See the [\*Accelerator packages\*](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.41.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the  $A$ ,  $\sigma$ ,  $d_1$ , and  $d_2$  coefficients and cutoff distance for this pair style can be mixed.  $A$  is an energy value mixed like a LJ epsilon.  $D_1$  and  $d_2$  are distance values and are mixed like  $\sigma$ . The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.41.5 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Normally, this pair style should be used with finite-size particles which have a diameter, e.g. see the *atom\_style sphere* command. However, this is not a requirement, since the only definition of particle size is via the pair\_coeff parameters for each type. In other words, the physical radius of the particle is ignored. Thus you should ensure that the  $d_1, d_2$  parameters you specify are consistent with the physical size of the particles of that type.

Per-particle polydispersity is not yet supported by this pair style; only per-type polydispersity is enabled via the pair\_coeff parameters.

### 4.42 pair\_style comb command

Accelerator Variants: *comb/omp*

## 4.43 pair\_style comb3 command

### 4.43.1 Syntax

```
pair_style comb
pair_style comb3 keyword
```

keyword = *polar*

*polar* value = *polar\_on* or *polar\_off* = whether or not to include atomic polarization

### 4.43.2 Examples

```
pair_style comb
pair_coeff * * ../potentials/ffield.comb Si
pair_coeff * * ../potentials/ffield.comb Hf Si 0

pair_style comb3 polar_off
pair_coeff * * ../potentials/ffield.comb3 0 Cu N C O
```

### 4.43.3 Description

Style *comb* computes the second generation variable charge COMB (Charge-Optimized Many-Body) potential. Style *comb3* computes the third-generation COMB potential. These COMB potentials are described in ([COMB](#)) and ([COMB3](#)). Briefly, the total energy  $E_T$  of a system of atoms is given by

$$E_T = \sum_i [E_i^{self}(q_i) + \sum_{j>i} [E_{ij}^{short}(r_{ij}, q_i, q_j) + E_{ij}^{Coul}(r_{ij}, q_i, q_j)] + E^{polar}(q_i, r_{ij}) + E^{vdW}(r_{ij}) + E^{barr}(q_i) + E^{corr}(r_{ij}, \theta_{jik})]$$

where  $E_i^{self}$  is the self-energy of atom  $i$  (including atomic ionization energies and electron affinities),  $E_{ij}^{short}$  is the bond-order potential between atoms  $i$  and  $j$ ,  $E_{ij}^{Coul}$  is the Coulomb interactions,  $E^{polar}$  is the polarization term for organic systems (style *comb3* only),  $E^{vdW}$  is the van der Waals energy (style *comb3* only),  $E^{barr}$  is a charge barrier function, and  $E^{corr}$  are angular correction terms.

The COMB potentials (styles *comb* and *comb3*) are variable charge potentials. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See [Rick](#) for further details. This is implemented by the [fix qeq/comb](#) command, which should normally be specified in the input script when running a model with the COMB potential. The [fix qeq/comb](#) command has options that determine how often charge equilibration is performed, its convergence criterion, and which atoms are included in the calculation.

Only a single *pair\_coeff* command is used with the *comb* and *comb3* styles which specifies the COMB potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the potential file in the *pair\_coeff* command, where N is the number of LAMMPS atom types.

For example, if your LAMMPS simulation of a Si/SiO<sub>2</sub>/HfO<sub>2</sub> interface has 4 atom types, and you want the first and last to be Si, the second to be Hf, and the third to be O, and you would use the following *pair\_coeff* command:

```
pair_coeff * * ../potentials/ffield.comb Si Hf O Si
```

The first two arguments must be \* \* so as to span all LAMMPS atom types. The first and last Si arguments map LAMMPS atom types 1 and 4 to the Si element in the *ffield.comb* file. The second Hf argument maps LAMMPS atom type 2 to the Hf element, and the third O argument maps LAMMPS atom type 3 to the O element in the potential file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *comb* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

For style *comb*, the provided potential file *ffield.comb* contains all currently-available second generation COMB parameterizations: for Si, Cu, Hf, Ti, O, their oxides and Zr, Zn and U metals. For style *comb3*, the potential file *ffield.comb3* contains all currently-available third generation COMB parameterizations: O, Cu, N, C, H, Ti, Zn and Zr. The status of the optimization of the compounds, for example Cu<sub>2</sub>O, TiN and hydrocarbons, are given in the following table:

	O	Cu	N	C	H	Ti	Zn	Zr
O	F	F	F	F	F	F	F	F
Cu	F	F	P	F	F	P	F	P
N	F	P	F	M	F	P	P	P
C	F	F	M	F	F	M	M	M
H	F	F	F	F	F	M	M	F
Ti	F	P	P	M	M	F	P	P
Zn	F	F	P	M	M	P	F	P
Zr	F	P	P	M	F	P	P	F

- F = Fully optimized
- M = Only optimized for dimer molecule
- P = in progress, but have it from mixing rule

For style *comb3*, in addition to *ffield.comb3*, a special parameter file, *lib.comb3*, that is exclusively used for C/O/H systems, will be automatically loaded if carbon atom is detected in LAMMPS input structure. This file must be in your working directory or in the directories listed in the environment variable LAMMPS\_POTENTIALS, as described on the [pair\\_coeff](#) command doc page.

The keyword *polar* indicates whether the force field includes the atomic polarization. Since the equilibration of the polarization has not yet been implemented, it can only set *polar\_off* at present.

---

**Note:** You can not use potential file *ffield.comb* with style *comb3*, nor file *ffield.comb3* with style *comb*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.43.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

These pair styles does not support the *pair\_modify* shift, table, and tail options.

These pair styles do not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style*, *pair\_coeff*, and *fix qeq/comb* commands in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.43.5 Restrictions

These pair styles are part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These pair styles requires the *newton* setting to be “on” for pair interactions.

The COMB potentials in the *ffield.comb* and *ffield.comb3* files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the COMB potential with any LAMMPS units, but you would need to create your own COMB potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

### 4.44 pair\_style cosine/squared command

#### 4.44.1 Syntax

**pair\_style** cosine/squared cutoff

- cutoff = global cutoff for cosine-squared interactions (distance units)

```
pair_coeff I J eps sigma
pair_coeff I J eps sigma cutoff
pair_coeff I J eps sigma wca
pair_coeff I J eps sigma cutoff wca
```

- I, J = a particle type
- eps = interaction strength, i.e. the depth of the potential minimum (energy units)
- sigma = distance of the potential minimum from 0
- cutoff = the cutoff distance for this pair type, if different from global (distance units)
- wca = if specified a Weeks-Chandler-Andersen potential (with eps strength and minimum at sigma) is added, otherwise not

#### 4.44.2 Examples

```
pair_style cosine/squared 3.0
pair_coeff * * 1.0 1.3
pair_coeff 1 3 1.0 1.3 2.0
pair_coeff 1 3 1.0 1.3 wca
pair_coeff 1 3 1.0 1.3 2.0 wca
```

#### 4.44.3 Description

Style *cosine/squared* computes a potential of the form

$$E = \begin{cases} -\epsilon & r < \sigma \\ -\epsilon \cos\left(\frac{\pi(r-\sigma)}{2(r_c-\sigma)}\right)^2 & \sigma \leq r < r_c \\ 0 & r \geq r_c \end{cases}$$

between two point particles, where  $(\sigma, -\epsilon)$  is the location of the (rightmost) minimum of the potential, as explained in the syntax section above.

This potential was first used in (Cooke) for a coarse-grained lipid membrane model. It is generally very useful as a non-specific interaction potential because it is fully adjustable in depth and width while joining the minimum at (sigma, -epsilon) and zero at (cutoff, 0) smoothly, requiring no shifting and causing no related artifacts, tail energy calculations etc. This evidently requires *cutoff* to be larger than *sigma*.

If the *wca* option is used then a Weeks-Chandler-Andersen potential (Weeks) is added to the above specified cosine-squared potential, specifically the following:

$$E = \epsilon \left[ \left(\frac{\sigma}{r}\right)^{12} - 2 \left(\frac{\sigma}{r}\right)^6 + 1 \right], \quad r < \sigma$$

In this case, and this case only, the  $\sigma$  parameter can be equal to *cutoff* ( $\sigma$  = cutoff) which will result in ONLY the WCA potential being used (and print a warning), so the minimum will be attained at (sigma, 0). This is a convenience feature that enables a purely repulsive potential to be used without a need to define an additional pair style and use the hybrid styles.

The energy and force of this pair style for parameters epsilon = 1.0, sigma = 1.0, cutoff = 2.5, with and without the WCA potential, are shown in the graphs below:

#### 4.44.4 Mixing, shift, table, tail correction, restart, rRESPA info

Mixing is not supported for this style.

The *shift*, *table* and *tail* options are not relevant for this style.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

#### 4.44.5 Restrictions

The *cosine/squared* style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS is build with that package. See the *Build package* page for more info.

### 4.55.3 Description

The *coul/cut* style computes the standard Coulombic interaction potential given by

$$E = \frac{Cq_iq_j}{\epsilon r} \quad r < r_c$$

where  $C$  is an energy-conversion constant,  $Q_i$  and  $Q_j$  are the charges on the two atoms, and  $\epsilon$  is the dielectric constant which can be set by the *dielectric* command. The cutoff  $r_c$  truncates the interaction distance.

Pair style *coul/cut/global* computes the same Coulombic interactions as style *coul/cut* except that it allows only a single global cutoff and thus makes it compatible for use in combination with long-range coulomb styles in *hybrid pair styles*.

Style *coul/debye* adds an additional  $\exp()$  damping factor to the Coulombic term, given by

$$E = \frac{Cq_iq_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c$$

where  $\kappa$  is the Debye length. This potential is another way to mimic the screening effect of a polar solvent.

Style *coul/dsf* computes Coulombic interactions via the damped shifted force model described in *Fennell*, given by:

$$E = q_iq_j \left[ \frac{\operatorname{erfc}(\alpha r)}{r} - \frac{\operatorname{erfc}(\alpha r_c)}{r_c} + \left( \frac{\operatorname{erfc}(\alpha r_c)}{r_c^2} + \frac{2\alpha \exp(-\alpha^2 r_c^2)}{\sqrt{\pi} r_c} \right) (r - r_c) \right] \quad r < r_c$$

where  $\alpha$  is the damping parameter and  $\operatorname{erfc}()$  is the complementary error-function. The potential corrects issues in the Wolf model (described below) to provide consistent forces and energies (the Wolf potential is not differentiable at the cutoff) and smooth decay to zero.

Style *coul/wolf* computes Coulombic interactions via the Wolf summation method, described in [Wolf](#), given by:

$$E_i = \frac{1}{2} \sum_{j \neq i} \frac{q_i q_j \operatorname{erfc}(\alpha r_{ij})}{r_{ij}} + \frac{1}{2} \sum_{j \neq i} \frac{q_i q_j \operatorname{erf}(\alpha r_{ij})}{r_{ij}} \quad r < r_c$$

where  $\alpha$  is the damping parameter, and  $\operatorname{erf}()$  and  $\operatorname{erfc}()$  are error-function and complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise  $1/r$  summation. With a manipulation of adding and subtracting a self term (for  $i = j$ ) to the first and second term on the right-hand-side, respectively, and a small enough  $\alpha$  damping parameter, the second term shrinks and the potential becomes a rapidly-converging real-space summation. With a long enough cutoff and small enough  $\alpha$  parameter, the energy and forces calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.

Style *coul/streitz* is the Coulomb pair interaction defined as part of the Streitz-Mintmire potential, as described in [this paper](#), in which charge distribution about an atom is modeled as a Slater  $1s$  orbital. More details can be found in the referenced paper. To fully reproduce the published Streitz-Mintmire potential, which is a variable charge potential, style *coul/streitz* must be used with *pair\_style eam/alloy* (or some other short-range potential that has been parameterized appropriately) via the *pair\_style hybrid/overlay* command. Likewise, charge equilibration must be performed via the *fix qeq/slater* command. For example:

```
pair_style hybrid/overlay coul/streitz 12.0 wolf 0.31 eam/alloy
pair_coeff * * coul/streitz AlO.streitz Al 0
pair_coeff * * eam/alloy AlO.eam.alloy Al 0
fix 1 all qeq/slater 1 12.0 1.0e-6 100 coul/streitz
```

The keyword *wolf* in the *coul/streitz* command denotes computing Coulombic interactions via Wolf summation. An additional damping parameter is required for the Wolf summation, as described for the *coul/wolf* potential above. Alternatively, Coulombic interactions can be computed via an Ewald summation. For example:

```
pair_style hybrid/overlay coul/streitz 12.0 ewald eam/alloy
kpspace_style ewald 1e-6
```

Keyword *ewald* does not need a damping parameter, but a *kpspace\_style* must be defined, which can be style *ewald* or *pppm*. The Ewald method was used in Streitz and Mintmire's original paper, but a Wolf summation offers a speed-up in some cases.

For the *fix qeq/slater* command, the *qfile* can be a filename that contains QEq parameters as discussed on the *fix qeq* command doc page. Alternatively *qfile* can be replaced by "coul/streitz", in which case the *fix* will extract QEq parameters from the *coul/streitz* pair style itself.

See the examples/streitz directory for an example input script that uses the Streitz-Mintmire potential. The potentials directory has the AlO.eam.alloy and AlO.streitz potential files used by the example.

Note that the Streitz-Mintmire potential is generally used for oxides, but there is no conceptual problem with extending it to nitrides and carbides (such as SiC, TiN). Pair *coul/streitz* used by itself or with any other pair style such as EAM, MEAM, Tersoff, or LJ in hybrid/overlay mode. To do this, you would need to provide a Streitz-Mintmire parameterization for the material being modeled.

Pair style *coul/exclude* computes Coulombic interactions like *coul/cut* but **only** applies them to excluded pairs using a scaling factor of  $\gamma - 1.0$  with  $\gamma$  being the factor assigned to that excluded pair via the *special\_bonds coul* setting. With this it is possible to treat Coulomb interactions for molecular systems with *kpspace\_style scafacos*, which always computes the full Coulomb interactions without exclusions. Pair style *coul/exclude* will then *subtract* the excluded interactions accordingly. So to achieve the same forces as with *pair\_style lj/cut/coul/long 12.0* with *kpspace\_style ppm*

1.0e-6, one would use `pair_style hybrid/overlay lj/cut 12.0 coul/exclude 12.0` with `kpace_style scafacos p3m 1.0e-6`.

Styles *coul/long* and *coul/msm* compute the same Coulombic interactions as style *coul/cut* except that an additional damping factor is applied so it can be used in conjunction with the *kpace\_style* command and its *ewald* or *pppm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

Styles *tip4p/cut* and *tip4p/long* implement the Coulomb part of the TIP4P water model of ([Jorgensen](#)), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as *pair\_style* arguments. Style *tip4p/cut* uses a global cutoff for Coulomb interactions; style *tip4p/long* is for use with a long-range Coulombic solver (Ewald or PPPM).

---

**Note:** For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

---

---

**Note:** If using type labels, the type labels must be defined before calling the *pair\_coeff* command.

---

See the [Howto tip4p](#) page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance  $2*qdist$  when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff  $\geq$  Coulombic cutoff +  $2*qdist$ , to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

---

Note that these potentials are designed to be combined with other pair potentials via the *pair\_style hybrid/overlay* command. This is because they have no repulsive core. Hence if they are used by themselves, there will be no repulsion to keep two oppositely charged particles from moving arbitrarily close to each other.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- cutoff (distance units)

For *coul/cut* and *coul/debye* the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the *pair\_style* command is used.

For *coul/cut/global*, *coul/long* and *coul/msm* no cutoff can be specified for an individual I,J type pair via the *pair\_coeff* command. All type pairs use the same global Coulomb cutoff specified in the *pair\_style* command.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.55.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the cutoff distance for the *coul/cut* style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

The *pair\_modify* shift option is not relevant for these pair styles.

The *coul/long* style supports the *pair\_modify* table option for tabulation of the short-range portion of the long-range Coulombic interaction.

These pair styles do not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.55.5 Restrictions

The *coul/long*, *coul/msm*, *coul/streitz*, and *tip4p/long* styles are part of the KSPACE package. The *coul/cut/global*, *coul/exclude* styles are part of the EXTRA-PAIR package. The *tip4p/cut* style is part of the MOLECULE package. A pair style is only enabled if LAMMPS was built with its corresponding package. See the *Build package* doc page for more info.

#### 4.55.6 Related commands

### 4.56 pair\_style coul/diel command

Accelerator Variants: *coul/diel/omp*

### 4.56.1 Syntax

```
pair_style coul/diel cutoff
```

cutoff = global cutoff (distance units)

### 4.56.2 Examples

```
pair_style coul/diel 3.5
pair_coeff 1 4 78. 1.375 0.112
```

### 4.56.3 Description

Style *coul/diel* computes a Coulomb correction for implicit solvent ion interactions in which the dielectric permittivity is distance dependent. The dielectric permittivity  $\epsilon_D(r)$  connects to limiting regimes: One limit is defined by a small dielectric permittivity (close to vacuum) at or close to contact separation between the ions. At larger separations the dielectric permittivity reaches a bulk value used in the regular Coulomb interaction *coul/long* or *coul/cut*. The transition is modeled by a hyperbolic function which is incorporated in the Coulomb correction term for small ion separations as follows

$$E = \frac{Cq_iq_j}{\epsilon r} \left( \frac{\epsilon}{\epsilon_D(r)} - 1 \right) \quad r < r_c$$
$$\epsilon_D(r) = \frac{5.2 + \epsilon}{2} + \frac{\epsilon - 5.2}{2} \tanh \left( \frac{r - r_{me}}{\sigma_e} \right)$$

where  $r_{me}$  is the inflection point of  $\epsilon_D(r)$  and  $\sigma_e$  is a slope defining length scale.  $C$  is the same Coulomb conversion factor as in the pair\_styles *coul/cut*, *coul/long*, and *coul/debye*. In this way the Coulomb interaction between ions is corrected at small distances  $r$ . The lower limit of  $\epsilon_D(r \rightarrow 0) = 5.2$  due to dielectric saturation ([Stiles](#)) while the Coulomb interaction reaches its bulk limit by setting  $\epsilon_D(r \rightarrow \infty) = \epsilon$ , the bulk value of the solvent which is 78 for water at 298K.

Examples of the use of this type of Coulomb interaction include implicit solvent simulations of salt ions ([Lenart](#)) and of ionic surfactants ([Jusuifi](#)). Note that this potential is only reasonable for implicit solvent simulations and in combination with *coul/cut* or *coul/long*. It is also usually combined with *gauss/cut*, see ([Lenart](#)) or ([Jusuifi](#)).

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $\epsilon$  (no units)
- $r_{me}$  (distance units)
- $\sigma_e$  (distance units)

The global cutoff ( $r_c$ ) specified in the *pair\_style* command is used.

#### 4.56.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs.

This pair style supports the *pair\_modify* shift option for the energy of the Gauss-potential portion of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.56.5 Restrictions

This style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.56.6 Related commands

*pair\_coeff pair\_style gauss/cut*

#### 4.56.7 Default

none

### 4.57 pair\_style coul/shield command

#### 4.57.1 Syntax

```
pair_style coul/shield cutoff tap_flag
```

- cutoff = global cutoff (distance units)
- tap\_flag = 0/1 to turn off/on the taper function

## 4.57.2 Examples

```
pair_style coul/shield 16.0 1
pair_coeff 1 2 0.70
```

## 4.57.3 Description

Style *coul/shield* computes a Coulomb interaction for boron and nitrogen atoms located in different layers of hexagonal boron nitride. This potential is designed be used in combination with the pair style *ilp/graphene/hbn*

**Note:** This potential is intended for electrostatic interactions between two different layers of hexagonal boron nitride. Therefore, to avoid interaction within the same layers, each layer should have a separate molecule id and is recommended to use the “full” atom style, so that charge and molecule ID information is included.

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = \text{Tap}(r_{ij}) \frac{\kappa q_i q_j}{\sqrt[3]{r_{ij}^3 + (1/\lambda_{ij})^3}}$$

$$\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1$$

Where  $\text{Tap}(r_{ij})$  is the taper function which provides a continuous cutoff (up to third derivative) for inter-atomic separations larger than  $r_c$  (*Leven1*), (*Leven2*) and (*Maaravi*). Here  $\lambda$  is the shielding parameter that eliminates the short-range singularity of the classical mono-polar electrostatic interaction expression (*Maaravi*).

The shielding parameter  $\lambda$  (1/distance units) must be defined for each pair of atom types via the *pair\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

The global cutoff ( $r_c$ ) specified in the *pair\_style* command is used.

## 4.57.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs.

The *pair\_modify table* option is not relevant for this pair style.

This pair style does not support the *pair\_modify tail* option for adding long-range tail corrections to energy and pressure.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.57.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.57.6 Related commands

*pair\_coeff pair\_style ilp/graphene/hbn*

### 4.57.7 Default

tap\_flag = 1

## 4.58 pair\_style coul/slater command

## 4.59 pair\_style coul/slater/cut command

## 4.60 pair\_style coul/slater/long command

Accelerator Variants: *coul/slater/long/gpu*

### 4.60.1 Syntax

```
pair_style coul/slater/cut lambda cutoff
pair_style coul/slater/long lambda cutoff
```

lambda = decay length of the charge (distance units) cutoff = cutoff (distance units)

### 4.60.2 Examples

```
pair_style coul/slater/cut 1.0 3.5
pair_coeff * *
pair_coeff 2 2 2.5

pair_style coul/slater/long 1.0 12.0
pair_coeff * *
pair_coeff 1 1 5.0
```

### 4.60.3 Description

Styles *coul/slater/\** compute electrostatic interactions in mesoscopic models which employ potentials without explicit excluded-volume interactions. The goal is to prevent artificial ionic pair formation by including a charge distribution in the Coulomb potential, following the formulation of ([Melchor](#)):

$$E = \frac{Cq_iq_j}{\epsilon r} \left( 1 - \left( 1 + \frac{r_{ij}}{\lambda} \exp(-2r_{ij}/\lambda) \right) \right) \quad r < r_c$$

where  $r_c$  is the cutoff distance and  $\lambda$  is the decay length of the charge.  $C$  is the same Coulomb conversion factor as in the pair\_styles *coul/cut* and *coul/long*. In this way the Coulomb interaction between ions is corrected at small distances  $r$ . For the *coul/slater/cut* style, the potential energy for distances larger than the cutoff is zero, while for the *coul/slater/long*, the long-range interactions are computed either by the Ewald or the PPPM technique.

Phenomena that can be captured at a mesoscopic level using this type of electrostatic interactions include the formation of polyelectrolyte-surfactant aggregates, charge stabilization of colloidal suspensions, and the formation of complexes driven by charged species in biological systems. ([Vaiwala](#)).

The cutoff distance is optional. If it is not used, the default global value specified in the pair\_style command is used. For each pair of atom types, a specific cutoff distance can be defined via the *pair\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $r_c$  (distance units)

The global decay length of the charge ( $\lambda$ ) specified in the pair\_style command is used for all pairs.

---

### 4.60.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the cutoff distance for the *coul/slater* styles can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

The *pair\_modify* shift and table options are not relevant for these pair styles.

These pair styles do not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.60.5 Restrictions

The *coul/slater/long* style requires the long-range solvers included in the KSPACE package.

These styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 4.60.6 Related commands

*pair\_coeff*, *pair\_style*, *hybrid/overlay*, *kpace\_style*

## 4.60.7 Default

none

(**Melchor**) Gonzalez-Melchor, Mayoral, Velazquez, and Alejandro, J Chem Phys, 125, 224107 (2006).

(**Vaiwala**) Vaiwala, Jadhav, and Thaokar, J Chem Phys, 146, 124904 (2017).

## 4.61 pair\_style coul/tt command

### 4.61.1 Syntax

```
pair_style style args
```

- style = *coul/tt*
- args = list of arguments for a particular style

*coul/tt* args = n cutoff

n = degree of polynomial

cutoff = global cutoff (distance units)

### 4.61.2 Examples

```
pair_style hybrid/overlay ... coul/tt 4 12.0
pair_coeff 1 2 coul/tt 4.5 1.0
pair_coeff 1 2 coul/tt 4.0 1.0 4 12.0
pair_coeff 1 3* coul/tt 4.5 1.0 4
```

Example input scripts available: [examples/PACKAGES/drude](#)

### 4.61.3 Description

The *coul/tt* pair style is meant to be used with force fields that include explicit polarization through Drude dipoles.

The *coul/tt* pair style should be used as a sub-style within in the *pair\_style hybrid/overlay* command, in conjunction with a main pair style including Coulomb interactions and *thole* pair style, or with *lj/cut/thole/long* pair style that is equivalent to the combination of preceding two.

The *coul/tt* pair styles compute the charge-dipole Coulomb interaction damped at short distances by a function

$$f_{n,ij}(r) = 1 - c_{ij} \cdot e^{-b_{ij}r} \sum_{k=0}^n \frac{(b_{ij}r)^k}{k!}$$

This function results from an adaptation to the Coulomb interaction (*Salanne*) of the damping function originally proposed by *Tang Toennies* for van der Waals interactions.

The polynomial takes the degree 4 for damping the Coulomb interaction. The parameters  $b_{ij}$  and  $c_{ij}$  could be determined from first-principle calculations for small, mainly mono-atomic, ions ([Salanne](#)), or else treated as empirical for large molecules.

In pair styles with Drude induced dipoles, this damping function is typically applied to the interactions between a Drude charge (either  $q_{D,i}$  on a Drude particle or  $-q_{D,i}$  on the respective Drude core)) and a charge on a non-polarizable atom,  $q_j$ .

The Tang-Toennies function could also be used to damp electrostatic interactions between the (non-polarizable part of the) charge of a core,  $q_i - q_{D,i}$ , and the Drude charge of another,  $-q_{D,j}$ . The  $b_{ij}$  and  $c_{ij}$  are equal to  $b_{ji}$  and  $c_{ji}$  in the case of core-core interactions.

For pair\_style *coul/tt*, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the example above.

- $b_{ij}$
- $c_{ij}$
- degree of polynomial (positive integer)
- cutoff (distance units)

The last two coefficients are optional. If not specified the global degree of the polynomial or the global cutoff specified in the pair\_style command are used. In order to specify a cutoff (forth argument), the degree of the polynomial (third argument) must also be specified.

---

#### 4.61.4 Mixing, shift, table, tail correction, restart, rRESPA info

The *coul/tt* pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

#### 4.61.5 Restrictions

These pair styles are part of the DRUDE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair\_style should currently not be used with the *charmm dihedral style* if the latter has non-zero 1-4 weighting factors. This is because the *coul/tt* pair style does not know which pairs are 1-4 partners of which dihedrals.

#### 4.61.6 Related commands

## 4.69.3 Description

These pair styles are designed to be used with the adiabatic core/shell model of (*Mitchell and Fincham*). See the *Howto coreshell* page for an overview of the model as implemented in LAMMPS.

All the styles are identical to the corresponding pair style without the “/cs” in the name:

- *pair\_style born/coul/dsf*
- *pair\_style born/coul/long*
- *pair\_style born/coul/wolf*

- *pair\_style buck/coul/long*
- *pair\_style coul/long*
- *pair\_style coul/wolf*
- *pair\_style lj/cut/coul/long*
- *pair\_style lj/class2/coul/long*

except that they correctly treat the special case where the distance between two charged core and shell atoms in the same core/shell pair approach  $r = 0.0$ .

Styles with a “/long” in the name are used with a long-range solver for Coulombic interactions via the *kspace\_style* command. They require special treatment of the short-range Coulombic interactions within the cor/shell model.

Specifically, the short-range Coulomb interaction between a core and its shell should be turned off using the *special\_bonds* command by setting the 1-2 weight to 0.0, which works because the core and shell atoms are bonded to each other. This induces a long-range correction approximation which fails at small distances ( $\sim < 10e-8$ ). Therefore, the Coulomb term which is used to calculate the correction factor is extended by a minimal distance ( $r_{\min} = 1.0-6$ ) when the interaction between a core/shell pair is treated, as follows

$$E = \frac{Cq_iq_j}{\epsilon(r + r_{\min})} \quad r \rightarrow 0$$

where  $C$  is an energy-conversion constant,  $q_i$  and  $q_j$  are the charges on the core and shell, epsilon is the dielectric constant and  $r_{\min}$  is the minimal distance.

For styles that are not used with a long-range solver, i.e. those with “/dsf” or “/wolf” in the name, the only correction is the addition of a minimal distance to avoid the possible  $r = 0.0$  case for a core/shell pair.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.69.4 Mixing, shift, table, tail correction, restart, rRESPA info

See the corresponding doc pages for pair styles without the “cs” suffix to see how mixing, shifting, tabulation, tail correction, restarting, and rRESPA are handled by these pair styles.

---

### 4.69.5 Restrictions

These pair styles are part of the CORESHELL package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.69.6 Related commands

*pair\_coeff*, *pair\_style born*, *pair\_style buck*

```

Used in input scripts:

```
examples/PACKAGES/dielectric/in.confined
examples/PACKAGES/dielectric/in.nopbc
```

## 4.76.3 Description

All these pair styles are derived from the corresponding pair styles without the *dielectric* suffix. In addition to computing atom forces and energies, these pair styles compute the electric field vector at each atom, which are intended to be used by the *fix polarize* commands to compute induced charges at interfaces between two regions of different dielectric constant.

These pair styles should be used with *atom\_style dielectric*.

The styles *lj/cut/coul/long/dielectric*, *lj/cut/coul/msm/dielectric*, and *lj/long/coul/long/dielectric* should be used with their kspace style counterparts, namely, *pppm/dielectric*, *pppm/disp/dielectric*, and *msm/dielectric*, respectively.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

#### 4.76.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distances for this pair style can be mixed. The default mix algorithm is *geometric*. See the *pair\_modify* command for details.

The *pair\_modify* table option is not relevant for this pair style.

These pair styles write its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.76.5 Restrictions

These styles are part of the DIELECTRIC package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.76.6 Related commands

### 4.79 pair\_style lj/cut/dipole/long command

Accelerator Variants: *lj/cut/dipole/long/gpu*

## 4.80 pair\_style lj/long/dipole/long command

### 4.80.1 Syntax

```
pair_style lj/cut/dipole/cut cutoff (cutoff2)
pair_style lj/sf/dipole/sf cutoff (cutoff2)
pair_style lj/cut/dipole/long cutoff (cutoff2)
pair_style lj/long/dipole/long flag_lj flag_coul cutoff (cutoff2)
```

- cutoff = global cutoff LJ (and Coulombic if only 1 arg) (distance units)
- cutoff2 = global cutoff for Coulombic and dipole (optional) (distance units)
- flag\_lj = *long* or *cut* or *off*  
*long* = use long-range damping on dispersion  $1/r^6$  term  
*cut* = use a cutoff on dispersion  $1/r^6$  term  
*off* = omit dispersion  $1/r^6$  term entirely
- flag\_coul = *long* or *off*  
*long* = use long-range damping on Coulombic  $1/r$  and point-dipole terms  
*off* = omit Coulombic and point-dipole terms entirely

### 4.80.2 Examples

```
pair_style lj/cut/dipole/cut 2.5 5.0
pair_coeff * * 1.0 1.0
pair_coeff 2 3 0.8 1.0 2.5 4.0

pair_style lj/sf/dipole/sf 9.0
pair_coeff * * 1.0 1.0
pair_coeff 2 3 1.0 1.0 2.5 4.0 scale 0.5
pair_coeff 2 3 0.8 1.0 2.5 4.0

pair_style lj/cut/dipole/long 2.5 3.5
pair_coeff * * 1.0 1.0
pair_coeff 2 3 0.8 1.0 3.0

pair_style lj/long/dipole/long long long 3.5
pair_coeff * * 1.0 1.0
pair_coeff 2 3 0.8 1.0

pair_style lj/long/dipole/long cut long 2.5 3.5
pair_coeff * * 1.0 1.0
pair_coeff 2 3 0.8 1.0 3.0
```

### 4.80.3 Description

Style *lj/cut/dipole/cut* computes interactions between pairs of particles that each have a charge and/or a point dipole moment. In addition to the usual Lennard-Jones interaction between the particles (Elj) the charge-charge (Eqq), charge-dipole (Eqp), and dipole-dipole (Epp) interactions are computed by these formulas for the energy (E), force (F), and torque (T) between particles I and J.

$$\begin{aligned}
 E_{LJ} &= 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \\
 E_{qq} &= \frac{q_i q_j}{r} \\
 E_{qp} &= \frac{q}{r^3} (\vec{p} \cdot \vec{r}) \\
 E_{pp} &= \frac{1}{r^3} (\vec{p}_i \cdot \vec{p}_j) - \frac{3}{r^5} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r}) \\
 \\ 
 F_{qq} &= \frac{q_i q_j}{r^3} \vec{r} \\
 F_{qp} &= -\frac{q}{r^3} \vec{p} + \frac{3q}{r^5} (\vec{p} \cdot \vec{r}) \vec{r} \\
 F_{pp} &= \frac{3}{r^5} (\vec{p}_i \cdot \vec{p}_j) \vec{r} - \frac{15}{r^7} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r}) \vec{r} + \frac{3}{r^5} [(\vec{p}_j \cdot \vec{r}) \vec{p}_i + (\vec{p}_i \cdot \vec{r}) \vec{p}_j] \\
 \\ 
 T_{pq} &= T_{ij} = \frac{q_j}{r^3} (\vec{p}_i \times \vec{r}) \\
 T_{qp} &= T_{ji} = -\frac{q_i}{r^3} (\vec{p}_j \times \vec{r}) \\
 T_{pp} &= T_{ij} = -\frac{1}{r^3} (\vec{p}_i \times \vec{p}_j) + \frac{3}{r^5} (\vec{p}_j \cdot \vec{r})(\vec{p}_i \times \vec{r}) \\
 T_{pp} &= T_{ji} = -\frac{1}{r^3} (\vec{p}_j \times \vec{p}_i) + \frac{3}{r^5} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \times \vec{r})
 \end{aligned}$$

where  $q_i$  and  $q_j$  are the charges on the two particles,  $\vec{p}_i$  and  $\vec{p}_j$  are the dipole moment vectors of the two particles,  $r$  is their separation distance, and the vector  $\vec{r} = \vec{R}_i - \vec{R}_j$  is the separation vector between the two particles. Note that Eqq and Fqq are simply Coulombic energy and force,  $F_{ij} = -F_{ji}$  as symmetric forces, and  $T_{ij} \neq -T_{ji}$  since the torques do not act symmetrically. These formulas are discussed in ([AllenTildesley](#)) and in ([Toukmaji](#)).

Also note, that in the code, all of these terms (except Elj) have a  $C/\epsilon$  prefactor, the same as the Coulombic term in the LJ + Coulombic pair styles discussed [here](#).  $C$  is an energy-conversion constant and  $\epsilon$  is the dielectric constant which can be set by the [dielectric](#) command. The same is true of the equations that follow for other dipole pair styles.

Style *lj/sf/dipole/sf* computes “shifted-force” interactions between pairs of particles that each have a charge and/or a point dipole moment. In general, a shifted-force potential is a (slightly) modified potential containing extra terms that make both the energy and its derivative go to zero at the cutoff distance; this removes (cutoff-related) problems in energy conservation and any numerical instability in the equations of motion ([AllenTildesley](#)). Shifted-force interactions for the Lennard-Jones (E\_LJ), charge-charge (Eqq), charge-dipole (Eqp), dipole-charge (Epq) and dipole-dipole (Epp)

potentials are computed by these formulas for the energy (E), force (F), and torque (T) between particles I and J:

$$\begin{aligned}
 E_{LJ} &= 4\epsilon \left\{ \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] + \left[ 6 \left( \frac{\sigma}{r_c} \right)^{12} - 3 \left( \frac{\sigma}{r_c} \right)^6 \right] \left( \frac{r}{r_c} \right)^2 - 7 \left( \frac{\sigma}{r_c} \right)^{12} + 4 \left( \frac{\sigma}{r_c} \right)^6 \right\} \\
 E_{qq} &= \frac{q_i q_j}{r} \left( 1 - \frac{r}{r_c} \right)^2 \\
 E_{pq} &= E_{ji} = -\frac{q}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p} \bullet \vec{r}) \\
 E_{qp} &= E_{ij} = \frac{q}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p} \bullet \vec{r}) \\
 E_{pp} &= \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] \left[ \frac{1}{r^3} (\vec{p}_i \bullet \vec{p}_j) - \frac{3}{r^5} (\vec{p}_i \bullet \vec{r})(\vec{p}_j \bullet \vec{r}) \right] \\
 F_{LJ} &= \left\{ \left[ 48\epsilon \left( \frac{\sigma}{r} \right)^{12} - 24\epsilon \left( \frac{\sigma}{r} \right)^6 \right] \frac{1}{r^2} - \left[ 48\epsilon \left( \frac{\sigma}{r_c} \right)^{12} - 24\epsilon \left( \frac{\sigma}{r_c} \right)^6 \right] \frac{1}{r_c^2} \right\} \vec{r} \\
 F_{qq} &= \frac{q_i q_j}{r} \left( \frac{1}{r^2} - \frac{1}{r_c^2} \right) \vec{r} \\
 F_{pq} &= F_{ij} = -\frac{3q}{r^5} \left[ 1 - \left( \frac{r}{r_c} \right)^2 \right] (\vec{p} \bullet \vec{r}) \vec{r} + \frac{q}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] \vec{p} \\
 F_{qp} &= F_{ij} = \frac{3q}{r^5} \left[ 1 - \left( \frac{r}{r_c} \right)^2 \right] (\vec{p} \bullet \vec{r}) \vec{r} - \frac{q}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] \vec{p} \\
 F_{pp} &= \frac{3}{r^5} \left\{ \left[ 1 - \left( \frac{r}{r_c} \right)^4 \right] \left[ (\vec{p}_i \bullet \vec{p}_j) - \frac{3}{r^2} (\vec{p}_i \bullet \vec{r})(\vec{p}_j \bullet \vec{r}) \right] \vec{r} + \right. \\
 &\quad \left. \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] \left[ (\vec{p}_j \bullet \vec{r}) \vec{p}_i + (\vec{p}_i \bullet \vec{r}) \vec{p}_j - \frac{2}{r^2} (\vec{p}_i \bullet \vec{r})(\vec{p}_j \bullet \vec{r}) \vec{r} \right] \right\} \\
 T_{pq} &= T_{ij} = \frac{q_j}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p}_i \times \vec{r}) \\
 T_{qp} &= T_{ji} = -\frac{q_i}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p}_j \times \vec{r}) \\
 T_{pp} &= T_{ij} = -\frac{1}{r^3} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_i \times \vec{p}_j) + \\
 &\quad \frac{3}{r^5} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_j \bullet \vec{r})(\vec{p}_i \times \vec{r}) \\
 T_{pp} &= T_{ji} = -\frac{1}{r^3} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_j \times \vec{p}_i) + \\
 &\quad \frac{3}{r^5} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_i \bullet \vec{r})(\vec{p}_j \times \vec{r})
 \end{aligned}$$

where  $\epsilon$  and  $\sigma$  are the standard LJ parameters,  $r_c$  is the cutoff,  $q_i$  and  $q_j$  are the charges on the two particles,  $\vec{p}_i$  and  $\vec{p}_j$  are the dipole moment vectors of the two particles,  $r$  is their separation distance, and the vector  $\mathbf{r} = \mathbf{R}_i - \mathbf{R}_j$  is the

separation vector between the two particles. Note that  $E_{qq}$  and  $F_{qq}$  are simply Coulombic energy and force,  $F_{ij} = -F_{ji}$  as symmetric forces, and  $T_{ij} \neq -T_{ji}$  since the torques do not act symmetrically. The shifted-force formula for the Lennard-Jones potential is reported in (Stoddard). The original (non-shifted) formulas for the electrostatic potentials, forces and torques can be found in (Price). The shifted-force electrostatic potentials have been obtained by applying equation 5.13 of (AllenTildesley). The formulas for the corresponding forces and torques have been obtained by applying the ‘chain rule’ as in appendix C.3 of (AllenTildesley).

If one cutoff is specified in the `pair_style` command, it is used for both the LJ and Coulombic (q,p) terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic (q,p) terms respectively. This pair style also supports an optional `scale` keyword as part of a `pair_coeff` statement, where the interactions can be scaled according to this factor. This scale factor is also made available for use with `fix adapt`.

Style `lj/cut/dipole/long` computes the short-range portion of point-dipole interactions as discussed in (Toukmaji). Dipole-dipole, dipole-charge, and charge-charge interactions are all supported, along with the standard 12/6 Lennard-Jones interactions, which are computed with a cutoff. A `kpace_style` must be defined to use this pair style. If only dipoles (not point charges) are included in the model, the `kpace` style can be one of these 3 options, all of which compute the long-range portion of dipole-dipole interactions. If the model includes point charges (in addition to dipoles), then only the first of these `kpace` styles can be used:

- `kpace_style ewald/disp`
- `kpace_style ewald/dipole`
- `kpace_style ppm/dipole`

Style `lj/long/dipole/long` has the same functionality as style `lj/cut/dipole/long`, except it also has an option to compute 12/6 Lennard-Jones interactions for use with a long-range dispersion `kpace` style. This is done by setting its `flag_lj` argument to `long`. For long-range LJ interactions, the `kpace_style ewald/disp` command must be used.

---

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- `cutoff1` (distance units)
- `cutoff2` (distance units)

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the `pair_style` command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair. When using a long-rang Coulomb solver, only a global Coulomb cutoff may be used and only the LJ cutoff may be changed with the `pair_coeff` command. When using the `lj/long/dipole/long` pair style with `long long` setting, only a single global cutoff may be provided and no cutoff for the `pair_coeff` command.

---

Note that for systems using these pair styles, typically particles should be able to exert torque on each other via their dipole moments so that the particle and its dipole moment can rotate. This requires they not be point particles, but finite-size spheres. Thus you should use a command like `atom_style hybrid sphere dipole` to use particles with both attributes.

The magnitude and orientation of the dipole moment for each particle can be defined by the `set` command or in the “Atoms” section of the data file read in by the `read_data` command.

Rotating finite-size particles have 6 degrees of freedom (DOFs), translation and rotational. You can use the `compute temp/sphere` command to monitor a temperature which includes all these DOFs.

Finite-size particles with dipole moments should be integrated using one of these options:

- *fix nve/sphere update dipole*
- *fix nve/sphere update dipole* plus *fix langevin omega yes*
- *fix nvt/sphere update dipole*
- *fix npt/sphere update dipole*

In all cases the “update dipole” setting ensures the dipole moments are also rotated when the finite-size spheres rotate. The 2nd and 3rd bullets perform thermostating; in the case of a Langevin thermostat the “omega yes” option also thermostats the rotational degrees of freedom (if desired). The 4th bullet performs thermostating and barostatting.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.80.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distances for this pair style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

For atom type pairs  $I, J$  and  $I \neq J$ , the A, sigma, d1, and d2 coefficients and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. D1 and d2 are distance values and are mixed like sigma. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style does not support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction; such energy goes to zero at the cutoff by construction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.80.5 Restrictions

The *lj/cut/dipole/cut*, *lj/cut/dipole/long*, *lj/long/dipole/long*, and *lj/sf/dipole/sf\** styles are part of the DIPOLE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Using dipole pair styles with *electron units* is not currently supported.

### 4.80.6 Related commands

*pair\_coeff*, *set*, *read\_data*, *fix nve/sphere*, *fix nvt/sphere*

### 4.80.7 Default

none

## 4.81 pair\_style dpd command

Accelerator Variants: *dpd/gpu*, *dpd/intel*, *dpd/kk*, *dpd/omp*

## 4.82 pair\_style dpd/tstat command

Accelerator Variants: *dpd/tstat/gpu*, *dpd/tstat/kk*, *dpd/tstat/omp*

### 4.82.1 Syntax

```
pair_style dpd T cutoff seed
pair_style dpd/tstat Tstart Tstop cutoff seed
```

- T = temperature (temperature units) (dpd only)
- Tstart,Tstop = desired temperature at start/end of run (temperature units) (dpd/tstat only)
- cutoff = global cutoff for DPD interactions (distance units)
- seed = random # seed (positive integer)

## 4.82.2 Examples

```
pair_style dpd 1.0 2.5 34387
pair_coeff * * 3.0 1.0
pair_coeff 1 1 3.0 1.0 1.0

pair_style hybrid/overlay lj/cut 2.5 dpd/tstat 1.0 1.0 2.5 34387
pair_coeff * * lj/cut 1.0 1.0
pair_coeff * * dpd/tstat 1.0
```

## 4.82.3 Description

Style *dpd* computes a force field for dissipative particle dynamics (DPD) following the exposition in (*Groot*).

Style *dpd/tstat* invokes a DPD thermostat on pairwise interactions, which is equivalent to the non-conservative portion of the DPD force field. This pairwise thermostat can be used in conjunction with any *pair style*, and instead of per-particle thermostats like *fix langevin* or ensemble thermostats like Nose Hoover as implemented by *fix nvt*. To use *dpd/tstat* as a thermostat for another pair style, use the *pair\_style hybrid/overlay* command to compute both the desired pair interaction and the thermostat for each pair of particles.

For style *dpd*, the force on atom I due to atom J is given as a sum of 3 terms

$$\begin{aligned}\vec{f} &= (F^C + F^D + F^R) \hat{r}_{ij} & r < r_c \\ F^C &= A w(r) \\ F^D &= -\gamma w^2(r) (\hat{r}_{ij} \bullet \vec{v}_{ij}) \\ F^R &= \sigma w(r) \alpha (\Delta t)^{-1/2} \\ w(r) &= 1 - \frac{r}{r_c}\end{aligned}$$

where  $F^C$  is a conservative force,  $F^D$  is a dissipative force, and  $F^R$  is a random force.  $\hat{r}_{ij}$  is a unit vector in the direction  $r_i - r_j$ ,  $\vec{v}_{ij}$  is the vector difference in velocities of the two atoms  $\vec{v}_i - \vec{v}_j$ ,  $\alpha$  is a Gaussian random number with zero mean and unit variance,  $\Delta t$  is the timestep size, and  $w(r)$  is a weighting factor that varies between 0 and 1.  $r_c$  is the pairwise cutoff.  $\sigma$  is set equal to  $\sqrt{2k_B T \gamma}$ , where  $k_B$  is the Boltzmann constant and  $T$  is the temperature parameter in the *pair\_style* command.

For style *dpd/tstat*, the force on atom I due to atom J is the same as the above equation, except that the conservative  $F^C$  term is dropped. Also, during the run,  $T$  is set each timestep to a ramped value from  $T_{start}$  to  $T_{stop}$ .

For style *dpd*, the pairwise energy associated with style *dpd* is only due to the conservative force term  $F^C$ , and is shifted to be zero at the cutoff distance  $r_c$ . The pairwise virial is calculated using all 3 terms. For style *dpd/tstat* there is no pairwise energy, but the last two terms of the formula make a contribution to the virial.

For style *dpd*, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- A (force units)
- $\gamma$  (force/velocity units)
- cutoff (distance units)

The cutoff coefficient is optional. If not specified, the global DPD cutoff is used. Note that sigma is set equal to  $\sqrt{2 T \gamma}$ , where T is the temperature set by the *pair\_style* command so it does not need to be specified.

For style *dpd/tstat*, the coefficients defined for each pair of atoms types via the *pair\_coeff* command are:

- $\gamma$  (force/velocity units)

- cutoff (distance units)

The cutoff coefficient is optional.

Styles with a *gpu* suffix are implemented based on the work of (*Afshar*) and (*Phillips*).

---

**Note:** If you are modeling DPD polymer chains, you may want to use the *pair\_style srp* command in conjunction with these pair styles. It is a soft segmental repulsive potential (SRP) that can prevent DPD polymer chains from crossing each other.

---

---

**Note:** The virial calculation for pressure when using these pair styles includes all the components of force listed above, including the random force. Since the random force depends on random numbers, everything that changes the order of atoms in the neighbor list (e.g. different number of MPI ranks or a different neighbor list skin distance) will also change the sequence in which the random numbers are applied and thus the individual forces and therefore also the virial/pressure.

---

---

**Note:** For more consistent time integration and force computation you may consider using *fix mvv/dpd* instead of *fix nve*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.82.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These pair styles do not support the *pair\_modify* shift option for the energy of the pair interaction. Note that as discussed above, the energy due to the conservative  $F^C$  term is already shifted to be 0.0 at the cutoff distance  $r_c$ .

The *pair\_modify* table option is not relevant for these pair styles.

These pair styles do not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

The *dpd/tstat* style can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

## 4.82.5 Restrictions

These styles are part of the DPD-BASIC package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The default frequency for rebuilding neighbor lists is every 10 steps (see the *neigh\_modify* command). This may be too infrequent for style *dpd* simulations since particles move rapidly and can overlap by large amounts. If this setting yields a non-zero number of “dangerous” reneighborings (printed at the end of a simulation), you should experiment with forcing reneighboring more often and see if system energies/trajectories change.

These pair styles requires you to use the *comm\_modify vel yes* command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the *read\_restart* command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the *read\_restart* command for more details.

## 4.82.6 Related commands

*pair\_style dpd/ext*, *pair\_coeff*, *fix nvt*, *fix langevin*, *pair\_style srp*, *fix mvv/dpd*.

## 4.82.7 Default

## 4.83 pair\_style dpd/coul/slatter/long command

Accelerator Variants: *dpd/coul/slatter/long/gpu*

### 4.83.1 Syntax

```
pair_style dpd/coul/slatter/long T cutoff_DPD seed lambda cutoff_coul
```

- T = temperature (temperature units)
- cutoff\_DPD = global cutoff for DPD interactions (distance units)
- seed = random # seed (positive integer)
- lambda = decay length of the charge (distance units)
- cutoff\_coul = global cutoff for Coulombic interactions (distance units)

## 4.83.2 Examples

```
pair_style dpd/coul/slater/long 1.0 2.5 34387 0.25 3.0
pair_coeff 1 1 78.0 4.5          # not charged by default
pair_coeff 2 2 78.0 4.5 yes
```

## 4.83.3 Description

New in version 27June2024.

Style *dpd/coul/slater/long* computes a force field for dissipative particle dynamics (DPD) following the exposition in (*Groot*). It also allows for the use of charged particles in the model by adding a long-range Coulombic term to the DPD interactions. The short-range portion of the Coulombics is calculated by this pair style. The long-range Coulombics are computed by use of the *kpace\_style* command, e.g. using the Ewald or PPPM styles.

Coulombic forces in mesoscopic models such as DPD employ potentials without explicit excluded-volume interactions. The goal is to prevent artificial ionic pair formation by including a charge distribution in the Coulomb potential, following the formulation in (*Melchor1*).

**Note:** This pair style is effectively the combination of the *pair\_style dpd* and *pair\_style coul/slater/long* commands, but should be more efficient (especially on GPUs) than using *pair\_style hybrid/overlay dpd coul/slater/long*. That is particularly true for the GPU package version of the pair style since this version is compatible with computing neighbor lists on the GPU instead of the CPU as is required for hybrid styles.

In the charged DPD model, the force on bead I due to bead J is given as a sum of 4 terms:

$$\begin{aligned}\vec{f} &= (F^C + F^D + F^R + F^E) \hat{r}_{ij} \\ F^C &= A w(r) & r < r_{DPD} \\ F^D &= -\gamma w^2(r) (\hat{r}_{ij} \bullet \vec{v}_{ij}) & r < r_{DPD} \\ F^R &= \sigma w(r) \alpha (\Delta t)^{-1/2} & r < r_{DPD} \\ w(r) &= 1 - \frac{r}{r_{DPD}} \\ F^E &= \frac{C q_i q_j}{\epsilon r^2} \left( 1 - \exp\left(\frac{2r_{ij}}{\lambda}\right) \left( 1 + \frac{2r_{ij}}{\lambda} \left( 1 + \frac{r_{ij}}{\lambda} \right) \right) \right)\end{aligned}$$

where  $F^C$  is a conservative force,  $F^D$  is a dissipative force,  $F^R$  is a random force, and  $F^E$  is an electrostatic force.  $\hat{r}_{ij}$  is a unit vector in the direction  $r_i - r_j$ ,  $\vec{v}_{ij}$  is the vector difference in velocities of the two atoms  $\vec{v}_i - \vec{v}_j$ ,  $\alpha$  is a Gaussian random number with zero mean and unit variance,  $dt$  is the timestep size, and  $w(r)$  is a weighting factor that varies between 0 and 1.

$\sigma$  is set equal to  $\sqrt{2k_B T \gamma}$ , where  $k_B$  is the Boltzmann constant and  $T$  is the temperature parameter in the *pair\_style* command.

$r_{DPD}$  is the pairwise cutoff for the first 3 DPD terms in the formula as specified by *cutoff\_DPD*. For the  $F^E$  term, pairwise interactions within the specified *cutoff\_coul* distance are computed directly; interactions beyond that distance are computed in reciprocal space.  $C$  is the same Coulomb conversion factor used in the Coulombic formulas described on the *pair\_coul* doc page.

The following parameters must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- A (force units)

- $\gamma$  (force/velocity units)
- `is_charged` (optional boolean, default = no)

The `is_charged` parameter is optional and can be specified as *yes* or *no*. *Yes* should be used for interactions between two types of charged particles. *No* is the default and should be used for interactions between two types of particles when one or both are uncharged.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.83.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style does not support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.83.5 Restrictions

This style is part of the DPD-BASIC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The default frequency for rebuilding neighbor lists is every 10 steps (see the *neigh\_modify* command). This may be too infrequent since particles move rapidly and can overlap by large amounts. If this setting yields a non-zero number of “dangerous” reneighborings (printed at the end of a simulation), you should experiment with forcing reneighboring more often and see if system energies/trajectories change.

This pair style requires use of the *comm\_modify vel yes* command so that velocities are stored by ghost atoms.

This pair style also requires use of a long-range solvers from the KSPACE package.

This pair style will not restart exactly when using the *read\_restart* command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the *read\_restart* command for more details.

### 4.83.6 Related commands

*pair\_style dpd*, *pair\_style coul/slater/long*,

### 4.83.7 Default

For the *pair\_coeff* command, the default is *is\_charged* = no.

## 4.84 *pair\_style dpd/ext* command

Accelerator Variants: *dpd/ext/kk dpd/ext/omp*

## 4.85 *pair\_style dpd/ext/tstat* command

Accelerator Variants: *dpd/ext/tstat/kk dpd/ext/tstat/omp*

### 4.85.1 Syntax

```
pair_style dpd/ext T cutoff seed
pair_style dpd/ext/tstat Tstart Tstop cutoff seed
```

- T = temperature (temperature units)
- Tstart,Tstop = desired temperature at start/end of run (temperature units)
- cutoff = global cutoff for DPD interactions (distance units)
- seed = random # seed (positive integer)

### 4.85.2 Examples

```
pair_style dpd/ext 1.0 2.5 34387
pair_coeff 1 1 25.0 4.5 4.5 0.5 0.5 1.2
pair_coeff 1 2 40.0 4.5 4.5 0.5 0.5 1.2

pair_style hybrid/overlay lj/cut 2.5 dpd/ext/tstat 1.0 1.0 2.5 34387
pair_coeff * * lj/cut 1.0 1.0
pair_coeff * * 4.5 4.5 0.5 0.5 1.2
```

### 4.85.3 Description

The style *dpd/ext* computes an extended force field for dissipative particle dynamics (DPD) following the exposition in (Groot), (Junghans).

Style *dpd/ext/tstat* invokes an extended DPD thermostat on pairwise interactions, equivalent to the non-conservative portion of the extended DPD force field. To use *dpd/ext/tstat* as a thermostat for another pair style, use the *pair\_style hybrid/overlay* command to compute both the desired pair interaction and the thermostat for each pair of particles.

For the style *dpd/ext*, the force on atom I due to atom J is given as a sum of 3 terms

$$\begin{aligned}\mathbf{f} &= \mathbf{f}^C + \mathbf{f}^D + \mathbf{f}^R & r < r_c \\ f^C &= A_{ij} w(r) \hat{\mathbf{r}}_{ij} \\ f^D &= -\gamma_{\parallel} w_{\parallel}^2(r) (\hat{\mathbf{r}}_{ij} \cdot \mathbf{v}_{ij}) \hat{\mathbf{r}}_{ij} - \gamma_{\perp} w_{\perp}^2(r) (\mathbf{I} - \hat{\mathbf{r}}_{ij} \hat{\mathbf{r}}_{ij}^T) \mathbf{v}_{ij} \\ f^R &= \sigma_{\parallel} w_{\parallel}(r) \frac{\alpha}{\sqrt{\Delta t}} \hat{\mathbf{r}}_{ij} + \sigma_{\perp} w_{\perp}(r) (\mathbf{I} - \hat{\mathbf{r}}_{ij} \hat{\mathbf{r}}_{ij}^T) \frac{\xi_{ij}}{\sqrt{\Delta t}} \\ w(r) &= 1 - r/r_c\end{aligned}$$

where  $\mathbf{f}^C$  is a conservative force,  $\mathbf{f}^D$  is a dissipative force, and  $\mathbf{f}^R$  is a random force.  $A_{ij}$  is the maximum repulsion between the two atoms,  $\hat{\mathbf{r}}_{ij}$  is a unit vector in the direction  $\mathbf{r}_i - \mathbf{r}_j$ ,  $\mathbf{v}_{ij} = \mathbf{v}_i - \mathbf{v}_j$  is the vector difference in velocities of the two atoms,  $\alpha$  and  $\xi_{ij}$  are Gaussian random numbers with zero mean and unit variance,  $\Delta t$  is the timestep,  $w(r) = 1 - r/r_c$  is a weight function for the conservative interactions that varies between 0 and 1,  $r_c$  is the corresponding cutoff,  $w_{\alpha}(r) = (1 - r/\bar{r}_c)^{s_{\alpha}}$ ,  $\alpha \equiv (\parallel, \perp)$ , are weight functions with coefficients  $s_{\alpha}$  that vary between 0 and 1,  $\bar{r}_c$  is the corresponding cutoff,  $\mathbf{I}$  is the unit matrix,  $\sigma_{\alpha} = \sqrt{2k_B T \gamma_{\alpha}}$ , where  $k_B$  is the Boltzmann constant and  $T$  is the temperature in the *pair\_style* command.

For the style *dpd/ext/tstat*, the force on atom I due to atom J is the same as the above equation, except that the conservative  $\mathbf{f}^C$  term is dropped. Also, during the run,  $T$  is set each timestep to a ramped value from  $T_{\text{start}}$  to  $T_{\text{stop}}$ .

For the style *dpd/ext*, the pairwise energy associated with style *dpd/ext* is only due to the conservative force term  $\mathbf{f}^C$ , and is shifted to be zero at the cutoff distance  $r_c$ . The pairwise virial is calculated using all three terms. There is no pairwise energy for style *dpd/ext/tstat*, but the last two terms of the formula contribute the virial.

For the style *dpd/ext/tstat*, the force on atom I due to atom J is the same as the above equation, except that the conservative  $\mathbf{f}^C$  term is dropped. Also, during the run,  $T$  is set each timestep to a ramped value from  $T_{\text{start}}$  to  $T_{\text{stop}}$ .

For the style *dpd/ext*, the pairwise energy associated with style *dpd/ext* is only due to the conservative force term  $\mathbf{f}^C$ , and is shifted to be zero at the cutoff distance  $r_c$ . The pairwise virial is calculated using all three terms. There is no pairwise energy for style *dpd/ext/tstat*, but the last two terms of the formula contribute the virial.

For the style *dpd/ext*, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above:

- A (force units)
- $\gamma_{\parallel}$  (force/velocity units)
- $\gamma_{\perp}$  (force/velocity units)
- $s_{\parallel}$  (unitless)
- $s_{\perp}$  (unitless)
- $r_c$  (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used. Note that  $\sigma$ 's are set equal to  $\sqrt{2k_B T \gamma}$ , where  $T$  is the temperature set by the *pair\_style* command so it does not need to be specified.

For the style *dpd/ext/tstat*, the coefficients defined for each pair of atoms types via the *pair\_coeff* command are:

- $\gamma_{\parallel}$  (force/velocity units)

- $\gamma_{\perp}$  (force/velocity units)
- $s_{\parallel}$  (unitless)
- $s_{\perp}$  (unitless)
- $r_c$  (distance units)

The last coefficient is optional.

---

**Note:** If you are modeling DPD polymer chains, you may want to use the *pair\_style srp* command in conjunction with these pair styles. It is a soft segmental repulsive potential (SRP) that can prevent DPD polymer chains from crossing each other.

---

---

**Note:** The virial calculation for pressure when using these pair styles includes all the components of force listed above, including the random force. Since the random force depends on random numbers, everything that changes the order of atoms in the neighbor list (e.g. different number of MPI ranks or a different neighbor list skin distance) will also change the sequence in which the random numbers are applied and thus the individual forces and therefore also the virial/pressure.

---

---

**Note:** For more consistent time integration and force computation you may consider using *fix mvv/dpd* instead of *fix nve*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### Mixing, shift, table, tail correction, restart, rRESPA info:

The style *dpd/ext* does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The pair styles do not support the *pair\_modify* shift option for the energy of the pair interaction. Note that as discussed above, the energy due to the conservative  $\mathbf{f}^C$  term is already shifted to be zero at the cutoff distance  $r_c$ .

The *pair\_modify* table option is not relevant for the style *dpd/ext*.

The style *dpd/ext* does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

The pair styles can only be used via the pair keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, and *outer* keywords.

The style *dpd/ext/tstat* can ramp its target temperature over multiple runs, using the start and stop keywords of the *run* command. See the *run* command for details of how to do this.

---

#### 4.85.4 Restrictions

These styles are part of the DPD-BASIC package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The default frequency for rebuilding neighbor lists is every 10 steps (see the [neigh\\_modify](#) command). This may be too infrequent for style *dpd/ext* simulations since particles move rapidly and can overlap by large amounts. If this setting yields a non-zero number of say {dangerous} reneighborings (printed at the end of a simulation), you should experiment with forcing reneighborings more often and see if system energies/trajectories change.

The pair styles require to use the [comm\\_modify vel yes](#) command so that velocities are stored by ghost atoms.

The pair styles will not restart exactly when using the [read\\_restart](#) command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the [read\\_restart](#) command for more details.

#### 4.85.5 Related commands

*pair\_style dpd*, *pair\_coeff*, *fix nvt*, *fix langevin*, *pair\_style srp*, *fix mvv/dpd*.

**Default:** none

### 4.86 pair\_style dpd/fdt command

#### 4.87 pair\_style dpd/fdt/energy command

Accelerator Variants: *dpd/fdt/energy/kk*

##### 4.87.1 Syntax

```
pair_style style args
```

- style = *dpd/fdt* or *dpd/fdt/energy*
- args = list of arguments for a particular style

*dpd/fdt* args = T cutoff seed

T = temperature (temperature units)

cutoff = global cutoff for DPD interactions (distance units)

seed = random # seed (positive integer)

*dpd/fdt/energy* args = cutoff seed

cutoff = global cutoff for DPD interactions (distance units)

seed = random # seed (positive integer)

## 4.87.2 Examples

```
pair_style dpd/fdt 300.0 2.5 34387
pair_coeff * * 3.0 1.0 2.5

pair_style dpd/fdt/energy 2.5 34387
pair_coeff * * 3.0 1.0 0.1 2.5
```

## 4.87.3 Description

Styles *dpd/fdt* and *dpd/fdt/energy* compute the force for dissipative particle dynamics (DPD) simulations. The *dpd/fdt* style is used to perform DPD simulations under isothermal and isobaric conditions, while the *dpd/fdt/energy* style is used to perform DPD simulations under isoenergetic and isoenthalpic conditions (see [Lisal](#)). For DPD simulations in general, the force on atom I due to atom J is given as a sum of 3 terms

$$\begin{aligned}\vec{f} &= (F^C + F^D + F^R)\hat{r}_{ij} & r < r_c \\ F^C &= Aw(r) \\ F^D &= -\gamma w^2(r)(\hat{r}_{ij} \bullet \vec{v}_{ij}) \\ F^R &= \sigma w(r)\alpha(\Delta t)^{-1/2} \\ w(r) &= 1 - \frac{r}{r_c}\end{aligned}$$

where  $F^C$  is a conservative force,  $F^D$  is a dissipative force, and  $F^R$  is a random force.  $\hat{r}_{ij}$  is a unit vector in the direction  $r_i - r_j$ ,  $\vec{v}_{ij}$  is the vector difference in velocities of the two atoms,  $\vec{v}_i - \vec{v}_j$ ,  $\alpha$  is a Gaussian random number with zero mean and unit variance,  $\Delta t$  is the timestep size, and  $w(r)$  is a weighting factor that varies between 0 and 1,  $r_c$  is the pairwise cutoff. Note that alternative definitions of the weighting function exist, but would have to be implemented as a separate pair style command.

For style *dpd/fdt*, the fluctuation-dissipation theorem defines  $\gamma$  to be set equal to  $\sigma^2/(2T)$ , where  $T$  is the set point temperature specified as a pair style parameter in the above examples. The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- A (force units)
- $\sigma$  (force\*time<sup>1/2</sup>) units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

Style *dpd/fdt/energy* is used to perform DPD simulations under isoenergetic and isoenthalpic conditions. The fluctuation-dissipation theorem defines  $\gamma$  to be set equal to  $\sigma^2/(2\theta)$ , where  $\theta$  is the average internal temperature for the pair. The particle internal temperature is related to the particle internal energy through a mesoparticle equation of state (see *fix eos*). The differential internal conductive and mechanical energies are computed within style *dpd/fdt/energy* as:

$$\begin{aligned}du_i^{cond} &= \kappa_{ij} \left( \frac{1}{\theta_i} - \frac{1}{\theta_j} \right) \omega_{ij}^2 + \alpha_{ij} \omega_{ij} \zeta_{ij}^q (\Delta t)^{-1/2} \\ du_i^{mech} &= -\frac{1}{2} \gamma_{ij} \omega_{ij}^2 \left( \frac{\vec{r}_{ij}}{r_{ij}} \bullet \vec{v}_{ij} \right)^2 - \frac{\sigma_{ij}^2}{4} \left( \frac{1}{m_i} + \frac{1}{m_j} \right) \omega_{ij}^2 - \frac{1}{2} \sigma_{ij} \omega_{ij} \left( \frac{\vec{r}_{ij}}{r_{ij}} \bullet \vec{v}_{ij} \right) \zeta_{ij} (\Delta t)^{-1/2}\end{aligned}$$

where

$$\begin{aligned}\alpha_{ij}^2 &= 2k_B \kappa_{ij} \\ \sigma_{ij}^2 &= 2\gamma_{ij} k_B \Theta_{ij} \\ \Theta_{ij}^{-1} &= \frac{1}{2} \left( \frac{1}{\theta_i} + \frac{1}{\theta_j} \right)\end{aligned}$$

$\zeta_i j^q$  is a second Gaussian random number with zero mean and unit variance that is used to compute the internal conductive energy. The fluctuation-dissipation theorem defines  $\alpha^2$  to be set equal to  $2k_B \kappa$ , where  $\kappa$  is the mesoparticle thermal conductivity parameter. The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- A (force units)
- $\sigma$  (force\*time<sup>1/2</sup> units)
- $\kappa$  (energy\*temperature/time units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

The pairwise energy associated with styles `dpd/fdt` and `dpd/fdt/energy` is only due to the conservative force term  $F^C$ , and is shifted to be zero at the cutoff distance  $r_c$ . The pairwise virial is calculated using only the conservative term.

The forces computed through the `dpd/fdt` and `dpd/fdt/energy` styles can be integrated with the velocity-Verlet integration scheme or the Shardlow splitting integration scheme described by (Lisal). In the cases when these pair styles are combined with the `fix shardlow`, these pair styles differ from the other dpd styles in that the dissipative and random forces are split from the force calculation and are not computed within the pair style. Thus, only the conservative force is computed by the pair style, while the stochastic integration of the dissipative and random forces are handled through the Shardlow splitting algorithm approach. The Shardlow splitting algorithm is advantageous, especially when performing DPD under isoenergetic conditions, as it allows significantly larger timesteps to be taken.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` *command-line switch* when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

### 4.87.4 Restrictions

These commands are part of the DPD-REACT package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Pair styles *dpd/fdt* and *dpd/fdt/energy* require use of the *comm\_modify vel yes* option so that velocities are stored by ghost atoms.

Pair style *dpd/fdt/energy* requires *atom\_style dpd* to be used in order to properly account for the particle internal energies and temperatures.

## 4.88 pair\_style drip command

### 4.88.1 Syntax

```
pair_style hybrid/overlay drip [styles ...]
```

- styles = other styles to be overlaid with drip (optional)

### 4.88.2 Examples

```
pair_style hybrid/overlay drip
pair_coeff * * none
pair_coeff * * drip C.drip C

pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C
pair_coeff * * rebo CH.airebo C

pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C NULL
pair_coeff * * rebo CH.airebo C H
```

### 4.88.3 Description

Style *drip* computes the interlayer interactions of layered materials using the dihedral-angle-corrected registry-dependent (DRIP) potential as described in (Wen), which is based on the (Kolmogorov) potential and provides an improved prediction for forces. The total potential energy of a system is

$$E = \frac{1}{2} \sum_i \sum_{j \notin \text{layer } i} \phi_{ij}$$

$$\phi_{ij} = f_c(x_r) \left[ e^{-\lambda(r_{ij}-z_0)} \left[ C + f(\rho_{ij}) + g(\rho_{ij}, \{\alpha_{ij}^{(m)}\}) \right] - A \left( \frac{z_0}{r_{ij}} \right)^6 \right]$$

where the  $r^{-6}$  term models the attractive London dispersion, the exponential term is designed to capture the registry effect due to overlapping *pi* bonds, and  $f_c$  is a cutoff function.

This potential (DRIP) only provides the interlayer interactions between graphene layers. So, to perform a realistic simulation, it should be used in combination with an intralayer potential such as *REBO* and *Tersoff*. To keep the intralayer interactions unaffected, we should avoid applying DRIP to contribute energy to intralayer interactions. This can be achieved by assigning different molecular IDs to atoms in different layers, and DRIP is implemented such that only atoms with different molecular ID can interact with each other. For this purpose, *atom style* “molecular” or “full” has to be used.

On the other way around, *REBO* (*Tersoff* or any other potential used to provide the intralayer interactions) should not interfere with the interlayer interactions described by DRIP. This is typically automatically achieved using the commands provided in the *Examples* section above, since the cutoff distance for carbon-carbon interaction in the intralayer potentials (e.g. 2 Angstrom for *REBO*) is much smaller than the equilibrium layer distance of graphene layers (about 3.4 Angstrom). If you want, you can enforce this by assigning different atom types to atoms in different layers, and apply an intralayer potential to one atom type. See *pair\_hybrid* for details.

The *pair\_coeff* command for DRIP takes  $4+N$  arguments, where  $N$  is the number of LAMMPS atom types. The first three arguments must be fixed to be *\* \* drip*, the fourth argument is the path to the DRIP parameter file, and the remaining  $N$  arguments specifying the mapping between element in the parameter file and atom types. For example, if your LAMMPS simulation has 3 atom types and you want all of them to be C, you would use the following *pair\_coeff* command:

```
pair_coeff * * drip C.drip C C C
```

If a mapping value is specified as NULL, the mapping is not performed. This could be useful when DRIP is used to model part of the system where other element exists. Suppose you have a hydrocarbon system, with C of atom type 1 and H of atom type 2, you can use the following command to inform DRIP not to model H atoms:

```
pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C NULL
pair_coeff * * rebo CH.airebo C H
```

**Note:** The potential parameters developed in (Wen) are provided with LAMMPS (see the “potentials” directory). Besides those in (Wen), an additional parameter “normal\_cutoff”, specific to the LAMMPS implementation, is used to find the three nearest neighbors of an atom to construct the normal.

#### 4.88.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

#### 4.88.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the [newton](#) setting to be “on” for pair interactions.

The *C.drip* parameter file provided with LAMMPS (see the “potentials” directory) is parameterized for metal [units](#). You can use the DRIP potential with any LAMMPS units, but you would need to create your own custom parameter file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

### 4.89 pair\_style dsmc command

#### 4.89.1 Syntax

```
pair_style dsmc max_cell_size seed weighting Tref Nrecompute Nsample
```

- `max_cell_size` = global maximum cell size for DSMC interactions (distance units)
- `seed` = random # seed (positive integer)
- `weighting` = macroparticle weighting
- `Tref` = reference temperature (temperature units)
- `Nrecompute` = re-compute `v*sigma_max` every this many timesteps (timesteps)
- `Nsample` = sample this many times in recomputing `v*sigma_max`

## 4.89.2 Examples

```
pair_style dsmc 2.5 34387 10 1.0 100 20
pair_coeff * * 1.0
pair_coeff 1 1 1.0
```

## 4.89.3 Description

Style *dsmc* computes collisions between pairs of particles for a direct simulation Monte Carlo (DSMC) model following the exposition in (*Bird*). Each collision resets the velocities of the two particles involved. The number of pairwise collisions for each pair or particle types and the length scale within which they occur are determined by the parameters of the *pair\_style* and *pair\_coeff* commands.

Stochastic collisions are performed using the variable hard sphere (VHS) approach, with the user-defined *max\_cell\_size* value used as the maximum DSMC cell size, and reference cross-sections for collisions given using the *pair\_coeff* command.

There is no pairwise energy or virial contributions associated with this pair style.

The following coefficient must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- sigma (area units, i.e. distance-squared)

The global DSMC *max\_cell\_size* determines the maximum cell length used in the DSMC calculation. A structured mesh is overlayed on the simulation box such that an integer number of cells are created in each direction for each processor's subdomain. Cell lengths are adjusted up to the user-specified maximum cell size.

To perform a DSMC simulation with LAMMPS, several additional options should be set in your input script, though LAMMPS does not check for these settings.

Since this pair style does not compute particle forces, you should use the “fix nve/noforce” time integration fix for the DSMC particles, e.g.

```
fix 1 all nve/noforce
```

This pair style assumes that all particles will be communicated to neighboring processors every timestep as they move. This makes it possible to perform all collisions between pairs of particles that are on the same processor. To ensure this occurs, you should use these commands:

```
neighbor 0.0 bin
neigh_modify every 1 delay 0 check no
atom_modify sort 0 0.0
communicate single cutoff 0.0
```

These commands ensure that LAMMPS communicates particles to neighboring processors every timestep and that no ghost atoms are created. The output statistics for a simulation run should indicate there are no ghost particles or neighbors.

In order to get correct DSMC collision statistics, users should specify a Gaussian velocity distribution when populating the simulation domain. Note that the default velocity distribution is uniform, which will not give good DSMC collision rates. Specify “dist gaussian” when using the *velocity* command as in the following:

```
velocity all create 594.6 87287 loop geom dist gaussian
```

#### 4.89.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style does not support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.89.5 Restrictions

This pair style is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires an *atom style* with per atom type masses.

#### 4.89.6 Related commands

### 4.90 pair\_style e3b command

#### 4.90.1 Syntax

```
pair_style e3b Otype
```

- Otype = atom type (numeric or type label) for oxygen

```
pair_coeff * * keyword
```

- one or more keyword/value pairs must be appended.
- keyword = *preset* or *Ea* or *Eb* or *Ec* or *E2* or *K3* or *K2* or *Rs* or *Rc3* or *Rc2* or *bondL* or *neigh*

- If the *preset* keyword is given, no others are needed. Otherwise, all are mandatory except for *neigh*. The *neigh* keyword is always optional.

```

preset arg = 2011 or 2015 = which set of predefined parameters to use
    2011 = use the potential parameters from (Tainter 2011)
    2015 = use the potential parameters from (Tainter 2015)
Ea arg = three-body energy for type A hydrogen bonding interactions (energy units)
Eb arg = three-body energy for type B hydrogen bonding interactions (energy units)
Ec arg = three-body energy for type C hydrogen bonding interactions (energy units)
E2 arg = two-body energy correction (energy units)
K3 arg = three-body exponential constant (inverse distance units)
K2 arg = two-body exponential constant (inverse distance units)
Rc3 arg = three-body cutoff (distance units)
Rc2 arg = two-body cutoff (distance units)
Rs arg = three-body switching function cutoff (distance units)
bondL arg = intramolecular OH bond length (distance units)
neigh arg = approximate integer number of molecules within Rc3 of an oxygen atom

```

## 4.90.2 Examples

```

pair_style e3b 1
pair_coeff * * Ea 35.85 Eb -240.2 Ec 449.3 E2 108269.9 K3 1.907 K2 4.872 Rc3 5.2 Rc2 5.2

→Rs 5.0 bondL 0.9572

```

Used in example input script:

```
examples/PACKAGES/e3b/in.e3b-tip4p2005
```

## 4.90.3 Description

The *e3b* style computes an "explicit three-body" (E3B) potential for water (Kumar 2008).

$$E = E_2 \sum_{i,j} e^{-k_2 r_{ij}} + E_A \sum_{\substack{i,j,k,\ell \\ \in \text{type A}}} f(r_{ij})f(r_{kl}) + E_B \sum_{\substack{i,j,k,\ell \\ \in \text{type B}}} f(r_{ij})f(r_{kl}) + E_C \sum_{\substack{i,j,k,\ell \\ \in \text{type C}}} f(r_{ij})f(r_{kl})$$

$$f(r) = e^{-k_3 r} s(r)$$

$$s(r) = \begin{cases} 1 & r < R_s \\ \frac{(R_f - r)^2 (R_f - 3R_s + 2r)}{(R_f - R_s)^3} & R_s \leq r \leq R_f \\ 0 & r > R_f \end{cases}$$

This potential was developed as a water model that includes the three-body cooperativity of hydrogen bonding explicitly. To use it in this way, it must be applied in conjunction with a conventional two-body water model, through pair

style *hybrid/overlay*. The three body interactions are split into three types: A, B, and C. Type A corresponds to anti-cooperative double hydrogen bond donor interactions. Type B corresponds to the cooperative interaction of molecules that both donate and accept a hydrogen bond. Type C corresponds to anti-cooperative double hydrogen bond acceptor interactions. The three-body interactions are smoothly cutoff by the switching function  $s(r)$  between  $R_s$  and  $R_{c3}$ . The two-body interactions are designed to correct for the effective many-body interactions implicitly included in the conventional two-body potential. The two-body interactions are cut off sharply at  $R_{c2}$ , because  $K_3$  is typically significantly smaller than  $K_2$ . See (Kumar 2008) for more details.

Only a single *pair\_coeff* command is used with the *e3b* style and the first two arguments must be `* *`. The oxygen atom type for the pair style is passed as the only argument to the *pair\_style* command, not in the *pair\_coeff* command. The hydrogen atom type is inferred from the ordering of the atoms.

---

**Note:** Every atom of type *Otype* must be part of a water molecule. Each water molecule must have consecutive IDs with the oxygen first. This pair style does not test that this criteria is met.

---

---

**Note:** If using type labels, the type labels must be defined before calling the *pair\_coeff* command.

---

The *pair\_coeff* command must have at least one keyword/value pair, as described above. The *preset* keyword sets the potential parameters to the values used in (Tainter 2011) or (Tainter 2015). To use the water models defined in those references, the *e3b* style should always be used in conjunction with an *lj/cut/tip4p/long* style through *pair\_style hybrid/overlay*, as demonstrated in the second example above. The *preset 2011* option should be used with the *TIP4P water model*. The *preset 2015* option should be used with the *TIP4P/2005 water model*. If the *preset* keyword is used, no other keyword is needed. Changes to the preset parameters can be made by specifying the *preset* keyword followed by the specific parameter to change, like *Ea*. Note that the other keywords must come after *preset* in the *pair\_style* command. The *e3b* style can also be used to implement any three-body potential of the same form by specifying all the keywords except *neigh*: *Ea*, *Eb*, *Ec*, *E2*, *K3*, *K2*, *Rc3*, *Rc2*, *Rs*, and *bondL*. The keyword *bondL* specifies the intramolecular OH bond length of the water model being used. This is needed to include H atoms that are within the cutoff even when the attached oxygen atom is not.

This pair style allocates arrays sized according to the number of pairwise interactions within  $R_{c3}$ . To do this it needs an estimate for the number of water molecules within  $R_{c3}$  of an oxygen atom. This estimate defaults to 10 and can be changed using the *neigh* keyword, which takes an integer as an argument. If the *neigh* setting is too small, the simulation will fail with the error “neigh is too small”. If the *neigh* setting is too large, the pair style will use more memory than necessary.

This pair style tallies a breakdown of the total E3B potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 4. The 4 values correspond to the terms in the first equation above: the *E2* term, the *Ea* term, the *Eb* term, and the *Ec* term.

See the examples/PACKAGES/e3b directory for a complete example script.

---

#### 4.90.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style is incompatible with *respa*.

---

### 4.90.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

This pair style requires a fixed number of atoms in the simulation, so it is incompatible with fixes like *fix deposit*. If the number of atoms changes between runs, this pair style must be re-initialized by calling the *pair\_style* and *pair\_coeffs* commands. This is not a fundamental limitation of the pair style, but the code currently does not support a variable number of atoms.

The *preset* keyword currently only works with real, metal, si, and cgs *units*.

### 4.90.6 Related commands

*pair\_coeff*, *compute pair*

### 4.90.7 Default

The option default for the *neigh* keyword is 10.

### 4.96.3 Description

Style *eam* computes pairwise interactions for metals and metal alloys using embedded-atom method (EAM) potentials (*Daw*). The total energy  $E_i$  of an atom  $I$  is given by

$$E_i = F_\alpha \left( \sum_{j \neq i} \rho_\beta(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij})$$

where  $F$  is the embedding energy which is a function of the atomic electron density  $\rho$ ,  $\phi$  is a pair potential interaction, and  $\alpha$  and  $\beta$  are the element types of atoms  $I$  and  $J$ . The multi-body nature of the EAM potential is a result of the embedding energy term. Both summations in the formula are over all neighbors  $J$  of atom  $I$  within the cutoff distance.

The cutoff distance and the tabulated values of the functionals  $F$ ,  $\rho$ , and  $\phi$  are listed in one or more files which are specified by the *pair\_coeff* command. These are ASCII text files in a DYNAMO-style format which is described below. DYNAMO was the original serial EAM MD code, written by the EAM originators. Several DYNAMO potential files for different metals are included in the “potentials” directory of the LAMMPS distribution. All of these files are parameterized in terms of LAMMPS *metal units*.

---

**Note:** The *eam* style reads single-element EAM potentials in the DYNAMO *funcfl* format. Either single element or alloy systems can be modeled using multiple *funcfl* files and style *eam*. For the alloy case LAMMPS mixes the single-element potentials to produce alloy potentials, the same way that DYNAMO does. Alternatively, a single DYNAMO *setfl* file or Finnis/Sinclair EAM file can be used by LAMMPS to model alloy systems by invoking the *eam/alloy* or *eam/cd* or *eam/fs* or *eam/he* styles as described below. These files require no mixing since they specify alloy interactions explicitly.

---

**Note:** Note that unlike for other potentials, cutoffs for EAM potentials are not set in the `pair_style` or `pair_coeff` command; they are specified in the EAM potential files themselves. Likewise, valid EAM potential files usually contain atomic masses; thus you may not need to use the `mass` command to specify them, unless the potential file uses a dummy value (e.g. 0.0). LAMMPS will print a warning, if this is the case.

There are web sites that distribute and document EAM potentials stored in DYNAMO or other formats:

- <https://www.ctcms.nist.gov/potentials>
- <https://openkim.org>

These potentials should be usable with LAMMPS, though the alternate formats would need to be converted to the DYNAMO format used by LAMMPS and described on this page. The NIST site is maintained by Chandler Becker (cbecker at nist.gov) who is good resource for info on interatomic potentials and file formats.

The OpenKIM Project at <https://openkim.org/browse/models/by-type> provides EAM potentials that can be used directly in LAMMPS with the `kim command` interface.

**Warning:** The EAM potential files tabulate the embedding energy as a function of the local electron density  $\rho$ . When atoms get too close, this electron density may exceed the range for which the embedding energy was tabulated for. To avoid crashes, LAMMPS will assume a linearly increasing embedding energy for electron densities beyond the maximum tabulated value. LAMMPS will print a warning when this happens. It may be acceptable at the beginning of an equilibration (e.g. when using randomized coordinates) but would be a big concern for accuracy if it happens during production runs. The EAM potential file triggering the warning during production is thus not a good choice, and the EAM model in general not likely a good model for the kind of system under investigation.

For style `eam`, potential values are read from a file that is in the DYNAMO single-element *funcfl* format. If the DYNAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or “E” for scientific notation.

For style `eam` a potential file must be assigned to each I,I pair of atom types by using one or more `pair_coeff` commands, each with a single argument:

- filename

Thus the following command

```
pair_coeff *2 1*2 cuu3.eam
```

will read the `cuu3` potential file and use the tabulated Cu values for F, phi, rho that it contains for type pairs 1,1 and 2,2 (type pairs 1,2 and 2,1 are ignored). See the `pair_coeff` doc page for alternate ways to specify the path for the potential file. In effect, this makes atom types 1 and 2 in LAMMPS be Cu atoms. Different single-element files can be assigned to different atom types to model an alloy system. The mixing to create alloy potentials for type pairs with  $I \neq J$  is done automatically the same way that the serial DYNAMO code originally did it; you do not need to specify coefficients for these type pairs.

*Funcfl* files in the *potentials* directory of the LAMMPS distribution have an “.eam” suffix. A DYNAMO single-element *funcfl* file is formatted as follows:

- line 1: comment (ignored)
- line 2: atomic number, mass, lattice constant, lattice type (e.g. FCC)
- line 3: Nrho, drho, Nr, dr, cutoff

On line 2, all values but the mass are ignored by LAMMPS. The mass is in mass *units*, e.g. mass number or grams/mole for metal units. The cubic lattice constant is in Angstroms. On line 3, Nrho and Nr are the number of tabulated values in the subsequent arrays, drho and dr are the spacing in density and distance space for the values in those arrays, and the specified cutoff becomes the pairwise cutoff used by LAMMPS for the potential. The units of dr are Angstroms; I'm not sure of the units for drho - some measure of electron density.

Following the three header lines are three arrays of tabulated values:

- embedding function F(rho) (Nrho values)
- effective charge function Z(r) (Nr values)
- density function rho(r) (Nr values)

The values for each array can be listed as multiple values per line, so long as each array starts on a new line. For example, the individual Z(r) values are for  $r = 0, dr, 2*dr, \dots (Nr-1)*dr$ .

The units for the embedding function F are eV. The units for the density function rho are the same as for drho (see above, electron density). The units for the effective charge Z are “atomic charge” or  $\sqrt{\text{Hartree} \cdot \text{Bohr-radius}}$ . For two interacting atoms i,j this is used by LAMMPS to compute the pair potential term in the EAM energy expression as  $r*\phi$ , in units of eV-Angstroms, via the formula

$$r \cdot \phi = 27.2 \cdot 0.529 \cdot Z_i \cdot Z_j$$

where 1 Hartree = 27.2 eV and 1 Bohr = 0.529 Angstroms.

---

Style *eam/alloy* computes pairwise interactions using the same formula as style *eam*. However the associated *pair\_coeff* command reads a DYNAMO *setfl* file instead of a *funcfl* file. *Setfl* files can be used to model a single-element or alloy system. In the alloy case, as explained above, *setfl* files contain explicit tabulated values for alloy interactions. Thus they allow more generality than *funcfl* files for modeling alloys.

For style *eam/alloy*, potential values are read from a file that is in the DYNAMO multi-element *setfl* format, except that element names (Ni, Cu, etc) are added to one of the lines in the file. If the DYNAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or “E” for scientific notation.

Only a single *pair\_coeff* command is used with the *eam/alloy* style which specifies a DYNAMO *setfl* file, which contains information for M elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the *pair\_coeff* command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of *setfl* elements to atom types

As an example, the potentials/NiAlH\_jea.eam.alloy file is a *setfl* file which has tabulated EAM values for 3 elements and their alloy interactions: Ni, Al, and H. See the *pair\_coeff* doc page for alternate ways to specify the path for the potential file. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Ni, and the fourth to be Al, you would use the following *pair\_coeff* command:

```
pair_coeff * * NiAlH_jea.eam.alloy Ni Ni Ni Al
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first three Ni arguments map LAMMPS atom types 1,2,3 to the Ni element in the *setfl* file. The final Al argument maps LAMMPS atom type 4 to the Al element in the *setfl* file. Note that there is no requirement that your simulation use all the elements specified by the *setfl* file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an *eam/alloy* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

*Setfl* files in the *potentials* directory of the LAMMPS distribution have an “.eam.alloy” suffix. A DYNAMO multi-element *setfl* file is formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 ... ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

In a DYNAMO *setfl* file, line 4 only lists Nelements = the # of elements in the *setfl* file. For LAMMPS, the element name (Ni, Cu, etc) of each element must be added to the line, in the order the elements appear in the file.

The meaning and units of the values in line 5 is the same as for the *funcfl* file described above. Note that the cutoff (in Angstroms) is a global value, valid for all pairwise interactions for all element pairings.

Following the 5 header lines are Nelements sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function F(rho) (Nrho values)
- density function rho(r) (Nr values)

As with the *funcfl* files, only the mass (in mass [units](#), e.g. mass number or grams/mole for metal units) is used by LAMMPS from the first line. The cubic lattice constant is in Angstroms. The F and rho arrays are unique to a single element and have the same format and units as in a *funcfl* file.

Following the Nelements sections, Nr values for each pair potential phi(r) array are listed for all i,j element pairs in the same format as other arrays. Since these interactions are symmetric (i,j = j,i) only phi arrays with i >= j are listed, in the following order: i,j = (1,1), (2,1), (2,2), (3,1), (3,2), (3,3), (4,1), ..., (Nelements, Nelements). Unlike the effective charge array Z(r) in *funcfl* files, the tabulated values for each phi function are listed in *setfl* files directly as r\*phi (in units of eV-Angstroms), since they are for atom pairs.

Style *eam/cd* is similar to the *eam/alloy* style, except that it computes alloy pairwise interactions using the concentration-dependent embedded-atom method (CD-EAM). This model can reproduce the enthalpy of mixing of alloys over the full composition range, as described in ([Stukowski](#)). Style *eam/cd/old* is an older, slightly different and slower two-site formulation of the model ([Caro](#)).

The pair\_coeff command is specified the same as for the *eam/alloy* style. However the DYNAMO *setfl* file must have two lines added to it, at the end of the file:

- line 1: Comment line (ignored)
- line 2: N Coefficient0 Coefficient1 ... CoefficientN

The last line begins with the degree N of the polynomial function  $h(x)$  that modifies the cross interaction between A and B elements. Then N+1 coefficients for the terms of the polynomial are then listed.

Modified EAM *setfl* files used with the *eam/cd* style must contain exactly two elements, i.e. in the current implementation the *eam/cd* style only supports binary alloys. The first and second elements in the input EAM file are always taken as the A and B species.

CD-EAM files in the *potentials* directory of the LAMMPS distribution have a “.cdeam” suffix.

Style *eam/fs* computes pairwise interactions for metals and metal alloys using a generalized form of EAM potentials due to Finnis and Sinclair ([Finnis](#)). Style *eam/he* is similar to *eam/fs* except that it allows for negative electron density in order to capture the behavior of helium in metals ([Zhou6](#)).

The total energy  $E_i$  of an atom I is given by

$$E_i = F_\alpha \left( \sum_{j \neq i} \rho_{\alpha\beta}(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij})$$

where  $\rho_{\alpha\beta}$  refers to the density contributed by a neighbor atom J of element  $\beta$  at the site of atom I of element  $\alpha$ . This has the same form as the EAM formula above, except that rho is now a functional specific to the elements of both atoms I and J, so that different elements can contribute differently to the total electron density at an atomic site depending on the identity of the element at that atomic site.

The associated `pair_coeff` command for style `eam/fs` or `eam/he` reads a DYNAMO `setfl` file that has been extended to include additional  $\rho_{\alpha\beta}$  arrays of tabulated values. A discussion of how FS EAM differs from conventional EAM alloy potentials is given in ([Ackland1](#)). An example of such a potential is the same author's Fe-P FS potential ([Ackland2](#)). Note that while FS potentials always specify the embedding energy with a square root dependence on the total density, the implementation in LAMMPS does not require that; the user can tabulate any functional form desired in the FS potential files.

For style `eam/fs` and `eam/he` the form of the `pair_coeff` command is exactly the same as for style `eam/alloy`, e.g.

```
pair_coeff * * NiAlH_jea.eam.fs Ni Ni Ni Al
```

with N additional arguments after the filename, where N is the number of LAMMPS atom types. See the `pair_coeff` doc page for alternate ways to specify the path for the potential file. The N values determine the mapping of LAMMPS atom types to EAM elements in the file, as described above for style `eam/alloy`. As with `eam/alloy`, if a mapping value is NULL, the mapping is not performed. This can be used when an `eam/fs` or `eam/he` potential is used as part of a *hybrid* pair style. The NULL values are used as placeholders for atom types that will be used with other potentials.

FS EAM and HE EAM files include more information than the DYNAMO `setfl` format files read by `eam/alloy`, in that i,j density functionals for all pairs of elements are included as needed by the Finnis/Sinclair formulation of the EAM.

FS EAM files in the *potentials* directory of the LAMMPS distribution have an “.eam.fs” suffix. They are formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 ... ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

The 5-line header section is identical to an EAM `setfl` file.

Following the header are Nelements sections, one for each element  $\beta$ , each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function  $F(\rho)$  (Nrho values)
- density function  $\rho_{1\beta}(r)$  for element  $\beta$  at element 1 (Nr values)
- density function  $\rho_{2\beta}(r)$  for element  $\beta$  at element 2
- ...
- density function  $\rho_{N_{elem}\beta}(r)$  for element  $\beta$  at element  $N_{elem}$

The units of these quantities in line 1 are the same as for `setfl` files. Note that the  $\rho(r)$  arrays in Finnis/Sinclair can be asymmetric ( $\rho_{\alpha\beta}(r) \neq \rho_{\beta\alpha}(r)$ ) so there are Nelements^2 of them listed in the file.

Following the Nelements sections, Nr values for each pair potential  $\phi(r)$  array are listed in the same manner ( $r \cdot \phi$ , units of eV-Angstroms) as in EAM `setfl` files. Note that in Finnis/Sinclair, the  $\phi(r)$  arrays are still symmetric, so only  $\phi$  arrays for  $i \geq j$  are listed.

HE EAM files in the *potentials* directory of the LAMMPS distribution have an “.eam.he” suffix. They are formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 ... ElementN
- line 5: Nrho, drho, Nr, dr, cutoff, rhomax

The 5-line header section is identical to an FS EAM file except that line 5 lists an additional value, `rhomax`. Unlike in FS EAM files where embedding energies  $F(\rho)$  are always defined between  $\rho = 0$  and  $\rho = (N_{\rho} - 1)d\rho$ ,  $F(\rho)$  in HE EAM files are defined between  $\rho = \rho_{\min}$  and  $\rho = \rho_{\max}$ . Since  $d\rho = (\rho_{\max} - \rho_{\min}) / (N_{\rho} - 1)$ ,  $\rho_{\min} = \rho_{\max} - (N_{\rho} - 1)d\rho$ . The embedding energies  $F(\rho)$  are listed for  $\rho = \rho_{\min}$ ,  $\rho_{\min} + d\rho$ ,  $\rho_{\min} + 2d\rho$ , ...,  $\rho_{\max}$ . This gives users additional flexibility to define a negative `rhomin` and therefore an embedding energy function that works for both positive and negative electron densities. The format and units of these sections are identical to the FS EAM files (see above).

---

New in version 3Nov2022.

The *eam*, *eam/alloy*, *eam/fs*, and *eam/he* pair styles support extraction of two per-atom quantities by the *fix pair* command. This allows the quantities to be output to files by the *dump* or otherwise processed by other LAMMPS commands.

The names of the two quantities are “rho” and “fp” for the density and derivative of the embedding energy for each atom. Neither quantity needs to be triggered by the *fix pair* command in order for these pair styles to calculate it.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.96.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS as described above with the individual styles. You never need to specify a `pair_coeff` command with  $I \neq J$  arguments for the *eam* styles.

This pair style does not support the *pair\_modify* shift, table, and tail options.

The *eam* pair styles do not write their information to *binary restart files*, since it is stored in tabulated potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

The *eam* pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

### 4.96.5 Restrictions

All of these styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 4.97 pair\_style edip command

Accelerator Variants: *edip/omp*

## 4.98 pair\_style edip/multi command

### 4.98.1 Syntax

`pair_style style`

- style = *edip* or *edip/multi*

## 4.98.2 Examples

```
pair_style edip
pair_coeff * * Si.edip Si
```

## 4.98.3 Description

The *edip* and *edip/multi* styles compute a 3-body **EDIP** potential which is popular for modeling silicon materials where it can have advantages over other models such as the *Stillinger-Weber* or *Tersoff* potentials. The *edip* style has been programmed for single element potentials, while *edip/multi* supports multi-element EDIP runs.

In EDIP, the energy  $E$  of a system of atoms is

$$E = \sum_{j \neq i} \phi_2(R_{ij}, Z_i) + \sum_{j \neq i} \sum_{k \neq i, k > j} \phi_3(R_{ij}, R_{ik}, Z_i)$$

$$\phi_2(r, Z) = A \left[ \left( \frac{B}{r} \right)^p - e^{-\beta Z^2} \right] \exp \left( \frac{\sigma}{r - a} \right)$$

$$\phi_3(R_{ij}, R_{ik}, Z_i) = \exp \left( \frac{\gamma}{R_{ij} - a} \right) \exp \left( \frac{\gamma}{R_{ik} - a} \right) h(\cos \theta_{ijk}, Z_i)$$

$$Z_i = \sum_{m \neq i} f(R_{im}) \quad f(r) = \begin{cases} 1 & r < c \\ \exp \left( \frac{\alpha}{1 - r^{-3}} \right) & c < r < a \\ 0 & r > a \end{cases}$$

$$h(l, Z) = \lambda [(1 - e^{-Q(Z)(l + \tau(Z))^2}) + \eta Q(Z)(l + \tau(Z))^2]$$

$$Q(Z) = Q_0 e^{-\mu Z} \quad \tau(Z) = u_1 + u_2(u_3 e^{-u_4 Z} - e^{-2u_4 Z})$$

where  $\phi_2$  is a two-body term and  $\phi_3$  is a three-body term. The summations in the formula are over all neighbors  $J$  and  $K$  of atom  $I$  within a cutoff distance  $= a$ . Both terms depend on the local environment of atom  $I$  through its effective coordination number defined by  $Z$ , which is unity for a cutoff distance  $< c$  and gently goes to 0 at distance  $= a$ .

Only a single `pair_coeff` command is used with the *edip* style which specifies a EDIP potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the `pair_coeff` command, where  $N$  is the number of LAMMPS atom types:

- filename
- $N$  element names = mapping of EDIP elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine a file `Si.edip` has EDIP values for Si.

EDIP files in the *potentials* directory of the LAMMPS distribution have a “.edip” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- A (energy units)
- B (distance units)
- cutoffA (distance units)

- cutoffC (distance units)
- $\alpha$
- $\beta$
- $\eta$
- $\gamma$  (distance units)
- $\lambda$  (energy units)
- $\mu$
- $\tau$
- $\sigma$  (distance units)
- Q0
- u1
- u2
- u3
- u4

The A, B, beta, sigma parameters are used only for two-body interactions. The eta, gamma, lambda, mu, Q0 and all u1 to u4 parameters are used only for three-body interactions. The alpha and cutoffC parameters are used for the coordination environment function only.

The EDIP potential file must contain entries for all the elements listed in the pair\_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify EDIP parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

At the moment, only a single element parameterization is implemented. However, the author is not aware of other multi-element EDIP parameterization. If you know any and you are interest in that, please contact the author of the EDIP package.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.98.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.98.5 Restrictions

This pair style can only be used if LAMMPS was built with the MANYBODY package. See the *Build package* doc page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

The EDIP potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the EDIP potential with any LAMMPS units, but you would need to create your own EDIP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

```

## 4.99.3 Description

This pair style contains a LAMMPS implementation of the electron Force Field (eFF) potential currently under development at Caltech, as described in (*Jaramillo-Botero*). The eFF for  $Z < 6$  was first introduced by (*Su*) in 2007. It has been extended to higher  $Z$ s by using effective core potentials (ECPs) that now cover up to second and third row p-block elements of the periodic table.

eFF can be viewed as an approximation to QM wave packet dynamics and Fermionic molecular dynamics, combining the ability of electronic structure methods to describe atomic structure, bonding, and chemistry in materials, and of plasma methods to describe nonequilibrium dynamics of large systems with a large number of highly excited electrons. Yet, eFF relies on a simplification of the electronic wave function in which electrons are described as floating Gaussian wave packets whose position and size respond to the various dynamic forces between interacting classical nuclear particles and spherical Gaussian electron wave packets. The wave function is taken to be a Hartree product of the wave packets. To compensate for the lack of explicit antisymmetry in the resulting wave function, a spin-dependent Pauli potential is included in the Hamiltonian. Substituting this wave function into the time-dependent Schrodinger equation produces equations of motion that correspond - to second order - to classical Hamiltonian relations between electron position and size, and their conjugate momenta. The N-electron wave function is described as a product of one-electron Gaussian functions, whose size is a dynamical variable and whose position is not constrained to a nuclear center. This form allows for straightforward propagation of the wave function, with time, using a simple formulation from which the equations of motion are then integrated with conventional MD algorithms. In addition to this spin-dependent Pauli repulsion potential term between Gaussians, eFF includes the electron kinetic energy from the Gaussians. These two terms are based on first-principles quantum mechanics. On the other hand, nuclei are described as point charges, which interact with other nuclei and electrons through standard electrostatic potential forms.

The full Hamiltonian (shown below), contains then a standard description for electrostatic interactions between a set of delocalized point and Gaussian charges which include, nuclei-nuclei (NN), electron-electron (ee), and nuclei-electron (Ne). Thus, eFF is a mixed QM-classical mechanics method rather than a conventional force field method (in which electron motions are averaged out into ground state nuclear motions, i.e a single electronic state, and particle interactions are described via empirically parameterized interatomic potential functions). This makes eFF uniquely suited to simulate materials over a wide range of temperatures and pressures where electronically excited and ionized states of matter can occur and coexist. Furthermore, the interactions between particles -nuclei and electrons- reduce to the sum of a set of effective pairwise potentials in the eFF formulation. The *eff/cut* style computes the pairwise Coulomb interactions between nuclei and electrons ( $E_{NN}, E_{Ne}, E_{ee}$ ), and the quantum-derived Pauli ( $E_{PR}$ ) and Kinetic energy interactions potentials between electrons ( $E_{KE}$ ) for a total energy expression given as,

$$U(R, r, s) = E_{NN}(R) + E_{Ne}(R, r, s) + E_{ee}(r, s) + E_{KE}(r, s) + E_{PR}(\uparrow\downarrow, S)$$

The individual terms are defined as follows:

$$\begin{aligned}
 E_{KE} &= \frac{\hbar^2}{m_e} \sum_i \frac{3}{2s_i^2} \\
 E_{NN} &= \frac{1}{4\pi\epsilon_0} \sum_{i<j} \frac{Z_i Z_j}{R_{ij}} \\
 E_{Ne} &= -\frac{1}{4\pi\epsilon_0} \sum_{i,j} \frac{Z_i}{R_{ij}} \operatorname{Erf} \left( \frac{\sqrt{2} R_{ij}}{s_j} \right) \\
 E_{ee} &= \frac{1}{4\pi\epsilon_0} \sum_{i<j} \frac{1}{r_{ij}} \operatorname{Erf} \left( \frac{\sqrt{2} r_{ij}}{\sqrt{s_i^2 + s_j^2}} \right) \\
 E_{Pauli} &= \sum_{\sigma_i=\sigma_j} E(\uparrow\uparrow)_{ij} + \sum_{\sigma_i\neq\sigma_j} E(\uparrow\downarrow)_{ij}
 \end{aligned}$$

where,  $s_i$  correspond to the electron sizes, the  $\sigma_i$ 's to the fixed spins of the electrons,  $Z_i$  to the charges on the nuclei,  $R_{ij}$  to the distances between the nuclei or the nuclei and electrons, and  $r_{ij}$  to the distances between electrons. For additional details see ([Jaramillo-Botero](#)).

The overall electrostatics energy is given in Hartree units of energy by default and can be modified by an energy-conversion constant, according to the units chosen (see [electron\\_units](#)). The cutoff  $R_c$ , given in Bohrs (by default), truncates the interaction distance. The recommended cutoff for this pair style should follow the minimum image criterion, i.e. half of the minimum unit cell length.

This potential is designed to be used with [atom\\_style electron](#) definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atoms types via the [pair\\_coeff](#) command as in the examples above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands, or by mixing as described below:

- cutoff (distance units)

For [eff/cut](#), the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the [pair\\_style](#) command is used.

The [limit/radius](#) and [pressure/evirials](#) keywords are optional. Neither or both must be specified. If not specified they are unset.

The [limit/radius](#) keyword is used to restrain electron size from becoming excessively diffuse at very high temperatures where the Gaussian wave packet representation breaks down, and from expanding as free particles to infinite size. If unset, electron radius is free to increase without bounds. If set, a restraining harmonic potential of the form  $E = 1/2k_{ss}s^2$  for  $s > L_{box}/2$ , where  $k_{ss} = 1$  Hartrees/Bohr<sup>2</sup>, is applied on the electron radius.

The [pressure/evirials](#) keyword is used to control between two types of pressure computation: if unset, the computed pressure does not include the electronic radial virials contributions to the total pressure (scalar or tensor). If set, the computed pressure will include the electronic radial virial contributions to the total pressure (scalar and tensor).

The [ecp](#) keyword is used to associate an ECP representation for a particular atom type. The ECP captures the orbital overlap between a core pseudo particle and valence electrons within the Pauli repulsion. A list of type:element-symbol pairs may be provided for all ECP representations, after the “ecp” keyword.

**Note:** Default ECP parameters are provided for C, N, O, Al, and Si. Users can modify these using the [pair\\_coeff](#) command as exemplified above. For this, the User must distinguish between two different functional forms supported, one that captures the orbital overlap assuming the s-type core interacts with an s-like valence electron (s-s) and another

that assumes the interaction is s-p. For systems that exhibit significant p-character (e.g. C, N, O) the s-p form is recommended. The “s” ECP form requires 3 parameters and the “p” 5 parameters.

---

**Note:** There are two different pressures that can be reported for eFF when defining this pair\_style, one (default) that considers electrons do not contribute radial virial components (i.e. electrons treated as incompressible ‘rigid’ spheres) and one that does. The radial electronic contributions to the virials are only tallied if the flexible pressure option is set, and this will affect both global and per-atom quantities. In principle, the true pressure of a system is somewhere in between the rigid and the flexible eFF pressures, but, for most cases, the difference between these two pressures will not be significant over long-term averaged runs (i.e. even though the energy partitioning changes, the total energy remains similar).

---

**Note:** This implementation of eFF gives a reasonably accurate description for systems containing nuclei from  $Z = 1$ -6 in “all electron” representations. For systems with increasingly non-spherical electrons, Users should use the ECP representations. ECPs are now supported and validated for most of the second and third row elements of the p-block. Predefined parameters are provided for C, N, O, Al, and Si. The ECP captures the orbital overlap between the core and valence electrons (i.e. Pauli repulsion) with one of the functional forms:

---

$$E_{Pauli(ECP_s)} = p_1 \exp\left(-\frac{p_2 r^2}{p_3 + s^2}\right)$$
$$E_{Pauli(ECP_p)} = p_1 \left(\frac{2}{p_2/s + s/p_2}\right) (r - p_3 s)^2 \exp\left[-\frac{p_4 (r - p_3 s)^2}{p_5 + s^2}\right]$$

Where the first form correspond to core interactions with s-type valence electrons and the second to core interactions with p-type valence electrons.

The current version adds full support for models with fixed-core and ECP definitions. to enable larger timesteps (i.e. by avoiding the high frequency vibrational modes -translational and radial- of the 2 s electrons), and in the ECP case to reduce the increased orbital complexity in higher Z elements (up to  $Z < 18$ ). A fixed-core should be defined with a mass that includes the corresponding nuclear mass plus the 2 s electrons in atomic mass units ( $2 \times 5.4857990943 \times 10^{-4}$ ), and a radius equivalent to that of minimized 1s electrons (see examples under /examples/PACKAGES/eff/fixed-core). An pseudo-core should be described with a mass that includes the corresponding nuclear mass, plus all the core electrons (i.e no outer shell electrons), and a radius equivalent to that of a corresponding minimized full-electron system. The charge for a pseudo-core atom should be given by the number of outer shell electrons.

In general, eFF excels at computing the properties of materials in extreme conditions and tracing the system dynamics over multi-picosecond timescales; this is particularly relevant where electron excitations can change significantly the nature of bonding in the system. It can capture with surprising accuracy the behavior of such systems because it describes consistently and in an unbiased manner many different kinds of bonds, including covalent, ionic, multicenter, ionic, and plasma, and how they interconvert and/or change when they become excited. eFF also excels in computing the relative thermochemistry of isodemic reactions and conformational changes, where the bonds of the reactants are of the same type as the bonds of the products. eFF assumes that kinetic energy differences dominate the overall exchange energy, which is true when the electrons present are nearly spherical and nodeless and valid for covalent compounds such as dense hydrogen, hydrocarbons, and diamond; alkali metals (e.g. lithium), alkali earth metals (e.g. beryllium) and semimetals such as boron; and various compounds containing ionic and/or multicenter bonds, such as boron dihydride.

---

#### 4.99.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the cutoff distance for the *eff/cut* style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

The *pair\_modify* shift option is not relevant for these pair styles.

The *eff/long* (not yet available) style supports the *pair\_modify* table option for tabulation of the short-range portion of the long-range Coulombic interaction.

These pair styles do not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.99.5 Restrictions

These pair styles will only be enabled if LAMMPS is built with the EFF package. It will only be enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These pair styles require that particles store electron attributes such as radius, radial velocity, and radial force, as defined by the *atom\_style*. The *electron* atom style does all of this.

These pair styles require you to use the *comm\_modify vel yes* command so that velocities are stored by ghost atoms.

#### 4.99.6 Related commands

*pair\_coeff*

#### 4.99.7 Default

If not specified, limit\_eradius = 0 and pressure\_with\_evirials = 0.

### 4.100.3 Description

Style *eim* computes pairwise interactions for ionic compounds using embedded-ion method (EIM) potentials ([Zhou](#)). The energy of the system  $E$  is given by

$$E = \frac{1}{2} \sum_{i=1}^N \sum_{j=i_1}^{i_N} \phi_{ij}(r_{ij}) + \sum_{i=1}^N E_i(q_i, \sigma_i)$$

The first term is a double pairwise sum over the  $J$  neighbors of all  $I$  atoms, where  $\phi_{ij}$  is a pair potential. The second term sums over the embedding energy  $E_i$  of atom  $I$ , which is a function of its charge  $q_i$  and the electrical potential  $\sigma_i$  at its location.  $E_i$ ,  $q_i$ , and  $\sigma_i$  are calculated as

$$q_i = \sum_{j=i_1}^{i_N} \eta_{ji}(r_{ij})$$

$$\sigma_i = \sum_{j=i_1}^{i_N} q_j \cdot \psi_{ij}(r_{ij})$$

$$E_i(q_i, \sigma_i) = \frac{1}{2} \cdot q_i \cdot \sigma_i$$

where  $\eta_{ji}$  is a pairwise function describing electron flow from atom  $I$  to atom  $J$ , and  $\psi_{ij}$  is another pairwise function. The multi-body nature of the EIM potential is a result of the embedding energy term. A complete list of all the pair functions used in EIM is summarized below

$$\phi_{ij}(r) = \begin{cases} \left[ \frac{E_{b,ij}\beta_{ij}}{\beta_{ij}-\alpha_{ij}} \exp\left(-\alpha_{ij} \frac{r-r_{e,ij}}{r_{e,ij}}\right) - \frac{E_{b,ij}\alpha_{ij}}{\beta_{ij}-\alpha_{ij}} \exp\left(-\beta_{ij} \frac{r-r_{e,ij}}{r_{e,ij}}\right) \right] f_c(r, r_{e,ij}, r_{c,\phi,ij}), & p_{ij} = 1 \\ \left[ \frac{E_{b,ij}\beta_{ij}}{\beta_{ij}-\alpha_{ij}} \left(\frac{r_{e,ij}}{r}\right)^{\alpha_{ij}} - \frac{E_{b,ij}\alpha_{ij}}{\beta_{ij}-\alpha_{ij}} \left(\frac{r_{e,ij}}{r}\right)^{\beta_{ij}} \right] f_c(r, r_{e,ij}, r_{c,\phi,ij}), & p_{ij} = 2 \end{cases}$$

$$\eta_{ji} = A_{\eta,ij} (\chi_j - \chi_i) f_c(r, r_{s,\eta,ij}, r_{c,\eta,ij})$$

$$\psi_{ij}(r) = A_{\psi,ij} \exp(-\zeta_{ij}r) f_c(r, r_{s,\psi,ij}, r_{c,\psi,ij})$$

$$f_c(r, r_p, r_c) = 0.510204 \cdot \operatorname{erfc}\left[\frac{1.64498(2r - r_p - r_c)}{r_c - r_p}\right] - 0.010204$$

Here  $E_b, r_e, r(c, \phi), \alpha, \beta, A(\psi), \zeta, r(s, \psi), r(c, \psi), A(\eta), r(s, \eta), r(c, \eta), \chi$ , and pair function type  $p$  are parameters, with subscripts  $ij$  indicating the two species of atoms in the atomic pair.

**Note:** Even though the EIM potential is treating atoms as charged ions, you should not use a LAMMPS *atom\_style* that stores a charge on each atom and thus requires you to assign a charge to each atom, e.g. the *charge* or *full* atom

styles. This is because the EIM potential infers the charge on an atom from the equation above for  $q_i$ ; you do not assign charges explicitly.

All the EIM parameters are listed in a potential file which is specified by the `pair_coeff` command. This is an ASCII text file in a format described below. The “ffield.eim” file included in the “potentials” directory of the LAMMPS distribution currently includes nine elements Li, Na, K, Rb, Cs, F, Cl, Br, and I. A system with any combination of these elements can be modeled. This file is parameterized in terms of LAMMPS *metal units*.

Note that unlike other potentials, cutoffs for EIM potentials are not set in the `pair_style` or `pair_coeff` command; they are specified in the EIM potential file itself. Likewise, the EIM potential file lists atomic masses; thus you do not need to use the `mass` command to specify them.

Only a single `pair_coeff` command is used with the `eim` style which specifies an EIM potential file and the element(s) to extract information for. The EIM elements are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- Elem1, Elem2, ...
- EIM potential file
- N element names = mapping of EIM elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the potential file.

As an example like one of those above, suppose you want to model a system with Na and Cl atoms. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Na, and the fourth to be Cl, you would use the following `pair_coeff` command:

```
pair_coeff * * Na Cl ffield.eim Na Na Na Cl
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The filename is the EIM potential file. The Na and Cl arguments (before the file name) are the two elements for which info will be extracted from the potential file. The first three trailing Na arguments map LAMMPS atom types 1,2,3 to the EIM Na element. The final Cl argument maps LAMMPS atom type 4 to the EIM Cl element.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an `eim` potential is used as part of the `hybrid` pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The `ffield.eim` file in the `potentials` directory of the LAMMPS distribution is formatted as follows:

Lines starting with `#` are comments and are ignored by LAMMPS. Lines starting with “global:” include three global values. The first value divides the cations from anions, i.e., any elements with electronegativity above this value are viewed as anions, and any elements with electronegativity below this value are viewed as cations. The second and third values are related to the cutoff function - i.e. the 0.510204, 1.64498, and 0.010204 shown in the above equation can be derived from these values.

