as the number of atoms. Also the *section-string* may be specified as NULL, and in that case the fix ID is used as section name.

The formatting of individual lines in the data file (indentation, spacing between words and numbers) is not important except that header and section keywords (e.g. atoms, xlo xhi, Masses, Bond Coeffs) must be capitalized as shown and cannot have extra white-space between their words - e.g. two spaces or a tab between the 2 words in "xlo xhi" or the 2 words in "Bond Coeffs", is not valid.

---

### 1.85.6 Format of the header of a data file

These are the recognized header keywords. Header lines can come in any order. Each keyword takes a single value unless noted in this list. The value(s) are read from the beginning of the line. Thus the keyword *atoms* should be in a line like "1000 atoms"; the keyword *ylo yhi* should be in a line like "-10.0 10.0 ylo yhi"; the keyword *xy xz yz* should be in a line like "0.0 5.0 6.0 xy xz yz".

All these settings have a default value of 0, except for the simulation box size settings; their defaults are explained below. A keyword line need only appear if its value is different than the default.

- *atoms* = # of atoms in system

- *bonds* = # of bonds in system
  - *angles* = # of angles in system
  - *dihedrals* = # of dihedrals in system
  - *impropers* = # of impropers in system
  - *atom types* = # of atom types in system
  - *bond types* = # of bond types in system
  - *angle types* = # of angle types in system
  - *dihedral types* = # of dihedral types in system
  - *improper types* = # of improper types in system
  - *extra bond per atom* = leave space for this many new bonds per atom (deprecated, use *extra/bond/per/atom* keyword)
  - *extra angle per atom* = leave space for this many new angles per atom (deprecated, use *extra/angle/per/atom* keyword)
  - *extra dihedral per atom* = leave space for this many new dihedrals per atom (deprecated, use *extra/dihedral/per/atom* keyword)
  - *extra improper per atom* = leave space for this many new impropers per atom (deprecated, use *extra/improper/per/atom* keyword)
  - *extra special per atom* = leave space for this many new special bonds per atom (deprecated, use *extra/special/per/atom* keyword)
  - *ellipsoids* = # of ellipsoids in system
  - *lines* = # of line segments in system
  - *triangles* = # of triangles in system
  - *bodies* = # of bodies in system
  - *xlo xhi* = simulation box boundaries in x dimension (2 values)
  - *ylo yhi* = simulation box boundaries in y dimension (2 values)
  - *zlo zhi* = simulation box boundaries in z dimension (2 values)
  - *xy xz yz* = simulation box tilt factors for triclinic system (3 values)
  - *avec* = first edge vector of a general triclinic simulation box (3 values)
  - *bvec* = second edge vector of a general triclinic simulation box (3 values)
  - *cvec* = third edge vector of a general triclinic simulation box (3 values)
  - *abc origin* = origin of a general triclinic simulation box (3 values)
-

### 1.85.7 Header specification of the simulation box size and shape

The last 8 keywords in the list of header keywords are for simulation boxes of 3 kinds which LAMMPS supports:

- orthogonal box = faces are perpendicular to the xyz coordinate axes
- restricted triclinic box = a parallelepiped defined by 3 edge vectors oriented in a constrained manner
- general triclinic box = a parallelepiped defined by 3 arbitrary edge vectors

For restricted and general triclinic boxes, see the [Howto\\_triclinic](#) doc page for a fuller description than is given here.

The units of the values for all 8 keywords are in distance units; see the [units](#) command for details.

For all 3 kinds of simulation boxes, the system may be periodic or non-periodic in any dimension; see the [boundary](#) command for details.

When the simulation box is created by the `read_data` command, it is also partitioned into a regular 3d grid of subdomains, one per processor, based on the number of processors being used and the settings of the [processors](#) command. For each kind of simulation box the subdomains have the same shape as the simulation box, i.e. smaller orthogonal bricks for orthogonal boxes, smaller parallelepipeds for triclinic boxes. The partitioning can later be changed by the [balance](#) or [fix balance](#) commands.

For an orthogonal box, only the `xlo xhi`, `ylo yhi`, `zlo zhi` keywords are used. They define the extent of the simulation box in each dimension so that the resulting edge vectors of an orthogonal box are:

- $\mathbf{A} = (xhi-xlo, 0, 0)$
- $\mathbf{B} = (0, yhi-ylo, 0)$
- $\mathbf{C} = (0, 0, zhi-zlo)$

The origin (lower left corner) of the orthogonal box is at  $(xlo, ylo, zlo)$ . The default values for these 3 keywords are -0.5 and 0.5 for each lo/hi pair. For a 2d simulation, the `zlo` and `zhi` values must straddle zero. The default `zlo/zhi` values do this, so that keyword is not needed in 2d.

For a restricted triclinic box, the `xy xz yz` keyword is used in addition to the `xlo xhi`, `ylo yhi`, `zlo zhi` keywords. The three `xy, xz, yz` values can be 0.0 or positive or negative, and are called “tilt factors” because they are the amount of displacement applied to edges of faces of an orthogonal box to transform it into a restricted triclinic parallelepiped.

The [Howto\\_triclinic](#) doc page discusses the tilt factors in detail and explains that the resulting edge vectors of a restricted triclinic box are:

- $\mathbf{A} = (xhi-xlo, 0, 0)$
- $\mathbf{B} = (xy, yhi-ylo, 0)$
- $\mathbf{C} = (xz, yz, zhi-zlo)$

This restricted form of edge vectors requires that  $\mathbf{A}$  be in the direction of the x-axis,  $\mathbf{B}$  be in the xy plane with its y-component in the +y direction, and  $\mathbf{C}$  have its z-component in the +z direction. The origin (lower left corner) of the restricted triclinic box is at  $(xlo, ylo, zlo)$ .

For a 2d simulation, the `zlo` and `zhi` values must straddle zero. The default `zlo/zhi` values do this, so that keyword is not needed in 2d. The `xz` and `yz` values must also be zero in 2d. The shape of the 2d restricted triclinic simulation box is effectively a parallelogram.

---

**Note:** When a restricted triclinic box is used, the simulation domain should normally be periodic in any dimensions that tilt is applied to, which is given by the second dimension of the tilt factor (e.g. y for xy tilt). This is so that pairs of atoms interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the [boundary](#) command which also describes the shifting by the tilt factor. For example, if the xy tilt factor is non-zero, then the y

dimension should be periodic. Similarly, the  $z$  dimension should be periodic if  $xz$  or  $yz$  is non-zero. LAMMPS does not require this periodicity, but you may lose atoms if this is not the case.

---

**Note:** Normally, the specified tilt factors ( $xy, xz, yz$ ) should not skew the simulation box by more than half the distance of the corresponding parallel box length for computational efficiency. For example, if  $x_{lo} = 2$  and  $x_{hi} = 12$ , then the  $x$  box length is 10 and the  $xy$  tilt factor should be between  $-5$  and  $5$ . LAMMPS will issue a warning if this is not the case. See the last sub-section of the [Howto\\_triclinic](#) doc page for more details.

---

---

**Note:** If a simulation box is initially orthogonal, but will tilt during a simulation, e.g. via the [fix deform](#) command, then the box should be defined as restricted triclinic with all 3 tilt factors = 0.0. Alternatively, the [change box](#) command can be used to convert an orthogonal box to a restricted triclinic box.

---

For a general triclinic box, the *avec*, *bvec*, *cvec*, and *abc origin* keywords are used. The *xlo xhi*, *ylo yhi*, *zlo zhi*, and *xy xz yz* keywords are NOT used. The first 3 keywords define the 3 edge vectors **A**, **B**, **C** of the general triclinic box. They can be arbitrary vectors so long as they are distinct, non-zero, and not co-planar. They must also define a right-handed system such that  $(\mathbf{A} \times \mathbf{B})$  points in the direction of **C**. Note that a left-handed system can be converted to a right-handed system by simply swapping the order of any pair of the **A**, **B**, **C** vectors. The origin of the box (origin of the 3 edge vectors) is set by the *abc origin* keyword.

The default values for these 4 keywords are as follows:

- *avec* = (1,0,0)
- *bvec* = (0,1,0)
- *cvec* = (0,0,1)
- *abc origin* = (0,0,0) for 3d, (0,0,-0.5) for 2d

For 2d simulations, *cvec* = (0,0,1) is required, and the 3rd value of *abc origin* must be -0.5. These are the default values, so the *cvec* keyword is not needed in 2d.

---

**Note:** LAMMPS allows specification of general triclinic simulation boxes as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the [Howto\\_triclinic](#) doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box and per-atom information (e.g. coordinates, velocities) in the data file are converted (rotated) from general to restricted triclinic form when the file is read. Other sections of the data file must also list their per-atom data appropriately if vector quantities are specified. This requirement is explained below for the relevant sections. The [Howto\\_triclinic](#) doc page also discusses other LAMMPS commands which can input/output general triclinic representations of the simulation box and per-atom data.

---

The following explanations apply to all 3 kinds of simulation boxes: orthogonal, restricted triclinic, and general triclinic.

If the system is periodic (in a dimension), then atom coordinates can be outside the bounds (in that dimension); they will be remapped (in a periodic sense) back inside the box. For triclinic boxes, periodicity in  $x, y, z$  refers to the faces of the parallelepiped defined by the **A**, **B**, **C** edge vectors of the simulation box. See the [boundary](#) command doc page for a fuller discussion.

Note that if the *add* option is being used to add atoms to a simulation box that already exists, this periodic remapping will be performed using simulation box bounds that are the union of the existing box and the box boundaries in the new data file.

If the system is non-periodic (in a dimension), then an image flag for that direction has no meaning, since there cannot be periodic images without periodicity and the data file is therefore - technically speaking - invalid. This situation

would happen when a data file was written with periodic boundaries and then read back for non-periodic boundaries. Accepting a non-zero image flag can lead to unexpected results for any operations and computations in LAMMPS that internally use unwrapped coordinates (for example computing the center of mass of a group of atoms). Thus all non-zero image flags for non-periodic dimensions will be reset to zero on reading the data file and LAMMPS will print a warning message, if that happens. This is equivalent to wrapping atoms individually back into the principal unit cell in that direction. This operation is equivalent to the behavior of the *change\_box command* when used to change periodicity.

If those atoms with non-zero image flags are involved in bonded interactions, this reset can lead to undesired changes, when the image flag values differ between the atoms, i.e. the bonded interaction straddles domain boundaries. For example a bond can become stretched across the unit cell if one of its atoms is wrapped to one side of the cell and the second atom to the other. In those cases the data file needs to be pre-processed externally to become valid again. This can be done by first unwrapping coordinates and then wrapping entire molecules instead of individual atoms back into the principal simulation cell and finally expanding the cell dimensions in the non-periodic direction as needed, so that the image flag would be zero.

---

**Note:** If the system is non-periodic (in a dimension), then all atoms in the data file must have coordinates (in that dimension) that are “greater than or equal to” the lo value and “less than or equal to” the hi value. If the non-periodic dimension is of style “fixed” (see the *boundary command*), then the atom coords must be strictly “less than” the hi value, due to the way LAMMPS assign atoms to processors. Note that you should not make the lo/hi values radically smaller/larger than the extent of the atoms. For example, if atoms extend from 0 to 50, you should not specify the box bounds as -10000 and 10000 unless you also use the *processors command*. This is because LAMMPS uses the specified box size to layout the 3d grid of processors. A huge (mostly empty) box will be sub-optimal for performance when using “fixed” boundary conditions (see the *boundary command*). When using “shrink-wrap” boundary conditions (see the *boundary command*), a huge (mostly empty) box may cause a parallel simulation to lose atoms when LAMMPS shrink-wraps the box around the atoms. The read\_data command will generate an error in this case.

---

### 1.85.8 Meaning of other header keywords

The “extra bond per atom” setting (angle, dihedral, improper) is only needed if new bonds (angles, dihedrals, impropers) will be added to the system when a simulation runs, e.g. by using the *fix bond/create* command. Using this header flag is deprecated; please use the *extra/bond/per/atom* keyword (and correspondingly for angles, dihedrals and impropers) in the read\_data command instead. Either will pre-allocate space in LAMMPS data structures for storing the new bonds (angles, dihedrals, impropers).

The “extra special per atom” setting is typically only needed if new bonds/angles/etc will be added to the system, e.g. by using the *fix bond/create* command. Or if entire new molecules will be added to the system, e.g. by using the *fix deposit* or *fix pour* commands, which will have more special 1-2,1-3,1-4 neighbors than any other molecules defined in the data file. Using this header flag is deprecated; please use the *extra/special/per/atom* keyword instead. Using this setting will pre-allocate space in the LAMMPS data structures for storing these neighbors. See the *special\_bonds* and *molecule* doc pages for more discussion of 1-2,1-3,1-4 neighbors.

---

**Note:** All of the “extra” settings are only applied in the first data file read and when no simulation box has yet been created; as soon as the simulation box is created (and read\_data implies that), these settings are *locked* and cannot be changed anymore. Please see the description of the *add* keyword above for reading multiple data files. If they appear in later data files, they are ignored.

---

The “ellipsoids” and “lines” and “triangles” and “bodies” settings are only used with *atom\_style ellipsoid or line or tri or body* and specify how many of the atoms are finite-size ellipsoids or lines or triangles or bodies; the remainder are point particles. See the discussion of ellipsoidflag and the *Ellipsoids* section below. See the discussion of lineflag

and the *Lines* section below. See the discussion of *triangleflag* and the *Triangles* section below. See the discussion of *bodyflag* and the *Bodies* section below.

---

**Note:** For *atom\_style template*, the molecular topology (bonds, angles, etc) is contained in the molecule templates read-in by the *molecule* command. This means you cannot set the *bonds*, *angles*, etc header keywords in the data file, nor can you define *Bonds*, *Angles*, etc sections as discussed below. You can set the *bond types*, *angle types*, etc header keywords, though it is not necessary. If specified, they must match the maximum values defined in any of the template molecules.

---

### 1.85.9 Format of the body of a data file

These are the section keywords for the body of the file.

- *Atoms*, *Velocities*, *Masses*, *Ellipsoids*, *Lines*, *Triangles*, *Bodies* = atom-property sections
- *Bonds*, *Angles*, *Dihedrals*, *Impropers* = molecular topology sections
- *Atom Type Labels*, *Bond Type Labels*, *Angle Type Labels*, *Dihedral Type Labels*, *Improper Type Labels* = type label maps
- *Pair Coeffs*, *PairIJ Coeffs*, *Bond Coeffs*, *Angle Coeffs*, *Dihedral Coeffs*, *Improper Coeffs* = force field sections
- *BondBond Coeffs*, *BondAngle Coeffs*, *MiddleBondTorsion Coeffs*, *EndBondTorsion Coeffs*, *AngleTorsion Coeffs*, *AngleAngleTorsion Coeffs*, *BondBond13 Coeffs*, *AngleAngle Coeffs* = class 2 force field sections

These keywords will check an appended comment for a match with the currently defined style:

- *Atoms*, *Pair Coeffs*, *PairIJ Coeffs*, *Bond Coeffs*, *Angle Coeffs*, *Dihedral Coeffs*, *Improper Coeffs*

For example, these lines:

```
Atoms # sphere
Pair Coeffs # lj/cut
```

will check if the currently-defined *atom\_style* is *sphere*, and the current *pair\_style* is *lj/cut*. If not, LAMMPS will issue a warning to indicate that the data file section likely does not contain the correct number or type of parameters expected for the currently-defined style.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for where it can appear in the data file.

Any individual line in the various sections can have a trailing comment starting with “#” for annotation purposes. There must be at least one blank between valid content and the comment. E.g. in the *Atoms* section:

```
10 1 17 -1.0 10.0 5.0 6.0 # salt ion
```

*Angle Coeffs* section:

- one line per angle type
- line syntax: ID coeffs

```
ID = angle type (1-N)
coeffs = list of coeffs
```

- example:

```
6 70 108.5 0 0
```

The number and meaning of the coefficients are specific to the defined angle style. See the [angle\\_style](#) and [angle\\_coeff](#) commands for details. Coefficients can also be set via the [angle\\_coeff](#) command in the input script.

---

*Angle Type Labels* section:

- one line per angle type
- line syntax: ID label

```
ID = angle type (1-N)  
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric angle type. These can be used in the Angles section in place of a numeric type, but only if this section appears before the Angles section.

See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*AngleAngle Coeffs* section:

- one line per improper type
- line syntax: ID coeffs

```
ID = improper type (1-N)  
coeffs = list of coeffs (see improper\_coeff)
```

*AngleAngleTorsion Coeffs* section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)  
coeffs = list of coeffs (see dihedral\_coeff)
```

*Angles* section:

- one line per angle
- line syntax: ID type atom1 atom2 atom3

```
ID = number of angle (1-Nangles)  
type = angle type (1-Nangletype, or type label)  
atom1,atom2,atom3 = IDs of 1st,2nd,3rd atom in angle
```

example:

```
2 2 17 29 430
```

The three atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list. E.g. H,O,H for a water molecule. The *Angles* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the *labelmap* command or an Angle Type Labels section earlier in the data file. See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*AngleTorsion Coeffs* section:

- one line per dihedral type
  - line syntax: ID coeffs
- ID = dihedral type (1-N)  
coeffs = list of coeffs (see [dihedral\\_coeff](#))
- 

*Atom Type Labels* section:

- one line per atom type
- line syntax: ID label

ID = numeric atom type (1-N)  
label = alphanumeric type label

Define alphanumeric type labels for each numeric atom type. These can be used in the Atoms section in place of a numeric type, but only if the Atom Type Labels section appears before the Atoms section.

See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*Atoms* section:

- one line per atom
- line syntax: depends on atom style

An *Atoms* section must appear in the data file if natoms > 0 in the header section. The atoms can be listed in any order. These are the line formats for each *atom style* in LAMMPS. As discussed below, each line can optionally have 3 flags (nx,ny,nz) appended to it, which indicate which image of a periodic simulation box the atom is in. These may be important to include for some kinds of analysis.

---

**Note:** For orthogonal and restricted and general triclinic simulation boxes, the atom coordinates (x,y,z) listed in this section should be inside the corresponding simulation box. For restricted triclinic boxes that means the parallelepiped defined by the *xlo xhi*, *ylo yhi*, *zlo zhi*, and *xy xz yz*, keywords. For general triclinic boxes that means the parallelepiped defined by the 3 edge vectors and origin specified by the *avec*, *bvec*, *cvec*, and *abc origin* header keywords. See the discussion in the header section above about how atom coordinates outside the simulation box are (or are not) remapped to be inside the box.

---

angle	atom-ID molecule-ID atom-type x y z

hybrid	atom-ID atom-type x y z sub-style1 sub-style2 ...

The per-atom values have these meanings and units, listed alphabetically:

- atom-ID = integer ID of atom
- atom-type = type of atom (1-Ntype, or type label)
- bodyflag = 1 for body particles, 0 for point particles
- ccN = chemical concentration for tDPD particles for each species (mole/volume units)
- cradius = contact radius for SMD particles (distance units)
- cs\_re,cs\_im = real/imaginary parts of wave packet coefficients
- cv = heat capacity (need units) for SPH particles
- density = density of particle (mass/distance<sup>3</sup> or mass/distance<sup>2</sup> or mass/distance units, depending on dimensionality of particle)
- diameter = diameter of spherical atom (distance units)
- edpd\_temp = temperature for eDPD particles (temperature units)
- edpd\_cv = volumetric heat capacity for eDPD particles (energy/temperature/volume units)
- ellipsoidflag = 1 for ellipsoidal particles, 0 for point particles
- eradius = electron radius (or fixed-core radius)
- esph = energy (need units) for SPH particles

- `espin` = electron spin (+1/-1), 0 = nuclei, 2 = fixed-core, 3 = pseudo-cores (i.e. ECP)
- `etag` = integer ID of electron that each wave packet belongs to
- `kradius` = kernel radius for SMD particles (distance units)
- `lineflag` = 1 for line segment particles, 0 for point or spherical particles
- `mass` = mass of particle (mass units)
- `molecule-ID` = integer ID of molecule the atom belongs to
- `mux,muy,muz` = components of dipole moment of atom (dipole units) (see general triclinic note below)
- `q` = charge on atom (charge units)
- `rho` = density (need units) for SPH particles
- `sp` = magnitude of magnetic spin of atom (Bohr magnetons)
- `spx,spy,spz` = components of magnetic spin of atom (unit vector) (see general triclinic note below)
- `template-atom` = which atom within a template molecule the atom is
- `template-index` = which molecule within the molecule template the atom is part of
- `theta` = internal temperature of a DPD particle
- `triangleflag` = 1 for triangular particles, 0 for point or spherical particles
- `volume` = volume of Peridynamic particle (distance<sup>3</sup> units)
- `x,y,z` = coordinates of atom (distance units)
- `x0,y0,z0` = original (strain-free) coordinates of atom (distance units) (see general triclinic note below)

The units for these quantities depend on the unit style; see the [units](#) command for details.

For 2d simulations, the atom coordinate `z` must be specified as 0.0. If the data file is created by another program, then `z` values for a 2d simulation can be within epsilon of 0.0, and LAMMPS will force them to zero.

---

**Note:** If the data file defines a general triclinic box, then the following per-atom values in the list above are per-atom vectors which imply an orientation: (`mux,muy,muz`) and (`spx,spy,spz`). This means they should be specified consistent with the general triclinic box and its orientation relative to the standard `x,y,z` coordinate axes. For example a dipole moment vector which will be in the `+x` direction once LAMMPS converts from a general to restricted triclinic box, should be specified in the data file in the direction of the **A** edge vector. Likewise the (`x0,y0,z0`) per-atom strain-free coordinates should be inside the general triclinic simulation box as explained in the note above. See the [Howto triclinic](#) doc page for more details.

---

The atom-ID is used to identify the atom throughout the simulation and in dump files. Normally, it is a unique value from 1 to `Natoms` for each atom. Unique values larger than `Natoms` can be used, but they will cause extra memory to be allocated on each processor, if an atom map array is used, but not if an atom map hash is used; see the [atom\\_modify](#) command for details. If an atom map is not used (e.g. an atomic system with no bonds), and you don't care if unique atom IDs appear in dump files, then the atom-IDs can all be set to 0.

The atom-type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the [labelmap](#) command or an Atom Type Labels section earlier in the data file. See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

The molecule ID is a second identifier attached to an atom. Normally, it is a number from 1 to `N`, identifying which molecule the atom belongs to. It can be 0 if it is a non-bonded atom or if you don't care to keep track of molecule assignments.

The diameter specifies the size of a finite-size spherical particle. It can be set to 0.0, which means that atom is a point particle.

The `ellipsoidflag`, `lineflag`, `triangleflag`, and `bodyflag` determine whether the particle is a finite-size ellipsoid or line or triangle or body of finite size, or whether the particle is a point particle. Additional attributes must be defined for each ellipsoid, line, triangle, or body in the corresponding *Ellipsoids*, *Lines*, *Triangles*, or *Bodies* section.

The `template-index` and `template-atom` are only defined used by `atom_style template`. In this case the `molecule` command is used to define a molecule template which contains one or more molecules (as separate files). If an atom belongs to one of those molecules, its `template-index` and `template-atom` are both set to positive integers; if not the values are both 0. The `template-index` is which molecule (1 to `Nmols`) the atom belongs to. The `template-atom` is which atom (1 to `Natoms`) within the molecule the atom is.

Some pair styles and fixes and computes that operate on finite-size particles allow for a mixture of finite-size and point particles. See the doc pages of individual commands for details.

For finite-size particles, the density is used in conjunction with the particle volume to set the mass of each particle as  $\text{mass} = \text{density} * \text{volume}$ . In this context, volume can be a 3d quantity (for spheres or ellipsoids), a 2d quantity (for triangles), or a 1d quantity (for line segments). If the volume is 0.0, meaning a point particle, then the density value is used as the mass. One exception is for the body atom style, in which case the mass of each particle (body or point particle) is specified explicitly. This is because the volume of the body is unknown.

Note that for 2d simulations of spheres, this command will treat them as spheres when converting density to mass. However, they can also be modeled as 2d discs (circles) if the `set density/disc` command is used to reset their mass after the `read_data` command is used. A `disc` keyword can also be used with time integration fixes, such as `fix nve/sphere` and `fix nvt/sphere` to time integrate their motion as 2d discs (not 3d spheres), by changing their moment of inertia.

For `atom_style hybrid`, following the 5 initial values (ID,type,x,y,z), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the `atom_style` command. The specific values for each sub-style are those that are not the 5 standard ones (ID,type,x,y,z). For example, for the “charge” sub-style, a “q” value would appear. For the “full” sub-style, a “molecule-ID” and “q” would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid charge sphere
```

were used in the input script, each atom line would have these fields:

```
atom-ID atom-type x y z q diameter density
```

Note that if a non-standard value is defined by multiple sub-styles, it only appears once in the atom line. E.g. the atom line for `atom_style hybrid dipole full` would list “q” only once, with the dipole sub-style fields; “q” does not appear with the full sub-style fields.

```
atom-ID atom-type x y z q mux muy myz molecule-ID
```

Atom lines specify the (x,y,z) coordinates of atoms. These can be inside or outside the simulation box. When the data file is read, LAMMPS wraps coordinates outside the box back into the box for dimensions that are periodic. As discussed above, if an atom is outside the box in a non-periodic dimension, it will be lost.

LAMMPS always stores atom coordinates as values which are inside the simulation box. It also stores 3 flags which indicate which image of the simulation box (in each dimension) the atom would be in if its coordinates were unwrapped across periodic boundaries. An image flag of 0 means the atom is still inside the box when unwrapped. A value of 2 means add 2 box lengths to get the unwrapped coordinate. A value of -1 means subtract 1 box length to get the unwrapped coordinate. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The `dump` command can output atom coordinates in wrapped or unwrapped form, as well as the 3 image flags.

In the data file, atom lines (all lines or none of them) can optionally list 3 trailing integer values (nx,ny,nz), which are used to initialize the atom’s image flags. If nx,ny,nz values are not listed in the data file, LAMMPS initializes them to

0. Note that the image flags are immediately updated if an atom's coordinates need to be wrapped back into the simulation box.

It is only important to set image flags correctly in a data file if a simulation model relies on unwrapped coordinates for some calculation; otherwise they can be left unspecified. Examples of LAMMPS commands that use unwrapped coordinates internally are as follows:

- Atoms in a rigid body (see [fix rigid](#), [fix rigid/small](#)) must have consistent image flags, so that when the atoms are unwrapped, they are near each other, i.e. as a single body.
- If the [replicate](#) command is used to generate a larger system, image flags must be consistent for bonded atoms when the bond crosses a periodic boundary. I.e. the values of the image flags should be different by 1 (in the appropriate dimension) for the two atoms in such a bond.
- If you plan to [dump](#) image flags and perform post-analysis that will unwrap atom coordinates, it may be important that a continued run (restarted from a data file) begins with image flags that are consistent with the previous run.

---

**Note:** If your system is an infinite periodic crystal with bonds then it is impossible to have fully consistent image flags. This is because some bonds will cross periodic boundaries and connect two atoms with the same image flag.

---

Atom velocities and other atom quantities not defined above are set to 0.0 when the *Atoms* section is read. Velocities can be set later by a *Velocities* section in the data file or by a [velocity](#) or [set](#) command in the input script.

---

*Bodies* section:

- one or more lines per body
- first line syntax: atom-ID Ninteger Ndouble

Ninteger = # of integer quantities for this particle  
 Ndouble = # of floating-point quantities for this particle

- 0 or more integer lines with total of Ninteger values
- 0 or more double lines with total of Ndouble values
- example:

```
12 3 6
2 3 2
1.0 2.0 3.0 1.0 2.0 4.0
```

- example:

```
12 0 14
1.0 2.0 3.0 1.0 2.0 4.0 1.0
2.0 3.0 1.0 2.0 4.0 4.0 2.0
```

The *Bodies* section must appear if [atom\\_style body](#) is used and any atoms listed in the *Atoms* section have a bodyflag = 1. The number of bodies should be specified in the header section via the “bodies” keyword.

Each body can have a variable number of integer and/or floating-point values. The number and meaning of the values is defined by the body style, as described in the [Howto body](#) doc page. The body style is given as an argument to the [atom\\_style body](#) command.

The Ninteger and Ndouble values determine how many integer and floating-point values are specified for this particle. Ninteger and Ndouble can be as large as needed and can be different for every body. Integer values are then listed

next on subsequent lines. Lines are read one at a time until Ninteger values are read. Floating-point values follow on subsequent lines. Again lines are read one at a time until Ndouble values are read. Note that if there are no values of a particular type, no lines appear for that type.

The *Bodies* section must appear after the *Atoms* section.

---

*Bond Coeffs* section:

- one line per bond type
- line syntax: ID coeffs

```
ID = bond type (1-N)
coeffs = list of coeffs
```

- example:

```
4 250 1.49
```

The number and meaning of the coefficients are specific to the defined bond style. See the [bond\\_style](#) and [bond\\_coeff](#) commands for details. Coefficients can also be set via the [bond\\_coeff](#) command in the input script.

---

*Bond Type Labels* section:

- one line per bond type
- line syntax: ID label

```
ID = bond type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric bond type. These can be used in the Bonds section in place of a numeric type, but only if this section appears before the Angles section.

See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*BondAngle Coeffs* section:

- one line per angle type
- line syntax: ID coeffs

```
ID = angle type (1-N)
coeffs = list of coeffs (see class 2 section of angle\_coeff)
```

*BondBond Coeffs* section:

- one line per angle type
- line syntax: ID coeffs

```
ID = angle type (1-N)
coeffs = list of coeffs (see class 2 section of angle\_coeff)
```

*BondBond13 Coeffs* section:

- one line per dihedral type
  - line syntax: ID coeffs  
ID = dihedral type (1-N)  
coeffs = list of coeffs (see class 2 section of [dihedral\\_coeff](#))
- 

*Bonds* section:

- one line per bond
- line syntax: ID type atom1 atom2

```
ID = bond number (1-Nbonds)
type = bond type (1-Nbondtype, or type label)
atom1,atom2 = IDs of 1st,2nd atom in bond
```

- example:

```
12 3 17 29
```

The *Bonds* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the [labelmap](#) command or a Bond Type Labels section earlier in the data file. See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*Dihedral Coeffs* section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs
```

- example:

```
3 0.6 1 0 1
```

The number and meaning of the coefficients are specific to the defined dihedral style. See the [dihedral\\_style](#) and [dihedral\\_coeff](#) commands for details. Coefficients can also be set via the [dihedral\\_coeff](#) command in the input script.

---

*Dihedral Type Labels* section:

- one line per dihedral type
- line syntax: ID label

```
ID = dihedral type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric dihedral type. These can be used in the Dihedrals section in place of a numeric type, but only if the this section appears before the Dihedrals section.

See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*Dihedrals* section:

- one line per dihedral
- line syntax: ID type atom1 atom2 atom3 atom4

```
ID = number of dihedral (1-Ndihedrals)
type = dihedral type (1-Ndihedraltype, or type label)
atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in dihedral
```

- example:

```
12 4 17 29 30 21
```

The 4 atoms are ordered linearly within the dihedral. The *Dihedrals* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the [labelmap](#) command or a Dihedral Type Labels section earlier in the data file. See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*Ellipsoids* section:

- one line per ellipsoid
- line syntax: atom-ID shapex shapey shapez quatw quati quatj quatk

```
atom-ID = ID of atom which is an ellipsoid
shapex,shapey,shapez = 3 diameters of ellipsoid (distance units)
quatw,quati,quatj,quatk = quaternion components for orientation of atom
```

- example:

```
12 1 2 1 1 0 0 0
```

The *Ellipsoids* section must appear if [atom\\_style ellipsoid](#) is used and any atoms are listed in the *Atoms* section with an ellipsoidflag = 1. The number of ellipsoids should be specified in the header section via the “ellipsoids” keyword.

The 3 shape values specify the 3 diameters or aspect ratios of a finite-size ellipsoidal particle, when it is oriented along the 3 coordinate axes. They must all be non-zero values.

The values *quatw*, *quati*, *quatj*, and *quatk* set the orientation of the atom as a quaternion (4-vector). Note that the shape attributes specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box’s x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle theta around a unit vector (a,b,c), then the quaternion that represents its new orientation is given by (cos(theta/2), a\*sin(theta/2), b\*sin(theta/2), c\*sin(theta/2)). These 4 components are quatw, quati, quatj, and quatk as specified above. LAMMPS normalizes each atom’s quaternion in case (a,b,c) is not specified as a unit vector.

If the data file defines a general triclinic box, then the quaternion for each ellipsoid should be specified for its orientation relative to the standard x,y,z coordinate axes. When the system is converted to a restricted triclinic box, the ellipsoid quaternions will be altered to reflect the new orientation of the ellipsoid.

The *Ellipsoids* section must appear after the *Atoms* section.

---

*EndBondTorsion Coeffs* section:

- one line per dihedral type
  - line syntax: ID coeffs  
ID = dihedral type (1-N)  
coeffs = list of coeffs (see class 2 section of [dihedral\\_coeff](#))
- 

*Improper Coeffs* section:

- one line per improper type
- line syntax: ID coeffs

```
ID = improper type (1-N)
coeffs = list of coeffs
```

- example:

```
2 20 0.0548311
```

The number and meaning of the coefficients are specific to the defined improper style. See the [improper\\_style](#) and [improper\\_coeff](#) commands for details. Coefficients can also be set via the [improper\\_coeff](#) command in the input script.

---

*Improper Type Labels* section:

- one line per improper type
- line syntax: ID label

```
ID = improper type (1-N)
label = alphanumeric type label
```

Define alphanumeric type labels for each numeric improper type. These can be used in the Improvers section in place of a numeric type, but only if this section appears before the Improvers section.

See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*Improvers* section:

- one line per improper
- line syntax: ID type atom1 atom2 atom3 atom4

```
ID = number of improper (1-Nimprovers)
type = improper type (1-Nimproptype, or type label)
atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in improper
```

- example:

```
12 3 17 29 13 100
```

The ordering of the 4 atoms determines the definition of the improper angle used in the formula for each *improper style*. See the doc pages for individual styles for details.

The *Impropers* section must appear after the *Atoms* section.

All values in this section must be integers (1, not 1.0). However, the type can be a numeric value or an alphanumeric label. The latter is only allowed if the type label has been defined by the *labelmap* command or a *Improper Type Labels* section earlier in the data file. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

---

*Lines* section:

- one line per line segment
- line syntax: atom-ID x1 y1 x2 y2

```
atom-ID = ID of atom which is a line segment
x1,y1 = 1st end point
x2,y2 = 2nd end point
```

- example:

```
12 1.0 0.0 2.0 0.0
```

The *Lines* section must appear if *atom\_style line* is used and any atoms are listed in the *Atoms* section with a *lineflag* = 1. The number of lines should be specified in the header section via the “lines” keyword.

The 2 end points are the end points of the line segment. They should be values close to the center point of the line segment specified in the *Atoms* section of the data file, even if individual end points are outside the simulation box.

The ordering of the 2 points should be such that using a right-hand rule to cross the line segment with a unit vector in the +z direction, gives an “outward” normal vector perpendicular to the line segment. I.e.  $\text{normal} = (c_2 - c_1) \times (0,0,1)$ . This orientation may be important for defining some interactions.

If the data file defines a general triclinic box, then the x1,y1 and x2,y2 values for each line segment should be specified for its orientation relative to the standard x,y,z coordinate axes. When the system is converted to a restricted triclinic box, the x1,y1,x2,y2 values will be altered to reflect the new orientation of the line segment.

The *Lines* section must appear after the *Atoms* section.

---

*Masses* section:

- one line per atom type
- line syntax: ID mass

```
ID = atom type (1-N or atom type label)
mass = mass value
```

- example:

```
3 1.01
```

This defines the mass of each atom type. This can also be set via the [mass](#) command in the input script. This section cannot be used for atom styles that define a mass for individual atoms - e.g. [atom\\_style sphere](#).

Using type labels instead of atom type numbers is only allowed if the type label has been defined by the [labelmap](#) command or a Atom Type Labels section earlier in the data file. See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

*MiddleBondTorsion Coeffs* section:

- one line per dihedral type
- line syntax: ID coeffs  
ID = dihedral type (1-N)  
coeffs = list of coeffs (see class 2 section of [dihedral\\_coeff](#))

*Pair Coeffs* section:

- one line per atom type
- line syntax: ID coeffs

```
ID = atom type (1-N)
coeffs = list of coeffs
```

- example:

```
3 0.022 2.35197 0.022 2.35197
```

The number and meaning of the coefficients are specific to the defined pair style. See the [pair\\_style](#) and [pair\\_coeff](#) commands for details. Since pair coefficients for types  $I \neq J$  are not specified, these will be generated automatically by the pair style's mixing rule. See the individual pair\_style doc pages and the [pair\\_modify mix](#) command for details. Pair coefficients can also be set via the [pair\\_coeff](#) command in the input script.

*PairIJ Coeffs* section:

- one line per pair of atom types for all I,J with  $I \leq J$
- line syntax: ID1 ID2 coeffs

```
ID1 = atom type I = 1-N
ID2 = atom type J = I-N, with I <= J
coeffs = list of coeffs
```

- examples:

```
3 3 0.022 2.35197 0.022 2.35197
3 5 0.022 2.35197 0.022 2.35197
```

This section must have  $N*(N+1)/2$  lines where  $N$  = # of atom types. The number and meaning of the coefficients are specific to the defined pair style. See the [pair\\_style](#) and [pair\\_coeff](#) commands for details. Since pair coefficients for types  $I \neq J$  are all specified, these values will turn off the default mixing rule defined by the pair style. See the individual pair\_style doc pages and the [pair\\_modify mix](#) command for details. Pair coefficients can also be set via the [pair\\_coeff](#) command in the input script.

*Triangles* section:

- one line per triangle
- line syntax: atom-ID x1 y1 z1 x2 y2 z2 x3 y3 z3

```
atom-ID = ID of atom which is a line segment
x1,y1,z1 = 1st corner point
x2,y2,z2 = 2nd corner point
x3,y3,z3 = 3rd corner point
```

- example:

```
12 0.0 0.0 0.0 2.0 0.0 1.0 0.0 2.0 1.0
```

The *Triangles* section must appear if *atom\_style tri* is used and any atoms are listed in the *Atoms* section with a triangleflag = 1. The number of lines should be specified in the header section via the “triangles” keyword.

The 3 corner points are the corner points of the triangle. They should be values close to the center point of the triangle specified in the *Atoms* section of the data file, even if individual corner points are outside the simulation box.

The ordering of the 3 points should be such that using a right-hand rule to go from point1 to point2 to point3 gives an “outward” normal vector to the face of the triangle. I.e.  $\text{normal} = (c2-c1) \times (c3-c1)$ . This orientation may be important for defining some interactions.

If the data file defines a general triclinic box, then the x1,y1,z1 and x2,y2,z2 and x3,y3,z3 values for each triangle should be specified for its orientation relative to the standard x,y,z coordinate axes. When the system is converted to a restricted triclinic box, the x1,y1,z1,x2,y2,z2,x3,y3,z3 values will be altered to reflect the new orientation of the triangle.

The *Triangles* section must appear after the *Atoms* section.

---

*Velocities* section:

- one line per atom
- line syntax: depends on atom style

all styles except those listed	atom-ID vx vy vz
electron	atom-ID vx vy vz ervel
ellipsoid	atom-ID vx vy vz lx ly lz
sphere	atom-ID vx vy vz wx wy wz
hybrid	atom-ID vx vy vz sub-style1 sub-style2 ...

where the keywords have these meanings:

```
vx,vy,vz = translational velocity of atom
lx,ly,lz = angular momentum of aspherical atom
wx,wy,wz = angular velocity of spherical atom
ervel = electron radial velocity (0 for fixed-core)
```

The velocity lines can appear in any order. This section can only be used after an *Atoms* section. This is because the *Atoms* section must have assigned a unique atom ID to each atom so that velocities can be assigned to them.

Vx, vy, vz, and ervel are in *units* of velocity. Lx, ly, lz are in units of angular momentum (distance-velocity-mass). Wx, Wy, Wz are in units of angular velocity (radians/time).

If the data file defines a general triclinic box, then each of the 3 vectors (translational velocity, angular momentum, angular velocity) should be specified for the rotated coordinate axes of the general triclinic box. See the [Howto triclinic](#) doc page for more details.

For atom\_style hybrid, following the 4 initial values (ID,vx,vy,vz), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the [atom\\_style](#) command. The sub-style specific values are those that are not the 5 standard ones (ID,vx,vy,vz). For example, for the “sphere” sub-style, “wx”, “wy”, “wz” values would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid electron sphere
```

were used in the input script, each velocity line would have these fields:

```
atom-ID vx vy vz ervel wx wy wz
```

Translational velocities can also be (re)set by the [velocity](#) command in the input script.

## 1.85.10 Restrictions

To read gzipped data files, you must compile LAMMPS with the -DLAMMPS\_GZIP option. See the [Build settings](#) doc page for details.

Label maps are currently not supported when using the KOKKOS package.

## 1.85.11 Related commands

[read\\_dump](#), [read\\_restart](#), [create\\_atoms](#), [write\\_data](#), [labelmap](#)

## 1.85.12 Default

The default for all the *extra* keywords is 0.

# 1.86 read\_dump command

## 1.86.1 Syntax

```
read_dump file Nstep field1 field2 ... keyword values ...
```

- file = name of dump file to read
- Nstep = snapshot timestep to read from file
- one or more fields may be appended

```
field = x or y or z or vx or vy or vz or q or ix or iy or iz or fx or fy or fz
x,y,z = atom coordinates
vx,vy,vz = velocity components
q = charge
ix,iy,iz = image flags in each dimension
fx,fy,fz = force components
```

- zero or more keyword/value pairs may be appended
- keyword = *nfile* or *box* or *timestep* or *replace* or *purge* or *trim* or *add* or *label* or *scaled* or *wrapped* or *format*

*nfile* value = *Nfiles* = how many parallel dump files exist

*box* value = *yes* or *no* = replace simulation box with dump box

*timestep* value = *yes* or *no* = reset simulation timestep with dump timestep

*replace* value = *yes* or *no* = overwrite atoms with dump atoms

*purge* value = *yes* or *no* = delete all atoms before adding dump atoms

*trim* value = *yes* or *no* = trim atoms not in dump snapshot

*add* value = *yes* or *keep* or *no* = add new dump atoms to system

*label* value = field column

field = one of the listed fields or *id* or *type*

column = label on corresponding column in dump file

*scaled* value = *yes* or *no* = coords in dump file are scaled/unscaled

*wrapped* value = *yes* or *no* = coords in dump file are wrapped/unwrapped

*format* values = format of dump file, must be last keyword if used

native = native LAMMPS dump file

xyz = XYZ file

*adios* [*timeout* value] = dump file written by the *dump adios* command

timeout = specify waiting time for the arrival of the timestep when running  
→concurrently.

The value is a float number and is interpreted in seconds.

*molfile* style path = VMD molfile plugin interface

style = *dcd* or *xyz* or others supported by molfile plugins

path = optional path for location of molfile plugins

## 1.86.2 Examples

```
read_dump dump.file 5000 x y z
read_dump dump.xyz 5 x y z box no format xyz
read_dump dump.xyz 10 x y z box no format molfile xyz "../plugins"
read_dump dump.dcd 0 x y z box yes format molfile dcd
read_dump dump.file 1000 x y z vx vy vz box yes format molfile lammprj /usr/local/lib/
→vmd/plugins/LINUXAMD64/plugins/molfile
read_dump dump.file 5000 x y vx vy trim yes
read_dump dump.file 5000 x y vx vy add yes box no timestep no
read_dump ../run7/dump.file.gz 10000 x y z box yes
read_dump dump.xyz 10 x y z box no format molfile xyz ../plugins
read_dump dump.dcd 0 x y z format molfile dcd
read_dump dump.file 1000 x y z vx vy vz format molfile lammprj /usr/local/lib/vmd/
→plugins/LINUXAMD64/plugins/molfile
read_dump dump.bp 5000 x y z vx vy vz format adios
read_dump dump.bp 5000 x y z vx vy vz format adios timeout 60.0
```

### 1.86.3 Description

Read atom information from a dump file to overwrite the current atom coordinates, and optionally the atom velocities and image flags, the simulation timestep, and the simulation box dimensions. This is useful for restarting a run from a particular snapshot in a dump file. See the [read\\_restart](#) and [read\\_data](#) commands for alternative methods to do this. Also see the [rerun](#) command for a means of reading multiple snapshots from a dump file.

Note that a simulation box must already be defined before using the `read_dump` command. This can be done by the [create\\_box](#), [read\\_data](#), or [read\\_restart](#) commands. The `read_dump` command can reset the simulation box dimensions, as explained below.

Also note that reading per-atom information from a dump snapshot is limited to the atom coordinates, velocities and image flags, as explained below. Other atom properties, which may be necessary to run a valid simulation, such as atom charge, or bond topology information for a molecular system, are not read from (or may not even be contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a [read\\_data](#) command, before using the `read_dump` command, or by the [set](#) command, after the dump snapshot is read.

---

If the dump filename specified as *file* ends with “.gz”, the dump file is read in gzipped format.

You can read dump files that were written (in parallel) to multiple files via the “%” wild-card character in the dump file name. If any specified dump file name contains a “%”, they must all contain it. See the [dump](#) command for details. The “%” wild-card character is only supported by the *native* format for dump files, described next.

If reading parallel dump files, you must also use the *nfile* keyword to tell LAMMPS how many parallel files exist, via its specified *Nfiles* value.

The format of the dump file is selected through the *format* keyword. If specified, it must be the last keyword used, since all remaining arguments are passed on to the dump reader. The *native* format is for native LAMMPS dump files, written with a [dump\\_atom](#) or [dump\\_custom](#) command. The *xyz* format is for generic XYZ formatted dump files. These formats take no additional values.

The *molfile* format supports reading data through using the [VMD](#) molfile plugin interface. This dump reader format is only available, if the MOLFILE package has been installed when compiling LAMMPS.

The *molfile* format takes one or two additional values. The *style* value determines the file format to be used and can be any format that the molfile plugins support, such as DCD or XYZ. Note that DCD dump files can be written by LAMMPS via the [dump\\_dcd](#) command. The *path* value specifies a list of directories which LAMMPS will search for the molfile plugins appropriate to the specified *style*. The syntax of the *path* value is like other search paths: it can contain multiple directories separated by a colon (or semicolon on windows). The *path* keyword is optional and defaults to “.”, i.e. the current directory.

The *adios* format supports reading data that was written by the [dump\\_adios](#) command. The entire dump is read in parallel across all the processes, dividing the atoms evenly among the processes. The number of writers that has written the dump file does not matter. Using the *adios* style for dump and `read_dump` is a convenient way to dump all atoms from *N* writers and read it back by *M* readers. If one is running two LAMMPS instances concurrently where one dumps data and the other is reading it with the `rerun` command, the *timeout* option can be specified to wait on the reader side for the arrival of the requested step.

Support for other dump format readers may be added in the future.

---

Global information is first read from the dump file, namely timestep and box information.

The dump file is scanned for a snapshot with a timestamp that matches the specified *Nstep*. This means the LAMMPS timestep the dump file snapshot was written on for the *native* or *adios* formats.

The list of timestamps available in an *adios* .bp file is stored in the variable *ntimestep*:

```
console
```

```
$ bpls dump.bp -d ntimestep
uint64_t ntimestep 5*scalar
(0)      0 50 100 150 200
```

Note that the *xyz* and *molfile* formats do not store the timestep. For these formats, timesteps are numbered logically, in a sequential manner, starting from 0. Thus to access the 10th snapshot in an *xyz* or *molfile* formatted dump file, use  $Nstep = 9$ .

The dimensions of the simulation box for the selected snapshot are also read; see the *box* keyword discussion below. For the *native* format, an error is generated if the snapshot is for a triclinic box and the current simulation box is orthogonal or vice versa. A warning will be generated if the snapshot box boundary conditions (periodic, shrink-wrapped, etc) do not match the current simulation boundary conditions, but the boundary condition information in the snapshot is otherwise ignored. See the “boundary” command for more details. The *adios* reader does the same as the *native* format reader.

For the *xyz* format, no information about the box is available, so you must set the *box* flag to *no*. See details below.

For the *molfile* format, reading simulation box information is typically supported, but the location of the simulation box origin is lost and no explicit information about periodicity or orthogonal/triclinic box shape is available. The MOLFILE package makes a best effort to guess based on heuristics, but this may not always work perfectly.

---

Per-atom information from the dump file snapshot is then read from the dump file snapshot. This corresponds to the specified *fields* listed in the *read\_dump* command. It is an error to specify a z-dimension field, namely *z*, *vz*, or *iz*, for a 2d simulation.

For dump files in *native* format, each column of per-atom data has a text label listed in the file. A matching label for each field must appear, e.g. the label “vy” for the field *vy*. For the *x*, *y*, *z* fields any of the following labels are considered a match:

```
x, xs, xu, xsu for field x
y, ys, yu, ysu for field y
z, zs, zu, zsu for field z
```

The meaning of *xs* (scaled), *xu* (unwrapped), and *xsu* (scaled and unwrapped) is explained on the [dump](#) command doc page. These labels are searched for in the list of column labels in the dump file, in order, until a match is found.

The dump file must also contain atom IDs, with a column label of “id”.

If the *add* keyword is specified with a value of *yes* or *keep*, as discussed below, the dump file must contain atom types, with a column label of “type”.

If a column label you want to read from the dump file is not a match to a specified field, the *label* keyword can be used to specify the specific column label from the dump file to associate with that field. An example is if a time-averaged coordinate is written to the dump file via the [fix ave/atom](#) command. The column will then have a label corresponding to the fix-ID rather than “x” or “xs”. The *label* keyword can also be used to specify new column labels for fields *id* and *type*.

For dump files in *xyz* format, only the *x*, *y*, and *z* fields are supported. The dump file does not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should ensure that order of atoms is consistent from snapshot to snapshot in the XYZ dump file. See the [dump\\_modify sort](#) command if the XYZ dump file was written by LAMMPS.

For dump files in *molfile* format, the *x*, *y*, *z*, *vx*, *vy*, and *vz* fields can be specified. However, not all molfile formats store velocities, or their respective plugins may not support reading of velocities. The molfile dump files do not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should

ensure that order of atoms are consistent from snapshot to snapshot in the molfile dump file. See the [dump\\_modify sort](#) command if the dump file was written by LAMMPS.

The *adios* format supports all fields that the *native* format supports except for the *q* charge field. The list of fields stored in an *adios* .bp file is recorded in the attributes *columns* (array of short strings) and *columnstr* (space-separated single string).

console

```
$ bpls -la dump.bp column*
  string      columns      attr  = {"id", "type", "x", "y", "z", "vx", "vy", "vz"}
  string      columnstr    attr  = "id type x y z vx vy vz "
```

Information from the dump file snapshot is used to overwrite or replace properties of the current system. There are various options for how this is done, determined by the specified fields and optional keywords.

Changed in version 3Aug2022.

The timestep of the snapshot becomes the current timestep for the simulation unless the *timestep* keyword is specified with a *no* value (default setting is *yes*). See the [reset\\_timestep](#) command if you wish to change this to a different value after the dump snapshot is read.

If the *box* keyword is specified with a *yes* value, then the current simulation box dimensions are replaced by the dump snapshot box dimensions. If the *box* keyword is specified with a *no* value, the current simulation box is unchanged.

If the *purge* keyword is specified with a *yes* value, then all current atoms in the system are deleted before any of the operations invoked by the *replace*, *trim*, or *add* keywords take place.

If the *replace* keyword is specified with a *yes* value, then atoms with IDs that are in both the current system and the dump snapshot have their properties overwritten by field values. If the *replace* keyword is specified with a *no* value, atoms with IDs that are in both the current system and the dump snapshot are not modified.

If the *trim* keyword is specified with a *yes* value, then atoms with IDs that are in the current system but not in the dump snapshot are deleted. These atoms are unaffected if the *trim* keyword is specified with a *no* value.

If the *add* keyword is specified with a *no* value (default), then dump file atoms with IDs that are not in the current system are not added to the system. They are simply ignored.

If a *yes* value is specified, the atoms with new IDs are added to the system but their atom IDs are not preserved. Instead, after all the atoms are added, new IDs are assigned to them in the same manner as is described for the [create\\_atoms](#) command. Basically the largest existing atom ID in the system is identified, and all the added atoms are assigned IDs that consecutively follow the largest ID.

If a *keep* value is specified, the atoms with new IDs are added to the system and their atom IDs are preserved. This may lead to non-contiguous IDs for the combined system.

Note that atoms added via the *add* keyword will only have the attributes read from the dump file due to the *field* arguments. For example, if *x* or *y* or *z* or *q* is not specified as a field, a value of 0.0 is used for added atoms. Added atoms must have an atom type, so this value must appear in the dump file.

Any other attributes (e.g. charge or particle diameter for spherical particles) will be set to default values, the same as if the [create\\_atoms](#) command were used.

Atom coordinates read from the dump file are first converted into unscaled coordinates, relative to the box dimensions of the snapshot. These coordinates are then be assigned to an existing or new atom in the current simulation. The coordinates will then be remapped to the simulation box, whether it is the original box or the dump snapshot box. If periodic boundary conditions apply, this means the atom will be remapped back into the simulation box if necessary.

If shrink-wrap boundary conditions apply, the new coordinates may change the simulation box dimensions. If fixed boundary conditions apply, the atom will be lost if it is outside the simulation box.

For *native* format dump files, the 3 xyz image flags for an atom in the dump file are set to the corresponding values appearing in the dump file if the *ix*, *iy*, *iz* fields are specified. If not specified, the image flags for replaced atoms are not changed and image flags for new atoms are set to default values. If coordinates read from the dump file are in unwrapped format (e.g. *xu*) then the image flags for read-in atoms are also set to default values. The remapping procedure described in the previous paragraph will then change image flags for all atoms (old and new) if periodic boundary conditions are applied to remap an atom back into the simulation box.

---

**Note:** If you get a warning about inconsistent image flags after reading in a dump snapshot, it means one or more pairs of bonded atoms now have inconsistent image flags. As discussed on the [Errors common](#) page this may or may not cause problems for subsequent simulations. One way this can happen is if you read image flag fields from the dump file but do not also use the dump file box parameters.

---

LAMMPS knows how to compute unscaled and remapped coordinates for the snapshot column labels discussed above, e.g. *x*, *xs*, *xu*, *xsu*. If another column label is assigned to the *x* or *y* or *z* field via the *label* keyword, e.g. for coordinates output by the [fix ave/atom](#) command, then LAMMPS needs to know whether the coordinate information in the dump file is scaled and/or wrapped. This can be set via the *scaled* and *wrapped* keywords. Note that the value of the *scaled* and *wrapped* keywords is ignored for fields *x* or *y* or *z* if the *label* keyword is not used to assign a column label to that field.

The scaled/unscaled and wrapped/unwrapped setting must be identical for any of the *x*, *y*, *z* fields that are specified. Thus you cannot read *xs* and *yu* from the dump file. Also, if the dump file coordinates are scaled and the simulation box is triclinic, then all 3 of the *x*, *y*, *z* fields must be specified, since they are all needed to generate absolute, unscaled coordinates.

---

## 1.86.4 Restrictions

To read gzipped dump files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option. See the [Build settings](#) doc page for details.

The *molfile* dump file formats are part of the MOLFILE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

To write and read adios .bp files, you must compile LAMMPS with the [ADIOS](#) package.

## 1.86.5 Related commands

*dump*, *dump molfile*, *dump adios*, *read\_data*, *read\_restart*, *rerun*

## 1.86.6 Default

The option defaults are `box = yes`, `timestep = yes`, `replace = yes`, `purge = no`, `trim = no`, `add = no`, `scaled = no`, `wrapped = yes`, and `format = native`.

## 1.87 read\_restart command

### 1.87.1 Syntax

```
read_restart file
```

- file = name of binary restart file to read in

### 1.87.2 Examples

```
read_restart save.10000
read_restart restart.*
```

### 1.87.3 Description

Read in a previously saved system configuration from a restart file. This allows continuation of a previous run. Details about what information is stored (and not stored) in a restart file is given below. Basically this operation will re-create the simulation box with all its atoms and their attributes as well as some related global settings, at the point in time it was written to the restart file by a previous simulation. The simulation box will be partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors in the current simulation and the settings of the *processors* command. The partitioning can later be changed by the *balance* or *fix balance* commands.

Deprecated since version 23Jun2022.

Atom coordinates that are found to be outside the simulation box when reading the restart will be remapped back into the box and their image flags updated accordingly. This previously required specifying the *remap* option, but that is no longer required.

Restart files are saved in binary format to enable exact restarts, meaning that the trajectories of a restarted run will precisely match those produced by the original run had it continued on.

Some information about a restart file can be gathered directly from the command line when using LAMMPS with the *-restart2info* command line flag. On Unix-like operating systems (like Linux or macOS), one can also *configure the "file" command line program* to display basic information about a restart file

The binary restart file format was not designed with backward, forward, or cross-platform compatibility in mind, so the files are only expected to be read correctly by the same LAMMPS executable on the same platform. Changes to the architecture, compilation settings, or LAMMPS version can render a restart file unreadable or it may read the data incorrectly. If you want a more portable format, you can use the data file format as created by the *write\_data* command. Binary restart files can also be converted into a data file from the command line by the LAMMPS executable that wrote them using the *-restart2data* command line flag.

Several things can prevent exact restarts due to round-off effects, in which case the trajectories in the 2 runs will slowly diverge. These include running on a different number of processors or changing certain settings such as those set by the *newton* or *processors* commands. LAMMPS will issue a warning in these cases.

Certain fixes will not restart exactly, though they should provide statistically similar results. These include *fix shake* and *fix langevin*.

Certain pair styles will not restart exactly, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities, which are used at half-step values every timestep when forces are computed. When a run restarts, forces are initially evaluated with a full-step velocity, which is different than if the run had continued. These pair styles include *granular pair styles*, *pair dpd*, and *pair lubricate*.

If a restarted run is immediately different than the run which produced the restart file, it could be a LAMMPS bug, so consider *reporting it* if you think the behavior is a bug.

Because restart files are binary, they may not be portable to other machines. In this case, you can use the *-restart command-line switch* to convert a restart file to a data file.

Similar to how restart files are written (see the *write\_restart* and *restart* commands), the restart filename can contain two wild-card characters. If a “\*” appears in the filename, the directory is searched for all filenames that match the pattern where “\*” is replaced with a timestep value. The file with the largest timestep value is read in. Thus, this effectively means, read the latest restart file. It’s useful if you want your script to continue a run from where it left off. See the *run* command and its “upto” option for how to specify the run command so it does not need to be changed either.

If a “%” character appears in the restart filename, LAMMPS expects a set of multiple files to exist. The *restart* and *write\_restart* commands explain how such sets are created. Read\_restart will first read a filename where “%” is replaced by “base”. This file tells LAMMPS how many processors created the set and how many files are in it. Read\_restart then reads the additional files. For example, if the restart file was specified as save.% when it was written, then read\_restart reads the files save.base, save.0, save.1, ... save.P-1, where P is the number of processors that created the restart file.

Note that P could be the total number of processors in the previous simulation, or some subset of those processors, if the *fileper* or *nfile* options were used when the restart file was written; see the *restart* and *write\_restart* commands for details. The processors in the current LAMMPS simulation share the work of reading these files; each reads a roughly equal subset of the files. The number of processors which created the set can be different the number of processors in the current LAMMPS simulation. This can be a fast mode of input on parallel machines that support parallel I/O.

---

Here is the list of information included in a restart file, which means these quantities do not need to be re-specified in the input script that reads the restart file, though you can redefine many of these settings after the restart file is read.

- *units*
- *newton bond* (see discussion of newton command below)
- *atom style* and *atom\_modify* settings id, map, sort
- *comm style* and *comm\_modify* settings mode, cutoff, vel
- *timestep size* and *timestep number*
- simulation box size and shape and *boundary* settings
- atom *group* definitions
- per-type atom settings such as *mass*
- per-atom attributes including their group assignments and molecular topology attributes (bonds, angles, etc)
- force field styles (*pair*, *bond*, *angle*, etc)
- force field coefficients (*pair*, *bond*, *angle*, etc) in some cases (see below)
- *pair\_modify* settings, except the compute option
- *special\_bonds* settings

Here is a list of information not stored in a restart file, which means you must re-issue these commands in your input script, after reading the restart file.

- *newton pair* (see discussion of newton command below)
- *fix* commands (see below)
- *compute* commands (see below)
- *variable* commands

- *region* commands
- *neighbor list* criteria including *neigh\_modify* settings
- *kpace\_style* and *kpace\_modify* settings
- info for *thermodynamic*, *dump*, or *restart* output

The *newton* command has two settings, one for pairwise interactions, the other for bonded. Both settings are stored in the restart file. For the bond setting, the value in the file will overwrite the current value (at the time the *read\_restart* command is issued) and warn if the two values are not the same and the current value is not the default. For the pair setting, the value in the file will not overwrite the current value (so that you can override the previous run's value), but a warning is issued if the two values are not the same and the current value is not the default.

Note that some force field styles (pair, bond, angle, etc) do not store their coefficient info in restart files. Typically these are many-body or tabulated potentials which read their parameters from separate files. In these cases you will need to re-specify the *pair\_coeff*, *bond\_coeff*, etc commands in your restart input script. The doc pages for individual force field styles mention if this is the case. This is also true of *pair\_style hybrid* (bond hybrid, angle hybrid, etc) commands; they do not store coefficient info.

As indicated in the above list, the *fixes* used for a simulation are not stored in the restart file. This means the new input script should specify all fixes it will use. However, note that some fixes store an internal “state” which is written to the restart file. This allows the fix to continue on with its calculations in a restarted simulation. To re-enable such a fix, the fix command in the new input script must be of the same style and use the same fix-ID as was used in the input script that wrote the restart file.

If a match is found, LAMMPS prints a message indicating that the fix is being re-enabled. If no match is found before the first run or minimization is performed by the new script, the “state” information for the saved fix is discarded. At the time the discard occurs, LAMMPS will also print a list of fixes for which the information is being discarded. See the doc pages for individual fixes for info on which ones can be restarted in this manner. Note that fixes which are created internally by other LAMMPS commands (computes, fixes, etc) will have style names which are all-capitalized, and IDs which are generated internally.

Likewise, the *computes* used for a simulation are not stored in the restart file. This means the new input script should specify all computes it will use. However, some computes create a fix internally to store “state” information that persists from timestep to timestep. An example is the *compute msd* command which uses a fix to store a reference coordinate for each atom, so that a displacement can be calculated at any later time. If the compute command in the new input script uses the same compute-ID and group-ID as was used in the input script that wrote the restart file, then it will create the same fix in the restarted run. This means the re-created fix will be re-enabled with the stored state information as described in the previous paragraph, so that the compute can continue its calculations in a consistent manner.

---

**Note:** There are a handful of commands which can be used before or between runs which may require a system initialization. Examples include the “balance”, “displace\_atoms”, “delete\_atoms”, “set” (some options), and “velocity” (some options) commands. This is because they can migrate atoms to new processors. Thus they will also discard unused “state” information from fixes. You will know the discard has occurred because a list of discarded fixes will be printed to the screen and log file, as explained above. This means that if you wish to retain that info in a restarted run, you must re-specify the relevant fixes and computes (which create fixes) before those commands are used.

---

Some pair styles, like the *granular pair styles*, also use a fix to store “state” information that persists from timestep to timestep. In the case of granular potentials, it is contact information between pairs of touching particles. This info will also be re-enabled in the restart script, assuming you re-use the same granular pair style.

LAMMPS allows bond interactions (angle, etc) to be turned off or deleted in various ways, which can affect how their info is stored in a restart file.

If bonds (angles, etc) have been turned off by the *fix shake* or *delete\_bonds* command, their info will be written to a restart file as if they are turned on. This means they will need to be turned off again in a new run after the restart file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are written to the restart file as broken bonds with a type of 0. Thus these bonds will still be broken when the restart file is read.

Bonds that have been broken by the *fix bond/break* command have disappeared from the system. No information about these bonds is written to the restart file.

```

### 1.88.3 Description

This command defines a geometric region of space. Various other commands use regions. For example, the region can be filled with atoms via the [create\\_atoms](#) command. Or a bounding box around the region, can be used to define the simulation box via the [create\\_box](#) command. Or the atoms in the region can be identified as a group via the [group](#) command, or deleted via the [delete\\_atoms](#) command. Or the surface of the region can be used as a boundary wall via the [fix wall/region](#) command.

Commands which use regions typically test whether an atom's position is contained in the region or not. For this purpose, coordinates exactly on the region boundary are considered to be interior to the region. This means, for example, for a spherical region, an atom on the sphere surface would be part of the region if the sphere were defined with the *side in* keyword, but would not be part of the region if it were defined using the *side out* keyword. See more details on the *side* keyword below.

Normally, regions in LAMMPS are “static”, meaning their geometric extent does not change with time. If the *move* or *rotate* keyword is used, as described below, the region becomes “dynamic”, meaning it's location or orientation changes with time. This may be useful, for example, when thermostatting a region, via the `compute temp/region` command, or when the `fix wall/region` command uses a region surface as a bounding wall on particle motion, i.e. a rotating container.

The *delete* style removes the named region. Since there is little overhead to defining extra regions, there is normally no need to do this, unless you are defining and discarding large numbers of regions in your input script.

The lo/hi values for *block* or *cone* or *cylinder* or *prism* styles can be specified as EDGE or INF. EDGE means they extend all the way to the global simulation box boundary. Note that this is the current box boundary; if the box changes size during a simulation, the region does not. INF means a large negative or positive number (1.0e20), so it should encompass the simulation box even if it changes size. If a region is defined before the simulation box has been created (via [create\\_box](#) or [read\\_data](#) or [read\\_restart](#) commands), then an EDGE or INF parameter cannot be used. For a *prism* region, a non-zero tilt factor in any pair of dimensions cannot be used if both the lo/hi values in either of those dimensions are INF. E.g. if the xy tilt is non-zero, then xlo and xhi cannot both be INF, nor can ylo and yhi.

---

**Note:** Regions in LAMMPS do not get wrapped across periodic boundaries, as specified by the [boundary](#) command. For example, a spherical region that is defined so that it overlaps a periodic boundary is not treated as 2 half-spheres, one on either side of the simulation box.

---

---

**Note:** Regions in LAMMPS are always 3d geometric objects, regardless of whether the [dimension](#) of a simulation is 2d or 3d. Thus when using regions in a 2d simulation, you should be careful to define the region so that its intersection with the 2d x-y plane of the simulation has the 2d geometric extent you want.

---

For style *cone*, an axis-aligned cone is defined which is like a *cylinder* except that two different radii (one at each end) can be defined. Either of the radii (but not both) can be 0.0.

For style *cone* and *cylinder*, the c1,c2 params are coordinates in the 2 other dimensions besides the cylinder axis dimension. For dim = x, c1/c2 = y/z; for dim = y, c1/c2 = x/z; for dim = z, c1/c2 = x/y. Thus the third example above specifies a cylinder with its axis in the y-direction located at x = 2.0 and z = 3.0, with a radius of 5.0, and extending in the y-direction from -5.0 to the upper box boundary.

New in version 4May2022.

For style *ellipsoid*, an axis-aligned ellipsoid is defined. The ellipsoid has its center at (x,y,z) and is defined by 3 axis-aligned vectors given by A = (a,0,0); B = (0,b,0); C = (0,0,c). Note that although the ellipsoid is specified as axis-aligned it can be rotated via the optional *rotate* keyword.

For style *plane*, a plane is defined which contain the point (px,py,pz) and has a normal vector (nx,ny,nz). The normal vector does not have to be of unit length. The “inside” of the plane is the half-space in the direction of the normal vector; see the discussion of the *side* option below.

For style *prism*, a parallelepiped is defined (it's too hard to spell parallelepiped in an input script!). The parallelepiped has its "origin" at  $(xlo,ylo,zlo)$  and is defined by 3 edge vectors starting from the origin given by  $A = (xhi-xlo,0,0)$ ;  $B = (xy,yhi-ylo,0)$ ;  $C = (xz,yz,zhi-zlo)$ .  $Xy,xz,yz$  can be 0.0 or positive or negative values and are called "tilt factors" because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

A prism region that will be used with the [create\\_box](#) command to define a triclinic simulation box must have tilt factors  $(xy,xz,yz)$  that do not skew the box more than half the distance of corresponding the parallel box length. For example, if  $xlo = 2$  and  $xhi = 12$ , then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between  $-(xhi-xlo)/2$  and  $+(yhi-ylo)/2$ . Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all geometrically equivalent.

For style *sphere*, a sphere is defined with its center at  $(x,y,z)$  and with radius as its radius.

The *radius* value for styles *sphere* and *cylinder*, and the parameters a,b,c for style *ellipsoid*, can each be specified as an equal-style [variable](#). Likewise, for style *sphere* and *ellipsoid* the x-, y-, and z- coordinates of the center of the sphere/ellipsoid can be specified as an equal-style variable. And for style *cylinder* the two center positions c1 and c2 for the location of the cylinder axes can be specified as a equal-style variable. For style *cone* all properties can be defined via equal-style variables.

If the value is a variable, it should be specified as `v_name`, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the radius of the region.

Equal-style variables can specify formulas with various mathematical functions, and include [thermo\\_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent radius or have a time dependent position of the sphere or cylinder region.

See the [Howto triclinic](#) page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

The *union* style creates a region consisting of the volume of all the listed regions combined. The *intersect* style creates a region consisting of the volume that is common to all the listed regions.

---

**Note:** The *union* and *intersect* regions operate by invoking methods from their list of sub-regions. Thus you cannot delete the sub-regions after defining a *union* or *intersection* region.

---

The *side* keyword determines whether the region is considered to be inside or outside of the specified geometry. Using this keyword in conjunction with *union* and *intersect* regions, complex geometries can be built up. For example, if the interior of two spheres were each defined as regions, and a *union* style with *side* = out was constructed listing the region-IDs of the 2 spheres, the resulting region would be all the volume in the simulation box that was outside both of the spheres.

The *units* keyword determines the meaning of the distance units used to define the region for any argument above listed as having distance units. It also affects the scaling of the velocity vector specified with the *vel* keyword, the amplitude vector specified with the *wiggle* keyword, and the rotation point specified with the *rotate* keyword, since they each involve a distance metric.

A *box* value selects standard distance units as defined by the [units](#) command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The [lattice](#) command must have been previously used to define the lattice spacings which are used as follows:

- For style *block*, the lattice spacing in dimension x is applied to xlo and xhi, similarly the spacings in dimensions y,z are applied to ylo/yhi and zlo/zhi.
- For style *cone*, the lattice spacing in argument *dim* is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The two cone radii are scaled by the lattice spacing in the dimension corresponding to c1.

- For style *cylinder*, the lattice spacing in argument *dim* is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The cylinder radius is scaled by the lattice spacing in the dimension corresponding to c1.
  - For style *ellipsoid*, the lattice spacing in dimensions x,y,z are applied to the ellipsoid center x,y,z. The spacing in dimensions x,y,z are applied to the ellipsoid radii a,b,c respectively.
  - For style *plane*, the lattice spacing in dimension x is applied to px and nx, similarly the spacings in dimensions y,z are applied to py/ny and pz/nz.
  - For style *prism*, the lattice spacing in dimension x is applied to xlo and xhi, similarly for ylo/yhi and zlo/zhi. The lattice spacing in dimension x is applied to xy and xz, and the spacing in dimension y to yz.
  - For style *sphere*, the lattice spacing in dimensions x,y,z are applied to the sphere center x,y,z. The spacing in dimension x is applied to the sphere radius.
- 

If the *move* or *rotate* keywords are used, the region is “dynamic”, meaning its location or orientation changes with time. These keywords cannot be used with a *union* or *intersect* style region. Instead, the keywords should be used to make the individual sub-regions of the *union* or *intersect* region dynamic. Normally, each sub-region should be “dynamic” in the same manner (e.g. rotate around the same point), though this is not a requirement.

The *move* keyword allows one or more *equal-style variables* to be used to specify the x,y,z displacement of the region, typically as a function of time. A variable is specified as v\_name, where name is the variable name. Any of the three variables can be specified as NULL, in which case no displacement is calculated in that dimension.

Note that equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a region displacement that change as a function of time or spans consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo\_style custom* for details.

For example, these commands would displace a region from its initial position, in the positive x direction, effectively at a constant velocity:

```
variable dx equal ramp(0,10)
region 2 sphere 10.0 10.0 0.0 5 move v_dx NULL NULL
```

Note that the initial displacement is 0.0, though that is not required.

Either of these variables would “wiggle” the region back and forth in the y direction:

```
variable dy equal swiggle(0,5,100)
variable dysame equal 5*sin(2*PI*elaplong*dt/100)
region 2 sphere 10.0 10.0 0.0 5 move NULL v_dy NULL
```

The *rotate* keyword rotates the region around a rotation axis  $R = (R_x, R_y, R_z)$  that goes through a point  $P = (P_x, P_y, P_z)$ . The rotation angle is calculated, presumably as a function of time, by a variable specified as v\_theta, where theta is the variable name. The variable should generate its result in radians. The direction of rotation for the region around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along  $R$ , then your fingers wrap around the axis in the direction of rotation.

The *move* and *rotate* keywords can be used together. In this case, the displacement specified by the *move* keyword is applied to the  $P$  point of the *rotate* keyword.

---

The *open* keyword can be used (multiple times) to indicate that one or more faces of the region are ignored for purposes of particle/wall interactions. This keyword is only relevant for regions used by the *fix wall/region* and *fix wall/gran/region* commands. It can be used to create “open” containers where only some of the region faces are walls.

For example, a funnel can be created with a *cone* style region that has an open face at the smaller radius for particles to flow out, or at the larger radius for pouring particles into the cone, or both.

Note that using the *open* keyword partly overrides the *side* keyword, since both exterior and interior surfaces of an open region are tested for particle contacts. The exception to this is a *union* or *intersect* region which includes an open sub-region. In that case the *side* keyword is still used to define the union/intersect region volume, and the *open* settings are only applied to the individual sub-regions that use them.

The indices specified as part of the *open* keyword have the following meanings:

For style *block*, indices 1-6 correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces of the block. I.e. 1 is the yz plane at  $x = xlo$ , 2 is the yz-plane at  $x = xhi$ , 3 is the xz plane at  $y = ylo$ , 4 is the xz plane at  $y = yhi$ , 5 is the xy plane at  $z = zlo$ , 6 is the xy plane at  $z = zhi$ ). In the second-to-last example above, the region is a box open at both xy planes.

For style *prism*, values 1-6 have the same mapping as for style *block*. I.e. in an untilted *prism*, *open* indices correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces.

For style *cylinder*, index 1 corresponds to the flat end cap at the low coordinate along the cylinder axis, index 2 corresponds to the high-coordinate flat end cap along the cylinder axis, and index 3 is the curved cylinder surface. For example, a *cylinder* region with *open 1 open 2* keywords will be open at both ends (e.g. a section of pipe), regardless of the cylinder orientation.

For style *cone*, the mapping is the same as for style *cylinder*. Index 1 is the low-coordinate flat end cap, index 2 is the high-coordinate flat end cap, and index 3 is the curved cone surface. In the last example above, a *cone* region is defined along the z-axis that is open at the zlo value (e.g. for use as a funnel).

For all other styles, the *open* keyword is ignored. As indicated above, this includes the *intersect* and *union* regions, though their sub-regions can be defined with the *open* keyword.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

**Note:** Currently, only *block* style regions are supported by Kokkos. The code using the region (such as a fix or compute) must also be supported by Kokkos or no acceleration will occur.

---

### 1.88.4 Restrictions

A prism cannot be of 0.0 thickness in any dimension; use a small z thickness for 2d simulations. For 2d simulations, the xz and yz parameters must be 0.0.

### 1.88.5 Related commands

*lattice, create\_atoms, delete\_atoms, group*

### 1.88.6 Default

The option defaults are side = in, units = lattice, and no move or rotation.

## 1.89 replicate command

### 1.89.1 Syntax

```
replicate nx ny nz keyword ...
```

nx,ny,nz = replication factors in each dimension

- zero or more keywords may be appended
- keyword = *bbox* or *bond/periodic*

*bbox* = use a bounding-box algorithm which is faster for large proc counts

*bond/periodic* = use an algorithm that correctly replicates periodic bond loops

### 1.89.2 Examples

For examples of replicating simple linear polymer chains (periodic or non-periodic) or periodic carbon nanotubes, see [examples/replicate](#).

```
replicate 2 3 2
replicate 2 3 2 bbox
replicate 2 3 2 bond/periodic
```

### 1.89.3 Description

Replicate the current system one or more times in each dimension. For example, replication factors of 2,2,2 will create a simulation with 8x as many atoms by doubling the size of the simulation box in each dimension. A replication factor of 1 leaves the simulation domain unchanged in that dimension.

When the new simulation box is created it is partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the *processors* command. The partitioning can be changed by subsequent *balance* or *fix balance* commands.

All properties of each atom are replicated (except per-atom fix data, see the Restrictions section below). This includes their velocities, which may or may not be desirable. New atom IDs are assigned to new atoms, as are new molecule

IDs. Bonds and other topology interactions are created between pairs of new atoms as well as between old and new atoms.

---

**Note:** The bond discussion which follows only refers to models with permanent covalent bonds typically defined in LAMMPS via a data file. It is not relevant to systems modeled with many-body potentials which can define bonds on-the-fly, based on the current positions of nearby atoms, e.g. models using the *AIREBO* or *ReaxFF* potentials.

---

If the *bond/periodic* keyword is not specified, bond replication is done by using the image flag for each atom to “unwrap” it out of the periodic box before replicating it. After replication is performed, atoms outside the new periodic box are wrapped back into it. This assigns correct images flags to all atoms in the system. For this to work, all original atoms in the original simulation box must have consistent image flags. This means that if two atoms have a bond between them which crosses a periodic boundary, their respective image flags will differ by 1 in that dimension.

Image flag consistency is not possible if a system has a periodic bond loop, meaning there is a chain of bonds which crosses an entire dimension and re-connects to itself across a periodic boundary. In this case you **MUST** use the *bond/periodic* keyword to correctly replicate the system. This option zeroes the image flags for all atoms and uses a different algorithm to find new (nearby) bond neighbors in the replicated system. In the final replicated system all image flags are zero (in each dimension).

---

**Note:** LAMMPS does not check for image flag consistency before performing the replication (it does issue a warning about this before a simulation is run). If the original image flags are inconsistent, the replicated system will also have inconsistent image flags, but will otherwise be correctly replicated. This is **NOT** the case if there is a periodic bond loop. See the next note.

---

---

**Note:** LAMMPS does not check for periodic bond loops. If you use the *bond/periodic* keyword for a system without periodic bond loops, the system will be correctly replicated, but image flag information will be lost (which may or may not be important to your model). If you do not use the *bond/periodic* keyword for a system with periodic bond loops, the replicated system will have invalid bonds (typically very long), resulting in bad dynamics.

---

If possible, the *bbox* keyword should be used when running on a large number of processors, as it can result in a substantial speed-up for the replication operation. It uses a bounding box to only check atoms in replicas that overlap with each processor’s new subdomain when assigning atoms to processors. It also preserves image flag information. The only drawback to the *bbox* option is that it requires a temporary use of more memory. Each processor must be able to store all atoms (and their per-atom data) in the original system, before it is replicated.

---

**Note:** The algorithm used by the *bond/periodic* keyword builds on the algorithm used by the *bbox* keyword and thus has the same memory requirements. If you specify only the *bond/periodic* keyword it will internally set the *bbox* keyword as well.

---

### 1.89.4 Restrictions

A 2d simulation cannot be replicated in the z dimension.

If a simulation is non-periodic in a dimension, care should be used when replicating it in that dimension, as it may generate atoms nearly on top of each other.

If the current simulation was read in from a restart file (before a run is performed), there must not be any fix information stored in the file for individual atoms. Similarly, no fixes can be defined at the time the replicate command is used that require vectors of atom information to be stored. This is because the replicate command does not know how to replicate that information for new atoms it creates.

To work around this restriction two options are possible. (1) Fixes which use the stored data in the restart file can be defined before replication and then deleted via the `unfix` command and re-defined after it. Or (2) the restart file can be converted to a data file (which deletes the stored fix information) and fixes defined after the replicate command. In both these scenarios, the per-atom fix information in the restart file is lost.

### 1.89.5 Related commands

none

### 1.89.6 Default

No settings for using the *bbox* or *bond/periodic* algorithms.

## 1.90 rerun command

### 1.90.1 Syntax

```
rerun file1 file2 ... keyword args ...
```

- file1,file2,... = dump file(s) to read
- one or more keywords may be appended, keyword *dump* must appear and be last

keyword = *first* or *last* or *every* or *skip* or *start* or *stop* or *post* or *dump*

*first* args = Nfirst

Nfirst = dump timestep to start on

*last* args = Nlast

Nlast = dumptimestep to stop on

*every* args = Nevery

Nevery = read snapshots matching every this many timesteps

*skip* args = Nskip

Nskip = read one out of every Nskip snapshots

*start* args = Nstart

Nstart = timestep on which pseudo run will start

*stop* args = Nstop

Nstop = timestep to which pseudo run will end

*post* value = *yes* or *no*

*dump* args = same as `read_dump` command starting with its field arguments

## 1.90.2 Examples

```
rerun dump.file dump x y z vx vy vz
rerun dump1.txt dump2.txt first 10000 every 1000 dump x y z
rerun dump.vels dump x y z vx vy vz box yes format molfile lammprj
rerun dump.dcd dump x y z box no format molfile dcd
rerun ../run7/dump.file.gz skip 2 dump x y z box yes
rerun dump.bp dump x y z box no format adios
rerun dump.bp dump x y z vx vy vz format adios timeout 10.0
```

## 1.90.3 Description

Perform a pseudo simulation run where atom information is read one snapshot at a time from a dump file(s), and energies and forces are computed on the snapshot to produce thermodynamic or other output.

This can be useful in the following kinds of scenarios, after an initial simulation produced the dump file:

- Compute the energy and forces of snapshots using a different potential.
- Calculate one or more diagnostic quantities on the snapshots that were not computed in the initial run. These can also be computed with settings not used in the initial run, e.g. computing an RDF via the *compute rdf* command with a longer cutoff than was used initially.
- Calculate the portion of per-atom forces resulting from a subset of the potential. E.g. compute only Coulombic forces. This can be done by only defining only a Coulombic pair style in the rerun script. Doing this in the original script would result in different (bad) dynamics.

Conceptually, using the rerun command is like running an input script that has a loop in it (see the *next* and *jump* commands). Each iteration of the loop reads one snapshot from the dump file via the *read\_dump* command, sets the timestep to the appropriate value, and then invokes a *run* command for zero timesteps to simply compute energy and forces, and any other *thermodynamic output* or diagnostic info you have defined. This computation also invokes any fixes you have defined that apply constraints to the system, such as *fix shake* or *fix indent*.

Note that a simulation box must already be defined before using the rerun command. This can be done by the *create\_box*, *read\_data*, or *read\_restart* commands.

Also note that reading per-atom information from dump snapshots is limited to the atom coordinates, velocities and image flags as explained in the *read\_dump* command. Other atom properties, which may be necessary to compute energies and forces, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a *read\_data* command, before using the rerun command.

Also note that the frequency of thermodynamic or dump output from the rerun simulation will depend on settings made in the rerun script, the same as for output from any LAMMPS simulation. See further info below as to what that means if the timesteps for snapshots read from dump files do not match the specified output frequency.

If more than one dump file is specified, the dump files are read one after the other in the order specified. It is assumed that snapshot timesteps will be in ascending order. If a snapshot is encountered that is not in ascending order, it will skip the snapshot until it reads one that is. This allows skipping of a duplicate snapshot (same timestep), e.g. that appeared at the end of one file and beginning of the next. However if you specify a series of dump files in an incorrect order (with respect to the timesteps they contain), you may skip large numbers of snapshots.

Note that the dump files specified as part of the *dump* keyword can be parallel files, i.e. written as multiple files either per processor and/or per snapshot. If that is the case they will also be read in parallel which can make the rerun command operate dramatically faster for large systems. See the page for the *read\_dump* and *dump* commands which describe how to read and write parallel dump files.

The *first*, *last*, *every*, *skip* keywords determine which snapshots are read from the dump file(s). Snapshots are skipped until they have a timestep  $\geq N_{first}$ . When a snapshot with a timestep  $> N_{last}$  is encountered, the rerun command finishes. Note that the defaults for *first* and *last* are to read all snapshots. If the *every* keyword is set to a value  $> 0$ , then only snapshots with timesteps that are a multiple of *Nevery* are read (the first snapshot is always read). If *Nevery* = 0, then this criterion is ignored, i.e. every snapshot is read that meets the other criteria. If the *skip* keyword is used, then after the first snapshot is read, every Nth snapshot is read, where  $N = N_{skip}$ . E.g. if *Nskip* = 3, then only 1 out of every 3 snapshots is read, assuming the snapshot timestep is also consistent with the other criteria.

---

**Note:** Not all dump formats contain the timestep and not all dump readers support reading it. In that case individual snapshots are assigned consecutive timestep numbers starting at 1.

---

The *start* and *stop* keywords do not affect which snapshots are read from the dump file(s). Rather, they have the same meaning that they do for the *run* command. They only need to be defined if (a) you are using a *fix* command that changes some value over time, and (b) you want the reference point for elapsed time (from start to stop) to be different than the *first* and *last* settings. See the page for individual fixes to see which ones can be used with the *start/stop* keywords. Note that if you define neither of the *start/stop* or *first/last* keywords, then LAMMPS treats the pseudo run as going from 0 to a huge value (effectively infinity). This means that any quantity that a fix scales as a fraction of elapsed time in the run, will essentially remain at its initial value. Also note that an error will occur if you read a snapshot from the dump file with a timestep value larger than the *stop* setting you have specified.

The *post* keyword can be used to minimize the output to the screen that happens after a *rerun* command, similar to the *post* keyword of the *run* command. It is set to *no* by default.

The *dump* keyword is required and must be the last keyword specified. Its arguments are passed internally to the *read\_dump* command. The first argument following the *dump* keyword should be the *field1* argument of the *read\_dump* command. See the *read\_dump* page for details on the various options it allows for extracting information from the dump file snapshots, and for using that information to alter the LAMMPS simulation.

---

In general, a LAMMPS input script that uses a rerun command can include and perform all the usual operations of an input script that uses the *run* command. There are a few exceptions and points to consider, as discussed here.

Fixes that perform time integration, such as *fix nve* or *fix npt* are not invoked, since no time integration is performed. Fixes that perturb or constrain the forces on atoms will be invoked, just as they would during a normal run. Examples are *fix indent* and *fix langevin*. So you should think carefully as to whether that makes sense for the manner in which you are reprocessing the dump snapshots.

If you only want the rerun script to perform an analysis that does not involve pair interactions, such as use compute msd to calculated displacements over time, you do not need to define a *pair style*, which may also mean neighbor lists will not need to be calculated which saves time. The *comm\_modify cutoff* command can also be used to ensure ghost atoms are acquired from far enough away for operations like bond and angle evaluations, if no pair style is being used.

Every time a snapshot is read, the timestep for the simulation is reset, as if the *reset\_timestep* command were used. This command has some restrictions as to what fixes can be defined. See its documentation page for details. For example, the *fix deposit* and *fix dt/reset* fixes are in this category. They also make no sense to use with a rerun command.

If time-averaging fixes like *fix ave/time* are used, they are invoked on timesteps that are a function of their *Nevery*, *Nrepeat*, and *Nfreq* settings. As an example, see the *fix ave/time* page for details. You must ensure those settings are consistent with the snapshot timestamps that are read from the dump file(s). If an averaging fix is not invoked on a timestep it expects to be, LAMMPS will flag an error.

The various forms of LAMMPS output, as defined by the *thermo\_style*, *thermo*, *dump*, and *restart* commands occur with specified frequency, e.g. every N steps. If the timestep for a dump snapshot is not a multiple of N, then it will be read and processed, but no output will be produced. If you want output for every dump snapshot, you can simply use *N=1* for an output frequency, e.g. for thermodynamic output or new dump file output.

---

## 1.90.4 Restrictions

The *rerun* command is subject to all restrictions of the *read\_dump* command.

## 1.90.5 Related commands

*read\_dump*

## 1.90.6 Default

The option defaults are first = 0, last = a huge value (effectively infinity), start = same as first, stop = same as last, every = 0, skip = 1, post = no;

# 1.91 reset\_atoms command

## 1.91.1 Syntax

```
reset_atoms property arguments ...
```

- property = *id* or *image* or *mol*
- additional arguments depend on the property

```
reset_atoms id keyword value ...
```

- zero or more keyword/value pairs can be appended
- keyword = *sort*
- sort* value = *yes* or *no*

```
reset_atoms image group-ID
```

- group-ID = ID of group of atoms whose image flags will be reset

```
reset_atoms mol group-ID keyword value ...
```

- group-ID = ID of group of atoms whose molecule IDs will be reset
- zero or more keyword/value pairs can be appended
- keyword = *compress* or *offset* or *single*
- compress* value = *yes* or *no*
- offset* value = *Offset* >= -1
- single* value = *yes* or *no* to treat single atoms (no bonds) as molecules

### 1.91.2 Examples

```
reset_atoms id
reset_atoms id sort yes
reset_atoms image all
reset_atoms image mobile
reset_atoms mol all
reset_atoms mol all offset 10 single yes
reset_atoms mol solvent compress yes offset 100
reset_atoms mol solvent compress no
```

### 1.91.3 Description

New in version 22Dec2022.

The `reset_atoms` command resets the values of a specified atom property. In contrast to the `set` command, it does this in a collective manner which resets the values for many atoms in a self-consistent way. This command is often useful when the simulated system has undergone significant modifications like adding or removing atoms or molecules, joining data files, changing bonds, or large-scale diffusion.

The new values can be thought of as a *reset*, similar to values atoms would have if a new data file were being read or a new simulation performed. Note that the `set` command also resets atom properties to new values, but it treats each atom independently.

The *property* setting can be *id* or *image* or *mol*. For *id*, the IDs of all the atoms are reset to contiguous values. For *image*, the image flags of atoms in the specified *group-ID* are reset so that at least one atom in each molecule is in the simulation box (image flag = 0). For *mol*, the molecule IDs of all atoms are reset to contiguous values.

More details on these operations and their arguments or optional keyword/value settings are given below.

---

Property: *id*

Reset atom IDs for the entire system, including all the global IDs stored for bond, angle, dihedral, improper topology data. This will create a set of IDs that are numbered contiguously from 1 to N for a N atoms system.

This can be useful to do after performing a “delete\_atoms” command for a molecular system. The delete\_atoms compress yes option will not perform this operation due to the existence of bond topology. It can also be useful to do after any simulation which has lost atoms, e.g. due to atoms moving outside a simulation box with fixed boundaries (see the “boundary command”), or due to evaporation (see the “fix evaporate” command).

If the *sort* keyword is used with a setting of *yes*, then the assignment of new atom IDs will be the same no matter how many processors LAMMPS is running on. This is done by first doing a spatial sort of all the atoms into bins and sorting them within each bin. Because the set of bins is independent of the number of processors, this enables a consistent assignment of new IDs to each atom.

This can be useful to do after using the “create\_atoms” command and/or “replicate” command. In general those commands do not guarantee assignment of the same atom ID to the same physical atom when LAMMPS is run on different numbers of processors. Enforcing consistent IDs can be useful for debugging or comparing output from two different runs.

Note that the spatial sort requires communication of atom IDs and coordinates between processors in an all-to-all manner. This is done efficiently in LAMMPS, but it is more expensive than how atom IDs are reset without sorting.

Note that whether sorting or not, the resetting of IDs is not a compression, where gaps in atom IDs are removed by decrementing atom IDs that are larger. Instead the IDs for all atoms are erased, and new IDs are assigned so that the atoms owned by an individual processor have consecutive IDs, as the `create_atoms` command explains.

**Note:** If this command is used before a *pair style* is defined, an error about bond topology atom IDs not being found may result. This is because the cutoff distance for ghost atom communication was not sufficient to find atoms in bonds, angles, etc that are owned by other processors. The *comm\_modify cutoff* command can be used to correct this issue. Or you can define a pair style before using this command. If you do the former, you should unset the *comm\_modify cutoff* after using *reset atoms id* so that subsequent communication is not inefficient.

---

Property: *image*

Reset the image flags of atoms so that at least one atom in each molecule has an image flag of 0. Molecular topology is respected so that if the molecule straddles a periodic simulation box boundary, the images flags of all atoms in the molecule will be consistent. This avoids inconsistent image flags that could result from resetting all image flags to zero with the *set* command.

**Note:** If the system has no bonds, there is no reason to use this command, since image flags for different atoms do not need to be consistent. Use the *set* command with its *image* keyword instead.

---

Only image flags for atoms in the specified *group-ID* are reset; all others remain unchanged. No check is made for whether the group covers complete molecule fragments and thus whether the command will result in inconsistent image flags.

Molecular fragments are identified by the algorithm used by the *compute fragment/atom* command. For each fragment the average of the largest and the smallest image flag in each direction across all atoms in the fragment is computed and subtracted from the current image flag in the same direction.

This can be a useful operation to perform after running longer equilibration runs of mobile systems where molecules would pass through the system multiple times and thus produce non-zero image flags.

**Note:** Same as explained for the *compute fragment/atom* command, molecules are identified using the current bond topology. This will **not** account for bonds broken by the *bond\_style quartic* command, because this bond style does not perform a full update of the bond topology data structures within LAMMPS. In that case, using the *delete\_bonds all bond 0 remove* will permanently delete such broken bonds and should thus be used first.

---

Property: *mol*

Reset molecule IDs for a specified group of atoms based on current bond connectivity. This will typically create a new set of molecule IDs for atoms in the group. Only molecule IDs for atoms in the specified *group-ID* are reset; molecule IDs for atoms not in the group are not changed.

For purposes of this operation, molecules are identified by the current bond connectivity in the system, which may or may not be consistent with the current molecule IDs. A molecule in this context is a set of atoms connected to each other with explicit bonds. The specific algorithm used is the one of *compute fragment/atom*. Once the molecules are identified and a new molecule ID computed for each, this command will update the current molecule ID for all atoms in the group with the new molecule ID. Note that if the group excludes atoms within molecules, one (physical) molecule may become two or more (logical) molecules. For example if the group excludes atoms in the middle of a linear chain, then each end of the chain is considered an independent molecule and will be assigned a different molecule ID.

This can be a useful operation to perform after running reactive molecular dynamics run with *fix bond/react*, *fix bond/create*, or *fix bond/break*, all of which can change molecule topologies. It can also be useful after molecules have been deleted with the *delete\_atoms* command or after a simulation which has lost molecules, e.g. via the *fix evaporate* command.

The *compress* keyword determines how new molecule IDs are computed. If the setting is *yes* (the default) and there are *N* molecules in the group, the new molecule IDs will be a set of *N* contiguous values. See the *offset* keyword for details on selecting the range of these values. If the setting is *no*, the molecule ID of every atom in the molecule will be set to the smallest atom ID of any atom in the molecule.

The *single* keyword determines whether single atoms (not bonded to another atom) are treated as one-atom molecules or not, based on the *yes* or *no* setting. If the setting is *no* (the default), their molecule IDs are set to 0. This setting can be important if the new molecule IDs will be used as input to other commands such as *compute chunk/atom molecule* or *fix rigid molecule*.

The *offset* keyword is only used if the *compress* setting is *yes*. Its default value is *Noffset* = -1. In that case, if the specified group is *all*, then the new compressed molecule IDs will range from 1 to *N*. If the specified group is not *all* and the largest molecule ID of atoms outside that group is *M*, then the new compressed molecule IDs will range from *M*+1 to *M*+*N*, to avoid collision with existing molecule IDs. If an *Noffset* >= 0 is specified, then the new compressed molecule IDs will range from *Noffset*+1 to *Noffset*+*N*. If the group is not *all* there may be collisions with the molecule IDs of other atoms.

---

**Note:** Same as explained for the *compute fragment/atom* command, molecules are identified using the current bond topology. This will **not** account for bonds broken by the *bond\_style quartic* command, because this bond style does not perform a full update of the bond topology data structures within LAMMPS. In that case, using the *delete\_bonds all bond 0 remove* will permanently delete such broken bonds and should thus be used first.

---

## 1.91.4 Restrictions

The *image* property can only be used when the atom style supports bonds.

## 1.91.5 Related commands

*compute fragment/atom*, *fix bond/react*, *fix bond/create*, *fix bond/break*, *fix evaporate*, *delete\_atoms*, *delete\_bonds*

## 1.91.6 Defaults

For property *id*, the default keyword setting is *sort* = *no*.

For property *mol*, the default keyword settings are *compress* = *yes*, *single* = *no*, and *offset* = -1.

# 1.92 reset\_timestep command

## 1.92.1 Syntax

**reset\_timestep** *N* keyword values ...

- *N* = timestep number
- zero or more keyword/value pairs may be appended
- keyword = *time*
  - time* value = *atime*
  - atime* = accumulated simulation time

## 1.92.2 Examples

```
reset_timestep 0
reset_timestep 40000000
reset_timestep 1000 time 100.0
```

## 1.92.3 Description

Set the timestep counter to the specified value. This command usually comes after the timestep has been set by reading a restart file via the [read\\_restart](#) command, or a previous simulation run or minimization advanced the timestep.

The optional *time* keyword allows to also set the accumulated simulation time. This is usually the number of timesteps times the size of the timestep, but when using variable size timesteps with [fix dt/reset](#) it can differ.

The [read\\_data](#) and [create\\_box](#) commands set the timestep to 0; the [read\\_restart](#) command sets the timestep to the value it had when the restart file was written. The same applies to the accumulated simulation time.

## 1.92.4 Restrictions

This command cannot be used when any fixes are defined that keep track of elapsed time to perform certain kinds of time-dependent operations. Examples are the [fix deposit](#) and [fix dt/reset](#) commands. The former adds atoms on specific timesteps. The latter keeps track of accumulated time.

Various fixes use the current timestep to calculate related quantities. If the timestep is reset, this may produce unexpected behavior, but LAMMPS allows the fixes to be defined even if the timestep is reset. For example, commands which thermostat the system, e.g. [fix nvt](#), allow you to specify a target temperature which ramps from Tstart to Tstop which may persist over several runs. If you change the timestep, you may induce an instantaneous change in the target temperature.

Resetting the timestep clears flags for [computes](#) that may have calculated some quantity from a previous run. This means these quantity cannot be accessed by a variable in between runs until a new run is performed. See the [variable](#) command for more details.

## 1.92.5 Related commands

*rerun, timestep, fix dt/reset*

## 1.92.6 Default

none

# 1.93 restart command

## 1.93.1 Syntax

```
restart 0
restart N root keyword value ...
restart N file1 file2 keyword value ...
```

- N = write a restart file on timesteps which are multiples of N
- N can be a variable (see below)
- root = filename to which timestep # is appended
- file1,file2 = two full filenames, toggle between them when writing file
- zero or more keyword/value pairs may be appended
- keyword = *fileper* or *nfile*

*fileper* arg = Np

Np = write one file for every this many processors

*nfile* arg = Nf

Nf = write this many files, one from each of Nf processors

### 1.93.2 Examples

```
restart 0
restart 1000 poly.restart
restart 1000 restart.*.equil
restart 10000 poly.%1 poly.%2 nfile 10
restart v_mystep poly.restart
```

### 1.93.3 Description

Write out a binary restart file with the current state of the simulation on timesteps which are a multiple of N. A value of N = 0 means do not write out any restart files, which is the default. Restart files are written in one (or both) of two modes as a run proceeds. If one filename is specified, a series of filenames will be created which include the timestep in the filename. If two filenames are specified, only 2 restart files will be created, with those names. LAMMPS will toggle between the 2 names as it writes successive restart files.

Note that you can specify the restart command twice, once with a single filename and once with two filenames. This would allow you, for example, to write out archival restart files every 100000 steps using a single filename, and more frequent temporary restart files every 1000 steps, using two filenames. Using restart 0 will turn off both modes of output.

Similar to *dump* files, the restart filename(s) can contain two wild-card characters.

If a “\*” appears in the single filename, it is replaced with the current timestep value. This is only recognized when a single filename is used (not when toggling back and forth). Thus, the third example above creates restart files as follows: restart.1000.equil, restart.2000.equil, etc. If a single filename is used with no “\*”, then the timestep value is appended. E.g. the second example above creates restart files as follows: poly.restart.1000, poly.restart.2000, etc.

If a “%” character appears in the restart filename(s), then one file is written for each processor and the “%” character is replaced with the processor ID from 0 to P-1. An additional file with the “%” replaced by “base” is also written, which contains global information. For example, the files written on step 1000 for filename restart.% would be restart.base.1000, restart.0.1000, restart.1.1000, ..., restart.P-1.1000. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional *fileper* and *nfile* keywords discussed below can alter the number of files written.

Restart files are written on timesteps that are a multiple of N but not on the first timestep of a run or minimization. You can use the *write\_restart* command to write a restart file before a run begins. A restart file is not written on the last timestep of a run unless it is a multiple of N. A restart file is written on the last timestep of a minimization if N > 0 and the minimization converges.

Instead of a numeric value, N can be specified as an *equal-style variable*, which should be specified as v\_name, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a restart file will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for *equal-style variables*, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for *equal-style variables*.

For example, the following commands will write restart files every step from 1100 to 1200, and could be useful for debugging a simulation where something goes wrong at step 1163:

```
variable      s equal stride(1100,1200,1)
restart       v_s tmp.restart
```

---

See the *read\_restart* command for information about what is stored in a restart file.

Restart files can be read by a *read\_restart* command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the *-r command-line switch* to convert a restart file to a data file.

---

**Note:** Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. See the *read\_restart* command for information about what is stored in a restart file.

---

The optional *nfile* or *fileper* keywords can be used in conjunction with the “%” wildcard character in the specified restart file name(s). As explained above, the “%” character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The *nfile* or *fileper* keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The *nfile* keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the *fileper* keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

---

## 1.93.4 Restrictions

none

### 1.93.5 Related commands

*write\_restart, read\_restart*

### 1.93.6 Default

```
restart 0
```

## 1.94 run command

### 1.94.1 Syntax

```
run N keyword values ...
```

- N = # of timesteps
- zero or more keyword/value pairs may be appended
- keyword = *upto* or *start* or *stop* or *pre* or *post* or *every*

*upto* value = none

*start* value = N1

N1 = timestep at which 1st run started

*stop* value = N2

N2 = timestep at which last run will end

*pre* value = *no* or *yes*

*post* value = *no* or *yes*

*every* values = M c1 c2 ...

M = break the run into M-timestep segments and invoke one or more commands.

→ between each segment

c1,c2,...,cN = one or more LAMMPS commands, each enclosed in quotes

c1 = NULL means no command will be invoked

### 1.94.2 Examples

```
run 10000
run 1000000 upto
run 100 start 0 stop 1000
run 1000 pre no post yes
run 100000 start 0 stop 1000000 every 1000 "print 'Protein Rg = $r'"
run 100000 every 1000 NULL
```

### 1.94.3 Description

Run or continue dynamics for a specified number of timesteps.

When the *run style* is *respa*, N refers to outer loop (largest) timesteps.

A value of N = 0 is acceptable; only the thermodynamics of the system are computed and printed without taking a timestep.

The *upto* keyword means to perform a run starting at the current timestep up to the specified timestep. E.g. if the current timestep is 10,000 and “run 100000 upto” is used, then an additional 90,000 timesteps will be run. This can be useful for very long runs on a machine that allocates chunks of time and terminate your job when time is exceeded. If you need to restart your script multiple times (reading in the last restart file), you can keep restarting your script with the same run command until the simulation finally completes.

The *start* or *stop* keywords can be used if multiple runs are being performed and you want a *fix* command that changes some value over time (e.g. temperature) to make the change across the entire set of runs and not just a single run. See the page for individual fixes to see which ones can be used with the *start/stop* keywords.

For example, consider this fix followed by 10 run commands:

```
fix          1 all nvt 200.0 300.0 1.0
run          1000 start 0 stop 10000
run          1000 start 0 stop 10000
...
run          1000 start 0 stop 10000
```

The NVT fix ramps the target temperature from 200.0 to 300.0 during a run. If the run commands did not have the start/stop keywords (just “run 1000”), then the temperature would ramp from 200.0 to 300.0 during the 1000 steps of each run. With the start/stop keywords, the ramping takes place over the 10000 steps of all runs together.

The *pre* and *post* keywords can be used to streamline the setup, clean-up, and associated output to the screen that happens before and after a run. This can be useful if you wish to do many short runs in succession (e.g. LAMMPS is being called as a library which is doing other computations between successive short LAMMPS runs).

By default (*pre* and *post* = yes), LAMMPS creates neighbor lists, computes forces, and imposes fix constraints before every run. And after every run it gathers and prints timings statistics. If a run is just a continuation of a previous run (i.e. no settings are changed), the initial computation is not necessary; the old neighbor list is still valid as are the forces. So if *pre* is specified as “no” then the initial setup is skipped, except for printing thermodynamic info. Note that if *pre* is set to “no” for the very first run LAMMPS performs, then it is overridden, since the initial setup computations must be done.

---

**Note:** If your input script changes the system between 2 runs, then the initial setup must be performed to ensure the change is recognized by all parts of the code that are affected. Examples are adding a *fix* or *dump* or *compute*, changing a *neighbor* list parameter, or writing restart file which can migrate atoms between processors. LAMMPS has no easy way to check if this has happened, but it is an error to use the *pre no* option in this case.

---

If *post* is specified as “no”, the full timing summary is skipped; only a one-line summary timing is printed.

The *every* keyword provides a means of breaking a LAMMPS run into a series of shorter runs. Optionally, one or more LAMMPS commands (c1, c2, ..., cN) will be executed in between the short runs. If used, the *every* keyword must be the last keyword, since it has a variable number of arguments. Each of the trailing arguments is a single LAMMPS command, and each command should be enclosed in quotes, so that the entire command will be treated as a single argument. This will also prevent any variables in the command from being evaluated until it is executed multiple times during the run. Note that if a command itself needs one of its arguments quoted (e.g. the *print* command), then you can use a combination of single and double quotes, as in the example above or below.

The *every* keyword is a means to avoid listing a long series of runs and interleaving commands in your input script. For example, a *print* command could be invoked or a *fix* could be redefined, e.g. to reset a thermostat temperature. Or this could be useful for invoking a command you have added to LAMMPS that wraps some other code (e.g. as a library) to perform a computation periodically during a long LAMMPS run. See the *Modify* doc page for info about how to add new commands to LAMMPS. See the *Howto couple* page for ideas about how to couple LAMMPS to other codes.

With the *every* option, N total steps are simulated, in shorter runs of M steps each. After each M-length run, the specified commands are invoked. If only a single command is specified as NULL, then no command is invoked. Thus these lines:

```
variable q equal x[100]
run 6000 every 2000 "print 'Coord = $q'"
```

are the equivalent of:

```
variable q equal x[100]
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
```

which does 3 runs of 2000 steps and prints the x-coordinate of a particular atom between runs. Note that the variable “\$q” will be evaluated afresh each time the print command is executed.

Note that by using the line continuation character “&”, the run every command can be spread across many lines, though it is still a single command:

```
run 100000 every 1000 &
  "print 'Minimum value = $a'" &
  "print 'Maximum value = $b'" &
  "print 'Temp = $c'" &
  "print 'Press = $d'"
```

If the *pre* and *post* options are set to “no” when used with the *every* keyword, then the first run will do the full setup and the last run will print the full timing summary, but these operations will be skipped for intermediate runs.

---

**Note:** You might wish to specify a command that exits the run by jumping out of the loop, e.g.

---

```
variable t equal temp
run 10000 every 100 "if '$t < 300.0' then 'jump SELF afterrun'"
```

However, this will not work. The run command simply executes each command one at a time each time it pauses, then continues the run.

Instead, you should use the *fix halt* command, which has additional options for how to exit the run.

### 1.94.4 Restrictions

When not using the *upto* keyword, the number of specified timesteps *N* must fit in a signed 32-bit integer, so you are limited to slightly more than 2 billion steps ( $2^{31}$ ) in a single run. When using *upto*, *N* can be larger than a signed 32-bit integer, however the difference between *N* and the current timestep must still be no larger than  $2^{31}$  steps.

However, with or without the *upto* keyword, you can perform successive runs to run a simulation for any number of steps (ok, up to  $2^{63}$  total steps). I.e. the timestep counter within LAMMPS is a 64-bit signed integer.

### 1.94.5 Related commands

*minimize*, *run\_style*, *temper*, *fix halt*

### 1.94.6 Default

The option defaults are start = the current timestep, stop = current timestep + *N*, pre = yes, and post = yes.

## 1.95 run\_style command

### 1.95.1 Syntax

*M* = which level (1-*N*) to compute pair middle forces in

```
cut1 = inner cutoff between pair middle and pair outer (distance units)
cut2 = outer cutoff between pair middle and pair outer (distance units)
outer value = M
M = which level (1-N) to compute pair outer forces in
hybrid values = M1 M2 ... (as many values as there are hybrid sub-styles
M1 = which level (1-N) to compute the first pair_style hybrid sub-style in
M2 = which level (1-N) to compute the second pair_style hybrid sub-style in
M3,etc
kspace value = M
M = which level (1-N) to compute kspace forces in
```

## 1.95.2 Examples

```
run_style verlet
run_style respa 4 2 2 2 bond 1 dihedral 2 pair 3 kspace 4
run_style respa 4 2 2 2 bond 1 dihedral 2 inner 3 5.0 6.0 outer 4 kspace 4
run_style respa 3 4 2 bond 1 hybrid 2 2 1 kspace 3
```

## 1.95.3 Description

Choose the style of time integrator used for molecular dynamics simulations performed by LAMMPS.

The *verlet* style is the velocity form of the Stoermer-Verlet time integration algorithm (velocity-Verlet)

---

The *verlet/split* style is also a velocity-Verlet integrator, but it splits the force calculation within each timestep over 2 partitions of processors. See the *-partition command-line switch* for info on how to run LAMMPS with multiple partitions.

Specifically, this style performs all computation except the *kspace\_style* portion of the force field on the first partition. This include the *pair style*, *bond style*, *neighbor list building*, *fixes* including time integration, and output. The *kspace\_style* portion of the calculation is performed on the second partition.

This can lead to a significant speedup, if the number of processors can be easily increased and the fraction of time is spent in computing Kspace interactions is significant, too. The two partitions may have a different number of processors. This is most useful for the PPPM *kspace\_style* when its performance on a large number of processors degrades due to the cost of communication in its 3d FFTs. In this scenario, splitting your P total processors into 2 subsets of processors, P1 in the first partition and P2 in the second partition, can enable your simulation to run faster. This is because the long-range forces in PPPM can be calculated at the same time as pairwise and bonded forces are being calculated *and* the parallel 3d FFTs can be faster to compute when running on fewer processors. Please note that the scenario of using fewer MPI processes to reduce communication overhead can also be implemented through using MPI with OpenMP threads via the INTEL, KOKKOS, or OPENMP package. This alternative option is typically more effective in case of a fixed number of available processors and less complex to execute.

To use the *verlet/split* style, you must define 2 partitions with the *-partition command-line switch*, where partition P1 is either the same size or an integer multiple of the size of the partition P2. Typically having P1 be 3x larger than P2 is a good choice, since the (serial) performance of LAMMPS is often best if the time spent in the Pair computation versus Kspace is a 3:1 split. The 3d processor layouts in each partition must overlay in the following sense. If P1 is a Px1 by Py1 by Pz1 grid, and P2 = Px2 by Py2 by Pz2, then Px1 must be an integer multiple of Px2, and similarly for Py1 a multiple of Py2, and Pz1 a multiple of Pz2.

Typically the best way to do this is to let the first partition choose its own optimal layout, then require the second partition's layout to match the integer multiple constraint. See the *processors* command with its *part* keyword for a way to control this, e.g.

```
processors * * * part 1 2 multiple
```

You can also use the *partition* command to explicitly specify the processor layout on each partition. E.g. for 2 partitions of 60 and 15 processors each:

```
partition yes 1 processors 3 4 5
partition yes 2 processors 3 1 5
```

When you run in 2-partition mode with the *verlet/split* style, the thermodynamic data for the entire simulation will be output to the log and screen file of the first partition, which are log.lammps.0 and screen.0 by default; see the *-plog and -pscreen command-line switches* to change this. The log and screen file for the second partition will not contain thermodynamic output beyond the first timestep of the run.

See the *Accelerator packages* page for performance details of the speed-up offered by the *verlet/split* style. One important performance consideration is the assignment of logical processors in the 2 partitions to the physical cores of a parallel machine. The *processors* command has options to support this, and strategies are discussed in *Section 5* of the manual.

The *respa* style implements the rRESPA multi-timescale integrator (*Tuckerman*) with N hierarchical levels, where level 1 is the innermost loop (shortest timestep) and level N is the outermost loop (largest timestep). The loop factor arguments specify what the looping factor is between levels. N1 specifies the number of iterations of level 1 for a single iteration of level 2, N2 is the iterations of level 2 per iteration of level 3, etc. N-1 looping parameters must be specified.

Thus with a 4-level respa setting of “2 2 2” for the 3 loop factors, you could choose to have bond interactions computed 8x per large timestep, angle interactions computed 4x, pair interactions computed 2x, and long-range interactions once per large timestep.

The *timestep* command sets the large timestep for the outermost rRESPA level. Thus if the 3 loop factors are “2 2 2” for 4-level rRESPA, and the outer timestep is set to 4.0 fs, then the inner timestep would be 8x smaller or 0.5 fs. All other LAMMPS commands that specify number of timesteps (e.g. *thermo* for thermo output every N steps, *neigh\_modify delay/every* parameters, *dump* every N steps, etc) refer to the outermost timesteps.

The rRESPA keywords enable you to specify at what level of the hierarchy various forces will be computed. If not specified, the defaults are that bond forces are computed at level 1 (innermost loop), angle forces are computed where bond forces are, dihedral forces are computed where angle forces are, improper forces are computed where dihedral forces are, pair forces are computed at the outermost level, and kspace forces are computed where pair forces are. The inner, middle, outer forces have no defaults.

For fixes that support it, the rRESPA level at which a given fix is active, can be selected through the *fix\_modify* command.

The *inner* and *middle* keywords take additional arguments for cutoffs that are used by the pairwise force computations. If the 2 cutoffs for *inner* are 5.0 and 6.0, this means that all pairs up to 6.0 apart are computed by the inner force. Those between 5.0 and 6.0 have their force go ramped to 0.0 so the overlap with the next regime (middle or outer) is smooth. The next regime (middle or outer) will compute forces for all pairs from 5.0 outward, with those from 5.0 to 6.0 having their value ramped in an inverse manner.

Note that you can use *inner* and *outer* without using *middle* to split the pairwise computations into two portions instead of three. Unless you are using a very long pairwise cutoff, a 2-way split is often faster than a 3-way split, since it avoids too much duplicate computation of pairwise interactions near the intermediate cutoffs.

Also note that only a few pair potentials support the use of the *inner* and *middle* and *outer* keywords. If not, only the *pair* keyword can be used with that pair style, meaning all pairwise forces are computed at the same rRESPA level. See the doc pages for individual pair styles for details.

Another option for using pair potentials with rRESPA is with the *hybrid* keyword, which requires the use of the *pair\_style hybrid or hybrid/overlay* command. In this scenario, different sub-styles of the hybrid pair style are evaluated at different rRESPA levels. This can be useful, for example, to set different timesteps for hybrid coarse-grained/all-atom

models. The *hybrid* keyword requires as many level assignments as there are hybrid sub-styles, which assigns each sub-style to a rRESPA level, following their order of definition in the *pair\_style* command. Since the *hybrid* keyword operates on pair style computations, it is mutually exclusive with either the *pair* or the *inner/middle/outer* keywords.

When using rRESPA (or for any MD simulation) care must be taken to choose a timestep size(s) that ensures the Hamiltonian for the chosen ensemble is conserved. For the constant NVE ensemble, total energy must be conserved. Unfortunately, it is difficult to know *a priori* how well energy will be conserved, and a fairly long test simulation (~10 ps) is usually necessary in order to verify that no long-term drift in energy occurs with the trial set of parameters.

With that caveat, a few rules-of-thumb may be useful in selecting *respa* settings. The following applies mostly to biomolecular simulations using the CHARMM or a similar all-atom force field, but the concepts are adaptable to other problems. Without SHAKE, bonds involving hydrogen atoms exhibit high-frequency vibrations and require a timestep on the order of 0.5 fs in order to conserve energy. The relatively inexpensive force computations for the bonds, angles, impropers, and dihedrals can be computed on this innermost 0.5 fs step. The outermost timestep cannot be greater than 4.0 fs without risking energy drift. Smooth switching of forces between the levels of the rRESPA hierarchy is also necessary to avoid drift, and a 1-2 Angstrom “healing distance” (the distance between the outer and inner cutoffs) works reasonably well. We thus recommend the following settings for use of the *respa* style without SHAKE in biomolecular simulations:

```
timestep 4.0
run_style respa 4 2 2 2 inner 2 4.5 6.0 middle 3 8.0 10.0 outer 4
```

With these settings, users can expect good energy conservation and roughly a 2.5 fold speedup over the *verlet* style with a 0.5 fs timestep.

If SHAKE is used with the *respa* style, time reversibility is lost, but substantially longer time steps can be achieved. For biomolecular simulations using the CHARMM or similar all-atom force field, bonds involving hydrogen atoms exhibit high frequency vibrations and require a time step on the order of 0.5 fs in order to conserve energy. These high frequency modes also limit the outer time step sizes since the modes are coupled. It is therefore desirable to use SHAKE with *respa* in order to freeze out these high frequency motions and increase the size of the time steps in the *respa* hierarchy. The following settings can be used for biomolecular simulations with SHAKE and rRESPA:

```
fix 2 all shake 0.000001 500 0 m 1.0 a 1
timestep 4.0
run_style respa 2 2 inner 1 4.0 5.0 outer 2
```

With these settings, users can expect good energy conservation and roughly a 1.5 fold speedup over the *verlet* style with SHAKE and a 2.0 fs timestep.

For non-biomolecular simulations, the *respa* style can be advantageous if there is a clear separation of time scales - fast and slow modes in the simulation. For example, a system of slowly-moving charged polymer chains could be setup as follows:

```
timestep 4.0
run_style respa 2 8
```

This is two-level rRESPA with an 8x difference between the short and long timesteps. The bonds, angles, dihedrals will be computed every 0.5 fs (assuming real units), while the pair and kspace interactions will be computed once every 4 fs. These are the default settings for each kind of interaction, so no additional keywords are necessary.

Even a LJ system can benefit from rRESPA if the interactions are divided by the inner, middle and outer keywords. A 2-fold or more speedup can be obtained while maintaining good energy conservation. In real units, for a pure LJ fluid at liquid density, with a sigma of 3.0 Angstroms, and epsilon of 0.1 kcal/mol, the following settings seem to work well:

```
timestep 36.0
run_style respa 3 3 4 inner 1 3.0 4.0 middle 2 6.0 7.0 outer 3
```

The *respa/omp* style is a variant of *respa* adapted for use with pair, bond, angle, dihedral, improper, or kspace styles with an *omp* suffix. It is functionally equivalent to *respa* but performs additional operations required for managing *omp* styles. For more on *omp* styles see the *Speed omp* doc page. Accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

You can specify *respa/omp* explicitly in your input script, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 1.95.4 Restrictions

The *verlet/split* style can only be used if LAMMPS was built with the REPLICA package. Correspondingly the *respa/omp* style is available only if the OPENMP package was included. See the *Build package* page for more info.

Run style *verlet/split* is not compatible with kspace styles from the INTEL package and it is not compatible with any tip4p, dipole, or spin kspace styles.

Whenever using rRESPA, the user should experiment with trade-offs in speed and accuracy for their system, and verify that they are conserving energy to adequate precision.

## 1.95.5 Related commands

*timestep, run*

## 1.95.6 Default

**run\_style** verlet

For run\_style *respa*, the default assignment of interactions to rRESPA levels is as follows:

- bond forces = level 1 (innermost loop)
- angle forces = same level as bond forces
- dihedral forces = same level as angle forces
- improper forces = same level as dihedral forces
- pair forces = level N (outermost level)
- kspace forces = same level as pair forces
- inner, middle, outer forces = no default

---

(**Tuckerman**) Tuckerman, Berne and Martyna, J Chem Phys, 97, p 1990 (1992).

## 1.96 set command

### 1.96.1 Syntax

```
set style ID keyword values ...
```

- style = *atom* or *type* or *mol* or *group* or *region*
- ID = depends on style

for style = *atom*, ID = a range of atom IDs

for style = *type*, ID = a range of numeric types or a single type label

for style = *mol*, ID = a range of molecule IDs

for style = *group*, ID = a group ID

for style = *region*, ID = a region ID

- one or more keyword/value pairs may be appended
- keyword = *type* or *type/fraction* or *type/ratio* or *type/subset* or *mol* or *x* or *y* or *z* or *vx* or *vy* or *vz* or *charge* or *dipole* or *dipole/random* or *quat* or *spin/atom* or *spin/atom/random* or *spin/electron* or *radius/electron* or *quat* or *quat/random* or *diameter* or *shape* or *length* or *tri* or *theta* or *theta/random* or *angmom* or *omega* or *mass* or *density* or *density/disc* or *temperature* or *volume* or *image* or *bond* or *angle* or *dihedral* or *improper* or *sph/e* or *sph/cv* or *sph/rho* or *smd/contact/radius* or *smd/mass/density* or *dpd/theta* or *edpd/temp* or *edpd/cv* or *cc* or *epsilon* or *i\_name* or *d\_name* or *i2\_name* or *d2\_name*

*type* value = numeric atom type or type label

value can be an atom-style variable (see below)

*type/fraction* values = type fraction seed

type = numeric atom type or type label

fraction = approximate fraction of selected atoms to set to new atom type

seed = random # seed (positive integer)

*type/ratio* values = type fraction seed

fraction = exact fraction of selected atoms to set to new atom type

seed = random # seed (positive integer)

*type/subset* values = type Nsubset seed

type = numeric atom type or type label

Nsubset = exact number of selected atoms to set to new atom type

seed = random # seed (positive integer)

*mol* value = molecule ID

value can be an atom-style variable (see below)

*x,y,z* value = atom coordinate (distance units)

value can be an atom-style variable (see below)

*vx,vy,vz* value = atom velocity (velocity units)

value can be an atom-style variable (see below)

*charge* value = atomic charge (charge units)

value can be an atom-style variable (see below)

*dipole* values = x y z

x,y,z = orientation of dipole moment vector

any of x,y,z can be an atom-style variable (see below)

*dipole/random* value = seed Dlen

seed = random # seed (positive integer) for dipole moment orientations

Dlen = magnitude of dipole moment (dipole units)

*spin/atom* values = g x y z

g = magnitude of magnetic spin vector (in Bohr magneton's unit)

`x,y,z` = orientation of magnetic spin vector  
 any of `x,y,z` can be an atom-style variable (see below)  
`spin/atom/random` value = seed `Dlen`  
 seed = random # seed (positive integer) for magnetic spin orientations  
`Dlen` = magnitude of magnetic spin vector (in Bohr magneton's unit)  
`radius/electron` values = `eradius`  
`eradius` = electron radius (or fixed-core radius) (distance units)  
`spin/electron` value = `espin`  
`espin` = electron spin (+1/-1), 0 = nuclei, 2 = fixed-core, 3 = pseudo-cores (i.e. `→ECP`)  
`quat` values = `a b c theta`  
`a,b,c` = unit vector to rotate particle around via right-hand rule  
`theta` = rotation angle (degrees)  
 any of `a,b,c,theta` can be an atom-style variable (see below)  
`quat/random` value = seed  
 seed = random # seed (positive integer) for quaternion orientations  
`diameter` value = diameter of spherical particle (distance units)  
 value can be an atom-style variable (see below)  
`shape` value = `Sx Sy Sz`  
`Sx,Sy,Sz` = 3 diameters of ellipsoid (distance units)  
`length` value = `len`  
`len` = length of line segment (distance units)  
`len` can be an atom-style variable (see below)  
`tri` value = `side`  
`side` = side length of equilateral triangle (distance units)  
`side` can be an atom-style variable (see below)  
`theta` value = `angle` (degrees)  
`angle` = orientation of line segment with respect to x-axis  
`angle` can be an atom-style variable (see below)  
`theta/random` value = seed  
 seed = random # seed (positive integer) for line segment orientations  
`angmom` values = `Lx Ly Lz`  
`Lx,Ly,Lz` = components of angular momentum vector (distance-mass-velocity units)  
 any of `Lx,Ly,Lz` can be an atom-style variable (see below)  
`omega` values = `Wx Wy Wz`  
`Wx,Wy,Wz` = components of angular velocity vector (radians/time units)  
 any of `wx,wy,wz` can be an atom-style variable (see below)  
`mass` value = per-atom mass (mass units)  
 value can be an atom-style variable (see below)  
`density` value = particle density for a sphere or ellipsoid (mass/distance<sup>3</sup> units), `→`  
`→`or for a triangle (mass/distance<sup>2</sup> units) or line (mass/distance units) particle  
 value can be an atom-style variable (see below)  
`density/disc` value = particle density for a 2d disc or ellipse (mass/distance<sup>2</sup>, `→`  
`→`units)  
 value can be an atom-style variable (see below)  
`temperature` value = temperature for finite-size particles (temperature units)  
 value can be an atom-style variable (see below)  
`volume` value = particle volume for Peridynamic particle (distance<sup>3</sup> units)  
 value can be an atom-style variable (see below)  
`image nx ny nz`  
`nx,ny,nz` = which periodic image of the simulation box the atom is in  
 any of `nx,ny,nz` can be an atom-style variable (see below)  
`bond` value = numeric bond type or bond type label, for all bonds between selected, `→`  
`→`atoms

*angle* value = numeric angle type or angle type label, for all angles between  
 ↳selected atoms  
*dihedral* value = numeric dihedral type or dihedral type label, for all dihedrals  
 ↳between selected atoms  
*improper* value = numeric improper type or improper type label, for all impropers  
 ↳between selected atoms  
*rheo/rho* value = density of RHEO particles (mass/distance<sup>3</sup>)  
*rheo/status* value = status or phase of RHEO particles (unitless)  
*sph/e* value = energy of SPH particles (need units)  
 value can be an atom-style variable (see below)  
*sph/cv* value = heat capacity of SPH particles (need units)  
 value can be an atom-style variable (see below)  
*sph/rho* value = density of SPH particles (need units)  
 value can be an atom-style variable (see below)  
*smd/contact/radius* = radius for short range interactions, i.e. contact and friction  
 value can be an atom-style variable (see below)  
*smd/mass/density* = set particle mass based on volume by providing a mass density  
 value can be an atom-style variable (see below)  
*dpd/theta* value = internal temperature of DPD particles (temperature units)  
 value can be an atom-style variable (see below)  
 value can be NULL which sets internal temp of each particle to KE temp  
*edpd/temp* value = temperature of eDPD particles (temperature units)  
 value can be an atom-style variable (see below)  
*edpd/cv* value = volumetric heat capacity of eDPD particles (energy/temperature/  
 ↳volume units)  
 value can be an atom-style variable (see below)  
*cc* values = index cc  
 index = index of a chemical species (1 to Nspecies)  
 cc = chemical concentration of tDPD particles for a species (mole/volume units)  
*epsilon* value = dielectric constant of the medium where the atoms reside  
*i\_name* value = custom integer vector with name  
*d\_name* value = custom floating-point vector with name  
*i2\_name* value = column of a custom integer array with name  
 column specified as *i2\_name*[N] where N is 1 to Ncol  
*d2\_name* value = column of a custom floating-point array with name  
 column specified as *d2\_name*[N] where N is 1 to Ncol

## 1.96.2 Examples

```

set group solvent type 2
set group solvent type C
set group solvent type/fraction 2 0.5 12393
set group solvent type/fraction C 0.5 12393
set group edge bond 4
set region half charge 0.5
set type 3 charge 0.5
set type H charge 0.5
set type 1*3 charge 0.5
set atom * charge v_atomfile
set atom 100*200 x 0.5 y 1.0
set atom 100 vx 0.0 vy 0.0 vz -1.0
set atom 1492 type 3
  
```

(continues on next page)

(continued from previous page)

```
set atom 1492 type H
set atom * i_myVal 5
set atom * d2_Sxyz[1] 6.4
```

### 1.96.3 Description

Set one or more properties of one or more atoms. Since atom properties are initially assigned by the *read\_data*, *read\_restart* or *create\_atoms* commands, this command changes those assignments. This can be useful for overriding the default values assigned by the *create\_atoms* command (e.g. charge = 0.0). It can be useful for altering pairwise and molecular force interactions, since force-field coefficients are defined in terms of types. It can be used to change the labeling of atoms by atom type or molecule ID when they are output in *dump* files. It can also be useful for debugging purposes; i.e. positioning an atom at a precise location to compute subsequent forces or energy.

Note that the *style* and *ID* arguments determine which atoms have their properties reset. The remaining keywords specify which properties to reset and what the new values are. Some strings like *type* or *mol* can be used as a style and/or a keyword.

---

This section describes how to select which atoms to change the properties of, via the *style* and *ID* arguments.

Changed in version 28Mar2023: Support for type labels was added for selecting atoms by type

The style *atom* selects all the atoms in a range of atom IDs.

The style *type* selects all the atoms in a range of types or type labels. The style *type* selects atoms in one of two ways. A range of numeric atom types can be specified. Or a single atom type label can be specified, e.g. "C". The style *mol* selects all the atoms in a range of molecule IDs.

In each of the range cases, the range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form "\*" or "\*n" or "n\*" or "m\*n". For example, for the style *type*, if N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). For all the styles except *mol*, the lowest value for the wildcard is 1; for *mol* it is 0.

The style *group* selects all the atoms in the specified group. The style *region* selects all the atoms in the specified geometric region. See the *group* and *region* commands for details of how to specify a group or region.

---

This section describes the keyword options for which properties to change, for the selected atoms.

Note that except where explicitly prohibited below, all of the keywords allow an *atom-style* or *atomfile-style variable* to be used as the specified value(s). If the value is a variable, it should be specified as v\_name, where name is the variable name. In this case, the variable will be evaluated, and its resulting per-atom value used to determine the value assigned to each selected atom. Note that the per-atom value from the variable will be ignored for atoms that are not selected via the *style* and *ID* settings explained above. A simple way to use per-atom values from the variable to reset a property for all atoms is to use style *atom* with *ID* = "\*"; this selects all atom IDs.

Atom-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. They can also include per-atom values, such as atom coordinates. Thus it is easy to specify a time-dependent or spatially-dependent set of per-atom values. As explained on the *variable* doc page, atomfile-style variables can be used in place of atom-style variables, and thus as arguments to the set command. Atomfile-style variables read their per-atoms values from a file.

**Note:** Atom-style and atomfile-style variables return floating point per-atom values. If the values are assigned to an integer variable, such as the molecule ID, then the floating point value is truncated to its integer portion, e.g. a value of 2.6 would become 2.

---

Changed in version 28Mar2023: Support for type labels was added for setting atom, bond, angle, dihedral, and improper types

Keyword *type* sets the atom type for all selected atoms. A specified value can be either a numeric atom type or an atom type label. When using a numeric type, the specified value must be from 1 to *ntypes*, where *ntypes* was set by the *create\_box* command or the *atom types* field in the header of the data file read by the *read\_data* command. When using a type label it must have been defined previously. See the *Howto type labels* doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Keyword *type/fraction* sets the atom type for a fraction of the selected atoms. The actual number of atoms changed is not guaranteed to be exactly the specified fraction ( $0 \leq \text{fraction} \leq 1$ ), but should be statistically close. Random numbers are used in such a way that a particular atom is changed or not changed, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keywords *type/ratio* and *type/subset* also set the atom type for a fraction of the selected atoms. The actual number of atoms changed will be exactly the requested number. For *type/ratio* the specified fraction ( $0 \leq \text{fraction} \leq 1$ ) determines the number. For *type/subset*, the specified *Nsubset* is the number. An iterative algorithm is used which ensures the correct number of atoms are selected, in a perfectly random fashion. Which atoms are selected will change with the number of processors used. These keywords do not allow use of an atom-style variable.

Keyword *mol* sets the molecule ID for all selected atoms. The *atom style* being used must support the use of molecule IDs.

Keywords *x*, *y*, *z*, and *charge* set the coordinates or charge of all selected atoms. For *charge*, the *atom style* being used must support the use of atomic charge. Keywords *vx*, *vy*, and *vz* set the velocities of all selected atoms.

Keyword *dipole* uses the specified x,y,z values as components of a vector to set as the orientation of the dipole moment vectors of the selected atoms. The magnitude of the dipole moment is set by the length of this orientation vector.

Keyword *dipole/random* randomizes the orientation of the dipole moment vectors for the selected atoms and sets the magnitude of each to the specified *Dlen* value. For 2d systems, the z component of the orientation is set to 0.0. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Changed in version 15Sep2022.

Keyword *spin/atom* uses the specified *g* value to set the magnitude of the magnetic spin vectors, and the x,y,z values as components of a vector to set as the orientation of the magnetic spin vectors of the selected atoms. This keyword was previously called *spin*.

Changed in version 15Sep2022.

Keyword *spin/atom/random* randomizes the orientation of the magnetic spin vectors for the selected atoms and sets the magnitude of each to the specified *Dlen* value. This keyword was previously called *spin/random*.

New in version 15Sep2022.

Keyword *radius/electron* uses the specified value to set the radius of electrons or fixed cores.

New in version 15Sep2022.

Keyword *spin/electron* sets the spin of an electron (+/- 1) or indicates nuclei (=0), fixed-cores (=2), or pseudo-cores (=3).

Keyword *quat* uses the specified values to create a quaternion (4-vector) that represents the orientation of the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined

by the *atom\_style* command. Note that particles defined by *atom\_style ellipsoid* have 3 shape parameters. The 3 values must be non-zero for each particle set by this command. They are used to specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box's x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle  $\theta$  around a unit rotation vector  $(a,b,c)$ , then the quaternion that represents its new orientation is given by  $(\cos(\theta/2), a*\sin(\theta/2), b*\sin(\theta/2), c*\sin(\theta/2))$ . The  $\theta$  and  $a,b,c$  values are the arguments to the *quat* keyword. LAMMPS normalizes the quaternion in case  $(a,b,c)$  was not specified as a unit vector. For 2d systems, the  $a,b,c$  values are ignored, since a rotation vector of  $(0,0,1)$  is the only valid choice.

Keyword *quat/random* randomizes the orientation of the quaternion for the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the *atom\_style* command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. For 2d systems, only orientations in the xy plane are generated. As with keyword *quat*, for ellipsoidal particles, the 3 shape values must be non-zero for each particle set by this command. This keyword does not allow use of an atom-style variable.

Keyword *diameter* sets the size of the selected atoms. The particles must be finite-size spheres as defined by the *atom\_style sphere* command. The diameter of a particle can be set to 0.0, which means they will be treated as point particles. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read\_data* command.

Keyword *shape* sets the size and shape of the selected atoms. The particles must be ellipsoids as defined by the *atom\_style ellipsoid* command. The  $S_x$ ,  $S_y$ ,  $S_z$  settings are the 3 diameters of the ellipsoid in each direction. All 3 can be set to the same value, which means the ellipsoid is effectively a sphere. They can also all be set to 0.0 which means the particle will be treated as a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read\_data* command.

Keyword *length* sets the length of selected atoms. The particles must be line segments as defined by the *atom\_style line* command. If the specified value is non-zero the line segment is (re)set to a length = the specified value, centered around the particle position, with an orientation along the x-axis. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read\_data* command.

Keyword *tri* sets the size of selected atoms. The particles must be triangles as defined by the *atom\_style tri* command. If the specified value is non-zero the triangle is (re)set to be an equilateral triangle in the xy plane with side length = the specified value, with a centroid at the particle position, with its base parallel to the x axis, and the y-axis running from the center of the base to the top point of the triangle. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the *read\_data* command.

Keyword *theta* sets the orientation of selected atoms. The particles must be line segments as defined by the *atom\_style line* command. The specified value is used to set the orientation angle of the line segments with respect to the x axis.

Keyword *theta/random* randomizes the orientation of  $\theta$  for the selected atoms. The particles must be line segments as defined by the *atom\_style line* command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword *angmom* sets the angular momentum of selected atoms. The particles must be ellipsoids as defined by the *atom\_style ellipsoid* command or triangles as defined by the *atom\_style tri* command. The angular momentum vector of the particles is set to the 3 specified components.

Keyword *omega* sets the angular velocity of selected atoms. The particles must be spheres as defined by the *atom\_style sphere* command. The angular velocity vector of the particles is set to the 3 specified components.

Keyword *mass* sets the mass of all selected particles. The particles must have a per-atom mass attribute, as defined by the *atom\_style* command. See the “mass” command for how to set mass values on a per-type basis.

Keyword *density* or *density/disc* also sets the mass of all selected particles, but in a different way. The particles must

have a per-atom mass attribute, as defined by the [atom\\_style](#) command. If the atom has a radius attribute (see [atom\\_style sphere](#)) and its radius is non-zero, its mass is set from the density and particle volume for 3d systems (the input density is assumed to be in mass/distance<sup>3</sup> units). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the *density/disc* keyword is used, then they can be modeled as 2d discs (circles). Their mass is set from the density and particle area (the input density is assumed to be in mass/distance<sup>2</sup> units).

If the atom has a shape attribute (see [atom\\_style ellipsoid](#)) and its 3 shape parameters are non-zero, then its mass is set from the density and particle volume (the input density is assumed to be in mass/distance<sup>3</sup> units). The *density/disc* keyword has no effect; it does not (yet) treat 3d ellipsoids as 2d ellipses.

If the atom has a length attribute (see [atom\\_style line](#)) and its length is non-zero, then its mass is set from the density and line segment length (the input density is assumed to be in mass/distance units). If the atom has an area attribute (see [atom\\_style tri](#)) and its area is non-zero, then its mass is set from the density and triangle area (the input density is assumed to be in mass/distance<sup>2</sup> units).

If none of these cases are valid, then the mass is set to the density value directly (the input density is assumed to be in mass units).

Keyword *temperature* sets the temperature of a finite-size particle. Currently, only the GRANULAR package supports this attribute. The temperature must be added using an instance of [fix property/atom](#). The values for the temperature must be positive.

Keyword *volume* sets the volume of all selected particles. Currently, only the [atom\\_style peri](#) command defines particles with a volume attribute. Note that this command does not adjust the particle mass.

Keyword *image* sets which image of the simulation box the atom is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The flags can be output with atom snapshots via the [dump](#) command. If a value of NULL is specified for any of nx,ny,nz, then the current image value for that dimension is unchanged. For non-periodic dimensions only a value of 0 can be specified. This command can be useful after a system has been equilibrated and atoms have diffused one or more box lengths in various directions. This command can then reset the image values for atoms so that they are effectively inside the simulation box, e.g if a diffusion coefficient is about to be measured via the [compute msd](#) command. Care should be taken not to reset the image flags of two atoms in a bond to the same value if the bond straddles a periodic boundary (rather they should be different by +/- 1). This will not affect the dynamics of a simulation, but may mess up analysis of the trajectories if a LAMMPS diagnostic or your own analysis relies on the image flags to unwrap a molecule which straddles the periodic box.

Keywords *bond*, *angle*, *dihedral*, and *improper*, set the bond type (angle type, etc) of all bonds (angles, etc) of selected atoms to the specified value. The value can be a numeric type from 1 to nbondtypes (nangletypes, etc). Or it can be a type label (bond type label, angle type label, etc). See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used. All atoms in a particular bond (angle, etc) must be selected atoms in order for the change to be made. The value of nbondtypes (nangletypes, etc) was set by the *bond types (angle types, etc)* field in the header of the data file read by the [read\\_data](#) command. These keywords do not allow use of an atom-style variable.

Keywords *rheo/rho* and *rheo/status* set the density and the status of rheo particles. In particular, one can only set the phase in the status as described by the [RHEO howto page](#).

Keywords *sph/e*, *sph/cv*, and *sph/rho* set the energy, heat capacity, and density of smoothed particle hydrodynamics (SPH) particles. See [this PDF guide](#) to using SPH in LAMMPS.

Keyword *smd/mass/density* sets the mass of all selected particles, but it is only applicable to the Smooth Mach Dynamics package MACHDYN. It assumes that the particle volume has already been correctly set and calculates particle mass from the provided mass density value.

Keyword *smd/contact/radius* only applies to simulations with the Smooth Mach Dynamics package MACHDYN. It sets an interaction radius for computing short-range interactions, e.g. repulsive forces to prevent different individual physical

bodies from penetrating each other. Note that the SPH smoothing kernel diameter used for computing long range, nonlocal interactions, is set using the *diameter* keyword.

Keyword *dpd/theta* sets the internal temperature of a DPD particle as defined by the DPD-REACT package. If the specified value is a number it must be  $\geq 0.0$ . If the specified value is NULL, then the kinetic temperature  $T_{kin}$  of each particle is computed as  $\frac{3}{2} k T_{kin} = KE = \frac{1}{2} m v^2 = \frac{1}{2} m (v_x^2 + v_y^2 + v_z^2)$ . Each particle's internal temperature is set to  $T_{kin}$ . If the specified value is an atom-style variable, then the variable is evaluated for each particle. If a value  $\geq 0.0$ , the internal temperature is set to that value. If it is  $< 0.0$ , the computation of  $T_{kin}$  is performed and the internal temperature is set to that value.

Keywords *edpd/temp* and *edpd/cv* set the temperature and volumetric heat capacity of an eDPD particle as defined by the DPD-MESO package. Currently, only *atom\_style edpd* defines particles with these attributes. The values for the temperature and heat capacity must be positive.

Keyword *cc* sets the chemical concentration of a tDPD particle for a specified species as defined by the DPD-MESO package. Currently, only *atom\_style tdpd* defines particles with this attribute. An integer for “index” selects a chemical species (1 to  $N_{species}$ ) where  $N_{species}$  is set by the *atom\_style* command. The value for the chemical concentration must be  $\geq 0.0$ .

Keyword *epsilon* sets the dielectric constant of a particle, precisely of the medium where the particle resides as defined by the DIELECTRIC package. Currently, only *atom\_style dielectric* defines particles with this attribute. The value for the dielectric constant must be  $\geq 0.0$ . Note that the set command with this keyword will rescale the particle charge accordingly so that the real charge (e.g., as read from a data file) stays intact. To change the real charges, one needs to use the set command with the *charge* keyword. Care must be taken to ensure that the real and scaled charges, and dielectric constants are consistent.

Keywords *i\_name*, *d\_name*, *i2\_name*, *d2\_name* refer to custom per-atom integer and floating-point vectors or arrays that have been added via the *fix property/atom* command. When that command is used specific names are given to each attribute which are the “name” portion of these keywords. For arrays *i2\_name* and *d2\_name*, the column of the array must also be included following the name in brackets: e.g. *d2\_xyz[2]*, *i2\_mySpin[3]*.

### 1.96.4 Restrictions

You cannot set an atom attribute (e.g. *mol* or *q* or *volume*) if the *atom\_style* does not have that attribute.

This command requires inter-processor communication to coordinate the setting of bond types (angle types, etc). This means that your system must be ready to perform a simulation before using one of these keywords (force fields set, atom mass set, etc). This is not necessary for other keywords.

Using the *region* style with the bond (angle, etc) keywords can give unpredictable results if there are bonds (angles, etc) that straddle periodic boundaries. This is because the region may only extend up to the boundary and partner atoms in the bond (angle, etc) may have coordinates outside the simulation box if they are ghost atoms.

### 1.96.5 Related commands

*create\_box*, *create\_atoms*, *read\_data*

## 1.96.6 Default

none

## 1.97 shell command

### 1.97.1 Syntax

```
shell command args
```

- command = *cd* or *mkdir* or *mv* or *rm* or *rmdir* or *putenv* or arbitrary command

*cd* arg = dir

dir = directory to change to

*mkdir* args = dir1 dir2 ...

dir1,dir2 = one or more directories to create

*mv* args = old new

old = old filename

new = new filename or destination folder

*rm* args = [-f] file1 file2 ...

-f = turn off warnings (optional)

file1,file2 = one or more filenames to delete

*rmdir* args = dir1 dir2 ...

dir1,dir2 = one or more directories to delete

*putenv* args = var1=value1 var2=value2

var=value = one of more definitions of environment variables

anything else is passed as a command to the shell for direct execution

### 1.97.2 Examples

```
shell cd sub1
shell cd ..
shell mkdir tmp1 tmp2/tmp3
shell rmdir tmp1 tmp2
shell mv log.lammps hold/log.1
shell rm TMP/file1 TMP/file2
shell putenv LAMMPS_POTENTIALS=../../potentials
shell my_setup file1 10 file2
shell my_post_process 100 dump.out
```

### 1.97.3 Description

Execute a shell command. A few simple file-based shell commands are supported directly, in Unix-style syntax. Any command not listed above is passed as-is to the C-library `system()` call, which invokes the command in a shell. To use the external executable instead of the built-in version one needs to use a full path, for example */bin/rm* instead of *rm*. The built-in commands will also work on operating systems, that do not - by default - provide the corresponding external executables (like *mkdir* on Windows).

This command provides a ways to invoke custom commands or executables from your input script. For example, you can move files around in preparation for the next section of the input script. Or you can run a program that pre-processes data for input into LAMMPS. Or you can run a program that post-processes LAMMPS output data.

With the exception of *cd*, all commands, including ones invoked via a `system()` call, are executed by only a single processor, so that files/directories are not being manipulated by multiple processors concurrently which may result in unexpected errors or corrupted files.

The *cd* command changes the current working directory similar to the `cd` command. All subsequent LAMMPS commands that read/write files will use the new directory. All processors execute this command.

The *mkdir* command creates directories similar to the Unix `mkdir -p` command. That is, it will attempt to create the entire path of subdirectories if they do not exist yet.

The *mv* command renames a file and/or moves it to a new directory. It cannot rename files across filesystem boundaries or between drives.

The *rm* command deletes file similar to the Unix `rm` command.

The *rmdir* command deletes directories similar to Unix `rmdir` command. If a directory is not empty, its contents are also removed recursively similar to the Unix `rm -r` command.

The *putenv* command defines or updates an environment variable directly. Since this command does not pass through the shell, no shell variable expansion or globbing is performed, only the usual substitution for LAMMPS variables defined with the *variable* command is performed. The resulting string is then used literally.

Any other command is passed as-is to the shell along with its arguments as one string, invoked by the C-library `system()` call. For example, these lines in your input script:

```
variable n equal 10
variable foo string file2
shell my_setup file1 $n ${foo}
```

would be the same as invoking

```
my_setup file1 10 file2
```

from a command-line prompt. The executable program “my\_setup” is run with 3 arguments: file1 10 file2.

### 1.97.4 Restrictions

LAMMPS will do a best effort to detect errors and print suitable warnings, but due to the nature of delegating commands to the C-library `system()` call, this is not always reliable.

### 1.97.5 Related commands

none

## 1.97.6 Default

### 1.98.1 Syntax

`special_bonds` keyword values ...

- one or more keyword/value pairs may be appended
- keyword = *amber* or *charmm* or *dreiding* or *fene* or *lj/coul* or *lj* or *coul* or *angle* or *dihedral* or *one/five*

*amber* values = none

*charmm* values = none

*dreiding* values = none

*fene* values = none

*lj/coul* values = w1,w2,w3

w1,w2,w3 = weights (0.0 to 1.0) on pairwise Lennard-Jones and Coulombic  
→interactions

*lj* values = w1,w2,w3

w1,w2,w3 = weights (0.0 to 1.0) on pairwise Lennard-Jones interactions

*coul* values = w1,w2,w3

w1,w2,w3 = weights (0.0 to 1.0) on pairwise Coulombic interactions

*angle* value = yes or no

*dihedral* value = yes or no

*one/five* value = yes or no

### 1.98.2 Examples

`special_bonds` amber  
`special_bonds` charmm  
`special_bonds` fene dihedral no  
`special_bonds` lj/coul 0.0 0.0 0.5 angle yes dihedral yes  
`special_bonds` lj 0.0 0.0 0.5 coul 0.0 0.0 0.0 dihedral yes

### 1.98.3 Description

Set weighting coefficients for pairwise energy and force contributions between pairs of atoms that are also permanently bonded to each other, either directly or via one or two intermediate bonds. These weighting factors are used by nearly all *pair styles* in LAMMPS that compute simple pairwise interactions. Permanent bonds between atoms are specified by defining the bond topology in the data file read by the *read\_data* command. Typically a *bond\_style* command is also used to define a bond potential. The rationale for using these weighting factors is that the interaction between a pair of bonded atoms is all (or mostly) specified by the bond, angle, dihedral potentials, and thus the non-bonded Lennard-Jones or Coulombic interaction between the pair of atoms should be excluded (or reduced by a weighting factor).

---

**Note:** These weighting factors are NOT used by *pair styles* that compute many-body interactions, since the “bonds” that result from such interactions are not permanent, but are created and broken dynamically as atom conformations change.

Examples of pair styles in this category are EAM, MEAM, Stillinger-Weber, Tersoff, COMB, AIREBO, and ReaxFF. In fact, it generally makes no sense to define permanent bonds between atoms that interact via these potentials, though such bonds may exist elsewhere in your system, e.g. when using the *pair\_style hybrid* command. Thus LAMMPS ignores *special\_bonds* settings when many-body potentials are calculated. Please note, that the existence of explicit bonds for atoms that are described by a many-body potential will alter the neighbor list and thus can render the computation of those interactions invalid, since those pairs are not only used to determine direct pairwise interactions but also neighbors of neighbors and more. The recommended course of action is to remove such bonds, or - if that is not possible - use a *special\_bonds* setting of 1.0 1.0 1.0.

---

**Note:** Unlike some commands in LAMMPS, you cannot use this command multiple times in an incremental fashion: e.g. to first set the LJ settings and then the Coulombic ones. Each time you use this command it sets all the coefficients to default values and only overrides the one you specify, so you should set all the options you need each time you use it. See more details at the bottom of this page.

---

The Coulomb factors are applied to any Coulomb (charge interaction) term that the potential calculates. The LJ factors are applied to the remaining terms that the potential calculates, whether they represent LJ interactions or not. The weighting factors are a scaling prefactor on the energy and force between the pair of atoms.

A value of 1.0 means include the full interaction without flagging the pair as a “special pair”; a value of 0.0 means exclude the pair completely from the neighbor list, except for pair styles that require a *k-space style* and pair styles *amoeba*, *hippo*, *thole*, *coul/exclude*, and pair styles that include “coul/dsf” or “coul/wolf”.

---

**Note:** To include pairs that would otherwise be excluded (so they are included in the neighbor list for certain analysis compute styles), you can use a very small but non-zero value like 1.0e-100 instead of 0.0. Due to using floating-point math, the computed force, energy, and virial contributions from the pairs will be too small to cause differences.

---

The first of the 3 coefficients (LJ or Coulombic) is the weighting factor on 1-2 atom pairs, which are pairs of atoms directly bonded to each other. The second coefficient is the weighting factor on 1-3 atom pairs which are those separated by 2 bonds (e.g. the two H atoms in a water molecule). The third coefficient is the weighting factor on 1-4 atom pairs which are those separated by 3 bonds (e.g. the first and fourth atoms in a dihedral interaction). Thus if the 1-2 coefficient is set to 0.0, then the pairwise interaction is effectively turned off for all pairs of atoms bonded to each other. If it is set to 1.0, then that interaction will be at full strength.

---

**Note:** For purposes of computing weighted pairwise interactions, 1-3 and 1-4 interactions are not defined from the list of angles or dihedrals used by the simulation. Rather, they are inferred topologically from the set of bonds specified when the simulation is defined from a data or restart file (see *read\_data* or *read\_restart* commands). Thus the set of 1-2,1-3,1-4 interactions that the weights apply to is the same whether angle and dihedral potentials are computed or not, and remains the same even if bonds are constrained, or turned off, or removed during a simulation.

---

The two exceptions to this rule are (a) if the *angle* or *dihedral* keywords are set to *yes* (see below), or (b) if the *delete\_bonds* command is used with the *special* option that re-computes the 1-2,1-3,1-4 topologies after bonds are deleted; see the *delete\_bonds* command for more details.

The *amber* keyword sets the 3 coefficients to 0.0, 0.0, 0.5 for LJ interactions and to 0.0, 0.0, 0.8333 for Coulombic interactions, which is the default for a commonly used version of the AMBER force field, where the last value is really 5/6. See (*Cornell*) for a description of the AMBER force field.

The *charmm* keyword sets the 3 coefficients to 0.0, 0.0, 0.0 for both LJ and Coulombic interactions, which is the default for a commonly used version of the CHARMM force field. Note that in pair styles *lj/charmm/coul/charmm* and *lj/charmm/coul/long* the 1-4 coefficients are defined explicitly, and these pairwise contributions are computed as part of the charmm dihedral style - see the *pair\_coeff* and *dihedral\_style* commands for more information. See (*MacKerell*)

for a description of the CHARMM force field.

The *dreiding* keyword sets the 3 coefficients to 0.0, 0.0, 1.0 for both LJ and Coulombic interactions, which is the default for the Dreiding force field, as discussed in (*Mayo*).

The *fene* keyword sets the 3 coefficients to 0.0, 1.0, 1.0 for both LJ and Coulombic interactions, which is consistent with a coarse-grained polymer model with *FENE bonds*. See (*Kremer*) for a description of FENE bonds.

The *lj/coul*, *lj*, and *coul* keywords allow the 3 coefficients to be set explicitly. The *lj/coul* keyword sets both the LJ and Coulombic coefficients to the same 3 values. The *lj* and *coul* keywords only set either the LJ or Coulombic coefficients. Use both of them if you wish to set the LJ coefficients to different values than the Coulombic coefficients.

The *angle* keyword allows the 1-3 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any angle defined in the simulation or as 1,3 or 2,4 atoms in any dihedral defined in the simulation. For example, imagine the 1-3 weighting factor is set to 0.5 and you have a linear molecule with 4 atoms and bonds as follows: 1-2-3-4. If your data file defines 1-2-3 as an angle, but does not define 2-3-4 as an angle or 1-2-3-4 as a dihedral, then the pairwise interaction between atoms 1 and 3 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 4. If the *angle* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 4 will be unaffected (full weighting of 1.0). If the *angle* keyword is specified as *no* which is the default, then the 2,4 interaction will also be weighted by 0.5.

The *dihedral* keyword allows the 1-4 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any dihedral defined in the simulation. For example, imagine the 1-4 weighting factor is set to 0.5 and you have a linear molecule with 5 atoms and bonds as follows: 1-2-3-4-5. If your data file defines 1-2-3-4 as a dihedral, but does not define 2-3-4-5 as a dihedral, then the pairwise interaction between atoms 1 and 4 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 5. If the *dihedral* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 5 will be unaffected (full weighting of 1.0). If the *dihedral* keyword is specified as *no* which is the default, then the 2,5 interaction will also be weighted by 0.5.

The *one/five* keyword enable calculation and storage of a list of 1-5 neighbors in the molecular topology for each atom. It is required by some pair styles, such as *pair\_style amoeba* and *pair\_style hippo*.

---

**Note:** LAMMPS stores and maintains a data structure with a list of the first, second, and third neighbors of each atom (within the bond topology of the system). If new bonds are created (or molecules added containing atoms with more special neighbors), the size of this list needs to grow. Note that adding a single bond always adds a new first neighbor but may also induce \*many\* new second and third neighbors, depending on the molecular topology of your system. Using the *extra/special/per/atom* keyword to either *read\_data* or *create\_box* reserves empty space in the list for this N additional first, second, or third neighbors to be added. If you do not do this, you may get an error when bonds (or molecules) are added.

---

---

**Note:** If you reuse this command in an input script, you should set all the options you need each time. This command cannot be used a second time incrementally. E.g. these two commands:

---

```
special_bonds lj 0.0 1.0 1.0
special_bonds coul 0.0 0.0 1.0
```

are not the same as

```
special_bonds lj 0.0 1.0 1.0 coul 0.0 0.0 1.0
```

In the first case you end up with (after the second command):

```
LJ: 0.0 0.0 0.0
Coul: 0.0 0.0 1.0
```

while only in the second case do you get the desired settings of:

```
LJ: 0.0 1.0 1.0
Coul: 0.0 0.0 1.0
```

This happens because the LJ (and Coul) settings are reset to their default values before modifying them, each time the *special\_bonds* command is issued.

## 1.98.4 Restrictions

none

## 1.98.5 Related commands

*delete\_bonds*, *fix bond/create*

## 1.98.6 Default

All 3 Lennard-Jones and 3 Coulombic weighting coefficients = 0.0, angle = no, dihedral = no.

## 1.99 suffix command

### 1.99.1 Syntax

```
suffix style args
```

- style = *off* or *on* or *gpu* or *intel* or *kk* or *omp* or *opt* or *hybrid*
- args = for hybrid style, default suffix to be used and alternative suffix

## 1.99.2 Examples

```
suffix off
suffix on
suffix gpu
suffix intel
suffix hybrid intel omp
suffix kk
```

## 1.99.3 Description

This command allows you to use variants of various styles if they exist. In that respect it operates the same as the *-suffix command-line switch*. It also has options to turn off or back on any suffix setting made via the command line.

The specified style can be *gpu*, *intel*, *kk*, *omp*, *opt* or *hybrid*. These refer to optional packages that LAMMPS can be built with, as described on the *Build package* doc page. The “gpu” style corresponds to the GPU package, the “intel” style to the INTEL package, the “kk” style to the KOKKOS package, the “omp” style to the OPENMP package, and the “opt” style to the OPT package.