Lines starting with “element:” are formatted as follows: name of element, atomic number, atomic mass, electronic negativity, atomic radius (LAMMPS ignores it), ionic radius (LAMMPS ignores it), cohesive energy (LAMMPS ignores it), and  $q_0$  (must be 0).

Lines starting with “pair:” are entered as: element 1, element 2,  $r_c(\phi)$ ,  $r_c(\phi)$  (redundant for historical reasons),  $E_b$ ,  $r_e$ ,  $\alpha$ ,  $\beta$ ,  $r_c(\eta)$ ,  $A(\eta)$ ,  $r_c(\psi)$ ,  $A(\psi)$ ,  $\zeta$ ,  $r_c(\psi)$ , and  $p$ .

The lines in the file can be in any order; LAMMPS extracts the info it needs.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#)

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.100.4 Restrictions

This style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

```

### 4.101.3 Description

Style *exp6/rx* is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of  $m$  species whose reaction rate kinetics are determined from a set of  $n$  reaction rate equations through the *fix rx* command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. The *exp6/rx* style computes an exponential-6 potential given by

$$U_{ij}(r) = \frac{\epsilon}{\alpha - 6} \left\{ 6 \exp\left[\alpha\left(1 - \frac{r_{ij}}{R_m}\right)\right] - \alpha\left(\frac{R_m}{r_{ij}}\right)^6 \right\}$$

where the  $\epsilon$  parameter determines the depth of the potential minimum located at  $R_m$ , and  $\alpha$  determines the softness of the repulsion.

The coefficients must be defined for each species in a given particle type via the *pair\_coeff* command as in the examples above, where the first argument is the filename that includes the exponential-6 parameters for each species. The file includes the species tag followed by the  $\alpha$ ,  $\epsilon$  and  $R_m$  parameters. The format of the file is described below.

The second and third arguments specify the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the *fix rx* command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the *fractional* or *molecular* weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

The fourth argument specifies the type of scaling that will be used to scale the EXP-6 parameters as reactions occur. Currently, there are three scaling options: *exponent*, *polynomial* and *none*.

Exponent scaling requires two additional arguments for scaling the  $R_m$  and  $\epsilon$  parameters, respectively. The scaling factor is computed by  $\phi^{\text{exponent}}$ , where  $\phi$  is the number of molecules represented by the coarse-grain particle and exponent is specified as a pair coefficient argument for  $R_m$  and  $\epsilon$ , respectively. The  $R_m$  and  $\epsilon$  parameters are multiplied by the scaling factor to give the scaled interaction parameters for the CG particle.

Polynomial scaling requires a filename to be specified as a pair coeff argument. The file contains the coefficients to a fifth order polynomial for the  $\alpha$ ,  $\epsilon$  and  $R_m$  parameters that depend upon  $\phi$  (the number of molecules represented by the CG particle). The format of a polynomial file is provided below.

The *none* option to the scaling does not have any additional pair coeff arguments. This is equivalent to specifying the *exponent* option with  $R_m$  and  $\epsilon$  exponents of 0.0 and 0.0, respectively.

The final argument specifies the interaction cutoff (optional).

The format of a tabulated file is as follows (without the parenthesized comments):

```
# exponential-6 parameters for various species      (one or more comment or blank lines)

h2o  exp6  11.00  0.02  3.50                        (species, exp6, alpha, Rm, epsilon)
no2  exp6  13.60  0.01  3.70
...
co2  exp6  13.00  0.03  3.20
```

The format of the polynomial scaling file as follows (without the parenthesized comments):

```
# POLYNOMIAL FILE          (one or more comment or blank lines)

# General Functional Form:
# A*phi^5 + B*phi^4 + C*phi^3 + D*phi^2 + E*phi + F
#
# Parameter  A          B          C          D          E          F
#                                     (blank)
alpha        0.0000    0.00000    0.000008   0.04955   -0.73804   13.63201
epsilon      0.0000    0.00478   -0.06283   0.24486   -0.33737   2.60097
rm           0.0001   -0.00118  -0.00253   0.05812   -0.00509   1.50106
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections.

Following a blank line, the next N lines list the species and their corresponding parameters. The first argument is the species tag, the second argument is the exp6 tag, the third argument is the  $\alpha$  parameter (energy units), the fourth argument is the  $\epsilon$  parameter (energy-distance<sup>6</sup> units), and the fifth argument is the  $R_m$  parameter (distance units). If a species tag of “1fluid” is listed as a pair coefficient, a one-fluid approximation is specified where a concentration-dependent combination of the parameters is computed through the following equations:

$$R_m^3 = \sum_a \sum_b x_a x_b R_{m,ab}^3$$

$$\epsilon = \frac{1}{R_m^3} \sum_a \sum_b x_a x_b \epsilon_{ab} R_{m,ab}^3$$

$$\alpha = \frac{1}{\epsilon R_m^3} \sum_a \sum_b x_a x_b \alpha_{ab} \epsilon_{ab} R_{m,ab}^3$$

where

$$\epsilon_{ab} = \sqrt{\epsilon_a \epsilon_b}$$

$$R_{m,ab} = \frac{R_{m,a} + R_{m,b}}{2}$$

$$\alpha_{ab} = \sqrt{\alpha_a \alpha_b}$$

and  $x_a$  and  $x_b$  are the mole fractions of a and b, respectively, which comprise the gas mixture.

#### 4.101.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift option for the energy of the exp() and 1/r<sup>6</sup> portion of the pair interaction.

This style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure for the A,C terms in the pair interaction.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 4.101.5 Restrictions

Example input scripts available: `examples/PACKAGES/fep`

### 4.114.3 Description

These pair styles have a soft repulsive core, tunable by a parameter `lambda`, in order to avoid singularities during free energy calculations when sites are created or annihilated (*Beutler*). When `lambda` tends to 0 the pair interaction vanishes with a soft repulsive core. When `lambda` tends to 1, the pair interaction approaches the normal, non-soft potential. These pair styles are suited for “alchemical” free energy calculations using the *fix adapt/fep* and *compute fep* commands.

The *lj/cut/soft* style and related sub-styles compute the 12-6 Lennard-Jones and Coulomb potentials modified by a soft

core, with the functional form

$$E = \lambda^n 4\epsilon \left\{ \frac{1}{\left[ \alpha_{\text{LJ}}(1 - \lambda)^2 + \left(\frac{r}{\sigma}\right)^6 \right]^2} - \frac{1}{\alpha_{\text{LJ}}(1 - \lambda)^2 + \left(\frac{r}{\sigma}\right)^6} \right\} \quad r < r_c$$

The *lj/class2/soft* style is a 9-6 potential with the exponent of the denominator of the first term in brackets taking the value 1.5 instead of 2 (other details differ, see the form of the potential in *pair\_style lj/class2*).

Coulomb interactions can also be damped with a soft core at short distance,

$$E = \lambda^n \frac{Cq_i q_j}{\epsilon [\alpha_C(1 - \lambda)^2 + r^2]^{1/2}} \quad r < r_c$$

In the Coulomb part  $C$  is an energy-conversion constant,  $q_i$  and  $q_j$  are the charges on the two atoms, and epsilon is the dielectric constant which can be set by the *dielectric* command.

The coefficient lambda is an activation parameter. When  $\lambda = 1$  the pair potential is identical to a Lennard-Jones term or a Coulomb term or a combination of both. When  $\lambda = 0$  the interactions are deactivated. The transition between these two extrema is smoothed by a soft repulsive core in order to avoid singularities in potential energy and forces when sites are created or annihilated and can overlap (*Beutler*).

The parameters  $n$ ,  $\alpha_{\text{LJ}}$  and  $\alpha_C$  are set in the *pair\_style* command, before the cutoffs. Usual choices for the exponent are  $n = 2$  or  $n = 1$ . For the remaining coefficients  $\alpha_{\text{LJ}} = 0.5$  and  $\alpha_C = 10 \text{ \AA}^2$  are appropriate choices. Plots of the 12-6 LJ and Coulomb terms are shown below, for lambda ranging from 1 to 0 every 0.1.

For the *lj/cut/coul/cut/soft* or *lj/cut/coul/long/soft* pair styles, as well as for the equivalent *class2* versions, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $\lambda$  (activation parameter, between 0 and 1)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter two coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the *pair\_style* command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style *lj/cut/soft*, since it has no Coulombic terms. For the *coul/cut/soft* and *coul/long/soft* only lambda and the optional cutoff2 are to be specified.

Style *lj/cut/tip4p/long/soft* implements a soft-core version of the TIP4P water model. The usage of the TIP4P pair style is documented in the *pair\_lj* styles. In the soft version the parameters  $n$ ,  $\alpha_{LJ}$  and  $\alpha_C$  are set in the *pair\_style* command, after the specific parameters of the TIP4P water model and before the cutoffs. The activation parameter lambda is supplied as an argument of the *pair\_coeff* command, after epsilon and sigma and before the optional cutoffs.

---

**Note:** If using type labels, the type labels must be defined before calling the *pair\_coeff* command.

---

Style *lj/charmm/coul/long/soft* implements a soft-core version of the modified 12-6 LJ potential used in CHARMM and documented in the *pair\_style lj/charmm/coul/long* style. In the soft version the parameters  $n$ ,  $\alpha_{LJ}$  and  $\alpha_C$  are set in the *pair\_style* command, before the global cutoffs. The activation parameter lambda is introduced as an argument of the *pair\_coeff* command, after  $\epsilon$  and  $\sigma$  and before the optional eps14 and sigma14.

Style *lj/class2/soft* implements a soft-core version of the 9-6 potential in *pair\_style lj/class2*. In the soft version the parameters  $n$ ,  $\alpha_{LJ}$  and  $\alpha_C$  are set in the *pair\_style* command, before the global cutoffs. The activation parameter lambda is introduced as an argument of the *pair\_coeff* command, after  $\epsilon$  and  $\sigma$  and before the optional cutoffs.

The *coul/cut/soft*, *coul/long/soft* and *tip4p/long/soft* sub-styles are designed to be combined with other pair potentials via the *pair\_style hybrid/overlay* command. This is because they have no repulsive core. Hence, if used by themselves, there will be no repulsion to keep two oppositely charged particles from overlapping each other. In this case, if  $\lambda = 1$ , a singularity may occur. These sub-styles are suitable to represent charges embedded in the Lennard-Jones radius of another site (for example hydrogen atoms in several water models). The  $\lambda$  must be defined for each pair, and *coul/cut/soft* can accept an optional cutoff as the second coefficient.

---

**Note:** When using the soft-core Coulomb potentials with long-range solvers (*coul/long/soft*, *lj/cut/coul/long/soft*, etc.) in a free energy calculation in which sites holding electrostatic charges are being created or annihilated (using *fix adapt/fep* and *compute fep*) it is important to adapt both the  $\lambda$  activation parameter (from 0 to 1, or the reverse) and the value of the charge (from 0 to its final value, or the reverse). This ensures that long-range electrostatic terms (k-space) are correct. It is not necessary to use soft-core Coulomb potentials if the van der Waals site is present during the free-energy route, thus avoiding overlap of the charges. Examples are provided in the LAMMPS source directory tree, under examples/PACKAGES/fep.

---

---

**Note:** To avoid division by zero do not set  $\sigma = 0$  in the *lj/cut/soft* and related styles; use the lambda parameter instead to activate/deactivate interactions, or use  $\epsilon = 0$  and  $\sigma = 1$ . Alternatively, when sites do not interact though the Lennard-Jones term the *coul/long/soft* or similar sub-style can be used via the *pair\_style hybrid/overlay* command.

---

The *morse/soft* variant modifies the *pair\_morse* style at short range to have a soft core. The functional form differs from that of the *lj/soft* styles, and is instead given by:

$$\begin{aligned}s(\lambda) &= (1 - \lambda)/(1 - \lambda_f), & B &= -2De^{-2\alpha r_0}(e^{\alpha r_0} - 1)/3 \\ E &= D_0 [e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)}] + s(\lambda)Be^{-3\alpha(r-r_0)}, & \lambda &\geq \lambda_f, \quad r < r_c \\ E &= (D_0 [e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)}] + Be^{-3\alpha(r-r_0)}) (\lambda/\lambda_f)^n, & \lambda &< \lambda_f, \quad r < r_c\end{aligned}$$

The *morse/soft* style requires the following pair coefficients:

- $D_0$  (energy units)
- $\alpha$  (1/distance units)
- $r_0$  (distance units)
- $\lambda$  (unitless, between 0.0 and 1.0)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global morse cutoff is used.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.114.4 Mixing, shift, table, tail correction, restart, rRESPA info

The different versions of the *lj/cut/soft* pair styles support mixing. For atom type pairs I,J and I != J, the  $\epsilon$  and  $\sigma$  coefficients and cutoff distance for these pair styles can be mixed. The default mix value is *geometric* for 12-6 styles.

The mixing rule for epsilon and sigma for *lj/class2/soft* 9-6 potentials is to use the *sixthpower* formulas. The *pair\_modify mix* setting is thus ignored for class2 potentials for  $\epsilon$  and  $\sigma$ . However it is still followed for mixing the cutoff distance. See the *pair\_modify* command for details.

The *morse/soft* pair style does not support mixing. Thus, coefficients for all LJ pairs must be specified explicitly.

All of the pair styles with soft core support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction.

The different versions of the *lj/cut/soft* pair styles support the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

---

**Note:** The analytical form of the tail corrections for energy and pressure used in the *lj/cut/soft* potentials are approximate, being identical to that of the corresponding non-soft potentials scaled by a factor  $\lambda^n$ . The errors due to this approximation should be negligible. For example, for a cutoff of  $2.5\sigma$  this approximation leads to maximum relative

errors in tail corrections of the order of  $1e-4$  for energy and virial ( $\alpha_{LJ} = 0.5, n = 2$ ). The error vanishes when lambda approaches 0 or 1. Note that these are the errors affecting the long-range tail (itself a correction to the interaction energy) which includes other approximations, namely that the system is homogeneous (local density equal the average density) beyond the cutoff.

---

The *morse/soft* pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

All of these pair styles write information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

---

#### 4.114.5 Restrictions

The pair styles with soft core are only enabled if LAMMPS was built with the FEP package. The *long* versions also require the KSPACE package to be installed. The soft *tip4p* versions also require the MOLECULE package to be installed. These styles are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

#### 4.114.6 Related commands

### 4.115 pair\_style gauss command

Accelerator Variants: *gauss/gpu*, *gauss/omp*

### 4.116 pair\_style gauss/cut command

Accelerator Variants: *gauss/cut/omp*

#### 4.116.1 Syntax

```
pair_style gauss cutoff
pair_style gauss/cut cutoff
```

- cutoff = global cutoff for Gauss interactions (distance units)

## 4.116.2 Examples

```
pair_style gauss 12.0
pair_coeff * * 1.0 0.9
pair_coeff 1 4 1.0 0.9 10.0

pair_style gauss/cut 3.5
pair_coeff 1 4 0.2805 1.45 0.112
```

## 4.116.3 Description

Style *gauss* computes a tethering potential of the form

$$E = -A \exp(-Br^2) \quad r < r_c$$

between an atom and its corresponding tether site which will typically be a frozen atom in the simulation.  $r_c$  is the cutoff.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- A (energy units)
- B (1/distance<sup>2</sup> units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Style *gauss/cut* computes a generalized Gaussian interaction potential between pairs of particles:

$$E = \frac{H}{\sigma_h \sqrt{2\pi}} \exp \left[ -\frac{(r - r_{mh})^2}{2\sigma_h^2} \right]$$

where H determines together with the standard deviation  $\sigma_h$  the peak height of the Gaussian function, and  $r_{mh}$  the peak position. Examples of the use of the Gaussian potentials include implicit solvent simulations of salt ions (*Lenart*) and of surfactants (*Jusuifi*). In these instances the Gaussian potential mimics the hydration barrier between a pair of particles. The hydration barrier is located at  $r_{mh}$  and has a width of  $\sigma_h$ . The prefactor determines the height of the potential barrier.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- H (energy \* distance units)
- $r_{mh}$  (distance units)
- $\sigma_h$  (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.116.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the A, B, H, sigma\_h, r\_mh parameters, and the cutoff distance for these pair styles can be mixed:

- A (energy units)
- $\sqrt{\frac{1}{B}}$  (distance units, see below)
- H (energy units)
- $r_{mh}$  (distance units)
- $\sigma_h$  (distance units)
- cutoff (distance units)

The default mix value is *geometric*. Only *arithmetic* and *geometric* mix values are supported. See the “pair\_modify” command for details.

The A and H parameters are mixed using the same rules normally used to mix the “epsilon” parameter in a Lennard Jones interaction. The sigma\_h, r\_mh, and the cutoff distance are mixed using the same rules used to mix the “sigma” parameter in a Lennard Jones interaction. The B parameter is converted to a distance (sigma), before mixing (using  $\text{sigma} = B^{-0.5}$ ), and converted back to a coefficient afterwards (using  $B = \text{sigma}^2$ ). Negative A values are converted to positive A values (using  $\text{abs}(A)$ ) before mixing, and converted back after mixing (by multiplying by  $\min(\text{sign}(A_i), \text{sign}(A_j))$ ). This way, if either particle is repulsive (if  $A_i < 0$  or  $A_j < 0$ ), then the default interaction between both particles will be repulsive.

For the *gauss* style there is no effect due to the Gaussian well beyond the cutoff; hence reasonable cutoffs need to be specified.

The *gauss/cut* style supports the *pair\_modify* shift option for the energy of the Gauss-potential portion of the pair interaction.

The *pair\_modify* table and tail options are not relevant for these pair styles.

These pair styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

The *gauss* pair style tallies an “occupancy” count of how many Gaussian-well sites have an atom within the distance at which the force is a maximum =  $\sqrt{0.5/b}$ . This quantity can be accessed via the *compute pair* command as a vector of values of length 1.

To print this quantity to the log file (with a descriptive column heading) the following commands could be included in an input script:

```
compute gauss all pair gauss
variable occ equal c_gauss[1]
thermo_style custom step temp epair v_occ
```

### 4.116.5 Restrictions

The *gauss* and *gauss/cut* styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS is build with that package. See the [Build package](#) page for more info.

Changed in version 28Mar2023.

Prior to this version, the *gauss* pair style did not apply *special\_bonds* factors.

## 4.117 pair\_style gayberne command

Accelerator Variants: *gayberne/gpu*, *gayberne/intel*, *gayberne/omp*

### 4.117.1 Syntax

```
pair_style gayberne gamma epsilon mu cutoff
```

- gamma = shift for potential minimum (typically 1)
- epsilon = exponent for eta orientation-dependent energy function
- mu = exponent for chi orientation-dependent energy function
- cutoff = global cutoff for interactions (distance units)

### 4.117.2 Examples

```
pair_style gayberne 1.0 1.0 1.0 10.0
pair_coeff * * 1.0 1.7 1.7 3.4 3.4 1.0 1.0 1.0
```

### 4.117.3 Description

The *gayberne* styles compute a Gay-Berne anisotropic LJ interaction ([Berardi](#)) between pairs of ellipsoidal particles or an ellipsoidal and spherical particle via the formulas

$$U(\mathbf{A}_1, \mathbf{A}_2, \mathbf{r}_{12}) = U_r(\mathbf{A}_1, \mathbf{A}_2, \mathbf{r}_{12}, \gamma) \cdot \eta_{12}(\mathbf{A}_1, \mathbf{A}_2, v) \cdot \chi_{12}(\mathbf{A}_1, \mathbf{A}_2, \mathbf{r}_{12}, \mu)$$

$$U_r = 4\varepsilon(\rho^{12} - \rho^6)$$

$$\rho = \frac{\sigma}{h_{12} + \gamma\sigma}$$

where  $\mathbf{A}_1$  and  $\mathbf{A}_2$  are the transformation matrices from the simulation box frame to the body frame and  $r_{12}$  is the center to center vector between the particles.  $U_r$  controls the shifted distance dependent interaction based on the distance of closest approach of the two particles ( $h_{12}$ ) and the user-specified shift parameter  $\gamma$ . When both particles are spherical, the formula reduces to the usual Lennard-Jones interaction (see details below for when Gay-Berne treats a particle as “spherical”).

For large uniform molecules it has been shown that the energy parameters are approximately representable in terms of local contact curvatures ([Everaers](#)):

$$\varepsilon_a = \sigma \cdot \frac{a}{b \cdot c}; \varepsilon_b = \sigma \cdot \frac{b}{a \cdot c}; \varepsilon_c = \sigma \cdot \frac{c}{a \cdot b}$$

The variable names utilized as potential parameters are for the most part taken from ([Everaers](#)) in order to be consistent with the *RE-squared pair potential*. Details on the epsilon and mu parameters are given [here](#).

More details of the Gay-Berne formulation are given in the references listed below and in [this supplementary document](#).

Use of this pair style requires the NVE, NVT, or NPT fixes with the *asphere* extension (e.g. *fix nve/asphere*) in order to integrate particle rotation. Additionally, *atom\_style ellipsoid* should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\varepsilon$  = well depth (energy units)
- $\sigma$  = minimum effective particle radii (distance units)
- $\varepsilon_{i,a}$  = relative well depth of type I for side-to-side interactions
- $\varepsilon_{i,b}$  = relative well depth of type I for face-to-face interactions
- $\varepsilon_{i,c}$  = relative well depth of type I for end-to-end interactions
- $\varepsilon_{j,a}$  = relative well depth of type J for side-to-side interactions
- $\varepsilon_{j,b}$  = relative well depth of type J for face-to-face interactions
- $\varepsilon_{j,c}$  = relative well depth of type J for end-to-end interactions
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the *pair\_style* command is used.

It is typical with the Gay-Berne potential to define  $\sigma$  as the minimum of the 3 shape diameters of the particles involved in an I,I interaction, though this is not required. Note that this is a different meaning for  $\sigma$  than the *pair\_style resquared* potential uses.

The  $\varepsilon_i$  and  $\varepsilon_j$  coefficients are actually defined for atom types, not for pairs of atom types. Thus, in a series of *pair\_coeff* commands, they only need to be specified once for each atom type.

Specifically, if any of  $\varepsilon_{i,a}$ ,  $\varepsilon_{i,b}$ ,  $\varepsilon_{i,c}$  are non-zero, the three values are assigned to atom type I. If all the  $\varepsilon_i$  values are zero, they are ignored. If any of  $\varepsilon_{j,a}$ ,  $\varepsilon_{j,b}$ ,  $\varepsilon_{j,c}$  are non-zero, the three values are assigned to atom type J. If all three

epsilon\_j values are zero, they are ignored. Thus the typical way to define the  $\epsilon_i$  and  $\epsilon_j$  coefficients is to list their values in “pair\_coeff I J” commands when  $I = J$ , but set them to 0.0 when  $I \neq J$ . If you do list them when  $I \neq J$ , you should ensure they are consistent with their values in other pair\_coeff commands, since only the last setting will be in effect.

Note that if this potential is being used as a sub-style of *pair\_style hybrid*, and there is no “pair\_coeff I I” setting made for Gay-Berne for a particular type I (because I-I interactions are computed by another hybrid pair potential), then you still need to ensure the  $\epsilon_{a,b,c}$  coefficients are assigned to that type. e.g. in a “pair\_coeff I J” command.

---

**Note:** If the  $\epsilon_a = \epsilon_b = \epsilon_c$  for an atom type, and if the shape of the particle itself is spherical, meaning its 3 shape parameters are all the same, then the particle is treated as an LJ sphere by the Gay-Berne potential. This is significant because if two LJ spheres interact, then the simple Lennard-Jones formula is used to compute their interaction energy/force using the specified epsilon and sigma as the standard LJ parameters. This is much cheaper to compute than the full Gay-Berne formula. To treat the particle as a LJ sphere with sigma = D, you should normally set  $\epsilon_a = \epsilon_b = \epsilon_c = 1.0$ , set the pair\_coeff  $\sigma = D$ , and also set the 3 shape parameters for the particle to D. The one exception is that if the 3 shape parameters are set to 0.0, which is a valid way in LAMMPS to specify a point particle, then the Gay-Berne potential will treat that as shape parameters of 1.0 (i.e. a LJ particle with  $\sigma = 1$ ), since it requires finite-size particles. In this case you should still set the pair\_coeff  $\sigma$  to 1.0 as well.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.117.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.117.5 Restrictions

The *gayberne* style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These pair styles require that atoms store torque and a quaternion to represent their orientation, as defined by the *atom\_style*. It also require they store a per-type *shape*. The particles cannot store a per-particle diameter.

This pair style requires that atoms be ellipsoids as defined by the *atom\_style ellipsoid* command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The Gay-Berne potential does not become isotropic as  $r$  increases (*Everaers*). The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

### 4.117.6 Related commands

## 4.118 pair\_style gran/hooke command

Accelerator Variants: *gran/hooke/omp*

## 4.119 pair\_style gran/hooke/history command

Accelerator Variants: *gran/hooke/history/omp*, *gran/hooke/history/kk*

## 4.120 pair\_style gran/hertz/history command

Accelerator Variants: *gran/hertz/history/omp*

### 4.120.1 Syntax

```
pair_style style Kn Kt gamma_n gamma_t xmu dampflag keyword
```

- style = *gran/hooke* or *gran/hooke/history* or *gran/hertz/history*
- Kn = elastic constant for normal particle repulsion (force/distance units or pressure units - see discussion below)
- Kt = elastic constant for tangential contact (force/distance units or pressure units - see discussion below)
- gamma\_n = damping coefficient for collisions in normal direction (1/time units or 1/time-distance units - see discussion below)
- gamma\_t = damping coefficient for collisions in tangential direction (1/time units or 1/time-distance units - see discussion below)
- xmu = static yield criterion (unitless value between 0.0 and 1.0e4)
- dampflag = 0 or 1 if tangential damping force is excluded or included
- keyword = *limit\_damping*  
    *limit\_damping* value = none  
    limit damping to prevent attractive interaction

---

**Note:** Versions of LAMMPS before 9Jan09 had different style names for granular force fields. This is to emphasize the fact that the Hertzian equation has changed to model polydispersity more accurately. A side effect of the change is that the Kn, Kt, gamma\_n, and gamma\_t coefficients in the pair\_style command must be specified with different values in order to reproduce calculations made with earlier versions of LAMMPS, even for monodisperse systems. See the NOTE below for details.

---

### 4.120.2 Examples

```

### 4.120.3 Description

The *gran* styles use the following formulas for the frictional force between two granular particles, as described in ([Brilliantov](#)), ([Silbert](#)), and ([Zhang](#)), when the distance *r* between two particles of radii *Ri* and *Rj* is less than their contact distance *d* = *Ri* + *Rj*. There is no force between the particles when *r* > *d*.

The two Hookean styles use this formula:

$$F_{hk} = (k_n \delta \mathbf{n}_{ij} - m_{eff} \gamma_n \mathbf{v}_n) - (k_t \Delta \mathbf{s}_t + m_{eff} \gamma_t \mathbf{v}_t)$$

The Hertzian style uses this formula:

$$F_{hz} = \sqrt{\delta} \sqrt{\frac{R_i R_j}{R_i + R_j}} F_{hk} = \sqrt{\delta} \sqrt{\frac{R_i R_j}{R_i + R_j}} \left[ (k_n \delta \mathbf{n}_{ij} - m_{eff} \gamma_n \mathbf{v}_n) - (k_t \Delta \mathbf{s}_t + m_{eff} \gamma_t \mathbf{v}_t) \right]$$

In both equations the first parenthesized term is the normal force between the two particles and the second parenthesized term is the tangential force. The normal force has 2 terms, a contact force and a damping force. The tangential force also has 2 terms: a shear force and a damping force. The shear force is a “history” effect that accounts for the tangential displacement between the particles for the duration of the time they are in contact. This term is included in pair styles *hooke/history* and *hertz/history*, but is not included in pair style *hooke*. The tangential damping force term is included in all three pair styles if *dampflag* is set to 1; it is not included if *dampflag* is set to 0.

The other quantities in the equations are as follows:

- $\delta = d - r$  = overlap distance of 2 particles
- $K_n$  = elastic constant for normal contact
- $K_t$  = elastic constant for tangential contact
- $\gamma_n$  = viscoelastic damping constant for normal contact
- $\gamma_t$  = viscoelastic damping constant for tangential contact
- $m_{eff} = M_i M_j / (M_i + M_j)$  = effective mass of 2 particles of mass  $M_i$  and  $M_j$
- $\Delta \mathbf{s}_t$  = tangential displacement vector between 2 particles which is truncated to satisfy a frictional yield criterion
- $\mathbf{n}_{ij}$  = unit vector along the line connecting the centers of the 2 particles
- $\mathbf{V}_n$  = normal component of the relative velocity of the 2 particles
- $\mathbf{V}_t$  = tangential component of the relative velocity of the 2 particles

The  $K_n$ ,  $K_t$ ,  $\gamma_n$ , and  $\gamma_t$  coefficients are specified as parameters to the pair\_style command. If a NULL is used for  $K_t$ , then a default value is used where  $K_t = 2/7 K_n$ . If a NULL is used for  $\gamma_t$ , then a default value is used where  $\gamma_t = 1/2 \gamma_n$ .

The interpretation and units for these 4 coefficients are different in the Hookean versus Hertzian equations.

The Hookean model is one where the normal push-back force for two overlapping particles is a linear function of the overlap distance. Thus the specified  $K_n$  is in units of (force/distance). Note that this push-back force is independent of absolute particle size (in the monodisperse case) and of the relative sizes of the two particles (in the polydisperse case). This model also applies to the other terms in the force equation so that the specified  $\gamma_n$  is in units of (1/time),  $K_t$  is in units of (force/distance), and  $\gamma_t$  is in units of (1/time).

The Hertzian model is one where the normal push-back force for two overlapping particles is proportional to the area of overlap of the two particles, and is thus a non-linear function of overlap distance. Thus  $K_n$  has units of force per area and is thus specified in units of (pressure). The effects of absolute particle size (monodispersity) and relative size (polydispersity) are captured in the radii-dependent prefactors. When these prefactors are carried through to the other terms in the force equation it means that the specified  $\gamma_n$  is in units of (1/(time\*distance)),  $K_t$  is in units of (pressure), and  $\gamma_t$  is in units of (1/(time\*distance)).

Note that in the Hookean case,  $K_n$  can be thought of as a linear spring constant with units of force/distance. In the Hertzian case,  $K_n$  is like a non-linear spring constant with units of force/area or pressure, and as shown in the (Zhang) paper,  $K_n = 4G/(3(1 - \nu))$  where  $\nu$  = the Poisson ratio,  $G$  = shear modulus =  $E/(2(1 + \nu))$ , and  $E$  = Young’s modulus. Similarly,  $K_t = 4G/(2 - \nu)$ . (NOTE: in an earlier version of the manual, we incorrectly stated that  $K_t = 8G/(2 - \nu)$ .)

Thus in the Hertzian case  $K_n$  and  $K_t$  can be set to values that corresponds to properties of the material being modeled. This is also true in the Hookean case, except that a spring constant must be chosen that is appropriate for the absolute size of particles in the model. Since relative particle sizes are not accounted for, the Hookean styles may not be a suitable model for polydisperse systems.

**Note:** In versions of LAMMPS before 9Jan09, the equation for Hertzian interactions did not include the  $\sqrt{r_i r_j / (r_i + r_j)}$  term and thus was not as accurate for polydisperse systems. For monodisperse systems,  $\sqrt{r_i r_j / (r_i + r_j)}$  is a constant factor that effectively scales all 4 coefficients:  $K_n, K_t, \gamma_n, \gamma_t$ . Thus you can set the values of these 4 coefficients appropriately in the current code to reproduce the results of a previous Hertzian monodisperse calculation. For example, for the common case of a monodisperse system with particles of diameter 1, all 4 of these coefficients should now be set 2x larger than they were previously.

---

Xmu is also specified in the `pair_style` command and is the upper limit of the tangential force through the Coulomb criterion  $F_t = xmu * F_n$ , where  $F_t$  and  $F_n$  are the total tangential and normal force components in the formulas above. Thus in the Hookean case, the tangential force between 2 particles grows according to a tangential spring and dash-pot model until  $F_t/F_n = xmu$  and is then held at  $F_t = F_n * xmu$  until the particles lose contact. In the Hertzian case, a similar analogy holds, though the spring is no longer linear.

---

**Note:** Normally, `xmu` should be specified as a fractional value between 0.0 and 1.0, however LAMMPS allows large values (up to 1.0e4) to allow for modeling of systems which can sustain very large tangential forces.

---

The effective mass  $m_{eff}$  is given by the formula above for two isolated particles. If either particle is part of a rigid body, its mass is replaced by the mass of the rigid body in the formula above. This is determined by searching for a `fix rigid` command (or its variants).

For granular styles there are no additional coefficients to set for each pair of atom types via the `pair_coeff` command. All settings are global and are made via the `pair_style` command. However you must still use the `pair_coeff` for all pairs of granular atom types. For example the command

```
pair_coeff * *
```

should be used if all atoms in the simulation interact via a granular potential (i.e. one of the pair styles above is used). If a granular potential is used as a sub-style of `pair_style hybrid`, then specific atom types can be used in the `pair_coeff` command to determine which atoms interact via a granular potential.

If two particles are moving away from each other while in contact, there is a possibility that the particles could experience an effective attractive force due to damping. If the `limit_damping` keyword is used, this option will zero out the normal component of the force if there is an effective attractive force.

---

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.120.4 Mixing, shift, table, tail correction, restart, rRESPA info

The *pair\_modify* mix, shift, table, and tail options are not relevant for granular pair styles.

These pair styles write their information to *binary restart files*, so a *pair\_style* command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

The *single()* function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the *single()* function also calculates 10 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the relative velocity in the normal direction (along the line joining the 2 sphere centers). The last 3 (8-10) the components of the relative velocity in the tangential direction.

These extra quantities can be accessed by the *compute pair/local* command, as *p1*, *p2*, ..., *p10*.

---

#### 4.120.5 Restrictions

All the granular pair styles are part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These pair styles require that atoms store torque and angular velocity (*omega*) as defined by the *atom\_style*. They also require a per-particle radius is stored. The *sphere* atom style does all of this.

This pair style requires you to use the *comm\_modify vel yes* command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the *read\_restart* command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the *read\_restart* command for more details.

Accumulated values for individual contacts are saved to to restart files but are not saved to data files. Therefore, forces may differ significantly when a system is reloaded using A *read\_data* command.

### 4.121.3 Description

The *granular* styles support a variety of options for the normal, tangential, rolling and twisting forces resulting from contact between two granular particles. This expands on the options offered by the *pair gran/\** pair styles. The total computed forces and torques are the sum of various models selected for the normal, tangential, rolling and twisting modes of motion.

All model choices and parameters are entered in the *pair\_coeff* command, as described below. Unlike e.g. *pair gran/hooke*, coefficient values are not global, but can be set to different values for different combinations of particle types, as determined by the *pair\_coeff* command. If the contact model choice is the same for two particle types, the mixing for the cross-coefficients can be carried out automatically. This is shown in the last example, where model

choices are the same for type 1 - type 1 as for type 2 - type2 interactions, but coefficients are different. In this case, the mixed coefficients for type 1 - type 2 interactions can be determined from mixing rules discussed below. For additional flexibility, coefficients as well as model forms can vary between particle types, as shown in the fourth example: type 1 - type 1 interactions are based on a Johnson-Kendall-Roberts normal contact model and 2-2 interactions are based on a DMT cohesive model (see below). In that example, 1-1 and 2-2 interactions have different model forms, in which case mixing of coefficients cannot be determined, so 1-2 interactions must be explicitly defined via the *pair\_coeff 1 \** command, otherwise an error would result.

The first required keyword for the *pair\_coeff* command is the normal contact model. Currently supported options for normal contact models and their required arguments are:

1. *hooke* :  $k_n$ ,  $\eta_{n0}$  (or  $e$ )
2. *hertz* :  $k_n$ ,  $\eta_{n0}$  (or  $e$ )
3. *hertz/material* :  $E$ ,  $\eta_{n0}$  (or  $e$ ),  $\nu$
4. *dmf* :  $E$ ,  $\eta_{n0}$  (or  $e$ ),  $\nu$ ,  $\gamma$
5. *jkr* :  $E$ ,  $\eta_{n0}$  (or  $e$ ),  $\nu$ ,  $\gamma$

Here,  $k_n$  is spring stiffness (with units that depend on model choice, see below);  $\eta_{n0}$  is a damping prefactor (or, in its place a coefficient of restitution  $e$ , depending on the choice of damping mode, see below);  $E$  is Young's modulus in units of *force/length*<sup>2</sup>, i.e. *pressure*;  $\nu$  is Poisson's ratio and  $\gamma$  is a surface energy density, in units of *energy/length*<sup>2</sup>.

For the *hooke* model, the normal, elastic component of force acting on particle  $i$  due to contact with particle  $j$  is given by:

$$\mathbf{F}_{ne,Hooke} = k_n \delta_{ij} \mathbf{n}$$

Where  $\delta_{ij} = R_i + R_j - \|\mathbf{r}_{ij}\|$  is the particle overlap,  $R_i, R_j$  are the particle radii,  $\mathbf{r}_{ij} = \mathbf{r}_i - \mathbf{r}_j$  is the vector separating the two particle centers (note the i-j ordering so that  $\mathbf{F}_{ne}$  is positive for repulsion), and  $\mathbf{n} = \frac{\mathbf{r}_{ij}}{\|\mathbf{r}_{ij}\|}$ . Therefore, for *hooke*, the units of the spring constant  $k_n$  are *force/distance*, or equivalently *mass/time*<sup>2</sup>.

For the *hertz* model, the normal component of force is given by:

$$\mathbf{F}_{ne,Hertz} = k_n R_{eff}^{1/2} \delta_{ij}^{3/2} \mathbf{n}$$

Here,  $R_{eff} = R = \frac{R_i R_j}{R_i + R_j}$  is the effective radius, denoted for simplicity as  $R$  from here on. For *hertz*, the units of the spring constant  $k_n$  are *force/length*<sup>2</sup>, or equivalently *pressure*.

For the *hertz/material* model, the force is given by:

$$\mathbf{F}_{ne,Hertz/material} = \frac{4}{3} E_{eff} R^{1/2} \delta_{ij}^{3/2} \mathbf{n}$$

Here,  $E_{eff} = E = \left( \frac{1-\nu_i^2}{E_i} + \frac{1-\nu_j^2}{E_j} \right)^{-1}$  is the effective Young's modulus, with  $\nu_i, \nu_j$  the Poisson ratios of the particles of types  $i$  and  $j$ .  $E_{eff}$  is denoted as  $E$  from here on. Note that if the elastic modulus and the shear modulus of the two particles are the same, the *hertz/material* model is equivalent to the *hertz* model with  $k_n = 4/3E$ .

The *dmf* model corresponds to the (*Derjaguin-Muller-Toporov*) cohesive model, where the force is simply Hertz with an additional attractive cohesion term:

$$\mathbf{F}_{ne,dmf} = \left( \frac{4}{3} E R^{1/2} \delta_{ij}^{3/2} - 4\pi\gamma R \right) \mathbf{n}$$

The *jkr* model is the (*Johnson-Kendall-Roberts*) model, where the force is computed as:

$$\mathbf{F}_{ne,jkr} = \left( \frac{4Ea^3}{3R} - 2\pi a^2 \sqrt{\frac{4\gamma E}{\pi a}} \right) \mathbf{n}$$

Here,  $a$  is the radius of the contact zone, related to the overlap  $\delta$  according to:

$$\delta = a^2/R - 2\sqrt{\pi\gamma a/E}$$

LAMMPS internally inverts the equation above to solve for  $a$  in terms of  $\delta$ , then solves for the force in the previous equation. Additionally, note that the JKR model allows for a tensile force beyond contact (i.e. for  $\delta < 0$ ), up to a maximum of  $3\pi\gamma R$  (also known as the ‘pull-off’ force). Note that this is a hysteretic effect, where particles that are not contacting initially will not experience force until they come into contact  $\delta \geq 0$ ; as they move apart and ( $\delta < 0$ ), they experience a tensile force up to  $3\pi\gamma R$ , at which point they lose contact.

---

In addition, the normal force is augmented by a damping term of the following general form:

$$\mathbf{F}_{n,damp} = -\eta_n \mathbf{v}_{n,rel}$$

Here,  $\mathbf{v}_{n,rel} = (\mathbf{v}_j - \mathbf{v}_i) \cdot \mathbf{n} \mathbf{n}$  is the component of relative velocity along  $\mathbf{n}$ .

The optional *damping* keyword to the *pair\_coeff* command followed by a keyword determines the model form of the damping factor  $\eta_n$ , and the interpretation of the  $\eta_{n0}$  or  $e$  coefficients specified as part of the normal contact model settings. The *damping* keyword and corresponding model form selection may be appended anywhere in the *pair\_coeff* command. Note that the choice of damping model affects both the normal and tangential damping (and depending on other settings, potentially also the twisting damping). The options for the damping model currently supported are:

1. *velocity*
2. *mass\_velocity*
3. *viscoelastic*
4. *tsuji*
5. *coeff\_restitution*

If the *damping* keyword is not specified, the *viscoelastic* model is used by default.

For *damping velocity*, the normal damping is simply equal to the user-specified damping coefficient in the *normal* model:

$$\eta_n = \eta_{n0}$$

Here,  $\eta_{n0}$  is the damping coefficient specified for the normal contact model, in units of *mass/time*.

For *damping mass\_velocity*, the normal damping is given by:

$$\eta_n = \eta_{n0} m_{eff}$$

Here,  $\eta_{n0}$  is the damping coefficient specified for the normal contact model, in units of *1/time* and  $m_{eff} = m_i m_j / (m_i + m_j)$  is the effective mass. Use *damping mass\_velocity* to reproduce the damping behavior of *pair gran/hooke/\**.

The *damping viscoelastic* model is based on the viscoelastic treatment of ([Brilliantov et al](#)), where the normal damping is given by:

$$\eta_n = \eta_{n0} a m_{eff}$$

Here,  $a$  is the contact radius, given by  $a = \sqrt{R\delta}$  for all models except *jdkr*, for which it is given implicitly according to  $\delta = a^2/R - 2\sqrt{\pi\gamma a/E}$ . For *damping viscoelastic*,  $\eta_{n0}$  is in units of *1/(time\*distance)*.

The *tsuji* model is based on the work of ([Tsuji et al](#)). Here, the damping coefficient specified as part of the normal model is interpreted as a restitution coefficient  $e$ . The damping constant  $\eta_n$  is given by:

$$\eta_n = \alpha(m_{eff} k_n)^{1/2}$$

For normal contact models based on material parameters,  $k_n = 4/3Ea$ . This damping model is not compatible with cohesive normal models such as *JKR* or *DMT*. The parameter  $\alpha$  is related to the restitution coefficient  $e$  according to:

$$\alpha = 1.2728 - 4.2783e + 11.087e^2 - 22.348e^3 + 27.467e^4 - 18.022e^5 + 4.8218e^6$$

The dimensionless coefficient of restitution  $e$  specified as part of the normal contact model parameters should be between 0 and 1, but no error check is performed on this.

The *coeff\_restitution* model is useful when a specific normal coefficient of restitution  $e$  is required. In these models, the normal coefficient of restitution  $e$  is specified as an input. Following the approach of (*Brilliantov et al*), when using the *hooke* normal model, *coeff\_restitution* calculates the damping coefficient as:

$$\eta_n = \sqrt{\frac{4m_{eff}k_n}{1 + \left(\frac{\pi}{\log(e)}\right)^2}},$$

For any other normal model, e.g. the *hertz* and *hertz/material* models, the damping coefficient is:

$$\eta_n = -2\sqrt{\frac{5}{6}} \frac{\log(e)}{\sqrt{\pi^2 + (\log(e))^2}} (R_{eff}\delta_{ij})^{\frac{1}{4}} \sqrt{\frac{3}{2}k_n m_{eff}},$$

where  $k_n = \frac{4}{3}E_{eff}$  for the *hertz/material* model. Since *coeff\_restitution* accounts for the effective mass, effective radius, and pairwise overlaps (except when used with the *hooke* normal model) when calculating the damping coefficient, it accurately reproduces the specified coefficient of restitution for both monodisperse and polydisperse particle pairs. This damping model is not compatible with cohesive normal models such as *JKR* or *DMT*.

The total normal force is computed as the sum of the elastic and damping components:

$$\mathbf{F}_n = \mathbf{F}_{ne} + \mathbf{F}_{n,damp}$$

The *pair\_coeff* command also requires specification of the tangential contact model. The required keyword *tangential* is expected, followed by the model choice and associated parameters. Currently supported tangential model choices and their expected parameters are as follows:

1. *linear\_nohistory* :  $x_{\gamma,t}$ ,  $\mu_s$
2. *linear\_history* :  $k_t$ ,  $x_{\gamma,t}$ ,  $\mu_s$
3. *mindlin* :  $k_t$  or NULL,  $x_{\gamma,t}$ ,  $\mu_s$
4. *mindlin/force* :  $k_t$  or NULL,  $x_{\gamma,t}$ ,  $\mu_s$
5. *mindlin\_rescale* :  $k_t$  or NULL,  $x_{\gamma,t}$ ,  $\mu_s$
6. *mindlin\_rescale/force* :  $k_t$  or NULL,  $x_{\gamma,t}$ ,  $\mu_s$

Here,  $x_{\gamma,t}$  is a dimensionless multiplier for the normal damping  $\eta_n$  that determines the magnitude of the tangential damping,  $\mu_t$  is the tangential (or sliding) friction coefficient, and  $k_t$  is the tangential stiffness coefficient.

For *tangential linear\_nohistory*, a simple velocity-dependent Coulomb friction criterion is used, which mimics the behavior of the *pair gran/hooke* style. The tangential force  $\mathbf{F}_t$  is given by:

$$\mathbf{F}_t = -\min(\mu_t F_{n0}, \|\mathbf{F}_{t,damp}\|)\mathbf{t}$$

The tangential damping force  $\mathbf{F}_{t,damp}$  is given by:

$$\mathbf{F}_{t,damp} = -\eta_t \mathbf{v}_{t,rel}$$

The tangential damping prefactor  $\eta_t$  is calculated by scaling the normal damping  $\eta_n$  (see above):

$$\eta_t = -x_{\gamma,t} \eta_n$$

The normal damping prefactor  $\eta_n$  is determined by the choice of the *damping* keyword, as discussed above. Thus, the *damping* keyword also affects the tangential damping. The parameter  $x_{\gamma,t}$  is a scaling coefficient. Several works in the literature use  $x_{\gamma,t} = 1$  (*Marshall, Tsuji et al, Silbert et al*). The relative tangential velocity at the point of contact is given by  $\mathbf{v}_{t,rel} = \mathbf{v}_t - (R_i \Omega_i + R_j \Omega_j) \times \mathbf{n}$ , where  $\mathbf{v}_t = \mathbf{v}_r - \mathbf{v}_r \cdot \mathbf{n} \mathbf{n}$ ,  $\mathbf{v}_r = \mathbf{v}_j - \mathbf{v}_i$ . The direction of the applied force is  $\mathbf{t} = \mathbf{v}_{t,rel} / \|\mathbf{v}_{t,rel}\|$ .

The normal force value  $F_{n0}$  used to compute the critical force depends on the form of the contact model. For non-cohesive models (*hertz, hertz/material, hooke*), it is given by the magnitude of the normal force:

$$F_{n0} = \|\mathbf{F}_n\|$$

For cohesive models such as *jkr* and *dmt*, the critical force is adjusted so that the critical tangential force approaches  $\mu_t F_{pulloff}$ , see *Marshall*, equation 43, and *Thornton*. For both models,  $F_{n0}$  takes the form:

$$F_{n0} = \|\mathbf{F}_{ne} + 2F_{pulloff}\|$$

Where  $F_{pulloff} = 3\pi\gamma R$  for *jkr*, and  $F_{pulloff} = 4\pi\gamma R$  for *dmt*.

The remaining tangential options all use accumulated tangential displacement (i.e. contact history), except for the options *mindlin/force* and *mindlin\_rescale/force*, that use accumulated tangential force instead, and are discussed further below. The accumulated tangential displacement is discussed in details below in the context of the *linear\_history* option. The same treatment of the accumulated displacement applies to the other options as well.

For *tangential linear\_history*, the tangential force is given by:

$$\mathbf{F}_t = -\min(\mu_t F_{n0}, \|\mathbf{F}_t\|) \mathbf{t}$$

Here,  $\xi$  is the tangential displacement accumulated during the entire duration of the contact:

$$\xi = \int_{t_0}^t \mathbf{v}_{t,rel}(\tau) d\tau$$

This accumulated tangential displacement must be adjusted to account for changes in the frame of reference of the contacting pair of particles during contact. This occurs due to the overall motion of the contacting particles in a rigid-body-like fashion during the duration of the contact. There are two modes of motion that are relevant: the ‘tumbling’ rotation of the contacting pair, which changes the orientation of the plane in which tangential displacement occurs; and ‘spinning’ rotation of the contacting pair about the vector connecting their centers of mass ( $\mathbf{n}$ ). Corrections due to the former mode of motion are made by rotating the accumulated displacement into the plane that is tangential to the contact vector at each step, or equivalently removing any component of the tangential displacement that lies along  $\mathbf{n}$ , and rescaling to preserve the magnitude. This follows the discussion in *Luding*, see equation 17 and relevant discussion in that work:

$$\xi = (\xi' - (\mathbf{n} \cdot \xi') \mathbf{n}) \frac{\|\xi'\|}{\|\xi' - (\mathbf{n} \cdot \xi') \mathbf{n}\|}$$

Here,  $\xi'$  is the accumulated displacement prior to the current time step and  $\xi$  is the corrected displacement. Corrections to the displacement due to the second mode of motion described above (rotations about  $\mathbf{n}$ ) are not currently implemented, but are expected to be minor for most simulations.

Furthermore, when the tangential force exceeds the critical force, the tangential displacement is re-scaled to match the value for the critical force (see *Luding*, equation 20 and related discussion):

$$\xi = -\frac{1}{k_t} (\mu_t F_{n0} \mathbf{t} - \mathbf{F}_{t,damp})$$

The tangential force is added to the total normal force (elastic plus damping) to produce the total force on the particle. The tangential force also acts at the contact point (defined as the center of the overlap region) to induce a torque on each particle according to:

$$\boldsymbol{\tau}_i = -(R_i - 0.5\delta)\mathbf{n} \times \mathbf{F}_t$$

$$\boldsymbol{\tau}_j = -(R_j - 0.5\delta)\mathbf{n} \times \mathbf{F}_t$$

For *tangential mindlin*, the *Mindlin* no-slip solution is used which differs from the *linear\_history* option by an additional factor of  $a$ , the radius of the contact region. The tangential force is given by:

$$\mathbf{F}_t = -\min(\mu_t F_{n0}, \|\mathbf{F}_t - k_t a \boldsymbol{\xi} + \mathbf{F}_{t,damp}\|)\mathbf{t}$$

Here,  $a$  is the radius of the contact region, given by  $a = \sqrt{R\delta}$  for all normal contact models, except for *jkr*, where it is given implicitly by  $\delta = a^2/R - 2\sqrt{\pi\gamma a/E}$ , see discussion above. To match the Mindlin solution, one should set  $k_t = 8G_{eff}$ , where  $G_{eff}$  is the effective shear modulus given by:

$$G_{eff} = \left( \frac{2 - \nu_i}{G_i} + \frac{2 - \nu_j}{G_j} \right)^{-1}$$

where  $G_i$  is the shear modulus of a particle of type  $i$ , related to Young's modulus  $E_i$  and Poisson's ratio  $\nu_i$  by  $G_i = E_i/(2(1 + \nu_i))$ . This can also be achieved by specifying *NULL* for  $k_t$ , in which case a normal contact model that specifies material parameters  $E_i$  and  $\nu_i$  is required (e.g. *hertz/material*, *dmt* or *jkr*). In this case, mixing of the shear modulus for different particle types  $i$  and  $j$  is done according to the formula above.

---

**Note:** The radius of the contact region  $a$  depends on the normal overlap. As a result, the tangential force for *mindlin* can change due to a variation in normal overlap, even with no change in tangential displacement.

---

For *tangential mindlin/force*, the accumulated elastic tangential force characterizes the contact history, instead of the accumulated tangential displacement. This prevents the dependence of the tangential force on the normal overlap as noted above. The tangential force is given by:

$$\mathbf{F}_t = -\min(\mu_t F_{n0}, \|\mathbf{F}_{te} + \mathbf{F}_{t,damp}\|)\mathbf{t}$$

The increment of the elastic component of the tangential force  $\mathbf{F}_{te}$  is given by:

$$d\mathbf{F}_{te} = -k_t a \mathbf{v}_{t,rel} d\tau$$

The changes in frame of reference of the contacting pair of particles during contact are accounted for by the same formula as above, replacing the accumulated tangential displacement  $\boldsymbol{\xi}$ , by the accumulated tangential elastic force  $\mathbf{F}_{te}$ . When the tangential force exceeds the critical force, the tangential force is directly re-scaled to match the value for the critical force:

$$\mathbf{F}_{te} = -\mu_t F_{n0} \mathbf{t} + \mathbf{F}_{t,damp}$$

The same rules as those described for *mindlin* apply regarding the tangential stiffness and mixing of the shear modulus for different particle types.

The *mindlin\_rescale* option uses the same form as *mindlin*, but the magnitude of the tangential displacement is re-scaled as the contact unloads, i.e. if  $a < a_{t_{n-1}}$ :

$$\boldsymbol{\xi} = \boldsymbol{\xi}_{t_{n-1}} \frac{a}{a_{t_{n-1}}}$$

Here,  $t_{n-1}$  indicates the value at the previous time step. This rescaling accounts for the fact that a decrease in the contact area upon unloading leads to the contact being unable to support the previous tangential loading, and spurious energy is created without the rescaling above (*Walton*).

---

**Note:** For *mindlin*, a decrease in the tangential force already occurs as the contact unloads, due to the dependence of the tangential force on the normal force described above. By re-scaling  $\xi$ , *mindlin\_rescale* effectively re-scales the tangential force twice, i.e., proportionally to  $a^2$ . This peculiar behavior results from use of the accumulated tangential displacement to characterize the contact history. Although *mindlin\_rescale* remains available for historic reasons and backward compatibility purposes, it should be avoided in favor of *mindlin\_rescale/force*.

---

The *mindlin\_rescale/force* option uses the same form as *mindlin/force*, but the magnitude of the tangential elastic force is re-scaled as the contact unloads, i.e. if  $a < a_{t_{n-1}}$ :

$$\mathbf{F}_{te} = \mathbf{F}_{te,t_{n-1}} \frac{a}{a_{t_{n-1}}}$$

This approach provides a better approximation of the *Mindlin-Deresiewicz* laws and is more consistent than *mindlin\_rescale*. See discussions in *Thornton et al, 2013*, particularly equation 18(b) of that work and associated discussion, and *Agnolin and Roux, 2007*, particularly Appendix A.

---

The optional *rolling* keyword enables rolling friction, which resists pure rolling motion of particles. The options currently supported are:

1. *none*
2. *sds* :  $k_{roll}$ ,  $\gamma_{roll}$ ,  $\mu_{roll}$

If the *rolling* keyword is not specified, the model defaults to *none*.

For *rolling sds*, rolling friction is computed via a spring-dashpot-slider, using a ‘pseudo-force’ formulation, as detailed by *Luding*. Unlike the formulation in *Marshall*, this allows for the required adjustment of rolling displacement due to changes in the frame of reference of the contacting pair. The rolling pseudo-force is computed analogously to the tangential force:

$$\mathbf{F}_{roll,0} = k_{roll}\xi_{roll} - \gamma_{roll}\mathbf{v}_{roll}$$

Here,  $\mathbf{v}_{roll} = -R(\Omega_i - \Omega_j) \times \mathbf{n}$  is the relative rolling velocity, as given in *Wang et al* and *Luding*. This differs from the expressions given by *Kuhn and Bagi* and used in *Marshall*; see *Wang et al* for details. The rolling displacement is given by:

$$\xi_{roll} = \int_{t_0}^t \mathbf{v}_{roll}(\tau) d\tau$$

A Coulomb friction criterion truncates the rolling pseudo-force if it exceeds a critical value:

$$\mathbf{F}_{roll} = \min(\mu_{roll}F_{n,0}, \|\mathbf{F}_{roll,0}\|)\mathbf{k}$$

Here,  $\mathbf{k} = \mathbf{v}_{roll}/\|\mathbf{v}_{roll}\|$  is the direction of the pseudo-force. As with tangential displacement, the rolling displacement is rescaled when the critical force is exceeded, so that the spring length corresponds the critical force. Additionally, the displacement is adjusted to account for rotations of the frame of reference of the two contacting particles in a manner analogous to the tangential displacement.

The rolling pseudo-force does not contribute to the total force on either particle (hence ‘pseudo’), but acts only to induce an equal and opposite torque on each particle, according to:

$$\begin{aligned}\boldsymbol{\tau}_{roll,i} &= R\mathbf{n} \times \mathbf{F}_{roll} \\ \boldsymbol{\tau}_{roll,j} &= -\boldsymbol{\tau}_{roll,i}\end{aligned}$$

---

The optional *twisting* keyword enables twisting friction, which resists rotation of two contacting particles about the vector  $\mathbf{n}$  that connects their centers. The options currently supported are:

1. *none*
2. *sds* :  $k_{twist}$ ,  $\gamma_{twist}$ ,  $\mu_{twist}$
3. *marshall*

If the *twisting* keyword is not specified, the model defaults to *none*.

For both *twisting sds* and *twisting marshall*, a history-dependent spring-dashpot-slider is used to compute the twisting torque. Because twisting displacement is a scalar, there is no need to adjust for changes in the frame of reference due to rotations of the particle pair. The formulation in *Marshall* therefore provides the most straightforward treatment:

$$\tau_{twist,0} = -k_{twist}\xi_{twist} - \gamma_{twist}\Omega_{twist}$$

Here  $\xi_{twist} = \int_{t_0}^t \Omega_{twist}(\tau) d\tau$  is the twisting angular displacement, and  $\Omega_{twist} = (\mathbf{r}_i - \mathbf{r}_j) \cdot \mathbf{n}$  is the relative twisting angular velocity. The torque is then truncated according to:

$$\tau_{twist} = \min(\mu_{twist} F_{n,0}, \tau_{twist,0})$$

Similar to the sliding and rolling displacement, the angular displacement is rescaled so that it corresponds to the critical value if the twisting torque exceeds this critical value:

$$\xi_{twist} = \frac{1}{k_{twist}}(\mu_{twist} F_{n,0} \text{sgn}(\Omega_{twist}) - \gamma_{twist}\Omega_{twist})$$

For *twisting sds*, the coefficients  $k_{twist}$ ,  $\gamma_{twist}$  and  $\mu_{twist}$  are simply the user input parameters that follow the *twisting sds* keywords in the *pair\_coeff* command.

For *twisting\_marshall*, the coefficients are expressed in terms of sliding friction coefficients, as discussed in *Marshall* (see equations 32 and 33 of that work):

$$k_{twist} = 0.5k_t a^2$$

$$\eta_{twist} = 0.5\eta_t a^2$$

$$\mu_{twist} = \frac{2}{3}a\mu_t$$

Finally, the twisting torque on each particle is given by:

$$\tau_{twist,i} = \tau_{twist} \mathbf{n}$$

$$\tau_{twist,j} = -\tau_{twist,i}$$

If two particles are moving away from each other while in contact, there is a possibility that the particles could experience an effective attractive force due to damping. If the optional *limit\_damping* keyword is used, this option will zero out the normal component of the force if there is an effective attractive force. This keyword cannot be used with the JKR or DMT models.

The optional *heat* keyword enables heat conduction. The options currently supported are:

1. *none*
2. *radius* :  $k_s$
3. *area* :  $h_s$

If the *heat* keyword is not specified, the model defaults to *none*.

For *heat radius*, the heat  $Q$  conducted between two particles is given by

$$Q = 2k_s a \Delta T$$

where  $\Delta T$  is the difference in the two particles' temperature,  $k_s$  is a non-negative numeric value for the conductivity (in units of power/(length\*temperature)), and  $a$  is the radius of the contact and depends on the normal force model. This is the model proposed by [Vargas and McCarthy](#).

For *heat area*, the heat  $Q$  conducted between two particles is given by

$$Q = h_s A \Delta T$$

where  $\Delta T$  is the difference in the two particles' temperature,  $h_s$  is a non-negative numeric value for the heat transfer coefficient (in units of power/(area\*temperature)), and  $A = \pi a^2$  is the area of the contact and depends on the normal force model.

Note that the option *none* must either be used in all or none of the *pair\_coeff* calls. See [fix heat/flow](#) and [fix property/atom](#) for more information on this option.

---

The *granular* pair style can reproduce the behavior of the *pair gran/\** styles with the appropriate settings (some very minor differences can be expected due to corrections in displacement history frame-of-reference, and the application of the torque at the center of the contact rather than at each particle). The first example above is equivalent to *pair gran/hooke 1000.0 NULL 50.0 50.0 0.4 1*. The second example is equivalent to *pair gran/hooke/history 1000.0 500.0 50.0 50.0 0.4 1*. The third example is equivalent to *pair gran/hertz/history 1000.0 500.0 50.0 50.0 0.4 1 limit\_damping*.

---

LAMMPS automatically sets pairwise cutoff values for *pair\_style granular* based on particle radii (and in the case of *jkr* pull-off distances). In the vast majority of situations, this is adequate. However, a cutoff value can optionally be appended to the *pair\_style granular* command to specify a global cutoff (i.e. a cutoff for all atom types). Additionally, the optional *cutoff* keyword can be passed to the *pair\_coeff* command, followed by a cutoff value. This will set a pairwise cutoff for the atom types in the *pair\_coeff* command. These options may be useful in some rare cases where the automatic cutoff determination is not sufficient, e.g. if particle diameters are being modified via the *fix adapt* command. In that case, the global cutoff specified as part of the *pair\_style granular* command is applied to all atom types, unless it is overridden for a given atom type combination by the *cutoff* value specified in the *pair coeff* command. If *cutoff* is only specified in the *pair coeff* command and no global cutoff is appended to the *pair\_style granular* command, then LAMMPS will use that cutoff for the specified atom type combination, and automatically set pairwise cutoffs for the remaining atom types.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.121.4 Mixing, shift, table, tail correction, restart, rRESPA info

The *pair\_modify* mix, shift, table, and tail options are not relevant for granular pair styles.

Mixing of coefficients is carried out using geometric averaging for most quantities, e.g. if friction coefficient for type 1-type 1 interactions is set to  $\mu_1$ , and friction coefficient for type 2-type 2 interactions is set to  $\mu_2$ , the friction coefficient for type1-type2 interactions is computed as  $\sqrt{\mu_1\mu_2}$  (unless explicitly specified to a different value by a *pair\_coeff* 1 2 ... command). The exception to this is elastic modulus, only applicable to *hertz/material*, *dmt* and *jkr* normal contact models. In that case, the effective elastic modulus is computed as:

$$E_{eff,ij} = \left( \frac{1 - \nu_i^2}{E_i} + \frac{1 - \nu_j^2}{E_j} \right)^{-1}$$

If the *i-j* coefficients  $E_{ij}$  and  $\nu_{ij}$  are explicitly specified, the effective modulus is computed as:

$$E_{eff,ij} = \left( \frac{1 - \nu_{ij}^2}{E_{ij}} + \frac{1 - \nu_{ij}^2}{E_{ij}} \right)^{-1}$$

or

$$E_{eff,ij} = \frac{E_{ij}}{2(1 - \nu_{ij}^2)}$$

These pair styles write their information to *binary restart files*, so a *pair\_style* command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

The *single()* function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the *single()* function also calculates 13 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the rolling torque acting on particle I. The next entry (8) is the magnitude of the rolling torque. The next entry (9) is the magnitude of the twisting torque acting about the vector connecting the two particle centers. The next 3 (10-12) are the components of the vector connecting the centers of the two particles ( $x_I - x_J$ ). The last quantity (13) is the heat flow between the two particles, set to 0 if no heat model is active.

These extra quantities can be accessed by the *compute pair/local* command, as *p1*, *p2*, ..., *p12*.

#### 4.121.5 Restrictions

This pair style is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires that atoms store per-particle radius, torque, and angular velocity (omega) as defined by the *atom\_style sphere*.

This pair style requires you to use the *comm\_modify vel yes* command so that velocities are stored by ghost atoms.

This pair style will not restart exactly when using the *read\_restart* command, though it should provide statistically similar results. This is because the forces it computes depend on atom velocities and the atom velocities have been propagated half a timestep between the force computation and when the restart is written, due to using Velocity Verlet time integration. See the *read\_restart* command for more details.

Accumulated values for individual contacts are saved to restart files but are not saved to data files. Therefore, forces may differ significantly when a system is reloaded using the *read\_data* command.

### 4.121.6 Related commands

```

### 4.123.3 Description

The *lj/gromacs* styles compute shifted LJ and Coulombic interactions with an additional switching function  $S(r)$  that ramps the energy and force smoothly to zero between an inner and outer cutoff. It is a commonly used potential in the

GROMACS MD code and for the coarse-grained models of ([Marrink](#)).

$$\begin{aligned}E_{LJ} &= 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] + S_{LJ}(r) & r < r_c \\E_C &= \frac{Cq_iq_j}{\epsilon r} + S_C(r) & r < r_c \\S(r) &= C & r < r_1 \\S(r) &= \frac{A}{3}(r - r_1)^3 + \frac{B}{4}(r - r_1)^4 + C & r_1 < r < r_c \\A &= (-3E'(r_c) + (r_c - r_1)E''(r_c))/(r_c - r_1)^2 \\B &= (2E'(r_c) - (r_c - r_1)E''(r_c))/(r_c - r_1)^3 \\C &= -E(r_c) + \frac{1}{2}(r_c - r_1)E'(r_c) - \frac{1}{12}(r_c - r_1)^2E''(r_c)\end{aligned}$$

$r_1$  is the inner cutoff;  $r_c$  is the outer cutoff. The coefficients A, B, and C are computed by LAMMPS to perform the shifting and smoothing. The function S(r) is actually applied once to each term of the LJ formula and once to the Coulombic formula, so there are 2 or 3 sets of A,B,C coefficients depending on which pair\_style is used. The boundary conditions applied to the smoothing function are as follows:  $S'(r_1) = S''(r_1) = 0$ ,  $S(r_c) = -E(r_c)$ ,  $S'(r_c) = -E'(r_c)$ , and  $S''(r_c) = -E''(r_c)$ , where E(r) is the corresponding term in the LJ or Coulombic potential energy function. Single and double primes denote first and second derivatives with respect to r, respectively.

The inner and outer cutoff for the LJ and Coulombic terms can be the same or different depending on whether 2 or 4 arguments are used in the pair\_style command. The inner LJ cutoff must be > 0, but the inner Coulombic cutoff can be >= 0.

The following coefficients must be defined for each pair of atoms types via the [pair\\_coeff](#) command as in the examples above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- inner (distance units)
- outer (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at  $2^{1/6}\sigma$ .

The last 2 coefficients are optional inner and outer cutoffs for style *lj/gromacs*. If not specified, the global *inner* and *outer* values are used.

The last 2 coefficients cannot be used with style *lj/gromacs/coul/gromacs* because this force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the pair\_style command.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.123.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

None of the GROMACS pair styles support the *pair\_modify* shift option, since the Lennard-Jones portion of the pair interaction is already smoothed to 0.0 at the cutoff.

The *pair\_modify* table option is not relevant for this pair style.

None of the GROMACS pair styles support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

All of the GROMACS pair styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

All of the GROMACS pair styles can only be used via the pair keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.123.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.124 pair\_style gw command

### 4.125 pair\_style gw/zbl command

#### 4.125.1 Syntax

```
pair_style style
```

- style = gw or gw/zbl

## 4.125.2 Examples

```
pair_style gw
pair_coeff * * SiC.gw Si C C

pair_style gw/zbl
pair_coeff * * SiC.gw.zbl C Si
```

## 4.125.3 Description

The *gw* style computes a 3-body *Gao-Weber* potential; similarly *gw/zbl* combines this potential with a modified repulsive ZBL core function in a similar fashion as implemented in the *tersoff/zbl* pair style.

Unfortunately the author of this contributed code has not been able to submit a suitable documentation explaining the details of the potentials. The LAMMPS developers thus have finally decided to release the code anyway with only the technical explanations. For details of the model and the parameters, please refer to the linked publication.

Only a single *pair\_coeff* command is used with the *gw* and *gw/zbl* styles which specifies a Gao-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the *pair\_coeff* command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of GW elements to atom types

See the *pair\_coeff* page for alternate ways to specify the path for the potential file.

As an example, imagine a file *SiC.gw* has Gao-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following *pair\_coeff* command:

```
pair_coeff * * SiC.gw Si Si Si C
```

The first 2 arguments must be *\* \** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the GW file. The final C argument maps LAMMPS atom type 4 to the C element in the GW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *gw* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Gao-Weber files in the *potentials* directory of the LAMMPS distribution have a “.gw” suffix. Gao-Weber with ZBL files have a “.gz.zbl” suffix. The structure of the potential files is similar to other many-body potentials supported by LAMMPS. You have to refer to the comments in the files and the literature to learn more details.

---

## 4.125.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.125.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the [newton](#) setting to be “on” for pair interactions.

The Gao-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal [units](#). You can use the GW potential with any LAMMPS units, but you would need to create your own GW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

### 4.125.6 Related commands

[pair\\_coeff](#)

### 4.125.7 Default

none

## 4.126 pair\_style harmonic/cut command

Accelerator Variants: *harmonic/cut/omp*

### 4.126.1 Syntax

```
pair_style style
```

- style = *harmonic/cut*

### 4.126.2 Examples

```
pair_style harmonic/cut
pair_coeff * * 0.2 2.0
pair_coeff 1 1 0.5 2.5
```

### 4.126.3 Description

New in version 17Feb2022.

Style *harmonic/cut* computes pairwise repulsive-only harmonic interactions with the formula

$$E = k(r_c - r)^2 \quad r < r_c$$

where  $r_c$  is the cutoff. Note that the usual 1/2 factor is included in  $k$ .

The following coefficients must be defined for each pair of atoms types via the [pair\\_coeff](#) command as in the examples above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $k$  (energy/distance<sup>2</sup> units)
  - $r_c$  (distance units)
- 

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.126.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the  $k$  and  $r_c$  coefficients can be mixed. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

Since the potential is zero at and beyond the cutoff parameter by construction, there is no need to support the *pair\_modify* shift or tail options for the energy and pressure of the pair interaction.

These pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.126.5 Restrictions

The *harmonic/cut* pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the [Build package](#) page for more info.

#### 4.126.6 Related commands

*pair\_coeff*

#### 4.126.7 Default

## 4.127 pair\_style hbond/dreiding/lj command

Accelerator Variants: *hbond/dreiding/lj/omp*

## 4.128 pair\_style hbond/dreiding/morse command

Accelerator Variants: *hbond/dreiding/morse/omp*

### 4.128.1 Syntax

```
pair_style style N inner_distance_cutoff outer_distance_cutoff angle_cutof
```

- style = *hbond/dreiding/lj* or *hbond/dreiding/morse*
- n = cosine angle periodicity
- inner\_distance\_cutoff = global inner cutoff for Donor-Acceptor interactions (distance units)
- outer\_distance\_cutoff = global cutoff for Donor-Acceptor interactions (distance units)
- angle\_cutoff = global angle cutoff for Acceptor-Hydrogen-Donor interactions (degrees)

### 4.128.2 Examples

```
pair_style hybrid/overlay lj/cut 10.0 hbond/dreiding/lj 4 9.0 11.0 90
pair_coeff 1 2 hbond/dreiding/lj 3 i 9.5 2.75 4 9.0 11.0 90.0

pair_style hybrid/overlay lj/cut 10.0 hbond/dreiding/morse 2 9.0 11.0 90
pair_coeff 1 2 hbond/dreiding/morse 3 i 3.88 1.7241379 2.9 2 9 11 90

labelmap atom 1 C 2 O 3 H
pair_coeff C O hbond/dreiding/morse H i 3.88 1.7241379 2.9 2 9 11 90
```

### 4.128.3 Description

The *hbond/dreiding* styles compute the Acceptor-Hydrogen-Donor (AHD) 3-body hydrogen bond interaction for the *DREIDING* force field, given by:

$$\begin{aligned}
 E &= [LJ(r)|Morse(r)] & r < r_{in} \\
 &= S(r) * [LJ(r)|Morse(r)] & r_{in} < r < r_{out} \\
 &= 0 & r > r_{out}
 \end{aligned}$$

$$LJ(r) = AR^{-12} - BR^{-10} \cos^n \theta = \varepsilon \left\{ 5 \left[ \frac{\sigma}{r} \right]^{12} - 6 \left[ \frac{\sigma}{r} \right]^{10} \right\} \cos^n \theta$$

$$Morse(r) = D_0 \{ \chi^2 - 2\chi \} \cos^n \theta = D_0 \{ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \} \cos^n \theta$$

$$S(r) = \frac{[r_{out}^2 - r^2]^2 [r_{out}^2 + 2r^2 - 3r_{in}^2]}{[r_{out}^2 - r_{in}^2]^3}$$

where  $r_{\text{in}}$  is the inner spline distance cutoff,  $r_{\text{out}}$  is the outer distance cutoff,  $\theta_c$  is the angle cutoff, and  $n$  is the cosine periodicity.

Here,  $r$  is the radial distance between the donor (D) and acceptor (A) atoms and  $\theta$  is the bond angle between the acceptor, the hydrogen (H) and the donor atoms:

These 3-body interactions can be defined for pairs of acceptor and donor atoms, based on atom types. For each donor/acceptor atom pair, the third atom in the interaction is a hydrogen permanently bonded to the donor atom, e.g. in a bond list read in from a data file via the [read\\_data](#) command. The atom types of possible hydrogen atoms for each donor/acceptor type pair are specified by the [pair\\_coeff](#) command (see below).

Style [hbond/dreiding/lj](#) is the original DREIDING potential of (Mayo). It uses a LJ 12/10 functional for the Donor-Acceptor interactions. To match the results in the original paper, use  $n = 4$ .

Style [hbond/dreiding/morse](#) is an improved version using a Morse potential for the Donor-Acceptor interactions. (Liu) showed that the Morse form gives improved results for Dendrimer simulations, when  $n = 2$ .

See the [Howto bioFF](#) page for more information on the DREIDING force field.

---

**Note:** Because the Dreiding hydrogen bond potential is only one portion of an overall force field which typically includes other pairwise interactions, it is common to use it as a sub-style in a [pair\\_style hybrid/overlay](#) command, where another pair style provides the repulsive core interaction between pairs of atoms, e.g. a  $1/r^{12}$  Lennard-Jones repulsion.

---

---

**Note:** When using the [hbond/dreiding](#) pair styles with [pair\\_style hybrid/overlay](#), you should explicitly define pair interactions between the donor atom and acceptor atoms, (as well as between these atoms and ALL other atoms in your system). Whenever [pair\\_style hybrid/overlay](#) is used, ordinary mixing rules are not applied to atoms like the donor and acceptor atoms because they are typically referenced in multiple pair styles. Neglecting to do this can cause difficult-to-detect physics problems.

---

---

**Note:** In the original Dreiding force field paper 1-4 non-bonded interactions ARE allowed. If this is desired for your model, use the `special_bonds` command (e.g. “`special_bonds lj 0.0 0.0 1.0`”) to turn these interactions on.

---

The following coefficients must be defined for pairs of eligible donor/acceptor types via the *pair\_coeff* command as in the examples above.

---

**Note:** Unlike other pair styles and their associated *pair\_coeff* commands, you do not need to specify *pair\_coeff* settings for all possible I,J type pairs. Only I,J type pairs for atoms which act as joint donors/acceptors need to be specified; all other type pairs are assumed to be inactive.

---

---

**Note:** A *pair\_coeff* command can be specified multiple times for the same donor/acceptor type pair. This enables multiple hydrogen types to be assigned to the same donor/acceptor type pair. For other *pair\_styles*, if the *pair\_coeff* command is re-used for the same I,J type pair, the settings for that type pair are overwritten. For the hydrogen bond potentials this is not the case; the settings are cumulative. This means the only way to turn off a previous setting, is to re-use the *pair\_style* command and start over.

---

For the *hbond/dreiding/lj* style the list of coefficients is as follows:

- K = hydrogen atom type = 1 to Ntypes, or type label
- donor flag = *i* or *j*
- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $n$  = exponent in formula above
- distance cutoff  $r_{in}$  (distance units)
- distance cutoff  $r_{out}$  (distance units)
- angle cutoff (degrees)

For the *hbond/dreiding/morse* style the list of coefficients is as follows:

- K = hydrogen atom type = 1 to Ntypes, or type label
- donor flag = *i* or *j*
- $D_0$  (energy units)
- $\alpha$  (1/distance units)
- $r_0$  (distance units)
- $n$  = exponent in formula above
- distance cutoff  $r_{in}$  (distance units)
- distance cutoff  $r_{out}$  (distance units)
- angle cutoff (degrees)

A single hydrogen atom type K can be specified, or a wild-card asterisk can be used in place of or in conjunction with the K arguments to select multiple types as hydrogen atoms. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. See the *pair\_coeff* command page for details.

If the donor flag is *i*, then the atom of type I in the *pair\_coeff* command is treated as the donor, and J is the acceptor. If the donor flag is *j*, then the atom of type J in the *pair\_coeff* command is treated as the donor and I is the donor. This option is required because the *pair\_coeff* command requires that  $I \leq J$ .

$\epsilon$  and  $\sigma$  are settings for the hydrogen bond potential based on a Lennard-Jones functional form. Note that sigma is defined as the zero-crossing distance for the potential, not as the energy minimum at  $2^{1/6}\sigma$ .

$D_0$  and  $\alpha$  and  $r_0$  are settings for the hydrogen bond potential based on a Morse functional form.

The last 3 coefficients for both styles are optional. If not specified, the global n, distance cutoff, and angle cutoff specified in the `pair_style` command are used. If you wish to only override the second or third optional parameter, you must also specify the preceding optional parameters.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.128.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. You must explicitly identify each donor/acceptor type pair.

These styles do not support the *pair\_modify* shift option for the energy of the interactions.

The *pair\_modify* table option is not relevant for these pair styles.

These pair styles do not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles do not write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands need to be re-specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

These pair styles tally a count of how many hydrogen bonding interactions they calculate each timestep and the hbond energy. These quantities can be accessed via the *compute pair* command as a vector of values of length 2.

To print these quantities to the log file (with a descriptive column heading) the following commands could be included in an input script:

```
compute hb all pair hbond/dreiding/lj
variable n_hbond equal c_hb[1] #number hbonds
variable E_hbond equal c_hb[2] #hbond energy
thermo_style custom step temp epair v_E_hbond
```

## 4.128.5 Restrictions

This pair style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

# 4.129 pair\_style hdnnp command

## 4.129.1 Syntax

**pair\_style** hdnnp cutoff keyword value ...

- cutoff = short-range cutoff of HDNNP (maximum symmetry function cutoff radius)
- zero or more keyword/value pairs may be appended
- keyword = *dir* or *showew* or *showewsum* or *maxew* or *resetew* or *cflength* or *cfenergy*
- value depends on the preceding keyword:

*dir* value = directory

directory = Path to HDNNP configuration files

*showew* value = yes or no

*showewsum* value = summary

summary = Write EW summary every this many timesteps (0 turns summary off)

*maxew* value = threshold

threshold = Maximum number of EWs allowed

*resetew* value = yes or no

*cflength* value = length

length = Length unit conversion factor

*cfenergy* value = energy

energy = Energy unit conversion factor

## 4.129.2 Examples

```
pair_style hdnnp 6.35 showew yes showewsum 100 maxew 1000 resetew yes cflength 1.
→8897261328 cfenergy 0.0367493254
pair_coeff * * H O

pair_style hdnnp 6.01 dir "./" showewsum 10000
pair_coeff * * S Cu NULL Cu
```

## 4.129.3 Description

This pair style adds an interaction based on the high-dimensional neural network potential (HDNNP) method as presented in (Behler and Parrinello 2007). HDNNPs are machine learning potentials which require careful training of neural networks prior to application in MD simulations. The pair style uses an interface to the *n2p2* library (Singraber, Behler and Dellago 2019) which is available on Github [here](#). Please see the *n2p2* documentation for further details. *n2p2* (and hence this pair style) is compatible with neural network potentials trained with its own tools (Singraber et al 2019) and with RuNNer.

Only a single *pair\_coeff* command with two asterisk wild-cards is used with this pair style. Its additional arguments define the mapping of LAMMPS atom types to *n2p2* elements.

```
pair_coeff * * H O
```

In the above example LAMMPS types 1 and 2 are mapped to the elements “H” and “O” in *n2p2*, respectively. Multiple types may map to the same element, or some types may not be mapped at all. For example, if the LAMMPS simulation has four atom types, the command

```
pair_coeff * * H H O NULL
```

maps atom types 1 and 2 to the element “H”, type 3 to “O” and type 4 is not mapped (indicated by NULL). Atoms mapped to NULL are ignored by the HDNNP calculation, i.e. they do not contribute in any way to the evaluation of HDNNP energies and forces. This may be useful in a setup with *hybrid pair styles*.

The mandatory pair style argument *cutoff* must match the short-range cutoff radius of the HDNNP. This corresponds to the maximum cutoff radius of all symmetry functions (the atomic environment descriptors of HDNNPs) used.

**Note:** The cutoff must be given in LAMMPS length units, even if the neural network potential has been trained using a different unit system (see remarks about the *cflength* and *cfenergy* keywords below for details).

The numeric value may be slightly larger than the actual maximum symmetry function cutoff radius (to account for rounding errors when converting units), but must not be smaller.

Use the *dir* keyword to specify the directory containing the HDNNP configuration files. The directory must contain *input.nn* with neural network and symmetry function setup, *scaling.data* with symmetry function scaling data and *weights.??? .data* with weight parameters for each element.

The keyword *showew* can be used to turn on/off the display of extrapolation warnings (EWs) which are issued whenever a symmetry function value is out of bounds defined by minimum/maximum values in *scaling.data*. An extrapolation warning may look like this:

```
### NNP EXTRAPOLATION WARNING ### STRUCTURE:      0 ATOM:      119 ELEMENT: Cu SYMFUNC:
→ 32 TYPE: 3 VALUE: 2.166E-02 MIN: 2.003E-05 MAX: 1.756E-02
```

stating that the value 2.166E-02 of symmetry function 32 of type 3 (Narrow Angular symmetry function), element Cu (see the log file for a symmetry function listing) was out of bounds (maximum in `scaling.data` is 1.756E-02) for atom 119. Here, the atom index refers to the LAMMPS tag (global index) and the structure index is used to print out the MPI rank the atom belongs to.

**Note:** The `showew` keyword should only be set to `yes` for debugging purposes. Extrapolation warnings may add lots of overhead as they are communicated each timestep. Also, if the simulation is run in a region where the HDNNP was not correctly trained, lots of extrapolation warnings may clog log files and the console. In a production run use `showewsum` instead.

The keyword `showewsum` can be used to get an overview of extrapolation warnings occurring during an MD simulation. The argument specifies the interval at which extrapolation warning summaries are displayed and logged. An EW summary may look like this:

```
### NNP EW SUMMARY ### TS:      100 EW      11 EWPERSTEP  1.100E-01
```

Here, at timestep 100 the occurrence of 11 extrapolation warnings since the last summary is reported, which corresponds to an EW rate of 0.11 per timestep. Setting `showewsum` to 0 deactivates the EW summaries.

A maximum number of allowed extrapolation warnings can be specified with the `maxew` keyword. If the number of EWs exceeds the `maxew` argument the simulation is stopped. Note however that this is merely an approximate threshold since the check is only performed at the end of each timestep and each MPI process counts individually to minimize communication overhead.

The keyword `resetew` alters the behavior of the above mentioned `maxew` threshold. If `resetew` is set to `yes` the threshold is applied on a per-timestep basis and the internal EW counters are reset at the beginning of each timestep. With `resetew` set to `no` the counters accumulate EWs along the whole trajectory.

If the training of a neural network potential has been performed with different physical units for length and energy than those set in LAMMPS, it is still possible to use the potential when the unit conversion factors are provided via the `cflength` and `cfenergy` keywords. If for example, the HDNNP was parameterized with Bohr and Hartree training data and symmetry function parameters (i.e. distances and energies in “input.nn” are given in Bohr and Hartree) but LAMMPS is set to use *metal* units (Angstrom and eV) the correct conversion factors are:

```
cflength 1.8897261328
```

```
cfenergy 0.0367493254
```

Thus, arguments of `cflength` and `cfenergy` are the multiplicative factors required to convert lengths and energies given in LAMMPS units to respective quantities in native HDNNP units (1 Angstrom = 1.8897261328 Bohr, 1 eV = 0.0367493254 Hartree).

#### 4.129.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. The `pair_coeff` command should only be invoked with asterisk wild cards (see above).

This style does not support the `pair_modify` shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.129.5 Restrictions

This pair style is part of the ML-HDNNP package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) doc page for more info.

Please report bugs and feature requests to the [n2p2 GitHub issue page](#).

#### Related commands

```

### 4.133.3 Description

The *hybrid*, *hybrid/overlay*, *hybrid/molecular*, and *hybrid/scaled* styles enable the use of multiple pair styles in one simulation. With the *hybrid* style, exactly one pair style is assigned to each pair of atom types. With the *hybrid/overlay* and *hybrid/scaled* styles, one or more pair styles can be assigned to each pair of atom types. With the *hybrid/molecular* style, pair styles are assigned to either intra- or inter-molecular interactions.

The assignment of pair styles to type pairs is made via the *pair\_coeff* command. The major difference between the *hybrid/overlay* and *hybrid/scaled* styles is that the *hybrid/scaled* adds a scale factor for each sub-style contribution to forces, energies and stresses. Because of the added complexity, the *hybrid/scaled* style has more overhead and thus may be slower than *hybrid/overlay*.

The *hybrid/molecular* pair style accepts *only* two sub-styles: the first is assigned to intra-molecular interactions (i.e. both atoms have the same molecule ID), the second to inter-molecular interactions (i.e. interacting atoms have different molecule IDs).

Here are two examples of hybrid simulations. The *hybrid* style could be used for a simulation of a metal droplet on a LJ surface. The metal atoms interact with each other via an *eam* potential, the surface atoms interact with each other via a *lj/cut* potential, and the metal/surface interaction is also computed via a *lj/cut* potential. The *hybrid/overlay* style could be used as in the second example above, where multiple potentials are superimposed in an additive fashion to compute the interaction between atoms. In this example, using *lj/cut* and *coul/long* together gives the same result as if the *lj/cut/coul/long* potential were used by itself. In this case, it would be more efficient to use the single combined potential, but in general any combination of pair potentials can be used together in to produce an interaction that is not encoded in any single pair\_style file, e.g. adding Coulombic forces between granular particles. Another limitation of using the *hybrid/overlay* variant, that it does not generate *lj/cut* parameters for mixed atom types from a mixing rule due to restrictions discussed below.

If the *hybrid/scaled* style is used instead of *hybrid/overlay*, contributions from sub-styles are weighted by their scale factors, which may be fractional or even negative. Furthermore the scale factors may be variables that may change during a simulation. This enables switching smoothly between two different pair styles or two different parameter sets during a run in a similar fashion as could be done with *fix adapt* or *fix alchemy*.

All pair styles that will be used are listed as “sub-styles” following the *hybrid* or *hybrid/overlay* keyword, in any order. In case of the *hybrid/scaled* pair style, each sub-style is prefixed with a scale factor. The scale factor is either a floating point number or an equal style (or equivalent) variable. Each sub-style’s name is followed by its usual arguments, as illustrated in the examples above. See the doc pages of the individual pair styles for a listing and explanation of the appropriate arguments for them.

Note that an individual pair style can be used multiple times as a sub-style. For efficiency reasons this should only be done if your model requires it. E.g. if you have different regions of Si and C atoms and wish to use a Tersoff potential for pure Si for one set of atoms, and a Tersoff potential for pure C for the other set (presumably with some third potential for Si-C interactions), then the sub-style *tersoff* could be listed twice. But if you just want to use a Lennard-Jones or other pairwise potential for several different atom type pairs in your model, then you should just list the sub-style once and use the pair\_coeff command to assign parameters for the different type pairs.

---

**Note:** There is one exception to this option to list an individual pair style multiple times: GPU-enabled pair styles in the GPU package. This is because the GPU package currently assumes that only one instance of a pair style is being used.

---

In the pair\_coeff commands, the name of a pair style must be added after the I,J type specification, with the remaining coefficients being those appropriate to that style. If the pair style is used multiple times in the pair\_style command, then an additional numeric argument must also be specified which is a number from 1 to M where M is the number of times the sub-style was listed in the pair style command. The extra number indicates which instance of the sub-style these coefficients apply to.

For example, consider a simulation with 3 atom types: types 1 and 2 are Ni atoms, type 3 are LJ atoms with charges. The following commands would set up a hybrid simulation:

```
pair_style hybrid eam/alloy lj/cut/coul/cut 10.0 lj/cut 8.0
pair_coeff * * eam/alloy nialhjea Ni Ni NULL
pair_coeff 3 3 lj/cut/coul/cut 1.0 1.0
pair_coeff 1*2 3 lj/cut 0.8 1.3
```

As an example of using the same pair style multiple times, consider a simulation with 2 atom types. Type 1 is Si, type 2 is C. The following commands would model the Si atoms with Tersoff, the C atoms with Tersoff, and the cross-interactions with Lennard-Jones:

```
pair_style hybrid lj/cut 2.5 tersoff tersoff
pair_coeff * * tersoff 1 Si.tersoff Si NULL
pair_coeff * * tersoff 2 C.tersoff NULL C
pair_coeff 1 2 lj/cut 1.0 1.5
```

It is not recommended to read pair coefficients for a hybrid style from a “Pair Coeffs” or “PairIJ Coeffs” section of a data file via the `read_data` command, since those sections expect a fixed number of lines, either one line per atom type or one line pair pair of atom types, respectively. When reading from a data file, the lines of the “Pair Coeffs” and “PairIJ Coeffs” are changed in the same way as the `pair_coeff` command, i.e. the name of the pair style to which the parameters apply must follow the atom type (or atom types), e.g.

#### Pair Coeffs

```
1 lj/cut/coul/cut 1.0 1.0
...
```

#### PairIJ Coeffs

```
1 1 lj/cut/coul/cut 1.0 1.0
...
```

Note that the `pair_coeff` command for some potentials such as `pair_style eam/alloy` includes a mapping specification of elements to all atom types, which in the hybrid case, can include atom types not assigned to the `eam/alloy` potential. The NULL keyword is used by many such potentials (`eam/alloy`, Tersoff, AIREBO, etc), to denote an atom type that will be assigned to a different sub-style.

For the *hybrid* style, each atom type pair I,J is assigned to exactly one sub-style. Just as with a simulation using a single pair style, if you specify the same atom type pair in a second `pair_coeff` command, the previous assignment will be overwritten.

For the *hybrid/overlay* and *hybrid/scaled* styles, each atom type pair I,J can be assigned to one or more sub-styles. If you specify the same atom type pair in a second `pair_coeff` command with a new sub-style, then the second sub-style is added to the list of potentials that will be calculated for two interacting atoms of those types. If you specify the same atom type pair in a second `pair_coeff` command with a sub-style that has already been defined for that pair of atoms, then the new pair coefficients simply override the previous ones, as in the normal usage of the `pair_coeff` command. E.g. these two sets of commands are the same:

```
pair_style lj/cut 2.5
pair_coeff * * 1.0 1.0
pair_coeff 2 2 1.5 0.8

pair_style hybrid/overlay lj/cut 2.5
pair_coeff * * lj/cut 1.0 1.0
pair_coeff 2 2 lj/cut 1.5 0.8
```

Coefficients must be defined for each pair of atoms types via the `pair_coeff` command as described above, or in the “Pair Coeffs” or “PairIJ Coeffs” section of the data file read by the `read_data` command, or by mixing as described below.

For all of the *hybrid*, *hybrid/overlay*, and *hybrid/scaled* styles, every atom type pair I,J (where  $I \leq J$ ) must be assigned to at least one sub-style via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data`, or by mixing as described below. Also all sub-styles must be used at least once in a `pair_coeff` command.

**Warning:** With hybrid pair styles the use of mixing to generate pair coefficients is significantly limited compared to the individual pair styles. LAMMPS **never** performs mixing of parameters from different sub-styles, **even** if they use the same type of coefficients, e.g. contain a Lennard-Jones potential variant. Those parameters must be provided explicitly. Also for *hybrid/overlay* and *hybrid/scaled* mixing is **only** performed for pairs of atom types for which only a single pair style is assigned.

Thus it is strongly recommended to provide all mixed terms explicitly. For non-hybrid styles those could be gener-

ated and written out using the *write\_coeff command* and then edited as needed to comply with the requirements for hybrid styles as explained above.

If you want there to be no interactions between a particular pair of atom types, you have 3 choices. You can assign the pair of atom types to some sub-style and use the *neigh\_modify exclude type* command. You can assign it to some sub-style and set the coefficients so that there is effectively no interaction (e.g.  $\epsilon = 0.0$  in a LJ potential). Or, for *hybrid*, *hybrid/overlay*, or *hybrid/scaled* simulations, you can use this form of the *pair\_coeff* command in your input script or the “PairIJ Coeffs” section of your data file:

```
pair_coeff 2 3 none
```

or this form in the “Pair Coeffs” section of the data file:

```
3 none
```

If an assignment to *none* is made in a simulation with the *hybrid/overlay* or *hybrid/scaled* pair style, it wipes out all previous assignments of that pair of atom types to sub-styles.

Note that you may need to use an *atom\_style* hybrid command in your input script, if atoms in the simulation will need attributes from several atom styles, due to using multiple pair styles with different requirements.

Different force fields (e.g. CHARMM vs. AMBER) may have different rules for applying exclusions or weights that change the strength of pairwise non-bonded interactions between pairs of atoms that are also 1-2, 1-3, and 1-4 neighbors in the molecular bond topology. This is normally a global setting defined the *special\_bonds* command. However, different weights can be assigned to different hybrid sub-styles via the *pair\_modify special* command. This allows multiple force fields to be used in a model of a hybrid system, however, there is no consistent approach to determine parameters automatically for the interactions **between** atoms of the two force fields, thus this approach this is only recommended when particles described by the different force fields do not mix.

Here is an example for combining CHARMM and AMBER: The global *amber* setting sets the 1-4 interactions to non-zero scaling factors and then overrides them with 0.0 only for CHARMM:

```
special_bonds amber
pair_style hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

This input achieves the same effect:

```
special_bonds 0.0 0.0 0.1
pair_style hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/cut/coul/long special lj 0.0 0.0 0.5
pair_modify pair lj/cut/coul/long special coul 0.0 0.0 0.83333333
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

Here is an example for combining Tersoff with OPLS/AA based on a data file that defines bonds for all atoms where - for the Tersoff part of the system - the force constants for the bonded interactions have been set to 0. Note the global settings are effectively *lj/coul 0.0 0.0 0.5* as required for OPLS/AA:

```
special_bonds lj/coul 1e-20 1e-20 0.5
pair_style hybrid tersoff lj/cut/coul/long 12.0
pair_modify pair tersoff special lj/coul 1.0 1.0 1.0
```

For use with the various *compute \*/tally* computes, the *pair\_modify compute/tally* command can be used to selectively turn off processing of the compute tally styles, for example, if those pair styles (e.g. many-body styles) do not support this feature.

See the *pair\_modify* page for details on the specific syntax, requirements and restrictions.

The potential energy contribution to the overall system due to an individual sub-style can be accessed and output via the *compute pair* command. Note that in the case of pair style *hybrid/scaled* this is the **unscaled** potential energy of the selected sub-style.

**Note:** Several of the potentials defined via the *pair\_style* command in LAMMPS are really many-body potentials, such as Tersoff, AIREBO, MEAM, ReaxFF, etc. The way to think about using these potentials in a hybrid setting is as follows.

A subset of atom types is assigned to the many-body potential with a single *pair\_coeff* command, using “\* \*” to include all types and the NULL keywords described above to exclude specific types not assigned to that potential. If types 1,3,4 were assigned in that way (but not type 2), this means that all many-body interactions between all atoms of types 1,3,4 will be computed by that potential. Pair\_style hybrid allows interactions between type pairs 2-2, 1-2, 2-3, 2-4 to be specified for computation by other pair styles. You could even add a second interaction for 1-1 to be computed by another pair style, assuming pair\_style hybrid/overlay is used.

But you should not, as a general rule, attempt to exclude the many-body interactions for some subset of the type pairs within the set of 1,3,4 interactions, e.g. exclude 1-1 or 1-3 interactions. That is not conceptually well-defined for many-body interactions, since the potential will typically calculate energies and forces for small groups of atoms, e.g. 3 or 4 atoms, using the neighbor lists of the atoms to find the additional atoms in the group.

However, you can still use the *pair\_coeff none* setting or the *neigh\_modify exclude* command to exclude certain type pairs from the neighbor list that will be passed to a many-body sub-style. This will alter the calculations made by a many-body potential beyond the specific pairs, since it builds its list of 3-body, 4-body, etc interactions from the pair lists. You will need to think **carefully** as to whether excluding such pairs produces a physically meaningful result for your model.

For example, imagine you have two atom types in your model, type 1 for atoms in one surface, and type 2 for atoms in the other, and you wish to use a Tersoff potential to compute interactions within each surface, but not between the surfaces. Then either of these two command sequences would implement that model:

```
pair_style hybrid tersoff
pair_coeff * * tersoff SiC.tersoff C C
pair_coeff 1 2 none

pair_style tersoff
pair_coeff * * SiC.tersoff C C
neigh_modify exclude type 1 2
```

Either way, only neighbor lists with 1-1 or 2-2 interactions would be passed to the Tersoff potential, which means it would compute no 3-body interactions containing both type 1 and 2 atoms.

Here is another example to use 2 many-body potentials together in an overlapping manner using hybrid/overlay. Imagine you have CNT (C atoms) on a Si surface. You want to use Tersoff for Si/Si and Si/C interactions, and AIREBO for C/C interactions. Si atoms are type 1; C atoms are type 2. Something like this will work:

```
pair_style hybrid/overlay tersoff airebo 3.0
pair_coeff * * tersoff SiC.tersoff.custom Si C
pair_coeff * * airebo CH.airambo NULL C
```

Note that to prevent the Tersoff potential from computing C/C interactions, you would need to **modify** the `SiC.tersoff` potential file to turn off C/C interaction, i.e. by setting the appropriate coefficients to 0.0.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

**Note:** Since the *hybrid*, *hybrid/overlay*, *hybrid/scaled* styles delegate computation to the individual sub-styles, the suffix versions of the *hybrid* and *hybrid/overlay* styles are used to propagate the corresponding suffix to all sub-styles, if those versions exist. Otherwise the non-accelerated version will be used. The individual accelerated sub-styles are part of the GPU, KOKKOS, INTEL, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

---

#### 4.133.4 Mixing, shift, table, tail correction, restart, rRESPA info

Any pair potential settings made via the *pair\_modify* command are passed along to all sub-styles of the hybrid potential.

For atom type pairs *I,J* and *I != J*, if the sub-style assigned to *I,I* and *J,J* is the same, and if the sub-style allows for mixing, then the coefficients for *I,J* can be mixed. This means you do not have to specify a *pair\_coeff* command for *I,J* since the *I,J* type pair will be assigned automatically to the sub-style defined for both *I,I* and *J,J* and its coefficients generated by the mixing rule used by that sub-style. For the *hybrid/overlay* and *hybrid/scaled* style, there is an additional requirement that both the *I,I* and *J,J* pairs are assigned to a single sub-style. If this requirement is not met, no *I,J* coeffs will be generated, even if the sub-styles support mixing, and *I,J* pair coefficients must be explicitly defined.

See the *pair\_modify* command for details of mixing rules. See the [page for the sub-style](#) to see if allows for mixing.

The hybrid pair styles supports the *pair\_modify* shift, table, and tail options for an *I,J* pair interaction, if the associated sub-style supports it.

For the hybrid pair styles, the list of sub-styles and their respective settings are written to *binary restart files*, so a *pair\_style* command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file. The same is true for *data files*. Thus, *pair\_coeff* commands need to be re-specified in the restart input script. For pair style *hybrid/scaled* also the names of any variables used as scale factors are restored, but not the variables themselves, so those may need to be redefined when continuing from a restart.

These pair styles support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, if their sub-styles do.

### 4.133.5 Restrictions

When using a long-range Coulombic solver (via the *kpace\_style* command) with a hybrid pair\_style, one or more sub-styles will be of the “long” variety, e.g. *lj/cut/coul/long* or *buck/coul/long*. You must ensure that the short-range Coulombic cutoff used by each of these long pair styles is the same or else LAMMPS will generate an error.

Pair style *hybrid/scaled* currently only works for non-accelerated pair styles and pair styles from the OPT package.

Pair style *hybrid/molecular* is not compatible with manybody potentials.

When using pair styles from the GPU package they must not be listed multiple times. LAMMPS will detect this and abort.

### 4.133.6 Related commands

## 4.134 pair\_style ilp/graphene/hbn command

Accelerator Variant: *ilp/graphene/hbn/opt*

### 4.134.1 Syntax

```
pair_style [hybrid/overlay ...] ilp/graphene/hbn cutoff tap_flag
```

- cutoff = global cutoff (distance units)
- tap\_flag = 0/1 to turn off/on the taper function

### 4.134.2 Examples

```
pair_style hybrid/overlay ilp/graphene/hbn 16.0 1
pair_coeff * * ilp/graphene/hbn BNCH.ILP B N C

pair_style hybrid/overlay rebo tersoff ilp/graphene/hbn 16.0 coul/shield 16.0
pair_coeff * * rebo CH.rebo NULL NULL C
pair_coeff * * tersoff BNC.tersoff B N NULL
pair_coeff * * ilp/graphene/hbn BNCH.ILP B N C
pair_coeff 1 1 coul/shield 0.70
pair_coeff 1 2 coul/shield 0.695
pair_coeff 2 2 coul/shield 0.69
```

### 4.134.3 Description

The *ilp/graphene/hbn* style computes the registry-dependent interlayer potential (ILP) potential as described in ([Leven1](#)), ([Leven2](#)) and ([Maaravi](#)). The normals are calculated in the way as described in ([Kolmogorov](#)).

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta-1)} [\varepsilon + f(\rho_{ij}) + f(\rho_{ji})] - \frac{1}{1 + e^{-d[(r_{ij}/(s_R \cdot r^{eff})) - 1]}} \cdot \frac{C_6}{r_{ij}^6} \right\}$$

$$\rho_{ij}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_i)^2$$

$$\rho_{ji}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_j)^2$$

$$f(\rho) = C e^{-(\rho/\delta)^2}$$

$$\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1$$

Where  $\text{Tap}(r_{ij})$  is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than  $r_c$  ([Maaravi](#)). The definitions of each parameter in the above equation can be found in ([Leven1](#)) and ([Maaravi](#)).

It is important to include all the pairs to build the neighbor list for calculating the normals.

---

**Note:** This potential (ILP) is intended for interlayer interactions between two different layers of graphene, hexagonal boron nitride (h-BN) and their hetero-junction. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as *AIREBO* or *Tersoff* potential. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.

---

The parameter file (e.g. BNCH.ILP), is intended for use with *metal* [units](#), with energies in meV. Two additional parameters,  $S$ , and  $rcut$  are included in the parameter file.  $S$  is designed to facilitate scaling of energies.  $rcut$  is designed to build the neighbor list for calculating the normals for each atom pair.

---

**Note:** The parameters presented in the parameter file (e.g. BNCH.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful. The parameters for atoms pairs between Boron and Nitrogen are fitted with a screened Coulomb interaction *coul/shield*. Therefore, to simulated the properties of h-BN correctly, this potential must be used in combination with the pair style *coul/shield*.

---

---

**Note:** Four new sets of parameters of ILP for 2D layered Materials with bilayer and bulk configurations are presented in ([Ouyang1](#)) and ([Ouyang2](#)), respectively. These parameters provide a good description in both short- and long-range interaction regimes. While the old ILP parameters published in ([Leven2](#)) and ([Maaravi](#)) are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in ([Ouyang1](#)) and ([Ouyang2](#)).

---

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair\_style none.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1.  $E_{vdW}$  = vdW (attractive) energy
2.  $E_{Rep}$  = Repulsive energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute 0 all pair ilp/graphene/hbn
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.134.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

#### 4.134.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the `newton` setting to be *on* for pair interactions.

The BNCH.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for *metal* units. You can use this potential with any LAMMPS units, but you would need to create your own custom BNCH.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use *metal* units.

pair_style hybrid/overlay sw/mod sw/mod ilp/tmd 16.0
pair_coeff * * sw/mod 1 tmd.sw.mod Mo S S NULL NULL NULL
pair_coeff * * sw/mod 2 tmd.sw.mod NULL NULL NULL W Se Se
pair_coeff * * ilp/tmd TMD.ILP Mo S S W Se Se
```

### 4.135.3 Description

New in version 17Feb2022.

The *ilp/tmd* style computes the registry-dependent interlayer potential (ILP) potential for transition metal dichalco-

genides (TMD) as described in (Ouyang7) and (Jiang).

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta-1)} [\varepsilon + f(\rho_{ij}) + f(\rho_{ji})] - \frac{1}{1 + e^{-d[(r_{ij}/(s_R \cdot r_{eff})) - 1]}} \cdot \frac{C_6}{r_{ij}^6} \right\}$$

$$\rho_{ij}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_i)^2$$

$$\rho_{ji}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_j)^2$$

$$f(\rho) = C e^{-(\rho/\delta)^2}$$

$$\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1$$

Where  $\text{Tap}(r_{ij})$  is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than  $r_c$  *pair\_style ilp\_graphene\_hbn*.

It is important to include all the pairs to build the neighbor list for calculating the normals.

---

**Note:** Since each MX<sub>2</sub> (M = Mo, W and X = S, Se Te) layer contains two sub-layers of X atoms and one sub-layer of M atoms, the definition of the normal vectors used for graphene and h-BN is no longer valid for TMDs. In (Ouyang7), a new definition is proposed, where for each atom  $i$ , its six nearest neighboring atoms belonging to the same sub-layer are chosen to define the normal vector  $\{bfn\}_i$ .

---

The parameter file (e.g. TMD.ILP), is intended for use with *metal units*, with energies in meV. Two additional parameters,  $S$ , and  $rcut$  are included in the parameter file.  $S$  is designed to facilitate scaling of energies.  $rcut$  is designed to build the neighbor list for calculating the normals for each atom pair.

---

**Note:** The parameters presented in the parameter file (e.g. TMD.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful. These parameters provide a good description in both short- and long-range interaction regimes. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in (Ouyang7).

---

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using *pair\_style none*.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1.  $E_{vdW}$  = vdW (attractive) energy
2.  $E_{Rep}$  = Repulsive energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute 0 all pair ilp/tmd
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages*

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.135.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

#### 4.135.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the `newton` setting to be *on* for pair interactions.

The TMD.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for *metal* units. You can use this potential with any LAMMPS units, but you would need to create your own custom TMD.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use *metal* units.

#### 4.135.6 Related commands

## 4.136 pair\_style kim command

### 4.136.1 Syntax

```
pair_style kim model
```

model = name of a KIM model (the KIM ID for models archived in OpenKIM)

### 4.136.2 Examples

```
pair_style kim SW_StillingerWeber_1985_Si__MO_405512056662_005
pair_coeff * * Si
```

### 4.136.3 Description

This pair style is a wrapper on the [Open Knowledgebase of Interatomic Models \(OpenKIM\)](#) repository of interatomic potentials to enable their use in LAMMPS scripts.

The preferred interface for using interatomic models archived in OpenKIM is the *kim command* interface. That interface supports both “KIM Portable Models” (PMs) that conform to the KIM API Portable Model Interface (PMI) and can be used by any simulation code that conforms to the KIM API/PMI, and “KIM Simulator Models” (SMs) that are natively implemented within a single simulation code (like LAMMPS) and can only be used with it. The *pair\_style kim* command is limited to KIM PMs. It is used by the *kim command* interface as needed.

---

**Note:** Since *pair\_style kim* is called by *kim interactions* as needed, it is not recommended to be directly used in input scripts.

---

The argument *model* is the name of the KIM PM. For potentials archived in OpenKIM this is the extended KIM ID (see *kim command* for details). LAMMPS can invoke any KIM PM, however there can be incompatibilities (for example due to unit matching issues). In the event of an incompatibility, the code will terminate with an error message. Check both the LAMMPS and KIM log files for details.

Only a single *pair\_coeff* command is used with the *kim* style, which specifies the mapping of LAMMPS atom types to the species supported by the KIM PM. This is done by specifying *N* additional arguments after the *\*\** in the *pair\_coeff* command, where *N* is the number of LAMMPS atom types:

- *N* element names = mapping of KIM elements to atom types

For example, consider a KIM PM that supports Si and C species. If the LAMMPS simulation has four atom types, where the first three are Si, and the fourth is C, the following *pair\_coeff* command would be used:

```
pair_coeff * * Si Si Si C
```

The first two arguments must be *\*\** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1, 2, and 3 to Si as defined within KIM PM. The final C argument maps LAMMPS atom type 4 to C.

In addition to the usual LAMMPS error messages, the KIM library itself may generate errors, which should be printed to the screen. In this case it is also useful to check the *kim.log* file for additional error information. The file *kim.log* should be generated in the same directory where LAMMPS is running.

To download, build, and install the KIM library on your system, see the *lib/kim/README* file. Once you have done this and built LAMMPS with the KIM package installed you can run the example input scripts in *examples/kim*.

---

#### 4.136.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since KIM stores the potential parameters. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.136.5 Restrictions

This pair style is part of the KIM package. See details on restrictions in *kim command*.

This current version of *pair\_style kim* is compatible with the *kim-api* package version 2.0.0 and higher.

#### 4.136.6 Related commands

*pair\_coeff*, *kim command*

#### 4.136.7 Default

none

### 4.137 *pair\_style kolmogorov/crespi/full* command

#### 4.137.1 Syntax

```
pair_style hybrid/overlay kolmogorov/crespi/full cutoff tap_flag
```

- cutoff = global cutoff (distance units)
- tap\_flag = 0/1 to turn off/on the taper function

#### 4.137.2 Examples

```
pair_style hybrid/overlay kolmogorov/crespi/full 20.0 0
pair_coeff * * none
pair_coeff * * kolmogorov/crespi/full CH.KC C C

pair_style hybrid/overlay rebo kolmogorov/crespi/full 16.0 1
pair_coeff * * rebo CH.rebo C H
pair_coeff * * kolmogorov/crespi/full CH_taper.KC C H
```

### 4.137.3 Description

The *kolmogorov/crespi/full* style computes the Kolmogorov-Crespi (KC) interaction potential as described in (*Kolmogorov*). No simplification is made,

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = e^{-\lambda(r_{ij}-z_0)} [C + f(\rho_{ij}) + f(\rho_{ji})] - A \left( \frac{r_{ij}}{z_0} \right)^{-6}$$

$$\rho_{ij}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_i)^2$$

$$\rho_{ji}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_j)^2$$

$$f(\rho) = e^{-(\rho/\delta)^2} \sum_{n=0}^2 C_{2n} (\rho/\delta)^{2n}$$

It is important to have a sufficiently large cutoff to ensure smooth forces and to include all the pairs to build the neighbor list for calculating the normals. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of  $V_{ij}$  (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for  $V_{ij}$  above. This is essential only when the taper function is turned off. The formula of taper function can be found in pair style *ilp/graphene/hbn*.

---

**Note:** This potential (ILP) is intended for interlayer interactions between two different layers of graphene. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as *AIREBO* or *Tersoff* potential. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.

---

The parameter file (e.g. CH.KC), is intended for use with *metal units*, with energies in meV. Two additional parameters, *S*, and *rcut* are included in the parameter file. *S* is designed to facilitate scaling of energies. *rcut* is designed to build the neighbor list for calculating the normals for each atom pair.

---

**Note:** Two new sets of parameters of KC potential for hydrocarbons, CH.KC (without the taper function) and CH\_taper.KC (with the taper function) are presented in (*Ouyang1*). The energy for the KC potential with the taper function goes continuously to zero at the cutoff. The parameters in both CH.KC and CH\_taper.KC provide a good description in both short- and long-range interaction regimes. While the original parameters (CC.KC) published in (*Kolmogorov*) are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in (*Ouyang1*) and (*Ouyang2*).