These are the variants these packages provide:

- GPU = a handful of pair styles and the PPPM *kpace\_style*, optimized to run on one or more GPUs or multicore CPU/GPU nodes
- INTEL = a collection of pair styles and neighbor routines optimized to run in single, mixed, or double precision on CPUs and Intel(R) Xeon Phi(TM) co-processors.
- KOKKOS = a collection of atom, pair, and fix styles optimized to run using the Kokkos library on various kinds of hardware, including GPUs via CUDA and many-core chips via OpenMP or threading.
- OPENMP = a collection of pair, bond, angle, dihedral, improper, *kpace*, compute, and fix styles with support for OpenMP multi-threading
- OPT = a handful of pair styles, cache-optimized for faster CPU performance
- HYBRID = a combination of two packages can be specified (see below)

As an example, all of the packages provide a *pair\_style lj/cut* variant, with style names *lj/cut/opt*, *lj/cut/omp*, *lj/cut/gpu*, *lj/cut/intel*, or *lj/cut/kk*. A variant styles can be specified explicitly in your input script, e.g. *pair\_style lj/cut/gpu*. If the suffix command is used with the appropriate style, you do not need to modify your input script. The specified suffix (*opt,omp,gpu,intel,kk*) is automatically appended whenever your input script command creates a new *atom*, *pair*, *bond*, *angle*, *dihedral*, *improper*, *kpace*, *fix*, *compute*, or *run* style. If the variant version does not exist, the standard version is created.

For “hybrid”, two packages are specified. The first is used whenever available. If a style with the first suffix is not available, the style with the suffix for the second package will be used if available. For example, “hybrid intel omp” will use styles from the INTEL package as a first choice and styles from the OPENMP package as a second choice if no INTEL variant is available.

If the specified style is *off*, then any previously specified suffix is temporarily disabled, whether it was specified by a command-line switch or a previous suffix command. If the specified style is *on*, a disabled suffix is turned back on. The use of these 2 commands lets your input script use a standard LAMMPS style (i.e. a non-accelerated variant), which can be useful for testing or benchmarking purposes. Of course this is also possible by not using any suffix commands, and explicitly appending or not appending the suffix to the relevant commands in your input script.

---

**Note:** The default *run\_style* *verlet* is invoked prior to reading the input script and is therefore not affected by a suffix command in the input script. The KOKKOS package requires “*run\_style verlet/kk*”, so when using the KOKKOS

package it is necessary to either use the command line “-sf kk” command or add an explicit “run\_style verlet” command to the input script.

## 1.99.4 Restrictions

none

## 1.99.5 Related commands

*-suffix command-line switch*

# 1.100 tad command

## 1.100.1 Syntax

```
tad N t_event T_lo T_hi delta tmax compute-ID keyword value ...
```

- N = # of timesteps to run (not including dephasing/quenching)
- t\_event = timestep interval between event checks
- T\_lo = temperature at which event times are desired
- T\_hi = temperature at which MD simulation is performed
- delta = desired confidence level for stopping criterion
- tmax = reciprocal of lowest expected pre-exponential factor (time units)
- compute-ID = ID of the compute used for event detection
- zero or more keyword/value pairs may be appended
- keyword = *min* or *neb* or *neb\_style* or *neb\_step* or *neb\_log*

*min* values = etol ftol maxiter maxeval

etol = stopping tolerance for energy (energy units)

ftol = stopping tolerance for force (force units)

maxiter = max iterations of minimize

maxeval = max number of force/energy evaluations

*neb* values = ftol N1 N2 Nevery

etol = stopping tolerance for energy (energy units)

ftol = stopping tolerance for force (force units)

N1 = max # of iterations (timesteps) to run initial NEB

N2 = max # of iterations (timesteps) to run barrier-climbing NEB

Nevery = print NEB statistics every this many timesteps

*neb\_style* value = *quickmin* or *fire*

*neb\_step* value = dtneb

dtneb = timestep for NEB damped dynamics minimization

`neb_log` value = file where NEB statistics are printed

## 1.100.2 Examples

```

  neb 0.0 0.01 200 200 20 &
  min_style cg &
  neb_style fire &
  neb_log log.neb
```

## 1.100.3 Description

Run a temperature accelerated dynamics (TAD) simulation. This method requires two or more partitions to perform NEB transition state searches.

TAD is described in [this paper](#) by Art Voter. It is a method that uses accelerated dynamics at an elevated temperature to generate results at a specified lower temperature. A good overview of accelerated dynamics methods (AMD) for such systems is given in [this review paper](#) from the same group. To quote from the review paper: “The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by  $p(t) = k \cdot \exp(-kt)$  where  $k$  is the rate constant.”

TAD is a suitable AMD method for infrequent-event systems, where in addition, the transition kinetics are well-approximated by harmonic transition state theory (hTST). In hTST, the temperature dependence of transition rates follows the Arrhenius relation. As a consequence a set of event times generated in a high-temperature simulation can be mapped to a set of much longer estimated times in the low-temperature system. However, because this mapping involves the energy barrier of the transition event, which is different for each event, the first event at the high temperature may not be the earliest event at the low temperature. TAD handles this by first generating a set of possible events from the current basin. After each event, the simulation is reflected backwards into the current basin. This is repeated until the stopping criterion is satisfied, at which point the event with the earliest low-temperature occurrence time is selected. The stopping criterion is that the confidence measure be greater than  $1 - \delta$ . The confidence measure is the probability that no earlier low-temperature event will occur at some later time in the high-temperature simulation. hTST provides an lower bound for this probability, based on the user-specified minimum pre-exponential factor (reciprocal of  $t_{max}$ ).

In order to estimate the energy barrier for each event, the TAD method invokes the [NEB](#) method. Each NEB replica runs on a partition of processors. The current NEB implementation in LAMMPS restricts you to having exactly one processor per replica. For more information, see the documentation for the [neb](#) command. In the current LAMMPS implementation of TAD, all the non-NEB TAD operations are performed on the first partition, while the other partitions remain idle. See the [Howto replica](#) doc page for further discussion of multi-replica simulations.

A TAD run has several stages, which are repeated each time an event is performed. The logic for a TAD run is as follows:

```
while (time remains):
  while (time < tstop):
    until (event occurs):
      run dynamics for t_event steps
      quench
    run neb calculation using all replicas
    compute tlo from energy barrier
    update earliest event
    update tstop
```

(continues on next page)

(continued from previous page)

```
reflect back into current basin
execute earliest event
```

Before this outer loop begins, the initial potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

Inside the inner loop, dynamics is run continuously according to whatever integrator has been specified by the user, stopping every  $t\_event$  steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the *min\_style* command; its default is the CG minimizer. The tolerances and limits for each quench can be set by the *min* keyword. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event.

The event check is performed by a compute with the specified *compute-ID*. Currently there is only one compute that works with the TAD command, which is the *compute event/displace* command. Other event-checking computes may be added. *Compute event/displace* checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an “event” has occurred.

The NEB calculation is similar to that invoked by the *neb* command, except that the final state is generated internally, instead of being read in from a file. The style of minimization performed by NEB is determined by the *neb\_style* keyword and must be a damped dynamics minimizer. The tolerances and limits for each NEB calculation can be set by the *neb* keyword. As discussed on the *neb*, it is often advantageous to use a larger timestep for NEB than for normal dynamics. Since the size of the timestep set by the *timestep* command is used by TAD for performing dynamics, there is a *neb\_step* keyword which can be used to set a larger timestep for each NEB calculation if desired.

A key aspect of the TAD method is setting the stopping criterion appropriately. If this criterion is too conservative, then many events must be generated before one is finally executed. Conversely, if this criterion is too aggressive, high-entropy high-barrier events will be over-sampled, while low-entropy low-barrier events will be under-sampled. If the lowest pre-exponential factor is known fairly accurately, then it can be used to estimate  $t_{max}$ , and the value of  $\delta$  can be set to the desired confidence level e.g.  $\delta = 0.05$  corresponds to 95% confidence. However, for systems where the dynamics are not well characterized (the most common case), it will be necessary to experiment with the values of  $\delta$  and  $t_{max}$  to get a good trade-off between accuracy and performance.

A second key aspect is the choice of  $t_{hi}$ . A larger value greatly increases the rate at which new events are generated. However, too large a value introduces errors due to anharmonicity (not accounted for within hTST). Once again, for any given system, experimentation is necessary to determine the best value of  $t_{hi}$ .

Five kinds of output can be generated during a TAD run: event statistics, NEB statistics, thermodynamic output by each replica, dump files, and restart files.

Event statistics are printed to the screen and master log.lammps file each time an event is executed. The quantities are the timestep, CPU time, global event number  $N$ , local event number  $M$ , event status, energy barrier, time margin,  $t_{lo}$  and  $\delta t_{lo}$ . The timestep is the usual LAMMPS timestep, which corresponds to the high-temperature time at which the event was detected, in units of timestep. The CPU time is the total processor time since the start of the TAD run. The global event number  $N$  is a counter that increments with each executed event. The local event number  $M$  is a counter that resets to zero upon entering each new basin. The event status is  $E$  when an event is executed, and is  $D$  for an event that is detected, while  $DF$  is for a detected event that is also the earliest (first) event at the low temperature.

The time margin is the ratio of the high temperature time in the current basin to the stopping time. This last number can be used to judge whether the stopping time is too short or too long (see above).

$t_{lo}$  is the low-temperature event time when the current basin was entered, in units of timestep.  $\delta t_{lo}$  is the time of each detected event, measured relative to  $t_{lo}$ .  $\delta t_{lo}$  is equal to the high-temperature time since entering the current basin, scaled by an exponential factor that depends on the hi/lo temperature ratio and the energy barrier for that event.

On lines for executed events, with status *E*, the global event number is incremented by one, the local event number and time margin are reset to zero, while the global event number, energy barrier, and *delt\_lo* match the last event with status *DF* in the immediately preceding block of detected events. The low-temperature event time *t\_lo* is incremented by *delt\_lo*.

NEB statistics are written to the file specified by the *neb\_log* keyword. If the keyword value is “none”, then no NEB statistics are printed out. The statistics are written every *Nevery* timesteps. See the *neb* command for a full description of the NEB statistics. When invoked from TAD, NEB statistics are never printed to the screen.

Because the NEB calculation must run on multiple partitions, LAMMPS produces additional screen and log files for each partition, e.g. *log.lammps.0*, *log.lammps.1*, etc. For the TAD command, these contain the thermodynamic output of each NEB replica. In addition, the log file for the first partition, *log.lammps.0*, will contain thermodynamic output from short runs and minimizations corresponding to the dynamics and quench operations, as well as a line for each new detected event, as described above.

After the TAD command completes, timing statistics for the TAD run are printed in each replica’s log file, giving a breakdown of how much CPU time was spent in each stage (NEB, dynamics, quenching, etc).

Any *dump files* defined in the input script will be written to during a TAD run at timesteps when an event is executed. This means the requested dump frequency in the *dump* command is ignored. There will be one dump file (per dump command) created for all partitions. The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following the executed event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each TAD run.

If the *restart* command is used, a single restart file for all the partitions is generated, which allows a TAD run to be continued by a new input script in the usual manner. The restart file is generated after an event is executed. The restart file contains a snapshot of the system in the new quenched state, including the event number and the low-temperature time. The restart frequency specified in the *restart* command is interpreted differently when performing a TAD run. It does not mean the timestep interval between restart files. Instead it means an event interval for executed events. Thus a frequency of 1 means write a restart file every time an event is executed. A frequency of 10 means write a restart file every 10th executed event. When an input script reads a restart file from a previous TAD run, the new script can be run on a different number of replicas or processors.

Note that within a single state, the dynamics will typically temporarily continue beyond the event that is ultimately chosen, until the stopping criterion is satisfied. When the event is eventually executed, the timestep counter is reset to the value when the event was detected. Similarly, after each quench and NEB minimization, the timestep counter is reset to the value at the start of the minimization. This means that the timesteps listed in the replica log files do not always increase monotonically. However, the timestep values printed to the master log file, dump files, and restart files are always monotonically increasing.

---

## 1.100.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

*N* setting must be integer multiple of *t\_event*.

Runs restarted from restart files written during a TAD run will only produce identical results if the user-specified integrator supports exact restarts. So *fix nvt* will produce an exact restart, but *fix langevin* will not.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the “ave” fixes such as *fix ave/chunk*. Also *fix dt/reset* and *fix deposit*.

### 1.100.5 Related commands

*compute event/displace, min\_modify, min\_style, run\_style, minimize, temper, neb, prd*

### 1.100.6 Default

The option defaults are *min* = 0.1 0.1 40 50, *neb* = 0.01 100 100 10, *neb\_style* = *quickmin*, *neb\_step* = the same timestep set by the *timestep* command, and *neb\_log* = “none”.

## 1.101 temper command

### 1.101.1 Syntax

```
temper N M temp fix-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- temp = initial temperature for this ensemble
- fix-ID = ID of the fix that will control temperature during the run
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)

### 1.101.2 Examples

```
temper 100000 100 $t tempfix 0 58728
temper 40000 100 $t tempfix 0 32285 $w
```

### 1.101.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system. Two or more replicas must be used.

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the *partition command-line switch*. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the *Howto replica* doc page for further discussion.

Each replica’s temperature is controlled at a different value by a fix with *fix-ID* that controls temperature. Most thermostat fix styles (with and without included time integration) are supported. The command will print an error message and abort, if the chosen fix is unsupported. The desired temperature is specified by *temp*, which is typically a variable

previously set in the input script, so that each partition is assigned a different temperature. See the *variable* command for more details. For example:

```
variable t world 300.0 310.0 320.0 330.0
fix myfix all nvt temp $t $t 100.0
temper 100000 100 $t myfix 3847 58382
```

would define 4 temperatures, and assign one of them to the thermostat used by each replica, and to the temper command.

As the tempering simulation runs for  $N$  timesteps, a temperature swap between adjacent ensembles will be attempted every  $M$  timesteps. If *seed1* is 0, then the swap attempts will alternate between odd and even pairings. If *seed1* is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Boltzmann-weighted Metropolis criterion which uses *seed2* in the random number generator.

As a tempering run proceeds, multiple log files and screen output files are created, one per replica. By default these files are named log.lammps.M and screen.M where M is the replica number from 0 to N-1, with N = # of replicas. See the *-log and -screen command-line switches* for info on how to change these names.

The main screen and log file (log.lammps) will list information about which temperature is assigned to each replica at each thermodynamic output timestep. E.g. for a simulation with 16 replicas:

```
Running on 16 partitions of processors
Step T0 T1 T2 T3 T4 T5 T6 T7 T8 T9 T10 T11 T12 T13 T14 T15
0    0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
500  1 0 3 2 5 4 6 7 8 9 10 11 12 13 14 15
1000 2 0 4 1 5 3 6 7 8 9 10 11 12 14 13 15
1500 2 1 4 0 5 3 6 7 9 8 10 11 12 14 13 15
2000 2 1 3 0 6 4 5 7 10 8 9 11 12 14 13 15
2500 2 1 3 0 6 4 5 7 11 8 9 10 12 14 13 15
...
```

The column headings T0 to TN-1 mean which temperature is currently assigned to the replica 0 to N-1. Thus the columns represent replicas and the value in each column is its temperature (also numbered 0 to N-1). For example, a 0 in the fourth column (column T3, step 2500) means that the fourth replica is assigned temperature 0, i.e. the lowest temperature. You can verify this time sequence of temperature assignments for the Nth replica by comparing the Nth column of screen output to the thermodynamic data in the corresponding log.lammps.N or screen.N files as time proceeds.

You can have each replica create its own dump file in the following manner:

```
variable rep world 0 1 2 3 4 5 6 7
dump 1 all atom 1000 dump.temper.${rep}
```

**Note:** Each replica's dump file will contain a continuous trajectory for its atoms where the temperature varies over time as swaps take place involving that replica. If you want a series of dump files, each with snapshots (from all replicas) that are all at a single temperature, then you will need to post-process the dump files using the information from the log.lammps file. E.g. you could produce one dump file with snapshots at 300K (from all replicas), another with snapshots at 310K, etc. Note that these new dump files will not contain "continuous trajectories" for individual atoms, because two successive snapshots (in time) may be from different replicas. The *reorder\_remd\_traj* python script can do the reordering for you (and additionally also calculated configurational log-weights of trajectory snapshots in the canonical ensemble). The script can be found in the tools/replica directory while instructions on how to use it is available in doc/Tools (in brief) and as a README file in tools/replica (in detail).

The last argument *index* in the temper command is optional and is used when restarting a tempering run from a set of

restart files (one for each replica) which had previously swapped to new temperatures. The *index* value (from 0 to N-1, where N is the # of replicas) identifies which temperature the replica was simulating on the timestep the restart files were written. Obviously, this argument must be a variable so that each partition has the correct value. Set the variable to the *N* values listed in the log file for the previous run for the replica temperatures at that timestep. For example if the log file listed the following for a simulation with 5 replicas:

```
5000000 2 4 0 1 3
```

then a setting of

```
variable w world 2 4 0 1 3
```

would be used to restart the run with a tempering command like the example above with \$w as the last argument.

---

## 1.101.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the [Build package](#) doc page for more info.

## 1.101.5 Related commands

*variable, prd, neb*

## 1.101.6 Default

none

# 1.102 temper/grem command

## 1.102.1 Syntax

```
temper/grem N M lambda fix-ID thermostat-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- lambda = initial lambda for this ensemble
- fix-ID = ID of *fix grem*
- thermostat-ID = ID of the thermostat that controls kinetic temperature
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)

## 1.102.2 Examples

```
temper/grem 100000 1000 ${lambda} fxgREM fxnvt 0 58728
temper/grem 40000 100 ${lambda} fxgREM fxnpt 0 32285 ${walkers}
```

## 1.102.3 Description

Run a parallel tempering or replica exchange simulation in LAMMPS partition mode using multiple generalized replicas (ensembles) of a system defined by *fix grem*, which stands for the generalized replica exchange method (gREM) originally developed by (Kim). It uses non-Boltzmann ensembles to sample over first order phase transitions. The is done by defining replicas with an enthalpy dependent effective temperature

Two or more replicas must be used. See the *temper* command for an explanation of how to run replicas on multiple partitions of one or more processors.

This command is a modification of the *temper* command and has the same dependencies, restraints, and input variables which are discussed there in greater detail.

Instead of temperature, this command performs replica exchanges in lambda as per the generalized ensemble enforced by *fix grem*. The desired lambda is specified by *lambda*, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the *variable* command for more details. For example:

```
variable lambda world 400 420 440 460
fix fxnvt all nvt temp 300.0 300.0 100.0
fix fxgREM all grem ${lambda} -0.05 -50000 fxnvt
temper/grem 100000 100 ${lambda} fxgREM fxnvt 3847 58382
```

would define 4 lambdas with constant kinetic temperature but unique generalized temperature, and assign one of them to *fix grem* used by each replica, and to the *grem* command.

As the gREM simulation runs for  $N$  timesteps, a swap between adjacent ensembles will be attempted every  $M$  timesteps. If *seed1* is 0, then the swap attempts will alternate between odd and even pairings. If *seed1* is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Metropolis criterion, derived for gREM by (Kim), which uses *seed2* in the random number generator.

File management works identical to the *temper* command. Dump files created by this fix contain continuous trajectories and require post-processing to obtain per-replica information.

The last argument *index* in the *grem* command is optional and is used when restarting a run from a set of restart files (one for each replica) which had previously swapped to new lambda. This is done using a variable. For example if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable walkers world 2 4 0 1 3
```

would be used to restart the run with a *grem* command like the example above with *\${walkers}* as the last argument. This functionality is identical to *temper*.

### 1.102.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

This command must be used with *fix grem*.

### 1.102.5 Related commands

*fix grem*, *temper*, *variable*

### 1.102.6 Default

none

## 1.103 temper/npt command

### 1.103.1 Syntax

```
temper/npt N M temp fix-ID seed1 seed2 pressure index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- temp = initial temperature for this ensemble
- fix-ID = ID of the fix that will control temperature and pressure during the run
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- pressure = setpoint pressure for the ensemble
- index = which temperature (0 to N-1) I am simulating (optional)

### 1.103.2 Examples

```
temper/npt 100000 100 $t nptfix 0 58728 1
temper/npt 2500000 1000 300 nptfix 0 32285 $p
temper/npt 5000000 2000 $t nptfix 0 12523 1 $w
```

### 1.103.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system in the isothermal-isobaric (NPT) ensemble. The command `temper/npt` works like *temper* but requires running replicas in the NPT ensemble instead of the canonical (NVT) ensemble and allows for pressure to be set in the ensembles. These multiple ensembles can run in parallel at different temperatures or different pressures. The acceptance criteria for `temper/npt` is specific to the NPT ensemble and can be found in references (*Okabe*) and (*Mori*).

Apart from the difference in acceptance criteria and the specification of pressure, this command works much like the *temper* command. See the documentation on *temper* for information on how the parallel tempering is handled in general.

---

### 1.103.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* page for more info.

This command should be used with a fix that maintains the isothermal-isobaric (NPT) ensemble.

### 1.103.5 Related commands

## 1.104 thermo command

### 1.104.1 Syntax

```
thermo N
```

- N = output thermodynamics every N timesteps
- N can be a variable (see below)

## 1.104.2 Examples

```
thermo 100
```

## 1.104.3 Description

Compute and print thermodynamic info (e.g. temperature, energy, pressure) on timesteps that are a multiple of N and at the beginning and end of a simulation. A value of 0 will only print thermodynamics at the beginning and end.

The content and format of what is printed is controlled by the *thermo\_style* and *thermo\_modify* commands.

Instead of a numeric value, N can be specified as an *equal-style variable*, which should be specified as v\_name, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which thermodynamic info will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for *equal-style variables*, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for *equal-style variables*.

For example, the following commands will output thermodynamic info at timesteps 0, 10, 20, 30, 100, 200, 300, 1000, 2000, etc:

```
variable      s equal logfreq(10,3,10)
thermo        v_s
```

## 1.104.4 Restrictions

none

thermo_modify temp myTemp format line "%ld %g %g %15.8g"
thermo_modify line multi format float %g
thermo_modify line yaml format none
thermo_modify colname 1 Timestep colname -2 Pressure colname f_1[1] AvgDensity
```

## 1.105.3 Description

Set options for how thermodynamic information is computed and printed by LAMMPS.

---

**Note:** These options apply to the *currently defined* thermo style. When you specify a *thermo\_style* command, all thermodynamic settings are restored to their default values, including those previously reset by a *thermo\_modify* command. Thus if your input script specifies a *thermo\_style* command, you should use the *thermo\_modify* command **after** it.

---

The *lost* keyword determines whether LAMMPS checks for lost atoms each time it computes thermodynamics and what it does if atoms are lost. An atom can be “lost” if it moves across a non-periodic simulation box *boundary* or if it moves more than a box length outside the simulation domain (or more than a processor subdomain length) before reneighboring occurs. The latter case is typically due to bad dynamics (e.g., too large a time step and/or huge forces and velocities). If the value is *ignore*, LAMMPS does not check for lost atoms. If the value is *error* or *warn*, LAMMPS checks and either issues an error or warning. The simulation will exit with an error and continue with a warning. A warning will only be issued once, the first time an atom is lost. This can be a useful debugging option.

The *lost/bond* keyword determines whether LAMMPS throws an error or not if an atom in a bonded interaction (bond, angle, etc) cannot be found when it creates bonded neighbor lists. By default this is a fatal error. However in some scenarios it may be desirable to only issue a warning or ignore it and skip the computation of the missing bond, angle,

etc. An example would be when gas molecules in a vapor are drifting out of the box through a fixed boundary condition (see the *boundary* command). In this case one atom may be deleted before the rest of the molecule is, on a later timestep.

The *warn* keyword allows you to control whether LAMMPS will print warning messages and how many of them. Most warning messages are only printed by MPI rank 0. They are usually pointing out important issues that should be investigated, but LAMMPS cannot determine for certain whether they are an indication of an error.

Some warning messages are printed during a run (or immediately before) each time a specific MPI rank encounters the issue (e.g., bonds that are stretched too far or dihedrals in extreme configurations). These number of these can quickly blow up the size of the log file and screen output. Thus, a limit of 100 warning messages is applied by default. The warning count is applied to the entire input unless reset with a *thermo\_modify warn reset* command. If there are more warnings than the limit, LAMMPS will print one final warning that it will not print any additional warning messages.

---

**Note:** The warning limit is enforced on either the per-processor count or the total count across all processors. For efficiency reasons, however, the total count is only updated at steps with thermodynamic output. Thus when running on a large number of processors in parallel, the total number of warnings printed can be significantly larger than the given limit.

---

Any number after the keyword *warn* will change the warning limit accordingly. With the value *ignore* all warnings will be suppressed, with the value *always* no limit will be applied and warnings will always be printed, with the value *reset* the internal warning counter will be reset to zero, and with the value *default*, the counter is reset and the limit set to 100. An example usage of either *reset* or *default* would be to re-enable warnings that were disabled or have reached the limit during equilibration, where the warnings would be acceptable while the system is still adjusting, but then change to all warnings for the production run, where they would indicate problems that would require a closer look at what is causing them.

The *norm* keyword determines whether various thermodynamic output values are normalized by the number of atoms or not, depending on whether it is set to *yes* or *no*. Different unit styles have different defaults for this setting (see below). Even if *norm* is set to *yes*, a value is only normalized if it is an “extensive” quantity, meaning that it scales with the number of atoms in the system. For the thermo keywords described by the page for the *thermo\_style* command, all energy-related keywords are extensive, such as *pe* or *ebond* or *enthalpy*. Other keywords such as *temp* or *press* are “intensive” meaning their value is independent (in a statistical sense) of the number of atoms in the system and thus are never normalized. For thermodynamic output values extracted from *fixes* and *computes* in a *thermo\_style custom* command, the page for the individual *fix* or *compute* lists whether the value is “extensive” or “intensive” and thus whether it is normalized. Thermodynamic output values calculated by a variable formula are assumed to be “intensive” and thus are never normalized. You can always include a divide by the number of atoms in the variable formula if this is not the case.

The *flush* keyword invokes a flush operation after thermodynamic info is written to the screen and log file. This ensures the output is updated and not buffered (by the application) even if LAMMPS halts before the simulation completes. Please note that this does not affect buffering by the OS or devices, so you may still lose data in case the simulation stops due to a hardware failure.

The *line* keyword determines whether thermodynamics will be output as a series of numeric values on one line (“one”), in a multi-line format with 3 quantities with text strings per line and a dashed-line header containing the timestep and CPU time (“multi”), or in a YAML format block (“yaml”). This modify option overrides the *one*, *multi*, or *yaml* *thermo\_style* settings.

New in version 4May2022.

The *colname* keyword can be used to change the default header keyword for a column or field of thermodynamic output. The setting for *ID string* replaces the default text with the provided string. *ID* can be a positive integer when it represents the column number counting from the left, a negative integer when it represents the column number from the right (i.e., -1 is the last column/keyword), or a thermo keyword (or *compute*, *fix*, *property*, or *variable* reference) and then it replaces the string for that specific thermo keyword.

The *colname* keyword can be used multiple times. If multiple *colname* settings refer to the same keyword, the last setting has precedence. A setting of *default* clears all previous settings, reverting all values to their default values.

The *format* keyword can be used to change the default numeric format of any of quantities the *thermo\_style* command outputs. All the specified format strings are C-style formats (i.e., as used by the C/C++ `printf()` command). The *line* keyword takes a single argument which is the format string for the entire line of thermo output, with *N* fields, which you must enclose in quotes if it is more than one field. The *int* and *float* keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for *ID string* also takes a single format argument that is used for the indexed value in each line. The interpretation is the same as for *colname* (i.e., a positive integer is the *n*-th value corresponding to the *n*-th thermo keyword, a negative integer is counting backwards, and a string matches the entry with the thermo keyword). For example, the fifth column is output in high precision for “format 5 %20.15g”, and the pair energy for “format epair %20.15g”. The *ID* field can be a range, such as “3\*6”, “\*”, “2\*”, or “\*3”; in such cases, all fields in the range (inclusive) are set to the specified format string. Ranges containing negative numbers are not supported.

The *format* keyword can be used multiple times. The precedence is that for each value in a line of output, the *ID* format (if specified) is used, else the *int* or *float* setting (if specified) is used, else the *line* setting (if specified) for that value is used, else the default setting is used. A setting of *none* clears all previous settings, reverting all values to their default format.

---

**Note:** The thermo output values *step* and *atoms* are stored internally as 8-byte signed integers, rather than the usual 4-byte signed integers. When specifying the *format int* option you can use a “%d”-style format identifier in the format string and LAMMPS will convert this to the corresponding 8-byte form when it is applied to those keywords. However, when specifying the *line* option or *format ID string* option for *step* and *natoms*, you should specify a format string appropriate for an 8-byte signed integer (i.e., one with “%ld” or “%lld”, depending on the platform).

---

The *temp* keyword is used to determine how thermodynamic temperature is calculated, which is used by all thermo quantities that require a temperature (“temp”, “press”, “ke”, “etotal”, “enthalpy”, “pxx”, etc). The specified compute ID must have been previously defined by the user via the *compute* command and it must be a style of compute that calculates a temperature. As described in the *thermo\_style* command, thermo output uses a default compute for temperature with *ID = thermo\_temp*. This option allows the user to override the default.

The *press* keyword is used to determine how thermodynamic pressure is calculated, which is used by all thermo quantities that require a pressure (“press”, “enthalpy”, “pxx”, etc). The specified compute ID must have been previously defined by the user via the *compute* command and it must be a style of compute that calculates a pressure. As described in the *thermo\_style* command, thermo output uses a default compute for pressure with *ID = thermo\_press*. This option allows the user to override the default.

---

**Note:** If both the *temp* and *press* keywords are used in a single *thermo\_modify* command (or in two separate commands), then the order in which the keywords are specified is important. Note that a *pressure compute* defines its own temperature compute as an argument when it is specified. The *temp* keyword will override this (for the pressure compute being used by thermodynamics), but only if the *temp* keyword comes after the *press* keyword. If the *temp* keyword comes before the *press* keyword, then the new pressure compute specified by the *press* keyword will be unaffected by the *temp* setting.

---

The *triclinic/general* keyword can only be used with a value of *yes* if the simulation box was created as a general triclinic box. See the [Howto\\_triclinic](#) doc page for a detailed explanation of orthogonal, restricted triclinic, and general triclinic simulation boxes.

If this keyword is *yes*, the output of the simulation box edge vectors and the pressure tensor components for the system are affected. These are specified by the *avec,bvec,cvec* and *pxx,pyy,pzz,pxy,pxz,pyz* keywords of the *thermo\_style* command. See the [thermo\\_style](#) doc page for details.

## 1.105.4 Restrictions

none

## 1.105.5 Related commands

*thermo*, *thermo\_style*

## 1.105.6 Default

The option defaults are `lost = error`, `warn = 100`, `norm = yes` for unit style of *lj*, `norm = no` for unit style of *real* and *metal*, `flush = no`, `temp/press = compute` IDs defined by *thermo\_style*, and `triclinic/general = no`.

The defaults for the line and format options depend on the thermo style. For styles “one” and “custom”, the line and format defaults are “one”, “%10d”, and “%14.8g”. For style “multi”, the line and format defaults are “multi”, “%14d”, and “%14.4f”. For style “yaml”, the line and format defaults are “%d” and “%.15g”.

## 1.106.2 Examples

```
thermo_style multi
thermo_style yaml
thermo_style one
thermo_style custom step temp pe etotal press vol
thermo_style custom step temp etotal c_myTemp v_abc
thermo_style custom step temp etotal c_myTemp[*] v_abc
```

## 1.106.3 Description

Set the style and content for printing thermodynamic data to the screen and log files. The units for each column of output corresponding to the list of keywords is determined by the [units](#) command for the simulation. E.g. energies will be in energy units, temperature in temperature units, pressure in pressure units.

Style *one* prints a single line of thermodynamic info that is the equivalent of “thermo\_style custom step temp epair emol etotal press”. The line contains only numeric values.

Style *multi* prints a multiple-line listing of thermodynamic info that is the equivalent of “thermo\_style custom etotal ke temp pe ebond eangle edihed eimp evdwl ecoul elong press”. The listing contains numeric values and a string ID for each quantity.

New in version 24Mar2022.

Style *yaml* is similar to style *one* but prints the output in [YAML](#) format which can be easily read by a variety of script languages and data handling packages. Since LAMMPS may print other output before, after, or in between thermodynamic output, the YAML format content needs to be separated from the rest. All YAML format thermodynamic output can be matched with a regular expression and can thus be extracted with commands like `egrep` as follows:

```
egrep '^ (keywords:|data:$|---$|\\.\\.\\. $| - \D)' log.lammps > log.yaml
```

Information about processing such YAML files is in the [structured data output howto](#).

Style *custom* is the most general setting and allows you to specify which of the keywords listed above you want printed on each thermodynamic timestep. Note that the keywords `c_ID`, `f_ID`, `v_name` are references to [computes](#), [fixes](#), and equal-style [variables](#) that have been defined elsewhere in the input script or can even be new styles which users have added to LAMMPS. See the [Modify](#) page for details on the latter. Thus the *custom* style provides a flexible means of outputting essentially any desired quantity as a simulation proceeds.

All styles except *custom* have *vol* appended to their list of outputs if the simulation box volume changes during the simulation.

The values printed by the various keywords are instantaneous values, calculated on the current timestep. Time-averaged quantities, which include values from previous timesteps, can be output by using the `f_ID` keyword and accessing a fix that does time-averaging such as the [fix ave/time](#) command.

Options invoked by the [thermo\\_modify](#) command can be used to set the one- or multi-line format of the print-out, the normalization of thermodynamic output (total values versus per-atom values for extensive quantities (ones which scale with the number of atoms in the system)), and the numeric precision of each printed value.

**Note:** When you use a “thermo\_style” command, all thermodynamic settings are restored to their default values, including those previously set by a *thermo\_modify* command. Thus if your input script specifies a thermo\_style command, you should use the thermo\_modify command after it.

---

Several of the thermodynamic quantities require a temperature to be computed: “temp”, “press”, “ke”, “etotal”, “enthalpy”, “pxx”, etc. By default this is done by using a *temperature* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_temp all temp
```

See the *compute temp* command for details. Note that the ID of this compute is *thermo\_temp* and the group is *all*. You can change the attributes of this temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command. Alternatively, you can directly assign a new compute (that calculates temperature) which you have defined, to be used for calculating any thermodynamic quantity that requires a temperature. This is done via the *thermo\_modify* command.

Several of the thermodynamic quantities require a pressure to be computed: “press”, “enthalpy”, “pxx”, etc. By default this is done by using a *pressure* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_press all pressure thermo_temp
```

See the *compute pressure* command for details. Note that the ID of this compute is *thermo\_press* and the group is *all*. You can change the attributes of this pressure via the *compute\_modify* command. Alternatively, you can directly assign a new compute (that calculates pressure) which you have defined, to be used for calculating any thermodynamic quantity that requires a pressure. This is done via the *thermo\_modify* command.

Several of the thermodynamic quantities require a potential energy to be computed: “pe”, “etotal”, “ebond”, etc. This is done by using a *pe* compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_pe all pe
```

See the *compute pe* command for details. Note that the ID of this compute is *thermo\_pe* and the group is *all*. You can change the attributes of this potential energy via the *compute\_modify* command.

---

The kinetic energy of the system *ke* is inferred from the temperature of the system with  $\frac{1}{2}k_B T$  of energy for each degree of freedom. Thus, using different *compute commands* for calculating temperature, via the *thermo\_modify temp* command, may yield different kinetic energies, since different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc).

The potential energy of the system *pe* will include contributions from fixes if the *fix\_modify energy yes* option is set for a fix that calculates such a contribution. For example, the *fix wall/lj93* fix calculates the energy of atoms interacting with the wall. See the doc pages for “individual fixes” to see which ones contribute and whether their default *fix\_modify energy* setting is *yes* or *no*.

A long-range tail correction *etail* for the van der Waals pairwise energy will be non-zero only if the *pair\_modify tail* option is turned on. The *etail* contribution is included in *evdwl*, *epair*, *pe*, and *etotal*, and the corresponding tail correction to the pressure is included in *press* and *pxx*, *pyy*, etc.

---

Here is more information on other keywords whose meaning may not be clear.

The *step*, *elapsed*, and *elaplong* keywords refer to timestep count. *Step* is the current timestep, or iteration count when a *minimization* is being performed. *Elapsed* is the number of timesteps elapsed since the beginning of this run. *Elaplong*

is the number of timesteps elapsed since the beginning of an initial run in a series of runs. See the *start* and *stop* keywords for the *run* for info on how to invoke a series of runs that keep track of an initial starting time. If these keywords are not used, then *elapsed* and *elaplong* are the same value.

The *dt* keyword is the current timestep size in time *units*. The *time* keyword is the current elapsed simulation time, also in time *units*, which is simply (step\*dt) if the timestep size has not changed and the timestep has not been reset. If the timestep has changed (e.g. via *fix dt/reset*) or the timestep has been reset (e.g. via the “reset\_timestep” command), then the simulation time is effectively a cumulative value up to the current point.

The *cpu* keyword is elapsed CPU seconds since the beginning of this run. The *tpcpu* and *spcpu* keywords are measures of how fast your simulation is currently running. The *tpcpu* keyword is simulation time per CPU second, where simulation time is in time *units*. E.g. for metal units, the *tpcpu* value would be picoseconds per CPU second. The *spcpu* keyword is the number of timesteps per CPU second. Both quantities are on-the-fly metrics, measured relative to the last time they were invoked. Thus if you are printing out thermodynamic output every 100 timesteps, the two keywords will continually output the time and timestep rate for the last 100 steps. The *tpcpu* keyword does not attempt to track any changes in timestep size, e.g. due to using the *fix dt/reset* command.

The *cpuremain* keyword estimates the CPU time remaining in the current run, based on the time elapsed thus far. It will only be a good estimate if the CPU time/timestep for the rest of the run is similar to the preceding timesteps. On the initial timestep the value will be 0.0 since there is no history to estimate from. For a minimization run performed by the “minimize” command, the estimate is based on the *maxiter* parameter, assuming the minimization will proceed for the maximum number of allowed iterations.

The *part* keyword is useful for multi-replica or multi-partition simulations to indicate which partition this output and this file corresponds to, or for use in a *variable* to append to a filename for output specific to this partition. See discussion of the *-partition command-line switch* for details on running in multi-partition mode.

The *timeremain* keyword is the seconds remaining when a timeout has been configured via the *timer timeout* command. If the timeout timer is inactive, the value of this keyword is 0.0 and if the timer is expired, it is negative. This allows for example to exit loops cleanly, if the timeout is expired with:

```
if "${timeremain} < 0.0" then "quit 0"
```

The *ecouple* keyword is cumulative energy change in the system due to any thermostating or barostating fixes that are being used. A positive value means that energy has been subtracted from the system (added to the coupling reservoir). See the *econserve* keyword for an explanation of why this sign choice makes sense.

The *econserve* keyword is the sum of the potential and kinetic energy of the system as well as the energy that has been transferred by thermostating or barostating to their coupling reservoirs – that is,  $econserve = pe + ke + ecouple$ . Ideally, for a simulation in the NVT, NPH, or NPT ensembles, the *econserve* quantity should remain constant over time even though *etotal* may change.

In LAMMPS, the simulation box can be defined as orthogonal or triclinic (non-orthogonal). See the *Howto\_triclinic* doc page for a detailed explanation of orthogonal, restricted triclinic, and general triclinic simulation boxes and how LAMMPS rotates a general triclinic box to be restricted triclinic internally.

The *lx*, *ly*, *lz* keywords are the extent of the simulation box in each dimension. The *xlo*, *xhi*, *ylo*, *yhi*, *zlo*, *zhi* keywords are the lower and upper bounds of the simulation box in each dimension. I.e.  $lx = xhi - xlo$ . These 9 values are the same for all 3 kinds of boxes. I.e. for a restricted triclinic box, they are the values as if the box were not tilted. For a general triclinic box, they are the values after it is internally rotated to be a restricted triclinic box.

The *xy*, *xz*, *yz* are the current tilt factors for a triclinic box. They are the same for restricted and general triclinic boxes.

The *avecx*, *avecy*, *avecz*, *bvecx*, *bvecy*, *bvecz*, *cvecx*, *cvecy*, *cvecz* are the components of the 3 edge vectors of the current general simulation box. If it is an orthogonal box the vectors are along the x, y, z coordinate axes. If it is a restricted triclinic box, the **A** vector is along the x axis, the **B** vector is in the xy plane with a +y coordinate, and the **C** vector has a +z coordinate, as explained on the *Howto\_triclinic* doc page. If the *thermo\_modify triclinic/general* option is set then they are the **A**, **B**, **C** vector which define the general triclinic box.

The *cella*, *cellb*, *cellc*, *cellalpha*, *cellbeta*, *cellgamma* keywords correspond to the usual crystallographic quantities that define the periodic simulation box of a crystalline system. See the [Howto triclinic](#) page for a precise definition of these quantities in terms of the LAMMPS representation of a restricted triclinic simulation box via *lx*, *ly*, *lz*, *yz*, *xz*, *xy*.

The *pxx*, *pyy*, *pzz*, *pxy*, *pxz*, *pyz* keywords are the 6 components of the symmetric pressure tensor for the system. See the [compute pressure](#) command doc page for details of how it is calculated.

If the [thermo\\_modify triclinic/general](#) option is set then the 6 components will be output as values consistent with the orientation of the general triclinic box relative to the standard xyz coordinate axes. If this keyword is not used, the values will be consistent with the orientation of the restricted triclinic box (which aligns with the xyz coordinate axes). As explained on the [Howto triclinic](#) doc page, even if the simulation box is created as a general triclinic box, internally LAMMPS uses a restricted triclinic box.

Note that because the pressure tensor components are computed using force vectors and atom coordinates, both of which are rotated in the general versus restricted triclinic representation, the values will typically be different for the two cases.

The *fmax* and *fnorm* keywords are useful for monitoring the progress of an [energy minimization](#). The *fmax* keyword calculates the maximum force in any dimension on any atom in the system, or the infinity-norm of the force vector for the system. The *fnorm* keyword calculates the 2-norm or length of the force vector.

The *nbuild* and *ndanger* keywords are useful for monitoring neighbor list builds during a run. Note that both these values are also printed with the end-of-run statistics. The *nbuild* keyword is the number of re-builds during the current run. The *ndanger* keyword is the number of re-builds that LAMMPS considered potentially “dangerous”. If atom movement triggered neighbor list rebuilding (see the [neigh\\_modify](#) command), then dangerous reneighborings are those that were triggered on the first timestep atom movement was checked for. If this count is non-zero you may wish to reduce the delay factor to ensure no force interactions are missed by atoms moving beyond the neighbor skin distance before a rebuild takes place.

---

For output values from a *compute* or *fix* or *variable*, the bracketed index *I* used to index a vector, as in *c\_ID[I]* or *f\_ID[I]* or *v\_name[I]*, can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If *N* = the size of the vector, then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 *thermo\_style* commands are equivalent, since the [compute temp](#) command creates a global vector with 6 values.

```
compute myTemp all temp
thermo_style custom step temp etotal c_myTemp[*]
thermo_style custom step temp etotal &
    c_myTemp[1] c_myTemp[2] c_myTemp[3] &
    c_myTemp[4] c_myTemp[5] c_myTemp[6]
```

---

**Note:** For a vector-style variable, only the wildcard forms “\*n” or “m\*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If *n* is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

---

The *c\_ID* and *c\_ID[I]* and *c\_ID[I][J]* keywords allow global values calculated by a *compute* to be output. As discussed on the [compute](#) doc page, computes can calculate global, per-atom, local, and per-grid values. Only global values can be referenced by this command. However, per-atom compute values for an individual atom can be referenced in a [equal-style variable](#) and the variable referenced by *thermo\_style* custom, as discussed below. See the discussion above

for how the  $I$  in `c_ID[I]` can be specified with a wildcard asterisk to effectively specify multiple values from a global compute vector.

The  $ID$  in the keyword should be replaced by the actual  $ID$  of a compute that has been defined elsewhere in the input script. See the `compute` command for details. If the compute calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the compute.

Note that some computes calculate “intensive” global quantities like temperature; others calculate “extensive” global quantities like kinetic energy that are summed over all atoms in the compute group. Intensive quantities are printed directly without normalization by `thermo_style` custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the compute group) when output, depending on the `thermo_modify norm` option being used.

The `f_ID` and `f_ID[I]` and `f_ID[I][J]` keywords allow global values calculated by a fix to be output. As discussed on the `fix` doc page, fixes can calculate global, per-atom, local, and per-grid values. Only global values can be referenced by this command. However, per-atom fix values can be referenced for an individual atom in a `equal-style variable` and the variable referenced by `thermo_style` custom, as discussed below. See the discussion above for how the  $I$  in `f_ID[I]` can be specified with a wildcard asterisk to effectively specify multiple values from a global fix vector.

The  $ID$  in the keyword should be replaced by the actual  $ID$  of a fix that has been defined elsewhere in the input script. See the `fix` command for details. If the fix calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the fix.

Note that some fixes calculate “intensive” global quantities like timestep size; others calculate “extensive” global quantities like energy that are summed over all atoms in the fix group. Intensive quantities are printed directly without normalization by `thermo_style` custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the fix group) when output, depending on the `thermo_modify norm` option being used.

The `v_name` keyword allow the current value of a variable to be output. The name in the keyword should be replaced by the variable name that has been defined elsewhere in the input script. Only equal-style and vector-style variables can be referenced; the latter requires a bracketed term to specify the  $I$ th element of the vector calculated by the variable. However, an equal-style variable can use an atom-style variable in its formula indexed by the  $ID$  of an individual atom. This is a way to output a specific atom’s per-atom coordinates or other per-atom properties in thermo output. See the `variable` command for details. Note that variables of style `equal` and `vector` and `atom` define a formula which can reference per-atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when evaluated, so this is a very general means of creating thermodynamic output.

Note that equal-style and vector-style variables are assumed to produce “intensive” global quantities, which are thus printed as-is, without normalization by `thermo_style` custom. You can include a division by “natoms” in the variable formula if this is not the case.

---

#### 1.106.4 Restrictions

This command must come after the simulation box is defined by a `read_data`, `read_restart`, or `create_box` command.

## 1.106.5 Related commands

*thermo*, *thermo\_modify*, *fix\_modify*, *compute temp*, *compute pressure*

## 1.106.6 Default

```
thermo_style one
```

# 1.107 third\_order command

Accelerator Variant: third\_order/kk

## 1.107.1 Syntax

```
third_order group-ID style delta args keyword value ...
```

- group-ID = ID of group of atoms to displace
- style = *regular* or *eskm*
- delta = finite different displacement length (distance units)
- one or more keyword/arg pairs may be appended

keyword = *file* or *binary*

*file* name = name of output file for the third order tensor

*binary* arg = *yes* or *no* or *gzip*

## 1.107.2 Examples

```
third_order 1 regular 0.000001
third_order 1 eskm 0.000001
third_order 3 regular 0.00004 file third_order.dat
third_order 5 eskm 0.00000001 file third_order.dat binary yes
```

## 1.107.3 Description

Calculate the third order force constant tensor by finite difference of the selected group,

$$\Phi_{ijk}^{\alpha\beta\gamma} = \frac{\partial^3 U}{\partial x_{i,\alpha} \partial x_{j,\beta} \partial x_{k,\gamma}}$$

where Phi is the third order force constant tensor.

The output of the command is the tensor, three elements at a time. The three elements correspond to the three gamma elements for a specific i/alpha/j/beta/k. The initial five numbers are i, alpha, j, beta, and k respectively.

If the style eskm is selected, the tensor will be using energy units of 10 J/mol. These units conform to eskm style from the dynamical\_matrix command, which will simplify operations using dynamical matrices with third order tensors.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 1.107.4 Restrictions

The command collects a 9 times the number of atoms in the group on every single MPI rank, so the memory requirements can be very significant for large systems.

This command is part of the PHONON package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 1.107.5 Related commands

*fix phonon dynamical\_matrix*

## 1.107.6 Default

The default settings are file = “third\_order.dat”, binary = no

# 1.108 timer command

## 1.108.1 Syntax

**timer** args

- *args* = one or more of *off* or *loop* or *normal* or *full* or *sync* or *nosync* or *timeout* or *every*

*off* = do not collect or print any timing information

*loop* = collect only the total time for the simulation loop

*normal* = collect timer information broken down by sections (default)

*full* = like *normal* but also include CPU and thread utilization

*sync* = explicitly synchronize MPI tasks between sections

*nosync* = do not synchronize MPI tasks between sections (default)

*timeout* elapse = set wall time limit to *elapse*

*every* Ncheck = perform timeout check every *Ncheck* steps

## 1.108.2 Examples

```
timer full sync
timer timeout 2:00:00 every 100
timer loop
```

## 1.108.3 Description

Select the level of detail at which LAMMPS performs its CPU timings. Multiple keywords can be specified with the *timer* command. For keywords that are mutually exclusive, the last one specified takes precedence.

During a simulation run LAMMPS collects information about how much time is spent in different sections of the code and thus can provide information for determining performance and load imbalance problems. This can be done at different levels of detail and accuracy. For more information about the timing output, see the [Run output](#) doc page.

The *off* setting will turn all time measurements off. The *loop* setting will only measure the total time for a run and not collect any detailed per section information. With the *normal* setting, timing information for portions of the timestep (pairwise calculations, neighbor list construction, output, etc) are collected as well as information about load imbalances for those sections across processors. The *full* setting adds information about CPU utilization and thread utilization, when multi-threading is enabled.

With the *sync* setting, all MPI tasks are synchronized at each timer call which measures load imbalance for each section more accurately, though it can also slow down the simulation by prohibiting overlapping independent computations on different MPI ranks. Using the *nosync* setting (which is the default) turns this synchronization off.

With the *timeout* keyword a wall time limit can be imposed, that affects the [run](#) and [minimize](#) commands. This can be convenient when calculations have to comply with execution time limits, e.g. when running under a batch system when you want to maximize the utilization of the batch time slot, especially for runs where the time per timestep varies much and thus it becomes difficult to predict how many steps a simulation can perform for a given wall time limit. This also applies for difficult to converge minimizations. The *timeout* *elapse* value should be somewhat smaller than the maximum wall time requested from the batch system, as there is usually some overhead to launch jobs, and it is advisable to write out a restart after terminating a run due to a timeout.

The *timeout* timer starts when the command is issued. When the time limit is reached, the run or energy minimization will exit on the next step or iteration that is a multiple of the *Ncheck* value which can be set with the *every* keyword. Default is checking every 10 steps. After the timer timeout has expired all subsequent run or minimize commands in the input script will be skipped. The remaining time or timer status can be accessed with the [thermo](#) variable *timeremain*, which will be zero, if the timeout is inactive (default setting), it will be negative, if the timeout time is expired and positive if there is time remaining and in this case the value of the variable are the number of seconds remaining.

When the *timeout* key word is used a second time, the timer is restarted with a new time limit. The *timeout* *elapse* value can be specified as *off* or *unlimited* to impose a no timeout condition (which is the default). The *elapse* setting can be specified as a single number for seconds, two numbers separated by a colon (MM:SS) for minutes and seconds, or as three numbers separated by colons for hours, minutes, and seconds (H:MM:SS).

The *every* keyword sets how frequently during a run or energy minimization the wall clock will be checked. This check count applies to the outer iterations or time steps during minimizations or *r-RESPA* runs, respectively. Checking for timeout too often, can slow a calculation down. Checking too infrequently can make the timeout measurement less accurate, with the run being stopped later than desired.

---

**Note:** Using the *full* and *sync* options provides the most detailed and accurate timing information, but can also have a negative performance impact due to the overhead of the many required system calls. It is thus recommended to use these settings only when testing tests to identify performance bottlenecks. For calculations with few atoms or a very

large number of processors, even the *normal* setting can have a measurable negative performance impact. In those cases you can just use the *loop* or *off* setting.

timestep 0.003
```

## 1.109.3 Description

Set the timestep size for subsequent molecular dynamics simulations. See the *units* command for the time units associated with each choice of units that LAMMPS supports.

The default value for the timestep size also depends on the choice of units for the simulation; see the default values below.

When the *run style* is *respa*, dt is the timestep for the outer loop (largest) timestep.

## 1.109.4 Restrictions

none

## 1.109.5 Related commands

*fix dt/reset*, *run*, *run\_style* respa, *units*

## 1.109.6 Default

choice of <i>units</i>	time units	default timestep size
lj	$\tau$	0.005 $\tau$
real	fs	1.0 fs
metal	ps	0.001 ps
si	s	1.0e-8 s (10 ns)
cgs	s	1.0e-8 s (10 ns)
electron	fs	0.001 fs
micro	$\mu$ s	2.0 $\mu$ s
nano	ns	0.00045 ns

# 1.110 uncompute command

## 1.110.1 Syntax

```
uncompute compute-ID
```

- compute-ID = ID of a previously defined compute

## 1.110.2 Examples

```
uncompute 2
uncompute lower-boundary
```

## 1.110.3 Description

Delete a compute that was previously defined with a *compute* command. This also wipes out any additional changes made to the compute via the *compute\_modify* command.

## 1.110.4 Restrictions

none

## 1.110.5 Related commands

## 1.113.2 Examples

```
units metal
units lj
```

## 1.113.3 Description

This command sets the style of units used for a simulation. It determines the units of all quantities specified in the input script and data file, as well as quantities output to the screen, log file, and dump files. Typically, this command is used at the very beginning of an input script.

For all units except *lj*, LAMMPS uses physical constants from [www.physics.nist.gov](http://www.physics.nist.gov). For the definition of kcal in real units, LAMMPS uses the thermochemical calorie = 4.184 J.

The choice you make for units simply sets some internal conversion factors within LAMMPS. This means that any simulation you perform for one choice of units can be duplicated with any other unit setting LAMMPS supports. In this context “duplicate” means the particles will have identical trajectories and all output generated by the simulation will be identical. This will be the case for some number of timesteps until round-off effects accumulate, since the conversion factors for two different unit systems are not identical to infinite precision.

To perform the same simulation in a different set of units you must change all the unit-based input parameters in your input script and other input files (data file, potential files, etc) correctly to the new units. And you must correctly convert all output from the new units to the old units when comparing to the original results. That is often not simple to do.

Potential or table files may have a **UNITS:** tag included in the first line indicating the unit style those files were created for. If the tag exists, its value will be compared to the chosen unit style and LAMMPS will stop with an error message if there is a mismatch. In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

For style *lj*, all quantities are unitless. Without loss of generality, LAMMPS sets the fundamental quantities mass,  $\sigma$ ,  $\epsilon$ , and the Boltzmann constant  $k_B = 1$ . The masses, distances, energies you specify are multiples of these fundamental values. The formulas relating the reduced or unitless quantity (with an asterisk) to the same quantity with units is also given. Thus you can use the mass,  $\sigma$ , and  $\epsilon$  values for a specific material and convert the results from a unitless LJ simulation into physical quantities. Please note that using these three properties as base, your unit of time has to conform to the relation  $\epsilon = \frac{m\sigma^2}{\tau^2}$  since energy is a derived unit (in SI units you equivalently have the relation  $1\text{ J} = 1 \frac{\text{kg}\cdot\text{m}^2}{\text{s}^2}$ ).

- mass = mass or  $m$ , where  $M^* = \frac{M}{m}$
- distance =  $\sigma$ , where  $x^* = \frac{x}{\sigma}$
- time =  $\tau$ , where  $\tau^* = \tau \sqrt{\frac{\epsilon}{m\sigma^2}}$
- energy =  $\epsilon$ , where  $E^* = \frac{E}{\epsilon}$
- velocity =  $\frac{\sigma}{\tau}$ , where  $v^* = v \frac{\tau}{\sigma}$
- force =  $\frac{\epsilon}{\sigma}$ , where  $f^* = f \frac{\sigma}{\epsilon}$
- torque =  $\epsilon$ , where  $t^* = \frac{t}{\epsilon}$
- temperature = reduced LJ temperature, where  $T^* = \frac{T k_B}{\epsilon}$
- pressure = reduced LJ pressure, where  $p^* = p \frac{\sigma^3}{\epsilon}$
- dynamic viscosity = reduced LJ viscosity, where  $\eta^* = \eta \frac{\sigma^3}{\epsilon \tau}$

- charge = reduced LJ charge, where  $q^* = q \frac{1}{\sqrt{4\pi\epsilon_0\sigma\epsilon}}$
- dipole = reduced LJ dipole, moment where  $\mu^* = \mu \frac{1}{\sqrt{4\pi\epsilon_0\sigma^3\epsilon}}$
- electric field = force/charge, where  $E^* = E \frac{\sqrt{4\pi\epsilon_0\sigma\epsilon}}{\epsilon}$
- density = mass/volume, where  $\rho^* = \rho \frac{\sigma^{dim}}{m}$

Note that for LJ units, the default mode of thermodynamic output via the *thermo\_style* command is to normalize all extensive quantities by the number of atoms. E.g. potential energy is extensive because it is summed over atoms, so it is output as energy/atom. Temperature is intensive since it is already normalized by the number of atoms, so it is output as-is. This behavior can be changed via the *thermo\_modify norm* command.

For style *real*, these are the units:

- mass = grams/mole
- distance = Angstroms
- time = femtoseconds
- energy = kcal/mol
- velocity = Angstroms/femtosecond
- force = (kcal/mol)/Angstrom
- torque = kcal/mol
- temperature = Kelvin
- pressure = atmospheres
- dynamic viscosity = Poise
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge\*Angstroms
- electric field = volts/Angstrom
- density = g/cm<sup>dim</sup>

For style *metal*, these are the units:

- mass = grams/mole
- distance = Angstroms
- time = picoseconds
- energy = eV
- velocity = Angstroms/picosecond
- force = eV/Angstrom
- torque = eV
- temperature = Kelvin
- pressure = bars
- dynamic viscosity = Poise
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge\*Angstroms

- electric field = volts/Angstrom
- density = gram/cm<sup>dim</sup>

For style *si*, these are the units:

- mass = kilograms
- distance = meters
- time = seconds
- energy = Joules
- velocity = meters/second
- force = Newtons
- torque = Newton-meters
- temperature = Kelvin
- pressure = Pascals
- dynamic viscosity = Pascal\*second
- charge = Coulombs (1.6021765e-19 is a proton)
- dipole = Coulombs\*meters
- electric field = volts/meter
- density = kilograms/meter<sup>dim</sup>

For style *cgs*, these are the units:

- mass = grams
- distance = centimeters
- time = seconds
- energy = ergs
- velocity = centimeters/second
- force = dynes
- torque = dyne-centimeters
- temperature = Kelvin
- pressure = dyne/cm<sup>2</sup> or barye = 1.0e-6 bars
- dynamic viscosity = Poise
- charge = statcoulombs or esu (4.8032044e-10 is a proton)
- dipole = statcoul-cm = 10<sup>18</sup> debye
- electric field = statvolt/cm or dyne/esu
- density = grams/cm<sup>dim</sup>

For style *electron*, these are the units:

- mass = atomic mass units
- distance = Bohr
- time = femtoseconds

- energy = Hartrees
- velocity = Bohr/atomic time units [1.03275e-15 seconds]
- force = Hartrees/Bohr
- temperature = Kelvin
- pressure = Pascals
- charge = multiple of electron charge (1.0 is a proton)
- dipole moment = Debye
- electric field = volts/cm

For style *micro*, these are the units:

- mass = picograms
- distance = micrometers
- time = microseconds
- energy = picogram-micrometer<sup>2</sup>/microsecond<sup>2</sup>
- velocity = micrometers/microsecond
- force = picogram-micrometer/microsecond<sup>2</sup>
- torque = picogram-micrometer<sup>2</sup>/microsecond<sup>2</sup>
- temperature = Kelvin
- pressure = picogram/(micrometer-microsecond<sup>2</sup>)
- dynamic viscosity = picogram/(micrometer-microsecond)
- charge = picocoulombs (1.6021765e-7 is a proton)
- dipole = picocoulomb-micrometer
- electric field = volt/micrometer
- density = picograms/micrometer<sup>dim</sup>

For style *nano*, these are the units:

- mass = attograms
- distance = nanometers
- time = nanoseconds
- energy = attogram-nanometer<sup>2</sup>/nanosecond<sup>2</sup>
- velocity = nanometers/nanosecond
- force = attogram-nanometer/nanosecond<sup>2</sup>
- torque = attogram-nanometer<sup>2</sup>/nanosecond<sup>2</sup>
- temperature = Kelvin
- pressure = attogram/(nanometer-nanosecond<sup>2</sup>)
- dynamic viscosity = attogram/(nanometer-nanosecond)
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge-nanometer

- electric field = volt/nanometer
- density = attograms/nanometer<sup>dim</sup>

The units command also sets the timestep size and neighbor skin distance to default values for each style:

- For style *lj* these are  $dt = 0.005 \tau$  and  $skin = 0.3 \sigma$ .
- For style *real* these are  $dt = 1.0$  femtoseconds and  $skin = 2.0$  Angstroms.
- For style *metal* these are  $dt = 0.001$  picoseconds and  $skin = 2.0$  Angstroms.
- For style *si* these are  $dt = 1.0e-8$  seconds and  $skin = 0.001$  meters.
- For style *cgs* these are  $dt = 1.0e-8$  seconds and  $skin = 0.1$  centimeters.
- For style *electron* these are  $dt = 0.001$  femtoseconds and  $skin = 2.0$  Bohr.
- For style *micro* these are  $dt = 2.0$  microseconds and  $skin = 0.1$  micrometers.
- For style *nano* these are  $dt = 0.00045$  nanoseconds and  $skin = 0.1$  nanometers.

### 1.113.4 Restrictions

print "Elapsed time: $(v_stop-v_start:%.6f)"

```

### 1.114.3 Description

This command assigns one or more strings to a variable name for evaluation later in the input script or during a simulation.

Variables can thus be useful in several contexts. A variable can be defined and then referenced elsewhere in an input script to become part of a new input command. For variable styles that store multiple strings, the *next* command can be used to increment which string is assigned to the variable. Variables of style *equal* store a formula which when evaluated produces a single numeric value which can be output either directly (see the *print*, *fix print*, and *run every* commands) or as part of thermodynamic output (see the *thermo\_style* command), or used as input to an averaging fix (see the *fix ave/time* command). Variables of style *vector* store a formula which produces a vector of such values which can be used as input to various averaging fixes, or elements of which can be part of thermodynamic output. Variables of style *atom* store a formula which when evaluated produces one numeric value per atom which can be output to a dump file (see the *dump custom* command) or used as input to an averaging fix (see the *fix ave/chunk* and *fix ave/atom* commands). Variables of style *atomfile* can be used anywhere in an input script that atom-style variables are used; they

get their per-atom values from a file rather than from a formula. Variables of style *python* can be hooked to Python functions using code you provide, so that the variable gets its value from the evaluation of the Python code. Variables of style *internal* are used by a few commands which set their value directly.

---

**Note:** As discussed on the [Commands parse](#) doc page, an input script can use “immediate” variables, specified as \$(formula) with parenthesis, where the numeric formula has the same syntax as equal-style variables described on this page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then evaluate that variable. The formula can include a trailing colon and format string which determines the precision with which the numeric value is generated. This is also explained on the [Commands parse](#) doc page.

---

In the discussion that follows, the “name” of the variable is the arbitrary string that is the first argument in the variable command. This name can only contain alphanumeric characters and underscores. The “string” is one or more of the subsequent arguments. The “string” can be simple text as in the first example above, it can contain other variables as in the second example, or it can be a formula as in the third example. The “value” is the numeric quantity resulting from evaluation of the string. Note that the same string can generate different values when it is evaluated at different times during a simulation.

---

**Note:** When an input script line is encountered that defines a variable of style *equal* or *vector* or *atom* or *python* that contains a formula or Python code, the formula is NOT immediately evaluated. It will be evaluated every time when the variable is **used** instead. If you simply want to evaluate a formula in place you can use as so-called. See the section below about “Immediate Evaluation of Variables” for more details on the topic. This is also true of a *format* style variable since it evaluates another variable when it is invoked.

---

Variables of style *equal* and *vector* and *atom* can be used as inputs to various other commands which evaluate their formulas as needed, e.g. at different timesteps during a *run*. In this context, variables of style *timer* or *internal* or *python* can be used in place of an equal-style variable, with the following two caveats.

First, internal-style variables can be used except by commands that set the value stored by the internal variable. When the LAMMPS command evaluates the internal-style variable, it will use the value set (internally) by another command. Second, python-style variables can be used so long as the associated Python function, as defined by the *python* command, returns a numeric value. When the LAMMPS command evaluates the python-style variable, the Python function will be executed.

---

**Note:** When a variable command is encountered in the input script and the variable name has already been specified, the command is ignored. This means variables can NOT be re-defined in an input script (with two exceptions, read further). This is to allow an input script to be processed multiple times without resetting the variables; see the *jump* or *include* commands. It also means that using the *command-line switch* -var will override a corresponding index variable setting in the input script.

---

There are two exceptions to this rule. First, variables of style *string*, *getenv*, *internal*, *equal*, *vector*, *atom*, and *python* ARE redefined each time the command is encountered. This allows these style of variables to be redefined multiple times in an input script. In a loop, this means the formula associated with an *equal* or *atom* style variable can change if it contains a substitution for another variable, e.g. \$x or v\_x.

Second, as described below, if a variable is iterated on to the end of its list of strings via the *next* command, it is removed from the list of active variables, and is thus available to be re-defined in a subsequent variable command. The *delete* style does the same thing.

Variables are **not** deleted by the *clear* command with the exception of atomfile-style variables.

---

The *Commands parse* page explains how occurrences of a variable name in an input script line are replaced by the variable's string. The variable name can be referenced as `$x` if the name "x" is a single character, or as `${LoopVar}` if the name "LoopVar" is one or more characters.

As described below, for variable styles *index*, *loop*, *file*, *universe*, and *uloop*, which string is assigned to a variable can be incremented via the *next* command. When there are no more strings to assign, the variable is exhausted and a flag is set that causes the next *jump* command encountered in the input script to be skipped. This enables the construction of simple loops in the input script that are iterated over and then exited from.

As explained above, an exhausted variable can be re-used in an input script. The *delete* style also removes the variable, the same as if it were exhausted, allowing it to be redefined later in the input script or when the input script is looped over. This can be useful when breaking out of a loop via the *if* and *jump* commands before the variable would become exhausted. For example,

```
label      loop
variable   a loop 5
print      "A = $a"
if         "$a > 2" then "jump in.script break"
next       a
jump       in.script loop
label      break
variable   a delete
```

The next sections describe in how all the various variable styles are defined and what they store. The styles are listed alphabetically, except for the *equal* and *vector* and *atom* styles, which are explained together after all the others.

Many of the styles store one or more strings. Note that a single string can contain spaces (multiple words), if it is enclosed in quotes in the variable command. When the variable is substituted for in another input script command, its returned string will then be interpreted as multiple arguments in the expanded command.

For the *atomfile* style, a filename is provided which contains one or more sets of values, to assign on a per-atom basis to the variable. The format of the file is described below.

When an atomfile-style variable is defined, the file is opened and the first set of per-atom values are read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return those values. There are two ways to cause the next set of per-atom values from the file to be read: use the *next* command or the `next()` function in an atom-style variable, as discussed below. Unlike most variable styles, which remain defined, atomfile-style variables are **deleted** during a *clear* command.

The rules for formatting the file are as follows. Each time a set of per-atom values is read, a non-blank line is searched for in the file. The file is read line by line but only up to 254 characters are used. The rest are ignored. A comment character "#" can be used anywhere on a line and all text following and the "#" character are ignored; text starting with the comment character is stripped. Blank lines are skipped. The first non-blank line is expected to contain a single integer number as the count *N* of per-atom lines to follow. *N* can be the total number of atoms in the system or less, indicating that data for a subset is read. The next *N* lines must consist of two numbers, the atom-ID of the atom for which a value is set followed by a floating point number with the value. The atom-IDs may be listed in any order.

**Note:** Every time a set of per-atom lines is read, the value of the atomfile variable for **all** atoms is first initialized to 0.0. Thus values for atoms whose ID do not appear in the set in the file will remain at 0.0.

Below is a small example for the atomfile variable file format:

```
# first set
4
# atom-ID value
3 1
4 -4
1 0.5
2 -0.5

# second set
2

2 1.0
4 -1.0
```

---

For the *file* style, a filename is provided which contains a list of strings to assign to the variable, one per line. The strings can be numeric values if desired. See the discussion of the `next()` function below for equal-style variables, which will convert the string of a file-style variable into a numeric value in a formula.

When a file-style variable is defined, the file is opened and the string on the first line is read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return that string. There are two ways to cause the next string from the file to be read: use the *next* command or the `next()` function in an equal- or atom-style variable, as discussed below.

The rules for formatting the file are as follows. A comment character “#” can be used anywhere on a line; text starting with the comment character is stripped. Blank lines are skipped. The first “word” of a non-blank line, delimited by white-space, is the “string” assigned to the variable.

---

For the *format* style, an equal-style or compatible variable is specified along with a C-style format string, e.g. “%f” or “%.10g”, which must be appropriate for formatting a double-precision floating-point value and may not have extra characters. The default format is “%.15g”. This variable style allows an equal-style variable to be formatted precisely when it is evaluated.

Note that if you simply wish to print a variable value with desired precision to the screen or logfile via the *print* or *fix print* commands, you can also do this by specifying an “immediate” variable with a trailing colon and format string, as part of the string argument of those commands. This is explained on the *Commands parse* doc page.

---

For the *getenv* style, a single string is assigned to the variable which should be the name of an environment variable. When the variable is evaluated, it returns the value of the environment variable, or an empty string if it not defined. This style of variable can be used to adapt the behavior of LAMMPS input scripts via environment variable settings, or to retrieve information that has been previously stored with the *shell putenv* command. Note that because environment variable settings are stored by the operating systems, they persist even if the corresponding *getenv* style variable is deleted, and also are set for sub-shells executed by the *shell* command.

---

For the *index* style, one or more strings are specified. Initially, the first string is assigned to the variable. Each time a *next* command is used with the variable name, the next string is assigned. All processors assign the same string to the variable.

Index-style variables with a single string value can also be set by using the *command-line switch -var*.

---

For the *internal* style a numeric value is provided. This value will be assigned to the variable until a LAMMPS command sets it to a new value. There are currently only two LAMMPS commands that require *internal* variables as inputs, because they reset them: *create\_atoms* and *fix controller*. As mentioned above, an internal-style variable can be used in place of an equal-style variable anywhere else in an input script, e.g. as an argument to another command that allows for equal-style variables.

---

The *loop* style is identical to the *index* style except that the strings are the integers from 1 to N inclusive, if only one argument N is specified. This allows generation of a long list of runs (e.g. 1000) without having to list N strings in the input script. Initially, the string “1” is assigned to the variable. Each time a *next* command is used with the variable name, the next string (“2”, “3”, etc) is assigned. All processors assign the same string to the variable. The *loop* style can also be specified with two arguments N1 and N2. In this case the loop runs from N1 to N2 inclusive, and the string N1 is initially assigned to the variable. N1 <= N2 and N2 >= 0 is required.

---

For the *python* style a Python function name is provided. This needs to match a function name specified in a *python* command which returns a value to this variable as defined by its *return* keyword. For example these two commands would be self-consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

The two commands can appear in either order so long as both are specified before the Python function is invoked for the first time.

Each time the variable is evaluated, the associated Python function is invoked, and the value it returns is also returned by the variable. Since the Python function can use other LAMMPS variables as input, or query internal LAMMPS quantities to perform its computation, this means the variable can return a different value each time it is evaluated.

The type of value stored in the variable is determined by the *format* keyword of the *python* command. It can be an integer (i), floating point (f), or string (s) value. As mentioned above, if it is a numeric value (integer or floating point), then the python-style variable can be used in place of an equal-style variable anywhere in an input script, e.g. as an argument to another command that allows for equal-style variables.

---

For the *string* style, a single string is assigned to the variable. Two differences between this style and using the *index* style exist: a variable with *string* style can be redefined, e.g. by another command later in the input script, or if the script is read again in a loop. The other difference is that *string* performs variable substitution even if the string parameter is quoted.

---

The *uloop* style is identical to the *universe* style except that the strings are the integers from 1 to N. This allows generation of long list of runs (e.g. 1000) without having to list N strings in the input script.

---

For the *universe* style, one or more strings are specified. There must be at least as many strings as there are processor partitions or “worlds”. LAMMPS can be run with multiple partitions via the *-partition command-line switch*. This variable command initially assigns one string to each world. When a *next* command is encountered using this variable, the first processor partition to encounter it, is assigned the next available string. This continues until all the variable strings are consumed. Thus, this command can be used to run 50 simulations on 8 processor partitions. The simulations will be run one after the other on whatever partition becomes available, until they are all finished. Universe-style variables are incremented using the files “tmp.lammps.variable” and “tmp.lammps.variable.lock” which you will see in your directory during such a LAMMPS run.

---

For the *world* style, one or more strings are specified. There must be one string for each processor partition or “world”. LAMMPS can be run with multiple partitions via the *-partition command-line switch*. This variable command assigns one string to each world. All processors in the world are assigned the same string. The next command cannot be used with equal-style variables, since there is only one value per world. This style of variable is useful when you wish to run different simulations on different partitions, or when performing a parallel tempering simulation (see the *temper* command), to assign different temperatures to different partitions.

---

For the *equal* and *vector* and *atom* styles, a single string is specified which represents a formula that will be evaluated afresh each time the variable is used. If you want spaces in the string, enclose it in double quotes so the parser will treat it as a single argument. For *equal*-style variables the formula computes a scalar quantity, which becomes the value of the variable whenever it is evaluated. For *vector*-style variables the formula must compute a vector of quantities, which becomes the value of the variable whenever it is evaluated. The calculated vector can be of length one, but it cannot be a simple scalar value like that produced by an equal-style compute. I.e. the formula for a vector-style variable must have at least one quantity in it that refers to a global vector produced by a compute, fix, or other vector-style variable. For *atom*-style variables the formula computes one quantity for each atom whenever it is evaluated.

Note that *equal*, *vector*, and *atom* variables can produce different values at different stages of the input script or at different times during a run. For example, if an *equal* variable is used in a *fix print* command, different values could be printed each timestep it was invoked. If you want a variable to be evaluated immediately, so that the result is stored by the variable instead of the string, see the section below on “Immediate Evaluation of Variables”.

The next command cannot be used with *equal* or *vector* or *atom* style variables, since there is only one string.

The formula for an *equal*, *vector*, or *atom* variable can contain a variety of quantities. The syntax for each kind of quantity is simple, but multiple quantities can be nested and combined in various ways to build up formulas of arbitrary complexity. For example, this is a valid (though strange) variable formula:

```
variable x equal "pe + c_MyTemp / vol^(1/3)"
```

Specifically, a formula can contain numbers, constants, thermo keywords, math operators, math functions, group functions, region functions, special functions, feature functions, atom values, atom vectors, custom atom properties, compute references, fix references, and references to other variables.

Num- ber	0.2, 100, 1.0e20, -15.4, etc
Con- stant	PI, version, on, off, true, false, yes, no
Thermo key- words	vol, pe, ebond, etc
Math opera- tors	(), -x, x+y, x-y, x*y, x/y, x^y, x%y, x == y, x != y, x < y, x <= y, x > y, x >= y, x && y, x    y, x  ^ y, !x
Math func- tions	sqrt(x), exp(x), ln(x), log(x), abs(x), sin(x), cos(x), tan(x), asin(x), acos(x), atan(x), atan2(y,x), random(x,y,z), normal(x,y,z), ceil(x), floor(x), round(x), ternary(x,y,z), ramp(x,y), stagger(x,y), logfreq(x,y,z), logfreq2(x,y,z), logfreq3(x,y,z), stride(x,y,z), stride2(x,y,z,a,b,c), vdisplace(x,y), swiggle(x,y,z), cwiggle(x,y,z)
Group func- tions	count(ID), mass(ID), charge(ID), xcm(ID,dim), vcm(ID,dim), fcm(ID,dim), bound(ID,dir), gyration(ID), ke(ID), angmom(ID,dim), torque(ID,dim), inertia(ID,dimdim), omega(ID,dim)
Region func- tions	count(ID,IDR), mass(ID,IDR), charge(ID,IDR), xcm(ID,dim,IDR), vcm(ID,dim,IDR), fcm(ID,dim,IDR), bound(ID,dir,IDR), gyration(ID,IDR), ke(ID,IDR), angmom(ID,dim,IDR), torque(ID,dim,IDR), inertia(ID,dimdim,IDR), omega(ID,dim,IDR)
Special func- tions	sum(x), min(x), max(x), ave(x), trap(x), slope(x), sort(x), rsort(x), gmask(x), rmask(x), grmask(x,y), next(x), is_file(name), is_os(name), extract_setting(name), label2type(kind,label), is_tpyelabel(kind,label), is_timeout()
Feature func- tions	is_available(category,feature), is_active(category,feature), is_defined(category,id)
Atom values	id[i], mass[i], type[i], mol[i], x[i], y[i], z[i], vx[i], vy[i], vz[i], fx[i], fy[i], fz[i], q[i]
Atom vectors	id, mass, type, mol, x, y, z, vx, vy, vz, fx, fy, fz, q
Custom atom proper- ties	i_name, d_name, i_name[i], d_name[i], i2_name[i], d2_name[i], i2_name[i][j], d_name[i][j]
Com- pute refer- ences	c_ID, c_ID[i], c_ID[i][j], C_ID, C_ID[i]
Fix ref- erences	f_ID, f_ID[i], f_ID[i][j], F_ID, F_ID[i]
Other vari- ables	v_name, v_name[i]

Most of the formula elements produce a scalar value. Some produce a global or per-atom vector of values. Global vectors can be produced by computes or fixes or by other vector-style variables. Per-atom vectors are produced by atom vectors, computes or fixes which output a per-atom vector or array, and variables that are atom-style variables. Math functions that operate on scalar values produce a scalar value; math function that operate on global or per-atom vectors do so element-by-element and produce a global or per-atom vector.

A formula for equal-style variables cannot use any formula element that produces a global or per-atom vector. A formula for a vector-style variable can use formula elements that produce either a scalar value or a global vector value, but cannot use a formula element that produces a per-atom vector. A formula for an atom-style variable can use formula

elements that produce either a scalar value or a per-atom vector, but not one that produces a global vector.

Atom-style variables are evaluated by other commands that define a *group* on which they operate, e.g. a *dump* or *compute* or *fix* command. When they invoke the atom-style variable, only atoms in the group are included in the formula evaluation. The variable evaluates to 0.0 for atoms not in the group.

---

## Numbers, constants, and thermo keywords

Numbers can contain digits, scientific notation (3.0e20,3.0e-20,3.0E20,3.0E-20), and leading minus signs.

Constants are set at compile time and cannot be changed. *PI* will return the number 3.14159265358979323846; *on*, *true* or *yes* will return 1.0; *off*, *false* or *no* will return 0.0; *version* will return a numeric version code of the current LAMMPS version (e.g. version 2 Sep 2015 will return the number 20150902). The corresponding value for newer versions of LAMMPS will be larger, for older versions of LAMMPS will be smaller. This can be used to have input scripts adapt automatically to LAMMPS versions, when non-backwards compatible syntax changes are introduced. Here is an illustrative example (which will not work, since the *version* has been introduced more recently):

```
if $(version<20140513) then "communicate vel yes" else "comm_modify vel yes"
```

The thermo keywords allowed in a formula are those defined by the *thermo\_style custom* command. Thermo keywords that require a *compute* to calculate their values such as “temp” or “press”, use computes stored and invoked by the *thermo\_style* command. This means that you can only use those keywords in a variable if the style you are using with the thermo\_style command (and the thermo keywords associated with that style) also define and use the needed compute. Note that some thermo keywords use a compute indirectly to calculate their value (e.g. the enthalpy keyword uses temp, pe, and pressure). If a variable is evaluated directly in an input script (not during a run), then the values accessed by the thermo keyword must be current. See the discussion below about “Variable Accuracy”.