---

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair\_style *none*.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1.  $E_{vdW}$  = vdW (attractive) energy
2.  $E_{Rep}$  = Repulsive energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute 0 all pair kolmogorov/crespi/full
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

---

#### 4.137.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair\_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair\_style and pair\_coeff commands in an input script that reads a restart file.

#### 4.137.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the newton setting to be *on* for pair interactions.

The CH.KC potential file provided with LAMMPS (see the potentials folder) is parameterized for metal units. You can use this pair style with any LAMMPS units, but you would need to create your own custom CH.KC potential file with all coefficients converted to the appropriate units.

#### 4.137.6 Related commands

*pair\_coeff*, *pair\_none*, *pair\_style hybrid/overlay*, *pair\_style drip*, *pair\_style pair\_lebedeva\_z*, *pair\_style kolmogorov/crespi/z*, *pair\_style ilp/graphene/hbn*.

### 4.138 pair\_style kolmogorov/crespi/z command

#### 4.138.1 Syntax

```
pair_style [hybrid/overlay ...] kolmogorov/crespi/z cutoff
```

## 4.138.2 Examples

```
pair_style hybrid/overlay kolmogorov/crespi/z 20.0
pair_coeff * * none
pair_coeff 1 2 kolmogorov/crespi/z CC.KC C C

pair_style hybrid/overlay rebo kolmogorov/crespi/z 14.0
pair_coeff * * rebo CH.rebo C C
pair_coeff 1 2 kolmogorov/crespi/z CC.KC C C
```

## 4.138.3 Description

The *kolmogorov/crespi/z* style computes the Kolmogorov-Crespi interaction potential as described in (*Kolmogorov*). An important simplification is made, which is to take all normals along the z-axis.

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = e^{-\lambda(r_{ij}-z_0)} [C + f(\rho_{ij}) + f(\rho_{ji})] - A \left( \frac{r_{ij}}{z_0} \right)^{-6} + A \left( \frac{\text{cutoff}}{z_0} \right)^{-6}$$

$$\rho_{ij}^2 = \rho_{ji}^2 = x_{ij}^2 + y_{ij}^2 \quad (\mathbf{n}_i \equiv \hat{\mathbf{z}})$$

$$f(\rho) = e^{-(\rho/\delta)^2} \sum_{n=0}^2 C_{2n} (\rho/\delta)^{2n}$$

It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of  $V_{ij}$  (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for  $V_{ij}$  above.

This potential is intended for interactions between two layers of graphene. Therefore, to avoid interaction between layers in multi-layered materials, each layer should have a separate atom type and interactions should only be computed between atom types of neighboring layers.

The parameter file (e.g. CC.KC), is intended for use with metal *units*, with energies in meV. An additional parameter,  $S$ , is available to facilitate scaling of energies in accordance with (*vanWijk*).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair\_style *none*.

#### 4.138.4 Restrictions

This fix is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

#### 4.138.5 Related commands

### 4.139 pair\_style lcbop command

#### 4.139.1 Syntax

```
pair_style lcbop
```

#### 4.139.2 Examples

```
pair_style lcbop
pair_coeff * * ../potentials/C.lcbop C
```

#### 4.139.3 Description

The *lcbop* pair style computes the long-range bond-order potential for carbon (LCBOP) of ([Los and Fasolino](#)). See section II in that paper for the analytic equations associated with the potential.

Only a single *pair\_coeff* command is used with the *lcbop* style which specifies an LCBOP potential file with parameters for specific elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the *pair\_coeff* command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of LCBOP elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C you would use the following *pair\_coeff* command:

```
pair_coeff * * C.lcbop C C C NULL
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first C argument maps LAMMPS atom type 1 to the C element in the LCBOP file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *lcbop* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the LCBOP potential as applied to C are listed in the C.lcbop file to agree with the original (*Los and Fasolino*) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done carefully.

#### 4.139.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the pair\_style and pair\_coeff commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.139.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair potential requires the *newton* setting to be “on” for pair interactions.

The C.lcbop potential file provided with LAMMPS (see the potentials directory) is parameterized for *metal units*. You can use the LCBOP potential with any LAMMPS units, but you would need to create your own LCBOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

#### 4.139.6 Related commands

*pair\_airebo*, *pair\_coeff*

#### 4.139.7 Default

none

## 4.140 pair\_style lebedeva/z command

### 4.140.1 Syntax

```
pair_style [hybrid/overlay ...] lebedeva/z cutoff
```

### 4.140.2 Examples

```
pair_style hybrid/overlay lebedeva/z 20.0
pair_coeff * * none
pair_coeff 1 2 lebedeva/z CC.Lebedeva C C

pair_style hybrid/overlay rebo lebedeva/z 14.0
pair_coeff * * rebo CH.rebo C C
pair_coeff 1 2 lebedeva/z CC.Lebedeva C C
```

### 4.140.3 Description

The *lebedeva/z* pair style computes the Lebedeva interaction potential as described in (*Lebedeva1*) and (*Lebedeva2*). An important simplification is made, which is to take all normals along the z-axis.

The Lebedeva potential is intended for the description of the interlayer interaction between graphene layers. To perform a realistic simulation, this potential must be used in combination with an intralayer potential such as *AIREBO* or *Tersoff* facilitated by using pair style *hybrid/overlay*. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. This can be achieved by assigning different atom types to atoms of different layers (e.g. 1 and 2 in the examples above).

Other interactions can be set to zero using pair\_style *none*.

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = B e^{-\alpha(r_{ij} - z_0)}$$

$$+ C(1 + D_1 \rho_{ij}^2 + D_2 \rho_{ij}^4) e^{-\lambda_1 \rho_{ij}^2} e^{-\lambda_2 (z_{ij}^2 - z_0^2)}$$

$$- A \left( \frac{z_0}{r_{ij}} \right)^6 + A \left( \frac{z_0}{r_c} \right)^6$$

$$\rho_{ij}^2 = x_{ij}^2 + y_{ij}^2 \quad (\mathbf{n}_i \equiv \hat{\mathbf{z}})$$

It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of  $V_{ij}$  (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for  $V_{ij}$  above.

The provided parameter file (CC.Lebedeva) contains two sets of parameters.

- The first set (element name “C”) is suitable for normal conditions and is taken from (*Popov1*)
- The second set (element name “C1”) is suitable for high-pressure conditions and is taken from (*Koziol1*)

Both sets contain an additional parameter,  $S$ , that can be used to facilitate scaling of energies and is set to 1.0 by default.

#### 4.140.4 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

#### 4.140.5 Related commands

*pair\_coeff*, *pair\_style none*, *pair\_style hybrid/overlay*, *pair\_style drip*, *pair\_style ilp/graphene/hbd*, *pair\_style kolmogorov/crespi/z*, *pair\_style kolmogorov/crespi/full*.

pair_coeff 1 1 "qi*qj/r*erfc(alpha*r); alpha=1.067"

pair_style lepton/sphere 2.5
pair_coeff 1 * "k*((r-r0)^2*step(r0-r)); k=200; r0=radi+radj"
pair_coeff 2 2 "4.0*eps*((sig/r)^12 - (sig/r)^6); eps=1.0; sig=2.0*sqrt(radi*radj)"
```

## 4.141.3 Description

New in version 8Feb2023: added pair styles *lepton* and *lepton/coul*

Changed in version 15Jun2023: added pair style *lepton/sphere*

Pair styles *lepton*, *lepton/coul*, *lepton/sphere* compute pairwise interactions between particles which depend on the distance and have a cutoff. The potential function must be provided as an expression string using “r” as the distance variable. With pair style *lepton/coul* one may additionally reference the charges of the two atoms of the pair with “qi” and “qj”, respectively. With pair style *lepton/sphere* one may instead reference the radii of the two atoms of the pair with “radi” and “radj”, respectively; this is half of the diameter that can be set in [data files](#) or the [set command](#).

Note that further constants in the expressions can be defined in the same string as additional expressions separated by semicolons as shown in the examples above.

The expression “ $200.0*(r-1.5)^2$ ” represents a harmonic potential around the pairwise distance  $r_0$  of 1.5 distance units and a force constant  $K$  of 200.0 energy units:

$$U_{ij} = K(r - r_0)^2$$

The expression “ $qi*qj/r$ ” represents a regular Coulombic potential with cutoff:

$$U_{ij} = \frac{Cq_iq_j}{\epsilon r} \quad r < r_c$$

The expression “ $200.0*(r-(radi+radj))^2$ ” represents a harmonic potential that has the equilibrium distance chosen so that the radii of the two atoms touch:

$$U_{ij} = K(r - (r_i + r_j))^2$$

The [Lepton library](#), that the *lepton* pair style interfaces with, evaluates this expression string at run time to compute the pairwise energy. It also creates an analytical representation of the first derivative of this expression with respect to “r” and then uses that to compute the force between the pairs of particles within the given cutoff.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- Lepton expression (energy units)
- cutoff (distance units)

The Lepton expression must be either enclosed in quotes or must not contain any whitespace so that LAMMPS recognizes it as a single keyword. More on valid Lepton expressions below. The last coefficient is optional; it allows to set the cutoff for a pair of atom types to a different value than the global cutoff.

For pair style *lepton* only the “lj” values of the *special\_bonds* settings apply in case the interacting pair is also connected with a bond. The potential energy will *only* be added to the “evdwl” property.

For pair style *lepton/coul* only the “coul” values of the *special\_bonds* settings apply in case the interacting pair is also connected with a bond. The potential energy will *only* be added to the “ecoul” property.

For pair style *lepton/sphere* only the “lj” values of the *special\_bonds* settings apply in case the interacting pair is also connected with a bond. The potential energy will *only* be added to the “evdwl” property.

In addition to the functions listed below, both pair styles support in addition a custom “zbl(zi,zj,r)” function which computes the Ziegler-Biersack-Littmark (ZBL) screened nuclear repulsion for describing high-energy collisions between atoms. For details of the function please see the documentation for *pair style zbl*. The arguments of the function are the atomic numbers of atom i (zi), atom j (zj) and the distance r. Please see the examples above.

#### 4.141.4 Lepton expression syntax and features

Lepton supports the following operators in expressions:

+	Add	-	Subtract	*	Multiply	/	Divide	^	Power
---	-----	---	----------	---	----------	---	--------	---	-------

The following mathematical functions are available:

sqrt(x)	Square root	exp(x)	Exponential
log(x)	Natural logarithm	sin(x)	Sine (angle in radians)
cos(x)	Cosine (angle in radians)	sec(x)	Secant (angle in radians)
csc(x)	Cosecant (angle in radians)	tan(x)	Tangent (angle in radians)
cot(x)	Cotangent (angle in radians)	asin(x)	Inverse sine (in radians)
acos(x)	Inverse cosine (in radians)	atan(x)	Inverse tangent (in radians)
sinh(x)	Hyperbolic sine	cosh(x)	Hyperbolic cosine
tanh(x)	Hyperbolic tangent	erf(x)	Error function
erfc(x)	Complementary Error function	abs(x)	Absolute value
min(x,y)	Minimum of two values	max(x,y)	Maximum of two values
delta(x)	delta(x) is 1 for $x = 0$ , otherwise 0	step(x)	step(x) is 0 for $x < 0$ , otherwise 1

Numbers may be given in either decimal or exponential form. All of the following are valid numbers: 5, -3.1, 1e6, and 3.12e-2.

As an extension to the standard Lepton syntax, it is also possible to use LAMMPS *variables* in the format “v\_name”. Before evaluating the expression, “v\_name” will be replaced with the value of the variable “name”. This is compatible with all kinds of scalar variables, but not with vectors, arrays, local, or per-atom variables. If necessary, a custom scalar variable needs to be defined that can access the desired (single) item from a non-scalar variable. As an example, the following lines will instruct LAMMPS to ramp the force constant for a harmonic bond from 100.0 to 200.0 during the next run:

```
variable fconst equal ramp(100.0, 200)
bond_style lepton
bond_coeff 1 1.5 "v_fconst * (r^2)"
```

An expression may be followed by definitions for intermediate values that appear in the expression. A semicolon “;” is used as a delimiter between value definitions. For example, the expression:

```
a^2+a*b+b^2; a=a1+a2; b=b1+b2
```

is exactly equivalent to

```
(a1+a2)^2+(a1+a2)*(b1+b2)+(b1+b2)^2
```

The definition of an intermediate value may itself involve other intermediate values. Whitespace and quotation characters (” and “”) are ignored. All uses of a value must appear *before* that value’s definition. For efficiency reasons, the expression string is parsed, optimized, and then stored in an internal, pre-parsed representation for evaluation.

Evaluating a Lepton expression is typically between 2.5 and 5 times slower than the corresponding compiled and optimized C++ code. If additional speed or GPU acceleration (via GPU or KOKKOS) is required, the interaction can be represented as a table. Suitable table files can be created either internally using the *pair\_write* or *bond\_write* command or through the Python scripts in the *tools/tabulate* folder.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.141.5 Mixing, shift, table, tail correction, restart, rRESPA info

Pair styles *lepton*, *lepton/coul*, and *lepton/sphere* do not support mixing. Thus, expressions for *all* I,J pairs must be specified explicitly.

Only pair style *lepton* supports the *pair\_modify shift* option for shifting the potential energy of the pair interaction so that it is 0 at the cutoff, pair styles *lepton/coul* and *lepton/sphere* do *not*.

The *pair\_modify table* options are not relevant for these pair styles.

These pair styles do not support the *pair\_modify tail* option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

### 4.141.6 Restrictions

These pair styles are part of the LEPTON package and only enabled if LAMMPS was built with this package. See the [Build package](#) page for more info.

Pair style *lepton/coul* requires that atom atoms have a charge property, e.g. via *atom\_style charge*.

Pair style *lepton/sphere* requires that atom atoms have a radius property, e.g. via *atom\_style sphere*.

### 4.141.7 Related commands

*pair\_coeff*, *pair\_style python*, *pair\_style table*, *pair\_write*

### 4.141.8 Default

none

## 4.142 pair\_style line/lj command

### 4.142.1 Syntax

```
pair_style line/lj cutoff
```

cutoff = global cutoff for interactions (distance units)

### 4.142.2 Examples

```
pair_style line/lj 3.0
pair_coeff * * 1.0 1.0 1.0 0.8 1.12
pair_coeff 1 2 1.0 2.0 1.0 1.5 1.12 5.0
pair_coeff 1 2 1.0 0.0 1.0 1.0 2.5
```

### 4.142.3 Description

Style *line/lj* treats particles which are line segments as a set of small spherical particles that tile the line segment length as explained below. Interactions between two line segments, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1\*N2 Lennard-Jones interactions. Interactions between a line segment with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the [pair\\_style lj/cut](#) page for the definition of Lennard-Jones interactions.

The set of non-overlapping spherical sub-particles that represent a line segment are generated in the following manner. Their size is a function of the line segment length and the specified sub-particle size for that particle type. If a line segment has a length L and is of type I, then the number of spheres N that represent the segment is calculated as  $N = L/\text{sizeI}$ , rounded up to an integer value. Thus if L is not evenly divisible by sizeI, N is incremented to include one extra sphere. The centers of the spheres are spaced equally along the line segment. Imagine N+1 equally-space points, which include the 2 end points of the segment. The sphere centers are halfway between each pair of points.

The LJ interaction between 2 spheres on different line segments (or a sphere on a line segment and a point particles) is computed with sub-particle  $\epsilon$ ,  $\sigma$ , and *cutoff* values that are set by the *pair\_coeff* command, as described below. If

the distance between the 2 spheres is greater than the sub-particle cutoff, there is no interaction. This means that some pairs of sub-particles on 2 line segments may interact, but others may not.

For purposes of creating the neighbor list for pairs of interacting line segments or lines/point particles, a regular particle-particle cutoff is used, as defined by the *cutoff* setting above in the *pair\_style* command or overridden with an optional argument in the *pair\_coeff* command for a type pair as discussed below. The distance between the centers of 2 line segments, or the center of a line segment and a point particle, must be less than this distance (plus the neighbor skin; see the *neighbor* command), for the pair of particles to be included in the neighbor list.

---

**Note:** This means that a too-short value for the *cutoff* setting can exclude a pair of particles from the neighbor list even if pairs of their sub-particle spheres would interact, based on the sub-particle cutoff specified in the *pair\_coeff* command. E.g. sub-particles at the ends of the line segments that are close to each other. Which may not be what you want, since it means the ends of 2 line segments could pass through each other. It is up to you to specify a *cutoff* setting that is consistent with the length of the line segments you are using and the sub-particle cutoff settings.

---

For style *line/lj*, the following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *sizeI* (distance units)
- *sizeJ* (distance units)
- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- *subcutoff* (distance units)
- *cutoff* (distance units)

The *sizeI* and *sizeJ* coefficients are the sub-particle sizes for line particles of type I and type J. They are used to define the N sub-particles per segment as described above. These coefficients are actually stored on a per-type basis. Thus if there are multiple *pair\_coeff* commands that involve type I, as either the first or second atom type, you should use consistent values for *sizeI* or *sizeJ* in all of them. If you do not do this, the last value specified for *sizeI* will apply to all segments of type I. If typeI or typeJ refers to point particles, the corresponding *sizeI* or *sizeJ* is ignored; it can be set to 0.0.

The  $\epsilon$ ,  $\sigma$ , and *subcutoff* coefficients are used to compute an LJ interactions between a pair of sub-particles on 2 line segments (of type I and J), or between a sub particle/point particle pair. As discussed above, the *subcutoff* and *cutoff* params are different. The latter is only used for building the neighbor list when the distance between centers of two line segments or one segment and a point particle is calculated.

The *cutoff* coefficient is optional. If not specified, the global cutoff is used.

---

#### 4.142.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , coefficients must be specified. No default mixing rules are used.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.142.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Defining particles to be line segments so they participate in line/line or line/particle interactions requires the use the *atom\_style line* command.

### 4.142.6 Related commands

*pair\_coeff*, *pair\_style tri/lj*

### 4.142.7 Default

none

## 4.143 pair\_style list command

### 4.143.1 Syntax

```
pair_style list listfile cutoff keyword
```

- listfile = name of file with list of pairwise interactions
- cutoff = global cutoff (distance units)
- keyword = optional flag *nocheck* or *check* (default is *check*)

### 4.143.2 Examples

```
pair_style list restraints.txt 200.0
pair_coeff * *

pair_style hybrid/overlay lj/cut 1.1225 list pair_list.txt 300.0
pair_coeff * * lj/cut 1.0 1.0
pair_coeff 3* 3* list
```

### 4.143.3 Description

Style *list* computes interactions between explicitly listed pairs of atoms with the option to select functional form and parameters for each individual pair. Because the parameters are set in the list file, the *pair\_coeff* command has no parameters (but still needs to be provided). The *check* and *nocheck* keywords enable/disable tests that checks whether all listed pairs of atom IDs were present and the interactions computed. If *nocheck* is set and either atom ID is not present, the interaction is skipped.

This pair style can be thought of as a hybrid between bonded, non-bonded, and restraint interactions. It will typically be used as an additional interaction within the *hybrid/overlay* pair style. It currently supports three interaction styles: a 12-6 Lennard-Jones, a Morse and a harmonic potential.

The format of the list file is as follows:

- one line per pair of atoms
- empty lines will be ignored
- comment text starts with a '#' character
- line syntax: *ID1 ID2 style coeffs cutoff*

```
ID1 = atom ID of first atom
ID2 = atom ID of second atom
style = style of interaction
coeffs = list of coeffs
cutoff = cutoff for interaction (optional)
```

The cutoff parameter is optional for all but the *quartic* interactions. If it is not specified, the global cutoff is used.

Here is an example file:

```
# this is a comment

15 259 lj126      1.0 1.0      50.0
15 603 morse     10.0 1.2 2.0  10.0 # and another comment
18 470 harmonic  50.0 1.2      5.0
19 332 quartic   10.0 5.0 -1.2 1.2
```

The style *lj126* computes pairwise interactions with the formula

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

and the coefficients:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)

The style *morse* computes pairwise interactions with the formula

$$E = D_0 \left[ 1 - e^{-\alpha(r-r_0)} \right]^2 \quad r < r_c$$

and the coefficients:

- $D_0$  (energy units)
- $\alpha$  (1/distance units)
- $r_0$  (distance units)

The style *harmonic* computes pairwise interactions with the formula

$$E = K(r - r_0)^2 \quad r < r_c$$

and the coefficients:

- $K$  (energy units)
- $r_0$  (distance units)

Note that the usual 1/2 factor is included in  $K$ .

The style *quartic* computes pairwise interactions with the formula

$$E = K(r - r_0)^2(r - r_0 - b_1)(r - r_0 - b_2) \quad r < r_c$$

and the coefficients:

- $K$  (energy units)
  - $r_0$  (distance units)
  - $b_1$  (distance units)
  - $b_2$  (distance units)
- 

#### 4.143.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing since all parameters are explicit for each pair.

The *pair\_modify* shift option is supported by this pair style.

The *pair\_modify* table and tail options are not relevant for this pair style.

This pair style does not write its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.143.5 Restrictions

This pair style does not use a neighbor list and instead identifies atoms by their IDs. This has two consequences: 1) The cutoff has to be chosen sufficiently large, so that the second atom of a pair has to be a ghost atom on the same node on which the first atom is local; otherwise the interaction will be skipped. You can use the *check* option to detect, if interactions are missing. 2) Unlike other pair styles in LAMMPS, an atom I will not interact with multiple images of atom J (assuming the images are within the cutoff distance), but only with the closest image.

This style is part of the MISC package. It is only enabled if LAMMPS is build with that package. See the *Build package* page on for more info.

#### 4.143.6 Related commands

#### 4.143.7 Default

none

### 4.144 pair\_style lj/cut command

Accelerator Variants: *lj/cut/gpu*, *lj/cut/intel*, *lj/cut/kk*, *lj/cut/opt*, *lj/cut/omp*

### 4.144.1 Syntax

```
pair_style style args
```

- style = *lj/cut*
- args = list of arguments for a particular style

*lj/cut* args = cutoff

cutoff = global cutoff for Lennard Jones interactions (distance units)

### 4.144.2 Examples

```
pair_style lj/cut 2.5
pair_coeff * * 1 1
pair_coeff 1 1 1 1.1 2.8
```

### 4.144.3 Description

The *lj/cut* styles compute the standard 12/6 Lennard-Jones potential, given by

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

$r_c$  is the cutoff.

See the *lj/cut/coul* styles to add a Coulombic pairwise interaction and the *lj/cut/tip4p* styles to add the TIP4P water model.

### 4.144.4 Coefficients

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- LJ cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the *pair\_style* command is used.

Note that  $\sigma$  is defined in the LJ formula as the zero-crossing distance for the potential, *not* as the energy minimum at  $r_0 = 2^{\frac{1}{6}} \sigma$ . The *\_same\_* potential function becomes:

$$E = \epsilon \left[ \left( \frac{r_0}{r} \right)^{12} - 2 \left( \frac{r_0}{r} \right)^6 \right] \quad r < r_c$$

When using the minimum as reference width. In the literature both formulations are used, but they describe the same potential, only the  $\sigma$  value must be computed by  $\sigma = r_0 / 2^{\frac{1}{6}}$  for use with LAMMPS, if this latter formulation is used.

A version of these styles with a soft core, *lj/cut/soft*, suitable for use in free energy calculations, is part of the FEP package and is documented with the *pair\_style \*/soft* styles.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.144.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs *I,J* and *I != J*, the epsilon and sigma coefficients and cutoff distance for all of the *lj/cut* pair styles can be mixed. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

All of the *lj/cut* pair styles support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction.

All of the *lj/cut* pair styles support the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the *lj/cut* pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

The *lj/cut* pair styles support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the *pair* keyword of *run\_style respa*. See the *run\_style* command for details.

---

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.145.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style supports the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the *run\_style* command for details.

---

#### 4.145.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

#### 4.145.6 Related commands

*pair\_coeff*

#### 4.145.7 Default

none

### 4.146 pair\_style lj/cubic command

Accelerator Variants: *lj/cubic/gpu*, *lj/cubic/omp*

#### 4.146.1 Syntax

```
pair_style lj/cubic
```

## 4.146.2 Examples

```
pair_style lj/cubic
pair_coeff * * 1.0 0.8908987
```

## 4.146.3 Description

The *lj/cubic* style computes a truncated LJ interaction potential whose energy and force are continuous everywhere. Inside the inflection point the interaction is identical to the standard 12/6 *Lennard-Jones* potential. The LJ function outside the inflection point is replaced with a cubic function of distance. The energy, force, and second derivative are continuous at the inflection point. The cubic coefficient  $A_3$  is chosen so that both energy and force go to zero at the cutoff distance. Outside the cutoff distance the energy and force are zero.

$$\begin{aligned} E &= u_{LJ}(r) & r &\leq r_s \\ &= u_{LJ}(r_s) + (r - r_s)u'_{LJ}(r_s) - \frac{1}{6}A_3(r - r_s)^3 & r_s < r \leq r_c \\ &= 0 & r > r_c \end{aligned}$$

The location of the inflection point  $r_s$  is defined by the LJ diameter,  $r_s/\sigma = (26/7)^{1/6}$ . The cutoff distance is defined by  $r_c/r_s = 67/48$  or  $r_c/\sigma = 1.737\dots$ . The analytic expression for the cubic coefficient  $A_3r_{min}^3/\epsilon = 27.93\dots$  is given in the paper by Holian and Ravelo (*Holian*).

This potential is commonly used to study the shock mechanics of FCC solids, as in Ravelo et al. (*Ravelo*).

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)

Note that  $\sigma$  is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum, which is located at  $r_{min} = 2^{\frac{1}{6}}\sigma$ . In the above example,  $\sigma = 0.8908987$ , so  $r_{min} = 1.0$ .

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.146.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

The lj/cubic pair style does not support the *pair\_modify* shift option, since pair interaction is already smoothed to 0.0 at the cutoff.

The *pair\_modify* table option is not relevant for this pair style.

The lj/cubic pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

The lj/cubic pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/cubic pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.146.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.146.6 Related commands

## 4.152.3 Description

The *lj/cut/coul* styles compute the standard 12/6 Lennard-Jones potential, given by

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

$r_c$  is the cutoff.

Style *lj/cut/coul/cut* adds a Coulombic pairwise interaction given by

$$E = \frac{Cq_iq_j}{\epsilon r} \quad r < r_c$$

where  $C$  is an energy-conversion constant,  $q_i$  and  $q_j$  are the charges on the two atoms, and  $\epsilon$  is the dielectric constant which can be set by the *dielectric* command. If one cutoff is specified in the *pair\_style* command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

Style *lj/cut/coul/debye* adds an additional  $\exp()$  damping factor to the Coulombic term, given by

$$E = \frac{Cq_iq_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c$$

where  $\kappa$  is the inverse of the Debye length. This potential is another way to mimic the screening effect of a polar solvent.

Style *lj/cut/coul/dsf* computes the Coulombic term via the damped shifted force model described in [Fennell](#), given by:

$$E = q_i q_j \left[ \frac{\text{erfc}(\alpha r)}{r} - \frac{\text{erfc}(\alpha r_c)}{r_c} + \left( \frac{\text{erfc}(\alpha r_c)}{r_c^2} + \frac{2\alpha}{\sqrt{\pi}} \frac{\exp(-\alpha^2 r_c^2)}{r_c} \right) (r - r_c) \right] \quad r < r_c$$

where  $\alpha$  is the damping parameter and  $\text{erfc}()$  is the complementary error-function. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise  $1/r$  summation. The potential is based on Wolf summation, proposed as an alternative to Ewald summation for condensed phase systems where charge screening causes electrostatic interactions to become effectively short-ranged. In order for the electrostatic sum to be absolutely convergent, charge neutralization within the cutoff radius is enforced by shifting the potential through placement of image charges on the cutoff sphere. Convergence can often be improved by setting  $\alpha$  to a small non-zero value.

Styles *lj/cut/coul/long* and *lj/cut/coul/msm* compute the same Coulombic interactions as style *lj/cut/coul/cut* except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *k<sub>space</sub> style* command and its *ewald* or *pppm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

Style *lj/cut/coul/wolf* adds a Coulombic pairwise interaction via the Wolf summation method, described in [Wolf](#), given by:

$$E_i = \frac{1}{2} \sum_{j \neq i} \frac{q_i q_j \text{erfc}(\alpha r_{ij})}{r_{ij}} + \frac{1}{2} \sum_{j \neq i} \frac{q_i q_j \text{erf}(\alpha r_{ij})}{r_{ij}} \quad r < r_c$$

where  $\alpha$  is the damping parameter, and  $\text{erfc}()$  is the complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise  $1/r$  summation. With a manipulation of adding and subtracting a self term (for  $i = j$ ) to the first and second term on the right-hand-side, respectively, and a small enough  $\alpha$  damping parameter, the second term shrinks and the potential becomes a rapidly-converging real-space summation. With a long enough cutoff and small enough  $\alpha$  parameter, the energy and forces calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.

## 4.152.4 Coefficients

For all of the *lj/cut/coul* pair styles, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

Note that  $\sigma$  is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at  $2^{\frac{1}{6}}\sigma$ .

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the *pair\_style* command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

For *lj/cut/coul/long* and *lj/cut/coul/msm* only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the *pair\_style* command.

A version of these styles with a soft core, *lj/cut/coul/soft* and *lj/cut/coul/long/soft*, suitable for use in free energy calculations, is part of the FEP package and is documented with the *pair\_style \*/soft* styles.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 4.152.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the *lj/cut* pair styles can be mixed. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

All of the *lj/cut* pair styles support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction.

The *lj/cut/coul/long* pair styles support the *pair\_modify* table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the *lj/cut* pair styles support the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the *lj/cut* pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

The *lj/cut/coul/long* pair styles support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the *pair* keyword of *run\_style respa*. See the *run\_style* command for details.

---

### 4.152.6 Restrictions

The *lj/cut/coul/long* and *lj/cut/coul/msm* styles are part of the KSPACE package.

The *lj/cut/coul/debye*, *lj/cut/coul/dsf*, and *lj/cut/coul/wolf* styles are part of the EXTRA-PAIR package.

These styles are only enabled if LAMMPS was built with those respective packages. See the *Build package* page for more info.

## 4.153 pair\_style lj/cut/sphere command

Accelerator Variant: *lj/cut/sphere/omp*

### 4.153.1 Syntax

```
pair_style style args
```

- style = *lj/cut/sphere*
- args = list of arguments for a particular style

*lj/cut/sphere* args = cutoff ratio

cutoff = global cutoff ratio for Lennard Jones interactions (unitless)

### 4.153.2 Examples

```
pair_style lj/cut/sphere 2.5
pair_coeff * * 1.0
pair_coeff 1 1 1.1 2.8
```

### 4.153.3 Description

New in version 15Jun2023.

The *lj/cut/sphere* style compute the standard 12/6 Lennard-Jones potential, given by

$$E = 4\epsilon \left[ \left( \frac{\sigma_{ij}}{r} \right)^{12} - \left( \frac{\sigma_{ij}}{r} \right)^6 \right] \quad r < r_c * \sigma_{ij}$$

$r_c$  is the cutoff ratio.

This is the same potential function used by the *lj/cut* pair style, but the  $\sigma_{ij}$  parameter is not set as a per-type parameter via the *pair\_coeff* command. Instead it is calculated individually for each pair using the per-atom diameter attribute of *atom\_style sphere* for the two atoms as  $\sigma_i$  and  $\sigma_j$ ;  $\sigma_{ij}$  is then computed by the mixing rule for pair coefficients as set by the *pair\_modify mix* command (defaults to geometric mixing). The cutoff is not specified as a distance, but as ratio that is internally multiplied by  $\sigma_{ij}$  to obtain the actual cutoff for each pair of atoms.

Note that  $\sigma_{ij}$  is defined in the LJ formula above as the zero-crossing distance for the potential, *not* as the energy minimum which is at  $2^{\frac{1}{6}}\sigma_{ij}$ .

### Notes on cutoffs, neighbor lists, and efficiency

If your system is mildly polydisperse, meaning the ratio of the diameter of the largest particle to the smallest is less than 2.0, then the neighbor lists built by the code should be reasonably efficient. Which means they will not contain too many particle pairs that do not interact. However, if your system is highly polydisperse (ratio > 2.0), the neighbor list build and force computations may be inefficient. There are two ways to try and speed up the simulations.

The first is to assign atoms to different atom types so that atoms of each type are similar in size. E.g. if particle diameters range from 1 to 5 use 4 atom types, ensuring atoms of type 1 have diameters from 1.0-2.0, type 2 from 2.0-3.0, etc. This will reduce the number of non-interacting pairs in the neighbor lists and thus reduce the time spent on computing pairwise interactions.

The second is to use the *neighbor multi* command which enabled a different algorithm for building neighbor lists. This will also require that you assign multiple atom types according to diameters, but will in addition use a more efficient size-dependent strategy to construct the neighbor lists and thus reduce the time spent on building neighbor lists.

Here are example input script commands using both ideas for a highly polydisperse system:

```
units          lj
atom_style     sphere
lattice        fcc 0.8442
region         box block 0 10 0 10 0 10
create_box     2 box
create_atoms   1 box

# create atoms with random diameters from bimodal distribution
variable switch atom random(0.0,1.0,345634)
variable diam atom (v_switch<0.75)*normal(0.4,0.075,325)+(v_switch>=0.7)*normal(1.2,0.2,
→453)
set group all diameter v_diam

# assign type 2 to atoms with diameter > 0.6
variable large atom (2.0*radius)>0.6
group large variable large
set group large type 2

pair_style      lj/cut/sphere 2.5
pair_coeff       * * 1.0

neighbor 0.3 multi
```

Using multiple atom types speeds up the calculation for this example by more than a factor of 2, and using the multi-style neighbor list build causes an additional speedup of about 20 percent.

#### 4.153.4 Coefficients

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- LJ cutoff ratio (unitless) (optional)

The last coefficient is optional. If not specified, the global LJ cutoff ratio specified in the *pair\_style command* is used.

If a repulsive only LJ interaction is desired, the coefficient for the cutoff ratio should be set to the minimum of the LJ potential using  $(2.0^{(1.0/6.0)})$

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.153.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon coefficients and cutoff ratio for the *lj/cut/sphere* pair style can be mixed. The default mixing style is *geometric*. See the *pair\_modify command* for details.

The *lj/cut/sphere* pair style supports the *pair\_modify shift* option for the energy of the Lennard-Jones portion of the pair interaction.

The *lj/cut/sphere* pair style does *not* support the *pair\_modify tail* option for adding a long-range tail corrections to the energy and pressure.

The *lj/cut/sphere* pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does *not* support the *inner*, *middle*, *outer* keywords.

---

### 4.153.6 Restrictions

The *lj/cut/sphere* pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the [Build package](#) page for more info.

The *lj/cut/sphere* pair style does not support the *sixthpower* mixing rule.

## 4.155.3 Description

The *lj/cut/tip4p* styles implement the TIP4P water model of ([Jorgensen](#)) and similar models, which introduce a massless site M located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as *pair\_style* arguments and are used to identify the TIP4P-like molecules and determine the position of the M site from the positions of the hydrogen and oxygen atoms of the water molecules. The M site location is used for all Coulomb interactions instead of the oxygen atom location, also with all other atom types, while the location of the oxygen atom is used for the Lennard-Jones interactions. Style *lj/cut/tip4p/cut* uses a cutoff for Coulomb interactions; style *lj/cut/tip4p/long* is for use with a long-range Coulombic solver (Ewald or PPPM).

---

**Note:** For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

---

---

**Note:** If using type labels, the type labels must be defined before calling the *pair\_coeff* command.

---

See the [Howto tip4p](#) page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance  $2*qdist$  when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff  $\geq$  Coulombic cutoff +  $2*qdist$ , to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

The *lj/cut/tip4p* styles compute the standard 12/6 Lennard-Jones potential, given by

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

$r_c$  is the cutoff.

They add Coulombic pairwise interactions given by

$$E = \frac{Cq_iq_j}{\epsilon r} \quad r < r_c$$

where  $C$  is an energy-conversion constant,  $q_i$  and  $q_j$  are the charges on the two atoms, and  $\epsilon$  is the dielectric constant which can be set by the [dielectric](#) command. If one cutoff is specified in the `pair_style` command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

Style `lj/cut/tip4p/long` compute the same Coulombic interactions as style `lj/cut/tip4p/cut` except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the `kspace_style` command and its `ewald` or `pppm` option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

#### 4.155.4 Coefficients

For all of the `lj/cut` pair styles, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- LJ cutoff (distance units)

Note that  $\sigma$  is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at  $2^{\frac{1}{6}}\sigma$ .

The last coefficient is optional. If not specified, the global LJ cutoff specified in the `pair_style` command is used.

For `lj/cut/tip4p/cut` and `lj/cut/tip4p/long` only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the `pair_style` command.

**Warning:** Because of how these pair styles implement the coulomb interactions by implicitly defining a fourth site for the negative charge of the TIP4P and similar water models, special care must be taken when using these pair styles with other computations that also use charges. Unless they are specially set up to also handle the implicit definition of the 4th site, results are likely incorrect. Example: [compute dipole/chunk](#). For the same reason, when using one of these pair styles with `pair_style hybrid`, **all** coulomb interactions should be handled by a single sub-style with TIP4P support. All other instances and styles will “see” the M point charges at the position of the Oxygen atom and thus compute incorrect forces and energies. LAMMPS will print a warning when it detects one of these issues.

A version of these styles with a soft core, `lj/cut/tip4p/long/soft`, suitable for use in free energy calculations, is part of the FEP package and is documented with the `pair_style */soft` styles.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` [command-line switch](#) when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.155.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the `lj/cut` pair styles can be mixed. The default mix value is *geometric*. See the “`pair_modify`” command for details.

All of the `lj/cut` pair styles support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction.

The `lj/cut/coul/long` and `lj/cut/tip4p/long` pair styles support the *pair\_modify* table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the `lj/cut` pair styles support the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the `lj/cut` pair styles write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

The `lj/cut` and `lj/cut/coul/long` pair styles support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the *pair* keyword of *run\_style respa*. See the *run\_style* command for details.

---

#### 4.155.6 Restrictions

The `lj/cut/tip4p/long` styles are part of the KSPACE package. The `lj/cut/tip4p/cut` style is part of the MOLECULE package. These styles are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

### 4.156 pair\_style lj/expand command

Accelerator Variants: *lj/expand/gpu*, *lj/expand/kk*, *lj/expand/omp*

## 4.157 pair\_style lj/expand/coul/long command

Accelerator Variants: *lj/expand/coul/long/gpu*, *lj/expand/coul/long/kk*

### 4.157.1 Syntax

```
pair_style lj/expand cutoff
```

- cutoff = global cutoff for lj/expand interactions (distance units)

### 4.157.2 Examples

```
pair_style lj/expand 2.5
pair_coeff * * 1.0 1.0 0.5
pair_coeff 1 1 1.0 1.0 -0.2 2.0

pair_style lj/expand/coul/long 2.5
pair_style lj/expand/coul/long 2.5 4.0
pair_coeff * * 1.0 1.0 0.5
pair_coeff 1 1 1.0 1.0 -0.2 3.0
```

### 4.157.3 Description

Style *lj/expand* computes a LJ interaction with a distance shifted by delta which can be useful when particles are of different sizes, since it is different that using different sigma values in a standard LJ formula:

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r - \Delta} \right)^{12} - \left( \frac{\sigma}{r - \Delta} \right)^6 \right] \quad r < r_c + \Delta$$

$r_c$  is the cutoff which does not include the  $\Delta$  distance. I.e. the actual force cutoff is the sum of  $r_c + \Delta$ .

For all of the *lj/expand* pair styles, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $\Delta$  (distance units)
- cutoff (distance units)

The  $\Delta$  values can be positive or negative. The last coefficient is optional. If not specified, the global LJ cutoff is used.

For *lj/expand/coul/long* only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the *pair\_style* command.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* *command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.157.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I,J$  and  $I \neq J$ , the epsilon, sigma, and shift coefficients and cutoff distance for this pair style can be mixed. Shift is always mixed via an *arithmetic* rule. The other coefficients are mixed according to the *pair\_modify* mix value. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style supports the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.158 *pair\_style lj/expand/sphere* command

Accelerator Variant: *lj/expand/sphere/omp*

## 4.158.1 Syntax

```
pair_style style args
```

- style = *lj/expand/sphere*
- args = list of arguments for a particular style

*lj/expand/sphere* args = cutoff

cutoff = global cutoff for Lennard Jones interactions (distance units)

## 4.158.2 Examples

```
pair_style lj/expand/sphere 2.5
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.1 0.4 2.8
```

## 4.158.3 Description

New in version 15Jun2023.

The *lj/expand/sphere* style compute a 12/6 Lennard-Jones potential with a distance shifted by  $\Delta = \frac{1}{2}(d_i + d_j)$ , the average diameter of both atoms. This can be used to model particles of different sizes but same interactions, which is different from using different sigma values as in *pair style lj/cut/sphere*.

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r - \Delta} \right)^{12} - \left( \frac{\sigma}{r - \Delta} \right)^6 \right] \quad r < r_c + \Delta$$

$r_c$  is the cutoff which does not include the distance  $\Delta$ . I.e. the actual force cutoff is the sum  $r_c + \Delta$ .

This is the same potential function used by the *lj/expand* pair style, but the  $\Delta$  parameter is not set as a per-type parameter via the *pair\_coeff* command. Instead it is calculated individually for each pair using the per-atom diameter attribute of *atom\_style sphere* for the two atoms as the average diameter,  $\Delta = \frac{1}{2}(d_i + d_j)$

Note that  $\sigma$  is defined in the LJ formula above as the zero-crossing distance for the potential, *not* as the energy minimum which is at  $2^{\frac{1}{6}}\sigma$ .

---

### Notes on cutoffs, neighbor lists, and efficiency

If your system is mildly polydisperse, meaning the ratio of the diameter of the largest particle to the smallest is less than 2.0, then the neighbor lists built by the code should be reasonably efficient. Which means they will not contain too many particle pairs that do not interact. However, if your system is highly polydisperse (ratio > 2.0), the neighbor list build and force computations may be inefficient. There are two ways to try and speed up the simulations.

The first is to assign atoms to different atom types so that atoms of each type are similar in size. E.g. if particle diameters range from 1 to 5 use 4 atom types, ensuring atoms of type 1 have diameters from 1.0-2.0, type 2 from 2.0-3.0, etc. This will reduce the number of non-interacting pairs in the neighbor lists and thus reduce the time spent on computing pairwise interactions.

The second is to use the *neighbor multi* command which enabled a different algorithm for building neighbor lists. This will also require that you assign multiple atom types according to diameters, but will in addition use a more efficient size-dependent strategy to construct the neighbor lists and thus reduce the time spent on building neighbor lists.

Here are example input script commands using the first option for a highly polydisperse system:

```
units          lj
atom_style     sphere
lattice        fcc 0.8442
region         box block 0 10 0 10 0 10
create_box     2 box
create_atoms   1 box

# create atoms with random diameters from bimodal distribution
variable switch atom random(0.0,1.0,345634)
variable diam atom (v_switch<0.75)*normal(0.2,0.04,325)+(v_switch>=0.7)*normal(0.6,0.2,
→453)
set group all diameter v_diam

# assign type 2 to atoms with diameter > 0.35
variable large atom (2.0*radius)>0.35
group large variable large
set group large type 2

pair_style      lj/expand/sphere 2.0
pair_coeff      * * 1.0 0.5

neighbor 0.3 bin
```

Using multiple atom types speeds up the calculation for this example by more than 30 percent, but using the multi-style neighbor list does not provide a speedup.

---

#### 4.158.4 Coefficients

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- LJ cutoff (distance units) (optional)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the *pair\_style* command is used.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 4.158.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon, sigma, and cutoff coefficients for the *lj/expand/sphere* pair style can be mixed. The default mixing style is *geometric*. See the *pair\_modify command* for details.

The *lj/expand/sphere* pair style supports the *pair\_modify shift* option for the energy of the Lennard-Jones portion of the pair interaction.

The *lj/expand/sphere* pair style does *not* support the *pair\_modify tail* option for adding a long-range tail corrections to the energy and pressure.

The *lj/expand/sphere* pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does *not* support the *inner*, *middle*, *outer* keywords.

---

### 4.158.6 Restrictions

The *lj/expand/sphere* pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the *Build package* page for more info.

```

### 4.160.3 Description

Style *lj/long/coul/long* computes the standard 12/6 Lennard-Jones potential:

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

with  $\epsilon$  and  $\sigma$  being the usual Lennard-Jones potential parameters, plus the Coulomb potential, given by:

$$E = \frac{Cq_iq_j}{\epsilon r} \quad r < r_c$$

where  $C$  is an energy-conversion constant,  $q_i$  and  $q_j$  are the charges on the two atoms,  $\epsilon$  is the dielectric constant which can be set by the *dielectric* command, and  $r_c$  is the cutoff. If one cutoff is specified in the *pair\_style* command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive  $1/r^6$  Lennard-Jones and Coulombic  $1/r$  interactions. This is done by use of the *flag\_lj* and *flag\_coul* settings. The *In 't Veld* paper has more details on when it is appropriate to include long-range  $1/r^6$  interactions, using this potential.

Style *lj/long/tip4p/long* implements the TIP4P water model of (*Jorgensen*), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as *pair\_style* arguments.

---

**Note:** For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

---

---

**Note:** If using type labels, the type labels must be defined before calling the *pair\_coeff* command.

---

See the *Howto tip4p* page for more information on how to use the TIP4P pair style. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance  $2*qd_{\text{ist}}$  when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff  $\geq$  Coulombic cutoff +  $2*qd_{\text{ist}}$ , to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

If *flag\_lj* is set to *long*, no cutoff is used on the LJ  $1/r^6$  dispersion term. The long-range portion can be calculated by using the *kpspace\_style ewald/disp* or *pppm/disp* commands. The specified LJ cutoff then determines which portion of the LJ interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If *flag\_lj* is set to *cut*, the LJ interactions are simply cutoff, as with *pair\_style lj/cut*.

If *flag\_coul* is set to *long*, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several *kpspace\_style* command options such as *pppm* or *ewald*. Note that if *flag\_lj* is also set to *long*, then the *ewald/disp* or *pppm/disp* Kspace style needs to be used to perform the long-range calculations for both the LJ and Coulombic interactions. If *flag\_coul* is set to *off*, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- cutoff1 (distance units)

- cutoff2 (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at  $2^{1/6}$  sigma.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the `pair_style` command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

Note that if you are using `flag_lj` set to *long*, you cannot specify a LJ cutoff for an atom type pair, since only one global LJ cutoff is allowed. Similarly, if you are using `flag_coul` set to *long*, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.

For *lj/long/tip4p/long* only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the `pair_style` command.

---

A version of these styles with a soft core, *lj/cut/soft*, suitable for use in free energy calculations, is part of the FEP package and is documented with the *pair\_style \*/soft* styles. The version with soft core is only available if LAMMPS was built with that package. See the *Build package* page for more info.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.160.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the *lj/long* pair styles can be mixed. The default mix value is *geometric*. See the “`pair_modify`” command for details.

These pair styles support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction, assuming *flag\_lj* is *cut*.

These pair styles support the *pair\_modify* table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.

These pair styles do not support the *pair\_modify* tail option for adding a long-range tail correction to the Lennard-Jones portion of the energy and pressure.

These pair styles write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

The pair *lj/long/coul/long* styles support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the *run\_style* command for details.

---

### 4.160.5 Restrictions

These styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 4.161 pair\_style lj/relres command

Accelerator Variants: *lj/relres/omp*

### 4.161.1 Syntax

```
pair_style lj/relres Rsi Rso Rci Rco
```

- Rsi = inner switching cutoff between the fine-grained and coarse-grained potentials (distance units)
- Rso = outer switching cutoff between the fine-grained and coarse-grained potentials (distance units)
- Rci = inner cutoff beyond which the force smoothing for all interactions is applied (distance units)
- Rco = outer cutoff for all interactions (distance units)

### 4.161.2 Examples

```
pair_style lj/relres 4.0 5.0 8.0 10.0
pair_coeff 1 1 0.5 1.0 1.5 1.1
pair_coeff 2 2 0.5 1.0 0.0 0.0 3.0 3.5 6.0 7.0
```

### 4.161.3 Description

Pair style *lj/relres* computes a LJ interaction using the Relative Resolution (RelRes) framework which applies a fine-grained (FG) potential between near neighbors and a coarse-grained (CG) potential between far neighbors

(*Chaimovich1*). This approach can improve the computational efficiency by almost an order of magnitude, while maintaining the correct static and dynamic behavior of a reference system (*Chaimovich2*).

$$E = \begin{cases} 4\epsilon^{FG} \left[ \left( \frac{\sigma^{FG}}{r} \right)^{12} - \left( \frac{\sigma^{FG}}{r} \right)^6 \right] - \Gamma_{si}, & \text{if } r < r_{si}, \\ \sum_{m=0}^4 \gamma_{sm} (r - r_{si})^m - \Gamma_{so}, & \text{if } r_{si} \leq r < r_{so}, \\ 4\epsilon^{CG} \left[ \left( \frac{\sigma^{CG}}{r} \right)^{12} - \left( \frac{\sigma^{CG}}{r} \right)^6 \right] - \Gamma_c, & \text{if } r_{so} \leq r < r_{ci}, \\ \sum_{m=0}^4 \gamma_{cm} (r - r_{ci})^m - \Gamma_c, & \text{if } r_{ci} \leq r < r_{co}, \\ 0, & \text{if } r \geq r_{co}. \end{cases}$$

The FG parameters of the LJ potential ( $\epsilon^{FG}$  and  $\sigma^{FG}$ ) are applied up to the inner switching cutoff,  $r_{si}$ , while the CG parameters of the LJ potential ( $\epsilon^{CG}$  and  $\sigma^{CG}$ ) are applied beyond the outer switching cutoff,  $r_{so}$ . Between  $r_{si}$  and  $r_{so}$  a polynomial smoothing function is applied so that the force and its derivative are continuous between the FG and CG potentials. An analogous smoothing function is applied between the inner and outer cutoffs ( $r_{ci}$  and  $r_{co}$ ). The offsets  $\Gamma_{si}$ ,  $\Gamma_{so}$  and  $\Gamma_c$  ensure the continuity of the energy over the entire domain. The corresponding polynomial coefficients  $\gamma_{sm}$  and  $\gamma_{cm}$ , as well as the offsets are automatically computed by LAMMPS.

---

**Note:** Energy and force resulting from this methodology can be plotted via the `pair_write` command.

---

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as will be described below:

- $\epsilon^{FG}$  (energy units)
- $\sigma^{FG}$  (distance units)
- $\epsilon^{CG}$  (energy units)
- $\sigma^{CG}$  (distance units)

Additional parameters can be defined to specify different  $r_{si}$ ,  $r_{so}$ ,  $r_{ci}$ ,  $r_{co}$  for a particular set of atom types:

- $r_{si}$  (distance units)
- $r_{so}$  (distance units)
- $r_{ci}$  (distance units)
- $r_{co}$  (distance units)

These parameters are optional, and they are used to override the global cutoffs as defined in the `pair_style` command. If not specified, the global values for  $r_{si}$ ,  $r_{so}$ ,  $r_{ci}$ , and  $r_{co}$  are used. If this override option is employed, all four arguments must be specified.

---

Here are some guidelines for using the `pair_style lj/relres` command.

In general, RelRes focuses on the speedup of pairwise interactions between all LJ sites. Importantly, it works with any settings and flags (e.g., `special_bonds` settings and `newton` flags) that can be used in a molecular simulation with the conventional LJ potential. In particular, all intramolecular topology with its energetics (i.e., bonds, angles, etc.) remains unaltered.

At the most basic level in the RelRes framework, all sites are mapped into clusters. Each cluster is just a collection of sites bonded together (the bonds themselves are not part of the cluster). In general, a molecule may be comprised of several clusters, and preferably, no two sites in a cluster are separated by more than two bonds. There are two categories of sites in RelRes: “hybrid” sites embody both FG and CG models, while “ordinary” sites embody just FG characteristics with no CG features. A given cluster has a single hybrid site (typically its central site) and several

ordinary sites (typically its peripheral sites). Notice that while clusters are necessary for the RelRes parameterization (discussed below), they are not actually defined in LAMMPS. Besides, the total number of sites in the cluster are called the “mapping ratio”, and this substantially impacts the computational efficiency of RelRes: For a mapping ratio of 3, the efficiency factor is around 4, and for a mapping ratio of 5, the efficiency factor is around 5 ([Chaimovich2](#)).

The flexibility of LAMMPS allows placing any values for the LJ parameters in the input script. However, here are the optimal recommendations for the RelRes parameters, which yield the correct structural and thermal behavior in a system of interest ([Chaimovich1](#)). One must first assign a complete set of parameters for the FG interactions that are applicable to all atom types. Regarding the parameters for the CG interactions, the rules rely on the site category (if it is a hybrid or an ordinary site). For atom types of ordinary sites,  $\epsilon^{CG}$  must be set to 0 (zero) while the specific value of  $\sigma^{CG}$  is irrelevant. For atom types of hybrid sites, the CG parameters should be generally calculated using the following equations:

$$\sigma_I^{CG} = \frac{\left( \sum_{\alpha \in A} \sqrt{\epsilon_{\alpha}^{FG} (\sigma_{\alpha}^{FG})^{12}} \right)^{1/2}}{\left( \sum_{\alpha \in A} \sqrt{\epsilon_{\alpha}^{FG} (\sigma_{\alpha}^{FG})^6} \right)^{1/3}} \quad \text{and} \quad \epsilon_I^{CG} = \frac{\left( \sum_{\alpha \in A} \sqrt{\epsilon_{\alpha}^{FG} (\sigma_{\alpha}^{FG})^6} \right)^4}{\left( \sum_{\alpha \in A} \sqrt{\epsilon_{\alpha}^{FG} (\sigma_{\alpha}^{FG})^{12}} \right)^2}$$

where  $I$  is an atom type of a hybrid site of a particular cluster  $A$ , and corresponding with this cluster, the summation proceeds over all of its sites  $\alpha$ . These equations are derived from the monopole term in the underlying Taylor series, and they are indeed relevant only if geometric mixing is applicable for the FG model; if this is not the case, Ref. ([Chaimovich2](#)) discusses the alternative formula, and in such a situation, the `pair_coeff` command should be explicitly used for all combinations of atom types  $I \neq J$ .

The switching distance (the midpoint between inner and outer switching cutoffs) is another crucial factor in RelRes: decreasing it improves the computational efficiency, yet if it is too small, the molecular simulations may not capture the system behavior correctly. As a rule of thumb, the switching distance should be approximately  $\sim 1.5\sigma$  ([Chaimovich1](#)); recommendations can be found in Ref. ([Chaimovich2](#)). Regarding the switching smoothing zone,  $\sim 0.1\sigma$  is recommended; if desired, smoothing can be eliminated by setting the inner switching cutoff,  $r_{si}$ , equal to the outer switching cutoff,  $r_{so}$  (the same is true for the other cutoffs  $r_{ci}$  and  $r_{co}$ ).

As an example, imagine that in your system, a molecule is comprised just of one cluster such that one atom type (#1) is associated with its hybrid site, and another atom type (#2) is associated with its ordinary sites (in total, there are 2 atom types). If geometric mixing is applicable, the following commands should be used:

```
pair_style lj/relres Rsi Rso Rci Rco
pair_coeff 1 1 epsilon_FG1 sigma_FG1 epsilon_CG1 sigma_CG1
pair_coeff 2 2 epsilon_FG2 sigma_FG2 0.0 0.0
pair_modify shift yes
```

In a more complex situation, there may be two distinct clusters in a system (these two clusters may be on same molecule or on different molecules), each with its own switching cutoffs. If there are still two atom types in each cluster as in the earlier example, the commands should be:

```
pair_style lj/relres Rsi Rso Rci Rco
pair_coeff 1 1 epsilon_FG1 sigma_FG1 epsilon_CG1 sigma_CG1 Rsi1 Rso1 Rci Rco
pair_coeff 2 2 epsilon_FG2 sigma_FG2 0.0 0.0 Rsi1 Rso1 Rci Rco
pair_coeff 3 3 epsilon_FG3 sigma_FG3 epsilon_CG3 sigma_CG3
pair_coeff 4 4 epsilon_FG4 sigma_FG4 0.0 0.0
pair_modify shift yes
```

In this example, the switching cutoffs for the first cluster (atom types 1 and 2) is defined explicitly in the `pair_coeff` command which overrides the global values, while the second cluster (atom types 3 and 4) uses the global definition from the `pair_style` command. The emphasis here is that the atom types that belong to a specific cluster should have the same switching/cutoff arguments.

In the case that geometric mixing is not applicable, for simulating the system from the previous example, we recommend using the following commands:

```
pair_style lj/relres Rsi Rso Rci Rco
pair_coeff 1 1 epsilon_FG1 sigma_FG1 epsilon_CG1 sigma_CG1 Rsi1 Rso1 Rci Rco
pair_coeff 1 2 epsilon_FG12 sigma_FG12 0.0 0.0 Rsi1 Rso1 Rci Rco
pair_coeff 1 3 epsilon_FG13 sigma_FG13 epsilon_CG13 sigma_CG13 Rsi13 Rso13 Rci Rco
pair_coeff 1 4 epsilon_FG14 sigma_FG14 0.0 0.0 Rsi13 Rso13 Rci Rco
pair_coeff 2 2 epsilon_FG2 sigma_FG2 0.0 0.0 Rsi1 Rso1 Rci Rco
pair_coeff 2 3 epsilon_FG23 sigma_FG23 0.0 0.0 Rsi13 Rso13 Rci Rco
pair_coeff 2 4 epsilon_FG24 sigma_FG24 0.0 0.0 Rsi13 Rso13 Rci Rco
pair_coeff 3 3 epsilon_FG3 sigma_FG3 epsilon_CG3 sigma_CG3
pair_coeff 3 4 epsilon_FG34 sigma_FG34 0.0 0.0
pair_coeff 4 4 epsilon_FG4 sigma_FG4 0.0 0.0
pair_modify shift yes
```

Notice that the CG parameters are mixed only for interactions between atom types associated with hybrid sites, and that the cutoffs are mixed on the cluster basis.

More examples can be found in the *examples/relres* folder.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.161.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  with  $I \neq J$ , the  $\epsilon^{FG}$ ,  $\sigma^{FG}$ ,  $\epsilon^{CG}$ ,  $\sigma^{CG}$ ,  $r_{si}$ ,  $r_{so}$ ,  $r_{ci}$ , and  $r_{co}$  parameters for this pair style can be mixed, if not defined explicitly. All parameters are mixed according to the *pair\_modify* mix option. The default mix value is *geometric*, and it is recommended to use with this *lj/relres* style. See the “*pair\_modify*” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction. It is recommended to set this option to *yes*. Otherwise, the offset  $\Gamma_c$  is set to zero. Constants  $\Gamma_{si}$  and  $\Gamma_{so}$  are not impacted by this option.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.161.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.161.6 Related commands

## 4.162 pair\_style lj/smooth command

Accelerator Variants: *lj/smooth/gpu*, *lj/smooth/omp*

### 4.162.1 Syntax

```
pair_style lj/smooth Rin Rc
```

- Rin = inner cutoff beyond which force smoothing will be applied (distance units)
- Rc = outer cutoff for lj/smooth interactions (distance units)

### 4.162.2 Examples

```
pair_style lj/smooth 8.0 10.0
pair_coeff * * 10.0 1.5
pair_coeff 1 1 20.0 1.3 7.0 9.0
```

### 4.162.3 Description

Style *lj/smooth* computes a LJ interaction with a force smoothing applied between the inner and outer cutoff.

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_{in}$$

$$F = C_1 + C_2(r - r_{in}) + C_3(r - r_{in})^2 + C_4(r - r_{in})^3 \quad r_{in} < r < r_c$$

The polynomial coefficients C1, C2, C3, C4 are computed by LAMMPS to cause the force to vary smoothly from the inner cutoff  $r_{in}$  to the outer cutoff  $r_c$ .

At the inner cutoff the force and its first derivative will match the non-smoothed LJ formula. At the outer cutoff the force and its first derivative will be 0.0. The inner cutoff cannot be 0.0.

**Note:** this force smoothing causes the energy to be discontinuous both in its values and first derivative. This can lead to poor energy conservation and may require the use of a thermostat. Plot the energy and force resulting from this formula via the *pair\_write* command to see the effect.

---

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $r_{in}$  (distance units)
- $r_c$  (distance units)

The last 2 coefficients are optional inner and outer cutoffs. If not specified, the global values for  $r_{in}$  and  $r_c$  are used.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.162.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , the epsilon, sigma,  $R_{in}$  coefficients and the cutoff distance for this pair style can be mixed.  $R_{in}$  is a cutoff value and is mixed like the cutoff. The other coefficients are mixed according to the *pair\_modify* mix option. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.162.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.162.6 Related commands

*pair\_coeff*, *pair lj/smooth/linear*

### 4.162.7 Default

none

## 4.163 pair\_style lj/smooth/linear command

Accelerator Variants: *lj/smooth/linear/omp*

### 4.163.1 Syntax

```
pair_style lj/smooth/linear cutoff
```

- cutoff = global cutoff for Lennard-Jones interactions (distance units)

### 4.163.2 Examples

```
pair_style lj/smooth/linear 2.5
pair_coeff * * 1.0 1.0
pair_coeff 1 1 0.3 3.0 9.0
```

### 4.163.3 Description

Style *lj/smooth/linear* computes a truncated and force-shifted LJ interaction (aka Shifted Force Lennard-Jones) that combines the standard 12/6 Lennard-Jones function and subtracts a linear term based on the cutoff distance, so that both, the potential and the force, go continuously to zero at the cutoff  $r_c$  ([Toxvaerd](#)):

$$\phi(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right]$$

$$E(r) = \phi(r) - \phi(r_c) - (r - r_c) \left. \frac{d\phi}{dr} \right|_{r=r_c} \quad r < r_c$$

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)

- cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the `pair_style` command is used.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.163.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance can be mixed. The default mix value is geometric. See the “`pair_modify`” command for details.

This pair style does not support the *pair\_modify* shift option for the energy of the pair interaction, since it goes to 0.0 at the cutoff by construction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.163.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 4.164 pair\_style lj/switch3/coulgauss/long command

## 4.165 pair\_style mm3/switch3/coulgauss/long command

### 4.165.1 Syntax

```
pair_style style args
```

- style = *lj/switch3/coulgauss/long* or *mm3/switch3/coulgauss/long*
- args = list of arguments for a particular style

*lj/switch3/coulgauss/long* args = cutoff (cutoff2) width

cutoff = global cutoff for LJ (and Coulombic if only 1 arg) (distance units)

cutoff2 = global cutoff for Coulombic (optional) (distance units)

width = width parameter of the smoothing function (distance units)

*mm3/switch3/coulgauss/long* args = cutoff (cutoff2) width

cutoff = global cutoff for MM3 (and Coulombic if only 1 arg) (distance units)

cutoff2 = global cutoff for Coulombic (optional) (distance units)

width = width parameter of the smoothing function (distance units)

### 4.165.2 Examples

```
pair_style lj/switch3/coulgauss/long    12.0 3.0
pair_coeff 1 0.2 2.5 1.2

pair_style lj/switch3/coulgauss/long    12.0 10.0 3.0
pair_coeff 1 0.2 2.5 1.2

pair_style mm3/switch3/coulgauss/long    12.0 3.0
pair_coeff 1 0.2 2.5 1.2

pair_style mm3/switch3/coulgauss/long    12.0 10.0 3.0
pair_coeff 1 0.2 2.5 1.2
```

### 4.165.3 Description

The *lj/switch3/coulgauss* style evaluates the LJ vdW potential

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right]$$

The *mm3/switch3/coulgauss/long* style evaluates the MM3 vdW potential (*Allinger*)

$$E = \epsilon_{ij} \left[ -2.25 \left( \frac{r_{v,ij}}{r_{ij}} \right)^6 + 1.84(10)^5 \exp \left[ -12.0 r_{ij} / r_{v,ij} \right] \right] S_3(r_{ij})$$
$$r_{v,ij} = r_{v,i} + r_{v,j}$$
$$\epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j}$$

Both potentials go smoothly to zero at the cutoff  $r_c$  as defined by the switching function

$$S_3(r) = \begin{cases} 1 & \text{if } r < r_c - w \\ 3x^2 - 2x^3 & \text{if } r < r_c \text{ with } x = \frac{r_c - r}{w} \\ 0 & \text{if } r \geq r_c \end{cases}$$

where  $w$  is the width defined in the arguments. This potential is combined with Coulomb interaction between Gaussian charge densities:

$$E = \frac{q_i q_j \operatorname{erf} \left( r / \sqrt{\gamma_1^2 + \gamma_2^2} \right)}{\epsilon r_{ij}}$$

where  $q_i$  and  $q_j$  are the charges on the two atoms,  $\epsilon$  is the dielectric constant which can be set by the *dielectric* command,  $\gamma_i$  and  $\gamma_j$  are the widths of the Gaussian charge distribution and  $\operatorname{erf}()$  is the error-function. This style has to be used in conjunction with the *kpace\_style* command

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $\epsilon$  (energy)
- $\sigma$  (distance)
- $\gamma$  (distance)

---

### 4.165.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the *lj/long* pair styles can be mixed. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

Shifting the potential energy is not necessary because the switching function ensures that the potential is zero at the cut-off.

These pair styles support the *pair\_modify* table and options since they can tabulate the short-range portion of the long-range Coulombic interactions.

These pair styles do not support the *pair\_modify* tail option for adding a long-range tail correction to the Lennard-Jones portion of the energy and pressure.

These pair styles write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

## 4.165.5 Restrictions

These styles are part of the YAFF package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 4.165.6 Related commands

# 4.166 pair\_style local/density command

## 4.166.1 Syntax

```
pair_style style arg
```

- `style` = *local/density*
- `arg` = name of file containing tabulated values of local density and the potential

## 4.166.2 Examples

```
pair_style local/density benzene_water.localdensity.table
pair_style hybrid/overlay table spline 500 local/density
pair_coeff * * local/density benzene_water.localdensity.table
```

## 4.166.3 Description

The local density (LD) potential is a mean-field manybody potential, and, in some way, a generalization of embedded atom models (EAM). The name “local density potential” arises from the fact that it assigns an energy to an atom depending on the number of neighboring atoms of a given type around it within a predefined spherical volume (i.e., within the cutoff). The bottom-up coarse-graining (CG) literature suggests that such potentials can be widely useful in capturing effective manybody forces in a computationally efficient manner and thus improve the quality of CG models of implicit solvation (*Sanyal1*) and phase-segregation in liquid mixtures (*Sanyal2*), and provide guidelines to determine the extent of manybody correlations present in a CG model (*Rosenberger*). The LD potential in LAMMPS is primarily intended to be used as a corrective potential over traditional pair potentials in bottom-up CG models via *hybrid/overlay pair style* with other explicit pair interaction terms (e.g., tabulated, Lennard-Jones, Morse etc.). Because

the LD potential is not a pair potential per se, it is implemented simply as a single auxiliary file with all specifications that will be read upon initialization.

---

**Note:** Thus when used as the only interaction in the system, there is no corresponding pair\_coeff command and when used with other pair styles using the hybrid/overlay option, the corresponding pair\_coeff command must be supplied \* as placeholders for the atom types.

---

### System with a single CG atom type:

A system of a single atom type (e.g., LJ argon) with a single local density (LD) potential would have an energy given by:

$$U_{LD} = \sum_i F(\rho_i)$$

where  $\rho_i$  is the LD at atom  $i$  and  $F(\rho)$  is similar in spirit to the embedding function used in EAM potentials. The LD at atom  $i$  is given by the sum

$$\rho_i = \sum_{j \neq i} \varphi(r_{ij})$$

where  $\varphi$  is an indicator function that is one at  $r=0$  and zero beyond a cutoff distance  $R_2$ . The choice of the functional form of  $\varphi$  is somewhat arbitrary, but the following piecewise cubic function has proven sufficiently general: ([Sanyal1](#)), ([Sanyal2](#)) ([Rosenberger](#))

$$\varphi(r) = \begin{cases} 1 & r \leq R_1 \\ c_0 + c_2 r^2 + c_4 r^4 + c_6 r^6 & r \in (R_1, R_2) \\ 0 & r \geq R_2 \end{cases}$$

The constants  $c$  are chosen so that the indicator function smoothly interpolates between 1 and 0 between the distances  $R_1$  and  $R_2$ , which are called the inner and outer cutoffs, respectively. Thus  $\varphi$  satisfies  $\varphi(R_1) = 1$ ,  $\varphi(R_2) = d\varphi/dr @ (r=R_1) = d\varphi/dr @ (r=R_2) = 0$ . The embedding function  $F(\rho)$  may or may not have a closed-form expression. To maintain generality, it is practically represented with a spline-interpolated table over a predetermined range of  $\rho$ . Outside of that range it simply adopts zero values at the endpoints.

It can be shown that the total force between two atoms due to the LD potential takes the form of a pair force, which motivates its designation as a LAMMPS pair style. Please see ([Sanyal1](#)) for details of the derivation.

---

### Systems with arbitrary numbers of atom types:

The potential is easily generalized to systems involving multiple atom types:

$$U_{LD} = \sum_i a_\alpha F(\rho_i)$$

with the LD expressed as

$$\rho_i = \sum_{j \neq i} b_\beta \varphi(r_{ij})$$

where  $\alpha$  gives the type of atom  $i$ ,  $\beta$  the type of atom  $j$ , and the coefficients  $a$  and  $b$  filter for atom types as specified by the user.  $a$  is called the central atom filter as it determines to which atoms the potential applies;  $a_\alpha = 1$  if the LD potential applies to atom type  $\alpha$  else zero. On the other hand,  $b$  is called the neighbor atom filter because it specifies which atom types to use in the calculation of the LD;  $b_\beta = 1$  if atom type  $\beta$  contributes to the LD and zero otherwise.

**Note:** Note that the potentials need not be symmetric with respect to atom types, which is the reason for two distinct sets of coefficients  $a$  and  $b$ . An atom type may contribute to the LD but not the potential, or to the potential but not the LD. Such decisions are made by the user and should (ideally) be motivated on physical grounds for the problem at hand.

### General form for implementation in LAMMPS:

Of course, a system with many atom types may have many different possible LD potentials, each with their own atom type filters, cutoffs, and embedding functions. The most general form of this potential as implemented in the pair\_style local/density is:

$$U_{LD} = \sum_k U_{LD}^{(k)} = \sum_i \left[ \sum_k a_{\alpha}^{(k)} F^{(k)} \left( \rho_i^{(k)} \right) \right]$$

where,  $k$  is an index that spans the (arbitrary) number of applied LD potentials N\_LD. Each LD is calculated as before with:

$$\rho_i^{(k)} = \sum_j b_{\beta}^{(k)} \varphi^{(k)}(r_{ij})$$

The superscript on the indicator function phi simply indicates that it is associated with specific values of the cutoff distances R1(k) and R2(k). In summary, there may be N\_LD distinct LD potentials. With each potential type (k), one must specify:

- the inner and outer cutoffs as R1 and R2
- the central type filter a(k), where  $k = 1, 2, \dots, N\_LD$
- the neighbor type filter b(k), where  $k = 1, 2, \dots, N\_LD$
- the LD potential function F(k)(rho), typically as a table that is later spline-interpolated

### Tabulated input file format:

```

Line 1:      comment or blank (ignored)
Line 2:      comment or blank (ignored)
Line 3:      N_LD N_rho (# of LD potentials and # of tabulated values, single_
→space separated)
Line 4:      blank (ignored)
Line 5:      R1(k) R2(k) (lower and upper cutoffs, single space separated)
Line 6:      central-types (central atom types, single space separated)
Line 7:      neighbor-types (neighbor atom types single space separated)
Line 8:      rho_min rho_max drho (min, max and diff. in tabulated rho values,
→single space separated)
Line 9:      F(k)(rho_min + 0.drho)
Line 10:     F(k)(rho_min + 1.drho)
Line 11:     F(k)(rho_min + 2.drho)
...
Line 9+N_rho: F(k)(rho_min + N_rho . drho)
Line 10+N_rho: blank (ignored)

Block 2

```

(continues on next page)

(continued from previous page)

Block 3

Block N\_LD

Lines 5 to 9+N\_rho constitute the first block. Thus the input file is separated (by blank lines) into N\_LD blocks each representing a separate LD potential and each specifying its own upper and lower cutoffs, central and neighbor atoms, and potential. In general, blank lines anywhere are ignored.

---

#### 4.166.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support automatic mixing. For atom type pairs  $\alpha$ ,  $\beta$  and  $\alpha \neq \beta$ , even if LD potentials of type  $(\alpha, \alpha)$  and  $(\beta, \beta)$  are provided, you will need to explicitly provide LD potential types  $(\alpha, \beta)$  and  $(\beta, \alpha)$  if need be (Here, the notation  $(\alpha, \beta)$  means that  $\alpha$  is the central atom to which the LD potential is applied and  $\beta$  is the neighbor atom which contributes to the LD potential on  $\alpha$ ).

This pair style does not support the *pair\_modify* shift, table, and tail options.

The local/density pair style does not write its information to *binary restart files*, since it is stored in tabulated potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

---

#### 4.166.5 Restrictions

The local/density pair style is a part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.166.6 Related commands

*pair\_coeff*

#### 4.166.7 Default

## 4.167 pair\_style lubricate command

Accelerator Variants: *lubricate/omp*

## 4.168 pair\_style lubricate/poly command

Accelerator Variants: *lubricate/poly/omp*

### 4.168.1 Syntax

```
pair_style style mu flaglog flagfld cutinner cutoff flagHI flagVF
```

- style = *lubricate* or *lubricate/poly*
- mu = dynamic viscosity (dynamic viscosity units)
- flaglog = 0/1 to exclude/include log terms in the lubrication approximation
- flagfld = 0/1 to exclude/include Fast Lubrication Dynamics (FLD) effects
- cutinner = inner cutoff distance (distance units)
- cutoff = outer cutoff for interactions (distance units)
- flagHI (optional) = 0/1 to exclude/include 1/r hydrodynamic interactions
- flagVF (optional) = 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

### 4.168.2 Examples

(all assume radius = 1)

```
pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff 1 1 2.05 2.8
pair_coeff * *

pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff * *
variable mu equal ramp(1,2)
fix 1 all adapt 1 pair lubricate mu * * v_mu
```

### 4.168.3 Description

Styles *lubricate* and *lubricate/poly* compute hydrodynamic interactions between mono-disperse finite-size spherical particles in a pairwise fashion. The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in (*Ball and Melrose*)

$$W = -a_{sq}|(v_1 - v_2) \bullet \mathbf{nn}|^2 - a_{sh}|(\omega_1 + \omega_2) \bullet (\mathbf{I} - \mathbf{nn}) - 2\Omega_N|^2 - a_{pu}|(\omega_1 - \omega_2) \bullet (\mathbf{I} - \mathbf{nn})|^2 - a_{tw}|(\omega_1 - \omega_2) \bullet \mathbf{nn}|^2 \quad r < r_c$$

$$\Omega_N = \mathbf{n} \times (v_1 - v_2)/r$$

which represents the dissipation  $W$  between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity  $\mu$ . Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The *Asq* (squeeze) term is the strongest and is included if *flagHI* is set to 1 (default). It scales as  $1/\text{gap}$  where *gap* is the separation between the surfaces of the 2 particles. The *Ash* (shear) and *Apu* (pump) terms are only included if *flaglog* is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as  $\log(\text{gap})$ . Note that *flaglog* = 1 and *flagHI* = 0 is invalid, and will result in a warning message, after which *flagHI* will be set to 1. The *Atw* (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.

The *flagHI* and *flagVF* settings are optional. Neither should be used, or both must be defined.

*Cutinner* sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. *Cutoff* is the maximum center-to-center separation at which an interaction is computed. Using a *cutoff* less than 3 radii is recommended if *flaglog* is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in ([Kumar](#)), which can be represented by the following equation

$$F^H = -R_{FU}(U - U^\infty) + R_{FE}E^\infty$$

where  $U$  represents the velocities and angular velocities of the particles,  $U^\infty$  represents the velocity and the angular velocity of the undisturbed fluid, and  $E^\infty$  represents the rate of strain tensor of the undisturbed fluid with viscosity  $\mu$ . Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity. Volume fraction corrections to  $R_{FU}$  are included as long as *flagVF* is set to 1 (default).

---

**Note:** When using the FLD terms, these pair styles are designed to be used with explicit time integration and a correspondingly small timestep. Thus either *fix nve/sphere* or *fix nve/asphere* should be used for time integration. To perform implicit FLD, see the *pair\_style lubricateU* command.

---

Style *lubricate* requires monodisperse spherical particles; style *lubricate/poly* allows for polydisperse spherical particles.

The viscosity  $\mu$  can be varied in a time-dependent manner over the course of a simulation, in which case in which case the *pair\_style* setting for  $\mu$  will be overridden. See the *fix adapt* command for details.

If the suspension is sheared via the *fix deform* command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to *fix deform* are accounted for when computing the volume fraction corrections to  $R_{FU}$ .

When computing the volume fraction corrections to  $R_{FU}$ , the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: *wall/lj93*, *wall/lj126*, *wall/colloid*, and *wall/harmonic*. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. Other wall styles may still work, but they will result in the volume fraction being computed based on the box boundaries. Several wall styles are not compatible with these pair styles and using them will result in an error.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the *pair\_style brownian* command. These pair styles and the brownian style should use consistent parameters for  $\mu$ , *flaglog*, *flagfld*, *cutinner*, *cutoff*, *flagHI* and *flagVF*.

---

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- *cutinner* (distance units)

- cutoff (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the `pair_style` command are used. Otherwise both must be specified.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.168.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the two cutoff distances for this pair style can be mixed. The default mix value is *geometric*. See the “`pair_modify`” command for details.

This pair style does not support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.168.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Only spherical monodisperse particles are allowed for `pair_style lubricate`.

Only spherical particles are allowed for `pair_style lubricate/poly`.

These pair styles will not restart exactly when using the *read\_restart* command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the *read\_restart* command for more details.

### 4.168.6 Related commands

*pair\_coeff*, *pair\_style lubricateU*

### 4.168.7 Default

The default settings for the optional args are flagHI = 1 and flagVF = 1.

## 4.169 pair\_style lubricateU command

## 4.170 pair\_style lubricateU/poly command

### 4.170.1 Syntax

```
pair_style style mu flaglog cutinner cutoff gdot flagHI flagVF
```

- style = *lubricateU* or *lubricateU/poly*
- mu = dynamic viscosity (dynamic viscosity units)
- flaglog = 0/1 to exclude/include log terms in the lubrication approximation
- cutinner = inner cut off distance (distance units)
- cutoff = outer cutoff for interactions (distance units)
- gdot = shear rate (1/time units)
- flagHI (optional) = 0/1 to exclude/include 1/r hydrodynamic interactions
- flagVF (optional) = 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

### 4.170.2 Examples

(all assume radius = 1)

```
pair_style lubricateU 1.5 1 2.01 2.5 0.01 1 1
pair_coeff 1 1 2.05 2.8
pair_coeff * *
```

### 4.170.3 Description

Styles *lubricateU* and *lubricateU/poly* compute velocities and angular velocities for finite-size spherical particles such that the hydrodynamic interaction balances the force and torque due to all other types of interactions.

The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in (*Ball and Melrose*)

$$W = -a_{sq}|(v_1 - v_2) \bullet \mathbf{nn}|^2 - a_{sh}|(\omega_1 + \omega_2) \bullet (\mathbf{I} - \mathbf{nn}) - 2\Omega_N|^2 - a_{pu}|(\omega_1 - \omega_2) \bullet (\mathbf{I} - \mathbf{nn})|^2 - a_{tw}|(\omega_1 - \omega_2) \bullet \mathbf{nn}|^2 \quad r < r_c$$

$$\Omega_N = \mathbf{n} \times (v_1 - v_2)/r$$

which represents the dissipation  $W$  between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity  $\mu$ . Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The  $A_{sq}$  (squeeze) term is the strongest and is included as long as *flagHI* is set to 1 (default). It scales as  $1/\text{gap}$  where  $\text{gap}$  is the separation between the surfaces of the 2 particles. The  $A_{sh}$  (shear) and  $A_{pu}$  (pump) terms are only included if *flaglog* is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as  $\log(\text{gap})$ . Note that *flaglog* = 1 and *flagHI* = 0 is invalid, and will result in a warning message, after which *flagHI* will be set to 1. The  $A_{tw}$  (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.

The *flagHI* and *flagVF* settings are optional. Neither should be used, or both must be defined.

*Cutinner* sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. *Cutoff* is the maximum center-to-center separation at which an interaction is computed. Using a *cutoff* less than 3 radii is recommended if *flaglog* is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in (*Kumar*). The equation being solved to balance the forces and torques is

$$-R_{FU}(U - U^\infty) = -R_{FE}E^\infty - F^{rest}$$

where  $U$  represents the velocities and angular velocities of the particles,  $U^\infty$  represents the velocities and the angular velocities of the undisturbed fluid, and  $E^\infty$  represents the rate of strain tensor of the undisturbed fluid flow with viscosity  $\mu$ . Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity. Volume fraction corrections to  $R_{FU}$  are included if *flagVF* is set to 1 (default).

$F^{rest}$  represents the forces and torques due to all other types of interactions, e.g. Brownian, electrostatic etc. Note that this algorithm neglects the inertial terms, thereby removing the restriction of resolving the small inertial time scale, which may not be of interest for colloidal particles. These pair styles solve for the velocity such that the hydrodynamic force balances all other types of forces, thereby resulting in a net zero force (zero inertia limit). When defining these pair styles, they must be defined last so that when these styles are invoked all other types of forces have already been computed. For the same reason, they won't work if additional non-pair styles are defined (such as bond or Kspace forces) as they are calculated in LAMMPS after the pairwise interactions have been computed.

---

**Note:** When using these styles, the pair styles are designed to be used with implicit time integration and a correspondingly larger timestep. Thus either *fix nve/noforce* should be used for spherical particles defined via *atom\_style sphere* or *fix nve/asphere/noforce* should be used for spherical particles defined via *atom\_style ellipsoid*. This is because the velocity and angular momentum of each particle is set by the pair style, and should not be reset by the time integration *fix*.

---

Style *lubricateU* requires monodisperse spherical particles; style *lubricateU/poly* allows for polydisperse spherical particles.

If the suspension is sheared via the *fix deform* command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to fix deform are accounted for when computing the volume fraction corrections to R\_FU.

When computing the volume fraction corrections to R\_FU, the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: *wall/lj93*, *wall/lj126*, *wall/colloid*, and *wall/harmonic*. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. To use these wall styles with pair\_style *lubricateU* or *lubricateU/poly*, the *fld yes* option must be specified in the fix wall command. Other wall styles may still work, but they will result in the volume fraction being computed based on the box boundaries. Several wall styles are not compatible with these pair styles and using them will result in an error.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the *pair\_style brownian* command. These pair styles and the brownian style should use consistent parameters for *mu*, *flaglog*, *flagfld*, *cutinner*, *cutoff*, *flagHI* and *flagVF*.

---

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- *cutinner* (distance units)
- *cutoff* (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair\_style command are used. Otherwise both must be specified.

---

#### 4.170.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the two cutoff distances for this pair style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

These pair styles do not support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for these pair styles.

These pair styles do not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

## 4.170.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Currently, these pair styles assume that all other types of forces/torques on the particles have been already been computed when it is invoked. This requires this style to be defined as the last of the pair styles, and that no fixes apply additional constraint forces. One exception is the [fix wall/colloid](#) commands, which has an “fld” option to apply their wall forces correctly.

Only spherical monodisperse particles are allowed for pair\_style lubricateU.

Only spherical particles are allowed for pair\_style lubricateU/poly.

For sheared suspensions, it is assumed that the shearing is done in the xy plane, with x being the velocity direction and y being the velocity-gradient direction. In this case, one must use [fix deform](#) with the same rate of shear (erate).

These pair styles are only compatible with the following wall fixes: `doc:fix wall/lj93`, `fix wall/lj126`, `fix wall/lj1043`, `fix wall/colloid`, `fix wall/harmonic`, `fix wall/lepton`, `fix wall/morse`, `fix wall/table <fix_wall>`.

pair_coeff 1 1 1021760.3664 2120.317338 3.0 3.2

```

### 4.173.3 Description

The *lj/mdf*, *buck/mdf* and *lennard/mdf* compute the standard 12-6 Lennard-Jones and Buckingham potential with the addition of a taper function that ramps the energy and force smoothly to zero between an inner and outer cutoff.

$$E_{smooth}(r) = E(r) * f(r)$$

The tapering,  $f(r)$ , is done by using the Mei, Davenport, Fernando function (*Mei*).

$$\begin{aligned}
 f(r) &= 1.0 && \text{for } r < r_m \\
 f(r) &= (1 - x)^3 * (1 + 3x + 6x^2) && \text{for } r_m < r < r_{cut} \\
 f(r) &= 0.0 && \text{for } r \geq r_{cut}
 \end{aligned}$$

where

$$x = \frac{(r - r_m)}{(r_{cut} - r_m)}$$

Here  $r_m$  is the inner cutoff radius and  $r_{cut}$  is the outer cutoff radius.

---

For the *lj/mdf* pair\_style, the potential energy,  $E(r)$ , is the standard 12-6 Lennard-Jones written in the epsilon/sigma form:

$$E(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right]$$

Either the first two or all of the following coefficients must be defined for each pair of atoms types via the pair\_coeff command as in the examples above, or in the data file read by the [read\\_data](#). The two cutoffs default to the global values and  $\epsilon$  and  $\sigma$  can also be determined by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $r_m$  (distance units)

- $r_{cut}$  (distance units)
- 

For the *buck/mdf* pair\_style, the potential energy,  $E(r)$ , is the standard Buckingham potential with three required coefficients. The two cutoffs can be omitted and default to the corresponding global values:

$$E(r) = Ae^{(-r/\rho)} - \frac{C}{r^6}$$

- $A$  (energy units)
  - $\rho$  (distance units)
  - $C$  (energy-distance<sup>6</sup> units)
  - $r_m$  (distance units)
  - $r_{cut}$  (distance units)
- 

For the *lennard/mdf* pair\_style, the potential energy,  $E(r)$ , is the standard 12-6 Lennard-Jones written in the A/B form:

$$E(r) = \frac{A}{r^{12}} - \frac{B}{r^6}$$

The following coefficients must be defined for each pair of atoms types via the pair\_coeff command as in the examples above, or in the data file read by the read\_data commands, or by mixing as described below. The two cutoffs default to their global values and must be either both given or both left out:

- $A$  (energy-distance<sup>12</sup> units)
  - $B$  (energy-distance<sup>6</sup> units)
  - $r_m$  (distance units)
  - $r_{cut}$  (distance units)
- 

#### 4.173.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , the  $\epsilon$  and  $\sigma$  coefficients and cutoff distances for the lj/mdf pair style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details. The other two pair styles buck/mdf and lennard/mdf do not support mixing, so all I,J pairs of coefficients must be specified explicitly.

None of the lj/mdf, buck/mdf, or lennard/mdf pair styles supports the *pair\_modify* shift option or long-range tail corrections to pressure and energy.

These styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

### 4.173.5 Restrictions

These pair styles can only be used if LAMMPS was built with the EXTRA-PAIR package. See the [Build package](#) doc page for more info.

### 4.175.3 Description

**Note:** The behavior of the MEAM potential for alloy systems has changed as of November 2010; see description below of the `mixture_ref_t` parameter

Pair style *meam* computes non-bonded interactions for a variety of materials using the modified embedded-atom method (MEAM) (*Baskes*). Conceptually, it is an extension to the original *EAM method* which adds angular forces. It is thus suitable for modeling metals and alloys with fcc, bcc, hcp and diamond cubic structures, as well as materials with covalent interactions like silicon and carbon.

The *meam* pair style is a translation of the original Fortran version to C++. It is functionally equivalent but more efficient and has additional features. The Fortran version of the *meam* pair style has been removed from LAMMPS after the 12 December 2018 release.

Pair style *meam/ms* uses the multi-state MEAM (MS-MEAM) method according to (*Baskes2*), which is an extension to MEAM. This pair style is mostly equivalent to *meam* and differs only where noted in the documentation below.

In the MEAM formulation, the total energy  $E$  of a system of atoms is given by:

$$E = \sum_i \left\{ F_i(\bar{\rho}_i) + \frac{1}{2} \sum_{i \neq j} \phi_{ij}(r_{ij}) \right\}$$

where  $F$  is the embedding energy which is a function of the atomic electron density  $\rho$ , and  $\phi$  is a pair potential interaction. The pair interaction is summed over all neighbors  $J$  of atom  $I$  within the cutoff distance. As with EAM, the multi-body nature of the MEAM potential is a result of the embedding energy term. Details of the computation of the embedding and pair energies, as implemented in LAMMPS, are given in (*Gullet*) and references therein.

The various parameters in the MEAM formulas are listed in two files which are specified by the *pair\_coeff* command. These are ASCII text files in a format consistent with other MD codes that implement MEAM potentials, such as the serial DYNAMO code and Warp. Several MEAM potential files with parameters for different materials are included in the “potentials” directory of the LAMMPS distribution with a “.meam” suffix. All of these are parameterized in terms of LAMMPS *metal units*.

Note that unlike for other potentials, cutoffs for MEAM potentials are not set in the *pair\_style* or *pair\_coeff* command; they are specified in the MEAM potential files themselves.

Only a single *pair\_coeff* command is used with the *meam* style which specifies two MEAM files and the element(s) to extract information for. The MEAM elements are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the second filename in the *pair\_coeff* command, where  $N$  is the number of LAMMPS atom types:

- MEAM library file
- Element1, Element2, ...
- MEAM parameter file
- $N$  element names = mapping of MEAM elements to atom types

See the *pair\_coeff* page for alternate ways to specify the path for the potential files.

As an example, the `potentials/library.meam` file has generic MEAM settings for a variety of elements. The `potentials/SiC.meam` file has specific parameter settings for a Si and C alloy system. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following *pair\_coeff* command:

```
pair_coeff * * library.meam Si C sic.meam Si Si Si C
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first filename is the element library file. The list of elements following it extracts lines from the library file and assigns numeric indices to these elements.

The second filename is the alloy parameter file, which refers to elements using the numeric indices assigned before. The arguments after the parameter file map LAMMPS atom types to elements, i.e. LAMMPS atom types 1,2,3 to the MEAM Si element. The final C argument maps LAMMPS atom type 4 to the MEAM C element.

If the second filename is specified as NULL, no parameter file is read, which simply means the generic parameters in the library file are used. Use of the NULL specification for the parameter file is discouraged for systems with more than a single element type (e.g. alloys), since the parameter file is expected to set element interaction terms that are not captured by the information in the library file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *meam* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

---

**Note:** If the second filename is NULL, the element names between the two filenames can appear in any order, e.g. “Si C” or “C Si” in the example above. However, if the second filename is **not** NULL (as in the example above), it contains settings that are indexed **by numbers** for the elements that precede it. Thus you need to ensure that you list the elements between the filenames in an order consistent with how the values in the second filename are indexed. See details below on the syntax for settings in the second file.

---

The MEAM library file provided with LAMMPS has the name `potentials/library.meam`. It is the “meamf” file used by other MD codes. Aside from blank and comment lines (starting with # which can appear anywhere), it is formatted as a series of entries, each of which has 19 parameters and can span multiple lines:

`elt, lat, z, ielement, atwt, alpha, b0, b1, b2, b3, alat, esub, asub, t0, t1, t2, t3, rozero, ibar`

The *elt* and *lat* parameters are text strings, such as *elt* = Si or Cu and *lat* = dia or fcc. Because the library file is used by Fortran MD codes, these strings may be enclosed in single quotes, but this is not required. The other numeric parameters match values in the formulas above. The value of the *elt* string is what is used in the `pair_coeff` command to identify which settings from the library file you wish to read in. There can be multiple entries in the library file with the same *elt* value; LAMMPS reads the first matching entry it finds and ignores the rest.

Other parameters in the MEAM library file correspond to single-element potential parameters:

```
lat      = lattice structure of reference configuration
z        = number of nearest neighbors in the reference structure
ielement = atomic number
atwt     = atomic weight
alat     = lattice constant of reference structure
esub     = energy per atom (eV) in the reference structure at equilibrium
asub     = "A" parameter for MEAM (see e.g. (Baskes))
```

The *alpha*, *b0*, *b1*, *b2*, *b3*, *t0*, *t1*, *t2*, *t3* parameters correspond to the standard MEAM parameters in the literature ([Baskes](#)) (the b parameters are the standard beta parameters). Note that only parameters normalized to *t0* = 1.0 are supported. The *rozero* parameter is an element-dependent density scaling that weights the reference background density (see e.g. equation 4.5 in ([Gullet](#))) and is typically 1.0 for single-element systems. The *ibar* parameter selects the form of the function G(Gamma) used to compute the electron density; options are

```
0 => G = sqrt(1+Gamma)
1 => G = exp(Gamma/2)
2 => not implemented
3 => G = 2/(1+exp(-Gamma))
4 => G = sqrt(1+Gamma)
-5 => G = +-sqrt(abs(1+Gamma))
```

If used, the MEAM parameter file contains settings that override or complement the library file settings. Examples of such parameter files are in the potentials directory with a “.meam” suffix. Their format is the same as is read by other

Fortran MD codes. Aside from blank and comment lines (start with # which can appear anywhere), each line has one of the following forms. Each line can also have a trailing comment (starting with #) which is ignored.

```
keyword = value
keyword(I) = value
keyword(I,J) = value
keyword(I,J,K) = value
```

The indices I, J, K correspond to the elements selected from the MEAM library file numbered in the order of how those elements were selected starting from 1. Thus for the example given before

```
pair_coeff * * library.meam Si C sic.meam Si Si Si C
```

an index of 1 would refer to Si and an index of 2 to C.

The recognized keywords for the parameter file are as follows:

```
rc          = cutoff radius for cutoff function; default = 4.0
delr        = length of smoothing distance for cutoff function; default = 0.1
rho0(I)     = relative density for element I (overwrites value
              read from meamf file)
Ec(I,J)     = cohesive energy of reference structure for I-J mixture
delta(I,J)  = heat of formation for I-J alloy; if Ec_IJ is input as
              zero, then LAMMPS sets Ec_IJ = (Ec_II + Ec_JJ)/2 - delta_IJ
alpha(I,J)  = alpha parameter for pair potential between I and J (can
              be computed from bulk modulus of reference structure)
re(I,J)     = equilibrium distance between I and J in the reference
              structure
Cmax(I,J,K) = Cmax screening parameter when I-J pair is screened
              by K (I<=J); default = 2.8
Cmin(I,J,K) = Cmin screening parameter when I-J pair is screened
              by K (I<=J); default = 2.0
lattce(I,J) = lattice structure of I-J reference structure:
              fcc = face centered cubic
              bcc = body centered cubic
              hcp = hexagonal close-packed
              dim = dimer
              dia = diamond (interlaced fcc for alloy)
              dia3= diamond structure with primary 1NN and secondary 3NN interaction
              b1  = rock salt (NaCl structure)
              c11 = MoSi2 structure
              l12 = Cu3Au structure (lower case L, followed by 12)
              b2  = CsCl structure (interpenetrating simple cubic)
              ch4 = methane-like structure, only for binary system
              lin = linear structure (180 degree angle)
              zig = zigzag structure with a uniform angle
              tri = H2O-like structure that has an angle
              sc  = simple cubic
nn2(I,J)    = turn on second-nearest neighbor MEAM formulation for
              I-J pair (see for example Lee).
              0 = second-nearest neighbor formulation off
              1 = second-nearest neighbor formulation on
              default = 0
attrac(I,J) = additional cubic attraction term in Rose energy I-J pair potential
              default = 0
```

`repuls(I,J)` = additional cubic repulsive term in Rose energy I-J pair potential  
                  default = 0

`zbl(I,J)` = blend the MEAM I-J pair potential with the ZBL potential for small  
                  atom separations ([ZBL](#))  
                  default = 1

`theta(I,J)` = angle between three atoms in line, zigzag, and trimer reference structures.  
→ in degrees  
                  default = 180

`gsmooth_factor` = factor determining the length of the G-function smoothing  
                  region; only significant for `ibar=0` or `ibar=4`.  
                  99.0 = short smoothing region, sharp step  
                  0.5 = long smoothing region, smooth step  
                  default = 99.0

`augt1` = integer flag for whether to augment `t1` parameter by  
                   $3/5*t3$  to account for old vs. new meam formulations;  
                  0 = don't augment `t1`  
                  1 = augment `t1`  
                  default = 1

`ialloy` = integer flag to use alternative averaging rule for `t` parameters,  
                  for comparison with the DYNAMO MEAM code  
                  0 = standard averaging (matches `ialloy=0` in DYNAMO)  
                  1 = alternative averaging (matches `ialloy=1` in DYNAMO)  
                  2 = no averaging of `t` (use single-element values)  
                  default = 0

`mixture_ref_t` = integer flag to use mixture average of `t` to compute the background  
                  reference density for alloys, instead of the single-element values  
                  (see description and warning elsewhere in this doc page)  
                  0 = do not use mixture averaging for `t` in the reference density  
                  1 = use mixture averaging for `t` in the reference density  
                  default = 0

`erose_form` = integer value to select the form of the Rose energy function  
                  (see description below).  
                  default = 0

`emb_lin_neg` = integer value to select embedding function for negative densities  
                  0 =  $F(\rho)=0$   
                  1 =  $F(\rho) = -a_{\text{sub}}*e_{\text{sub}}*\rho$  (linear in  $\rho$ , matches DYNAMO)  
                  default = 0

`bkgd_dyn` = integer value to select background density formula  
                  0 =  $\rho_{\text{bkgd}} = \rho_{\text{ref\_meam}}(a)$  (as in the reference structure)  
                  1 =  $\rho_{\text{bkgd}} = \rho_{\text{meam}}(a)*Z_{\text{meam}}(a)$  (matches DYNAMO)  
                  default = 0

*Rc*, *delr*, *re* are in distance units (Angstroms in the case of metal units). *Ec* and *delta* are in energy units (eV in the case of metal units).

Each keyword represents a quantity which is either a scalar, vector, 2d array, or 3d array and must be specified with the correct corresponding array syntax. The indices I,J,K each run from 1 to N where N is the number of MEAM elements being used.

Thus these lines

```
rho0(2) = 2.25
alpha(1,2) = 4.37
```

set *rho0* for the second element to the value 2.25 and set *alpha* for the alloy interaction between elements 1 and 2 to 4.37.

The *augt1* parameter is related to modifications in the MEAM formulation of the partial electron density function. In recent literature, an extra term is included in the expression for the third-order density in order to make the densities orthogonal (see for example (Wang), equation 3d); this term is included in the MEAM implementation in LAMMPS. However, in earlier published work this term was not included when deriving parameters, including most of those provided in the `library.meam` file included with LAMMPS, and to account for this difference the parameter *t1* must be augmented by  $3/5 \cdot t^3$ . If *augt1* = 1, the default, this augmentation is done automatically. When parameter values are fit using the modified density function, as in more recent literature, *augt1* should be set to 0.

The *mixture\_ref\_t* parameter is available to match results with those of previous versions of LAMMPS (before January 2011). Newer versions of LAMMPS, by default, use the single-element values of the *t* parameters to compute the background reference density. This is the proper way to compute these parameters. Earlier versions of LAMMPS used an alloy mixture averaged value of *t* to compute the background reference density. Setting *mixture\_ref\_t* = 1 gives the old behavior. WARNING: using *mixture\_ref\_t* = 1 will give results that are demonstrably incorrect for second-neighbor MEAM, and non-standard for first-neighbor MEAM; this option is included only for matching with previous versions of LAMMPS and should be avoided if possible.

The parameters *attrac* and *repuls*, along with the integer selection parameter *erose\_form*, can be used to modify the Rose energy function used to compute the pair potential. This function gives the energy of the reference state as a function of interatomic spacing. The form of this function is:

```
astar = alpha * (r/re - 1.d0)
if erose_form = 0: erose = -Ec*(1+astar+a3*(astar**3)/(r/re))*exp(-astar)
if erose_form = 1: erose = -Ec*(1+astar+(-attrac+repuls/r)*(astar**3))*exp(-astar)
if erose_form = 2: erose = -Ec*(1 +astar + a3*(astar**3))*exp(-astar)
a3 = repuls, astar < 0
a3 = attrac, astar >= 0
```

Most published MEAM parameter sets use the default values *attrac* = *repulse* = 0. Setting *repuls* = *attrac* = *delta* corresponds to the form used in several recent published MEAM parameter sets, such as (Valone)

Then using *meam/ms* pair style the multi-state MEAM (MS-MEAM) method is activated. This requires 6 extra parameters in the MEAM library file, resulting in 25 parameters ordered that are ordered like this:

elt, lat, z, ielement, atwt, alpha, b0, b1, b2, b3, b1m, b2m, b3m, alat, esub, asub, t0, t1, t2, t3, t1m, t2m, t3m, rozero, ibar

The 6 extra MS-MEAM parameters are *b1m*, *b2m*, *b3m*, *t1m*, *t2m*, *t3m*. In the LAMMPS `potentials` folder, compatible files have an “.msmeam” extension.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

**Note:** The default form of the *erose* expression in LAMMPS was corrected in March 2009. The current version is correct, but may show different behavior compared with earlier versions of LAMMPS with the *attrac* and/or *repuls* parameters are non-zero. To obtain the previous default form, use *erose\_form* = 1 (this form does not seem to appear in the literature). An alternative form (see e.g. (Lee2)) is available using *erose\_form* = 2.

#### 4.175.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above.

This pair style does not support the *pair\_modify* *shift*, *table*, and *tail* options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.175.5 Restrictions

The *meam* and *meam/ms* pair styles are provided in the MEAM package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The maximum number of elements that can be read from the MEAM library file is determined at compile time. The default is 8. If you need support for more elements, you have to change the constant 'MAXELT' at the beginning of the file `src/MEAM/meam.h` and update/recompile LAMMPS. There is no limit on the number of atoms types.

#### 4.175.6 Related commands

*pair\_coeff*, *pair\_style eam*, *pair\_style meam/spline*

## 4.176 pair\_style meam/spline command

Accelerator Variants: *meam/spline/omp*

### 4.176.1 Syntax

```
pair_style meam/spline
```

### 4.176.2 Examples

```
pair_style meam/spline
pair_coeff * * Ti.meam.spline Ti
pair_coeff * * Ti.meam.spline Ti 0
```

### 4.176.3 Description

The *meam/spline* style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials ([Lenosky](#)). For a single species (“old-style”) MEAM, the total energy  $E$  is given by

$$E = \sum_{i < j} \phi(r_{ij}) + \sum_i U(n_i)$$

$$n_i = \sum_j \rho(r_{ij}) + \sum_{\substack{j < k, \\ j, k \neq i}} f(r_{ij})f(r_{ik})g[\cos(\theta_{jik})]$$

where  $\rho_i$  is the density at atom  $i$ ,  $\theta_{jik}$  is the angle between atoms  $j$ ,  $i$ , and  $k$  centered on atom  $i$ . The five functions  $\phi$ ,  $U$ ,  $\rho$ ,  $f$ , and  $g$  are represented by cubic splines.

The *meam/spline* style also supports a new style multicomponent modified embedded-atom method (MEAM) potential ([Zhang](#)), where the total energy  $E$  is given by

$$E = \sum_{i < j} \phi_{ij}(r_{ij}) + \sum_i U_i(n_i)$$

$$n_i = \sum_{j \neq i} \rho_j(r_{ij}) + \sum_{\substack{j < k, \\ j, k \neq i}} f_j(r_{ij})f_k(r_{ik})g_{jk}[\cos(\theta_{jik})]$$

where the five functions  $\phi$ ,  $U$ ,  $\rho$ ,  $f$ , and  $g$  depend on the chemistry of the atoms in the interaction. In particular, if there are  $N$  different chemistries, there are  $N$  different  $U$ ,  $\rho$ , and  $f$  functions, while there are  $N(N+1)/2$  different  $\phi$  and  $g$  functions. The new style multicomponent MEAM potential files are indicated by the second line in the file starts with “meam/spline” followed by the number of elements and the name of each element.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the *pair\_coeff* command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.spline” file suffix. All of these files are parameterized in terms of LAMMPS *metal units*.

Note that unlike for other potentials, cutoffs for spline-based MEAM potentials are not set in the *pair\_style* or *pair\_coeff* command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM potentials do not include mass information; thus you need to use the *mass* command to specify it.

Only a single `pair_coeff` command is used with the *meam/spline* style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of spline-based MEAM elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine the `Ti.meam.spline` file has values for Ti (old style). In that case your LAMMPS simulation may only have one atom type which has to be mapped to the Ti element as follows:

```
pair_coeff * * Ti.meam.spline Ti
```

The first 2 arguments must be `* *` and there may be only one element following or `NULL`. Systems where there would be multiple atom types assigned to the same element are **not** supported by this pair style due to limitations in its implementation. If a mapping value is specified as `NULL`, the mapping is not performed. This can be used when a *meam/spline* potential is used as part of the *hybrid* pair style. The `NULL` values are placeholders for atom types that will be used with other potentials.

An example with a two component spline (new style) is `TiO.meam.spline`, where the command

```
pair_coeff * * TiO.meam.spline Ti O
```

will map the first atom type to Ti and the second atom type to O. Note in this case that the species names need to match exactly with the names of the elements in the `TiO.meam.spline` file; otherwise an error will be raised. This behavior is different than the old style MEAM files.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.176.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* shift, table, and tail options.

The *meam/spline* pair style does not write its information to *binary restart files*, since it is stored in an external potential parameter file. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

The *meam/spline* pair style can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

## 4.176.5 Restrictions

This pair style requires the *newton* setting to be “on” for pair interactions.

This pair style does not support mapping multiple atom types to the same element.

This pair style is only enabled if LAMMPS was built with the MANYBODY package. See the *Build package* page for more info.

## 4.176.6 Related commands

*pair\_coeff*, *pair\_style meam*

## 4.177 pair\_style meam/sw/spline command

### 4.177.1 Syntax

```
pair_style meam/sw/spline
```

### 4.177.2 Examples

```
pair_style meam/sw/spline
pair_coeff * * Ti.meam.sw.spline Ti
pair_coeff * * Ti.meam.sw.spline Ti Ti Ti
```

### 4.177.3 Description

The *meam/sw/spline* style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials (*Lenosky*) with an additional Stillinger-Weber (SW) term (*Stillinger*) in the energy. This form of the potential was first proposed by Nicklas, Fellingner, and Park (*Nicklas*). We refer to it as MEAM+SW. The total energy  $E$  is given by

$$\begin{aligned}
 E &= E_{MEAM} + E_{SW} \\
 E_{MEAM} &= \sum_{IJ} \phi(r_{IJ}) + \sum_I U(\rho_I) \\
 E_{SW} &= \sum_I \sum_{JK} F(r_{IJ}) F(r_{IK}) G(\cos(\theta_{JIK})) \\
 \rho_I &= \sum_J \rho(r_{IJ}) + \sum_{JK} f(r_{IJ}) f(r_{IK}) g(\cos(\theta_{JIK}))
 \end{aligned}$$

where  $\rho_I$  is the density at atom I,  $\theta_{JIK}$  is the angle between atoms J, I, and K centered on atom I. The seven functions  $\phi$ ,  $F$ ,  $G$ ,  $U$ ,  $\rho$ ,  $f$ , and  $g$  are represented by cubic splines.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the `pair_coeff` command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.sw.spline” file suffix. All of these files are parameterized in terms of LAMMPS *metal units*.

Note that unlike for other potentials, cutoffs for spline-based MEAM+SW potentials are not set in the `pair_style` or `pair_coeff` command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM+SW potentials do not include mass information; thus you need to use the `mass` command to specify it.

Only a single `pair_coeff` command is used with the meam/sw/spline style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of spline-based MEAM+SW elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the potential file.

As an example, imagine the `Ti.meam.sw.spline` file has values for Ti. If your LAMMPS simulation has 3 atoms types and they are all to be treated with this potential, you would use the following `pair_coeff` command:

```
pair_coeff * * Ti.meam.sw.spline Ti Ti Ti
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The three Ti arguments map LAMMPS atom types 1,2,3 to the Ti element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *meam/sw/spline* potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

---

**Note:** The *meam/sw/spline* style currently supports only single-element MEAM+SW potentials. It may be extended for alloy systems in the future.

---

Example input scripts that use this pair style are provided in the `examples/PACKAGES/meam_sw_spline` directory.

---

#### 4.177.4 Mixing, shift, table, tail correction, restart, rRESPA info

The pair style does not support multiple element types or mixing. It has been designed for pure elements only.

This pair style does not support the `pair_modify` shift, table, and tail options.

The *meam/sw/spline* pair style does not write its information to *binary restart files*, since it is stored in an external potential parameter file. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

The *meam/sw/spline* pair style can only be used via the `pair` keyword of the `run_style respa` command. They do not support the *inner*, *middle*, *outer* keywords.

---

### 4.177.5 Restrictions

This pair style requires the *newton* setting to be “on” for pair interactions.

This pair style is only enabled if LAMMPS was built with the MANYBODY package. See the *Build package* page for more info.

### 4.177.6 Related commands

## 4.178 pair\_style mesocnt command

## 4.179 pair\_style mesocnt/viscous command

### 4.179.1 Syntax

```
pair_style style neigh_cutoff mode neigh_mode
```

- style = *mesocnt* or *mesocnt/viscous*
- neigh\_cutoff = neighbor list cutoff (distance units)
- mode = *chain* or *segment* (optional)
- neigh\_mode = *id* or *topology* (optional)

### 4.179.2 Examples

```
pair_style mesocnt 30.0
pair_coeff * * C_10_10.mesocnt 2

pair_style mesocnt/viscous 60.0 chain topology
pair_coeff * * C_10_10.mesocnt 0.001 20.0 0.2 2 4
```

### 4.179.3 Description

Style *mesocnt* implements a mesoscopic potential for the interaction of carbon nanotubes (CNTs), or other quasi-1D objects such as other kinds of nanotubes or nanowires. In this potential, CNTs are modelled as chains of cylindrical segments in which each infinitesimal surface element interacts with all other CNT surface elements with the Lennard-Jones (LJ) term adopted from the *airebo* style. The interaction energy is then computed by integrating over the surfaces of all interacting CNTs.

In LAMMPS, cylindrical segments are represented by bonds. Each segment is defined by its two end points (“nodes”) which correspond to atoms in LAMMPS. For the exact functional form of the potential and implementation details, the reader is referred to the original papers (*Volkov1*) and (*Volkov2*).

Changed in version 15Sep2022.

The potential supports two modes, *segment* and *chain*. By default, *chain* mode is enabled. In *segment* mode, interactions are pair-wise between all neighboring segments based on a segment-segment approach (keyword *segment* in *pair\_style* command). In *chain* mode, interactions are calculated between each segment and infinitely or semi-infinitely long CNTs as described in (*Volkov1*). Chains of segments are converted to these (semi-)infinite CNTs bases on an approximate chain approach outlined in (*Volkov2*). Hence, interactions are calculated on a segment-chain basis (keyword *chain* in the *pair\_style* command). Using *chain* mode allows to simplify the computation of the interactions significantly and reduces the computational times to the same order of magnitude as for regular bead spring models where beads interact with the standard *pair\_lj/cut* potential. However, this method is only valid when the curvature of the CNTs in the system is small. When CNTs are buckled (see *angle\_mesocnt*), local curvature can be very high and the *pair\_style* automatically switches to *segment* mode for interactions involving buckled CNTs.

The potential further implements two different neighbor list construction modes. Mode *id* uses atom and mol IDs to construct neighbor lists while *topology* modes uses only the bond topology of the system. While *id* mode requires bonded atoms to have consecutive LAMMPS atom IDs and atoms in different CNTs to have different LAMMPS molecule IDs, *topology* mode has no such requirement. Using *id* mode is faster and is enabled by default.

---

**Note:** Neighbor *id* mode requires all CNTs in the system to have distinct LAMMPS molecule IDs and bonded atoms to have consecutive LAMMPS atom IDs. If this is not possible (e.g. in simulations of CNT rings), *topology* mode needs to be enabled in the *pair\_style* command.

---

New in version 15Sep2022.

In addition to the LJ interactions described above, style *mesocnt/viscous* explicitly models friction between neighboring segments. Friction forces are a function of the relative velocity between a segment and its neighboring approximate chain (even in *segment* mode) and only act along the axes of the interacting segment and chain. In this potential, friction forces acting per unit length of a nanotube segment are modelled as a shifted logistic function:

$$F^{\text{FRICTION}}(v)/L = \frac{F^{\text{max}}}{1 + \exp(-k(v - v_0))} - \frac{F^{\text{max}}}{1 + \exp(kv_0)}$$

---

In the *pair\_style* command, the modes described above can be toggled using the *segment* or *chain* keywords. The neighbor list cutoff defines the cutoff within which atoms are included in the neighbor list for constructing neighboring CNT chains. This is different from the potential cutoff, which is directly calculated from parameters specified in the potential file. We recommend using a neighbor list cutoff of at least 3 times the maximum segment length used in the simulation to ensure proper neighbor chain construction.

---

**Note:** CNT ends are treated differently by all *mesocnt* styles. Atoms on CNT ends need to be assigned different LAMMPS atom types than atoms not on CNT ends.

---

Style *mesocnt* requires tabulated data provided in a single ASCII text file, as well as a list of integers corresponding to all LAMMPS atom types representing CNT ends:

- filename
- $N$  CNT end atom types

For example, if your LAMMPS simulation of (10, 10) nanotubes has 4 atom types where atom types 1 and 3 are assigned to ‘inner’ nodes and atom types 2 and 4 are assigned to CNT end nodes, the `pair_coeff` command would be:

```
pair_coeff * * C_10_10.mesocnt 2 4
```

Likewise, style *mesocnt/viscous* also requires the same information as style *mesocnt*, with the addition of 3 parameters for the viscous friction forces as listed above:

- filename
- $F^{\max}$
- $k$
- $v_0$
- $N$  CNT end atom types

Using the same example system as with style *mesocnt* with the addition of friction, the `pair_coeff` command is:

```
pair_coeff * * C_10_10.mesocnt 0.03 20.0 0.20 2 4
```

Potential files for CNTs can be readily generated using the freely available code provided on

```
https://github.com/phank1/cntpot
```

Using the same approach, it should also be possible to generate potential files for other 1D systems mentioned above.