---

## Math Operators

Math operators are written in the usual way, where the “x” and “y” in the examples can themselves be arbitrarily complex formulas, as in the examples above. In this syntax, “x” and “y” can be scalar values or per-atom vectors. For example, “ke/natoms” is the division of two scalars, where “vy+vz” is the element-by-element sum of two per-atom vectors of y and z velocities.

Operators are evaluated left to right and have the usual C-style precedence: unary minus and unary logical NOT operator “!” have the highest precedence, exponentiation “^” is next; multiplication and division and the modulo operator “%” are next; addition and subtraction are next; the 4 relational operators “<”, “<=”, “>”, and “>=” are next; the two remaining relational operators “==” and “!=” are next; then the logical AND operator “&&”; and finally the logical OR operator “||” and logical XOR (exclusive or) operator “|^” have the lowest precedence. Parenthesis can be used to group one or more portions of a formula and/or enforce a different order of evaluation than what would occur with the default precedence.

---

**Note:** Because a unary minus is higher precedence than exponentiation, the formula “-2^2” will evaluate to 4, not -4. This convention is compatible with some programming languages, but not others. As mentioned, this behavior can be easily overridden with parenthesis; the formula “-(2^2)” will evaluate to -4.

---

The 6 relational operators return either a 1.0 or 0.0 depending on whether the relationship between x and y is TRUE or FALSE. For example the expression  $x < 10.0$  in an atom-style variable formula will return 1.0 for all atoms whose x-coordinate is less than 10.0, and 0.0 for the others. The logical AND operator will return 1.0 if both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments is non-zero, else

it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0.

These relational and logical operators can be used as a masking or selection operation in a formula. For example, the number of atoms whose properties satisfy one or more criteria could be calculated by taking the returned per-atom vector of ones and zeroes and passing it to the *compute reduce* command.

## Math Functions

Math functions are specified as keywords followed by one or more parenthesized arguments “x”, “y”, “z”, each of which can themselves be arbitrarily complex formulas. In this syntax, the arguments can represent scalar values or global vectors or per-atom vectors. In the latter case, the math operation is performed on each element of the vector. For example, “sqrt(natoms)” is the sqrt() of a scalar, where “sqrt(y\*z)” yields a per-atom vector with each element being the sqrt() of the product of one atom’s y and z coordinates.

Most of the math functions perform obvious operations. The ln() is the natural log; log() is the base 10 log.

The random(x,y,z) function takes 3 arguments: x = lo, y = hi, and z = seed. It generates a uniform random number between lo and hi. The normal(x,y,z) function also takes 3 arguments: x = mu, y = sigma, and z = seed. It generates a Gaussian variate centered on mu with variance sigma^2. In both cases the seed is used the first time the internal random number generator is invoked, to initialize it. For equal-style and vector-style variables, every processor uses the same seed so that they each generate the same sequence of random numbers. For atom-style variables, a unique seed is created for each processor, based on the specified seed. This effectively generates a different random number for each atom being looped over in the atom-style variable.

**Note:** Internally, there is just one random number generator for all equal-style and vector-style variables and another one for all atom-style variables. If you define multiple variables (of each style) which use the random() or normal() math functions, then the internal random number generators will only be initialized once, which means only one of the specified seeds will determine the sequence of generated random numbers.

The ceil(), floor(), and round() functions are those in the C math library. Ceil() is the smallest integer not less than its argument. Floor() is the largest integer not greater than its argument. Round() is the nearest integer to its argument.

New in version 7Feb2024.

The ternary(x,y,z) function is the equivalent of the ternary operator (? and :) in C or C++. It takes 3 arguments. The first argument is a conditional. The result of the function is y if x evaluates to true (non-zero). The result is z if x evaluates to false (zero).

The ramp(x,y) function uses the current timestep to generate a value linearly interpolated between the specified x,y values over the course of a run, according to this formula:

$$\text{value} = x + (y-x) * (\text{timestep}-\text{startstep}) / (\text{stopstep}-\text{startstep})$$

The run begins on startstep and ends on stopstep. Startstep and stopstep can span multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this. If called in between runs or during a *run 0* command, the ramp(x,y) function will return the value of x.

The stagger(x,y) function uses the current timestep to generate a new timestep. X,y > 0 and x > y are required. The generated timesteps increase in a staggered fashion, as the sequence x,x+y,2x,2x+y,3x,3x+y,etc. For any current timestep, the next timestep in the sequence is returned. Thus if stagger(1000,100) is used in a variable by the *dump\_modify every* command, it will generate the sequence of output timesteps:

100, 1000, 1100, 2000, 2100, 3000, etc

The `logfreq(x,y,z)` function uses the current timestep to generate a new timestep.  $X,y,z > 0$  and  $y < z$  are required. The generated timesteps are on a base- $z$  logarithmic scale, starting with  $x$ , and the  $y$  value is how many of the  $z-1$  possible timesteps within one logarithmic interval are generated. I.e. the timesteps follow the sequence  $x, 2x, 3x, \dots y*x, x*z, 2x*z, 3x*z, \dots y*x*z, x*z^2, 2x*z^2, \text{etc.}$  For any current timestep, the next timestep in the sequence is returned. Thus if `logfreq(100,4,10)` is used in a variable by the `dump_modify every` command, it will generate this sequence of output timesteps:

```
100, 200, 300, 400, 1000, 2000, 3000, 4000, 10000, 20000, etc
```

The `logfreq2(x,y,z)` function is similar to `logfreq`, except a single logarithmic interval is divided into  $y$  equally-spaced timesteps and all of them are output.  $Y < z$  is not required. Thus, if `logfreq2(100,18,10)` is used in a variable by the `dump_modify every` command, then the interval between 100 and 1000 is divided as  $900/18 = 50$  steps, and it will generate the sequence of output timesteps:

```
100, 150, 200, ... 950, 1000, 1500, 2000, ... 9500, 10000, 15000, etc
```

The `logfreq3(x,y,z)` function generates  $y$  points between  $x$  and  $z$  (inclusive), that are separated by a multiplicative ratio:  $(z/x)^{1/(y-1)}$ . Constraints are:  $x,z > 0$ ,  $y > 1$ ,  $z-x \geq y-1$ . For e.g., if `logfreq3(10,25,1000)` is used in a variable by the `fix print` command, then the interval between 10 and 1000 is divided into 24 parts with a multiplicative separation of  $\sim 1.21$ , and it will generate the following sequence of output timesteps:

```
10, 13, 15, 18, 22, 27, 32, ... 384, 465, 563, 682, 826, 1000
```

The `stride(x,y,z)` function uses the current timestep to generate a new timestep.  $X,y \geq 0$  and  $z > 0$  and  $x \leq y$  are required. The generated timesteps increase in increments of  $z$ , from  $x$  to  $y$ , i.e. it generates the sequence  $x, x+z, x+2z, \dots, y$ . If  $y-x$  is not a multiple of  $z$ , then similar to the way a for loop operates, the last value will be one that does not exceed  $y$ . For any current timestep, the next timestep in the sequence is returned. Thus if `stride(1000,2000,100)` is used in a variable by the `dump_modify every` command, it will generate the sequence of output timesteps:

```
1000, 1100, 1200, ... , 1900, 2000
```

The `stride2(x,y,z,a,b,c)` function is similar to the `stride()` function except it generates two sets of strided timesteps, one at a coarser level and one at a finer level. Thus it is useful for debugging, e.g. to produce output every timestep at the point in simulation when a problem occurs.  $X,y \geq 0$  and  $z > 0$  and  $x \leq y$  are required, as are  $a,b \geq 0$  and  $c > 0$  and  $a < b$ . Also,  $a \geq x$  and  $b \leq y$  are required so that the second stride is inside the first. The generated timesteps increase in increments of  $z$ , starting at  $x$ , until  $a$  is reached. At that point the timestep increases in increments of  $c$ , from  $a$  to  $b$ , then after  $b$ , increments by  $z$  are resumed until  $y$  is reached. For any current timestep, the next timestep in the sequence is returned. Thus if `stride2(1000,2000,100,1350,1360,1)` is used in a variable by the `dump_modify every` command, it will generate the sequence of output timesteps:

```
1000, 1100, 1200, 1300, 1350, 1351, 1352, ... 1359, 1360, 1400, 1500, ... , 2000
```

The `vdisplace(x,y)` function takes 2 arguments:  $x = \text{value0}$  and  $y = \text{velocity}$ , and uses the elapsed time to change the value by a linear displacement due to the applied velocity over the course of a run, according to this formula:

$$\text{value} = \text{value0} + \text{velocity} * (\text{timestep} - \text{startstep}) * \text{dt}$$

where  $\text{dt} = \text{the timestep size}$ .

The run begins on `startstep`. `Startstep` can span multiple runs, using the `start` keyword of the `run` command. See the `run` command for details of how to do this. Note that the `thermo_style` keyword `elaplong = timestep-startstep`. If used between runs this function will return the value according to the end of the last run or the value of  $x$  if used before *any* runs. This function assumes the length of the time step does not change and thus may not be used in combination with `fix dt/reset`.

The `swiggle(x,y,z)` and `cwiggle(x,y,z)` functions each take 3 arguments:  $x = \text{value0}$ ,  $y = \text{amplitude}$ ,  $z = \text{period}$ . They use the elapsed time to oscillate the value by a `sin()` or `cos()` function over the course of a run, according to one of these

formulas, where  $\omega = 2 \pi / \text{period}$ :

```
value = value0 + Amplitude * sin(omega*(timestep-startstep)*dt)
value = value0 + Amplitude * (1 - cos(omega*(timestep-startstep)*dt))
```

where  $dt$  = the timestep size.

The run begins on startstep. Startstep can span multiple runs, using the *start* keyword of the *run* command. See the *run* command for details of how to do this. Note that the *thermo\_style* keyword *elaplong* = timestep-startstep. If used between runs these functions will return the value according to the end of the last run or the value of *x* if used before any runs. These functions assume the length of the time step does not change and thus may not be used in combination with *fix dt/reset*.

---

## Group and Region Functions

Group functions are specified as keywords followed by one or two parenthesized arguments. The first argument *ID* is the group-ID. The *dim* argument, if it exists, is *x* or *y* or *z*. The *dir* argument, if it exists, is *xmin*, *xmax*, *ymin*, *ymax*, *zmin*, or *zmax*. The *dimdim* argument, if it exists, is *xx* or *yy* or *zz* or *xy* or *yz* or *xz*.

The group function *count()* is the number of atoms in the group. The group functions *mass()* and *charge()* are the total mass and charge of the group. *Xcm()* and *vcm()* return components of the position and velocity of the center of mass of the group. *Fcm()* returns a component of the total force on the group of atoms. *Bound()* returns the min/max of a particular coordinate for all atoms in the group. *Gyration()* computes the radius-of-gyration of the group of atoms. See the *compute gyration* command for a definition of the formula. *Angmom()* returns components of the angular momentum of the group of atoms around its center of mass. *Torque()* returns components of the torque on the group of atoms around its center of mass, based on current forces on the atoms. *Inertia()* returns one of 6 components of the symmetric inertia tensor of the group of atoms around its center of mass, ordered as *Ixx*, *Iyy*, *Izz*, *Ixy*, *Iyz*, *Ixz*. *Omega()* returns components of the angular velocity of the group of atoms around its center of mass.

Region functions are specified exactly the same way as group functions except they take an extra final argument *IDR* which is the region ID. The function is computed for all atoms that are in both the group and the region. If the group is “all”, then the only criteria for atom inclusion is that it be in the region.

---

## Special Functions

Special functions take specific kinds of arguments, meaning their arguments cannot be formulas themselves.

The *sum(x)*, *min(x)*, *max(x)*, *ave(x)*, *trap(x)*, *slope(x)*, *sort(x)*, and *rsort(x)* functions each take 1 argument which is of the form “*c\_ID*” or “*c\_ID*[*N*]” or “*f\_ID*” or “*f\_ID*[*N*]” or “*v\_name*”. The first two are computes and the second two are fixes; the ID in the reference should be replaced by the ID of a compute or fix defined elsewhere in the input script. The compute or fix must produce either a global vector or array. If it produces a global vector, then the notation without “[*N*]” should be used. If it produces a global array, then the notation with “[*N*]” should be used, where *N* is an integer, to specify which column of the global array is being referenced. The last form of argument “*v\_name*” is for a vector-style variable where “name” is replaced by the name of the variable.

The *sum(x)*, *min(x)*, *max(x)*, *ave(x)*, *trap(x)*, and *slope(x)* functions operate on a global vector of inputs and reduce it to a single scalar value. This is analogous to the operation of the *compute reduce* command, which performs similar operations on per-atom and local vectors.

The *sort(x)* and *rsort(x)* functions operate on a global vector of inputs and return a global vector of the same length.

The *sum()* function calculates the sum of all the vector elements. The *min()* and *max()* functions find the minimum and maximum element respectively. The *ave()* function is the same as *sum()* except that it divides the result by the length of the vector.

The `trap()` function is the same as `sum()` except the first and last elements are multiplied by a weighting factor of 1/2 when performing the sum. This effectively implements an integration via the trapezoidal rule on the global vector of data. I.e. consider a set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the  $V_i$  are the values in the global vector of length N. The integral from 1 to N of these points is `trap()`. When appropriately normalized by the timestep size, this function is useful for calculating integrals of time-series data, like that generated by the `fix ave/correlate` command.

The `slope()` function uses linear regression to fit a line to the set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the  $V_i$  are the values in the global vector of length N. The returned value is the slope of the line. If the line has a single point or is vertical, it returns 1.0e20.

New in version 27June2024.

The `sort(x)` and `rsort(x)` functions sort the data of the input vector by their numeric value: `sort(x)` sorts in ascending order, `rsort(x)` sorts in descending order.

The `gmask(x)` function takes 1 argument which is a group ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the group, and a 0 for atoms that are not.

The `rmask(x)` function takes 1 argument which is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the geometric region, and a 0 for atoms that are not.

The `grmask(x,y)` function takes 2 arguments. The first is a group ID, and the second is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in both the group and region, and a 0 for atoms that are not in both.

The `next(x)` function takes 1 argument which is a variable ID (not “v\_foo”, just “foo”). It must be for a file-style or atomfile-style variable. Each time the `next()` function is invoked (i.e. each time the equal-style or atom-style variable is evaluated), the following steps occur.

For file-style variables, the current string value stored by the file-style variable is converted to a numeric value and returned by the function. And the next string value in the file is read and stored. Note that if the line previously read from the file was not a numeric string, then it will typically evaluate to 0.0, which is likely not what you want.

For atomfile-style variables, the current per-atom values stored by the atomfile-style variable are returned by the function. And the next set of per-atom values in the file is read and stored.

Since file-style and atomfile-style variables read and store the first line of the file or first set of per-atoms values when they are defined in the input script, these are the value(s) that will be returned the first time the `next()` function is invoked. If `next()` is invoked more times than there are lines or sets of lines in the file, the variable is deleted, similar to how the `next` command operates.

The `is_file(name)` function is a test whether *name* is a (readable) file and returns 1 in this case, otherwise it returns 0. For that *name* is taken as a literal string and must not have any blanks in it.

The `is_os(name)` function is a test whether *name* is part of the OS information that LAMMPS collects and provides in the `platform::os_info()` function. The argument *name* is interpreted as a regular expression as documented for the `utils::strmatch()` function. This allows to adapt LAMMPS inputs to the OS it runs on:

```
if $(is_os(^Windows)) then &
  "shell copy ${input_dir}\some_file.txt ." &
else &
  "shell cp ${input_dir}/some_file.txt ."
```

The `extract_setting(name)` function enables access to basic settings for the LAMMPS executable and the running simulation via calling the `lammmps_extract_setting()` library function. For example, the number of processors (MPI ranks) being used by the simulation or the MPI process ID (for this processor) can be queried, or the number of atom types, bond types and so on. For the full list of available keywords *name* and their meaning, see the documentation for `extract_setting()` via the link in this paragraph.

The `label2type(kind,label)` function converts type labels into numeric types, using label maps created by the `labelmap` or `read_data` commands. The first argument is the label map kind (atom, bond, angle, dihedral, or improper) and the second argument is the label. The function returns the corresponding numeric type or triggers an error if the queried label does not exist.

New in version 15Jun2023.

The `is_typelabel(kind,label)` function has the same arguments as `label2type()`, but returns 1 if the type label has been assigned, otherwise it returns 0. This function can be used to check if a particular type label already exists in the simulation.

New in version 29Aug2024.

The `is_timeout()` function returns 1 when the `timer timeout` has expired otherwise it returns 0. This function can be used to check inputs in combination with the `if command` to execute commands after the timer has expired. Example:

```
variable timeout equal is_timeout()
timer timeout 0:10:00 every 10
run 10000
if ${timeout} then "print 'Timer has expired'"
```

## Feature Functions

Feature functions allow probing of the running LAMMPS executable for whether specific features are available, active, or defined. All 3 of the functions take two arguments, a *category* and a category-specific second argument. Both are strings and thus cannot be formulas themselves; only `$`-style immediate variable expansion is possible. The return value of the functions is either 1.0 or 0.0 depending on whether the function evaluates to true or false, respectively.

The `is_available(category,name)` function queries whether a specific feature is available in the LAMMPS executable that is being run, i.e. whether it was included or enabled at compile time.

This supports the following categories: *command*, *compute*, *fix*, *pair\_style* and *feature*. For all the categories except *feature* the *name* is a style name, e.g. *nve* for the *fix* category. Note that many LAMMPS input script commands such as *create\_atoms* are actually instances of a command style which LAMMPS defines, as opposed to built-in commands. For all of these styles except *command*, appending of active suffixes is also tried before reporting failure.

The *feature* category checks the availability of the following compile-time enabled features: GZIP support, PNG support, JPEG support, FFMPEG support, and C++ exceptions for error handling. Corresponding names are *gzip*, *png*, *jpeg*, *ffmpeg* and *exceptions*.

Example: Only dump in a given format if the compiled binary supports it.

```
if "${is_available(feature,png)}" then "print 'PNG supported'" else "print 'PNG not_
→supported'"
if "${is_available(feature,ffmpeg)}" then "dump 3 all movie 25 movie.mp4 type type zoom 1.
→6 adiam 1.0"
```

The `is_active(category,feature)` function queries whether a specific feature is currently active within LAMMPS. The features are grouped by categories. Supported categories and features are:

- *package*: features = *gpu* or *intel* or *kokkos* or *omp*
- *newton*: features = *pair* or *bond* or *any*
- *pair*: features = *single* or *respa* or *manybody* or *tail* or *shift*
- *comm\_style*: features = *brick* or *tiled*

- *min\_style*: features = a minimizer style name
- *run\_style*: features = a run style name
- *atom\_style*: features = an atom style name
- *pair\_style*: features = a pair style name
- *bond\_style*: features = a bond style name
- *angle\_style*: features = an angle style name
- *dihedral\_style*: features = a dihedral style name
- *improper\_style*: features = an improper style name
- *kspace\_style*: features = a kspace style name

Most of the settings are self-explanatory. For the *package* category, a package may have been included in the LAMMPS build, but not have enabled by any input script command, and hence be inactive. The *single* feature in the *pair* category checks whether the currently defined pair style supports a `Pair::single()` function as needed by compute group/group and others features or LAMMPS. Similarly, the *respa* feature checks whether the inner/middle/outer mode of r-RESPA is supported by the current pair style.

For the categories with *style* in their name, only a single instance of the style is ever active at any time in a LAMMPS simulation. Thus the check is whether the currently active style matches the specified name. This check is also done using suffix flags, if available and enabled.

Example 1: Disable use of suffix for PPPM when using GPU package (i.e. run it on the CPU concurrently while running the pair style on the GPU), but do use the suffix otherwise (e.g. with OPENMP).

```
pair_style lj/cut/coul/long 14.0
if $(is_active(package,gpu)) then "suffix off"
kspace_style ppm
```

Example 2: Use r-RESPA with inner/outer cutoff, if supported by the current pair style, otherwise fall back to using r-RESPA with simply the pair keyword and reducing the outer time step.

```
timestep $(2.0*(1.0+2.0*is_active(pair,respa)))
if $(is_active(pair,respa)) then "run_style respa 4 3 2 2 improper 1 inner 2 5.5 7.0_
→outer 3 kspace 4" else "run_style respa 3 3 2 improper 1 pair 2 kspace 3"
```

The `is_defined(category,id)` function checks whether an instance of a style or variable with a specific ID or name is currently defined within LAMMPS. The supported categories are *compute*, *dump*, *fix*, *group*, *region*, and *variable*. Each of these styles (as well as the variable command) can be specified multiple times within LAMMPS, each with a unique *id*. This function checks whether the specified *id* exists. For category *variable*, the *\*id* is the variable name.

---

## Atom Values and Vectors

Atom values take an integer argument *I* from 1 to *N*, where *I* is the atom-ID, e.g. `x[243]`, which means use the *x* coordinate of the atom with ID = 243. Or they can take a variable name, specified as `v_name`, where *name* is the name of the variable, like `x[v_myIndex]`. The variable can be of any style except *vector* or *atom* or *atomfile* variables. The variable is evaluated and the result is expected to be numeric and is cast to an integer (i.e. 3.4 becomes 3), to use an index, which must be a value from 1 to *N*. Note that a “formula” cannot be used as the argument between the brackets, e.g. `x[243+10]` or `x[v_myIndex+1]` are not allowed. To do this a single variable can be defined that contains the needed formula.

Note that the  $0 < \text{atom-ID} \leq N$ , where  $N$  is the largest atom ID in the system. If an ID is specified for an atom that does not currently exist, then the generated value is 0.0.

Atom vectors generate one value per atom, so that a reference like “vx” means the x-component of each atom’s velocity will be used when evaluating the variable.

The meaning of the different atom values and vectors is mostly self-explanatory. *Mol* refers to the molecule ID of an atom, and is only defined if an *atom\_style* is being used that defines molecule IDs.

Note that many other atom attributes can be used as inputs to a variable by using the *compute property/atom* command and then referencing that compute.

## Custom atom properties

New in version 7Feb2024.

Custom atom properties refer to per-atom integer and floating point vectors or arrays that have been added via the *fix property/atom* command. When that command is used specific names are given to each attribute which are the “name” portion of these references. References beginning with *i* and *d* refer to integer and floating point properties respectively. Per-atom vectors are referenced by *i\_name* and *d\_name*; per-atom arrays are referenced by *i2\_name* and *d2\_name*.

The various allowed references to integer custom atom properties in the variable formulas for equal-, vector-, and atom-style variables are listed in the following table. References to floating point custom atom properties are the same; just replace the leading “i” with “d”.

equal	i_name[I]	element of per-atom vector (I = atom ID)
equal	i2_name[I][J]	element of per-atom array (I = atom ID)
vector	i_name[I]	element of per-atom vector (I = atom ID)
vector	i2_name[I][J]	element of per-atom array (I = atom ID)
atom	i_name	per-atom vector
atom	i2_name[I]	column of per-atom array

The I and J indices in these custom atom property references can be integers or can be a variable name, specified as v\_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the “Atom Values and Vectors” discussion above.

## Compute References

Compute references access quantities calculated by a *compute*. The ID in the reference should be replaced by the ID of a compute defined elsewhere in the input script.

As discussed on the page for the *compute* command, computes can produce global, per-atom, local, and per-grid values. Only global and per-atom values can be used in a variable. Computes can also produce scalars (global only), vectors, and arrays. See the doc pages for individual computes to see what different kinds of data they produce.

An equal-style variable can only use scalar values, either from global or per-atom data. In the case of per-atom data, this would be a value for a specific atom.

A vector-style variable can use scalar values (same as for equal-style variables), or global vectors of values. The latter can also be a column of a global array.

Atom-style variables can use scalar values (same as for equal-style variables), or per-atom vectors of values. The latter can also be a column of a per-atom array.

The various allowed compute references in the variable formulas for equal-, vector-, and atom-style variables are listed in the following table:

equal	c_ID	global scalar
equal	c_ID[I]	element of global vector
equal	c_ID[I][J]	element of global array
equal	C_ID[I]	element of per-atom vector (I = atom ID)
equal	C_ID[I][J]	element of per-atom array (I = atom ID)
vector	c_ID	global vector
vector	c_ID[I]	column of global array
atom	c_ID	per-atom vector
atom	c_ID[I]	column of per-atom array

Note that if an equal-style variable formula wishes to access per-atom data from a compute, it must use capital “C” as the ID prefix and not lower-case “c”.

Also note that if a vector- or atom-style variable formula needs to access a scalar value from a compute (i.e. the 5 kinds of values in the first 5 lines of the table), it can not do so directly. Instead, it can use a reference to an equal-style variable which stores the scalar value from the compute.

The I and J indices in these compute references can be integers or can be a variable name, specified as v\_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the “Atom Values and Vectors” discussion above.

If a variable containing a compute is evaluated directly in an input script (not during a run), then the values accessed by the compute should be current. See the discussion below about “Variable Accuracy”.

---

## Fix References

Fix references access quantities calculated by a *fix*. The ID in the reference should be replaced by the ID of a fix defined elsewhere in the input script.

As discussed on the page for the *fix* command, fixes can produce global, per-atom, local, and per-grid values. Only global and per-atom values can be used in a variable. Fixes can also produce scalars (global only), vectors, and arrays. See the doc pages for individual fixes to see what different kinds of data they produce.

An equal-style variable can only use scalar values, either from global or per-atom data. In the case of per-atom data, this would be a value for a specific atom.

A vector-style variable can use scalar values (same as for equal-style variables), or global vectors of values. The latter can also be a column of a global array.

Atom-style variables can use scalar values (same as for equal-style variables), or per-atom vectors of values. The latter can also be a column of a per-atom array.

The allowed fix references in variable formulas for equal-, vector-, and atom-style variables are listed in the following table:

equal	f_ID	global scalar
equal	f_ID[I]	element of global vector
equal	f_ID[I][J]	element of global array
equal	F_ID[I]	element of per-atom vector (I = atom ID)
equal	F_ID[I][J]	element of per-atom array (I = atom ID)
vector	f_ID	global vector
vector	f_ID[I]	column of global array
atom	f_ID	per-atom vector
atom	f_ID[I]	column of per-atom array

Note that if an equal-style variable formula wishes to access per-atom data from a fix, it must use capital “F” as the ID prefix and not lower-case “f”.

Also note that if a vector- or atom-style variable formula needs to access a scalar value from a fix (i.e. the 5 kinds of values in the first 5 lines of the table), it can not do so directly. Instead, it can use a reference to an equal-style variable which stores the scalar value from the fix.

The I and J indices in these fix references can be integers or can be a variable name, specified as v\_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the “Atom Values and Vectors” discussion above.

Note that some fixes only generate quantities on certain timesteps. If a variable attempts to access the fix on non-allowed timesteps, an error is generated. For example, the *fix ave/time* command may only generate averaged quantities every 100 steps. See the doc pages for individual fix commands for details.

If a variable containing a fix is evaluated directly in an input script (not during a run), then the values accessed by the fix should be current. See the discussion below about “Variable Accuracy”.

## Variable References

Variable references access quantities stored or calculated by other variables, which will cause those variables to be evaluated. The name in the reference should be replaced by the name of a variable defined elsewhere in the input script.

As discussed on this doc page, equal-style variables generate a single global numeric value, vector-style variables generate a vector of global numeric values, and atom-style and atomfile-style variables generate a per-atom vector of numeric values. All other variables store one or more strings.

The formula for an equal-style variable can use any style of variable including a vector\_style or atom-style or atomfile-style. For these 3 styles, a subscript must be used to access a single value from the vector-, atom-, or atomfile-style variable. If a string-storing variable is used, the string is converted to a numeric value. Note that this will typically produce a 0.0 if the string is not a numeric string, which is likely not what you want.

The formula for a vector-style variable can use any style of variable, including atom-style or atomfile-style variables. For these 2 styles, a subscript must be used to access a single value from the atom-, or atomfile-style variable.

The formula for an atom-style variable can use any style of variable, including other atom-style or atomfile-style variables. If it uses a vector-style variable, a subscript must be used to access a single value from the vector-style variable.

The allowed variable references in variable formulas for equal-, vector-, and atom-style variables are listed in the following table. Note that there is no ambiguity as to what a reference means, since referenced variables produce only a global scalar or global vector or per-atom vector.

equal	v_name	global scalar from an equal-style variable
equal	v_name[I]	element of global vector from a vector-style variable
equal	v_name[I]	element of per-atom vector (I = atom ID) from an atom- or atomfile-style variable
vector	v_name	global scalar from an equal-style variable
vector	v_name	global vector from a vector-style variable
vector	v_name[I]	element of global vector from a vector-style variable
vector	v_name[I]	element of per-atom vector (I = atom ID) from an atom- or atomfile-style variable
atom	v_name	global scalar from an equal-style variable
atom	v_name	per-atom vector from an atom-style or atomfile-style variable
atom	v_name[I]	element of global vector from a vector-style variable
atom	v_name[I]	element of per-atom vector (I = atom ID) from an atom- or atomfile-style variable

For the I index, an integer can be specified or a variable name, specified as v\_name, where name is the name of the variable. The rules for this syntax are the same as for indices in the “Atom Values and Vectors” discussion above.

---

## Vector Initialization

New in version 15Jun2023.

*Vector*-style variables only can be initialized with a special syntax, instead of using a formula. The syntax is a bracketed, comma-separated syntax like the following:

```
variable myvec vector [1,3.5,7,10.2]
```

The 3rd argument formula is replaced by the vector values in brackets, separated by commas. This example creates a 4-length vector with specific numeric values, each of which can be specified as an integer or floating point value. Note that while whitespace can be added before or after individual values, no other mathematical operations can be specified. E.g. “3\*10” or “3\*v\_abc” are not valid vector elements, nor is “10\*[1,2,3,4]” valid for the entire vector.

Unlike vector variables specified with formulas, this vector variable is static; its length and values never changes. Its values can be used in other commands (including vector-style variables specified with formulas) via the usual syntax for accessing individual vector elements or the entire vector.

---

### 1.114.4 Immediate Evaluation of Variables

If you want an equal-style variable to be evaluated immediately, it may be the case that you do not need to define a variable at all. See the [Commands parse](#) page for info on how to use “immediate” variables in an input script, specified as \$(formula) with parenthesis, where the formula has the same syntax as equal-style variables described on this page. This effectively evaluates a formula immediately without using the variable command to define a named variable.

More generally, there is a difference between referencing a variable with a leading \$ sign (e.g. \$x or \${abc}) versus with a leading “v\_” (e.g. v\_x or v\_abc). The former can be used in any input script command, including a variable command. The input script parser evaluates the reference variable immediately and substitutes its value into the command. As explained on the [Commands parse](#) doc page, you can also use un-named “immediate” variables for this purpose. For example, a string like this \$((xlo+xhi)/2+sqrt(v\_area)) in an input script command evaluates the string between the parenthesis as an equal-style variable formula.

Referencing a variable with a leading “v\_” is an optional or required kind of argument for some commands (e.g. the *fix ave/chunk* or *dump custom* or *thermo\_style* commands) if you wish it to evaluate a variable periodically during a run. It can also be used in a variable formula if you wish to reference a second variable. The second variable will be evaluated whenever the first variable is evaluated.

As an example, suppose you use this command in your input script to define the variable “v” as

```
variable v equal vol
```

before a run where the simulation box size changes. You might think this will assign the initial volume to the variable “v”. That is not the case. Rather it assigns a formula which evaluates the volume (using the *thermo\_style* keyword “vol”) to the variable “v”. If you use the variable “v” in some other command like *fix ave/time* then the current volume of the box will be evaluated continuously during the run.

If you want to store the initial volume of the system, you can do it this way:

```
variable v equal vol
variable v0 equal $v
```

The second command will force “v” to be evaluated (yielding the initial volume) and assign that value to the variable “v0”. Thus the command

```
thermo_style custom step v_v v_v0
```

would print out both the current and initial volume periodically during the run.

Note that it is a mistake to enclose a variable formula in double quotes if it contains variables preceded by \$ signs. For example,

```
variable vratio equal "${vfinal}/${v0}"
```

This is because the quotes prevent variable substitution (explained on the *Commands parse* doc page), and thus an error will occur when the formula for “vratio” is evaluated later.

### 1.114.5 Variable Accuracy

Obviously, LAMMPS attempts to evaluate variables which contain formulas (*equal* and *vector* and *atom* style variables) accurately whenever the evaluation is performed. Depending on what is included in the formula, this may require invoking a *compute*, either directly or indirectly via a thermo keyword, or accessing a value previously calculated by a compute, or accessing a value calculated and stored by a *fix*. If the compute is one that calculates the energy or pressure of the system, then the corresponding energy or virial quantities need to be tallied during the evaluation of the interatomic potentials (pair, bond, etc) on any timestep that the variable needs the tallies. An input script can also request variables be evaluated before or after or in between runs, e.g. by including them in a *print* command.

LAMMPS keeps track of all of this as it performs a *run* or *minimize* simulation, as well as in between simulations. An error will be generated if you attempt to evaluate a variable when LAMMPS knows it cannot produce accurate values. For example, if a *thermo\_style custom* command prints a variable which accesses values stored by a *fix ave/time* command and the timesteps on which thermo output is generated are not multiples of the averaging frequency used in the *fix* command, then an error will occur.

However, there are two special cases to be aware when a variable requires invocation of a compute (directly or indirectly). The first is if the variable is evaluated before the first *run* or *minimize* command in the input script. In this case, LAMMPS will generate an error. This is because many computes require initializations which have not yet taken

place. One example is the calculation of degrees of freedom for temperature computes. Another example are the computes mentioned above which require tallying of energy or virial quantities; these values are not tallied until the first simulation begins.

The second special case is when a variable that depends on a compute is evaluated in between *run* or *minimize* commands. It is possible for other input script commands issued following the previous run, but before the variable is evaluated, to change the system. For example, the *delete\_atoms* command could be used to remove atoms. Since the compute will not re-initialize itself until the next simulation or it may depend on energy/virial computations performed before the system was changed, it will potentially generate an incorrect answer when evaluated. Note that LAMMPS will not generate an error in this case; the evaluated variable may simply be incorrect.

The way to get around both of these special cases is to perform a 0-timestep run before evaluating the variable. For example, these commands

```
# delete_atoms random fraction 0.5 yes all NULL 49839
# run 0 post no
variable t equal temp      # this thermo keyword invokes a temperature compute
print "Temperature of system = $t"
run 1000
```

will generate an error if the “run 1000” command is the first simulation in the input script. If there were a previous run, these commands will print the correct temperature of the system. But if the *delete\_atoms* command is uncommented, the printed temperature will be incorrect, because information stored by temperature compute is no longer valid.

Both these issues are resolved, if the “run 0” command is uncommented. This is because the “run 0” simulation will initialize (or re-initialize) the temperature compute correctly.

---

### 1.114.6 Restrictions

Indexing any formula element by global atom ID, such as an atom value, requires the *atom style* to use a global mapping in order to look up the vector indices. By default, only atom styles with molecular information create global maps. The *atom\_modify map* command can override the default, e.g. for atomic-style atom styles.

All *universe*- and *uloop*-style variables defined in an input script must have the same number of values.

### 1.114.7 Related commands

*next*, *jump*, *include*, *temper*, *fix print*, *print*

### 1.114.8 Default

none

## 1.115 velocity command

### 1.115.1 Syntax

```
velocity group-ID style args keyword value ...
```

- group-ID = ID of group of atoms whose velocity will be changed
- style = *create* or *set* or *scale* or *ramp* or *zero*
  - create* args = temp seed  
temp = temperature value (temperature units)  
seed = random # seed (positive integer)
  - set* args = vx vy vz  
vx,vy,vz = velocity value or NULL (velocity units)  
any of vx,vy,vz can be a variable (see below)
  - scale* arg = temp  
temp = temperature value (temperature units)
  - ramp* args = vdim vlo vhi dim clo chi  
vdim = vx or vy or vz  
vlo,vhi = lower and upper velocity value (velocity units)  
dim = x or y or z  
clo,chi = lower and upper coordinate bound (distance units)
  - zero* arg = *linear* or *angular*  
*linear* = zero the linear momentum  
*angular* = zero the angular momentum
- zero or more keyword/value pairs may be appended
- keyword = *dist* or *sum* or *mom* or *rot* or *temp* or *bias* or *loop* or *rigid* or *units*
  - dist* value = *uniform* or *gaussian*
  - sum* value = *no* or *yes*
  - mom* value = *no* or *yes*
  - rot* value = *no* or *yes*
  - temp* value = temperature compute ID
  - bias* value = *no* or *yes*
  - loop* value = *all* or *local* or *geom*
  - rigid* value = fix-ID  
fix-ID = ID of rigid body fix
  - units* value = *box* or *lattice*

### 1.115.2 Examples

```
velocity all create 300.0 4928459 rot yes dist gaussian
velocity border set NULL 4.0 v_vz sum yes units box
velocity flow scale 300.0
velocity flow ramp vx 0.0 5.0 y 5 25 temp mytemp
velocity all zero linear
```

### 1.115.3 Description

Set or change the velocities of a group of atoms in one of several styles. For each style, there are required arguments and optional keyword/value parameters. Not all options are used by each style. Each option has a default as listed below.

The *create* style generates an ensemble of velocities using a random number generator with the specified seed at the specified temperature.

The *set* style sets the velocities of all atoms in the group to the specified values. If any component is specified as NULL, then it is not set. Any of the vx,vy,vz velocity components can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v\_name, where name is the variable name. In this case, the variable will be evaluated, and its value used to determine the velocity component. Note that if a variable is used, the velocity it calculates must be in box units, not lattice units; see the discussion of the *units* keyword below.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters or other parameters.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field.

The *scale* style computes the current temperature of the group of atoms and then rescales the velocities to the specified temperature.

The *ramp* style is similar to that used by the *compute temp/ramp* command. Velocities ramped uniformly from vlo to vhi are applied to dimension vx, or vy, or vz. The value assigned to a particular atom depends on its relative coordinate value (in dim) from clo to chi. For the example above, an atom with y-coordinate of 10 (1/4 of the way from 5 to 25), would be assigned a x-velocity of 1.25 (1/4 of the way from 0.0 to 5.0). Atoms outside the coordinate bounds (less than 5 or greater than 25 in this case), are assigned velocities equal to vlo or vhi (0.0 or 5.0 in this case).

The *zero* style adjusts the velocities of the group of atoms so that the aggregate linear or angular momentum is zero. No other changes are made to the velocities of the atoms. If the *rigid* option is specified (see below), then the zeroing is performed on individual rigid bodies, as defined by the *fix rigid* or *fix rigid/small* commands. In other words, zero linear will set the linear momentum of each rigid body to zero, and zero angular will set the angular momentum of each rigid body to zero. This is done by adjusting the velocities of the atoms in each rigid body.

All temperatures specified in the velocity command are in temperature units; see the *units* command. The units of velocities and coordinates depend on whether the *units* keyword is set to *box* or *lattice*, as discussed below.

For all styles, no atoms are assigned z-component velocities if the simulation is 2d; see the *dimension* command.

---

The keyword/value options are used in the following ways by the various styles.

The *dist* keyword is used by *create*. The ensemble of generated velocities can be a *uniform* distribution from some minimum to maximum value, scaled to produce the requested temperature. Or it can be a *gaussian* distribution with a mean of 0.0 and a sigma scaled to produce the requested temperature.

The *sum* keyword is used by all styles, except *zero*. The new velocities will be added to the existing ones if sum = yes, or will replace them if sum = no.

The *mom* and *rot* keywords are used by *create*. If mom = yes, the linear momentum of the newly created ensemble of velocities is zeroed; if rot = yes, the angular momentum is zeroed.

---

If specified, the *temp* keyword is used by *create* and *scale* to specify a *compute* that calculates temperature in a desired way, e.g. by first subtracting out a velocity bias, as discussed on the *Howto thermostat* doc page. If this keyword is not specified, *create* and *scale* calculate temperature using a compute that is defined internally as follows:

```
compute velocity_temp group-ID temp
```

where *group-ID* is the same ID used in the *velocity* command. i.e. the group of atoms whose velocity is being altered. This *compute* is deleted when the *velocity* command is finished. See the *compute temp* command for details. If the calculated temperature should have degrees-of-freedom removed due to fix constraints (e.g. SHAKE or rigid-body constraints), then the appropriate *fix* command must be specified before the *velocity* command is issued.

The *bias* keyword with a *yes* setting is used by *create* and *scale*, but only if the *temp* keyword is also used to specify a *compute* that calculates temperature in a desired way. If the temperature *compute* also calculates a velocity bias, the bias is subtracted from atom velocities before the *create* and *scale* operations are performed. After the operations, the bias is added back to the atom velocities. See the *Howto thermostat* page for more discussion of temperature computes with biases. Note that the velocity bias is only applied to atoms in the temperature *compute* specified with the *temp* keyword.

As an example, assume atoms are currently streaming in a flow direction (which could be separately initialized with the *ramp* style), and you wish to initialize their thermal velocity to a desired temperature. In this context thermal velocity means the per-particle velocity that remains when the streaming velocity is subtracted. This can be done using the *create* style with the *temp* keyword specifying the ID of a *compute temp/ramp* or *compute temp/profile* command, and the *bias* keyword set to a *yes* value.

The *loop* keyword is used by *create* in the following ways.

If *loop* = *all*, then each processor loops over all atoms in the simulation to create velocities, but only stores velocities for atoms it owns. This can be a slow loop for a large simulation. If atoms were read from a data file, the velocity assigned to a particular atom will be the same, independent of how many processors are being used. This will not be the case if atoms were created using the *create\_atoms* command, since atom IDs will likely be assigned to atoms differently.

If *loop* = *local*, then each processor loops over only its atoms to produce velocities. The random number seed is adjusted to give a different set of velocities on each processor. This is a fast loop, but the velocity assigned to a particular atom will depend on which processor owns it. Thus the results will always be different when a simulation is run on a different number of processors.

If *loop* = *geom*, then each processor loops over only its atoms. For each atom a unique random number seed is created, based on the atom's xyz coordinates. A velocity is generated using that seed. This is a fast loop and the velocity assigned to a particular atom will be the same, independent of how many processors are used. However, the set of generated velocities may be more correlated than if the *all* or *local* keywords are used.

Note that the *loop geom* keyword will not necessarily assign identical velocities for two simulations run on different machines. This is because the computations based on xyz coordinates are sensitive to tiny differences in the double-precision value for a coordinate as stored on a particular machine.

The *rigid* keyword only has meaning when used with the *zero* style. It allows specification of a fix-ID for one of the *rigid-body fix* variants which defines a set of rigid bodies. The zeroing of linear or angular momentum is then performed for each rigid body defined by the fix, as described above.

The *units* keyword is used by *set* and *ramp*. If *units* = *box*, the velocities and coordinates specified in the *velocity* command are in the standard units described by the *units* command (e.g. Angstroms/fs for real units). If *units* = *lattice*, velocities are in units of lattice spacings per time (e.g. spacings/fs) and coordinates are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing.

### 1.115.4 Restrictions

Assigning a temperature via the *create* style to a system with *rigid bodies* or *SHAKE constraints* may not have the desired outcome for two reasons. First, the velocity command can be invoked before all of the relevant fixes are created and initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a *run 0* command, which ensures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

```
velocity all create 300.0 12345
run 0                                # temperature may not be 300K
velocity all scale 300.0             # now it should be
```

### 1.115.5 Related commands

*fix rigid, fix shake, lattice*

### 1.115.6 Default

The keyword defaults are dist = uniform, sum = no, mom = yes, rot = no, bias = no, loop = all, and units = lattice. The temp and rigid keywords are not defined by default.

## 1.116 write\_coeff command

### 1.116.1 Syntax

```
write_coeff file
```

- file = name of data file to write out

### 1.116.2 Examples

```
write_coeff polymer.coeff
```

### 1.116.3 Description

Write a text format file with the currently defined force field coefficients in a way, that it can be read by LAMMPS with the *include* command. In combination with the nocoeff option of *write\_data* this can be used to move the Coeff's sections from a data file into a separate file.

---

**Note:** The write\_coeff command is not yet fully implemented as some pair styles do not output their coefficient information. This means you will need to add/copy this information manually.

---

## 1.116.4 Restrictions

none

## 1.116.5 Related commands

*read\_data*, *write\_restart*, *write\_data*

## 1.117 write\_data command

### 1.117.1 Syntax

```
write_data file keyword value ...
```

- file = name of data file to write out
- zero or more keyword/value pairs may be appended
- keyword = *nocoeff* or *nofix* or *nolabelmap* or *triclinic/general* or *types* or *pair*
  - nocoeff* = do not write out force field info
  - nofix* = do not write out extra sections read by fixes
  - nolabelmap* = do not write out type labels
  - triclinic/general* = write data file in general triclinic format
  - types* value = *numeric* or *labels*
  - pair* value = *ii* or *ij*
    - ii* = write one line of pair coefficient info per atom type
    - ij* = write one line of pair coefficient info per IJ atom type pair

### 1.117.2 Examples

```
write_data data.polymer
write_data data.*
write_data data.solid triclinic/general
```

### 1.117.3 Description

Write a data file in text format of the current state of the simulation. Data files can be read by the *read\_data* command to begin a simulation. The *read\_data* command also describes their format.

Similar to *dump* files, the data filename can contain a “\*” wild-card character. The “\*” is replaced with the current timestep value.

---

#### Data in Coeff sections

The *write\_data* command may not always write all coefficient settings to the corresponding Coeff sections of the data file. This can have one of multiple reasons. 1) The style may be a hybrid style. In that case *no* coeff information is written. 2) A few styles may be missing the code that would write those sections (This is rare these days, but if you come across one, please notify the LAMMPS developers). 3) Some pair styles require a single *pair\_coeff* statement and those are not compatible with data files. 4) The default for *write\_data* is to write a *PairCoeff* section, which has only

entries for atom types  $i == j$ . The remaining coefficients would be inferred through the currently selected mixing rule. If there has been a `pair_coeff` command with  $i \neq j$ , this setting would be lost. LAMMPS will detect this and print a warning message unless `pair ij` is appended to the `write_data` command. This will request writing a `PairIJCoeff` section which has information for all pairs of atom types. In cases where the coefficient data in the data file is incomplete, you will need to re-specify that information in your input script that reads the data file.

---

Because a data file is in text format, if you use a data file written out by this command to restart a simulation, the initial state of the new run will be slightly different than the final state of the old run (when the file was written) which was represented internally by LAMMPS in binary format. A new simulation which reads the data file will thus typically diverge from a simulation that continued in the original input script.

If you want to do more exact restarts, using binary files, see the [restart](#), [write\\_restart](#), and [read\\_restart](#) commands. You can also convert binary restart files to text data files, after a simulation has run, using the [-r command-line switch](#).

---

**Note:** Only limited information about a simulation is stored in a data file. For example, no information about atom [groups](#) and [fixes](#) are stored. [Binary restart files](#) store more information.

---

Bond interactions (angle, etc) that have been turned off by the [fix shake](#) or [delete\\_bonds](#) command will be written to a data file as if they are turned on. This means they will need to be turned off again in a new run after the data file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are not written to the data file. Thus these bonds will not exist when the data file is read.

---

Use of the `nocoeff` keyword means no force field parameters are written to the data file. This can be helpful, for example, if you want to make significant changes to the force field or if the force field parameters are read in separately, e.g. from an include file.

Use of the `nofix` keyword means no extra sections read by `fixes` are written to the data file (see the `fix` option of the [read\\_data](#) command for details). For example, this option excludes sections for user-created per-atom properties from [fix property/atom](#).

The `nolabelmap` and `types` keywords refer to type labels that may be defined for numeric atom types, bond types, angle types, etc. The label map can be defined in two ways, either by the [labelmap](#) command or in data files read by the [read\\_data](#) command which have sections for Atom Type Labels, Bond Type Labels, Angle Type Labels, etc. See the [Howto type labels](#) doc page for the allowed syntax of type labels and a general discussion of how type labels can be used.

Use of the `nolabelmap` keyword means that even if type labels exist for a given type-kind (Atoms, Bonds, Angles, etc.), type labels are not written to the data file. By default, they are written if they exist. A type label must be defined for every numeric type (within a given type-kind) to be written to the data file.

Use of the `triclinic/general` keyword will output a data file which specifies a general triclinic simulation box as well as per-atom quantities consistent with the general triclinic box. The latter means that per-atom vectors, such as velocities and dipole moments will be oriented consistent with the 3d rotation implied by the general triclinic box (relative to the associated restricted triclinic box).

This option can only be requested if the simulation box was initially defined to be general triclinic. If it was and the `triclinic/general` keyword is not used, then the data file will specify a restricted triclinic box, since that is the internal format LAMMPS uses for both general and restricted triclinic simulations. See the [Howto triclinic](#) doc page for more explanation of how general triclinic simulation boxes are supported by LAMMPS. And see the [read\\_data](#) doc page for details of how the format is altered for general triclinic data files.

The `types` keyword determines how atom types, bond types, angle types, etc are written into these data file sections: Atoms, Bonds, Angles, etc. The default is the `numeric` setting, even if type label maps exist. If the `labels` setting is used, type labels will be written to the data file, if the corresponding label map exists. Note that when using `types labels`, the `nolabelmap` keyword cannot be used.

The *pair* keyword lets you specify in what format the pair coefficient information is written into the data file. If the value is specified as *ii*, then one line per atom type is written, to specify the coefficients for each of the  $I=J$  interactions. This means that no cross-interactions for  $I \neq J$  will be specified in the data file and the pair style will apply its mixing rule, as documented on individual *pair\_style* doc pages. Of course this behavior can be overridden in the input script after reading the data file, by specifying additional *pair\_coeff* commands for any desired  $I,J$  pairs.

If the value is specified as *ij*, then one line of coefficients is written for all  $I,J$  pairs where  $I \leq J$ . These coefficients will include any specific settings made in the input script up to that point. The presence of these  $I \neq J$  coefficients in the data file will effectively turn off the default mixing rule for the pair style. Again, the coefficient values in the data file can be overridden in the input script after reading the data file, by specifying additional *pair\_coeff* commands for any desired  $I,J$  pairs.

---

### 1.117.4 Restrictions

This command requires inter-processor communication to migrate atoms before the data file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

### 1.117.5 Related commands

*read\_data*, *write\_restart*

### 1.117.6 Default

The option defaults are *pair* = *ii* and *types* = *numeric*.

## 1.118 write\_dump command

### 1.118.1 Syntax

```
write_dump group-ID style file dump-args modify dump_modify-args
```

- group-ID = ID of the group of atoms to be dumped
- style = any of the supported *dump styles*
- file = name of file to write dump info to
- dump-args = any additional args needed for a particular *dump style*
- modify = all args after this keyword are passed to *dump\_modify* (optional)
- dump-modify-args = args for *dump\_modify* (optional)

## 1.118.2 Examples

```
write_dump all atom dump.atom
write_dump subgroup atom dump.run.bin
write_dump all custom dump.myforce.* id type x y vx fx
write_dump flow custom dump.%myforce id type c_myF[3] v_ke modify sort id
write_dump all xyz system.xyz modify sort id element O H
write_dump all image snap*.jpg type type size 960 960 modify backcolor white
write_dump all image snap*.jpg element element &
    bond atom 0.3 shiny 0.1 ssao yes 6345 0.2 size 1600 1600 &
    modify backcolor white element C C O H N C C C O H H S O H
write_dump all atom/gz dump.atom.gz modify compression_level 9
write_dump flow custom/zstd dump.%myforce.zst &
    id type c_myF[3] v_ke &
    modify sort id &
    compression_level 15
```

## 1.118.3 Description

Dump a single snapshot of atom quantities to one or more files for the current state of the system. This is a one-time immediate operation, in contrast to the *dump* command which will set up a dump style to write out snapshots periodically during a running simulation.

The syntax for this command is mostly identical to that of the *dump* and *dump\_modify* commands as if they were concatenated together, with the following exceptions: There is no need for a dump ID or dump frequency and the keyword *modify* is added. The latter is so that the full range of *dump\_modify* options can be specified for the single snapshot, just as they can be for multiple snapshots. The *modify* keyword separates the arguments that would normally be passed to the *dump* command from those that would be given the *dump\_modify*. Both support optional arguments and thus LAMMPS needs to be able to cleanly separate the two sets of args.

Note that if the specified filename uses wildcard characters “\*” or “%”, as supported by the *dump* command, they will operate in the same fashion to create the new filename(s). Normally, *dump image* files require a filename with a “\*” character for the timestep. That is not the case for the *write\_dump* command; no wildcard “\*” character is necessary.

---

## 1.118.4 Restrictions

All restrictions for the *dump* and *dump\_modify* commands apply to this command as well, with the exception of the *dump image* filename not requiring a wildcard “\*” character, as noted above.

Since dumps are normally written during a *run* or *energy minimization*, the simulation has to be ready to run before this command can be used. Similarly, if the dump requires information from a compute, fix, or variable, the information needs to have been calculated for the current timestep (e.g. by a prior run), else LAMMPS will generate an error message.

For example, it is not possible to dump per-atom energy with this command before a run has been performed, since no energies and forces have yet been calculated. See the *variable* doc page section on Variable Accuracy for more information on this topic.

## 1.118.5 Related commands

*dump*, *dump image*, *dump\_modify*

## 1.118.6 Default

The defaults are listed on the doc pages for the *dump* and *dump image* and *dump\_modify* commands.

# 1.119 write\_restart command

## 1.119.1 Syntax

```
write_restart file keyword value ...
```

- file = name of file to write restart information to
- zero or more keyword/value pairs may be appended
- keyword = *fileper* or *nfile*

*fileper* arg = Np

Np = write one file for every this many processors

*nfile* arg = Nf

Nf = write this many files, one from each of Nf processors

## 1.119.2 Examples

```
write_restart restart.equil
write_restart poly.%.* nfile 10
```

## 1.119.3 Description

Write a binary restart file of the current state of the simulation.

During a long simulation, the *restart* command is typically used to output restart files periodically. The *write\_restart* command is useful after a minimization or whenever you wish to write out a single current restart file.

Similar to *dump* files, the restart filename can contain two wild-card characters. If a “\*” appears in the filename, it is replaced with the current timestep value. If a “%” character appears in the filename, then one file is written by each processor and the “%” character is replaced with the processor ID from 0 to P-1. An additional file with the “%” replaced by “base” is also written, which contains global information. For example, the files written for filename *restart.%* would be *restart.base*, *restart.0*, *restart.1*, ... *restart.P-1*. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional *fileper* and *nfile* keywords discussed below can alter the number of files written.

Restart files can be read by a *read\_restart* command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the *-r command-line switch* to convert a restart file to a data file.

**Note:** Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not

stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. Details are usually given in the documentation of the respective command. Also, see the [read\\_restart](#) command for general information about what is stored in a restart file.

---

The optional *nfile* or *fileper* keywords can be used in conjunction with the “%” wildcard character in the specified restart file name. As explained above, the “%” character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The *nfile* or *fileper* keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The *nfile* keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the *fileper* keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

---

#### 1.119.4 Restrictions

This command requires inter-processor communication to migrate atoms before the restart file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

#### 1.119.5 Related commands

*restart*, *read\_restart*, *write\_data*

#### 1.119.6 Default

none

## 2.1 fix accelerate/cos command

### 2.1.1 Syntax

```
fix ID group-ID accelerate value
```

- ID, group-ID are documented in *fix* command
- accelerate/cos = style name of this fix command
- value = amplitude of acceleration (in unit of velocity/time)

### 2.1.2 Examples

```
fix 1 all accelerate/cos 2.0e-7
```

### 2.1.3 Description

Give each atom a acceleration in x-direction based on its z coordinate. The acceleration is a periodic function along the z-direction:

$$a_x(z) = A \cos \left( \frac{2\pi z}{l_z} \right)$$

where  $A$  is the acceleration amplitude,  $l_z$  is the z-length of the simulation box. At steady state, the acceleration generates a velocity profile:

$$v_x(z) = V \cos \left( \frac{2\pi z}{l_z} \right)$$

The generated velocity amplitude  $V$  is related to the shear viscosity  $\eta$  by:

$$V = \frac{A\rho}{\eta} \left( \frac{l_z}{2\pi} \right)^2$$

and it can be obtained from ensemble average of the velocity profile:

$$V = \frac{\sum_i 2m_i v_{i,x} \cos \left( \frac{2\pi z_i}{l_z} \right)}{\sum_i m_i},$$

where  $m_i$ ,  $v_{i,x}$ , and  $z_i$  are the mass,  $x$ -component velocity, and  $z$ -coordinate of a particle, respectively.

The velocity amplitude  $V$  can be calculated with `compute viscosity/cos`, which enables viscosity calculation with periodic perturbation method, as described by [Hess](#). Because the applied acceleration drives the system away from equilibrium, the calculated shear viscosity is lower than the intrinsic viscosity due to the shear-thinning effect. Extrapolation to zero acceleration should generally be performed to predict the zero-shear viscosity. As the shear stress decreases, the signal-to-noise ratio decreases rapidly, and the simulation time must be extended accordingly to get converged results.

In order to get meaningful results, the group ID of this fix should be all.

---

## 2.1.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is not invoked during energy minimization.

## 2.1.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Since this fix depends on the  $z$ -coordinate of atoms, it cannot be used in 2d simulations.

## 2.1.6 Related commands

`compute viscosity/cos`

## 2.1.7 Default

none

---

(Hess) Hess, B. Journal of Chemical Physics 2002, 116 (1), 209–217.

## 2.2 fix acks2/reaxff command

Accelerator Variants: `acks2/reaxff/kk`

## 2.2.1 Syntax

```
fix ID group-ID acks2/reaxff Nevery cutlo cuthi tolerance params args
```

- ID, group-ID are documented in *fix* command
- acks2/reaxff = style name of this fix command
- Nevery = perform ACKS2 every this many steps
- cutlo,cuthi = lo and hi cutoff for Taper radius
- tolerance = precision to which charges will be equilibrated
- params = reaxff or a filename
- one or more keywords or keyword/value pairs may be appended

keyword = *maxiter*

*maxiter* N = limit the number of iterations to N

## 2.2.2 Examples

```
fix 1 all acks2/reaxff 1 0.0 10.0 1.0e-6 reaxff
fix 1 all acks2/reaxff 1 0.0 10.0 1.0e-6 param.acks2 maxiter 500
```

## 2.2.3 Description

Perform the atom-condensed Kohn–Sham DFT to second order (ACKS2) charge equilibration method as described in (*Verstraelen*). ACKS2 impedes unphysical long-range charge transfer sometimes seen with QEq (e.g., for dissociation of molecules), at increased computational cost. It is typically used in conjunction with the ReaxFF force field model as implemented in the *pair\_style reaxff* command, but it can be used with any potential in LAMMPS, so long as it defines and uses charges on each atom. For more technical details about the charge equilibration performed by *fix acks2/reaxff*, see the (*O’Hearn*) paper.

The ACKS2 method minimizes the electrostatic energy of the system by adjusting the partial charge on individual atoms based on interactions with their neighbors. It requires some parameters for each atom type. If the *params* setting above is the word “reaxff”, then these are extracted from the *pair\_style reaxff* command and the ReaxFF force field file it reads in. If a file name is specified for *params*, then the parameters are taken from the specified file and the file must contain one line for each atom type. The latter form must be used when performing Qeq with a non-ReaxFF potential. The lines should be formatted as follows:

```
bond_softness
itype chi eta gamma bcut
```

where the first line is the global parameter *bond\_softness*. The remaining 1 to Ntypes lines include *itype*, the atom type from 1 to Ntypes, *chi*, the electronegativity in eV, *eta*, the self-Coulomb potential in eV, *gamma*, the valence orbital exponent, and *bcut*, the bond cutoff distance. Note that these 4 quantities are also in the ReaxFF potential file, except that eta is defined here as twice the eta value in the ReaxFF file. Note that unlike the rest of LAMMPS, the units of this fix are hard-coded to be Å, eV, and electronic charge.

The optional *maxiter* keyword allows changing the max number of iterations in the linear solver. The default value is 200.

**Note:** In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.

---

## 2.2.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. This fix computes a global scalar (the number of iterations) for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is invoked during *energy minimization*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 2.2.5 Restrictions

This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix does not correctly handle interactions involving multiple periodic images of the same atom. Hence, it should not be used for periodic cell dimensions less than 10 Å.

This fix may be used in combination with *fix efield* and will apply the external electric field during charge equilibration, but there may be only one fix efield instance used, it may only use a constant electric field, and the electric field vector may only have components in non-periodic directions.

## 2.2.6 Related commands

*pair\_style reaxff*, *fix qeq/reaxff*

## 2.2.7 Default

maxiter 200

## 2.3 fix adapt command

### 2.3.1 Syntax

```
fix ID group-ID adapt N attribute args ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- adapt = style name of this fix command
- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = *pair* or *bond* or *angle* or *kspace* or *atom*

```
pair args = pstyle pparam I J v_name
  pstyle = pair style name (e.g., lj/cut)
  pparam = parameter to adapt over time
  I,J = type pair(s) to set parameter for (integer or type label)
  v_name = variable with name that calculates value of pparam
bond args = bstyle bparam I v_name
  bstyle = bond style name (e.g., harmonic)
  bparam = parameter to adapt over time
  I = type bond to set parameter for (integer or type label)
  v_name = variable with name that calculates value of bparam
angle args = astyle aparam I v_name
  astyle = angle style name (e.g., harmonic)
  aparam = parameter to adapt over time
  I = type angle to set parameter for (integer or type label)
  v_name = variable with name that calculates value of aparam
kspace arg = v_name
  v_name = variable with name that calculates scale factor on k-space terms
atom args = atomparam v_name
  atomparam = charge or diameter or diameter/disc = parameter to adapt over time
  v_name = variable with name that calculates value of atomparam
```

- zero or more keyword/value pairs may be appended
- keyword = *scale* or *reset* or *mass*

```
scale value = no or yes
  no = the variable value is the new setting
  yes = the variable value multiplies the original setting
reset value = no or yes
  no = values will remain altered at the end of a run
  yes = reset altered values to their original values at the end of a run
```

```
mass value = no or yes
  no = mass is not altered by changes in diameter
  yes = mass is altered by changes in diameter
```

## 2.3.2 Examples

```
fix 1 all adapt 1 pair soft a 1 1 v_prefactor
fix 1 all adapt 1 pair soft a 2* 3 v_prefactor
fix 1 all adapt 1 pair lj/cut epsilon * * v_scale1 pair coul/cut scale 3 3 v_scale2_
→scale yes reset yes
fix 1 all adapt 10 atom diameter v_size

variable ramp_up equal "ramp(0.01,0.5)"
fix stretch all adapt 1 bond harmonic r0 1 v_ramp_up

labelmap atom 1 c1
fix 1 all adapt 1 pair soft a c1 c1 v_prefactor
```

## 2.3.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs. Pair potential and  $k$ -space and atom attributes which can be varied by this fix are discussed below. Many other fixes can also be used to time-vary simulation parameters (e.g., the [fix deform](#) command will change the simulation box size/shape and the [fix move](#) command will change atom positions and velocities in a prescribed manner). Also note that many commands allow variables as arguments for specific parameters, if described in that manner on their doc pages. An equal-style variable can calculate a time-dependent quantity, so this is another way to vary a simulation parameter over time.

If  $N$  is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If  $N > 0$ , then changes are made every  $N$  steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the *reset* keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if *reset* is specified as *yes*, a restart file written during a simulation will contain the modified settings.

If the *scale* keyword is set to *no*, which is the default, then the value of the altered parameter will be whatever the variable generates. If the *scale* keyword is set to *yes*, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates (i.e., the variable is now a “scale factor” applied in (presumably) a time-varying fashion to the parameter).

Note that whether *scale* is *no* or *yes*, internally, the parameters themselves are actually altered by this fix. Make sure you use the *reset yes* option if you want the parameters to be restored to their initial values after the run.

---

The *pair* keyword enables various parameters of potentials defined by the [pair\\_style](#) command to be changed, if the pair style supports it. Note that the [pair\\_style](#) and [pair\\_coeff](#) commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

The *pstyle* argument is the name of the pair style. If [pair\\_style hybrid](#) or [pair\\_style hybrid/overlay](#) is used, *pstyle* should be a sub-style name. If there are multiple sub-styles using the same pair style, then *pstyle* should be specified as “style: $N$ ”, where  $N$  is which instance of the pair style you wish to adapt (e.g., the first or second). For example, *pstyle* could be specified as “soft” or “lubricate” or “lj/cut:1” or “lj/cut:2”. The *pparam* argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

<i>born</i>	a,b,c	type pairs
<i>born/coul/long, born/coul/msm</i>	coulombic_cutoff	type global
<i>born/gauss</i>	biga0,biga1,r0	type pairs
<i>buck, buck/coul/cut</i>	a,c	type pairs
<i>buck/coul/long, buck/coul/msm</i>	a,c,coulombic_cutoff	type pairs
<i>buck/mdf</i>	a,c	type pairs

<i>spin/neel</i>	coulombic_cutoff	type global
<i>soft</i>	a	type pairs
<i>table</i>	table_cutoff	type pairs
<i>ufm</i>	epsilon,sigma,scale	type pairs
<i>wf/cut</i>	epsilon,sigma,nu,mu	type pairs

**Note:** It is easy to add new pairwise potentials and their parameters to this list. All it typically takes is adding an `extract()` method to the `pair_*.cpp` file associated with the potential.

Some parameters are global settings for the pair style (e.g., the viscosity setting “mu” for *pair\_style lubricate*). Other parameters apply to atom type pairs within the pair style (e.g., the prefactor *a* for *pair\_style soft*).

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential (e.g., the lj/cut epsilon). The parameters listed as “scale” are exactly that, since the energy expression for the *coul/cut* potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the *Buckingham potential* needs both the *A* and *C* terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for *A* and once for *C*.

If a type pair parameter is specified, the *I* and *J* settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the *I* and *J* settings still need to be specified, but are ignored.

Similar to the *pair\_coeff* command, *I* and *J* can be specified in one of several ways. Explicit numeric values can be used for each, as in the first example above. Or, one or both of the types in the I,J pair can be a *type label*. LAMMPS sets the coefficients for the symmetric *J, I* interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the *I, J* arguments to set the coefficients for multiple pairs of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *m* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive). For the asterisk syntax, note that only type pairs with  $I \leq J$  are considered; if asterisks imply type pairs where  $J < I$ , they are ignored.

IMPORTANT NOTE: If *pair\_style hybrid* or *hybrid/overlay* is being used, then the *pstyle* will be a sub-style name. You must specify *I, J* arguments that correspond to type pair values defined (via the *pair\_coeff* command) for that sub-style.

The *v\_name* argument for keyword *pair* is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as *v\_name*, where *name* is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo\_style custom* for details.

For example, these commands would change the prefactor coefficient of the *pair\_style soft* potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

---

The *bond* keyword uses the specified variable to change the value of a bond coefficient over time, very similar to how the *pair* keyword operates. The only difference is that now a bond coefficient for a given bond type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the bond type argument to set the coefficients for multiple bond types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the number of bond types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *m* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive).

Currently *bond* does not support *bond\_style hybrid* nor *bond\_style hybrid/overlay* as bond styles. The bond styles that currently work with *fix\_adapt* are

<i>class2</i>	r0	type bonds
<i>fene</i>	k,r0	type bonds
<i>fene/nm</i>	k,r0	type bonds
<i>gromos</i>	k,r0	type bonds
<i>harmonic</i>	k,r0	type bonds
<i>morse</i>	r0	type bonds
<i>nonlinear</i>	epsilon,r0	type bonds

New in version 4May2022.

The *angle* keyword uses the specified variable to change the value of an angle coefficient over time, very similar to how the *pair* keyword operates. The only difference is that now an angle coefficient for a given angle type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the angle type argument to set the coefficients for multiple angle types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the number of angle types, then an asterisk with no numeric values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $m$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive).

Currently *angle* does not support *angle\_style* hybrid nor *angle\_style* hybrid/overlay as angle styles. The angle styles that currently work with *fix\_adapt* are

<i>harmonic</i>	k,theta0	type angles
<i>cosine</i>	k	type angles

Note that internally, theta0 is stored in radians, so the variable this fix uses to reset theta0 needs to generate values in radians.

The *kspace* keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever  $k$ -space solver is defined by the *kspace\_style* command. If the variable has a value of 1.0, then the solver is unaltered.

The *kspace* keyword works this way whether the *scale* keyword is set to *no* or *yes*.

The *atom* keyword enables various atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter or diameter/disc = diameter of particle

The *v\_name* argument of the *atom* keyword is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set, or scale the parameter to a new value. It should be specified as *v\_name*, where name is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is *diameter* and per-atom density and per-atom mass are defined for particles (e.g., *atom\_style granular*), then the mass of each particle is, by default, also changed when the diameter changes. The mass is set from the particle volume for 3d systems (density is assumed to stay constant). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the atom parameter is *diameter/disc*, then the mass is set from the particle area (the density is assumed to be in mass/distance<sup>2</sup> units). The mass of the particle may also be kept constant if the *mass* keyword is set to *no*. This can be useful to account for diameter changes that do not involve mass changes (e.g., thermal expansion).

For example, these commands would shrink the diameter of all granular particles in the “center” group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter v_size
```

This fix can be used in long simulations which are restarted one or more times to continuously adapt simulation parameters, but it must be done carefully. There are two issues to consider. The first is how to adapt the parameters in a continuous manner from one simulation to the next. The second is how, if desired, to reset the parameters to their original values at the end of the last restarted run.

Note that all the parameters changed by this fix are written into a restart file in their current changed state. A new restarted simulation does not know the original time=0 values, unless the input script explicitly resets the parameters (after the restart file is read) to the original values.

Also note that the time-dependent variable(s) used in the restart script should typically be written as a function of time elapsed since the original simulation began.

With this in mind, if the *scale* keyword is set to *no* (the default) in a restarted simulation, original parameters are not needed. The adapted parameters should seamlessly continue their variation relative to the preceding simulation.

If the *scale* keyword is set to *yes*, then the input script should typically reset the parameters being adapted to their original values, so that the scaling formula specified by the variable will operate correctly. An exception is if the *atom* keyword is being used with *scale yes*. In this case, information is added to the restart file so that per-atom properties in the new run will automatically be scaled relative to their original values. This will only work if the fix adapt command specified in the restart script has the same ID as the one used in the original script.

In a restarted run, if the *reset* keyword is set to *yes*, and the run ends in this script (as opposed to just writing more restart files), parameters will be restored to the values they were at the beginning of the run command in the restart script, which as explained above, may or may not be the original values of the parameters. Again, an exception is if the *atom* keyword is being used with *reset yes* (in all the runs). In that case, the original per-atom parameters are stored in the restart file, and will be restored when the restarted run finally completes.

---

### 2.3.4 Restart, fix\_modify, output, run start/stop, minimize info

If the *atom* keyword is used and the *scale* or *reset* keyword is set to *yes*, then this fix writes information to a restart file so that in a restarted run scaling can continue in a seamless manner and/or the per-atom values can be restored, as explained above.

None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

For *rRESPA time integration*, this fix changes parameters on the outermost rRESPA level.

### 2.3.5 Restrictions

none

## 2.3.6 Related commands

*compute ti, fix adapt/fep*

## 2.3.7 Default

The option defaults are scale = no, reset = no, mass = yes.

## 2.4 fix adapt/fep command

### 2.4.1 Syntax

```
fix ID group-ID adapt/fep N attribute args ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- adapt/fep = style name of this fix command
- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = *pair* or *kpace* or *atom*

*pair* args = pstyle pparam I J v\_name

pstyle = pair style name (e.g., lj/cut)

pparam = parameter to adapt over time

I,J = type pair(s) to set parameter for (integer or type label)

v\_name = variable with name that calculates value of pparam

*kpace* arg = v\_name

v\_name = variable with name that calculates scale factor on K-space terms

*atom* args = aparam v\_name

aparam = parameter to adapt over time

I = type(s) to set parameter for (integer or type label)

v\_name = variable with name that calculates value of aparam

- zero or more keyword/value pairs may be appended
- keyword = *scale* or *reset* or *after*

*scale* value = no or yes

no = the variable value is the new setting

yes = the variable value multiplies the original setting

*reset* value = no or yes

no = values will remain altered at the end of a run

yes = reset altered values to their original values at the end of a run

*after* value = no or yes

no = parameters are adapted at timestep N

yes = parameters are adapted one timestep after N

## 2.4.2 Examples

```
fix 1 all adapt/fep 1 pair soft a 1 1 v_prefactor
fix 1 all adapt/fep 1 pair soft a 2* 3 v_prefactor
fix 1 all adapt/fep 1 pair lj/cut epsilon * * v_scale1 coul/cut scale 3 3 v_scale2 scale_
→yes reset yes
fix 1 all adapt/fep 10 atom diameter 1 v_size

labelmap atom 1 c1
fix 1 all adapt/fep 1 pair soft a c1 c1 v_prefactor
```

Example input scripts available: examples/PACKAGES/fep

## 2.4.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs.

This is an enhanced version of the *fix adapt* command with two differences:

- It is possible to modify the charges of chosen atom types only, instead of scaling all the charges in the system.
- There is a new option *after* for better compatibility with *fix ave/time*.

This version is suited for free energy calculations using *compute ti* or *compute fep*.

If  $N$  is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If  $N > 0$ , then changes are made every  $N$  steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the *reset* keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if *reset* is specified as *yes*, a restart file written during a simulation will contain the modified settings.

If the *scale* keyword is set to *no*, then the value the parameter is set to will be whatever the variable generates. If the *scale* keyword is set to *yes*, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates (i.e., the variable is now a “scale factor” applied in (presumably) a time-varying fashion to the parameter). Internally, the parameters themselves are actually altered; make sure you use the *reset yes* option if you want the parameters to be restored to their initial values after the run.

If the *after* keyword is set to *yes*, then the parameters are changed one timestep after the multiple of  $N$ . In this manner, if a fix such as “fix ave/time” is used to calculate averages at every  $N$  timesteps, all the contributions to the average will be obtained with the same values of the parameters.

The *pair* keyword enables various parameters of potentials defined by the *pair\_style* command to be changed, if the pair style supports it. Note that the *pair\_style* and *pair\_coeff* commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

The *pstyle* argument is the name of the pair style. If *pair\_style hybrid* or *hybrid/overlay* is used, *pstyle* should be a sub-style name. For example, *pstyle* could be specified as “soft” or “lubricate”. The *pparam* argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

<i>snap</i>	scale	type pairs
<i>soft</i>	a	type pairs
<i>ufm</i>	epsilon,sigma,scale	type pairs
<i>wf/cut</i>	epsilon,sigma,nu,mu	type pairs

**Note:** It is easy to add new potentials and their parameters to this list. All it typically takes is adding an `extract()` method to the `pair_*.cpp` file associated with the potential.

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential (e.g., the `lj/cut` epsilon). The parameters listed as “scale” are exactly that, since the energy expression for the *coul/cut* potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the *Buckingham potential* needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the *I* and *J* settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the *I* and *J* settings still need to be specified, but are ignored.

Similar to the *pair\_coeff* command, *I* and *J* can be specified in one of several ways. Explicit numeric values can be used for each, as in the first example above. Or, one or both of the types in the *I,J* pair can be a *type label*. LAMMPS sets the coefficients for the symmetric *J,I* interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the  $I, J$  arguments to set the coefficients for multiple pairs of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the number of atom types, then an asterisk with no numeric values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $m$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive). For the asterisk syntax, note that only type pairs with  $I \leq J$  are considered; if asterisks imply type pairs where  $J < I$ , they are ignored.

IMPOTANT NOTE: If *pair\_style hybrid* or *hybrid/overlay* is being used, then the *pstyle* will be a sub-style name. You must specify  $I, J$  arguments that correspond to type pair values defined (via the *pair\_coeff* command) for that sub-style.

The *v\_name* argument for keyword *pair* is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as *v\_name*, where *name* is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo\_style custom* for details.

For example, these commands would change the prefactor coefficient of the *pair\_style soft* potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

---

The *kspace* keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever  $k$ -space solver is defined by the *kspace\_style* command. If the variable has a value of 1.0, then the solver is unaltered.

The *kspace* keyword works this way whether the *scale* keyword is set to *no* or *yes*.

---

The *atom* keyword enables various atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter = diameter of particle

The  $I$  argument indicates which atom types are affected. A wild-card asterisk can be used in place of or in conjunction with the  $I$  argument to set the coefficients for multiple atom types.

The *v\_name* argument of the *atom* keyword is the name of an *equal-style variable* which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as *v\_name*, where *name* is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is *diameter* and per-atom density and per-atom mass are defined for particles (e.g., *atom\_style granular*), then the mass of each particle is also changed when the diameter changes (density is assumed to stay constant).

For example, these commands would shrink the diameter of all granular particles in the “center” group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter * v_size
```

For *rRESPA time integration*, this fix changes parameters on the outermost rRESPA level.

---

## 2.4.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.4.5 Restrictions

The keyword “scale yes” is not supported for scaling per-atom parameters diameter and change. You can use *fix adapt* for those.

## 2.4.6 Related commands

*compute fep, fix adapt, compute ti, pair\_style \*/soft*

## 2.4.7 Default

The option defaults are scale = no, reset = no, after = no.

# 2.5 fix add/heat command

## 2.5.1 Syntax

```
fix ID group-ID add/heat style args keyword values ...
```

- ID, group-ID are documented in *fix* command
- add/heat = style name of this fix command
- style = *constant* or *linear* or *quartic*
  - constant* args = rate  
rate = rate of heat flow (energy/time units)
  - linear* args = Ttarget k  
Ttarget = target temperature (temperature units)  
k = prefactor (energy/(time\*temperature) units)
  - quartic* args = Ttarget k  
Ttarget = target temperature (temperature units)  
k = prefactor (energy/(time\*temperature^4) units)
- zero or more keyword/value pairs may be appended to args
- keyword = *overwrite*
  - overwrite* value = yes or no  
yes = sets current heat flow of particle  
no = adds to current heat flow of particle

## 2.5.2 Examples

```
fix 1 all add/heat constant v_heat  
fix 1 all add/heat linear 10.0 1.0 overwrite yes
```

## 2.5.3 Description

This fix adds heat to particles with the temperature attribute every timestep at a given rate. Note that this is an internal temperature of a particle intended for use with non-atomistic models like the discrete element method.

For the *constant* style, heat is added at the specified rate. For the *linear* style, heat is added at a rate of  $k(T_{target} - T)$  where  $k$  is the specified prefactor,  $T_{target}$  is the specified target temperature, and  $T$  is the temperature of the atom. This may be more representative of a conductive process. For the *quartic* style, heat is added at a rate of  $k(T_{target}^4 - T^4)$ , akin to radiative heat transfer.

The rate or temperature can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as `v_name`, where `name` is the variable name. In this case, the variable will be evaluated each time step, and its value will be used to determine the rate of heat added.