---

**Note:** Because of their size, *mesocnt* style potential files are not bundled with LAMMPS. When compiling LAMMPS from source code, the file `C_10_10.mesocnt` should be downloaded separately from [https://download.lammps.org/potentials/C\\_10\\_10.mesocnt](https://download.lammps.org/potentials/C_10_10.mesocnt)

The first line of the potential file provides a time stamp and general information. The second line lists four integers giving the number of data points provided in the subsequent four data tables. The third line lists four floating point numbers: the CNT radius  $R$ , the LJ parameter  $\sigma$  and two numerical parameters  $\delta_1$  and  $\delta_2$ . These four parameters are given in Angstroms. This is followed by four data tables each separated by a single empty line. The first two tables have two columns and list the parameters `uInfParallel` and `Gamma` respectively. The last two tables have three columns giving data on a quadratic array and list the parameters `Phi` and `uSemiParallel` respectively. `uInfParallel` and `uSemiParallel` are given in eV/Angstrom, `Phi` is given in eV and `Gamma` is unitless.

If a simulation produces many warnings about segment-chain interactions falling outside the interpolation range, we recommend generating a potential file with lower values of  $\delta_1$  and  $\delta_2$ .

---

#### 4.179.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles does not support mixing.

These pair styles does not support the *pair\_modify* shift, table, and tail options.

These pair styles do not write their information to *binary restart files*, since it is stored in tabulated potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.179.5 Restrictions

These styles are part of the MESONT package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These pair styles require the *newton* setting to be “on” for pair interactions.

These pair styles require all 3 *special\_bonds lj* settings to be non-zero for proper neighbor list construction.

Pair style *mesocnt/viscous* requires you to use the *comm\_modify vel yes* command so that velocities are stored by ghost atoms.

#### 4.179.6 Related commands

*pair\_coeff*, *bond\_style mesocnt*, *angle\_style mesocnt*

#### 4.179.7 Default

mode = chain, neigh\_mode = id

### 4.183.3 Description

The *edpd* style computes the pairwise interactions and heat fluxes for eDPD particles following the formulations in ([Li2014\\_JCP](#)) and [Li2015\\_CC](#). The time evolution of an eDPD particle is governed by the conservation of momentum and energy given by

$$\frac{d^2 \mathbf{r}_i}{dt^2} = \frac{d\mathbf{v}_i}{dt} = \mathbf{F}_i = \sum_{i \neq j} (\mathbf{F}_{ij}^C + \mathbf{F}_{ij}^D + \mathbf{F}_{ij}^R)$$

$$C_v \frac{dT_i}{dt} = q_i = \sum_{i \neq j} (q_{ij}^C + q_{ij}^V + q_{ij}^R),$$

where the three components of  $F_i$  including the conservative force  $F_{ij}^C$ , dissipative force  $F_{ij}^D$  and random force  $F_{ij}^R$  are expressed as

$$\begin{aligned}\mathbf{F}_{ij}^C &= \alpha_{ij} \omega_C(r_{ij}) \mathbf{e}_{ij} \\ \mathbf{F}_{ij}^D &= -\gamma \omega_D(r_{ij}) (\mathbf{e}_{ij} \cdot \mathbf{v}_{ij}) \mathbf{e}_{ij} \\ \mathbf{F}_{ij}^R &= \sigma \omega_R(r_{ij}) \xi_{ij} \Delta t^{-1/2} \mathbf{e}_{ij} \\ \omega_C(r) &= 1 - r/r_c \\ \alpha_{ij} &= A \cdot k_B (T_i + T_j) / 2 \\ \omega_D(r) &= \omega_R^2(r) = (1 - r/r_c)^s \\ \sigma_{ij}^2 &= 4\gamma k_B T_i T_j / (T_i + T_j)\end{aligned}$$

in which the exponent of the weighting function  $s$  can be defined as a temperature-dependent variable. The heat flux between particles accounting for the collisional heat flux  $q^C$ , viscous heat flux  $q^V$ , and random heat flux  $q^R$  are given by

$$\begin{aligned}q_i^C &= \sum_{j \neq i} k_{ij} \omega_{CT}(r_{ij}) \left( \frac{1}{T_i} - \frac{1}{T_j} \right) \\ q_i^V &= \frac{1}{2C_v} \sum_{j \neq i} \left\{ \omega_D(r_{ij}) \left[ \gamma_{ij} (\mathbf{e}_{ij} \cdot \mathbf{v}_{ij})^2 - \frac{(\sigma_{ij})^2}{m} \right] - \sigma_{ij} \omega_R(r_{ij}) (\mathbf{e}_{ij} \cdot \mathbf{v}_{ij}) \xi_{ij} \right\} \\ q_i^R &= \sum_{j \neq i} \beta_{ij} \omega_{RT}(r_{ij}) \Delta t^{-1/2} \xi_{ij}^e \\ \omega_{CT}(r) &= \omega_{RT}^2(r) = (1 - r/r_{ct})^{s_T} \\ k_{ij} &= C_v^2 \kappa (T_i + T_j)^2 / 4k_B \\ \beta_{ij}^2 &= 2k_B k_{ij}\end{aligned}$$

where the mesoscopic heat friction  $\kappa$  is given by

$$\kappa = \frac{315k_B \nu}{2\pi \rho C_v r_{ct}^5 Pr},$$

with  $\nu$  being the kinematic viscosity. For more details, see Eq.(15) in ([Li2014\\_JCP](#)).

The following coefficients must be defined in eDPD system for each pair of atom types via the *pair\_coeff* command as in the examples above.

- A (force units)
- $\gamma$  (force/velocity units)
- power\_f (positive real)
- cutoff (distance units)

- kappa (thermal conductivity units)
- power\_T (positive real)
- cutoff\_T (distance units)
- optional keyword = power or kappa

The keyword *power* or *kappa* is optional. Both “power” and “kappa” require 4 parameters  $c_1, c_2, c_3, c_4$  showing the temperature dependence of the exponent  $s(T) = \text{power}_f(1 + c_1(T - 1) + c_2(T - 1)^2 + c_3(T - 1)^3 + c_4(T - 1)^4)$  and of the mesoscopic heat friction  $s_T(T) = \kappa(1 + c_1(T - 1) + c_2(T - 1)^2 + c_3(T - 1)^3 + c_4(T - 1)^4)$ . If the keyword *power* or *kappa* is not specified, the eDPD system will use constant  $\text{power}_f$  and  $\kappa$ , which is independent to temperature changes.

The *mdpd/rhosum* style computes the local particle mass density  $\rho$  for mDPD particles by kernel function interpolation.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above.

- cutoff (distance units)

The *mdpd* style computes the many-body interactions between mDPD particles following the formulations in ([Li2013\\_POF](#)). The dissipative and random forces are in the form same as the classical DPD, but the conservative force is local density dependent, which are given by

$$\begin{aligned}\mathbf{F}_{ij}^C &= A w_c(r_{ij}) \mathbf{e}_{ij} + B(\rho_i + \rho_j) w_d(r_{ij}) \mathbf{e}_{ij} \\ \mathbf{F}_{ij}^D &= -\gamma \omega_D(r_{ij}) (\mathbf{e}_{ij} \cdot \mathbf{v}_{ij}) \mathbf{e}_{ij} \\ \mathbf{F}_{ij}^R &= \sigma \omega_R(r_{ij}) \xi_{ij} \Delta t^{-1/2} \mathbf{e}_{ij}\end{aligned}$$

where the first term in  $F_C$  with a negative coefficient  $A < 0$  stands for an attractive force within an interaction range  $r_c$ , and the second term with  $B > 0$  is the density-dependent repulsive force within an interaction range  $r_d$ .

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above.

- A (force units)
- B (force units)
- $\gamma$  (force/velocity units)
- cutoff\_c (distance units)
- cutoff\_d (distance units)

The *tdpd* style computes the pairwise interactions and chemical concentration fluxes for tDPD particles following the formulations in ([Li2015\\_JCP](#)). The time evolution of a tDPD particle is governed by the conservation of momentum and concentration given by

$$\begin{aligned}\frac{d^2 \mathbf{r}_i}{dt^2} &= \frac{d\mathbf{v}_i}{dt} = \mathbf{F}_i = \sum_{i \neq j} (\mathbf{F}_{ij}^C + \mathbf{F}_{ij}^D + \mathbf{F}_{ij}^R) \\ \frac{dC_i}{dt} &= Q_i = \sum_{i \neq j} (Q_{ij}^D + Q_{ij}^R) + Q_i^S\end{aligned}$$

where the three components of  $F_i$  including the conservative force  $F_{ij}^C$ , dissipative force  $F_{ij}^D$  and random force  $F_{ij}^R$  are expressed as

$$\begin{aligned}\mathbf{F}_{ij}^C &= A\omega_C(r_{ij})\mathbf{e}_{ij} \\ \mathbf{F}_{ij}^D &= -\gamma\omega_D(r_{ij})(\mathbf{e}_{ij} \cdot \mathbf{v}_{ij})\mathbf{e}_{ij} \\ \mathbf{F}_{ij}^R &= \sigma\omega_R(r_{ij})\xi_{ij}\Delta t^{-1/2}\mathbf{e}_{ij} \\ \omega_C(r) &= 1 - r/r_c \\ \omega_D(r) &= \omega_R^2(r) = (1 - r/r_c)^{\text{power}_f} \\ \sigma^2 &= 2\gamma k_B T\end{aligned}$$

The concentration flux between two tDPD particles includes the Fickian flux  $Q_{ij}^D$  and random flux  $Q_{ij}^R$ , which are given by

$$\begin{aligned}Q_{ij}^D &= -\kappa_{ij}w_{DC}(r_{ij})(C_i - C_j) \\ Q_{ij}^R &= \epsilon_{ij}(C_i + C_j)w_{RC}(r_{ij})\xi_{ij} \\ w_{DC}(r_{ij}) &= w_{RC}^2(r_{ij}) = (1 - r/r_{cc})^{\text{power}_{cc}} \\ \epsilon_{ij}^2 &= m_s^2\kappa_{ij}\rho\end{aligned}$$

where the parameters kappa and epsilon determine the strength of the Fickian and random fluxes.  $m_s$  is the mass of a single solute molecule. In general,  $m_s$  is much smaller than the mass of a tDPD particle  $m$ . For more details, see ([Li2015\\_JCP](#)).

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- A (force units)
- $\gamma$  (force/velocity units)
- power\_f (positive real)
- cutoff (distance units)
- cutoff\_CC (distance units)
- $\kappa_i$  (diffusivity units)
- $\epsilon_i$  (diffusivity units)
- power\_cc\_i (positive real)

The last 3 values must be repeated Nspecies times, so that values for each of the Nspecies chemical species are specified, as indicated by the “I” suffix. In the first pair\_coeff example above for pair\_style tdpd, Nspecies = 1. In the second example, Nspecies = 2, so 3 additional coeffs are specified (for species 2).

---

#### 4.183.4 Example scripts

There are example scripts for using all these pair styles in examples/PACKAGES/mesodpd. The example for an eDPD simulation models heat conduction with source terms analog of periodic Poiseuille flow problem. The setup follows Fig.12 in ([Li2014\\_JCP](#)). The output of the short eDPD simulation (about 2 minutes on a single core) gives a temperature and density profiles as

The example for a mDPD simulation models the oscillations of a liquid droplet started from a liquid film. The mDPD parameters are adopted from (*Li2013\_POF*). The short mDPD run (about 2 minutes on a single core) generates a particle trajectory which can be visualized as follows.

The first image is the initial state of the simulation. If you click it a GIF movie should play in your browser. The second

image is the final state of the simulation.

The example for a tDPD simulation computes the effective diffusion coefficient of a tDPD system using a method analogous to the periodic Poiseuille flow. The tDPD system is specified with two chemical species, and the setup follows Fig.1 in ([Li2015\\_JCP](#)). The output of the short tDPD simulation (about one and a half minutes on a single core) gives the concentration profiles of the two chemical species as

---

#### 4.183.5 Mixing, shift, table, tail correction, restart, rRESPA info

The styles *edpd*, *mdpd*, *mdpd/rhosum* and *tdpd* do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The styles *edpd*, *mdpd*, *mdpd/rhosum* and *tdpd* do not support the *pair\_modify* shift, table, and tail options.

The styles *edpd*, *mdpd*, *mdpd/rhosum* and *tdpd* do not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

#### 4.183.6 Restrictions

The pair styles *edpd*, *mdpd*, *mdpd/rhosum* and *tdpd* are part of the DPD-MESO package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

#### 4.183.7 Related commands

```

### 4.184.3 Description

Within DFT quantum mechanics, generalized pseudopotential theory (GPT) ([Moriarty1](#)) provides a first-principles approach to multi-ion interatomic potentials in d-band transition metals, with a volume-dependent, real-space total-energy functional for the N-ion elemental bulk material in the form

$$E_{\text{tot}}(\mathbf{R}_1 \dots \mathbf{R}_N) = NE_{\text{vol}}(\Omega) + \frac{1}{2} \sum'_{i,j} v_2(ij; \Omega) + \frac{1}{6} \sum'_{i,j,k} v_3(ijk; \Omega) + \frac{1}{24} \sum'_{i,j,k,l} v_4(ijkl; \Omega)$$

where the prime on each summation sign indicates the exclusion of all self-interaction terms from the summation. The leading volume term  $E_{\text{vol}}$  as well as the two-ion central-force pair potential  $v_2$  and the three- and four-ion angular-force potentials,  $v_3$  and  $v_4$ , depend explicitly on the atomic volume  $\Omega$ , but are structure independent and transferable to all bulk ion configurations, either ordered or disordered, and with or without the presence of point and line defects. The simplified model GPT or MGPT ([Moriarty2](#), [Moriarty3](#)), which retains the form of  $E_{\text{tot}}$  and permits more efficient large-scale atomistic simulations, derives from the GPT through a series of systematic approximations applied to  $E_{\text{vol}}$  and the potentials  $v_n$  that are valid for mid-period transition metals with nearly half-filled d bands.

Both analytic ([Moriarty2](#)) and matrix ([Moriarty3](#)) representations of MGPT have been developed. In the more general matrix representation, which can also be applied to f-band actinide metals and permits both canonical and non-canonical d/f bands, the multi-ion potentials are evaluated on the fly during a simulation through d- or f-state matrix multiplication, and the forces that move the ions are determined analytically. Fast matrix-MGPT algorithms have been developed independently by Glosli ([Glosli](#), [Moriarty3](#)) and by Oppelstrup ([Oppelstrup](#))

The *mgpt* pair style calculates forces, energies, and the total energy per atom,  $E_{\text{tot}}/N$ , using the Oppelstrup matrix-MGPT algorithm. Input potential and control data are entered through the *pair\_coeff* command. Each material treated requires input parmin and potin potential files, as shown in the above examples, as well as specification by the user of the initial atomic volume  $\Omega$  through *pair\_coeff*. At the beginning of a time step in any simulation, the total volume of the simulation cell  $V$  should always be equal to  $\Omega \cdot N$ , where  $N$  is the number of metal ions present, taking into account the presence of any vacancies and/or interstitials in the case of a solid. In a constant-volume simulation, which is the normal mode of operation for the *mgpt* pair style,  $\Omega$ ,  $V$  and  $N$  all remain constant throughout the simulation and thus are equal to their initial values. In a constant-stress simulation, the cell volume  $V$  will change (slowly) as the simulation proceeds. After each time step, the atomic volume should be updated by the code as  $\Omega = V/N$ . In addition, the volume term  $E_{\text{vol}}$  and the potentials  $v_2$ ,  $v_3$  and  $v_4$  have to be removed at the end of the time step, and then respecified at the new value of  $\Omega$ . In all simulations,  $\Omega$  must remain within the defined volume range for  $E_{\text{vol}}$  and the potentials for the given material.

The default option `volpress yes` in the `pair_coeff` command includes all volume derivatives of  $E_{\text{tot}}$  required to calculate the stress tensor and pressure correctly. The option `volpress no` disregards the pressure contribution resulting from the volume term  $E_{\text{vol}}$ , and can be used for testing and analysis purposes. The additional optional variable `nbody` controls the specific terms in  $E_{\text{tot}}$  that are calculated. The default option and the normal option for mid-period transition and actinide metals is `nbody 1234` for which all four terms in  $E_{\text{tot}}$  are retained. The option `nbody 12`, for example, retains only the volume term and the two-ion pair potential term and can be used for GPT series-end transition metals that can be well described without  $v_3$  and  $v_4$ . The `nbody` option can also be used to test or analyze the contribution of any of the four terms in  $E_{\text{tot}}$  to a given calculated property.

The `mgpt` pair style makes extensive use of matrix algebra and includes optimized kernels for the BlueGene/Q architecture and the Intel/AMD (x86) architectures. When compiled with the appropriate compiler and compiler switches (`-msse3` on x86, and using the IBM XL compiler on BG/Q), these optimized routines are used automatically. For BG/Q machines, building with the default Makefile for that architecture (e.g., “`make bgq`”) should enable the optimized algebra routines. For x-86 machines, there is a provided Makefile.mgptfast which enables the fast algebra routines, i.e. build LAMMPS with “`make mgptfast`”. The user will be informed in the output files of the matrix kernels in use. To further improve speed, on x86 the option `precision single` can be added to the `pair_coeff` command line, which improves speed (up to a factor of two) at the cost of doing matrix calculations with 7 digit precision instead of the default 16. For consistency the default option can be specified explicitly by the option `precision double`.

All remaining potential and control data are contained with the `parmin` and `potin` files, including cutoffs, atomic mass, and other basic MGPT variables. Specific MGPT potential data for the transition metals tantalum (Ta4 and Ta6.8x potentials), molybdenum (Mo5.2 potentials), and vanadium (V6.1 potentials) are contained in the LAMMPS potentials directory. The stored files are, respectively, `Ta4.mgpt.parmin`, `Ta4.mgpt.potin`, `Ta6.8x.mgpt.parmin`, `Ta6.8x.mgpt.potin`, `Mo5.2.mgpt.parmin`, `Mo5.2.mgpt.potin`, `V6.1.mgpt.parmin`, and `V6.1.mgpt.potin`. Useful corresponding informational “README” files on the Ta4, Ta6.8x, Mo5.2 and V6.1 potentials are also included in the potentials directory. These latter files indicate the volume mesh and range for each potential and give appropriate references for the potentials. It is expected that MGPT potentials for additional materials will be added over time.

Useful example MGPT scripts are given in the `examples/PACKAGES/mgpt` directory. These scripts show the necessary steps to perform constant-volume calculations and simulations. It is strongly recommended that the user work through and understand these examples before proceeding to more complex simulations.

---

**Note:** For good performance, LAMMPS should be built with the compiler flags “`-O3 -msse3 -funroll-loops`” when including this pair style. The `src/MAKE/OPTIONS/Makefile.mgptfast` is an example machine Makefile with these options included as part of a standard MPI build. Note that it as provided, it will build with whatever low-level compiler (g++, icc, etc) is the default for your MPI installation.

---

#### 4.184.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you needs to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.184.5 Restrictions

This pair style is part of the MGPT package and is only enabled if LAMMPS is built with that package. See the [Build package](#) page for more info.

The MGPT potentials require the [newtion](#) setting to be “on” for pair style interactions.

The stored parmin and potin potential files provided with LAMMPS in the “potentials” directory are written in Rydberg atomic units, with energies in Rydbergs and distances in Bohr radii. The *mgpt* pair style converts Rydbergs to Hartrees to make the potential files compatible with LAMMPS electron [units](#).

The form of  $E_{\text{tot}}$  used in the *mgpt* pair style is only appropriate for elemental bulk solids and liquids. This includes solids with point and extended defects such as vacancies, interstitials, grain boundaries and dislocations. Alloys and free surfaces, however, require significant modifications, which are not included in the *mgpt* pair style. Likewise, the *hybrid* pair style is not allowed, where MGPT would be used for some atoms but not for others.

Electron-thermal effects are not included in the standard MGPT potentials provided in the “potentials” directory, where the potentials have been constructed at zero electron temperature. Physically, electron-thermal effects may be important in 3d (e.g., V) and 4d (e.g., Mo) transition metals at high temperatures near melt and above. It is expected that temperature-dependent MGPT potentials for such cases will be added over time.

### 4.184.6 Related commands

[pair\\_coeff](#)

### 4.184.7 Default

The options defaults for the [pair\\_coeff](#) command are volpress yes, nbody 1234, and precision double.

## 4.185 pair\_style mie/cut command

Accelerator Variants: *mie/cut/gpu*

### 4.185.1 Syntax

```
pair_style mie/cut cutoff
```

- cutoff = global cutoff for mie/cut interactions (distance units)

### 4.185.2 Examples

```
pair_style mie/cut 10.0
pair_coeff 1 1 0.72 3.40 23.00 6.66
pair_coeff 2 2 0.30 3.55 12.65 6.00
pair_coeff 1 2 0.46 3.32 16.90 6.31
```

### 4.185.3 Description

The *mie/cut* style computes the Mie potential, given by

$$E = C\epsilon \left[ \left( \frac{\sigma}{r} \right)^{\gamma_{rep}} - \left( \frac{\sigma}{r} \right)^{\gamma_{att}} \right] \quad r < r_c$$

$r_c$  is the cutoff and  $C$  is a function that depends on the repulsive and attractive exponents, given by:

$$C = \left( \frac{\gamma_{rep}}{\gamma_{rep} - \gamma_{att}} \right) \left( \frac{\gamma_{rep}}{\gamma_{att}} \right)^{\left( \frac{\gamma_{att}}{\gamma_{rep} - \gamma_{att}} \right)}$$

Note that for 12/6 exponents,  $C$  is equal to 4 and the formula is the same as the standard Lennard-Jones potential.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- epsilon (energy units)
- sigma (distance units)
- gammaR
- gammaA
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the *pair\_style* command is used.

---

### 4.185.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the *mie/cut* pair styles can be mixed. If not explicitly defined, both the repulsive and attractive gamma exponents for different atoms will be calculated following the same mixing rule defined for distances. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

This pair style supports the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the *run\_style* command for details.

---

## 4.185.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 4.185.6 Related commands

## 4.186 pair\_style mliap command

Accelerator Variants: *mliap/kk*

### 4.186.1 Syntax

```
pair_style mliap ... keyword values ...
```

- one or two keyword/value pairs must be appended
- keyword = *model* or *descriptor* or *unified*

*model* values = style filename

style = *linear* or *quadratic* or *nn* or *mliappy*

filename = name of file containing model definitions

*descriptor* values = style filename

style = *sna* or *so3* or *ace*

filename = name of file containing descriptor definitions

*unified* values = filename ghostneigh\_flag

filename = name of file containing serialized unified Python object

ghostneigh\_flag = 0/1 to turn off/on inclusion of ghost neighbors in neighbors.

→list

## 4.186.2 Examples

```
pair_style mliap model linear InP.mliap.model descriptor sna InP.mliap.descriptor
pair_style mliap model quadratic W.mliap.model descriptor sna W.mliap.descriptor
pair_style mliap model nn Si.nn.mliap.model descriptor so3 Si.nn.mliap.descriptor
pair_style mliap model mliappy ACE_NN_Pytorch.pt descriptor ace ccs_single_element.yace
pair_style mliap unified mliap_unified_lj_Ar.pkl 0
pair_coeff * * In P
```

## 4.186.3 Description

Pair style *mliap* provides a general interface to families of machine-learning interatomic potentials. It allows separate definitions of the interatomic potential functional form (*model*) and the geometric quantities that characterize the atomic positions (*descriptor*).

By defining *model* and *descriptor* separately, it is possible to use many different models with a given descriptor, or many different descriptors with a given model. The pair style currently supports *sna*, *so3* and *ace* descriptor styles, but it is straightforward to add new descriptor styles. By using the *unified* keyword, it is possible to define a Python model that combines functionalities of both *model* and *descriptor*.

The SNAP descriptor style *sna* is the same as that used by *pair\_style snap*, including the linear, quadratic, and chem variants. The available models are *linear*, *quadratic*, *nn*, and *mliappy*. The *mliappy* style can be used to couple python models, e.g. PyTorch neural network energy models, and requires building LAMMPS with the PYTHON package (see below). In order to train a model, it is useful to know the gradient or derivative of energy, force, and stress w.r.t. model parameters. This information can be accessed using the related *compute mliap* command.

New in version 2Jun2022.

The descriptor style *so3* is a descriptor that is derived from the the smooth SO(3) power spectrum with the explicit inclusion of a radial basis (*Bartok*) and (*Zagaceta*). The available models are *linear* and *nn*.

New in version 17Apr2024.

The descriptor style *ace* is a class of highly general atomic descriptors, atomic cluster expansion descriptors (ACE) from (*Drautz*), that include a radial basis, an angular basis, and bases for other variables (such as chemical species) if relevant. In descriptor style *ace*, the *ace* descriptors may be defined up to an arbitrary body order. This descriptor style is the same as that used in *pair\_style pace* and *compute pace*. The available models with *ace* in ML-IAP are *linear* and *mliappy*. The *ace* descriptors and models require building LAMMPS with the ML-PACE package (see below). The *mliappy* model style may be used with *ace* descriptors, but it requires that LAMMPS is also built with the PYTHON package. As with other model styles, the *mliappy* model style can be used to couple arbitrary python models that use the *ace* descriptors such as Pytorch NNs. Note that *ALL* mliap model styles with *ace* descriptors require that descriptors and hyperparameters are supplied in a *.yace* or *.ace* file, similar to *compute pace*.

The *pair\_style mliap* command must be followed by two keywords *model* and *descriptor* in either order, or the one keyword *unified*. A single *pair\_coeff* command is also required. The first 2 arguments must be \* \* so as to span all LAMMPS atom types. This is followed by a list of N arguments that specify the mapping of MLIAP element names to LAMMPS atom types, where N is the number of LAMMPS atom types.

The *model* keyword is followed by the model style. This is followed by a single argument specifying the model filename containing the parameters for a set of elements. The model filename usually ends in the *.mliap.model* extension. It may contain parameters for many elements. The only requirement is that it contain at least those element names appearing in the *pair\_coeff* command.

The top of the model file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain two integers:

- nelems = Number of elements

- *nparams* = Number of parameters

When the *model* keyword is *linear* or *quadratic*, this is followed by one block for each of the *nelem* elements. Each block consists of *nparams* parameters, one per line. Note that this format is similar, but not identical to that used for the *pair\_style snap* coefficient file. Specifically, the line containing the element weight and radius is omitted, since these are handled by the *descriptor*.

When the *model* keyword is *nn* (neural networks), the model file can contain blank and comment lines (start with #) anywhere. The second non-blank non-comment line must contain the string NET, followed by two integers:

- *ndescriptors* = Number of descriptors
- *nlayers* = Number of layers (including the hidden layers and the output layer)

and followed by a sequence of a string and an integer for each layer:

- Activation function (linear, sigmoid, tanh or relu)
- *nnodes* = Number of nodes

This is followed by one block for each of the *nelem* elements. Each block consists of *scale0* minimum value, *scale1* (maximum - minimum) value, in order to normalize the descriptors, followed by *nparams* parameters, including *bias* and *weights* of the model, starting with the first node of the first layer and so on, with a maximum of 30 values per line.

The detail of *nn* module implementation can be found at ([Yanxon](#)).

---

### Notes on mliappy models

When the *model* keyword is *mliappy*, if the filename ends in '.pt', or '.pth', it will be loaded using pytorch; otherwise, it will be loaded as a pickle file. To load a model from memory (i.e. an existing python object), specify the filename as "LATER", and then call *lammps.mliap.load\_model(model)* from python before using the pair style. When using LAMMPS via the library mode, you will need to call *lammps.mliappy.activate\_mliappy(lmp)* on the active LAMMPS object before the pair style is defined. This call locates and loads the mliap-specific python module that is built into LAMMPS.

---

The *descriptor* keyword is followed by a descriptor style, and additional arguments. Currently three descriptor styles are available: *sna*, *so3*, and *ace*.

- *sna* indicates the bispectrum component descriptors used by the Spectral Neighbor Analysis Potential (SNAP) potentials of *pair\_style snap*. A single additional argument specifies the descriptor filename containing the parameters and setting used by the SNAP descriptor. The descriptor filename usually ends in the *.mliap.descriptor* extension.
- *so3* indicated the power spectrum component descriptors. A single additional argument specifies the descriptor filename containing the parameters and setting.
- *ace* indicates the atomic cluster expansion (ACE) descriptors. A single additional argument specifies the filename containing parameters, settings, and definitions of the ace descriptors (through tabulated basis function indices and corresponding generalized Clebsch-Gordan coefficients) in the ctilde file format, e.g. in the potential file format with \*.ace or \*.yace extensions from *pair\_style pace*. Note that unlike the potential file, the Clebsch-Gordan coefficients in the descriptor file supplied should *NOT* be multiplied by linear or square root embedding terms.

The SNAP descriptor file closely follows the format of the *pair\_style snap* parameter file. The file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. The required keywords are *rcutfac* and *twojmax*. There are many optional keywords that are described on the *pair\_style snap* doc page. In addition, the SNAP descriptor file must contain the *nelems*, *elems*, *radelems*, and *welems* keywords. The *nelems* keyword specifies the number of elements provided in the other three keywords. The *elems* keyword is followed by a list of *nelems* element names that must include the element names appearing in the *pair\_coeff* command, but can contain other names too. Similarly, the *radelems* and *welems* keywords are followed by lists of *nelems* numbers

giving the element radius and element weight of each element. Obviously, the order in which the elements are listed must be consistent for all three keywords.

The SO3 descriptor file is similar to the SNAP descriptor except that it contains a few more arguments (e.g., *nmax* and *alpha*). The preparation of SO3 descriptor and model files can be done with the [Pyxtal\\_FF](#) package.

The ACE descriptor file differs from the SNAP and SO3 files. It more closely resembles the potential file format for linear or square-root embedding ACE potentials used in the [pair\\_style pace](#). As noted above, the key difference is that the Clebsch-Gordan coefficients in the descriptor file with *mliap descriptor ace* are *NOT* multiplied by linear or square root embedding terms. In other words, the model is separated from the descriptor definitions and hyperparameters. In [pair\\_style pace](#), they are combined. The ACE descriptor files required by *mliap* are generated automatically in [FitSNAP](#) during linear, pytorch, etc. ACE model fitting. Additional tools are provided there to prepare *ace* descriptor files and hyperparameters before model fitting. The *ace* descriptor files can also be extracted from ACE model fits in [python-ace](#). It is important to note that order of the types listed in [pair\\_coeff](#) must match the order of the elements/types listed in the ACE descriptor file for all *mliap* styles when using *ace* descriptors.

See the [pair\\_coeff](#) page for alternate ways to specify the path for these *model* and *descriptor* files.

---

**Note:** To significantly reduce SO3 descriptor/force calculation time, some properties are pre-computed and reused during the calculation. These can consume a significant amount of RAM for simulations of larger systems since their size depends on the total number of neighbors per MPI process.

---

New in version 3Nov2022.

The *unified* keyword is followed by an argument specifying the filename containing the serialized unified Python object and the “ghostneigh” toggle (0/1) to disable/enable the construction of neighbors lists including neighbors of ghost atoms. If the filename ends in ‘.pt’, or ‘.pth’, it will be loaded using pytorch; otherwise, it will be loaded as a pickle file. If ghostneigh is enabled, it is recommended to set [comm\\_modify](#) cutoff manually, such as in the following example.

```
variable ninteractions equal 2
variable cutdist equal 7.5
variable skin equal 1.0
variable commcut equal (${ninteractions}*${cutdist})+${skin}
neighbor ${skin} bin
comm_modify cutoff ${commcut}
```

---

**Note:** To load a model from memory (i.e. an existing python object), call *lammps.mliap.load\_unified(unified)* from python, and then specify the filename as “EXISTS”. When using LAMMPS via the library mode, you will need to call *lammps.mliappy.activate\_mliappy(lmp)* on the active LAMMPS object before the pair style is defined. This call locates and loads the mliap-specific python module that is built into LAMMPS.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.186.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a `pair_coeff` command with  $I \neq J$  arguments for this style.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.186.5 Restrictions

This pair style is part of the ML-IAP package. It is only enabled if LAMMPS was built with that package. In addition, building LAMMPS with the ML-IAP package requires building LAMMPS with the ML-SNAP package. The *mliappy* model requires building LAMMPS with the PYTHON package. The *ace* descriptor requires building LAMMPS with the ML-PACE package. See the *Build package* page for more info. Note that *pair\_mliap/kk* acceleration will *not* invoke the *kk* accelerated variants of SNAP or ACE descriptors.

#### 4.186.6 Related commands

*pair\_style snap*, *compute mliap*

#### 4.186.7 Default

none

### 4.187 pair\_style momb command

#### 4.187.1 Syntax

```
pair_style momb cutoff s6 d
```

- cutoff = global cutoff (distance units)
- s6 = global scaling factor of the exchange-correlation functional used (unitless)
- d = damping scaling factor of Grimme's method (unitless)

## 4.187.2 Examples

```
pair_style momb 12.0 0.75 20.0
pair_style hybrid/overlay eam/fs lj/charmm/coul/long 10.0 12.0 momb 12.0 0.75 20.0 morse_
→ 5.5

pair_coeff 1 2 momb 0.0 1.0 1.0 10.2847 2.361
```

## 4.187.3 Description

Style *momb* computes pairwise van der Waals (vdW) and short-range interactions using the Morse potential and (*Grimme*) method implemented in the Many-Body Metal-Organic (MOMB) force field described comprehensively in (*Fichthorn*) and (*Zhou*). Grimme's method is widely used to correct for dispersion in density functional theory calculations.

$$E = D_0[\exp^{-2\alpha(r-r_0)} - 2\exp^{-\alpha(r-r_0)}] - s_6 \frac{C_6}{r^6} f_{damp}(r, R_r)$$
$$f_{damp}(r, R_r) = \frac{1}{1 + \exp^{-d(r/R_r-1)}}$$

For the *momb* pair style, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* as described below:

- $D_0$  (energy units)
- $\alpha$  (1/distance units)
- $r_0$  (distance units)
- $C_6$  (energy\*distance<sup>6</sup> units)
- $R_r$  (distance units, typically sum of atomic vdW radii)

---

## 4.187.4 Restrictions

This style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS is built with that package. See the *Build package* page on for more info.

## 4.187.5 Related commands

*pair\_coeff*, *pair\_style morse*

## 4.187.6 Default

## 4.188 `pair_style morse` command

Accelerator Variants: *morse/gpu*, *morse/omp*, *morse/opt*, *morse/kk*

## 4.189 `pair_style morse/smooth/linear` command

Accelerator Variants: *morse/smooth/linear/omp*

### 4.189.1 Syntax

```
pair_style style args
```

- `style` = *morse* or *morse/smooth/linear* or *morse/soft*
- `args` = list of arguments for a particular style

*morse* args = cutoff

cutoff = global cutoff for Morse interactions (distance units)

*morse/smooth/linear* args = cutoff

cutoff = global cutoff for Morse interactions (distance units)

### 4.189.2 Examples

```
pair_style morse 2.5
pair_style morse/smooth/linear 2.5
pair_coeff * * 100.0 2.0 1.5
pair_coeff 1 1 100.0 2.0 1.5 3.0
```

### 4.189.3 Description

Style *morse* computes pairwise interactions with the formula

$$E = D_0 [e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)}] \quad r < r_c$$

$r_c$  is the cutoff.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $D_0$  (energy units)
- $\alpha$  (1/distance units)
- $r_0$  (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global morse cutoff is used.

The *morse/smooth/linear* variant is similar to the *lj/smooth/linear* variant in that it adds to the potential a shift and a linear term so that both, potential energy and force, go to zero at the cut-off:

$$\begin{aligned}\phi(r) &= D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] & r < r_c \\ E(r) &= \phi(r) - \phi(r_c) - (r - r_c) \left. \frac{d\phi}{dr} \right|_{r=r_c} & r < r_c\end{aligned}$$

The syntax of the `pair_style` and `pair_coeff` commands are the same for the *morse* and *morse/smooth/linear* styles.

---

A version of the *morse* style with a soft core, *morse/soft*, suitable for use in free energy calculations, is part of the FEP package and is documented with the *pair\_style \*/soft* styles. The version with soft core is only available if LAMMPS was built with that package. See the *Build package* page for more info.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.189.4 Mixing, shift, table, tail correction, restart, rRESPA info

None of these pair styles support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

All of these pair styles support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table options are not relevant for the Morse pair styles.

None of these pair styles support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

All of these pair styles write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.189.5 Restrictions

The *morse/smooth/linear* pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the *Build package* page for more info.

## 4.189.6 Related commands

*pair\_coeff*, *pair\_style \*/soft*

## 4.189.7 Default

none

## 4.190 pair\_style multi/lucy command

### 4.190.1 Syntax

```
pair_style multi/lucy style N keyword ...
```

- style = *lookup* or *linear* = method of interpolation
- N = use N values in *lookup*, *linear* tables

### 4.190.2 Examples

```
pair_style multi/lucy linear 1000
pair_coeff * * multibody.table ENTRY1 7.0
```

### 4.190.3 Description

Style *multi/lucy* computes a density-dependent force following from the many-body form described in ([Moore](#)) and ([Warren](#)) as

$$F_i^{DD}(\rho_i, \rho_j, r_{ij}) = \frac{1}{2} \omega_{DD}(r_{ij}) [A(\rho_i) + A(\rho_j)] e_{ij}$$

which consists of a density-dependent function,  $A(\rho)$ , and a radial-dependent weight function,  $\omega_{DD}(r_{ij})$ . The radial-dependent weight function,  $\omega_{DD}(r_{ij})$ , is taken as the Lucy function:

$$\omega_{DD}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_{cut}}\right) \left(1 + \frac{r_{ij}}{r_{cut}}\right)^3$$

The density-dependent energy for a given particle is given by:

$$u_i^{DD}(\rho_i) = \frac{\pi r_{cut}^4}{84} \int_{\rho_0}^{\rho_i} A(\rho') d\rho'$$

See the supporting information of ([Brennan](#)) or the publication by ([Moore](#)) for more details on the functional form.

An interpolation table is used to evaluate the density-dependent energy ( $\int A(\rho') d\rho'$ ) and force ( $A(\rho')$ ). Note that the prefactor to the energy is computed after the interpolation, thus the  $\int A(\rho') d\rho'$  will have units of energy / length<sup>4</sup>.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force at each of  $N$  densities. During a simulation, the tables are used to interpolate the density-dependent energy and force as needed for each pair of particles separated by a distance  $R$ . The interpolation is done in one of 2 styles: *lookup* and *linear*.

For the *lookup* style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the *linear* style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- filename
- keyword
- cutoff (distance units)

The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

---

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

# Density-dependent function (one or more comment or blank lines)

```
DD-FUNCTION          (keyword is first text on line)
N 500 R 1.0 10.0      (N, R, RSQ parameters)
                     (blank)
1 1.0 25.5 102.34      (index, density, energy/r^4, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the *pair\_coeff* command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the *N* specified in the *pair\_style multi/lucy* command. Let  $N_{\text{table}} = N$  in the *pair\_style* command, and  $N_{\text{file}} = “N”$  in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the  $N_{\text{file}}$  tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at  $N_{\text{table}}$  different points. The resulting tables of length  $N_{\text{table}}$  are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length  $N_{\text{table}}$  to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set  $N_{\text{table}} = N_{\text{file}}$ , and use the “RSQ” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in *density* uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values *rlo* and *rhi*. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the table file are ignored in this case. For “R”, distances uniformly spaced between *rlo* and *rhi* are computed; for “RSQ”, squared distances uniformly spaced between *rlo*\**rlo* and *rhi*\**rhi* are computed.

**Note:** If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.

---

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in density units), the third value is the density-dependent function value (in energy units / length<sup>4</sup>), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

#### 4.190.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The *pair\_modify* shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair\_style multi/lucy” command to *binary restart files*, so a pair\_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair\_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.190.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.190.6 Related commands

*pair\_coeff*

## 4.191 pair\_style multi/lucy/rx command

Accelerator Variants: *multi/lucy/rx/kk*

### 4.191.1 Syntax

```
pair_style multi/lucy/rx style N keyword ...
```

- style = *lookup* or *linear* = method of interpolation
- N = use N values in *lookup*, *linear* tables
- weighting = fractional or molecular (optional)

### 4.191.2 Examples

```
pair_style multi/lucy/rx linear 1000
pair_style multi/lucy/rx linear 1000 fractional
pair_style multi/lucy/rx linear 1000 molecular
pair_coeff * * multibody.table ENTRY1 h2o h2o 7.0
pair_coeff * * multibody.table ENTRY1 h2o 1fluid 7.0
```

### 4.191.3 Description

Style *multi/lucy/rx* is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of  $m$  species whose reaction rate kinetics are determined from a set of  $n$  reaction rate equations through the *fix rx* command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style *multi/lucy/rx* computes the site-site density-dependent force following from the many-body form described in ([Moore](#)) and ([Warren](#)) as

$$F_i^{DD}(\rho_i, \rho_j, r_{ij}) = \frac{1}{2} \omega_{DD}(r_{ij}) [A(\rho_i) + A(\rho_j)] e_{ij}$$

which consists of a density-dependent function,  $A(\rho)$ , and a radial-dependent weight function,  $\omega_{DD}(r_{ij})$ . The radial-dependent weight function,  $\omega_{DD}(r_{ij})$ , is taken as the Lucy function:

$$\omega_{DD}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_{cut}}\right) \left(1 + \frac{r_{ij}}{r_{cut}}\right)^3$$

The density-dependent energy for a given particle is given by:

$$u_i^{DD}(\rho_i) = \frac{\pi r_{cut}^4}{84} \int_{\rho_0}^{\rho_i} A(\rho') d\rho'$$

See the supporting information of ([Brennan](#)) or the publication by ([Moore](#)) for more details on the functional form.

An interpolation table is used to evaluate the density-dependent energy ( $\int A(\rho') d\rho'$ ) and force ( $A(\rho')$ ). Note that the prefactor to the energy is computed after the interpolation, thus the  $\int A(\rho') d\rho'$  will have units of energy / length<sup>4</sup>.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force at each of  $N$  densities. During a simulation, the tables are used to interpolate the density-dependent energy and force as needed for each pair of particles separated by a distance  $R$ . The interpolation is done in one of 2 styles: *lookup* and *linear*.

For the *lookup* style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the *linear* style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- filename
- keyword
- species1
- species2
- cutoff (distance units)

The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the *fix rx* command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the *fractional* or *molecular* weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

---

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

# Density-dependent function (one or more comment or blank lines)

```
DD-FUNCTION          (keyword is first text on line)
N 500 R 1.0 10.0      (N, R, RSQ parameters)
                     (blank)
1 1.0 25.5 102.34     (index, density, energy/r^4, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the *pair\_coeff* command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the *N* specified in the *pair\_style multi/lucy/rx* command. Let *Ntable* = *N* in the *pair\_style* command, and *Nfile* = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the *Nfile* tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at *Ntable* different points. The resulting tables of length *Ntable* are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length *Ntable* to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set *Ntable* = *Nfile*, and use the “RSQ” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in *density* uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values *rlo* and *rhi*. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the table file are ignored in this case. For “R”, distances uniformly spaced between *rlo* and *rhi* are computed; for “RSQ”, squared distances uniformly spaced between *rlo\*rlo* and *rhi\*rhi* are computed.

---

**Note:** If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.

---

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is *r* (in density units), the third value is the density-dependent function value (in energy units /  $\text{length}^4$ ), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

#### 4.191.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The *pair\_modify* shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair\_style multi/lucy/rx” command to *binary restart files*, so a pair\_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair\_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 4.192 pair\_style nb3b/harmonic command

## 4.193 pair\_style nb3b/screened command

### 4.193.1 Syntax

```
pair_style style
```

- style = *nb3b/harmonic* or *nb3b/screened*

### 4.193.2 Examples

```
pair_style nb3b/harmonic
pair_coeff * * MgOH.nb3bharmonic Mg O H

pair_style nb3b/screened
pair_coeff * * P0.nb3b.screened P NULL O
pair_coeff * * SiOH.nb3b.screened Si O H
```

### 4.193.3 Description

The pair style *nb3b/harmonic* computes a non-bonded 3-body harmonic potential for the energy  $E$  of a system of atoms as

$$E = K(\theta - \theta_0)^2$$

where  $\theta_0$  is the equilibrium value of the angle and  $K$  is a prefactor. Note that the usual 1/2 factor is included in  $K$ . The form of the potential is identical to that used in angle\_style *harmonic*, but in this case, the atoms do not need to be explicitly bonded.

Style *nb3b/screened* adds an additional exponentially decaying factor to the harmonic term, given by

$$E = K(\theta - \theta_0)^2 \exp\left(-\frac{r_{ij}}{\rho_{ij}} - \frac{r_{ik}}{\rho_{ik}}\right)$$

where  $\rho_{ij}$  and  $\rho_{ik}$  are the screening factors along the two bonds. Note that the usual 1/2 factor is included in  $K$ .

Only a single pair\_coeff command is used with these styles which specifies a potential file with parameters for specified elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair\_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.nb3b.harmonic has potential values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair\_coeff command:

```
pair_coeff * * SiC.nb3b.harmonic Si Si Si C
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the potential file. The final C argument maps LAMMPS atom type 4 to the C element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials. Two examples of pair\_coeff command for use with the *hybrid* pair style are:

```
pair_coeff * * nb3b/harmonic MgOH.nb3b.harmonic Mg O H
```

Three-body non-bonded harmonic files in the *potentials* directory of the LAMMPS distribution have a “.nb3b.harmonic” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements.

Each entry has six arguments. The first three are atom types as referenced in the LAMMPS input file. The first argument specifies the central atom. The fourth argument indicates the  $K$  parameter. The fifth argument indicates  $\theta_0$ . The sixth argument indicates a separation cutoff in Angstroms.

For a given entry, if the second and third arguments are identical, then the entry is for a cutoff for the distance between types 1 and 2 (values for  $K$  and  $\theta_0$  are irrelevant in this case).

For a given entry, if the first three arguments are all different, then the entry is for the  $K$  and  $\theta_0$  parameters (the cutoff in this case is irrelevant).

It is required that the potential file contains entries for *all* permutations of the elements listed in the pair\_coeff command. If certain combinations are not parameterized the corresponding parameters should be set to zero. The potential file can also contain entries for additional elements which are not used in a particular simulation; LAMMPS ignores those entries.

#### 4.193.4 Restrictions

This pair style can only be used if LAMMPS was built with the MANYBODY package. See the [Build package](#) page for more info.

## 4.197.3 Description

Style *nm* computes site-site interactions based on the N-M potential by [Clarke](#), mainly used for ionic liquids. A site can represent a single atom or a united-atom site. The energy of an interaction has the following form:

$$E = \frac{E_0}{(n-m)} \left[ m \left( \frac{r_0}{r} \right)^n - n \left( \frac{r_0}{r} \right)^m \right] \quad r < r_c$$

where  $r_c$  is the cutoff and  $r_0$  is the minimum of the potential. Please note that this differs from the convention used for other Lennard-Jones potentials in LAMMPS where  $\sigma$  represents the location where the energy is zero.

Style *nm/cut/split* applies the standard LJ (12-6) potential above  $r_0 = 2^{\frac{1}{6}}\sigma$ . Style *nm/cut/split* is employed in polymer equilibration protocols that combine core-softening approaches with topology-changing moves [Dietz](#).

Style *nm/cut/coul/cut* adds a Coulombic pairwise interaction given by

$$E = \frac{Cq_iq_j}{\epsilon r} \quad r < r_c$$

where  $C$  is an energy-conversion constant,  $q_i$  and  $q_j$  are the charges on the two atoms, and epsilon is the dielectric constant which can be set by the [dielectric](#) command. If one cutoff is specified in the *pair\_style* command, it is used for both the N-M and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the N-M and Coulombic terms respectively.

Styles *nm/cut/coul/long* compute the same Coulombic interactions as style *nm/cut/coul/cut* except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the [kspace\\_style](#) command and its *ewald* or *pppm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

For all of the *nm* pair styles, the following coefficients must be defined for each pair of atoms types via the [pair\\_coeff](#) command as in the examples above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands.

- $E_0$  (energy units)
- $r_0$  (distance units)
- $n$  (unitless)
- $m$  (unitless)
- cutoff1 (distance units)

- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global N-M and Coulombic cutoffs specified in the `pair_style` command are used. If only one cutoff is specified, it is used as the cutoff for both N-M and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the N-M and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style *nm*, since it has no Coulombic terms.

For *nm/cut/coul/long* only the N-M cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the `pair_style` command.

---

#### 4.197.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

All of the *nm* pair styles supports the *pair\_modify* shift option for the energy of the pair interaction.

The *nm/cut/coul/long* pair styles support the *pair\_modify* table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the *nm* pair styles support the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure for the N-M portion of the pair interaction.

All of the *nm* pair styles write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

All of the *nm* pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.197.5 Restrictions

These pair styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.197.6 Related commands

*pair\_coeff*, *pair style lj/cut*, *bond style fene/nm*

### 4.197.7 Default

none

## 4.198 pair\_style none command

### 4.198.1 Syntax

```
pair_style none
```

### 4.198.2 Examples

```
pair_style none
```

### 4.198.3 Description

Using a pair style of *none* means that any previous pair style setting will be deleted and pairwise forces and energies are not computed.

As a consequence there will be a pairwise force cutoff of 0.0, which has implications for the default setting of the neighbor list and the communication cutoff. Those are the sum of the largest pairwise cutoff and the neighbor skin distance (see the documentation of the *neighbor* command and the *comm\_modify* command). When you have bonds, angles, dihedrals, or impropers defined at the same time, you must set the communication cutoff so that communication cutoff distance is large enough to acquire and communicate sufficient ghost atoms from neighboring subdomains as needed for computing bonds, angles, etc.

A pair style of *none* will also not request a pairwise neighbor list. However if the *neighbor* style is *bin*, data structures for binning are still allocated. If the neighbor list cutoff is small, then these data structures can consume a large amount of memory. So you should either set the neighbor style to *nsq* or set the skin distance to a larger value.

See the *pair\_style zero* for a way to set a pairwise cutoff and thus trigger the building of a neighbor lists and setting a corresponding communication cutoff, but compute no pairwise interactions.

#### 4.198.4 Restrictions

You must not use a *pair\_coeff* command with this pair style. Since there is no interaction computed, you cannot set any coefficients for it.

**Note:** The coefficients in the above examples are provided in forms compatible with both *units lj* and *units real* (see documentation of *units*). These can also be read from a potential file with correct unit style by specifying the name of the file. Several potential files for each unit style are included in the `potentials` directory of the LAMMPS distribution.

### 4.203.3 Description

The *oxdna* pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction *oxdna/excv*, the stacking *oxdna/stk*, cross-stacking *oxdna/xstk* and coaxial stacking interaction *oxdna/coaxstk* as well as the hydrogen-bonding interaction *oxdna/hbond* between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (*Sulc*). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (*Ouldridge-DPhil*) and (*Ouldridge*) for a detailed description of the oxDNA force field.

**Note:** These pair styles have to be used together with the related oxDNA bond style *oxdna/fene* for the connectivity of the phosphate backbone (see also documentation of *bond\_style oxdna/fene*). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after *oxdna/stk* (seq=seqdep, T=0.1, xi=1.3448 and kappa=2.6568 and corresponding *real unit* equivalents in the above examples) and the first coefficient after *oxdna/hbond* (seq=seqdep in the above example). When using a Langevin thermostat, e.g. through *fix langevin* or *fix nve/dotc/langevin* the temperature coefficients have to be matched to the one used in the fix.

**Note:** These pair styles have to be used with the *atom\_style hybrid bond ellipsoid oxdna* (see documentation of *atom\_style*). The *atom\_style oxdna* stores the 3'-to-5' polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3'-end (5'-end) of the strand.

Example input and data files for DNA duplexes can be found in `examples/PACKAGES/cgdna/examples/oxDNA/` and `.../oxDNA2/`. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in `examples/PACKAGES/cgdna/util/`.

Please cite (*Henrich*) in any publication that uses this implementation. An updated documentation that contains general information on the model, its implementation and performance as well as the structure of the data and input file can be

found [here](#).

Please cite also the relevant oxDNA publications (*Ouldridge*), (*Ouldridge-DPhil*) and (*Sulc*).

---

#### 4.203.4 Potential file reading

For each pair style above the first non-modifiable argument can be a filename, and if it is, no further arguments should be supplied. Therefore the following command:

```
pair_coeff 1 4 oxdna/hbond seqav oxdna_lj.cgdna
```

will be interpreted as a request to read the corresponding hydrogen bonding potential parameters from the file with the given name. The file can define multiple potential parameters for both bonded and pair interactions, but for the example pair interaction above there must exist in the file a line of the form:

```
1 4 hbond <coefficients>
```

If potential customization is required, the potential file reading can be mixed with the manual specification of the potential parameters. For example, the following command:

```
pair_style hybrid/overlay oxdna/excv oxdna/stk oxdna/hbond oxdna/xstk oxdna/coaxstk
pair_coeff * * oxdna/excv oxdna_lj.cgdna
pair_coeff * * oxdna/stk seqav 0.1 1.3448 2.6568 6.0 0.4 0.9 0.32 0.75 1.3 0 0.8 0.9
→ 0 0.95 0.9 0 0.95 2.0 0.65 2.0 0.65
pair_coeff * * oxdna/hbond seqav oxdna_lj.cgdna
pair_coeff 1 4 oxdna/hbond seqav oxdna_lj.cgdna
pair_coeff 2 3 oxdna/hbond seqav oxdna_lj.cgdna
pair_coeff * * oxdna/xstk oxdna_lj.cgdna
pair_coeff * * oxdna/coaxstk 46.0 0.4 0.6 0.22 0.58 2.0 2.541592653589793 0.65 1.3 0 0.8
→ 0.9 0 0.95 0.9 0 0.95 2.0 -0.65 2.0 -0.65
```

will read the stacking and coaxial stacking potential parameters from the manual specification and all others from the potential file *oxdna\_lj.cgdna*.

There are sample potential files for each unit style in the `potentials` directory of the LAMMPS distribution. The potential file unit system must align with the units defined via the `units` command. For conversion between different *LJ* and *real* unit systems for oxDNA, the python tool *lj2real.py* located in the `examples/PACKAGES/cgdna/util/` directory can be used. This tool assumes similar file structure to the examples found in `examples/PACKAGES/cgdna/examples/`.

---

#### 4.203.5 Restrictions

These pair styles can only be used if LAMMPS was built with the CG-DNA package and the MOLECULE and ASPHERE package. See the [Build package](#) page for more info.

**Note:** The coefficients in the above examples are provided in forms compatible with both *units lj* and *units real* (see documentation of *units*). These can also be read from a potential file with correct unit style by specifying the name of the file. Several potential files for each unit style are included in the `potentials` directory of the LAMMPS distribution.

### 4.209.3 Description

The *oxdna2* pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction *oxdna2/excv*, the stacking *oxdna2/stk*, cross-stacking *oxdna2/xstk* and coaxial stacking interaction *oxdna2/coaxstk*, electrostatic Debye-Hueckel interaction *oxdna2/dh* as well as the hydrogen-bonding interaction *oxdna2/hbond* between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (*Sulc*). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within  $N_{\text{types}}/4$  bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (*Snodin*) and the original oxDNA publications (*Ouldridge-DPhil*) and (*Ouldridge*) for a detailed description of the oxDNA2 force field.

**Note:** These pair styles have to be used together with the related oxDNA2 bond style *oxdna2/fene* for the connectivity of the phosphate backbone (see also documentation of *bond\_style oxdna2/fene*). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the

first four coefficients after *oxdna2/stk* (seq=seqdep, T=0.1, xi=1.3523 and kappa=2.6717 and corresponding *real unit* equivalents in the above examples). the first coefficient after *oxdna2/hbond* (seq=seqdep in the above example) and the three coefficients after *oxdna2/dh* (T=0.1, rhos=0.5, qeff=0.815 in the above example). When using a Langevin thermostat e.g. through *fix langevin* or *fix nve/dof/langevin* the temperature coefficients have to be matched to the one used in the fix.

**Note:** These pair styles have to be used with the *atom\_style hybrid bond ellipsoid oxdna* (see documentation of *atom\_style*). The *atom\_style oxdna* stores the 3'-to-5' polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3'-end (5'-end) of the strand.

Example input and data files for DNA duplexes can be found in `examples/PACKAGES/cgdna/examples/oxDNA/` and `.../oxDNA2/`. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in `examples/PACKAGES/cgdna/util/`.

Please cite ([Henrich](#)) in any publication that uses this implementation. An updated documentation that contains general information on the model, its implementation and performance as well as the structure of the data and input file can be found [here](#).

Please cite also the relevant oxDNA2 publications ([Snodin](#)) and ([Sulc](#)).

## 4.209.4 Potential file reading

For each pair style above the first non-modifiable argument can be a filename (with exception of Debye-Hueckel, for which the effective charge argument can be a filename), and if it is, no further arguments should be supplied. Therefore the following command:

```
pair_coeff 1 4 oxdna2/hbond seqdep oxdna_real.cgdna
```

will be interpreted as a request to read the corresponding hydrogen bonding potential parameters from the file with the given name. The file can define multiple potential parameters for both bonded and pair interactions, but for the example pair interaction above there must exist in the file a line of the form:

```
1 4 hbond <coefficients>
```

If potential customization is required, the potential file reading can be mixed with the manual specification of the potential parameters. For example, the following command:

```
pair_style hybrid/overlay oxdna2/excv oxdna2/stk oxdna2/hbond oxdna2/xstk oxdna2/coaxstk
→oxdna2/dh
pair_coeff * * oxdna2/excv 2.0 0.7 0.675 2.0 0.515 0.5 2.0 0.33 0.32
pair_coeff * * oxdna2/stk seqdep 0.1 1.3523 2.6717 oxdna2_lj.cgdna
pair_coeff * * oxdna2/hbond seqdep oxdna2_lj.cgdna
pair_coeff 1 4 oxdna2/hbond seqdep oxdna2_lj.cgdna
pair_coeff 2 3 oxdna2/hbond seqdep oxdna2_lj.cgdna
pair_coeff * * oxdna2/xstk oxdna2_lj.cgdna
pair_coeff * * oxdna2/coaxstk oxdna2_lj.cgdna
pair_coeff * * oxdna2/dh 0.1 0.5 0.815
```

will read the excluded volume and Debye-Hueckel effective charge *qeff* parameters from the manual specification and all others from the potential file *oxdna2\_lj.cgdna*.

There are sample potential files for each unit style in the `potentials` directory of the LAMMPS distribution. The potential file unit system must align with the units defined via the `units` command. For conversion between different *LJ* and *real* unit systems for oxDNA, the python tool `lj2real.py` located in the `examples/PACKAGES/cgdna/util/` directory can be used. This tool assumes similar file structure to the examples found in `examples/PACKAGES/cgdna/examples/`.

---

## 4.209.5 Restrictions

These pair styles can only be used if LAMMPS was built with the CG-DNA package and the MOLECULE and ASPHERE package. See the [Build package](#) page for more info.

**Note:** The coefficients in the above examples are provided in forms compatible with both *units lj* and *units real* (see documentation of *units*). These can also be read from a potential file with correct unit style by specifying the name of the file. Several potential files for each unit style are included in the `potentials` directory of the LAMMPS distribution.

### 4.215.3 Description

The *oxrna2* pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of RNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction *oxrna2/excv*, the stacking *oxrna2/stk*, cross-stacking *oxrna2/xstk* and coaxial stacking interaction *oxrna2/coaxstk*, electrostatic Debye-Hueckel interaction *oxrna2/dh* as well as the hydrogen-bonding interaction *oxrna2/hbond* between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (*Sulc2*). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within  $N_{\text{types}}/4$  bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (*Sulc1*) and the original oxDNA publications (*Ouldrige-DPhil*) and (*Ouldrige*) for a detailed description of the oxRNA2 force field.

**Note:** These pair styles have to be used together with the related oxDNA2 bond style *oxrna2/fene* for the connectivity of the phosphate backbone (see also documentation of *bond\_style oxrna2/fene*). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after *oxrna2/stk* (seq=seqdep,  $T=0.1$ ,  $\xi=1.40206$  and  $\kappa=2.77$  and corresponding *real unit* equivalents in the above examples), the first coefficient after *oxrna2/hbond* (seq=seqdep in the above example) and the three coefficients after *oxrna2/dh* ( $T=0.1$ ,  $\rho_{\text{hos}}=0.5$ ,  $q_{\text{eff}}=1.02455$  in the above example). When using a Langevin thermostat e.g. through *fix langevin* or *fix nve/dotc/langevin* the temperature coefficients have to be matched to the one

used in the fix.

**Note:** These pair styles have to be used with the *atom\_style hybrid bond ellipsoid oxdna* (see documentation of *atom\_style*). The *atom\_style oxdna* stores the 3'-to-5' polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3'-end (5'-end) of the strand.

Example input and data files for DNA duplexes can be found in `examples/PACKAGES/cgdna/examples/oxDNA/` and `.../oxDNA2/`. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in `examples/PACKAGES/cgdna/util/`.

Please cite ([Henrich](#)) in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found [here](#). Please cite also the relevant oxRNA2 publications ([Sulc1](#)) and ([Sulc2](#)).

#### 4.215.4 Potential file reading

For each pair style above the first non-modifiable argument can be a filename (with exception of Debye-Hueckel, for which the effective charge argument can be a filename), and if it is, no further arguments should be supplied. Therefore the following command:

```
pair_coeff 3 4 oxrna2/hbond seqdep oxrna2_lj.cgdna
```

will be interpreted as a request to read the corresponding hydrogen bonding potential parameters from the file with the given name. The file can define multiple potential parameters for both bonded and pair interactions, but for the example pair interaction above there must exist in the file a line of the form:

```
3 4 hbond <coefficients>
```

If potential customization is required, the potential file reading can be mixed with the manual specification of the potential parameters. For example, the following command:

```
pair_style hybrid/overlay oxrna2/excv oxrna2/stk oxrna2/hbond oxrna2/xstk oxrna2/coaxstk_
→oxrna2/dh
pair_coeff * * oxrna2/excv 2.0 0.7 0.675 2.0 0.515 0.5 2.0 0.33 0.32
pair_coeff * * oxrna2/stk seqdep 0.1 1.40206 2.77 oxrna2_lj.cgdna
pair_coeff * * oxrna2/hbond seqdep oxrna2_lj.cgdna
pair_coeff 1 4 oxrna2/hbond seqdep oxrna2_lj.cgdna
pair_coeff 2 3 oxrna2/hbond seqdep oxrna2_lj.cgdna
pair_coeff 3 4 oxrna2/hbond seqdep oxrna2_lj.cgdna
pair_coeff * * oxrna2/xstk oxrna2_lj.cgdna
pair_coeff * * oxrna2/coaxstk oxrna2_lj.cgdna
pair_coeff * * oxrna2/dh 0.1 0.5 1.02455
```

will read the excluded volume and Debye-Hueckel effective charge *qeff* parameters from the manual specification and all others from the potential file *oxrna2\_lj.cgdna*.

There are sample potential files for each unit style in the `potentials` directory of the LAMMPS distribution. The potential file unit system must align with the units defined via the [units](#) command. For conversion between different *LJ* and *real* unit systems for oxDNA, the python tool *lj2real.py* located in the `examples/PACKAGES/cgdna/util/`

directory can be used. This tool assumes similar file structure to the examples found in `examples/PACKAGES/cgdna/examples/`.

---

### 4.215.5 Restrictions

These pair styles can only be used if LAMMPS was built with the CG-DNA package and the MOLECULE and ASPHERE package. See the [Build package](#) page for more info.

## 4.216 pair\_style pace command

Accelerator Variants: *pace/kk, pace/extrapolation/kk*

## 4.217 pair\_style pace/extrapolation command

### 4.217.1 Syntax

```
pair_style pace ... keyword values ...
```

- one or more keyword/value pairs may be appended

keyword = *product* or *recursive* or *chunksize*

*product* = use product algorithm for basis functions

*recursive* = use recursive algorithm for basis functions

*chunksize* value = number of atoms in each pass

```
pair_style pace/extrapolation
```

## 4.217.2 Examples

```
pair_style pace
pair_style pace product chunksize 2048
pair_coeff * * Cu-PBE-core-rep.ace Cu

pair_style pace
pair_coeff * * Cu.yaml Cu

pair_style pace/extrapolation
pair_coeff * * Cu.yaml Cu.asi Cu
```

## 4.217.3 Description

Pair style *pace* computes interactions using the Atomic Cluster Expansion (ACE), which is a general expansion of the atomic energy in multi-body basis functions. ([Drautz19](#)). The *pace* pair style provides an efficient implementation that is described in this paper ([Lysogorskiy21](#)).

In ACE, the total energy is decomposed into a sum over atomic energies. The energy of atom *i* is expressed as a linear or non-linear function of one or more density functions. By projecting the density onto a local atomic base, the lowest order contributions to the energy can be expressed as a set of scalar polynomials in basis function contributions summed over neighbor atoms.

Only a single `pair_coeff` command is used with the *pace* style which specifies an ACE coefficient file followed by N additional arguments specifying the mapping of ACE elements to LAMMPS atom types, where N is the number of LAMMPS atom types:

- ACE coefficient file (.yaml or .pace/.ace format)
- N element names = mapping of ACE elements to atom types

Only a single `pair_coeff` command is used with the *pace* style which specifies an ACE file that fully defines the potential. Note that unlike for other potentials, cutoffs are not set in the `pair_style` or `pair_coeff` command; they are specified in the ACE file.

The `pair_style pace` command may be followed by the optional keyword *product* or *recursive*, which determines which of two algorithms is used for the calculation of basis functions and derivatives. The default is *recursive*.

The keyword *chunksize* is only applicable when using the pair style *pace* with the KOKKOS package on GPUs and is ignored otherwise. This keyword controls the number of atoms in each pass used to compute the atomic cluster expansion and is used to avoid running out of memory. For example if there are 8192 atoms in the simulation and the *chunksize* is set to 4096, the ACE calculation will be broken up into two passes (running on a single GPU).

## 4.217.4 Extrapolation grade

Calculation of extrapolation grade in PACE is implemented in `pair_style pace/extrapolation`. It is based on the MaxVol algorithm similar to Moment Tensor Potential (MTP) by Shapeev et al. and is described in ([Lysogorskiy23](#)). In order to compute extrapolation grade one needs to provide:

1. ACE potential in B-basis form (.yaml format) and
2. Active Set Inverted (ASI) file for corresponding potential (.asi format)

Calculation of extrapolation grades requires matrix-vector multiplication for each atom and is slower than the usual `pair_style pace recursive`, therefore it is *not* computed by default. Extrapolation grade calculation is involved by *fix pair*, which requests to compute *gamma*, as shown in example below:

```
pair_style pace/extrapolation
pair_coeff * * Cu.yaml Cu.asi Cu

fix pace_gamma all pair 10 pace/extrapolation gamma 1

compute max_pace_gamma all reduce max f_pace_gamma
variable dump_skip equal "c_max_pace_gamma < 5"

dump pace_dump all custom 20 extrapolative_structures.dump id type x y z f_pace_gamma
dump_modify pace_dump skip v_dump_skip

variable max_pace_gamma equal c_max_pace_gamma
fix extreme_extrapolation all halt 10 v_max_pace_gamma > 25
```

Here extrapolation grade gamma is computed every 10 steps and is stored in *f\_pace\_gamma* per-atom variable. The largest value of extrapolation grade among all atoms in a structure is reduced to *c\_max\_pace\_gamma* variable. Only if this value exceeds extrapolation threshold 5, then the structure will be dumped into *extrapolative\_structures.dump* file, but not more often than every 20 steps.

On all other steps *pair\_style pace recursive* will be used.

When using the pair style *pace/extrapolation* with the KOKKOS package on GPUs product B-basis evaluator is always used and only *linear* ASI is supported.

---

See the [pair\\_coeff](#) page for alternate ways to specify the path for the ACE coefficient file.

## 4.217.5 Core repulsion

The ACE potential can be configured to initiate core-repulsion from an inner cutoff, seamlessly transitioning from ACE to ZBL. The core repulsion factor can be accessed as a per-atom quantity, as demonstrated in the example below:

```
pair_style pace
pair_coeff * * CuNi.yaml Cu Ni

fix pace_corerep all pair 1 pace corerep 1
```

In this case, per-atom *f\_pace\_corerep* quantities represent the fraction of ZBL core-repulsion for each atom.

## 4.217.6 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a *pair\_coeff* command with  $I \neq J$  arguments for this style.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 4.217.7 Restrictions

This pair style is part of the ML-PACE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 4.217.8 Related commands

*pair\_style snap*, *fix pair*

## 4.217.9 Default

recursive, chunksize = 4096,

## 4.218 pair\_style pedone command

Accelerator Variants: *pedone/omp*

### 4.218.1 Syntax

**pair\_style** style args

- style = pedone\*
- args = list of arguments for a particular style

*pedone* args = cutoff

cutoff = global cutoff for Pedone interactions (distance units)

## 4.218.2 Examples

```
pair_style hybrid/overlay pedone 15.0 coul/long 15.0
kspace_style ppm 1.0e-5

pair_coeff * * coul/long
pair_coeff 1 2 pedone 0.030211 2.241334 2.923245 5.0
pair_coeff 2 2 pedone 0.042395 1.379316 3.618701 22.0
```

Used in input scripts:

```
examples/PACKAGES/pedone/in.pedone.relax
examples/PACKAGES/pedone/in.pedone.melt
```

## 4.218.3 Description

New in version 17Apr2024.

Pair style *pedone* computes the **non-Coulomb** interactions of the Pedone (or PMMCS) potential (*Pedone*) which combines Coulomb interactions, Morse potential, and repulsive  $r^{-12}$  Lennard-Jones terms (see below). The *pedone* pair style is meant to be used in addition to a *Coulomb pair style* via pair style *hybrid/overlay* (see example above). Using *coul/long* or *coul/dsf* (for solids) is recommended.

The full Pedone potential function from (*Pedone*) for each pair of atoms is:

$$E = \frac{Cq_iq_j}{\epsilon r} + D_0 [e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)}] + \frac{B_0}{r^{12}} \quad r < r_c$$

$r_c$  is the cutoff and  $C$  is a conversion factor that is specific to the choice of *units* so that the entire Coulomb term is in energy units with  $q_i$  and  $q_j$  as the assigned charges in multiples of the elementary charge.

The following coefficients must be defined for the selected pairs of atom types via the *pair\_coeff* command as in the example above:

- $D_0$  (energy units)
- $\alpha$  (1/distance units)
- $r_0$  (distance units)
- $C_0$  (energy units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global *pedone* cutoff is used.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

#### 4.218.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing.

This pair style support the *pair\_modify* shift option for the energy of the pair interaction.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands does not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, or *outer* keywords.

---

#### 4.218.5 Restrictions

The *pedone* pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the *Build package* page for more info.

#### 4.218.6 Related commands

*pair\_coeff*, *pair\_style*, *pair style coul/long and coul/dsf*, *pair style morse*

#### 4.218.7 Default

none

```

### 4.222.3 Description

The peridynamic pair styles implement material models that can be used at the mesoscopic and macroscopic scales. See [this document](#) for an overview of LAMMPS commands for Peridynamics modeling.

Style *peri/pmb* implements the Peridynamic bond-based prototype microelastic brittle (PMB) model.

Style *peri/lps* implements the Peridynamic state-based linear peridynamic solid (LPS) model.

Style *peri/ves* implements the Peridynamic state-based linear peridynamic viscoelastic solid (VES) model.

Style *peri/eps* implements the Peridynamic state-based elastic-plastic solid (EPS) model.

The canonical papers on Peridynamics are ([Silling 2000](#)) and ([Silling 2007](#)). The implementation of Peridynamics in LAMMPS is described in ([Parks](#)). Also see the [Peridynamics Howto](#) for more details about its implementation.

The peridynamic VES and EPS models in PDLAMMPS were implemented by R. Rahman and J. T. Foster at University of Texas at San Antonio. The original VES formulation is described in “(Mitchell2011)” and the original EPS formulation is in “(Mitchell2011a)”. Additional PDF docs that describe the VES and EPS implementations are include in the LAMMPS distribution in [doc/PDF/PDLammps\\_VES.pdf](#) and [doc/PDF/PDLammps\\_EPS.pdf](#). For questions regarding the VES and EPS models in LAMMPS you can contact R. Rahman ([rezwanur.rahman@utsa.edu](mailto:rezwanur.rahman@utsa.edu)).

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below.

For the *peri/pmb* style:

- c (energy/distance/volume<sup>2</sup> units)

- horizon (distance units)
- s00 (unitless)
- $\alpha$  (unitless)

C is the effectively a spring constant for Peridynamic bonds, the horizon is a cutoff distance for truncating interactions, and s00 and  $\alpha$  are used as a bond breaking criteria. The units of c are such that  $c/\text{distance} = \text{stiffness}/\text{volume}^2$ , where stiffness is energy/distance<sup>2</sup> and volume is distance<sup>3</sup>. See the users guide for more details.

For the *peri/lps* style:

- K (force/area units)
- G (force/area units)
- horizon (distance units)
- s00 (unitless)
- $\alpha$  (unitless)

K is the bulk modulus and G is the shear modulus. The horizon is a cutoff distance for truncating interactions, and s00 and  $\alpha$  are used as a bond breaking criteria. See the users guide for more details.

For the *peri/ves* style:

- K (force/area units)
- G (force/area units)
- horizon (distance units)
- s00 (unitless)
- $\alpha$  (unitless)
- m\_lambdai (unitless)
- m\_tau bi (unitless)

K is the bulk modulus and G is the shear modulus. The horizon is a cutoff distance for truncating interactions, and s00 and  $\alpha$  are used as a bond breaking criteria. m\_lambdai and m\_tau bi are the viscoelastic relaxation parameter and time constant, respectively. m\_lambdai varies within zero to one. For very small values of m\_lambdai the viscoelastic model responds very similar to a linear elastic model. For details please see the description in “(Mitchell2011)”.

For the *peri/eps* style:

- K (force/area units)
- G (force/area units)
- horizon (distance units)
- s00 (unitless)
- $\alpha$  (unitless)
- m\_yield\_stress (force/area units)

K is the bulk modulus and G is the shear modulus. The horizon is a cutoff distance and s00 and  $\alpha$  are used as a bond breaking criteria. m\_yield\_stress is the yield stress of the material. For details please see the description in “(Mitchell2011a)”.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#)

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.222.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These pair styles do not support the *pair\_modify* shift option.

The *pair\_modify* table and tail options are not relevant for these pair styles.

These pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.222.5 Restrictions

All of these styles are part of the PERI package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 4.223 pair\_style pod command

Accelerator Variants: *pod/kk*

### 4.223.1 Syntax

```
pair_style pod
```

### 4.223.2 Examples

```
pair_style pod
pair_coeff * * Ta_param.pod Ta_coefficients.pod Ta
```

### 4.223.3 Description

New in version 22Dec2022.

Pair style *pod* defines the proper orthogonal descriptor (POD) potential (*Nguyen and Rohskopf*), (*Nguyen2023*), (*Nguyen2024*), and (*Nguyen and Sema*). The *fitpod* is used to fit the POD potential.

Only a single *pair\_coeff* command is used with the *pod* style which specifies a POD parameter file followed by a coefficient file, a projection matrix file, and a centroid file.

The POD parameter file (*Ta\_param.pod*) can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. See *fitpod* for the description of all the keywords that can be assigned in the parameter file.

The coefficient file (*Ta\_coefficients.pod*) contains coefficients for the POD potential. The top of the coefficient file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain:

- `model_coefficients: ncoeff nproj ncentroid`

This is followed by *ncoeff* coefficients, *nproj* projection matrix entries, and *ncentroid* centroid coordinates, one per line. The coefficient file is generated after training the POD potential using *fitpod*.

As an example, if a LAMMPS indium phosphide simulation has 4 atoms types, with the first two being indium and the third and fourth being phosphorous, the *pair\_coeff* command would look like this:

```
pair_coeff * * pod InP_param.pod InP_coefficients.pod In In P P
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The two filenames are for the parameter and coefficient files, respectively. The two trailing 'In' arguments map LAMMPS atom types 1 and 2 to the POD 'In' element. The two trailing 'P' arguments map LAMMPS atom types 3 and 4 to the POD 'P' element.

If a POD mapping value is specified as NULL, the mapping is not performed. This can be used when a *pod* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Examples about training and using POD potentials are found in the directory `lammps/examples/PACKAGES/pod` and the Github repo <https://github.com/cesmix-mit/pod-examples>.

#### 4.223.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a `pair_coeff` command with  $I \neq J$  arguments for this style.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.223.5 Restrictions

This style is part of the ML-POD package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.223.6 Related commands

## 4.224 pair\_style polymorphic command

### 4.224.1 Syntax

```
pair_style polymorphic
```

style = *polymorphic*

### 4.224.2 Examples

```
pair_style polymorphic
pair_coeff * * FeCH_BOP_I.poly Fe C H
pair_coeff * * TlBr_msw.poly Tl Br
pair_coeff * * CuTa_eam.poly Cu Ta
pair_coeff * * GaN_tersoff.poly Ga N
pair_coeff * * GaN_sw.poly Ga N
```

### 4.224.3 Description

The *polymorphic* pair style computes a 3-body free-form potential ([Zhou3](#)) for the energy  $E$  of a system of atoms as

$$E = \frac{1}{2} \sum_{i=1}^{i=N} \sum_{j=1}^{j=N} [(1 - \delta_{ij}) \cdot U_{IJ}(r_{ij}) - (1 - \eta_{ij}) \cdot F_{IJ}(X_{ij}) \cdot V_{IJ}(r_{ij})]$$

$$X_{ij} = \sum_{k=i_1, k \neq j}^{i_N} W_{IK}(r_{ik}) \cdot G_{JIK}(\cos \theta_{jik}) \cdot P_{JIK}(\Delta r_{jik})$$

$$\Delta r_{jik} = r_{ij} - \xi_{IJ} \cdot r_{ik}$$

where I, J, K represent species of atoms i, j, and k,  $i_1, \dots, i_N$  represents a list of  $i$ 's neighbors,  $\delta_{ij}$  is a Dirac constant (i.e.,  $\delta_{ij} = 1$  when  $i = j$ , and  $\delta_{ij} = 0$  otherwise),  $\eta_{ij}$  is similar constant that can be set either to  $\eta_{ij} = \delta_{ij}$  or  $\eta_{ij} = 1 - \delta_{ij}$  depending on the potential type,  $U_{IJ}(r_{ij})$ ,  $V_{IJ}(r_{ij})$ ,  $W_{IK}(r_{ik})$  are pair functions,  $G_{JIK}(\cos \theta_{jik})$  is an angular function,  $P_{JIK}(\Delta r_{jik})$  is a function of atomic spacing differential  $\Delta r_{jik} = r_{ij} - \xi_{IJ} \cdot r_{ik}$  with  $\xi_{IJ}$  being a pair-dependent parameter, and  $F_{IJ}(X_{ij})$  is a function of the local environment variable  $X_{ij}$ . This generic potential is fully defined once the constants  $\eta_{ij}$  and  $\xi_{IJ}$ , and the six functions  $U_{IJ}(r_{ij})$ ,  $V_{IJ}(r_{ij})$ ,  $W_{IK}(r_{ik})$ ,  $G_{JIK}(\cos \theta_{jik})$ ,  $P_{JIK}(\Delta r_{jik})$ , and  $F_{IJ}(X_{ij})$  are given. Here LAMMPS uses a global parameter  $\eta$  to represent  $\eta_{ij}$ . When  $\eta = 1$ ,  $\eta_{ij} = 1 - \delta_{ij}$ , otherwise  $\eta_{ij} = \delta_{ij}$ . Additionally,  $\eta = 3$  indicates that the function  $P_{JIK}(\Delta r)$  depends on species I, J and K, otherwise  $P_{JIK}(\Delta r) = P_{IK}(\Delta r)$  only depends on species I and K. Note that these six functions are all one dimensional, and hence can be provided in a tabular form. This allows users to design different potentials solely based on a manipulation of these functions. For instance, the

potential reduces to a Stillinger-Weber potential ([SW](#)) if we set

$$\begin{aligned}
 \eta_{ij} &= \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 0 \\
 U_{IJ}(r) &= A_{IJ} \cdot \epsilon_{IJ} \cdot \left(\frac{\sigma_{IJ}}{r}\right)^q \cdot \left[B_{IJ} \cdot \left(\frac{\sigma_{IJ}}{r}\right)^{p-q} - 1\right] \cdot \exp\left(\frac{\sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}}\right) \\
 V_{IJ}(r) &= \sqrt{\lambda_{IJ} \cdot \epsilon_{IJ}} \cdot \exp\left(\frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}}\right) \\
 F_{IJ}(X) &= -X \\
 P_{JIK}(\Delta r) &= P_{IK}(\Delta r) = 1 \\
 W_{IJ}(r) &= \sqrt{\lambda_{IJ} \cdot \epsilon_{IJ}} \cdot \exp\left(\frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}}\right) \\
 G_{JIK}(\cos \theta) &= \left(\cos \theta + \frac{1}{3}\right)^2
 \end{aligned}$$

The potential reduces to a Tersoff potential ([Tersoff](#) or [Albe1](#)) if we set

$$\begin{aligned}
 \eta_{ij} &= \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 1 \\
 U_{IJ}(r) &= \frac{D_{e,IJ}}{S_{IJ} - 1} \cdot \exp\left[-\beta_{IJ} \sqrt{2S_{IJ}} (r - r_{e,IJ})\right] \cdot f_{c,IJ}(r) \\
 V_{IJ}(r) &= \frac{S_{IJ} \cdot D_{e,IJ}}{S_{IJ} - 1} \cdot \exp\left[-\beta_{IJ} \sqrt{\frac{2}{S_{IJ}}} (r - r_{e,IJ})\right] \cdot f_{c,IJ}(r) \\
 F_{IJ}(X) &= (1 + X)^{-\frac{1}{2}} \\
 P_{JIK}(\Delta r) &= P_{IK}(\Delta r) = \exp(2\mu_{IK} \cdot \Delta r) \\
 W_{IJ}(r) &= f_{c,IJ}(r) \\
 G_{JIK}(\cos \theta) &= \gamma_{IK} \left[1 + \frac{c_{IK}^2}{d_{IK}^2} - \frac{c_{IK}^2}{d_{IK}^2 + (h_{IK} + \cos \theta)^2}\right]
 \end{aligned}$$

where

$$f_{c,IJ}(r) = \begin{cases} 1, & r \leq R_{IJ} - D_{IJ} \\ \frac{1}{2} + \frac{1}{2} \cos\left[\frac{\pi(r+D_{IJ}-R_{IJ})}{2D_{IJ}}\right], & R_{IJ} - D_{IJ} < r < R_{IJ} + D_{IJ} \\ 0, & r \geq R_{IJ} + D_{IJ} \end{cases}$$

The potential reduces to a modified Stillinger-Weber potential ([Zhou3](#)) if we set

$$\begin{aligned}
 \eta_{ij} &= \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 0 \\
 U_{IJ}(r) &= \phi_{R,IJ}(r) - \phi_{A,IJ}(r) \\
 V_{IJ}(r) &= u_{IJ}(r) \\
 F_{IJ}(X) &= -X \\
 P_{JIK}(\Delta r) &= P_{IK}(\Delta r) = 1 \\
 W_{IJ}(r) &= u_{IJ}(r) \\
 G_{JIK}(\cos \theta) &= g_{JIK}(\cos \theta)
 \end{aligned}$$

The potential reduces to a Rockett-Tersoff potential ([Wang3](#)) if we set

$$\begin{aligned}
 \eta_{ij} &= \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 1 \\
 U_{IJ}(r) &= A_{IJ} \exp(-\lambda_{1,IJ} \cdot r) f_{c,IJ}(r) f_{ca,IJ}(r) \\
 V_{IJ}(r) &= \left\{ \begin{array}{l} B_{IJ} \exp(-\lambda_{2,IJ} \cdot r) f_{c,IJ}(r) + \\ A_{IJ} \exp(-\lambda_{1,IJ} \cdot r) f_{c,IJ}(r) [1 - f_{ca,IJ}(r)] \end{array} \right\} \\
 F_{IJ}(X) &= [1 + (\beta_{IJ} X)^{n_{IJ}}]^{-\frac{1}{2n_{IJ}}} \\
 P_{JIK}(\Delta r) &= P_{IK}(\Delta r) = \exp(\lambda_{3,IK} \cdot \Delta r^3) \\
 W_{IJ}(r) &= f_{c,IJ}(r) \\
 G_{JIK}(\cos \theta) &= 1 + \frac{c_{IK}^2}{d_{IK}^2} - \frac{c_{IK}^2}{d_{IK}^2 + (h_{IK} + \cos \theta)^2}
 \end{aligned}$$

where  $f_{ca,IJ}(r)$  is similar to the  $f_{c,IJ}(r)$  defined above:

$$f_{ca,IJ}(r) = \left\{ \begin{array}{l} 1, r \leq R_{a,IJ} - D_{a,IJ} \\ \frac{1}{2} + \frac{1}{2} \cos \left[ \frac{\pi(r + D_{a,IJ} - R_{a,IJ})}{2D_{a,IJ}} \right], R_{a,IJ} - D_{a,IJ} < r < R_{a,IJ} + D_{a,IJ} \\ 0, r \geq R_{a,IJ} + D_{a,IJ} \end{array} \right.$$

The potential becomes the embedded atom method ([Daw](#)) if we set

$$\begin{aligned}
 \eta_{ij} &= 1 - \delta_{ij}(\eta = 1), \xi_{IJ} = 0 \\
 U_{IJ}(r) &= \phi_{IJ}(r) \\
 V_{IJ}(r) &= 1 \\
 F_{IJ}(X) &= -2F_I(X) \\
 P_{JIK}(\Delta r) &= P_{IK}(\Delta r) = 1 \\
 W_{IJ}(r) &= f_J(r) \\
 G_{JIK}(\cos \theta) &= 1
 \end{aligned}$$

In the embedded atom method case,  $\phi_{IJ}(r)$  is the pair energy,  $F_I(X)$  is the embedding energy,  $X$  is the local electron density, and  $f_J(r)$  is the atomic electron density function.

The potential reduces to another type of Tersoff potential ([Zhou4](#)) if we set

$$\begin{aligned}
 \eta_{ij} &= \delta_{ij}(\eta = 3), \xi_{IJ} = 1 \\
 U_{IJ}(r) &= \frac{D_{e,IJ}}{S_{IJ} - 1} \cdot \exp \left[ -\beta_{IJ} \sqrt{2S_{IJ}} (r - r_{e,IJ}) \right] \cdot f_{c,IJ}(r) \cdot T_{IJ}(r) + V_{ZBL,IJ}(r) [1 - T_{IJ}(r)] \\
 V_{IJ}(r) &= \frac{S_{IJ} \cdot D_{e,IJ}}{S_{IJ} - 1} \cdot \exp \left[ -\beta_{IJ} \sqrt{\frac{2}{S_{IJ}}} (r - r_{e,IJ}) \right] \cdot f_{c,IJ}(r) \cdot T_{IJ}(r) \\
 F_{IJ}(X) &= (1 + X)^{-\frac{1}{2}} \\
 P_{JIK}(\Delta r) &= \omega_{JIK} \cdot \exp(\alpha_{JIK} \cdot \Delta r) \\
 W_{IJ}(r) &= f_{c,IJ}(r) \\
 G_{JIK}(\cos \theta) &= \gamma_{JIK} \left[ 1 + \frac{c_{JIK}^2}{d_{JIK}^2} - \frac{c_{JIK}^2}{d_{JIK}^2 + (h_{JIK} + \cos \theta)^2} \right] \\
 T_{IJ}(r) &= \frac{1}{1 + \exp[-b_{f,IJ}(r - r_{f,IJ})]} \\
 V_{ZBL,IJ}(r) &= 14.4 \cdot \frac{Z_I \cdot Z_J}{r} \sum_{k=1}^4 \mu_k \cdot \exp[-v_k (Z_I^{0.23} + Z_J^{0.23}) r]
 \end{aligned}$$

where  $f_{c,IJ}(r)$  is the same as defined above. This Tersoff potential differs from the one above because the  $P_{JIK}(\Delta r)$  function is now dependent on all three species I, J, and K.

If the tabulated functions are created using the parameters of Stillinger-Weber, Tersoff, and EAM potentials, the polymorphic pair style will produce the same global properties (energies and stresses) and the same forces as the *sw*, *tersoff*, and *eam* pair styles. The polymorphic pair style also produces the same per-atom properties (energies and stresses) as the corresponding *tersoff* and *eam* pair styles. However, due to a different partitioning of global properties to per-atom properties, the polymorphic pair style will produce different per-atom properties (energies and stresses) as the *sw* pair style. This does not mean that polymorphic pair style is different from the *sw* pair style. It just means that the definitions of the atom energies and atom stresses are different.

Only a single `pair_coeff` command is used with the polymorphic pair style which specifies a potential file for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of polymorphic potential elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the potential file. Several files for polymorphic potentials are included in the potentials directory of the LAMMPS distribution. They have a “poly” suffix.

As an example, imagine the `GaN_tersoff.poly` file has tabulated functions for Ga-N tersoff potential. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Ga, and the fourth to be N, you would use the following `pair_coeff` command:

```
pair_coeff * * GaN_tersoff.poly Ga Ga Ga N
```

The first two arguments must be `* *` to span all pairs of LAMMPS atom types. The first three `Ga` arguments map LAMMPS atom types 1,2,3 to the `Ga` element in the polymorphic file. The final `N` argument maps LAMMPS atom type 4 to the `N` element in the polymorphic file. If a mapping value is specified as `NULL`, the mapping is not performed. This can be used when an polymorphic potential is used as part of the hybrid pair style. The `NULL` values are placeholders for atom types that will be used with other potentials.

Potential files in the potentials directory of the LAMMPS distribution have a “.poly” suffix. At the beginning of the files, an unlimited number of lines starting with ‘#’ are used to describe the potential and are ignored by LAMMPS. The next line lists two numbers:

```
n types eta
```

Here *n types* represent total number of species defined in the potential file,  $\eta = 1$  reduces to embedded atom method,  $\eta = 3$  assumes a three species dependent  $P_{IJK}(\Delta r)$  function, and all other values of  $\eta$  assume a two species dependent  $P_{JK}(\Delta r)$  function. The value of *n types* must equal the total number of different species defined in the `pair_coeff` command. The next *n types* lines each lists two numbers and a character string representing atomic number, atomic mass, and name of the species of the *n types* elements:

```
atomic-number atomic-mass element-name(1)
atomic-number atomic-mass element-name(2)
...
atomic-number atomic-mass element-name(n types)
```

The next line contains four numbers:

```
nr ntheta nx xmax
```

Here *nr* is total number of tabular points for radial functions *U*, *V*, *W*, *P*, *ntheta* is total number of tabular points for the angular function *G*, *nx* is total number of tabular points for the function *F*, *xmax* is a maximum value of the argument of function *F*. Note that the pair functions  $U_{IJ}(r)$ ,  $V_{IJ}(r)$ ,  $W_{IJ}(r)$  are uniformly tabulated between 0 and cutoff distance of the *IJ* pair,  $G_{IJK}(\cos \theta)$  is uniformly tabulated between -1 and 1,  $P_{IJK}(\Delta r)$  is uniformly tabulated between -*rcmax* and *rcmax* where *rcmax* is the maximum cutoff distance of all pairs, and  $F_{IJ}(X)$  is uniformly tabulated between 0 and *xmax*. Linear extrapolation is assumed if actual simulations exceed these ranges.

The next  $\text{ntypes}*(\text{ntypes}+1)/2$  lines contain two numbers:

```
cut xi(1)
cut xi(2)
...
cut xi(ntypes*(ntypes+1)/2)
```

Here cut means the cutoff distance of the pair functions, “xi” is  $\xi$  as defined in the potential functions above. The  $\text{ntypes}*(\text{ntypes}+1)/2$  lines are related to the pairs according to the sequence of first ii (self) pairs,  $i = 1, 2, \dots, \text{ntypes}$ , and then ij (cross) pairs,  $i = 1, 2, \dots, \text{ntypes}-1$ , and  $j = i+1, i+2, \dots, \text{ntypes}$  (i.e., the sequence of the ij pairs follows 11, 22, ..., 12, 13, 14, ..., 23, 24, ...).

In the final blocks of the potential file, U, V, W, P, G, and F functions are listed sequentially. First, U functions are given for each of the  $\text{ntypes}*(\text{ntypes}+1)/2$  pairs according to the sequence described above. For each of the pairs, nr values are listed. Next, similar arrays are given for V and W functions. If P functions depend only on pair species, i.e.,  $\eta \neq 3$ , then P functions are also listed the same way the next. If P functions depend on three species, i.e.,  $\eta = 3$ , then P functions are listed for all the  $\text{ntypes}*\text{ntypes}*\text{ntypes}$  IJK triplets in a natural sequence I from 1 to ntypes, J from 1 to ntypes, and K from 1 to ntypes (i.e., IJK = 111, 112, 113, ..., 121, 122, 123 ..., 211, 212, ...). Next, G functions are listed for all the  $\text{ntypes}*\text{ntypes}*\text{ntypes}$  IJK triplets similarly. For each of the G functions, ntheta values are listed. Finally, F functions are listed for all the  $\text{ntypes}*(\text{ntypes}+1)/2$  pairs in the same sequence as described above. For each of the F functions, nx values are listed.

#### 4.224.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write their information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the pair\_style and pair\_coeff commands in an input script that reads a restart file.

---

#### 4.224.5 Restrictions

If using create\_atoms command, atomic masses must be defined in the input script. If using read\_data, atomic masses must be defined in the atomic structure data file.

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair potential requires the *newton* setting to be “on” for pair interactions.

The potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use any LAMMPS units, but you would need to create your own potential files.

#### 4.224.6 Related commands

*pair\_coeff*

## 4.225 pair\_style python command

### 4.225.1 Syntax

```
pair_style python cutoff
```

cutoff = global cutoff for interactions in python potential classes

### 4.225.2 Examples

```
pair_style python 2.5
pair_coeff * * py_pot.LJCutMelt lj

pair_style python 10.0
pair_coeff * * py_pot.HarmonicCut A B

pair_style hybrid/overlay coul/long 12.0 python 12.0
pair_coeff * * coul/long
pair_coeff * * python py_pot.LJCutSPCE OW NULL
```

### 4.225.3 Description

The *python* pair style provides a way to define pairwise additive potential functions as python script code that is loaded into LAMMPS from a python file which must contain specific python class definitions. This allows to rapidly evaluate different potential functions without having to modify and re-compile LAMMPS. Due to python being an interpreted language, however, the performance of this pair style is going to be significantly slower (often between 20x and 100x) than corresponding compiled code. This penalty can be significantly reduced through generating tabulations from the python code through the *pair\_write* command, which is supported by this style.

Only a single *pair\_coeff* command is used with the *python* pair style which specifies a python class inside a python module or a file that LAMMPS will look up in the current directory, a folder pointed to by the LAMMPS\_POTENTIALS environment variable or somewhere in your python path. A single python module can hold multiple python pair class definitions. The class definitions itself have to follow specific rules that are explained below.

Atom types in the python class are specified through symbolic constants, typically strings. These are mapped to LAMMPS atom types by specifying N additional arguments after the class name in the *pair\_coeff* command, where N must be the number of currently defined atom types:

As an example, imagine a file *py\_pot.py* has a python potential class names *LJCutMelt* with parameters and potential functions for a two Lennard-Jones atom types labeled as 'LJ1' and 'LJ2'. In your LAMMPS input and you would have defined 3 atom types, out of which the first two are supposed to be using the 'LJ1' parameters and the third the 'LJ2' parameters, then you would use the following *pair\_coeff* command:

```
pair_coeff * * py_pot.LJCutMelt LJ1 LJ1 LJ2
```

The first two arguments **must** be `**` so as to span all LAMMPS atom types. The first two LJ1 arguments map LAMMPS atom types 1 and 2 to the LJ1 atom type in the `LJCutMelt` class of the `py_pot.py` file. The final LJ2 argument maps LAMMPS atom type 3 to the LJ2 atom type the python file. If a mapping value is specified as `NULL`, the mapping is not performed, any pair interaction with this atom type will be skipped. This can be used when a *python* potential is used as part of the *hybrid* or *hybrid/overlay* pair style. The `NULL` values are then placeholders for atom types that will be used with other potentials.

The python potential file has to start with the following code:

```
from __future__ import print_function

class LAMMSPairPotential(object):
    def __init__(self):
        self.pmap=dict()
        self.units='lj'
    def map_coeff(self,name,ltype):
        self.pmap[ltype]=name
    def check_units(self,units):
        if (units != self.units):
            raise Exception("Conflicting units: %s vs. %s" % (self.units,units))
```

Any classes with definitions of specific potentials have to be derived from this class and should be initialize in a similar fashion to the example given below.

**Note:** The class constructor has to set up a data structure containing the potential parameters supported by this class. It should also define a variable `self.units` containing a string matching one of the options of LAMMPS' *units* command, which is used to verify, that the potential definition in the python class and in the LAMMPS input match.

Here is an example for a single type Lennard-Jones potential class `LJCutMelt` in reduced units, which defines an atom type `lj` for which the parameters epsilon and sigma are both 1.0:

```
class LJCutMelt(LAMMSPairPotential):
    def __init__(self):
        super(LJCutMelt,self).__init__()
        # set coeffs: 48*eps*sig**12, 24*eps*sig**6,
        #               4*eps*sig**12, 4*eps*sig**6
        self.units = 'lj'
        self.coeff = {'lj' : {'lj' : (48.0,24.0,4.0,4.0)}}
```

The class also has to provide two methods for the computation of the potential energy and forces, which have been named `compute_force`, and `compute_energy`, which both take 3 numerical arguments:

- `rsq` = the square of the distance between a pair of atoms (float)
- `itype` = the (numerical) type of the first atom
- `jtype` = the (numerical) type of the second atom

These functions need to compute the (scaled) force and the energy, respectively, and use the result as return value. The functions need to use the `pmap` dictionary to convert the LAMMPS atom type number to the symbolic value of the internal potential parameter data structure. Following the `LJCutMelt` example, here are the two functions:

```

def compute_force(self,rsq,itype,jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0/rsq
    r6inv = r2inv*r2inv*r2inv
    lj1 = coeff[0]
    lj2 = coeff[1]
    return (r6inv * (lj1*r6inv - lj2))*r2inv

def compute_energy(self,rsq,itype,jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0/rsq
    r6inv = r2inv*r2inv*r2inv
    lj3 = coeff[2]
    lj4 = coeff[3]
    return (r6inv * (lj3*r6inv - lj4))

```

**Note:** for consistency with the C++ pair styles in LAMMPS, the `compute_force` function follows the conventions of the `Pair::single()` methods and does not return the pairwise force directly, but the force divided by the distance between the two atoms, so this value only needs to be multiplied by delta x, delta y, and delta z to conveniently obtain the three components of the force vector between these two atoms.

Below is a more complex example using *real* units and defines an interaction equivalent to:

```

units real
pair_style harmonic/cut
pair_coeff 1 1 0.2 9.0
pair_coeff 2 2 0.4 9.0

```

This uses the default geometric mixing. The equivalent input with pair style *python* is:

```

units real
pair_style python 10.0
pair_coeff * * py_pot.Harmonic A B

```

Note that while for pair style *harmonic/cut* the cutoff is implicitly set to the minimum of the harmonic potential, for pair style *python* a global cutoff must be set and it must be equal or larger to the implicit cutoff of the potential in python, which has to explicitly return zero force and energy beyond the cutoff. Also, the mixed parameters have to be explicitly provided. The corresponding python code is:

```

class Harmonic(LAMMPSPairPotential):
    def __init__(self):
        super(Harmonic,self).__init__()
        self.units = 'real'
        # set coeffs: K, r0
        self.coeff = {'A' : {'A' : (0.2,9.0),
                              'B' : (math.sqrt(0.2*0.4),9.0)},
                      'B' : {'A' : (math.sqrt(0.2*0.4),9.0),
                              'B' : (0.4,9.0)}}

    def compute_force(self,rsq,itype,jtype):
        coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
        r = math.sqrt(rsq)

```

(continues on next page)

(continued from previous page)

```

    delta = coeff[1]-r
    if (r < coeff[1]):
        return 2.0*delta*coeff[0]/r
    else:
        return 0.0

def compute_energy(self,rsq,itpe,jtpe):
    coeff = self.coeff[self.pmap[itpe]][self.pmap[jtpe]]
    r = math.sqrt(rsq)
    delta = coeff[1]-r
    if (r < coeff[1]):
        return delta*delta*coeff[0]
    else:
        return 0.0

```

### Performance Impact

The evaluation of scripted python code will slow down the computation of pairwise interactions quite significantly. However, this performance penalty can be worked around through using the python pair style not for the actual simulation, but to generate tabulated potentials using the *pair\_write* command. This will also enable GPU or multi-thread acceleration through the GPU, KOKKOS, or OPENMP package versions of the *table* pair style. Please see below for a LAMMPS input example demonstrating how to build a table file:

```

pair_style python 2.5
pair_coeff * * py_pot.LJCutMelt lj
shell rm -f lj.table
pair_write 1 1 2000 rsq 0.01 2.5 lj.table lj

```

Note that it is strongly recommended to try to **delete** the potential table file before generating it. Since the *pair\_write* command will always **append** to a table file, while pair style table will use the **first match**. Thus when changing the potential function in the python class, the table pair style will still read the old variant unless the table file is first deleted.

After switching the pair style to *table*, the potential tables need to be assigned to the LAMMPS atom types like this:

```

pair_style      table linear 2000
pair_coeff      1 1  lj.table lj

```

This can also be done for more complex systems. Please see the *examples/python* folders for a few more examples.

#### 4.225.4 Mixing, shift, table, tail correction, restart, rRESPA info

Mixing of potential parameters has to be handled inside the provided python module. The python pair style simply assumes that force and energy computation can be correctly performed for all pairs of atom types as they are mapped to the atom type labels inside the python potential class.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.225.5 Restrictions

This pair style is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.225.6 Related commands

*pair\_coeff*, *pair\_write*, *pair style table*

### 4.225.7 Default

none

## 4.226 pair\_style quip command

### 4.226.1 Syntax

```
pair_style quip
```

### 4.226.2 Examples

```
pair_style      quip
pair_coeff       * * gap_example.xml "Potential xml_label=GAP_2014_5_8_60_17_10_38_466" 14
pair_coeff       * * sw_example.xml  "IP SW" 14
```

### 4.226.3 Description

Style *quip* provides an interface for calling potential routines from the QUIP package. QUIP is built separately, and then linked to LAMMPS. The most recent version of the QUIP package can be downloaded from GitHub: <https://github.com/libAtoms/QUIP>. The interface is chiefly intended to be used to run Gaussian Approximation Potentials (GAP), which are described in the following publications: (*Bartok et al*) and (*PhD thesis of Bartok*).

Only a single *pair\_coeff* command is used with the *quip* style that specifies a QUIP potential file containing the parameters of the potential for all needed elements in XML format. This is followed by a QUIP initialization string. Finally, the QUIP elements are mapped to LAMMPS atom types by specifying N atomic numbers, where N is the number of LAMMPS atom types:

- QUIP filename
- QUIP initialization string
- N atomic numbers = mapping of QUIP elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

A QUIP potential is fully specified by the filename which contains the parameters of the potential in XML format, the initialization string, and the map of atomic numbers.

GAP potentials can be obtained from the [GAP models and databases page on the libAtoms homepage](#) <https://libatoms.github.io>, where the appropriate initialization strings are also advised. The list of atomic numbers must be matched to the LAMMPS atom types specified in the LAMMPS data file or elsewhere.

Two examples input scripts are provided in the examples/PACKAGES/quip directory.

#### 4.226.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the [pair\\_modify](#) mix, shift, table, and tail options.

This pair style does not write its information to [binary restart files](#), since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.226.5 Restrictions

This pair style is part of the ML-QUIP package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

QUIP potentials are parameterized in electron-volts and Angstroms and therefore should be used with LAMMPS metal *units*.

QUIP potentials are generally not designed to work with the scaling factors set by the [special\\_bonds](#) command. The recommended setting in molecular systems is to include all interactions, i.e. to use `special_bonds lj/coul 1.0 1.0 1.0`. Scaling factors > 0.0 will be ignored and treated as 1.0. The only exception to this rule is if you know that your QUIP potential needs to exclude bonded, 1-3, or 1-4 interactions and does not already do this exclusion within QUIP. Then a factor 0.0 needs to be used which will remove such pairs from the neighbor list. This needs to be very carefully tested, because it may remove pairs from the neighbor list that are still required.

### 4.227 pair\_style rann command

#### 4.227.1 Syntax

```
pair_style rann
pair_coeff file Type1_element Type2_element Type3_element...
```

## 4.227.2 Examples

```
pair_style rann
pair_coeff * * Mg.rann Mg
pair_coeff * * MgAlalloy.rann Mg Mg Al Mg
```

## 4.227.3 Description

Pair style *rann* computes pairwise interactions for a variety of materials using rapid atomistic neural network (RANN) potentials (*Dickel*, *Nitol*). Neural network potentials work by first generating a series of symmetry functions i.e. structural fingerprints from the neighbor list and then using these values as the input layer of a neural network. There is a single output neuron in the final layer which is the energy. Atomic forces are found by analytical derivatives computed via back-propagation. For alloy systems, each element has a unique network.

## 4.227.4 Potential file syntax

The RANN potential is defined by a single text file which contains all the fitting parameters for the alloy system. The potential file also defines the active fingerprints, network architecture, activation functions, etc. The potential file is divided into several sections which are identified by one of the following keywords:

- atomtypes
- mass
- fingerprintsperelement
- fingerprints
- fingerprintconstants
- screening (optional)
- networklayers
- layersize
- weight
- bias
- activationfunctions
- calibrationparameters (ignored)

The '#' character is treated as a comment marker, similar to LAMMPS input scripts. Sections are not required to follow a rigid ordering, but do require previous definition of prerequisite information. E.g., fingerprintconstants for a particular fingerprint must follow the fingerprints definition; layersize for a particular layer must follow the declaration of network layers.

*atomtypes* are defined as follows using element keywords separated by spaces.

```
atomtypes:
Fe Mg Al etc.
```

*mass* must be specified for each element keyword as follows:

```
mass:Mg:
24.305
mass:Fe:
55.847
mass:Al:
26.982
```

*fingerprintsperelement* specifies how many fingerprints are active for computing the energy of a given atom. This number must be specified for each element keyword. Active elements for each fingerprint depend upon the type of the central atom and the neighboring atoms. Pairwise fingerprints may be defined for a Mg atom based exclusively on its Al neighbors, for example. Bond fingerprints may use two neighbor lists of different element types. In computing fingerprintsperelement from all defined fingerprints, only the fingerprints defined for atoms of a particular element should be considered, regardless of the elements used in its neighbor list. In the following code, for example, some fingerprints may compute pairwise fingerprints summing contributions about Fe atoms based on a neighbor list of exclusively Al atoms, but if there are no fingerprints summing contributions of all neighbors about a central Al atom, then fingerprintsperelement of Al is zero:

```
fingerprintsperelement:Mg:
5
fingerprintsperelement:Fe:
2
fingerprintsperelement:Al:
0
```

*fingerprints* specifies the active fingerprints for a certain element combination. Pair fingerprints are specified for two elements, while bond fingerprints are specified for three elements. Only one fingerprints header should be used for an individual combination of elements. The ordering of the fingerprints in the network input layer is determined by the order of element combinations specified by subsequent *fingerprints* lines, and the order of the fingerprints defined for each element combination. Multiple fingerprints of the same style or different ones may be specified. If the same style and element combination is used for multiple fingerprints, they should have different id numbers. The first element specifies the atoms for which this fingerprint is computed while the other(s) specify which atoms to use in the neighbor lists for the computation. Switching the second and third element type in bond fingerprints has no effect on the computation:

```
fingerprints:Mg_Mg:
radial_0 radialscreened_0 radial_1
fingerprints:Mg_Al_Fe:
bond_0 bondspin_0
fingerprints:Mg_Al:
radial_0 radialscreened_0
```

The following fingerprint styles are currently defined. See the [formulation section](#) below for their definitions:

- radial
- radialscreened
- radials핀
- radialscreenedspin
- bond
- bondscreened
- bondspin
- bondscreenedspin

*fingerprintconstants* specifies the meta-parameters for a defined fingerprint. For all radial styles, *re*, *rc*, *alpha*, *dr*, *o*, and *n* must be specified. *re* should usually be the stable interatomic distance, *rc* is the cutoff radius, *dr* is the cutoff smoothing distance, *o* is the lowest radial power term (which may be negative), and *n* is the highest power term. The total length of the fingerprint vector is  $(n-o+1)$ . *alpha* is a list of decay parameters used for exponential decay of radial contributions. It may be set proportionally to the bulk modulus similarly to MEAM potentials, but other values may be provided better fitting in special cases. Bond style fingerprints require specification of *re*, *rc*, *alphak*, *dr*, *k*, and *m*. Here *m* is the power of the bond cosines and *k* is the number of decay parameters. Cosine powers go from 0 to *m*-1 and are each computed for all values of *alphak*. Thus the total length of the fingerprint vector is  $m*k$ .

```
fingerprintconstants:Mg_Mg:radialscreened_0:re:
3.193592
fingerprintconstants:Mg_Mg:radialscreened_0:rc:
6.000000
fingerprintconstants:Mg_Mg:radialscreened_0:alpha:
5.520000 5.520000 5.520000 5.520000 5.520000
fingerprintconstants:Mg_Mg:radialscreened_0:dr:
2.806408
fingerprintconstants:Mg_Mg:radialscreened_0:o:
-1
fingerprintconstants:Mg_Mg:radialscreened_0:n:
3
```

*screening* specifies the *Cmax* and *Cmin* values used in the screening fingerprints. Contributions from neighbors to the fingerprint are omitted if they are blocked by a closer neighbor, and reduced if they are partially blocked. Larger values of *Cmin* correspond to neighbors being blocked more easily. *Cmax* cannot be greater than 3, and *Cmin* cannot be greater than *Cmax* or less than zero. Screening may be omitted in which case the default values *Cmax* = 2.8, *Cmin* = 0.8 are used. Since screening is a bond computation, it is specified separately for each combination of three elements in which the latter two may be interchanged with no effect.

```
screening:Mg_Mg_Mg:Cmax:
2.700000
screening:Mg_Mg_Mg:Cmin:
0.400000
```

*networklayers* specifies the size of the neural network for each atom. It counts both the input and output layer and so is  $2 + \langle \text{hidden layers} \rangle$ .

```
networklayers:Mg:
3
```

*layersize* specifies the length of each layer, including the input layer and output layer. The input layer is layer 0. The size of the input layer size must match the summed length of all the fingerprints for that element, and the output layer size must be 1:

```
layersize:Mg:0:
14
layersize:Mg:1:
20
layersize:Mg:2:
1
```

*weight* specifies the weight for a given element and layer. Weight cannot be specified for the output layer. The weight of layer *i* is a  $m \times n$  matrix where *m* is the layer size of *i* and *n* is the layer size of *i*+1:

```
weight:Mg:0:
w11 w12 w13 ...
w21 w22 w23 ...
...
```

*bias* specifies the bias for a given element and layer. Bias cannot be specified for the output layer. The bias of layer *i* is a  $n \times 1$  vector where *n* is the layer size of *i*+1:

```
bias:Mg:0:
b1
b2
b3
...
```

*activationfunctions* specifies the activation function for a given element and layer. Activation functions cannot be specified for the output layer:

```
activationfunctions:Mg:0:
sigI
activationfunctions:Mg:1:
linear
```

The following activation styles are currently specified. See the [formulation section](#) below for their definitions.

- sigI
- linear

*calibrationparameters* specifies a number of parameters used to calibrate the potential. These are ignored by LAMMPS.

## 4.227.5 Formulation

In the RANN formulation, the total energy of a system of atoms is given by:

$$E = \sum_{\alpha} E^{\alpha}$$

$$E^{\alpha} = {}^N A^{\alpha}$$

$${}^{n+1}A_i^{\alpha} = {}^n F ({}^n W_{ij} {}^n A_j^{\alpha} + {}^n B_i)$$

$${}^0 A_i^{\alpha} = \begin{bmatrix} {}^1 S_f^{\alpha} \\ {}^2 S_f^{\alpha} \\ \dots \end{bmatrix}$$

Here  $E^{\alpha}$  is the energy of atom  $\alpha$ ,  ${}^n F()$ ,  ${}^n W_{ij}$  and  ${}^n B_i$  are the activation function, weight matrix and bias vector of the *n*-th layer respectively. The inputs to the first layer are a collection of structural fingerprints which are collected and reshaped into a single long vector. The individual fingerprints may be defined in any order and have various shapes and sizes. Multiple fingerprints of the same type and varying parameters may also be defined in the input layer.

Eight types of structural fingerprints are currently defined. In the following,  $\beta$  and  $\gamma$  span the full neighbor list of atom  $\alpha$ .  $\delta_i$  are decay meta-parameters, and  $r_c$  is a meta-parameter roughly proportional to the first neighbor distance.  $r_c$  and  $dr$  are the neighbor cutoff distance and cutoff smoothing distance respectively.  $S^{\alpha\beta}$  is the MEAM screening function

(*Baskes*),  $s_i^\alpha$  and  $s_i^\beta$  are the atom spin vectors (*Tranchida*).  $r^{\alpha\beta}$  is the distance from atom  $\alpha$  to atom  $\beta$ , and  $\theta^{\alpha\beta\gamma}$  is the bond angle:

$$\cos(\theta^{\alpha\beta\gamma}) = \frac{\mathbf{r}^{\alpha\beta} \cdot \mathbf{r}^{\alpha\gamma}}{r^{\alpha\beta} r^{\alpha\gamma}}$$

$S^{\alpha\beta}$  is defined as (*Baskes*):

$$X^{\gamma\beta} = \left( \frac{r^{\gamma\beta}}{r^{\alpha\beta}} \right)^2$$

$$X^{\alpha\gamma} = \left( \frac{r^{\alpha\gamma}}{r^{\alpha\beta}} \right)^2$$

$$C = \frac{2(X^{\alpha\gamma} + X^{\gamma\beta}) - (X^{\alpha\gamma} - X^{\gamma\beta})^2 - 1}{1 - (X^{\alpha\gamma} - X^{\gamma\beta})^2}$$

$$f_c(x) = \begin{cases} 1 & x \geq 1 \\ (1 - (1 - x)^4)^2 & 0 < x < 1 \\ 0 & x \leq 0 \end{cases}$$

$$S^{\alpha\beta\gamma} = f_c \left( \frac{C - C_{\min}}{C_{\max} - C_{\min}} \right)$$

$$S^{\alpha\beta} = \prod_{\gamma} S^{\alpha\beta\gamma}$$

The structural fingerprints are computed as follows:

- **radial**

$$rSf_i^\alpha = \sum_{\beta} \left( \frac{r^{\alpha\beta}}{r_e} \right)^i e^{-\delta_i \frac{r^{\alpha\beta}}{r_e}} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right)$$

- **bond**

$$bSf_{ij}^\alpha = \sum_{\beta} \sum_{\gamma} (\cos(\theta_{\alpha\beta\gamma}))^i e^{-\delta_j \frac{r^{\alpha\beta}}{r_e}} e^{-\delta_j \frac{r^{\alpha\gamma}}{r_e}} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right) f_c \left( \frac{r_c - r^{\alpha\gamma}}{dr} \right)$$

- **radialscreened**

$$rscSf_i^\alpha = \sum_{\beta} \left( \frac{r^{\alpha\beta}}{r_e} \right)^i e^{-\delta_i \frac{r^{\alpha\beta}}{r_e}} S^{\alpha\beta} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right)$$

- **bondscreened**

$$bscSf_{ij}^\alpha = \sum_{\beta} \sum_{\gamma} (\cos(\theta_{\alpha\beta\gamma}))^i e^{-\delta_j \frac{r^{\alpha\beta}}{r_e}} e^{-\delta_j \frac{r^{\alpha\gamma}}{r_e}} S^{\alpha\beta} S^{\alpha\gamma} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right) f_c \left( \frac{r_c - r^{\alpha\gamma}}{dr} \right)$$

- **radialspin**

$$rspSf_i^\alpha = \sum_{\beta} \left( \frac{r^{\alpha\beta}}{r_e} \right)^i e^{-\delta_i \frac{r^{\alpha\beta}}{r_e}} (\mathbf{s}^\alpha \cdot \mathbf{s}^\beta) f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right)$$

- **bondspin**

$$bssp_{f_{ij}}^{\alpha} = \sum_{\beta} \sum_{\gamma} (\cos(\theta_{\alpha\beta\gamma}))^i e^{-\delta_j \frac{r^{\alpha\beta}}{r_e}} e^{-\delta_j \frac{r^{\alpha\gamma}}{r_e}} (\mathbf{s}^{\alpha} \cdot \mathbf{s}^{\beta}) (\mathbf{s}^{\alpha} \cdot \mathbf{s}^{\gamma}) f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right) f_c \left( \frac{r_c - r^{\alpha\gamma}}{dr} \right)$$

- **radialscreenedspin**

$$rscsp_{f_i}^{\alpha} = \sum_{\beta} \left( \frac{r^{\alpha\beta}}{r_e} \right)^i e^{-\delta_i \frac{r^{\alpha\beta}}{r_e}} S^{\alpha\beta} (\mathbf{s}^{\alpha} \cdot \mathbf{s}^{\beta}) f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right)$$

- **bondscreenedspin**

$$bscsp_{f_{ij}}^{\alpha} = \sum_{\beta} \sum_{\gamma} (\cos(\theta_{\alpha\beta\gamma}))^i e^{-\delta_j \frac{r^{\alpha\beta}}{r_e}} e^{-\delta_j \frac{r^{\alpha\gamma}}{r_e}} S^{\alpha\beta} S^{\alpha\gamma} (\mathbf{s}^{\alpha} \cdot \mathbf{s}^{\beta}) (\mathbf{s}^{\alpha} \cdot \mathbf{s}^{\gamma}) f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right) f_c \left( \frac{r_c - r^{\alpha\gamma}}{dr} \right)$$

The activation functions are computed as follows:

- **sigI**

$$F^{sigI}(x) = 0.1x + 0.9 \ln(e^x + 1)$$

- **linear**

$$F^{linear}(x) = x$$

## 4.227.6 Restrictions

Pair style *rann* is part of the ML-RANN package. It is only enabled if LAMMPS was built with that package. Additionally, if any spin fingerprint styles are used LAMMPS must be built with the SPIN package as well.

Pair style *rann* does not support computing per-atom stress or using *pair\_modify nofdotr*.

## 4.227.7 Defaults

Cmin = 0.8, Cmax = 2.8.

## 4.228 pair\_style reaxff command

Accelerator Variants: *reaxff/kk*, *reaxff/omp*

## 4.228.1 Syntax

```
pair_style reaxff cfile keyword value
```

- cfile = NULL or name of a control file
- zero or more keyword/value pairs may be appended

```
keyword = checkqeq or lgvdw or safezone or mincap or minhbonds or tabulate or list/
→blocking
  checkqeq value = yes or no = whether or not to require qeq/reaxff or acks2/reaxff.
→fix
  enobonds value = yes or no = whether or not to tally energy of atoms with no bonds
  lgvdw value = yes or no = whether or not to use a low gradient vdW correction
  safezone = factor used for array allocation
  mincap = minimum size for array allocation
  minhbonds = minimum size use for storing hydrogen bonds
  tabulate value = size of interpolation table for Lennard-Jones and Coulomb.
→interactions
  list/blocking value = yes or no = whether or not to use "blocking" scheme for.
→bond list build
```

## 4.228.2 Examples

```
pair_style reaxff NULL
pair_style reaxff controlfile checkqeq no
pair_style reaxff NULL lgvdw yes
pair_style reaxff NULL safezone 1.6 mincap 100
pair_coeff * *ffield.reax C H O N
```

## 4.228.3 Description

Pair style *reaxff* computes the ReaxFF potential of van Duin, Goddard and co-workers. ReaxFF uses distance-dependent bond-order functions to represent the contributions of chemical bonding to the potential energy. There is more than one version of ReaxFF. The version implemented in LAMMPS uses the functional forms documented in the supplemental information of the following paper: ([Chenoweth et al., 2008](#)) and matches the version of the reference ReaxFF implementation from Summer 2010. For more technical details about the implementation of ReaxFF in pair style *reaxff*, see the ([Aktulga](#)) paper. The *reaxff* style was initially implemented as a stand-alone C code and is now converted to C++ and integrated into LAMMPS as a package.

The *reaxff/kk* style is a Kokkos version of the ReaxFF potential that is derived from the *reaxff* style. The Kokkos version can run on GPUs and can also use OpenMP multithreading. For more information about the Kokkos package, see [Packages details](#) and [Speed kokkos](#) doc pages. One important consideration when using the *reaxff/kk* style is the choice of either half or full neighbor lists. This setting can be changed using the Kokkos [package](#) command.

The *reaxff* style differs from the (obsolete) “pair\_style reax” command in the implementation details. The *reax* style was a Fortran library, linked to LAMMPS. The *reax* style has been removed from LAMMPS after the 12 December 2018 version.

LAMMPS provides several different versions of ffield.reax in its potentials dir, each called potentials/ffield.reax.label. These are documented in potentials/README.reax.

The format of these files is identical to that used originally by van Duin. We have tested the accuracy of *pair\_style reaxff* potential against the original ReaxFF code for the systems mentioned above. You can use other ffield files for specific chemical systems that may be available elsewhere (but note that their accuracy may not have been tested).

---

**Note:** We do not distribute a wide variety of ReaxFF force field files with LAMMPS. Adri van Duin's group at PSU is the central repository for this kind of data as they are continuously deriving and updating parameterizations for different classes of materials. You can submit a contact request at the Materials Computation Center (MCC) website <https://www.mri.psu.edu/materials-computation-center/connect-mcc>, describing the material(s) you are interested in modeling with ReaxFF. They can tell you what is currently available or what it would take to create a suitable ReaxFF parameterization.

---

The *cfile* setting can be specified as NULL, in which case default settings are used. A control file can be specified which defines values of control variables. Some control variables are global parameters for the ReaxFF potential. Others define certain performance and output settings. Each line in the control file specifies the value for a control variable. The format of the control file is described below.

---

**Note:** The LAMMPS default values for the ReaxFF global parameters correspond to those used by Adri van Duin's stand-alone serial code. If these are changed by setting control variables in the control file, the results from LAMMPS and the serial code will not agree.

---

Examples using *pair\_style reaxff* are provided in the examples/reax directory and its subdirectories.

Use of this pair style requires using an *atom\_style* that includes a per-atom charge property *or* using *fix property/atom q*. Charges can be set via *read\_data* or *set*. Using an initial charge that is close to the result of charge equilibration will speed up that process.

The ReaxFF parameter files provided were created using a charge equilibration (QEq) model for handling the electrostatic interactions. Therefore, by default, LAMMPS requires that either the *fix qeq/reaxff* or the *fix qeq/shielded* or *fix acks2/reaxff* command be used with *pair\_style reaxff* when simulating a ReaxFF model, to equilibrate the charges each timestep.

Using the keyword *checkqeq* with the value *no* turns off the check for the QEq fixes, allowing a simulation to be run without charge equilibration. In this case, the static charges you assign to each atom will be used for computing the electrostatic interactions in the system. See the *fix qeq/reaxff* or *fix qeq/shielded* or *fix acks2/reaxff* command documentation for more details.

Using the optional keyword *lgvdw* with the value *yes* turns on the low-gradient correction of ReaxFF for long-range London Dispersion, as described in the (Liu) paper. The bundled force field file *ffield.reax.lg* is designed for this correction, and is trained for several energetic materials (see "Liu"). When using *lgvdw yes*, the recommended value for parameter *thb* is 0.01, which can be set in the control file. Note: Force field files are different for the original or lg corrected pair styles, using the wrong ffield file generates an error.

Using the optional keyword *enobonds* with the value *yes*, the energy of atoms with no bonds (i.e. isolated atoms) is included in the total potential energy and the per-atom energy of that atom. If the value *no* is specified then the energy of atoms with no bonds is set to zero. The latter behavior is usual not desired, as it causes discontinuities in the potential energy when the bonding of an atom drops to zero.

Optional keywords *safezone*, *mincap*, and *minhbonds* are used for allocating reaxff arrays. Increasing these values can avoid memory problems, such as segmentation faults and bondchk failed errors, that could occur under certain conditions. These keywords are not used by the Kokkos version, which instead uses a more robust memory allocation scheme that checks if the sizes of the arrays have been exceeded and automatically allocates more memory.

The keyword *tabulate* controls the size of interpolation table for Lennard-Jones and Coulomb interactions. Tabulation may also be set in the control file (see below). If tabulation is set in both the input script and the control file, the value

in the control file will be ignored. A size of 10000 is typically used for the interpolation table. A value of 0 means no tabulation will be used.

The keyword *list/blocking* is only supported by the Kokkos version of ReaxFF and ignored otherwise. Setting the value to *yes* enables the “blocking” scheme (dynamically building interaction lists) for the ReaxFF bond neighbor list. This reduces the number of empty interactions and can improve performance in some cases (e.g. large number of atoms/GPU on AMD hardware). It is also enabled by default when running the CPU with Kokkos.

The thermo variable *evdwl* stores the sum of all the ReaxFF potential energy contributions, with the exception of the Coulombic and charge equilibration contributions which are stored in the thermo variable *ecoul*. The output of these quantities is controlled by the *thermo* command.

This pair style tallies a breakdown of the total ReaxFF potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 14. The 14 values correspond to the following sub-categories (the variable names in italics match those used in the original FORTRAN ReaxFF code):

1. *eb* = bond energy
2. *ea* = atom energy
3. *elp* = lone-pair energy
4. *emol* = molecule energy (always 0.0)
5. *ev* = valence angle energy
6. *epen* = double-bond valence angle penalty
7. *ecoa* = valence angle conjugation energy
8. *ehb* = hydrogen bond energy
9. *et* = torsion energy
10. *eco* = conjugation energy
11. *ew* = van der Waals energy
12. *ep* = Coulomb energy
13. *efi* = electric field energy (always 0.0)
14. *eqeq* = charge equilibration energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute reax all pair reaxff
variable eb      equal c_reax[1]
variable ea      equal c_reax[2]
[...]
variable eqeq    equal c_reax[14]
thermo_style custom step temp epair v_eb v_ea [...] v_eqeq
```

Only a single *pair\_coeff* command is used with the *reaxff* style which specifies a ReaxFF potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the *pair\_coeff* command, where N is the number of LAMMPS atom types:

- filename
- N indices = ReaxFF elements

The filename is the ReaxFF potential file.

In the ReaxFF potential file, near the top, after the general parameters, is the atomic parameters section that contains element names, each with a couple dozen numeric parameters. If there are *M* elements specified in the *ffield* file, think of these as numbered 1 to *M*. Each of the *N* indices you specify for the *N* atom types of LAMMPS atoms must be an integer from 1 to *M*. Atoms with LAMMPS type 1 will be mapped to whatever element you specify as the first index value, etc. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the *reaxff* style is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

As an example, say your LAMMPS simulation has 4 atom types and the elements are ordered as C, H, O, N in the *ffield* file. If you want the LAMMPS atom type 1 and 2 to be C, type 3 to be N, and type 4 to be H, you would use the following *pair\_coeff* command:

```
pair_coeff * * ffield.reax C C N H
```

#### 4.228.4 Control file

The format of a line in the control file is as follows:

```
variable_name value
```

and it may be followed by an “!” character and a trailing comment.

If the value of a control variable is not specified, then default values are used. What follows is the list of variables along with a brief description of their use and default values.

##### *simulation\_name*

Output files produced by *pair\_style reaxff* carry this name + extensions specific to their contents. Partial energies are reported with a “.pot” extension, while the trajectory file has “.trj” extension.

##### *tabulate\_long\_range*

To improve performance, long range interactions can optionally be tabulated (0 means no tabulation). Value of this variable denotes the size of the long range interaction table. The range from 0 to long range cutoff (defined in the *ffield* file) is divided into *tabulate\_long\_range* points. Then at the start of simulation, we fill in the entries of the long range interaction table by computing the energies and forces resulting from van der Waals and Coulomb interactions between every possible atom type pairs present in the input system. During the simulation we consult to the long range interaction table to estimate the energy and forces between a pair of atoms. Linear interpolation is used for estimation. (default value = 0)

##### *energy\_update\_freq*

Denotes the frequency (in number of steps) of writes into the partial energies file. (default value = 0)

##### *nbrhood\_cutoff*

Denotes the near neighbors cutoff (in Angstroms) regarding the bonded interactions. (default value = 5.0)

##### *hbond\_cutoff*

Denotes the cutoff distance (in Angstroms) for hydrogen bond interactions. (default value = 7.5. A value of 0.0 turns off hydrogen bonds)

##### *bond\_graph\_cutoff*

is the threshold used in determining what is a physical bond, what is not. Bonds and angles reported in the trajectory file rely on this cutoff. (default value = 0.3)

##### *thb\_cutoff*

cutoff value for the strength of bonds to be considered in three body interactions. (default value = 0.001)

***thb\_cutoff\_sq***

cutoff value for the strength of bond order products to be considered in three body interactions. (default value = 0.00001)

***write\_freq***

Frequency of writes into the trajectory file. (default value = 0)

***traj\_title***

Title of the trajectory - not the name of the trajectory file.

***atom\_info***

1 means print only atomic positions + charge (default = 0)

***atom\_forces***

1 adds net forces to atom lines in the trajectory file (default = 0)

***atom\_velocities***

1 adds atomic velocities to atoms line (default = 0)

***bond\_info***

1 prints bonds in the trajectory file (default = 0)

***angle\_info***

1 prints angles in the trajectory file (default = 0)

---

#### 4.228.5 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 4.228.6 Restrictions

This pair style is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The ReaxFF potential files provided with LAMMPS in the potentials directory are parameterized for *real units*. You can use the ReaxFF pair style with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “real” units.

## 4.228.7 Related commands

*pair\_coeff*, *fix qeq/reaxff*, *fix acks2/reaxff*, *fix reaxff/bonds*, *fix reaxff/species*, *compute reaxff/atom*

## 4.228.8 Default

The keyword defaults are checkqeq = yes, enobonds = yes, lgvdw = no, safezone = 1.2, mincap = 50, minhbonds = 25, tabulate = 0, list/blocking = yes on CPU, no on GPU.

## 4.229 pair\_style rebomos command

Accelerator Variants: *rebomos/omp*

### 4.229.1 Syntax

```
pair_style rebomos
```

- rebomos = name of this pair style

### 4.229.2 Examples

```
pair_style rebomos
pair_coeff * * ../potentials/MoS.rebomos Mo S
```

Example input scripts available: examples/threebody/

### 4.229.3 Description

New in version 17Apr2024.

The *rebomos* pair style computes the interactions between molybdenum and sulfur atoms ([Stewart](#)) utilizing an adaptive interatomic reactive empirical bond order potential that is similar in form to the AIREBO potential ([Stuart](#)). The potential is based on an earlier parameterizations for MoS<sub>2</sub> developed by ([Liang](#)).

The REBOMoS potential consists of two terms:

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} [E_{ij}^{\text{REBO}} + E_{ij}^{\text{LJ}}]$$

The  $E^{\text{REBO}}$  term describes the covalently bonded interactions between Mo and S atoms while the  $E^{\text{LJ}}$  term describes longer range dispersion forces between layers. A cubic spline function is applied to smoothly switch between covalent bonding at short distances to dispersion interactions at longer distances. This allows the model to capture bond formation and breaking events which may occur between adjacent MoS<sub>2</sub> layers, edges, defects, and more.

---

Only a single `pair_coeff` command is used with the *rebomos* pair style which specifies an REBOMoS potential file with parameters for Mo and S. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of REBOMoS elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has three atom types and you want the first two to be Mo, and the third to be S, you would use the following `pair_coeff` command:

```
pair_coeff * * MoS.rebomos Mo Mo S
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The first two Mo arguments map LAMMPS atom types 1 and 2 to the Mo element in the REBOMoS file. The final S argument maps LAMMPS atom type 3 to the S element in the REBOMoS file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *rebomos* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.229.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write their information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair styles can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.229.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These pair potentials require the *newton* setting to be “on” for pair interactions.

The MoS.rebomos potential file provided with LAMMPS (see the potentials directory) is parameterized for metal *units*. You can use the *rebomos* pair style with any LAMMPS units setting, but you would need to create your own REBOMoS potential file with coefficients listed in the appropriate units.

The pair style provided here **only** supports potential files parameterized for the elements molybdenum and sulfur (designated with “Mo” and “S” in the *pair\_coeff* command. Using potential files for other elements will trigger an error.

#### 4.229.6 Related commands

*pair\_coeff*, *pair style rebo*

#### 4.229.7 Default

none

### 4.230 *pair\_style resquared* command

Accelerator Variants: *resquared/gpu*, *resquared/omp*

#### 4.230.1 Syntax

```
pair_style resquared cutoff
```

- cutoff = global cutoff for interactions (distance units)

## 4.230.2 Examples

```
pair_style resquared 10.0
pair_coeff * * 1.0 1.0 1.7 3.4 3.4 1.0 1.0 1.0
```

## 4.230.3 Description

Style *resquared* computes the RE-squared anisotropic interaction (*Everaers*), (*Babadi*) between pairs of ellipsoidal and/or spherical Lennard-Jones particles. For ellipsoidal interactions, the potential considers the ellipsoid as being comprised of small spheres of size  $\sigma$ . LJ particles are a single sphere of size  $\sigma$ . The distinction is made to allow the pair style to make efficient calculations of ellipsoid/solvent interactions.

Details for the equations used are given in the references below and in [this supplementary document](#).

Use of this pair style requires the NVE, NVT, or NPT fixes with the *asphere* extension (e.g. *fix nve/asphere*) in order to integrate particle rotation. Additionally, *atom\_style ellipsoid* should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $A_{12}$  = Energy Prefactor/Hamaker constant (energy units)
- $\sigma$  = atomic interaction diameter (distance units)
- $\epsilon_{i,a}$  = relative well depth of type I for side-to-side interactions
- $\epsilon_{i,b}$  = relative well depth of type I for face-to-face interactions
- $\epsilon_{i,c}$  = relative well depth of type I for end-to-end interactions
- $\epsilon_{j,a}$  = relative well depth of type J for side-to-side interactions
- $\epsilon_{j,b}$  = relative well depth of type J for face-to-face interactions
- $\epsilon_{j,c}$  = relative well depth of type J for end-to-end interactions
- cutoff (distance units)

The parameters used depend on the type of the interacting particles, i.e. ellipsoids or LJ spheres. The type of a particle is determined by the diameters specified for its 3 shape parameters. If all 3 shape parameters = 0.0, then the particle is treated as an LJ sphere. The  $\epsilon_{i,*}$  or  $\epsilon_{j,*}$  parameters are ignored for LJ spheres. If the 3 shape parameters are > 0.0, then the particle is treated as an ellipsoid (even if the 3 parameters are equal to each other).

$A_{12}$  specifies the energy prefactor which depends on the types of the two interacting particles.

For ellipsoid/ellipsoid interactions, the interaction is computed by the formulas in the supplementary document referenced above.  $A_{12}$  is the Hamaker constant as described in (*Everaers*). In LJ units:

$$A_{12} = 4\pi^2 \epsilon_{LJ} (\rho \sigma^3)^2$$

where  $\rho$  gives the number density of the spherical particles composing the ellipsoids and  $\epsilon_{LJ}$  determines the interaction strength of the spherical particles.

For ellipsoid/LJ sphere interactions, the interaction is also computed by the formulas in the supplementary document referenced above.  $A_{12}$  has a modified form (see [here](#) for details):

$$A_{12} = 4\pi^2 \epsilon_{LJ} (\rho \sigma^3)$$

For ellipsoid/LJ sphere interactions, a correction to the distance- of-closest approach equation has been implemented to reduce the error from two particles of disparate sizes; see [this supplementary document](#).

For LJ sphere/LJ sphere interactions, the interaction is computed using the standard Lennard-Jones formula, which is much cheaper to compute than the ellipsoidal formulas. A12 is used as epsilon in the standard LJ formula:

$$A_{12} = \epsilon_{LJ}$$

and the specified  $\sigma$  is used as the  $\sigma$  in the standard LJ formula.

When one of both of the interacting particles are ellipsoids, then  $\sigma$  specifies the diameter of the continuous distribution of constituent particles within each ellipsoid used to model the RE-squared potential. Note that this is a different meaning for  $\sigma$  than the *pair\_style gayberne* potential uses.

The  $\epsilon_i$  and  $\epsilon_j$  coefficients are defined for atom types, not for pairs of atom types. Thus, in a series of *pair\_coeff* commands, they only need to be specified once for each atom type.

Specifically, if any of  $\epsilon_{i,a}$ ,  $\epsilon_{i,b}$ ,  $\epsilon_{i,c}$  are non-zero, the three values are assigned to atom type I. If all the  $\epsilon_i$  values are zero, they are ignored. If any of  $\epsilon_{j,a}$ ,  $\epsilon_{j,b}$ ,  $\epsilon_{j,c}$  are non-zero, the three values are assigned to atom type J. If all three  $\epsilon_i$  values are zero, they are ignored. Thus the typical way to define the  $\epsilon_i$  and  $\epsilon_j$  coefficients is to list their values in “*pair\_coeff I J*” commands when  $I = J$ , but set them to 0.0 when  $I \neq J$ . If you do list them when  $I \neq J$ , you should ensure they are consistent with their values in other *pair\_coeff* commands.

Note that if this potential is being used as a sub-style of *pair\_style hybrid*, and there is no “*pair\_coeff I I*” setting made for RE-squared for a particular type I (because I-I interactions are computed by another hybrid pair potential), then you still need to ensure the epsilon a,b,c coefficients are assigned to that type in a “*pair\_coeff I J*” command.

For large uniform molecules it has been shown that the  $\epsilon_{*,*}$  energy parameters are approximately representable in terms of local contact curvatures (*Everaers*):

$$\epsilon_a = \sigma \cdot \frac{a}{b \cdot c}; \epsilon_b = \sigma \cdot \frac{b}{a \cdot c}; \epsilon_c = \sigma \cdot \frac{c}{a \cdot b}$$

where a, b, and c give the particle diameters.

The last coefficient is optional. If not specified, the global cutoff specified in the *pair\_style* command is used.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

#### 4.230.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance can be mixed, but only for sphere pairs. The default mix value is *geometric*. See the “*pair\_modify*” command for details. Other type pairs cannot be mixed, due to the different meanings of the energy prefactors used to calculate the interactions and the implicit dependence of the ellipsoid-sphere interaction on the equation for the Hamaker constant presented here. Mixing of sigma and epsilon followed by calculation of the energy prefactors using the equations above is recommended.

This pair style supports the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords of the *run\_style command*.

---

## 4.230.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires that atoms be ellipsoids as defined by the *atom\_style ellipsoid* command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

## 4.231 pair\_style rheo command

### 4.231.1 Syntax

**pair\_style** rheo cutoff keyword values

- cutoff = global cutoff for kernel (distance units)
- zero or more keyword/value pairs may be appended to args
- keyword = *rho/damp* or *artificial/visc* or *harmonic/means*

*rho/damp* args = density damping prefactor  $\xi$   
*artificial/visc* args = artificial viscosity prefactor  $\zeta$   
*harmonic/means* args = none

## 4.231.2 Examples

```
pair_style rheo 3.0 rho/damp 1.0 artificial/visc 2.0
pair_coeff * *
```

## 4.231.3 Description

New in version 29Aug2024.

Pair style *rheo* computes pressure and viscous forces between particles in the *rheo package*. If thermal evolution is turned on in *fix rheo*, then the pair style also calculates heat exchanged between particles.

The *artificial/viscosity* keyword is used to specify the magnitude  $\zeta$  of an optional artificial viscosity contribution to forces. This factor can help stabilize simulations by smoothing out small length scale variations in velocity fields. Artificial viscous forces typically are only exchanged by fluid particles. However, if interfaces are not reconstructed in *fix rheo*, fluid particles will also exchange artificial viscous forces with solid particles to improve stability.

The *rho/damp* keyword is used to specify the magnitude  $\xi$  of an optional pairwise damping term between the density of particles. This factor can help stabilize simulations by smoothing out small length scale variations in density fields. However, in systems that develop a density gradient in equilibrium (e.g. in a hydrostatic column underlying gravity), this option may be inappropriate.

If particles have different viscosities or conductivities, the *harmonic/means* keyword changes how they are averaged before calculating pairwise forces or heat exchanges. By default, an arithmetic averaged is used, however, a harmonic mean may improve stability in systems with multiple fluid phases with large disparities in viscosities.

No coefficients are defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

## 4.231.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

## 4.231.5 Restrictions

This fix is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 4.231.6 Related commands

*fix rheo*, *fix rheo/pressure*, *fix rheo/thermal*, *fix rheo/viscosity*, *compute rheo/property/atom*

## 4.231.7 Default

Density damping and artificial viscous forces are not calculated. Arithmetic means are used for mixing particle properties.

# 4.232 pair\_style rheo/solid command

## 4.232.1 Syntax

```
pair_style rheo/solid
```

## 4.232.2 Examples

```
pair_style rheo/solid
pair_coeff * * 1.0 1.5 1.0
```

## 4.232.3 Description

New in version 29Aug2024.

Style *rheo/solid* is effectively a copy of pair style *bpm/spring* except it only applies forces between solid RHEO particles, determined by checking the status of each pair of neighboring particles before calculating forces.

The style computes pairwise forces with the formula

$$F = k(r - r_c)$$

where  $k$  is a stiffness and  $r_c$  is the cutoff length. An additional damping force is also applied to interacting particles. The force is proportional to the difference in the normal velocity of particles

$$F_D = -\gamma w(\hat{r} \bullet \vec{v})$$

where  $\gamma$  is the damping strength,  $\hat{r}$  is the displacement normal vector,  $\vec{v}$  is the velocity difference between the two particles, and  $w$  is a smoothing factor. This smoothing factor is constructed such that damping forces go to zero as particles come out of contact to avoid discontinuities. It is given by

$$w = 1.0 - \left(\frac{r}{r_c}\right)^8.$$

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $k$  (force/distance units)
- $r_c$  (distance units)
- $\gamma$  (force/velocity units)

#### 4.232.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the A coefficient and cutoff distance for this pair style can be mixed. A is always mixed via a *geometric* rule. The cutoff is mixed according to the `pair_modify` mix value. The default mix value is *geometric*. See the “`pair_modify`” command for details.

This pair style does not support the *pair\_modify* shift option, since the pair interaction goes to 0.0 at the cutoff.

The *pair\_modify* table and tail options are not relevant for this pair style.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.232.5 Restrictions

This pair style is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.232.6 Related commands

*fix rheo*, *fix rheo/thermal*, *pair bpm/spring*

#### 4.232.7 Default

none

### 4.233 pair\_style saip/metal command

Accelerator Variant: *saip/metal/opt*

#### 4.233.1 Syntax

```
pair_style [hybrid/overlay ...] saip/metal cutoff tap_flag
```

- cutoff = global cutoff (distance units)
- tap\_flag = 0/1 to turn off/on the taper function

## 4.233.2 Examples

```
pair_style hybrid/overlay saip/metal 16.0 1
pair_coeff * * saip/metal CHAu.ILP Au C H

pair_style hybrid/overlay eam rebo saip/metal 16.0
pair_coeff 1 1 eam Au_u3.eam Au NULL NULL
pair_coeff * * rebo CH.rebo NULL C H
pair_coeff * * saip/metal CHAu.ILP Au C H
```

## 4.233.3 Description

New in version 17Feb2022.

The *saip/metal* style computes the registry-dependent interlayer potential (ILP) potential for hetero-junctions formed with hexagonal 2D materials and metal surfaces, as described in (Ouyang6).

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta-1)} [\varepsilon + f(\rho_{ij}) + f(\rho_{ji})] - \frac{1}{1 + e^{-d[(r_{ij}/(s_R \cdot r_{eff})) - 1]}} \cdot \frac{C_6}{r_{ij}^6} \right\}$$

$$\rho_{ij}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_i)^2$$

$$\rho_{ji}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_j)^2$$

$$f(\rho) = C e^{-(\rho/\delta)^2}$$

$$\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1$$

Where  $\text{Tap}(r_{ij})$  is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than  $r_c$  *pair\_style ilp\_graphene\_hbn*.

It is important to include all the pairs to build the neighbor list for calculating the normals.

---

**Note:** To account for the isotropic nature of the isolated gold atom electron cloud, their corresponding normal vectors ( $\{bf\} n_i$ ) are assumed to lie along the interatomic vector  $\{bf\} r_{ij}$ . Notably, this assumption is suitable for many bulk material surfaces, for example, for systems possessing s-type valence orbitals or metallic surfaces, whose valence electrons are mostly delocalized, such that their Pauli repulsion with the electrons of adjacent surfaces are isotropic. Caution should be used in the case of very small gold contacts, for example, nano-clusters, where edge effects may become relevant.

---

The parameter file (e.g. CHAu.ILP), is intended for use with *metal units*, with energies in meV. Two additional parameters,  $S$ , and  $rcut$  are included in the parameter file.  $S$  is designed to facilitate scaling of energies.  $rcut$  is designed to build the neighbor list for calculating the normals for each atom pair.

---

**Note:** The parameters presented in the parameter file (e.g. BNCH.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful.

---

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using *pair\_style none*.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1.  $E_{vdW}$  = vdW (attractive) energy
2.  $E_{Rep}$  = Repulsive energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute 0 all pair saip/metal
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.233.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

#### 4.233.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the `newton` setting to be *on* for pair interactions.

The CHAu.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for *metal* units. You can use this potential with any LAMMPS units, but you would need to create your own custom CHAu.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use *metal* units.

### 4.233.6 Related commands

*pair\_coeff*, *pair\_none*, *pair\_style hybrid/overlay*, *pair\_style drip*, *pair\_style ilp\_tmd*, *pair\_style ilp\_graphene\_hbn*, *pair\_style pair\_kolmogorov\_crespi\_z*, *pair\_style pair\_kolmogorov\_crespi\_full*, *pair\_style pair\_lebedeva\_z*, *pair\_style pair\_coul\_shield*.

### 4.233.7 Default

tap\_flag = 1

## 4.234 pair\_style sdpd/taitwater/isothermal command

### 4.234.1 Syntax

```
pair_style sdpd/taitwater/isothermal temperature viscosity seed
```

- temperature = temperature of the fluid (temperature units)
- viscosity = dynamic viscosity of the fluid (mass\*distance/time units)
- seed = random number generator seed (positive integer, optional)

### 4.234.2 Examples

```
pair_style sdpd/taitwater/isothermal 300. 1. 28681
pair_coeff * * 1000.0 1430.0 2.4
```

### 4.234.3 Description

The sdpd/taitwater/isothermal style computes forces between mesoscopic particles according to the Smoothed Dissipative Particle Dynamics model described in this paper by (*Espanol and Revenga*) under the following assumptions:

1. The temperature is constant and uniform.
2. The shear viscosity is constant and uniform.
3. The volume viscosity is negligible before the shear viscosity.
4. The Boltzmann constant is negligible before the heat capacity of a single mesoscopic particle of fluid.

The third assumption is true for water in nearly incompressible flows. The fourth holds true for water for any reasonable size one can imagine for a mesoscopic particle.

The pressure forces between particles will be computed according to Tait's equation of state:

$$p = B \left[ \left( \frac{\rho}{\rho_0} \right)^\gamma - 1 \right]$$

where  $\gamma = 7$  and  $B = c_0^2 \rho_0 / \gamma$ , with  $\rho_0$  being the reference density and  $c_0$  the reference speed of sound.

The laminar viscosity and the random forces will be computed according to formulas described in (*Espanol and Revenga*).

**Warning:** Similar to *brownian* and *dpd* styles, the *newton* setting for pairwise interactions needs to be on when running LAMMPS in parallel if you want to ensure linear momentum conservation. Otherwise random forces generated for pairs straddling processor boundary will not be equal and opposite.

---

**Note:** The actual random seed used will be a mix of what you specify and other parameters like the MPI ranks. This is to ensure that different MPI tasks have distinct seeds.

---

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- $\rho_0$  reference density (mass/volume units)
  - $c_0$  reference soundspeed (distance/time units)
  - h kernel function cutoff (distance units)
- 

#### 4.234.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.234.5 Restrictions

This pair style is part of the DPD-SMOOTH package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.234.6 Related commands

*pair\_coeff*, *pair sph/rhosum*, *pair sph/taitwater*

## 4.234.7 Default

The default seed is 0 (before mixing).

---

(Espanol and Revenga) Espanol, Revenga, Physical Review E, 67, 026705 (2003).

## 4.235 pair\_style smatb command

## 4.236 pair\_style smatb/single command

### 4.236.1 Syntax

```
pair_style style args
```

- style = *smatb* or *smatb/single*
- args = none

### 4.236.2 Examples

```
pair_style smatb
pair_coeff 1 1 2.88 10.35 4.178 0.210 1.818 4.07293506 4.9883063257983666

pair_style smatb/single
pair_coeff 1 1 2.88 10.35 4.178 0.210 1.818 4.07293506 4.9883063257983666
```

### 4.236.3 Description

New in version 4May2022.

The *smatb* and *smatb/single* styles compute the Second Moment Approximation to the Tight Binding (*Cyrot*), (*Gupta*), (*Rosato*), given by

$$E_i = \sum_{j, R_{ij} \leq R_c} \alpha(R_{ij}) - \sqrt{\sum_{j, R_{ij} \leq R_c} \Xi^2(R_{ij})}$$

$R_{ij}$  is the distance between the atom  $i$  and  $j$ . And the two functions  $\alpha(r)$  and  $\Xi(r)$  are:

$$\alpha(r) = \begin{cases} Ae^{-p\left(\frac{r}{R_0}-1\right)} & r < R_{sc} \\ a_3(r-R_c)^3 + a_4(r-R_c)^4 + a_5(r-R_c)^5 & R_{sc} < r < R_c \end{cases}$$
$$\Xi(r) = \begin{cases} \xi e^{-q\left(\frac{r}{R_0}-1\right)} & r < R_{sc} \\ x_3(r-R_c)^3 + x_4(r-R_c)^4 + x_5(r-R_c)^5 & R_{sc} < r < R_c \end{cases}$$

The polynomial coefficients  $a_3, a_4, a_5, x_3, x_4, x_5$  are computed by LAMMPS: the two exponential terms and their first and second derivatives are smoothly reduced to zero, from the inner cutoff  $R_{sc}$  to the outer cutoff  $R_c$ .

The *smatb/single* style is an optimization when using only a single atom type.

#### 4.236.4 Coefficients

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $R_0$  (distance units)
- $p$  (dimensionless)
- $q$  (dimensionless)
- $A$  (energy units)
- $\xi$  (energy units)
- $R_{cs}$  (distance units)
- $R_c$  (distance units)

Note that:  $R_0$  is the nearest neighbor distance, usually coincides with the diameter of the atoms

See the *run\_style* command for details.

---

#### 4.236.5 Mixing info

For atom type pairs I,J and I != J the coefficients are not automatically mixed.

---

#### 4.236.6 Restrictions

These pair styles are part of the SMTBQ package and are only enabled if LAMMPS is built with that package. See the *Build package* page for more info.

These pair styles require the *newton* setting to be “on” for pair interactions.

#### 4.236.7 Related commands

- *pair\_coeff*

#### 4.236.8 Default

none

## 4.237 pair\_style smd/hertz command

### 4.237.1 Syntax

```
pair_style smd/hertz scale_factor
```

### 4.237.2 Examples

```
pair_style smd/hertz 1.0  
pair_coeff 1 1 <contact_stiffness>
```

### 4.237.3 Description

The *smd/hertz* style calculates contact forces between SPH particles belonging to different physical bodies.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between two particles (whose spatial extents are defined via its contact radius). The effect is that a particles cannot penetrate into each other. The parameter <contact\_stiffness> has units of pressure and should equal roughly one half of the Young's modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particles.

The parameter *scale\_factor* can be used to scale the particles' contact radii. This can be useful to control how close particles can approach each other. Usually, *scale\_factor* =1.0.

---

### 4.237.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

---

### 4.237.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.237.6 Related commands

*pair\_coeff*

### 4.237.7 Default

none

## 4.238 pair\_style smd/tlsph command

### 4.238.1 Syntax

```
pair_style smd/tlsph args
```

### 4.238.2 Examples

```
pair_style smd/tlsph
```

### 4.238.3 Description

The *smd/tlsph* style computes particle interactions according to continuum mechanics constitutive laws and a Total-Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked with the following command:

```
pair_style smd/tlsph  
pair_coeff i j *COMMON rho0 E nu Q1 Q2 hg Cp &  
          *END
```

Here, *i* and *j* denote the *LAMMPS* particle types for which this pair style is defined. Note that *i* and *j* must be equal, i.e., no *tlsph* cross interactions between different particle types are allowed. In contrast to the usual *LAMMPS pair coeff* definitions, which are given solely a number of floats and integers, the *tlsph pair coeff* definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The *pair coeff* line must be terminated with the *\*END* keyword. The use of the line continuation operator *&* is recommended. A typical invocation of the *tlsph* for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor). Damage and failure models can also be added.

Please see the [SMD user guide](#) for a complete listing of the possible keywords and material models.

---

### 4.238.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

---

### 4.238.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.238.6 Related commands

*pair\_coeff*

### 4.238.7 Default

none

## 4.239 pair\_style smd/tri\_surface command

### 4.239.1 Syntax

```
pair_style smd/tri_surface scale_factor
```

### 4.239.2 Examples

```
pair_style smd/tri_surface 1.0  
pair_coeff 1 1 <contact_stiffness>
```

### 4.239.3 Description

The *smd/tri\_surface* style calculates contact forces between SPH particles and a rigid wall boundary defined via the *smd/wall\_surface* fix.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between a particle (whose spatial extents are defined via its contact radius) and the triangle. The effect is that a particle cannot penetrate into the triangular surface. The parameter *<contact\_stiffness>* has units of pressure and should equal roughly one half of the Young's modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particle

The parameter *scale\_factor* can be used to scale the particles' contact radii. This can be useful to control how close particles can approach the triangulated surface. Usually, *scale\_factor* = 1.0.

---

#### 4.239.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

#### 4.239.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

#### 4.239.6 Related commands

*pair\_coeff*

#### 4.239.7 Default

none

### 4.240 pair\_style smd/ulsph command

#### 4.240.1 Syntax

```
pair_style smd/ulsph args
```

- these keywords must be given

keyword = \*DENSITY\_SUMMATION or \*DENSITY\_CONTINUITY and \*VELOCITY\_GRADIENT or \*NO\_VELOCITY\_GRADIENT and \*GRADIENT\_CORRECTION or \*NO\_GRADIENT\_CORRECTION

#### 4.240.2 Examples

```
pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION
```

#### 4.240.3 Description

The *smd/ulsph* style computes particle interactions according to continuum mechanics constitutive laws and an updated Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked similar to the following command:

```
pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION
pair_coeff i j *COMMON rho0 c0 Q1 Cp hg &
*END
```

Here,  $i$  and  $j$  denote the *LAMMPS* particle types for which this pair style is defined. Note that  $i$  and  $j$  can be different, i.e., *ulsph* cross interactions between different particle types are allowed. However,  $i$ - $i$  respectively  $j$ - $j$  *pair\_coeff* lines have to precede a cross interaction. In contrast to the usual *LAMMPS pair coeff* definitions, which are given solely a number of floats and integers, the *ulsph pair coeff* definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The *pair coeff* line must be terminated with the *\*END* keyword. The use the line continuation operator *&* is recommended. A typical invocation of the *ulsph* for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor).

Note that the use of *\*GRADIENT\_CORRECTION* can lead to severe numerical instabilities. For a general fluid simulation, *\*NO\_GRADIENT\_CORRECTION* is recommended.

Please see the [SMD user guide](#) for a complete listing of the possible keywords and material models.

---

#### 4.240.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

---

#### 4.240.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.241 pair\_style smtbq command

#### 4.241.1 Syntax

```
pair_style smtbq
```

## 4.241.2 Examples

```
pair_style smtbq
pair_coeff * *ffield.smtbq.Al2O3 0 Al
```

## 4.241.3 Description

This pair style computes a variable charge SMTB-Q (Second-Moment tight-Binding QEq) potential as described in [SMTB-Q\\_1](#) and [SMTB-Q\\_2](#). This potential was first proposed in [SMTB-Q\\_0](#). Briefly, the energy of metallic-oxygen systems is given by three contributions:

$$\begin{aligned}
 E_{tot} &= E_{ES} + E_{OO} + E_{MO} \\
 E_{ES} &= \sum_i \left[ \chi_i^0 Q_i + \frac{1}{2} J_i^0 Q_i^2 + \frac{1}{2} \sum_{j \neq i} J_{ij}(r_{ij}) f_{cut}^{R_{coul}}(r_{ij}) Q_i Q_j \right] \\
 E_{OO} &= \sum_{i,j}^{i,j=O} \left[ C \exp\left(-\frac{r_{ij}}{\rho}\right) - D f_{cut}^{r_1^{oo} r_2^{oo}}(r_{ij}) \exp(B r_{ij}) \right] \\
 E_{MO} &= \sum_i E_{cov}^i + \sum_{j \neq i} A f_{cut}^{r_{c1} r_{c2}}(r_{ij}) \exp\left[-p\left(\frac{r_{ij}}{r_0} - 1\right)\right]
 \end{aligned}$$

where  $E_{tot}$  is the total potential energy of the system,  $E_{ES}$  is the electrostatic part of the total energy,  $E_{OO}$  is the interaction between oxygen atoms and  $E_{MO}$  is a short-range interaction between metal and oxygen atoms. These interactions depend on interatomic distance  $r_{ij}$  and/or the charge  $Q_i$  of atoms  $i$ . Cut-off function enables smooth convergence to zero interaction.

The parameters appearing in the upper expressions are set in the `ffield.SMTBQ.Syst` file where `Syst` corresponds to the selected system (e.g. `field.SMTBQ.Al2O3`). Examples for  $\text{TiO}_2$ ,  $\text{Al}_2\text{O}_3$  are provided. A single `pair_coeff` command is used with the SMTBQ styles which provides the path to the potential file with parameters for needed elements. These are mapped to LAMMPS atom types by specifying additional arguments after the potential filename in the `pair_coeff` command. Note that atom type 1 must always correspond to oxygen atoms. As an example, to simulate a  $\text{TiO}_2$  system, atom type 1 has to be oxygen and atom type 2 Ti. The following `pair_coeff` command should then be used:

```
pair_coeff * * PathToLammps/potentials/ffield.smtbq.TiO2 0 Ti
```

The electrostatic part of the energy consists of two components

self-energy of atom  $i$  in the form of a second order charge dependent polynomial and a long-range Coulombic electrostatic interaction. The latter uses the wolf summation method described in [Wolf](#), spherically truncated at a longer cutoff,  $R_{coul}$ . The charge of each ion is modeled by an orbital Slater which depends on the principal quantum number ( $n$ ) of the outer orbital shared by the ion.

Interaction between oxygen,  $E_{OO}$ , consists of two parts, an attractive and a repulsive part. The attractive part is effective only at short range ( $< r_2^{oo}$ ). The attractive contribution was optimized to study surfaces reconstruction (e.g. [SMTB-Q\\_2](#) in  $\text{TiO}_2$ ) and is not necessary for oxide bulk modeling. The repulsive part is the Pauli interaction between the electron clouds of oxygen. The Pauli repulsion and the coulombic electrostatic interaction have same cut off value. In the `ffield.SMTBQ.Syst`, the keyword `'buck'` allows to consider only the repulsive O-O interactions. The keyword `'buckPlusAttr'` allows to consider the repulsive and the attractive O-O interactions.

The short-range interaction between metal-oxygen,  $E_{MO}$  is based on the second moment approximation of the density of states with a N-body potential for the band energy term,  $E_{cov}^i$ , and a Born-Mayer type repulsive terms as indicated by the keyword `'second_moment'` in the `ffield.SMTBQ.Syst`. The energy band term is given by:

$$\begin{aligned}
 E_{cov}^{i(i=M,O)} &= - \left\{ \eta_i (\mu \xi^0)^2 f_{cut}^{r_{c1} r_{c2}}(r_{ij}) \left( \sum_{j(j=O,M)} \exp[-2q(\frac{r_{ij}}{r_0} - 1)] \right) \delta Q_i \left( 2 \frac{n_0}{\eta_i} - \delta Q_i \right) \right\}^{1/2} \\
 \delta Q_i &= |Q_i^F| - |Q_i|
 \end{aligned}$$

where  $\eta_i$  is the stoichiometry of atom  $i$ ,  $\delta Q_i$  is the charge delocalization of atom  $i$ , compared to its formal charge  $Q_i^f$ .  $n_0$ , the number of hybridized orbitals, is calculated with to the atomic orbitals shared  $d_i$  and the stoichiometry  $\eta_i$ .  $r_{c1}$  and  $r_{c2}$  are the two cutoff radius around the fourth neighbors in the cutoff function.

In the formalism used here,  $\xi^0$  is the energy parameter.  $\xi^0$  is in tight-binding approximation the hopping integral between the hybridized orbitals of the cation and the anion. In the literature we find many ways to write the hopping integral depending on whether one takes the point of view of the anion or cation. These are equivalent vision. The correspondence between the two visions is explained in appendix A of the article in the SrTiO3 [SMTB-Q\\_3](#) (parameter  $\beta$  shown in this article is in fact the  $\beta_O$ ). To summarize the relationship between the hopping integral  $\xi^0$  and the others, we have in an oxide  $C_nO_m$  the following relationship:

$$\xi^0 = \frac{\xi_O}{m} = \frac{\xi_C}{n}$$

$$\frac{\beta_O}{\sqrt{m}} = \frac{\beta_C}{\sqrt{n}} = \xi^0 \frac{\sqrt{m} + \sqrt{n}}{2}$$

Thus parameter  $\mu$ , indicated above, is given by  $\mu = \frac{1}{2}(\sqrt{n} + \sqrt{m})$

The potential offers the possibility to consider the polarizability of the electron clouds of oxygen by changing the slater radius of the charge density around the oxygen atoms through the parameters  $rBB$ ,  $rB$  and  $rS$  in the `ffield.SMTBQ.Syst`. This change in radius is performed according to the method developed by E. Maras [SMTB-Q\\_2](#). This method needs to determine the number of nearest neighbors around the oxygen. This calculation is based on first ( $r_{1n}$ ) and second ( $r_{2n}$ ) distances neighbors.

The SMTB-Q potential is a variable charge potential. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See [Rick](#) for further detail. One can adjust the frequency, the maximum number of iterative loop and the convergence of the equilibrium charge calculation. To obtain the energy conservation in NVE thermodynamic ensemble, we recommend to use a convergence parameter in the interval  $10e-5$  -  $10e-6$  eV.

The `ffield.SMTBQ.Syst` files are provided for few systems. They consist of nine parts and the lines beginning with '#' are comments (note that the number of comment lines matter). The first sections are on the potential parameters and others are on the simulation options and might be modified. Keywords are character type and must be enclosed in quotation marks ('').

1) Number of different element in the oxide:

- N\_elem= 2 or 3
- Divider line

2) Atomic parameters

For the anion (oxygen)

- Name of element (char) and stoichiometry in oxide
- Formal charge and mass of element
- Principal quantum number of outer orbital (n), electronegativity ( $\chi_i^0$ ) and hardness ( $J_i^0$ )
- Ionic radius parameters : max coordination number ( $coordBB = 6$  by default), bulk coordination number ( $coordB$ ), surface coordination number ( $coordS$ ) and  $rBB$ ,  $rB$  and  $rS$  the slater radius for each coordination number. **(note : If you don't want to change the slater radius, use three identical radius values)**
- Number of orbital shared by the element in the oxide ( $d_i$ )
- Divider line

For each cations (metal):

- Name of element (char) and stoichiometry in oxide
- Formal charge and mass of element

- Number of electron in outer orbital ( $ne$ ), electronegativity ( $\chi_i^0$ ), hardness ( $J_i^0$ ) and  $r_{Slater}$  the slater radius for the cation.
  - Number of orbitals shared by the elements in the oxide ( $d_i$ )
  - Divider line
- 3) Potential parameters:
- Keyword for element1, element2 and interaction potential ('second\_moment' or 'buck' or 'buckPlusAttr') between element 1 and 2. If the potential is 'second\_moment', specify 'oxide' or 'metal' for metal-oxygen or metal-metal interactions respectively.
  - Potential parameter:
    - If type of potential is 'second\_moment' :  $A$  (eV),  $p$ ,  $\zeta^0$  (eV) and  $q$ ,  $r_{c1}(\text{\AA})$ ,  $r_{c2}(\text{\AA})$  and  $r_0(\text{\AA})$
    - If type of potential is 'buck' :  $C$  (eV) and  $\rho(\text{\AA})$
    - If type of potential is 'buckPlusAttr' :  $C$  (eV) and  $\rho(\text{\AA})$   $D$  (eV),  $B$  ( $\text{\AA}^{-1}$ ),  $r_1^{OO}(\text{\AA})$  and  $r_2^{OO}(\text{\AA})$
  - Divider line
- 4) Tables parameters:
- Cutoff radius for the Coulomb interaction ( $R_{coul}$ )
  - Starting radius ( $r_{min} = 1, 18845\text{\AA}$ ) and increments ( $dr = 0.001\text{\AA}$ ) for creating the potential table.
  - Divider line
- 5) Rick model parameter:
- *Nevery* : parameter to set the frequency of the charge resolution. The charges are evaluated each *Nevery* time steps.
  - Max number of iterative loop (*loopmax*) and convergence criterion (*prec*) in eV of the charge resolution
  - Divider line
- 6) Coordination parameter:
- First ( $r_{1n}$ ) and second ( $r_{2n}$ ) neighbor distances in angstroms
  - Divider line
- 7) Charge initialization mode:
- Keyword (*QInitMode*) and initial oxygen charge ( $Q_{init}$ ). If keyword = 'true', all oxygen charges are initially set equal to  $Q_{init}$ . The charges on the cations are initially set in order to respect the neutrality of the box. If keyword = 'false', all atom charges are initially set equal to 0 if you use the *create\_atoms* command or the charge specified in the file structure using *read\_data* command.
  - Divider line
- 8) Mode for the electronegativity equalization (QEq)
- Keyword (*mode*) followed by:
    - QEqAll (one QEq group) | no parameters
    - QEqAllParallel (several QEq groups) | no parameters
    - Surface | *zlim* (QEq only for  $z > zlim$ )
  - Parameter if necessary
  - Divider line

## 9) Verbose

- If you want the code to work in verbose mode or not : ‘true’ or ‘false’
- If you want to print or not in the file ‘Energy\_component.txt’ the three main contributions to the energy of the system according to the description presented above : ‘true’ or ‘false’ and  $N_{Energy}$ . This option writes to the file every  $N_{Energy}$  time steps. If the value is ‘false’ then  $N_{Energy} = 0$ . The file takes into account the possibility to have several QEq groups  $g$  then it writes: time step, number of atoms in group  $g$ , electrostatic part of energy,  $E_{ES}$ , the interaction between oxygen,  $E_{OO}$ , and short range metal-oxygen interaction,  $E_{MO}$ .
- If you want to print to the file ‘Electroneg\_component.txt’ the electronegativity component ( $\frac{\partial E_{tot}}{\partial Q_i}$ ) or not: ‘true’ or ‘false’ and  $N_{Electroneg}$ . This option writes to the file every  $N_{Electroneg}$  time steps. If the value is ‘false’ then  $N_{Electroneg} = 0$ . The file consist of atom number  $i$ , atom type (1 for oxygen and # higher than 1 for metal), atom position:  $x$ ,  $y$  and  $z$ , atomic charge of atom  $i$ , electrostatic part of atom  $i$  electronegativity, covalent part of atom  $i$  electronegativity, the hopping integral of atom  $i$  ( $Z\beta^2$ ) $_i$  and box electronegativity.

---

**Note:** This last option slows down the calculation dramatically. Use only with a single processor simulation.

---

#### 4.241.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you needs to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.241.5 Restrictions

This pair style is part of the SMTBQ package and is only enabled if LAMMPS is built with that package. See the *Build package* page for more info.

This potential requires using atom type 1 for oxygen and atom type higher than 1 for metal atoms.

This pair style requires the *newton* setting to be “on” for pair interactions.

The SMTB-Q potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*.

---

## 4.242 pair\_style snap command

Accelerator Variants: *snap/intel*, *snap/kk*

### 4.242.1 Syntax

```
pair_style snap
```

### 4.242.2 Examples

```
pair_style snap
pair_coeff * * InP.snapcoeff InP.snapparam In In P P
```

### 4.242.3 Description

Pair style *snap* defines the spectral neighbor analysis potential (SNAP), a machine-learning interatomic potential (*Thompson*). Like the GAP framework of Bartok et al. (*Bartok2010*), SNAP uses bispectrum components to characterize the local neighborhood of each atom in a very general way. The mathematical definition of the bispectrum calculation and its derivatives w.r.t. atom positions is identical to that used by *compute snap*, which is used to fit SNAP potentials to *ab initio* energy, force, and stress data. In SNAP, the total energy is decomposed into a sum over atom energies. The energy of atom *i* is expressed as a weighted sum over bispectrum components.

$$E_{SNAP}^i(B_1^i, \dots, B_K^i) = \beta_0^{\mu_i} + \sum_{k=1}^K \beta_k^{\mu_i} B_k^i$$

where  $B_k^i$  is the *k*-th bispectrum component of atom *i*, and  $\beta_k^{\mu_i}$  is the corresponding linear coefficient that depends on  $\mu_i$ , the SNAP element of atom *i*. The number of bispectrum components used and their definitions depend on the value of *twojmax* and other parameters defined in the SNAP parameter file described below. The bispectrum calculation is described in more detail in *compute sna/atom*.

Note that unlike for other potentials, cutoffs for SNAP potentials are not set in the *pair\_style* or *pair\_coeff* command; they are specified in the SNAP potential files themselves.

Only a single *pair\_coeff* command is used with the *snap* style which specifies a SNAP coefficient file followed by a SNAP parameter file and then N additional arguments specifying the mapping of SNAP elements to LAMMPS atom types, where N is the number of LAMMPS atom types:

- SNAP coefficient file
- SNAP parameter file
- N element names = mapping of SNAP elements to atom types

As an example, if a LAMMPS indium phosphide simulation has 4 atoms types, with the first two being indium and the third and fourth being phosphorous, the *pair\_coeff* command would look like this:

```
pair_coeff * * snap InP.snapcoeff InP.snapparam In In P P
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The two filenames are for the coefficient and parameter files, respectively. The two trailing ‘In’ arguments map LAMMPS atom types 1 and 2 to the SNAP ‘In’ element. The two trailing ‘P’ arguments map LAMMPS atom types 3 and 4 to the SNAP ‘P’ element.

If a SNAP mapping value is specified as NULL, the mapping is not performed. This can be used when a *snap* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The name of the SNAP coefficient file usually ends in the “.snapcoeff” extension. It may contain coefficients for many SNAP elements. The only requirement is that each of the unique element names appearing in the LAMMPS pair\_coeff command appear exactly once in the SNAP coefficient file. It is okay if the SNAP coefficient file contains additional elements not in the pair\_coeff command, except when using *chemflag* (see below). The name of the SNAP parameter file usually ends in the “.snapparam” extension. It contains a small number of parameters that define the overall form of the SNAP potential. See the *pair\_coeff* page for alternate ways to specify the path for these files.

SNAP potentials are quite commonly combined with one or more other LAMMPS pair styles using the *hybrid/overlay* pair style. As an example, the SNAP tantalum potential provided in the LAMMPS potentials directory combines the *snap* and *zbl* pair styles. It is invoked by the following commands:

```
variable zblcutinner equal 4
variable zblcutouter equal 4.8
variable zblz equal 73
pair_style hybrid/overlay &
zbl ${zblcutinner} ${zblcutouter} snap
pair_coeff * * zbl 0.0
pair_coeff 1 1 zbl ${zblz}
pair_coeff * * snap Ta06A.snapcoeff Ta06A.snapparam Ta
```

It is convenient to keep these commands in a separate file that can be inserted in any LAMMPS input script using the *include* command.

The top of the SNAP coefficient file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain two integers:

- nelem = Number of elements
- ncoeff = Number of coefficients

This is followed by one block for each of the *nelem* elements. The first line of each block contains three entries:

- Element name (text string)
- R = Element radius (distance units)
- w = Element weight (dimensionless)

This line is followed by *ncoeff* coefficients, one per line.

The SNAP parameter file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. The required keywords are *rcutfac* and *twojmax*. Optional keywords are *rfac0*, *rmin0*, *switchflag*, *bzeroflag*, *quadraticflag*, *chemflag*, *bnormflag*, *wselfallflag*, *switchinnerflag*, *sinner*, *dinner*, *chunksize*, and *parallethresh*.

The default values for these keywords are

- *rfac0* = 0.99363
- *rmin0* = 0.0
- *switchflag* = 1

- *bzero*flag = 1
- *quadratic*flag = 0
- *chem*flag = 0
- *bnorm*flag = 0
- *wself*allflag = 0
- *switchinner*flag = 0
- *chunk*size = 32768
- *parallel*thresh = 8192

For detailed definitions of all of these keywords, see the [compute sna/atom](#) doc page.

If *quadratic*flag is set to 1, then the SNAP energy expression includes additional quadratic terms that have been shown to increase the overall accuracy of the potential without much increase in computational cost ([Wood](#)).

$$E_{SNAP}^i(\mathbf{B}^i) = \beta_0^{\mu_i} + \beta^{\mu_i} \cdot \mathbf{B}_i + \frac{1}{2} \mathbf{B}_i^t \cdot \alpha^{\mu_i} \cdot \mathbf{B}_i$$

where  $\mathbf{B}_i$  is the  $K$ -vector of bispectrum components,  $\beta^{\mu_i}$  is the  $K$ -vector of linear coefficients for element  $\mu_i$ , and  $\alpha^{\mu_i}$  is the symmetric  $K$  by  $K$  matrix of quadratic coefficients. The SNAP coefficient file should contain  $K(K+1)/2$  additional coefficients in each element block, the upper-triangular elements of  $\alpha^{\mu_i}$ .

If *chem*flag is set to 1, then the energy expression is written in terms of explicit multi-element bispectrum components indexed on ordered triplets of elements, which has been shown to increase the ability of the SNAP potential to capture energy differences in chemically complex systems, at the expense of a significant increase in computational cost ([Cusentino](#)).

$$E_{SNAP}^i(\mathbf{B}^i) = \beta_0^{\mu_i} + \sum_{\kappa, \lambda, \mu} \beta_{\mu_i}^{\kappa \lambda \mu} \cdot \mathbf{B}_i^{\kappa \lambda \mu}$$

where  $\mathbf{B}_i^{\kappa \lambda \mu}$  is the  $K$ -vector of bispectrum components for neighbors of elements  $\kappa$ ,  $\lambda$ , and  $\mu$  and  $\beta_{\mu_i}^{\kappa \lambda \mu}$  is the corresponding  $K$ -vector of linear coefficients for element  $\mu_i$ . The SNAP coefficient file should contain a total of  $KN_{elem}^3$  coefficients in each element block, where  $N_{elem}$  is the number of elements in the SNAP coefficient file, which must equal the number of unique elements appearing in the LAMMPS pair\_coeff command, to avoid ambiguity in the number of coefficients.

The keyword *switchinner*flag activates an additional switching function that smoothly turns off contributions to the SNAP potential from neighbor atoms at short separations. If *switchinner*flag is set to 1 then the additional keywords *sinner* and *dinner* must also be provided. Each of these is followed by *nelements* values, where *nelements* is the number of unique elements appearing in appearing in the LAMMPS pair\_coeff command. The element order should correspond to the order in which elements first appear in the pair\_coeff command reading from left to right.

The keywords *chunk*size and *parallel*thresh are only applicable when using the pair style *snap* with the KOKKOS package on GPUs and are ignored otherwise. The *chunk*size keyword controls the number of atoms in each pass used to compute the bispectrum components and is used to avoid running out of memory. For example if there are 8192 atoms in the simulation and the *chunk*size is set to 4096, the bispectrum calculation will be broken up into two passes (running on a single GPU). The *parallel*thresh keyword controls a crossover threshold for performing extra parallelism. For small systems, exposing additional parallelism can be beneficial when there is not enough work to fully saturate the GPU threads otherwise. However, the extra parallelism also leads to more divergence and can hurt performance when the system is already large enough to saturate the GPU threads. Extra parallelism will be performed if the *chunk*size (or total number of atoms per GPU) is smaller than *parallel*thresh.

---

**Note:** The previously used *diagonalstyle* keyword was removed in 2019, since all known SNAP potentials use the default value of 3.

---

#### 4.242.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a `pair_coeff` command with  $I \neq J$  arguments for this style.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.242.5 Restrictions

This style is part of the ML-SNAP package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The *snap/intel* accelerator variant will *only* be available if LAMMPS is built with Intel *compilers* and for CPUs with AVX-512 support. While the INTEL package in general allows multiple floating point precision modes to be selected, *snap/intel* will currently always use full double precision regardless of the precision mode selected. Additionally, the *intel* variant of *snap* will **NOT** use multiple threads with OpenMP.

## 4.243 pair\_style soft command

Accelerator Variants: *soft/gpu*, *soft/kk*, *soft/omp*

### 4.243.1 Syntax

```
pair_style soft cutoff
```

- cutoff = global cutoff for soft interactions (distance units)

### 4.243.2 Examples

```
pair_style soft 1.0
pair_coeff * * 10.0
pair_coeff 1 1 10.0 3.0

pair_style soft 1.0
pair_coeff * * 0.0
variable prefactor equal ramp(0,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

### 4.243.3 Description

Style *soft* computes pairwise interactions with the formula

$$E = A \left[ 1 + \cos \left( \frac{\pi r}{r_c} \right) \right] \quad r < r_c$$

It is useful for pushing apart overlapping atoms, since it does not blow up as  $r$  goes to 0.  $A$  is a prefactor that can be made to vary in time from the start to the end of the run (see discussion below), e.g. to start with a very soft potential and slowly harden the interactions over time.  $r_c$  is the cutoff. See the *fix nve/limit* command for another way to push apart overlapping atoms.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $A$  (energy units)

- cutoff (distance units)

The last coefficient is optional. If not specified, the global soft cutoff is used.

---

**Note:** The syntax for *pair\_coeff* with a single A coeff is different in the current version of LAMMPS than in older versions which took two values, Astart and Astop, to ramp between them. This functionality is now available in a more general form through the *fix adapt* command, as explained below. Note that if you use an old input script and specify Astart and Astop without a cutoff, then LAMMPS will interpret that as A and a cutoff, which is probably not what you want.

---

The *fix adapt* command can be used to vary A for one or more pair types over the course of a simulation, in which case *pair\_coeff* settings for A must still be specified, but will be overridden. For example these commands will vary the prefactor A for all pairwise interactions from 0.0 at the beginning to 30.0 at the end of a run:

```
variable prefactor equal ramp(0,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

Note that a formula defined by an *equal-style variable* can use the current timestep, elapsed time in the current run, elapsed time since the beginning of a series of runs, as well as access other variables.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.243.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the A coefficient and cutoff distance for this pair style can be mixed. A is always mixed via a *geometric* rule. The cutoff is mixed according to the *pair\_modify* mix value. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

This pair style does not support the *pair\_modify* shift option, since the pair interaction goes to 0.0 at the cutoff.

The *pair\_modify* table and tail options are not relevant for this pair style.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.243.5 Restrictions

none

#### 4.243.6 Related commands

*pair\_coeff*, *fix nve/limit*, *fix adapt*

#### 4.243.7 Default

none

### 4.244 `pair_style sph/heatconduction` command

Accelerator Variants: *sph/heatconduction/gpu*

#### 4.244.1 Syntax

```
pair_style sph/heatconduction
```

#### 4.244.2 Examples

```
pair_style sph/heatconduction
pair_coeff * * 1.0 2.4
```

#### 4.244.3 Description

The `sph/heatconduction` style computes heat transport between SPH particles. The transport model is the diffusion equation for the internal energy.

See [this PDF guide](#) to using SPH in LAMMPS.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- D diffusion coefficient (length<sup>2</sup>/time units)
- h kernel function cutoff (distance units)

#### 4.244.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.244.5 Restrictions

This pair style is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.244.6 Related commands

*pair\_coeff*, *pair\_sph/rhsum*

#### 4.244.7 Default

none

### 4.245 pair\_style sph/idealgas command

#### 4.245.1 Syntax

```
pair_style sph/idealgas
```

#### 4.245.2 Examples

```
pair_style sph/idealgas
pair_coeff * * 1.0 2.4
```

#### 4.245.3 Description

The sph/idealgas style computes pressure forces between particles according to the ideal gas equation of state:

$$p = (\gamma - 1)\rho e$$

where  $\gamma = 1.4$  is the heat capacity ratio,  $\rho$  is the local density, and  $e$  is the internal energy per unit mass. This pair style also computes Monaghan's artificial viscosity to prevent particles from interpenetrating (*Monaghan*).

See [this PDF guide](#) to using SPH in LAMMPS.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- *v* artificial viscosity (no units)
  - *h* kernel function cutoff (distance units)
- 

#### 4.245.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.245.5 Restrictions

This pair style is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.245.6 Related commands

*pair\_coeff*, *pair\_sph/rhosum*

### 4.246 pair\_style sph/lj command

Accelerator Variants: *sph/lj/gpu*

#### 4.246.1 Syntax

```
pair_style sph/lj
```

## 4.246.2 Examples

```
pair_style sph/lj
pair_coeff * * 1.0 2.4
```

## 4.246.3 Description

The sph/lj style computes pressure forces between particles according to the Lennard-Jones equation of state, which is computed according to Ree's 1980 polynomial fit (*Ree*). The Lennard-Jones parameters epsilon and sigma are set to unity. This pair style also computes Monaghan's artificial viscosity to prevent particles from interpenetrating (*Monaghan*).

See [this PDF guide](#) to using SPH in LAMMPS.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- *v* artificial viscosity (no units)
- *h* kernel function cutoff (distance units)

---

## 4.246.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

## 4.246.5 Restrictions

As noted above, the Lennard-Jones parameters epsilon and sigma are set to unity.

This pair style is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 4.246.6 Related commands

*pair\_coeff*, *pair\_sph/rhosome*

## 4.246.7 Default

none

## 4.247 pair\_style sph/rhosome command

### 4.247.1 Syntax

```
pair_style sph/rhosome Nstep
```

- Nstep = timestep interval

### 4.247.2 Examples

```
pair_style sph/rhosome 10
pair_coeff * * 2.4
```

### 4.247.3 Description

The sph/rhosome style computes the local particle mass density  $\rho$  for SPH particles by kernel function interpolation, every Nstep timesteps.

See [this PDF guide](#) to using SPH in LAMMPS.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- h (distance units)

### 4.247.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the pair\_style and pair\_coeff commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 4.247.5 Restrictions

This pair style is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.247.6 Related commands

`pair_coeff`, `pair_sph/taitwater`

### 4.247.7 Default

## 4.248 `pair_style sph/taitwater` command

Accelerator Variants: `sph/taitwater/gpu`

### 4.248.1 Syntax

```
pair_style sph/taitwater
```

### 4.248.2 Examples

```
pair_style sph/taitwater
pair_coeff * * 1000.0 1430.0 1.0 2.4
```

### 4.248.3 Description

The `sph/taitwater` style computes pressure forces between SPH particles according to Tait's equation of state:

$$p = B \left[ \left( \frac{\rho}{\rho_0} \right)^\gamma - 1 \right]$$

where  $\gamma = 7$  and  $B = c_0^2 \rho_0 / \gamma$ , with  $\rho_0$  being the reference density and  $c_0$  the reference speed of sound.

This pair style also computes Monaghan's artificial viscosity to prevent particles from interpenetrating ([Monaghan](#)).

See [this PDF guide](#) to using SPH in LAMMPS.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.

- $\rho_0$  reference density (mass/volume units)
- $c_0$  reference soundspeed (distance/time units)
- $\nu$  artificial viscosity (no units)
- $h$  kernel function cutoff (distance units)

#### 4.248.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.248.5 Restrictions

This pair style is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.249 *pair\_style sph/taitwater/morris* command

#### 4.249.1 Syntax

```
pair_style sph/taitwater/morris
```

#### 4.249.2 Examples

```
pair_style sph/taitwater/morris  
pair_coeff * * 1000.0 1430.0 1.0 2.4
```

### 4.249.3 Description

The sph/taitwater/morris style computes pressure forces between SPH particles according to Tait's equation of state:

$$p = B \left[ \left( \frac{\rho}{\rho_0} \right)^\gamma - 1 \right]$$

where  $\gamma = 7$  and  $B = c_0^2 \rho_0 / \gamma$ , with  $\rho_0$  being the reference density and  $c_0$  the reference speed of sound.

This pair style also computes laminar viscosity ([Morris](#)).

See [this PDF guide](#) to using SPH in LAMMPS.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- $\rho_0$  reference density (mass/volume units)
  - $c_0$  reference soundspeed (distance/time units)
  - $\nu$  dynamic viscosity (mass\*distance/time units)
  - $h$  kernel function cutoff (distance units)
- 

### 4.249.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the *pair\_modify* shift, table, and tail options.

This style does not write information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

## 4.250 `pair_style lj/spica` command

Accelerator Variants: *lj/spica/gpu*, *lj/spica/kk*, *lj/spica/omp*

## 4.251 `pair_style lj/spica/coul/long` command

Accelerator Variants: *lj/spica/coul/long/gpu*, *lj/spica/coul/long/omp*, *lj/spica/coul/long/kk*

## 4.252 `pair_style lj/spica/coul/msm` command

Accelerator Variants: *lj/spica/coul/msm/omp*

### 4.252.1 Syntax

```
pair_style style args
```

- `style` = *lj/spica* or *lj/spica/coul/long*
- `args` = list of arguments for a particular style

*lj/spica* args = cutoff

cutoff = global cutoff for Lennard Jones interactions (distance units)

*lj/spica/coul/long* args = cutoff (cutoff2)

cutoff = global cutoff for LJ (and Coulombic if only 1 arg) (distance units)

cutoff2 = global cutoff for Coulombic (optional) (distance units)

### 4.252.2 Examples

```
pair_style lj/spica 2.5
pair_coeff 1 1 lj12_6 1 1.1 2.8

pair_style lj/spica/coul/long 10.0
pair_style lj/spica/coul/long 10.0 12.0
pair_coeff 1 1 lj9_6 100.0 3.5 12.0

pair_style lj/spica/coul/msm 10.0
pair_style lj/spica/coul/msm 10.0 12.0
pair_coeff 1 1 lj9_6 100.0 3.5 12.0
```

### 4.252.3 Description

The *lj/spica* styles compute a 9/6, 12/4, 12/5, or 12/6 Lennard-Jones potential, given by

$$\begin{aligned} E &= \frac{27}{4} \epsilon \left[ \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^6 \right] & r < r_c \\ E &= \frac{3\sqrt{3}}{2} \epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^4 \right] & r < r_c \\ E &= \frac{12}{7} \left( \frac{12}{5} \right)^{\left(\frac{5}{7}\right)} \epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^5 \right] & r < r_c \\ E &= 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] & r < r_c \end{aligned}$$

as required for the SPICA (formerly called SDK) and the pSPICA Coarse-grained MD parameterization discussed in (*Shinoda*), (*DeVane*), (*Seo*), and (*Miyazaki*).  $r_c$  is the cutoff. Summary information on these force fields can be found at <https://www.spica-ff.org>

Style *lj/spica/coul/long* computes the adds Coulombic interactions with an additional damping factor applied so it can be used in conjunction with the *kpace\_style* command and its *ewald* or *pppm* or *pppm/cg* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- *cg\_type* (lj9\_6, lj12\_4, lj12\_5, or lj12\_6)
- *epsilon* (energy units)
- *sigma* (distance units)
- *cutoff1* (distance units)

Note that *sigma* is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum. The prefactors are chosen so that the potential minimum is at -epsilon.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the *pair\_style* command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

For *lj/spica/coul/long* and *lj/spica/coul/msm* only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the *pair\_style* command.

The original implementation of the above styles are style *lj/sdk*, *lj/sdk/coul/long*, and *lj/sdk/coul/msm*, and available for backward compatibility.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.252.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the lj/spica pair styles *cannot* be mixed, since different pairs may have different exponents. So all parameters for all pairs have to be specified explicitly through the “pair\_coeff” command. Defining then in a data file is also not supported, due to limitations of that file format.

All of the lj/spica pair styles support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction.

The *lj/spica/coul/long* pair styles support the *pair\_modify* table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the lj/spica pair styles write their information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/spica and lj/cut/coul/long pair styles do not support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command.

---

#### 4.252.5 Restrictions

All of the lj/spica pair styles are part of the CG-SPICA package. The *lj/spica/coul/long* style also requires the KSPACE package to be built (which is enabled by default). They are only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

#### 4.252.6 Related commands

## 4.253 pair\_style spin/dipole/cut command

## 4.254 pair\_style spin/dipole/long command

### 4.254.1 Syntax

```
pair_style spin/dipole/cut cutoff
pair_style spin/dipole/long cutoff
```

- cutoff = global cutoff for magnetic dipole energy and forces (optional) (distance units)

### 4.254.2 Examples

```
pair_style spin/dipole/cut 10.0
pair_coeff * * 10.0
pair_coeff 2 3 8.0

pair_style spin/dipole/long 9.0
pair_coeff * * 10.0
pair_coeff 2 3 6.0
```

### 4.254.3 Description

Style *spin/dipole/cut* computes a short-range dipole-dipole interaction between pairs of magnetic particles that each have a magnetic spin. The magnetic dipole-dipole interactions are computed by the following formulas for the magnetic energy, magnetic precession vector omega and mechanical force between particles I and J.

$$\begin{aligned}\mathcal{H}_{\text{long}} &= -\frac{\mu_0(\mu_B)^2}{4\pi} \sum_{i,j,i \neq j}^N \frac{g_i g_j}{r_{ij}^3} \left( 3 (\vec{e}_{ij} \cdot \vec{s}_i) (\vec{e}_{ij} \cdot \vec{s}_j) - \vec{s}_i \cdot \vec{s}_j \right) \\ \omega_i &= \frac{\mu_0(\mu_B)^2}{4\pi\hbar} \sum_j \frac{g_i g_j}{r_{ij}^3} \left( 3 (\vec{e}_{ij} \cdot \vec{s}_j) \vec{e}_{ij} - \vec{s}_j \right) \\ \mathbf{F}_i &= \frac{3\mu_0(\mu_B)^2}{4\pi} \sum_j \frac{g_i g_j}{r_{ij}^4} \left[ ((\vec{s}_i \cdot \vec{s}_j) - 5(\vec{e}_{ij} \cdot \vec{s}_i)(\vec{e}_{ij} \cdot \vec{s}_j)) \vec{e}_{ij} + ((\vec{e}_{ij} \cdot \vec{s}_i) \vec{s}_j + (\vec{e}_{ij} \cdot \vec{s}_j) \vec{s}_i) \right]\end{aligned}$$

where  $\vec{s}_i$  and  $\vec{s}_j$  are the spin on two magnetic particles,  $r$  is their separation distance, and the vector  $\vec{e}_{ij} = \frac{\mathbf{r}_i - \mathbf{r}_j}{|\mathbf{r}_i - \mathbf{r}_j|}$  is the direction vector between the two particles.

Style *spin/dipole/long* computes long-range magnetic dipole-dipole interaction. A *kpace\_style* must be defined to use this pair style. Currently, *kpace\_style ewald/dipole/spin* and *kpace\_style ppm/dipole/spin* support long-range magnetic dipole-dipole interactions.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

#### 4.254.4 Restrictions

The *spin/dipole/cut* and *spin/dipole/long* styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Using dipole/spin pair styles with *electron units* is not currently supported.

#### 4.254.5 Related commands

*pair\_coeff*, *kpace\_style fix nve/spin*

#### 4.254.6 Default

none

### 4.255 pair\_style spin/dmi command

#### 4.255.1 Syntax

```
pair_style spin/dmi cutoff
```

- cutoff = global cutoff pair (distance in metal units)

#### 4.255.2 Examples

```
pair_style spin/dmi 4.0
pair_coeff * * dmi 2.6 0.001 1.0 0.0 0.0
pair_coeff 1 2 dmi 4.0 0.00109 0.0 0.0 1.0
```

#### 4.255.3 Description

Style *spin/dmi* computes the Dzyaloshinskii-Moriya (DM) interaction between pairs of magnetic spins. According to the expression reported in ([Rohart](#)), one has the following DM energy:

$$\mathbf{H}_{dm} = \sum_{i,j=1,i \neq j}^N \left( \vec{e}_{ij} \times \vec{D} \right) \cdot \left( \vec{s}_i \times \vec{s}_j \right),$$

where  $\vec{s}_i$  and  $\vec{s}_j$  are two neighboring magnetic spins of two particles,  $\vec{e}_{ij} = \frac{\vec{r}_i - \vec{r}_j}{|\vec{r}_i - \vec{r}_j|}$  is the unit vector between sites  $i$  and  $j$ , and  $\vec{D}$  is the DM vector defining the intensity (in eV) and the direction of the interaction.

In ([Rohart](#)),  $\vec{D}$  is defined as the direction normal to the film oriented from the high spin-orbit layer to the magnetic ultra-thin film.

The application of a spin-lattice Poisson bracket to this energy (as described in ([Tranchida](#))) allows to derive a magnetic torque omega, and a mechanical force F (for spin-lattice calculations only) for each magnetic particle i:

$$\vec{\omega}_i = -\frac{1}{\hbar} \sum_j^{Neighb} \vec{s}_j \times \left( \vec{e}_{ij} \times \vec{D} \right) \quad \text{and} \quad \vec{F}_i = - \sum_j^{Neighb} \frac{1}{r_{ij}} \vec{D} \times \left( \vec{s}_i \times \vec{s}_j \right)$$

More details about the derivation of these torques/forces are reported in ([Tranchida](#)).

For the *spin/dmi* pair style, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, and set in the following order:

- rc (distance units)
- |D| (energy units)
- Dx, Dy, Dz (direction of D)

Note that rc is the radius cutoff of the considered DM interaction, |D| is the norm of the DM vector (in eV), and Dx, Dy and Dz define its direction.

None of those coefficients is optional. If not specified, the *spin/dmi* pair style cannot be used.

---

## 4.255.4 Restrictions

All the *pair/spin* styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom\_style “spin” was declared. See the [Build package](#) page for more info.

```

## 4.257.3 Description

Style *spin/exchange* computes the exchange interaction between pairs of magnetic spins:

$$H_{ex} = - \sum_{i,j}^N J_{ij}(r_{ij}) \vec{s}_i \cdot \vec{s}_j$$

where  $\vec{s}_i$  and  $\vec{s}_j$  are two unit vectors representing the magnetic spins of two particles (usually atoms), and  $r_{ij} = |\vec{r}_i - \vec{r}_j|$  is the inter-atomic distance between those two particles. The summation is over pairs of nearest neighbors.  $J(r_{ij})$  is a function defining the intensity and the sign of the exchange interaction for different neighboring shells.

Style *spin/exchange/biquadratic* computes a biquadratic exchange interaction between pairs of magnetic spins:

$$H_{bi} = - \sum_{i,j}^N J_{ij}(r_{ij}) \vec{s}_i \cdot \vec{s}_j - \sum_{i,j}^N K_{ij}(r_{ij}) (\vec{s}_i \cdot \vec{s}_j)^2$$

where  $\vec{s}_i$ ,  $\vec{s}_j$ ,  $r_{ij}$  and  $J(r_{ij})$  have the same definitions as above, and  $K(r_{ij})$  is a second function, defining the intensity and the sign of the biquadratic term.

The interatomic dependence of  $J(r_{ij})$  and  $K(r_{ij})$  in both interactions above is defined by the following function:

$$f(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij})$$

where  $a$ ,  $b$  and  $d$  are the three constant coefficients defined in the associated “pair\_coeff” command, and  $R_c$  is the radius cutoff associated to the pair interaction (see below for more explanations).

The coefficients  $a$ ,  $b$ , and  $d$  need to be fitted so that the function above matches with the value of the exchange interaction for the  $N$  neighbor shells taken into account. Examples and more explanations about this function and its parameterization are reported in ([Tranchida](#)).

When a *spin/exchange/biquadratic* pair style is defined, six coefficients (three for  $J(r_{ij})$ , and three for  $K(r_{ij})$ ) have to be fitted.

From this exchange interaction, each spin  $i$  will be submitted to a magnetic torque  $\vec{\omega}_i$ , and its associated atom can be submitted to a force  $\vec{F}_i$  for spin-lattice calculations (see [fix nve/spin](#)), such as:

$$\vec{\omega}_i = \frac{1}{\hbar} \sum_j^{Neighb} J(r_{ij}) \vec{s}_j \text{ and } \vec{F}_i = \sum_j^{Neighb} \frac{\partial J(r_{ij})}{\partial r_{ij}} (\vec{s}_i \cdot \vec{s}_j) \vec{e}_{ij}$$

with  $\hbar$  the Planck constant (in metal units), and  $\vec{e}_{ij} = \frac{\vec{r}_i - \vec{r}_j}{|\vec{r}_i - \vec{r}_j|}$  the unit vector between sites  $i$  and  $j$ . Equivalent forces and magnetic torques are generated for the biquadratic term when a *spin/exchange/biquadratic* pair style is defined.

More details about the derivation of these torques/forces are reported in ([Tranchida](#)).

For the *spin/exchange* and *spin/exchange/biquadratic* pair styles, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, and set in the following order:

- $R_c$  (distance units)
- $a$  (energy units)
- $b$  (adim parameter)
- $d$  (distance units)

for the *spin/exchange* pair style, and:

- $R_c$  (distance units)
- $a_j$  (energy units)
- $b_j$  (adim parameter)
- $d_j$  (distance units)
- $a_k$  (energy units)
- $b_k$  (adim parameter)
- $d_k$  (distance units)

for the *spin/exchange/biquadratic* pair style.

Note that  $R_c$  is the radius cutoff of the considered exchange interaction, and  $a$ ,  $b$  and  $d$  are the three coefficients performing the parameterization of the function  $J(r_{ij})$  defined above (in the *biquadratic* style,  $a_j$ ,  $b_j$ ,  $d_j$  and  $a_k$ ,  $b_k$ ,  $d_k$  are the coefficients of  $J(r_{ij})$  and  $K(r_{ij})$  respectively).

None of those coefficients is optional. If not specified, the *spin/exchange* pair style cannot be used.

---

### Offsetting magnetic forces and energies:

For spin-lattice simulation, it can be useful to offset the mechanical forces and energies generated by the exchange interaction. The *offset* keyword allows to apply this offset. By setting *offset* to *yes*, the energy definitions above are replaced by:

$$H_{ex} = - \sum_{i,j}^N J_{ij}(r_{ij}) [\vec{s}_i \cdot \vec{s}_j - 1]$$

for the *spin/exchange* pair style, and:

$$H_{bi} = - \sum_{i,j}^N J_{ij}(r_{ij}) [\vec{s}_i \cdot \vec{s}_j - 1] - \sum_{i,j}^N K_{ij}(r_{ij}) [(\vec{s}_i \cdot \vec{s}_j)^2 - 1]$$

for the *spin/exchange/biquadratic* pair style.

Note that this offset only affects the calculation of the energy and mechanical forces. It does not modify the calculation of the precession vectors (and thus does not impact the purely magnetic properties). This ensures that when all spins are aligned, the magnetic energy and the associated mechanical forces (and thus the pressure generated by the magnetic potential) are null.

---

**Note:** This offset term can be very important when calculations such as equations of state (energy vs volume, or energy vs pressure) are being performed. Indeed, setting the *offset* term ensures that at the ground state of the crystal and at the equilibrium magnetic configuration (typically ferromagnetic), the pressure is null, as expected. Otherwise, magnetic forces could generate a residual pressure.

---

When the *offset* option is set to *no*, no offset is applied (also corresponding to the default option).

---

## 4.257.4 Restrictions

All the *pair/spin* styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom\_style “spin” was declared. See the [Build package](#) page for more info.

## 4.257.5 Related commands

*atom\_style spin*, *pair\_coeff*, *pair\_eam*,

## 4.257.6 Default

The default *offset* keyword value is *no*.

# 4.258 pair\_style spin/magelec command

## 4.258.1 Syntax

```
pair_style spin/magelec cutoff
```

- cutoff = global cutoff pair (distance in metal units)

## 4.258.2 Examples

```
pair_style spin/magelec 4.5
pair_coeff * * magelec 4.5 0.00109 1.0 1.0 1.0
```

## 4.258.3 Description

Style *spin/me* computes a magneto-electric interaction between pairs of magnetic spins. According to the derivation reported in ([Katsura](#)), this interaction is defined as:

$$\vec{\omega}_i = -\frac{1}{\hbar} \sum_j^{Neighb} \vec{s}_j \times \vec{D}(r_{ij})$$

$$\vec{F}_i = - \sum_j^{Neighb} \frac{\partial D(r_{ij})}{\partial r_{ij}} (\vec{s}_i \times \vec{s}_j) \cdot \vec{r}_{ij}$$

where  $\vec{s}_i$  and  $\vec{s}_j$  are neighboring magnetic spins of two particles.

From this magneto-electric interaction, each spin  $i$  will be submitted to a magnetic torque  $\vec{\omega}$ , and its associated atom can be submitted to a force  $\vec{F}$  for spin-lattice calculations (see [fix nve/spin](#)), such as:

$$\vec{F}^i = - \sum_j^{Neighbor} (\vec{s}_i \times \vec{s}_j) \times \vec{E}$$
$$\vec{\omega}^i = -\frac{1}{\hbar} \sum_j^{Neighbor} \vec{s}_j \times (\vec{E} \times \vec{r}_{ij})$$

with  $\hbar$  the Planck constant (in metal units) and  $\vec{E}$  an electric polarization vector. The norm and direction of  $\vec{E}$  are giving the intensity and the direction of a screened dielectric atomic polarization (in eV).

More details about the derivation of these torques/forces are reported in ([Tranchida](#)).

---

## 4.258.4 Restrictions

All the *pair/spin* styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom\_style “spin” was declared. See the [Build package](#) page for more info.

# 4.259 pair\_style spin/neel command

## 4.259.1 Syntax

`pair_style spin/neel cutoff`

- cutoff = global cutoff pair (distance in metal units)

## 4.259.2 Examples

```
pair_style spin/neel 4.0
pair_coeff * * neel 4.0 0.0048 0.234 1.168 2.6905 0.705 0.652
pair_coeff 1 2 neel 4.0 0.0048 0.234 1.168 0.0 0.0 1.0
```

## 4.259.3 Description

Style *spin/neel* computes the Neel pair anisotropy model between pairs of magnetic spins:

$$\mathcal{H}_{\text{Neel}} = - \sum_{i,j=1,i \neq j}^N g_1(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)(\mathbf{e}_{ij} \cdot \mathbf{s}_j) - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) + q_1(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)^2 - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_j)^2 - \frac{\mathbf{s}_j \cdot \mathbf{s}_i}{3} \right) + q_2(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)(\mathbf{e}_{ij} \cdot \mathbf{s}_j)^3 + (\mathbf{e}_{ij} \cdot \mathbf{s}_j)(\mathbf{e}_{ij} \cdot \mathbf{s}_i)^3 \right)$$

where  $\mathbf{s}_i$  and  $\mathbf{s}_j$  are two neighboring magnetic spins of two particles,  $r_{ij} = |\mathbf{r}_i - \mathbf{r}_j|$  is the inter-atomic distance between the two particles,  $\mathbf{e}_{ij} = \frac{\mathbf{r}_i - \mathbf{r}_j}{|\mathbf{r}_i - \mathbf{r}_j|}$  is their normalized separation vector and  $g_1$ ,  $q_1$  and  $q_2$  are three functions defining the intensity of the dipolar and quadrupolar contributions, with:

$$\begin{aligned} g_1(r_{ij}) &= g(r_{ij}) + \frac{12}{35}q(r_{ij}) \\ q_1(r_{ij}) &= \frac{9}{5}q(r_{ij}) \\ q_2(r_{ij}) &= -\frac{2}{5}q(r_{ij}) \end{aligned}$$

With the functions  $g(r_{ij})$  and  $q(r_{ij})$  defined and fitted according to the same Bethe-Slater function used to fit the exchange interaction:

$$J(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij})$$

where  $a$ ,  $b$  and  $d$  are the three constant coefficients defined in the associated “pair\_coeff” command.

The coefficients  $a$ ,  $b$ , and  $d$  need to be fitted so that the function above matches with the values of the magneto-elastic constant of the materials at stake.

Examples and more explanations about this function and its parameterization are reported in ([Tranchida](#)). More examples of parameterization will be provided in future work.

From this DM interaction, each spin  $i$  will be submitted to a magnetic torque  $\omega$  and its associated atom to a force  $\mathbf{F}$  (for spin-lattice calculations only).

More details about the derivation of these torques/forces are reported in ([Tranchida](#)).

### Description

Style *srp* computes a soft segmental repulsive potential (SRP) that acts between pairs of bonds. This potential is useful for preventing bonds from passing through one another when a soft non-bonded potential acts between beads in, for example, DPD polymer chains. An example input script that uses this command is provided in `examples/PACKAGES/srp`.

Bonds of specified type *btype* interact with one another through a bond-pairwise potential, such that the force on bond *i* due to bond *j* is as follows

$$F_{ij}^{\text{SRP}} = C(1 - r/r_c)\hat{r}_{ij} \quad r < r_c$$

where *r* and  $\hat{r}_{ij}$  are the distance and unit vector between the two bonds. Note that *btype* can be specified as an asterisk "\*", which case the interaction is applied to all bond types. The *mid* option computes *r* and  $\hat{r}_{ij}$  from the midpoint distance between bonds. The *min* option computes *r* and  $\hat{r}_{ij}$  from the minimum distance between bonds. The force acting on a bond is mapped onto the two bond atoms according to the lever rule,

$$F_{i1}^{\text{SRP}} = F_{ij}^{\text{SRP}}(L)$$

$$F_{i2}^{\text{SRP}} = F_{ij}^{\text{SRP}}(1 - L)$$

where *L* is the normalized distance from the atom to the point of closest approach of bond *i* and *j*. The *mid* option takes *L* as 0.5 for each interaction as described in (Sirk).

The following coefficients must be defined via the *pair\_coeff* command as in the examples above, or in the data file or restart file read by the *read\_data* or *read\_restart* commands:

- *C* (force units)
- *r<sub>c</sub>* (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

---

**Note:** Pair style *srp* considers each bond of type *btype* to be a fictitious "particle" of type *bptype*, where *bptype* is either the largest atom type in the system, or the type set by the *bptype* flag. Any actual existing particles with this atom type will be deleted at the beginning of a run. This means you must specify the number of types in your system accordingly; usually to be one larger than what would normally be the case, e.g. via the *create\_box* or by changing the header in your *data file*. The fictitious "bond particles" are inserted at the beginning of the run, and serve as placeholders that define the position of the bonds. This allows neighbor lists to be constructed and pairwise interactions to be computed in almost the same way as is done for actual particles. Because bonds interact only with other bonds, *pair\_style hybrid* should be used to turn off interactions between atom type *bptype* and all other types of atoms. An error will be flagged if *pair\_style hybrid* is not used.

---

---

**Note:** If using type labels, the type labels must be defined before calling the *pair\_coeff* command.

---

The optional *exclude* keyword determines if forces are computed between first neighbor (directly connected) bonds. For a setting of *no*, first neighbor forces are computed; for *yes* they are not computed. A setting of *no* cannot be used with the *min* option for distance calculation because the minimum distance between directly connected bonds is zero.

Pair style *srp* turns off normalization of thermodynamic properties by particle number, as if the command *thermo\_modify norm no* had been issued.

The pairwise energy associated with style *srp* is shifted to be zero at the cutoff distance  $r_c$ .

---

New in version 3Aug2022.

Pair style *srp/react* interfaces the pair style *srp* with the bond breaking and formation mechanisms provided by *fix bond/break* and *fix bond/create*, respectively. When using this pair style, whenever a bond breaking (or formation) reaction occurs, the corresponding fictitious particle is deleted (or inserted) during the same simulation time step as the reaction. This is useful in the simulation of reactive systems involving large polymeric molecules (*Palkar*) where the segmental repulsive potential is necessary to minimize topological violations, and also needs to be turned on and off according to the progress of the reaction.

---

### 4.261.3 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing.

This pair style does not support the *pair\_modify* shift option for the energy of the pair interaction. Note that as discussed above, the energy term is already shifted to be 0.0 at the cutoff distance  $r_c$ .

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes global and per-atom information to *binary restart files*. Pair *srp* should be used with *pair\_style hybrid*, thus the *pair\_coeff* commands need to be specified in the input script when reading a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.261.4 Restrictions

This pair style is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Making LAMMPS section for more info.

This pair style must be used with *pair\_style hybrid*.

This pair style requires the *newton* command to be *on* for non-bonded interactions.

This pair style is not compatible with *rigid body integrators*

## 4.261.5 Related commands

Accelerator Variants: *sw/gpu*, *sw/intel*, *sw/kk*, *sw/omp*

## 4.263 pair\_style sw/mod command

Accelerator Variants: *sw/mod/omp*

### 4.263.1 Syntax

**pair\_style** style keyword values

- style = *sw* or *sw/mod*
  - keyword = *maxdelcs* or *threebody*
- maxdelcs* value = *delta1 delta2* (optional, *sw/mod* only)
- delta1* = The minimum threshold for the variation of cosine of three-body angle
- delta2* = The maximum threshold for the variation of cosine of three-body angle
- threebody* value = *on* or *off* (optional, *sw* only)
- on* (default) = Compute both the three-body and two-body terms of the potential
- off* = Compute only the two-body term of the potential

### 4.263.2 Examples

```
pair_style sw
pair_coeff * * si.sw Si
pair_coeff * * GaN.sw Ga N Ga

pair_style sw/mod maxdelcs 0.25 0.35
pair_coeff * * tmd.sw.mod Mo S S

pair_style hybrid sw threebody on sw threebody off
pair_coeff * * sw 1 mW_xL.sw mW NULL
pair_coeff 1 2 sw 2 mW_xL.sw mW xL
pair_coeff 2 2 sw 2 mW_xL.sw mW xL
```

### 4.263.3 Description

The *sw* style computes a 3-body *Stillinger-Weber* potential for the energy  $E$  of a system of atoms as

$$E = \sum_i \sum_{j>i} \phi_2(r_{ij}) + \sum_i \sum_{j \neq i} \sum_{k>j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})$$

$$\phi_2(r_{ij}) = A_{ij} \epsilon_{ij} \left[ B_{ij} \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{p_{ij}} - \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{q_{ij}} \right] \exp \left( \frac{\sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right)$$

$$\phi_3(r_{ij}, r_{ik}, \theta_{ijk}) = \lambda_{ijk} \epsilon_{ijk} [\cos \theta_{ijk} - \cos \theta_{0ijk}]^2 \exp \left( \frac{\gamma_{ij} \sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right) \exp \left( \frac{\gamma_{ik} \sigma_{ik}}{r_{ik} - a_{ik} \sigma_{ik}} \right)$$

where  $\phi_2$  is a two-body term and  $\phi_3$  is a three-body term. The summations in the formula are over all neighbors  $J$  and  $K$  of atom  $I$  within a cutoff distance  $a^* \sigma$ .

New in version 14Dec2021.

The *sw/mod* style is designed for simulations of materials when distinguishing three-body angles are necessary, such as borophene and transition metal dichalcogenides, which cannot be described by the original code for the Stillinger-Weber potential. For instance, there are several types of angles around each Mo atom in *MoS\_2*, and some unnecessary angle types should be excluded in the three-body interaction. Such exclusion may be realized by selecting proper angle types directly. The exclusion of unnecessary angles is achieved here by the cut-off function ( $f_C(\delta)$ ), which induces only minimum modifications for LAMMPS.

Validation, benchmark tests, and applications of the *sw/mod* style can be found in (Jiang2) and (Jiang3).

The *sw/mod* style computes the energy  $E$  of a system of atoms, whose potential function is mostly the same as the Stillinger-Weber potential. The only modification is in the three-body term, where the value of  $\delta = \cos \theta_{ijk} - \cos \theta_{0ijk}$  used in the original energy and force expression is scaled by a switching factor  $f_C(\delta)$ :

$$f_C(\delta) = \begin{cases} 1 & : |\delta| < \delta_1 \\ \frac{1}{2} + \frac{1}{2} \cos \left( \pi \frac{|\delta| - \delta_1}{\delta_2 - \delta_1} \right) & : \delta_1 < |\delta| < \delta_2 \\ 0 & : |\delta| > \delta_2 \end{cases}$$

This cut-off function decreases smoothly from 1 to 0 over the range  $[\delta_1, \delta_2]$ . This smoothly turns off the energy and force contributions for  $|\delta| > \delta_2$ . It is suggested that  $\delta_1$  and  $\delta_2$  to be the value around  $0.5 |\cos \theta_1 - \cos \theta_2|$ , with  $\theta_1$  and  $\theta_2$  as the different types of angles around an atom. For borophene and transition metal dichalcogenides,  $\delta_1 = 0.25$  and  $\delta_2 = 0.35$ . This value enables the cut-off function to exclude unnecessary angles in the three-body SW terms.

---

**Note:** The cut-off function is just to be used as a technique to exclude some unnecessary angles, and it has no physical meaning. It should be noted that the force and potential are inconsistent with each other in the decaying range of the cut-off function, as the angle dependence for the cut-off function is not implemented in the force (first derivation of potential). However, the angle variation is much smaller than the given threshold value for actual simulations, so the inconsistency between potential and force can be neglected in actual simulations.

---

New in version 3Aug2022.

The *threebody* keyword is optional and determines whether or not the three-body term of the potential is calculated. The default value is “on” and it is only available for the plain *sw* pair style variants, but not available for the *sw/mod* and *sw/angle/table* pair style variants. To turn off the threebody contributions all  $\lambda_{ijk}$  parameters from the potential file are forcibly set to 0. In addition the pair style implementation may employ code optimizations for the *threebody off* setting that can result in significant speedups versus the default. These code optimizations are currently only available for the MANYBODY and OPENMP packages.

Only a single pair\_coeff command is used with the *sw* and *sw/mod* styles which specifies a Stillinger-Weber potential file with parameters for all needed elements, except for when the *threebody off* setting is used (see note below). These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the pair\_coeff command, where  $N$  is the number of LAMMPS atom types:

- filename
- N element names = mapping of SW elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.sw has Stillinger-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair\_coeff command:

```
pair_style sw
pair_coeff * * SiC.sw Si Si Si C
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1, 2, and 3 to the Si element in the SW file. The final C argument maps LAMMPS atom type 4 to the C element in the SW file. If an argument value is specified as NULL, the mapping is not performed. This can be used when an sw potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

---

**Note:** When the *threebody off* keyword is used, multiple pair\_coeff commands may be used to specific the pairs of atoms which don't require three-body term. In these cases, the first 2 arguments are not required to be \* \*, the potential parameter file is only read by the first [pair\\_coeff command](#) and the element to atom type mappings must be consistent across all *pair\_coeff* statements. If not LAMMPS will abort with an error.

---

Stillinger-Weber files in the *potentials* directory of the LAMMPS distribution have a “.sw” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $a$
- $\lambda$
- $\gamma$
- $\cos \theta_0$
- A
- B
- p
- q
- tol

The A, B, p, and q parameters are used only for two-body interactions. The  $\lambda$  and  $\cos \theta_0$  parameters are used only for three-body interactions. The  $\epsilon$ ,  $\sigma$  and  $a$  parameters are used for both two-body and three-body interactions.  $\gamma$  is used only in the three-body interactions, but is defined for pairs of atoms. The non-annotated parameters are unitless.

LAMMPS introduces an additional performance-optimization parameter tol that is used for both two-body and three-body interactions. In the Stillinger-Weber potential, the interaction energies become negligibly small at atomic separations substantially less than the theoretical cutoff distances. LAMMPS therefore defines a virtual cutoff distance based on a user defined tolerance tol. The use of the virtual cutoff distance in constructing atom neighbor lists can

significantly reduce the neighbor list sizes and therefore the computational cost. LAMMPS provides a *tol* value for each of the three-body entries so that they can be separately controlled. If *tol* = 0.0, then the standard Stillinger-Weber cutoff is used.

The Stillinger-Weber potential file must contain entries for all the elements listed in the *pair\_coeff* command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify SW parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The parameter values used for the two-body interaction come from the entry where the second and third elements are the same. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry. The three-body parameters can in principle be specific to the three elements of the configuration. In the literature, however, the three-body parameters are usually defined by simple formulas involving two sets of pairwise parameters, corresponding to the *ij* and *ik* pairs, where *i* is the center atom. The user must ensure that the correct combining rule is used to calculate the values of the three-body parameters for alloys. Note also that the function  $\phi_3$  contains two exponential screening factors with parameter values from the *ij* pair and *ik* pairs. So  $\phi_3$  for a C atom bonded to a Si atom and a second C atom will depend on the three-body parameters for the CSiC entry, and also on the two-body parameters for the CCC and CSiSi entries. Since the order of the two neighbors is arbitrary, the three-body parameters for entries CSiC and CCSi should be the same. Similarly, the two-body parameters for entries SiCC and CSiSi should also be the same. The parameters used only for two-body interactions (*A*, *B*, *p*, and *q*) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired. This is also true for the parameters in  $\phi_3$  that are taken from the *ij* and *ik* pairs ( $\sigma$ ,  $a$ ,  $\gamma$ )

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

**Note:** When using the INTEL package with this style, there is an additional 5 to 10 percent performance improvement when the Stillinger-Weber parameters *p* and *q* are set to 4 and 0 respectively. These parameters are common for modeling silicon and water.

---

#### 4.263.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

The *single()* function of the *sw* pair style is only enabled and supported for the case of the *threebody off* setting.

---

#### 4.263.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

The Stillinger-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the *sw* or *sw/mod* pair styles with any LAMMPS units, but you would need to create your own SW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units. If the potential file contains a ‘UNITS:’ metadata tag in the first line of the potential file, then LAMMPS can convert it transparently between “metal” and “real” units.

#### 4.263.6 Related commands

*pair\_coeff*

#### 4.263.7 Default

The default value for the *threebody* setting of the “sw” pair style is “on”, the default values for the “*maxdelcs*” setting of the *sw/mod* pair style are *delta1* = 0.25 and *delta2* = 0.35`.

## 4.264 pair\_style sw/angle/table command

### 4.264.1 Syntax

```
pair_style style
```

- style = sw/angle/table

### 4.264.2 Examples

```
pair_style sw/angle/table
pair_coeff * * spce.sw type
```

Used in example input script:

```
examples/PACKAGES/manybody_table/in.spce_sw
```

### 4.264.3 Description

New in version 2Jun2022.

The *sw/angle/table* style is a modification of the original *pair\_style sw*. It has been developed for coarse-grained simulations (of water) (*Scherer1*), but can be employed for all kinds of systems. It computes a modified 3-body *Stillinger-Weber* potential for the energy  $E$  of a system of atoms as

$$E = \sum_i \sum_{j>i} \phi_2(r_{ij}) + \sum_i \sum_{j \neq i} \sum_{k>j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})$$

$$\phi_2(r_{ij}) = A_{ij} \epsilon_{ij} \left[ B_{ij} \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{p_{ij}} - \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{q_{ij}} \right] \exp \left( \frac{\sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right)$$

$$\phi_3(r_{ij}, r_{ik}, \theta_{ijk}) = f^{3b}(\theta_{ijk}) \exp \left( \frac{\gamma_{ij} \sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right) \exp \left( \frac{\gamma_{ik} \sigma_{ik}}{r_{ik} - a_{ik} \sigma_{ik}} \right)$$

where  $\phi_2$  is a two-body term and  $\phi_3$  is a three-body term. The summations in the formula are over all neighbors  $J$  and  $K$  of atom  $I$  within a cutoff distance  $a\sigma$ . In contrast to the original *sw* style, *sw/angle/table* allows for a flexible three-body term  $f^{3b}(\theta_{ijk})$  which is read in as a tabulated interaction. It can be parameterized with the *csg\_fmacth* app of VOTCA as available at: <https://gitlab.mpcdf.mpg.de/votca/votca>.

Only a single *pair\_coeff* command is used with the *sw/angle/table* style which specifies a modified Stillinger-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying *N\_el* additional arguments after the “.sw” filename in the *pair\_coeff* command, where *N\_el* is the number of LAMMPS atom types:

- “.sw” filename
- *N\_el* element names = mapping of SW elements to atom types

See the *pair\_coeff* page for alternate ways to specify the path for the potential file.

As an example, imagine a file *SiC.sw* has Stillinger-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following *pair\_coeff* command:

```
pair_coeff * * SiC.sw Si Si Si C
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the SW file. The final C argument maps LAMMPS atom type 4 to the C element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *sw/angle/table* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The (modified) Stillinger-Weber files have a “.sw” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above. Here, also the suffix “.sw” is used though the original Stillinger-Weber file format is supplemented with four additional lines per parameter block to specify the tabulated three-body interaction. A single entry then contains:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $a$
- $\lambda$
- $\gamma$
- $\cos \theta_0$
- A
- B
- p
- q
- tol
- filename
- keyword
- style
- N

The A, B, p, and q parameters are used only for two-body interactions. The  $\lambda$  and  $\cos \theta_0$  parameters, only used for three-body interactions in the original Stillinger-Weber style, are read in but ignored in this modified pair style. The  $\epsilon$  parameter is only used for two-body interactions in this modified pair style and not for the three-body terms. The  $\sigma$  and  $a$  parameters are used for both two-body and three-body interactions.  $\gamma$  is used only in the three-body interactions, but is defined for pairs of atoms. The non-annotated parameters are unitless.

LAMMPS introduces an additional performance-optimization parameter *tol* that is used for both two-body and three-body interactions. In the Stillinger-Weber potential, the interaction energies become negligibly small at atomic separations substantially less than the theoretical cutoff distances. LAMMPS therefore defines a virtual cutoff distance based on a user defined tolerance *tol*. The use of the virtual cutoff distance in constructing atom neighbor lists can significantly reduce the neighbor list sizes and therefore the computational cost. LAMMPS provides a *tol* value for each of the three-body entries so that they can be separately controlled. If *tol* = 0.0, then the standard Stillinger-Weber cutoff is used.

The additional parameters *filename*, *keyword*, *style*, and *N* refer to the tabulated angular potential  $f^{3b}(\theta_{ijk})$ . The tabulated angular potential has to be of the format as used in the *angle\_style table* command:

An interpolation tables of length  $N$  is created. The interpolation is done in one of 2 styles: *linear* or *spline*. For the *linear* style, the angle is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation. For the *spline* style, a cubic spline coefficients are computed and stored at each of the  $N$  values in the table. The angle is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or derivative.

The *filename* specifies the file containing the tabulated energy and derivative values of  $f^{3b}(\theta_{ijk})$ . The *keyword* then specifies a section of the file. The format of this file is as follows (without the parenthesized comments):

```
# Angle potential for harmonic (one or more comment or blank lines)

HAM                                     (keyword is the first text on line)
N 181 FP 0 0 EQ 90.0                 (N, FP, EQ parameters)
                                     (blank line)
1 0.0 200.5 2.5                      (index, angle, energy, derivative)
2 1.0 198.0 2.5
...
181 180.0 0.0 0.0
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the  $N$  specified in the Stillinger-Weber potential file. Let  $N_{sw} = N$  in the “.sw” file, and  $N_{file} = “N”$  in the tabulated angular file. What LAMMPS does is a preliminary interpolation by creating splines using the  $N_{file}$  tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at  $N_{table}$  different points. The resulting tables of length  $N_{sw}$  are then used as described above, when computing energy and force for individual angles and their atoms. This means that if you want the interpolation tables of length  $N_{sw}$  to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set  $N_{sw} = N_{file}$ .

The “FP” parameter is optional. If used, it is followed by two values *fplo* and *fphi*, which are the second derivatives at the innermost and outermost angle settings. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two derivative values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium angle value, which is used, for example, by the *fix shake* command. If not used, the equilibrium angle is set to 180.0.

Following a blank line, the next  $N$  lines of the angular table file list the tabulated values. On each line, the first value is the index from 1 to  $N$ , the second value is the angle value (in degrees), the third value is the energy (in energy units), and the fourth is  $-dE/d(\theta)$  (also in energy units). The third term is the energy of the 3-atom configuration for the specified angle. The last term is the derivative of the energy with respect to the angle (in degrees, not radians). Thus the units of the last term are still energy, not force. The angle values must increase from one line to the next. The angle values must also begin with 0.0 and end with 180.0, i.e. span the full range of possible angles.

Note that one angular potential file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified *keyword* of appropriate section of the “.sw” file.

The Stillinger-Weber potential file must contain entries for all the elements listed in the *pair\_coeff* command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify SW parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The parameter values used for the two-body interaction come from the entry where the second and third elements are the same. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry. The three-body angular potential  $f^{3b}(\theta_{ijk})$  can in principle be specific to the three elements of the configuration. However, the user must ensure that it makes physically sense. Note also that the function  $\phi_3$  contains two exponential screening factors with parameter values from the ij pair and ik pairs. So  $\phi_3$  for a C atom bonded to a Si atom and a second C atom will depend on the three-body parameters for the CSiC entry, and also on the two-body parameters for the CCC and CSiSi entries. Since the order of the two neighbors is arbitrary, the three-body parameters and the tabulated angular potential for entries CSiC and CCSi should be the same. Similarly, the two-body parameters for entries SiCC and CSiSi should also be the same. The parameters used only for two-body interactions (A, B, p, and q) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired. This is also true for the parameters in  $\phi_3$  that are taken from the ij and ik pairs ( $\sigma$ ,  $a$ ,  $\gamma$ )

Additional input files and reference data can be found at: [https://gitlab.mpcdf.mpg.de/votca/votca/-/tree/master/csg-tutorials/spce/3body\\_sw](https://gitlab.mpcdf.mpg.de/votca/votca/-/tree/master/csg-tutorials/spce/3body_sw)

---

#### 4.264.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file, but not for the tabulated angular potential file.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.264.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

#### 4.264.6 Related commands

*pair\_coeff*, *pair\_style sw*, *pair\_style threebody/table*

## 4.265 pair\_style table command

Accelerator Variants: *table/gpu*, *table/kk*, *table/omp*

### 4.265.1 Syntax

```
pair_style table style N keyword ...
```

- style = *lookup* or *linear* or *spline* or *bitmap* = method of interpolation
- N = use N values in *lookup*, *linear*, *spline* tables
- N = use  $2^N$  values in *bitmap* tables
- zero or more keywords may be appended
- keyword = *ewald* or *pppm* or *msm* or *dispersion* or *tip4p*

### 4.265.2 Examples

```
pair_style table linear 1000
pair_style table linear 1000 ppm
pair_style table bitmap 12
pair_coeff * 3 morse.table ENTRY1
pair_coeff * 3 morse.table ENTRY1 7.0
```

### 4.265.3 Description

Style *table* creates interpolation tables from potential energy and force values listed in a file(s) as a function of distance. When performing dynamics or minimization, the interpolation tables are used to evaluate energy and forces for pairwise interactions between particles, similar to how analytic formulas are used for other pair styles.

The interpolation tables are created as a pre-computation by fitting cubic splines to the file values and interpolating energy and force values at each of  $N$  distances. During a simulation, the tables are used to interpolate energy and force values as needed for each pair of particles separated by a distance  $R$ . The interpolation is done in one of 4 styles: *lookup*, *linear*, *spline*, or *bitmap*.

For the *lookup* style, the distance  $R$  is used to find the nearest table entry, which is the energy or force.

For the *linear* style, the distance  $R$  is used to find the 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the *spline* style, cubic spline coefficients are computed and stored for each of the  $N$  values in the table, one set of splines for energy, another for force. Note that these splines are different than the ones used to pre-compute the  $N$  values. Those splines were fit to the  $N_{file}$  values in the tabulated file, where often  $N_{file} < N$ . The distance  $R$  is used to find the appropriate set of spline coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For the *bitmap* style, the specified  $N$  is used to create interpolation tables that are  $2^N$  in length. The distance  $R$  is used to index into the table via a fast bit-mapping technique due to (Wolff), and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- filename
- keyword
- cutoff (distance units)

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

If your tabulated potential(s) are designed to be used as the short-range part of one of the long-range solvers specified by the *kpace\_style* command, then you must use one or more of the optional keywords listed above for the *pair\_style* command. These are *ewald* or *pppm* or *msm* or *dispersion* or *tip4p*. This is so LAMMPS can ensure the short-range potential and long-range solver are compatible with each other, as it does for other short-range pair styles, such as *pair\_style lj/cut/coul/long*. Note that it is up to you to ensure the tabulated values for each pair of atom types has the correct functional form to be compatible with the matching long-range solver.

Here are some guidelines for using the *pair\_style* table command to best effect:

- Vary the number of table points; you may need to use more than you think to get good resolution.
- Always use the *pair\_write* command to produce a plot of what the final interpolated potential looks like. This can show up interpolation “features” you may not like.
- Start with the linear style; it’s the style least likely to have problems.
- Use *N* in the *pair\_style* command equal to the “N” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.
- Make sure that your tabulated forces and tabulated energies are consistent ( $dE/dr = -F$ ) over the entire range of *r* values. LAMMPS will warn if this is not the case.
- Use as large an inner cutoff as possible. This avoids fitting splines to very steep parts of the potential.

Suitable tables in the correct format for use with these pair styles can be created by LAMMPS itself using the *pair\_write* command. In combination with the pair styles *python*, *lepton*, or *lepton/coul* this can be a powerful mechanism to implement and test tables for use with LAMMPS. Another option to generate tables is the Python code in the *tools/tabulate* folder of the LAMMPS source code distribution.

The format of a tabulated file has an (optional) header followed by a series of one or more sections, defined as follows (without the parenthesized comments). The header must start with a # character and the DATE: and UNITS: tags will be parsed and used:

```
# DATE: 2020-06-10 UNITS: real CONTRIBUTOR: ... (header line)
# Morse potential for Fe (one or more comment or blank lines)

MORSE_FE (keyword is first text on line)
N 500 R 1.0 10.0 (N, R, RSQ, BITMAP, FPRIME parameters)
                (blank)
1 1.0 25.5 102.34 (index, r, energy, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can

contain additional text, but the initial text must match the argument specified in the `pair_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the  $N$  specified in the `pair_style table` command. Let  $N_{\text{table}} = N$  in the `pair_style` command, and  $N_{\text{file}} = “N”$  in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the  $N_{\text{file}}$  tabulated values as nodal points. It uses these to interpolate energy and force values at  $N_{\text{table}}$  different points. The resulting tables of length  $N_{\text{table}}$  are then used as described above, when computing energy and force for individual pair distances. This means that if you want the interpolation tables of length  $N_{\text{table}}$  to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set  $N_{\text{table}} = N_{\text{file}}$ , and use the “RSQ” or “BITMAP” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in  $r$  uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values *rlo* and *rhi*. If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between *rlo* and *rhi* are computed; for “RSQ”, squared distances uniformly spaced between  $rlo*rlo$  and  $rhi*rhi$  are computed.