Equal-style variables can specify formulas with various mathematical functions and include *thermo\_style* command keywords for the simulation box parameters, time step, and elapsed time to specify time-dependent heating.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates to specify spatially-dependent heating.

If the *overwrite* keyword is set to *yes*, this fix will set the total heat flow on a particle every timestep, overwriting contributions from pair styles or other fixes. If *overwrite* is *no*, this fix will add heat on top of other contributions.

---

## 2.5.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.5.5 Restrictions

This pair style is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store temperature and heat flow as defined by the *fix property/atom* command or included in certain atom styles, such as `atom_style rheo/thermal`.

## 2.5.6 Related commands

*fix heat/flow, fix property/atom, fix rheo/thermal*

## 2.5.7 Default

The default for the *overwrite* keyword is *no*

# 2.6 fix addforce command

## 2.6.1 Syntax

```
fix ID group-ID addforce fx fy fz keyword value ...
```

- ID, group-ID are documented in *fix* command
- addforce = style name of this fix command
- fx,fy,fz = force component values (force units)

any of fx,fy,fz can be a variable (see below)

- zero or more keyword/value pairs may be appended to args
- keyword = *every* or *region* or *energy*

*every* value = Nevery

Nevery = add force every this many time steps

*region* value = region-ID

region-ID = ID of region atoms must be in to have added force

*energy* value = v\_name

v\_name = variable with name that calculates the potential energy of each atom in  
→the added force field

## 2.6.2 Examples

```
fix kick flow addforce 1.0 0.0 0.0
fix kick flow addforce 1.0 0.0 v_oscillate
fix ff boundary addforce 0.0 0.0 v_push energy v_espace
```

## 2.6.3 Description

Add  $(f_x, f_y, f_z)$  to the corresponding component of the force for each atom in the group. This command can be used to give an additional push to atoms in a simulation, such as for a simulation of Poiseuille flow in a channel.

Any of the three quantities defining the force components, namely  $f_x$ ,  $f_y$ , and  $f_z$ , can be specified as an equal-style or atom-style *variable*. If the value is a variable, it should be specified as v\_name, where name is the variable name. In this case, the variable will be evaluated each time step, and its value(s) will be used to determine the force component(s).

Equal-style variables can specify formulas with various mathematical functions and include *thermo\_style* command keywords for the simulation box parameters, time step, and elapsed time. Thus, it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus, it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the *every* keyword is used, the *Nevery* setting determines how often the forces are applied. The default value is 1, for every time step.

If the *region* keyword is used, the atom must also be in the specified geometric *region* in order to have force added to it.

---

Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the “run” command, this energy can be optionally added to the system’s potential energy for thermodynamic output (see below). For energy minimization via the “minimize” command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

The *energy* keyword is not allowed if the added force is a constant vector  $\vec{F} = (f_x, f_y, f_z)$ , with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each atom directly as

$$E = -\vec{x} \cdot \vec{F} = -(xf_x + yf_y + zf_z),$$

so that  $-\vec{\nabla}E = \vec{F}$ .

The *energy* keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the *run* command. If the keyword is not used, LAMMPS will set the energy to 0.0, which is typically fine for dynamics.

The *energy* keyword is required if the added force is defined with one or more variables, and you are performing energy minimization via the “minimize” command. The keyword specifies the name of an atom-style *variable* which is used to compute the energy of each atom as function of its position. Like variables used for  $f_x, f_y, f_z$ , the energy variable is specified as *v\_name*, where name is the variable name.

Note that when the *energy* keyword is used during an energy minimization, you must ensure that the formula defined for the atom-style *variable* is consistent with the force variable formulas (i.e., that  $-\vec{\nabla}E = \vec{F}$ ). For example, if the force were a spring-like,  $\vec{F} = -k\vec{x}$ , then the energy formula should be  $E = \frac{1}{2}kx^2$ . If you do not do this correctly, the minimization will not converge properly.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.6.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy inferred by the added force to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*. Note that this energy is a fictitious quantity but is needed so that the *minimize* command can include the forces added by this fix in a consistent manner (i.e., there is a decrease in potential energy when atoms move in the direction of the added force).

The *fix\_modify virial* option is supported by this fix to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar and a global three-vector of forces, which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The vector is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the time step as the iteration count during the minimization.

---

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you **MUST** enable the *fix\_modify energy* option for this fix.

---

## 2.6.5 Restrictions

none

## 2.6.6 Related commands

*fix setforce*, *fix aveforce*

## 2.6.7 Default

The option default for the every keyword is every = 1.

# 2.7 fix addtorque command

## 2.7.1 Syntax

```
fix ID group-ID addtorque Tx Ty Tz
```

- ID, group-ID are documented in *fix* command
- addtorque = style name of this fix command

- $T_x, T_y, T_z$  = torque component values (torque units)
- any of  $T_x, T_y, T_z$  can be a variable (see below)

## 2.7.2 Examples

```
fix kick bead addtorque 2.0 3.0 5.0
fix kick bead addtorque 0.0 0.0 v_oscillate
```

## 2.7.3 Description

Add a set of forces to each atom in the group such that:

- the components of the total torque applied on the group (around its center of mass) are  $T_x$ ,  $T_y$ , and  $T_z$
- the group would move as a rigid body in the absence of other forces.

This command can be used to drive a group of atoms into rotation.

Any of the three quantities defining the torque components can be specified as an equal-style *variable*, namely  $T_x$ ,  $T_y$ ,  $T_z$ . If the value is a variable, it should be specified as `v_name`, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the torque component.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent torque.

---

## 2.7.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential “energy” inferred by the added torques to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*. Note that this is a fictitious quantity but is needed so that the *minimize* command can include the forces added by this fix in a consistent manner (i.e., there is a decrease in potential energy when atoms move in the direction of the added forces).

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its torque. Default is the outermost level.

This fix computes a global scalar and a global 3-vector, which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The vector is the total torque on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you **MUST** enable the *fix\_modify energy* option for this fix.

---

---

**Note:** You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

---

## 2.7.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 2.7.6 Related commands

*fix addforce*

## 2.7.7 Default

# 2.8 fix alchemy command

## 2.8.1 Syntax

```
fix ID group-ID alchemy v_name
```

- ID, group-ID are documented in *fix* command
- alchemy = style name of this fix command
- v\_name = variable with name that determines the  $\lambda_R$  value

## 2.8.2 Examples

```
fix trans all alchemy v_ramp
```

## 2.8.3 Description

New in version 28Mar2023.

This fix command enables an “alchemical transformation” to be performed between two systems, whereby one system slowly transforms into the other over the course of a molecular dynamics run. This is useful for measuring thermodynamic differences between two different systems. It also allows transformations that are not easily possible with the *pair style hybrid/scaled*, *fix adapt* or *fix adapt/fep* commands.

Example inputs are included in the `examples/PACKAGES/alchemy` directory for (a) transforming a pure copper system into a copper/aluminum bronze alloy and (b) transforming two water molecules in a box of water into a hydronium and a hydroxyl ion.

The two systems must be defined as *separate replica* and run in separate partitions of processors using the *-partition* command-line switch. Exactly two partitions must be specified, and each partition must use the same number of processors and the same domain decomposition.

Because the forces applied to the atoms are the same mix of the forces from each partition and the simulation starts with the same atom positions across both partitions, they will generate the same trajectory of coordinates for each atom, and the same simulation box size and shape. The latter two conditions are *enforced* by this fix; it exchanges coordinates and box information between the replicas. This is not strictly required, but since MD simulations are an example of a chaotic system, even the tiniest random difference will eventually grow exponentially into an unwanted divergence.

Otherwise, the properties of each atom (type, charge, bond and angle partners, etc.), as well as energy and forces between interacting atoms (pair, bond, angle styles, etc.) can be different in the two systems.

This can be initialized in the same input script by using commands which only apply to one or the other replica. The example scripts use a world-style *variable* command along with *if/then/else* commands for this purpose. The *partition* command can also be used.

```
create_box 2 box
create_atoms 1 box
pair_style eam/alloy
pair_coeff * * AlCu.eam.alloy Cu Al

# replace 5% of copper with aluminum on the second partition only

variable name world pure alloy
if "${name} == alloy" then &
  "set type 1 type/fraction 2 0.05 6745234"
```

Both replicas must define an instance of this fix, but with a different *v\_name* variable. The named variable must be an equal-style or equivalent *variable*. The two variables should be defined so that one ramps *down* from 1.0 to 0.0 for the *first* replica ( $R=0$ ) and the other ramps *up* from 0.0 to 1.0 for the *second* replica ( $R=1$ ). A simple way is to do this is linearly, which can be done using the *ramp()* function of the *variable* command. You could also define a variable which returns a value between 0.0 and 1.0 as a non-linear function of the timestep. Here is a linear example:

```
partition yes 1 variable ramp equal ramp(1.0,0.0)
partition yes 2 variable ramp equal ramp(0.0,1.0)
fix 2 all alchemy v_ramp
```

---

**Note:** For an alchemical transformation, the two variables should sum to exactly 1.0 at any timestep. LAMMPS does *NOT* check that this is the case.

---

If you use the *ramp()* function to define the two variables, this fix can easily be used across successive runs in the same input script by ensuring each instance of the *run* command specifies the appropriate *start* or *stop* options.

At each timestep of an MD run, the two instances of this fix evaluate their respective variables as a  $\lambda_R$  factor, where  $R = 0$  or  $1$  for each replica. The forces used by each system for the propagation of their atoms is set to the sum of the forces for the two systems, each scaled by their respective  $\lambda_R$  factor. Thus, during the MD run, the system will transform incrementally from the first system to the second system.

---

**Note:** As mentioned above, the coordinates of the atoms and box size/shape must be exactly the same in the two replicas. Therefore, it is generally not a good idea to initialize the two replicas by reading different data files or creating them individually from scratch. Rather, a single system should be initialized and then desired modifications applied to the system to either replica. If your input script somehow induces the two systems to become different (e.g. by performing *atom\_modify sort* differently, or by adding or depositing a different number of atoms), then LAMMPS will

detect the mismatch and generate an error. This is done by ensuring that each step the number and ordering of atoms is identical within each pair of processors in the two replicas.

---

## 2.8.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix stores a global scalar (the current value of  $\lambda_R$ ) and a global vector of length 3 which contains the potential energy of the first partition, the second partition and the combined value, respectively. The global scalar is unitless and “intensive”, the vector is in *energy units* and “extensive”. These values can be used by any command that uses a global value from a fix as input. See the *output howto* page for an overview of LAMMPS output options.

This fix is not invoked during *energy minimization*.

## 2.8.5 Restrictions

This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

There may be only one instance of this fix in use at a time within each replica.

## 2.8.6 Related commands

*compute pressure/alchemy* command, *fix adapt* command, *fix adapt/fep* command, *pair\_style hybrid/scaled* command.

## 2.8.7 Default

none

# 2.9 fix amoeba/bitorsion command

## 2.9.1 Syntax

**fix** ID group-ID amoeba/bitorsion filename

- ID, group-ID are documented in *fix* command
- amoeba/bitorsion = style name of this fix command
- filename = force-field file with AMOEBA bitorsion coefficients

## 2.9.2 Examples

```
fix          bit all amoeba/bitorsion bitorsion.ubiquitin.data
read_data    proteinX.data fix bit bitorsions BiTorsions
fix_modify   bit energy yes
```

## 2.9.3 Description

This command enables 5-body torsion/torsion interactions to be added to simulations which use the AMOEBA and HIPPO force fields. It matches how the Tinker MD code computes its torsion/torsion interactions for the AMOEBA and HIPPO force fields. See the [Howto amoeba](#) doc page for more information about the implementation of AMOEBA and HIPPO in LAMMPS.

Bitorsion interactions add additional potential energy contributions to pairs of overlapping phi-psi dihedrals of amino-acids, which are important to properly represent their conformational behavior. Each bitorsion interaction is thus defined for a 5-tuple of atoms *IJKLM* with bonds between successive atoms in the list, i.e. two overlapping dihedral interactions for atoms *IJKL* and *JKLM*.

The examples/amoeba directory has a sample input script and data file for ubiquitin, which illustrates use of the fix amoeba/bitorsion command.

As in the example above, this fix should be used before reading a data file that contains a listing of bitorsion interactions. The *filename* specified should contain the bitorsion parameters for the AMOEBA or HIPPO force field.

The data file read by the [read\\_data](#) command must contain the topology of all the bitorsion interactions, similar to the topology data for bonds, angles, dihedrals, etc. Specifically it should have a line like this in its header section:

```
N bitorsions
```

where *N* is the number of bitorsion 5-body interactions. It should also have a section in the body of the data file like this with *N* lines:

```
BiTorsions
```

1	1	8	10	12	18	20
2	5	18	20	22	25	27
[...]						
N	3	314	315	317	318	330

The first column is an index from 1 to *N* to enumerate the bitorsion 5-atom tuples; it is ignored by LAMMPS. The second column is the *type* of the interaction; it is an index into the bitorsion force field file. The remaining 5 columns are the atom IDs of the atoms (in order) for the 5-tuple *IJKLM*, as described above.

Note that the *bitorsions* and *BiTorsions* keywords for the header and body sections match those specified in the [read\\_data](#) command following the data file name.

The data file should be generated by using the tools/tinker/tinker2lmp.py conversion script which creates a LAMMPS data file from Tinker input files, including its PRM file which contains the parameters necessary for computing bitorsion interactions. The script must be invoked with the optional “-bitorsion” flag to do this; see the example for the ubiquitin system in the tools/tinker/README file. The same conversion script also creates the file of bitorsion coefficient data which is read by this command.

The potential energy associated with bitorsion interactions can be output as described below. It can also be included in the total potential energy of the system, as output by the [thermo\\_style](#) command, if the [fix\\_modify energy](#) command is used, as in the example above. See the note below about how to include the bitorsion energy when performing an [energy minimization](#).

## 2.9.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the list of bitorsion interactions to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify energy* option is supported by this fix to add the potential energy of the bitorsion interactions to both the global potential energy and peratom potential energies of the system as part of *thermodynamic output* or output by the *compute pe/atom* command. The default setting for this fix is *fix\_modify energy yes*.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the bitorsion interactions to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

---

**Note:** For energy minimization, if you want the potential energy associated with the bitorsion terms forces to be included in the total potential energy of the system (the quantity being minimized), you **MUST** not disable the *fix\_modify energy* option for this fix.

---

## 2.9.5 Restrictions

To function as expected this fix command must be issued *before* a *read\_data* command but *after* a *read\_restart* command.

This fix can only be used if LAMMPS was built with the AMOEBA package. See the *Build package* page for more info.

## 2.9.6 Related commands

## 2.10 fix amoeba/pitorsion command

### 2.10.1 Syntax

```
fix ID group-ID amoeba/pitorsion
```

- ID, group-ID are documented in *fix* command
- amoeba/pitorsion = style name of this fix command

### 2.10.2 Examples

```
fix          pit all amoeba/pitorsion
read_data    proteinX.data fix pit "pitorsion types" "PiTorsion Coeffs" &
              fix pit pitorsions PiTorsions
fix_modify   pit energy yes
```

### 2.10.3 Description

This command enables 6-body pitorsion interactions to be added to simulations which use the AMOEBA and HIPPO force fields. It matches how the Tinker MD code computes its pitorsion interactions for the AMOEBA and HIPPO force fields. See the [Howto amoeba](#) doc page for more information about the implementation of AMOEBA and HIPPO in LAMMPS.

Pitorsion interactions add additional potential energy contributions to 6-tuples of atoms *IJKLMN* that have a bond between atoms *K* and *L*, where both *K* and *L* are additionally bonded to exactly two other atoms. Namely, *K* is also bonded to *I* and *J*, and *L* is also bonded to *M* and *N*.

The examples/amoeba directory has a sample input script and data file for ubiquitin, which illustrates use of the fix amoeba/pitorsion command.

As in the example above, this fix should be used before reading a data file that contains a listing of pitorsion interactions.

The data file read by the *read\_data* command must contain the topology of all the pitorsion interactions, similar to the topology data for bonds, angles, dihedrals, etc. Specifically, it should have two lines like these in its header section:

```
M pitorsion types
N pitorsions
```

where *N* is the number of pitorsion 6-body interactions and *M* is the number of pitorsion types. It should also have two sections in the body of the data file like these with *M* and *N* lines each:

```
PiTorsion Coeffs
```

```
1 6.85
2 10.2
[...]
M 6.85
```

```
PiTorsions
```

```
1      1      2      4      3      20      21      24
```

(continues on next page)

(continued from previous page)

2	5	21	23	22	37	38	41
[...]							
N	7	27	29	28	30	35	36

For PiTorsion Coeffs, the first column is an index from 1 to  $M$  to enumerate the pitorsion types. The second column is the single prefactor coefficient needed for each type.

For PiTorsions, the first column is an index from 1 to  $N$  to enumerate the pitorsion 6-atom tuples; it is ignored by LAMMPS. The second column is the “type” of the interaction; it is an index into the PiTorsion Coeffs. The remaining 6 columns are the atom IDs of the atoms (in order) for the 6-tuple  $IJKLMN$ , as described above.

Note that the *pitorsion types* and *pitorsions* and *PiTorsion Coeffs* and *PiTorsions* keywords for the header and body sections of the data file match those specified in the [read\\_data](#) command following the data file name.

The data file should be generated by using the tools/tinker/tinker2lmp.py conversion script which creates a LAMMPS data file from Tinker input files, including its PRM file which contains the parameters necessary for computing pitorsion interactions.

The potential energy associated with pitorsion interactions can be output as described below. It can also be included in the total potential energy of the system, as output by the [thermo\\_style](#) command, if the [fix\\_modify energy](#) command is used, as in the example above. See the note below about how to include the pitorsion energy when performing an *energy minimization*.

## 2.10.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the list of pitorsion interactions to [binary restart files](#). See the [read\\_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The [fix\\_modify energy](#) option is supported by this fix to add the potential energy of the pitorsion interactions to both the global potential energy and peratom potential energies of the system as part of [thermodynamic output](#) or output by the [compute pe/atom](#) command. The default setting for this fix is [fix\\_modify energy yes](#).

The [fix\\_modify virial](#) option is supported by this fix to add the contribution due to the pitorsion interactions to both the global pressure and per-atom stress of the system via the [compute pressure](#) and [compute stress/atom](#) commands. The former can be accessed by [thermodynamic output](#). The default setting for this fix is [fix\\_modify virial yes](#).

This fix computes a global scalar which can be accessed by various [output commands](#). The scalar is the potential energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command.

The forces due to this fix are imposed during an energy minimization, invoked by the [minimize](#) command.

The [fix\\_modify respa](#) option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

**Note:** For energy minimization, if you want the potential energy associated with the pitorsion terms forces to be included in the total potential energy of the system (the quantity being minimized), you MUST not disable the [fix\\_modify energy](#) option for this fix.

## 2.10.5 Restrictions

To function as expected this fix command must be issued *before* a *read\_data* command but *after* a *read\_restart* command.

This fix can only be used if LAMMPS was built with the AMOEBA package. See the *Build package* page for more info.

## 2.10.6 Related commands

*fix\_modify*, *read\_data*

## 2.10.7 Default

none

# 2.11 fix append/atoms command

## 2.11.1 Syntax

**fix** ID group-ID append/atoms face ... keyword value ...

- ID, group-ID are documented in *fix* command
- append/atoms = style name of this fix command
- face = *zhi*
- zero or more keyword/value pairs may be appended
- keyword = *basis* or *size* or *freq* or *temp* or *random* or *units*

*basis* values = M itype

M = which basis atom

itype = atom type (1-N) to assign to this basis atom

*size* args = Lz

Lz = z size of lattice region appended in a single event(distance units)

*freq* args = freq

freq = the number of timesteps between append events

*temp* args = target damp seed extent

target = target temperature for the region between zhi-extent and zhi

→(temperature units)

damp = damping parameter (time units)

seed = random number seed for langevin kicks

extent = extent of thermostatted region (distance units)

*random* args = xmax ymax zmax seed

xmax, ymax, zmax = maximum displacement in particular direction (distance units)

seed = random number seed for random displacement

*units* value = *lattice* or *box*

*lattice* = the wall position is defined in lattice units

*box* = the wall position is defined in simulation box units

## 2.11.2 Examples

```
fix 1 all append/atoms zhi size 5.0 freq 295 units lattice
fix 4 all append/atoms zhi size 15.0 freq 5 units box
fix A all append/atoms zhi size 1.0 freq 1000 units lattice
```

## 2.11.3 Description

This fix creates atoms on a lattice, appended on the zhi edge of the system box. This can be useful when a shock or wave is propagating from zlo. This allows the system to grow with time to accommodate an expanding wave. A simulation box must already exist, which is typically created via the [create\\_box](#) command. Before using this command, a lattice must also be defined using the [lattice](#) command.

This fix will automatically freeze atoms on the zhi edge of the system, so that overlaps are avoided when new atoms are appended.

The *basis* keyword specifies an atom type that will be assigned to specific basis atoms as they are created. See the [lattice](#) command for specifics on how basis atoms are defined for the unit cell of the lattice. By default, all created atoms are assigned type = 1 unless this keyword specifies differently.

The *size* keyword defines the size in *z* of the chunk of material to be added.

The *random* keyword will give the atoms random displacements around their lattice points to simulate some initial temperature.

The *temp* keyword will cause a region to be thermostatted with a Langevin thermostat on the zhi boundary. The size of the region is measured from zhi and is set with the *extent* argument.

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. A *box* value selects standard distance units as defined by the *units* command (e.g., Å for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The [lattice](#) command must have been previously used to define the lattice spacings.

## 2.11.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to [binary restart files](#). None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various [output commands](#). No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command. This fix is not invoked during [energy minimization](#).

## 2.11.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The boundary on which atoms are added with *append/atoms* must be shrink/minimum. The opposite boundary may be any boundary type other than periodic.

## 2.11.6 Related commands

*fix wall/piston* command

## 2.11.7 Default

The keyword defaults are size = 0.0, freq = 0, units = lattice. All added atoms are of type 1 unless the basis keyword is used.

## 2.12 fix atc command

### 2.12.1 Syntax

```
fix <fixID> <group> atc <type> <parameter_file>
```

- fixID = name of fix
- group = name of group fix is to be applied
- type = *thermal* or *two\_temperature* or *hardy* or *field*

*thermal* = thermal coupling with fields: temperature

*two\_temperature* = electron-phonon coupling with field: temperature and electron\_  
→temperature

*hardy* = on-the-fly post-processing using kernel localization functions

*field* = on-the-fly post-processing using mesh-based localization functions

- parameter\_file = name of the file with material parameters. Note: Neither hardy nor field requires a parameter file

### 2.12.2 Examples

```
fix AtC internal atc thermal Ar_thermal.dat  
fix AtC internal atc two_temperature Ar_ttm.mat  
fix AtC internal atc hardy  
fix AtC internal atc field
```

### 2.12.3 Description

This fix is the beginning to creating a coupled FE/MD simulation and/or an on-the-fly estimation of continuum fields. The coupled versions of this fix do Verlet integration and the post-processing does not. After instantiating this fix, several other fix\_modify commands will be needed to set up the problem (i.e., define the finite element mesh and prescribe initial and boundary conditions).

The following coupling example is typical, but non-exhaustive:

```
# ... commands to create and initialize the MD system

# initial fix to designate coupling type and group to apply it to
# tag group physics material_file
fix AtC internal atc thermal Ar_thermal.mat

# create a uniform 12 x 2 x 2 mesh that covers region contain the group
# nx ny nz region periodicity
fix_modify AtC mesh create 12 2 2 mdRegion f p p

# specify the control method for the type of coupling
# physics control_type
fix_modify AtC thermal control flux

# specify the initial values for the empirical field "temperature"
# field node_group value
fix_modify AtC initial temperature all 30

# create an output stream for nodal fields
# filename output_frequency
fix_modify AtC output atc_fe_output 100

run 1000
```

likewise for this post-processing example:

```
# ... commands to create and initialize the MD system

# initial fix to designate post-processing and the group to apply it to
# no material file is allowed nor required
fix AtC internal atc hardy

# for hardy fix, specific kernel function (function type and range) to # be used as a
→ localization function
```

(continues on next page)

(continued from previous page)

```
fix AtC kernel quartic_sphere 10.0

# create a uniform 1 x 1 x 1 mesh that covers region contain the group
# with periodicity this effectively creates a system average
fix_modify AtC mesh create 1 1 1 box p p p

# change from default lagrangian map to eulerian
# refreshed every 100 steps
fix_modify AtC atom_element_map eulerian 100

# start with no field defined
# add mass density, potential energy density, stress and temperature
fix_modify AtC fields add density energy stress temperature

# create an output stream for nodal fields
# filename output_frequency
fix_modify AtC output nvtFE 100 text

run 1000
```

the mesh's linear interpolation functions can be used as the localization function by using the field option:

```
fix AtC internal atc field
fix_modify AtC mesh create 1 1 1 box p p p
...
```

Note coupling and post-processing can be combined in the same simulations using separate fixes.

---

## 2.12.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is not supported by this fix, but this fix does add the kinetic energy imparted to atoms by the momentum coupling mode of the AtC package to the global potential energy of the system as part of *thermodynamic output*.

Additional *fix\_modify* options relevant to this fix are listed below.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the energy discussed in the previous paragraph. The scalar value is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.12.5 Restrictions

Thermal and two\_temperature (coupling) types use a Verlet time-integration algorithm. The hardy type does not contain its own time-integrator and must be used with a separate fix that does contain one (e.g., nve, nvt). In addition, currently:

- the coupling is restricted to thermal physics
- the FE computations are done in serial on each processor.

### 2.12.6 Related commands

After specifying this fix in your input script, several *fix\_modify AtC* commands are used to setup the problem (e.g., define the finite element mesh and prescribe initial and boundary conditions). Each of these options has its own doc page.

*fix\_modify* commands for setup:

- *fix\_modify AtC mesh create*
- *fix\_modify AtC mesh quadrature*
- *fix\_modify AtC mesh read*
- *fix\_modify AtC mesh write*
- *fix\_modify AtC mesh create\_nodeset*
- *fix\_modify AtC mesh add\_to\_nodeset*
- *fix\_modify AtC mesh create\_faceset box*
- *fix\_modify AtC mesh create\_faceset plane*
- *fix\_modify AtC mesh create\_elementset*
- *fix\_modify AtC mesh delete\_elements*
- *fix\_modify AtC mesh nodeset\_to\_elementset*
- *fix\_modify AtC boundary type*
- *fix\_modify AtC internal\_quadrature*
- *fix\_modify AtC time\_integration*
- *fix\_modify AtC extrinsic electron\_integration*
- *fix\_modify AtC internal\_element\_set*
- *fix\_modify AtC decomposition*

*fix\_modify* commands for boundary and initial conditions:

- *fix\_modify AtC initial*
- *fix\_modify AtC fix*
- *fix\_modify AtC unfix*
- *fix\_modify AtC fix\_flux*
- *fix\_modify AtC unfix\_flux*
- *fix\_modify AtC source*
- *fix\_modify AtC remove\_source*

*fix\_modify* commands for control and filtering:

- *fix\_modify AtC control thermal*
- *fix\_modify AtC control momentum*
- *fix\_modify AtC control localized\_lambda*
- *fix\_modify AtC control lumped\_lambda\_solve*
- *fix\_modify AtC control mask\_direction*
- *fix\_modify AtC filter*
- *fix\_modify AtC filter scale*
- *fix\_modify AtC filter type*
- *fix\_modify AtC equilibrium\_start*
- *fix\_modify AtC extrinsic exchange*
- *fix\_modify AtC poisson\_solver*

*fix\_modify* commands for output:

- *fix\_modify AtC output*
- *fix\_modify AtC output nodeset*
- *fix\_modify AtC output volume\_integral*
- *fix\_modify AtC output boundary\_integral*
- *fix\_modify AtC output contour\_integral*
- *fix\_modify AtC mesh output*
- *fix\_modify AtC write\_restart*
- *fix\_modify AtC read\_restart*

*fix\_modify* commands for post-processing:

- *fix\_modify AtC kernel*
- *fix\_modify AtC fields*
- *fix\_modify AtC gradients*
- *fix\_modify AtC rates*
- *fix\_modify AtC computes*
- *fix\_modify AtC on\_the\_fly*
- *fix\_modify AtC pair/bond\_interactions*
- *fix\_modify AtC sample\_frequency*
- *fix\_modify AtC set*

miscellaneous *fix\_modify* commands:

- *fix\_modify AtC atom\_element\_map*
- *fix\_modify AtC atom\_weight*
- *fix\_modify AtC write\_atom\_weights*
- *fix\_modify AtC kernel\_bandwidth*

- *fix\_modify AtC reset\_time*
- *fix\_modify AtC reset\_atomic\_reference\_positions*
- *fix\_modify AtC fe\_md\_boundary*
- *fix\_modify AtC boundary\_faceset*
- *fix\_modify AtC consistent\_fe\_initialization*
- *fix\_modify AtC mass\_matrix*
- *fix\_modify AtC material*
- *fix\_modify AtC atomic\_charge*
- *fix\_modify AtC source\_integration*
- *fix\_modify AtC temperature\_definition*
- *fix\_modify AtC track\_displacement*
- *fix\_modify AtC boundary\_dynamics*
- *fix\_modify AtC add\_species*
- *fix\_modify AtC add\_molecule*
- *fix\_modify AtC remove\_species*
- *fix\_modify AtC remove\_molecule*

Note: a set of example input files with the attendant material files are included in the `examples/PACKAGES/atc` folders.

## 2.13 fix atom/swap command

### 2.13.1 Syntax

```
fix ID group-ID atom/swap N X seed T keyword values ...
```

- ID, group-ID are documented in *fix* command
- atom/swap = style name of this fix command
- N = invoke this fix every N steps
- X = number of swaps to attempt every N steps
- seed = random # seed (positive integer)
- T = scaling temperature of the MC swaps (temperature units)
- one or more keyword/value pairs may be appended to args
- keyword = *types* or *mu* or *ke* or *semi-grand* or *region*

*types* values = two or more atom types (1-Ntypes or type label)

*mu* values = chemical potential of swap types (energy units)

*ke* value = *no* or *yes*

*no* = no conservation of kinetic energy after atom swaps

*yes* = kinetic energy is conserved after atom swaps

*semi-grand* value = *no* or *yes*

*no* = particle type counts and fractions conserved

*yes* = semi-grand canonical ensemble, particle fractions not conserved

*region* value = region-ID

region-ID = ID of region to use as an exchange/move volume

### 2.13.2 Examples

```
fix 2 all atom/swap 1 1 29494 300.0 ke no types 1 2
fix myFix all atom/swap 100 1 12345 298.0 region my_swap_region types 5 6
fix SGMCM all atom/swap 1 100 345 1.0 semi-grand yes types 1 2 3 mu 0.0 4.3 -5.0
```

### 2.13.3 Description

This fix performs Monte Carlo swaps of atoms of one given atom type with atoms of the other given atom types. The specified scaling temperature  $T$  is used in the Metropolis criterion dictating swap probabilities.

Perform  $X$  swaps of atoms of one type with atoms of another type according to a Monte Carlo probability. Swap candidates must be in the fix group, must be in the region (if specified), and must be of one of the listed types. Swaps are attempted between candidates that are chosen randomly with equal probability among the candidate atoms. Swaps are not attempted between atoms of the same type since nothing would happen.

All atoms in the simulation domain can be moved using regular time integration displacements (e.g., via *fix nvt*), resulting in a hybrid MC+MD simulation. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the swapped atoms are not well equilibrated.

The *types* keyword is required. At least two atom types must be specified. If not using *semi-grand*, exactly two atom types are required.

The *ke* keyword can be set to *no* to turn off kinetic energy conservation for swaps. The default is *yes*, which means that swapped atoms have their velocities scaled by the ratio of the masses of the swapped atom types. This ensures that the kinetic energy of each atom is the same after the swap as it was before the swap, even though the atom masses have changed.

The *semi-grand* keyword can be set to *yes* to switch to the semi-grand canonical ensemble as discussed in (*Sadigh*). This means that the total number of each particle type does not need to be conserved. The default is *no*, which means that the only kind of swap allowed exchanges an atom of one type with an atom of a different given type. In other words, the relative mole fractions of the swapped atoms remains constant. Whereas in the semi-grand canonical ensemble, the composition of the system can change. Note that when using *semi-grand*, atoms in the *fix* group whose type is not listed in the *types* keyword are ineligible for attempted conversion. An attempt is made to switch the selected atom (if eligible) to one of the other listed types with equal probability. Acceptance of each attempt depends upon the Metropolis criterion.

The *mu* keyword allows users to specify chemical potentials. This is required and allowed only when using *semi-grand*. All chemical potentials are absolute, so there is one for each swap type listed following the *types* keyword. In semi-grand canonical ensemble simulations the chemical composition of the system is controlled by the difference in these values. So shifting all values by a constant amount will have no effect on the simulation.

This command may optionally use the *region* keyword to define swap volume. The specified region must have been previously defined with a *region* command. It must be defined with *side = in*. Swap attempts occur only between atoms that are both within the specified region. Swaps are not otherwise attempted.

You should ensure you do not swap atoms belonging to a molecule, or LAMMPS will eventually generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for swapping have a non-zero molecule ID, but does not check for this at the time of swapping.

If not using *semi-grand* this fix checks to ensure all atoms of the given types have the same atomic charge. LAMMPS does not enforce this in general, but it is needed for this fix to simplify the swapping procedure. Successful swaps will swap the atom type and charge of the swapped atoms. Conversely, when using *semi-grand*, it is assumed that all the atom types involved in switches have the same charge. Otherwise, charge would not be conserved. As a consequence, no checks on atomic charges are performed, and successful switches update the atom type but not the atom charge. While it is possible to use *semi-grand* with groups of atoms that have different charges, these charges will not be changed when the atom types change.

Since this fix computes total potential energies before and after proposed swaps, so even complicated potential energy calculations are OK, including the following:

- long-range electrostatics (*k*-space)
- many body pair styles
- hybrid pair styles
- eam pair styles
- triclinic systems
- need to include potential energy contributions from other fixes

Some fixes have an associated potential energy. Examples of such fixes include: *efield*, *gravity*, *addforce*, *langevin*, *restrain*, *temp/berendsen*, *temp/rescale*, and *wall fixes*. For that energy to be included in the total potential energy of the system (the quantity used when performing GCMC moves), you **must** enable the *fix\_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

### 2.13.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the fix to *binary restart files*. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of exchange attempts and successes, etc. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset\_timestep*. The fix will try to detect it and stop with an error.

---

None of the *fix\_modify* options are relevant to this fix.

This fix computes a global vector of length 2, which can be accessed by various *output commands*. The vector values are the following global cumulative quantities:

1. swap attempts
2. swap accepts

The vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.13.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

This fix cannot be used with systems that do not have per-type masses (e.g. atom style sphere) since the implemented algorithm pre-computes velocity rescaling factors from per-type masses and ignores any per-atom masses, if present. In case both, per-type and per-atom masses are present, a warning is printed.

### 2.13.6 Related commands

*fix nvt, neighbor, fix deposit, fix evaporate, delete\_atoms, fix gcmc, fix mol/swap, fix sgcmc*

### 2.13.7 Default

The option defaults are *ke* = yes, *semi-grand* = no, *mu* = 0.0 for all atom types.

---

(Sadigh) B Sadigh, P Erhart, A Stukowski, A Caro, E Martinez, and L Zepeda-Ruiz, Phys. Rev. B, 85, 184203 (2012).

## 2.14 fix ave/atom command

### 2.14.1 Syntax

```
fix ID group-ID ave/atom Nevery Nrepeat Nfreq value1 value2 ...
```

- ID, group-ID are documented in *fix* command
- ave/atom = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many timesteps
- one or more input values can be listed
- value = *x, y, z, vx, vy, vz, fx, fy, fz, c\_ID, c\_ID[i], f\_ID, f\_ID[i], v\_name*

```
x,y,z,vx,vy,vz,fx,fy,fz = atom attribute (position, velocity, force component)
c_ID = per-atom vector calculated by a compute with ID
c_ID[I] = Ith column of per-atom array calculated by a compute with ID, I can
→include wildcard (see below)
f_ID = per-atom vector calculated by a fix with ID
f_ID[I] = Ith column of per-atom array calculated by a fix with ID, I can include
→wildcard (see below)
v_name = per-atom vector calculated by an atom-style variable with name
```

### 2.14.2 Examples

```
fix 1 all ave/atom 1 100 100 vx vy vz
fix 1 all ave/atom 10 20 1000 c_my_stress[1]
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
```

### 2.14.3 Description

Use one or more per-atom vectors as inputs every few timesteps, and average them atom by atom over longer timescales. The resulting per-atom averages can be used by other *output commands* such as the *fix ave/chunk* or *dump custom* commands.

The group specified with the command means only atoms within the group have their averages computed. Results are set to 0.0 for atoms not in the group.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a *compute* or *fix* or the evaluation of an atom-style *variable*. In the latter cases, the compute, fix, or variable must produce a per-atom vector, not a global quantity or local quantity. If you wish to time-average global quantities from a compute, fix, or variable, then see the *fix ave/time* command.

Each per-atom value of each input vector is averaged independently.

*Computes* that produce per-atom vectors or arrays are those which have the word *atom* in their style name. See the doc pages for individual *fixes* to determine which ones produce per-atom vectors or arrays. *Variables* of style *atom* are the only ones that can be used with this fix since they produce per-atom vectors.

Note that for values from a compute or fix, the bracketed index  $I$  can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to  $N$ . A leading asterisk means all indices from 1 to  $n$  (inclusive). A trailing asterisk means all indices from  $m$  to  $N$  (inclusive). A middle asterisk means all indices from  $m$  to  $n$  (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. For example, these two fix ave/atom commands are equivalent, since the *compute stress/atom* command creates a per-atom array with six columns:

```
compute my_stress all stress/atom NULL
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
fix 1 all ave/atom 10 20 1000 c_my_stress[1] c_my_stress[2] &
                                c_my_stress[3] c_my_stress[4] &
                                c_my_stress[5] c_my_stress[6]
```

---

The  $N_{\text{every}}$ ,  $N_{\text{repeat}}$ , and  $N_{\text{freq}}$  arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of  $N_{\text{freq}}$ . The average is over  $N_{\text{repeat}}$  quantities, computed in the preceding portion of the simulation every  $N_{\text{every}}$  timesteps.  $N_{\text{freq}}$  must be a multiple of  $N_{\text{every}}$  and  $N_{\text{every}}$  must be non-zero even if  $N_{\text{repeat}}$  is 1. Also, the timesteps contributing to the average value cannot overlap; that is,  $N_{\text{repeat}} \times N_{\text{every}}$  cannot exceed  $N_{\text{freq}}$ .

For example, if  $N_{\text{every}} = 2$ ,  $N_{\text{repeat}} = 6$ , and  $N_{\text{freq}} = 100$ , then values on timesteps 90, 92, 94, 96, 98, and 100 will be used to compute the final average on time step 100. Similarly for timesteps 190, 192, 194, 196, 198, and 200 on time step 200, etc.

---

The atom attribute values ( $x$ ,  $y$ ,  $z$ ,  $vx$ ,  $vy$ ,  $vz$ ,  $fx$ ,  $fy$ , and  $fz$ ) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the *compute property/atom* command and then specifying an input value from that compute.

---

**Note:** The  $x$ ,  $y$ , and  $z$  attributes are values that are re-wrapped inside the periodic box whenever an atom crosses a periodic boundary. Thus, if you time-average an atom that spends half of its time on either side of the periodic box, you will get a value in the middle of the box. If this is not what you want, consider averaging unwrapped coordinates, which can be provided by the *compute property/atom* command via its  $xu$ ,  $yu$ , and  $zu$  attributes.

---

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by the compute is used. If a bracketed term containing an index  $I$  is appended, the  $I^{\text{th}}$  column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by the fix is used. If a bracketed term containing an index  $I$  is appended, the  $I^{\text{th}}$  column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with  $N_{\text{every}}$ , else an error will result. Users can also write code for their own fix styles and *add them to LAMMPS*. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script as an *atom-style variable*. Variables of style *atom* can reference thermodynamic keywords or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to time average.

---

## 2.14.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global scalar or vector quantities are stored by this fix for access by various *output commands*.

This fix produces a per-atom vector or array which can be accessed by various *output commands*. A vector is produced if only a single quantity is averaged by this fix. If two or more quantities are averaged, then an array of values is produced. The per-atom values can only be accessed on timesteps that are multiples of  $N_{\text{freq}}$  since that is when averaging is performed.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

*title3* arg = string  
string = text to print as 3rd line of output file

## 2.15.2 Examples

```
fix 1 all ave/chunk 10000 1 10000 binchunk c_myCentro title1 "My output values"
fix 1 flow ave/chunk 100 10 1000 molchunk vx vz norm sample file vel.profile
fix 1 flow ave/chunk 100 5 1000 binchunk density/mass ave running
fix 1 flow ave/chunk 100 5 1000 binchunk density/mass ave running
```

**Note:** Changed in version 31May2016.

If you are trying to replace a deprecated `fix ave/spatial` command with the newer, more flexible `fix ave/chunk` and `compute chunk/atom` commands, you simply need to split the `fix ave/spatial` arguments across the two new commands. For example, this command:

```
fix 1 flow ave/spatial 100 10 1000 y 0.0 1.0 vx vz norm sample file vel.profile
```

could be replaced by:

```
compute cc1 flow chunk/atom bin/1d y 0.0 1.0
fix 1 flow ave/chunk 100 10 1000 cc1 vx vz norm sample file vel.profile
```

### 2.15.3 Description

Use one or more per-atom vectors as inputs every few timesteps, sum the values over the atoms in each chunk at each timestep, then average the per-chunk values over longer timescales. The resulting chunk averages can be used by other *output commands* such as *thermo\_style custom*, and can also be written to a file.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* page and the *Howto chunk* page for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

Note that if the *compute chunk/atom* command defines spatial bins, the *fix ave/chunk* command performs a similar computation as the *fix ave/grid* command. However, the per-bin outputs from the *fix ave/chunk* command are global; each processor stores a copy of the entire set of bin data. By contrast, the *fix ave/grid* command uses a distributed grid where each processor owns a subset of the bins. Thus it is more efficient to use the *fix ave/grid* command when the grid is large and a simulation is run on many processors.

Note that only atoms in the specified group contribute to the summing and averaging calculations. The *compute chunk/atom* command defines its own group as well as an optional region. Atoms will have a chunk ID = 0, meaning they belong to no chunk, if they are not in that group or region. Thus you can specify the “all” group for this command if you simply want to use the chunk definitions provided by chunkID.

Each specified per-atom value can be an atom attribute (position, velocity, force component), a number or mass density, a mass or temperature, or the result of a *compute* or *fix* or the evaluation of an atom-style *variable*. In the latter cases, the *compute*, *fix*, or *variable* must produce a per-atom quantity, not a global quantity. Note that the *compute property/atom* command provides access to any attribute defined and stored by atoms. If you wish to time-average global quantities from a *compute*, *fix*, or *variable*, then see the *fix ave/time* command.

The per-atom values of each input vector are summed and averaged independently of the per-atom values in other input vectors.

*Computes* that produce per-atom quantities are those which have the word *atom* in their style name. See the doc pages for individual *fixes* to determine which ones produce per-atom quantities. *Variables* of style *atom* are the only ones that can be used with this *fix* since all other styles of *variable* produce global quantities.

Note that for values from a *compute* or *fix* that produces a per-atom array (multiple values per atom), the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If *N* = the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *m* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. For example, these two *fix ave/chunk* commands are equivalent, since the *compute property/atom* command creates, in this case, a per-atom array with three columns:

```
compute myAng all property/atom angmomx angmomy angmomz
fix 1 all ave/chunk 100 1 100 cc1 c_myAng[*] file tmp.angmom
fix 2 all ave/chunk 100 1 100 cc1 c_myAng[1] c_myAng[2] c_myAng[3] file tmp.angmom
```

**Note:** This fix works by creating an array of size  $N_{\text{chunk}} \times N_{\text{values}}$  on each processor.  $N_{\text{chunk}}$  is the number of chunks, which is defined by the `compute chunk/atom` command.  $N_{\text{values}}$  is the number of input values specified. Each processor loops over its atoms, tallying its values to the appropriate chunk. Then the entire array is summed across all processors. This means that using a large number of chunks will incur an overhead in memory and computational cost (summing across processors), so be careful to define a reasonable number of chunks.

The  $N_{\text{every}}$ ,  $N_{\text{repeat}}$ , and  $N_{\text{freq}}$  arguments specify on what time steps the input values will be accessed and contribute to the average. The final averaged quantities are generated on time steps that are a multiples of  $N_{\text{freq}}$ . The average is over  $N_{\text{repeat}}$  quantities, computed in the preceding portion of the simulation every  $N_{\text{every}}$  time steps.  $N_{\text{freq}}$  must be a multiple of  $N_{\text{every}}$  and  $N_{\text{every}}$  must be non-zero even if  $N_{\text{repeat}} = 1$ . Also, the time steps contributing to the average value cannot overlap (i.e.,  $N_{\text{repeat}} \times N_{\text{every}}$  cannot exceed  $N_{\text{freq}}$ ).

For example, if  $N_{\text{every}} = 2$ ,  $N_{\text{repeat}} = 6$ , and  $N_{\text{freq}} = 100$ , then values on time steps 90, 92, 94, 96, 98, 100 will be used to compute the final average on time step 100. Similarly for time steps 190, 192, 194, 196, 198, 200 on time step 200, etc. If  $N_{\text{repeat}} = 1$  and  $N_{\text{freq}} = 100$ , then no time averaging is done; values are simply generated on time steps 100, 200, etc.

Each input value can also be averaged over the atoms in each chunk. The way the averaging is done across the  $N_{\text{repeat}}$  time steps to produce output on the  $N_{\text{freq}}$  time steps, and across multiple  $N_{\text{freq}}$  outputs, is determined by the `norm` and `ave` keyword settings, as discussed below.

**Note:** To perform per-chunk averaging within a  $N_{\text{freq}}$  time window, the number of chunks  $N_{\text{chunk}}$  defined by the `compute chunk/atom` command must remain constant. If the `ave` keyword is set to *running* or *window* then  $N_{\text{chunk}}$  must remain constant for the duration of the simulation. This fix forces the chunk/atom compute specified by chunkID to hold  $N_{\text{chunk}}$  constant for the appropriate time windows, by not allowing it to re-calculate  $N_{\text{chunk}}$ , which can also affect how it assigns chunk IDs to atoms. This is particularly important to understand if the chunks defined by the `compute chunk/atom` command are spatial bins. If its `units` keyword is set to *box* or *lattice*, then the number of bins  $N_{\text{chunk}}$  and size of each bin will be fixed over the  $N_{\text{freq}}$  time window, which can affect which atoms are discarded if the simulation box size changes. If its `units` keyword is set to *reduced*, then the number of bins  $N_{\text{chunk}}$  will still be fixed, but the size of each bin can vary at each time step if the simulation box size changes (e.g., for an NPT simulation).

The atom attribute values (`vx`, `vy`, `vz`, `fx`, `fy`, `fz`, `mass`) are self-explanatory. As noted above, any other atom attributes can be used as input values to this fix by using the `compute property/atom` command and then specifying an input value from that compute.

The `density/number` value means the number density is computed for each chunk (i.e., number/volume). The `density/mass` value means the mass density is computed for each chunk (i.e., total-mass/volume). The output values are in units of 1/volume or mass density (mass/volume). See the `units` command page for the definition of density for each choice of units (e.g., g/cm<sup>3</sup>). If the chunks defined by the `compute chunk/atom` command are spatial bins, the volume is the bin volume. Otherwise, it is the volume of the entire simulation box.

The `temp` value means the temperature is computed for each chunk, by the formula

$$\text{KE} = \frac{\text{DOF}}{2} k_B T,$$

where KE is the total kinetic energy of the chunk of atoms (sum of  $\frac{1}{2}mv^2$ ), DOF is the the total number of degrees of freedom for all atoms in the chunk,  $k_B$  is the Boltzmann constant, and  $T$  is the absolute temperature.

The DOF is calculated as  $N \cdot \text{adof} + \text{cdof}$ , where  $N$  is the number of atoms in the chunk,  $\text{adof}$  is the number of degrees of freedom per atom, and  $\text{cdof}$  is the number of degrees of freedom per chunk. By default,  $\text{adof} = 2$  or  $3$  = dimensionality of system, as set via the *dimension* command, and  $\text{cdof} = 0.0$ . This gives the usual formula for temperature.

Note that currently this temperature only includes translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also, no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as *compute temp/partial*, *fix shake*, or *fix rigid*. This is because those degrees of freedom (e.g., a constrained bond) could apply to sets of atoms that are both included and excluded from a specific chunk, and hence the concept is somewhat ill-defined. In some cases, you can use the *adof* and *cdof* keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Also note that a bias can be subtracted from atom velocities before they are used in the above formula for KE, by using the *bias* keyword. This allows, for example, a thermal temperature to be computed after removal of a flow velocity profile.

Note that the per-chunk temperature calculated by this fix and the *compute temp/chunk* command can be different. The compute calculates the temperature for each chunk for a single snapshot. This fix can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the chunk on different time steps were collected together as one set of atoms to calculate their temperature. The compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; this fix does not.

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the  $i$ th column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the  $i$ th column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain time steps, which must be compatible with  $N_{\text{every}}$ , else an error results. Users can also write code for their own fix styles and *add them to LAMMPS*. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. Variables of style *atom* can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to average within chunks.

---

Additional optional keywords also affect the operation of this fix and its outputs.

The *norm* keyword affects how averaging is done for the per-chunk values that are output every  $N_{\text{freq}}$  time steps.

If the *norm* setting is *all*, which is the default, a chunk value is summed over all atoms in all  $N_{\text{repeat}}$  samples, as is the count of atoms in the chunk. The averaged output value for the chunk on the  $N_{\text{freq}}$  time steps is  $\text{Total-sum} / \text{Total-count}$ . In other words it is an average over atoms across the entire  $N_{\text{freq}}$  timescale. For the *density/number* and *density/mass* values, the volume (bin volume or system volume) used in the final normalization will be the volume at the final  $N_{\text{freq}}$  time step. For the *temp* values, degrees of freedom and kinetic energy are summed separately across the entire  $N_{\text{freq}}$  timescale, and the output value is calculated by dividing those two sums.

If the *norm* setting is *sample*, the chunk value is summed over atoms for each sample, as is the count, and an “average sample value” is computed for each sample (i.e.,  $\text{Sample-sum} / \text{Sample-count}$ ). The output value for the chunk on the  $N_{\text{freq}}$  time steps is the average of the  $N_{\text{repeat}}$  “average sample values” (i.e., the sum of  $N_{\text{repeat}}$  “average sample values” divided by  $N_{\text{repeat}}$ ). In other words, it is an average of an average. For the *density/number* and *density/mass* values, the volume (bin volume or system volume) used in the per-sample normalization will be the current volume at each sampling step.

If the *norm* setting is *none*, a similar computation as for the *sample* setting is done, except the individual “average sample values” are “summed sample values”. A summed sample value is simply the chunk value summed over atoms in the sample, without dividing by the number of atoms in the sample. The output value for the chunk on the  $N_{\text{freq}}$  timesteps is the average of the  $N_{\text{repeat}}$  “summed sample values” (i.e., the sum of  $N_{\text{repeat}}$  “summed sample values” divided by  $N_{\text{repeat}}$ ). For the *density/number* and *density/mass* values, the volume (bin volume or system volume) used in the per-sample sum normalization will be the current volume at each sampling step.

---

The *ave* keyword determines how the per-chunk values produced every  $N_{\text{freq}}$  steps are averaged with values produced on previous steps that were multiples of  $N_{\text{freq}}$ , before they are accessed by another output command or written to a file.

If the *ave* setting is *one*, which is the default, then the chunk values produced on timesteps that are multiples of  $N_{\text{freq}}$  are independent of each other; they are output as-is without further averaging.

If the *ave* setting is *running*, then the chunk values produced on timesteps that are multiples of  $N_{\text{freq}}$  are summed and averaged in a cumulative sense before being output. Each output chunk value is thus the average of the chunk value produced on that timestep with all preceding values for the same chunk. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the *unfix* command, or re-defining the fix by re-specifying it.

If the *ave* setting is *window*, then the chunk values produced on timesteps that are multiples of  $N_{\text{freq}}$  are summed and averaged within a moving “window” of time, so that the last  $M$  values for the same chunk are used to produce the output. For example, if  $M = 3$  and  $N_{\text{freq}} = 1000$ , then the output on step 10000 will be the average of the individual chunk values on time steps 8000, 9000, and 10000. Outputs on early steps will average over less than  $M$  values if they are not available.

---

The *bias* keyword specifies the ID of a temperature compute that removes a “bias” velocity from each atom, specified as *bias-ID*. It is only used when the *temp* value is calculated, to compute the thermal temperature of each chunk after the translational kinetic energy components have been altered in a prescribed way (e.g., to remove a flow velocity profile). See the doc pages for individual computes that calculate a temperature to see which ones implement a bias.

The *adof* and *cdof* keywords define the values used in the degree of freedom (DOF) formula described above for temperature calculation for each chunk. They are only used when the *temp* value is calculated. They can be used to calculate a more appropriate temperature for some kinds of chunks. Here are three examples:

If spatially binned chunks contain some number of water molecules and *fix shake* is used to make each molecule rigid, then you could calculate a temperature with six degrees of freedom (DOF) (three translational, three rotational) per molecule by setting *adof* to 2.0.

If *compute temp/partial* is used with the *bias* keyword to only allow the  $x$  component of velocity to contribute to the temperature, then *adof* = 1.0 would be appropriate.

If each chunk consists of a large molecule, with some number of its bonds constrained by *fix shake* or the entire molecule by *fix rigid/small*, *adof* = 0.0 and *cdof* could be set to the remaining degrees of freedom for the entire molecule (entire chunk in this case), that is, 6 for 3d or 3 for 2d for a rigid molecule.

---

New in version 17Apr2024: new keyword *append*

The *file* or *append* keywords allow a filename to be specified. If *file* is used, then the filename is overwritten if it already exists. If *append* is used, then the filename is appended to if it already exists, or created if it does not exist. Every  $N_{\text{freq}}$  timesteps, a section of chunk info will be written to a text file in the following format. A line with the timestep and number of chunks is written. Then one line per chunk is written, containing the chunk ID ( $1 - N_{\text{chunk}}$ ), an optional original ID value, optional coordinate values for chunks that represent spatial bins, the number of atoms in the chunk, and one or more calculated values. More explanation of the optional values is given below. The number of values in each line corresponds to the number of values specified in the fix ave/chunk command. The number of atoms and the value(s) are summed or average quantities, as explained above.

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the *ave running* setting.

The *format* keyword sets the numeric format of each value when it is printed to a file via the *file* keyword. Note that all values are floating point quantities. The default format is %g. You can specify a higher precision if desired (e.g., %20.16g).

The *title1* and *title2* and *title3* keywords allow specification of the strings that will be printed as the first three lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Chunk-averaged data for fix ID and group name
# Timestep Number-of-chunks
# Chunk (OrigID) (Coord1) (Coord2) (Coord3) Ncount value1 value2 ...
```

In the first line, ID and name are replaced with the fix-ID and group name. The second line describes the two values that are printed at the first of each section of output. In the third line the values are replaced with the appropriate value names (e.g., *fx* or *c\_myCompute[2]*).

The words in parenthesis only appear with corresponding columns if the chunk style specified for the *compute chunk/atom* command supports them. The OrigID column is only used if the *compress* keyword was set to *yes* for the *compute chunk/atom* command. This means that the original chunk IDs (e.g., molecule IDs) will have been compressed to remove chunk IDs with no atoms assigned to them. Thus a compressed chunk ID of 3 may correspond to an original chunk ID or molecule ID of 415. The OrigID column will list 415 for the third chunk.

The CoordN columns only appear if a *binning* style was used in the *compute chunk/atom* command. For *bin/1d*, *bin/2d*, and *bin/3d* styles the column values are the center point of the bin in the corresponding dimension. Just Coord1 is used for *bin/1d*, Coord2 is added for *bin/2d*, Coord3 is added for *bin/3d*. For *bin/sphere*, just Coord1 is used, and it is the radial coordinate. For *bin/cylinder*, Coord1 and Coord2 are used. Coord1 is the radial coordinate (away from the cylinder axis), and coord2 is the coordinate along the cylinder axis.

Note that if the value of the *units* keyword used in the *compute chunk/atom command* is *box* or *lattice*, the coordinate values will be in distance *units*. If the value of the *units* keyword is *reduced*, the coordinate values will be in unitless reduced units (0–1). This is not true for the Coord1 value of style *bin/sphere* or *bin/cylinder* which both represent radial dimensions. Those values are always in distance *units*.

## 2.15.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global array of values which can be accessed by various *output commands*. The values can only be accessed on timesteps that are multiples of  $N_{\text{freq}}$ , since that is when averaging is performed. The global array has # of rows = the number of chunks  $N_{\text{chunk}}$ , as calculated by the specified *compute chunk/atom* command. The # of columns is  $M + 1 + N_{\text{values}}$ , where  $M \in \{1, \dots, 4\}$ , depending on whether the optional columns for OrigID and CoordN are used, as explained above. Following the optional columns, the next column contains the count of atoms in the chunk, and the remaining columns are the Nvalue quantities. When the array is accessed with a row *I* that exceeds the current number of chunks, then a 0.0 is returned by the fix instead of an error, since the number of chunks can vary as a simulation runs depending on how that value is computed by the compute chunk/atom command.

The array values calculated by this fix are treated as “intensive”, since they are typically already normalized by the count of atoms in each chunk.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

      type upper ave running title1 "My correlation data"
fix 1 all ave/correlate 1 50 10000 c_thermo_press[*]

```

## 2.16.3 Description

Use one or more global scalar values as inputs every few timesteps, calculate time correlations between them at varying time intervals, and average the correlation data over longer timescales. The resulting correlation values can be time integrated by *variables* or used by other *output commands* such as *thermo\_style custom*, and can also be written to a file. See the *fix ave/correlate/long* command for an alternate method for computing correlation functions efficiently over very long time windows.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a *compute* or *fix* or the evaluation of an equal-style or vector-style *variable*. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a compute, fix, or variable, then see the *fix ave/chunk*, *fix ave/atom*, or *fix ave/histo* commands. If you wish to convert a per-atom quantity into a single global value, see the *compute reduce* command.

The input values must be all scalars. What kinds of correlations between input values are calculated is determined by the *type* keyword as discussed below.

*Computes* that produce global quantities are those which do not have the word *atom* in their style name. Only a few *fixes* produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. *Variables* of style *equal* and *vector* are the only ones that can be used with this fix. Variables of style *atom* cannot be used, since they produce per-atom values.

For input values from a compute or fix or variable, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the

size of the vector, then an asterisk with no numeric values means all indices from 1 to  $N$ . A leading asterisk means all indices from 1 to  $n$  (inclusive). A trailing asterisk means all indices from  $m$  to  $N$  (inclusive). A middle asterisk means all indices from  $m$  to  $n$  (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. For example, the following two fix ave/correlate commands are equivalent, since the *compute pressure* command creates a global vector with six values:

```
compute myPress all pressure NULL
fix 1 all ave/correlate 1 50 10000 c_myPress[*]
fix 1 all ave/correlate 1 50 10000 &
      c_myPress[1] c_myPress[2] c_myPress[3] &
      c_myPress[4] c_myPress[5] c_myPress[6]
```

**Note:** For a vector-style variable, only the wildcard forms “\*n” or “m\*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If  $n$  is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

The  $N_{\text{every}}$ ,  $N_{\text{repeat}}$ , and  $N_{\text{freq}}$  arguments specify on what timesteps the input values will be used to calculate correlation data. The input values are sampled every  $N_{\text{every}}$  time steps. The correlation data for the preceding samples is computed on time steps that are a multiple of  $N_{\text{freq}}$ . Consider a set of samples from some initial time up to an output timestep. The initial time could be the beginning of the simulation or the last output time; see the *ave* keyword for options. For the set of samples, the correlation value  $C_{ij}$  is calculated as:

$$C_{ij}(\Delta t) = \langle V_i(t)V_j(t + \Delta t) \rangle,$$

which is the correlation value between input values  $V_i$  and  $V_j$ , separated by time  $\Delta t$ . Note that the second value  $V_j$  in the pair is always the one sampled at the later time. The average is an average over every pair of samples in the set that are separated by time  $\Delta t$ . The maximum  $\Delta t$  used is of size  $(N_{\text{repeat}} - 1)N_{\text{every}}$ . Thus the correlation between a pair of input values yields  $N_{\text{repeat}}$  correlation data:

$$C_{ij}(0), C_{ij}(N_{\text{every}}), C_{ij}(2N_{\text{every}}), \dots, C_{ij}((N_{\text{repeat}} - 1)N_{\text{every}})$$

For example, if  $N_{\text{every}} = 5$ ,  $N_{\text{repeat}} = 6$ , and  $N_{\text{freq}} = 100$ , then values on time steps 0, 5, 10, 15, ..., 100 will be used to compute the final averages on time step 100. Six averages will be computed:  $C_{ij}(0)$ ,  $C_{ij}(5)$ ,  $C_{ij}(10)$ ,  $C_{ij}(15)$ ,  $C_{ij}(20)$ , and  $C_{ij}(25)$ .  $C_{ij}(10)$  on time step 100 will be the average of 19 samples, namely  $V_i(0)V_j(10)$ ,  $V_i(5)V_j(15)$ ,  $V_i(10)V_j(20)$ ,  $V_i(15)V_j(25)$ , ...,  $V_i(85)V_j(95)$ , and  $V_i(90)V_j(100)$ .

$N_{\text{freq}}$  must be a multiple of  $N_{\text{every}}$ ;  $N_{\text{every}}$  and  $N_{\text{repeat}}$  must be non-zero. Also, if the *ave* keyword is set to *one* which is the default, then  $N_{\text{freq}} \geq (N_{\text{repeat}} - 1)N_{\text{every}}$  is required.

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the  $I^{\text{th}}$  element of the global vector calculated by the compute is used. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a *compute reduce* command that can sum per-atom quantities into a global scalar or vector which can then be accessed by fix ave/correlate. It can also be a compute defined not in your input script, but by *thermodynamic output* or other fixes such as *fix nvt* or *fix temp/rescale*. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and *add them to LAMMPS*.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the  $I^{\text{th}}$  element of the

global vector calculated by the fix is used. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with  $N_{\text{every}}$ , else an error will result. Users can also write code for their own fix styles and [add them to LAMMPS](#).

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. Only equal-style or vector-style variables can be referenced; the latter requires a bracketed term to specify the  $I^{\text{th}}$  element of the vector calculated by the variable. See the [variable](#) command for details. Note that variables of style *equal* or *vector* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to time correlate.

Additional optional keywords also affect the operation of this fix.

The *type* keyword determines which pairs of input values are correlated with each other. For  $N$  input values  $V_i$ , with  $i \in \{1, \dots, N\}$ , let the number of pairs be  $N_{\text{pair}}$ . Note that the second value in the pair,  $V_i(t)V_j(t + \Delta t)$ , is always the one sampled at the later time.

- If *type* is set to *auto* then each input value is correlated with itself (i.e.,  $C_{ii} = V_i^2$  for  $i \in \{1, \dots, N\}$ , so  $N_{\text{pair}} = N$ ).
- If *type* is set to *upper* then each input value is correlated with every succeeding value (i.e.,  $C_{ij} = V_i V_j$  for  $i < j$ , so  $N_{\text{pair}} = N(N - 1)/2$ ).
- If *type* is set to *lower* then each input value is correlated with every preceding value (i.e.,  $C_{ij} = V_i V_j$  for  $i > j$ , so  $N_{\text{pair}} = N(N - 1)/2$ ).
- If *type* is set to *auto/upper* then each input value is correlated with itself and every succeeding value (i.e.,  $C_{ij} = V_i V_j$  for  $i \geq j$ , so  $N_{\text{pair}} = N(N + 1)/2$ ).
- If *type* is set to *auto/lower* then each input value is correlated with itself and every preceding value (i.e.,  $C_{ij} = V_i V_j$  for  $i \leq j$ , so  $N_{\text{pair}} = N(N + 1)/2$ ).
- If *type* is set to *full* then each input value is correlated with itself and every other value (i.e.,  $C_{ij} = V_i V_j$  for  $\{i, j\} = \{1, N\}$ , so  $N_{\text{pair}} = N^2$ ).

The *ave* keyword determines what happens to the accumulation of correlation samples every  $N_{\text{freq}}$  timesteps. If the *ave* setting is *one*, then the accumulation is restarted or zeroed every  $N_{\text{freq}}$  timesteps. Thus the outputs on successive  $N_{\text{freq}}$  timesteps are essentially independent of each other. The exception is that the  $C_{ij}(0) = V_i(t)V_j(t)$  value at a time step  $t$ , where  $t$  is a multiple of  $N_{\text{freq}}$ , contributes to the correlation output both at time  $t$  and at time  $t + N_{\text{freq}}$ .

If the *ave* setting is *running*, then the accumulation is never zeroed. Thus the output of correlation data at any timestep is the average over samples accumulated every  $N_{\text{every}}$  steps since the fix was defined. It can only be restarted by deleting the fix via the [unfix](#) command, or by re-defining the fix by re-specifying it.

The *start* keyword specifies what time step the accumulation of correlation samples will begin on. The default is step 0. Setting it to a larger value can avoid adding non-equilibrated data to the correlation averages.

The *prefactor* keyword specifies a constant which will be used as a multiplier on the correlation data after it is averaged. It is effectively a scale factor on  $V_i V_j$ , which can be used to account for the size of the time window or other unit conversions.

The *file* keyword allows a filename to be specified. Every  $N_{\text{freq}}$  steps, an array of correlation data is written to the file. The number of rows is  $N_{\text{repeat}}$ , as described above. The number of columns is  $N_{\text{pair}} + 2$ , also as described above. Thus the file ends up to be a series of these array sections.

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the *ave running* setting.

The *title1*, *title2*, and *title3* keywords allow specification of the strings that will be printed as the first three lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Time-correlated data for fix ID
# TimeStep Number-of-time-windows
# Index TimeDelta Ncount valueI*valueJ valueI*valueJ ...
```

In the first line, ID is replaced with the fix-ID. The second line describes the two values that are printed at the first of each section of output. In the third line the value pairs are replaced with the appropriate fields from the fix ave/correlate command.

Let  $S_{ij}$  be a set of time correlation data for input values  $I$  and  $J$ , namely the  $N_{\text{repeat}}$  values:

$$S_{ij} = C_{ij}(0), C_{ij}(N_{\text{every}}), C_{ij}(2N_{\text{every}}), \dots, C_{ij}((N_{\text{repeat}} - 1)N_{\text{every}})$$

As explained below, these data are output as one column of a global array, which is effectively the correlation matrix.

The *trap* function defined for *equal-style variables* can be used to perform a time integration of this vector of data, using a trapezoidal rule. This is useful for calculating various quantities which can be derived from time correlation data. If a normalization factor is needed for the time integration, it can be included in the variable formula or via the *prefactor* keyword.

## 2.16.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global array of values which can be accessed by various *output commands*. The values can only be accessed on timesteps that are multiples of  $N_{\text{freq}}$  since that is when averaging is performed. The global array has # of rows  $N_{\text{repeat}}$  and # of columns  $N_{\text{pair}} + 2$ . The first column has the time  $\Delta t$  (in time steps) between the pairs of input values used to calculate the correlation, as described above. The second column has the number of samples contributing to the correlation average, as described above. The remaining  $N_{\text{pair}}$  columns are for  $I, J$  pairs of the  $N$  input values, as determined by the *type* keyword, as described above.

- For *type* = *auto*, the  $N_{\text{pair}} = N$  columns are ordered:  $C_{11}, C_{22}, \dots, C_{NN}$
- For *type* = *upper*, the  $N_{\text{pair}} = N(N - 1)/2$  columns are ordered:  $C_{12}, C_{13}, \dots, C_{1N}, C_{23}, \dots, C_{2N}, C_{34}, \dots, C_{N-1,N}$
- For *type* = *lower*, the  $N_{\text{pair}} = N(N - 1)/2$  columns are ordered:  $C_{21}, C_{31}, C_{32}, C_{41}, C_{42}, C_{43}, \dots, C_{N1}, C_{N2}, \dots, C_{N,N-1}$
- For *type* = *auto/upper*, the  $N_{\text{pair}} = N(N + 1)/2$  columns are ordered:  $C_{11}, C_{12}, C_{13}, \dots, C_{1N}, C_{22}, C_{23}, \dots, C_{2N}, C_{33}, C_{34}, \dots, C_{N-1,N}, C_{NN}$
- For *type* = *auto/lower*, the  $N_{\text{pair}} = N(N + 1)/2$  columns are ordered:  $C_{11}, C_{21}, C_{22}, C_{31}, C_{32}, C_{33}, C_{41}, \dots, C_{44}, C_{N1}, C_{N2}, \dots, C_{N,N-1}, C_{NN}$
- For *type* = *full*, the  $N_{\text{pair}} = N^2$  columns are ordered:  $C_{11}, C_{12}, \dots, C_{1N}, C_{21}, C_{22}, \dots, C_{2N}, C_{31}, \dots, C_{3N}, \dots, C_{N1}, \dots, C_{N,N-1}, C_{NN}$

The array values calculated by this fix are treated as extensive. If you need to divide them by the number of atoms, you must do this in a later processing step (e.g., when using them in a *variable*).

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

      type upper title1 "My correlation data" nlen 15 ncount 3
fix 1 all ave/correlate/long 1 10000 c_thermo_press[*]

```

## 2.17.3 Description

This fix is similar in spirit and syntax to the [fix ave/correlate](#). However, this fix allows the efficient calculation of time correlation functions on-the-fly over extremely long time windows with little additional CPU overhead, using a multiple- $\tau$  method ([Ramirez](#)) that decreases the resolution of the stored correlation function with time. It is not a full drop-in replacement.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style or vector-style variable. For vector-style variables, the specified indices can include a wildcard character. See the [fix ave/correlate](#) page for details.

The *Nevery* and *Nfreq* arguments specify on what time steps the input values will be used to calculate correlation data and the frequency with which the time correlation functions will be output to a file, respectively. Note that there is no *Nrepeat* argument, unlike the [fix ave/correlate](#) command.

The optional keywords *ncorr*, *nlen*, and *ncount* are unique to this command and determine the number of correlation points calculated and the memory and CPU overhead used by this calculation. *Nlen* and *ncount* determine the amount of averaging done at longer correlation times. The default values *nlen* = 16 and *ncount* = 2 ensure that the systematic error of the multiple- $\tau$  correlator is always below the level of the statistical error of a typical simulation (which depends on the ensemble size and the simulation length).

The maximum correlation time (in time steps) that can be reached is given by the formula  $(nlen - 1)ncount^{(ncorr-1)}$ . Longer correlation times are discarded and not calculated. With the default values of the parameters (*ncorr* = 20, *nlen* = 16 and *ncount* = 2), this corresponds to 7864320 time steps. If longer correlation times are needed, the value of *ncorr* should be increased. Using *nlen* = 16 and *ncount* = 2, with *ncorr* = 30, the maximum number of steps that can be correlated is 8053063680. If *ncorr* = 40, correlation times in excess of  $8 \times 10^{12}$  time steps can be calculated.

The total memory needed for each correlation pair is roughly  $4 \times n_{corr} \times n_{len} \times 8$  bytes. With the default values of the parameters, this corresponds to about 10 KB.

For the meaning of the additional optional keywords, see the *fix ave/correlate* doc page.

## 2.17.4 Restart, fix\_modify, output, run start/stop, minimize info

Contrary to *fix ave/correlate* this fix does **not** provide access to its internal data to various output options. Since this fix is intended for the calculation of time correlation functions over very long MD simulations, the information about this fix is written automatically to binary restart files, so that the time correlation calculation can continue in subsequent simulations. None of the *fix\_modify* options are relevant to this fix.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

## 2.17.5 Restrictions

This compute is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.17.6 Related commands

*fix ave/correlate*

## 2.17.7 Default

none

The option defaults for keywords that are also keywords for the *fix ave/correlate* command are as follows: type = auto, start = 0, no file output, title 1,2 = strings as described on the *fix ave/correlate* doc page.

The option defaults for keywords unique to this command are as follows: ncorr=20, nlen=16, ncount=2.

# 2.18 fix ave/grid command

## 2.18.1 Syntax

**fix** ID group-ID ave/grid Nevery Nrepeat Nfreq Nx Ny Nz value1 value2 ... keyword args ...

- ID, group-ID are documented in *fix* command
- ave/grid = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many timesteps
- Nx, Ny, Nz = grid size in each dimension

- one or more per-atom or per-grid input values can be listed
- per-atom value = vx, vy, vz, fx, fy, fz, density/mass, density/number, mass, temp, c\_ID, c\_ID[I], f\_ID, f\_ID[I], v\_name

```
vx,vy,vz,fx,fy,fz,mass = atom attribute (velocity, force component, mass)
density/number, density/mass = number or mass density (per volume)
temp = temperature
c_ID = per-atom vector calculated by a compute with ID
c_ID[I] = Ith column of per-atom array calculated by a compute with ID, I can
→include wildcard (see below)
f_ID = per-atom vector calculated by a fix with ID
f_ID[I] = Ith column of per-atom array calculated by a fix with ID, I can include
→wildcard (see below)
v_name = per-atom vector calculated by an atom-style variable with name
```

- per-grid value = c\_ID:gname:dname, c\_ID:gname:dname[I], f\_ID:gname:dname, f\_ID:gname:dname[I]

```
gname = name of grid defined by compute or fix
dname = name of data field defined by compute or fix
c_ID = per-grid vector calculated by a compute with ID
c_ID[I] = Ith column of per-grid array calculated by a compute with ID, I can
→include wildcard (see below)
f_ID = per-grid vector calculated by a fix with ID
f_ID[I] = Ith column of per-grid array calculated by a fix with ID, I can include
→wildcard (see below)
```

- zero or more keyword/arg pairs may be appended
- keyword = *discard* or *norm* or *ave* or *bias* or *adof* or *cdof*
  - discard* arg = *yes* or *no*
    - yes = discard an atom outside grid in a non-periodic dimension
    - no = remap an atom outside grid in a non-periodic dimension to first or last grid
  - cell
  - norm* arg = *all* or *sample* or *none* = how output on *Nfreq* steps is normalized
    - all = output is sum of atoms across all *Nrepeat* samples, divided by atom count
    - sample = output is sum of *Nrepeat* sample averages, divided by *Nrepeat*
    - none = output is sum of *Nrepeat* sample sums, divided by *Nrepeat*
  - ave* args = *one* or *running* or *window M*
    - one = output new average value every *Nfreq* steps
    - running = output cumulative average of all previous *Nfreq* steps
    - window *M* = output average of *M* most recent *Nfreq* steps
  - bias* arg = *bias-ID*
    - bias-ID = ID of a temperature compute that removes a velocity bias for
  - temperature calculation
  - adof* value = *dof\_per\_atom*
    - dof\_per\_atom = define this many degrees-of-freedom per atom for temperature
  - calculation
  - cdof* value = *dof\_per\_grid\_cell*
    - dof\_per\_grid\_cell = add this many degrees-of-freedom per grid\_cell for
  - temperature calculation

## 2.18.2 Examples

```
fix 1 all ave/grid 10000 1 10000 10 10 10 fx fy fz c_myMSD[*]
fix 1 flow ave/grid 100 10 1000 20 20 30 f_TTM:grid:data
```

## 2.18.3 Description

Overlay the 2d or 3d simulation box with a uniformly spaced 2d or 3d grid and use it to either (a) time-average per-atom quantities for the atoms in each grid cell, or to (b) time-average per-grid quantities produced by other computes or fixes. This fix operates in either “per-atom mode” (all input values are per-atom) or in “per-grid mode” (all input values are per-grid). You cannot use both per-atom and per-grid inputs in the same command.

The grid created by this command is distributed; each processor owns the grid points that are within its subdomain. This is similar to the *fix ave/chunk* command when it uses chunks from the *compute chunk/atom* command which are 2d or 3d regular bins. However, the per-bin outputs in that case are global; each processor stores a copy of the entire set of bin data. Thus it more efficient to use the *fix ave/grid* command when the grid is large and a simulation is run on many processors.

For per-atom mode, only atoms in the specified group contribute to the summing and averaging calculations. For per-grid mode, the specified group is ignored.

The  $N_{\text{every}}$ ,  $N_{\text{repeat}}$ , and  $N_{\text{freq}}$  arguments specify on what time steps the input values will be accessed and contribute to the average. The final averaged quantities are generated on time steps that are a multiples of  $N_{\text{freq}}$ . The average is over  $N_{\text{repeat}}$  quantities, computed in the preceding portion of the simulation every  $N_{\text{every}}$  time steps.  $N_{\text{freq}}$  must be a multiple of  $N_{\text{every}}$  and  $N_{\text{every}}$  must be non-zero even if  $N_{\text{repeat}} = 1$ . Also, the time steps contributing to the average value cannot overlap (i.e.,  $N_{\text{repeat}} \times N_{\text{every}}$  cannot exceed  $N_{\text{freq}}$ ).

For example, if  $N_{\text{every}} = 2$ ,  $N_{\text{repeat}} = 6$ , and  $N_{\text{freq}} = 100$ , then values on time steps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If  $N_{\text{repeat}} = 1$  and  $N_{\text{freq}} = 100$ , then no time averaging is done; values are simply generated on timesteps 100,200,etc.

In per-atom mode, each input value can also be averaged over the atoms in each grid cell. The way the averaging is done across the  $N_{\text{repeat}}$  timesteps to produce output on the  $N_{\text{freq}}$  timesteps, and across multiple  $N_{\text{freq}}$  outputs, is determined by the *norm* and *ave* keyword settings, as discussed below.

The  $N_x$ ,  $N_y$ , and  $N_z$  arguments specify the size of the grid that overlays the simulation box. For 2d simulations,  $N_z$  must be 1. The  $N_x$ ,  $N_y$ ,  $N_z$  values can be any positive integer. The grid can be very coarse compared to the particle count, or very fine. If one or more of the values = 1, then bins are 2d planes or 1d slices of the simulation domain. Note that if the total number of grid cells is small, it may be more efficient to use the *fix ave/chunk* command which can treat a grid defined by the *compute chunk/atom* command as a global grid where each processor owns a copy of all the grid cells. If  $N_x = N_y = N_z = 1$  is used, the same calculation would be more efficiently performed by the *fix ave/atom* command.

If the simulation box size or shape changes during a simulation, the grid always conforms to the size/shape of the current simulation box. If one more dimensions have non-periodic shrink-wrapped boundary conditions, as defined by the *boundary* command, then the grid will extend over the (dynamic) shrink-wrapped extent in each dimension. If the box shape is triclinic, as explained in *Howto triclinic*, then the grid is also triclinic; each grid cell is a small triclinic cell with the same shape as the simulation box.