---

**Note:** If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the distance value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning energy/force values to a different distance, which is probably not what you want. LAMMPS will warn if this is occurring.

---

If used, the parameter “BITMAP” is also followed by 2 values *rlo* and *rhi*. These values, along with the “N” value determine the ordering of the  $N$  lines that follow and what distance is associated with each. This ordering is complex, so it is not documented here, since this file is typically produced by the `pair_write` command with its `bitmap` option. When the table is in BITMAP format, the “N” parameter in the file must be equal to  $2^M$  where  $M$  is the value specified in the `pair_style` command. Also, a cutoff parameter cannot be used as an optional third argument in the `pair_coeff` command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values *fplo* and *fphi* which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next  $N$  lines list the tabulated values. On each line, the first value is the index from 1 to  $N$ , the second value is  $r$  (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The  $r$  values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.265.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The *pair\_modify* shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair\_style table” command to *binary restart files*, so a pair\_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair\_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.265.5 Restrictions

none

#### 4.265.6 Related commands

*pair\_coeff*, *pair\_write*

#### 4.265.7 Default

### 4.266 pair\_style table/rx command

Accelerator Variants: *table/rx/kk*

#### 4.266.1 Syntax

```
pair_style table style N ...
```

- style = *lookup* or *linear* or *spline* or *bitmap* = method of interpolation
- N = use N values in *lookup*, *linear*, *spline* tables
- weighting = fractional or molecular (optional)

## 4.266.2 Examples

```
pair_style table/rx linear 1000
pair_style table/rx linear 1000 fractional
pair_style table/rx linear 1000 molecular
pair_coeff * * rxn.table ENTRY1 h2o h2o 10.0
pair_coeff * * rxn.table ENTRY1 1fluid 1fluid 10.0
pair_coeff * 3 rxn.table ENTRY1 h2o no2 10.0
```

## 4.266.3 Description

Style *table/rx* is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of  $m$  species whose reaction rate kinetics are determined from a set of  $n$  reaction rate equations through the *fix rx* command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style *table/rx* creates interpolation tables of length  $N$  from pair potential and force values listed in a file(s) as a function of distance. The files are read by the *pair\_coeff* command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of  $N$  distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 4 styles: *lookup*, *linear*, *spline*, or *bitmap*.

For the *lookup* style, the distance between two atoms is used to find the nearest table entry, which is the energy or force.

For the *linear* style, the pair distance is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the *spline* style, a cubic spline coefficients are computed and stored at each of the  $N$  values in the table. The pair distance is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For the *bitmap* style, the  $N$  means to create interpolation tables that are  $2^N$  in length. The pair distance is used to index into the table via a fast bit-mapping technique (*Wolff*) and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above.

- filename
- keyword
- species1
- species2
- cutoff (distance units)

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the *fix rx* command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the *fractional* or *molecular* weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

Here are some guidelines for using the `pair_style table/rx` command to best effect:

- Vary the number of table points; you may need to use more than you think to get good resolution.
- Always use the `pair_write` command to produce a plot of what the final interpolated potential looks like. This can show up interpolation “features” you may not like.
- Start with the linear style; it’s the style least likely to have problems.
- Use  $N$  in the `pair_style` command equal to the “N” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.
- Make sure that your tabulated forces and tabulated energies are consistent ( $dE/dr = -F$ ) along the entire range of  $r$  values.
- Use as large an inner cutoff as possible. This avoids fitting splines to very steep parts of the potential.

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

```
# Morse potential for Fe      (one or more comment or blank lines)

MORSE_FE                     (keyword is first text on line)
N 500 R 1.0 10.0             (N, R, RSQ, BITMAP, FPRIME parameters)
                             (blank)
1 1.0 25.5 102.34            (index, r, energy, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `pair_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the  $N$  specified in the `pair_style table/rx` command. Let  $N_{\text{table}} = N$  in the `pair_style` command, and  $N_{\text{file}} = “N”$  in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the  $N_{\text{file}}$  tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at  $N_{\text{table}}$  different points. The resulting tables of length  $N_{\text{table}}$  are then used as described above, when computing energy and force for individual pair distances. This means that if you want the interpolation tables of length  $N_{\text{table}}$  to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set  $N_{\text{table}} = N_{\text{file}}$ , and use the “RSQ” or “BITMAP” parameter. The internal table abscissa is RSQ (separation distance squared).

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in  $r$  uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values  $r_{\text{lo}}$  and  $r_{\text{hi}}$ . If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between  $r_{\text{lo}}$  and  $r_{\text{hi}}$  are computed; for “RSQ”, squared distances uniformly spaced between  $r_{\text{lo}}*r_{\text{lo}}$  and  $r_{\text{hi}}*r_{\text{hi}}$  are computed.

If used, the parameter “BITMAP” is also followed by 2 values *rlo* and *rhi*. These values, along with the “N” value determine the ordering of the N lines that follow and what distance is associated with each. This ordering is complex, so it is not documented here, since this file is typically produced by the [pair\\_write](#) command with its *bitmap* option. When the table is in BITMAP format, the “N” parameter in the file must be equal to  $2^M$  where M is the value specified in the *pair\_style* command. Also, a cutoff parameter cannot be used as an optional third argument in the *pair\_coeff* command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values *fplo* and *fphi* which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is *r* (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The *r* values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

#### 4.266.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The [pair\\_modify](#) shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair\_style table/rx” command to [binary restart files](#), so a *pair\_style* command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, *pair\_coeff* commands do need to be specified in the restart input script.

This pair style can only be used via the *pair* keyword of the [run\\_style respa](#) command. It does not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 4.266.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.266.6 Related commands

## 4.267 pair\_style tersoff command

Accelerator Variants: *tersoff/gpu*, *tersoff/intel*, *tersoff/kk*, *tersoff/omp*

## 4.268 pair\_style tersoff/table command

Accelerator Variants: *tersoff/table/omp*

### 4.268.1 Syntax

```
pair_style style keywords values
```

- style = *tersoff* or *tersoff/table*
- keyword = *shift*  
*shift* value = delta  
delta = negative shift in equilibrium bond length

### 4.268.2 Examples

```
pair_style tersoff
pair_coeff * * Si.tersoff Si
pair_coeff * * SiC.tersoff Si C Si

pair_style tersoff/table
pair_coeff * * SiCGe.tersoff Si(D)

pair_style tersoff shift 0.05
pair_coeff * * Si.tersoff Si
```

### 4.268.3 Description

The *tersoff* style computes a 3-body Tersoff potential (*Tersoff\_1*) for the energy  $E$  of a system of atoms as

$$\begin{aligned}
 E &= \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \\
 V_{ij} &= f_C(r_{ij} + \delta) [f_R(r_{ij} + \delta) + b_{ij} f_A(r_{ij} + \delta)] \\
 f_C(r) &= \begin{cases} 1 & : r < R - D \\ \frac{1}{2} - \frac{1}{2} \sin\left(\frac{\pi}{2} \frac{r-R}{D}\right) & : R - D < r < R + D \\ 0 & : r > R + D \end{cases} \\
 f_R(r) &= A \exp(-\lambda_1 r) \\
 f_A(r) &= -B \exp(-\lambda_2 r) \\
 b_{ij} &= (1 + \beta^n \zeta_{ij}^n)^{-\frac{1}{2n}} \\
 \zeta_{ij} &= \sum_{k \neq i,j} f_C(r_{ik} + \delta) g[\theta_{ijk}(r_{ij}, r_{ik})] \exp[\lambda_3^m (r_{ij} - r_{ik})^m] \\
 g(\theta) &= \gamma_{ijk} \left( 1 + \frac{c^2}{d^2} - \frac{c^2}{[d^2 + (\cos \theta - \cos \theta_0)^2]} \right)
 \end{aligned}$$

where  $f_R$  is a two-body term and  $f_A$  includes three-body interactions. The summations in the formula are over all neighbors  $J$  and  $K$  of atom  $I$  within a cutoff distance  $= R + D$ .  $\delta$  is an optional negative shift of the equilibrium bond length, as described below.

The *tersoff/table* style uses tabulated forms for the two-body, environment and angular functions. Linear interpolation is performed between adjacent table entries. The table length is chosen to be accurate within  $10^{-6}$  with respect to the *tersoff* style energy. The *tersoff/table* should give better performance in terms of speed.

Only a single `pair_coeff` command is used with the *tersoff* style which specifies a Tersoff potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the `pair_coeff` command, where  $N$  is the number of LAMMPS atom types:

- filename
- $N$  element names = mapping of Tersoff elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine the `SiC.tersoff` file has Tersoff values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```
pair_coeff * * SiC.tersoff Si Si Si C
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The first three `Si` arguments map LAMMPS atom types 1,2,3 to the `Si` element in the Tersoff file. The final `C` argument maps LAMMPS atom type 4 to the `C` element in the Tersoff file. If a mapping value is specified as `NULL`, the mapping is not performed. This can be used when a *tersoff* potential is used as part of the *hybrid* pair style. The `NULL` values are placeholders for atom types that will be used with other potentials.

Tersoff files in the *potentials* directory of the LAMMPS distribution have a “.tersoff” suffix. Lines that are not blank or comments (starting with `#`) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)

- $m$
- $\gamma$
- $\lambda_3$  (1/distance units)
- $c$
- $d$
- $\cos \theta_0$  (can be a value  $< -1$  or  $> 1$ )
- $n$
- $\beta$
- $\lambda_2$  (1/distance units)
- $B$  (energy units)
- $R$  (distance units)
- $D$  (distance units)
- $\lambda_1$  (1/distance units)
- $A$  (energy units)

The  $n$ ,  $\beta$ ,  $\lambda_2$ ,  $B$ ,  $\lambda_1$ , and  $A$  parameters are only used for two-body interactions. The  $m$ ,  $\gamma$ ,  $\lambda_3$ ,  $c$ ,  $d$ , and  $\cos \theta_0$  parameters are only used for three-body interactions. The  $R$  and  $D$  parameters are used for both two-body and three-body interactions. The non-annotated parameters are unitless. The value of  $m$  must be 3 or 1.

The Tersoff potential file must contain entries for all the elements listed in the `pair_coeff` command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify Tersoff parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiCSi and SiSiC entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions ( $n$ ,  $\beta$ ,  $\lambda_2$ ,  $B$ ,  $\lambda_1$ , and  $A$ ) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired.

Note that the twobody parameters in entries such as SiCC and CSiSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and  $n$  parameters in Tersoff\_2 (*Tersoff\_2*) are not symmetric. Similarly, the threebody parameters in entries such as SiCSi and SiSiC are often the same, but this is not always the case, particularly the value of  $R$ , which is sometimes typed on the first and second elements, sometimes on the first and third elements. Hence the need to specify  $R$  and  $D$  explicitly for all element triples. For example, while Tersoff's notation in Tersoff\_2 (*Tersoff\_2*) is ambiguous on this point, and properties of the zincblende lattice are the same for either choice, Tersoff's results for rocksalt are consistent with typing on the first and third elements. *Albe et al.* adopts the same convention. Conversely, the potential for B/N/C from the Cagin group uses the opposite convention, typing on the first and second elements.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff potential. In particular, our form reduces to the original Tersoff form when  $m = 3$  and  $\gamma = 1$ , while it reduces to the form of *Albe et al.* when  $\beta = 1$  and  $m = 1$ . Note that in the current Tersoff implementation in LAMMPS,  $m$  must be specified as either

3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff\_2 potential ([Tersoff\\_2](#)). The *tersoff/table* style implements Tersoff\_2 parameterization only.

LAMMPS parameter values for Tersoff\_2 can be obtained as follows:  $\gamma_{ijk} = \omega_{ik}$ ,  $\lambda_3 = 0$  and the value of  $m$  has no effect. The parameters for species  $i$  and  $j$  can be calculated using the Tersoff\_2 mixing rules:

$$\lambda_1^{i,j} = \frac{1}{2}(\lambda_1^i + \lambda_1^j)$$

$$\lambda_2^{i,j} = \frac{1}{2}(\lambda_2^i + \lambda_2^j)$$

$$A_{i,j} = (A_i A_j)^{1/2}$$

$$B_{i,j} = \chi_{ij} (B_i B_j)^{1/2}$$

$$R_{i,j} = (R_i R_j)^{1/2}$$

$$S_{i,j} = (S_i S_j)^{1/2}$$

Tersoff\_2 parameters  $R$  and  $S$  must be converted to the LAMMPS parameters  $R$  and  $D$  ( $R$  is different in both forms), using the following relations:  $R = (R' + S')/2$  and  $D = (S' - R')/2$ , where the primes indicate the Tersoff\_2 parameters.

In the potentials directory, the file `SiCGe.tersoff` provides the LAMMPS parameters for Tersoff's various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (`SiC.tersoff`) and the GaN (`GaN.tersoff`) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers.

The *shift* keyword computes the energy  $E$  of a system of atoms, whose formula is the same as the Tersoff potential. The only modification is that the original equilibrium bond length ( $r_0$ ) of the system is shifted to  $r_0 - \delta$ . The minus sign arises because each radial distance  $r$  is replaced by  $r + \delta$ .

The *shift* keyword is designed for simulations of closely matched van der Waals heterostructures. For instance, consider the case of a system with few-layers graphene atop a thick hexagonal boron nitride (h-BN) substrate simulated using periodic boundary conditions. The experimental lattice mismatch of ~1.8% between graphene and h-BN is not well captured by the equilibrium lattice constants of available potentials, thus a small in-plane strain will be introduced in the system when building a periodic supercell. To minimize the effect of strain on simulation results, the *shift* keyword allows adjusting the equilibrium bond length of one of the two materials (e.g., h-BN). Validation, benchmark tests, and applications of the *shift* keyword can be found in ([Mandelli\\_1](#)) and ([Ouyang\\_1](#)).

For the specific case discussed above, the force field can be defined as

```
pair_style hybrid/overlay rebo tersoff shift -0.00407 ilp/graphene/hbn 16.0 coul/shield_
→16.0
pair_coeff * * rebo CH.rebo NULL NULL C
pair_coeff * * tersoff BNC.tersoff B N NULL
pair_coeff * * ilp/graphene/hbn BNCH.ILP B N C
pair_coeff 1 1 coul/shield 0.70
pair_coeff 1 2 coul/shield 0.695
pair_coeff 2 2 coul/shield 0.69
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.268.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.268.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

The *shift* keyword is not supported by the *tersoff/gpu*, *tersoff/intel*, *tersoff/kk*, *tersoff/table* or *tersoff/table/omp* variants.

The *tersoff/intel* pair style is only available when compiling LAMMPS with the Intel compilers.

The Tersoff potential files provided with LAMMPS (see the potentials directory) are parameterized for “*metal*” units. In addition the pair style supports converting potential parameters on-the-fly between “metal” and “real” units. You can use the *tersoff* pair style variants with any LAMMPS units setting, but you would need to create your own Tersoff potential file with coefficients listed in the appropriate units if your simulation does not use “metal” or “real” units.

Accelerator Variants: *tersoff/mod/gpu*, *tersoff/mod/kk*, *tersoff/mod/omp*

## 4.270 `pair_style tersoff/mod/c` command

Accelerator Variants: *tersoff/mod/c/omp*

### 4.270.1 Syntax

```
pair_style style keywords values
```

- style = *tersoff/mod* or *tersoff/mod/c*
- keyword = *shift*  
    *shift* value = delta  
    delta = negative shift in equilibrium bond length

### 4.270.2 Examples

```
pair_style tersoff/mod  
pair_coeff * * Si.tersoff.mod Si Si  
  
pair_style tersoff/mod/c  
pair_coeff * * Si.tersoff.modc Si Si
```

### 4.270.3 Description

The *tersoff/mod* and *tersoff/mod/c* styles computes a bond-order type interatomic potential ([Kumagai](#)) based on a 3-body Tersoff potential ([Tersoff\\_1](#)), ([Tersoff\\_2](#)) with modified cutoff function and angular-dependent term, giving the energy  $E$  of a system of atoms as

$$\begin{aligned}
 E &= \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \\
 V_{ij} &= f_C(r_{ij} + \delta) [f_R(r_{ij} + \delta) + b_{ij} f_A(r_{ij} + \delta)] \\
 f_C(r) &= \begin{cases} 1 & : r < R - D \\ \frac{1}{2} - \frac{9}{16} \sin\left(\frac{\pi}{2} \frac{r-R}{D}\right) - \frac{1}{16} \sin\left(\frac{3\pi}{2} \frac{r-R}{D}\right) & : R - D < r < R + D \\ 0 & : r > R + D \end{cases} \\
 f_R(r) &= A \exp(-\lambda_1 r) \\
 f_A(r) &= -B \exp(-\lambda_2 r) \\
 b_{ij} &= (1 + \zeta_{ij}^\eta)^{-\frac{1}{2\eta}} \\
 \zeta_{ij} &= \sum_{k \neq i, j} f_C(r_{ik} + \delta) g(\theta_{ijk}) \exp[\alpha(r_{ij} - r_{ik})^\beta] \\
 g(\theta) &= c_1 + g_o(\theta) g_a(\theta) \\
 g_o(\theta) &= \frac{c_2(h - \cos \theta)^2}{c_3 + (h - \cos \theta)^2} \\
 g_a(\theta) &= 1 + c_4 \exp[-c_5(h - \cos \theta)^2]
 \end{aligned}$$

where  $f_R$  is a two-body term and  $f_A$  includes three-body interactions.  $\delta$  is an optional negative shift of the equilibrium bond length, as described below.

The summations in the formula are over all neighbors  $J$  and  $K$  of atom  $I$  within a cutoff distance =  $R + D$ . The *tersoff/mod/c* style differs from *tersoff/mod* only in the formulation of the  $V_{ij}$  term, where it contains an additional  $c_0$  term.

$$V_{ij} = f_C(r_{ij} + \delta) [f_R(r_{ij} + \delta) + b_{ij} f_A(r_{ij} + \delta) + c_0]$$

The modified cutoff function  $f_C$  proposed by ([Murty](#)) and having a continuous second-order differential is employed. The angular-dependent term  $g(\theta)$  was modified to increase the flexibility of the potential.

The *tersoff/mod* potential is fitted to both the elastic constants and melting point by employing the modified Tersoff potential function form in which the angular-dependent term is improved. The model performs extremely well in describing the crystalline, liquid, and amorphous phases ([Schelling](#)).

Only a single `pair_coeff` command is used with the *tersoff/mod* style which specifies a Tersoff/MOD potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the `pair_coeff` command, where  $N$  is the number of LAMMPS atom types:

- filename
- $N$  element names = mapping of Tersoff/MOD elements to atom types

As an example, imagine the `Si.tersoff_mod` file has Tersoff values for Si. If your LAMMPS simulation has 3 Si atoms types, you would use the following `pair_coeff` command:

```
pair_coeff * * Si.tersoff_mod Si Si Si
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/MOD file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *tersoff/mod* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff/MOD file in the *potentials* directory of the LAMMPS distribution have a “.tersoff.mod” suffix. Potential files for the *tersoff/mod/c* style have the suffix “.tersoff.modc”. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- $\beta$
- $\alpha$
- $h$
- $\eta$
- $\beta_{ters} = 1$  (dummy parameter)
- $\lambda_2$  (1/distance units)
- $B$  (energy units)
- $R$  (distance units)
- $D$  (distance units)
- $\lambda_1$  (1/distance units)
- $A$  (energy units)
- $n$
- $c1$
- $c2$
- $c3$
- $c4$
- $c5$
- $c0$  (energy units, tersoff/mod/c only)

The  $n$ ,  $\eta$ ,  $\lambda_2$ ,  $B$ ,  $\lambda_1$ , and  $A$  parameters are only used for two-body interactions. The  $\beta$ ,  $\alpha$ ,  $c1$ ,  $c2$ ,  $c3$ ,  $c4$ ,  $c5$ ,  $h$  parameters are only used for three-body interactions. The  $R$  and  $D$  parameters are used for both two-body and three-body interactions. The  $c0$  term applies to *tersoff/mod/c* only. The non-annotated parameters are unitless.

The Tersoff/MOD potential file must contain entries for all the elements listed in the `pair_coeff` command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiSiSi means Si bonded to a Si with another Si atom influencing the bond.

The *shift* keyword computes the energy  $E$  of a system of atoms, whose formula is the same as the Tersoff potential. The only modification is that the original equilibrium bond length ( $r_0$ ) of the system is shifted to  $r_0 - \delta$ . The minus sign arises because each radial distance  $r$  is replaced by  $r + \delta$ . More information on this option is given on the main [pair\\_tersoff](#) page.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#)

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.270.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.270.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

The *shift* keyword is not supported by the *tersoff/gpu*, *tersoff/intel*, *tersoff/kk*, *tersoff/table* or *tersoff/table/omp* variants.

The *tersoff/mod* potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the *tersoff/mod* pair style with any LAMMPS units, but you would need to create your own Tersoff/MOD potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

## 4.271 pair\_style tersoff/zbl command

Accelerator Variants: *tersoff/zbl/gpu*, *tersoff/zbl/kk*, *tersoff/zbl/omp*

### 4.271.1 Syntax

```
pair_style tersoff/zbl keywords values
```

- keyword = *shift*  
    *shift* value = delta  
    delta = negative shift in equilibrium bond length

### 4.271.2 Examples

```
pair_style tersoff/zbl  
pair_coeff * * SiC.tersoff.zbl Si C Si
```

### 4.271.3 Description

The *tersoff/zbl* style computes a 3-body Tersoff potential (*Tersoff\_1*) with a close-separation pairwise modification based on a Coulomb potential and the Ziegler-Biersack-Littmark universal screening function (*ZBL*), giving the energy

E of a system of atoms as

$$\begin{aligned}
 E &= \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \\
 V_{ij} &= (1 - f_F(r_{ij} + \delta)) V^{ZBL}(r_{ij} + \delta) + f_F(r_{ij} + \delta) V^{Tersoff}(r_{ij} + \delta) \\
 f_F(r) &= \frac{1}{1 + e^{-A_F(r - r_C)}} \\
 V^{ZBL}(r) &= \frac{1}{4\pi\epsilon_0} \frac{Z_1 Z_2 e^2}{r} \phi(r/a) \\
 a &= \frac{0.8854 a_0}{Z_1^{0.23} + Z_2^{0.23}} \\
 \phi(x) &= 0.1818e^{-3.2x} + 0.5099e^{-0.9423x} + 0.2802e^{-0.4029x} + 0.02817e^{-0.2016x} \\
 V^{Tersoff}(r) &= f_C(r) [f_R(r) + b_{ij} f_A(r)] \\
 f_C(r) &= \begin{cases} 1 & : r < R - D \\ \frac{1}{2} - \frac{1}{2} \sin\left(\frac{\pi}{2} \frac{r - R}{D}\right) & : R - D < r < R + D \\ 0 & : r > R + D \end{cases} \\
 f_R(r) &= A \exp(-\lambda_1 r) \\
 f_A(r) &= -B \exp(-\lambda_2 r) \\
 b_{ij} &= (1 + \beta^n \zeta_{ij}^n)^{-\frac{1}{2n}} \\
 \zeta_{ij} &= \sum_{k \neq i, j} f_C(r_{ik} + \delta) g(\theta_{ijk}) \exp[\lambda_3^m (r_{ij} - r_{ik})^m] \\
 g(\theta) &= \gamma_{ijk} \left( 1 + \frac{c^2}{d^2} - \frac{c^2}{[d^2 + (\cos \theta - \cos \theta_0)^2]} \right)
 \end{aligned}$$

The  $f_F$  term is a fermi-like function used to smoothly connect the ZBL repulsive potential with the Tersoff potential. There are 2 parameters used to adjust it:  $A_F$  and  $r_C$ .  $A_F$  controls how “sharp” the transition is between the two, and  $r_C$  is essentially the cutoff for the ZBL potential.

For the ZBL portion, there are two terms. The first is the Coulomb repulsive term, with  $Z_1$ ,  $Z_2$  as the number of protons in each nucleus,  $e$  as the electron charge (1 for metal and real units) and  $\epsilon_0$  as the permittivity of vacuum. The second part is the ZBL universal screening function, with  $a_0$  being the Bohr radius (typically 0.529 Angstroms), and the remainder of the coefficients provided by the original paper. This screening function should be applicable to most systems. However, it is only accurate for small separations (i.e. less than 1 Angstrom).

For the Tersoff portion,  $f_R$  is a two-body term and  $f_A$  includes three-body interactions. The summations in the formula are over all neighbors  $J$  and  $K$  of atom  $I$  within a cutoff distance =  $R + D$ .

$\delta$  is an optional negative shift of the equilibrium bond length, as described below.

Only a single `pair_coeff` command is used with the `tersoff/zbl` style which specifies a Tersoff/ZBL potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the `pair_coeff` command, where  $N$  is the number of LAMMPS atom types:

- filename
- $N$  element names = mapping of Tersoff/ZBL elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine the SiC.tersoff.zbl file has Tersoff/ZBL values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair\_coeff command:

```
pair_coeff * * SiC.tersoff Si Si Si C
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/ZBL file. The final C argument maps LAMMPS atom type 4 to the C element in the Tersoff/ZBL file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *tersoff/zbl* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff/ZBL files in the *potentials* directory of the LAMMPS distribution have a “.tersoff.zbl” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- m
- $\gamma$
- $\lambda_3$  (1/distance units)
- c
- d
- $\cos \theta_0$  (can be a value  $< -1$  or  $> 1$ )
- n
- $\beta$
- $\lambda_2$  (1/distance units)
- B (energy units)
- R (distance units)
- D (distance units)
- $\lambda_1$  (1/distance units)
- A (energy units)
- $Z_i$
- $Z_j$
- ZBLcut (distance units)
- ZBLexpscale (1/distance units)

The n,  $\beta$ ,  $\lambda_2$ , B,  $\lambda_1$ , and A parameters are only used for two-body interactions. The m,  $\gamma$ ,  $\lambda_3$ , c, d, and  $\cos \theta_0$  parameters are only used for three-body interactions. The R and D parameters are used for both two-body and three-body interactions. The  $Z_i$ ,  $Z_j$ , ZBLcut, ZBLexpscale parameters are used in the ZBL repulsive portion of the potential and in the Fermi-like function. The non-annotated parameters are unitless. The value of m must be 3 or 1.

The Tersoff/ZBL potential file must contain entries for all the elements listed in the pair\_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCsi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify Tersoff parameters for

all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiCSi and SiSiC entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions ( $n$ ,  $\beta$ ,  $\lambda_2$ ,  $B$ ,  $\lambda_1$ , and  $A$ ) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired.

Note that the twobody parameters in entries such as SiCC and CSiSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and n parameters in Tersoff\_2 (*Tersoff\_2*) are not symmetric.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff portion of the potential. In particular, our form reduces to the original Tersoff form when  $m = 3$  and  $\gamma = 1$ , while it reduces to the form of *Albe et al.* when  $\beta = 1$  and  $m = 1$ . Note that in the current Tersoff implementation in LAMMPS,  $m$  must be specified as either 3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff\_2 potential (*Tersoff\_2*).

LAMMPS parameter values for Tersoff\_2 can be obtained as follows:  $\gamma = \omega_{ijk}$ ,  $\lambda_3 = 0$  and the value of  $m$  has no effect. The parameters for species  $i$  and  $j$  can be calculated using the Tersoff\_2 mixing rules:

$$\lambda_1^{i,j} = \frac{1}{2}(\lambda_1^i + \lambda_1^j)$$

$$\lambda_2^{i,j} = \frac{1}{2}(\lambda_2^i + \lambda_2^j)$$

$$A_{i,j} = (A_i A_j)^{1/2}$$

$$B_{i,j} = \chi_{ij}(B_i B_j)^{1/2}$$

$$R_{i,j} = (R_i R_j)^{1/2}$$

$$S_{i,j} = (S_i S_j)^{1/2}$$

Tersoff\_2 parameters  $R$  and  $S$  must be converted to the LAMMPS parameters  $R$  and  $D$  ( $R$  is different in both forms), using the following relations:  $R = (R' + S')/2$  and  $D = (S' - R')/2$ , where the primes indicate the Tersoff\_2 parameters.

In the potentials directory, the file SiCGe.tersoff provides the LAMMPS parameters for Tersoff's various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (SiC.tersoff) and the GaN (GaN.tersoff) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers. Also thanks to Ram Devanathan for providing the base ZBL implementation.

The *shift* keyword computes the energy  $E$  of a system of atoms, whose formula is the same as the Tersoff potential. The only modification is that the original equilibrium bond length ( $r_0$ ) of the system is shifted to  $r_0 - \delta$ . The minus sign arises because each radial distance  $r$  is replaced by  $r + \delta$ . More information on this option is given on the main [pair\\_tersoff](#) page.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.271.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.271.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

The *shift* keyword is currently not supported for the *tersoff/gpu* and *tersoff/kk* variants of this pair style.

The *tersoff/zbl* potential files provided with LAMMPS (see the potentials directory) are parameterized for “*metal*” *units*. Also the pair style supports converting potential file parameters on-the-fly between “metal” and “real” units. You can use the *tersoff/zbl* pair style with any LAMMPS units, but you would need to create your own *tersoff/zbl* potential file with coefficients listed in the appropriate units if your simulation does not use “metal” or “real” units.

## 4.272 `pair_style thole` command

## 4.273 `pair_style lj/cut/thole/long` command

Accelerator Variants: *lj/cut/thole/long/omp*

### 4.273.1 Syntax

```
pair_style style args
```

- style = *thole* or *lj/cut/thole/long*
- args = list of arguments for a particular style

*thole* args = damp cutoff

damp = global damping parameter

cutoff = global cutoff (distance units)

*lj/cut/thole/long* args = damp cutoff (cutoff2)

damp = global damping parameter

cutoff = global cutoff for LJ (and Thole if only 1 arg) (distance units)

cutoff2 = global cutoff for Thole (optional) (distance units)

### 4.273.2 Examples

```
pair_style hybrid/overlay ... thole 2.6 12.0
pair_coeff 1 1 thole 1.0
pair_coeff 1 2 thole 1.0 2.6 10.0
pair_coeff * 2 thole 1.0 2.6

pair_style lj/cut/thole/long 2.6 12.0
```

Example input scripts available: `examples/PACKAGES/drude`

### 4.273.3 Description

The *thole* pair styles are meant to be used with force fields that include explicit polarization through Drude dipoles. This link describes how to use the *thermalized Drude oscillator model* in LAMMPS and polarizable models in LAMMPS are discussed on the *Howto polarizable* doc page.

The *thole* pair style should be used as a sub-style within in the *pair\_style hybrid/overlay* command, in conjunction with a main pair style including Coulomb interactions, i.e. any pair style containing *coul/cut* or *coul/long* in its style name.

The *lj/cut/thole/long* pair style is equivalent to, but more convenient than the frequent combination *hybrid/overlay lj/cut/coul/long cutoff thole damp cutoff2*. It is not only a shorthand for this `pair_style` combination, but it also allows for mixing pair coefficients instead of listing them all. The *lj/cut/thole/long* pair style is also a bit faster because it avoids an overlay and can benefit from OMP acceleration. Moreover, it uses a more precise approximation of the direct Coulomb interaction at short range similar to *coul/long/cs*, which stabilizes the temperature of Drude particles.

The *thole* pair styles compute the Coulomb interaction damped at short distances by a function

$$T_{ij}(r_{ij}) = 1 - \left(1 + \frac{s_{ij}r_{ij}}{2}\right) \exp(-s_{ij}r_{ij})$$

This function results from an adaptation to point charges ([Noskov](#)) of the dipole screening scheme originally proposed by [Thole](#). The scaling coefficient  $s_{ij}$  is determined by the polarizability of the atoms,  $\alpha_i$ , and by a Thole damping parameter  $a$ . This Thole damping parameter usually takes a value of 2.6, but in certain force fields the value can depend upon the atom types. The mixing rule for Thole damping parameters is the arithmetic average, and for polarizabilities the geometric average between the atom-specific values.

$$s_{ij} = \frac{a_{ij}}{(\alpha_{ij})^{1/3}} = \frac{(a_i + a_j)/2}{[(\alpha_i \alpha_j)^{1/2}]^{1/3}}$$

The damping function is only applied to the interactions between the point charges representing the induced dipoles on polarizable sites, that is, charges on Drude particles,  $q_{D,i}$ , and opposite charges,  $-q_{D,i}$ , located on the respective core particles (to which each Drude particle is bonded). Therefore, Thole screening is not applied to the full charge of the core particle  $q_i$ , but only to the  $-q_{D,i}$  part of it.

The interactions between core charges are subject to the weighting factors set by the [special\\_bonds](#) command. The interactions between Drude particles and core charges or non-polarizable atoms are also subject to these weighting factors. The Drude particles inherit the 1-2, 1-3 and 1-4 neighbor relations from their respective cores.

For pair\_style *thole*, the following coefficients must be defined for each pair of atoms types via the [pair\\_coeff](#) command as in the example above.

- $\alpha$  (distance units<sup>3</sup>)
- damp
- cutoff (distance units)

The last two coefficients are optional. If not specified the global Thole damping parameter or global cutoff specified in the pair\_style command are used. In order to specify a cutoff (third argument) a damp parameter (second argument) must also be specified.

For pair style *lj/cut/thole/long*, the following coefficients must be defined for each pair of atoms types via the [pair\\_coeff](#) command.

- $\epsilon$  (energy units)
- $\sigma$  (length units)
- $\alpha$  (distance units<sup>3</sup>)
- damp
- LJ cutoff (distance units)

The last two coefficients are optional and default to the global values from the *pair\_style* command line.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.273.4 Mixing, shift, table, tail correction, restart, rRESPA info

The *thole* pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The *lj/cut/thole/long* pair style does support mixing. Mixed coefficients are defined using

$$\alpha_{ij} = \sqrt{\alpha_i \alpha_j}$$

$$a_{ij} = \frac{1}{2}(a_i + a_j)$$

#### 4.273.5 Restrictions

These pair styles are part of the DRUDE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair\_style should currently not be used with the *charmm dihedral style* if the latter has non-zero 1-4 weighting factors. This is because the *thole* pair style does not know which pairs are 1-4 partners of which dihedrals.

The *lj/cut/thole/long* pair style should be used with a *Kspace solver* like PPPM or Ewald, which is only enabled if LAMMPS was built with the kspace package.

#### 4.273.6 Related commands

*fix drude*, *fix langevin/drude*, *fix drude/transform*, *compute temp/drude pair\_style lj/cut/coul/long*

#### 4.273.7 Default

none

### 4.274 pair\_style threebody/table command

#### 4.274.1 Syntax

**pair\_style** style

- style = *threebody/table*

## 4.274.2 Examples

```
pair_style threebody/table
pair_coeff * * spce2.3b type1 type2

pair_style hybrid/overlay table linear 1200 threebody/table
pair_coeff 1 1 table table_CG_CG.txt VOTCA
pair_coeff * * threebody/table spce.3b type
```

Used in example input scripts:

```
examples/PACKAGES/manybody_table/in.spce
examples/PACKAGES/manybody_table/in.spce2
```

## 4.274.3 Description

New in version 2Jun2022.

The *threebody/table* style is a pair style for generic tabulated three-body interactions. It has been developed for (coarse-grained) simulations (of water) with Kernel-based machine learning (ML) potentials ([Scherer2](#)). As for many other MANYBODY package pair styles the energy of a system is computed as a sum over three-body terms:

$$E = \sum_i \sum_{j \neq i} \sum_{k > j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})$$

The summations in the formula are over all neighbors J and K of atom I within a cutoff distance *cut*. In contrast to the Stillinger-Weber potential, all forces are not calculated analytically, but read in from a three-body force/energy table which can be generated with the *csg\_ml* app of VOTCA as available at: <https://gitlab.mpcdf.mpg.de/votca/votca>.

Only a single *pair\_coeff* command is used with the *threebody/table* style which specifies a threebody potential (“*.3b*”) file with parameters for all needed elements. These are then mapped to LAMMPS atom types by specifying *N\_el* additional arguments after the “*.3b*” filename in the *pair\_coeff* command, where *N\_el* is the number of LAMMPS atom types:

- “*.3b*” filename
- *N\_el* element names = mapping of threebody elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine a file *SiC.3b* has three-body values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following *pair\_coeff* command:

```
pair_coeff * * SiC.3b Si Si Si C
```

The first 2 arguments must be *\* \** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the “*.3b*” file. The final C argument maps LAMMPS atom type 4 to the C element in the threebody file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *threebody/table* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The three-body files have a “*.3b*” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry specify to the (three-body) cutoff distance and the tabulated three-body interaction. A single entry then contains:

- element 1 (the center atom in a 3-body interaction)
- element 2

- element 3
- cut (distance units)
- filename
- keyword
- style
- N

The parameter *cut* is the (three-body) cutoff distance. When set to 0, no interaction is calculated for this element triplet. The parameters *filename*, *keyword*, *style*, and *N* refer to the tabulated three-body potential.

The tabulation is done on a three-dimensional grid of the two distances  $r_{ij}$  and  $r_{ik}$  as well as the angle  $\theta_{ijk}$  which is constructed in the following way. There are two different cases. If element 2 and element 3 are of the same type (e.g. SiCC), the distance  $r_{ij}$  is varied in “N” steps from *rmin* to *rmax* and the distance  $r_{ik}$  is varied from  $r_{ij}$  to *rmax*. This can be done, due to the symmetry of the triplet. If element 2 and element 3 are not of the same type (e.g. SiCSi), there is no additional symmetry and the distance  $r_{ik}$  is also varied from *rmin* to *rmax* in “N” steps. The angle  $\theta_{ijk}$  is always varied in “2N” steps from  $(0.0 + 180.0/(4N))$  to  $(180.0 - 180.0/(4N))$ . Therefore, the total number of table entries is “M = N \* N \* (N+1)” for the symmetric (element 2 and element 3 are of the same type) and “M = 2 \* N \* N \* N” for the general case (element 2 and element 3 are not of the same type).

The forces on all three particles I, J, and K of a triplet of this type of three-body interaction potential ( $\phi_3(r_{ij}, r_{ik}, \theta_{ijk})$ ) lie within the plane defined by the three inter-particle distance vectors  $\mathbf{r}_{ij}$ ,  $\mathbf{r}_{ik}$ , and  $\mathbf{r}_{jk}$ . This property is used to project the forces onto the inter-particle distance vectors as follows

$$\begin{pmatrix} \mathbf{f}_i \\ \mathbf{f}_j \\ \mathbf{f}_k \end{pmatrix} = \begin{pmatrix} f_{i1} & f_{i2} & 0 \\ f_{j1} & 0 & f_{j2} \\ 0 & f_{k1} & f_{k2} \end{pmatrix} \begin{pmatrix} \mathbf{r}_{ij} \\ \mathbf{r}_{ik} \\ \mathbf{r}_{jk} \end{pmatrix}$$

and then tabulate the 6 force constants  $f_{i1}$ ,  $f_{i2}$ ,  $f_{j1}$ ,  $f_{j2}$ ,  $f_{k1}$ , and  $f_{k2}$ , as well as the energy of a triplet *e*. Due to symmetry reasons, the following relations hold:  $f_{i1} = -f_{j1}$ ,  $f_{i2} = -f_{k1}$ , and  $f_{j2} = -f_{k2}$ . As in this pair style the forces are read in directly, a correct MD simulation is also performed in the case that the triplet energies are set to *e*=0.

The *filename* specifies the file containing the tabulated energy and derivative values of  $\phi_3(r_{ij}, r_{ik}, \theta_{ijk})$ . The *keyword* then specifies a section of the file. The format of this file is as follows (without the parenthesized comments):

```
# Tabulated three-body potential for spce water (one or more comment or blank lines)

ENTRY1                                     (keyword is,
→the first text on line)
N 12 rmin 2.55 rmax 3.65                  (N, rmin,
→rmax parameters)
                                           (blank line)
1 2.55 2.55 3.75 -867.212 -611.273 867.212 21386.8 611.273 -21386.8 0.0 (index, r_ij,
→ r_ik, theta, f_i1, f_i2, f_j1, f_j2, f_k1, f_k2, e)
2 2.55 2.55 11.25 -621.539 -411.189 621.539 5035.95 411.189 -5035.95 0.0
...
1872 3.65 3.65 176.25 -0.00215132 -0.00412886 0.00215137 0.00111754 0.00412895 -0.
→00111757 0.0
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required. It should be the same than the parameter “N” of the “.3b” file, otherwise its value is overwritten. “N” determines the number of table entries “M” that follow: “M = N \* N \* (N+1)” (symmetric triplet,

e.g. SiCC) or “ $M = 2 * N * N * N$ ” (asymmetric triplet, e.g. SiCSi). Therefore “ $M = 12 * 12 * 13 = 1872$ ” in the above symmetric example. The parameters “rmin” and “rmax” are also required and determine the minimum and maximum of the inter-particle distances  $r_{ij}$  and  $r_{ik}$ .

Following a blank line, the next  $M$  lines of the angular table file list the tabulated values. On each line, the first value is the index from 1 to  $M$ , the second value is the distance  $r_{ij}$ , the third value is the distance  $r_{ik}$ , the fourth value is the angle  $\theta_{ijk}$ , the next six values are the force constants  $f_{i1}$ ,  $f_{i2}$ ,  $f_{j1}$ ,  $f_{j2}$ ,  $f_{k1}$ , and  $f_{k2}$ , and the last value is the energy  $e$ .

Note that one three-body potential file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified *keyword* of appropriate section of the “.3b” file.

At the moment, only the *style linear* is allowed and implemented. After reading in the force table, it is internally stored in LAMMPS as a lookup table. For each triplet configuration occurring in the simulation within the cutoff distance, the next nearest tabulated triplet configuration is looked up. No interpolation is done. This allows for a very efficient force calculation with the stored force constants and energies. Due to the known table structure, the lookup can be done efficiently. It has been tested (*Scherer2*) that with a reasonably small bin size, the accuracy and speed is comparable to that of a Stillinger-Weber potential with tabulated three-body interactions (*pair\_style sw/angle/table*) while the table format of this pair style allows for more flexible three-body interactions.

As for the Stillinger-Weber potential, the three-body potential file must contain entries for all the elements listed in the *pair\_coeff* command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify threebody parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The tabulated three-body forces can in principle be specific to the three elements of the configuration. However, the user must ensure that it makes physically sense. E.g., the tabulated three-body forces for the entries CSiC and CCSi should be the same exchanging  $r_{ij}$  with  $r_{ik}$ ,  $f_{j1}$  with  $f_{k1}$ , and  $f_{j2}$  with  $f_{k2}$ .

Additional input files and reference data can be found at: <https://gitlab.mpcdf.mpg.de/votca/votca/-/tree/master/csg-tutorials/ml>

---

#### 4.274.4 Mixing, shift, table, tail correction, restart, rRESPA info

As all interactions are tabulated, no mixing is performed.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

## 4.274.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

## 4.274.6 Related commands

*pair\_coeff*, *pair sw/angle/table*

(Scherer2) C. Scherer, R. Scheid, D. Andrienko, and T. Bereau, J. Chem. Theor. Comp. 16, 3194-3204 (2020).

## 4.275 pair\_style tracker command

### 4.275.1 Syntax

```
pair_style tracker fix_ID N keyword values attribute1 attribute2 ...
```

- fix\_ID = ID of associated internal fix to store data
- N = prepare data for output every this many timesteps
- zero or more keywords may be appended
- keyword = *finite* or *time/min* or *type/include*

*finite* value = none

pair style uses atomic diameters to identify contacts

*time/min* value = T

T = minimum number of timesteps of interaction

*type/include* value = list1 list2

list1,list2 = separate lists of types (see below)

- one or more attributes may be appended

```
possible attributes = id1 id2 time/created time/broken time/total
                    r/min r/ave x y z
```

id1, id2 = IDs of the two atoms in each pair interaction

time/created = the timestep that the two atoms began interacting

time/broken = the timestep that the two atoms stopped interacting

time/total = the total number of timesteps the two atoms interacted

r/min = the minimum radial distance between the two atoms during the interaction.  
→(distance units)

r/ave = the average radial distance between the two atoms during the interaction.  
→(distance units)

x, y, z = the center of mass position of the two atoms when they stopped.  
→interacting (distance units)

## 4.275.2 Examples

```
pair_style hybrid/overlay tracker myfix 1000 id1 id2 type/include 1 * type/include 2 3,4
→ lj/cut 2.5
pair_coeff 1 1 tracker 2.0

pair_style hybrid/overlay tracker myfix 1000 finite x y z time/min 100 granular
pair_coeff * * tracker

dump 1 all local 1000 dump.local f_myfix[1] f_myfix[2] f_myfix[3]
dump_modify 1 write_header no
```

## 4.275.3 Description

Style *tracker* monitors information about pairwise interactions. It does not calculate any forces on atoms. *Pair hybrid/overlay* can be used to combine this pair style with any other pair style, as shown in the examples above.

At each timestep, if two neighboring atoms move beyond the interaction cutoff, pairwise data is processed and transferred to an internal fix labeled *fix\_ID*. This allows the local data to be accessed by other LAMMPS commands. Additional filters can be applied using the *time/min* or *type/include* keywords described below. Note that this is the interaction cutoff defined by this pair style, not the short-range cutoff defined by the pair style that is calculating forces on atoms.

Following any optional keyword/value arguments, a list of one or more attributes is specified. These include the IDs of the two atoms in the pair. The other attributes for the pair of atoms are the duration of time they were “interacting” or at the point in time they started or stopped interacting. In this context, “interacting” means the time window during which the two atoms were closer than the interaction cutoff distance. The attributes for *time/\** refer to timesteps.

Data is continuously accumulated by the internal fix over intervals of *N* timesteps. At the end of each interval, all of the saved accumulated data is deleted to make room for new data. Individual datum may therefore persist anywhere between 1 to *N* timesteps depending on when they are saved. This data can be accessed using the *fix\_ID* and a *dump local* command. To ensure all data is output, the dump frequency should correspond to the same interval of *N* timesteps. A dump frequency of an integer multiple of *N* can be used to regularly output a sample of the accumulated data.

The following optional keywords may be used.

If the *finite* keyword is not used, the following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- cutoff (distance units)

If the *finite* keyword is used, there are no additional coefficients to set for each pair of atom types via the *pair\_coeff* command. Interaction cutoffs are instead calculated based on the diameter of finite particles. However you must still use the *pair\_coeff* for all atom types. For example the command

```
pair_coeff * *
```

should be used.

The *time/min* keyword sets a minimum amount of time that an interaction must persist to be included. This setting can be used to censor short-lived interactions.

The *type/include* keyword filters interactions based on the types of the two atoms. Data is only saved for interactions between atoms whose two atom types appear in *list1* and *list2*. Atom type 1 must be in *list1* and atom type 2 in *list2*. Or vice versa.

Each type list consists of a series of type ranges separated by commas. Each range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. For example, if M = the number of atom types, then an asterisk with no numeric values means all types from 1 to M. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to M (inclusive). A middle asterisk means all types from m to n (inclusive). Note that the *type/include* keyword can be specified multiple times.

#### 4.275.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , the cutoff coefficient and cutoff distance for this pair style can be mixed. The cutoff is always mixed via a *geometric* rule. The cutoff is mixed according to the pair\_modify mix value. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

The *pair\_modify* shift, table, and tail options are not relevant for this pair style.

The accumulated data is not written to restart files and should be output before a restart file is written to avoid missing data.

The internal fix calculates a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of recorded, lost interactions. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array will be floating point values that correspond to the specified attribute.

---

#### 4.275.5 Restrictions

This pair style is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style is currently incompatible with granular pair styles that extend beyond the contact (e.g. JKR and DMT).

#### 4.275.6 Related commands

#### 4.275.7 Default

none

### 4.276 pair\_style tri/lj command

#### 4.276.1 Syntax

```
pair_style tri/lj cutoff
```

cutoff = global cutoff for interactions (distance units)

## 4.276.2 Examples

```
pair_style tri/lj 3.0
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5
```

## 4.276.3 Description

Style *tri/lj* treats particles which are triangles as a set of small spherical particles that tile the triangle surface as explained below. Interactions between two triangles, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1\*N2 Lennard-Jones interactions. Interactions between a triangle with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the [pair\\_style lj/cut](#) doc page for the definition of Lennard-Jones interactions.

The cutoff distance for an interaction between 2 triangles, or between a triangle and a point particle, is calculated from the position of the triangle (its centroid), not between pairs of individual spheres comprising the triangle. Thus an interaction is either calculated in its entirety or not at all.

The set of non-overlapping spherical particles that represent a triangle, for purposes of this pair style, are generated in the following manner. Assume the triangle is of type I, and sigma\_II has been specified. We want a set of spheres with centers in the plane of the triangle, none of them larger in diameter than sigma\_II, which completely cover the triangle's area, but with minimal overlap and a minimal total number of spheres. This is done in a recursive manner. Place a sphere at the centroid of the original triangle. Calculate what diameter it must have to just cover all 3 corner points of the triangle. If that diameter is equal to or smaller than sigma\_II, then include a sphere of the calculated diameter in the set of covering spheres. If the diameter is larger than sigma\_II, then split the triangle into 2 triangles by bisecting its longest side. Repeat the process on each sub-triangle, recursing as far as needed to generate a set of covering spheres. When finished, the original criteria are met, and the set of covering spheres should be near minimal in number and overlap, at least for input triangles with a reasonable aspect-ratio.

The LJ interaction between 2 spheres on different triangles of types I,J is computed with an arithmetic mixing of the sigma values of the 2 spheres and using the specified epsilon value for I,J atom types. Note that because the sigma values for triangles spheres is computed using only sigma\_II values, specific to the triangles's type, this means that any specified sigma\_IJ values (for I != J) are effectively ignored.

For style *tri/lj*, the following coefficients must be defined for each pair of atoms types via the [pair\\_coeff](#) command as in the examples above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- epsilon (energy units)
- sigma (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

#### 4.276.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of this pair style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.276.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Defining particles to be triangles so they participate in tri/tri or tri/particle interactions requires the use the *atom\_style tri* command.

#### 4.276.6 Related commands

*pair\_coeff*, *pair\_style line/lj*

#### 4.276.7 Default

none

### 4.277 pair\_style uf3 command

Accelerator Variants: *uf3/kk*

#### 4.277.1 Syntax

```
pair_style style BodyFlag
```

- style = *uf3* or *uf3/kk*

BodyFlag = Indicates whether to calculate only 2-body or 2 and 3-body interactions. ↪  
↪ Possible values: 2 or 3

## 4.277.2 Examples

```
pair_style uf3 3
pair_coeff * * Nb.uf3 Nb

pair_style uf3 2
pair_coeff * * NbSn.uf3 Nb Sn

pair_style uf3 3
pair_coeff * * NbSn.uf3 Nb Sn
```

## 4.277.3 Description

New in version 27June2024.

The *uf3* style computes the *Ultra-Fast Force Fields (UF3)* potential, a machine-learning interatomic potential. In UF3, the total energy of the system is defined via two- and three-body interactions:

$$E = \sum_{i,j} V_2(r_{ij}) + \sum_{i,j,k} V_3(r_{ij}, r_{ik}, r_{jk})$$

$$V_2(r_{ij}) = \sum_{n=0}^N c_n B_n(r_{ij})$$

$$V_3(r_{ij}, r_{ik}, r_{jk}) = \sum_{l=0}^{N_l} \sum_{m=0}^{N_m} \sum_{n=0}^{N_n} c_{l,m,n} B_l(r_{ij}) B_m(r_{ik}) B_n(r_{jk})$$

where  $V_2(r_{ij})$  and  $V_3(r_{ij}, r_{ik}, r_{jk})$  are the two- and three-body interactions, respectively. For the two-body the summation is over all neighbors J and for the three-body the summation is over all neighbors J and K of atom I within a cutoff distance determined from the potential files.  $B_n(r_{ij})$  are the cubic b-spline basis,  $c_n$  and  $c_{l,m,n}$  are the machine-learned interaction parameters and  $N$ ,  $N_l$ ,  $N_m$ , and  $N_n$  denote the number of basis functions per spline or tensor spline dimension.

With *uf3* style only a single `pair_coeff` command is used to indicate the UF3 LAMMPS potential file containing all the two- and three-body interactions followed by N additional arguments specifying the mapping of UF3 elements to LAMMPS atom types, where N is the number of LAMMPS atom types:

- UF3 LAMMPS potential file
- N elements names = mapping of UF3 elements to atom types

As an example, if a LAMMPS simulation contains 2 atom types (elements ‘A’ and ‘B’), the `pair_coeff` command will be:

```
pair_style uf3 3
pair_coeff * * AB.uf3 A B
```

The AB.uf3 file should contain all two-body (A-A, A-B, B-B) and three-body (A-A-A, A-A-B, A-B-B, B-A-A, B-A-B, B-B-B).

If a value of “2” is specified in the `pair_style uf3` command, only the two-body potentials are needed. For 3-body interaction the first atom type is the central atom. We recommend using the `generate_uf3_lammps_pots.py` script (found [here](#)) for generating the UF3 LAMMPS potential file from the UF3 JSON potentials.

UF3 LAMMPS potential file in the *potentials* directory of the LAMMPS distribution have a “.uf3” suffix. The interaction block in UF3 LAMMPS potential file should start with #UF3 POT and end with # characters. Following shows the format of a generic 2-body and 3-body potential block in UF3 LAMMPS potential file-

```

The second line indicates whether the block contains data for 2-body (2B) or 3-body (3B) interaction. This is followed by element combination interaction, LEADING\_TRIM and TRAILING\_TRIM number on the same line. The current implementation is only tested for LEADING\_TRIM=0 and TRAILING\_TRIM=3. If other values are used LAMMPS is terminated after issuing an error message. The `Rij_CUTOFF` sets the 2-body cutoff for the interaction described by the potential block. `NUM_OF_KNOTS` is the number of knots (or the length of the knot vector) present on the very next line. The `BSPLINE_KNOTS` line should contain all the knots in ascending order. `NUM_OF_COEFF` is the number of coefficients in the `COEFF` line. All the numbers in the `BSPLINE_KNOTS` and `COEFF` line should be space-separated. Similar to the 2-body potential block, the third line sets the cutoffs and length of the knots. The cutoff distance between atom-type I and J is `Rij_CUTOFF`, atom-type I and K is `Rik_CUTOFF` and between J and K is `Rjk_CUTOFF`.

---

**Note:** The current implementation only works for UF3 potentials with cutoff distances for 3-body interactions that follows `2Rij_CUTOFF=2Rik_CUTOFF=Rjk_CUTOFF` relation.

---

The `BSPLINE_KNOTS_FOR_JK`, `BSPLINE_KNOTS_FOR_IK`, and `BSPLINE_KNOTS_FOR_IJ` lines (note the order) contain the knots in increasing order for atoms J and K, I and K, and atoms I and J respectively. The number of knots is defined by the `NUM_OF_KNOTS_*` characters in the previous line. The shape of the coefficient matrix is defined on the `SHAPE_OF_COEFF_MATRIX[I][J][K]` line followed by the columns of the coefficient matrix, one per line, as shown above. For example, if the coefficient matrix has the shape of 8x8x13, then `SHAPE_OF_COEFF_MATRIX[I][J][K]` will be 8 8 13 followed by 64 (8x8) lines each containing 13 coefficients separated by space.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.277.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.277.5 Restrictions

The ‘uf3’ pair style is part of the ML-UF3 package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the *newton* setting to be “on”.

The UF3 LAMMPS potential file provided with LAMMPS (see the potentials directory) are parameterized for metal *units*.

The *single()* function of ‘uf3’ pair style only return the 2-body interaction energy.

#### 4.277.6 Related commands

*pair\_coeff*

#### 4.277.7 Default

none

## 4.278 pair\_style ufm command

Accelerator Variants: *ufm/gpu*, *ufm/omp*, *ufm/opt*

### 4.278.1 Syntax

```
pair_style ufm cutoff
```

- cutoff = global cutoff for *ufm* interactions (distance units)

### 4.278.2 Examples

```
pair_style ufm 4.0
pair_coeff 1 1 100.0 1.0 2.5
pair_coeff * * 100.0 1.0

pair_style ufm 4.0
pair_coeff * * 10.0 1.0
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_prefactor
```

### 4.278.3 Description

Style *ufm* computes pairwise interactions using the Uhlenbeck-Ford model (UFM) potential ([Paula Leite2016](#)) which is given by

$$E = -\varepsilon \ln [1 - \exp(-r^2/\sigma^2)] \quad r < r_c$$

$$\varepsilon = p k_B T$$

where  $r_c$  is the cutoff,  $\sigma$  is a distance-scale and  $\varepsilon$  is an energy-scale, i.e., a product of Boltzmann constant  $k_B$ , temperature  $T$  and the Uhlenbeck-Ford p-parameter which is responsible to control the softness of the interactions ([Paula Leite2017](#)). This model is useful as a reference system for fluid-phase free-energy calculations ([Paula Leite2016](#)).

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\varepsilon$  (energy units)
- $\sigma$  (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global *ufm* cutoff is used.

The *fix adapt* command can be used to vary epsilon and sigma for this pair style over the course of a simulation, in which case *pair\_coeff* settings for epsilon and sigma must still be specified, but will be overridden. For example these commands will vary the prefactor epsilon for all pairwise interactions from 10.0 at the beginning to 100.0 at the end of a run:

```
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_prefactor
```

---

**Note:** The thermodynamic integration procedure can be performed with this potential using *fix adapt*. This command will rescale the force on each atom by varying a scale variable, which always starts with value 1.0. The syntax is the same described above, however, changing epsilon to scale. A detailed explanation of how to use this command and perform nonequilibrium thermodynamic integration in LAMMPS is given in the paper by (Freitas).

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.278.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table and tail are not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.278.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 4.279 pair\_style vashishta command

Accelerator Variants: *vashishta/gpu*, *vashishta/omp*, *vashishta/kk*

## 4.280 pair\_style vashishta/table command

Accelerator Variants: *vashishta/table/omp*

### 4.280.1 Syntax

```
pair_style style args
```

- style = *vashishta* or *vashishta/table*
- args = list of arguments for a particular style

*vashishta* args = none

*vashishta/table* args = Ntable cutinner

Ntable = # of tabulation points

cutinner = tabulate from cutinner to cutoff

### 4.280.2 Examples

```
pair_style vashishta
pair_coeff * * SiC.vashishta Si C

pair_style vashishta/table 100000 0.2
pair_coeff * * SiC.vashishta Si C
```

### 4.280.3 Description

The *vashishta* and *vashishta/table* styles compute the combined 2-body and 3-body family of potentials developed in the group of Priya Vashishta and collaborators. By combining repulsive, screened Coulombic, screened charge-dipole, and dispersion interactions with a bond-angle energy based on the Stillinger-Weber potential, this potential has been used to describe a variety of inorganic compounds, including SiO2 [Vashishta1990](#), SiC [Vashishta2007](#), and InP [Branicio2009](#).

The potential for the energy  $U$  of a system of atoms is

$$U = \sum_i \sum_{j>i}^N U_{ij}^{(2)}(r_{ij}) + \sum_i \sum_{j \neq i}^N \sum_{k>j, k \neq i}^N U_{ijk}^{(3)}(r_{ij}, r_{ik}, \theta_{ijk})$$

$$U_{ij}^{(2)}(r) = \frac{H_{ij}}{r^{\eta_{ij}}} + \frac{Z_i Z_j}{r} \exp(-r/\lambda_{1,ij}) - \frac{D_{ij}}{r^4} \exp(-r/\lambda_{4,ij}) - \frac{W_{ij}}{r^6}, r < r_{c,ij}$$

$$U_{ijk}^{(3)}(r_{ij}, r_{ik}, \theta_{ijk}) = B_{ijk} \frac{[\cos \theta_{ijk} - \cos \theta_{0ijk}]^2}{1 + C_{ijk} [\cos \theta_{ijk} - \cos \theta_{0ijk}]^2} \times$$

$$\exp\left(\frac{\gamma_{ij}}{r_{ij} - r_{0,ij}}\right) \exp\left(\frac{\gamma_{ik}}{r_{ik} - r_{0,ik}}\right), r_{ij} < r_{0,ij}, r_{ik} < r_{0,ik}$$

where we follow the notation used in [Branicio2009](#).  $U^2$  is a two-body term and  $U^3$  is a three-body term. The summation over two-body terms is over all neighbors  $j$  within a cutoff distance  $= r_c$ . The twobody terms are shifted and tilted by a linear function so that the energy and force are both zero at  $r_c$ . The summation over three-body terms is over all neighbors  $i$  and  $k$  within a cut-off distance  $= r_0$ , where the exponential screening function becomes zero.

The *vashishta* style computes these formulas analytically. The *vashishta/table* style tabulates the analytic values for  $N_{table}$  points from cutinner to the cutoff of the potential. The points are equally spaced in  $R^2$  space from cutinner<sup>2</sup> to cutoff<sup>2</sup>. For the two-body term in the above equation, a linear interpolation for each pairwise distance between adjacent points in the table. In practice the tabulated version can run 3-5x faster than the analytic version with moderate to little loss of accuracy for  $N_{table}$  values between 10000 and 1000000. It is not recommended to use less than 5000 tabulation points.

Only a single `pair_coeff` command is used with either style which specifies a Vashishta potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the `pair_coeff` command, where  $N$  is the number of LAMMPS atom types:

- filename
- $N$  element names = mapping of Vashishta elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the potential file.

As an example, imagine a file `SiC.vashishta` has parameters for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```
pair_coeff * * SiC.vashishta Si Si Si C
```

The first 2 arguments must be `**` so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the file. The final C argument maps LAMMPS atom type 4 to the C element in the file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *vashishta* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Vashishta files in the *potentials* directory of the LAMMPS distribution have a “.vashishta” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- $H$  (energy units)
- $\eta$
- $Z_i$  (electron charge units)

- $Z_j$  (electron charge units)
- $\lambda_1$  (distance units)
- $D$  (energy units)
- $\lambda_4$  (distance units)
- $W$  (energy units)
- $r_c$  (distance units)
- $B$  (energy units)
- $\gamma$
- $r_0$  (distance units)
- $C$
- $\cos \theta_0$

The non-annotated parameters are unitless. The Vashishta potential file must contain entries for all the elements listed in the `pair_coeff` command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries. For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

Depending on the particular version of the Vashishta potential, the values of these parameters may be keyed to the identities of zero, one, two, or three elements. In order to make the input file format unambiguous, general, and simple to code, LAMMPS uses a slightly confusing method for specifying parameters. All parameters are divided into two classes: two-body and three-body. Two-body and three-body parameters are handled differently, as described below. The two-body parameters are  $H$ ,  $\eta$ ,  $\lambda_1$ ,  $D$ ,  $\lambda_4$ ,  $W$ ,  $r_c$ ,  $\gamma$ , and  $r_0$ . They appear in the above formulae with two subscripts. The parameters  $Z_i$  and  $Z_j$  are also classified as two-body parameters, even though they only have 1 subscript. The three-body parameters are  $B$ ,  $C$ ,  $\cos \theta_0$ . They appear in the above formulae with three subscripts. Two-body and three-body parameters are handled differently, as described below.

The first element in each entry is the center atom in a three-body interaction, while the second and third elements are two neighbor atoms. Three-body parameters for a central atom I and two neighbors J and K are taken from the IJK entry. Note that even though three-body parameters do not depend on the order of J and K, LAMMPS stores three-body parameters for both IJK and IKJ. The user must ensure that these values are equal. Two-body parameters for an atom I interacting with atom J are taken from the IJJ entry, where the second and third elements are the same. Thus the two-body parameters for Si interacting with C come from the SiCC entry. Note that even though two-body parameters (except possibly gamma and  $r_0$  in U3) do not depend on the order of the two elements, LAMMPS will get the Si-C value from the SiCC entry and the C-Si value from the CSiSi entry. The user must ensure that these values are equal. Two-body parameters appearing in entries where the second and third elements are different are stored but never used. It is good practice to enter zero for these values. Note that the three-body function U3 above contains the two-body parameters  $\gamma$  and  $r_0$ . So U3 for a central C atom bonded to an Si atom and a second C atom will take three-body parameters from the CSiC entry, but two-body parameters from the CCC and CSiSi entries.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 4.280.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

## 4.280.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

These pair styles requires the *newton* setting to be “on” for pair interactions.

The Vashishta potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the Vashishta potential with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

## 4.280.6 Related commands

*pair\_coeff*

## 4.280.7 Default

none

## 4.281 pair\_style wf/cut command

### 4.281.1 Syntax

**pair\_style** wf/cut cutoff

- cutoff = cutoff for wf interactions (distance units)

## 4.281.2 Examples

```
pair_style      wf/cut 2.0
pair_coeff      1 1 1.0 1.0 1 1 2.0
```

## 4.281.3 Description

The *wf/cut* (Wang-Frenkel) style computes LJ-like potentials as described in [Wang2020](#). This potential is by construction finite ranged and it vanishes quadratically at the cutoff distance, avoiding truncation, shifting, interpolation and other typical procedures with the LJ potential. The *wf/cut* can be used when a typical short-ranged potential with attraction is required. The potential is given by which is given by:

$$\phi(r) = \varepsilon \alpha \left( \left[ \frac{\sigma}{r} \right]^{2\mu} - 1 \right) \left( \left[ \frac{r_c}{r} \right]^{2\mu} - 1 \right)^{2\nu}$$

with

$$\alpha = 2\nu \left( \frac{r_c}{\sigma} \right)^{2\mu} \left[ \frac{1 + 2\nu}{2\nu \left[ (r_c/\sigma)^{2\mu} - 1 \right]} \right]^{2\nu+1}$$

and

$$r_{min} = r_c \left[ \frac{1 + 2\nu}{1 + 2\nu(r_c/\sigma)^{2\nu}} \right]^{1/2\nu}$$

$r_c$  is the cutoff.

Comparison of the non-truncated Lennard-Jones 12-6 potential (red curve), and the WF potentials with  $\mu = 1$  and  $\nu = 1$  are shown in the figure below. The blue curve has  $r_c = 2.0$  and the green curve has  $r_c = 1.2$  and can be used to describe colloidal interactions.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $\varepsilon$  (energy units)
- $\sigma$  (distance units)
- $\nu$

- $\mu$
- $r_c$  (distance units)

The last coefficient is optional. If not specified, the global cutoff given in the `pair_style` command is used. The exponents  $\nu$  and  $\mu$  are positive integers, usually set to 1. There is usually little to be gained by choosing other values of  $\nu$  and  $\mu$  (See discussion in [Wang2020](#))

---

#### Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support the `pair_modify` mixing and table options.

The `pair_modify` tail and shift options are not relevant for this pair style as it goes to zero at the cut-off radius.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style does not support the use of the *inner*, *middle*, and *outer* keywords of the `run_style respa` command.

---

## 4.281.4 Restrictions

This pair style can only be used if LAMMPS was built with the EXTRA-PAIR package. See the [Build package](#) doc page for more info.

## 4.281.5 Related commands

`pair_coeff`

**Default:** none

---

## 4.282 pair\_style ylz command

### 4.282.1 Syntax

```
pair_style ylz cutoff
```

- `cutoff` = global cutoff for interactions (distance units)

## 4.282.2 Examples

```
pair_style      ylz 2.6
pair_coeff      * * 1.0 1.0 4 3 0.0 2.6
```

## 4.282.3 Description

New in version 3Nov2022.

The *ylz* (Yuan-Li-Zhang) style computes an anisotropic interaction between pairs of coarse-grained particles considering the relative particle orientations. This potential was originally developed as a particle-based solvent-free model for biological membranes ([Yuan2010a](#)). Unlike *pair\_style gayberne*, whose orientation dependence is strictly derived from the closest distance between two ellipsoidal rigid bodies, the orientation-dependence of this pair style is mathematically defined such that the particles can self-assemble into one-particle-thick fluid membranes. The potential of this pair style is described by:

$$U(\mathbf{r}_{ij}, \mathbf{n}_i, \mathbf{n}_j) = \begin{cases} u_R(r) + [1 - \phi(\hat{\mathbf{r}}_{ij}, \mathbf{n}_i, \mathbf{n}_j)] \varepsilon, & r < r_{min} \\ u_A(r) \phi(\hat{\mathbf{r}}_{ij}, \mathbf{n}_i, \mathbf{n}_j), & r_{min} < r < r_c \end{cases}$$

$$\phi(\hat{\mathbf{r}}_{ij}, \mathbf{n}_i, \mathbf{n}_j) = 1 + [\mu(a(\hat{\mathbf{r}}_{ij}, \mathbf{n}_i, \mathbf{n}_j) - 1)]$$

$$a(\hat{\mathbf{r}}_{ij}, \mathbf{n}_i, \mathbf{n}_j) = (\mathbf{n}_i \times \hat{\mathbf{r}}_{ij}) \cdot (\mathbf{n}_j \times \hat{\mathbf{r}}_{ij}) + \beta(\mathbf{n}_i - \mathbf{n}_j) \cdot \hat{\mathbf{r}}_{ij} - \beta^2$$

$$u_R(r) = \varepsilon \left[ \left( \frac{r_{min}}{r} \right)^4 - 2 \left( \frac{r_{min}}{r} \right)^2 \right]$$

$$u_A(r) = -\varepsilon \cos^{2\zeta} \left[ \frac{\pi}{2} \frac{(r - r_{min})}{(r_c - r_{min})} \right]$$

where  $\mathbf{r}_i$  and  $\mathbf{r}_j$  are the center position vectors of particles *i* and *j*, respectively,  $\mathbf{r}_{ij} = \mathbf{r}_i - \mathbf{r}_j$  is the inter-particle distance vector,  $r = |\mathbf{r}_{ij}|$  and  $\hat{\mathbf{r}}_{ij} = \mathbf{r}_{ij}/r$ . The unit vectors  $\mathbf{n}_i$  and  $\mathbf{n}_j$  represent the axes of symmetry of particles *i* and *j*, respectively,  $u_R$  and  $u_A$  are the repulsive and attractive potentials,  $\phi$  is an angular function which depends on the relative orientation between pair particles,  $\mu$  is the parameter related to the bending rigidity of the membrane,  $\beta$  is the parameter related to the spontaneous curvature, and  $\varepsilon$  is the energy unit, respectively. The  $\zeta$  controls the slope of the attractive branch and hence the diffusivity of the particles in the in-plane direction of the membrane.  $r_c$  is the cutoff radius,  $r_{min}$  is the distance which minimizes the potential energy  $u_A(r)$  and  $r_{min} = 2^{1/6}\sigma$ , where  $\sigma$  is the length unit.

This pair style is suited for solvent-free coarse-grained simulations of biological systems involving lipid bilayer membranes, such as vesicle shape transformations ([Yuan2010b](#)), nanoparticle endocytosis ([Huang](#)), modeling of red blood cell membranes ([Fu](#)), ([Appshaw](#)), and modeling of cell elasticity ([Becton](#)).

Use of this pair style requires the NVE, NVT, or NPT fixes with the *asphere* extension (e.g. *fix nve/asphere*) in order to integrate particle rotation. Additionally, *atom\_style ellipsoid* should be used since it defines the rotational state of each particle.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\varepsilon$  = well depth (energy units)
- $\sigma$  = minimum effective particle radii (distance units)
- $\zeta$  = tuning parameter for the slope of the attractive branch

- $\mu$  = parameter related to bending rigidity
- $\beta$  = parameter related to the spontaneous curvature
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the `pair_style` command is used.

---

#### 4.282.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is *geometric*. See the “`pair_modify`” command for details.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.282.5 Restrictions

The *ylz* style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires that atoms store torque and a quaternion to represent their orientation, as defined by the *atom\_style*. It also requires they store a per-atom *shape*. The particles cannot store a per-particle diameter. To avoid being mistakenly considered as point particles, the shape parameters ought to be non-spherical, like [1 0.99 0.99]. Unlike the *resquared* pair style for which the shape directly determines the mathematical expressions of the potential, the shape parameters for this pair style is only involved in the computation of the moment of inertia and thus only influences the rotational dynamics of individual particles.

This pair style requires that **all** atoms are ellipsoids as defined by the *atom\_style ellipsoid* command.

#### 4.282.6 Related commands

*pair\_coeff*, *fix nve/asphere*, *compute temp/asphere*, *pair\_style resquared*, *pair\_style gayberne*

## 4.283 pair\_style yukawa command

Accelerator Variants: *yukawa/gpu*, *yukawa/omp*, *yukawa/kk*

### 4.283.1 Syntax

```
pair_style yukawa kappa cutoff
```

- kappa = screening length (inverse distance units)
- cutoff = global cutoff for Yukawa interactions (distance units)

### 4.283.2 Examples

```
pair_style yukawa 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0
```

### 4.283.3 Description

Style *yukawa* computes pairwise interactions with the formula

$$E = A \frac{e^{-\kappa r}}{r} \quad r < r_c$$

$r_c$  is the cutoff.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- A (energy\*distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global yukawa cutoff is used.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.283.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the  $A$  coefficient and cutoff distance for this pair style can be mixed.  $A$  is an energy value mixed like a LJ epsilon. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.284 pair\_style yukawa/colloid command

Accelerator Variants: *yukawa/colloid/gpu*, *yukawa/colloid/kk*, *yukawa/colloid/omp*

#### 4.284.1 Syntax

**pair\_style** yukawa/colloid kappa cutoff

- kappa = screening length (inverse distance units)
- cutoff = global cutoff for colloidal Yukawa interactions (distance units)

## 4.284.2 Examples

```
pair_style yukawa/colloid 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0
```

## 4.284.3 Description

Style *yukawa/colloid* computes pairwise interactions with the formula

$$E = \frac{A}{\kappa} e^{-\kappa(r-(r_i+r_j))} \quad r < r_c$$

where  $r_i$  and  $r_j$  are the radii of the two particles and  $r_c$  is the cutoff.

In contrast to *pair\_style yukawa*, this functional form arises from the Coulombic interaction between two colloid particles, screened due to the presence of an electrolyte, see the book by [Safran](#) for a derivation in the context of DLVO theory. *Pair\_style yukawa* is a screened Coulombic potential between two point-charges and uses no such approximation.

This potential applies to nearby particle pairs for which the Derjagin approximation holds, meaning  $h \ll r_i + r_j$ , where  $h$  is the surface-to-surface separation of the two particles.

When used in combination with *pair\_style colloid*, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- A (energy/distance units)
- cutoff (distance units)

The prefactor A is determined from the relationship between surface charge and surface potential due to the presence of electrolyte. Note that the A for this potential style has different units than the A used in *pair\_style yukawa*. For low surface potentials, i.e. less than about 25 mV, A can be written as:

$$A = 2\pi R \epsilon \epsilon_0 \kappa \psi^2$$

where

- $R$  = colloid radius (distance units)
- $\epsilon_0$  = permittivity of free space (charge<sup>2</sup>/energy/distance units)
- $\epsilon$  = relative permittivity of fluid medium (dimensionless)
- $\kappa$  = inverse screening length (1/distance units)
- $\psi$  = surface potential (energy/charge units)

The last coefficient is optional. If not specified, the global yukawa/colloid cutoff is used.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.284.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the A coefficient and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.284.5 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires that atoms be finite-size spheres with a diameter, as defined by the *atom\_style sphere* command.

Per-particle polydispersity is not yet supported by this pair style; per-type polydispersity is allowed. This means all particles of the same type must have the same diameter. Each type can have a different diameter.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

(**Safran**) Safran, Statistical Thermodynamics of Surfaces, Interfaces, And Membranes, Westview Press, ISBN: 978-0813340791 (2003).

## 4.285 pair\_style zbl command

Accelerator Variants: *zbl/gpu*, *zbl/kk*, *zbl/omp*

### 4.285.1 Syntax

```
pair_style zbl inner outer
```

- inner = distance where switching function begins
- outer = global cutoff for ZBL interaction

### 4.285.2 Examples

```
pair_style zbl 3.0 4.0
pair_coeff * * 73.0 73.0
pair_coeff 1 1 14.0 14.0
```

### 4.285.3 Description

Style *zbl* computes the Ziegler-Biersack-Littmark (ZBL) screened nuclear repulsion for describing high-energy collisions between atoms. (*Ziegler*). It includes an additional switching function that ramps the energy, force, and curvature smoothly to zero between an inner and outer cutoff. The potential energy due to a pair of atoms at a distance  $r_{ij}$  is given by:

$$E_{ij}^{ZBL} = \frac{1}{4\pi\epsilon_0} \frac{Z_i Z_j e^2}{r_{ij}} \phi(r_{ij}/a) + S(r_{ij})$$

$$a = \frac{0.46850}{Z_i^{0.23} + Z_j^{0.23}}$$

$$\phi(x) = 0.18175e^{-3.19980x} + 0.50986e^{-0.94229x} + 0.28022e^{-0.40290x} + 0.02817e^{-0.20162x}$$

where  $e$  is the electron charge,  $\epsilon_0$  is the electrical permittivity of vacuum, and  $Z_i$  and  $Z_j$  are the nuclear charges of the two atoms. The switching function  $S(r)$  is identical to that used by *pair\_style lj/gromacs*. Here, the inner and outer cutoff are the same for all pairs of atom types.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the LAMMPS data file.

- $Z_i$  (atomic number for first atom type, e.g. 13.0 for aluminum)
- $Z_j$  (ditto for second atom type)

The values of  $Z_i$  and  $Z_j$  are normally equal to the atomic numbers of the two atom types. Thus, the user may optionally specify only the coefficients for each  $i == j$  pair, and rely on the obvious mixing rule for cross interactions (see below). Note that when  $i == j$  it is required that  $Z_i == Z_j$ . When used with *hybrid/overlay* and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a `pair_coeff` command.

---

**Note:** The numerical values of the exponential decay constants in the screening function depend on the unit of distance. In the above equation they are given for units of Angstroms. LAMMPS will automatically convert these values to the distance unit of the specified LAMMPS *units* setting. The values of  $Z$  should always be given as multiples of a proton's charge, e.g. 29.0 for copper.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.285.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $i, j$  and  $i \neq j$ , the  $Z_i$  and  $Z_j$  coefficients can be mixed by taking  $Z_i$  and  $Z_j$  from the values specified for  $i == i$  and  $j == j$  cases. When used with *hybrid/overlay* and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a `pair_coeff` command. The *pair\_modify* mix option has no effect on the mixing behavior.

The ZBL pair style does not support the *pair\_modify* shift option, since the ZBL interaction is already smoothed to 0.0 at the cutoff.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

This pair style does not write information to *binary restart files*, so `pair_style` and `pair_coeff` commands must be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

(Ziegler) J.F. Ziegler, J. P. Biersack and U. Littmark, “The Stopping and Range of Ions in Matter”, Volume 1, Pergamon, 1985.

# 4.286 pair\_style zero command

## 4.286.1 Syntax

```
pair_style zero cutoff [nocoeff] [full]
```

- zero = style name of this pair style
- cutoff = global cutoff (distance units)
- nocoeff = ignore all pair\_coeff parameters (optional)
- full = build full neighbor list (optional)

## 4.286.2 Examples

```
pair_style zero 10.0
pair_style zero 5.0 nocoeff
pair_coeff * *
pair_coeff 1 2*4 3.0
```

## 4.286.3 Description

Define a global or per-type cutoff length for the purpose of building a neighbor list and acquiring ghost atoms, but do not compute any pairwise forces or energies.

This can be useful for fixes or computes which require a neighbor list to enumerate pairs of atoms within some cutoff distance, but when pairwise forces are not otherwise needed. Examples are the *fix bond/create*, *compute rdf*, *compute voronoi/atom* commands.

Note that the *comm\_modify cutoff* command can be used to ensure communication of ghost atoms even when a pair style is not defined, but it will not trigger neighbor list generation.

The optional *nocoeff* flag allows to read data files with a PairCoeff section for any pair style. Similarly, any pair\_coeff commands will only be checked for the atom type numbers and the rest ignored. In this case, only the global cutoff will be used.

New in version 3Nov2022.

The optional *full* flag builds a full neighbor list instead of the default half neighbor list.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- cutoff (distance units)

This coefficient is optional. If not specified, the global cutoff specified in the pair\_style command is used. If the pair\_style has been specified with the optional *nocoeff* flag, then a cutoff pair coefficient is ignored.

---

#### 4.286.4 Mixing, shift, table, tail correction, restart, rRESPA info

The cutoff distance for this pair style can be mixed. The default mix value is *geometric*. See the “pair\_modify” command for details.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style writes its information to *binary restart files*, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command.

## BOND STYLES

### 5.1 bond\_style bpm/rotational command

#### 5.1.1 Syntax

`bond_style bpm/rotational keyword value attribute1 attribute2 ...`

- optional keyword = *overlay/pair* or *store/local* or *smooth* or *break*

*store/local* values = fix\_ID N attributes ...

\* fix\_ID = ID of associated internal fix to store data

\* N = prepare data for output every this many timesteps

\* attributes = zero or more of the below attributes may be appended

*id1, id2* = IDs of two atoms in the bond

*time* = the timestep the bond broke

*x, y, z* = the center of mass position of the two atoms when the bond broke ↵

↵(distance units)

*x/ref, y/ref, z/ref* = the initial center of mass position of the two atoms ↵

↵(distance units)

*overlay/pair* value = *yes* or *no*

bonded particles will still interact with pair forces

*smooth* value = *yes* or *no*

smooths bond forces near the breaking point

*normalize* value = *yes* or *no*

normalizes normal and shear forces by the reference length

*break* value = *yes* or *no*

indicates whether bonds break during a run

## 5.1.2 Examples

```

bond_style bpm/rotational
bond_coeff 1 1.0 0.2 0.02 0.02 0.20 0.04 0.04 0.04 0.1 0.02 0.002 0.002

bond_style bpm/rotational store/local myfix 1000 time id1 id2
dump 1 all local 1000 dump.broken f_myfix[1] f_myfix[2] f_myfix[3]
dump_modify 1 write_header no

```

## 5.1.3 Description

New in version 4May2022.

The *bpm/rotational* bond style computes forces and torques based on deviations from the initial reference state of the two atoms. The reference state is stored by each bond when it is first computed in the setup of a run. Data is then preserved across run commands and is written to *binary restart files* such that restarting the system will not reset the reference state of a bond.

Forces include a normal and tangential component. The base normal force has a magnitude of

$$f_r = k_r(r - r_0)$$

where  $k_r$  is a stiffness and  $r$  is the current distance and  $r_0$  is the initial distance between the two particles.

A tangential force is applied perpendicular to the normal direction which is proportional to the tangential shear displacement with a stiffness of  $k_s$ . This tangential force also induces a torque. In addition, bending and twisting torques are also applied to particles which are proportional to angular bending and twisting displacements with stiffnesses of  $k_b$  and  $k_t$ , respectively. Details on the calculations of shear displacements and angular displacements can be found in (Wang) and (Wang and Mora).

Bonds will break under sufficient stress. A breaking criterion is calculated

$$B = \max \left\{ 0, \frac{f_r}{f_{r,c}} + \frac{|f_s|}{f_{s,c}} + \frac{|\tau_b|}{\tau_{b,c}} + \frac{|\tau_t|}{\tau_{t,c}} \right\}$$

where  $|f_s|$  is the magnitude of the shear force and  $|\tau_b|$  and  $|\tau_t|$  are the magnitudes of the bending and twisting torques, respectively. The corresponding variables  $f_{r,c}$ ,  $f_{s,c}$ ,  $\tau_{b,c}$ , and  $\tau_{t,c}$  are critical limits to each force or torque. If  $B$  is ever equal to or exceeds one, the bond will break. This is done by setting the bond type to 0 such that forces and torques are no longer computed.

After computing the base magnitudes of the forces and torques, they can be optionally multiplied by an extra factor  $w$  to smoothly interpolate forces and torques to zero as the bond breaks. This term is calculated as  $w = (1.0 - B^4)$ . This smoothing factor can be added or removed by setting the *smooth* keyword to *yes* or *no*, respectively.

Finally, additional damping forces and torques are applied to the two particles. A force is applied proportional to the difference in the normal velocity of particles using a similar construction as dissipative particle dynamics (Groot):

$$F_D = -\gamma_n w(\hat{r} \bullet \vec{v})$$

where  $\gamma_n$  is the damping strength,  $\hat{r}$  is the radial normal vector, and  $\vec{v}$  is the velocity difference between the two particles. Similarly, tangential forces are applied to each atom proportional to the relative differences in sliding velocities with a constant prefactor  $\gamma_s$  (Wang et al.) along with their associated torques. The rolling and twisting components of the relative angular velocities of the two atoms are also damped by applying torques with prefactors of  $\gamma_r$  and  $\gamma_t$ , respectively.

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $k_r$  (force/distance units)
- $k_s$  (force/distance units)
- $k_t$  (force\*distance/radians units)
- $k_b$  (force\*distance/radians units)
- $f_{r,c}$  (force units)
- $f_{s,c}$  (force units)
- $\tau_{b,c}$  (force\*distance units)
- $\tau_{t,c}$  (force\*distance units)
- $\gamma_n$  (force/velocity units)
- $\gamma_s$  (force/velocity units)
- $\gamma_r$  (force\*distance/velocity units)
- $\gamma_t$  (force\*distance/velocity units)

If the *normalize* keyword is set to *yes*, the radial and shear forces will be normalized by  $r_0$  such that  $k_r$  and  $k_s$  must be given in force units.

By default, pair forces are not calculated between bonded particles. Pair forces can alternatively be overlaid on top of bond forces by setting the *overlay/pair* keyword to *yes*. These settings require specific *special\_bonds* settings described in the restrictions. Further details can be found in the *how to* page on BPMs.

New in version 28Mar2023.

If the *break* keyword is set to *no*, LAMMPS assumes bonds should not break during a simulation run. This will prevent some unnecessary calculation. However, if a bond reaches a damage criterion greater than one, it will trigger an error.

If the *store/local* keyword is used, an internal fix will track bonds that break during the simulation. Whenever a bond breaks, data is processed and transferred to an internal fix labeled *fix\_ID*. This allows the local data to be accessed by other LAMMPS commands. Following this optional keyword, a list of one or more attributes is specified. These include the IDs of the two atoms in the bond. The other attributes for the two atoms include the timestep during which the bond broke and the current/initial center of mass position of the two atoms.

Data is continuously accumulated over intervals of  $N$  timesteps. At the end of each interval, all of the saved accumulated data is deleted to make room for new data. Individual datum may therefore persist anywhere between 1 to  $N$  timesteps depending on when they are saved. This data can be accessed using the *fix\_ID* and a *dump local* command. To ensure all data is output, the dump frequency should correspond to the same interval of  $N$  timesteps. A dump frequency of an integer multiple of  $N$  can be used to regularly output a sample of the accumulated data.

Note that when unbroken bonds are dumped to a file via the *dump local* command, bonds with type 0 (broken bonds) are not included. The *delete\_bonds* command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```
delete_bonds all stats
delete_bonds all bond 0 remove
```

### 5.1.4 Restart and other info

This bond style writes the reference state of each bond to *binary restart files*. Loading a restart file will properly resume bonds. However, the reference state is NOT written to data files. Therefore reading a data file will not restore bonds and will cause their reference states to be redefined.

If the *store/local* option is used, an internal fix will calculate a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of recorded, broken bonds. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array will be floating point values that correspond to the specified attribute.

The `single()` function of this bond style returns 0.0 for the energy of a bonded interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the bonded interaction force. However, the `single()` function also calculates 7 extra bond quantities. The first 4 are data from the reference state of the bond including the initial distance between particles  $r_0$  followed by the  $x$ ,  $y$ , and  $z$  components of the initial unit vector pointing to particle I from particle J. The next 3 quantities (5-7) are the  $x$ ,  $y$ , and  $z$  components of the total force, including normal and tangential contributions, acting on particle I.

These extra quantities can be accessed by the *compute bond/local* command, as  $b1, b2, \dots, b7$ .

### 5.1.5 Restrictions

This bond style is part of the BPM package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

By default if pair interactions between bonded atoms are to be disabled, this bond style requires setting

```
special_bonds lj 0 1 1 coul 1 1 1
```

and *newton* must be set to bond off. If the *overlay/pair* keyword is set to *yes*, this bond style alternatively requires setting

```
special_bonds lj/coul 1 1 1
```

The *bpm/rotational* style requires *atom style bpm/sphere*.

### 5.1.6 Related commands

*bond\_coeff*, *fix nve/bpm/sphere*

### 5.1.7 Default

The option defaults are *overlay/pair* = *no*, *smooth* = *yes*, *normalize* = *no*, and *break* = *yes*

---

(Wang et al, 2015) Wang, Y., Alonso-Marroquin, F., & Guo, W. W. (2015). Rolling and sliding in 3-D discrete element models. Particuology, 23, 49-55.

## 5.2 bond\_style bpm/spring command

### 5.2.1 Syntax

```
bond_style bpm/spring keyword value attribute1 attribute2 ...
```

- optional keyword = *overlay/pair* or *store/local* or *smooth* or *break*

*store/local* values = fix\_ID N attributes ...

\* fix\_ID = ID of associated internal fix to store data

\* N = prepare data for output every this many timesteps

\* attributes = zero or more of the below attributes may be appended

*id1, id2* = IDs of two atoms in the bond

*time* = the timestep the bond broke

*x, y, z* = the center of mass position of the two atoms when the bond broke.

→(distance units)

*x/ref, y/ref, z/ref* = the initial center of mass position of the two atoms.

→(distance units)

*overlay/pair* value = *yes* or *no*

bonded particles will still interact with pair forces

*smooth* value = *yes* or *no*

smooths bond forces near the breaking point

*normalize* value = *yes* or *no*

normalizes bond forces by the reference length

*break* value = *yes* or *no*

indicates whether bonds break during a run

### 5.2.2 Examples

```
bond_style bpm/spring
bond_coeff 1 1.0 0.05 0.1

bond_style bpm/spring myfix 1000 time id1 id2
dump 1 all local 1000 dump.broken f_myfix[1] f_myfix[2] f_myfix[3]
dump_modify 1 write_header no
```

### 5.2.3 Description

New in version 4May2022.

The *bpm/spring* bond style computes forces based on deviations from the initial reference state of the two atoms. The reference state is stored by each bond when it is first computed in the setup of a run. Data is then preserved across run commands and is written to *binary restart files* such that restarting the system will not reset the reference state of a bond.

This bond style only applies central-body forces which conserve the translational and rotational degrees of freedom of a bonded set of particles based on a model described by Clemmer and Robbins (*Clemmer*). The force has a magnitude

of

$$F = k(r - r_0)w$$

where  $k$  is a stiffness,  $r$  is the current distance and  $r_0$  is the initial distance between the two particles, and  $w$  is an optional smoothing factor discussed below. Bonds will break at a strain of  $\epsilon_c$ . This is done by setting the bond type to 0 such that forces are no longer computed.

An additional damping force is applied to the bonded particles. This force is proportional to the difference in the normal velocity of particles using a similar construction as dissipative particle dynamics (*Groot*):

$$F_D = -\gamma w(\hat{r} \bullet \vec{v})$$

where  $\gamma$  is the damping strength,  $\hat{r}$  is the radial normal vector, and  $\vec{v}$  is the velocity difference between the two particles.

The smoothing factor  $w$  can be added or removed by setting the *smooth* keyword to *yes* or *no*, respectively. It is constructed such that forces smoothly go to zero, avoiding discontinuities, as bonds approach the critical strain

$$w = 1.0 - \left( \frac{r - r_0}{r_0 \epsilon_c} \right)^8.$$

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $k$  (force/distance units)
- $\epsilon_c$  (unit less)
- $\gamma$  (force/velocity units)

If the *normalize* keyword is set to *yes*, the elastic bond force will be normalized by  $r_0$  such that  $k$  must be given in force units.

By default, pair forces are not calculated between bonded particles. Pair forces can alternatively be overlaid on top of bond forces by setting the *overlay/pair* keyword to *yes*. These settings require specific *special\_bonds* settings described in the restrictions. Further details can be found in the *how to* page on BPMs.

New in version 28Mar2023.

If the *break* keyword is set to *no*, LAMMPS assumes bonds should not break during a simulation run. This will prevent some unnecessary calculation. However, if a bond reaches a strain greater than  $\epsilon_c$ , it will trigger an error.

If the *store/local* keyword is used, an internal fix will track bonds that break during the simulation. Whenever a bond breaks, data is processed and transferred to an internal fix labeled *fix\_ID*. This allows the local data to be accessed by other LAMMPS commands. Following this optional keyword, a list of one or more attributes is specified. These include the IDs of the two atoms in the bond. The other attributes for the two atoms include the timestep during which the bond broke and the current/initial center of mass position of the two atoms.

Data is continuously accumulated over intervals of  $N$  timesteps. At the end of each interval, all of the saved accumulated data is deleted to make room for new data. Individual datum may therefore persist anywhere between 1 to  $N$  timesteps depending on when they are saved. This data can be accessed using the *fix\_ID* and a *dump local* command. To ensure all data is output, the dump frequency should correspond to the same interval of  $N$  timesteps. A dump frequency of an integer multiple of  $N$  can be used to regularly output a sample of the accumulated data.

Note that when unbroken bonds are dumped to a file via the *dump local* command, bonds with type 0 (broken bonds) are not included. The *delete\_bonds* command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```
delete_bonds all stats
delete_bonds all bond 0 remove
```

### 5.2.4 Restart and other info

This bond style writes the reference state of each bond to *binary restart files*. Loading a restart file will properly restore bonds. However, the reference state is NOT written to data files. Therefore reading a data file will not restore bonds and will cause their reference states to be redefined.

If the *store/local* option is used, an internal fix will calculate a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of recorded, broken bonds. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array will be floating point values that correspond to the specified attribute.

The `single()` function of this bond style returns 0.0 for the energy of a bonded interaction, since energy is not conserved in these dissipative potentials. The `single()` function also calculates an extra bond quantity, the initial distance  $r_0$ . This extra quantity can be accessed by the *compute bond/local* command as *b1*.

### 5.2.5 Restrictions

This bond style is part of the BPM package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

By default if pair interactions between bonded atoms are to be disabled, this bond style requires setting

```
special_bonds lj 0 1 1 coul 1 1 1
```

and *newton* must be set to bond off. If the *overlay/pair* keyword is set to *yes*, this bond style alternatively requires setting

```
special_bonds lj/coul 1 1 1
```

### 5.2.6 Related commands

*bond\_coeff*, *pair bpm/spring*

### 5.2.7 Default

The option defaults are *overlay/pair* = *no*, *smooth* = *yes*, *normalize* = *no*, and *break* = *yes*

---

## 5.3 bond\_style class2 command

Accelerator Variants: *class2/omp*, *class2/kk*

### 5.3.1 Syntax

```
bond_style class2
```

### 5.3.2 Examples

```
bond_style class2  
bond_coeff 1 1.0 100.0 80.0 80.0
```

### 5.3.3 Description

The *class2* bond style uses the potential

$$E = K_2(r - r_0)^2 + K_3(r - r_0)^3 + K_4(r - r_0)^4$$

where  $r_0$  is the equilibrium bond distance.

See ([Sun](#)) for a description of the COMPASS class2 force field.

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $r_0$  (distance)
- $K_2$  (energy/distance<sup>2</sup>)
- $K_3$  (energy/distance<sup>3</sup>)
- $K_4$  (energy/distance<sup>4</sup>)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 5.3.4 Restrictions

This bond style can only be used if LAMMPS was built with the CLASS2 package. See the [Build package](#) page for more info.

### 5.3.5 Related commands

*bond\_coeff*, *delete\_bonds*

### 5.3.6 Default

none

---

(Sun) Sun, J Phys Chem B 102, 7338-7364 (1998).

## 5.4 bond\_style fene command

Accelerator Variants: *fene/intel*, *fene/kk*, *fene/omp*

## 5.5 bond\_style fene/nm command

### 5.5.1 Syntax

```
bond_style fene
bond_style fene/nm
```

### 5.5.2 Examples

```
bond_style fene
bond_coeff 1 30.0 1.5 1.0 1.0

bond_style fene/nm
bond_coeff 1 2.25344 1.5 1.0 1.12246 2 6
```

### 5.5.3 Description

The *fene* bond style uses the potential

$$E = -0.5KR_0^2 \ln \left[ 1 - \left( \frac{r}{R_0} \right)^2 \right] + 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] + \epsilon$$

to define a finite extensible nonlinear elastic (FENE) potential ([Kremer](#)), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive. The first term extends to  $R_0$ , the maximum extent of the bond. The second term is cutoff at  $2^{\frac{1}{6}}\sigma$ , the minimum of the LJ potential.

The *fene/nm* bond style substitutes the standard LJ potential with the generalized LJ potential in the same form as in pair style *nm/cut*. The bond energy is then given by

$$E = -0.5KR_0^2 \ln \left[ 1 - \left( \frac{r}{R_0} \right)^2 \right] + \frac{E_0}{(n-m)} \left[ m \left( \frac{r_0}{r} \right)^n - n \left( \frac{r_0}{r} \right)^m \right]$$

Similar to the *fene* style, the generalized Lennard-Jones is cut off at the potential minimum,  $r_0$ , to be repulsive only. The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy/distance<sup>2</sup>)
- $R_0$  (distance)
- $\epsilon$  (energy)
- $\sigma$  (distance)

For the *fene/nm* style, the following coefficients are used. Please note, that the standard LJ potential and thus the regular FENE potential is recovered for ( $n=12$   $m=6$ ) and  $r_0 = 2^{\frac{1}{6}}\sigma$ .

- $K$  (energy/distance<sup>2</sup>)
- $R_0$  (distance)
- $E_0$  (energy)
- $r_0$  (distance)
- $n$  (unitless)
- $m$  (unitless)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* *command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 5.5.4 Restrictions

The *fene* bond style can only be used if LAMMPS was built with the MOLECULE package; the *fene/nm* bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) page for more info.

You typically should specify *special\_bonds fene* or *special\_bonds lj/coul 0 1 1* to use this bond style. LAMMPS will issue a warning if that's not the case.

### 5.5.5 Related commands

*bond\_coeff*, *delete\_bonds*, *pair style lj/cut*, *pair style nm/cut*.

### 5.5.6 Default

none

(**Kremer**) Kremer, Grest, J Chem Phys, 92, 5057 (1990).

## 5.6 bond\_style fene/expand command

Accelerator Variants: *fene/expand/omp*

### 5.6.1 Syntax

```
bond_style fene/expand
```

### 5.6.2 Examples

```
bond_style fene/expand
bond_coeff 1 30.0 1.5 1.0 1.0 0.5
```

### 5.6.3 Description

The *fene/expand* bond style uses the potential

$$E = -0.5KR_0^2 \ln \left[ 1 - \left( \frac{(r - \Delta)}{R_0} \right)^2 \right] + 4\epsilon \left[ \left( \frac{\sigma}{(r - \Delta)} \right)^{12} - \left( \frac{\sigma}{(r - \Delta)} \right)^6 \right] + \epsilon$$

to define a finite extensible nonlinear elastic (FENE) potential ([Kremer](#)), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive.

The *fene/expand* bond style is similar to *fene* except that an extra shift factor of  $\Delta$  (positive or negative) is added to  $r$  to effectively change the bead size of the bonded atoms. The first term now extends to  $R_0 + \Delta$  and the second term is cutoff at  $2^{\frac{1}{6}}\sigma + \Delta$ .

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy/distance<sup>2</sup>)
- $R_0$  (distance)
- $\epsilon$  (energy)
- $\sigma$  (distance)
- $\Delta$  (distance)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 5.6.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) page for more info.

You typically should specify *special\_bonds fene* or *special\_bonds lj/coul 0 1 1* to use this bond style. LAMMPS will issue a warning if that's not the case.

## 5.6.5 Related commands

*bond\_coeff*, *delete\_bonds*

## 5.6.6 Default

none

---

(**Kremer**) Kremer, Grest, J Chem Phys, 92, 5057 (1990).

## 5.7 bond\_style gaussian command

### 5.7.1 Syntax

```
bond_style gaussian
```

### 5.7.2 Examples

```
bond_style gaussian  
bond_coeff 1 300.0 2 0.0128 0.375 3.37 0.0730 0.148 3.63
```

### 5.7.3 Description

The *gaussian* bond style uses the potential:

$$E = -k_B T \ln \left( \sum_{i=1}^n \frac{A_i}{w_i \sqrt{\pi/2}} \exp \left( \frac{-2(r - r_i)^2}{w_i^2} \right) \right)$$

This analytical form is a suitable potential for obtaining mesoscale effective force fields which can reproduce target atomistic distributions (*Milano*)

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *T* temperature at which the potential was derived
- *n* (integer >=1)
- *A*<sub>1</sub> (> 0, distance)
- *w*<sub>1</sub> (> 0, distance)
- *r*<sub>1</sub> (>= 0, distance)
- ...
- *A*<sub>*n*</sub> (> 0, distance)
- *w*<sub>*n*</sub> (> 0, distance)
- *r*<sub>*n*</sub> (>= 0, distance)

### 5.7.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the *Build package* doc page for more info.

### 5.7.5 Related commands

*bond\_coeff*

### 5.7.6 Default

none

(*Milano*) G. Milano, S. Goudeau, F. Mueller-Plathe, J. Polym. Sci. B Polym. Phys. 43, 871 (2005).

## 5.8 bond\_style gromos command

Accelerator Variants: *gromos/omp*

### 5.8.1 Syntax

```
bond_style gromos
```

### 5.8.2 Examples

```
bond_style gromos  
bond_coeff 5 80.0 1.2
```

### 5.8.3 Description

The *gromos* bond style uses the potential

$$E = K(r^2 - r_0^2)^2$$

where  $r_0$  is the equilibrium bond distance. Note that the usual 1/4 factor is included in  $K$ .

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy/distance<sup>4</sup>)
- $r_0$  (distance)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 5.8.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) page for more info.

## 5.8.5 Related commands

*bond\_coeff*, *delete\_bonds*

## 5.8.6 Default

none

## 5.9 bond\_style harmonic command

Accelerator Variants: *harmonic/intel*, *harmonic/kk*, *harmonic/omp*

### 5.9.1 Syntax

```
bond_style harmonic
```

### 5.9.2 Examples

```
bond_style harmonic
bond_coeff 5 80.0 1.2
```

### 5.9.3 Description

The *harmonic* bond style uses the potential

$$E = K(r - r_0)^2$$

where  $r_0$  is the equilibrium bond distance. Note that the usual 1/2 factor is included in  $K$ .

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy/distance<sup>2</sup>)
- $r_0$  (distance)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 5.9.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) page for more info.

## 5.9.5 Related commands

*bond\_coeff*, *delete\_bonds*

## 5.9.6 Default

none

# 5.10 bond\_style harmonic/restrain command

## 5.10.1 Syntax

```
bond_style harmonic/restrain
```

## 5.10.2 Examples

```
bond_style harmonic  
bond_coeff 5 80.0
```

## 5.10.3 Description

New in version 28Mar2023.

The *harmonic/restrain* bond style uses the potential

$$E = K(r - r_{t=0})^2$$

where  $r_{t=0}$  is the distance between the bonded atoms at the beginning of the first *run* or *minimize* command after the bond style has been defined ( $t=0$ ). Note that the usual 1/2 factor is included in  $K$ . This will effectively restrain bonds to their initial length, whatever that is. This is where this bond style differs from *bond style harmonic* where the bond length is set through the per bond type coefficients.

The following coefficient must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands

- $K$  (energy/distance<sup>2</sup>)

This bond style differs from other options to add harmonic restraints like *fix restrain* or *pair style list* or *fix colvars* in that it requires a bond topology, and thus the defined bonds will trigger exclusion of special neighbors from the neighbor list according to the *special\_bonds* settings.

### 5.10.4 Restart info

This bond style supports the *write\_restart* and *read\_restart* commands. The state of the initial bond lengths is stored with restart files and read back.

### 5.10.5 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the *Build package* page for more info.

This bond style maintains internal data to determine the original bond lengths  $r_{i=0}$ . This information will be written to *binary restart files* but **not** to *data files*. Thus, continuing a simulation is *only* possible with *read\_restart*. When using the *read\_data command*, the reference bond lengths  $r_{i=0}$  will be re-initialized from the current geometry.

This bond style cannot be used with *fix shake* or *fix rattle*, with *fix filter/corotate*, or any *tip4p pair style* since there is no specific equilibrium distance for a given bond type.

### 5.10.6 Related commands

*bond\_coeff*, *bond\_harmonic*, *fix restrain*, *pair style list*

### 5.10.7 Default

none

## 5.11 bond\_style harmonic/shift command

Accelerator Variants: *harmonic/shift/omp*

### 5.11.1 Syntax

```
bond_style harmonic/shift
```

### 5.11.2 Examples

```
bond_style harmonic/shift
bond_coeff 5 10.0 0.5 1.0
```

### 5.11.3 Description

The *harmonic/shift* bond style is a shifted harmonic bond that uses the potential

$$E = \frac{U_{\min}}{(r_0 - r_c)^2} [(r - r_0)^2 - (r_c - r_0)^2]$$

where  $r_0$  is the equilibrium bond distance, and  $r_c$  the critical distance. The potential is  $-U_{\min}$  at  $r_0$  and zero at  $r_c$ . The spring constant is  $k = U_{\min}/[2(r_0 - r_c)^2]$ .

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $U_{\min}$  (energy)
- $r_0$  (distance)
- $r_c$  (distance)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 5.11.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

### 5.11.5 Related commands

*bond\_coeff*, *delete\_bonds*, *bond\_harmonic*

### 5.11.6 Default

none

## 5.12 bond\_style harmonic/shift/cut command

Accelerator Variants: *harmonic/shift/cut/omp*

### 5.12.1 Syntax

```
bond_style harmonic/shift/cut
```

### 5.12.2 Examples

```
bond_style harmonic/shift/cut
bond_coeff 5 10.0 0.5 1.0
```

### 5.12.3 Description

The *harmonic/shift/cut* bond style is a shifted harmonic bond that uses the potential

$$E = \frac{U_{\min}}{(r_0 - r_c)^2} [(r - r_0)^2 - (r_c - r_0)^2]$$

where  $r_0$  is the equilibrium bond distance, and  $r_c$  the critical distance. The bond potential is zero for distances  $r > r_c$ . The potential is  $-U_{\min}$  at  $r_0$  and zero at  $r_c$ . The spring constant is  $k = U_{\min}/[2(r_0 - r_c)^2]$ .

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $U_{\min}$  (energy)
- $r_0$  (distance)
- $r_c$  (distance)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

### 5.12.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

### 5.12.5 Related commands

*bond\_coeff*, *delete\_bonds*, *bond\_harmonic*, *bond\_style harmonic/shift*

### 5.12.6 Default

none

## 5.13 bond\_style hybrid command

Accelerator Variants: *hybrid/kk*

### 5.13.1 Syntax

```
bond_style hybrid style1 style2 ...
```

- style1,style2 = list of one or more bond styles

### 5.13.2 Examples

```
bond_style hybrid harmonic fene  
bond_coeff 1 harmonic 80.0 1.2  
bond_coeff 2* fene 30.0 1.5 1.0 1.0
```

### 5.13.3 Description

The *hybrid* style enables the use of multiple bond styles in one simulation. A bond style is assigned to each bond type. For example, bonds in a polymer flow (of bond type 1) could be computed with a *fene* potential and bonds in the wall boundary (of bond type 2) could be computed with a *harmonic* potential. The assignment of bond type to style is made via the *bond\_coeff* command or in the data file.

In the *bond\_coeff* commands, the name of a bond style must be added after the bond type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 *bond\_coeff* commands set bonds of bond type 1 to be computed with a *harmonic* potential with coefficients 80.0, 1.2 for  $K$ ,  $r_0$ . All other bond types (2-N) are computed with a *fene* potential with coefficients 30.0, 1.5, 1.0, 1.0 for  $K$ ,  $R_0$ ,  $\epsilon$ ,  $\sigma$ .

If bond coefficients are specified in the data file read via the [read\\_data](#) command, then the same rule applies. E.g. “harmonic” or “fene” must be added after the bond type, for each line in the “Bond Coeffs” section, e.g.

**Bond Coeffs**

```
1 harmonic 80.0 1.2
2 fene 30.0 1.5 1.0 1.0
...
```

A bond style of *none* with no additional coefficients can be used in place of a bond style, either in a input script `bond_coeff` command or in the data file, if you desire to turn off interactions for specific bond types.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 5.13.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) page for more info.

Unlike other bond styles, the hybrid bond style does not store bond coefficient info for individual sub-styles in [binary restart files](#) or [data files](#). Thus when restarting a simulation, you need to re-specify the `bond_coeff` commands.

### 5.13.5 Related commands

*bond\_coeff*, *delete\_bonds*

### 5.13.6 Default

*none*

## 5.14 bond\_style lepton command

Accelerator Variants: *lepton/omp*

### 5.14.1 Syntax

```
bond_style style args
```

- style = *lepton*
- args = optional arguments

args = *auto\_offset* or *no\_offset*

*auto\_offset* = offset the potential energy so that the value at  $r_0$  is 0.0 (default)

*no\_offset* = do not offset the potential energy

### 5.14.2 Examples

```
bond_style lepton
bond_style lepton no_offset

bond_coeff 1 1.5 "k*r^2; k=250.0"
bond_coeff 2 1.1 "k2*r^2 + k3*r^3 + k4*r^4; k2=300.0; k3=-100.0; k4=50.0"
bond_coeff 3 1.3 "k*r^2; k=350.0"
```

### 5.14.3 Description

New in version 8Feb2023.

Bond style *lepton* computes bonded interactions between two atoms with a custom function. The potential function must be provided as an expression string using “r” as the distance variable relative to the reference distance  $r_0$  which is provided as a bond coefficient. For example “ $200.0*r^2$ ” represents a harmonic potential with a force constant  $K$  of 200.0 energy units:

$$U_{bond,i} = K(r_i - r_0)^2 = Kr^2 \quad r = r_i - r_0$$

Changed in version 7Feb2024.

By default the potential energy  $U$  is shifted so that the value  $U$  is 0.0 for  $r = r_0$ . This is equivalent to using the optional keyword *auto\_offset*. When using the keyword *no\_offset* instead, the potential energy is not shifted.

The [Lepton library](#), that the *lepton* bond style interfaces with, evaluates this expression string at run time to compute the pairwise energy. It also creates an analytical representation of the first derivative of this expression with respect to “r” and then uses that to compute the force between the atom pairs forming bonds as defined by the topology data.

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- Lepton expression (energy units)
- $r_0$  (distance)

The Lepton expression must be either enclosed in quotes or must not contain any whitespace so that LAMMPS recognizes it as a single keyword. More on valid Lepton expressions below. The  $r_0$  is the “equilibrium distance”. The potential energy function in the Lepton expression is shifted in such a way, that the potential energy is 0 for a bond length  $r_i == r_0$ .

### 5.14.4 Lepton expression syntax and features

Lepton supports the following operators in expressions:

+	Add	-	Subtract	*	Multiply	/	Divide	^	Power
---	-----	---	----------	---	----------	---	--------	---	-------

The following mathematical functions are available:

sqrt(x)	Square root	exp(x)	Exponential
log(x)	Natural logarithm	sin(x)	Sine (angle in radians)
cos(x)	Cosine (angle in radians)	sec(x)	Secant (angle in radians)
csc(x)	Cosecant (angle in radians)	tan(x)	Tangent (angle in radians)
cot(x)	Cotangent (angle in radians)	asin(x)	Inverse sine (in radians)
acos(x)	Inverse cosine (in radians)	atan(x)	Inverse tangent (in radians)
sinh(x)	Hyperbolic sine	cosh(x)	Hyperbolic cosine
tanh(x)	Hyperbolic tangent	erf(x)	Error function
erfc(x)	Complementary Error function	abs(x)	Absolute value
min(x,y)	Minimum of two values	max(x,y)	Maximum of two values
delta(x)	delta(x) is 1 for $x = 0$ , otherwise 0	step(x)	step(x) is 0 for $x < 0$ , otherwise 1

Numbers may be given in either decimal or exponential form. All of the following are valid numbers: 5, -3.1, 1e6, and 3.12e-2.

As an extension to the standard Lepton syntax, it is also possible to use LAMMPS *variables* in the format “v\_name”. Before evaluating the expression, “v\_name” will be replaced with the value of the variable “name”. This is compatible with all kinds of scalar variables, but not with vectors, arrays, local, or per-atom variables. If necessary, a custom scalar variable needs to be defined that can access the desired (single) item from a non-scalar variable. As an example, the following lines will instruct LAMMPS to ramp the force constant for a harmonic bond from 100.0 to 200.0 during the next run:

```
variable fconst equal ramp(100.0, 200)
bond_style lepton
bond_coeff 1 1.5 "v_fconst * (r^2)"
```

An expression may be followed by definitions for intermediate values that appear in the expression. A semicolon “;” is used as a delimiter between value definitions. For example, the expression:

```
a^2+a*b+b^2; a=a1+a2; b=b1+b2
```

is exactly equivalent to

```
(a1+a2)^2+(a1+a2)*(b1+b2)+(b1+b2)^2
```

The definition of an intermediate value may itself involve other intermediate values. Whitespace and quotation characters (“” and “”) are ignored. All uses of a value must appear *before* that value’s definition. For efficiency reasons, the expression string is parsed, optimized, and then stored in an internal, pre-parsed representation for evaluation.

Evaluating a Lepton expression is typically between 2.5 and 5 times slower than the corresponding compiled and optimized C++ code. If additional speed or GPU acceleration (via GPU or KOKKOS) is required, the interaction can be represented as a table. Suitable table files can be created either internally using the *pair\_write* or *bond\_write* command or through the Python scripts in the *tools/tabulate* folder.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 5.14.5 Restrictions

This bond style is part of the LEPTON package and only enabled if LAMMPS was built with this package. See the [Build package](#) page for more info.

### 5.14.6 Related commands

*bond\_coeff*, *bond\_style table*, *bond\_write*, *angle\_style lepton*, *dihedral\_style lepton*

### 5.14.7 Default

none

## 5.15 bond\_style mesocnt command

### 5.15.1 Syntax

```
bond_style mesocnt
```

### 5.15.2 Examples

```
bond_style mesocnt
bond_coeff 1 C 10 10 20.0
bond_coeff 4 custom 800.0 10.0
```

### 5.15.3 Description

New in version 15Sep2022.

The *mesocnt* bond style is a wrapper for the *harmonic* style, and uses the potential

$$E = K(r - r_0)^2$$

where  $r_0$  is the equilibrium bond distance. Note that the usual 1/2 factor is included in  $K$ . The style implements parameterization presets of  $K$  for mesoscopic simulations of carbon nanotubes based on the atomistic simulations of (Srivastava).

Other presets can be readily implemented in the future.

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- preset = *C* or *custom*
- additional parameters depending on preset

Preset *C* is for carbon nanotubes, and the additional parameters are:

- chiral index  $n$  (unitless)
- chiral index  $m$  (unitless)
- $r_0$  (distance)

Preset *custom* is simply a direct wrapper for the *harmonic* style, and the additional parameters are:

- $K$  (energy/distance<sup>2</sup>)
- $r_0$  (distance)

### 5.15.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE and MESONT packages. See the *Build package* page for more info.

### 5.15.5 Related commands

*bond\_coeff*, *delete\_bonds*

### 5.15.6 Default

none

## 5.16 bond\_style mm3 command

### 5.16.1 Syntax

```
bond_style mm3
```

### 5.16.2 Examples

```
bond_style mm3
bond_coeff 1 100.0 107.0
```

### 5.16.3 Description

The *mm3* bond style uses the potential that is anharmonic in the bond as defined in (*Allinger*)

$$E = K(r - r_0)^2 \left[ 1 - 2.55(r - r_0) + \frac{7}{12}2.55^2(r - r_0)^2 \right]$$

where  $r_0$  is the equilibrium value of the bond, and  $K$  is a prefactor. The anharmonic prefactors have units  $\text{\AA}^{-n}$ :  $-2.55\text{\AA}^{-1}$  and  $\frac{7}{12}2.55^2\text{\AA}^{-2}$ . The code takes care of the necessary unit conversion for these factors internally. Note that the MM3 papers contain an error in Eq (1):  $\frac{7}{12}2.55$  should be replaced with  $\frac{7}{12}2.55^2$

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy/distance<sup>2</sup>)
- $r_0$  (distance)

### 5.16.4 Restrictions

This bond style can only be used if LAMMPS was built with the YAFF package. See the *Build package* doc page for more info.

### 5.16.5 Related commands

*bond\_coeff*

### 5.16.6 Default

none

## 5.17 bond\_style morse command

Accelerator Variants: *morse/omp*

### 5.17.1 Syntax

```
bond_style morse
```

### 5.17.2 Examples

```
bond_style morse
bond_coeff 5 1.0 2.0 1.2
```

### 5.17.3 Description

The *morse* bond style uses the potential

$$E = D \left[ 1 - e^{-\alpha(r-r_0)} \right]^2$$

where  $r_0$  is the equilibrium bond distance,  $\alpha$  is a stiffness parameter, and  $D$  determines the depth of the potential well.

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $D$  (energy)
- $\alpha$  (inverse distance)
- $r_0$  (distance)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

### 5.17.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* page for more info.

### 5.17.5 Related commands

*bond\_coeff*, *delete\_bonds*

### 5.17.6 Default

## 5.18 bond\_style none command

### 5.18.1 Syntax

```
bond_style none
```

### 5.18.2 Examples

```
bond_style none
```

### 5.18.3 Description

Using a bond style of none means bond forces and energies are not computed, even if pairs of bonded atoms were listed in the data file read by the *read\_data* command.

See the *bond\_style zero* command for a way to calculate bond statistics, but compute no bond interactions.

### 5.18.4 Restrictions

none

### 5.18.5 Related commands

none

*bond\_style zero*

### 5.18.6 Default

none

## 5.19 bond\_style nonlinear command

Accelerator Variants: *nonlinear/omp*

### 5.19.1 Syntax

```
bond_style nonlinear
```

### 5.19.2 Examples

```
bond_style nonlinear
bond_coeff 2 100.0 1.1 1.4
```

### 5.19.3 Description

The *nonlinear* bond style uses the potential

$$E = \frac{\epsilon(r - r_0)^2}{[\lambda^2 - (r - r_0)^2]}$$

to define an anharmonic spring (*Rector*) of equilibrium length  $r_0$  and maximum extension  $\lambda$ .

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $\epsilon$  (energy)
- $r_0$  (distance)
- $\lambda$  (distance)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 5.19.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) page for more info.

## 5.20 bond\_style oxdna/fene command

## 5.21 bond\_style oxdna2/fene command

## 5.22 bond\_style oxrna2/fene command

### 5.22.1 Syntax

```
bond_style oxdna/fene
bond_style oxdna2/fene
bond_style oxrna2/fene
```

### 5.22.2 Examples

```
# LJ units
bond_style oxdna/fene
bond_coeff * 2.0 0.25 0.7525

bond_style oxdna2/fene
bond_coeff * 2.0 0.25 0.7564

bond_style oxrna2/fene
bond_coeff * 2.0 0.25 0.76107

bond_style oxdna/fene
bond_coeff * oxdna_lj.cgdna

# Real units
```

(continues on next page)

(continued from previous page)

```

bond_style oxdna/fene
bond_coeff * 11.92337812042065 2.1295 6.409795

bond_style oxdna2/fene
bond_coeff * 11.92337812042065 2.1295 6.4430152

bond_style oxrna2/fene
bond_coeff * 11.92337812042065 2.1295 6.482800913

bond_style oxrna2/fene
bond_coeff * oxrna2_real.cgdna

```

**Note:** The coefficients in the above examples have to be kept fixed and cannot be changed without reparameterizing the entire model. They are provided in forms compatible with both *units lj* and *units real* (see documentation of *units*). These can also be read from a potential file with correct unit style by specifying the name of the file. Several potential files for each unit style are included in the `potentials` directory of the LAMMPS distribution.

### 5.22.3 Description

The *oxdna/fene*, *oxdna2/fene*, and *oxrna2/fene* bond styles use the potential

$$E = -\frac{\epsilon}{2} \ln \left[ 1 - \left( \frac{r - r_0}{\Delta} \right)^2 \right]$$

to define a modified finite extensible nonlinear elastic (FENE) potential (*Ouldridge*) to model the connectivity of the phosphate backbone in the oxDNA/oxRNA force field for coarse-grained modelling of DNA/RNA.

The following coefficients must be defined for the bond type via the `bond_coeff` command as given in the above example, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $\epsilon$  (energy)
- $\Delta$  (distance)
- $r_0$  (distance)

**Note:** The oxDNA bond style has to be used together with the corresponding oxDNA pair styles for excluded volume interaction *oxdna/excv*, stacking *oxdna/stk*, cross-stacking *oxdna/xstk* and coaxial stacking interaction *oxdna/coaxstk* as well as hydrogen-bonding interaction *oxdna/hbond* (see also documentation of *pair\_style oxdna/excv*). For the oxDNA2 (*Snodin*) bond style the analogous pair styles *oxdna2/excv*, *oxdna2/stk*, *oxdna2/xstk*, *oxdna2/coaxstk*, *oxdna2/hbond* and an additional Debye-Hueckel pair style *oxdna2/dh* have to be defined. The same applies to the oxRNA2 (*Sulc1*) styles.

**Note:** This bond style has to be used with the *atom\_style hybrid bond ellipsoid oxdna* (see documentation of *atom\_style*). The *atom\_style oxdna* stores the 3'-to-5' polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3'-end (5'-end) of the strand.

**Warning:** If data files are produced with `write_data`, then the `newton` command should be set to `newton on` or `newton off on`. Otherwise the data files will not have the same 3'-to-5' polarity as the initial data file. This limitation does not apply to binary restart files produced with `write_restart`.

Example input and data files for DNA and RNA duplexes can be found in `examples/PACKAGES/cgdna/examples/oxDNA/``, ``.../oxDNA2/` and `.../oxRNA2/`. A simple python setup tool which creates single straight or helical DNA strands, DNA/RNA duplexes or arrays of DNA/RNA duplexes can be found in `examples/PACKAGES/cgdna/util/`.

Please cite ([Henrich](#)) in any publication that uses this implementation. An updated documentation that contains general information on the model, its implementation and performance as well as the structure of the data and input file can be found [here](#).

Please cite also the relevant oxDNA/oxRNA publications. These are ([Ouldridge](#)) and ([Ouldridge-DPhil](#)) for oxDNA, ([Snodin](#)) for oxDNA2, ([Sulc1](#)) for oxRNA2 and for sequence-specific hydrogen-bonding and stacking interactions ([Sulc2](#)).

---

### 5.22.4 Potential file reading

For each style `oxdna`, `oxdna2` and `oxrna2`, the first parameter argument can be a filename, and if it is, no further arguments should be supplied. Therefore the following command:

```
bond_style oxdna/fene
bond_coeff * oxdna_lj.cgdna
```

will be interpreted as a request to read the (FENE) potential ([Ouldridge](#)) parameters from the file with the given name. The file can define multiple potential parameters for both bonded and pair interactions, but for the above bonded interactions there must exist in the file a line of the form:

```
* fene epsilon delta r0
```

There are sample potential files for each unit style in the `potentials` directory of the LAMMPS distribution. The potential file unit system must align with the units defined via the `units` command. For conversion between different *LJ* and *real* unit systems for oxDNA, the python tool `lj2real.py` located in the `examples/PACKAGES/cgdna/util/` directory can be used. This tool assumes similar file structure to the examples found in `examples/PACKAGES/cgdna/examples/`.

---

### 5.22.5 Restrictions

This bond style can only be used if LAMMPS was built with the CG-DNA package and the MOLECULE and ASPHERE package. See the [Build package](#) page for more info.

### 5.22.6 Related commands

*pair\_style oxdna/excv*, *pair\_style oxdna2/excv*, *pair\_style oxrna2/excv*, *bond\_coeff*, *atom\_style oxdna*, *fix nve/dotc/langevin*

## 5.23 bond\_style quartic command

Accelerator Variants: *quartic/omp*

### 5.23.1 Syntax

```
bond_style quartic
```

### 5.23.2 Examples

```
bond_style quartic
bond_coeff 2 1200 -0.55 0.25 1.3 34.6878
```

### 5.23.3 Description

The *quartic* bond style uses the potential

$$E = E_q + E_{LJ}$$

$$E_q = K(r - R_c)^2(r - R_c - B_1)(r - R_c - B_2) + U_0$$

$$E_{LJ} = \begin{cases} 4\epsilon \left[ \left(\frac{\sigma}{r}\right)^{12} - \left(\frac{\sigma}{r}\right)^6 \right] + \epsilon & : r < 2^{\frac{1}{6}}, \epsilon = 1, \sigma = 1 \\ 0 & : r \geq 2^{\frac{1}{6}} \end{cases}$$

to define a bond that can be broken as the simulation proceeds (e.g. due to a polymer being stretched). The  $\sigma$  and  $\epsilon$  used in the LJ portion of the formula are both set equal to 1.0 by LAMMPS and the LJ portion is cut off at its minimum, i.e. at  $r_c = 2^{\frac{1}{6}}$ .

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy/distance<sup>4</sup>)
- $B_1$  (distance)
- $B_2$  (distance)
- $R_c$  (distance)
- $U_0$  (energy)

This potential was constructed to mimic the FENE bond potential for coarse-grained polymer chains. When monomers with  $\sigma = \epsilon = 1.0$  are used, the following choice of parameters gives a quartic potential that looks nearly like the FENE potential:

$$\begin{aligned}K &= 1200 \\B_1 &= -0.55 \\B_2 &= 0.25 \\R_c &= 1.3 \\U_0 &= 34.6878\end{aligned}$$

Different parameters can be specified using the *bond\_coeff* command, but you will need to choose them carefully so they form a suitable bond potential.

$R_c$  is the cutoff length at which the bond potential goes smoothly to a local maximum. If a bond length ever becomes  $> R_c$ , LAMMPS “breaks” the bond, which means two things. First, the bond potential is turned off by setting its type to 0, and is no longer computed. Second, a pairwise interaction between the two atoms is turned on, since they are no longer bonded. See the *Howto* page on broken bonds for more information.

LAMMPS does the second task via a computational sleight-of-hand. It subtracts the pairwise interaction as part of the bond computation. When the bond breaks, the subtraction stops. For this to work, the pairwise interaction must always be computed by the *pair\_style* command, whether the bond is broken or not. This means that *special\_bonds* must be set to 1,1,1, as indicated as a restriction below.

Note that when bonds are dumped to a file via the *dump local* command, bonds with type 0 are not included. The *delete\_bonds* command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```
delete_bonds all stats
delete_bonds all bond 0 remove
```

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 5.23.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) page for more info.