In both per-atom and per-grid mode, input values from a compute or fix that produces an array of values (multiple values per atom or per grid point), the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If N = the number of columns in

the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. if there were a `compute fft/grid` command which produced 3 values for each grid point, these two `fix ave/grid` commands would be equivalent:

```
compute myFFT all fft/grid 10 10 10 ...
fix 1 all ave/grid 100 1 100 10 10 10 c_myFFT:grid:data[*]
fix 2 all ave/grid 100 1 100 10 10 10 c_myFFT:grid:data[*][1] c_myFFT:grid:data[*][2] c_
    myFFT:grid:data[3]
```

---

#### *Per-atom mode:*

Each specified per-atom value can be an atom attribute (velocity, force component), a number or mass density, a mass or temperature, or the result of a *compute* or *fix* or the evaluation of an atom-style *variable*. In the latter cases, the compute, fix, or variable must produce a per-atom quantity, not a global quantity. Note that the *compute property/atom* command provides access to any attribute defined and stored by atoms.

The per-atom values of each input vector are summed and averaged independently of the per-atom values in other input vectors.

*Computes* that produce per-atom quantities are those which have the word *atom* in their style name. See the doc pages for individual *fixes* to determine which ones produce per-atom quantities. *Variables* of style *atom* are the only ones that can be used with this fix since all other styles of variable produce global quantities.

---

The atom attribute values (vx,vy,vz,fx,fy,fz,mass) are self-explanatory. As noted above, any other atom attributes can be used as input values to this fix by using the *compute property/atom* command and then specifying an input value from that compute.

The *density/number* value means the number density is computed for each grid cell, i.e. number/volume. The *density/mass* value means the mass density is computed for each grid/cell, i.e. total-mass/volume. The output values are in units of 1/volume or density (mass/volume). See the *units* command page for the definition of density for each choice of units, e.g. gram/cm<sup>3</sup>.

The *temp* value computes the temperature for each grid cell, by the formula

$$KE = \frac{DOF}{2} k_B T,$$

where KE = total kinetic energy of the atoms in the grid cell ( $\frac{1}{2}mv^2$ ), DOF = the total number of degrees of freedom for all atoms in the grid cell,  $k_B$  = Boltzmann constant, and  $T$  = temperature.

The DOF is calculated as  $N \cdot adof + cdof$ , where  $N$  = number of atoms in the grid cell,  $adof$  = degrees of freedom per atom, and  $cdof$  = degrees of freedom per grid cell. By default  $adof = 2$  or  $3$  = dimensionality of system, as set via the *dimension* command, and  $cdof = 0.0$ . This gives the usual formula for temperature.

Note that currently this temperature only includes translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as *compute temp/partial*, or *fix shake* or *fix rigid*. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that are both inside and outside a specific grid cell, and hence the concept is somewhat ill-defined. In some cases, you can use the *adof* and *cdof* keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Also note that a bias can be subtracted from atom velocities before they are used in the above formula for KE, by using the *bias* keyword. This allows, for example, a thermal temperature to be computed after removal of a flow velocity profile.

Note that the per-grid-cell temperature calculated by this fix and the `compute temp/chunk` command (using bins) can be different. The compute calculates the temperature for each chunk for a single snapshot. This fix can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the grid cell on different timesteps were collected together as one set of atoms to calculate their temperature. The compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; this fix does not.

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with  $N_{\text{every}}$ , else an error results. Users can also write code for their own fix styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. Variables of style *atom* can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to average within grid cells.

---

#### *Per-grid mode:*

The attributes that begin with *c\_ID* and *f\_ID* both take colon-separated fields *gname* and *dname*. These refer to a grid name and data field name which is defined by the compute or fix. Note that a compute or fix can define one or more grids (of different sizes) and one or more data fields for each of those grids. The sizes of all grids used as values for one instance of this fix must be the same.

The *c\_ID:gname:dname* and *c\_ID:gname:dname[I]* attributes allow per-grid vectors or arrays calculated by a *compute* to be accessed. The ID in the attribute should be replaced by the actual ID of the compute that has been defined previously in the input script.

If *c\_ID:gname:dname* is used as a attribute, then the per-grid vector calculated by the compute is accessed. If *c\_ID:gname:dname[I]* is used, then I must be in the range from 1-M, which will access the Ith column of the per-grid array with M columns calculated by the compute. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

The *f\_ID:gname:dname* and *f\_ID:gname:dname[I]* attributes allow per-grid vectors or arrays calculated by a *fix* to be output. The ID in the attribute should be replaced by the actual ID of the fix that has been defined previously in the input script.

If *f\_ID:gname:dname* is used as a attribute, then the per-grid vector calculated by the fix is printed. If *f\_ID:gname:dname[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the per-grid with M columns calculated by the fix. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

---

Additional optional keywords also affect the operation of this fix and its outputs. Some are only applicable to per-atom mode. Some are applicable to both per-atom and per-grid mode.

The *discard* keyword is only applicable to per-atom mode. If a dimension of the system is non-periodic, then grid cells will only span the box dimension (fixed or shrink-wrap boundaries as set by the *boundary command* command). An atom may thus be slightly outside the range of grid cells on a particular timestep. If *discard* is set to *yes* (the default),

then the atom will be assigned to the closest grid cell (lowest or highest) in that dimension. If *discard* is set to *no* the atom will be ignored.

---

The *norm* keyword is only applicable to per-atom mode. In per-grid mode, the *norm* keyword setting is ignored. The output grid value on an  $N_{\text{freq}}$  timestep is the sum of the grid values in each of the  $N_{\text{repeat}}$  samples, divided by  $N_{\text{repeat}}$ .

In per-atom mode, the *norm* keyword affects how averaging is done for the per-grid values that are output on an  $N_{\text{freq}}$  timestep.  $N_{\text{repeat}}$  samples contribute to the output. The *norm* keyword has 3 possible settings: *all* or *sample* or *none*. *All* is the default.

In the formulas that follow, SumI is the sum of a per-atom property over the CountI atoms in a grid cell for a single sample I, where I varies from 1 to N, and  $N = N_{\text{repeat}}$ . These formulas are used for any per-atom input value listed above, except *density/number*, *density/mass*, and *temp*. Those input values are discussed below.

In per-atom mode, for *norm all* the output grid value on the  $N_{\text{freq}}$  timestep is an average over atoms across the entire  $N_{\text{freq}}$  timescale:

$$\text{Output} = (\text{Sum1} + \text{Sum2} + \dots + \text{SumN}) / (\text{Count1} + \text{Count2} + \dots + \text{CountN})$$

In per-atom mode, for *norm sample* the output grid value on the  $N_{\text{freq}}$  timestep is an average of an average:

$$\text{Output} = (\text{Sum1}/\text{Count1} + \text{Sum2}/\text{Count2} + \dots + \text{SumN}/\text{CountN}) / N_{\text{repeat}}$$

In per-atom mode, for *norm none* the output grid value on the  $N_{\text{freq}}$  timestep is not normalized by the atom counts:

$$\text{Output} = (\text{Sum1} + \text{Sum2} + \dots + \text{SumN}) / N_{\text{repeat}}$$

For *density/number* and *density/mass*, the output value is the same as in the formulas above for *norm all* and *norm sample*, except that the result is also divided by the grid cell volume. For *norm all*, this will be the volume at the final  $N_{\text{freq}}$  timestep. For *norm sample*, the divide-by-volume is done for each sample, using the grid cell volume at the sample timestep. For *norm none*, the output is the same as for *norm all*.

For *temp*, the output temperature uses the formula for kinetic energy KE listed above, and is normalized similarly to the formulas above for *norm all* and *norm sample*, except for the way the degrees of freedom (DOF) are calculated. For *norm none*, the output is the same as for *norm all*.

For *norm all*, the  $\text{DOF} = N_{\text{repeat}} \times \text{cdof}$  plus *Count* times *adof*, where  $\text{Count} = (\text{Count1} + \text{Count2} + \dots + \text{CountN})$ . The *cdof* and *adof* keywords are discussed below. The output temperature is computed with all atoms across all samples contributing.

For *norm sample*, the DOF for a single sample = *cdof* plus *Count* times *adof*, where  $\text{Count} = \text{CountI}$  for a single sample. The output temperature is the average of  $N_{\text{sample}}$  temperatures calculated for each sample.

Finally, for all 3 *norm* settings the output count of atoms per grid cell is:

$$\text{Output count} = (\text{Count1} + \text{Count2} + \dots + \text{CountN}) / N_{\text{repeat}}$$

This count is the same for all per-atom input values, including *density/number*, *density/mass*, and *temp*.

---

The *ave* keyword is applied to both per-atom and per-grid mode. It determines how the per-grid values produced once every  $N_{\text{freq}}$  steps are averaged with values produced on previous steps that were multiples of  $N_{\text{freq}}$ , before they are accessed by another output command.

If the *ave* setting is *one*, which is the default, then the grid values produced on  $N_{\text{freq}}$  timesteps are independent of each other; they are output as-is without further averaging.

If the *ave* setting is *running*, then the grid values produced on  $N_{\text{freq}}$  timesteps are summed and averaged in a cumulative sense before being output. Each output grid value is thus the average of the grid value produced on that timestep with all preceding values for the same grid value. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the *unfix* command, or re-defining the fix by re-specifying it.

If the *ave* setting is *window*, then the grid values produced on  $N_{\text{freq}}$  timesteps are summed and averaged within a moving “window” of time, so that the last M values for the same grid are used to produce the output. E.g. if  $M = 3$  and  $N_{\text{freq}} = 1000$ , then the grid value output on step 10000 will be the average of the grid values on steps 8000,9000,10000. Outputs on early steps will average over less than M values if they are not available.

---

The *bias*, *adof*, and *cdof* keywords are only applicable to per-atom mode.

The *bias* keyword specifies the ID of a temperature compute that removes a “bias” velocity from each atom, specified as *bias-ID*. It is only used when the *temp* value is calculated, to compute the thermal temperature of each grid cell after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. See the doc pages for individual computes that calculate a temperature to see which ones implement a bias.

The *adof* and *cdof* keywords define the values used in the degree of freedom (DOF) formula described above for temperature calculation for each grid cell. They are only used when the *temp* value is calculated. They can be used to calculate a more appropriate temperature in some cases. Here are 3 examples:

If grid cells contain some number of water molecules and *fix shake* is used to make each molecule rigid, then you could calculate a temperature with 6 degrees of freedom (DOF) (3 translational, 3 rotational) per molecule by setting *adof* to 2.0.

If *compute temp/partial* is used with the *bias* keyword to only allow the x component of velocity to contribute to the temperature, then *adof* = 1.0 would be appropriate.

Using *cdof* = -2 or -3 (for 2d or 3d simulations) will subtract out 2 or 3 degrees of freedom for each grid cell, similar to how the *compute temp* command subtracts out 3 DOF for the entire system.

---

## 2.18.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix calculates a per-grid array which has one column for each of the specified input values. The units for each column will be in the *units* for the per-atom or per-grid quantity for the corresponding input value. If the fix is used in per-atom mode, it also calculates a per-grid vector with the count of atoms in each grid cell. The number of rows in the per-grid array and number of values in the per-grid vector (distributed across all processors) is  $N_x * N_y * N_z$ .

For access by other commands, the name of the single grid produced by this fix is “grid”. The names of its two per-grid datums are “data” for the per-grid array and “count” for the per-grid vector (if using per-atom values). Both datums can be accessed by various *output commands*.

In per-atom mode, the per-grid array values calculated by this fix are treated as “intensive”, since they are typically already normalized by the count of atoms in each grid cell.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.18.5 Restrictions

none

## 2.18.6 Related commands

*fix ave/atom*, *fix ave/chunk*

## 2.18.7 Default

The option defaults are discard = yes, norm = all, ave = one, and bias = none.

## 2.19 fix ave/histo command

## 2.20 fix ave/histo/weight command

### 2.20.1 Syntax

```
fix ID group-ID style Nevery Nrepeat Nfreq lo hi Nbin value1 value2 ... keyword args ...
```

- ID, group-ID are documented in *fix* command
- style = *ave/histo* or *ave/histo/weight* = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating histogram
- Nfreq = calculate histogram every this many timesteps
- lo,hi = lo/hi bounds within which to histogram
- Nbin = # of histogram bins
- one or more input values can be listed
- value = *x*, *y*, *z*, *vx*, *vy*, *vz*, *fx*, *fy*, *fz*, *c\_ID*, *c\_ID[N]*, *f\_ID*, *f\_ID[N]*, *v\_name*

```
x,y,z,vx,vy,vz,fx,fy,fz = atom attribute (position, velocity, force component)
c_ID = scalar or vector calculated by a compute with ID
c_ID[I] = Ith component of vector or Ith column of array calculated by a compute.
→with ID, I can include wildcard (see below)
f_ID = scalar or vector calculated by a fix with ID
f_ID[I] = Ith component of vector or Ith column of array calculated by a fix with.
→ID, I can include wildcard (see below)
v_name = value(s) calculated by an equal-style or vector-style or atom-style.
→variable with name
v_name[I] = value calculated by a vector-style variable with name, I can include.
→wildcard (see below)
```

- zero or more keyword/arg pairs may be appended
- keyword = *mode* or *kind* or *file* or *append* or *ave* or *start* or *beyond* or *overwrite* or *title1* or *title2* or *title3*  
*mode* arg = *scalar* or *vector*  
    *scalar* = all input values are scalars  
    *vector* = all input values are vectors  
*kind* arg = *global* or *peratom* or *local*  
*file* arg = filename

```

    filename = name of file to output histogram(s) to
    append arg = filename
    filename = name of file to append histogram(s) to
    ave args = one or running or window
    one = output a new average value every Nfreq steps
    running = output cumulative average of all previous Nfreq steps
    window M = output average of M most recent Nfreq steps
    start args = Nstart
    Nstart = start averaging on this timestep
    beyond arg = ignore or end or extra
    ignore = ignore values outside histogram lo/hi bounds
    end = count values outside histogram lo/hi bounds in end bins
    extra = create 2 extra bins for value outside histogram lo/hi bounds
    overwrite arg = none = overwrite output file with only latest output
    title1 arg = string
    string = text to print as 1st line of output file
    title2 arg = string
    string = text to print as 2nd line of output file
    title3 arg = string
    string = text to print as 3rd line of output file, only for vector mode

```

fix 1 all ave/histo/weight 1 1 1 10 100 2000 c_XRD[1] c_XRD[2]

```

## 2.20.3 Description

Use one or more values as inputs every few timesteps to create a single histogram. The histogram can then be averaged over longer timescales. The resulting histogram can be used by other *output commands*, and can also be written to a file. The fix `ave/histo/weight` command has identical syntax to `fix ave/histo`, except that exactly two values must be specified. See details below.

The group specified with this command is ignored for global and local input values. For per-atom input values, only atoms in the group contribute to the histogram. Note that regardless of the specified group, specified values may represent calculations performed by computes and fixes which store their own “group” definition.

A histogram is simply a count of the number of values that fall within a histogram bin. *Nbins* are defined, with even spacing between *lo* and *hi*. Values that fall outside the lo/hi bounds can be treated in different ways; see the discussion of the *beyond* keyword below.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a *compute* or *fix* or the evaluation of an equal-style or vector-style or atom-style *variable*. The set of input values can be either all global, all per-atom, or all local quantities. Inputs of different kinds (e.g. global and per-atom) cannot be mixed. Atom attributes are per-atom vector values. See the page for individual “compute” and “fix” commands to see what kinds of quantities they generate.

Note that a compute or fix can produce multiple kinds of data (global, per-atom, local). If LAMMPS cannot unambiguously determine which kind of data to use, the optional *kind* keyword discussed below can force the desired disambiguation.

Note that the output of this command is a single histogram for all input values combined together, not one histogram per input value. See below for details on the format of the output of this fix.

The input values must either be all scalars or all vectors (or arrays), depending on the setting of the *mode* keyword.

If *mode* = scalar, then the input values must be scalars, or vectors with a bracketed term appended, indicating the *I*th value of the vector is used.

If *mode* = vector, then the input values must be vectors, or arrays with a bracketed term appended, indicating the *I*th column of the array is used.

If the fix ave/histo/weight command is used, exactly two values must be specified. If the values are vectors, they must be the same length. The first value (a scalar or vector) is what is histogrammed into bins, in the same manner the fix ave/histo command operates. The second value (a scalar or vector) is used as a “weight”. This means that instead of each value tallying a “1” to its bin, the corresponding weight is tallied. For example, the  $N^{\text{th}}$  entry (weight) in the second vector is tallied to the bin corresponding to the  $N^{\text{th}}$  entry in the first vector.

---

For input values from a compute or fix or variable, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *m* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. For example, the following two fix ave/histo commands are equivalent, since the *compute com/chunk* command creates a global array with three columns:

```
compute myCOM all com/chunk
fix 1 all ave/histo 100 1 100 -10.0 10.0 100 c_myCOM[*] file tmp1.com mode vector
fix 2 all ave/histo 100 1 100 -10.0 10.0 100 c_myCOM[1] c_myCOM[2] c_myCOM[3] file tmp2.
->com mode vector
```

---

**Note:** For a vector-style variable, only the wildcard forms “\*n” or “m\*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If *n* is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

---

The  $N_{\text{every}}$ ,  $N_{\text{repeat}}$ , and  $N_{\text{freq}}$  arguments specify on what time steps the input values will be used in order to contribute to the histogram. The final histogram is generated on time steps that are multiple of  $N_{\text{freq}}$ . It is averaged over  $N_{\text{repeat}}$  histograms, computed in the preceding portion of the simulation every  $N_{\text{every}}$  time steps.  $N_{\text{freq}}$  must be a multiple of  $N_{\text{every}}$  and  $N_{\text{every}}$  must be non-zero even if  $N_{\text{repeat}}$  is 1. Also, the time steps contributing to the histogram value cannot overlap (i.e.,  $N_{\text{repeat}} \times N_{\text{every}}$  cannot exceed  $N_{\text{freq}}$ ).

For example, if  $N_{\text{every}} = 2$ ,  $N_{\text{repeat}} = 6$ , and  $N_{\text{freq}} = 100$ , then input values on time steps 90, 92, 94, 96, 98, and 100 will be used to compute the final histogram on timestep 100. Similarly for timesteps 190, 192, 194, 196, 198, and 200 on timestep 200, etc. If  $N_{\text{repeat}} = 1$  and  $N_{\text{freq}} = 100$ , then no time averaging of the histogram is done; a histogram is simply generated on timesteps 100, 200, etc.

---

The atom attribute values (*x*, *y*, *z*, *vx*, *vy*, *vz*, *fx*, *fy*, and *fz*) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the *compute property/atom* command and then specifying an input value from that compute.

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If *mode* = scalar, then if no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed

term is appended, the  $I$ th element of the global vector calculated by the compute is used. If *mode* = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the compute is used. If a bracketed term is appended, the  $I$ th column of the global or per-atom or local array calculated by the compute is used. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a *compute reduce* command that can sum per-atom quantities into a global scalar or vector, which can then be accessed by *fix ave/histo*. It can also be a compute defined not in your input script, but by *thermodynamic output* or other fixes such as *fix nvt* or *fix temp/rescale*. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and *add them to LAMMPS*.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If *mode* = scalar, then if no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the  $I$ th element of the global vector calculated by the fix is used. If *mode* = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the fix is used. If a bracketed term is appended, the  $I$ th column of the global or per-atom or local array calculated by the fix is used. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with  $N_{\text{every}}$ , else an error will result. Users can also write code for their own fix styles and *add them to LAMMPS*.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. If *mode* = scalar, then only equal-style or vector-style variables can be used, which both produce global values. In this mode, a vector-style variable requires a bracketed term to specify the  $I$ th element of the vector calculated by the variable. If *mode* = vector, then only vector-style or atom-style variables can be used, which produce a global or per-atom vector respectively. The vector-style variable must be used without a bracketed term. See the *variable* command for details.

Note that variables of style *equal*, *vector*, and *atom* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to histogram.

Additional optional keywords also affect the operation of this fix.

If the *mode* keyword is set to *scalar*, then all input values must be global scalars, or elements of global vectors. If the *mode* keyword is set to *vector*, then all input values must be global or per-atom or local vectors, or columns of global or per-atom or local arrays.

The *kind* keyword only needs to be used if any of the specified input computes or fixes produce more than one kind of output (global, per-atom, local). If not, LAMMPS will determine the kind of data all the inputs produce and verify it is all the same kind. If not, an error will be triggered. If a compute or fix produces more than one kind of output, the *kind* keyword should be used to specify which output will be used. The other input arguments must still be consistent.

The *beyond* keyword determines how input values that fall outside the *lo* to *hi* bounds are treated. Values such that  $lo \leq \text{value} \leq hi$  are assigned to one bin. Values on a bin boundary are assigned to the lower of the two bins. If *beyond* is set to *ignore* then values  $< lo$  and values  $> hi$  are ignored (i.e., they are not binned). If *beyond* is set to *end*, then values  $< lo$  are counted in the first bin and values  $> hi$  are counted in the last bin. If *beyond* is set to *extend*, then two extra bins are created so that there are  $N_{\text{bins}} + 2$  total bins. Values  $< lo$  are counted in the first bin and values  $> hi$  are counted in the last bin ( $N_{\text{bins}} + 2$ ). Values between *lo* and *hi* (inclusive) are counted in bins 2 through  $N_{\text{bins}} + 1$ . The “coordinate” stored and printed for these two extra bins is *lo* and *hi*.

The *ave* keyword determines how the histogram produced every  $N_{\text{freq}}$  steps are averaged with histograms produced on previous steps that were multiples of  $N_{\text{freq}}$ , before they are accessed by another output command or written to a file.

If the *ave* setting is *one*, then the histograms produced on timesteps that are multiples of  $N_{\text{freq}}$  are independent of each other; they are output as-is without further averaging.

If the *ave* setting is *running*, then the histograms produced on timesteps that are multiples of  $N_{\text{freq}}$  are summed and averaged in a cumulative sense before being output. Each bin value in the histogram is thus the average of the bin value produced on that timestep with all preceding values for the same bin. This running average begins when the fix

is defined; it can only be restarted by deleting the fix via the `unfix` command, or by re-defining the fix by re-specifying it.

If the `ave` setting is `window`, then the histograms produced on timesteps that are multiples of  $N_{\text{freq}}$  are summed within a moving “window” of time, so that the last  $M$  histograms are used to produce the output (e.g., if  $M = 3$  and  $N_{\text{freq}} = 1000$ , then the output on step 10000 will be the combined histogram of the individual histograms on steps 8000, 9000, and 10000. Outputs on early steps will be sums over less than  $M$  histograms if they are not available.

The `start` keyword specifies what timestep histogramming will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting `start` to a larger value can avoid including a 0.0 in a running or windowed histogram.

New in version 17Apr2024: new keyword `append`

The `file` or `append` keywords allow a filename to be specified. If `file` is used, then the filename is overwritten if it already exists. If `append` is used, then the filename is appended to if it already exists, or created if it does not exist. Every  $N_{\text{freq}}$  steps, one histogram is written to the file. This includes a leading line that contains the timestep, number of bins, the total count of values contributing to the histogram, the count of values that were not histogrammed (see the `beyond` keyword), the minimum value encountered, and the maximum value encountered. The min/max values include values that were not histogrammed. Following the leading line, one line per bin is written into the file. Each line contains the bin #, the coordinate for the center of the bin (between `lo` and `hi`), the count of values in the bin, and the normalized count. The normalized count is the bin count divided by the total count (not including values not histogrammed), so that the normalized values sum to 1.0 across all bins.

The `overwrite` keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the `ave running` setting.

The `title1`, `title2`, and `title3` keywords allow specification of the strings that will be printed as the first three lines of the output file, assuming the `file` keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Histogram for fix ID
# TimeStep Number-of-bins Total-counts Missing-counts Min-value Max-value
# Bin Coord Count Count/Total
```

In the first line, ID is replaced with the fix-ID. The second line describes the six values that are printed at the first of each section of output. The third describes the four values printed for each bin in the histogram.

---

## 2.20.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the `fix_modify` options are relevant to this fix.

This fix produces a global vector and global array which can be accessed by various *output commands*. The values can only be accessed on timesteps that are multiples of  $N_{\text{freq}}$  since that is when a histogram is generated. The global vector has four values:

1. total counts in the histogram
2. values that were not histogrammed (see `beyond` keyword)
3. min value of all input values, including ones not histogrammed
4. max value of all input values, including ones not histogrammed

The global array has  $N_{\text{bins}}$  rows and three columns. The first column has the bin coordinate, the second column has the count of values in that histogram bin, and the third column has the bin count divided by the total count (not including missing counts), so that the values in the third column sum to 1.0.

The vector and array values calculated by this fix are all treated as intensive. If this is not the case (e.g., due to histogramming per-atom input values), then you will need to account for that when interpreting the values produced by this fix.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.20.5 Restrictions

none

## 2.20.6 Related commands

*compute*, *fix ave/atom*, *fix ave/chunk*, *fix ave/time*, *variable*, *fix ave/correlate*,

## 2.20.7 Default

none

The option defaults are mode = scalar, kind = figured out from input arguments, ave = one, start = 0, no file output, beyond = ignore, and title 1,2,3 = strings as described above.

## 2.21 fix ave/spatial command

Deprecated since version 11Dec2015.

The *fix ave/spatial* command has been superseded by *fix ave/chunk*.

## 2.22 fix ave/spatial/sphere command

Deprecated since version 11Dec2015.

The *fix ave/spatial/sphere* command has been superseded by *fix ave/chunk*.

## 2.23 fix ave/time command

### 2.23.1 Syntax

```
fix ID group-ID ave/time Nevery Nrepeat Nfreq value1 value2 ... keyword args ...
```

- ID, group-ID are documented in *fix* command
- ave/time = style name of this fix command
- Nevery = use input values every this many time steps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many time steps

- one or more input values can be listed
- value = c\_ID, c\_ID[N], f\_ID, f\_ID[N], v\_name

c\_ID = global scalar or vector calculated by a compute with ID  
c\_ID[I] = Ith component of global vector or Ith column of global array calculated.  
→by a compute with ID, I can include wildcard (see below)  
f\_ID = global scalar or vector calculated by a fix with ID  
f\_ID[I] = Ith component of global vector or Ith column of global array calculated.  
→by a fix with ID, I can include wildcard (see below)  
v\_name = value(s) calculated by an equal-style or vector-style variable with name  
v\_name[I] = value calculated by a vector-style variable with name, I can include.  
→wildcard (see below)

- zero or more keyword/arg pairs may be appended
- keyword = *mode* or *file* or *append* or *ave* or *start* or *off* or *overwrite* or *format* or *title1* or *title2* or *title3*

*mode* arg = *scalar* or *vector*

scalar = all input values are global scalars

vector = all input values are global vectors or global arrays

*ave* args = *one* or *running* or *window M*

one = output a new average value every Nfreq steps

running = output cumulative average of all previous Nfreq steps

window M = output average of M most recent Nfreq steps

*start* args = Nstart

Nstart = start averaging on this time step

*off* arg = M = do not average this value

M = value # from 1 to Nvalues

*file* arg = filename

filename = name of file to output time averages to

*append* arg = filename

filename = name of file to append time averages to

*overwrite* arg = none = overwrite output file with only latest output

*format* arg = string

string = C-style format string

*title1* arg = string

string = text to print as 1st line of output file

*title2* arg = string

string = text to print as 2nd line of output file

*title3* arg = string

string = text to print as 3rd line of output file, only for vector mode

## 2.23.2 Examples

```
fix 1 all ave/time 100 5 1000 c_myTemp c_thermo_temp file temp.profile
fix 1 all ave/time 100 5 1000 c_thermo_press[2] ave window 20 &
      title1 "My output values"
fix 1 all ave/time 100 5 1000 c_thermo_press[*]
fix 1 all ave/time 1 100 1000 f_indent f_indent[1] file temp.indent off 1
```

### 2.23.3 Description

Use one or more global values as inputs every few time steps, and average them over longer timescales. The resulting averages can be used by other *output commands* such as *thermo\_style custom*, and can also be written to a file. Note that if no time averaging is done, this command can be used as a convenient way to simply output one or more global values to a file.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a *compute* or *fix* or the evaluation of an equal-style or vector-style *variable*. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a compute, fix, or variable, then see the *fix ave/chunk*, *fix ave/atom*, or *fix ave/histo* commands. If you wish to sum a per-atom quantity into a single global quantity, see the *compute reduce* command.

*Computes* that produce global quantities are those which do not have the word *atom* in their style name. Only a few *fixes* produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. *Variables* of style *equal* and *vector* are the only ones that can be used with this fix. Variables of style *atom* cannot be used, since they produce per-atom values.

The input values must either be all scalars or all vectors depending on the setting of the *mode* keyword. In both cases, the averaging is performed independently on each input value (i.e., each input scalar is averaged independently or each element of each input vector is averaged independently).

If *mode* = scalar, then the input values must be scalars, or vectors with a bracketed term appended, indicating the  $I^{\text{th}}$  value of the vector is used.

If *mode* = vector, then the input values must be vectors, or arrays with a bracketed term appended, indicating the  $I^{\text{th}}$  column of the array is used. All vectors must be the same length, which is the length of the vector or number of rows in the array.

For input values from a compute or fix or variable, the bracketed index  $I$  can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to  $N$ . A leading asterisk means all indices from 1 to  $n$  (inclusive). A trailing asterisk means all indices from  $n$  to  $N$  (inclusive). A middle asterisk means all indices from  $m$  to  $n$  (inclusive).

Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. For example, the following two *fix ave/time* commands are equivalent, since the *compute rdf* command creates, in this case, a global array with three columns, each of length 50:

```
compute myRDF all rdf 50 1 2
fix 1 all ave/time 100 1 100 c_myRDF[*] file tmp1.rdf mode vector
fix 2 all ave/time 100 1 100 c_myRDF[1] c_myRDF[2] c_myRDF[3] file tmp2.rdf mode vector
```

**Note:** For a vector-style variable, only the wildcard forms “\*n” or “m\*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If  $n$  is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

The  $N_{\text{every}}$ ,  $N_{\text{repeat}}$ , and  $N_{\text{freq}}$  arguments specify on what time steps the input values will be used in order to contribute to the average. The final averaged quantities are generated on time steps that are a multiple of  $N_{\text{freq}}$ . The average is over  $N_{\text{repeat}}$  quantities, computed in the preceding portion of the simulation every  $N_{\text{every}}$  time steps.  $N_{\text{freq}}$  must be a multiple

of  $N_{\text{every}}$  and  $N_{\text{repeat}}$  must be non-zero even if  $N_{\text{repeat}} = 1$ . Also, the time steps contributing to the average value cannot overlap (i.e.,  $N_{\text{repeat}} \times N_{\text{every}}$  cannot exceed  $N_{\text{freq}}$ ).

For example, if  $N_{\text{every}} = 2$ ,  $N_{\text{repeat}} = 6$ , and  $N_{\text{freq}} = 100$ , then values on time steps 90, 92, 94, 96, 98, and 100 will be used to compute the final average on time step 100. Similarly for time steps 190, 192, 194, 196, 198, and 200 on time step 200, etc. If  $N_{\text{repeat}} = 1$  and  $N_{\text{freq}} = 100$ , then no time averaging is done; values are simply generated on time steps 100, 200, etc.

---

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If *mode* = scalar, then if no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. If *mode* = vector, then if no bracketed term is appended, the global vector calculated by the compute is used. If a bracketed term is appended, the Ith column of the global array calculated by the compute is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a *compute reduce* command that can sum per-atom quantities into a global scalar or vector, which can then be accessed by fix ave/time. It can also be a compute defined not in your input script, but by *thermodynamic output* or other fixes such as *fix nvt* or *fix temp/rescale*. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and *add them to LAMMPS*.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If *mode* = scalar, then if no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. If *mode* = vector, then if no bracketed term is appended, the global vector calculated by the fix is used. If a bracketed term is appended, the Ith column of the global array calculated by the fix is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain time steps, which must be compatible with *Nevery*, else an error will result. Users can also write code for their own fix styles and *add them to LAMMPS*.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. If *mode* = scalar, then only equal-style or vector-style variables can be used, which both produce global values. In this mode, a vector-style variable requires a bracketed term to specify the Ith element of the vector calculated by the variable. If *mode* = vector, then only a vector-style variable can be used, without a bracketed term. See the *variable* command for details.

Note that variables of style *equal* and *vector* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to time average.

---

Additional optional keywords also affect the operation of this fix.

If the *mode* keyword is set to *scalar*, then all input values must be global scalars, or elements of global vectors. If the *mode* keyword is set to *vector*, then all input values must be global vectors, or columns of global arrays. They can also be global arrays, which are converted into a series of global vectors (one per column), as explained above.

The *ave* keyword determines how the values produced every  $N_{\text{freq}}$  steps are averaged with values produced on previous steps that were multiples of  $N_{\text{freq}}$ , before they are accessed by another output command or written to a file.

If the *ave* setting is *one*, then the values produced on time steps that are multiples of  $N_{\text{freq}}$  are independent of each other; they are output as-is without further averaging.

If the *ave* setting is *running*, then the values produced on time steps that are multiples of  $N_{\text{freq}}$  are summed and averaged in a cumulative sense before being output. Each output value is thus the average of the value produced on that time step with all preceding values. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the *unfix* command, or by re-defining the fix by re-specifying it.

If the *ave* setting is *window*, then the values produced on time steps that are multiples of  $N_{freq}$  are summed and averaged within a moving “window” of time, so that the last  $M$  values are used to produce the output. For example, if  $M = 3$  and  $N_{freq} = 1000$ , then the output on step 10000 will be the average of the individual values on steps 8000, 9000, and 10000. Outputs on early steps will average over less than  $M$  values if they are not available.

The *start* keyword specifies what time step averaging will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting *start* to a larger value can avoid including a 0.0 in a running or windowed average.

The *off* keyword can be used to flag any of the input values. If a value is flagged, it will not be time averaged. Instead the most recent input value will always be stored and output. This is useful if one of more of the inputs produced by a compute or fix or variable are effectively constant or are simply current values (e.g., they are being written to a file with other time-averaged values for purposes of creating well-formatted output).

New in version 17Apr2024: new keyword *append*

The *file* or *append* keywords allow a filename to be specified. If *file* is used, then the filename is overwritten if it already exists. If *append* is used, then the filename is appended to if it already exists, or created if it does not exist. Every  $N_{freq}$  steps, one quantity or vector of quantities is written to the file for each input value specified in the fix ave/time command. For *mode* = scalar, this means a single line is written each time output is performed. Thus the file ends up to be a series of lines, i.e. one column of numbers for each input value. For *mode* = vector, an array of numbers is written each time output is performed. The number of rows is the length of the input vectors, and the number of columns is the number of values. Thus the file ends up to be a series of these array sections.

New in version 4May2022.

If the filename ends in ‘.yaml’ or ‘.yml’ then the output format conforms to the [YAML standard](#) which allows easy import that data into tools and scripts that support reading YAML files. The [structured data Howto](#) contains examples for parsing and plotting such data with very little programming effort in Python using the *pyyaml*, *pandas*, and *matplotlib* packages.

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one time step worth of output. This option can only be used with the *ave running* setting.

The *format* keyword sets the numeric format of each value when it is printed to a file via the *file* keyword. Note that all values are floating point quantities. The default format is %g. You can specify a higher precision if desired (e.g., %20.16g).

The *title1* and *title2* and *title3* keywords allow specification of the strings that will be printed as the first 2 or 3 lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows for *mode* = scalar:

```
# Time-averaged data for fix ID
# TimeStep value1 value2 ...
```

In the first line, ID is replaced with the fix-ID. In the second line the values are replaced with the appropriate fields from the fix ave/time command. There is no third line in the header of the file, so the *title3* setting is ignored when *mode* = scalar.

By default, these header lines are as follows for *mode* = vector:

```
# Time-averaged data for fix ID
# TimeStep Number-of-rows
# Row value1 value2 ...
```

In the first line, ID is replaced with the fix-ID. The second line describes the two values that are printed at the first of each section of output. In the third line the values are replaced with the appropriate fields from the fix ave/time command.

### 2.23.4 Restart, fix\_modify, output, run start/stop, minimize info

New in version 4May2022.

No information about this fix is written to *binary restart files*. The *fix\_modify colname* option can be used to change the name of the column in the output file. When writing a YAML format file this name will be in the list of keywords.

This fix produces a global scalar or global vector or global array which can be accessed by various *output commands*. The values can only be accessed on time steps that are multiples of  $N_{\text{freq}}$  since that is when averaging is performed.

A scalar is produced if only a single input value is averaged and *mode* = scalar. A vector is produced if multiple input values are averaged for *mode* = scalar, or a single input value for *mode* = vector. In the first case, the length of the vector is the number of inputs. In the second case, the length of the vector is the same as the length of the input vector. An array is produced if multiple input values are averaged and *mode* = vector. The global array has # of rows = length of the input vectors and # of columns = number of inputs.

If the fix produces a scalar or vector, then the scalar and each element of the vector can be either “intensive” or “extensive”, depending on whether the values contributing to the scalar or vector element are “intensive” or “extensive”. If the fix produces an array, then all elements in the array must be the same, either “intensive” or “extensive”. If a compute or fix provides the value being time averaged, then the compute or fix determines whether the value is intensive or extensive; see the page for that compute or fix for further info. Values produced by a variable are treated as intensive.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.23.5 Restrictions

none

### 2.23.6 Related commands

*compute*, *fix ave/atom*, *fix ave/chunk*, *fix ave/histo*, *variable*, *fix ave/correlate*,

### 2.23.7 Default

The option defaults are *mode* = scalar, *ave* = one, *start* = 0, no file output, *format* = %g, *title* 1,2,3 = strings as described above, and no off settings for any input values.

## 2.24 fix aveforce command

### 2.24.1 Syntax

**fix** ID group-ID aveforce fx fy fz keyword value ...

- ID, group-ID are documented in *fix* command
- aveforce = style name of this fix command
- fx,fy,fz = force component values (force units)

any of fx,fy,fz can be a variable (see below)

- zero or more keyword/value pairs may be appended to args

- keyword = *region*

*region* value = region-ID

region-ID = ID of region atoms must be in to have added force

## 2.24.2 Examples

```
fix pressdown topwall aveforce 0.0 -1.0 0.0
fix 2 bottomwall aveforce NULL -1.0 0.0 region top
fix 2 bottomwall aveforce NULL -1.0 v_oscillate region top
```

## 2.24.3 Description

Apply an additional external force to a group of atoms in such a way that every atom experiences the same force. This is useful for pushing on wall or boundary atoms so that the structure of the wall does not change over time.

The existing force is averaged for the group of atoms, component by component. The actual force on each atom is then set to the average value plus the component specified in this command. This means each atom in the group receives the same force.

Any of the *fx*, *fy*, or *fz* values can be specified as NULL, which means the force in that dimension is not changed. Note that this is not the same as specifying a 0.0 value, since that sets all forces to the same average value without adding in any additional force.

Any of the three quantities defining the force components, namely *fx*, *fy*, and *fz*, can be specified as an equal-style *variable*. If the value is a variable, it should be specified as *v\_name*, where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the average force.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent average force.

If the *region* keyword is used, the atom must also be in the specified geometric *region* in order to have force added to it.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* *command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 2.24.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global three-vector of forces, which can be accessed by various *output commands*. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

## 2.24.5 Restrictions

none

## 2.24.6 Related commands

→store allweight
fix 2 all balance 1000 1.1 rcb
  
```

## 2.25.3 Description

This command adjusts the size and shape of processor subdomains within the simulation box, to attempt to balance the number of particles and thus the computational cost (load) evenly across processors. The load balancing is “dynamic” in the sense that re-balancing is performed periodically during the simulation. To perform “static” balancing, before or between runs, see the `balance` command.

New in version 17Apr2024.

The `report` balance style only computes the load imbalance but does not attempt any re-balancing. This way the load imbalance information can be used otherwise, for instance for stopping a run with `fix halt`.

Load-balancing is typically most useful if the particles in the simulation box have a spatially-varying density distribution or where the computational cost varies significantly between different atoms (e.g., a model of a vapor/liquid interface, or a solid with an irregular-shaped geometry containing void regions, or *hybrid pair style simulations* that combine pair styles with different computational cost). In these cases, the LAMMPS default of dividing the simulation box volume into a regular-spaced grid of 3d bricks, with one equal-volume subdomain per processor, may assign numbers of particles per processor in a way that the computational effort varies significantly. This can lead to poor performance when the simulation is run in parallel.

The balancing can be performed with or without per-particle weighting. With no weighting, the balancing attempts to assign an equal number of particles to each processor. With weighting, the balancing attempts to assign an equal aggregate computational weight to each processor, which typically induces a different number of atoms assigned to each processor.

---

**Note:** The weighting options listed above are documented with the *balance* command in [this section of the \*balance\* command](#) doc page. That section describes the various weighting options and gives a few examples of how they can be used. The weighting options are the same for both the fix *balance* and *balance* commands.

---

Note that the *processors* command allows some control over how the box volume is split across processors. Specifically, for a  $P_x \times P_y \times P_z$  grid of processors, it allows choices of  $P_x$ ,  $P_y$ , and  $P_z$  subject to the constraint that  $P_x P_y P_z = P$ , the total number of processors. This is sufficient to achieve good load-balance for some problems on some processor counts. However, all the processor subdomains will still have the same shape and the same volume.

On a particular time step, a load-balancing operation is only performed if the current “imbalance factor” in particles owned by each processor exceeds the specified *thresh* parameter. The imbalance factor is defined as the maximum number of particles (or weight) owned by any processor, divided by the average number of particles (or weight) per processor. Thus, an imbalance factor of 1.0 is perfect balance.

As an example, for 10000 particles running on 10 processors, if the most heavily loaded processor has 1200 particles, then the imbalance factor is 1.2, meaning there is a 20% imbalance. Note that re-balances can be forced even if the current balance is perfect (1.0) by specifying a *thresh* < 1.0.

---

**Note:** This command attempts to minimize the imbalance factor, as defined above. But depending on the method a perfect balance (1.0) may not be achieved. For example, “grid” methods (defined below) that create a logical 3d grid cannot achieve perfect balance for many irregular distributions of particles. Likewise, if a portion of the system is a perfect, non-rotated lattice (e.g., the initial system is generated by the *create\_atoms* command with no rotations), then “grid” methods may be unable to achieve exact balance. This is because entire lattice planes will be owned or not owned by a single processor.

---

---

**Note:** The imbalance factor is also an estimate of the maximum speed-up you can hope to achieve by running a perfectly balanced simulation versus an imbalanced one. In the example above, the 10000-particle simulation could run up to 20% faster if it were perfectly balanced, versus when imbalanced. However, computational cost is not strictly proportional to particle count, and changing the relative size and shape of processor subdomains may lead to additional computational and communication overheads (e.g., in the PPPM solver used via the *kspace\_style* command). Thus, you should benchmark the run times of a simulation before and after balancing.

---

The method used to perform a load balance is specified by one of the listed styles, which are described in detail below. There are two kinds of styles.

The *shift* style is a “grid” method which produces a logical 3d grid of processors. It operates by changing the cutting planes (or lines) between processors in 3d (or 2d), to adjust the volume (area in 2d) assigned to each processor, as in the following 2d diagram where processor subdomains are shown and atoms are colored by the processor that owns them.

The leftmost diagram is the default partitioning of the simulation box across processors (one sub-box for each of 16 processors); the middle diagram is after a “grid” method has been applied. The *rcb* style is a “tiling” method which does not produce a logical 3d grid of processors. Rather it tiles the simulation domain with rectangular sub-boxes of varying size and shape in an irregular fashion so as to have equal numbers of particles (or weight) in each sub-box, as in the rightmost diagram above.

The “grid” methods can be used with either of the *comm\_style* command options, *brick* or *tiled*. The “tiling” methods can only be used with *comm\_style tiled*.

When a “grid” method is specified, the current domain partitioning can be either a logical 3d grid or a tiled partitioning. In the former case, the current logical 3d grid is used as a starting point and changes are made to improve the imbalance factor. In the latter case, the tiled partitioning is discarded and a logical 3d grid is created with uniform spacing in all dimensions. This is the starting point for the balancing operation.

When a “tiling” method is specified, the current domain partitioning (“grid” or “tiled”) is ignored, and a new partitioning is computed from scratch.

---

The *group-ID* is ignored. However the impact of balancing on different groups of atoms can be affected by using the *group weight* style as described below.

The  $N_{\text{freq}}$  setting determines how often a re-balance is performed. If  $N_{\text{freq}} > 0$ , then re-balancing will occur every  $N_{\text{freq}}$  steps. Each time a re-balance occurs, a reneighboring is triggered, so  $N_{\text{freq}}$  should not be too small. If  $N_{\text{freq}} = 0$ , then re-balancing will be done every time reneighboring normally occurs, as determined by the *neighbor* and *neigh\_modify* command settings.

On re-balance steps, re-balancing will only be attempted if the current imbalance factor, as defined above, exceeds the *thresh* setting.

---

The *shift* style invokes a “grid” method for balancing, as described above. It changes the positions of cutting planes between processors in an iterative fashion, seeking to reduce the imbalance factor.

The *dimstr* argument is a string of characters, each of which must be *x* or *y* or *z*. Each character can appear zero or one time, since there is no advantage to balancing on a dimension more than once. You should normally only list dimensions where you expect there to be a density variation in the particles.

Balancing proceeds by adjusting the cutting planes in each of the dimensions listed in *dimstr*, one dimension at a time. For a single dimension, the balancing operation (described below) is iterated on up to  $N_{\text{iter}}$  times. After each dimension finishes, the imbalance factor is re-computed, and the balancing operation halts if the *stopthresh* criterion is met.

A re-balance operation in a single dimension is performed using a density-dependent recursive multisectioning algorithm, where the position of each cutting plane (line in 2d) in the dimension is adjusted independently. This is similar to a recursive bisectioning for a single value, except that the bounds used for each bisectioning take advantage of information from neighboring cuts if possible, as well as counts of particles at the bounds on either side of each cuts, which

themselves were cuts in previous iterations. The latter is used to infer a density of particles near each of the current cuts. At each iteration, the count of particles on either side of each plane is tallied. If the counts do not match the target value for the plane, the position of the cut is adjusted based on the local density. The low and high bounds are adjusted on each iteration, using new count information, so that they become closer together over time. Thus as the recursion progresses, the count of particles on either side of the plane gets closer to the target value.

The density-dependent part of this algorithm is often an advantage when you re-balance a system that is already nearly balanced. It typically converges more quickly than the geometric bisectioning algorithm used by the *balance* command. However, it can be a disadvantage if you attempt to re-balance a system that is far from balanced, and converge more slowly. In this case you probably want to use the *balance* command before starting a run, so that you begin the run with a balanced system.

Once the re-balancing is complete and final processor subdomains assigned, particles migrate to their new owning processor as part of the normal reneighboring procedure.

---

**Note:** At each re-balance operation, the bisectioning for each cutting plane (line in 2d) typically starts with low and high bounds separated by the extent of a processor's subdomain in one dimension. The size of this bracketing region shrinks based on the local density, as described above, which should typically be 1/2 or more every iteration. Thus if  $N_{\text{iter}}$  is specified as 10, the cutting plane will typically be positioned to better than 1 part in 1000 accuracy (relative to the perfect target position). For  $N_{\text{iter}} = 20$ , it will be accurate to better than 1 part in a million. Thus there is no need to set  $N_{\text{iter}}$  to a large value. This is especially true if you are re-balancing often enough that each time you expect only an incremental adjustment in the cutting planes is necessary. LAMMPS will check if the threshold accuracy is reached (in a dimension) is less iterations than  $N_{\text{iter}}$  and exit early.

---

The *rcb* style invokes a “tiled” method for balancing, as described above. It performs a recursive coordinate bisectioning (RCB) of the simulation domain. The basic idea is as follows.

The simulation domain is cut into two boxes by an axis-aligned cut in the longest dimension, leaving one new box on either side of the cut. All the processors are also partitioned into two groups, half assigned to the box on the lower side of the cut, and half to the box on the upper side. If the processor count is odd, one side gets an extra processor. The cut is positioned so that the number of atoms in the lower box is exactly the number that the processors assigned to that box should own for load balance to be perfect. This also makes load balance for the upper box perfect. The positioning is done iteratively, by a bisectioning method. Note that counting atoms on either side of the cut requires communication between all processors at each iteration.

That is the procedure for the first cut. Subsequent cuts are made recursively, in exactly the same manner. The subset of processors assigned to each box make a new cut in the longest dimension of that box, splitting the box, the subset of processors, and the atoms in the box in two. The recursion continues until every processor is assigned a sub-box of the entire simulation domain, and owns the atoms in that sub-box.

---

The *sort* keyword determines whether the communication of per-atom data to other processors during load-balancing will be random or deterministic. Random is generally faster; deterministic will ensure the new ordering of atoms on each processor is the same each time the same simulation is run. This can be useful for debugging purposes. Since the fix balance command is performed during timestepping, the default is *no* so that sorting is not performed.

The *out* keyword writes text to the specified *filename* with the results of each re-balancing operation. The file contains the bounds of the subdomain for each processor after the balancing operation completes. The format of the file is compatible with the *Pizza.py mdump* tool which has support for manipulating and visualizing mesh files. An example is shown here for a balancing by four processors for a 2d problem:

```
ITEM: TIMESTEP
```

```
0
```

(continues on next page)

(continued from previous page)

```

ITEM: NUMBER OF NODES
16
ITEM: BOX BOUNDS
0 10
0 10
0 10
ITEM: NODES
1 1 0 0 0
2 1 5 0 0
3 1 5 5 0
4 1 0 5 0
5 1 5 0 0
6 1 10 0 0
7 1 10 5 0
8 1 5 5 0
9 1 0 5 0
10 1 5 5 0
11 1 5 10 0
12 1 10 5 0
13 1 5 5 0
14 1 10 5 0
15 1 10 10 0
16 1 5 10 0
ITEM: TIMESTEP
0
ITEM: NUMBER OF SQUARES
4
ITEM: SQUARES
1 1 1 2 3 4
2 1 5 6 7 8
3 1 9 10 11 12
4 1 13 14 15 16

```

The coordinates of all the vertices are listed in the NODES section, five per processor. Note that the four subdomains share vertices, so there will be duplicate nodes in the list.

The “SQUARES” section lists the node IDs of the four vertices in a rectangle for each processor (1 to 4).

For a 3d problem, the syntax is similar but with eight vertices listed for each processor instead of four, and “SQUARES” replaced by “CUBES”.

## 2.25.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar which is the imbalance factor after the most recent re-balance and a global vector of length 3 with additional information about the most recent re-balancing. The three values in the vector are as follows:

1. max # of particles per processor
2. total # iterations performed in last re-balance
3. imbalance factor right before the last re-balance was performed

As explained above, the imbalance factor is the ratio of the maximum number of particles (or total weight) on any processor to the average number of particles (or total weight) per processor.

These quantities can be accessed by various *output commands*. The scalar and vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

---

## 2.25.5 Restrictions

For 2d simulations, the *z* style cannot be used, nor can *z* appear in *dimstr* for the *shift* style.

Balancing through recursive bisectioning (*rcb* style) requires *comm\_style tiled*.

## 2.25.6 Related commands

*group, processors, balance, comm\_style*

## 2.25.7 Default

The default setting is *sort = no*.

# 2.26 fix bocs command

## 2.26.1 Syntax

```
fix ID group-ID bocs keyword values ...
```

- ID, group-ID are documented in *fix* command
- bocs = style name of this fix command
- two or more keyword/value pairs may be appended
- keyword = *temp* or *cgiso* or *tchain* or *pchain* or *mtk* or *tloop* or *ploop*

*temp* values = Tstart Tstop Tdamp

*cgiso* values = Pstart Pstop Pdamp basis\_set args

basis\_set = *analytic* or *linear\_spline* or *cubic\_spline*

*analytic* args = V\_avg N\_particles N\_coeff Coeff\_1 Coeff\_2 ... Coeff\_N

*linear\_spline* args = input\_filename

*cubic\_spline* args = input\_filename

*tchain* value = N = length of thermostat chain (1 = single thermostat)

*pchain* value = N = length of thermostat on barostat (0 = no thermostat)

*mtk* value = *yes* or *no* = add MTK adjustment term or not

*tloop* value = M = number of sub-cycles to perform on thermostat

*ploop* value = M = number of sub-cycles to perform on barostat

## 2.26.2 Examples

```
fix 1 all bocs temp 300.0 300.0 100.0 cgiso 0.986 0.986 1000.0 analytic 66476.015 968 2.
↪245030.10 8962.20
fix 1 all bocs temp 300.0 300.0 100.0 cgiso 0.986 0.986 1000.0 cubic_spline input_Fv.dat
thermo_modify press 1_press
```

## 2.26.3 Description

These commands incorporate a pressure correction as described by Dunn and Noid ([Dunn1](#)) to the standard MTK barostat by Martyna et al. ([Martyna](#)). The first half of the command mimics a standard `fix npt` command:

```
fix 1 all bocs temp Tstart Tstop Tcoupl cgiso Pstart Pstop Pdamp
```

The two differences are replacing `npt` with `bocs`, and replacing `isolaniso/etc.` with `cgiso`. The rest of the command details what form you would like to use for the pressure correction equation. The choices are: *analytic*, *linear\_spline*, or *cubic\_spline*.

With either spline method, the only argument that needs to follow it is the name of a file that contains the desired pressure correction as a function of volume. The file must be formatted so each line has:

```
Volume_i, PressureCorrection_i
```

Note both the COMMA and the SPACE separating the volume's value and its corresponding pressure correction. The volumes in the file must be uniformly spaced. Both the volumes and the pressure corrections should be provided in the proper units (e.g., if you are using *units real*, the volumes should all be in  $\text{\AA}^3$  and the pressure corrections should all be in atm). Furthermore, the table should start/end at a volume considerably smaller/larger than you expect your system to sample during the simulation. If the system ever reaches a volume outside of the range provided, the simulation will stop.

With the *analytic* option, the arguments are as follows:

```
... analytic V_avg N_particles N_coeff Coeff_1 Coeff_2 ... Coeff_N
```

Note that *V\_avg* and *Coeff\_i* should all be in the proper units (e.g., if you are using *units real*, *V\_avg* should be in  $\text{\AA}^3$  and the coefficients should all be in  $\text{atm} \cdot \text{\AA}^3$ ).

## 2.26.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the cumulative global energy change to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a temperature *compute* you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.26.5 Restrictions

This fix is part of the BOCS package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

As this is computing a (modified) pressure, group-ID should be *all*.

The pressure correction has only been tested for use with an isotropic pressure coupling in 3 dimensions.

By default, LAMMPS will still report the normal value for the pressure if the pressure is printed via a *thermo* command, or if the pressures are written to a file every so often. In order to have LAMMPS report the modified pressure, you must include the *thermo\_modify* command given in the examples. For the last argument in the command, you should put XXXX\_press, where XXXX is the ID given to the fix bocs command (in the example, the ID of the fix bocs command is 1).

## 2.26.6 Further information

For more details about the pressure correction and the entire BOCS software package, visit the [BOCS package on GitHub](#) and read the release paper by Dunn et al. ([Dunn2](#)).

## 2.27 fix bond/break command

### 2.27.1 Syntax

**fix** ID group-ID bond/break Nevery bondtype Rmax keyword values ...

- ID, group-ID are documented in *fix* command
- bond/break = style name of this fix command
- Nevery = attempt bond breaking every this many steps
- bondtype = type of bonds to break (integer or type label)
- Rmax = bond longer than Rmax can break (distance units)
- zero or more keyword/value pairs may be appended
- keyword = *prob*  
*prob* values = fraction seed  
fraction = break a bond with this probability if otherwise eligible  
seed = random number seed (positive integer)

## 2.27.2 Examples

```
fix 5 all bond/break 10 2 1.2
fix 5 polymer bond/break 1 1 2.0 prob 0.5 49829
```

## 2.27.3 Description

Break bonds between pairs of atoms as a simulation runs according to specified criteria. This can be used to model the dissolution of a polymer network due to stretching of the simulation box or other deformations. In this context, a bond means an interaction between a pair of atoms computed by the *bond\_style* command. Once the bond is broken it will be permanently deleted, as will all angle, dihedral, and improper interactions that bond is part of.

This is different than a *pair-wise* bond-order potential such as Tersoff or AIREBO which infers bonds and many-body interactions based on the current geometry of a small cluster of atoms and effectively creates and destroys bonds and higher-order many-body interactions from timestep to timestep as atoms move.

A check for possible bond breakage is performed every *Nevery* timesteps. If two bonded atoms *i* and *j* are farther than the distance *Rmax* from each other, the bond is of type *bondtype*, and both *i* and *j* are in the specified fix group, then the bond between *i* and *j* is labeled as a “possible” bond to break.

If several bonds involving an atom are stretched, it may have multiple possible bonds to break. Every atom checks its list of possible bonds to break and labels the longest such bond as its “sole” bond to break. After this is done, if atom *i* is bonded to atom *j* in its sole bond, and atom *j* is bonded to atom *j* in its sole bond, then the bond between *i* and *j* is “eligible” to be broken.

Note that these rules mean an atom will only be part of at most one broken bond on a given time step. It also means that if atom *i* chooses atom *j* as its sole partner, but atom *j* chooses atom *k* as its sole partner (because  $R_{jk} > R_{ij}$ ), then this means atom *i* will not be part of a broken bond on this time step, even if it has other possible bond partners.

The *prob* keyword can effect whether an eligible bond is actually broken. The *fraction* setting must be a value between 0.0 and 1.0. A uniform random number between 0.0 and 1.0 is generated and the eligible bond is only broken if the random number is less than *fraction*.

When a bond is broken, data structures within LAMMPS that store bond topologies are updated to reflect the breakage. Likewise, if the bond is part of a 3-body (angle) or 4-body (dihedral, improper) interaction, that interaction is removed as well. These changes typically affect pair-wise interactions between atoms that used to be part of bonds, angles, etc.

---

**Note:** One data structure that is not updated when a bond breaks are the molecule IDs stored by each atom. Even though one molecule becomes two molecules due to the broken bond, all atoms in both new molecules retain their original molecule IDs.

---

Computationally, each time step this fix is invoked, it loops over all the bonds in the system and computes distances between pairs of bonded atoms. It also communicates between neighboring processors to coordinate which bonds are broken. Moreover, if any bonds are broken, neighbor lists must be immediately updated on the same time step. This is to ensure that any pair-wise interactions that should be turned “on” due to a bond breaking, because they are no longer excluded by the presence of the bond and the settings of the *special\_bonds* command, will be immediately recognized. All of these operations increase the cost of a time step. Thus, you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the *dump local* command.

---

**Note:** Breaking a bond typically alters the energy of a system. You should be careful not to choose bond breaking criteria that induce a dramatic change in energy. For example, if you define a very stiff harmonic bond and break it when two atoms are separated by a distance far from the equilibrium bond length, then the two atoms will be dramatically

---

released when the bond is broken. More generally, you may need to thermostat your system to compensate for energy changes resulting from broken bonds (as well as angles, dihedrals, and impropers).

---

See the [Howto](#) page on broken bonds for more information on related features in LAMMPS.

---

## 2.27.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes two statistics, which it stores in a global vector of length 2. This vector can be accessed by various *output commands*. The vector values calculated by this fix are “intensive”.

The two quantities in the global vector are

- (1) number of bonds broken on the most recent breakage time step
- (2) cumulative number of bonds broken

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.27.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) doc page for more info.

## 2.27.6 Related commands

*fix bond/create*, *fix bond/react*, *fix bond/swap*, *dump local*, *special\_bonds*

## 2.27.7 Default

The option defaults are prob = 1.0.

# 2.28 fix bond/create command

```

## 2.29.3 Description

Create bonds between pairs of atoms as a simulation runs according to specified criteria. This can be used to model the cross-linking of polymers, the formation of a percolation network, etc. In this context, a bond means an interaction between a pair of atoms computed by the *bond\_style* command. Once the bond is created it will be permanently in place. Optionally, the creation of a bond can also create angle, dihedral, and improper interactions that the bond is part of. See the discussion of the *atype*, *dtype*, and *itype* keywords below.

This process is different than a *pair-wise* bond-order potential such as Tersoff or AIREBO, which infer bonds and many-body interactions based on the current geometry of a small cluster of atoms and effectively create and destroy bonds and higher-order many-body interactions from time step to time step as the atoms move.

A check for possible new bonds is performed every *Nevery* time steps. If two atoms *i* and *j* are within a distance *Rmin* of each other, atom *i* is of type *itype*, atom *j* is of type *jtype*, and both *i* and *j* are in the specified fix group, then if

a bond does not already exist between atoms  $i$  and  $j$ , and if both  $i$  and  $j$  meet their respective *maxbond* requirements (explained below), then  $i$  and  $j$  are labeled as a “possible” bond pair.

If several atoms are close to an atom, it may have multiple possible bond partners. Every atom checks its list of possible bond partners and labels the closest such partner as its “sole” bond partner. After this is done, if atom  $i$  has atom  $j$  as its sole partner and atom  $j$  has atom  $i$  as its sole partner, then the  $i, j$  bond is “eligible” to be formed.

Note that these rules mean that an atom will only be part of at most one created bond on a given time step. It also means that if atom  $i$  chooses atom  $j$  as its sole partner, but atom  $j$  chooses atom  $k$  as its sole partner (because  $R_{jk} < R_{ij}$ ), then atom  $i$  will not form a bond on this time step, even if it has other possible bond partners.

It is permissible to have  $itype = jtype$ .  $Rmin$  must be  $\leq$  the pair-wise cutoff distance between  $itype$  and  $jtype$  atoms, as defined by the *pair\_style* command.

The *iparam* and *jparam* keywords can be used to limit the bonding functionality of the participating atoms. Each atom keeps track of how many bonds of *bondtype* it already has. If atom  $i$  of type *itype* already has *maxbond* bonds (as set by the *iparam* keyword), then it will not form any more, and likewise for atom  $j$ . If *maxbond* is set to 0, then there is no limit on the number of bonds that can be formed with that atom.

The *newtype* value for *iparam* and *jparam* can be used to change the atom type of atom  $i$  or  $j$  when it reaches *maxbond* number of bonds of type *bondtype*. This means it can now interact in a pair-wise fashion with other atoms in a different way by specifying different *pair\_coeff* coefficients. If you do not wish the atom type to change, simply specify *newtype* as *itype* or *jtype*.

The *prob* keyword can also affect whether an eligible bond is actually created. The *fraction* setting must be a value between 0.0 and 1.0. A uniform random number between 0.0 and 1.0 is generated and the eligible bond is only created if the random number is less than *fraction*.

The *aconstrain* keyword is only available with the fix bond/create/angle command. It allows one to specify minimum and maximum angles *amin* and *amax*, respectively, between the two prospective bonding partners and a third particle that is already bonded to one of the two partners. Such a criterion can be important when new angles are defined together with the formation of a new bond. Without a restriction on the permissible angle, and for stiffer angle potentials, very large energies can arise and lead to unphysical behavior.

Any bond that is created is assigned a bond type of *bondtype*.

When a bond is created, data structures within LAMMPS that store bond topologies are updated to reflect the creation. If the bond is part of new 3-body (angle) or 4-body (dihedral, improper) interactions, you can choose to create new angles, dihedrals, and impropers as well using the *atype*, *dtype*, and *itype* keywords. All of these changes typically affect pair-wise interactions between atoms that are now part of new bonds, angles, etc.

---

**Note:** One data structure that is not updated when a bond breaks are the molecule IDs stored by each atom. Even though two molecules become one molecule due to the created bond, all atoms in the new molecule retain their original molecule IDs.

---

If the *atype* keyword is used and if an angle potential is defined via the *angle\_style* command, then any new 3-body interactions inferred by the creation of a bond will create new angles of type *angletype*, with parameters assigned by the corresponding *angle\_coeff* command. Likewise, the *dtype* and *itype* keywords will create new dihedrals and impropers of type *dihedralttype* and *impropertype*.

---

**Note:** To create a new bond, the internal LAMMPS data structures that store this information must have space for it. When LAMMPS is initialized from a data file, the list of bonds is scanned and the maximum number of bonds per atom is tallied. If some atom will acquire more bonds than this limit as this fix operates, then the “extra bond per atom” parameter must be set to allow for it. Ditto for “extra angle per atom”, “extra dihedral per atom”, and “extra improper per atom” if angles, dihedrals, or impropers are being added when bonds are created. See the *read\_data* or *create\_box*

command for more details. Note that a data file with no atoms can be used if you wish to add non-bonded atoms via the *create atoms* command (e.g., for a percolation simulation).

---

**Note:** LAMMPS stores and maintains a data structure with a list of the first, second, and third neighbors of each atom (within the bond topology of the system) for use in weighting pair-wise interactions for bonded atoms. Note that adding a single bond always adds a new first neighbor but may also induce **many** new second and third neighbors, depending on the molecular topology of your system. The “extra special per atom” parameter must typically be set to allow for the new maximum total size (first + second + third neighbors) of this per-atom list. There are two ways to do this. See the *read\_data* or *create\_box* commands for details.

---

**Note:** Even if you do not use the *atype*, *dtype*, or *itype* keywords, the list of topological neighbors is updated for atoms affected by the new bond. This in turn affects which neighbors are considered for pair-wise interactions, using the weighting rules set by the *special\_bonds* command. Consider a new bond created between atoms *i* and *j*. If *j* has a bonded neighbor *k*, then *k* becomes a second neighbor of *i*. Even if the *atype* keyword is not used to create angle  $\angle ijk$ , the pair-wise interaction between *i* and *k* could potentially be turned off or weighted by the 1–3 weighting specified by the *special\_bonds* command. This is the case even if the “angle yes” option was used with that command. The same is true for third neighbors (1–4 interactions), the *dtype* keyword, and the “dihedral yes” option used with the *special\_bonds* command.

---

Note that even if your simulation starts with no bonds, you must define a *bond\_style* and use the *bond\_coeff* command to specify coefficients for the *bondtype*. Similarly, if new atom types are specified by the *iparam* or *jparam* keywords, they must be within the range of atom types allowed by the simulation and pair-wise coefficients must be specified for the new types.

Computationally, each time step this fix is invoked, it loops over neighbor lists and computes distances between pairs of atoms in the list. It also communicates between neighboring processors to coordinate which bonds are created. Moreover, if any bonds are created, neighbor lists must be immediately updated on the same time step. This is to ensure that any pair-wise interactions that should be turned “off” due to a bond creation, because they are now excluded by the presence of the bond and the settings of the *special\_bonds* command, will be immediately recognized. All of these operations increase the cost of a time step. Thus, you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the *dump local* command.

---

**Note:** Creating a bond typically alters the energy of a system. You should be careful not to choose bond creation criteria that induce a dramatic change in energy. For example, if you define a very stiff harmonic bond and create it when two atoms are separated by a distance far from the equilibrium bond length, then the two atoms will oscillate dramatically when the bond is formed. More generally, you may need to thermostat your system to compensate for energy changes resulting from created bonds (and angles, dihedrals, impropers).

---

## 2.29.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes two statistics which it stores in a global vector of length 2, which can be accessed by various *output commands*. The vector values calculated by this fix are “intensive”.

The two quantities in the global vector are

- (1) number of bonds created on the most recent creation time step
- (2) cumulative number of bonds created

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.29.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

## 2.30.3 Description

Initiate complex covalent bonding (topology) changes. These topology changes will be referred to as ‘reactions’ throughout this documentation. Topology changes are defined in pre- and post-reaction molecule templates and can include creation and deletion of bonds, angles, dihedrals, impropers, bond types, angle types, dihedral types, atom types, or atomic charges. In addition, reaction by-products or other molecules can be identified and deleted. Finally, atoms can be created and inserted at specific positions relative to the reaction site.

Fix `bond/react` does not use quantum mechanical (e.g., *fix qmmm*) or pairwise bond-order potential (e.g., *Tersoff* or *AIREBO*) methods to determine bonding changes a priori. Rather, it uses a distance-based probabilistic criteria to effect predetermined topology changes in simulations using standard force fields.

This fix was created to facilitate the dynamic creation of polymeric, amorphous or highly cross-linked systems. A suggested workflow for using this fix is

- (1) identify a reaction to be simulated
- (2) build a molecule template of the reaction site before the reaction has occurred
- (3) build a molecule template of the reaction site after the reaction has occurred
- (4) create a map that relates the template-atom-IDs of each atom between pre- and post-reaction molecule templates
- (5) fill a simulation box with molecules and run a simulation with `fix bond/react`.

---

**Note:** New in version 15Sep2022.

*Type labels* allow for molecule templates and data files to use alphanumeric atom types that match those of a force field. Input files that use type labels are inherently compatible with each other and portable between different simulations. Therefore, it is highly recommended to use type labels to specify atom, bond, etc. types when using `fix bond/react`.

---

Only one ‘`fix bond/react`’ command can be used at a time. Multiple reactions can be simultaneously applied by specifying multiple *react* arguments to a single ‘`fix bond/react`’ command. This syntax is necessary because the “common” keywords are applied to all reactions.

The *stabilization* keyword enables reaction site stabilization. Reaction site stabilization is performed by including reacting atoms in an internally-created fix *nve/limit* time integrator for a set number of time steps given by the *stabilize\_steps* keyword. While reacting atoms are being time integrated by the internal *nve/limit*, they are prevented from being involved in any new reactions. The *xmax* value keyword should typically be set to the maximum distance that non-reacting atoms move during the simulation.

Fix bond/react creates and maintains two important dynamic groups of atoms when using the *stabilization* keyword. The first group contains all atoms currently involved in a reaction; this group is automatically time-integrated by an internally-created *nve/limit* integrator. The second group contains all atoms currently not involved in a reaction. This group should be controlled by a thermostat in order to time integrate the system. The name of this group of non-reacting atoms is created by appending ‘\_REACT’ to the group-ID argument of the *stabilization* keyword, as shown in the second example above.

---

**Note:** When using reaction stabilization, you should generally **not** have a separate thermostat that acts on the “all” group.

---

The group-ID set using the *stabilization* keyword can be an existing static group or a previously-unused group-ID. It cannot be specified as “all”. If the group-ID is previously unused, the fix bond/react command creates a *dynamic group* that is initialized to include all atoms. If the group-ID is that of an existing static group, the group is used as the parent group of new, internally-created dynamic group. In both cases, this new dynamic group is named by appending ‘\_REACT’ to the group-ID (e.g., *nvt\_grp\_REACT*). By specifying an existing group, you may thermostat constant-topology parts of your system separately. The dynamic group contains only atoms not involved in a reaction at a given time step, and therefore should be used by a subsequent system-wide time integrator such as *fix nvt*, *fix npt*, or *fix nve*, as shown in the second example above (full examples can be found in examples/PACKAGES/reaction). The time integration command should be placed after the fix bond/react command due to the internal dynamic grouping performed by fix bond/react.

---

**Note:** If the group-ID is an existing static group, react-group-IDs should also be specified as this static group or a subset.

---

The *reset\_mol\_ids* keyword invokes the *reset\_atoms mol* command after a reaction occurs, to ensure that molecule IDs are consistent with the new bond topology. The group-ID used for *reset\_atoms mol* is the group-ID for this fix. Resetting molecule IDs is necessarily a global operation, so it can be slow for very large systems.

The following comments pertain to each *react* argument (in other words, they can be customized for each reaction, or reaction step):

A check for possible new reaction sites is performed every *Nevery* time steps. *Nevery* can be specified with an equal-style *variable*, whose value is rounded up to the nearest integer.

Three physical conditions must be met for a reaction to occur. First, an initiator atom pair must be identified within the reaction distance cutoffs. Second, the topology surrounding the initiator atom pair must match the topology of the pre-reaction template. Only atom types and bond connectivity are used to identify a valid reaction site (not bond types, etc.). Finally, any reaction constraints listed in the map file (see below) must be satisfied. If all of these conditions are met, the reaction site is eligible to be modified to match the post-reaction template.

An initiator atom pair will be identified if several conditions are met. First, a pair of atoms *i* and *j* within the specified react-group-ID of type *itype* and *jtype* must be separated by a distance between *Rmin* and *Rmax*. *Rmin* and *Rmax* can be specified with equal-style *variables*. For example, these reaction cutoffs can be functions of the reaction conversion using the following commands:

```
variable rmax equal 0 # initialize variable before bond/react
fix myrxn all bond/react react myrxn1 all 1 0 v_rmax mol1 mol2 map_file.txt
variable rmax equal 3+f_myrxn[1]/100 # arbitrary function of reaction count
```

The following criteria are used if multiple candidate initiator atom pairs are identified within the cutoff distance:

- (1) If the initiator atoms in the pre-reaction template are not 1–2 neighbors (i.e., not directly bonded) the closest potential partner is chosen.
- (2) Otherwise, if the initiator atoms in the pre-reaction template are 1–2 neighbors (i.e. directly bonded) the farthest potential partner is chosen.
- (3) Then, if both an atom  $i$  and atom  $j$  have each other as initiator partners, these two atoms are identified as the initiator atom pair of the reaction site.

Note that it can be helpful to select unique atom types for the initiator atoms: if an initiator atom pair is identified, as described in the previous steps, but it does not correspond to the same pair specified in the pre-reaction template, an otherwise eligible reaction could be prevented from occurring. Once this unique initiator atom pair is identified for each reaction, there could be two or more reactions that involve the same atom on the same time step. If this is the case, only one such reaction is permitted to occur. This reaction is chosen randomly from all potential reactions involving the overlapping atom. This capability allows, for example, different reaction pathways to proceed from identical reaction sites with user-specified probabilities.

The pre-reacted molecule template is specified by a molecule command. This molecule template file contains a sample reaction site and its surrounding topology. As described below, the initiator atom pairs of the pre-reacted template are specified by atom ID in the map file. The pre-reacted molecule template should contain as few atoms as possible while still completely describing the topology of all atoms affected by the reaction (which includes all atoms that change atom type or connectivity, and all bonds that change bond type). For example, if the force field contains dihedrals, the pre-reacted template should contain any atom within three bonds of reacting atoms.

Some atoms in the pre-reacted template that are not reacting may have missing topology with respect to the simulation. For example, the pre-reacted template may contain an atom that, in the simulation, is currently connected to the rest of a long polymer chain. These are referred to as edge atoms, and are also specified in the map file. All pre-reaction template atoms should be linked to an initiator atom, via at least one path that does not involve edge atoms. When the pre-reaction template contains edge atoms, not all atoms, bonds, charges, etc. specified in the reaction templates will be updated. Specifically, topology that involves only atoms that are “too near” to template edges will not be updated. The definition of “too near the edge” depends on which interactions are defined in the simulation. If the simulation has defined dihedrals, atoms within two bonds of edge atoms are considered “too near the edge.” If the simulation defines angles, but not dihedrals, atoms within one bond of edge atoms are considered “too near the edge.” If just bonds are defined, only edge atoms are considered “too near the edge.”

---

**Note:** Small molecules (i.e., ones that have all their atoms contained within the reaction templates) never have edge atoms.

---

Note that some care must be taken when building a molecule template for a given simulation. All atom types in the pre-reacted template must be the same as those of a potential reaction site in the simulation. A detailed discussion of matching molecule template atom types with the simulation is provided on the [molecule](#) command page. It is highly recommended to use [Type labels](#) (added in version 15Sep2022) in both molecule templates and data files, which automates the process of syncing atom types between different input files.

The post-reacted molecule template contains a sample of the reaction site and its surrounding topology after the reaction has occurred. It must contain the same number of atoms as the pre-reacted template (unless there are created atoms). A one-to-one correspondence between the atom IDs in the pre- and post-reacted templates is specified in the map file as described below. Note that during a reaction, an atom, bond, etc. type may change to one that was previously not present in the simulation. These new types must also be defined during the setup of a given simulation. A discussion of correctly handling this is also provided on the [molecule](#) command page.

---

**Note:** When a reaction occurs, it is possible that the resulting topology/atom (e.g., special bonds, dihedrals) exceeds that of the existing system and reaction templates. As when inserting molecules, enough space for this increased

topology/atom must be reserved by using the relevant “extra” keywords to the *read\_data* or *create\_box* commands.

The map file is a text document with the following format:

A map file has a header and a body. The header of map file the contains one mandatory keyword and five optional keywords. The mandatory keyword is *equivalences*:

*N equivalences* = # of atoms *N* in the reaction molecule templates

The optional keywords are *edgeIDs*, *deleteIDs*, *chiralIDs*, and *constraints*:

*N edgeIDs* = # of edge atoms *N* in the pre-reacted molecule template

*N deleteIDs* = # of atoms *N* that are deleted

*N createIDs* = # of atoms *N* that are created

*N chiralIDs* = # of chiral centers *N*

*N constraints* = # of reaction constraints *N*

The body of the map file contains two mandatory sections and five optional sections. The first mandatory section begins with the keyword “InitiatorIDs” and lists the two atom IDs of the initiator atom pair in the pre-reacted molecule template. The second mandatory section begins with the keyword “Equivalences” and lists a one-to-one correspondence between atom IDs of the pre- and post-reacted templates. The first column is an atom ID of the pre-reacted molecule template, and the second column is the corresponding atom ID of the post-reacted molecule template. The first optional section begins with the keyword “EdgeIDs” and lists the atom IDs of edge atoms in the pre-reacted molecule template. The second optional section begins with the keyword “DeleteIDs” and lists the atom IDs of pre-reaction template atoms to delete. The third optional section begins with the keyword “CreateIDs” and lists the atom IDs of the post-reaction template atoms to create. The fourth optional section begins with the keyword “ChiralIDs” lists the atom IDs of chiral atoms whose handedness should be enforced. The fifth optional section begins with the keyword “Constraints” and lists additional criteria that must be satisfied in order for the reaction to occur. Currently, there are six types of constraints available, as discussed below: “distance”, “angle”, “dihedral”, “arrhenius”, “rmsd”, and “custom”.

A sample map file is given below:

```
# this is a map file

```

(continues on next page)

(continued from previous page)

6	6
7	7

A user-specified set of atoms can be deleted by listing their pre-reaction template IDs in the DeleteIDs section. A deleted atom must still be included in the post-reaction molecule template, in which it cannot be bonded to an atom that is not deleted. In addition to deleting unwanted reaction by-products, this feature can be used to remove specific topologies, such as small rings, that may be otherwise indistinguishable.

Atoms can be created by listing their post-reaction template IDs in the CreateIDs section. A created atom should not be included in the pre-reaction template. The inserted positions of created atoms are determined by the coordinates of the post-reaction template, after optimal translation and rotation of the post-reaction template to the reaction site (using a fit with atoms that are neither created nor deleted). The *modify\_create* keyword can be used to modify the default behavior when creating atoms. The *modify\_create* keyword has two sub-keywords, *fit* and *overlap*. One or more of the sub-keywords may be used after the *modify\_create* keyword. The *fit* sub-keyword can be used to specify which post-reaction atoms are used for the optimal translation and rotation of the post-reaction template. The fragment-ID value of the *fit* sub-keyword must be the name of a molecule fragment defined in the post-reaction *molecule* template, and only atoms in this fragment are used for the fit. Atoms are created only if no current atom in the simulation is within a distance *R* of any created atom, including the effect of periodic boundary conditions if applicable. *R* is defined by the *overlap* sub-keyword. Note that the default value for *R* is 0.0, which will allow atoms to strongly overlap if you are inserting where other atoms are present. The velocity of each created atom is initialized in a random direction with a magnitude calculated from the instantaneous temperature of the reaction site.

---

**Note:** The ‘Coords’ section must be included in the post-reaction template when creating atoms because these coordinates are used to determine where new atoms are inserted.

---

The handedness of atoms that are chiral centers can be enforced by listing their IDs in the ChiralIDs section. A chiral atom must be bonded to four atoms with mutually different atom types. This feature uses the coordinates and types of the involved atoms in the pre-reaction template to determine handedness. Three atoms bonded to the chiral center are arbitrarily chosen, to define an oriented plane, and the relative position of the fourth bonded atom determines the chiral center’s handedness.

Any number of additional constraints may be specified in the Constraints section of the map file. The constraint of type “distance” has syntax as follows:

```
distance ID1 ID2 rmin rmax
```

where “distance” is the required keyword, *ID1* and *ID2* are pre-reaction atom IDs (or molecule-fragment IDs, see below), and these two atoms must be separated by a distance between *rmin* and *rmax* for the reaction to occur.

The constraint of type “angle” has the following syntax:

```
angle ID1 ID2 ID3 amin amax
```

where “angle” is the required keyword, *ID1*, *ID2* and *ID3* are pre-reaction atom IDs (or molecule-fragment IDs, see below), and these three atoms must form an angle between *amin* and *amax* for the reaction to occur (where *ID2* is the central atom). Angles must be specified in degrees. This constraint can be used to enforce a certain orientation between reacting molecules.

The constraint of type “dihedral” has the following syntax:

```
dihedral ID1 ID2 ID3 ID4 amin amax amin2 amax2
```

where “dihedral” is the required keyword, and *ID1*, *ID2*, *ID3* and *ID4* are pre-reaction atom IDs (or molecule-fragment IDs, see below). Dihedral angles are calculated in the interval  $(-180^\circ, 180^\circ]$ . Refer to the *dihedral style* documentation for further details on convention. If *amin* is less than *amax*, these four atoms must form a dihedral angle greater than

*amin* **and** less than *amax* for the reaction to occur. If *amin* is greater than *amax*, these four atoms must form a dihedral angle greater than *amin* **or** less than *amax* for the reaction to occur. Angles must be specified in degrees. Optionally, a second range of permissible angles *amin2* to *amax2* can be specified.

For the ‘distance’, ‘angle’, and ‘dihedral’ constraints (explained above), atom IDs can be replaced by pre-reaction molecule-fragment IDs. The molecule-fragment ID must begin with a letter. The location of the ID is the geometric center of all atom positions in the fragment. The molecule fragment must have been defined in the *molecule* command for the pre-reaction template.

The constraint of type ‘arrhenius’ imposes an additional reaction probability according to the modified Arrhenius equation,

$$k = AT^n e^{-E_a/k_B T}.$$

The Arrhenius constraint has the following syntax:

```
arrhenius A n E_a seed
```

where “arrhenius” is the required keyword, *A* is the pre-exponential factor, *n* is the exponent of the temperature dependence, *E<sub>a</sub>* is the activation energy (*units* of energy), and *seed* is a random number seed. The temperature is defined as the instantaneous temperature averaged over all atoms in the reaction site and is calculated in the same manner as for example *compute temp/chunk*. Currently, there are no options for additional temperature averaging or velocity-biased temperature calculations. A uniform random number between 0 and 1 is generated using *seed*; if this number is less than the result of the Arrhenius equation above, the reaction is permitted to occur.

The constraint of type ‘rmsd’ has the following syntax:

```
rmsd RMSDmax molfragment
```

where “rmsd” is the required keyword, and *RMSDmax* is the maximum root-mean-square deviation between atom positions of the pre-reaction template and the local reaction site (distance units), after optimal translation and rotation of the pre-reaction template. Optionally, the name of a molecule fragment (of the pre-reaction template) can be specified by *molfragment*. If a molecule fragment is specified, only atoms that are part of this molecule fragment are used to determine the RMSD. A molecule fragment must have been defined in the *molecule* command for the pre-reaction template. For example, the molecule fragment could consist of only the backbone atoms of a polymer chain. This constraint can be used to enforce a specific relative position and orientation between reacting molecules.

Changed in version 22Dec2022.

The constraint of type “custom” has the following syntax:

```
custom varstring
```

where ‘custom’ is the required keyword, and *varstring* is a variable expression. The expression must be a valid equal-style variable formula that can be read by the *variable* command, after any special reaction functions are evaluated. If the resulting expression is zero, the reaction is prevented from occurring; otherwise, it is permitted to occur. There are three special reaction functions available, ‘rxnbond’, ‘rxnsum’, and ‘rxnave’. The ‘rxnbond’ function allows per-bond values to be included in the variable strings of the custom constraint. The ‘rxnbond’ function has two mandatory arguments. The first argument is the ID of a previously defined ‘compute bond/local’ command. This ‘compute bond/local’ must compute only one value, e.g. bond force. This value is returned by the ‘rxnbond’ function. The second argument is the name of a molecule fragment in the pre-reaction template. The fragment must contain exactly two atoms, corresponding to the atoms involved in the bond whose value should be calculated. An example of a constraint that uses the force experienced by a bond is provided below. The ‘rxnsum’ and ‘rxnave’ functions operate over the atoms in a given reaction site, and have one mandatory argument and one optional argument. The mandatory argument is the identifier for an atom-style variable. The second, optional argument is the name of a molecule fragment in the pre-reaction template, and can be used to operate over a subset of atoms in the reaction site. The ‘rxnsum’ function sums the atom-style variable over the reaction site, while the ‘rxnave’ returns the average value. For example, a constraint on the total potential energy of atoms involved in the reaction can be imposed as follows:

```
compute 1 all pe/atom # in LAMMPS input script
variable my_pe atom c_1 # in LAMMPS input script
```

```
custom "rxnsum(v_my_pe) > 100" # in Constraints section of map file
```

The above example prevents the reaction from occurring unless the total potential energy of the reaction site is above 100. As a second example, this time using the ‘rxnbond’ function, consider a modified Arrhenius constraint that depends on the bond force of a specific bond:

```
# in LAMMPS input script

compute bondforce all bond/local force

compute ke_atom all ke/atom
variable ke atom c_ke_atom

variable E_a equal 100.0 # activation energy
variable l0 equal 1.0 # characteristic length
```

```
# in Constraints section of map file

custom "exp(-(v_E_a-rxnbond(c_bondforce,bondlfrag)*v_l0)/(2/3*rxnave(v_ke))) < random(0,
→1,12345)"
```

By using an inequality and the ‘random(x,y,z)’ function, the left-hand side can be interpreted as the probability of the reaction occurring, similar to the ‘arrhenius’ constraint above.

By default, all constraints must be satisfied for the reaction to occur. In other words, constraints are evaluated as a series of logical values using the logical AND operator “&&”. More complex logic can be achieved by explicitly adding the logical AND operator “&&” or the logical OR operator “||” after a given constraint command. If a logical operator is specified after a constraint, it must be placed after all constraint parameters, on the same line as the constraint (one per line). Similarly, parentheses can be used to group constraints. The expression that results from concatenating all constraints should be a valid logical expression that can be read by the *variable* command after converting each constraint to a logical value. Because exactly one constraint is allowed per line, having a valid logical expression implies that left parentheses “(” should only appear before a constraint, and right parentheses “)” should only appear after a constraint and before any logical operator.

Once a reaction site has been successfully identified, data structures within LAMMPS that store bond topology are updated to reflect the post-reacted molecule template. All force fields with fixed bonds, angles, dihedrals or impropers are supported.

A few capabilities to note:

- (1) You may specify as many *react* arguments as desired. For example, you could break down a complicated reaction mechanism into several reaction steps, each defined by its own *react* argument.
- (2) While typically a bond is formed or removed between the initiator atoms specified in the pre-reacted molecule template, this is not required.
- (3) By reversing the order of the pre- and post-reacted molecule templates in another *react* argument, you can allow for the possibility of one or more reverse reactions.

The optional keywords deal with the probability of a given reaction occurring as well as the stable equilibration of each reaction site as it occurs.

The *prob* keyword can affect whether or not an eligible reaction actually occurs. The fraction setting must be a value between 0.0 and 1.0, and can be specified with an equal-style *variable*. A uniform random number between 0.0 and

1.0 is generated and the eligible reaction only occurs if the random number is less than the fraction. Up to  $N$  reactions are permitted to occur, as optionally specified by the *max\_rxn* keyword.

New in version 22Dec2022.

The *rate\_limit* keyword can enforce an upper limit on the overall rate of the reaction. The number of reaction occurrences is limited to *Nlimit* within an interval of *Nsteps* timesteps. No reactions are permitted to occur within the first *Nsteps* timesteps of the first run after reading a data file. *Nlimit* can be specified with an equal-style *variable*.

The *stabilize\_steps* keyword allows for the specification of how many time steps a reaction site is stabilized before being returned to the overall system thermostat. In order to produce the most physical behavior, this “reaction site equilibration time” should be tuned to be as small as possible while retaining stability for a given system or reaction step. After a limited number of case studies, this number has been set to a default of 60 time steps. Ideally, it should be individually tuned for each fix reaction step. Note that in some situations, decreasing rather than increasing this parameter will result in an increase in stability.

The *custom\_charges* keyword can be used to specify which atoms’ atomic charges are updated. When the value is set to *no*, all atomic charges are updated to those specified by the post-reaction template (default). Otherwise, the value should be the name of a molecule fragment defined in the pre-reaction molecule template. In this case, only the atomic charges of atoms in the molecule fragment are updated.

New in version 22Dec2022.

The *rescale\_charges* keyword can be used to ensure the total charge of the system does not change as reactions occur. When the argument is set to *yes*, a fixed value is added to the charges of post-reaction atoms such that their total charge equals that of the pre-reaction site. If only a subset of atomic charges are updated via the *custom\_charges* keyword, this rescaling is applied to the subset. This keyword could be useful for systems that contain different molecules with the same reactive site, if the partial charges on the reaction site vary from molecule to molecule, or when removing reaction by-products.

The *molecule* keyword can be used to force the reaction to be intermolecular, intramolecular or either. When the value is set to *off*, molecule IDs are not considered when searching for reactions (default). When the value is set to *inter*, the initiator atoms must have different molecule IDs in order to be considered for the reaction. When the value is set to *intra*, only initiator atoms with the same molecule ID are considered for the reaction.

A few other considerations:

Optionally, you can enforce additional behaviors on reacting atoms. For example, it may be beneficial to force reacting atoms to remain at a certain temperature. For this, you can use the internally-created dynamic group named “bond\_react\_MASTER\_group”, which consists of all atoms currently involved in a reaction. For example, adding the following command would add an additional thermostat to the group of all currently-reacting atoms:

```
fix 1 bond_react_MASTER_group temp/rescale 1 300 300 10 1
```

---

**Note:** This command must be added after the *fix bond/react* command, and will apply to all reactions.

---

Computationally, each time step this fix is invoked, it loops over neighbor lists (for bond-forming reactions) and computes distances between pairs of atoms in the list. It also communicates between neighboring processors to coordinate which bonds are created and/or removed. All of these operations increase the cost of a time step. Thus, you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the *dump local* command.

---

## 2.30.4 Restart, fix\_modify, output, run start/stop, minimize info

Cumulative reaction counts for each reaction are written to *binary restart files*. These values are associated with the reaction name (react-ID). Additionally, internally-created per-atom properties are stored to allow for smooth restarts. None of the *fix\_modify* options are relevant to this fix.

This fix computes one statistic for each *react* argument that it stores in a global vector, of length (number of react arguments), that can be accessed by various *output commands*. The vector values calculated by this fix are “intensive”.

There is one quantity in the global vector for each *react* argument:

- (1) cumulative number of reactions that occurred

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

When fix bond/react is “*unfixed*”, all internally-created groups are deleted. Therefore, fix bond/react can only be unfixed after unfixing all other fixes that use any group created by fix bond/react.

## 2.30.5 Restrictions

This fix is part of the REACTION package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.30.6 Related commands

*fix bond/create, fix bond/break, fix bond/swap, dump local, special\_bonds*

## 2.30.7 Default

The option defaults are stabilization = no, prob = 1.0, stabilize\_steps = 60, reset\_mol\_ids = yes, custom\_charges = no, molecule = off, modify\_create = *fit all*

## 2.31 fix bond/swap command

### 2.31.1 Syntax

**fix** ID group-ID bond/swap Nevery fraction cutoff seed

- ID, group-ID are documented in *fix* command
- bond/swap = style name of this fix command
- Nevery = attempt bond swapping every this many steps
- fraction = fraction of group atoms to consider for swapping

- cutoff = distance at which swapping will be considered (distance units)
- seed = random # seed (positive integer)

## 2.31.2 Examples

```
fix 1 all bond/swap 50 0.5 1.3 598934
```

## 2.31.3 Description

In a simulation of polymer chains this command attempts to swap a pair of bonds, as illustrated below. This is done via Monte Carlo rules using the Boltzmann acceptance criterion, typically with the goal of equilibrating the polymer system more quickly. This fix is designed for use with idealized bead-spring polymer chains where each polymer is a linear chain of monomers, but LAMMPS does not check that is the case for your system.

Here are two use cases for this fix.

The first use case is for swapping bonds on two different chains, effectively grafting the end of one chain onto the other chain and vice versa. The purpose is to equilibrate the polymer chain conformations more rapidly than dynamics alone would do it, by enabling instantaneous large conformational changes in a dense polymer melt. The polymer chains should thus more rapidly converge to the proper end-to-end distances and radii of gyration.

A schematic of the kinds of bond swaps that can occur in this use case is shown here:

On the left, the red and blue chains have two monomers A1 and B1 close to each other, which are currently bonded to monomers A2 and B2 respectively within their own chains. The bond swap operation will attempt to delete the A1-A2 and B1-B2 bonds and replace them with A1-B2 and B1-A2 bonds. If the swap is energetically favorable, the two chains on the right are the result and each polymer chain has undergone a dramatic conformational change. This reference, ([Sides](#)) provides more details on the algorithm's effectiveness for this use case.

The second use case is a collection of polymer chains with some fraction of their sites identified as “sticker” sites. Initially each polymer chain is isolated from the others in a topological sense, and there is an intra-chain bond between every pair of sticker sites on the same chain. Over time, bonds swap so that inter-molecular sticker bonds are created. This models a vitrification-style process whereby the polymer chains all become interconnected. For this use case, if angles are defined they should not include bonds between sticker sites.

---

**Note:** For the sticker site model, you should set the newton flag for bonds to “off”, via the `newton on off` command (“on” is the default for the 2nd argument). This is to ensure appropriate randomness in bond selection because the I,J bond will be stored by both atom I and atom J. LAMMPS cannot check for this, because it is not aware that a sticker site model is being used.

---

The bond swapping operation is invoked once every *Nevery* timesteps. If any bond in the entire system is swapped, a re-build of the neighbor lists is triggered, since a swap alters the list of which neighbors are considered for pairwise

interaction. At each invocation, each processor considers a random specified *fraction* of its atoms as potential swapping monomers for this timestep. Choosing a small *fraction* value can reduce the likelihood of a reverse swap occurring soon after an initial swap.

For each monomer A1, its neighbors are looped over as B1 monomers. For each A1,B1 an additional double loop of bond partners A2 of A1, and bond partners B2 of B1 is performed. For each pair of A1-A2 and B1-B2 bonds to be eligible for swapping, the following 4 criteria must be met:

1. All 4 monomers must be in the fix group.
2. All 4 monomers must be owned by the processor (not ghost atoms). This ensures that another processor does not attempt to swap bonds involving the same atoms on the same timestep. Note that this also means that bond pairs which straddle processor boundaries are not eligible for swapping on this step.
3. The distances between 4 pairs of atoms – (A1,A2), (B1,B2), (A1,B2), (B1,A2) – must all be less than the specified *cutoff*.
4. The molecule IDs of A1 and B1 must be the same (see below).

If an eligible B1 partner is found, the energy change due to swapping the two bonds is computed. This includes changes in pairwise, bond, and angle energies due to the altered connectivity of the 2 chains. Dihedral and improper interactions are not allowed to be defined when this fix is used.

If the energy decreases due to the swap operation, the bond swap is accepted. If the energy increases it is accepted with probability  $\exp(-\Delta/kT)$  where  $\Delta$  is the increase in energy,  $k$  is the Boltzmann constant, and  $T$  is the current temperature of the system.

---

**Note:** Whether the swap is accepted or rejected, no other swaps are attempted by this processor on this timestep. No other eligible 4-tuples of atoms are considered. This means that each processor will perform either a single swap or none on timesteps this fix is invoked.

---

The criterion for matching molecule IDs is how the first use case described above can be simulated while conserving chain lengths. This is done by setting up the molecule IDs for the polymer chains in a specific way, typically in the data file, read by the [read\\_data](#) command.

Consider a system of 6-mer chains. You have 2 choices. If the molecule IDs for monomers on each chain are set to 1,2,3,4,5,6 then swaps will conserve chain length. For a particular monomer there will be only one other monomer on another chain which is a potential swap partner. If the molecule IDs for monomers on each chain are set to 1,2,3,3,2,1 then swaps will conserve chain length but swaps will be able to occur at either end of a chain. Thus for a particular monomer there will be 2 possible swap partners on another chain. In this scenario, swaps can also occur within a single chain, i.e. the two ends of a chain swap with each other.

---

**Note:** If your simulation uses molecule IDs in the usual way, where all monomers on a single chain are assigned the same ID (different for each chain), then swaps will only occur within the same chain. If you assign the same molecule ID to all monomers in all chains then inter-chain swaps will occur, but they will not conserve chain length. Neither of these scenarios is probably what you want for this fix.

---

---

**Note:** When a bond swap occurs the image flags of monomers in the new polymer chains can become inconsistent. See the [dump](#) command for a discussion of image flags. This is not an issue for running dynamics, but can affect calculation of some diagnostic quantities or the printing of unwrapped coordinates to a dump file.

---

For the second use case described above, the molecule IDs for all sticker sites should be the same.

---

This fix computes a temperature each time it is invoked for use by the Boltzmann criterion. To do this, the fix creates its own compute of style *temp*, as if this command had been issued:

```
compute fix-ID_temp all temp
```

See the *compute temp* command for details. Note that the ID of the new compute is the fix-ID with underscore + “temp” appended and the group for the new compute is “all”, so that the temperature of the entire system is used.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp*. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command or print this temperature during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* will have no effect on this fix.

### 2.31.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Also note that each processor generates possible swaps independently of other processors. Thus if you repeat the same simulation on a different number of processors, the specific swaps performed will be different.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a *compute* you have defined to this fix which will be used to compute the temperature for the Boltzmann criterion.

This fix computes two statistical quantities as a global 2-vector of output, which can be accessed by various *output commands*. The first component of the vector is the cumulative number of swaps performed by all processors. The second component of the vector is the cumulative number of swaps attempted (whether accepted or rejected). Note that a swap “attempt” only occurs when swap partners meeting the criteria described above are found on a particular timestep. The vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.31.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

The settings of the “special\_bond” command must be 0,1,1 in order to use this fix, which is typical of bead-spring chains with FENE or harmonic bonds. This means that pairwise interactions between bonded atoms are turned off, but are turned on between atoms two or three hops away along the chain backbone.

Currently, energy changes in dihedral and improper interactions due to a bond swap are not considered. Thus a simulation that uses this fix cannot use a dihedral or improper potential.

### 2.32.2 Examples

```
fix 1 all box/relax iso 0.0 vmax 0.001
fix 2 water box/relax aniso 0.0 dilate partial
fix 2 ice box/relax tri 0.0 couple xy nreset 100
```

### 2.32.3 Description

Apply an external pressure or stress tensor to the simulation box during an *energy minimization*. This allows the box size and shape to vary during the iterations of the minimizer so that the final configuration will be both an energy minimum for the potential energy of the atoms, and the system pressure tensor will be close to the specified external tensor. Conceptually, specifying a positive pressure is like squeezing on the simulation box; a negative pressure typically allows the box to expand.

The external pressure tensor is specified using one or more of the *iso*, *aniso*, *tri*, *x*, *y*, *z*, *xy*, *xz*, *yz*, and *couple* keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during the minimization.

Orthogonal simulation boxes have 3 adjustable dimensions (*x,y,z*). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (*x,y,z,xy,xz,yz*). The *create\_box*, *read\_data*, and *read\_restart* commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the *xy,xz,yz* tilt factors.

The target pressures *Ptarget* for each of the 6 components of the stress tensor can be specified independently via the *x*, *y*, *z*, *xy*, *xz*, *yz* keywords, which correspond to the 6 simulation box dimensions. For example, if the *y* keyword is used, the *y*-box length will change during the minimization. If the *xy* keyword is used, the *xy* tilt factor will change. A box dimension will not change if that component is not specified.

Note that in order to use the *xy*, *xz*, or *yz* keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

When the size of the simulation box changes, all atoms are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the atoms in the fix group are re-scaled. This can be useful for leaving the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

The *scalexz*, *scalexy*, and *scalexz* keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when relaxing triclinic periodic cells. The default values *yes* will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing *no* ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to *no*.

The *fixedpoint* keyword specifies the fixed point for cell relaxation. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to *fixedpoint*, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle positions at each iteration are unaffected by the chosen value, except that all particles are displaced by the same amount, different on each iteration.

**Note:** Applying an external pressure to tilt dimensions *xy*, *xz*, *yz* can sometimes result in arbitrarily large values of the tilt factors, i.e. a dramatically deformed simulation box. This typically indicates that there is something badly wrong with how the simulation was constructed. The two most common sources of this error are applying a shear stress to a liquid system or specifying an external shear stress tensor that exceeds the yield stress of the solid. In either case the minimization may converge to a bogus conformation or not converge at all. Also note that if the box shape tilts to an extreme shape, LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor's irregular-shaped subdomain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

**Note:** Performing a minimization with this fix is not a mathematically well-defined minimization problem. This is because the objective function being minimized changes if the box size/shape changes. In practice this means the minimizer can get “stuck” before you have reached the desired tolerance. The solution to this is to restart the minimizer

from the new adjusted box size/shape, since that creates a new objective function valid for the new box size/shape. Repeat as necessary until the box size/shape has reached its new equilibrium.

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, *xz* means the  $P_{xx}$  and  $P_{zz}$  components of the stress tensor are coupled. *xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The *Ptarget* values for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the *z* dimension is simply ignored.

The *iso*, *aniso*, and *tri* keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso Ptarget” is the same as specifying these 4 keywords:

```
x Ptarget y Ptarget z Ptarget couple xyz
```

The keyword *aniso* means *x*, *y*, and *z* dimensions are controlled independently using the  $P_{xx}$ ,  $P_{yy}$ , and  $P_{zz}$  components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “aniso Ptarget” is the same as specifying these 4 keywords:

```
x Ptarget y Ptarget z Ptarget couple none
```

The keyword *tri* means *x*, *y*, *z*, *xy*, *xz*, and *yz* dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “tri Ptarget” is the same as specifying these 7 keywords:

```
x Ptarget y Ptarget z Ptarget xy 0.0 yz 0.0 xz 0.0 couple none
```

The *vmax* keyword can be used to limit the fractional change in the volume of the simulation box that can occur in one iteration of the minimizer. If the pressure is not settling down during the minimization this can be because the volume is fluctuating too much. The specified fraction must be greater than 0.0 and should be  $< 1.0$ . A value of 0.001 means the volume cannot change by more than 1/10 of a percent in one iteration when *couple xyz* has been specified. For any other case it means no linear dimension of the simulation box can change by more than 1/10 of a percent.

With this fix, the potential energy used by the minimizer is augmented by an additional energy provided by the fix. The overall objective function then is:

$$E = U + P_t (V - V_0) + E_{strain}$$

where  $U$  is the system potential energy,  $P_t$  is the desired hydrostatic pressure,  $V$  and  $V_0$  are the system and reference volumes, respectively.  $E_{strain}$  is the strain energy expression proposed by Parrinello and Rahman ([Parrinello1981](#)). Taking derivatives of  $E$  w.r.t. the box dimensions, and setting these to zero, we find that at the minimum of the objective function, the global system stress tensor  $\mathbf{P}$  will satisfy the relation:

$$\mathbf{P} = P_t \mathbf{I} + \mathbf{S}_t (\mathbf{h}_0^{-1})^t \mathbf{h}_{0d}$$

where  $\mathbf{I}$  is the identity matrix,  $\mathbf{h}_0$  is the box dimension tensor of the reference cell, and  $\mathbf{h}_{0d}$  is the diagonal part of  $\mathbf{h}_0$ .  $\mathbf{S}_t$  is a symmetric stress tensor that is chosen by LAMMPS so that the upper-triangular components of  $\mathbf{P}$  equal the stress tensor specified by the user.

This equation only applies when the box dimensions are equal to those of the reference dimensions. If this is not the case, then the converged stress tensor will not equal that specified by the user. We can resolve this problem by periodically resetting the reference dimensions. The keyword *nreset* controls how often this is done. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. A value of *nstep* means that every *nstep* minimization steps, the reference dimensions are set to those of the current simulation domain. Note that resetting the reference dimensions changes the objective function and gradients, which sometimes causes the minimization to fail. This can be resolved by changing the value of *nreset*, or simply continuing the minimization from a restart file.

---

**Note:** As normally computed, pressure includes a kinetic- energy or temperature-dependent component; see the *compute pressure* command. However, atom velocities are ignored during a minimization, and the applied pressure(s) specified with this command are assumed to only be the virial component of the pressure (the non-kinetic portion). Thus if atoms have a non-zero temperature and you print the usual thermodynamic pressure, it may not appear the system is converging to your specified pressure. The solution for this is to either (a) zero the velocities of all atoms before performing the minimization, or (b) make sure you are monitoring the pressure without its kinetic component. The latter can be done by outputting the pressure from the pressure compute this command creates (see below) or a pressure compute you define yourself.

---

---

**Note:** Because pressure is often a very sensitive function of volume, it can be difficult for the minimizer to equilibrate the system the desired pressure with high precision, particularly for solids. Some techniques that seem to help are (a) use the “min\_modify line quadratic” option when minimizing with box relaxations, (b) minimize several times in succession if need be, to drive the pressure closer to the target pressure, (c) relax the atom positions before relaxing the box, and (d) relax the box to the target hydrostatic pressure before relaxing to a target shear stress state. Also note that some systems (e.g. liquids) will not sustain a non-hydrostatic applied pressure, which means the minimizer will not converge.

---

This fix computes a temperature and pressure each timestep. The temperature is used to compute the kinetic contribution to the pressure, even though this is subsequently ignored by default. To do this, the fix creates its own computes of style “temp” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp virial
```

See the *compute temp* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix\_ID + underscore + “press”, and the group for the new computes is the same as the fix group. Also note that the pressure compute does not include a kinetic component.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

---

## 2.32.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its temperature and pressure calculation, as described above. Note that as described above, if you assign a pressure compute to this fix that includes a kinetic energy component it will affect the minimization, most likely in an undesirable way.

---

**Note:** If both the *temp* and *press* keywords are used in a single thermo\_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a *pressure compute* defines its own temperature compute as an argument when it is specified. The *temp* keyword will override this (for the pressure compute being used by fix box/relax), but only if the *temp* keyword comes after the *press* keyword. If the *temp* keyword comes before the *press* keyword, then the new pressure compute specified by the *press* keyword will be unaffected by the *temp* setting.

---

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the pressure-volume energy, plus the strain energy, if it exists, as described above. The energy values reported at the end of a minimization run under “Minimization stats” include this energy, and so differ from what LAMMPS normally reports as potential energy. This fix does not support the *fix\_modify energy* option, because that would result in double-counting of the fix energy in the minimization energy. Instead, the fix energy can be explicitly added to the potential energy using one of these two variants:

```
variable emin equal pe+f_1
variable emin equal pe+f_1/atoms
```

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is invoked during *energy minimization*, but not for the purpose of adding a contribution to the energy or forces being minimized. Instead it alters the simulation box geometry as described above.

## 2.32.5 Restrictions

Only dimensions that are available can be adjusted by this fix. Non-periodic dimensions are not available. *z*, *xz*, and *yz*, are not available for 2D simulations. *xy*, *xz*, and *yz* are only available if the simulation domain is non-orthogonal. The *create\_box*, *read\_data*, and *read\_restart* commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the *xy,xz,yz* tilt factors.

The *scaleyz yes* and *scalexz yes* keyword/value pairs can not be used for 2D simulations. *scaleyz yes*, *scalexz yes*, and *scalexy yes* options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords *tri*, *yz*, *xz*, and *xy*.

## 2.32.6 Related commands

*fix npt*, *minimize*

## 2.32.7 Default

The keyword defaults are dilate = all, vmax = 0.0001, nreset = 0.

## 2.35.3 Description

Perform Brownian Dynamics time integration to update position, velocity, dipole orientation (for spheres) and quaternion orientation (for ellipsoids, with optional dipole update as well) of all particles in the fix group in each timestep. Brownian Dynamics uses Newton's laws of motion in the limit that inertial forces are negligible compared to viscous forces. The stochastic equation of motion for the center of mass positions is

$$d\mathbf{r} = \gamma_t^{-1} \mathbf{F} dt + \sqrt{2k_B T} \gamma_t^{-1/2} d\mathbf{W}_t,$$

in the lab-frame (i.e.,  $\gamma_t$  is not diagonal, but only depends on orientation and so the noise is still additive).

The rotational motion for the spherical and ellipsoidal particles is not as simple an expression, but is chosen to replicate the Boltzmann distribution for the case of conservative torques (see [\(Ilie\)](#) or [\(Delong\)](#)).

For the style *brownian*, only the positions of the particles are updated. This is therefore suitable for point particle simulations.

For the style *brownian/sphere*, the positions of the particles are updated, and a dipole slaved to the spherical orientation is also updated. This style therefore requires the hybrid atom style *atom\_style dipole* and *atom\_style sphere*. The equation of motion for the dipole is

$$\mu(t + dt) = \frac{\mu(t) + \omega \times \mu dt}{|\mu(t) + \omega \times \mu|}$$

which correctly reproduces a Boltzmann distribution of orientations and rotational diffusion moments (see [\(Ilie\)](#)) when

$$\omega = \frac{\mathbf{T}}{\gamma_r} + \sqrt{\frac{2k_B T_{rot}}{\gamma_r}} \frac{d\mathbf{W}}{dt},$$

with  $d\mathbf{W}$  being a random number with zero mean and variance  $dt$  and  $T_{rot}$  is *rotation\_temp*.

For the style *brownian/asphere*, the center of mass positions and the quaternions of ellipsoidal particles are updated. This fix style is suitable for equations of motion where the rotational and translational friction tensors can be diagonalized in a certain (body) reference frame. In this case, the rotational equation of motion is updated via the quaternion

$$\mathbf{q}(t + dt) = \frac{\mathbf{q}(t) + d\mathbf{q}}{\|\mathbf{q}(t) + d\mathbf{q}\|}$$

which correctly reproduces a Boltzmann distribution of orientations and rotational diffusion moments [see [\(Ilie\)](#)] when the quaternion step is given by

$$d\mathbf{q} = \Psi \omega dt$$

where  $\Psi$  has rows  $(-q_1, -q_2, -q_3)$ ,  $(q_0, -q_3, q_2)$ ,  $(q_3, q_0, -q_1)$ , and  $(-q_2, q_1, q_0)$ .  $\omega$  is evaluated in the body frame of reference where the friction tensor is diagonal. See [\(Delong\)](#) for more details of a similar algorithm.

---

**Note:** This integrator does not by default assume a relationship between the rotational and translational friction tensors, though such a relationship should exist in the case of no-slip boundary conditions between the particles and the surrounding (implicit) solvent. For example, in the case of spherical particles, the condition  $\gamma_r = 3\gamma_t/\sigma^2$  must be explicitly accounted for by setting *gamma\_t* to 3x and *gamma\_r* to x (where  $\sigma$  is the sphere's diameter). A similar (though more complex) relationship holds for ellipsoids and rod-like particles. The translational diffusion and rotational diffusion are given by *temp/gamma\_t* and *rotation\_temp/gamma\_r*.

---

---

**Note:** Temperature computation using the *compute temp* will not correctly compute the temperature of these over-damped dynamics since we are explicitly neglecting inertial effects. Furthermore, this time integrator does not add the stochastic terms or viscous terms to the force and/or torques. Rather, they are just added in to the equations of motion to update the degrees of freedom.

---

---

If the *rng* keyword is used with the *uniform* value, then the noise is generated from a uniform distribution (see ([Dunweg](#)) for why this works). This is the same method of noise generation as used in *fix langevin*.

If the *rng* keyword is used with the *gaussian* value, then the noise is generated from a Gaussian distribution. Typically this added complexity is unnecessary, and one should be fine using the *uniform* value for reasons argued in ([Dunweg](#)).

If the *rng* keyword is used with the *none* value, then the noise terms are set to zero.

The *gamma\_t* keyword sets the (isotropic) translational viscous damping. Required for (and only compatible with) *brownian* and *brownian/sphere*. The units of *gamma\_t* are mass/time.

The *gamma\_r* keyword sets the (isotropic) rotational viscous damping. Required for (and only compatible with) *brownian/sphere*. The units of *gamma\_r* are mass\*length\*\*2/time.

The *gamma\_r\_eigen*, and *gamma\_t\_eigen* keywords are the eigenvalues of the rotational and viscous damping tensors (having the same units as their isotropic counterparts). Required for (and only compatible with) *brownian/asphere*. For a 2D system, the first two values of *gamma\_r\_eigen* must be *inf* (only rotation in *x*-*y* plane), and the third value of *gamma\_t\_eigen* must be *inf* (only diffusion in the *x*-*y* plane).

If the *dipole* keyword is used, then the dipole moments of the particles are updated as described above. Only compatible with *brownian/asphere* (as *brownian/sphere* updates dipoles automatically).

If the *rotation\_temp* keyword is used, then the rotational diffusion will be occur at this prescribed temperature instead of *temp*. Only compatible with *brownian/sphere* and *brownian/asphere*.

If the *planar\_rotation* keyword is used, then rotation is constrained to the *x*-*y* plane in a 3D simulation. Only compatible with *brownian/sphere* and *brownian/asphere* in 3D.

---

---

**Note:** For style *brownian/asphere*, the components *gamma\_t\_eigen* = (x,x,x) and *gamma\_r\_eigen* = (y,y,y), the dynamics will replicate those of the *brownian/sphere* style with *gamma\_t* = x and *gamma\_r* = y.

---

## 2.35.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. No global or per-atom quantities are stored by this fix for access by various *output commands*.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.35.5 Restrictions

The style *brownian/sphere* fix requires that atoms store torque and angular velocity (*omega*) as defined by the *atom\_style sphere* command. The style *brownian/asphere* fix requires that atoms store torque and quaternions as defined by the *atom\_style ellipsoid* command. If the *dipole* keyword is used, they must also store a dipole moment as defined by the *atom\_style dipole* command.

This fix is part of the BROWNIAN package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

## 2.35.6 Related commands

*fix propel/self*, *fix langevin*, *fix nve/sphere*,

## 2.35.7 Default

The default for *rng* is *uniform*. The default for the rotational and translational friction tensors are the identity tensor.

## 2.36 fix charge/regulation command

### 2.36.1 Syntax

**fix** ID group-ID charge/regulation cation\_type anion\_type keyword value(s)

- ID, group-ID are documented in fix command
- charge/regulation = style name of this fix command
- cation\_type = atom type of free cations (integer or type label)
- anion\_type = atom type of free anions (integer or type label)
- zero or more keyword/value pairs may be appended

keyword = *pH*, *pKa*, *pKb*, *pIp*, *pIm*, *pKs*, *acid\_type*, *base\_type*, *lunit\_nm*, *temp*,  
→ *tempfixid*, *never*, *nmc*, *rxn*, *seed*, *tag*, *group*, *onlysalt*, *pmcmoves*  
*pH* value = pH of the solution (can be specified as an equal-style variable)  
*pKa* value = acid dissociation constant (in the -log10 representation)

`pKb` value = base dissociation constant (in the  $-\log_{10}$  representation)  
`pIp` value = activity (effective concentration) of free cations (in the  $-\log_{10}$  representation)  
`pIm` value = activity (effective concentration) of free anions (in the  $-\log_{10}$  representation)  
`pKs` value = solvent self-dissociation constant (in the  $-\log_{10}$  representation)  
`acid_type` = atom type of acid groups (integer or type label)  
`base_type` = atom type of base groups (integer or type label)  
`lunit_nm` value = unit length used by LAMMPS (# in the units of nanometers)  
`temp` value = temperature  
`tempfixid` value = fix ID of temperature thermostat  
`nevery` value = invoke this fix every nevery steps  
`nmc` value = number of charge regulation MC moves to attempt every nevery steps  
`rxn` value = cutoff distance for acid/base reaction  
`seed` value = random # seed (positive integer)  
`tag` value = yes or no (yes: The code assign unique tags to inserted ions; no: The tag of all inserted ions is "0")  
`group` value = group-ID, inserted ions are assigned to group group-ID. Can be used multiple times to assign inserted ions to multiple groups.  
`onlysalt` values = flag charge\_cation charge\_anion.  
     flag = yes or no (yes: the fix performs only ion insertion/deletion, no: perform acid/base dissociation and ion insertion/deletion)  
     charge\_cation, charge\_anion = value of cation/anion charge, must be an integer (only specify if flag = yes)  
`pmcmoves` values = pmcA pmcB pmcI - MC move fractions for acid ionization (pmcA), base ionization (pmcB) and free ion exchange (pmcI)

## 2.36.2 Examples

```

labelmap atom 1 H+ 2 OH-
fix chareg all charge/regulation H+ OH- pIp 3 pIm 3 onlysalt yes 2 -1 seed 123 tag yes temp 1.0

```

## 2.36.3 Description

This fix performs Monte Carlo (MC) sampling of charge regulation and exchange of ions with a reservoir as discussed in *(Curk1)* and *(Curk2)*. The implemented method is largely analogous to the grand-reaction ensemble method in *(Landsgesell)*. The implementation is parallelized, compatible with existing LAMMPS functionalities, and applicable to any system utilizing discrete, ionizable groups or surface sites.

Specifically, the fix implements the following three types of MC moves, which discretely change the charge state of individual particles and insert ions into the systems:  $A \rightleftharpoons A^- + X^+$ ,  $B \rightleftharpoons B^+ + X^-$ , and  $\emptyset \rightleftharpoons Z^- X^{Z^+} + Z^+ X^{-Z^-}$ . In the former two types of reactions, Monte Carlo moves alter the charge value of specific atoms (A, B) and simultaneously insert a counterion to preserve the charge neutrality of the system, modeling the dissociation/association process. The last type of reaction performs grand canonical MC exchange of ion pairs with a (fictitious) reservoir.

In our implementation “acid” refers to particles that can attain charge  $q = \{0, -1\}$  and “base” to particles with  $q = \{0, 1\}$ , whereas the MC exchange of free ions allows any integer charge values of  $Z^+$  and  $Z^-$ .

Here we provide several practical examples for modeling charge regulation effects in solvated systems. An acid ionization reaction ( $A \rightleftharpoons A^- + H^+$ ) can be defined via a single line in the input file

```
fix acid_reaction all charge/regulation 2 3 acid_type 1 pH 7.0 pKa 5.0 pIp 7.0 pIm 7.0
```

where the fix attempts to charge A (discharge  $A^-$ ) to  $A^-$  (A) and insert (delete) a proton (atom type 2). Besides, the fix implements self-ionization reaction of water  $\emptyset \rightleftharpoons H^+ + OH^-$ .

However, this approach is highly inefficient at  $pH \approx 7$  when the concentration of both protons and hydroxyl ions is low, resulting in a relatively low acceptance rate of MC moves.

A more efficient way is to allow salt ions to participate in ionization reactions, which can be easily achieved via

```
fix acid_reaction2 all charge/regulation 4 5 acid_type 1 pH 7.0 pKa 5.0 pIp 2.0 pIm 2.0
```

where particles of atom type 4 and 5 are the salt cations and anions, both at activity (effective concentration) of  $10^{-2}$  mol/l, see (*Curkl*) and (*Landsgesell*) for more details.

We could have simultaneously added a base ionization reaction ( $B \rightleftharpoons B^+ + OH^-$ )

```
fix acid_base_reaction all charge/regulation 2 3 acid_type 1 base_type 6 pH 7.0 pKa 5.0
→pKb 6.0 pIp 7.0 pIm 7.0
```

where the fix will attempt to charge B (discharge  $B^+$ ) to  $B^+$  (B) and insert (delete) a hydroxyl ion  $OH^-$  of atom type 3.

Dissociated ions and salt ions can be combined into a single particle type, which reduces the number of necessary MC moves and increases sampling performance, see (*Curkl*). The  $H^+$  and monovalent salt cation ( $S^+$ ) are combined into a single particle type,  $X^+ = \{H^+, S^+\}$ . In this case “pIp” refers to the effective concentration of the combined cation type  $X^+$  and its value is determined by  $10^{-pIp} = 10^{-pH} + 10^{-pSp}$ , where  $10^{-pSp}$  is the effective concentration of salt cations. For example, at  $pH=7$  and  $pSp=6$  we would find  $pIp \sim 5.958$  and the command that performs reactions with combined ions could read,

```
fix acid_reaction_combined all charge/regulation 2 3 acid_type 1 pH 7.0 pKa 5.0 pIp 5.
→958 pIm 5.958
```

If neither the acid or the base type is specified, for example,

```
fix salt_reaction all charge/regulation 4 5 pIp 2.0 pIm 2.0
```

the fix simply inserts or deletes an ion pair of a free cation (atom type 4) and a free anion (atom type 5) as done in a conventional grand-canonical MC simulation. Multivalent ions can be inserted (deleted) by using the *onlysalt* keyword.

This fix is compatible with LAMMPS packages such as MOLECULE or RIGID. The acid and base particles can be part of larger molecules or rigid bodies. Free ions that are inserted to or deleted from the system must be defined as single particles (no bonded interactions allowed) and cannot be part of larger molecules or rigid bodies. If an atom style with molecule IDs is used, all inserted ions have a molecule ID equal to zero.

Note that LAMMPS implicitly assumes a constant number of particles (degrees of freedom). Since using this fix alters the total number of particles during the simulation, any thermostat used by LAMMPS, such as NVT or Langevin, must use a dynamic calculation of system temperature. This can be achieved by specifying a dynamic temperature compute (e.g. dtemp) and using it with the desired thermostat, e.g. a Langevin thermostat:

```
compute dtemp all temp
compute_modify dtemp dynamic/dof yes
```

(continues on next page)

(continued from previous page)

```
fix ft all langevin 1.0 1.0 1.0 123
fix_modify ft temp dtemp
```

The units of pH, pKa, pKb, pIp, pIm are considered to be in the standard  $-\log_{10}$  representation assuming reference concentration  $\rho_0 = \text{mol/l}$ . For example, in the dilute ideal solution limit, the concentration of free cations will be  $c_1 = 10^{-\text{pIp}} \text{mol/l}$ . To perform the internal unit conversion, the value of the LAMMPS unit length must be specified in nanometers via *lunit\_nm*. The default value is set to the Bjerrum length in water at room temperature (0.71 nm), *lunit\_nm* = 0.71.

The temperature used in MC acceptance probability is set by *temp*. This temperature should be the same as the temperature set by the molecular dynamics thermostat. For most purposes, it is probably best to use *tempfixid* keyword which dynamically sets the temperature equal to the chosen MD thermostat temperature, in the example above we assumed the thermostat fix-ID is *fT*. The inserted particles attain a random velocity corresponding to the specified temperature. Using *tempfixid* overrides any fixed temperature set by *temp*.

The *rxid* keyword can be used to restrict the inserted/deleted counterions to a specific radial distance from an acid or base particle that is currently participating in a reaction. This can be used to simulate more realistic reaction dynamics. If *rxid* = 0 or *rxid* >  $L/2$ , where  $L$  is the smallest box dimension, the radial restriction is automatically turned off and free ion can be inserted or deleted anywhere in the simulation box.

If the *tag yes* is used, every inserted atom gets a unique tag ID, otherwise, the tag of every inserted atom is set to 0. *tag yes* might cause an integer overflow in very long simulations since the tags are unique to every particle and thus increase with every successful particle insertion.

The *pmcmoves* keyword sets the relative probability of attempting the three types of MC moves (reactions): acid charging, base charging, and ion pair exchange. The fix only attempts to perform particle charging MC moves if *acid\_type* or *base\_type* is defined. Otherwise fix only performs free ion insertion/deletion. For example, if *acid\_type* is not defined, *pmcA* is automatically set to 0. The vector *pmcmoves* is automatically normalized, for example, if set to *pmcmoves* 0 0.33 0.33, the vector would be normalized to [0,0.5,0.5].

The *only\_salt* option can be used to perform multivalent grand-canonical ion-exchange moves. If *only\_salt yes* is used, no charge exchange is performed, only ion insertion/deletion (*pmcmoves* is set to [0,0,1]), but ions can be multivalent. In the example above, an MC move would consist of three ion insertion/deletion to preserve the charge neutrality of the system.

The *group* keyword can be used to add inserted particles to a specific group-ID. All inserted particles are automatically added to group *all*.

## 2.36.4 Output

This fix computes a global vector of length 8, which can be accessed by various output commands. The vector values are the following global quantities:

1. cumulative MC attempts
2. cumulative MC successes
3. current # of neutral acid atoms
4. current # of -1 charged acid atoms
5. current # of neutral base atoms
6. current # of +1 charged base atoms
7. current # of free cations
8. current # of free anions

## 2.36.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The *atom\_style*, used must contain the charge property and have per atom type masses, for example, the style could be *charge* or *full*. Only usable for 3D simulations. Atoms specified as free ions cannot be part of rigid bodies or molecules and cannot have bonding interactions. The scheme is limited to integer charges, any atoms with non-integer charges will not be considered by the fix.

All interaction potentials used must be continuous, otherwise the MD integration and the particle exchange MC moves do not correspond to the same equilibrium ensemble. For example, if an lj/cut pair style is used, the LJ potential must be shifted so that it vanishes at the cutoff. This can be easily achieved using the *pair\_modify* command, i.e., by using: *pair\_modify shift yes*.

---

**Note:** Region restrictions are not yet implemented.

## 2.37 fix cmap command

### 2.37.1 Syntax

`fix ID group-ID cmap filename`

- ID, group-ID are documented in *fix* command
- cmap = style name of this fix command
- filename = force-field file with CMAP coefficients

## 2.37.2 Examples

```
fix          myCmap all cmap ../potentials/cmap36.data
read_data    proteinX.data fix myCmap crossterm CMAP
fix_modify   myCmap energy yes
```

## 2.37.3 Description

This command enables CMAP 5-body interactions to be added to simulations which use the CHARMM force field. These are relevant for any CHARMM model of a peptide or protein sequences that is 3 or more amino-acid residues long; see ([Buck](#)) and ([Brooks](#)) for details, including the analytic energy expressions for CMAP interactions. The CMAP 5-body terms add additional potential energy contributions to pairs of overlapping phi-psi dihedrals of amino-acids, which are important to properly represent their conformational behavior.

The examples/cmap directory has a sample input script and data file for a small peptide, that illustrates use of the fix cmap command.

As in the example above, this fix should be used before reading a data file that contains a listing of CMAP interactions. The *filename* specified should contain the CMAP parameters for a particular version of the CHARMM force field. Two such files are including in the lammps/potentials directory: charmm22.cmap and charmm36.cmap.

The data file read by the “read\_data” must contain the topology of all the CMAP interactions, similar to the topology data for bonds, angles, dihedrals, etc. Specially it should have a line like this in its header section:

```
N crossterms
```

where N is the number of CMAP 5-body interactions. It should also have a section in the body of the data file like this with N lines:

```
CMAP
```

1	1	8	10	12	18	20
2	5	18	20	22	25	27
[...]						
N	3	314	315	317	318	330

The first column is an index from 1 to N to enumerate the CMAP 5-atom tuples; it is ignored by LAMMPS. The second column is the “type” of the interaction; it is an index into the CMAP force field file. The remaining 5 columns are the atom IDs of the atoms in the two 4-atom dihedrals that overlap to create the CMAP interaction. Note that the “crossterm” and “CMAP” keywords for the header and body sections match those specified in the read\_data command following the data file name; see the [read\\_data](#) page for more details.

A data file containing CMAP 5-body interactions can be generated from a PDB file using the charmm2lammps.pl script in the tools/ch2lmp directory of the LAMMPS distribution. The script must be invoked with the optional “-cmap” flag to do this; see the tools/ch2lmp/README file for more information. The same conversion script also creates the file of CMAP coefficient data which is read by this command.

The potential energy associated with CMAP interactions can be output as described below. It can also be included in the total potential energy of the system, as output by the *thermo\_style* command, if the *fix\_modify energy* command is used, as in the example above. See the note below about how to include the CMAP energy when performing an *energy minimization*.

### 2.37.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the list of CMAP cross-terms to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify energy* option is supported by this fix to add the potential energy of the CMAP interactions to both the global potential energy and peratom potential energies of the system as part of *thermodynamic output* or output by the *compute pe/atom* command. The default setting for this fix is *fix\_modify energy yes*.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the CMAP interactions to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

---

**Note:** For energy minimization, if you want the potential energy associated with the CMAP terms forces to be included in the total potential energy of the system (the quantity being minimized), you **MUST** not disable the *fix\_modify energy* option for this fix.

---

### 2.37.5 Restrictions

To function as expected this fix command must be issued *before* a *read\_data* command but *after* a *read\_restart* command.

This fix can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* page for more info.

## 2.38 fix colvars command

### 2.38.1 Syntax

```
fix ID group-ID colvars *configfile* keyword value ...
```

- *ID*, *group-ID* are documented in *fix* command
- “colvars” = style name of this fix command
- *configfile* = configuration file for Colvars (use “none” to provide it inline)
- keyword = *output* or *input* or *unwrap* or *tstat* or *seed*  
*output* value = state filename/prefix for Colvars (default: "out")  
*input* value = input state filename/prefix for Colvars (optional, default: "NULL")  
*unwrap* value = "yes" or "no" (default: "yes")  
*tstat* value = fix ID of thermostat applied to relevant atoms (default: "NULL")  
*seed* value = seed for random number generator (default: 1966)

### 2.38.2 Examples

```
# Create the fix using a config file, set prefix for its output files
fix Colvars all colvars colvars.inp output ${JOB}

# Communicate the LAMMPS target temperature to the Colvars module
fix_modify Colvars tstat NPT

# Add a new restraint specific to this LAMMPS run
fix_modify Colvars config ""
harmonic {
    name restraint
    colvars distance1 distance2
    centers ${ref1} ${ref2}
    forceConstant ${kappa}
}""
```

### 2.38.3 Description

This fix interfaces LAMMPS to the collective variables [Colvars](#) library, which allows to accelerate sampling of rare events and the computation of free energy surfaces and potentials of mean force (PMFs) for any set of collective variables using a variety of sampling methods (e.g. umbrella-sampling, metadynamics, ABF...).

This documentation describes only the “fix colvars” command itself in a LAMMPS script. The Colvars library is fully documented in the included [PDF manual](#) or in the webpage <https://colvars.github.io/colvars-refman-lammps/colvars-refman-lammps.html>.

The Colvars library is developed at <https://github.com/Colvars/colvars>. A detailed discussion of its implementation is in (*Fiorin*); additional citations for specific features are printed at runtime if these features are used.

There are example scripts on the [Colvars website](#) as well as in the `examples/PACKAGES/colvars` directory in the LAMMPS source tree.

The only required argument to the fix is the name of the Colvars configuration file. The contents of this file are independent from the MD engine in which the Colvars library has been integrated, save for the units that are specific to each engine. In LAMMPS, the units used by Colvars are consistent with those specified by the *units* command.

New in version Colvars\_2023-06-04: The special value “none” (lowercase) initializes an empty Colvars module, which allows loading configuration dynamically using *fix\_modify* (see below).

The *group-ID* entry is ignored. “fix colvars” will always apply to the entire system, but specific atoms will be selected based on selection keywords in the Colvars configuration file or files. There is no need to define multiple “fix colvars” instances and it is not allowed.

The “output” keyword allows to specify the prefix of output files generated by Colvars, for example “output.colvars.traj” or “output.pmf”. Supplying an empty string suppresses any file output from Colvars to file, except for data saved into the LAMMPS *binary restart* files.

The “input” keyword allows to specify an optional state file that contains the restart information needed to continue a previous simulation state. However, because “fix colvars” records its state in LAMMPS *binary restart* files, this is usually not needed when using the *read\_restart* command.

The *unwrap* keyword controls whether wrapped or unwrapped coordinates are passed to the Colvars library for calculation of the collective variables and the resulting forces. The default is *yes*, i.e. the image flags are used to reconstruct the absolute atom positions. Setting this to *no* will use the current local coordinates that are wrapped back into the simulation cell at each re-neighboring step instead. For information about when and how this affects results, please see [https://colvars.github.io/colvars-refman-lammps/colvars-refman-lammps.html#sec:colvar\\_atom\\_groups\\_wrapping](https://colvars.github.io/colvars-refman-lammps/colvars-refman-lammps.html#sec:colvar_atom_groups_wrapping).

The *tstat* keyword can be either “NULL” or the label of a thermostating fix that thermostats all atoms in the fix colvars group. This will be used to provide the colvars module with the current thermostat target temperature.

The *seed* keyword contains the seed for the random number generator that will be used in the colvars module.

## 2.38.4 Restarting

This fix writes the current state of the Colvars module into *binary restart files*. This is in addition to the text-mode “.colvars.state” state file that is written by the Colvars module itself. The information contained in both files is identical, and the binary LAMMPS restart file is also used by fix colvars when *read\_restart* is called in a LAMMPS script. In that case, there is typically no need to specify the *input* keyword.

As long as LAMMPS binary restarts will be used to continue a simulation, it is safe to delete the “.colvars.state” files to save space. However, when a LAMMPS simulation is restarted using *read\_data*, the Colvars state file must be available and loaded via the “input” keyword or via a “fix\_modify Colvars load” command (see below).

When restarting, the fix and the Colvars module should be created and configured using the original configuration file(s).

## 2.38.5 Output

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the energy due to all external potentials defined in the Colvars configuration. The scalar value calculated by this fix is “extensive”.

Aside from the state information in a “.colvars.state” file, other *output files* are produced by Colvars depending on the type of simulation. For this reason, the “output” keyword is required for fix colvars.

## 2.38.6 Controlling Colvars via *fix\_modify*

New in version Colvars\_2023-06-04.

The *fix\_modify* command may be used on “fix colvars” in either one of two ways:

- (1) Provide updated values for the fix parameters, such as *output*, *input*, *unwrap*, *tstat* and *seed*. Additionally, the *fix\_modify energy* keyword is supported by this fix to add the energy change from the biasing force added by Colvars to the global potential energy of the system as part of *thermodynamic output* (the default is *fix\_modify energy no*). For example, in a multi-step LAMMPS script involving multiple thermostats (e.g. fix nvt followed by fix npt), Colvars can read a new thermostat’s target temperature like this:

```
fix NVT all nvt ...
fix Colvars all colvars <configfile> output equil1 tstat NVT
run <NUMSTEPS>
unfix nvt
fix NPT all n ...
fix_modify Colvars tstat NPT
fix_modify Colvars output equil2
```

- (2) Call one of the scripting functions provided by the Colvars module itself (a full list is available in the Colvars doc). The arguments to these functions are provided as strings and passed to Colvars.

LAMMPS variables referenced by their string representation “\${variable}” will be expanded immediately. Note also that this variable expansion *will also happen within quotes*, similar to what the *mdi* command provides. This feature makes it possible to use the values of certain LAMMPS variables in Colvars configuration strings. For example, to synchronize the LAMMPS and Colvars dump frequencies:

```
variable freq index 10000
dump myDump all atom/zstd ${freq} dump.atom.zstd
fix_modify Colvars config "colvarsTrajFrequency ${freq}"
```

---

**Note:** Although it is possible to use *fix\_modify* at any time, its results will only reflect the state of the Colvars module at the end of the most recent “run” or “minimize” command. Any new configuration added via “fix\_modify Colvars configfile” or “fix\_modify Colvars config” will only be loaded when the simulation resumes. Configuration files or strings will be parsed in the same sequence as they were provided in the LAMMPS script.

---

## 2.38.7 Restrictions

This fix is provided by the COLVARS package and is only available if LAMMPS was built with that package (default in most builds). Some of the features also require code available from the LEPTON package. See the [Build package](#) page for more info.

There can only be one Colvars instance defined at a time. Since the interface communicates only the minimum required amount of information, and the Colvars module itself can handle an arbitrary number of collective variables, this is not a limitation of functionality.

## 2.38.8 Related commands

*fix smd, fix spring, fix plumed*

---

## 2.39 fix controller command

### 2.39.1 Syntax

```
fix ID group-ID controller Nevery alpha Kp Ki Kd pvar setpoint cvar
```

- ID, group-ID are documented in *fix* command
- controller = style name of this fix command
- Nevery = invoke controller every this many timesteps
- alpha = coupling constant for PID equation (see units discussion below)
- Kp = proportional gain in PID equation (unitless)
- Ki = integral gain in PID equation (unitless)
- Kd = derivative gain in PID equation (unitless)
- pvar = process variable of form c\_ID, c\_ID[I], f\_ID, f\_ID[I], or v\_name

```
c_ID = global scalar calculated by a compute with ID
c_ID[I] = Ith component of global vector calculated by a compute with ID
f_ID = global scalar calculated by a fix with ID
f_ID[I] = Ith component of global vector calculated by a fix with ID
v_name = value calculated by an equal-style variable with name
```

- setpoint = desired value of process variable (same units as process variable)
- cvar = name of control variable

### 2.39.2 Examples

```
fix 1 all controller 100 1.0 0.5 0.0 0.0 c_thermo_temp 1.5 tcontrol
fix 1 all controller 100 0.2 0.5 0 100.0 v_pxxwall 1.01325 xwall
fix 1 all controller 10000 0.2 0.5 0 2000 v_avpe -3.785 tcontrol
```

### 2.39.3 Description

This fix enables control of a LAMMPS simulation using a control loop feedback mechanism known as a proportional-integral-derivative (PID) controller. The basic idea is to define a “process variable” which is a quantity that can be monitored during a running simulation. A desired target value is chosen for the process variable. A “control variable” is also defined which is an adjustable attribute of the running simulation, which the process variable will respond to. The PID controller continuously adjusts the control variable based on the difference between the process variable and the target.

Here are examples of ways in which this fix can be used. The examples/pid directory contains a script that implements the simple thermostat.

Goal	process variable	control variable
Simple thermostat	instantaneous T	thermostat target T
Find melting temperature	average PE per atom	thermostat target T
Control pressure in non-periodic system	force on wall	position of wall

**Note:** For this fix to work, the control variable must actually induce a change in a running LAMMPS simulation. Typically this will only occur if there is some other command (e.g. a thermostat fix) which uses the control variable as an input parameter. This could be done directly or indirectly, e.g. the other command uses a variable as input whose formula uses the control variable. The other command should alter its behavior dynamically as the variable changes.

**Note:** If there is a command you think could be used in this fashion, but does not currently allow a variable as an input parameter, please notify the LAMMPS developers. It is often not difficult to enable a command to use a variable as an input parameter.

The group specified with this command is ignored. However, note that the process variable may be defined by calculations performed by computes and fixes which store their own “group” definitions.

The PID controller is invoked once each *Nevery* timesteps.

The PID controller is implemented as a discretized version of the following dynamic equation:

$$\frac{dc}{dt} = -\alpha(K_p e + K_i \int_0^t e dt + K_d \frac{de}{dt})$$

where  $c$  is the continuous time analog of the control variable,  $e = pvar - setpoint$  is the error in the process variable, and  $\alpha$ ,  $K_p$ ,  $K_i$ , and  $K_d$  are constants set by the corresponding keywords described above. The discretized version of this equation is:

$$c_n = c_{n-1} - \alpha \left( K_p \tau e_n + K_i \tau^2 \sum_{i=1}^n e_i + K_d (e_n - e_{n-1}) \right)$$

where  $\tau = Nevery \cdot timestep$  is the time interval between updates, and the subscripted variables indicate the values of  $c$  and  $e$  at successive updates.

From the first equation, it is clear that if the three gain values  $K_p$ ,  $K_i$ ,  $K_d$  are dimensionless constants, then  $\alpha$  must have units of  $[unit\ cvar]/[unit\ pvar]/[unit\ time]$  e.g.  $[eV/K/ps]$ . The advantage of this unit scheme is that the value of the constants should be invariant under a change of either the MD timestep size or the value of *Nevery*. Similarly, if the LAMMPS *unit style* is changed, it should only be necessary to change the value of  $\alpha$  to reflect this, while leaving  $K_p$ ,  $K_i$ , and  $K_d$  unaltered.

When choosing the values of the four constants, it is best to first pick a value and sign for  $\alpha$  that is consistent with the magnitudes and signs of  $pvar$  and  $cvar$ . The magnitude of  $K_p$  should then be tested over a large positive range keeping  $K_i = K_d = 0$ . A good value for  $K_p$  will produce a fast response in  $pvar$ , without overshooting the *setpoint*. For many applications, proportional feedback is sufficient, and so  $K_i = K_d = 0$  can be used. In cases where there is a substantial lag time in the response of  $pvar$  to a change in  $cvar$ , this can be counteracted by increasing  $K_d$ . In situations where  $pvar$  plateaus without reaching *setpoint*, this can be counteracted by increasing  $K_i$ . In the language of Charles Dickens,  $K_p$  represents the error of the present,  $K_i$  the error of the past, and  $K_d$  the error yet to come.

Because this fix updates  $cvar$ , but does not initialize its value, the initial value  $c_0$  is that assigned by the user in the input script via the *internal-style variable* command. This value is used (by every other LAMMPS command that uses the variable) until this fix performs its first update of  $cvar$  after *Nevery* timesteps. On the first update, the value of the derivative term is set to zero, because the value of  $e_{n-1}$  is not yet defined.

---

The process variable  $pvar$  can be specified as the output of a *compute* or *fix* or the evaluation of a *variable*. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity.

If  $pvar$  begins with “c\_”, a compute ID must follow which has been previously defined in the input script and which generates a global scalar or vector. See the individual *compute* doc page for details. If no bracketed integer is appended, the scalar calculated by the compute is used. If a bracketed integer is appended, the *I*th value of the vector calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*.

If  $pvar$  begins with “f\_”, a fix ID must follow which has been previously defined in the input script and which generates a global scalar or vector. See the individual *fix* page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when fix controller references the values, or else an error results. If no bracketed integer is appended, the scalar calculated by the fix is used. If a bracketed integer is appended, the *I*th value of the vector calculated by the fix is used. Users can also write code for their own fix style and *add them to LAMMPS*.

If  $pvar$  begins with “v\_”, a variable name must follow which has been previously defined in the input script. Only equal-style variables can be referenced. See the *variable* command for details. Note that variables of style *equal* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying the process variable.

The target value *setpoint* for the process variable must be a numeric value, in whatever units  $pvar$  is defined for.

The control variable  $cvar$  must be the name of an *internal-style variable* previously defined in the input script. Note that it is not specified with a “v\_” prefix, just the name of the variable. It must be an internal-style variable, because this fix updates its value directly. Note that other commands can use an equal-style versus internal-style variable interchangeably.

---

## 2.39.4 Restart, fix\_modify, output, run start/stop, minimize info

Currently, no information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix produces a global vector with 3 values which can be accessed by various *output commands*. The values can be accessed on any timestep, though they are only updated on timesteps that are a multiple of *Nevery*.

The three values are the most recent updates made to the control variable by each of the 3 terms in the PID equation above. The first value is the proportional term, the second is the integral term, the third is the derivative term.

The units of the vector values will be whatever units the control variable is in. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.39.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 2.39.6 Related commands

*fix adapt*

### 2.39.7 Default

none

## 2.40 fix damping/cundall command

### 2.40.1 Syntax

```
fix ID group-ID damping/cundall gamma_l gamma_a keyword values ...
```

- ID, group-ID are documented in *fix* command
- damping/cundall = style name of this fix command
- gamma\_l = linear damping coefficient (dimensionless)
- gamma\_a = angular damping coefficient (dimensionless)
- zero or more keyword/value pairs may be appended

keyword = *scale*

scale values = *type ratio* or *v\_name*

type = atom type (1-N)

ratio = factor to scale the damping coefficients by

v\_name = reference to atom style variable *name*

### 2.40.2 Examples

```
fix 1 all damping/cundall 0.8 0.8
fix 1 all damping/cundall 0.8 0.5 scale 3 2.5
fix a all damping/cundall 0.8 0.5 scale v_radscale
```

### 2.40.3 Description

Add damping force and torque to finite-size spherical particles in the group following the model of [Cundall, 1987](#), as implemented in other granular physics code (e.g., [Yade-DEM](#), [PFC](#)).

The damping is constructed to always have negative mechanical power with respect to the current velocity/angular velocity to ensure dissipation of kinetic energy. If used without additional thermostating (to add kinetic energy to the system), it has the effect of slowly (or rapidly) freezing the system; hence it can also be used as a simple energy minimization technique.

The magnitude of the damping force/torque  $F_d/T_d$  is a fraction  $\gamma \in [0; 1]$  of the current force/torque  $F/T$  on the particle. Damping is applied component-by-component in each direction  $k \in \{x, y, z\}$ :

$$F_{dk} = -\gamma_l F_k \text{sign}(F_k v_k)$$

$$T_{dk} = -\gamma_a T_k \text{sign}(T_k \omega_k)$$

The larger the coefficients, the faster the kinetic energy is reduced.

If the optional keyword *scale* is used,  $\gamma_l$  and  $\gamma_a$  can be scaled up or down by the specified factor for atoms. This factor can be set for different atom types and thus the *scale* keyword used multiple times followed by the atom type and the associated scale factor. Alternately the scaling factor can be computed for each atom (e.g. based on its radius) by using an *atom-style variable*.

---

**Note:** The damping force/torque is computed based on the force/torque at the moment this fix is invoked. Any force/torque added after this fix, e.g., by *fix addforce* or *fix addtorque* will not be damped. When performing simulations with gravity, invoking *fix gravity* after this fix will maintain the specified gravitational acceleration.

---

---

**Note:** This scheme is dependent on the coordinates system and does not correspond to realistic physical processes. It is constructed for numerical convenience and efficacy.

---

This non-viscous damping presents the following advantages:

1. damping is independent of velocity, equally damping regions with distinct natural frequencies,
  2. damping affects acceleration and vanishes for steady uniform motion of the particles,
  3. damping parameter  $\gamma$  is dimensionless and does not require scaling.
- 

### 2.40.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is modifying forces/torques. Default is the outermost level.

The forces/torques due to this fix are imposed during an energy minimization, invoked by the *minimize* command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the *min\_style* command for details.

## 2.40.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix requires that atoms store torque and a radius as defined by the [atom\\_style sphere](#) command.

## 2.40.6 Related commands

# 2.41 fix deform command

Accelerator Variants: *deform/kk*

## 2.41.1 Syntax

```
fix ID group-ID deform N parameter style args ... keyword value ...
```

- ID, group-ID are documented in [fix](#) command
- N = perform box deformation every this many timesteps
- one or more parameter/args sequences may be appended

parameter = x or y or z or xy or xz or yz

x, y, z args = style value(s)

style = *final* or *delta* or *scale* or *vel* or *erate* or *trate* or *volume* or *wiggle* or *↪*

*variable* or *pressure* or *pressure/mean*

*final* values = lo hi

lo hi = box boundaries at end of run (distance units)

*delta* values = dlo dhi

dlo dhi = change in box boundaries at end of run (distance units)

*scale* values = factor

factor = multiplicative factor for change in box length at end of run

*vel* value = V

V = change box length at this velocity (distance/time units),

effectively an engineering strain rate  
*erate* value = R  
R = engineering strain rate (1/time units)  
*trate* value = R  
R = true strain rate (1/time units)  
*volume* value = none = adjust this dim to preserve volume of system  
*wiggle* values = A Tp  
A = amplitude of oscillation (distance units)  
Tp = period of oscillation (time units)  
*variable* values = v\_name1 v\_name2  
v\_name1 = variable with name1 for box length change as function of time  
v\_name2 = variable with name2 for change rate as function of time

xy, xz, yz args = style value  
style = *final* or *delta* or *vel* or *erate* or *trate* or *wiggle* or *variable*  
*final* value = tilt  
tilt = tilt factor at end of run (distance units)  
*delta* value = dtilt  
dtilt = change in tilt factor at end of run (distance units)  
*vel* value = V  
V = change tilt factor at this velocity (distance/time units),  
effectively an engineering shear strain rate  
*erate* value = R  
R = engineering shear strain rate (1/time units)  
*trate* value = R  
R = true shear strain rate (1/time units)  
*wiggle* values = A Tp  
A = amplitude of oscillation (distance units)  
Tp = period of oscillation (time units)  
*variable* values = v\_name1 v\_name2  
v\_name1 = variable with name1 for tilt change as function of time  
v\_name2 = variable with name2 for change rate as function of time

- zero or more keyword/value pairs may be appended
- keyword = *remap* or *flip* or *units* or *couple* or *vol/balance/p* or *max/rate* or *normalize/pressure*

*remap* value = x or v or none  
x = remap coords of atoms in group into deforming box  
v = remap velocities of atoms in group when they cross periodic boundaries  
none = no remapping of x or v  
*flip* value = yes or no  
allow or disallow box flips when it becomes highly skewed  
*units* value = *lattice* or *box*  
lattice = distances are defined in lattice units  
box = distances are defined in simulation box units

## 2.41.2 Examples

```
fix 1 all deform 1 x final 0.0 9.0 z final 0.0 5.0 units box
fix 1 all deform 1 x trate 0.1 y volume z volume
fix 1 all deform 1 xy erate 0.001 remap v
fix 1 all deform 10 y delta -0.5 0.5 xz vel 1.0
```

## 2.41.3 Description

Change the volume and/or shape of the simulation box during a dynamics run. Orthogonal simulation boxes have 3 adjustable parameters (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable parameters (x,y,z,xy,xz,yz). Any or all of them can be adjusted independently and simultaneously.

The *fix deform/pressure* command extends this command with additional keywords and arguments. The rest of this page explains the options common to both commands. The *fix deform/pressure* page explains the options available ONLY with the *fix deform/pressure* command. Note that a simulation can define only a single deformation command: *fix deform* or *fix deform/pressure*.

Both these fixes can be used to perform non-equilibrium MD (NEMD) simulations of a continuously strained system. See the *fix nvt/sllod* and *compute temp/deform* commands for more details. Note that simulation of a continuously extended system (extensional flow) can be modeled using the *UEF package* and its *fix commands*.

---

### Inconsistent trajectories due to image flags

When running long simulations while shearing the box or using a high shearing rate, it is possible that the image flags used for storing unwrapped atom positions will “wrap around”. When LAMMPS is compiled with the default settings, case image flags are limited to a range of  $-512 \leq i \leq 511$ , which will overflow when atoms starting at zero image flag value have passed through a periodic box dimension more than 512 times.

Changing the *size of LAMMPS integer types* to the “bigbig” setting can make this overflow much less likely, since it increases the image flag value range to  $-1,048,576 \leq i \leq 1,048,575$

---

For the *x*, *y*, *z* parameters, the associated dimension cannot be shrink-wrapped. For the *xy*, *yz*, *xz* parameters, the associated second dimension cannot be shrink-wrapped. Dimensions not varied by this command can be periodic or non-periodic. Dimensions corresponding to unspecified parameters can also be controlled by a *fix npt* or *fix nph* command.

The size and shape of the simulation box at the beginning of the simulation run were either specified by the *create\_box* or *read\_data* or *read\_restart* command used to setup the simulation initially if it is the first run, or they are the values from the end of the previous run. The *create\_box*, *read\_data*, and *read\_restart* commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the *xy,xz,yz* tilt factors. If *fix deform* changes the *xy,xz,yz* tilt factors, then the simulation box must be triclinic, even if its initial tilt factors are 0.0.

As described below, the desired simulation box size and shape at the end of the run are determined by the parameters of the *fix deform* command. Every *N*th timestep during the run, the simulation box is expanded, contracted, or tilted to ramped values between the initial and final values.

---

For the *x*, *y*, and *z* parameters, this is the meaning of their styles and values.

The *final*, *delta*, *scale*, *vel*, and *erate* styles all change the specified dimension of the box via “constant displacement” which is effectively a “constant engineering strain rate”. This means the box dimension changes linearly with time from its initial to final value.

For style *final*, the final lo and hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *delta*, plus or minus changes in the lo/hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *scale*, a multiplicative factor to apply to the box length of a dimension is specified. For example, if the initial box length is 10, and the factor is 1.1, then the final box length will be 11. A factor less than 1.0 means compression.

For style *vel*, a velocity at which the box length changes is specified in units of distance/time. This is effectively a “constant engineering strain rate”, where  $\text{rate} = V/L_0$  and  $L_0$  is the initial box length. The distance can be in lattice or box distance units. See the discussion of the units keyword below. For example, if the initial box length is 100 Angstroms, and  $V$  is 10 Angstroms/ps, then after 10 ps, the box length will have doubled. After 20 ps, it will have tripled.

The *erate* style changes a dimension of the box at a “constant engineering strain rate”. The units of the specified strain rate are 1/time. See the [units](#) command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Tensile strain is unitless and is defined as  $\text{delta}/L_0$ , where  $L_0$  is the original box length and delta is the change relative to the original length. The box length  $L$  as a function of time will change as

$$L(t) = L_0 (1 + \text{erate} \cdot dt)$$

where  $dt$  is the elapsed time (in time units). Thus if *erate*  $R$  is specified as 0.1 and time units are picoseconds, this means the box length will increase by 10% of its original length every picosecond. I.e. strain after 1 ps = 0.1, strain after 2 ps = 0.2, etc.  $R = -0.01$  means the box length will shrink by 1% of its original length every picosecond. Note that for an “engineering” rate the change is based on the original box length, so running with  $R = 1$  for 10 picoseconds expands the box length by a factor of 11 (strain of 10), which is different than what the *trate* style would induce.

The *trate* style changes a dimension of the box at a “constant true strain rate”. Note that this is not an “engineering strain rate”, as the other styles are. Rather, for a “true” rate, the rate of change is constant, which means the box dimension changes non-linearly with time from its initial to final value. The units of the specified strain rate are 1/time. See the [units](#) command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Tensile strain is unitless and is defined as  $\text{delta}/L_0$ , where  $L_0$  is the original box length and delta is the change relative to the original length.

The box length  $L$  as a function of time will change as

$$L(t) = L_0 \exp(\text{trate} \cdot dt)$$

where  $dt$  is the elapsed time (in time units). Thus if *trate*  $R$  is specified as  $\ln(1.1)$  and time units are picoseconds, this means the box length will increase by 10% of its current (not original) length every picosecond. I.e. strain after 1 ps = 0.1, strain after 2 ps = 0.21, etc.  $R = \ln(2)$  or  $\ln(3)$  means the box length will double or triple every picosecond.  $R = \ln(0.99)$  means the box length will shrink by 1% of its current length every picosecond. Note that for a “true” rate the change is continuous and based on the current length, so running with  $R = \ln(2)$  for 10 picoseconds does not expand the box length by a factor of 11 as it would with *erate*, but by a factor of 1024 since the box length will double every picosecond.

Note that to change the volume (or cross-sectional area) of the simulation box at a constant rate, you can change multiple dimensions via *erate* or *trate*. E.g. to double the box volume in a picosecond, you could set “x erate  $M$ ”, “y erate  $M$ ”, “z erate  $M$ ”, with  $M = \text{pow}(2, 1/3) - 1 = 0.26$ , since if each box dimension grows by 26%, the box volume doubles. Or you could set “x trate  $M$ ”, “y trate  $M$ ”, “z trate  $M$ ”, with  $M = \ln(1.26) = 0.231$ , and the box volume would double every picosecond.

The *volume* style changes the specified dimension in such a way that the box volume remains constant while other box dimensions are changed explicitly via the styles discussed above. For example, “x scale 1.1 y scale 1.1 z volume” will shrink the z box length as the x,y box lengths increase, to keep the volume constant (product of x,y,z lengths). If “x scale 1.1 z volume” is specified and parameter y is unspecified, then the z box length will shrink as x increases to keep the product of x,z lengths constant. If “x scale 1.1 y volume z volume” is specified, then both the y,z box lengths will shrink as x increases to keep the volume constant (product of x,y,z lengths). In this case, the y,z box lengths shrink so as to keep their relative aspect ratio constant.

For solids or liquids, note that when one dimension of the box is expanded via `fix deform` (i.e. tensile strain), it may be physically undesirable to hold the other 2 box lengths constant (unspecified by `fix deform`) since that implies a density change. Using the *volume* style for those 2 dimensions to keep the box volume constant may make more physical sense, but may also not be correct for materials and potentials whose Poisson ratio is not 0.5. An alternative is to use *fix npt aniso* with zero applied pressure on those 2 dimensions, so that they respond to the tensile strain dynamically.

The *wiggle* style oscillates the specified box length dimension sinusoidally with the specified amplitude and period. I.e. the box length  $L$  as a function of time is given by

$$L(t) = L_0 + A \sin(2\pi t/T_p)$$

where  $L_0$  is its initial length. If the amplitude  $A$  is a positive number the box initially expands, then contracts, etc. If  $A$  is negative then the box initially contracts, then expands, etc. The amplitude can be in lattice or box distance units. See the discussion of the `units` keyword below.

The *variable* style changes the specified box length dimension by evaluating a variable, which presumably is a function of time. The variable with *name1* must be an *equal-style variable* and should calculate a change in box length in units of distance. Note that this distance is in box units, not lattice units; see the discussion of the `units` keyword below. The formula associated with variable *name1* can reference the current timestep. Note that it should return the “change” in box length, not the absolute box length. This means it should evaluate to 0.0 when invoked on the initial timestep of the run following the definition of `fix deform`. It should evaluate to a value  $> 0.0$  to dilate the box at future times, or a value  $< 0.0$  to compress the box.

The variable *name2* must also be an *equal-style variable* and should calculate the rate of box length change, in units of distance/time, i.e. the time-derivative of the *name1* variable. This quantity is used internally by LAMMPS to reset atom velocities when they cross periodic boundaries. It is computed internally for the other styles, but you must provide it when using an arbitrary variable.

Here is an example of using the *variable* style to perform the same box deformation as the *wiggle* style formula listed above, where we assume that the current timestep = 0.