The *quartic* style requires that *special\_bonds* parameters be set to 1,1,1. Three- and four-body interactions (angle, dihedral, etc) cannot be used with *quartic* bonds.

### 5.23.5 Related commands

*bond\_coeff*, *delete\_bonds*

### 5.23.6 Default

none

## 5.24 bond\_style rheo/shell command

### 5.24.1 Syntax

```
bond_style rheo/shell keyword value attribute1 attribute2 ...
```

- required keyword = *t/form*
- optional keyword = *store/local*

*t/form* value = formation time for a bond (time units)

*store/local* values = fix\_ID N attributes ...

- \* fix\_ID = ID of associated internal fix to store data
- \* N = prepare data for output every this many timesteps
- \* attributes = zero or more of the below attributes may be appended

*id1*, *id2* = IDs of two atoms in the bond

*time* = the timestep the bond broke

*x*, *y*, *z* = the center of mass position of the two atoms when the bond broke.↵

↵(distance units)

*x/ref*, *y/ref*, *z/ref* = the initial center of mass position of the two atoms.↵

↵(distance units)

### 5.24.2 Examples

```
bond_style rheo/shell t/form 10.0
bond_coeff 1 1.0 0.05 0.1
```

### 5.24.3 Description

New in version 29Aug2024.

The *rheo/shell* bond style is designed to work with *fix rheo/oxidation* which creates candidate bonds between eligible surface or near-surface particles. When a bond is first created, it computes no forces and starts a timer. Forces are not computed until the timer reaches the specified bond formation time, *tform*, and the bond is enabled and applies forces. If the two particles move outside of the maximum bond distance or move into the bulk before the timer reaches *tform*, the bond automatically deletes itself. This deletion is not recorded as a broken bond in the optional *store/local* fix.

Before bonds are enabled, they are still treated as regular bonds by all other parts of LAMMPS. This means they are written to data files and counted in computes such as *nbond/atom*. To only count enabled bonds, use the *nbond/shell* attribute in *compute rheo/property/atom*.

When enabled, the bond then computes forces based on deviations from the initial reference state of the two atoms much like a BPM style bond (as further discussed in the *BPM howto page*). The reference state is stored by each bond when it is first enabled. Data is then preserved across run commands and is written to *binary restart files* such that restarting the system will not reset the reference state of a bond or the timer.

This bond style is based on a model described in (*Clemmer*). The force has a magnitude of

$$F = 2k(r - r_0) + \frac{2k}{r_0^2 \epsilon_c^2} (r - r_0)^3$$

where *k* is a stiffness, *r* is the current distance and *r*<sub>0</sub> is the initial distance between the two particles, and  $\epsilon_c$  is maximum strain beyond which a bond breaks. This is done by setting the bond type to 0 such that forces are no longer computed.

A damping force proportional to the difference in the normal velocity of particles is also applied to bonded particles:

$$F_D = -\gamma w(\hat{r} \bullet \vec{v})$$

where  $\gamma$  is the damping strength,  $\hat{r}$  is the displacement normal vector, and  $\vec{v}$  is the velocity difference between the two particles.

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *k* (force/distance units)
- $\epsilon_c$  (unit less)
- $\gamma$  (force/velocity units)

Unlike other BPM-style bonds, this bond style does not update special bond settings when bonds are created or deleted. This bond style also does not enforce specific *special\_bonds* settings. This behavior is purposeful such *RHEO pair* forces and heat flows are still calculated.

If the *store/local* keyword is used, an internal fix will track bonds that break during the simulation. Whenever a bond breaks, data is processed and transferred to an internal fix labeled *fix\_ID*. This allows the local data to be accessed by other LAMMPS commands. Following this optional keyword, a list of one or more attributes is specified. These include the IDs of the two atoms in the bond. The other attributes for the two atoms include the timestep during which the bond broke and the current/initial center of mass position of the two atoms.

Data is continuously accumulated over intervals of *N* timesteps. At the end of each interval, all of the saved accumulated data is deleted to make room for new data. Individual datum may therefore persist anywhere between 1 to *N* timesteps depending on when they are saved. This data can be accessed using the *fix\_ID* and a *dump local* command. To ensure all data is output, the dump frequency should correspond to the same interval of *N* timesteps. A dump frequency of an integer multiple of *N* can be used to regularly output a sample of the accumulated data.

Note that when unbroken bonds are dumped to a file via the *dump local* command, bonds with type 0 (broken bonds) are not included. The *delete\_bonds* command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```
delete_bonds all stats
delete_bonds all bond 0 remove
```

### 5.24.4 Restart and other info

This bond style writes the reference state of each bond to *binary restart files*. Loading a restart file will properly restore bonds. However, the reference state is NOT written to data files. Therefore reading a data file will not restore bonds and will cause their reference states to be redefined.

If the *store/local* option is used, an internal fix will calculate a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of recorded, broken bonds. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array will be floating point values that correspond to the specified attribute.

The `single()` function of this bond style returns 0.0 for the energy of a bonded interaction, since energy is not conserved in these dissipative potentials. The `single()` function also calculates two extra bond quantities, the initial distance  $r_0$  and a time. These extra quantities can be accessed by the *compute bond/local* command as *b1* and *b2*.

### 5.24.5 Restrictions

This bond style is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 5.24.6 Related commands

*bond\_coeff*, *fix rheo/oxidation*

### 5.24.7 Default

NA

(Clemmer) Clemmer, Pierce, O'Connor, Nevins, Jones, Lechman, Tencer, Appl. Math. Model., 130, 310-326 (2024).

## 5.25 bond\_style special command

### 5.25.1 Syntax

```
bond_style special
```

## 5.25.2 Examples

```
bond_style special
bond_coeff 0.5 0.5
```

## 5.25.3 Description

The *special* bond style can be used to create conceptual bonds which effectively impose weightings on the pairwise Lennard Jones and/or Coulombic interactions between selected pairs of particles in the system. The form of the pairwise interaction will be whatever is computed by the *pair\_style* command defined for the system; this command defines the weightings for its two terms.

This command can thus be useful to apply weightings that cannot be handled by the *special\_bonds* command, such as on 1-5 or 1-6 interactions. Or it can be used to add pairwise forces between one or more pairs of atoms that otherwise would not be include in the *pair\_style* computation.

The potential for this bond style has the form

$$E = w_{LJ}E_{LJ} + w_{Coul}E_{Coul}$$

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $w_{LJ}$  weight (0.0 to 1.0) on pairwise Lennard-Jones interactions
- $w_{Coul}$  weight (0.0 to 1.0) on pairwise Coulombic interactions

---

Normally this bond style should be used in conjunction with one (or more) other bond styles which compute forces between atoms directly bonded to each other in a molecule. This means the *bond\_style hybrid* command should be used with *bond\_style special* as one of its sub-styles.

Note that the same as for any other bond style, pairs of bonded atoms must be enumerated in the data file read by the *read\_data* command. Thus if this command is used to weight all 1-5 interactions in the system, all the 1-5 pairs of atoms must be listed in the “Bonds” section of the data file.

This bond style imposes strict requirements on settings made with the *special\_bonds* command. These requirements ensure that the new bonds created by this style do not create spurious 1-2, 1-3, or 1-4 interactions within the molecular topology.

Specifically 1-2 interactions must have weights of zero, 1-3 interactions must either have weights of unity or *special\_bonds angle yes* must be used, and 1-4 interactions must have weights of unity or *special\_bonds dihedral yes* must be used.

If this command is used to create bonded interactions between particles that are further apart than usual (e.g. 1-5 or 1-6 interactions), this style may require an increase in the communication cutoff via the *comm\_modify cutoff* command. If LAMMPS cannot find a partner atom in a bond, an error will be issued.

### 5.25.4 Restrictions

This bond style can only be used if LAMMPS was built with the MISC package. See the [Build package](#) doc page for more info.

This bond style requires the use of a [pair\\_style](#) which computes a pairwise additive interaction and provides the ability to compute interactions for individual pairs of atoms. Manybody potentials are not compatible in general, but also some other pair styles are missing the required functionality and thus will cause an error.

This command is not compatible with long-range Coulombic interactions. If a *kspace\_style* <*kspace\_style*> is declared, an error will be issued.

### 5.25.5 Related commands

*bond\_coeff*, *special\_bonds*

### 5.25.6 Default

none

## 5.26 bond\_style table command

Accelerator Variants: *table/omp*

### 5.26.1 Syntax

```
bond_style table style N
```

- style = *linear* or *spline* = method of interpolation
- N = use N values in table

### 5.26.2 Examples

```
bond_style table linear 1000
bond_coeff 1 file.table ENTRY1
```

### 5.26.3 Description

Style *table* creates interpolation tables of length *N* from bond potential and force values listed in a file(s) as a function of bond length. The files are read by the [bond\\_coeff](#) command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of *N* distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 2 styles: *linear* or *spline*.

For the *linear* style, the bond length is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the *spline* style, a cubic spline coefficients are computed and stored at each of the  $N$  values in the table. The bond length is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

The following coefficients must be defined for each bond type via the *bond\_coeff* command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The format of this file is described below.

---

Suitable tables for use with this bond style can be created by LAMMPS itself from existing bond styles using the *bond\_write* command. This can be useful to have a template file for testing the bond style settings and to build a compatible custom file. Another option to generate tables is the Python code in the `tools/tabulate` folder of the LAMMPS source code distribution.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Bond potential for harmonic (one or more comment or blank lines)

HAM                                (keyword is the first text on line)
N 101 FP 0 0 EQ 0.5              (N, FP, EQ parameters)
                                (blank line)
1 0.00 338.0000 1352.0000        (index, bond-length, energy, force)
2 0.01 324.6152 1324.9600
...
101 1.00 338.0000 -1352.0000
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the *bond\_coeff* command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the  $N$  specified in the *bond\_style table* command. Let  $N_{\text{table}} = N$  in the *bond\_style* command, and  $N_{\text{file}} = “N”$  in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the  $N_{\text{file}}$  tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at  $N_{\text{table}}$  different points. The resulting tables of length  $N_{\text{table}}$  are then used as described above, when computing energy and force for individual bond lengths. This means that if you want the interpolation tables of length  $N_{\text{table}}$  to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set  $N_{\text{table}} = N_{\text{file}}$ .

The “FP” parameter is optional. If used, it is followed by two values *fplo* and *fphi*, which are the derivatives of the force at the innermost and outermost bond lengths. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two force values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium bond length, which is used, for example, by the *fix shake* command. If not used, the equilibrium bond length is to the distance in the table with the lowest potential energy.

Following a blank line, the next  $N$  lines list the tabulated values. On each line, the first value is the index from 1 to  $N$ , the second value is the bond length  $r$  (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The bond lengths must range from a LO value to a HI value, and increase from one line to the next. If the actual bond length is ever smaller than the LO value or larger than the HI value, then the calculation is aborted with an error, so it is advisable to cover the whole range of possible bond lengths.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 5.26.4 Restart info

This bond style writes the settings for the “bond\_style table” command to *binary restart files*, so a bond\_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, bond\_coeff commands do need to be specified in the restart input script.

## 5.26.5 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) page for more info.

## 5.26.6 Related commands

*bond\_coeff*, *delete\_bonds*, *bond\_write*

## 5.26.7 Default

none

# 5.27 bond\_style zero command

## 5.27.1 Syntax

**bond\_style** zero keyword

- zero or more keywords may be appended
- keyword = *nocoeff*

### 5.27.2 Examples

```
bond_style zero
bond_style zero nocoeff
bond_coeff *
bond_coeff * 2.14
```

### 5.27.3 Description

Using an bond style of zero means bond forces and energies are not computed, but the geometry of bond pairs is still accessible to other commands.

As an example, the *compute bond/local* command can be used to compute distances for the list of pairs of bond atoms listed in the data file read by the *read\_data* command. If no bond style is defined, this command cannot be used.

The optional *nocoeff* flag allows to read data files with a BondCoeff section for any bond style. Similarly, any bond\_coeff commands will only be checked for the bond type number and the rest ignored.

Note that the *bond\_coeff* command must be used for all bond types. If specified, there can be only one value, which is going to be used to assign an equilibrium distance, e.g. for use with *fix shake*.

### 5.27.4 Restrictions

none

### 5.27.5 Related commands

*bond\_style none*

### 5.27.6 Default

## ANGLE STYLES

### 6.1 angle\_style amoeba command

#### 6.1.1 Syntax

```
angle_style amoeba
```

#### 6.1.2 Examples

```
angle_style amoeba
angle_coeff * 75.0 -25.0 1.0 0.3 0.02 0.003
angle_coeff * ba 3.6551 24.895 1.0119 1.5228
angle_coeff * ub -7.6 1.5537
```

#### 6.1.3 Description

The *amoeba* angle style uses the potential

$$\begin{aligned}
 E &= E_a + E_{ba} + E_{ub} \\
 E_a &= K_2 (\theta - \theta_0)^2 + K_3 (\theta - \theta_0)^3 + K_4 (\theta - \theta_0)^4 + K_5 (\theta - \theta_0)^5 + K_6 (\theta - \theta_0)^6 \\
 E_{ba} &= N_1 (r_{ij} - r_1)(\theta - \theta_0) + N_2 (r_{jk} - r_2)(\theta - \theta_0) \\
 E_{UB} &= K_{ub} (r_{ik} - r_{ub})^2
 \end{aligned}$$

where  $E_a$  is the angle term,  $E_{ba}$  is a bond-angle term,  $E_{UB}$  is a Urey-Bradley bond term,  $\theta_0$  is the equilibrium angle,  $r_1$  and  $r_2$  are the equilibrium bond lengths, and  $r_{ub}$  is the equilibrium Urey-Bradley bond length.

These formulas match how the Tinker MD code performs its angle calculations for the AMOEBA and HIPPO force fields. See the [Howto amoeba](#) page for more information about the implementation of AMOEBA and HIPPO in LAMMPS.

Note that the  $E_a$  and  $E_{ba}$  formulas are identical to those used for the [angle\\_style class2/p6](#) command, however there is no bond-bond cross term formula for  $E_{bb}$ . Additionally, there is a  $E_{UB}$  term for a Urey-Bradley bond. It is effectively a harmonic bond between the I and K atoms of angle IJK, even though that bond is not enumerated in the “Bonds” section of the data file.

There are also two ways that Tinker computes the angle  $\theta$  in the  $E_a$  formula. The first is the standard way of treating IJK as an “in-plane” angle. The second is an “out-of-plane” method which Tinker may use if the center atom J in the angle is bonded to one additional atom in addition to I and K. In this case, all 4 atoms are used to compute the  $E_a$  formula, resulting in forces on all 4 atoms. In the Tinker PRM file, these 2 options are denoted by *angle* versus *anglep*

entries in the “Angle Bending Parameters” section of the PRM force field file. The *pflag* coefficient described below selects between the 2 options.

---

Coefficients for the  $E_a$ ,  $E_{bb}$ , and  $E_{ub}$  formulas must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands.

These are the 8 coefficients for the  $E_a$  formula:

- *pflag* = 0 or 1
- *ubflag* = 0 or 1
- $\theta_0$  (degrees)
- $K_2$  (energy)
- $K_3$  (energy)
- $K_4$  (energy)
- $K_5$  (energy)
- $K_6$  (energy)

A *pflag* value of 0 vs 1 selects between the “in-plane” and “out-of-plane” options described above. *Ubflag* is 1 if there is a Urey-Bradley term associated with this angle type, else it is 0.  $\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence the various  $K$  values are effectively energy per radian<sup>2</sup> or radian<sup>3</sup> or radian<sup>4</sup> or radian<sup>5</sup> or radian<sup>6</sup>.

For the  $E_{ba}$  formula, each line in a *angle\_coeff* command in the input script lists 5 coefficients, the first of which is “ba” to indicate they are BondAngle coefficients. In a data file, these coefficients should be listed under a “BondAngle Coeffs” heading and you must leave out the “ba”, i.e. only list 4 coefficients after the angle type.

- ba
- $N_1$  (energy/distance<sup>2</sup>)
- $N_2$  (energy/distance<sup>2</sup>)
- $r_1$  (distance)
- $r_2$  (distance)

The  $\theta_0$  value in the  $E_{ba}$  formula is not specified, since it is the same value from the  $E_a$  formula.

For the  $E_{ub}$  formula, each line in a *angle\_coeff* command in the input script lists 3 coefficients, the first of which is “ub” to indicate they are UreyBradley coefficients. In a data file, these coefficients should be listed under a “UreyBradley Coeffs” heading and you must leave out the “ub”, i.e. only list 2 coefficients after the angle type.

- ub
  - $K_{ub}$  (energy/distance<sup>2</sup>)
  - $r_{ub}$  (distance)
-

### 6.1.4 Restrictions

This angle style can only be used if LAMMPS was built with the AMOEBA package. See the [Build package](#) doc page for more info.

### 6.1.5 Related commands

*angle\_coeff*

### 6.1.6 Default

none

## 6.2 angle\_style charmm command

Accelerator Variants: *charmm/intel*, *charmm/kk*, *charmm/omp*

### 6.2.1 Syntax

```
angle_style charmm
```

### 6.2.2 Examples

```
angle_style charmm
angle_coeff 1 300.0 107.0 50.0 3.0
```

### 6.2.3 Description

The *charmm* angle style uses the potential

$$E = K(\theta - \theta_0)^2 + K_{ub}(r - r_{ub})^2$$

with an additional Urey-Bradley term based on the distance  $r$  between the first and third atoms in the angle.  $K$ ,  $\theta_0$ ,  $K_{ub}$ , and  $r_{ub}$  are coefficients defined for each angle type.

See ([MacKerell](#)) for a description of the CHARMM force field.

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\theta_0$  (degrees)
- $K_{ub}$  (energy/distance<sup>2</sup>)
- $r_{ub}$  (distance)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 6.2.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

## 6.2.5 Related commands

## 6.3 angle\_style class2 command

Accelerator Variants: *class2/kk*, *class2/omp*

## 6.4 angle\_style class2/p6 command

### 6.4.1 Syntax

```
angle_style class2
```

## 6.4.2 Examples

```
angle_style class2
angle_coeff * 75.0 25.0 0.3 0.002
angle_coeff 1 bb 10.5872 1.0119 1.5228
angle_coeff * ba 3.6551 24.895 1.0119 1.5228
```

## 6.4.3 Description

The *class2* angle style uses the potential

$$\begin{aligned}
 E &= E_a + E_{bb} + E_{ba} \\
 E_a &= K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4 \\
 E_{bb} &= M(r_{ij} - r_1)(r_{jk} - r_2) \\
 E_{ba} &= N_1(r_{ij} - r_1)(\theta - \theta_0) + N_2(r_{jk} - r_2)(\theta - \theta_0)
 \end{aligned}$$

where  $E_a$  is the angle term,  $E_{bb}$  is a bond-bond term, and  $E_{ba}$  is a bond-angle term.  $\theta_0$  is the equilibrium angle and  $r_1$  and  $r_2$  are the equilibrium bond lengths.

See (Sun) for a description of the COMPASS *class2* force field.

Coefficients for the  $E_a$ ,  $E_{bb}$ , and  $E_{ba}$  formulas must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands.

These are the 4 coefficients for the  $E_a$  formula:

- $\theta_0$  (degrees)
- $K_2$  (energy)
- $K_3$  (energy)
- $K_4$  (energy)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence the various  $K$  are effectively energy per radian<sup>2</sup> or radian<sup>3</sup> or radian<sup>4</sup>.

For the  $E_{bb}$  formula, each line in a *angle\_coeff* command in the input script lists 4 coefficients, the first of which is “bb” to indicate they are BondBond coefficients. In a data file, these coefficients should be listed under a “BondBond Coeffs” heading and you must leave out the “bb”, i.e. only list 3 coefficients after the angle type.

- bb
- $M$  (energy/distance<sup>2</sup>)
- $r_1$  (distance)
- $r_2$  (distance)

For the  $E_{ba}$  formula, each line in a *angle\_coeff* command in the input script lists 5 coefficients, the first of which is “ba” to indicate they are BondAngle coefficients. In a data file, these coefficients should be listed under a “BondAngle Coeffs” heading and you must leave out the “ba”, i.e. only list 4 coefficients after the angle type.

- ba
- $N_1$  (energy/distance)
- $N_2$  (energy/distance)
- $r_1$  (distance)

- $r_2$  (distance)

The  $\theta_0$  value in the  $E_{ba}$  formula is not specified, since it is the same value from the  $E_a$  formula.

---

**Note:** It is important that the order of the I,J,K atoms in each angle listed in the Angles section of the data file read by the `read_data` command be consistent with the order of the  $r_1$  and  $r_2$  BondBond and BondAngle coefficients. This is because the terms in the formulas for  $E_{bb}$  and  $E_{ba}$  will use the I,J atoms to compute  $r_{ij}$  and the J,K atoms to compute  $r_{jk}$ .

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

The *class2/p6* angle style uses the *class2* potential expanded to sixth order:

$$E_a = K_2 (\theta - \theta_0)^2 + K_3 (\theta - \theta_0)^3 + K_4 (\theta - \theta_0)^4 + K_5 (\theta - \theta_0)^5 + K_6 (\theta - \theta_0)^6$$

In this expanded term 6 coefficients for the  $E_a$  formula need to be set:

- $\theta_0$  (degrees)
- $K_2$  (energy)
- $K_3$  (energy)
- $K_4$  (energy)
- $K_5$  (energy)
- $K_6$  (energy)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence the various  $K$  are effectively energy per radian<sup>2</sup> or radian<sup>3</sup> or radian<sup>4</sup> or radian<sup>5</sup> or radian<sup>6</sup>.

The bond-bond and bond-angle terms remain unchanged.

---

## 6.4.4 Restrictions

This angle style can only be used if LAMMPS was built with the CLASS2 package. For the *class2/p6* style LAMMPS needs to be built with the MOFFF package. See the [Build package](#) doc page for more info.

## 6.4.5 Related commands

# 6.5 angle\_style cosine command

Accelerator Variants: *cosine/omp*, *cosine/kk*

## 6.5.1 Syntax

```
angle_style cosine
```

## 6.5.2 Examples

```
angle_style cosine
angle_coeff * 75.0
```

## 6.5.3 Description

The *cosine* angle style uses the potential

$$E = K[1 + \cos(\theta)]$$

where *K* is defined for each angle type.

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *K* (energy)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 6.5.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

### 6.5.5 Related commands

*angle\_coeff*

### 6.5.6 Default

none

## 6.6 angle\_style cosine/buck6d command

### 6.6.1 Syntax

```
angle_style cosine/buck6d
```

### 6.6.2 Examples

```
angle_style cosine/buck6d
angle_coeff 1 cosine/buck6d 1.978350 4 180.000000
```

### 6.6.3 Description

The *cosine/buck6d* angle style uses the potential

$$E = K [1 + \cos(n\theta - \theta_0)]$$

where  $K$  is the energy constant,  $n$  is the periodic multiplicity and  $\theta_0$  is the equilibrium angle.

The coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands in the following order:

- $K$  (energy)
- $n$
- $\theta_0$  (degrees)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally.

Additional to the cosine term the *cosine/buck6d* angle style computes the short range (vdW) interaction belonging to the *pair\_style buck6d* between the end atoms of the angle. For this reason this angle style only works in combination with the *pair\_style buck6d* styles and needs the *special\_bonds* 1-3 interactions to be weighted 0.0 to prevent double counting.

## 6.6.4 Restrictions

*cosine/buck6d* can only be used in combination with the *pair\_style buck6d* style and with a *special\_bonds* 0.0 weighting of 1-3 interactions.

This angle style can only be used if LAMMPS was built with the MOFFF package. See the *Build package* doc page for more info.

## 6.6.5 Related commands

```
angle_style cosine/delta
```

## 6.7.2 Examples

```
angle_style cosine/delta
angle_coeff 2*4 75.0 100.0
```

## 6.7.3 Description

The *cosine/delta* angle style uses the potential

$$E = K[1 - \cos(\theta - \theta_0)]$$

where  $\theta_0$  is the equilibrium value of the angle, and  $K$  is a prefactor. Note that the usual 1/2 factor is included in  $K$ .

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\theta_0$  (degrees)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages*

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 6.7.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

## 6.7.5 Related commands

*angle\_coeff*, *angle\_style cosine/squared*

## 6.7.6 Default

none

# 6.8 angle\_style cosine/periodic command

Accelerator Variants: *cosine/periodic/omp*

## 6.8.1 Syntax

```
angle_style cosine/periodic
```

## 6.8.2 Examples

```
angle_style cosine/periodic
angle_coeff * 75.0 1 6
```

### 6.8.3 Description

The *cosine/periodic* angle style uses the following potential, which may be particularly used for organometallic systems where  $n = 4$  might be used for an octahedral complex and  $n = 3$  might be used for a trigonal center:

$$E = \frac{2.0}{n^2} * C [1 - B(-1)^n \cos(n\theta)]$$

where  $C$ ,  $B$  and  $n$  are coefficients defined for each angle type.

The following coefficients must be defined for each angle type via the [angle\\_coeff](#) command as in the example above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $C$  (energy)
- $B = 1$  or  $-1$
- $n = 1, 2, 3, 4, 5$  or  $6$  for periodicity

Note that the prefactor  $C$  is specified as coefficient and not the overall force constant  $K = \frac{2C}{n^2}$ . When  $B = 1$ , it leads to a minimum for the linear geometry. When  $B = -1$ , it leads to a maximum for the linear geometry.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

## 6.9 angle\_style cosine/shift command

Accelerator Variants: *cosine/shift/omp*

### 6.9.1 Syntax

```
angle_style cosine/shift
```

### 6.9.2 Examples

```
angle_style cosine/shift
angle_coeff * 10.0 45.0
```

### 6.9.3 Description

The *cosine/shift* angle style uses the potential

$$E = -\frac{U_{\min}}{2} [1 + \cos(\theta - \theta_0)]$$

where  $\theta_0$  is the equilibrium angle. The potential is bounded between  $-U_{\min}$  and zero. In the neighborhood of the minimum  $E = -U_{\min} + U_{\min}/4(\theta - \theta_0)^2$  hence the spring constant is  $\frac{U_{\min}}{2}$ .

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $U_{\min}$  (energy)
- $\theta$  (angle)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

---

## 6.9.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

## 6.9.5 Related commands

*angle\_coeff*, *angle\_style cosine/shift/exp*

## 6.9.6 Default

none

# 6.10 angle\_style cosine/shift/exp command

Accelerator Variants: *cosine/shift/exp/omp*

## 6.10.1 Syntax

```
angle_style cosine/shift/exp
```

## 6.10.2 Examples

```
angle_style cosine/shift/exp
angle_coeff * 10.0 45.0 2.0
```

## 6.10.3 Description

The *cosine/shift/exp* angle style uses the potential

$$E = -U_{\min} \frac{e^{-aU(\theta, \theta_0)} - 1}{e^a - 1} \quad \text{with} \quad U(\theta, \theta_0) = -0.5 (1 + \cos(\theta - \theta_0))$$

where  $U_{\min}$ ,  $\theta$ , and  $a$  are defined for each angle type.

The potential is bounded between  $[-U_{\min}, 0]$  and the minimum is located at the angle  $\theta_0$ . The  $a$  parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by  $k = A \exp(A) U_{\min} / [2(\exp(a) - 1)]$ . For  $a > 3$ ,  $\frac{k}{U_{\min}} = \frac{a}{2}$  to better than 5% relative error. For negative values of the  $a$  parameter, the spring constant is essentially zero, and anharmonic terms takes over. The potential is furthermore well behaved in the limit  $a \rightarrow 0$ , where it has been implemented to linear order in  $a$  for  $a < 0.001$ . In this limit the potential reduces to the cosineshifted potential.

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $U_{\min}$  (energy)
- $\theta$  (angle)

- $A$  (real number)
- 

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. ```
angle_style cosine/squared/restricted
```

### 6.12.2 Examples

```
angle_style cosine/squared/restricted
angle_coeff 2*4 75.0 100.0
```

### 6.12.3 Description

New in version 17Apr2024.

The *cosine/squared/restricted* angle style uses the potential

$$E = K[\cos(\theta) - \cos(\theta_0)]^2 / \sin^2(\theta)$$

, which is commonly used in the MARTINI force field, where  $\theta_0$  is the equilibrium value of the angle, and  $K$  is a prefactor. Note that the usual 1/2 factor is included in  $K$ .

See ([Bulacu](#)) for a description of the restricted angle for the MARTINI force field.

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\theta_0$  (degrees)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 6.12.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

## 6.12.5 Related commands

*angle\_coeff*

## 6.12.6 Default

none

## 6.13 angle\_style cross command

### 6.13.1 Syntax

```
angle_style cross
```

### 6.13.2 Examples

```
angle_style cross
angle_coeff 1 200.0 100.0 100.0 1.25 1.25 107.0
```

### 6.13.3 Description

The *cross* angle style uses a potential that couples the bond stretches of a bend with the angle stretch of that bend:

$$E = K_{SS} (r_{12} - r_{12,0}) (r_{32} - r_{32,0}) + K_{BS0} (r_{12} - r_{12,0}) (\theta - \theta_0) + K_{BS1} (r_{32} - r_{32,0}) (\theta - \theta_0)$$

where  $r_{12,0}$  is the rest value of the bond length between atom 1 and 2,  $r_{32,0}$  is the rest value of the bond length between atom 3 and 2, and  $\theta_0$  is the rest value of the angle.  $K_{SS}$  is the force constant of the bond stretch-bond stretch term and  $K_{BS0}$  and  $K_{BS1}$  are the force constants of the bond stretch-angle stretch terms.

The following coefficients must be defined for each angle type via the [angle\\_coeff](#) command as in the example above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $K_{SS}$  (energy/distance<sup>2</sup>)
- $K_{BS0}$  (energy/distance)
- $K_{BS1}$  (energy/distance)
- $r_{12,0}$  (distance)
- $r_{32,0}$  (distance)

- $\theta_0$  (degrees)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence the  $K_{BS0}$  and  $K_{BS1}$  are effectively energy/distance per radian.

### 6.13.4 Restrictions

This angle style can only be used if LAMMPS was built with the YAFF package. See the [Build package](#) doc page for more info.

## 6.14 angle\_style dipole command

Accelerator Variants: *dipole/omp*

### 6.14.1 Syntax

```
angle_style dipole
```

### 6.14.2 Examples

```
angle_style dipole
angle_coeff 6 2.1 180.0
```

### 6.14.3 Description

The *dipole* angle style is used to control the orientation of a dipolar atom within a molecule (*Orsi*). Specifically, the *dipole* angle style restrains the orientation of a point dipole  $\mu_j$  (embedded in atom  $j$ ) with respect to a reference (bond) vector  $\vec{r}_{ij} = \vec{r}_i - \vec{r}_j$ , where  $i$  is another atom of the same molecule (typically,  $i$  and  $j$  are also covalently bonded).

It is convenient to define an angle gamma between the ‘free’ vector  $\vec{\mu}_j$  and the reference (bond) vector  $\vec{r}_{ij}$ :

$$\cos \gamma = \frac{\vec{\mu}_j \cdot \vec{r}_{ij}}{\mu_j r_{ij}}$$

The *dipole* angle style uses the potential:

$$E = K(\cos \gamma - \cos \gamma_0)^2$$

where  $K$  is a rigidity constant and gamma0 is an equilibrium (reference) angle.

The torque on the dipole can be obtained by differentiating the potential using the ‘chain rule’ as in appendix C.3 of ([AllenTildesley](#)):

$$\vec{T}_j = \frac{2K(\cos \gamma - \cos \gamma_0)}{\mu_j r_{ij}} \vec{r}_{ij} \times \vec{\mu}_j$$

Example: if  $\gamma_0$  is set to 0 degrees, the torque generated by the potential will tend to align the dipole along the reference direction defined by the (bond) vector  $\vec{r}_{ij}$  (in other words,  $\vec{\mu}_j$  is restrained to point towards atom  $i$ ).

The dipolar torque  $\vec{T}_j$  must be counterbalanced in order to conserve the local angular momentum. This is achieved via an additional force couple generating a torque equivalent to the opposite of  $\vec{T}_j$ :

$$\begin{aligned} -\vec{T}_j &= \vec{r}_{ij} \times \vec{F}_i \\ \vec{F}_j &= -\vec{F}_i \end{aligned}$$

where  $\vec{F}_i$  and  $\vec{F}_j$  are applied on atoms  $i$  and  $j$ , respectively.

The following coefficients must be defined for each angle type via the [angle\\_coeff](#) command as in the example above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $K$  (energy)
- $\gamma_0$  (degrees)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 6.14.4 Restrictions

This angle style can only be used if LAMMPS was built with the DIPOLE package. See the [Build package](#) doc page for more info.

**Note:** In the “Angles” section of the data file, the atom ID  $j$  defining the direction of the dipole vector to restrain must come before the atom ID of the reference atom  $i$ . A third atom ID  $k$  must also be provided to comply with the requirement of a valid angle definition. This atom ID  $k$  should be chosen to be that of an atom bonded to atom  $i$  to avoid errors with “lost angle atoms” when running in parallel. Since the LAMMPS code checks for valid angle definitions, cannot use the same atom ID of either  $i$  or  $j$  (this was allowed and recommended with older LAMMPS versions).

The *newton* command for intramolecular interactions must be “on” (which is the default except when using some accelerator packages).

**Note:** This angle style should **NOT** be used with fix shake.

## 6.15 angle\_style fourier command

Accelerator Variants: *fourier/omp*

### 6.15.1 Syntax

```
angle_style fourier
```

### 6.15.2 Examples

```
angle_style fourier
angle_coeff 75.0 1.0 1.0 1.0
```

### 6.15.3 Description

The *fourier* angle style uses the potential

$$E = K[C_0 + C_1 \cos(\theta) + C_2 \cos(2\theta)]$$

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
  - $C_0$  (real)
  - $C_1$  (real)
  - $C_2$  (real)
- 

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 6.15.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

# 6.16 angle\_style fourier/simple command

Accelerator Variants: *fourier/simple/omp*

## 6.16.1 Syntax

```
angle_style fourier/simple
```

## 6.16.2 Examples

```
angle_style fourier/simple
angle_coeff 100.0 -1.0 1.0
```

## 6.16.3 Description

The *fourier/simple* angle style uses the potential

$$E = K[1.0 + c \cos(n\theta)]$$

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *K* (energy)
- *c* (real)

- *n* (real)
- 

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 6.16.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

### 6.16.5 Related commands

*angle\_coeff*

### 6.16.6 Default

## 6.17 angle\_style gaussian command

### 6.17.1 Syntax

```
angle_style gaussian
```

### 6.17.2 Examples

```
angle_style gaussian  
angle_coeff 1 300.0 2 0.0128 0.375 80.0 0.0730 0.148 123.0
```

### 6.17.3 Description

The *gaussian* angle style uses the potential:

$$E = -k_B T \ln \left( \sum_{i=1}^n \frac{A_i}{w_i \sqrt{\pi/2}} \exp \left( \frac{-2(\theta - \theta_i)^2}{w_i^2} \right) \right)$$

This analytical form is a suitable potential for obtaining mesoscale effective force fields which can reproduce target atomistic distributions (*Milano*).

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $T$  temperature at which the potential was derived
- $n$  (integer  $\geq 1$ )
- $A_1$  ( $> 0$ , radians)
- $w_1$  ( $> 0$ , radians)
- $\theta_1$  (degrees)
- ...
- $A_n$  ( $> 0$ , radians)
- $w_n$  ( $> 0$ , radians)
- $\theta_n$  (degrees)

### 6.17.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the *Build package* doc page for more info.

## 6.18 angle\_style harmonic command

Accelerator Variants: *harmonic/intel*, *harmonic/kk*, *harmonic/omp*

## 6.18.1 Syntax

```
angle_style harmonic
```

## 6.18.2 Examples

```
angle_style harmonic  
angle_coeff 1 300.0 107.0
```

## 6.18.3 Description

The *harmonic* angle style uses the potential

$$E = K(\theta - \theta_0)^2$$

where  $\theta_0$  is the equilibrium value of the angle, and  $K$  is a prefactor. Note that the usual 1/2 factor is included in  $K$ .

The following coefficients must be defined for each angle type via the [angle\\_coeff](#) command as in the example above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $K$  (energy)
- $\theta_0$  (degrees)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 6.18.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

## 6.18.5 Related commands

*angle\_coeff*

## 6.18.6 Default

none

# 6.19 angle\_style hybrid command

Accelerator Variants: *hybrid/kk*

## 6.19.1 Syntax

```
angle_style hybrid style1 style2 ...
```

- style1,style2 = list of one or more angle styles

## 6.19.2 Examples

```
angle_style hybrid harmonic cosine
angle_coeff 1 harmonic 80.0 30.0
angle_coeff 2* cosine 50.0
```

## 6.19.3 Description

The *hybrid* style enables the use of multiple angle styles in one simulation. An angle style is assigned to each angle type. For example, angles in a polymer flow (of angle type 1) could be computed with a *harmonic* potential and angles in the wall boundary (of angle type 2) could be computed with a *cosine* potential. The assignment of angle type to style is made via the *angle\_coeff* command or in the data file.

In the *angle\_coeff* commands, the name of an angle style must be added after the angle type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 *angle\_coeff* commands set angles of angle type 1 to be computed with a *harmonic* potential with coefficients 80.0, 30.0 for  $K$ ,  $\theta_0$ . All other angle types ( $2 - N$ ) are computed with a *cosine* potential with coefficient 50.0 for  $K$ .

If angle coefficients are specified in the data file read via the *read\_data* command, then the same rule applies. E.g. “harmonic” or “cosine”, must be added after the angle type, for each line in the “Angle Coeffs” section, e.g.

Angle Coeffs

```
1 harmonic 80.0 30.0
2 cosine 50.0
...
```

If *class2* is one of the angle hybrid styles, the same rule holds for specifying additional BondBond (and BondAngle) coefficients either via the input script or in the data file. I.e. *class2* must be added to each line after the angle type. For lines in the BondBond (or BondAngle) section of the data file for angle types that are not *class2*, you must use an angle style of *skip* as a placeholder, e.g.

**BondBond Coeffs**

```
1 skip
2 class2 3.6512 1.0119 1.0119
...
```

Note that it is not necessary to use the angle style *skip* in the input script, since BondBond (or BondAngle) coefficients need not be specified at all for angle types that are not *class2*.

An angle style of *none* with no additional coefficients can be used in place of an angle style, either in a input script *angle\_coeff* command or in the data file, if you desire to turn off interactions for specific angle types.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 6.19.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

Unlike other angle styles, the hybrid angle style does not store angle coefficient info for individual sub-styles in *binary restart files* or *data files*. Thus when restarting a simulation, you need to re-specify the *angle\_coeff* commands.

### 6.19.5 Related commands

*angle\_coeff*

### 6.19.6 Default

## 6.20 angle\_style lepton command

Accelerator Variants: *lepton/omp*

## 6.20.1 Syntax

```
angle_style style args
```

- style = *lepton*
- args = optional arguments

args = *auto\_offset* or *no\_offset*

*auto\_offset* = offset the potential energy so that the value at theta0 is 0.0 (default)

*no\_offset* = do not offset the potential energy

## 6.20.2 Examples

```
angle_style lepton
angle_style lepton no_offset

angle_coeff 1 120.0 "k*theta^2; k=250.0"
angle_coeff 2 90.0 "k2*theta^2 + k3*theta^3 + k4*theta^4; k2=300.0; k3=-100.0; k4=50.
→0"
angle_coeff 3 109.47 "k*theta^2; k=350.0"
```

## 6.20.3 Description

New in version 8Feb2023.

Angle style *lepton* computes angular interactions between three atoms with a custom potential function. The potential function must be provided as an expression string using “theta” as the angle variable relative to the reference angle  $\theta_0$  which is provided as an angle coefficient. For example “ $200.0*\theta^2$ ” represents a *harmonic angle* potential with a force constant  $K$  of 200.0 energy units:

$$U_{angle,i} = K(\theta_i - \theta_0)^2 = K\theta^2 \quad \theta = \theta_i - \theta_0$$

Changed in version 7Feb2024.

By default the potential energy  $U$  is shifted so that the value  $U$  is 0.0 for  $\theta = \theta_0$ . This is equivalent to using the optional keyword *auto\_offset*. When using the keyword *no\_offset* instead, the potential energy is not shifted.

The *Lepton* library, that the *lepton* angle style interfaces with, evaluates this expression string at run time to compute the pairwise energy. It also creates an analytical representation of the first derivative of this expression with respect to “theta” and then uses that to compute the force between the angle atoms as defined by the topology data.

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- Lepton expression (energy units)
- $\theta_0$  (degrees)

The Lepton expression must be either enclosed in quotes or must not contain any whitespace so that LAMMPS recognizes it as a single keyword. More on valid Lepton expressions below. The  $\theta_0$  coefficient is the “equilibrium angle”. It is entered in degrees, but internally converted to radians. Thus the expression must assume “theta” is in radians. The potential energy function in the Lepton expression is shifted in such a way, that the potential energy is 0 for a angle  $\theta_i == \theta_0$ .

## 6.20.4 Lepton expression syntax and features

Lepton supports the following operators in expressions:

+	Add	-	Subtract	*	Multiply	/	Divide	^	Power
---	-----	---	----------	---	----------	---	--------	---	-------

The following mathematical functions are available:

sqrt(x)	Square root	exp(x)	Exponential
log(x)	Natural logarithm	sin(x)	Sine (angle in radians)
cos(x)	Cosine (angle in radians)	sec(x)	Secant (angle in radians)
csc(x)	Cosecant (angle in radians)	tan(x)	Tangent (angle in radians)
cot(x)	Cotangent (angle in radians)	asin(x)	Inverse sine (in radians)
acos(x)	Inverse cosine (in radians)	atan(x)	Inverse tangent (in radians)
sinh(x)	Hyperbolic sine	cosh(x)	Hyperbolic cosine
tanh(x)	Hyperbolic tangent	erf(x)	Error function
erfc(x)	Complementary Error function	abs(x)	Absolute value
min(x,y)	Minimum of two values	max(x,y)	Maximum of two values
delta(x)	delta(x) is 1 for $x = 0$ , otherwise 0	step(x)	step(x) is 0 for $x < 0$ , otherwise 1

Numbers may be given in either decimal or exponential form. All of the following are valid numbers: 5, -3.1, 1e6, and 3.12e-2.

As an extension to the standard Lepton syntax, it is also possible to use LAMMPS *variables* in the format “v\_name”. Before evaluating the expression, “v\_name” will be replaced with the value of the variable “name”. This is compatible with all kinds of scalar variables, but not with vectors, arrays, local, or per-atom variables. If necessary, a custom scalar variable needs to be defined that can access the desired (single) item from a non-scalar variable. As an example, the following lines will instruct LAMMPS to ramp the force constant for a harmonic bond from 100.0 to 200.0 during the next run:

```
variable fconst equal ramp(100.0, 200)
bond_style lepton
bond_coeff 1 1.5 "v_fconst * (r^2)"
```

An expression may be followed by definitions for intermediate values that appear in the expression. A semicolon “;” is used as a delimiter between value definitions. For example, the expression:

```
a^2+a*b+b^2; a=a1+a2; b=b1+b2
```

is exactly equivalent to

```
(a1+a2)^2+(a1+a2)*(b1+b2)+(b1+b2)^2
```

The definition of an intermediate value may itself involve other intermediate values. Whitespace and quotation characters (“” and “”) are ignored. All uses of a value must appear *before* that value’s definition. For efficiency reasons, the expression string is parsed, optimized, and then stored in an internal, pre-parsed representation for evaluation.

Evaluating a Lepton expression is typically between 2.5 and 5 times slower than the corresponding compiled and optimized C++ code. If additional speed or GPU acceleration (via GPU or KOKKOS) is required, the interaction can be represented as a table. Suitable table files can be created either internally using the *pair\_write* or *bond\_write* command or through the Python scripts in the *tools/tabulate* folder.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 6.20.5 Restrictions

This angle style is part of the LEPTON package and only enabled if LAMMPS was built with this package. See the [Build package](#) page for more info.

## 6.21 angle\_style mesocnt command

### 6.21.1 Syntax

```
angle_style mesocnt
```

### 6.21.2 Examples

```
angle_style mesocnt
angle_coeff 1 buckling C 10 10 20.0
angle_coeff 4 harmonic C 8 4 10.0
angle_coeff 2 buckling custom 400.0 50.0 5.0
angle_coeff 1 harmonic custom 300.0
```

### 6.21.3 Description

New in version 15Sep2022.

The *mesocnt* angle style uses the potential

$$E = K_H \Delta\theta^2, \quad |\Delta\theta| < \Delta\theta_B$$
$$E = K_H \Delta\theta_B^2 + K_B (\Delta\theta - \Delta\theta_B), \quad |\Delta\theta| \geq \Delta\theta_B$$

where  $\Delta\theta = \theta - \pi$  is the bending angle of the nanotube,  $K_H$  and  $K_B$  are prefactors for the harmonic and linear regime respectively and  $\Delta\theta_B$  is the buckling angle. Note that the usual 1/2 factor for the harmonic potential is included in  $K_H$ .

The style implements parameterization presets of  $K_H$ ,  $K_B$  and  $\Delta\theta_B$  for mesoscopic simulations of carbon nanotubes based on the atomistic simulations of ([Srivastava](#)) and buckling considerations of ([Zhigilei](#)).

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- mode = *buckling* or *harmonic*
- preset = *C* or *custom*
- additional parameters depending on preset

If mode *harmonic* is chosen, the potential is simply harmonic and does not switch to the linear term when the buckling angle is reached. In *buckling* mode, the full piecewise potential is used.

Preset *C* is for carbon nanotubes, and the additional parameters are:

- chiral index  $n$  (unitless)
- chiral index  $m$  (unitless)
- $r_0$  (distance)

Here,  $r_0$  is the equilibrium distance of the bonds included in the angle, see *bond\_style mesocnt*.

In harmonic mode with preset *custom*, the additional parameter is:

- $K_H$  (energy)

Hence, this setting is simply a wrapper for *bond\_style harmonic* with an equilibrium angle of 180 degrees.

In harmonic mode with preset *custom*, the additional parameters are:

- $K_H$  (energy)
- $K_B$  (energy)
- $\Delta\theta_B$  (degrees)

$\Delta\theta_B$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K_H$  is effectively energy per radian<sup>2</sup> and  $K_B$  is energy per radian.

---

In *buckling* mode, this angle style adds the *buckled* property to all atoms in the simulation, which is an integer flag indicating whether the bending angle at a given atom has exceeded  $\Delta\theta_B$ . It can be accessed as an atomic variable, e.g. for custom dump commands, as *i\_buckled*.

---

**Note:** If the initial state of the simulation contains buckled nanotubes and *pair\_style mesocnt* is used, the *i\_buckled* atomic variable needs to be initialized before the *pair\_style* is defined by doing a *run 0* command straight after the *angle\_style* command. See below for an example.

---

If CNTs are already buckled at the start of the simulation, this script will correctly initialize *i\_buckled*:

```
angle_style mesocnt
angle_coeff 1 buckling C 10 10 20.0

run 0

pair_style mesocnt 60.0
pair_coeff * * C_10_10.mesocnt 1
```

### 6.21.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE and MESONT packages. See the [Build package](#) doc page for more info.

### 6.21.5 Related commands

*angle\_coeff*

### 6.21.6 Default

none

---

(Srivastava) Zhigilei, Wei, Srivastava, Phys. Rev. B 71, 165417 (2005).

## 6.22 angle\_style mm3 command

### 6.22.1 Syntax

```
angle_style mm3
```

### 6.22.2 Examples

```
angle_style mm3
angle_coeff 1 100.0 107.0
```

### 6.22.3 Description

The *mm3* angle style uses the potential that is anharmonic in the angle as defined in (*Allinger*)

$$E = K(\theta - \theta_0)^2 [1 - 0.014(\theta - \theta_0) + 5.6(10)^{-5}(\theta - \theta_0)^2 - 7.0(10)^{-7}(\theta - \theta_0)^3 + 9(10)^{-10}(\theta - \theta_0)^4]$$

where  $\theta_0$  is the equilibrium value of the angle, and  $K$  is a prefactor. The anharmonic prefactors have units  $\text{deg}^{-n}$ , for example  $-0.014 \text{ deg}^{-1}$ ,  $5.6 \cdot 10^{-5} \text{ deg}^{-2}$ , ...

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\theta_0$  (degrees)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>.

### 6.22.4 Restrictions

This angle style can only be used if LAMMPS was built with the YAFF package. See the *Build package* doc page for more info.

### 6.22.5 Related commands

*angle\_coeff*

### 6.22.6 Default

## 6.24 angle\_style quartic command

Accelerator Variants: *quartic/omp*

### 6.24.1 Syntax

```
angle_style quartic
```

### 6.24.2 Examples

```
angle_style quartic
angle_coeff 1 129.1948 56.8726 -25.9442 -14.2221
```

### 6.24.3 Description

The *quartic* angle style uses the potential

$$E = K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4$$

where  $\theta_0$  is the equilibrium value of the angle, and  $K$  is a prefactor. Note that the usual 1/2 factor is included in  $K$ .

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $\theta_0$  (degrees)
- $K_2$  (energy)
- $K_3$  (energy)

- $K_4$  (energy)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence the various  $K$  are effectively energy per radian<sup>2</sup> or radian<sup>3</sup> or radian<sup>4</sup>.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 6.24.4 Restrictions

### 6.25 angle\_style spica command

Accelerator Variants: *spica/omp*, *spica/kk*

#### 6.25.1 Syntax

```
angle_style spica
angle_style spica/omp
```

## 6.25.2 Examples

```
angle_style spica
angle_coeff 1 300.0 107.0
```

## 6.25.3 Description

The *spica* angle style is a combination of the harmonic angle potential,

$$E = K(\theta - \theta_0)^2$$

where  $\theta_0$  is the equilibrium value of the angle and  $K$  a prefactor, with the *repulsive* part of the non-bonded *lj/spica* pair style between the atoms 1 and 3. This angle potential is intended for coarse grained MD simulations with the SPICA (formerly called SDK) parameterization using the *pair\_style lj/spica*. Relative to the pair\_style *lj/spica*, however, the energy is shifted by  $\epsilon$ , to avoid sudden jumps. Note that the usual 1/2 factor is included in  $K$ .

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above:

- $K$  (energy)
- $\theta_0$  (degrees)

$\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>.

The required *lj/spica* parameters are extracted automatically from the *pair\_style*.

Style *sdk*, the original implementation of style *spica*, is available for backward compatibility.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

## 6.26 angle\_style table command

Accelerator Variants: *table/omp*

### 6.26.1 Syntax

```
angle_style table style N
```

- style = *linear* or *spline* = method of interpolation
- N = use N values in table

### 6.26.2 Examples

```
angle_style table linear 1000  
angle_coeff 3 file.table ENTRY1
```

### 6.26.3 Description

Style *table* creates interpolation tables of length *N* from angle potential and derivative values listed in a file(s) as a function of angle. The files are read by the *angle\_coeff* command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of *N* angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: *linear* or *spline*.

For the *linear* style, the angle is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the *spline* style, a cubic spline coefficients are computed and stored at each of the *N* values in the table. The angle is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or derivative.

The following coefficients must be defined for each angle type via the *angle\_coeff* command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies a section of the file. The format of this file is described below.

Suitable tables for use with this angle style can be created by LAMMPS itself from existing angle styles using the [angle\\_write](#) command. This can be useful to have a template file for testing the angle style settings and to build a compatible custom file. Another option to generate tables is the Python code in the `tools/tabulate` folder of the LAMMPS source code distribution.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Angle potential for harmonic (one or more comment or blank lines)

HAM                                     (keyword is the first text on line)
N 181 FP 0 0 EQ 90.0                 (N, FP, EQ parameters)
                                     (blank line)
1 0.0 200.5 2.5                       (index, angle, energy, derivative)
2 1.0 198.0 2.5
...
181 180.0 0.0 0.0
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the [angle\\_coeff](#) command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the  $N$  specified in the [angle\\_style table](#) command. Let  $N_{\text{table}} = N$  in the `angle_style` command, and  $N_{\text{file}} = “N”$  in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the  $N_{\text{file}}$  tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at  $N_{\text{table}}$  different points. The resulting tables of length  $N_{\text{table}}$  are then used as described above, when computing energy and force for individual angles and their atoms. This means that if you want the interpolation tables of length  $N_{\text{table}}$  to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set  $N_{\text{table}} = N_{\text{file}}$ .

The “FP” parameter is optional. If used, it is followed by two values `fplo` and `fphi`, which are the second derivatives at the innermost and outermost angle settings. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two derivative values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium angle value, which is used, for example, by the [fix shake](#) command. If not used, the equilibrium angle is set to 180.0.

Following a blank line, the next  $N$  lines list the tabulated values. On each line, the first value is the index from 1 to  $N$ , the second value is the angle value (in degrees), the third value is the energy (in energy units), and the fourth is  $-dE/d(\text{theta})$  (also in energy units). The third term is the energy of the 3-atom configuration for the specified angle. The last term is the derivative of the energy with respect to the angle (in degrees, not radians). Thus the units of the last term are still energy, not force. The angle values must increase from one line to the next. The angle values must also begin with 0.0 and end with 180.0, i.e. span the full range of possible angles.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 6.26.4 Restart, fix\_modify, output, run start/stop, minimize info

This angle style writes the settings for the “angle\_style table” command to *binary restart files*, so a angle\_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, angle\_coeff commands do need to be specified in the restart input script.

### 6.26.5 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

### 6.26.6 Related commands

*angle\_coeff*, *angle\_write*

### 6.26.7 Default

none

## 6.27 angle\_style zero command

### 6.27.1 Syntax

```
angle_style zero keyword
```

- zero or more keywords may be appended
- keyword = *nocoeff*

### 6.27.2 Examples

```
angle_style zero
angle_style zero nocoeff
angle_coeff *
angle_coeff * 120.0
```

### 6.27.3 Description

Using an angle style of zero means angle forces and energies are not computed, but the geometry of angle triplets is still accessible to other commands.

As an example, the *compute angle/local* command can be used to compute the theta values for the list of triplets of angle atoms listed in the data file read by the *read\_data* command. If no angle style is defined, this command cannot be used.

The optional *nocoeff* flag allows to read data files with AngleCoeff section for any angle style. Similarly, any *angle\_coeff* commands will only be checked for the angle type number and the rest ignored.

Note that the *angle\_coeff* command must be used for all angle types. If specified, there can be only one value, which is going to be used to assign an equilibrium angle, e.g. for use with *fix shake*.

### 6.27.4 Restrictions

none

### 6.27.5 Related commands

*angle\_style none*

### 6.27.6 Default

## DIHEDRAL STYLES

### 7.1 dihedral\_style charmm command

Accelerator Variants: *charmm/intel*, *charmm/kk*, *charmm/omp*

### 7.2 dihedral\_style charmmfsw command

Accelerator Variants: *charmmfsw/kk*

#### 7.2.1 Syntax

```
dihedral_style style
```

- style = *charmm* or *charmmfsw*

#### 7.2.2 Examples

```
dihedral_style charmm
dihedral_style charmmfsw
dihedral_coeff 1 0.2 1 180 1.0
dihedral_coeff 2 1.8 1 0 1.0
dihedral_coeff 1 3.1 2 180 0.5
```

#### 7.2.3 Description

The *charmm* and *charmmfsw* dihedral styles use the potential

$$E = K[1 + \cos(n\phi - d)]$$

See ([MacKerell](#)) for a description of the CHARMM force field. This dihedral style can also be used for the AMBER force field (see comment on weighting factors below). See ([Cornell](#)) for a description of the AMBER force field.

---

**Note:** The newer *charmmfsw* style was released in March 2017. We recommend it be used instead of the older *charmm* style when running a simulation with the CHARMM force field, either with long-range Coulombics or a Coulombic cutoff, via the *pair\_style lj/charmmfsw/coul/long* and *pair\_style lj/charmmfsw/coul/charmmfsh* commands respectively.

Otherwise the older *charmm* style is fine to use. See the discussion below and more details on the *pair\_style charmm* doc page.

---

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *K* (energy)
- *n* (integer  $\geq 0$ )
- *d* (integer value of degrees)
- weighting factor (1.0, 0.5, or 0.0)

The weighting factor is required to correct for double counting pairwise non-bonded Lennard-Jones interactions in cyclic systems or when using the CHARMM dihedral style with non-CHARMM force fields. With the CHARMM dihedral style, interactions between the first and fourth atoms in a dihedral are skipped during the normal non-bonded force computation and instead evaluated as part of the dihedral using special epsilon and sigma values specified with the *pair\_coeff* command of pair styles that contain “lj/charmm” (e.g. *pair\_style lj/charmm/coul/long*). In 6-membered rings, the same 1-4 interaction would be computed twice (once for the clockwise 1-4 pair in dihedral 1-2-3-4 and once in the counterclockwise dihedral 1-6-5-4) and thus the weighting factor has to be 0.5 in this case. In 4-membered or 5-membered rings, the 1-4 dihedral also is counted as a 1-2 or 1-3 interaction when going around the ring in the opposite direction and thus the weighting factor is 0.0, as the 1-2 and 1-3 exclusions take precedence.

Note that this dihedral weighting factor is unrelated to the scaling factor specified by the *special\_bonds* command which applies to all 1-4 interactions in the system. For CHARMM force fields, the special\_bonds 1-4 interaction scaling factor should be set to 0.0. Since the corresponding 1-4 non-bonded interactions are computed with the dihedral. This means that if any of the weighting factors defined as dihedral coefficients (fourth coeff above) are non-zero, then you must use a pair style with “lj/charmm” and set the special\_bonds 1-4 scaling factor to 0.0 (which is the default). Otherwise 1-4 non-bonded interactions in dipoles will be computed twice.

For simulations using the CHARMM force field with a Coulombic cutoff, the difference between the *charmm* and *charmmfsw* styles is in the computation of the 1-4 non-bond interactions, though only if the distance between the two atoms is within the switching region of the pairwise potential defined by the corresponding CHARMM pair style, i.e. within the outer cutoff specified for the pair style. The *charmmfsw* style should only be used when using the corresponding *pair\_style lj/charmmfsw/coul/charmmfsw* or *pair\_style lj/charmmfsw/coul/long* commands. Use the *charmm* style with the older *pair\_style* commands that have just “charmm” in their style name. See the discussion on the *CHARMM pair\_style* page for details.

Note that for AMBER force fields, which use pair styles with “lj/cut”, the special\_bonds 1-4 scaling factor should be set to the AMBER defaults (1/2 and 5/6) and all the dihedral weighting factors (fourth coeff above) must be set to 0.0. In this case, you can use any pair style you wish, since the dihedral does not need any Lennard-Jones parameter information and will not compute any 1-4 non-bonded interactions. Likewise the *charmm* or *charmmfsw* styles are identical in this case since no 1-4 non-bonded interactions are computed.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 7.2.4 Restrictions

When using run\_style *respa*, these dihedral styles must be assigned to the same r-RESPA level as *pair* or *outer*.

When used in combination with CHARMM pair styles, the 1-4 *special\_bonds* scaling factors must be set to 0.0. Otherwise non-bonded contributions for these 1-4 pairs will be computed multiple times.

These dihedral styles can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

dihedral_coeff * bb13 0.0 1.0119 1.1010
```

### 7.3.3 Description

The *class2* dihedral style uses the potential

$$\begin{aligned}
 E &= E_d + E_{mbt} + E_{ebt} + E_{at} + E_{aat} + E_{bb13} \\
 E_d &= \sum_{n=1}^3 K_n [1 - \cos(n\phi - \phi_n)] \\
 E_{mbt} &= (r_{jk} - r_2) [A_1 \cos(\phi) + A_2 \cos(2\phi) + A_3 \cos(3\phi)] \\
 E_{ebt} &= (r_{ij} - r_1) [B_1 \cos(\phi) + B_2 \cos(2\phi) + B_3 \cos(3\phi)] + \\
 &\quad (r_{kl} - r_3) [C_1 \cos(\phi) + C_2 \cos(2\phi) + C_3 \cos(3\phi)] \\
 E_{at} &= (\theta_{ijk} - \theta_1) [D_1 \cos(\phi) + D_2 \cos(2\phi) + D_3 \cos(3\phi)] + \\
 &\quad (\theta_{jkl} - \theta_2) [E_1 \cos(\phi) + E_2 \cos(2\phi) + E_3 \cos(3\phi)] \\
 E_{aat} &= M(\theta_{ijk} - \theta_1)(\theta_{jkl} - \theta_2) \cos(\phi) \\
 E_{bb13} &= N(r_{ij} - r_1)(r_{kl} - r_3)
 \end{aligned}$$

where  $E_d$  is the dihedral term,  $E_{mbt}$  is a middle-bond-torsion term,  $E_{ebt}$  is an end-bond-torsion term,  $E_{at}$  is an angle-torsion term,  $E_{aat}$  is an angle-angle-torsion term, and  $E_{bb13}$  is a bond-bond-13 term.

$\theta_1$  and  $\theta_2$  are equilibrium angles and  $r_1$ ,  $r_2$ , and  $r_3$  are equilibrium bond lengths.

See [\(Sun\)](#) for a description of the COMPASS class2 force field.

Coefficients for the  $E_d$ ,  $E_{mbt}$ ,  $E_{ebt}$ ,  $E_{at}$ ,  $E_{aat}$ , and  $E_{bb13}$  formulas must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands.

These are the 6 coefficients for the  $E_d$  formula:

- $K_1$  (energy)
- $\phi_1$  (degrees)
- $K_2$  (energy)
- $\phi_2$  (degrees)
- $K_3$  (energy)
- $\phi_3$  (degrees)

For the  $E_{mbt}$  formula, each line in a *dihedral\_coeff* command in the input script lists 5 coefficients, the first of which is *mbt* to indicate they are MiddleBondTorsion coefficients. In a data file, these coefficients should be listed under a *MiddleBondTorsion Coeffs* heading and you must leave out the *mbt*, i.e. only list 4 coefficients after the dihedral type.

- *mbt*
- $A_1$  (energy/distance)
- $A_2$  (energy/distance)
- $A_3$  (energy/distance)
- $r_2$  (distance)

For the  $E_{ebt}$  formula, each line in a *dihedral\_coeff* command in the input script lists 9 coefficients, the first of which is *ebt* to indicate they are EndBondTorsion coefficients. In a data file, these coefficients should be listed under a *EndBondTorsion Coeffs* heading and you must leave out the *ebt*, i.e. only list 8 coefficients after the dihedral type.

- *ebt*
- $B_1$  (energy/distance)

- $B_2$  (energy/distance)
- $B_3$  (energy/distance)
- $C_1$  (energy/distance)
- $C_2$  (energy/distance)
- $C_3$  (energy/distance)
- $r_1$  (distance)
- $r_3$  (distance)

For the  $E_{at}$  formula, each line in a *dihedral\_coeff* command in the input script lists 9 coefficients, the first of which is *at* to indicate they are AngleTorsion coefficients. In a data file, these coefficients should be listed under a *AngleTorsion Coeffs* heading and you must leave out the *at*, i.e. only list 8 coefficients after the dihedral type.

- *at*
- $D_1$  (energy)
- $D_2$  (energy)
- $D_3$  (energy)
- $E_1$  (energy)
- $E_2$  (energy)
- $E_3$  (energy)
- $\theta_1$  (degrees)
- $\theta_2$  (degrees)

$\theta_1$  and  $\theta_2$  are specified in degrees, but LAMMPS converts them to radians internally; hence the various  $D$  and  $E$  are effectively energy per radian.

For the  $E_{aat}$  formula, each line in a *dihedral\_coeff* command in the input script lists 4 coefficients, the first of which is *aat* to indicate they are AngleAngleTorsion coefficients. In a data file, these coefficients should be listed under a *AngleAngleTorsion Coeffs* heading and you must leave out the *aat*, i.e. only list 3 coefficients after the dihedral type.

- *aat*
- $M$  (energy)
- $\theta_1$  (degrees)
- $\theta_2$  (degrees)

$\theta_1$  and  $\theta_2$  are specified in degrees, but LAMMPS converts them to radians internally; hence  $M$  is effectively energy per radian<sup>2</sup>.

For the  $E_{bb13}$  formula, each line in a *dihedral\_coeff* command in the input script lists 4 coefficients, the first of which is *bb13* to indicate they are BondBond13 coefficients. In a data file, these coefficients should be listed under a *BondBond13 Coeffs* heading and you must leave out the *bb13*, i.e. only list 3 coefficients after the dihedral type.

- *bb13*
- $N$  (energy/distance<sup>2</sup>)
- $r_1$  (distance)
- $r_3$  (distance)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 7.4 dihedral\_style cosine/shift/exp command

Accelerator Variants: *cosine/shift/exp/omp*

### 7.4.1 Syntax

```
dihedral_style cosine/shift/exp
```

### 7.4.2 Examples

```
dihedral_style cosine/shift/exp
dihedral_coeff 1 10.0 45.0 2.0
```

### 7.4.3 Description

The *cosine/shift/exp* dihedral style uses the potential

$$E = -U_{min} \frac{e^{-aU(\theta, \theta_0)} - 1}{e^a - 1} \quad \text{with} \quad U(\theta, \theta_0) = -0.5 (1 + \cos(\theta - \theta_0))$$

where  $U_{min}$ ,  $\theta$ , and  $a$  are defined for each dihedral type.

The potential is bounded between  $[-U_{min} : 0]$  and the minimum is located at the angle  $\theta_0$ . The  $a$  parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by  $k = ae^a \frac{U_{min}}{2(e^a - 1)}$ . For  $a > 3$  and  $\frac{k}{U_{min}} = \frac{a}{2}$  to better than 5% relative error. For negative values of the  $a$  parameter, the spring constant is essentially zero, and anharmonic terms takes over. The potential is furthermore well behaved in the limit  $a \rightarrow 0$ , where it has been implemented to linear order in  $a$  for  $a < 0.001$ .

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $U_{min}$  (energy)
- $\theta$  (angle)
- $a$  (real number)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 7.4.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

### 7.4.5 Related commands

*dihedral\_coeff*, *angle\_style cosine/shift/exp*

### 7.4.6 Default

none

## 7.5 dihedral\_style cosine/squared/restricted command

### 7.5.1 Syntax

```
dihedral_style cosine/squared/restricted
```

### 7.5.2 Examples

```
dihedral_style cosine/squared/restricted
dihedral_coeff 1 10.0 120
```

### 7.5.3 Description

New in version 17Apr2024.

The *cosine/squared/restricted* dihedral style uses the potential

$$E = K[\cos(\phi) - \cos(\phi_0)]^2 / \sin^2(\phi)$$

, which is commonly used in the MARTINI force field.

See ([Bulacu](#)) for a description of the restricted dihedral for the MARTINI force field.

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\phi_0$  (degrees)

$\phi_0$  is specified in degrees, but LAMMPS converts it to radians internally.

---

### 7.5.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

## 7.5.5 Related commands

*dihedral\_coeff*

## 7.5.6 Default

## 7.6 dihedral\_style fourier command

Accelerator Variants: *fourier/intel*, *fourier/omp*

### 7.6.1 Syntax

```
dihedral_style fourier
```

### 7.6.2 Examples

```
dihedral_style fourier
dihedral_coeff 1 3 -0.846200 3 0.0 7.578800 1 0 0.138000 2 -180.0
```

### 7.6.3 Description

The *fourier* dihedral style uses the potential:

$$E = \sum_{i=1,m} K_i [1.0 + \cos(n_i \phi - d_i)]$$

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $m$  (integer  $\geq 1$ )
- $K_1$  (energy)
- $n_1$  (integer  $\geq 0$ )
- $d_1$  (degrees)
- [...]
- $K_m$  (energy)
- $n_m$  (integer  $\geq 0$ )
- $d_m$  (degrees)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 7.7 dihedral\_style harmonic command

Accelerator Variants: *harmonic/intel*, *harmonic/kk*, *harmonic/omp*

### 7.7.1 Syntax

```
dihedral_style harmonic
```

### 7.7.2 Examples

```
dihedral_style harmonic
dihedral_coeff 1 80.0 1 2
```

### 7.7.3 Description

The *harmonic* dihedral style uses the potential

$$E = K[1 + d \cos(n\phi)]$$

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *K* (energy)
- *d* (+1 or -1)
- *n* (integer >= 0)

---

**Note:** Here are important points to take note of when defining LAMMPS dihedral coefficients for the harmonic style, so that they are compatible with how harmonic dihedrals are defined by other force fields:

---

- The LAMMPS convention is that the trans position = 180 degrees, while in some force fields trans = 0 degrees.
  - Some force fields reverse the sign convention on *d*.
  - Some force fields let *n* be positive or negative which corresponds to *d* = 1 or *d* = -1 for the harmonic style.
- 

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 7.7.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

## 7.8 dihedral\_style helix command

Accelerator Variants: *helix/omp*

### 7.8.1 Syntax

```
dihedral_style helix
```

### 7.8.2 Examples

```
dihedral_style helix
dihedral_coeff 1 80.0 100.0 40.0
```

### 7.8.3 Description

The *helix* dihedral style uses the potential

$$E = A[1 - \cos(\theta)] + B[1 + \cos(3\theta)] + C[1 + \cos(\theta + \frac{\pi}{4})]$$

This coarse-grain dihedral potential is described in ([Guo](#)). For dihedral angles in the helical region, the energy function is represented by a standard potential consisting of three minima, one corresponding to the trans (t) state and the other to gauche states (g+ and g-). The paper describes how the *A*, *B* and *C* parameters are chosen so as to balance secondary (largely driven by local interactions) and tertiary structure (driven by long-range interactions).

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *A* (energy)
- *B* (energy)
- *C* (energy)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

(Guo) Guo and Thirumalai, Journal of Molecular Biology, 263, 323-43 (1996).

## 7.9 dihedral\_style hybrid command

Accelerator Variants: *hybrid/kk*

### 7.9.1 Syntax

```
dihedral_style hybrid style1 style2 ...
```

- style1,style2 = list of one or more dihedral styles

### 7.9.2 Examples

```
dihedral_style hybrid harmonic helix
dihedral_coeff 1 harmonic 6.0 1 3
dihedral_coeff 2* helix 10 10 10
```

### 7.9.3 Description

The *hybrid* style enables the use of multiple dihedral styles in one simulation. An dihedral style is assigned to each dihedral type. For example, dihedrals in a polymer flow (of dihedral type 1) could be computed with a *harmonic* potential and dihedrals in the wall boundary (of dihedral type 2) could be computed with a *helix* potential. The assignment of dihedral type to style is made via the *dihedral\_coeff* command or in the data file.

In the *dihedral\_coeff* commands, the name of a dihedral style must be added after the dihedral type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 *dihedral\_coeff* commands set dihedrals of dihedral type 1 to be computed with a *harmonic* potential with coefficients 6.0, 1, 3 for K, d, n. All other dihedral types (2-N) are computed with a *helix* potential with coefficients 10, 10, 10 for A, B, C.

If dihedral coefficients are specified in the data file read via the [read\\_data](#) command, then the same rule applies. E.g. “harmonic” or “helix”, must be added after the dihedral type, for each line in the “Dihedral Coeffs” section, e.g.

**Dihedral Coeffs**

```
1 harmonic 6.0 1 3
2 helix 10 10 10
...
```

If *class2* is one of the dihedral hybrid styles, the same rule holds for specifying additional AngleTorsion (and EndBondTorsion, etc) coefficients either via the input script or in the data file. I.e. *class2* must be added to each line after the dihedral type. For lines in the AngleTorsion (or EndBondTorsion, etc) Coeffs section of the data file for dihedral types that are not *class2*, you must use an dihedral style of *skip* as a placeholder, e.g.

**AngleTorsion Coeffs**

```
1 skip
2 class2 1.0 1.0 1.0 3.0 3.0 3.0 30.0 50.0
...
```

Note that it is not necessary to use the dihedral style *skip* in the input script, since AngleTorsion (or EndBondTorsion, etc) coefficients need not be specified at all for dihedral types that are not *class2*.

A dihedral style of *none* with no additional coefficients can be used in place of a dihedral style, either in a input script dihedral\_coeff command or in the data file, if you desire to turn off interactions for specific dihedral types.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 7.9.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

Unlike other dihedral styles, the hybrid dihedral style does not store dihedral coefficient info for individual sub-styles in *binary restart files* or *data files*. Thus when restarting a simulation, you need to re-specify the dihedral\_coeff commands.

## 7.9.5 Related commands

*dihedral\_coeff*

## 7.9.6 Default

none

## 7.10 dihedral\_style lepton command

Accelerator Variants: *lepton/omp*

### 7.10.1 Syntax

```
dihedral_style lepton
```

### 7.10.2 Examples

```
dihedral_style lepton
dihedral_coeff 1 "k*(1 + d*cos(n*phi)); k=75.0; d=1; n=2"
dihedral_coeff 2 "45*(1-cos(4*phi))"
dihedral_coeff 2 "k2*cos(phi) + k3*cos(phi)^2; k2=100.0"
dihedral_coeff 3 "k*(phi-phi0)^2; k=85.0; phi0=120.0"
```

### 7.10.3 Description

New in version 8Feb2023.

Dihedral style *lepton* computes dihedral interactions between four atoms forming a dihedral angle with a custom potential function. The potential function must be provided as an expression string using “phi” as the dihedral angle variable. For example “*200.0\*(phi-120.0)^2*” represents a *quadratic dihedral* potential around a 120 degree dihedral angle with a force constant *K* of 200.0 energy units:

$$U_{dihedral,i} = K(\phi_i - \phi_0)^2$$

The *Lepton library*, that the *lepton* dihedral style interfaces with, evaluates this expression string at run time to compute the pairwise energy. It also creates an analytical representation of the first derivative of this expression with respect to “phi” and then uses that to compute the force between the dihedral atoms as defined by the topology data.

The potential function expression for each dihedral type is provided via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands. The expression is in energy units.

The Lepton expression must be either enclosed in quotes or must not contain any whitespace so that LAMMPS recognizes it as a single keyword. More on valid Lepton expressions below. Dihedral angles are internally computed in radians and thus the expression must assume “phi” is in radians.

### 7.10.4 Lepton expression syntax and features

Lepton supports the following operators in expressions:

+	Add	-	Subtract	*	Multiply	/	Divide	^	Power
---	-----	---	----------	---	----------	---	--------	---	-------

The following mathematical functions are available:

sqrt(x)	Square root	exp(x)	Exponential
log(x)	Natural logarithm	sin(x)	Sine (angle in radians)
cos(x)	Cosine (angle in radians)	sec(x)	Secant (angle in radians)
csc(x)	Cosecant (angle in radians)	tan(x)	Tangent (angle in radians)
cot(x)	Cotangent (angle in radians)	asin(x)	Inverse sine (in radians)
acos(x)	Inverse cosine (in radians)	atan(x)	Inverse tangent (in radians)
sinh(x)	Hyperbolic sine	cosh(x)	Hyperbolic cosine
tanh(x)	Hyperbolic tangent	erf(x)	Error function
erfc(x)	Complementary Error function	abs(x)	Absolute value
min(x,y)	Minimum of two values	max(x,y)	Maximum of two values
delta(x)	delta(x) is 1 for $x = 0$ , otherwise 0	step(x)	step(x) is 0 for $x < 0$ , otherwise 1

Numbers may be given in either decimal or exponential form. All of the following are valid numbers: 5, -3.1, 1e6, and 3.12e-2.

As an extension to the standard Lepton syntax, it is also possible to use LAMMPS *variables* in the format “v\_name”. Before evaluating the expression, “v\_name” will be replaced with the value of the variable “name”. This is compatible with all kinds of scalar variables, but not with vectors, arrays, local, or per-atom variables. If necessary, a custom scalar variable needs to be defined that can access the desired (single) item from a non-scalar variable. As an example, the following lines will instruct LAMMPS to ramp the force constant for a harmonic bond from 100.0 to 200.0 during the next run:

```
variable fconst equal ramp(100.0, 200)
bond_style lepton
bond_coeff 1 1.5 "v_fconst * (r^2)"
```

An expression may be followed by definitions for intermediate values that appear in the expression. A semicolon “;” is used as a delimiter between value definitions. For example, the expression:

```
a^2+a*b+b^2; a=a1+a2; b=b1+b2
```

is exactly equivalent to

```
(a1+a2)^2+(a1+a2)*(b1+b2)+(b1+b2)^2
```

The definition of an intermediate value may itself involve other intermediate values. Whitespace and quotation characters (“” and “”) are ignored. All uses of a value must appear *before* that value’s definition. For efficiency reasons, the expression string is parsed, optimized, and then stored in an internal, pre-parsed representation for evaluation.

Evaluating a Lepton expression is typically between 2.5 and 5 times slower than the corresponding compiled and optimized C++ code. If additional speed or GPU acceleration (via GPU or KOKKOS) is required, the interaction can be represented as a table. Suitable table files can be created either internally using the *pair\_write* or *bond\_write* command or through the Python scripts in the *tools/tabulate* folder.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 7.10.5 Restrictions

This dihedral style is part of the LEPTON package and only enabled if LAMMPS was built with this package. See the [Build package](#) page for more info.

## 7.14 dihedral\_style opls command

Accelerator Variants: *opls/intel*, *opls/kk*, *opls/omp*

### 7.14.1 Syntax

```
dihedral_style opls
```

### 7.14.2 Examples

```
dihedral_style opls
dihedral_coeff 1 1.740 -0.157 0.279 0.000 # CT-CT-CT-CT
dihedral_coeff 2 0.000 0.000 0.366 0.000 # CT-CT-CT-HC
dihedral_coeff 3 0.000 0.000 0.318 0.000 # HC-CT-CT-HC
```

### 7.14.3 Description

The *opls* dihedral style uses the potential

$$E = \frac{1}{2}K_1[1 + \cos(\phi)] + \frac{1}{2}K_2[1 - \cos(2\phi)] + \frac{1}{2}K_3[1 + \cos(3\phi)] + \frac{1}{2}K_4[1 - \cos(4\phi)]$$

Note that the usual 1/2 factor is not included in the K values.

This dihedral potential is used in the OPLS force field and is described in ([Watkins](#)).

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K_1$  (energy)
- $K_2$  (energy)
- $K_3$  (energy)
- $K_4$  (energy)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 7.15 dihedral\_style quadratic command

Accelerator Variants: *quadratic/omp*

### 7.15.1 Syntax

```
dihedral_style quadratic
```

### 7.15.2 Examples

```
dihedral_style quadratic
dihedral_coeff 100.0 80.0
```

### 7.15.3 Description

The *quadratic* dihedral style uses the potential:

$$E = K(\phi - \phi_0)^2$$

This dihedral potential can be used to keep a dihedral in a predefined value (cis=zero, right-hand convention is used).

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\phi_0$  (degrees)

$\phi_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 7.15.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

```

### 7.16.3 Description

The *spherical* dihedral style uses the potential:

$$E(\phi, \theta_1, \theta_2) = \sum_{i=1}^N C_i \Phi_i(\phi) \Theta_{1i}(\theta_1) \Theta_{2i}(\theta_2)$$

$$\Phi_i(\phi) = u_i - \cos((\phi - a_i)K_i)$$

$$\Theta_{1i}(\theta_1) = v_i - \cos((\theta_1 - b_i)L_i)$$

$$\Theta_{2i}(\theta_2) = w_i - \cos((\theta_2 - c_i)M_i)$$

For this dihedral style, the energy can be any function that combines the 4-body dihedral-angle ( $\phi$ ) and the two 3-body bond-angles ( $\theta_1, \theta_2$ ). For this reason, there is usually no need to define 3-body “angle” forces separately for the atoms participating in these interactions. It is probably more efficient to incorporate 3-body angle forces into the dihedral interaction even if it requires adding additional terms to the expansion (as was done in the second example). A careful choice of parameters can prevent singularities that occur with traditional force-fields whenever theta1 or theta2 approach 0 or 180 degrees.

The last example above corresponds to an interaction with a single energy minima located near  $\phi = 93.9$ ,  $\theta_1 = 74.4$ ,  $\theta_2 = 48.1$  degrees, and it remains numerically stable at all angles ( $\phi, \theta_1, \theta_2$ ). In this example, the coefficients 49.1, and 25.2 can be physically interpreted as the harmonic spring constants for theta1 and theta2 around their minima. The coefficient 69.3 is the harmonic spring constant for phi after division by  $\sin(74.4) \cdot \sin(48.1)$  (the minima positions for theta1 and theta2).

The following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above, or in the Dihedral Coeffs section of a data file read by the *read\_data* command:

- $n$  (integer  $\geq 1$ )
- $C_1$  (energy)
- $K_1$  (typically an integer)
- $a_1$  (degrees)
- $u_1$  (typically 0.0 or 1.0)
- $L_1$  (typically an integer)
- $b_1$  (degrees, typically 0.0 or 90.0)
- $v_1$  (typically 0.0 or 1.0)
- $M_1$  (typically an integer)
- $c_1$  (degrees, typically 0.0 or 90.0)
- $w_1$  (typically 0.0 or 1.0)
- [...]
- $C_n$  (energy)
- $K_n$  (typically an integer)
- $a_n$  (degrees)

- $u_n$  (typically 0.0 or 1.0)
  - $L_n$  (typically an integer)
  - $b_n$  (degrees, typically 0.0 or 90.0)
  - $v_n$  (typically 0.0 or 1.0)
  - $M_n$  (typically an integer)
  - $c_n$  (degrees, typically 0.0 or 90.0)
  - $w_n$  (typically 0.0 or 1.0)
- 

### 7.16.4 Restrictions

```

## 7.18.3 Description

The *table* and *table/cut* dihedral styles create interpolation tables of length *Ntable* from dihedral potential and derivative values listed in a file(s) as a function of the dihedral angle “phi”. The files are read by the *dihedral\_coeff* command. For dihedral style *table/cut* additionally an analytic cutoff that is quadratic in the bond-angle (theta) is applied in order to regularize the dihedral interaction.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of *Ntable* dihedral angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: *linear* or *spline*.

For the *linear* style, the dihedral angle (phi) is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the *spline* style, cubic spline coefficients are computed and stored at each of the *Ntable* evenly-spaced values in the interpolated table. For a given dihedral angle (phi), the appropriate coefficients are chosen from this list, and a cubic polynomial is used to compute the energy and the derivative at this angle.

For dihedral style *table* the following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies which section of the file to read. The format of this file is the same for both dihedral styles and described below.

For dihedral style *table/cut* the following coefficients must be defined for each dihedral type via the *dihedral\_coeff* command as in the example above.

- style (= aat)
- cutoff prefactor (unitless)
- cutoff angle1 (degrees)
- cutoff angle2 (degrees)
- filename
- keyword

The cutoff dihedral style uses a tabulated dihedral interaction with a cutoff function:

$$\begin{aligned}
 f(\theta) &= K & \theta < \theta_1 \\
 f(\theta) &= K \left( 1 - \frac{(\theta - \theta_1)^2}{(\theta_2 - \theta_1)^2} \right) & \theta_1 < \theta < \theta_2
 \end{aligned}$$

The cutoff includes a prefactor  $K$  to the cutoff function  $f(\theta)$ . While this value would ordinarily be 1, there may be situations where the value could be different.

The cutoff  $\theta_1$  specifies the angle (in degrees) below which the dihedral interaction is unmodified, i.e. the cutoff function is 1.

The cutoff function is applied between  $\theta_1$  and  $\theta_2$ , which is the angle at which the cutoff function drops to zero. The value of zero effectively “turns off” the dihedral interaction.

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies which section of the file to read. The format of this file is the same for both dihedral styles and described below.

Suitable tables for use with this dihedral style can be created using the Python code in the `tools/tabulate` folder of the LAMMPS source code distribution.

The format of a tabulated file is as follows (without the parenthesized comments). It can begin with one or more comment or blank lines.

```
# Table of the potential and its negative derivative

DIH_TABLE1                (keyword is the first text on line)
N 30 DEGREES              (N, NOF, DEGREES, RADIANS, CHECKU/F)
                          (blank line)
1 -168.0 -1.40351172223 0.0423346818422
2 -156.0 -1.70447981034 0.00811786522531
3 -144.0 -1.62956100432 -0.0184129719987
...
30 180.0 -0.707106781187 0.0719306095245

# Example 2: table of the potential. Forces omitted

DIH_TABLE2
N 30 NOF CHECKU testU.dat CHECKF testF.dat

1 -168.0 -1.40351172223
2 -156.0 -1.70447981034
3 -144.0 -1.62956100432
...
30 180.0 -0.707106781187
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `dihedral_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

Following a blank line, the next  $N$  lines list the tabulated values. On each line, the first value is the index from 1 to  $N$ , the second value is the angle value, the third value is the energy (in energy units), and the fourth is  $-dE/d(\phi)$  also in energy units). The third term is the energy of the 4-atom configuration for the specified angle. The fourth term (when present) is the negative derivative of the energy with respect to the angle (in degrees, or radians depending on whether the user selected DEGREES or RADIANS). Thus the units of the last term are still energy, not force. The dihedral angle values must increase from one line to the next.

Dihedral table splines are cyclic. There is no discontinuity at 180 degrees (or at any other angle). Although in the examples above, the angles range from -180 to 180 degrees, in general, the first angle in the list can have any value (positive, zero, or negative). However the *range* of angles represented in the table must be *strictly* less than 360 degrees

(2pi radians) to avoid angle overlap. (You may not supply entries in the table for both 180 and -180, for example.) If the user's table covers only a narrow range of dihedral angles, strange numerical behavior can occur in the large remaining gap.

#### Parameters:

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the *dihedral\_style table* command. Let *Ntable* be the number of table entries requested *dihedral\_style* command, and let *Nfile* be the parameter following “N” in the tabulated file (“30” in the sparse example above). What LAMMPS does is a preliminary interpolation by creating splines using the *Nfile* tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at *Ntable* different points (which are evenly spaced over a 360 degree range, even if the angles in the file are not). The resulting tables of length *Ntable* are then used as described above, when computing energy and force for individual dihedral angles and their atoms. This means that if you want the interpolation tables of length *Ntable* to match exactly what is in the tabulated file (with effectively nopreliminary interpolation), you should set *Ntable* = *Nfile*. To ensure the nodal points in the user's file are aligned with the interpolated table entries, the angles in the table should be integer multiples of  $360/Ntable$  degrees, or  $2\pi/Ntable$  radians (depending on your choice of angle units).

The optional “NOF” keyword allows the user to omit the forces (negative energy derivatives) from the table file (normally located in the fourth column). In their place, forces will be calculated automatically by differentiating the potential energy function indicated by the third column of the table (using either linear or spline interpolation).

The optional “DEGREES” keyword allows the user to specify angles in degrees instead of radians (default).

The optional “RADIANS” keyword allows the user to specify angles in radians instead of degrees. (Note: This changes the way the forces are scaled in the fourth column of the data file.)

The optional “CHECKU” keyword is followed by a filename. This allows the user to save all of the *Ntable* different entries in the interpolated energy table to a file to make sure that the interpolated function agrees with the user's expectations. (Note: You can temporarily increase the *Ntable* parameter to a high value for this purpose. “*Ntable*” is explained above.)

The optional “CHECKF” keyword is analogous to the “CHECKU” keyword. It is followed by a filename, and it allows the user to check the interpolated force table. This option is available even if the user selected the “NOF” option.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 7.18.4 Restart, fix\_modify, output, run start/stop, minimize info

These dihedral styles write the settings for the “dihedral\_style table” or “dihedral\_style table/cut” command to *binary restart files*, so a dihedral\_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information loaded from the table file(s) is not stored in the restart file, since it is tabulated in the potential files. Thus, suitable dihedral\_coeff commands do need to be specified in the restart input script after reading the restart file.

### 7.18.5 Restrictions

The *table* dihedral style can only be used if LAMMPS was built with the MOLECULE package. The *table/cut* dihedral style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the *Build package* doc page for more info.

## 7.19 dihedral\_style zero command

### 7.19.1 Syntax

```
dihedral_style zero keyword
```

- zero or more keywords may be appended
- keyword = *nocoeff*

### 7.19.2 Examples

```
dihedral_style zero
dihedral_style zero nocoeff
dihedral_coeff *
```

### 7.19.3 Description

Using a dihedral style of zero means dihedral forces and energies are not computed, but the geometry of dihedral quadruplets is still accessible to other commands.

As an example, the *compute dihedral/local* command can be used to compute the theta values for the list of quadruplets of dihedral atoms listed in the data file read by the *read\_data* command. If no dihedral style is defined, this command cannot be used.

The optional *nocoeff* flag allows to read data files with a DihedralCoeff section for any dihedral style. Similarly, any *dihedral\_coeff* commands will only be checked for the dihedral type number and the rest ignored.

Note that the *dihedral\_coeff* command must be used for all dihedral types, though no additional values are specified.

## IMPROPER STYLES

### 8.1 `improper_style amoeba` command

#### 8.1.1 Syntax

```
improper_style amoeba
```

#### 8.1.2 Examples

```
improper_style amoeba  
improper_coeff 1 49.6
```

#### 8.1.3 Description

The *amoeba* improper style uses the potential

$$E = K(\chi)^2$$

where  $\chi$  is the improper angle and  $K$  is a prefactor. Note that the usual 1/2 factor is included in  $K$ .

This formula seems like a simplified version of the formula for the *improper\_style harmonic* command with  $\chi_0 = 0.0$ . However the computation of the angle  $\chi$  is done differently to match how the Tinker MD code computes its out-of-plane improper for the AMOEBA and HIPPO force fields. See the [Howto amoeba](#) doc page for more information about the implementation of AMOEBA and HIPPO in LAMMPS.

If the 4 atoms in an improper quadruplet (listed in the data file read by the *read\_data* command are ordered I,J,K,L then atoms I,K,L are considered to lie in a plane and atom J is out-of-plane. The angle  $\chi_0$  is computed as the Allinger angle which is defined as the angle between the plane of I,K,L, and the vector from atom I to atom J.

The following coefficient must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)

Note that the angle  $\chi$  is computed in radians; hence  $K$  is effectively energy per radian<sup>2</sup>.

### 8.1.4 Restrictions

This improper style can only be used if LAMMPS was built with the AMOEBA package. See the [Build package](#) doc page for more info.

## 8.2 improper\_style class2 command

Accelerator Variants: *class2/omp*, *class2/kk*

### 8.2.1 Syntax

```
improper_style class2
```

### 8.2.2 Examples

```
improper_style class2
improper_coeff 1 100.0 0
improper_coeff * aa 0.0 0.0 0.0 115.06 130.01 115.06
```

### 8.2.3 Description

The *class2* improper style uses the potential

$$\begin{aligned} E &= E_i + E_{aa} \\ E_i &= K \left[ \frac{\chi_{ijkl} + \chi_{kjli} + \chi_{ljik}}{3} - \chi_0 \right]^2 \\ E_{aa} &= M_1(\theta_{ijk} - \theta_1)(\theta_{kjl} - \theta_3) + \\ &\quad M_2(\theta_{ijk} - \theta_1)(\theta_{ijl} - \theta_2) + \\ &\quad M_3(\theta_{ijl} - \theta_2)(\theta_{kjl} - \theta_3) \end{aligned}$$

where  $E_i$  is the improper term and  $E_{aa}$  is an angle-angle term. The 3  $\chi$  terms in  $E_i$  are an average over 3 out-of-plane angles.

The 4 atoms in an improper quadruplet (listed in the data file read by the [read\\_data](#) command) are ordered I,J,K,L.  $\chi_{ijkl}$  refers to the angle between the plane of I,J,K and the plane of J,K,L, and the bond JK lies in both planes. Similarly for  $\chi_{kjli}$  and  $\chi_{ljik}$ . Note that atom J appears in the common bonds (JI, JK, JL) of all 3 X terms. Thus J (the second atom in the quadruplet) is the atom of symmetry in the 3  $\chi$  angles.

The subscripts on the various  $\theta$ s refer to different combinations of three atoms (I,J,K,L) used to form a particular angle. E.g.  $\theta_{ijl}$  is the angle formed by atoms I,J,L with J in the middle.  $\theta_1, \theta_2, \theta_3$  are the equilibrium positions of those angles. Again, atom J (the second atom in the quadruplet) is the atom of symmetry in the theta angles, since it is always the center atom.

Since atom J is the atom of symmetry, normally the bonds J-I, J-K, J-L would exist for an improper to be defined between the 4 atoms, but this is not required.

See [\(Sun\)](#) for a description of the COMPASS class2 force field.

Coefficients for the  $E_i$  and  $E_{aa}$  formulas must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands.

These are the 2 coefficients for the  $E_i$  formula:

- $K$  (energy)
- $\chi_0$  (degrees)

$\chi_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>.

For the  $E_{aa}$  formula, each line in a *improper\_coeff* command in the input script lists 7 coefficients, the first of which is *aa* to indicate they are AngleAngle coefficients. In a data file, these coefficients should be listed under a *AngleAngle Coeffs* heading and you must leave out the *aa*, i.e. only list 6 coefficients after the improper type.

- *aa*
- $M_1$  (energy)
- $M_2$  (energy)
- $M_3$  (energy)
- $\theta_1$  (degrees)
- $\theta_2$  (degrees)
- $\theta_3$  (degrees)

The  $\theta$  values are specified in degrees, but LAMMPS converts them to radians internally; hence the various  $M$  are effectively energy per radian<sup>2</sup>.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 8.3 improper\_style cossq command

Accelerator Variants: *cossq/omp*

### 8.3.1 Syntax

```
improper_style cossq
```

### 8.3.2 Examples

```
improper_style cossq
improper_coeff 1 4.0 0.0
```

### 8.3.3 Description

The *cossq* improper style uses the potential

$$E = \frac{1}{2}K \cos^2(\chi - \chi_0)$$

where  $\chi$  is the improper angle,  $\chi_0$  is its equilibrium value, and  $K$  is a prefactor.

If the 4 atoms in an improper quadruplet (listed in the data file read by the [read\\_data](#) command) are ordered I,J,K,L then  $\chi$  is the angle between the plane of I,J,K and the plane of J,K,L. Alternatively, you can think of atoms J,K,L as being in a plane, and atom I above the plane, and  $\chi$  as a measure of how far out-of-plane I is with respect to the other 3 atoms.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $K$  (energy)
  - $\chi_0$  (degrees)
- 

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 8.3.4 Restrictions

This improper style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

## 8.4 improper\_style cvff command

Accelerator Variants: *cvff/intel*, *cvff/omp*

### 8.4.1 Syntax

```
improper_style cvff
```

### 8.4.2 Examples

```
improper_style cvff
improper_coeff 1 80.0 -1 4
```

### 8.4.3 Description

The *cvff* improper style uses the potential

$$E = K[1 + d \cos(n\phi)]$$

where phi is the improper dihedral angle.

If the 4 atoms in an improper quadruplet (listed in the data file read by the *read\_data* command) are ordered I,J,K,L then the improper dihedral angle is between the plane of I,J,K and the plane of J,K,L. Note that because this is effectively a dihedral angle, the formula for this improper style is the same as for *dihedral\_style harmonic*.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- *K* (energy)
- *d* (+1 or -1)
- *n* (0,1,2,3,4,6)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 8.4.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

### 8.4.5 Related commands

*improper\_coeff*

### 8.4.6 Default

none

## 8.5 improper\_style distance command

### 8.5.1 Syntax

```
improper_style distance
```

### 8.5.2 Examples

```
improper_style distance
improper_coeff 1 80.0 100.0
```

### 8.5.3 Description

The *distance* improper style uses the potential

$$E = K_2 d^2 + K_4 d^4$$

where  $d$  is the distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the [read\\_data](#) command) are ordered I,J,K,L then the I-atom is assumed to be the central atom.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K_2$  (energy/distance<sup>2</sup>)
  - $K_4$  (energy/distance<sup>4</sup>)
- 

## 8.5.4 Restrictions

This improper style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

## 8.5.5 Related commands

*improper\_coeff*

## 8.5.6 Default

# 8.6 improper\_style distharm command

## 8.6.1 Syntax

```
improper_style distharm
```

## 8.6.2 Examples

```
improper_style distharm
improper_coeff 1 25.0 0.5
```

## 8.6.3 Description

The *distharm* improper style uses the potential

$$E = K(d - d_0)^2$$

where  $d$  is the oriented distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the [read\\_data](#) command) are ordered I,J,K,L then the L-atom is assumed to be the central atom. Note that this is different from the convention used in the `improper_style distance`. The distance  $d$  is oriented and can take on negative values. This may lead to unwanted behavior if  $d_0$  is not equal to zero.

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K$  (energy/distance<sup>2</sup>)

- $d_0$  (distance)
- 

### 8.6.4 Restrictions

This improper style can only be used if LAMMPS was built with the YAFF package. See the [Build package](#) doc page for more info.

### 8.6.5 Related commands

*improper\_coeff*

### 8.6.6 Default

none

## 8.7 improper\_style fourier command

Accelerator Variants: *fourier/omp*

### 8.7.1 Syntax

```
improper_style fourier
```

### 8.7.2 Examples

```
improper_style fourier
improper_coeff 1 100.0 0.0 1.0 0.5 1
```

### 8.7.3 Description

The *fourier* improper style uses the following potential:

$$E = K[C_0 + C_1 \cos(\omega) + C_2 \cos(2\omega)]$$

where K is the force constant, C0, C1, C2 are dimensionless coefficients, and omega is the angle between the IL axis and the IJK plane:

If all parameter (see below) is not zero, the all the three possible angles will taken in account.

The following coefficients must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $C_0$  (unitless)
- $C_1$  (unitless)
- $C_2$  (unitless)
- all (0 or 1, optional)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 8.7.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

### 8.7.5 Related commands

*improper\_coeff*

### 8.7.6 Default

none

## 8.8 improper\_style harmonic command

Accelerator Variants: *harmonic/intel*, *harmonic/kk*, *harmonic/omp*

### 8.8.1 Syntax

```
improper_style harmonic
```

### 8.8.2 Examples

```
improper_style harmonic
improper_coeff 1 100.0 0
```

### 8.8.3 Description

The *harmonic* improper style uses the potential

$$E = K(\chi - \chi_0)^2$$

where  $\chi$  is the improper angle,  $\chi_0$  is its equilibrium value, and  $K$  is a prefactor. Note that the usual 1/2 factor is included in  $K$ .

If the 4 atoms in an improper quadruplet (listed in the data file read by the [read\\_data](#) command) are ordered I,J,K,L then  $\chi$  is the angle between the plane of I,J,K and the plane of J,K,L. Alternatively, you can think of atoms J,K,L as being in a plane, and atom I above the plane, and  $\chi$  as a measure of how far out-of-plane I is with respect to the other 3 atoms.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $K$  (energy)

- $\chi_0$  (degrees)

$\chi_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 8.8.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

## 8.8.5 Related commands

*improper\_coeff*

## 8.8.6 Default

none

# 8.9 improper\_style hybrid command

Accelerator Variants: *hybrid/kk*

## 8.9.1 Syntax

```
improper_style hybrid style1 style2 ...
```

- style1,style2 = list of one or more improper styles

## 8.9.2 Examples

```
improper_style hybrid harmonic cvff
improper_coeff 1 harmonic 120.0 30
improper_coeff 2 cvff 20.0 -1 2
```

## 8.9.3 Description

The *hybrid* style enables the use of multiple improper styles in one simulation. An improper style is assigned to each improper type. For example, impropers in a polymer flow (of improper type 1) could be computed with a *harmonic* potential and impropers in the wall boundary (of improper type 2) could be computed with a *cvff* potential. The assignment of improper type to style is made via the *improper\_coeff* command or in the data file.