```
variable A equal 5.0
variable Tp equal 10.0
variable displace equal "v_A * sin(2*PI * step*dt/v_Tp)"
variable rate equal "2*PI*v_A/v_Tp * cos(2*PI * step*dt/v_Tp)"
fix 2 all deform 1 x variable v_displace v_rate remap v
```

For the *scale*, *vel*, *erate*, *trate*, *volume*, *wiggle*, and *variable* styles, the box length is expanded or compressed around its mid point.

For the *xy*, *xz*, and *yz* parameters, this is the meaning of their styles and values. Note that changing the tilt factors of a triclinic box does not change its volume.

The *final*, *delta*, *vel*, and *erate* styles all change the shear strain at a “constant engineering shear strain rate”. This means the tilt factor changes linearly with time from its initial to final value.

For style *final*, the final tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the `units` keyword below.

For style *delta*, a plus or minus change in the tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the `units` keyword below.

For style *vel*, a velocity at which the tilt factor changes is specified in units of distance/time. This is effectively an “engineering shear strain rate”, where  $\text{rate} = V/L_0$  and  $L_0$  is the initial box length perpendicular to the direction of shear. The distance can be in lattice or box distance units. See the discussion of the `units` keyword below. For example, if the initial tilt factor is 5 Angstroms, and the  $V$  is 10 Angstroms/ps, then after 1 ps, the tilt factor will be 15 Angstroms. After 2 ps, it will be 25 Angstroms.

The *erate* style changes a tilt factor at a “constant engineering shear strain rate”. The units of the specified shear strain rate are 1/time. See the [units](#) command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Shear strain is unitless and is defined as offset/length, where length is the box length perpendicular to the shear direction (e.g. y box length for xy deformation) and offset is the displacement distance in the shear direction (e.g. x direction for xy deformation) from the unstrained orientation.

The tilt factor T as a function of time will change as

$$T(t) = T_0 + L_0 \cdot \text{erate} \cdot dt$$

where  $T_0$  is the initial tilt factor,  $L_0$  is the original length of the box perpendicular to the shear direction (e.g. y box length for xy deformation), and  $dt$  is the elapsed time (in time units). Thus if *erate* R is specified as 0.1 and time units are picoseconds, this means the shear strain will increase by 0.1 every picosecond. I.e. if the xy shear strain was initially 0.0, then strain after 1 ps = 0.1, strain after 2 ps = 0.2, etc. Thus the tilt factor would be 0.0 at time 0,  $0.1 \cdot y_{\text{box}}$  at 1 ps,  $0.2 \cdot y_{\text{box}}$  at 2 ps, etc, where  $y_{\text{box}}$  is the original y box length.  $R = 1$  or  $2$  means the tilt factor will increase by 1 or 2 every picosecond.  $R = -0.01$  means a decrease in shear strain by 0.01 every picosecond.

The *trate* style changes a tilt factor at a “constant true shear strain rate”. Note that this is not an “engineering shear strain rate”, as the other styles are. Rather, for a “true” rate, the rate of change is constant, which means the tilt factor changes non-linearly with time from its initial to final value. The units of the specified shear strain rate are 1/time. See the [units](#) command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Shear strain is unitless and is defined as offset/length, where length is the box length perpendicular to the shear direction (e.g. y box length for xy deformation) and offset is the displacement distance in the shear direction (e.g. x direction for xy deformation) from the unstrained orientation.

The tilt factor T as a function of time will change as

$$T(t) = T_0 \exp(\text{trate} \cdot dt)$$

where  $T_0$  is the initial tilt factor and  $dt$  is the elapsed time (in time units). Thus if *trate* R is specified as  $\ln(1.1)$  and time units are picoseconds, this means the shear strain or tilt factor will increase by 10% every picosecond. I.e. if the xy shear strain was initially 0.1, then strain after 1 ps = 0.11, strain after 2 ps = 0.121, etc.  $R = \ln(2)$  or  $\ln(3)$  means the tilt factor will double or triple every picosecond.  $R = \ln(0.99)$  means the tilt factor will shrink by 1% every picosecond. Note that the change is continuous, so running with  $R = \ln(2)$  for 10 picoseconds does not change the tilt factor by a factor of 10, but by a factor of 1024 since it doubles every picosecond. Note that the initial tilt factor must be non-zero to use the *trate* option.

Note that shear strain is defined as the tilt factor divided by the perpendicular box length. The *erate* and *trate* styles control the tilt factor, but assume the perpendicular box length remains constant. If this is not the case (e.g. it changes due to another fix deform parameter), then this effect on the shear strain is ignored.

The *wiggle* style oscillates the specified tilt factor sinusoidally with the specified amplitude and period. I.e. the tilt factor T as a function of time is given by

$$T(t) = T_0 + A \sin(2\pi t/T_p)$$

where  $T_0$  is its initial value. If the amplitude A is a positive number the tilt factor initially becomes more positive, then more negative, etc. If A is negative then the tilt factor initially becomes more negative, then more positive, etc. The amplitude can be in lattice or box distance units. See the discussion of the units keyword below.

The *variable* style changes the specified tilt factor by evaluating a variable, which presumably is a function of time. The variable with *name1* must be an [equal-style variable](#) and should calculate a change in tilt in units of distance. Note that this distance is in box units, not lattice units; see the discussion of the *units* keyword below. The formula associated with variable *name1* can reference the current timestep. Note that it should return the “change” in tilt factor, not the absolute tilt factor. This means it should evaluate to 0.0 when invoked on the initial timestep of the run following the definition of fix deform.

The variable *name2* must also be an [equal-style variable](#) and should calculate the rate of tilt change, in units of distance/time, i.e. the time-derivative of the *name1* variable. This quantity is used internally by LAMMPS to reset atom

velocities when they cross periodic boundaries. It is computed internally for the other styles, but you must provide it when using an arbitrary variable.

Here is an example of using the *variable* style to perform the same box deformation as the *wiggle* style formula listed above, where we assume that the current timestep = 0.

```
variable A equal 5.0
variable Tp equal 10.0
variable displace equal "v_A * sin(2*PI * step*dt/v_Tp)"
variable rate equal "2*PI*v_A/v_Tp * cos(2*PI * step*dt/v_Tp)"
fix 2 all deform 1 xy variable v_displace v_rate remap v
```

All of the tilt styles change the *xy*, *xz*, *yz* tilt factors during a simulation. In LAMMPS, tilt factors (*xy*, *xz*, *yz*) for triclinic boxes are normally bounded by half the distance of the parallel box length. See the discussion of the *flip* keyword below, to allow this bound to be exceeded, if desired.

For example, if *xlo* = 2 and *xhi* = 12, then the *x* box length is 10 and the *xy* tilt factor must be between -5 and 5. Similarly, both *xz* and *yz* must be between  $-(xhi-xlo)/2$  and  $+(yhi-ylo)/2$ . Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all equivalent.

To obey this constraint and allow for large shear deformations to be applied via the *xy*, *xz*, or *yz* parameters, the following algorithm is used. If *prd* is the associated parallel box length (10 in the example above), then if the tilt factor exceeds the accepted range of -5 to 5 during the simulation, then the box is flipped to the other limit (an equivalent box) and the simulation continues. Thus for this example, if the initial *xy* tilt factor was 0.0 and “*xy final 100.0*” was specified, then during the simulation the *xy* tilt factor would increase from 0.0 to 5.0, the box would be flipped so that the tilt factor becomes -5.0, the tilt factor would increase from -5.0 to 5.0, the box would be flipped again, etc. The flip occurs 10 times and the final tilt factor at the end of the simulation would be 0.0. During each flip event, atoms are remapped into the new box in the appropriate manner.

The one exception to this rule is if the first dimension in the tilt factor (*x* for *xy*) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

Each time the box size or shape is changed, the *remap* keyword determines whether atom positions are remapped to the new box. If *remap* is set to *x* (the default), atoms in the fix group are remapped; otherwise they are not. Note that their velocities are not changed, just their positions are altered. If *remap* is set to *v*, then any atom in the fix group that crosses a periodic boundary will have a delta added to its velocity equal to the difference in velocities between the *lo* and *hi* boundaries. Note that this velocity difference can include tilt components, e.g. a delta in the *x* velocity when an atom crosses the *y* periodic boundary. If *remap* is set to *none*, then neither of these remappings take place.

Conceptually, setting *remap* to *x* forces the atoms to deform via an affine transformation that exactly matches the box deformation. This setting is typically appropriate for solids. Note that though the atoms are effectively “moving” with the box over time, it is not due to their having a velocity that tracks the box change, but only due to the remapping. By contrast, setting *remap* to *v* is typically appropriate for fluids, where you want the atoms to respond to the change in box size/shape on their own and acquire a velocity that matches the box change, so that their motion will naturally track the box without explicit remapping of their coordinates.

**Note:** When non-equilibrium MD (NEMD) simulations are performed using this fix, the option “*remap v*” should normally be used. This is because *fix nvt/sllod* adjusts the atom positions and velocities to induce a velocity profile that matches the changing box size/shape. Thus atom coordinates should NOT be remapped by fix deform, but velocities SHOULD be when atoms cross periodic boundaries, since that is consistent with maintaining the velocity profile already created by fix nvt/sllod. LAMMPS will warn you if the *remap* setting is not consistent with fix nvt/sllod.

**Note:** For non-equilibrium MD (NEMD) simulations using “*remap v*” it is usually desirable that the fluid (or flowing material, e.g. granular particles) stream with a velocity profile consistent with the deforming box. As mentioned above, using a thermostat such as *fix nvt/sllod* or *fix langevin* (with a bias provided by *compute temp/deform*), will typically accomplish that. If you do not use a thermostat, then there is no driving force pushing the atoms to flow in a manner consistent with the deforming box. E.g. for a shearing system the box deformation velocity may vary from 0 at the bottom to 10 at the top of the box. But the stream velocity profile of the atoms may vary from -5 at the bottom to +5 at the top. You can monitor these effects using the *fix ave/chunk*, *compute temp/deform*, and *compute temp/profile* commands. One way to induce atoms to stream consistent with the box deformation is to give them an initial velocity profile, via the *velocity ramp* command, that matches the box deformation rate. This also typically helps the system come to equilibrium more quickly, even if a thermostat is used.

---

**Note:** If a *fix rigid* is defined for rigid bodies, and *remap* is set to *x*, then the center-of-mass coordinates of rigid bodies will be remapped to the changing simulation box. This will be done regardless of whether atoms in the rigid bodies are in the *fix deform* group or not. The velocity of the centers of mass are not remapped even if *remap* is set to *v*, since *fix nvt/sllod* does not currently do anything special for rigid particles. If you wish to perform a NEMD simulation of rigid particles, you can either thermostat them independently or include a background fluid and thermostat the fluid via *fix nvt/sllod*.

---

The *flip* keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed above. If the *flip* value is set to *yes*, the bound is enforced by flipping the box when it is exceeded. If the *flip* value is set to *no*, the tilt will continue to change without flipping. Note that if you apply large deformations, this means the box shape can tilt dramatically LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped subdomain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The *units* keyword determines the meaning of the distance units used to define various arguments. A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. Note that the units choice also affects the *vel* style parameters since it is defined in terms of distance/time. Also note that the units keyword does not affect the *variable* style. You should use the *xlat*, *ylat*, *zlat* keywords of the *thermo\_style* command if you want to include lattice spacings in a variable formula.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 2.41.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix will restore the initial box settings from *binary restart files*, which allows the fix to be properly continue deformation, when using the start/stop options of the *run* command. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*.

This fix can perform deformation over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

### 2.41.5 Restrictions

You cannot apply x, y, or z deformations to a dimension that is shrink-wrapped via the *boundary* command.

You cannot apply xy, yz, or xz deformations to a second dimension (y in xy) that is shrink-wrapped via the *boundary* command.

### 2.41.6 Related commands

*fix deform/pressure*, *change\_box*

### 2.41.7 Default

The option defaults are remap = x, flip = yes, and units = lattice.

## 2.42 fix deform/pressure command

### 2.42.1 Syntax

```
fix ID group-ID deform/pressure N parameter style args ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- deform/pressure = style name of this fix command
- N = perform box deformation every this many timesteps
- one or more parameter/args sequences may be appended

parameter = x or y or z or xy or xz or yz or box

x, y, z args = style value(s)

style = *final* or *delta* or *scale* or *vel* or *erate* or *trate* or *volume* or *wiggle* or *variable* or *pressure* or *pressure/mean*

*final* values = lo hi

lo hi = box boundaries at end of run (distance units)

*delta* values = dlo dhi

dlo dhi = change in box boundaries at end of run (distance units)

*scale* values = factor

factor = multiplicative factor for change in box length at end of run

*vel* value = V

V = change box length at this velocity (distance/time units),  
effectively an engineering strain rate

```
erate value = R
  R = engineering strain rate (1/time units)
trate value = R
  R = true strain rate (1/time units)
volume value = none = adjust this dim to preserve volume of system
wiggle values = A Tp
  A = amplitude of oscillation (distance units)
  Tp = period of oscillation (time units)
variable values = v_name1 v_name2
  v_name1 = variable with name1 for box length change as function of time
  v_name2 = variable with name2 for change rate as function of time
pressure values = target gain
  target = target pressure (pressure units)
  gain = proportional gain constant (1/(time * pressure) or 1/time units)
pressure/mean values = target gain
  target = target pressure (pressure units)
  gain = proportional gain constant (1/(time * pressure) or 1/time units)

xy, xz, yz args = style value
  style = final or delta or vel or erate or trate or wiggle or variable or pressure or erate/rescale
    final value = tilt
      tilt = tilt factor at end of run (distance units)
    delta value = dtilt
      dtilt = change in tilt factor at end of run (distance units)
    vel value = V
      V = change tilt factor at this velocity (distance/time units),
          effectively an engineering shear strain rate
    erate value = R
      R = engineering shear strain rate (1/time units)
    erate/rescale value = R
      R = engineering shear strain rate (1/time units)
    trate value = R
      R = true shear strain rate (1/time units)
    wiggle values = A Tp
      A = amplitude of oscillation (distance units)
      Tp = period of oscillation (time units)
    variable values = v_name1 v_name2
      v_name1 = variable with name1 for tilt change as function of time
      v_name2 = variable with name2 for change rate as function of time
    pressure values = target gain
      target = target pressure (pressure units)
      gain = proportional gain constant (1/(time * pressure) or 1/time units)
    erate/rescale value = R
      R = engineering shear strain rate (1/time units)

box = style value
  style = volume or pressure
    volume value = none = isotropically adjust system to preserve volume of system
    pressure values = target gain
      target = target mean pressure (pressure units)
      gain = proportional gain constant (1/(time * pressure) or 1/time units)
```

- zero or more keyword/value pairs may be appended

- keyword = *remap* or *flip* or *units* or *couple* or *vol/balance/p* or *max/rate* or *normalize/pressure*

```

remap value = x or v or none
  x = remap coords of atoms in group into deforming box
  v = remap velocities of atoms in group when they cross periodic boundaries
  none = no remapping of x or v
flip value = yes or no
  allow or disallow box flips when it becomes highly skewed
units value = lattice or box
  lattice = distances are defined in lattice units
  box = distances are defined in simulation box units
couple value = none or xyz or xy or yz or xz
  couple pressure values of various dimensions
vol/balance/p value = yes or no
  Modifies the behavior of the volume option to try and balance pressures
max/rate value = rate
  rate = maximum strain rate for pressure control
normalize/pressure value = yes or no
  Modifies pressure controls such that the deviation in pressure is normalized by
  → the target pressure

```

## 2.42.2 Examples

```

fix 1 all deform/pressure 1 x pressure 2.0 0.1 normalize/pressure yes max/rate 0.001
fix 1 all deform/pressure 1 x trate 0.1 y volume z volume vol/balance/p yes
fix 1 all deform/pressure 1 x trate 0.1 y pressure/mean 0.0 1.0 z pressure/mean 0.0 1.0

```

## 2.42.3 Description

New in version 17Apr2024.

This fix is an extension of the [fix deform](#) command, which allows all of its options to be used as well as new pressure-based controls implemented by this command.

All arguments described on the [fix deform](#) doc page also apply to this fix unless otherwise noted below. The rest of this page explains the arguments specific to this fix only. Note that a simulation can define only a single deformation command: `fix deform` or `fix deform/pressure`.

### Inconsistent trajectories due to image flags

When running long simulations while shearing the box or using a high shearing rate, it is possible that the image flags used for storing unwrapped atom positions will “wrap around”. When LAMMPS is compiled with the default settings, case image flags are limited to a range of  $-512 \leq i \leq 511$ , which will overflow when atoms starting at zero image flag value have passed through a periodic box dimension more than 512 times.

Changing the [size of LAMMPS integer types](#) to the “bigbig” setting can make this overflow much less likely, since it increases the image flag value range to  $-1,048,576 \leq i \leq 1,048,575$

For the *x*, *y*, and *z* parameters, this is the meaning of the styles and values provided by this fix.

The *pressure* style adjusts a dimension’s box length to control the corresponding component of the pressure tensor. This option attempts to maintain a specified target pressure using a linear controller where the box length *L* evolves

according to the equation

$$\frac{dL(t)}{dt} = L(t)k(P_t - P)$$

where  $k$  is a proportional gain constant,  $P_t$  is the target pressure, and  $P$  is the current pressure along that dimension. This approach is similar to the method used to control the pressure by [fix press/berendsen](#). The target pressure accepts either a constant numeric value or a LAMMPS [variable](#). Notably, this variable can be a function of time or other components of the pressure tensor. By default,  $k$  has units of 1/(time \* pressure) although this will change if the [normalize/pressure](#) option is set as [discussed below](#). There is no proven method to choosing an appropriate value of  $k$  as it will depend on the specific details of a simulation. Testing different values is recommended.

By default, there is no limit on the resulting strain rate in any dimension. A maximum limit can be applied using the [max/rate](#) option. Akin to [fix npt](#) and [nph](#), pressures in different dimensions can be coupled using the [couple](#) option. This means the instantaneous pressure along coupled dimensions are averaged and the box strains identically along the coupled dimensions.

The [pressure/mean](#) style changes a dimension's box length to maintain a constant mean pressure defined as the trace of the pressure tensor. This option has identical arguments to the [pressure](#) style and a similar functional equation, except the current and target pressures refer to the mean trace of the pressure tensor. All options for the [pressure](#) style also apply to the [pressure/mean](#) style except for the [couple](#) option.

Note that while this style can be identical to coupled [pressure](#) styles, it is generally not the same. For instance in 2D, a coupled [pressure](#) style in the  $x$  and  $y$  dimensions would be equivalent to using the [pressure/mean](#) style with identical settings in each dimension. However, it would not be the same if settings (e.g. gain constants) were used in the  $x$  and  $y$  dimensions or if the [pressure/mean](#) command was only applied along one dimension.

---

For the  $xy$ ,  $xz$ , and  $yz$  parameters, this is the meaning of the styles and values provided by this fix. Note that changing the tilt factors of a triclinic box does not change its volume.

The [pressure](#) style adjusts a tilt factor to control the corresponding off-diagonal component of the pressure tensor. This option attempts to maintain a specified target value using a linear controller where the tilt factor  $T$  evolves according to the equation

$$\frac{dT(t)}{dt} = L(t)k(P - P_t)$$

where  $k$  is a proportional gain constant,  $P_t$  is the target pressure,  $P$  is the current pressure, and  $L$  is the perpendicular box length. The target pressure accepts either a constant numeric value or a LAMMPS [variable](#). Notably, this variable can be a function of time or other components of the pressure tensor. By default,  $k$  has units of 1/(time \* pressure) although this will change if the [normalize/pressure](#) option is set as [discussed below](#). There is no proven method to choosing an appropriate value of  $k$  as it will depend on the specific details of a simulation and testing different values is recommended. One can also apply a maximum limit to the magnitude of the applied strain using the [max/rate](#) option.

The [erate/rescale](#) style operates similarly to the [erate](#) style with a specified strain rate in units of 1/time. The difference is that the change in the tilt factor will depend on the current length of the box perpendicular to the shear direction,  $L$ , instead of the original length,  $L_0$ . The tilt factor  $T$  as a function of time will change as

$$T(t) = T(t-1) + L \cdot \text{erate} \cdot \Delta t$$

where  $T(t-1)$  is the tilt factor on the previous timestep and  $\Delta t$  is the timestep size. This option may be useful in scenarios where  $L$  changes in time.

---

The [box](#) parameter provides an additional control over the  $x$ ,  $y$ , and  $z$  box lengths by isotropically dilating or contracting the box to either maintain a fixed mean pressure or volume. This isotropic scaling is applied after the box is deformed by the above  $x$ ,  $y$ ,  $z$ ,  $xy$ ,  $xz$ , and  $yz$  styles, acting as a second deformation step. This parameter will change the overall

strain rate in the  $x$ ,  $y$ , or  $z$  dimensions. This parameter can only be used in combination with the  $x$ ,  $y$ , or  $z$  commands: *vel*, *erate*, *trate*, *pressure*, or *wiggle*. This is the meaning of its styles and values.

The *volume* style isotropically scales box lengths to maintain a constant box volume in response to deformation from other parameters. This style may be useful in scenarios where one wants to apply a constant deviatoric pressure using *pressure* styles in the  $x$ ,  $y$ , and  $z$  dimensions (deforming the shape of the box), while maintaining a constant volume.

The *pressure* style isotropically scales box lengths in an attempt to maintain a target mean pressure (the trace of the pressure tensor) of the system. This is accomplished by isotropically scaling all box lengths  $L$  by an additional factor of  $k(P_t - P_m)$  where  $k$  is the proportional gain constant,  $P_t$  is the target pressure, and  $P_m$  is the current mean pressure. This style may be useful in scenarios where one wants to apply a constant deviatoric strain rate using various strain-based styles (e.g. *trate*) along the  $x$ ,  $y$ , and  $z$  dimensions (deforming the shape of the box), while maintaining a mean pressure.

The optional keywords provided by this fix are described below.

The *normalize/pressure* keyword changes how box dimensions evolve when using the *pressure* or *pressure/mean* deformation styles. If the *deform/normalize* value is set to *yes*, then the deviation from the target pressure is normalized by the absolute value of the target pressure such that the proportional gain constant scales a percentage error and has units of 1/time. If the target pressure is ever zero, this will produce an error unless the *max/rate* keyword is defined, described below, which will cap the divergence.

The *max/rate* keyword sets an upper threshold, *rate*, that limits the maximum magnitude of the instantaneous strain rate applied in any dimension. This keyword only applies to the *pressure* and *pressure/mean* options. If a pressure-controlled rate is used for both *box* and either  $x$ ,  $y$ , or  $z$ , then this threshold will apply separately to each individual controller such that the cumulative strain rate on a box dimension may be up to twice the value of *rate*.

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together for the *pressure* option. The value specified with the keyword determines which are coupled. For example, *xz* means the  $P_{xx}$  and  $P_{zz}$  components of the stress tensor are coupled. *xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. If a *pressure* style is defined for more than one coupled dimension, the target pressures and gain constants must be identical. Alternatively, if a *pressure* style is only defined for one of the coupled dimensions, its settings are copied to other dimensions with undefined styles. *Couple xyz* can be used for a 2d simulation; the  $z$  dimension is simply ignored.

The *vol/balance/p* keyword modifies the behavior of the *volume* style when applied to two of the  $x$ ,  $y$ , and  $z$  dimensions. Instead of straining the two dimensions in lockstep, the two dimensions are allowed to separately dilate or contract in a manner to maintain a constant volume while simultaneously trying to keep the pressure along each dimension equal using a method described in (Huang2014).

If any pressure controls are used, this fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp
```

See the *compute temp* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix-ID + underscore + “press”, and the group for the new computes is the same as the fix group.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

## 2.42.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix will restore the initial box settings from *binary restart files*, which allows the fix to be properly continue deformation, when using the start/stop options of the *run* command. No global or per-atom quantities are stored by this fix for access by various *output commands*.

If any pressure controls are used, the *fix\_modify temp* and *press* options are supported by this fix, unlike in *fix deform*. You can use them to assign a *compute* you have defined to this fix which will be used in its temperature and pressure calculations. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

This fix can perform deformation over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.42.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

You cannot apply x, y, or z deformations to a dimension that is shrink-wrapped via the *boundary* command.

You cannot apply xy, yz, or xz deformations to a second dimension (y in xy) that is shrink-wrapped via the *boundary* command.

## 2.42.6 Related commands

*fix deform*, *change\_box*

## 2.42.7 Default

The option defaults are normalize/pressure = no.

---

# 2.43 fix deposit command

## 2.43.1 Syntax

**fix** ID group-ID deposit N type M seed keyword values ...

- ID, group-ID are documented in *fix* command
- deposit = style name of this fix command
- N = # of atoms or molecules to insert
- type = atom type (1-Ntypes or type label) to assign to inserted atoms (offset for molecule insertion)

- M = insert a single atom or molecule every M steps
- seed = random # seed (positive integer)
- one or more keyword/value pairs may be appended to args
- keyword = *region* or *var* or *set* or *id* or *global* or *local* or *near* or *gaussian* or *attempt* or *rate* or *vx* or *vy* or *vz* or *target* or *mol* or *molfrac* or *rigid* or *shake* or *orient* or *units*

```

region value = region-ID
    region-ID = ID of region to use as insertion volume
var value = name = variable name to evaluate for test of atom creation
set values = dim name
    dim = x or y or z
    name = name of variable to set with x, y, or z atom position
id value = max or next
    max = atom ID for new atom(s) is max ID of all current atoms plus one
    next = atom ID for new atom(s) increments by one for every deposition
global values = lo hi
    lo,hi = put new atom/molecule a distance lo-hi above all other atoms (distance_
    →units)
local values = lo hi delta
    lo,hi = put new atom/molecule a distance lo-hi above any nearby atom beneath it_
    →(distance units)
    delta = lateral distance within which a neighbor is considered "nearby" (distance_
    →units)
near value = R
    R = only insert atom/molecule if further than R from existing particles (distance_
    →units)
gaussian values = xmid ymid zmid sigma
    xmid,ymid,zmid = center of the gaussian distribution (distance units)
    sigma = width of gaussian distribution (distance units)
attempt value = Q
    Q = attempt a single insertion up to Q times
rate value = V
    V = z velocity (y in 2d) at which insertion volume moves (velocity units)
vx values = vxlo vxhi
    vxlo,vxhi = range of x velocities for inserted atom/molecule (velocity units)
vy values = vylo vyhi
    vylo,vyhi = range of y velocities for inserted atom/molecule (velocity units)
vz values = vzlo vzhi
    vzlo,vzhi = range of z velocities for inserted atom/molecule (velocity units)
target values = tx ty tz
    tx,ty,tz = location of target point (distance units)

→units lattice
```

## 2.43.3 Description

Insert a single atom or molecule into the simulation domain every M timesteps until N atoms or molecules have been inserted. This is useful for simulating deposition onto a surface. For the remainder of this doc page, a single inserted atom or molecule is referred to as a “particle”.

If inserted particles are individual atoms, they are assigned the specified atom type. If they are molecules, the type of each atom in the inserted molecule is specified in the file read by the *molecule* command, and those values are added to the specified atom type. E.g. if the file specifies atom types 1,2,3, and those are the atom types you want for inserted molecules, then specify *type* = 0. If you specify *type* = 2, the in the inserted molecule will have atom types 3,4,5.

All atoms in the inserted particle are assigned to two groups: the default group “all” and the group specified in the fix deposit command (which can also be “all”).

If you are computing temperature values which include inserted particles, you will want to use the *compute\_modify dynamic/dof yes* option, which ensures the current number of atoms is used as a normalizing factor each time the temperature is computed.

Care must be taken that inserted particles are not too near existing atoms, using the options described below. When inserting particles above a surface in a non-periodic box (see the *boundary* command), the possibility of a particle escaping the surface and flying upward should be considered, since the particle may be lost or the box size may grow infinitely large. A *fix wall/reflect* command can be used to prevent this behavior. Note that if a shrink-wrap boundary is used, it is OK to insert the new particle outside the box, however the box will immediately be expanded to include the new particle. When simulating a sputtering experiment it is probably more realistic to ignore those atoms using the *thermo\_modify* command with the *lost ignore* option and a fixed *boundary*.

The fix deposit command must use the *region* keyword to define an insertion volume. The specified region must have been previously defined with a *region* command. It must be defined with *side = in*.

---

**Note:** LAMMPS checks that the specified region is wholly inside the simulation box. It can do this correctly for orthonormal simulation boxes. However for *triclinic boxes*, it only tests against the larger orthonormal box that bounds the tilted simulation box. If the specified region includes volume outside the tilted box, then an insertion will likely fail, leading to a “lost atoms” error. Thus for triclinic boxes you should ensure the specified region is wholly inside the simulation box.

---

The locations of inserted particles are taken from uniform distributed random numbers, unless the *gaussian* keyword is used. Then the individual coordinates are taken from a gaussian distribution of width *sigma* centered on *xmid,ymid,zmid*.

Individual atoms are inserted, unless the *mol* keyword is used. It specifies a *template-ID* previously defined using the *molecule* command, which reads files that define one or more molecules. The coordinates, atom types, charges, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in each file are the coordinates and types of atoms in the molecule.

If the molecule template contains more than one molecule, the relative probability of depositing each molecule can be specified by the *molfrac* keyword. N relative probabilities, each from 0.0 to 1.0, are specified, where N is the number of molecules in the template. Each time a molecule is deposited, a random number is used to sample from the list of relative probabilities. The N values must sum to 1.0.

If you wish to insert molecules via the *mol* keyword, that will be treated as rigid bodies, use the *rigid* keyword, specifying as its value the ID of a separate *fix rigid/small* command which also appears in your input script.

---

**Note:** If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via *fix rigid/small/nvt* or *fix rigid/small/npt*, then you need to use the *fix\_modify dynamic/dof yes* command for the rigid fix. This is to inform that fix that the molecule count will vary dynamically.

---

If you wish to insert molecules via the *mol* keyword, that will have their bonds or angles constrained via SHAKE, use the *shake* keyword, specifying as its value the ID of a separate *fix shake* command which also appears in your input script.

Each timestep a particle is inserted, the coordinates for its atoms are chosen as follows. For insertion of individual atoms, the “position” referred to in the following description is the coordinate of the atom. For insertion of molecule, the “position” is the geometric center of the molecule; see the *molecule* doc page for details. A random rotation of the molecule around its center point is performed, which determines the coordinates all the individual atoms.

A random position within the region insertion volume is generated. If neither the *global* or *local* keyword is used, the random position is the trial position. If the *global* keyword is used, the random x,y values are used, but the z position of the new particle is set above the highest current atom in the simulation by a distance randomly chosen between lo/hi. (For a 2d simulation, this is done for the y position.) If the *local* keyword is used, the z position is set a distance between lo/hi above the highest current atom in the simulation that is “nearby” the chosen x,y position. In this context, “nearby” means the lateral distance (in x,y) between the new and old particles is less than the *delta* setting.

Once a trial x,y,z position has been selected, the insertion is only performed if both the *near* and *var* keywords are satisfied (see below). If either the *near* or the *var* keyword is not satisfied, a new random position within the insertion volume is chosen and another trial is made. Up to Q attempts are made. If one or more particle insertions are not successful, LAMMPS prints a warning message.

The *near* keyword ensures that no current atom in the simulation is within a distance R of any atom in the new particle, including the effect of periodic boundary conditions if applicable. Note that the default value for R is 0.0, which will allow atoms to strongly overlap if you are inserting where other atoms are present. This distance test is performed independently for each atom in an inserted molecule, based on the randomly rotated configuration of the molecule.

---

**Note:** If you are inserting finite size particles or a molecule or rigid body consisting of finite-size particles, then you should typically set R larger than the distance at which any inserted particle may overlap with either a previously inserted particle or an existing particle. LAMMPS will issue a warning if R is smaller than this value, based on the radii of existing and inserted particles.

---

New in version 21Nov2023.

The *var* and *set* keywords can be used together to provide a criterion for accepting or rejecting the addition of an individual atom, based on its coordinates. The *name* specified for the *var* keyword is the name of an *equal-style variable* that should evaluate to a zero or non-zero value based on one or two or three variables that will store the x, y, or z coordinates of an atom (one variable per coordinate). If used, these other variables must be *internal-style variables*

defined in the input script; their initial numeric value can be anything. They must be internal-style variables, because this command resets their values directly. The *set* keyword is used to identify the names of these other variables, one variable for the *x*-coordinate of a created atom, one for *y*, and one for *z*. When an atom is created, its (*x*, *y*, *z*) coordinates become the values for any *set* variable that is defined. The *var* variable is then evaluated. If the returned value is 0.0, the atom is not created. If it is non-zero, the atom is created. For an example of how to use these keywords, see the *create\_atoms* command.

The *rate* option moves the insertion volume in the *z* direction (3d) or *y* direction (2d). This enables particles to be inserted from a successively higher height over time. Note that this parameter is ignored if the *global* or *local* keywords are used, since those options choose a *z*-coordinate for insertion independently.

The *vx*, *vy*, and *vz* components of velocity for the inserted particle are set by sampling a uniform distribution between the bounds set by the values specified for the *vx*, *vy*, and *vz* keywords. Note that normally, new particles should be assigned a negative vertical velocity so that they move towards the surface. For molecules, the same velocity is given to every particle (no rotation or bond vibration).

If the *target* option is used, the velocity vector of the inserted particle is changed so that it points from the insertion position towards the specified target point. The magnitude of the velocity is unchanged. This can be useful, for example, for simulating a sputtering process. E.g. the target point can be far away, so that all incident particles strike the surface as if they are in an incident beam of particles at a prescribed angle.

The *orient* keyword is only used when molecules are deposited. By default, each molecule is inserted at a random orientation. If this keyword is specified, then (*rx*,*ry*,*rz*) is used as an orientation vector, and each inserted molecule is rotated around that vector with a random value from zero to  $2\pi$ . For a 2d simulation, *rx* = *ry* = 0.0 is required, since rotations can only be performed around the *z* axis.

The *id* keyword determines how atom IDs and molecule IDs are assigned to newly deposited particles. Molecule IDs are only assigned if molecules are being inserted. For the *max* setting, the atom and molecule IDs of all current atoms are checked. Atoms in the new particle are assigned IDs starting with the current maximum plus one. If a molecule is inserted it is assigned an ID = current maximum plus one. This means that if particles leave the system, the new IDs may replace the lost ones. For the *next* setting, the maximum ID of any atom and molecule is stored at the time the fix is defined. Each time a new particle is added, this value is incremented to assign IDs to the new atom(s) or molecule. Thus atom and molecule IDs for deposited particles will be consecutive even if particles leave the system over time.

The *units* keyword determines the meaning of the distance units used for the other deposition parameters. A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. Note that the units choice affects all the keyword values that have units of distance or velocity.

---

**Note:** If you are monitoring the temperature of a system where the atom count is changing due to adding particles, you typically should use the *compute\_modify dynamic/dof yes* command for the temperature compute you are using.

---

#### 2.43.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the deposition to *binary restart files*. This includes information about how many particles have been deposited, the random number generator seed, the next timestep for deposition, etc. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset\_timestep*. The fix will try to detect it and stop with an error.

---

None of the *fix\_modify* options are relevant to this fix. This fix computes a global scalar, which can be accessed by various output commands. The scalar is the cumulative number of insertions. The scalar value calculated by this fix

is “intensive”. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.43.5 Restrictions

The specified insertion region cannot be a “dynamic” region, as defined by the *region* command.

### 2.43.6 Related commands

*fix pour, region*

### 2.43.7 Default

Insertions are performed for individual atoms, i.e. no *mol* setting is defined. If the *mol* keyword is used, the default for *molfrac* is an equal probabilities for all molecules in the template. Additional option defaults are *id* = max, *delta* = 0.0, *near* = 0.0, *attempt* = 10, *rate* = 0.0, *vx* = 0.0 0.0, *vy* = 0.0 0.0, *vz* = 0.0 0.0, and *units* = lattice.

## 2.44 fix dpd/energy command

Accelerator Variants: *dpd/energy/kk*

### 2.44.1 Syntax

```
fix ID group-ID dpd/energy
```

- ID, group-ID are documented in *fix* command
- dpd/energy = style name of this fix command

### 2.44.2 Examples

```
fix 1 all dpd/energy
```

### 2.44.3 Description

Perform constant energy dissipative particle dynamics (DPD-E) integration. This fix updates the internal energies for particles in the group at each timestep. It must be used in conjunction with a deterministic integrator (e.g. *fix nve*) that updates the particle positions and velocities.

For fix *dpd/energy*, the particle internal temperature is related to the particle internal energy through a mesoparticle equation of state. An additional fix must be specified that defines the equation of state for each particle, e.g. *fix eos/cv*.

This fix must be used with the *pair\_style dpd/fdt/energy* command.

Note that numerous variants of DPD can be specified by choosing an appropriate combination of the integrator and *pair\_style dpd/fdt/energy* command. DPD under isoenergetic conditions can be specified by using fix *dpd/energy*, fix *nve* and *pair\_style dpd/fdt/energy*. DPD under isoenthalpic conditions can be specified by using fix *dpd/energy*, fix

*nph* and *pair\_style dpd/fdt/energy*. Examples of each DPD variant are provided in the `examples/PACKAGES/dpd-react` directory.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.44.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix must be used with an additional fix that specifies time integration, e.g. *fix nve*.

The fix *dpd/energy* requires the *dpd atom\_style* to be used in order to properly account for the particle internal energies and temperature.

The fix *dpd/energy* must be used with an additional fix that specifies the mesoparticle equation of state for each particle.

## 2.44.5 Related commands

## 2.45 fix edpd/source command

## 2.46 fix tdpd/source command

### 2.46.1 Syntax

```
fix ID group-ID edpd/source keyword values ...
fix ID group-ID tdpd/source cc_index keyword values ...
```

- ID, group-ID are documented in *fix* command
- edpd/source or tdpd/source = style name of this fix command
- index (only specified for tdpd/source) = index of chemical species (1 to Nspecies)
- keyword = *sphere* or *cuboid* or *region*

```
sphere args = cx cy cz radius source
  cx,cy,cz = x,y,z center of spherical domain (distance units)
  radius = radius of a spherical domain (distance units)
  source = heat source or concentration source (flux units, see below)
cuboid values = cx cy cz dLx dLy dLz source
  cx,cy,cz = x,y,z center of a cuboid domain (distance units)
  dLx,dLy,dLz = x,y,z side length of a cuboid domain (distance units)
  source = heat source or concentration source (flux units, see below)
region values = region-ID source
  region = ID of region for heat or concentration source
  source = heat source or concentration source (flux units, see below)
```

## 2.46.2 Examples

```
fix 1 all edpd/source sphere 0.0 0.0 0.0 5.0 0.01
fix 1 all edpd/source cuboid 0.0 0.0 0.0 20.0 10.0 10.0 -0.01
fix 1 all tdpd/source 1 sphere 5.0 0.0 0.0 5.0 0.01
fix 1 all tdpd/source 2 cuboid 0.0 0.0 0.0 20.0 10.0 10.0 0.01
fix 1 all tdpd/source 1 region lower -0.01
```

## 2.46.3 Description

Fix *edpd/source* adds a heat source as an external heat flux to each atom in a spherical or cuboid domain, where the *source* is in units of energy/time. Fix *tdpd/source* adds an external concentration source of the chemical species specified by *index* as an external concentration flux for each atom in a spherical or cuboid domain, where the *source* is in units of mole/volume/time.

This command can be used to give an additional heat/concentration source term to atoms in a simulation, such as for a simulation of a heat conduction with a source term (see Fig.12 in (Li2014)) or diffusion with a source term (see Fig.1 in (Li2015)), as an analog of a periodic Poiseuille flow problem.

Deprecated since version 15Jun2023: The *sphere* and *cuboid* keywords will be removed in a future version of LAMMPS. The same functionality and more can be achieved with a region.

If the *sphere* keyword is used, the *cx*, *cy*, *cz*, *radius* values define a spherical domain to apply the source flux to.

If the *cuboid* keyword is used, the *cx*, *cy*, *cz*, *dLx*, *dLy*, *dLz* define a cuboid domain to apply the source flux to.

If the *region* keyword is used, the *region-ID* selects which *region* to apply the source flux to.

## 2.46.4 Restart, fix\_modify, output, run start/stop, minimize info

No information of these fixes is written to *binary restart files*. None of the *fix\_modify* options are relevant to these fixes. No global or per-atom quantities are stored by these fixes for access by various *output commands*. No parameter of these fixes can be used with the *start/stop* keywords of the *run* command. These fixes are not invoked during *energy minimization*.

## 2.46.5 Restrictions

These fixes are part of the DPD-MESO package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Fix *edpd/source* must be used with the *pair\_style edpd* command. Fix *tdpd/source* must be used with the *pair\_style tdpd* command.

## 2.46.6 Related commands

*pair\_style edpd*, *pair\_style tdpd*, *compute edpd/temp/atom*, *compute tdpd/cc/atom*

## 2.46.7 Default

none

## 2.47 fix drag command

### 2.47.1 Syntax

```
fix ID group-ID drag x y z fmag delta
```

- ID, group-ID are documented in *fix* command
- drag = style name of this fix command
- x,y,z = coord to drag atoms towards
- fmag = magnitude of force to apply to each atom (force units)
- delta = cutoff distance inside of which force is not applied (distance units)

## 2.47.2 Examples

```
fix center small-molecule drag 0.0 10.0 0.0 5.0 2.0
```

## 2.47.3 Description

Apply a force to each atom in a group to drag it towards the point (x,y,z). The magnitude of the force is specified by fmag. If an atom is closer than a distance delta to the point, then the force is not applied.

Any of the x,y,z values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

This command can be used to steer one or more atoms to a new location in the simulation.

## 2.47.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various *output commands*. This is the total force on the group of atoms by the drag force. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.47.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.47.6 Related commands

*fix spring*, *fix spring/self*, *fix spring/rg*, *fix smd*

## 2.47.7 Default

# 2.48 fix drude command

## 2.48.1 Syntax

```
fix ID group-ID drude flag1 flag2 ... flagN
```

- ID, group-ID are documented in *fix* command
- drude = style name of this fix command

- flag1 flag2 ... flagN = Drude flag for each atom type (1 to N) in the system

## 2.48.2 Examples

```
fix 1 all drude 1 1 0 1 0 2 2 2
fix 1 all drude C C N C N D D D
```

Example input scripts available: examples/PACKAGES/drude

## 2.48.3 Description

Assign each atom type in the system to be one of 3 kinds of atoms within the Drude polarization model. This fix is designed to be used with the *thermalized Drude oscillator model*. Polarizable models in LAMMPS are described on the *Howto polarizable* doc page.

The three possible types can be designated with an integer (0,1,2) or capital letter (N,C,D):

- 0 or N = non-polarizable atom (not part of Drude model)
- 1 or C = Drude core
- 2 or D = Drude electron

## 2.48.4 Restrictions

This fix should be invoked before any other commands that implement the Drude oscillator model, such as *fix langevin/drude*, *fix tgnvt/drude*, *fix drude/transform*, *compute temp/drude*, *pair\_style thole*.

## 2.48.5 Related commands

*fix langevin/drude*, *fix tgnvt/drude*, *fix drude/transform*, *compute temp/drude*, *pair\_style thole*

## 2.48.6 Default

none

## 2.49 fix drude/transform/direct command

## 2.50 fix drude/transform/inverse command

### 2.50.1 Syntax

```
fix ID group-ID style keyword value ...
```

- ID, group-ID are documented in *fix* command
- style = *drude/transform/direct* or *drude/transform/inverse*

## 2.50.2 Examples

```
fix 3 all drude/transform/direct
fix 1 all drude/transform/inverse
```

Example input scripts available: examples/PACKAGES/drude

## 2.50.3 Description

Transform the coordinates of Drude oscillators from real to reduced and back for thermalizing the Drude oscillators as described in ([Lamoureux](#)) using a Nose-Hoover thermostat. This fix is designed to be used with the *thermalized Drude oscillator model*. Polarizable models in LAMMPS are described on the [Howto polarizable](#) doc page.

Drude oscillators are a pair of atoms representing a single polarizable atom. Ideally, the mass of Drude particles would vanish and their positions would be determined self-consistently by iterative minimization of the energy, the cores' positions being fixed. It is however more efficient and it yields comparable results, if the Drude oscillators (the motion of the Drude particle relative to the core) are thermalized at a low temperature. In that case, the Drude particles need a small mass.

The thermostats act on the reduced degrees of freedom, which are defined by the following equations. Note that in these equations upper case denotes atomic or center of mass values and lower case denotes Drude particle or dipole values. Primes denote the transformed (reduced) values, while bare letters denote the original values.

Masses:

$$M' = M + m$$

$$m' = \frac{M m}{M'}$$

Positions:

$$X' = \frac{M X + m x}{M'}$$

$$x' = x - X$$

Velocities:

$$V' = \frac{M V + m v}{M'}$$

$$v' = v - V$$

Forces:

$$F' = F + f$$

$$f' = \frac{M f - m F}{M'}$$

This transform conserves the total kinetic energy

$$\frac{1}{2} (M V^2 + m v^2) = \frac{1}{2} (M' V'^2 + m' v'^2)$$

and the virial defined with absolute positions

$$X F + x f = X' F' + x' f'$$

This fix requires each atom know whether it is a Drude particle or not. You must therefore use the *fix drude* command to specify the Drude status of each atom type.

**Note:** only the Drude core atoms need to be in the group specified for this fix. A Drude electron will be transformed together with its core even if it is not itself in the group. It is safe to include Drude electrons or non-polarizable atoms in the group. The non-polarizable atoms will simply not be transformed.

This fix does NOT perform time integration. It only transform masses, coordinates, velocities and forces. Thus you must use separate time integration fixes, like *fix nve* or *fix npt* to actually update the velocities and positions of atoms. In order to thermalize the reduced degrees of freedom at different temperatures, two Nose-Hoover thermostats must be defined, acting on two distinct groups.

**Note:** The *fix drude/transform/direct* command must appear before any Nose-Hoover thermostating fixes. The *fix drude/transform/inverse* command must appear after any Nose-Hoover thermostating fixes.

Example:

```
fix fDIRECT all drude/transform/direct
fix fNVT gCORES nvt temp 300.0 300.0 100
fix fNVT gDRUDES nvt temp 1.0 1.0 100
fix fINVERSE all drude/transform/inverse
compute TDRUDE all temp/drude
thermo_style custom step cpu etotal ke pe ebond ecoul elong press vol temp c_TDRUDE[1] c_
→TDRUDE[2]
```

In this example, *gCORES* is the group of the atom cores and *gDRUDES* is the group of the Drude particles (electrons). The centers of mass of the Drude oscillators will be thermostatted at 300.0 and the internal degrees of freedom will be thermostatted at 1.0. The temperatures of cores and Drude particles, in center-of-mass and relative coordinates, are calculated using *compute temp/drude*

In addition, if you want to use a barostat to simulate a system at constant pressure, only one of the Nose-Hoover fixes must be *npt*, the other one should be *nvt*. You must add a *compute temp/com* and a *fix\_modify* command so that the temperature of the *npt* fix be just that of its group (the Drude cores) but the pressure be the overall pressure *thermo\_press*.

Example:

```
compute cTEMP_CORE gCORES temp/com
fix fDIRECT all drude/transform/direct
fix fNPT gCORES npt temp 298.0 298.0 100 iso 1.0 1.0 500
fix_modify fNPT temp cTEMP_CORE press thermo_press
fix fNVT gDRUDES nvt temp 5.0 5.0 100
fix fINVERSE all drude/transform/inverse
```

In this example, *gCORES* is the group of the atom cores and *gDRUDES* is the group of the Drude particles. The centers of mass of the Drude oscillators will be thermostatted at 298.0 and the internal degrees of freedom will be thermostatted at 5.0. The whole system will be barostatted at 1.0.

In order to avoid the flying ice cube problem (irreversible transfer of linear momentum to the center of mass of the system), you may need to add a *fix momentum* command:

```
fix fMOMENTUM all momentum 100 linear 1 1 1
```

## 2.50.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

## 2.50.5 Restrictions

none

# 2.51 fix dt/reset command

Accelerator Variants: *dt/reset/kk*

## 2.51.1 Syntax

```
fix ID group-ID dt/reset N Tmin Tmax Xmax keyword values ...
```

- ID, group-ID are documented in *fix* command
- dt/reset = style name of this fix command
- N = re-compute dt every N timesteps
- Tmin = minimum dt allowed which can be NULL (time units)
- Tmax = maximum dt allowed which can be NULL (time units)
- Xmax = maximum distance for an atom to move in one timestep (distance units)
- zero or more keyword/value pairs may be appended
- keyword = *emax* or *units*

*emax* value = Emax

Emax = maximum kinetic energy change for an atom in one timestep (energy units)

*units* value = *lattice* or *box*

*lattice* = Xmax is defined in lattice units

*box* = Xmax is defined in simulation box units

## 2.51.2 Examples

```
fix 5 all dt/reset 10 1.0e-5 0.01 0.1
fix 5 all dt/reset 10 0.01 2.0 0.2 units box
fix 5 all dt/reset 5 NULL 0.001 0.5 emax 30 units box
```

## 2.51.3 Description

Reset the timestep size every  $N$  steps during a run, so that no atom moves further than the specified  $X_{max}$  distance, based on current atom velocities and forces. Optionally an additional criterion is imposed by the *emax* keyword, so that no atom's kinetic energy changes by more than the specified  $E_{max}$ .

This can be useful when starting from a configuration with overlapping atoms, where forces will be large. Or it can be useful when running an impact simulation where one or more high-energy atoms collide with a solid, causing a damage cascade.

This fix overrides the timestep size setting made by the *timestep* command. The new timestep size  $dt$  is computed in the following manner.

For each atom, the timestep is computed that would cause it to displace  $X_{max}$  on the next integration step, as a function of its current velocity and force. Since performing this calculation exactly would require the solution to a quartic equation, a cheaper estimate is generated. The estimate is conservative in that the atom's displacement is guaranteed not to exceed  $X_{max}$ , though it may be smaller.

In addition if the *emax* keyword is used, the specified  $E_{max}$  value is enforced as a limit on how much an atom's kinetic energy can change. If the timestep required is even smaller than for the  $X_{max}$  displacement, then the smaller timestep is used.

Given this putative timestep for each atom, the minimum timestep value across all atoms is computed. Then the  $T_{min}$  and  $T_{max}$  bounds are applied, if specified. If one (or both) is specified as NULL, it is not applied.

When the *run style* is *respa*, this fix resets the outer loop (largest) timestep, which is the same timestep that the *timestep* command sets.

Note that the cumulative simulation time (in time units), which accounts for changes in the timestep size as a simulation proceeds, can be accessed by the *thermo\_style time* keyword.

Also note that the *dump\_modify every/time* option allows dump files to be written at intervals specified by simulation time, rather than by timesteps. Simulation time is in time units; see the *units* doc page for details.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.51.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar stores the last timestep on which the timestep was reset to a new value.

The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.51.5 Restrictions

none

## 2.51.6 Related commands

*timestep*, *dump\_modify every/time*

## 2.51.7 Default

The option defaults are units = lattice, and no emax kinetic energy limit.

# 2.52 fix efield command

## 2.53 fix efield/tip4p command

### 2.53.1 Syntax

```
fix ID group-ID style ex ey ez keyword value ...
```

- ID, group-ID are documented in *fix* command
- style = *efield* or *efield/tip4p*
- ex,ey,ez = E-field component values (electric field units)
- any of ex,ey,ez can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = *region* or *energy* or *potential*

*region* value = region-ID

region-ID = ID of region atoms must be in to have added force

*energy* value = v\_name

v\_name = variable with name that calculates the potential energy of each atom in  
→the added E-field

*potential* value = v\_name

v\_name = variable with name that calculates the electric potential of each atom  
→in the added E-field

## 2.53.2 Examples

```
fix kick external-field efield 1.0 0.0 0.0
fix kick external-field efield 0.0 0.0 v_oscillate
fix kick external-field efield/tip4p 1.0 0.0 0.0
```

## 2.53.3 Description

Add a force  $\vec{F} = q\vec{E}$  to each charged atom in the group due to an external electric field being applied to the system. If the system contains point-dipoles, also add a torque on the dipoles due to the external electric field.

New in version 28Mar2023.

When the *efield/tip4p* style is used, the E-field will be applied to the position of the virtual charge site M of a TIP4P molecule instead of the oxygen position as it is defined by a corresponding *TIP4P pair style*. The forces on the M site due to the external field are projected on the oxygen and hydrogen atoms of the TIP4P molecules.

For charges, any of the 3 quantities defining the E-field components can be specified as an equal-style or atom-style *variable*, namely *ex*, *ey*, *ez*. If the value is a variable, it should be specified as *v\_name*, where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the E-field component.

For point-dipoles, equal-style variables can be used, but atom-style variables are not currently supported, since they imply a spatial gradient in the electric field which means additional terms with gradients of the field are required for the force and torque on dipoles.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent E-field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent E-field with optional time-dependence as well.

If the *region* keyword is used, the atom must also be in the specified geometric *region* in order to have force added to it.

---

Adding a force or torque to atoms implies a change in their potential energy as they move or rotate due to the applied E-field.

For dynamics via the “run” command, this energy can be optionally added to the system’s potential energy for thermodynamic output (see below). For energy minimization via the “minimize” command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

The *energy* keyword is not allowed if the added field is a constant vector (*ex,ey,ez*), with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each charged particle directly as

$$U_{efield} = -\vec{x} \cdot q\vec{E} = -q(x \cdot E_x + y \cdot E_y + z \cdot E_z),$$

so that  $-\nabla U_{efield} = \vec{F}$ . Similarly for point-dipole particles the energy can be computed as

$$U_{efield} = -\vec{\mu} \cdot \vec{E} = -\mu_x \cdot E_x + \mu_y \cdot E_y + \mu_z \cdot E_z$$

The *energy* keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the *run* command. If the keyword is not used, LAMMPS will set the energy to 0.0, which is typically fine for dynamics.

The *energy* keyword (or *potential* keyword, described below) is required if the added force is defined with one or more variables, and you are performing energy minimization via the “minimize” command for charged particles. It is not required for point-dipoles, but a warning is issued since the minimizer in LAMMPS does not rotate dipoles, so you should not expect to be able to minimize the orientation of dipoles in an applied electric field.

The *energy* keyword specifies the name of an atom-style *variable* which is used to compute the energy of each atom as function of its position. Like variables used for *ex*, *ey*, *ez*, the energy variable is specified as “v\_name”, where “name” is the variable name.

Note that when the *energy* keyword is used during an energy minimization, you must ensure that the formula defined for the atom-style *variable* is consistent with the force variable formulas, i.e. that  $-\text{Grad}(E) = F$ . For example, if the force due to the electric field were a spring-like  $F = kx$ , then the energy formula should be  $E = -0.5kx^2$ . If you don’t do this correctly, the minimization will not converge properly.

New in version 15Jun2023.

The *potential* keyword can be used as an alternative to the *energy* keyword to specify the name of an atom-style variable, which is used to compute the added electric potential to each atom as a function of its position. The variable should have units of electric field multiplied by distance (that is, in *units real*, the potential should be in volts). As with the *energy* keyword, the variable name is specified as “v\_name”. The energy added by this fix is then calculated as the electric potential multiplied by charge.

The *potential* keyword is mainly intended for correct charge equilibration in simulations with *fix qeq/reaxff*, since with variable charges the electric potential can be known beforehand but the energy cannot. A small additional benefit is that the *energy* keyword requires an additional conversion to energy units which the *potential* keyword avoids. Thus, when the *potential* keyword is specified, the *energy* keyword must not be used. As with *energy*, the *potential* keyword is not allowed if the added field is a constant vector. The *potential* keyword is not supported by *fix efield/tip4p*.

---

## 2.53.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy inferred by the added force due to the electric field to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*. Note that this energy is a fictitious quantity but is needed so that the *minimize* command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force due to the electric field.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix adding its forces. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The vector is the total force added to the group of atoms. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

---

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix\_modify energy* option for this fix.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.53.5 Restrictions

Fix style *efield/tip4p* is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Fix style *efield/tip4p* can only be used with tip4p pair styles.

```

## 2.54.3 Description

This fix implements the asymmetric version of the enhanced heat exchange algorithm (*Wirnsberger*). The eHEX algorithm is an extension of the heat exchange algorithm (*Ikeshoji*) and adds an additional coordinate integration to account for higher-order truncation terms in the operator splitting. The original HEX algorithm (implemented as *fix heat*) is known to exhibit a slight energy drift limiting the accessible simulation times to a few nanoseconds. This issue is greatly improved by the new algorithm decreasing the energy drift by at least a factor of a hundred (LJ and SPC/E water) with little computational overhead.

In both algorithms (non-translational) kinetic energy is constantly swapped between regions (reservoirs) to impose a heat flux onto the system. The equations of motion are therefore modified if a particle  $i$  is located inside a reservoir  $\Gamma_k$  where  $k > 0$ . We use  $\Gamma_0$  to label those parts of the simulation box which are not thermostatted.) The input parameter *region-ID* of this fix corresponds to  $k$ . The energy swap is modelled by introducing an additional thermostating force to the equations of motion, such that the time evolution of coordinates and momenta of particle  $i$  becomes (*Wirnsberger*)

$$\begin{aligned}\dot{\mathbf{r}}_i &= \mathbf{v}_i, \\ \dot{\mathbf{v}}_i &= \frac{\mathbf{f}_i}{m_i} + \frac{\mathbf{g}_i}{m_i}.\end{aligned}$$

The thermostating force is given by

$$\mathbf{g}_i = \begin{cases} \frac{m_i}{2} \frac{F_{\Gamma_k(\mathbf{r}_i)}}{K_{\Gamma_k(\mathbf{r}_i)}} (\mathbf{v}_i - \mathbf{v}_{\Gamma_k(\mathbf{r}_i)}) & k(\mathbf{r}_i) > 0 \text{ (inside a reservoir),} \\ 0 & \text{otherwise,} \end{cases}$$

where  $m_i$  is the mass and  $k(\mathbf{r}_i)$  maps the particle position to the respective reservoir. The quantity  $F_{\Gamma_{k(\mathbf{r}_i)}}$  corresponds to the input parameter  $F$ , which is the energy flux into the reservoir. Furthermore,  $K_{\Gamma_{k(\mathbf{r}_i)}}$  and  $v_{\Gamma_{k(\mathbf{r}_i)}}$  denote the non-translational kinetic energy and the center of mass velocity of that reservoir. The thermostating force does not affect the center of mass velocities of the individual reservoirs and the entire simulation box. A derivation of the equations and details on the numerical implementation with velocity Verlet in LAMMPS can be found in reference “(Wirnsberger)”#\_Wirnsberger.

---

**Note:** This fix only integrates the thermostating force and must be combined with another integrator, such as *fix nve*, to solve the full equations of motion.

---

This fix is different from a thermostat such as *fix nvt* or *fix temp/rescale* in that energy is added/subtracted continually. Thus if there is not another mechanism in place to counterbalance this effect, the entire system will heat or cool continuously.

---

**Note:** If heat is subtracted from the system too aggressively so that the group’s kinetic energy would go to zero, then LAMMPS will halt with an error message. Increasing the value of *nevery* means that heat is added/subtracted less frequently but in larger portions. The resulting temperature profile will therefore be the same.

---

This fix will default to *fix\_heat* (HEX algorithm) if the keyword *hex* is specified.

---

#### Compatibility with SHAKE and RATTLE (rigid molecules):

This fix is compatible with *fix shake* and *fix rattle*. If either of these constraining algorithms is specified in the input script and the keyword *constrain* is set, the bond distances will be corrected a second time at the end of the integration step. It is recommended to specify the keyword *com* in addition to the keyword *constrain*. With this option all sites of a constrained cluster are rescaled, if its center of mass is located inside the region. Rescaling all sites of a cluster by the same factor does not introduce any velocity components along fixed bonds. No rescaling takes place if the center of mass lies outside the region.

---

**Note:** You can only use the keyword *com* along with *constrain*.

---

To achieve the highest accuracy it is recommended to use *fix rattle* with the keywords *constrain* and *com* as shown in the second example. Only if RATTLE is employed, the velocity constraints will be satisfied.

---

**Note:** Even if RATTLE is used and the keywords *com* and *constrain* are both set, the coordinate constraints will not necessarily be satisfied up to the target precision. The velocity constraints are satisfied as long as all sites of a cluster are rescaled (keyword *com*) and the cluster does not span adjacent reservoirs. The current implementation of the eHEX algorithm introduces a small error in the bond distances, which goes to zero with order three in the timestep. For example, in a simulation of SPC/E water with a timestep of 2 fs the maximum relative error in the bond distances was found to be on the order of  $10^{-7}$  for relatively large temperature gradients. A higher precision can be achieved by decreasing the timestep.

---

### 2.54.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.54.5 Restrictions

This fix is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

```

## 2.57.3 Description

The *electrode* fixes implement the constant potential method (CPM) ([Siepmann, Reed](#)), and modern variants, to accurately model electrified, conductive electrodes. This is primarily useful for studying electrode-electrolyte interfaces, especially at high potential differences or ionicities, with non-planar electrodes such as nanostructures or nanopores, and to study dynamic phenomena such as charging or discharging time scales or conductivity or ionic diffusivities.

Each *electrode* fix allows users to set additional electrostatic relationships between the specified groups which model useful electrostatic configurations:

- *electrode/conp* sets potentials or potential differences between electrodes
  - (resulting in changing electrode total charges)
- *electrode/conq* sets the total charge on each electrode
  - (resulting in changing electrode potentials)
- *electrode/thermo* sets a thermopotentiostat ([Deissenbeck](#)) between two electrodes
  - (resulting in changing charges and potentials with appropriate average potential difference and thermal variance)

The first group-ID provided to each fix specifies the first electrode group, and more group(s) are added using the *couple* keyword for each additional group. While *electrode/thermo* only accepts two groups, *electrode/conp* and *electrode/conq* accept any number of groups, up to LAMMPS's internal restrictions (see Restrictions below). Electrode groups must not overlap, i.e. the fix will issue an error if any particle is detected to belong to at least two electrode groups.

CPM involves updating charges on groups of electrode particles, per time step, so that the system's total energy is minimized with respect to those charges. From basic electrostatics, this is equivalent to making each group conductive, or imposing an equal electrostatic potential on every particle in the same group (hence the name CPM). The charges are usually modelled as a Gaussian distribution to make the charge-charge interaction matrix invertible ([Gingrich](#)). The keyword *eta* specifies the distribution's width in units of inverse length.

New in version 22Dec2022.

Three algorithms are available to minimize the energy, varying in how matrices are pre-calculated before a run to provide computational speedup. These algorithms can be selected using the keyword *algo*:

- *algo mat\_inv* pre-calculates the capacitance matrix and obtains the charge configuration in one matrix-vector calculation per time step
- *algo mat\_cg* pre-calculates the elastance matrix (inverse of capacitance matrix) and obtains the charge configuration using a conjugate gradient solver in multiple matrix-vector calculations per time step
- *algo cg* does not perform any pre-calculation and obtains the charge configuration using a conjugate gradient solver and multiple calculations of the electric potential per time step.

For both *cg* methods, the command must specify the conjugate gradient tolerance. *fix electrode/thermo* currently only supports the *mat\_inv* algorithm.

The keyword *symm* can be set *on* (or *off*) to turn on (or turn off) the capacitance matrix constraint that sets total electrode charge to be zero. This has slightly different effects for each *fix electrode* variant. For *fix electrode/conp*, with *symm*

*off*, the potentials specified are absolute potentials, but the charge configurations satisfying them may add up to an overall non-zero, varying charge for the electrodes (and thus the simulation box). With *symm on*, the total charge over all electrode groups is constrained to zero, and potential differences rather than absolute potentials are the physically relevant quantities.

For *fix electrode/conq*, with *symm off*, overall neutrality is explicitly obeyed or violated by the user input (which is not checked!). With *symm on*, overall neutrality is ensured by ignoring the user-input charge for the last listed electrode (instead, its charge will always be minus the total sum of all other electrode charges). For *fix electrode/thermo*, overall neutrality is always automatically imposed for any setting of *symm*, but *symm on* allows finite-field mode (*ffield on*, described below) for faster simulations.

For all three fixes, any potential (or charge for *conq*) can be specified as an equal-style variable prefixed with “v\_”. For example, the following code will ramp the potential difference between electrodes from 0.0V to 2.0V over the course of the simulation:

```
fix fxconp bot electrode/conp 0.0 1.805 couple top v_v symm on
variable v equal ramp(0.0, 2.0)
```

Note that these fixes only parse their supplied variable name when starting a run, and so these fixes will accept equal-style variables defined *after* the fix definition, including variables dependent on the fix’s own output. This is useful, for example, in the fix’s internal finite-field commands (see below). For an advanced example of this see the *in.conq2* input file in the directory *examples/PACKAGES/electrode/graph-il*.

This fix necessitates the use of a long range solver that calculates and provides the matrix of electrode-electrode interactions and a vector of electrode-electrolyte interactions. The Kspace styles *ewald/electrode*, *pppm/electrode* and *pppm/electrode/intel* are created specifically for this task (*Ahrens-Iwers*).

For systems with non-periodic boundaries in one or two directions dipole corrections are available with the *kpace\_modify*. For *ewald/electrode* a two-dimensional Ewald summation (*Hu*) can be used by setting “slab ew2d”:

```
kspace_modify slab <slab_factor>
kpace_modify wire <wire_factor>
kpace_modify slab ew2d
```

Two implementations for the calculation of the elastance matrix are available with *pppm* and can be selected using the *amat onestep/twostep* keyword. *onestep* is the default; *twostep* can be faster for large electrodes and a moderate mesh size but requires more memory.

```
kpace_modify amat onestep/twostep
```

For all versions of the fix, the keyword-value *ffield on* enables the finite-field mode (*Dufils, Tee*), which uses an electric field across a periodic cell instead of non-periodic boundary conditions to impose a potential difference between the two electrodes bounding the cell. The fix (with name *fix-ID*) detects which of the two electrodes is “on top” (has the larger maximum *z*-coordinate among all particles). Assuming the first electrode group is on top, it then issues the following commands internally:

```
variable fix-ID_ffield_zfield equal (f_fix-ID[2]-f_fix-ID[1])/lz
efield fix-ID_efield all efield 0.0 0.0 v_fix-ID_ffield_zfield
```

which implements the required electric field as the potential difference divided by cell length. The internal commands use variable so that the electric field will correctly vary with changing potentials in the correct way (for example with equal-style potential difference or with *fix electrode/conq*). This keyword requires two electrodes and will issue an error with any other number of electrodes. This keyword requires electroneutrality to be imposed (*symm on*) and will issue an error otherwise.

Changed in version 22Dec2022.

For all versions of the fix, the keyword-value *etypes on* enables type-based optimized neighbor lists. With this feature enabled, LAMMPS provides the fix with an occasional neighbor list restricted to electrode-electrode interactions for calculating the electrode matrix, and a perpetual neighbor list restricted to electrode-electrolyte interactions for calculating the electrode potentials, using particle types to list only desired interactions, and typically resulting in 5–10% less computational time. Without this feature the fix will simply use the active pair style's neighbor list. This feature cannot be enabled if any electrode particle has the same type as any electrolyte particle (which would be unusual in a typical simulation) and the fix will issue an error in that case.

New in version 17Apr2024.

The keyword *qtotal* causes *fix electrode/conp* and *fix electrode/thermo* to add an overall potential to all electrodes so that the total charge on the electrodes is a specified amount (which may be an equal-style variable). For example, if a user wanted to simulate a solution of excess cations such that the total electrolyte charge is +2, setting *qtotal* -2 would cause the total electrode charge to be -2, so that the simulation box remains overall electroneutral. Since *fix electrode/conp* constrains the total charges of individual electrodes, and since *symm on* constrains the total charge of all electrodes to be zero, either option is incompatible with the *qtotal* keyword (even if *qtotal* is set to zero).

New in version 17Apr2024.

The keyword *eta* takes the name of a custom double vector defined via *fix property/atom*. The values will be used instead of the standard eta value. The *property/atom* fix must be for vector of double values and use the *ghost on* option.

## 2.57.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix currently does not write any information to restart files.

The *fix\_modify tf* option enables the Thomas-Fermi metallicity model (*Scalfi*) and allows parameters to be set for each atom type.

```
fix_modify ID tf type length voronoi
```

If this option is used, these two parameters must be set for all atom types of the electrode:

- *tf* is the Thomas-Fermi length  $l_{TF}$
- *voronoi* is the Voronoi volume per atom in units of length cubed

Different types may have different *tf* and *voronoi* values. The following self-energy term is then added for all electrode atoms:

$$A_{ii+} = \frac{1}{4\pi\epsilon_0} \times \frac{4\pi l_{TF}^2}{\text{Voronoi volume}}$$

The *fix\_modify timer* option turns on (off) additional timer outputs in the log file, for code developers to track optimization.

```
fix_modify ID timer on/off
```

These fixes compute a global (extensive) scalar, a global (intensive) vector, and a global array, which can be accessed by various *output commands*.

The global scalar outputs the energy added to the system by this fix, which is the negative of the total charge on each electrode multiplied by that electrode's potential.

The global vector outputs the potential on each electrode (and thus has  $N$  entries if the fix manages  $N$  electrode groups), in *units* of electric field multiplied by distance (thus volts for *real* and *metal* units). The electrode groups' ordering follows the order in which they were input in the fix command using *couple*. The global vector output is useful for

*fix electrode/conq* and *fix electrode/thermo*, where potential is dynamically updated based on electrolyte configuration instead of being directly set.

The global array has  $N$  rows and  $2N+1$  columns, where the fix manages  $N$  electrode groups managed by the fix. For the  $I$ -th row of the array, the elements are:

- `array[I][1]` = total charge that group  $I$  would have had *if it were at 0 V applied potential*
- `array[I][2 to N + 1]` = the  $N$  entries of the  $I$ -th row of the electrode capacitance matrix (definition follows)
- `array[I][N + 2 to 2N + 1]` = the  $N$  entries of the  $I$ -th row of the electrode elastance matrix (the inverse of the electrode capacitance matrix)

The  $N \times N$  electrode capacitance matrix, denoted  $\mathbf{C}$  in the following equation, summarizes how the total charge induced on each electrode ( $\mathbf{Q}$  as an  $N$ -vector) is related to the potential on each electrode,  $\mathbf{V}$ , and the charge-at-0V  $\mathbf{Q}_{0V}$  (which is influenced by the local electrolyte structure):

$$\mathbf{Q} = \mathbf{Q}_{0V} + \mathbf{C} \cdot \mathbf{V}$$

The charge-at-0V, electrode capacitance and elastance matrices are internally used to calculate the potentials required to induce the specified total electrode charges in *fix electrode/conq* and *fix electrode/thermo*. With the *symm on* option, the electrode capacitance matrix would be singular, and thus its last row is replaced with  $N$  copies of its top-left entry ( $C_{11}$ ) for invertibility.

The global array output is mainly useful for quickly determining the ‘vacuum capacitance’ of the system (capacitance with only electrodes, no electrolyte), and can also be used for advanced simulations setting the potential as some function of the charge-at-0V (such as the *in.conq2* example mentioned above).

Please cite ([Ahrens-Iwers2022](#)) in any publication that uses this implementation. Please cite also the publication on the combination of the CPM with PPPM if you use *pppm/electrode* ([Ahrens-Iwers](#)).

---

## 2.57.5 Restrictions

For algorithms that use a matrix for the electrode-electrode interactions, positions of electrode particles have to be immobilized at all times.

With *ffield off* (i.e. the default), the box geometry is expected to be  $z$ -non-periodic (i.e. *boundary p p f*), and this fix will issue an error if the box is  $z$ -periodic. With *ffield on*, the box geometry is expected to be  $z$ -periodic, and this fix will issue an error if the box is  $z$ -non-periodic.

The parallelization for the fix works best if electrode atoms are evenly distributed across processors. For a system with two electrodes at the bottom and top of the cell this can be achieved with *processors \* 2*, or with the line

```
if "$(extract_setting(world_size) % 2) == 0" then "processors * 2"
```

which avoids an error if the script is run on an odd number of processors (such as on just one processor for testing).

The fix creates an additional group named `[fix-ID]_group` which is the union of all electrode groups supplied to LAMMPS. This additional group counts towards LAMMPS’s limitation on the total number of groups (currently 32), which may not allow scripts that use that many groups to run with this fix.

The matrix-based algorithms (*algo mat\_inv* and *algo mat\_cg*) currently store an interaction matrix (either elastance or capacitance) of  $N$  by  $N$  doubles for each MPI process. This memory requirement may be prohibitive for large electrode groups. The fix will issue a warning if it expects to use more than 0.5 GiB of memory.

## 2.57.6 Default

The default keyword-option settings are *algo mat\_inv*, *symm off*, *etypes off* and *ffield off*.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 2.58 fix electron/stopping command

## 2.59 fix electron/stopping/fit command

### 2.59.1 Syntax

```
fix ID group-ID style args
```

- ID, group-ID are documented in *fix* command
- style = *electron/stopping* or *electron/stopping/fit*

*electron/stopping* args = Ecut file keyword value ...

Ecut = minimum kinetic energy for electronic stopping (energy units)

file = name of the file containing the electronic stopping power table

*electron/stopping/fit* args = Ecut c1 c2 ...

Ecut = minimum kinetic energy for electronic stopping (energy units)

c1 c2 = linear and quadratic coefficients for the fitted quadratic polynomial

- zero or more keyword/value pairs may be appended to args for style = *electron/stopping*

keyword = *region* or *minneigh*  
  *region* value = region-ID  
    region-ID = region whose atoms will be affected by this fix  
  *minneigh* value = minneigh  
    minneigh = minimum number of neighbors an atom to have stopping applied

## 2.59.2 Examples

```
fix el all electron/stopping 10.0 elstop-table.txt
fix el all electron/stopping 10.0 elstop-table.txt minneigh 3
fix el mygroup electron/stopping 1.0 elstop-table.txt region bulk
fix 1 all electron/stopping/fit 4.63 3.3e-3 4.0e-8
fix 1 all electron/stopping/fit 3.49 1.8e-3 9.0e-8 7.57 4.2e-3 5.0e-8
```

## 2.59.3 Description

This fix implements inelastic energy loss for fast projectiles in solids. It applies a friction force to fast moving atoms to slow them down due to *electronic stopping* (energy lost via electronic collisions per unit of distance). This fix should be used for simulation of irradiation damage or ion implantation, where the ions can lose noticeable amounts of energy from electron excitations. If the electronic stopping power is not considered, the simulated range of the ions can be severely overestimated (*Nordlund98, Nordlund95*).

The electronic stopping is implemented by applying a friction force to each atom as:

$$\vec{F}_i = \vec{F}_i^0 - \frac{\vec{v}_i}{\|\vec{v}_i\|} \cdot S_e$$

where  $\vec{F}_i$  is the resulting total force on the atom.  $\vec{F}_i^0$  is the original force applied to the atom,  $\vec{v}_i$  is its velocity and  $S_e$  is the stopping power of the ion.

---

**Note:** In addition to electronic stopping, atomic cascades and irradiation simulations require the use of an adaptive timestep (see *fix dt/reset*) and the repulsive ZBL potential (see *ZBL* potential) or similar. Without these settings the interaction between the ion and the target atoms will be faulty. It is also common to use in such simulations a thermostat (*fix\_nvt*) in the borders of the simulation cell.

---

---

**Note:** This fix removes energy from fast projectiles without depositing it as a heat to the simulation cell. Such implementation might lead to the unphysical results when the amount of energy deposited to the electronic system is large, e.g. simulations of Swift Heavy Ions (energy per nucleon of 100 keV/amu or higher) or multiple projectiles. You could compensate energy loss by coupling bulk atoms with some thermostat or control heat transfer between electronic and atomic subsystems with the two-temperature model (*fix\_tm*).

---

At low velocities the electronic stopping is negligible. The electronic friction is not applied to atoms whose kinetic energy is smaller than *Ecut*, or smaller than the lowest energy value given in the table in *file*. Electronic stopping should be applied only when a projectile reaches bulk material. This fix scans neighbor list and excludes atoms with fewer than *minneigh* neighbors (by default one). If the pair potential cutoff is large, minneigh should be increased, though not above the number of nearest neighbors in bulk material. An alternative is to disable the check for neighbors by setting *minneigh* to zero and using the *region* keyword. This is necessary when running simulations of cluster bombardment.

If the *region* keyword is used, the atom must also be in the specified geometric *region* in order to have electronic stopping applied to it. This is useful if the position of the bulk material is fixed. By default the electronic stopping is applied everywhere in the simulation cell.

The energy ranges and stopping powers are read from the file *file*. Lines starting with # and empty lines are ignored. Otherwise each line must contain exactly  $N+1$  numbers, where  $N$  is the number of atom types in the simulation.

The first column is the energy for which the stopping powers on that line apply. The energies must be sorted from the smallest to the largest. The other columns are the stopping powers  $S_e$  for each atom type, in ascending order, in force *units*. The stopping powers for intermediate energy values are calculated with linear interpolation between 2 nearest points.

For example:

```
# This is a comment
#      atom-1    atom-2
# eV    eV/Ang    eV/Ang # units metal
10        0        0
250       60       80
750      100      150
```

If an atom which would have electronic stopping applied to it has a kinetic energy higher than the largest energy given in *file*, LAMMPS will exit with an error message.

The stopping power depends on the energy of the ion and the target material. The electronic stopping table can be obtained from scientific publications, experimental databases or by using *SRIM* software. Other programs such as *CasP* or *PASS* can calculate the energy deposited as a function of the impact parameter of the ion; these results can be used to derive the stopping power.

Style *electron/stopping/fit* calculates the electronic stopping power and cumulative energy lost to the electron gas via a quadratic functional and applies a drag force to the classical equations-of-motion for all atoms moving above some minimum cutoff velocity (i.e., kinetic energy). These coefficients can be determined by fitting a quadratic polynomial to electronic stopping data predicted by, for example, SRIM or TD-DFT. Multiple 'Ecut c1 c2' values can be provided for multi-species simulations in the order of the atom types. There is an examples/PACKAGES/electron\_stopping/ directory, which illustrates uses of this command. Details of this implementation are further described in *Stewart2018* and *Lee2020*.

## 2.59.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify* options are not supported.

This fix computes a global scalar, which can be accessed by various *output commands*. The scalar is the total energy loss from electronic stopping applied by this fix since the start of the latest run. It is considered “intensive”.

The *start/stop* keywords of the *run* command have no effect on this fix.

### 2.59.5 Restrictions

This pair style is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

### 2.59.6 Default

The default is no limitation by region, and minneigh = 1.

## 2.60 fix enforce2d command

Accelerator Variants: *enforce2d/kk*

### 2.60.1 Syntax

```
fix ID group-ID enforce2d
```

- ID, group-ID are documented in *fix* command
- enforce2d = style name of this fix command

### 2.60.2 Examples

```
fix 5 all enforce2d
```

### 2.60.3 Description

Zero out the z-dimension velocity and force on each atom in the group. This is useful when running a 2d simulation to ensure that atoms do not move from their initial z coordinate.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

### 2.60.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

### 2.60.5 Restrictions

none

### 2.60.6 Related commands

none

### 2.60.7 Default

none

## 2.61 fix eos/cv command

### 2.61.1 Syntax

```
fix ID group-ID eos/cv cv
```

- ID, group-ID are documented in *fix* command
- eos/cv = style name of this fix command
- cv = constant-volume heat capacity (energy/temperature units)

## 2.61.2 Examples

```
fix 1 all eos/cv 0.01
```

## 2.61.3 Description

Fix *eos/cv* applies a mesoparticle equation of state to relate the particle internal energy ( $u_i$ ) to the particle internal temperature ( $\theta_i$ ). The *eos/cv* mesoparticle equation of state requires the constant-volume heat capacity, and is defined as follows:

$$u_i = u_i^{mech} + u_i^{cond} = C_V \theta_i$$

where  $C_V$  is the constant-volume heat capacity,  $u^{cond}$  is the internal conductive energy, and  $u^{mech}$  is the internal mechanical energy. Note that alternative definitions of the mesoparticle equation of state are possible.

---

## 2.61.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command also requires use of the *atom\_style dpd* command.

## 2.61.5 Related commands

*fix shardlow*, *pair dpd/fdt*

## 2.61.6 Default

none