In the *improper\_coeff* command, the first coefficient sets the improper style and the remaining coefficients are those appropriate to that style. In the example above, the 2 *improper\_coeff* commands would set impropers of improper type 1 to be computed with a *harmonic* potential with coefficients 120.0, 30 for  $K$ ,  $\chi_0$ . Improper type 2 would be computed with a *cvff* potential with coefficients 20.0, -1, 2 for  $K$ ,  $d$ , and  $n$ , respectively.

If improper coefficients are specified in the data file read via the *read\_data* command, then the same rule applies. E.g. “harmonic” or “cvff”, must be added after the improper type, for each line in the “Improper Coeffs” section, e.g.

### Improper Coeffs

```
1 harmonic 120.0 30
2 cvff 20.0 -1 2
...
```

If *class2* is one of the improper hybrid styles, the same rule holds for specifying additional AngleAngle coefficients either via the input script or in the data file. I.e. *class2* must be added to each line after the improper type. For lines in the AngleAngle Coeffs section of the data file for dihedral types that are not *class2*, you must use an improper style of *skip* as a placeholder, e.g.

### AngleAngle Coeffs

```
1 skip
2 class2 0.0 0.0 0.0 115.06 130.01 115.06
...
```

Note that it is not necessary to use the improper style *skip* in the input script, since AngleAngle coefficients need not be specified at all for improper types that are not *class2*.

An improper style of *none* can be specified as the second argument to the *improper\_coeff* command, if you desire to turn off certain improper types.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 8.9.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

Unlike other improper styles, the hybrid improper style does not store improper coefficient info for individual sub-styles in *binary restart files* or *data files*. Thus when restarting a simulation, you need to re-specify the `improper_coeff` commands.

## 8.9.5 Related commands

*improper\_coeff*

## 8.9.6 Default

none

# 8.10 improper\_style inversion/harmonic command

## 8.10.1 Syntax

```
improper_style inversion/harmonic
```

## 8.10.2 Examples

```
improper_style inversion/harmonic
improper_coeff 1 18.776340 0.000000
```

## 8.10.3 Description

The *inversion/harmonic* improper style follows the Wilson-Decius out-of-plane angle definition and uses an harmonic potential:

$$E = K (\omega - \omega_0)^2$$

where  $K$  is the force constant and  $\omega$  is the angle evaluated for all three axis-plane combinations centered around the atom I. For the IL axis and the IJK plane  $\omega$  looks as follows:

Note that the *inversion/harmonic* angle term evaluation differs to the *improper\_umbrella* due to the cyclic evaluation of all possible angles  $\omega$ .

The following coefficients must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\omega_0$  (degrees)

If  $\omega_0 = 0$  the potential term has a single minimum for the planar structure. Otherwise it has two minima at  $\pm \omega_0$ , with a barrier in between.

#### 8.10.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOFFF package. See the *Build package* doc page for more info.

#### 8.10.5 Related commands

*improper\_coeff*

#### 8.10.6 Default

none

## 8.11 improper\_style none command

### 8.11.1 Syntax

```
improper_style none
```

### 8.11.2 Examples

```
improper_style none
```

### 8.11.3 Description

Using an improper style of none means improper forces and energies are not computed, even if quadruplets of improper atoms were listed in the data file read by the *read\_data* command.

See the *improper\_style zero* command for a way to calculate improper statistics, but compute no improper interactions.

### 8.11.4 Restrictions

none

*improper\_style zero*

### 8.11.6 Default

none

## 8.12 improper\_style ring command

Accelerator Variants: *ring/omp*

### 8.12.1 Syntax

```
improper_style ring
```

## 8.12.2 Examples

```
improper_style ring
improper_coeff 1 8000 70.5
```

## 8.12.3 Description

The *ring* improper style uses the potential

$$E = \frac{1}{6} K (\Delta_{ijl} + \Delta_{ijk} + \Delta_{kjl})^6$$

$$\Delta_{ijl} = \cos \theta_{ijl} - \cos \theta_0$$

$$\Delta_{ijk} = \cos \theta_{ijk} - \cos \theta_0$$

$$\Delta_{kjl} = \cos \theta_{kjl} - \cos \theta_0$$

where  $K$  is a prefactor,  $\theta$  is the angle formed by the atoms specified by (i,j,k,l) indices and  $\theta_0$  its equilibrium value.

If the 4 atoms in an improper quadruplet (listed in the data file read by the [read\\_data](#) command) are ordered i,j,k,l then  $\theta_{ijl}$  is the angle between atoms i,j and l,  $\theta_{ijk}$  is the angle between atoms i,j and k,  $\theta_{kjl}$  is the angle between atoms j,k, and l.

The “ring” improper style implements the improper potential introduced by Destree et al., in Equation (9) of ([Destree](#)). This potential does not affect small amplitude vibrations but is used in an ad-hoc way to prevent the onset of accidentally large amplitude fluctuations leading to the occurrence of a planar conformation of the three bonds i-j, j-k and j-l, an intermediate conformation toward the chiral inversion of a methine carbon. In the “Improvers” section of data file four atoms: i, j, k and l are specified with i,j and l lying on the backbone of the chain and k specifying the chirality of j.

The following coefficients must be defined for each improper type via the [improper\\_coeff](#) command as in the example above, or in the data file or restart files read by the [read\\_data](#) or [read\\_restart](#) commands:

- $K$  (energy)
- $\theta_0$  (degrees)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 8.12.4 Restrictions

This improper style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the [Build package](#) doc page for more info.

## 8.12.5 Related commands

## 8.13 improper\_style sqdistharm command

### 8.13.1 Syntax

```
improper_style sqdistharm
```

### 8.13.2 Examples

```
improper_style sqdistharm
improper_coeff 1 50.0 0.1
```

### 8.13.3 Description

The *sqdistharm* improper style uses the potential

$$E = K(d^2 - d_0^2)^2$$

where  $d$  is the distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the [read\\_data](#) command) are ordered I,J,K,L then the L-atom is assumed to be the central atom. Note that this is different from the convention used in the *improper\_style* distance.

The following coefficients must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy/distance<sup>4</sup>)
- $d_0^2$  (distance<sup>2</sup>)

Note that  $d_0^2$  (in units distance<sup>2</sup>) has be provided and not  $d_0$ .

---

### 8.13.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

### 8.13.5 Related commands

*improper\_coeff*

### 8.13.6 Default

## 8.14 improper\_style umbrella command

Accelerator Variants: *umbrella/omp*

### 8.14.1 Syntax

```
improper_style umbrella
```

### 8.14.2 Examples

```
improper_style umbrella
improper_coeff 1 100.0 180.0
```

### 8.14.3 Description

The *umbrella* improper style uses the following potential, which is commonly referred to as a classic inversion and used in the [DREIDING](#) force field:

$$E = \frac{1}{2} K \left( \frac{1}{\sin \omega_0} \right)^2 (\cos \omega - \cos \omega_0)^2 \quad \omega_0 \neq 0^\circ$$

$$E = K (1 - \cos \omega) \quad \omega_0 = 0^\circ$$

where  $K$  is the force constant and  $\omega$  is the angle between the IL axis and the IJK plane:

If  $\omega_0 = 0$  the potential term has a minimum for the planar structure. Otherwise it has two minima at  $\omega + / - \omega_0$ , with a barrier in between.

See ([Mayo](#)) for a description of the DREIDING force field.

The following coefficients must be defined for each improper type via the *improper\_coeff* command as in the example above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $K$  (energy)
- $\omega_0$  (degrees)

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* *command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 8.14.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the [Build package](#) doc page for more info.

## 8.15 improper\_style zero command

### 8.15.1 Syntax

```
improper_style zero [nocoeff]
```

### 8.15.2 Examples

```
improper_style zero  
improper_style zero nocoeff  
improper_coeff *
```

### 8.15.3 Description

Using an improper style of zero means improper forces and energies are not computed, but the geometry of improper quadruplets is still accessible to other commands.

As an example, the *compute improper/local* command can be used to compute the chi values for the list of quadruplets of improper atoms listed in the data file read by the *read\_data* command. If no improper style is defined, this command cannot be used.

The optional *nocoeff* flag allows to read data files with a *ImproperCoeff* section for any improper style. Similarly, any *improper\_coeff* commands will only be checked for the improper type number and the rest ignored.

Note that the *improper\_coeff* command must be used for all improper types, though no additional values are specified.

## 9.10.2 Examples

```
dump myDump all atom 100 dump.lammpstrj
dump myDump all atom/gz 100 dump.atom.gz
dump myDump all atom/zstd 100 dump.atom.zst
dump 2 subgroup atom 50 dump.run.bin
dump 4a all custom 100 dump.myforce.* id type x y vx fx
dump 4a all custom 100 dump.myvel.lammpsbin id type x y z vx vy vz
dump 4b flow custom 100 dump.%myforce id type c_myF[3] v_ke
dump 4b flow custom 100 dump.%myforce id type c_myF[*] v_ke
dump 2 inner cfg 10 dump.snap.*.cfg mass type xs ys zs vx vy vz
dump snap all cfg 100 dump.config.*.cfg mass type xs ys zs id type c_Stress[2]
dump 1 all xtc 1000 file.xtc
```

## 9.10.3 Description

Dump a snapshot of quantities to one or more files once every  $N$  timesteps in one of several styles. The timesteps on which dump output is written can also be controlled by a variable. See the [dump\\_modify every](#) command.

Almost all the styles output per-atom data, i.e. one or more values per atom. The exceptions are as follows. The *local* styles output one or more values per bond (angle, dihedral, improper) or per pair of interacting atoms (force or neighbor interactions). The *grid* styles output one or more values per grid cell, which are produced by other commands which overlay the simulation domain with a regular grid. See the [Howto grid](#) doc page for details. The *image* style renders a JPG, PNG, or PPM image file of the system for each snapshot, while the *movie* style combines and compresses the series of images into a movie file; both styles are discussed in detail on the [dump image](#) page.

Only information for atoms in the specified group is dumped. The [dump\\_modify thresh and region and refresh](#) commands can also alter what atoms are included. Not all styles support these options; see details on the [dump\\_modify](#) doc page.

As described below, the filename determines the kind of output: text or binary or gzipped, one big file or one per timestep, one file for all the processors or multiple smaller files.

---

**Note:** Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box. Re-neighbor timesteps will not typically coincide with the timesteps dump snapshots are written. See the [dump\\_modify pbc](#) command if you wish to force coordinates to be strictly inside the simulation box.

---

---

**Note:** Unless the [dump\\_modify sort](#) option is invoked, the lines of atom or grid information written to dump files (typically one line per atom or grid cell) will be in an indeterminate order for each snapshot. This is even true when running on a single processor, if the [atom\\_modify sort](#) option is on, which it is by default. In this case atoms are re-ordered periodically during a simulation, due to spatial sorting. It is also true when running in parallel, because data for a single snapshot is collected from multiple processors, each of which owns a subset of the atoms.

---

**Warning:** Without either including atom IDs or using the [dump\\_modify sort](#) option, it is impossible for visualization programs (e.g. OVITO or VMD) or analysis tools to assign data in different frames consistently to the same atom. This can lead to incorrect visualizations or results. LAMMPS will print a warning in such cases.

For the *atom*, *custom*, *cfg*, *grid*, and *local* styles, sorting is off by default. For the *dcd*, *grid/vtk*, *xtc*, *xyz*, and *molfile* styles, sorting by atom ID or grid ID is on by default. See the [dump\\_modify](#) page for details.

The *style* keyword determines what kind of data is written to the dump file(s) and in what format.

Note that *atom*, *custom*, *dcd*, *xtc*, *xyz*, and *yaml* style dump files can be read directly by [VMD](#), a popular tool for visualizing and analyzing trajectories from atomic and molecular systems. For reading *netcdf* style dump files, the *netcdf* plugin needs to be recompiled from source using a NetCDF version compatible with the one used by LAMMPS. The bundled plugin binary uses a very old version of NetCDF that is not compatible with LAMMPS.

Likewise the [OVITO visualization package](#), popular for materials modeling, can read the *atom*, *custom*, *local*, *xtc*, *cfg*, *netcdf*, and *xyz* style atom dump files directly. With version 3.8 and above, OVITO can also read and visualize *grid* style dump files with grid cell data, including iso-surface images of the grid cell values.

Note that settings made via the [dump\\_modify](#) command can also alter the format of individual values and content of the dump file itself. This includes the precision of values output to text-based dump files which is controlled by the [dump\\_modify format](#) command and its options.

---

Format of native LAMMPS format dump files:

The *atom*, *custom*, *grid*, and *local* styles create files in a simple LAMMPS-specific text format that is mostly self-explanatory when viewing a dump file. Many post-processing tools either included with LAMMPS or third-party tools can read this format, as does the [rerun](#) command. See tools described on the [Tools](#) doc page for examples, including [Pizza.py](#).

For all these styles, the dimensions of the simulation box are included in each snapshot. The simulation box in LAMMPS can be defined in one of 3 ways: orthogonal, restricted triclinic, and general triclinic. See the [Howto triclinic](#) doc page for a detailed description of all 3 options.

For an orthogonal simulation box the box information is formatted as:

```
ITEM: BOX BOUNDS xx yy zz
xlo xhi
ylo yhi
zlo zhi
```

where xlo,xhi are the maximum extents of the simulation box in the *x*-dimension, and similarly for *y* and *z*. The “xx yy zz” terms are six characters that encode the style of boundary for each of the six simulation box boundaries (xlo,xhi; ylo,yhi; and zlo,zhi). Each of the six characters is one of *p* (periodic), *f* (fixed), *s* (shrink wrap), or *m* (shrink wrapped with a minimum value). See the [boundary](#) command for details.

For a restricted triclinic simulation box, an orthogonal bounding box which encloses the restricted triclinic simulation box is output, along with the three tilt factors (*xy*, *xz*, *yz*) of the triclinic box, formatted as follows:

```
ITEM: BOX BOUNDS xy xz yz xx yy zz
xlo_bound xhi_bound xy
ylo_bound yhi_bound xz
zlo_bound zhi_bound yz
```

The presence of the text “xy xz yz” in the ITEM line indicates that the three tilt factors will be included on each of the three following lines. This bounding box is convenient for many visualization programs. The meaning of the six character flags for “xx yy zz” is the same as above.

Note that the first two numbers on each line are now xlo\_bound instead of xlo, etc. because they represent a bounding box. See the [Howto triclinic](#) page for a geometric description of triclinic boxes, as defined by LAMMPS, simple formulas for how the six bounding box extents (xlo\_bound, xhi\_bound, etc.) are calculated from the triclinic parameters, and how to transform those parameters to and from other commonly used triclinic representations.

For a general triclinic simulation box, see the “General triclinic” section below for a description of the `ITEM: BOX BOUNDS` format as well as how per-atom coordinates and per-atom vector quantities are output.

The *atom* and *custom* styles output a “ITEM: NUMBER OF ATOMS” line with the count of atoms in the snapshot. Likewise they output an “ITEM: ATOMS” line which includes column descriptors for the per-atom lines that follow. For example, the descriptors would be “id type xs ys zs” for the default *atom* style, and would be the atom attributes you specify in the dump command for the *custom* style. Each subsequent line will list the data for a single atom.

For style *atom*, atom coordinates are written to the file, along with the atom ID and atom type. By default, atom coords are written in a scaled format (from 0 to 1). That is, an *x* value of 0.25 means the atom is at a location 1/4 of the distance from *xlo* to *xhi* of the box boundaries. The format can be changed to unscaled coords via the *dump\_modify* settings. Image flags can also be added for each atom via *dump\_modify*.

Style *custom* allows you to specify a list of atom attributes to be written to the dump file for each atom. Possible attributes are listed above and will appear in the order specified. You cannot specify a quantity that is not defined for a particular simulation—such as *q* for atom style *bond*, since that atom style does not assign charges. Dumps occur at the very end of a timestep, so atom attributes will include effects due to fixes that are applied during the timestep. An explanation of the possible dump custom attributes is given below.

New in version 22Dec2022.

For style *grid* the dimension of the simulation domain and size of the *N<sub>x</sub>* by *N<sub>y</sub>* by *N<sub>z</sub>* grid that overlays the simulation domain are also output with each snapshot:

```
ITEM: DIMENSION
dim
ITEM: GRID SIZE
nx ny nz
```

The value *dim* will be 2 or 3 for 2d or 3d simulations. It is included so that post-processing tools like [OVITO](#), which can visualize grid-based quantities know how to draw each grid cell. The grid size will match the input script parameters for grid(s) created by the computes or fixes which are referenced by the the dump command. For 2d simulations (and grids), *nz* will always be 1.

There will also be an “ITEM: GRID DATA” line which includes column descriptors for the per grid cell data. Each subsequent line (*N<sub>x</sub>* \* *N<sub>y</sub>* \* *N<sub>z</sub>* lines) will list the data for a single grid cell. If grid cell IDs are included in the output via the *compute property/grid* command, then the IDs will range from 1 to *N* = *N<sub>x</sub>*\**N<sub>y</sub>*\**N<sub>z</sub>*. The ordering of IDs is with the *x* index varying fastest, then the *y* index, and the *z* index varying slowest.

For style *local*, local output generated by *computes* and *fixes* is used to generate lines of output that is written to the dump file. This local data is typically calculated by each processor based on the atoms it owns, but there may be zero or more entities per atom (e.g., a list of bond distances). An explanation of the possible dump local attributes is given below. Note that by using input from the *compute property/local* command with *dump local*, it is possible to generate information on bonds, angles, etc. that can be cut and pasted directly into a data file read by the *read\_data* command.

---

Dump files in other popular formats:

---

**Note:** This section only discusses file formats relevant to this doc page. The top of this page has links to other dump commands (with their own pages) which write files in additional popular formats.

---

Style *cfg* has the same command syntax as style *custom* and writes extended CFG format files, as used by the [AtomEye](#) visualization package. Since the extended CFG format uses a single snapshot of the system per file, a wildcard “\*” must be included in the filename, as discussed below. The list of atom attributes for style *cfg* must begin with either “mass type xs ys zs” or “mass type xsu ysu zsu” since these quantities are needed to write the CFG files in the appropriate format (though the “mass” and “type” fields do not appear explicitly in the file). Any remaining attributes will be stored as “auxiliary properties” in the CFG files. Note that you will typically want to use the *dump\_modify element* command

with CFG-formatted files, to associate element names with atom types, so that AtomEye can render atoms appropriately. When unwrapped coordinates *xsu*, *ysu*, and *zsu* are requested, the nominal AtomEye periodic cell dimensions are expanded by a large factor UNWRAPEXPAND = 10.0, which ensures atoms that are displayed correctly for up to UNWRAPEXPAND/2 periodic boundary crossings in any direction. Beyond this, AtomEye will rewrap the unwrapped coordinates. The expansion causes the atoms to be drawn farther away from the viewer, but it is easy to zoom the atoms closer, and the interatomic distances are unaffected.

The *dcd* style writes DCD files, a standard atomic trajectory format used by the CHARMM, NAMD, and XPlor molecular dynamics packages. DCD files are binary and thus may not be portable to different machines. The number of atoms per snapshot cannot change with the *dcd* style. The *unwrap* option of the *dump\_modify* command allows DCD coordinates to be written “unwrapped” by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

The *xtc* style writes XTC files, a compressed trajectory format used by the GROMACS molecular dynamics package, and described [here](#). The precision used in XTC files can be adjusted via the *dump\_modify* command. The default value of 1000 means that coordinates are stored to 1/1000 nanometer accuracy. XTC files are portable binary files written in the NFS XDR data format, so that any machine which supports XDR should be able to read them. The number of atoms per snapshot cannot change with the *xtc* style. The *unwrap* option of the *dump\_modify* command allows XTC coordinates to be written “unwrapped” by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

The *xyz* style writes XYZ files, which is a simple text-based coordinate format that many codes can read. Specifically it has a line with the number of atoms, then a comment line that is usually ignored followed by one line per atom with the atom type and the *x*-, *y*-, and *z*-coordinate of that atom. You can use the *dump\_modify element* option to change the output from using the (numerical) atom type to an element name (or some other label). This option will help many visualization programs to guess bonds and colors. You can use the *dump\_modify types labels* option to replace numeric atom types with *type labels*.

New in version 22Dec2022.

The *grid/vtk* style writes VTK files for grid data on a regular rectilinear grid. Its content is conceptually similar to that of the text file produced by the *grid* style, except that it is in an XML-based format which visualization programs which support the VTK format can read, e.g. the [ParaView tool](#). For this style, there can only be 1 or 3 per grid cell attributes specified. If it is a single value, it is a scalar quantity. If 3 values are specified it is encoded in the VTK file as a vector quantity (for each grid cell). The filename for this style must include a “\*” wildcard character to produce one file per snapshot; see details below.

New in version 4May2022.

Dump style *yaml* has the same command syntax as style *custom* and writes YAML format files that can be easily parsed by a variety of data processing tools and programming languages. Each timestep will be written as a YAML “document” (i.e., starts with “—” and ends with “..”). The style supports writing one file per timestep through the “\*” wildcard but not multi-processor outputs with the “%” token in the filename. In addition to per-atom data, *thermo* data can be included in the *yaml* style dump file using the *dump\_modify thermo yes*. The data included in the dump file uses the “thermo” tag and is otherwise identical to data specified by the *thermo\_style* command.

Below is an example for a YAML format dump created by the following commands.

```
dump out all yaml 100 dump.yaml id type x y z vx vy vz ix iy iz
dump_modify out time yes units yes thermo yes format 1 %5d format "% 10.6e"
```

The tags “time”, “units”, and “thermo” are optional and enabled by the *dump\_modify* command. The list under the “box” tag has three lines for orthogonal boxes and four lines for triclinic boxes, where the first three are the box boundaries and the fourth the three tilt factors (*xy*, *xz*, *yz*). The “thermo” data follows the format of the *yaml* thermo style.

The “keywords” tag lists the per-atom properties contained in the “data” columns, which contain a list with one line per atom. The keywords may be renamed using the `dump_modify` command same as for the *custom* dump style.

```

```

Frequency of dump output:

Dumps are performed on timesteps that are a multiple of  $N$  (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of  $N$ . This behavior can be changed via the `dump_modify first` command, which can also be useful if the dump command is invoked after a minimization ended on an arbitrary timestep.

The value of  $N$  can be changed between runs by using the `dump_modify every` command (not allowed for *dcd* style). The `dump_modify every` command also allows a variable to be used to determine the sequence of timesteps on which dump files are written. In this mode a dump on the first timestep of a run will also not be written unless the `dump_modify first` command is used.

If you instead want to dump snapshots based on simulation time (in time units of the `units command`), the `dump_modify every/time` command can be used. This can be useful when the timestep size varies during a simulation run, e.g. by use of the `fix dt/reset` command.

Dump filenames:

The specified dump filename determines how the dump file(s) is written. The default is to write one large text file, which is opened when the dump command is invoked and closed when an *undump* command is used or when LAMMPS exits. For the *dcd* and *xtc* styles, this is a single large binary file.

Many of the styles allow dump filenames to contain either or both of two wildcard characters. If a “\*” character appears in the filename, then one file per snapshot is written and the “\*” character is replaced with the timestep value. For example, *tmp.dump.\** becomes *tmp.dump.0*, *tmp.dump.10000*, *tmp.dump.20000*, etc. This option is not available for the *dcd* and *xtc* styles. Note that the *dump\_modify pad* command can be used to ensure all timestep numbers are the same length (e.g., 00010), which can make it easier to read a series of dump files in order with some post-processing tools.

If a “%” character appears in the filename, then each of *P* processors writes a portion of the dump file, and the “%” character is replaced with the processor ID from 0 to *P* – 1. For example, *tmp.dump.%* becomes *tmp.dump.0*, *tmp.dump.1*, ... *tmp.dump.math:P-1*, etc. This creates smaller files and can be a fast mode of output on parallel machines that support parallel I/O for output. This option is **not** available for the *dcd*, *xtc*, *xyz*, *grid/vtk*, and *yaml* styles.

By default, *P* is the the number of processors, meaning one file per processor, but *P* can be set to a smaller value via the *nfile* or *fileper* keywords of the *dump\_modify* command. These options can be the most efficient way of writing out dump files when running on large numbers of processors.

Note that using the “\*” and “%” characters together can produce a large number of small dump files!

Deprecated since version 21Nov2023.

The MPIIO package and the the corresponding “/mpiio” dump styles, except for the unrelated “netcdf/mpiio” style were removed from LAMMPS.

---

Compression of dump file data:

If the specified filename ends with “.bin” or “.lammpsbin”, the dump file (or files, if “\*” or “%” is also used) is written in binary format. A binary dump file will be about the same size as a text version, but will typically write out much faster. Of course, when post-processing, you will need to convert it back to text format (see the *binary2txt tool*) or write your own code to read the binary file. The format of the binary file can be understood by looking at the *tools/binary2txt.cpp* file. This option is only available for the *atom* and *custom* styles.

If the filename ends with “.gz”, the dump file (or files, if “\*” or “%” is also used) is written in gzipped format. A gzipped dump file will be about 3× smaller than the text version, but will also take longer to write. This option is not available for the *dcd* and *xtc* styles.

Note that styles that end with *gz* are identical in command syntax to the corresponding styles without “gz”, however, they generate compressed files using the zlib library. Thus the filename suffix “.gz” is mandatory. This is an alternative approach to writing compressed files via a pipe, as done by the regular dump styles, which may be required on clusters where the interface to the high-speed network disallows using the *fork()* library call (which is needed for a pipe). For the remainder of this page, you should thus consider the *atom* and *atom/gz* styles (etc.) to be inter-changeable, with the exception of the required filename suffix.

Similarly, styles that end with *zstd* are identical to the *gz* styles, but use the Zstd compression library instead and require a “.zst” suffix. See the *dump\_modify* page for details on how to control the compression level in both variants.

---

General triclinic simulation box output for the *atom* and *custom* styles:

As mentioned above, the simulation box can be defined as a general triclinic box, which means that 3 arbitrary box edge vectors **A**, **B**, **C** can be specified. See the *Howto triclinic* doc page for a detailed description of general triclinic boxes.

This option is provided as a convenience for users who may be converting data from solid-state crystallographic representations or from DFT codes for input to LAMMPS. However, as explained on the [Howto\\_triclinic](#) doc page, internally, LAMMPS only uses restricted triclinic simulation boxes. This means the box and per-atom information (e.g. coordinates, velocities) LAMMPS stores are converted (rotated) from general to restricted triclinic form when the system is created.

For dump output, if the [dump\\_modify triclinic/general](#) command is used, the box description and per-atom coordinates and other per-atom vectors will be converted (rotated) from restricted to general form when each dump file snapshots is output. This option can only be used if the simulation box was initially created as general triclinic. If the option is not used, and the simulation box is general triclinic, then the dump file snapshots will reflect the internal restricted triclinic geometry.

The `dump_modify triclinic/general` option affects 3 aspects of the dump file output.

First, the format for the BOX BOUNDS is as follows

```
ITEM: BOX BOUNDS abc origin
ax ay az originx
bx by bz originy
cx cy cz originz
```

where the **A** edge vector of the box is (ax,ay,az) and similarly for **B** and **C**. The origin of all 3 edge vectors is (originx, originy, originz).

Second, the coordinates of each atom are converted (rotated) so that the atom is inside (or near) the general triclinic box defined by the **A**, **B**, **C** edge vectors. For style *atom*, this only alters output for unscaled atom coords, via the [dump\\_modify scaled no](#) setting. For style *custom*, this alters output for either unscaled or unwrapped output of atom coords, via the *x,y,z* or *xu,yu,zu* attributes. For output of scaled atom coords by both styles, there is no difference between restricted and general triclinic values.

Third, the output for any attribute of the *custom* style which represents a per-atom vector quantity will be converted (rotated) to be oriented consistent with the general triclinic box and its orientation relative to the standard xyz coordinate axes.

This applies to the following *custom* style attributes:

- vx,vy,vz = atom velocities
- fx,fy,fz = forces on atoms
- mux,muy,muz = orientation of dipole moment of atom
- omegax,omegay,omegaz = angular velocity of spherical particle
- angmomx,angmomy,angmomz = angular momentum of aspherical particle
- tqx,tqy,tqz = torque on finite-size particles

For example, if the velocity of an atom in a restricted triclinic box is along the x-axis, then it will be output for a general triclinic box as a vector along the **A** edge vector of the box.

---

**Note:** For style *custom*, the [dump\\_modify thresh](#) command may access per-atom attributes either directly or indirectly through a compute or variable. If the attribute is an atom coordinate or one of the vectors mentioned above, its value will *NOT* be a general triclinic (rotated) value. Rather it will be a restricted triclinic value.

---

Arguments for different styles:

The sections below describe per-atom, local, and per grid cell attributes which can be used as arguments to the various styles.

Note that in the discussion below, for styles which can reference values from a compute or fix or custom atom property, like the *custom*, *cfg*, *grid* or *local* styles, the bracketed index *i* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the number of columns in the array, then an asterisk with no numeric values means all column indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *m* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. For example, these two dump commands are equivalent, since the *compute stress/atom* command creates a per-atom array with six columns:

```
compute myPress all stress/atom NULL
dump 2 all custom 100 tmp.dump id myPress[*]
dump 2 all custom 100 tmp.dump id myPress[1] myPress[2] myPress[3] &
                                     myPress[4] myPress[5] myPress[6]
```

Per-atom attributes used as arguments to the *custom* and *cfg* styles:

The *id*, *mol*, *proc*, *procp1*, *type*, *typelabel*, *element*, *mass*, *vx*, *vy*, *vz*, *fx*, *fy*, *fz*, *q* attributes are self-explanatory.

*Id* is the atom ID. *Mol* is the molecule ID, included in the data file for molecular systems. *Proc* is the ID of the processor (0 to  $N_{\text{procs}} - 1$ ) that currently owns the atom. *Procp1* is the proc ID+1, which can be convenient in place of a *type* attribute (1 to  $N_{\text{types}}$ ) for coloring atoms in a visualization program. *Type* is the atom type (1 to  $N_{\text{types}}$ ). *Typelabel* is the atom *type label*. *Element* is typically the chemical name of an element, which you must assign to each type via the *dump\_modify element* command. More generally, it can be any string you wish to associated with an atom type. *Mass* is the atom mass. The quantities *vx*, *vy*, *vz*, *fx*, *fy*, *fz*, and *q* are components of atom velocity and force and atomic charge.

There are several options for outputting atom coordinates. The *x*, *y*, and *z* attributes write atom coordinates “unscaled”, in the appropriate distance *units* (Å, σ, etc.). Use *xs*, *ys*, and *zs* if you want the coordinates “scaled” to the box size so that each value is 0.0 to 1.0. If the simulation box is triclinic (tilted), then all atom coords will still be between 0.0 and 1.0. The actual unscaled (*x*, *y*, *z*) coordinate is  $x_s a + y_s b + z_s c$ , where (*a*, *b*, *c*) are the non-orthogonal vectors of the simulation box edges, as discussed on the *Howto triclinic* page.

Use *xu*, *yu*, and *zu* if you want the coordinates “unwrapped” by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that using *xu*, *yu*, and *zu* means that the coordinate values may be far outside the box bounds printed with the snapshot. Using *xsu*, *ysu*, and *zsu* is similar to using *xu*, *yu*, and *zu*, except that the unwrapped coordinates are scaled by the box size. Atoms that have passed through a periodic boundary will have the corresponding coordinate increased or decreased by 1.0.

The image flags can be printed directly using the *ix*, *iy*, and *iz* attributes. For periodic dimensions, they specify which image of the simulation box the atom is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation.

The *mux*, *muy*, and *muz* attributes are specific to dipolar systems defined with an atom style of *dipole*. They give the orientation of the atom’s point dipole moment. The *mu* attribute gives the magnitude of the atom’s dipole moment.

The *radius* and *diameter* attributes are specific to spherical particles that have a finite size, such as those defined with an atom style of *sphere*.

The *omegax*, *omegay*, and *omegaz* attributes are specific to finite-size spherical particles that have an angular velocity. Only certain atom styles, such as *sphere*, define this quantity.

The *angmomx*, *angmomy*, and *angmomz* attributes are specific to finite-size aspherical particles that have an angular momentum. Only the *ellipsoid* atom style defines this quantity.

The *txx*, *tqy*, and *tzx* attributes are for finite-size particles that can sustain a rotational torque due to interactions with other particles.

The `c_ID` and `c_ID[I]` attributes allow per-atom vectors or arrays calculated by a `compute` to be output. The ID in the attribute should be replaced by the actual ID of the compute that has been defined previously in the input script. See the `compute` command for details. There are computes for calculating the per-atom energy, stress, centro-symmetry parameter, and coordination number of individual atoms.

Note that computes which calculate global or local quantities, as opposed to per-atom quantities, cannot be output in a dump custom command. Instead, global quantities can be output by the `thermo_style custom` command, and local quantities can be output by the dump local command.

If `c_ID` is used as a attribute, then the per-atom vector calculated by the compute is printed. If `c_ID[i]` is used, then *i* must be in the range from 1 to *M*, which will print the *i*th column of the per-atom array with *M* columns calculated by the compute. See the discussion above for how *i* can be specified with a wildcard asterisk to effectively specify multiple values.

The `f_ID` and `f_ID[I]` attributes allow vector or array per-atom quantities calculated by a `fix` to be output. The ID in the attribute should be replaced by the actual ID of the fix that has been defined previously in the input script. The `fix ave/atom` command is one that calculates per-atom quantities. Since it can time-average per-atom quantities produced by any `compute`, `fix`, or atom-style `variable`, this allows those time-averaged results to be written to a dump file.

If `f_ID` is used as a attribute, then the per-atom vector calculated by the fix is printed. If `f_ID[i]` is used, then *i* must be in the range from 1 to *M*, which will print the *i*th column of the per-atom array with *M* columns calculated by the fix. See the discussion above for how *i* can be specified with a wildcard asterisk to effectively specify multiple values.

The `v_name` attribute allows per-atom vectors calculated by a `variable` to be output. The name in the attribute should be replaced by the actual name of the variable that has been defined previously in the input script. Only an atom-style variable can be referenced, since it is the only style that generates per-atom values. Variables of style `atom` can reference individual atom attributes, per-atom attributes, thermodynamic keywords, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of creating quantities to output to a dump file.

The `i_name`, `d_name`, `i2_name`, `d2_name` attributes refer to custom per-atom integer and floating-point vectors or arrays that have been added via the `fix property/atom` command. When that command is used specific names are given to each attribute which are the “name” portion of these keywords. For arrays `i2_name` and `d2_name`, the column of the array must also be included following the name in brackets (e.g., `d2_xyz[i]`, `i2_mySpin[i]`, where *i* is in the range from 1 to *M*, where *M* is the number of columns in the custom array). See the discussion above for how *i* can be specified with a wildcard asterisk to effectively specify multiple values.

See the [Modify](#) page for information on how to add new compute and fix styles to LAMMPS to calculate per-atom quantities which could then be output into dump files.

---

Attributes used as arguments to the `local` style:

The `index` attribute can be used to generate an index number from 1 to *N* for each line written into the dump file, where *N* is the total number of local datums from all processors, or lines of output that will appear in the snapshot. Note that because data from different processors depend on what atoms they currently own, and atoms migrate between processor, there is no guarantee that the same index will be used for the same info (e.g. a particular bond) in successive snapshots.

The `c_ID` and `c_ID[I]` attributes allow local vectors or arrays calculated by a `compute` to be output. The ID in the attribute should be replaced by the actual ID of the compute that has been defined previously in the input script. See the `compute` command for details. There are computes for calculating local information such as indices, types, and energies for bonds and angles.

Note that computes which calculate global or per-atom quantities, as opposed to local quantities, cannot be output in a dump local command. Instead, global quantities can be output by the `thermo_style custom` command, and per-atom quantities can be output by the dump custom command.

If `c_ID` is used as a attribute, then the local vector calculated by the compute is printed. If `c_ID[I]` is used, then *I* must be in the range from 1-*M*, which will print the *I*th column of the local array with *M* columns calculated by the compute. See the discussion above for how *I* can be specified with a wildcard asterisk to effectively specify multiple values.

The *f\_ID* and *f\_ID[I]* attributes allow local vectors or arrays calculated by a *fix* to be output. The ID in the attribute should be replaced by the actual ID of the fix that has been defined previously in the input script.

If *f\_ID* is used as a attribute, then the local vector calculated by the fix is printed. If *f\_ID[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the local with M columns calculated by the fix. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Here is an example of how to dump bond info for a system, including the distance and energy of each bond:

```
compute 1 all property/local batom1 batom2 btype
compute 2 all bond/local dist eng
dump 1 all local 10000 tmp.dump index c_1[1] c_1[2] c_1[3] c_2[1] c_2[2]
```

Attributes used as arguments to the *grid* and *grid/vtk* styles:

The attributes that begin with *c\_ID* and *f\_ID* both take colon-separated fields *gname* and *dname*. These refer to a grid name and data field name which is defined by the compute or fix. Note that a compute or fix can define one or more grids (of different sizes) and one or more data fields for each of those grids. The sizes of all grids output in a single dump grid command must be the same.

The *c\_ID:gname:dname* and *c\_ID:gname:dname[I]* attributes allow per-grid vectors or arrays calculated by a *compute* to be output. The ID in the attribute should be replaced by the actual ID of the compute that has been defined previously in the input script.

If *c\_ID:gname:dname* is used as a attribute, then the per-grid vector calculated by the compute is printed. If *c\_ID:gname:dname[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the per-grid array with M columns calculated by the compute. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

The *f\_ID:gname:dname* and *f\_ID:gname:dname[I]* attributes allow per-grid vectors or arrays calculated by a *fix* to be output. The ID in the attribute should be replaced by the actual ID of the fix that has been defined previously in the input script.

If *f\_ID:gname:dname* is used as a attribute, then the per-grid vector calculated by the fix is printed. If *f\_ID:gname:dname[I]* is used, then I must be in the range from 1-M, which will print the Ith column of the per-grid with M columns calculated by the fix. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

### 9.10.4 Restrictions

To write gzipped dump files, you must either compile LAMMPS with the `-DLAMMPS_GZIP` option or use the styles from the COMPRESS package. See the [Build settings](#) page for details.

While a dump command is active (i.e., has not been stopped by using the [undump command](#)), no commands may be used that will change the timestep (e.g., [reset\\_timestep](#)). LAMMPS will terminate with an error otherwise.

The *atom/gz*, *cfg/gz*, *custom/gz*, and *xyz/gz* styles are part of the COMPRESS package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The *xtc*, *dcd*, and *yaml* styles are part of the EXTRA-DUMP package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 9.10.5 Related commands

*dump atom/adios*, *dump custom/adios*, *dump cfg/uef*, *dump h5md*, *dump image*, *dump molfile*, *dump netcdf*, *dump netcdf/mpiio*, *dump\_modify*, *undump*, *write\_dump*

### 9.10.6 Default

The defaults for the *image* and *movie* styles are listed on the *dump image* page.

## 9.11 dump atom/adios command

## 9.12 dump custom/adios command

### 9.12.1 Syntax

```
dump ID group-ID atom/adios N file.bp
dump ID group-ID custom/adios N file.bp args
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- adios = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the *dump* doc page)
- N = dump every this many timesteps
- file.bp = name of file/stream to write to
- args = same options as in *dump custom* command

### 9.12.2 Examples

```
dump adios1 all atom/adios 100 atoms.bp
dump 4a all custom/adios 100 dump_adios.bp id v_p x y z
dump 2 subgroup custom/adios 100 dump_adios.bp mass type xs ys zs vx vy vz
```

### 9.12.3 Description

Dump a snapshot of atom coordinates every *N* timesteps in the ADIOS-based “BP” file format, or using different I/O solutions in ADIOS, to a stream that can be read on-line by another program. ADIOS-BP files are binary, portable, and self-describing.

---

**Note:** To be able to use ADIOS, a file `adios2_config.xml` with specific configuration settings is expected in the current working directory. If the file is not present, LAMMPS will try to create a minimal default file. Please refer to the ADIOS documentation for details on how to adjust this file for optimal performance and desired features.

---

Use from *write\_dump*:

It is possible to use these dump styles with the *write\_dump* command. In this case, the sub-intervals must not be set at all. The *write\_dump* command can be used to create a new file at each individual dump.

```
dump 4      all atom/adios 100 dump.bp
write_dump all atom/adios singledump.bp
```

### 9.12.4 Restrictions

The number of atoms per snapshot **can** change with the adios style. When using the ADIOS tool ‘bpls’ to list the content of a .bp file, bpls will print `__` for the size of the output table indicating that its size is changing every step.

The *atom/adios* and *custom/adios* dump styles are part of the ADIOS package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 9.12.5 Related commands

*dump*, *dump\_modify*, *undump*

## 9.13 dump cfg/uef command

### 9.13.1 Syntax

```
dump ID group-ID cfg/uef N file mass type xs ys zs args
```

- ID = user-assigned name for the dump
  - group-ID = ID of the group of atoms to be dumped
  - N = dump every this many timesteps
  - file = name of file to write dump info to
- args = same as args for *dump custom*

### 9.13.2 Examples

```
dump 1 all cfg/uef 10 dump.*.cfg mass type xs ys zs
dump 2 all cfg/uef 100 dump.*.cfg mass type xs ys zs id c_stress
```

### 9.13.3 Description

This command is used to dump atomic coordinates in the reference frame of the applied flow field when *fix nvt/uef* or *fix npt/uef* is used. Only the atomic coordinates and frame-invariant scalar quantities will be in the flow frame. If velocities are selected as output, for example, they will not be in the same reference frame as the atomic positions.

### 9.13.4 Restrictions

This fix is part of the UEF package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command can only be used when *fix nvt/uef* or *fix npt/uef* is active.

### 9.13.5 Related commands

*dump*, *fix nvt/uef*

### 9.13.6 Default

none

## 9.14 dump h5md command

### 9.14.1 Syntax

**dump** ID group-ID h5md N file.h5 args

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- *h5md* = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file.h5 = name of file to write to
- args = *position* options or *image* or *velocity* options or *force* options or *species* options or *file\_from* ID or *box* value or *create\_group* value or *author* value = list of data elements to dump, with their dump “sub-intervals”

*position* options

*image*

*velocity* options

*force* options

*species* options

*file\_from* ID = do not open a new file, re-use the already opened file from dump ID

*box* value = yes or no

*create\_group* value = yes or no

*author* value = quoted string

Note that at least one element must be specified and that *image* may only be present if *position* is specified first.

For the elements *position*, *velocity*, *force* and *species*, a sub-interval may be specified to write the data only every  $N_{\text{element}}$  iterations of the dump (i.e. every  $N \cdot N_{\text{element}}$  time steps). This is specified by this option directly following the element declaration:

options = every  $N_{\text{element}}$

### 9.14.2 Examples

```
dump h5md1 all h5md 100 dump_h5md.h5 position image
dump h5md1 all h5md 100 dump_h5md.h5 position velocity every 10
dump h5md1 all h5md 100 dump_h5md.h5 velocity author "John Doe"
```

### 9.14.3 Description

Dump a snapshot of atom coordinates every  $N$  timesteps in the **HDF5** based **H5MD** file format (*de Buyl*). HDF5 files are binary, portable and self-describing. This dump style will write only one file, on the root node.

Several dumps may write to the same file, by using *file\_from* and referring to a previously defined dump. Several groups may also be stored within the same file by defining several dumps. A dump that refers (via *file\_from*) to an already open dump ID and that concerns another particle group must specify *create\_group* yes.

Each data element is written every  $N \cdot N_{\text{element}}$  steps. For *image*, no sub-interval is needed as it must be present at the same interval as *position*. *image* must be given after *position* in any case. The box information (edges in each dimension) is stored at the same interval than the *position* element, if present. Else it is stored every  $N$  steps.

---

**Note:** Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

---

#### Use from write\_dump:

It is possible to use this dump style with the *write\_dump* command. In this case, the sub-intervals must not be set at all. The *write\_dump* command can be used either to create a new file or to add current data to an existing dump file by using the *file\_from* keyword.

Typically, the *species* data is fixed. The following two commands store the position data every 100 timesteps, with the image data, and store once the species data in the same file.

```
dump h5md1 all h5md 100 dump.h5 position image
write_dump all h5md dump.h5 file_from h5md1 species
```

### 9.14.4 Restrictions

The number of atoms per snapshot cannot change with the `h5md` style. The position data is stored wrapped (box boundaries not enforced, see note above). Only orthogonal domains are currently supported. This is a limitation of the present `dump h5md` command and not of H5MD itself.

The `h5md` dump style is part of the H5MD package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info. It also requires (i) building the `ch5md` library provided with LAMMPS (See the [Build package](#) page for more info.) and (ii) having the [HDF5](#) library installed (C bindings are sufficient) on your system. The library `ch5md` is compiled with the `h5cc` wrapper provided by the HDF5 library.

---

### 9.14.5 Related commands

*dump*, *dump\_modify*, *undump*

---

(**de Buyl**) de Buyl, Colberg and Hofling, H5MD: A structured, efficient, and portable file format for molecular data, Comp. Phys. Comm. 185(6), 1546-1553 (2014) - [[arXiv:1308.6382](#)].

## 9.15 dump image command

## 9.16 dump movie command

(see below for *dump\_modify options* specific to dump image/movie)

### 9.16.1 Syntax

`dump ID group-ID style N file color diameter keyword value ...`

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- style = *image* or *movie* = style of dump command (other styles such as *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the *dump* doc page)
- N = dump every this many timesteps
- file = name of file to write image to
- color = atom attribute that determines color of each atom
- diameter = atom attribute that determines size of each atom
- zero or more keyword/value pairs may be appended
- keyword = *atom* or *adiam* or *bond* or *grid* or *line* or *tri* or *body* or *fix* or *size* or *view* or *center* or *up* or *zoom* or *box* or *axes* or *subbox* or *shiny* or *fsaa* or *ssao*

*atom* = *yes* or *no* = do or do not draw atoms  
*adiam* size = numeric value for atom diameter (distance units)  
*bond* values = color width = color and width of bonds  
    color = *atom* or *type* or *none*  
    width = number or *atom* or *type* or *none*  
        number = numeric value for bond width (distance units)  
*grid* = per-grid value to use when coloring each grid cell  
    per-grid value = *c\_ID:gname:dname*, *c\_ID:gname:dname[I]*, *f\_ID:gname:dname*, *f\_ID:gname:dname[I]*  
        gname = name of grid defined by compute or fix  
        dname = name of data field defined by compute or fix  
        *c\_ID* = per-grid vector calculated by a compute with ID  
        *c\_ID[I]* = Ith column of per-grid array calculated by a compute with ID  
        *f\_ID* = per-grid vector calculated by a fix with ID  
        *f\_ID[I]* = Ith column of per-grid array calculated by a fix with ID  
*line* = color width  
    color = *type*  
    width = numeric value for line width (distance units)  
*tri* = color tflag width  
    color = *type*  
    tflag = 1 for just triangle, 2 for just tri edges, 3 for both  
    width = numeric value for triangle edge width (distance units)  
*body* = color bflag1 bflag2  
    color = *type*  
    bflag1,bflag2 = 2 numeric flags to affect how bodies are drawn  
*fix* = fixID color fflag1 fflag2  
    fixID = ID of fix that generates objects to draw  
    color = *type*  
    fflag1,fflag2 = 2 numeric flags to affect how fix objects are drawn  
*size* values = width height = size of images  
    width = width of image in # of pixels  
    height = height of image in # of pixels  
*view* values = theta phi = view of simulation box  
    theta = view angle from +z axis (degrees)  
    phi = azimuthal view angle (degrees)  
    theta or phi can be a variable (see below)  
*center* values = flag Cx Cy Cz = center point of image  
    flag = *s* for static, *d* for dynamic  
    Cx,Cy,Cz = center point of image as fraction of box dimension (0.5 = center of box)  
    Cx,Cy,Cz can be variables (see below)  
*up* values = Ux Uy Uz = direction that is "up" in image  
    Ux,Uy,Uz = components of up vector  
    Ux,Uy,Uz can be variables (see below)  
*zoom* value = zfactor = size that simulation box appears in image  
    zfactor = scale image size by factor > 1 to enlarge, factor < 1 to shrink  
    zfactor can be a variable (see below)  
*box* values = *yes/no* diam = draw outline of simulation box  
    yes/no = do or do not draw simulation box lines  
    diam = diameter of box lines as fraction of shortest box length  
*axes* values = axes length diam = draw xyz axes  
    axes = *yes* or *no* = do or do not draw xyz axes lines next to simulation box  
    length = length of axes lines as fraction of respective box lengths  
    diam = diameter of axes lines as fraction of shortest box length

*subbox* values = lines diam = draw outline of processor subdomains  
lines = yes or no = do or do not draw subdomain lines  
diam = diameter of subdomain lines as fraction of shortest box length  
*shiny* value = sfactor = shininess of spheres and cylinders  
sfactor = shininess of spheres and cylinders from 0.0 to 1.0  
*fsaa* arg = yes/no  
yes/no = do or do not apply anti-aliasing  
*ssao* value = shading seed dfactor = SSAO depth shading  
shading = yes or no = turn depth shading on/off  
seed = random # seed (positive integer)  
dfactor = strength of shading from 0.0 to 1.0

## 9.17 dump\_modify options for dump image/movie

### 9.17.1 Syntax

`dump_modify dump-ID keyword values ...`

- these keywords apply only to the *image* and *movie* styles and are documented on this page
- keyword = *acolor* or *adiam* or *amap* or *gmap* or *backcolor* or *bcolor* or *bdiam* or *bitrate* or *boxcolor* or *color* or *framerate* or *gmap*
- see the *dump\_modify* doc page for more general keywords

*acolor* args = type color  
type = atom type (numeric or type label) or range of numeric types (see below)  
color = name of color or color1/color2/...

*adiam* args = type diam  
type = atom type (numeric or type label) or range of numeric types (see below)  
diam = diameter of atoms of that type (distance units)

*amap* args = lo hi style delta N entry1 entry2 ... entryN  
lo = number or *min* = lower bound of range of color map  
hi = number or *max* = upper bound of range of color map  
style = 2 letters = c or d or s plus a or f  
c for continuous  
d for discrete  
s for sequential  
a for absolute  
f for fractional  
delta = binsize (only used for style s, otherwise ignored)  
binsize = range is divided into bins of this width  
N = # of subsequent entries  
entry = value color (for continuous style)  
value = number or *min* or *max* = single value within range  
color = name of color used for that value  
entry = lo hi color (for discrete style)  
lo/hi = number or *min* or *max* = lower/upper bound of subset of range  
color = name of color used for that subset of values  
entry = color (for sequential style)  
color = name of color used for a bin of values

*backcolor* arg = color  
color = name of color for background

```

bcolor args = type color
    type = bond type (numeric or type label) or range of numeric types (see below)
    color = name of color or color1/color2/...
bdiam args = type diam
    type = bond type (numeric or type label) or range of numeric types (see below)
    diam = diameter of bonds of that type (distance units)
bitrate arg = rate
    rate = target bitrate for movie in kbps
boxcolor arg = color
    color = name of color for simulation box lines and processor subdomain lines
color args = name R G B
    name = name of color
    R,G,B = red/green/blue numeric values from 0.0 to 1.0
framerate arg = fps
    fps = frames per second for movie
gmap args = identical to amap args

```

## 9.17.2 Examples

```

dump d0 all image 100 dump.*.jpg type type
dump d1 mobile image 500 snap.*.png element element ssao yes 4539 0.6
dump d2 all image 200 img-*.ppm type type zoom 2.5 adiam 1.5 size 1280 720
dump m0 all movie 1000 movie.mpg type type size 640 480
dump m1 all movie 1000 movie.avi type type size 640 480
dump m2 all movie 100 movie.m4v type type zoom 1.8 adiam v_value size 1280 720

dump_modify 1 amap min max cf 0.0 3 min green 0.5 yellow max blue boxcolor red

labelmap atom 1 C 2 H 3 O 4 N
dump_modify 1 acolor C gray acolor H white acolor O red acolor N blue

```

## 9.17.3 Description

Dump a high-quality rendered image of the atom configuration every  $N$  timesteps and save the images either as a sequence of JPEG or PNG or PPM files, or as a single movie file. The options for this command as well as the *dump\_modify* command control what is included in the image or movie and how it appears. A series of such images can easily be manually converted into an animated movie of your simulation or the process can be automated without writing the intermediate files using the dump movie style; see further details below. Other dump styles store snapshots of numerical data associated with atoms in various formats, as discussed on the *dump* doc page.

Note that a set of images or a movie can be made after a simulation has been run, using the *rerun* command to read snapshots from an existing dump file, and using these dump commands in the rerun script to generate the images/movie.

Here are two sample images, rendered as  $1024 \times 1024$  JPEG files.

Only atoms in the specified group are rendered in the image. The *dump\_modify region and thresh* commands can also alter what atoms are included in the image. The filename suffix determines whether a JPEG, PNG, or PPM file is created with the *image* dump style. If the suffix is “.jpg” or “.jpeg”, then a *JPEG format* file is created, if the suffix is “.png”, then a *PNG format* is created, else a *PPM (aka NETPBM) format* file is created. The JPEG and PNG files are binary; PPM has a text mode header followed by binary data. JPEG images have lossy compression, PNG has lossless compression, and PPM files are uncompressed but can be compressed with gzip, if LAMMPS has been compiled with -DLAMMPS\_GZIP and a “.gz” suffix is used.

Similarly, the format of the resulting movie is chosen with the *movie* dump style. This is handled by the underlying FFmpeg converter and thus details have to be looked up in the *FFmpeg documentation*. Typical examples are: .avi, .mpg, .m4v, .mp4, .mkv, .flv, .mov, .gif. Additional settings of the movie compression like *bitrate* and *framerate* can be set using the *dump\_modify* command as described below.

To write out JPEG and PNG format files, you must build LAMMPS with support for the corresponding JPEG or PNG library. To convert images into movies, LAMMPS has to be compiled with the -DLAMMPS\_FFMPEG flag. See the *Build settings* page for details.

---

**Note:** Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom in the image may be slightly outside the simulation box.

---

Dumps are performed on timesteps that are a multiple of  $N$  (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of  $N$ . This behavior can be changed via the *dump\_modify first* command, which can be useful if the dump command is invoked after a minimization ended on an arbitrary timestep.  $N$  can be changed between runs by using the *dump\_modify every* command.

Dump *image* filenames must contain a wildcard character “\*” so that one image file per snapshot is written. The “\*” character is replaced with the timestep value. For example, tmp.dump.\*.jpg becomes tmp.dump.0.jpg, tmp.dump.10000.jpg, tmp.dump.20000.jpg, etc. Note that the *dump\_modify pad* command can be used to ensure all timestep numbers are the same length (e.g., 00010), which can make it easier to convert a series of images into a movie in the correct ordering.

Dump *movie* filenames on the other hand, must not have any wildcard character since only one file combining all images into a single movie will be written by the movie encoder.

The *color* and *diameter* settings determine the color and size of atoms rendered in the image. They can be any atom attribute defined for the *dump custom* command, including *type* and *element*. This includes per-atom quantities calculated by a *compute*, *fix*, or *variable*, which are prefixed by “c\_”, “f\_”, or “v\_”, respectively. Note that the *diameter* setting can be overridden with a numeric value applied to all atoms by the optional *adiam* keyword.

If *type* is specified for the *color* setting, then the color of each atom is determined by its atom type. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. This mapping can be changed by the “dump\_modify acolor” command, as described below.

If *type* is specified for the *diameter* setting then the diameter of each atom is determined by its atom type. By default all types have diameter 1.0. This mapping can be changed by the “dump\_modify adiam” command, as described below.

If *element* is specified for the *color* and/or *diameter* setting, then the color and/or diameter of each atom is determined by which element it is, which in turn is specified by the element-to-type mapping specified by the “dump\_modify element” command, as described below. By default every atom type is C (carbon). Every element has a color and diameter associated with it, which is the same as the colors and sizes used by the *AtomEye* visualization package.

If other atom attributes are used for the *color* or *diameter* settings, they are interpreted in the following way.

If “vx”, for example, is used as the *color* setting, then the color of the atom will depend on the x-component of its velocity. The association of a per-atom value with a specific color is determined by a “color map”, which can be specified via the *dump\_modify amap* command, as described below. The basic idea is that the atom-attribute will be within a range of values, and every value within the range is mapped to a specific color. Depending on how the color map is defined, that mapping can take place via interpolation so that a value of -3.2 is halfway between “red” and “blue”, or discretely so that the value of -3.2 is “orange”.

If “vx”, for example, is used as the *diameter* setting, then the atom will be rendered using the x-component of its velocity as the diameter. If the per-atom value  $\leq 0.0$ , then the atom will not be drawn. Note that finite-size spherical particles, as defined by *atom\_style sphere* define a per-particle radius or diameter, which can be used as the *diameter* setting.

---

The various keywords listed above control how the image is rendered. As listed below, all of the keywords have defaults, most of which you will likely not need to change. As described below, the *dump modify* command also has options specific to the *dump image* style, particularly for assigning colors to atoms, bonds, and other image features.

---

The *atom* keyword allow you to turn off the drawing of all atoms, if the specified value is *no*. Note that this will not turn off the drawing of particles that are represented as lines, triangles, or bodies, as discussed below. These particles can be drawn separately if the *line*, *tri*, or *body* keywords are used.

The *adiam* keyword allows you to override the *diameter* setting to set a single numeric *size*. All atoms will be drawn with that diameter, e.g. 1.5, which is in whatever distance *units* the input script defines, e.g. Angstroms.

---

The *bond* keyword allows you to alter how bonds are drawn. A bond is only drawn if both atoms in the bond are being drawn due to being in the specified group and due to other selection criteria (e.g. region, threshold settings of the *dump\_modify* command). By default, bonds are drawn if they are defined in the input data file as read by the *read\_data* command. Using *none* for both the bond *color* and *width* value will turn off the drawing of all bonds.

If *atom* is specified for the bond *color* value, then each bond is drawn in 2 halves, with the color of each half being the color of the atom at that end of the bond.

If *type* is specified for the *color* value, then the color of each bond is determined by its bond type. By default the mapping of bond types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for bond types > 6. This mapping can be changed by the “dump\_modify bcolor” command, as described below.

The bond *width* value can be a numeric value or *atom* or *type* (or *none* as indicated above).

If a numeric value is specified, then all bonds will be drawn as cylinders with that diameter, e.g. 1.0, which is in whatever distance *units* the input script defines, e.g. Angstroms.

If *atom* is specified for the *width* value, then each bond will be drawn with a width corresponding to the minimum diameter of the two atoms in the bond.

If *type* is specified for the *width* value then the diameter of each bond is determined by its bond type. By default all types have diameter 0.5. This mapping can be changed by the “dump\_modify bdiam” command, as described below.

---

The *line* keyword can be used when *atom\_style line* is used to define particles as line segments, and will draw them as lines. If this keyword is not used, such particles will be drawn as spheres, the same as if they were regular atoms. The only setting currently allowed for the *color* value is *type*, which will color the lines according to the atom type of the particle. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the dump\_modify command.

The line *width* can only be a numeric value, which specifies that all lines will be drawn as cylinders with that diameter, e.g. 1.0, which is in whatever distance *units* the input script defines, e.g. Angstroms.

---

The *tri* keyword can be used when *atom\_style tri* is used to define particles as triangles, and will draw them as triangles or edges (3 lines) or both, depending on the setting for *tflag*. If edges are drawn, the *width* setting determines the diameters of the line segments. If this keyword is not used, triangle particles will be drawn as spheres, the same as if

they were regular atoms. The only setting currently allowed for the *color* value is *type*, which will color the triangles according to the atom type of the particle. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the `dump_modify` command.

---

The *body* keyword can be used when *atom\_style body* is used to define body particles with internal state (e.g. sub-particles), and will drawn them in a manner specific to the body style. If this keyword is not used, such particles will be drawn as spheres, the same as if they were regular atoms.

The *Howto body* page describes the body styles LAMMPS currently supports, and provides more details as to the kind of body particles they represent and how they are drawn by this dump image command. For all the body styles, individual atoms can be either a body particle or a usual point (non-body) particle. Non-body particles will be drawn the same way they would be as a regular atom. The *bflag1* and *bflag2* settings are numerical values which are passed to the body style to affect how the drawing of a body particle is done. See the *Howto body* page for a description of what these parameters mean for each body style.

The only setting currently allowed for the *color* value is *type*, which will color the body particles according to the atom type of the particle. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the `dump_modify` command.

---

The *fix* keyword can be used with a *fix* that produces objects to be drawn.

The *fflag1* and *fflag2* settings are numerical values which are passed to the *fix* to affect how the drawing of its objects is done. See the individual *fix* page for a description of what these parameters mean for a particular *fix*.

The only setting currently allowed for the *color* value is *type*, which will color the *fix* objects according to their type. By default the mapping of types to colors is as follows:

- type 1 = red
- type 2 = green
- type 3 = blue
- type 4 = yellow
- type 5 = aqua
- type 6 = cyan

and repeats itself for types > 6. There is not yet an option to change this via the `dump_modify` command.

---

The *size* keyword sets the width and height of the created images, i.e. the number of pixels in each direction.

---

The *view*, *center*, *up*, and *zoom* values determine how 3d simulation space is mapped to the 2d plane of the image. Basically they control how the simulation box appears in the image.

All of the *view*, *center*, *up*, and *zoom* values can be specified as numeric quantities, whose meaning is explained below. Any of them can also be specified as an *equal-style variable*, by using `v_name` as the value, where “name” is the variable name. In this case the variable will be evaluated on the timestep each image is created to create a new value. If the equal-style variable is time-dependent, this is a means of changing the way the simulation box appears from image to image, effectively doing a pan or fly-by view of your simulation.

The *view* keyword determines the viewpoint from which the simulation box is viewed, looking towards the *center* point. The *theta* value is the vertical angle from the +z axis, and must be an angle from 0 to 180 degrees. The *phi* value is an azimuthal angle around the z axis and can be positive or negative. A value of 0.0 is a view along the +x axis, towards the *center* point. If *theta* or *phi* are specified via variables, then the variable values should be in degrees.

The *center* keyword determines the point in simulation space that will be at the center of the image. *Cx*, *Cy*, and *Cz* are specified as fractions of the box dimensions, so that (0.5,0.5,0.5) is the center of the simulation box. These values do not have to be between 0.0 and 1.0, if you want the simulation box to be offset from the center of the image. Note, however, that if you choose strange values for *Cx*, *Cy*, or *Cz* you may get a blank image. Internally, *Cx*, *Cy*, and *Cz* are converted into a point in simulation space. If *flag* is set to “s” for static, then this conversion is done once, at the time the dump command is issued. If *flag* is set to “d” for dynamic then the conversion is performed every time a new image is created. If the box size or shape is changing, this will adjust the center point in simulation space.

The *up* keyword determines what direction in simulation space will be “up” in the image. Internally it is stored as a vector that is in the plane perpendicular to the view vector implied by the *theta* and *phi* values, and which is also in the plane defined by the view vector and user-specified up vector. Thus this internal vector is computed from the user-specified *up* vector as

$$\text{up\_internal} = \text{view} \times (\text{up} \times \text{view})$$

This means the only restriction on the specified *up* vector is that it cannot be parallel to the *view* vector, implied by the *theta* and *phi* values.

The *zoom* keyword scales the size of the simulation box as it appears in the image. The default *zfactor* value of 1 should display an image mostly filled by the atoms in the simulation box. A *zfactor* > 1 will make the simulation box larger; a *zfactor* < 1 will make it smaller. *Zfactor* must be a value > 0.0.

---

The *box* keyword determines if and how the simulation box boundaries are rendered as thin cylinders in the image. If *no* is set, then the box boundaries are not drawn and the *diam* setting is ignored. If *yes* is set, the 12 edges of the box are drawn, with a diameter that is a fraction of the shortest box length in x,y,z (for 3d) or x,y (for 2d). The color of the box boundaries can be set with the “`dump_modify boxcolor`” command.

The *axes* keyword determines if and how the coordinate axes are rendered as thin cylinders in the image. If *no* is set, then the axes are not drawn and the *length* and *diam* settings are ignored. If *yes* is set, 3 thin cylinders are drawn to represent the x,y,z axes in colors red,green,blue. The origin of these cylinders will be offset from the lower left corner of the box by 10%. The *length* setting determines how long the cylinders will be as a fraction of the respective box lengths. The *diam* setting determines their thickness as a fraction of the shortest box length in x,y,z (for 3d) or x,y (for 2d).

The *subbox* keyword determines if and how processor subdomain boundaries are rendered as thin cylinders in the image. If *no* is set (default), then the subdomain boundaries are not drawn and the *diam* setting is ignored. If *yes* is

set, the 12 edges of each processor subdomain are drawn, with a diameter that is a fraction of the shortest box length in x,y,z (for 3d) or x,y (for 2d). The color of the subdomain boundaries can be set with the “dump\_modify boxcolor” command.

The *shiny* keyword determines how shiny the objects rendered in the image will appear. The *sfactor* value must be a value  $0.0 \leq sfactor \leq 1.0$ , where *sfactor* = 1 is a highly reflective surface and *sfactor* = 0 is a rough non-shiny surface.

New in version 21Nov2023.

The *fsaa* keyword can be used with the dump image command to improve the image quality by enabling full scene anti-aliasing. Internally the image is rendered at twice the width and height and then scaled down by computing the average of each 2x2 block of pixels to produce a single pixel in the final image at the original size. This produces images with smoother, less ragged edges. The application of this algorithm can increase the cost of computing the image by about 3x or more.

The *ssao* keyword turns on/off a screen space ambient occlusion (SSAO) model for depth shading. If *yes* is set, then atoms further away from the viewer are darkened via a randomized process, which is perceived as depth. The strength of the effect can be scaled by the *dfactor* parameter. If *no* is set, no depth shading is performed. The calculation of this effect can increase the cost of computing the image substantially by 5x or more, especially with larger images. When used in combination with the *fsaa* keyword the computational cost of depth shading is particularly large.

### 9.17.4 Image Quality Settings

The two keywords *fsaa* and *ssao* can be used to improve the image quality at the expense of additional computational cost to render the images. The images below show from left to right the same render with default settings, with *fsaa* added, with *ssao* added, and with both keywords added.

A series of JPEG, PNG, or PPM images can be converted into a movie file and then played as a movie using commonly available tools. Using dump style *movie* automates this step and avoids the intermediate step of writing (many) image snapshot file. But LAMMPS has to be compiled with -DLAMMPS\_FFMPEG and an FFmpeg executable have to be installed.

To manually convert JPEG, PNG or PPM files into an animated GIF or MPEG or other movie file you can use:

- a) Use the ImageMagick convert program.

```
convert *.jpg foo.gif
convert -loop 1 *.ppm foo.mpg
```

Animated GIF files from ImageMagick are not optimized. You can use a program like gifsicle to optimize and thus massively shrink them. MPEG files created by ImageMagick are in MPEG-1 format with a rather inefficient compression and low quality compared to more modern compression styles like MPEG-4, H.264, VP8, VP9, H.265 and so on.

- b) Use QuickTime.

Select “Open Image Sequence” under the File menu Load the images into QuickTime to animate them Select “Export” under the File menu Save the movie as a QuickTime movie (\*.mov) or in another format. QuickTime can generate very high quality and efficiently compressed movie files. Some of the supported formats require to buy a license and some are not readable on all platforms until specific runtime libraries are installed.

- c) Use FFmpeg

FFmpeg is a command line tool that is available on many platforms and allows extremely flexible encoding and decoding of movies.

```
cat snap.*.jpg | ffmpeg -y -f image2pipe -c:v mjpeg -i - -b:v 2000k movie.m4v
cat snap.*.ppm | ffmpeg -y -f image2pipe -c:v ppm -i - -b:v 2400k movie.avi
```

Front ends for FFmpeg exist for multiple platforms. For more information see the [FFmpeg homepage](#)

---

Play the movie:

- a) Use your browser to view an animated GIF movie.

Select “Open File” under the File menu Load the animated GIF file

- b) Use the freely available mplayer or ffplay tool to view a movie. Both are available for multiple OSes and support a large variety of file formats and decoders.

```
mplayer foo.mpg
ffplay bar.avi
```

- c) Use the [Pizza.py animate tool](#), which works directly on a series of image files.

```
a = animate("foo*.jpg")
```

- d) QuickTime and other Windows- or macOS-based media players can obviously play movie files directly. Similarly for corresponding tools bundled with Linux desktop environments. However, due to licensing issues with some file formats, the formats may require installing additional libraries, purchasing a license, or may not be supported.
- 

### 9.17.5 Dump\_modify keywords for dump image and dump movie

The following dump\_modify keywords apply only to the dump image and dump movie styles. Any keyword that works with dump image also works with dump movie, since the movie is simply a collection of images. Some of the keywords only affect the dump movie style. The descriptions give details.

---

The *acolor* keyword can be used with the dump image command, when its atom color setting is *type*, to set the color that atoms of each type will be drawn in the image.

The specified *type* should be a type label or integer from 1 to Ntypes = the number of atom types. For numeric types, a wildcard asterisk can be used in place of or in conjunction with the *type* argument to specify a range of atom types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

The specified *color* can be a single color which is any of the 140 pre-defined colors (see below) or a color name defined by the “dump\_modify color” command, as described below. Or it can be two or more colors separated by a “/” character, e.g. red/green/blue. In the former case, that color is assigned to all the specified atom types. In the latter case, the list of colors are assigned in a round-robin fashion to each of the specified atom types.

The *adiam* keyword can be used with the dump image command, when its atom diameter setting is *type*, to set the size that atoms of each type will be drawn in the image. The specified *type* should be a type label or integer from 1 to Ntypes. As with the *acolor* keyword, a wildcard asterisk can be used as part of the *type* argument to specify a range of numeric atom types. The specified *diam* is the size in whatever distance *units* the input script is using, e.g. Angstroms.

The *amap* keyword can be used with the dump image command, with its *atom* keyword, when its atom setting is an atom-attribute, to setup a color map. The color map is used to assign a specific RGB (red/green/blue) color value to an individual atom when it is drawn, based on the atom’s attribute, which is a numeric value, e.g. its x-component of velocity if the atom-attribute “vx” was specified.

The basic idea of a color map is that the atom-attribute will be within a range of values, and that range is associated with a series of colors (e.g. red, blue, green). An atom’s specific value (vx = -3.2) can then mapped to the series of colors (e.g. halfway between red and blue), and a specific color is determined via an interpolation procedure.

There are many possible options for the color map, enabled by the *amap* keyword. Here are the details.

The *lo* and *hi* settings determine the range of values allowed for the atom attribute. If numeric values are used for *lo* and/or *hi*, then values that are lower/higher than that value are set to the value. I.e. the range is static. If *lo* is specified as *min* or *hi* as *max* then the range is dynamic, and the lower and/or upper bound will be calculated each time an image is drawn, based on the set of atoms being visualized.

The *style* setting is two letters, such as “ca”. The first letter is either “c” for continuous, “d” for discrete, or “s” for sequential. The second letter is either “a” for absolute, or “f” for fractional.

A continuous color map is one in which the color changes continuously from value to value within the range. A discrete color map is one in which discrete colors are assigned to sub-ranges of values within the range. A sequential color map is one in which discrete colors are assigned to a sequence of sub-ranges of values covering the entire range.

An absolute color map is one in which the values to which colors are assigned are specified explicitly as values within the range. A fractional color map is one in which the values to which colors are assigned are specified as a fractional portion of the range. For example if the range is from -10.0 to 10.0, and the color red is to be assigned to atoms with a value of 5.0, then for an absolute color map the number 5.0 would be used. But for a fractional map, the number 0.75 would be used since 5.0 is 3/4 of the way from -10.0 to 10.0.

The *delta* setting must be specified for all styles, but is only used for the sequential style; otherwise the value is ignored. It specifies the bin size to use within the range for assigning consecutive colors to. For example, if the range is from -10.0 to 10.0 and a *delta* of 1.0 is used, then 20 colors will be assigned to the range. The first will be from  $-10.0 \leq \text{color1} < -9.0$ , then second from  $-9.0 \leq \text{color2} < -8.0$ , etc.

The *N* setting is how many entries follow. The format of the entries depends on whether the color map style is continuous, discrete or sequential. In all cases the *color* setting can be any of the 140 pre-defined colors (see below) or a color name defined by the dump\_modify color option.

For continuous color maps, each entry has a *value* and a *color*. The *value* is either a number within the range of values or *min* or *max*. The *value* of the first entry must be *min* and the *value* of the last entry must be *max*. Any entries in between must have increasing values. Note that numeric values can be specified either as absolute numbers or as fractions (0.0 to 1.0) of the range, depending on the “a” or “f” in the style setting for the color map.

Here is how the entries are used to determine the color of an individual atom, given the value *X* of its atom attribute. *X* will fall between 2 of the entry values. The color of the atom is linearly interpolated (in each of the RGB values) between the 2 colors associated with those entries. For example, if  $X = -5.0$  and the two surrounding entries are

“red” at  $-10.0$  and “blue” at  $0.0$ , then the atom’s color will be halfway between “red” and “blue”, which happens to be “purple”.

For discrete color maps, each entry has a *lo* and *hi* value and a *color*. The *lo* and *hi* settings are either numbers within the range of values or *lo* can be *min* or *hi* can be *max*. The *lo* and *hi* settings of the last entry must be *min* and *max*. Other entries can have any *lo* and *hi* values and the sub-ranges of different values can overlap. Note that numeric *lo* and *hi* values can be specified either as absolute numbers or as fractions ( $0.0$  to  $1.0$ ) of the range, depending on the “a” or “f” in the style setting for the color map.

Here is how the entries are used to determine the color of an individual atom, given the value  $X$  of its atom attribute. The entries are scanned from first to last. The first time that  $lo \leq X \leq hi$ ,  $X$  is assigned the color associated with that entry. You can think of the last entry as assigning a default color (since it will always be matched by  $X$ ), and the earlier entries as colors that override the default. Also note that no interpolation of a color RGB is done. All atoms will be drawn with one of the colors in the list of entries.

For sequential color maps, each entry has only a *color*. Here is how the entries are used to determine the color of an individual atom, given the value  $X$  of its atom attribute. The range is partitioned into  $N$  bins of width *binsize*. Thus  $X$  will fall in a specific bin from 1 to  $N$ , say the  $M$ th bin. If it falls on a boundary between 2 bins, it is considered to be in the higher of the 2 bins. Each bin is assigned a color from the  $E$  entries. If  $E < N$ , then the colors are repeated. For example if 2 entries with colors red and green are specified, then the odd numbered bins will be red and the even bins green. The color of the atom is the color of its bin. Note that the sequential color map is really a shorthand way of defining a discrete color map without having to specify where all the bin boundaries are.

Here is an example of using a sequential color map to color all the atoms in individual molecules with a different color. See the examples/pour/in.pour.2d.molecule input script for an example of how this is used.

```
variable      colors string &
              "red green blue yellow white &
              purple pink orange lime gray"
variable      mol atom mol%10
dump          1 all image 250 image.*.jpg v_mol type &
              zoom 1.6 adiam 1.5
dump_modify   1 pad 5 amap 0 10 sa 1 10 ${colors}
```

In this case, 10 colors are defined, and molecule IDs are mapped to one of the colors, even if there are 1000s of molecules.

---

The *backcolor* sets the background color of the images. The color name can be any of the 140 pre-defined colors (see below) or a color name defined by the *dump\_modify* color option.

---

The *bcolor* keyword can be used with the dump image command, with its *bond* keyword, when its color setting is *type*, to set the color that bonds of each type will be drawn in the image.

The specified *type* should be a type label or integer from 1 to  $N$ , where  $N$  is the number of bond types. For numeric types, a wildcard asterisk can be used in place of or in conjunction with the *type* argument to specify a range of bond types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the number of bond types, then an asterisk with no numerical values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $m$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive).

The specified *color* can be a single color which is any of the 140 pre-defined colors (see below) or a color name defined by the *dump\_modify* color option. Or it can be two or more colors separated by a “/” character (e.g., red/green/blue). In the former case, that color is assigned to all the specified bond types. In the latter case, the list of colors are assigned in a round-robin fashion to each of the specified bond types.

---

The *bdiam* keyword can be used with the dump image command, with its *bond* keyword, when its *diam* setting is *type*, to set the diameter that bonds of each type will be drawn in the image. The specified *type* should be a type label or integer from 1 to Nbondtypes. As with the *bcolor* keyword, a wildcard asterisk can be used as part of the *type* argument to specify a range of numeric bond types. The specified *diam* is the size in whatever distance *units* you are using (e.g., Angstroms).

---

The *bitrate* keyword can be used with the *dump movie* command to define the size of the resulting movie file and its quality via setting how many kbits per second are to be used for the movie file. Higher bitrates require less compression and will result in higher quality movies. The quality is also determined by the compression format and encoder. The default setting is 2000 kbit/s, which will result in average quality with older compression formats.

---

**Note:** Not all movie file formats supported by dump movie allow the bitrate to be set. If not, the setting is silently ignored.

---

The *boxcolor* keyword sets the color of the simulation box drawn around the atoms in each image as well as the color of processor subdomain boundaries. See the “dump image box” command for how to specify that a box be drawn via the *box* keyword, and the subdomain boundaries via the *subbox* keyword. The color name can be any of the 140 pre-defined colors (see below) or a color name defined by the dump\_modify color option.

---

The *color* keyword allows definition of a new color name, in addition to the 140-predefined colors (see below), and associates three red/green/blue RGB values with that color name. The color name can then be used with any other dump\_modify keyword that takes a color name as a value. The RGB values should each be floating point values between 0.0 and 1.0 inclusive.

When a color name is converted to RGB values, the user-defined color names are searched first, then the 140 pre-defined color names. This means you can also use the *color* keyword to overwrite one of the pre-defined color names with new RGB values.

---

The *framerate* keyword can be used with the *dump movie* command to define the duration of the resulting movie file. Movie files written by the dump movie command have a default frame rate of 24 frames per second and the images generated will be converted at that rate. Thus a sequence of 1000 dump images will result in a movie of about 42 seconds. To make a movie run longer you can either generate images more frequently or lower the frame rate. To speed a movie up, you can do the inverse. Using a frame rate higher than 24 is not recommended, as it will result in simply dropping the rendered images. It is more efficient to dump images less frequently.

---

The *gmap* keyword can be used with the dump image command, with its *grid* keyword, to setup a color map. The color map is used to assign a specific RGB (red/green/blue) color value to an individual grid cell when it is drawn, based on the grid cell value, which is a numeric quantity specified with the *grid* keyword.

The arguments for the *gmap* keyword are identical to those for the *amap* keyword (for atom coloring) described above.

---

### 9.17.6 Restrictions

To write JPEG images, you must use the `-DLAMMPS_JPEG` switch when building LAMMPS and link with a JPEG library. To write PNG images, you must use the `-DLAMMPS_PNG` switch when building LAMMPS and link with a PNG library.

To write *movie* dumps, you must use the `-DLAMMPS_FFMPEG` switch when building LAMMPS and have the FFmpeg executable available on the machine where LAMMPS is being run. Typically its name is lowercase (i.e., “ffmpeg”).

See the [Build settings](#) page for details.

Note that since FFmpeg is run as an external program via a pipe, LAMMPS has limited control over its execution and no knowledge about errors and warnings printed by it. Those warnings and error messages will be printed to the screen only. Due to the way image data are communicated to FFmpeg, it will often print the message

```
pipe:: Input/output error
```

which can be safely ignored. Other warnings and errors have to be addressed according to the FFmpeg documentation. One known issue is that certain movie file formats (e.g., MPEG level 1 and 2 format streams) have video bandwidth limits that can be crossed when rendering too large of image sizes. Typical warnings look like this:

```
[mpeg @ 0x98b5e0] packet too large, ignoring buffer limits to mux it
[mpeg @ 0x98b5e0] buffer underflow st=0 bufi=281407 size=285018
[mpeg @ 0x98b5e0] buffer underflow st=0 bufi=283448 size=285018
```

In this case it is recommended either to reduce the size of the image or to encode in a different format that is also supported by your copy of FFmpeg and which does not have this limitation (e.g., .avi, .mkv, mp4).

### 9.17.7 Related commands

*dump*, *dump\_modify*, *undump*

### 9.17.8 Default

The defaults for the dump image and dump movie keywords are as follows:

- `adiam` = not specified (use diameter setting)
- `atom` = yes
- `bond` = none none (if no bonds in system)
- `bond` = atom 0.5 (if bonds in system)
- `size` = 512 512
- `view` = 60 30 (for 3d)
- `view` = 0 0 (for 2d)
- `center` = s 0.5 0.5 0.5
- `up` = 0 0 1 (for 3d)
- `up` = 0 1 0 (for 2d)
- `zoom` = 1.0
- `box` = yes 0.02
- `axes` = no 0.0 0.0

- subbox no 0.0
  - shiny = 1.0
  - ssao = no
- 

The defaults for the dump\_modify keywords specific to dump image and dump movie are as follows:

- acolor = \* red/green/blue/yellow/aqua/cyan
  - adiam = \* 1.0
  - amap = min max cf 0.0 2 min blue max red
  - backcolor = black
  - bcolor = \* red/green/blue/yellow/aqua/cyan
  - bdiam = \* 0.5
  - bitrate = 2000
  - boxcolor = yellow
  - color = 140 color names are pre-defined as listed below
  - framerate = 24
  - fsaa = no
  - gmap = min max cf 0.0 2 min blue max red
- 

These are the standard 109 element names that LAMMPS pre-defines for use with the dump image and dump\_modify commands.

- 1-10 = “H”, “He”, “Li”, “Be”, “B”, “C”, “N”, “O”, “F”, “Ne”
  - 11-20 = “Na”, “Mg”, “Al”, “Si”, “P”, “S”, “Cl”, “Ar”, “K”, “Ca”
  - 21-30 = “Sc”, “Ti”, “V”, “Cr”, “Mn”, “Fe”, “Co”, “Ni”, “Cu”, “Zn”
  - 31-40 = “Ga”, “Ge”, “As”, “Se”, “Br”, “Kr”, “Rb”, “Sr”, “Y”, “Zr”
  - 41-50 = “Nb”, “Mo”, “Tc”, “Ru”, “Rh”, “Pd”, “Ag”, “Cd”, “In”, “Sn”
  - 51-60 = “Sb”, “Te”, “I”, “Xe”, “Cs”, “Ba”, “La”, “Ce”, “Pr”, “Nd”
  - 61-70 = “Pm”, “Sm”, “Eu”, “Gd”, “Tb”, “Dy”, “Ho”, “Er”, “Tm”, “Yb”
  - 71-80 = “Lu”, “Hf”, “Ta”, “W”, “Re”, “Os”, “Ir”, “Pt”, “Au”, “Hg”
  - 81-90 = “Tl”, “Pb”, “Bi”, “Po”, “At”, “Rn”, “Fr”, “Ra”, “Ac”, “Th”
  - 91-100 = “Pa”, “U”, “Np”, “Pu”, “Am”, “Cm”, “Bk”, “Cf”, “Es”, “Fm”
  - 101-109 = “Md”, “No”, “Lr”, “Rf”, “Db”, “Sg”, “Bh”, “Hs”, “Mt”
- 

These are the 140 colors that LAMMPS pre-defines for use with the dump image and dump\_modify commands. Additional colors can be defined with the dump\_modify color command. The 3 numbers listed for each name are the RGB (red/green/blue) values. Divide each value by 255 to get the equivalent 0.0 to 1.0 value.

## 9.18 dump\_modify command

## 9.19 dump\_modify command for image/movie options

### 9.19.1 Syntax

```
dump_modify dump-ID keyword values ...
```

- dump-ID = ID of dump to modify
- one or more keyword/value pairs may be appended
- these keywords apply to various dump styles
- keyword = *append* or *at* or *balance* or *buffer* or *colname* or *delay* or *element* or *every* or *every/time* or *fileper* or *first* or *flush* or *format* or *header* or *image* or *label* or *maxfiles* or *nfile* or *pad* or *pbcs* or *precision* or *region* or *refresh* or *scale* or *sfactor* or *skip* or *sort* or *tfactor* or *thermo* or *thresh* or *time* or *triclinic/general* or *types* or *units* or *unwrap*

*append* arg = *yes* or *no*

*at* arg = N

N = index of frame written upon first dump

*balance* arg = *yes* or *no*

*buffer* arg = *yes* or *no*

*colname* values = ID string, or *default*

string = new column header name

ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities.

→being output

or a custom dump keyword or reference to compute, fix, property or variable.

*delay* arg = Dstep

Dstep = delay output until this timestep

*element* args = E1 E2 ... EN, where N = # of atom types

E1,...,EN = element name (e.g., C or Fe or Ga)

*every* arg = N

N = dump on timesteps which are a multiple of N

N can be a variable (see below)

*every/time* arg = Delta

Delta = dump once every Delta interval of simulation time (time units)

Delta can be a variable (see below)

*fileper* arg = Np

Np = write one file for every this many processors

*first* arg = *yes* or *no*

*flush* arg = *yes* or *no*

*format* args = *line* string, *int* string, *float* string, ID string, or *none*

string = C-style format string

ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities.

→being output

or a custom dump keyword or reference to compute, fix, property or variable.

*header* arg = *yes* or *no*

*yes* to write the header

*no* to not write the header

*image* arg = *yes* or *no*

*label* arg = string

string = character string (e.g., BONDS) to use in header of dump local file

```
maxfiles arg = Fmax
  Fmax = keep only the most recent Fmax snapshots (one snapshot per file)
nfile arg = Nf
  Nf = write this many files, one from each of Nf processors
pad arg = Nchar = # of characters to convert timestep to
pbc arg = yes or no = remap atoms via periodic boundary conditions
precision arg = power-of-10 value from 10 to 1000000
region arg = region-ID or "none"
refresh arg = c_ID = compute ID that supports a refresh operation
scale arg = yes or no
sfactor arg = coordinate scaling factor (> 0.0)
skip arg = v_name
  v_name = variable with name which evaluates to non-zero (skip) or 0
sort arg = off or id or N or -N
  off = no sorting of per-atom lines within a snapshot
  id = sort per-atom lines by atom ID
  N = sort per-atom lines in ascending order by the Nth column
  -N = sort per-atom lines in descending order by the Nth column
tfactor arg = time scaling factor (> 0.0)
thermo arg = yes or no
thresh args = attribute operator value
  attribute = same attributes (x,fy,etotal,sxx,etc) used by dump custom style
  operator = "<" or "<=" or ">" or ">=" or "==" or "!=" or "|^"
  value = numeric value to compare to, or LAST
  these 3 args can be replaced by the word "none" to turn off thresholding
time arg = yes or no
triclinic/general arg = yes or no
types value = numeric or labels
units arg = yes or no
unwrap arg = yes or no
```

- these keywords apply only to the *image* and *movie* styles
- keyword = *acolor* or *adiam* or *amap* or *backcolor* or *bcolor* or *bdiam* or *boxcolor* or *color* or *bitrate* or *framerate*  
see the [dump image](#) doc page for details
- these keywords apply only to the */gz* and */zstd* dump styles
- keyword = *compression\_level*  
*compression\_level* args = level  
level = integer specifying the compression level that should be used (see below [↪](#) for supported levels)
- these keywords apply only to the */zstd* dump styles
- keyword = *checksum*  
*checksum* args = yes or no (add checksum at end of zst file)
- these keywords apply only to the *vtk\** dump style
- keyword = *binary*  
*binary* args = yes or no (select between binary and text mode VTK files)

## 9.19.2 Examples

```
dump_modify 1 format line "%d %d %20.15g %g %g" scale yes
dump_modify 1 format float %20.15g scale yes
dump_modify myDump image yes scale no flush yes
dump_modify 1 region mySphere thresh x < 0.0 thresh fx >= 3.2
dump_modify xtcdump precision 10000 sfactor 0.1
dump_modify 1 every 1000 nfile 20
dump_modify 1 every v_myVar
```

## 9.19.3 Description

Modify the parameters of a previously defined dump command. Not all parameters are relevant to all dump styles.

Unless otherwise noted, the following keywords apply to all the various dump styles, including the *dump image* and *dump movie* styles.

The *append* keyword applies to all dump styles except *cfg* and *xtc* and *dcd*. It also applies only to text output files, not to binary or gzipped or image/movie files. If specified as *yes*, then dump snapshots are appended to the end of an existing dump file. If specified as *no*, then a new dump file will be created which will overwrite an existing file with the same name.

The *at* keyword only applies to the *netcdf* dump style. It can only be used if the *append yes* keyword is also used. The *N* argument is the index of which frame to append to. A negative value can be specified for *N*, which means a frame counted from the end of the file. The *at* keyword can only be used if the *dump\_modify* command is before the first command that causes dump snapshots to be output (e.g., a *run* or *minimize* command). Once the dump file has been opened, this keyword has no further effect.

The *buffer* keyword applies only to dump styles *atom*, *cfg*, *custom*, *local*, and *xyz*. It also applies only to text output files, not to binary or gzipped files. If specified as *yes*, which is the default, then each processor writes its output into an internal text buffer, which is then sent to the processor(s) which perform file writes, and written by those processor(s) as one large chunk of text. If specified as *no*, each processor sends its per-atom data in binary format to the processor(s) which perform file writes, and those processor(s) format and write it line by line into the output file.

The buffering mode is typically faster since each processor does the relatively expensive task of formatting the output for its own atoms. However it requires about twice the memory (per processor) for the extra buffering.

New in version 4May2022.

The *colname* keyword can be used to change the default header keyword for dump styles: *atom*, *custom*, *cfg*, and *local* and their compressed, ADIOS variants. The setting for *ID string* replaces the default text with the provided string. *ID* can be a positive integer when it represents the column number counting from the left, a negative integer when it represents the column number from the right (i.e. -1 is the last column/keyword), or a custom dump keyword (or compute, fix, property, or variable reference) and then it replaces the string for that specific keyword. For *atom* dump styles only the keywords “id”, “type”, “x”, “y”, “z”, “ix”, “iy”, “iz” can be accessed via string regardless of whether scaled or unwrapped coordinates were enabled or disabled, and it always assumes 8 columns for indexing regardless of whether image flags are enabled or not. For dump style *cfg* only changes to the “auxiliary” keywords (6th or later keyword) will become visible.

The *colname* keyword can be used multiple times. If multiple *colname* settings refer to the same keyword, the last setting has precedence. A setting of *default* clears all previous settings, reverting all values to their default names. Using the *scale* or *image* keyword will also reset all header keywords to their default values.

---

The *delay* keyword applies to all dump styles. No snapshots will be output until the specified *Dstep* timestep or later. Specifying *Dstep* < 0 is the same as turning off the delay setting. This is a way to turn off unwanted output early in a simulation, for example, during an equilibration phase.

---

The *element* keyword applies only to the dump *cfg*, *xyz*, and *image* styles. It associates element names (e.g., H, C, Fe) with LAMMPS atom types. See the list of element names at the bottom of this page.

In the case of dump *cfg*, this allows the [AtomEye](#) visualization package to read the dump file and render atoms with the appropriate size and color.

In the case of dump *image*, the output images will follow the same [AtomEye](#) convention. An element name is specified for each atom type (1 to Ntype) in the simulation. The same element name can be given to multiple atom types.

In the case of *xyz* format dumps, there are no restrictions to what label can be used as an element name. Any white-space separated text will be accepted.

---

The *every* keyword can be used with any dump style except the *dcd* and *xtc* styles. It specifies that the output of dump snapshots will now be performed on timesteps which are a multiple of a new *N* value. This overrides the dump frequency originally specified by the *dump* command.

The *every* keyword can be specified in one of two ways. It can be a numeric value in which case it must be > 0. Or it can be an *equal-style variable*, which should be specified as *v\_name*, where name is the variable name.

In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a dump snapshot will be written out. On that timestep the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the *stagger()* and *logfreq()* and *stride()* math functions for *equal-style variables*, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for *equal-style variables*. Also see the *next()* function, which allows use of a file-style variable which reads successive values from a file, each time the variable is evaluated. Used with the *every* keyword, if the file contains a list of ascending timesteps, you can output snapshots whenever you wish.

Note that when using the variable option with the *every* keyword, you need to use the *first* option if you want an initial snapshot written to the dump file. The *every* keyword cannot be used with the dump *dcd* style.

For example, the following commands will write snapshots at timesteps 0,10,20,30,100,200,300,1000,2000,etc:

```
variable      s equal logfreq(10,3,10)
dump          1 all atom 100 tmp.dump
dump_modify   1 every v_s first yes
```

The following commands would write snapshots at the timesteps listed in file tmp.times:

```
variable      f file tmp.times
variable      s equal next(f)
dump          1 all atom 100 tmp.dump
dump_modify   1 every v_s
```

---

**Note:** When using a file-style variable with the *every* keyword, the file of timesteps must list a first timestep that is beyond the current timestep (e.g., it cannot be 0). And it must list one or more timesteps beyond the length of the run

you perform. This is because the dump command will generate an error if the next timestep it reads from the file is not a value greater than the current timestep. Thus if you wanted output on steps 0,15,100 of a 100-timestep run, the file should contain the values 15,100,101 and you should also use the `dump_modify` first command. Any final value > 100 could be used in place of 101.

---

New in version 7Jan2022.

The *every/time* keyword can be used with any dump style except the *dcd* and *xtc* styles. It changes the frequency of dump snapshots from being based on the current timestep to being determined by elapsed simulation time, i.e. in time units of the *units* command, and specifies *Delta* for the interval between snapshots. This can be useful when the timestep size varies during a simulation run, e.g. by use of the *fix dt/reset* command. The default is to perform output on timesteps which are multiples of specified timestep value *N*; see the *every* keyword.

The *every/time* keyword can be used with any dump style except the *dcd* and *xtc* styles. It does two things. It specifies that the interval between dump snapshots will be set in simulation time (i.e. in time units of the *units* command). This can be useful when the timestep size varies during a simulation run (e.g., by use of the *fix dt/reset* command). The default is to specify the interval in timesteps; see the *every* keyword. The *every/time* command also sets the interval value.

---

**Note:** If you wish dump styles *atom*, *custom*, *local*, or *xyz* to include the simulation time as a field in the header portion of each snapshot, you also need to use the `dump_modify time` keyword with a setting of *yes*. See its documentation below.

---

Note that since snapshots are output on simulation steps, each snapshot will be written on the first timestep whose associated simulation time is  $\geq$  the exact snapshot time value.

As with the *every* option, the *Delta* value can be specified in one of two ways. It can be a numeric value in which case it must be > 0.0. Or it can be an *equal-style variable*, which should be specified as `v_name`, where name is the variable name.

In this case, the variable is evaluated at the beginning of a run to determine the next simulation time at which a dump snapshot will be written out. On that timestep the variable will be evaluated again to determine the next simulation time, etc. Thus the variable should return values in time units. Note the current timestep or simulation time can be used in an *equal-style variable* since they are both thermodynamic keywords. Also see the `next()` function, which allows use of a file-style variable which reads successive values from a file, each time the variable is evaluated. Used with the *every/time* keyword, if the file contains a list of ascending simulation times, you can output snapshots whenever you wish.

Note that when using the variable option with the *every/time* keyword, you need to use the *first* option if you want an initial snapshot written to the dump file. The *every/time* keyword cannot be used with the dump *dcd* style.

For example, the following commands will write snapshots at successive simulation times which grow by a factor of 1.5 with each interval. The `dt` value used in the variable is to avoid a zero result when the initial simulation time is 0.0.

```
variable      increase equal 1.5*(time+dt)
dump          1 all atom 100 tmp.dump
dump_modify   1 every/time v_increase first yes
```

The following commands would write snapshots at the times listed in file `tmp.times`:

```
variable      f file tmp.times
variable      s equal next(f)
dump          1 all atom 100 tmp.dump
dump_modify   1 every/time v_s
```

---

**Note:** When using a file-style variable with the *every/time* keyword, the file of timesteps must list a first time that is beyond the time associated with the current timestep (e.g., it cannot be 0.0). And it must list one or more times beyond the length of the run you perform. This is because the dump command will generate an error if the next time it reads from the file is not a value greater than the current time. Thus if you wanted output at times 0,15,100 of a run of length 100 in simulation time, the file should contain the values 15,100,101 and you should also use the `dump_modify first` command. Any final value > 100 could be used in place of 101.

---

The *first* keyword determines whether a dump snapshot is written on the very first timestep after the dump command is invoked. This will always occur if the current timestep is a multiple of `$N$`, the frequency specified in the `dump` command or `dump_modify every` command, including timestep 0. It will also always occur if the current simulation time is a multiple of *Delta*, the time interval specified in the `dump_modify every/time` command.

But if this is not the case, a dump snapshot will only be written if the setting of this keyword is *yes*. If it is *no*, which is the default, then it will not be written.

Note that if the argument to the `dump_modify every dump_modify every/time` commands is a variable and not a numeric value, then specifying *first yes* is the only way to write a dump snapshot on the first timestep after the dump command is invoked.

---

The *flush* keyword determines whether a flush operation is invoked after a dump snapshot is written to the dump file. A flush ensures the output in that file is current (no buffering by the OS), even if LAMMPS halts before the simulation completes. Flushes cannot be performed with dump style *xtc*.

---

The *format* keyword can be used to change the default numeric format output by the text-based dump styles: *atom*, *local*, *custom*, *cfg*, and *xyz* styles. Only the *line* or *none* options can be used with the *atom* and *xyz* styles.

All the specified format strings are C-style formats, such as used by the C/C++ `printf()` command. The *line* keyword takes a single argument which is the format string for an entire line of output for each atom (do not include a trailing “n”), with *N* fields, which you must enclose in quotes if there is more than one field. The *int* and *float* keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for *M string* also takes a single format argument which is used for the *M*th value output in each line (e.g., the fifth column is output in high precision by “format 5 %20.15g”).

---

**Note:** When using the *line* keyword for the *cfg* style, the first two fields (atom ID and type) are not actually written into the CFG file, however you must include formats for them in the format string.

---

The *format* keyword can be used multiple times. The precedence is that for each value in a line of output, the *M* format (if specified) is used, else the *int* or *float* setting (if specified) is used, else the *line* setting (if specified) for that value is used, else the default setting is used. A setting of *none* clears all previous settings, reverting all values to their default format.

---

**Note:** Atom and molecule IDs are stored internally as 4-byte or 8-byte signed integers, depending on how LAMMPS was compiled. When specifying the *format int* option you can use a “%d”-style format identifier in the format string and LAMMPS will convert this to the corresponding 8-byte form if it is needed when outputting those values. However, when specifying the *line* option or *format M string* option for those values, you should specify a format string appropriate for an 8-byte signed integer (e.g., one with “%ld”) if LAMMPS was compiled with the `-DLAMMPS_BIGBIG` option for 8-byte IDs.

---

---

**Note:** Any value written to a text-based dump file that is a per-atom quantity calculated by a *compute* or *fix* is stored internally as a floating-point value. If the value is actually an integer and you wish it to appear in the text dump file as a (large) integer, then you need to use an appropriate format. For example, these commands:

---

```
compute      1 all property/local batom1 batom2
dump         1 all local 100 tmp.bonds index c_1[1] c_1[2]
dump_modify 1 format line "%d %0.0f %0.0f"
```

will output the two atom IDs for atoms in each bond as integers. If the `dump_modify` command were omitted, they would appear as floating-point values, assuming they were large integers (more than six digits). The “index” keyword should use the “%d” format since it is not generated by a `compute` or `fix`, and is stored internally as an integer.

---

The *fileper* keyword is documented below with the *nfile* keyword.

---

The *header* keyword toggles whether the dump file will include a header. Excluding a header will reduce the size of the dump file for data produced by *pair tracker* or *bpm bond styles* which may not require the information typically written to the header.

---

The *image* keyword applies only to the dump *atom* style. If the *image* value is *yes*, three flags are appended to each atom’s coords which are the absolute box image of the atom in each dimension. For example, an *x* image flag of  $-2$  with a normalized coord of 0.5 means the atom is in the center of the box, but has passed through the box boundary twice and is really two box lengths to the left of its current coordinate. Note that for dump style *custom* these various values can be printed in the dump file by using the appropriate atom attributes in the dump command itself. Using this keyword will reset all custom header names set with *dump\_modify colname* to their respective default values.

---

The *label* keyword applies only to the dump *local* style. When it writes local information, such as bond or angle topology to a dump file, it will use the specified *label* to format the header. By default this includes two lines:

```
ITEM: NUMBER OF ENTRIES
ITEM: ENTRIES ...
```

The word “ENTRIES” will be replaced with the string specified (e.g., BONDS or ANGLES).

---

The *maxfiles* keyword can only be used when a “\*” wildcard is included in the dump file name (i.e., when writing a new file(s) for each snapshot). The specified *Fmax* is how many snapshots will be kept. Once this number is reached, the file(s) containing the oldest snapshot is deleted before a new dump file is written. If the specified  $Fmax \leq 0$ , then all files are retained.

This can be useful for debugging, especially if you do not know on what timestep something bad will happen (e.g., when LAMMPS will exit with an error). You can dump every time step and limit the number of dump files produced, even if you run for thousands of steps.

---

The *nfile* or *fileper* keywords can be used in conjunction with the “%” wildcard character in the specified dump file name, for all dump styles except the *dcd*, *image*, *movie*, *xtc*, and *xyz* styles (for which “%” is not allowed). As explained on the *dump* command doc page, the “%” character causes the dump file to be written in pieces, one piece for each of

$P$  processors. By default,  $P$  is the number of processors the simulation is running on. The *nfile* or *fileper* keyword can be used to set  $P$  to a smaller value, which can be more efficient when running on a large number of processors.

The *nfile* keyword sets  $P$  to the specified  $N_f$  value. For example, if  $N_f = 4$ , and the simulation is running on 100 processors, four files will be written by processors 0, 25, 50, and 75. Each will collect information from itself and the next 24 processors and write it to a dump file.

For the *fileper* keyword, the specified value of  $N_p$  means write one file for every  $N_p$  processors. For example, if  $N_p = 4$ , every fourth processor (0, 4, 8, 12, etc.) will collect information from itself and the next three processors and write it to a dump file.

---

The *pad* keyword only applies when the dump filename is specified with a wildcard “\*” character which becomes the timestep. If *pad* is 0, which is the default, the timestep is converted into a string of unpadded length (e.g., 100 or 12000 or 2000000). When *pad* is specified with  $N_{char} > 0$ , the string is padded with leading zeroes so they are all the same length =  $N_{char}$ . For example, pad 7 would yield 0000100, 0012000, 2000000. This can be useful so that post-processing programs can easily read the files in ascending timestep order.

---

The *phc* keyword applies to all the dump styles. As explained on the [dump](#) doc page, atom coordinates in a dump file may be slightly outside the simulation box. This is because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, which will not typically coincide with the timesteps dump snapshots are written. If the setting of this keyword is set to *yes*, then all atoms will be remapped to the periodic box before the snapshot is written, then restored to their original position. If it is set to *no* they will not be. The *no* setting is the default because it requires no extra computation.

---

The *precision* keyword only applies to the dump *xtc* style. A specified value of  $N$  means that coordinates are stored to  $1/N$  nanometer accuracy (e.g., for  $N = 1000$ , the coordinates are written to 1/1000 nanometer accuracy).

---

The *refresh* keyword only applies to the dump *custom*, *cfg*, *image*, and *movie* styles. It allows an “incremental” dump file to be written, by refreshing a compute that is used as a threshold for determining which atoms are included in a dump snapshot. The specified *c\_ID* gives the ID of the compute. It is prefixed by “c\_” to indicate a compute, which is the only current option. At some point, other options may be added (e.g., fixes or variables).

---

**Note:** This keyword can only be specified once for a dump. Refreshes of multiple computes cannot yet be performed.

---

The definition and motivation of an incremental dump file is as follows. Instead of outputting all atoms at each snapshot (with some associated values), you may only wish to output the subset of atoms with a value that has changed in some way compared to the value the last time that atom was output. In some scenarios this can result in a dramatically smaller dump file. If desired, by post-processing the sequence of snapshots, the values for all atoms at all timesteps can be inferred.

A concrete example is a simulation of atom diffusion in a solid, represented as atoms on a lattice. Diffusive hops are rare. Imagine that when a hop occurs an atom moves more than a distance *Dhop*. For any snapshot we only want to output atoms that have hopped since the last snapshot. This can be accomplished with something the following commands:

```
variable      Dhop equal 0.6
variable      check atom "c_dsp[4] > v_Dhop"
compute       dsp all displace/atom refresh check
dump          1 all custom 20 tmp.dump id type x y z
dump_modify   1 append yes thresh c_dsp[4] > ${Dhop} refresh c_dsp
```

The *compute displace/atom* command calculates the displacement of each atom from its reference position. The “4” index is the scalar displacement; 1, 2, and 3 are the *xyz* components of the displacement. The *dump\_modify thresh* command will cause only atoms that have displaced more than 0.6 Å to be output on a given snapshot (assuming metal units). However, note that when an atom is output, we also need to update the reference position for that atom to its new coordinates. So that it will not be output in every snapshot thereafter. That reference position is stored by *compute displace/atom*. So the *dump\_modify refresh* option triggers a call to *compute displace/atom* at the end of every dump to perform that update. The *refresh check* option shown as part of the *compute displace/atom* command enables the compute to respond to the call from the dump command, and update the appropriate reference positions. This is done by defining an *atom-style variable*, *check* in this example, which calculates a Boolean value (0 or 1) for each atom, based on the same criterion used by *dump\_modify thresh*.

See the *compute displace/atom* command for more details, including an example of how to produce output that includes an initial snapshot with the reference position of all atoms.

Note that only computes with a *refresh* option will work with *dump\_modify refresh*. See individual compute doc pages for details. Currently, only *compute displace/atom* supports this option. Others may be added at some point. If you use a compute that does not support refresh operations, LAMMPS will not complain; *dump\_modify refresh* will simply do nothing.

---

The *region* keyword only applies to the dump *custom*, *cfg*, *image*, and *movie* styles. If specified, only atoms in the region will be written to the dump file or included in the image/movie. Only one region can be applied as a filter (the last one specified). See the *region* command for more details. Note that a region can be defined as the “inside” or “outside” of a geometric shape, and it can be the “union” or “intersection” of a series of simpler regions.

---

The *scale* keyword applies only to the dump *atom* style. A scale value of *yes* means atom coords are written in normalized units from 0.0 to 1.0 in each box dimension. If the simulation box is triclinic (tilted), then all atom coords will still be between 0.0 and 1.0. A value of *no* means they are written in absolute distance units (e.g., Å or σ). Using this keyword will reset all custom header names set with *dump\_modify colname* to their respective default values.

---

The *sfactor* and *tfactor* keywords only apply to the dump *xtc* style. They allow customization of the unit conversion factors used when writing to XTC files. By default, they are initialized for whatever *units* style is being used, to write out coordinates in nanometers and time in picoseconds. For example, for *real* units, LAMMPS defines *sfactor* = 0.1 and *tfactor* = 0.001, since the Å and fs used by *real* units are 0.1 nm and 0.001 ps, respectively. If you are using a units system with distance and time units far from nm and ps, you may wish to write XTC files with different units, since the compression algorithm used in XTC files is most effective when the typical magnitude of position data is between 10.0 and 0.1.

---

New in version 15Sep2022.

The *skip* keyword can be used with all dump styles. It allows a dump snapshot to be skipped (not written to the dump file), if a condition is met. The condition is computed by an *equal-style variable*, which should be specified as *v\_name*, where name is the variable name. If the variable evaluation returns a non-zero value, then the dump snapshot is skipped. If it returns zero, the dump proceeds as usual. Note that *equal-style variable* can contain Boolean operators which effectively evaluate as a true (non-zero) or false (zero) result.

The *skip* keyword can be useful for debugging purposes, e.g. to dump only on a particular timestep. Or to limit output to conditions of interest, e.g. only when the force on some atom exceeds a threshold value.

---

The *sort* keyword determines whether lines of per-atom output in a snapshot are sorted or not. A sort value of *off* means they will typically be written in indeterminate order, either in serial or parallel. This is the case even in serial

if the *atom\_modify sort* option is turned on, which it is by default, to improve performance. A sort value of *id* means sort the output by atom ID. A sort value of *N* or *-N* means sort the output by the value in the *N*th column of per-atom info in either ascending or descending order.

The dump *local* style cannot be sorted by atom ID, since there are typically multiple lines of output per atom. Some dump styles, such as *dcd* and *xtc*, require sorting by atom ID to format the output file correctly. If multiple processors are writing the dump file, via the “%” wildcard in the dump filename and the *nfile* or *fileper* keywords are set to non-default values (i.e., the number of dump file pieces is not equal to the number of procs), then sorting cannot be performed.

In a parallel run, the per-processor dump file pieces can have significant imbalance in number of lines of per-atom info. The *balance* keyword determines whether the number of lines in each processor snapshot are balanced to be nearly the same. A balance value of *no* means no balancing will be done, while *yes* means balancing will be performed. This balancing preserves dump sorting order. For a serial run, this option is ignored since the output is already balanced.

---

**Note:** Unless it is required by the dump style, sorting dump file output requires extra overhead in terms of CPU and communication cost, as well as memory, versus unsorted output.

---

The *thermo* keyword only applies the dump styles *netcdf* and *yaml*. It triggers writing of *thermo* information to the dump file alongside per-atom data. The values included in the dump file are cached values from the last thermo output and include the exact same the values as specified by the *thermo\_style* command. Because these are cached values, they are only up-to-date when dump output is on a timestep that also has thermo output. Dump style *yaml* will skip thermo output on incompatible steps.

---

The *thresh* keyword only applies to the dump *custom*, *cfg*, *image*, and *movie* styles. Multiple thresholds can be specified. Specifying *none* turns off all threshold criteria. If thresholds are specified, only atoms whose attributes meet all the threshold criteria are written to the dump file or included in the image. The possible attributes that can be tested for are the same as those that can be specified in the *dump custom* command, with the exception of the *element* attribute, since it is not a numeric value. Note that a different attributes can be used than those output by the *dump custom* command. For example, you can output the coordinates and stress of atoms whose energy is above some threshold.

If an atom-style variable is used as the attribute, then it can produce continuous numeric values or effective Boolean 0/1 values, which may be useful for the comparison operator. Boolean values can be generated by variable formulas that use comparison or Boolean math operators or special functions like *gmask()* and *rmask()* and *grmask()*. See the *variable* command page for details.

The specified value must be a simple numeric value or the word *LAST*. If *LAST* is used, it refers to the value of the attribute the last time the dump command was invoked to produce a snapshot. This is a way to only dump atoms whose attribute has changed (or not changed). Three examples follow.

```
dump_modify ... thresh ix != LAST
```

This will dump atoms which have crossed the periodic *x* boundary of the simulation box since the last dump. (Note that atoms that crossed once and then crossed back between the two dump timesteps would not be included.)

```
region foo sphere 10 20 10 15
variable inregion atom rmask(foo)
dump_modify ... thresh v_inregion |^ LAST
```

This will dump atoms which crossed the boundary of the spherical region since the last dump.

```
variable charge atom "(q > 0.5) || (q < -0.5)"
dump_modify ... thresh v_charge |^ LAST
```

This will dump atoms whose charge has changed from an absolute value less than  $\frac{1}{2}$  to greater than  $\frac{1}{2}$  (or vice versa) since the last dump (e.g., due to reactions and subsequent charge equilibration in a reactive force field).

The choice of operators listed above are the usual comparison operators. The XOR operation (exclusive or) is also included as “|”. In this context, XOR means that if either the attribute or value is 0.0 and the other is non-zero, then the result is “true” and the threshold criterion is met. Otherwise it is not met.

---

**Note:** For style *custom*, the *triclinic/general* keyword can alter dump output for general triclinic simulation boxes and their atoms. See the [dump](#) command for details of how this changes the format of dump file snapshots. The *thresh* keyword may access per-atom attributes either directly or indirectly through a compute or variable. If the attribute is an atom coordinate or a per-atom vector (such as velocity, force, or dipole moment), its value will *NOT* be a general triclinic (rotated) value. Rather it will be a restricted triclinic value.

---

The *time* keyword only applies to the dump *atom*, *custom*, *local*, and *xyz* styles (and their COMPRESS package versions *atom/gz*, *custom/gz* and *local/gz*). For the first three styles, if set to *yes*, each frame will contain two extra lines before the “ITEM: TIMESTEP” entry:

```
ITEM: TIME
<elapsed time>
```

For the *xyz* style, the simulation time is included on the same line as the timestep value.

This will output the current elapsed simulation time in current time units equivalent to the *thermo keyword time*. This is to simplify post-processing of trajectories using a variable time step (e.g., when using *fix dt/reset*). The default setting is *no*.

---

The *types* keyword applies only to the dump *xyz* style. If this keyword is used with a value of *numeric*, then numeric atom types are printed in the *xyz* file (default). If the value *labels* is specified, then *type labels* are printed for atom types.

---

The *triclinic/general* keyword only applies to the dump *atom* and *custom* styles. It can only be used with a value of *yes* if the simulation box was created as a general triclinic box. See the [Howto\\_triclinic](#) doc page for a detailed explanation of orthogonal, restricted triclinic, and general triclinic simulation boxes.

If this keyword is used with a value of *yes*, the box information at the beginning of each snapshot will include information about the 3 arbitrary edge vectors **A**, **B**, **C** that define the general triclinic box as well as their origin. The format is described on the [dump](#) doc page.

The coordinates of each atom will likewise be output as values in (or near) the general triclinic box. Likewise, per-atom vector quantities such as velocity, omega, dipole moment, etc will have orientations consistent with the general triclinic box, meaning they will be rotated relative to the standard *xyz* coordinate axes. See the [dump](#) doc page for a full list of which dump attributes this affects.

---

The *units* keyword only applies to the dump *atom*, *custom*, and *local* styles (and their COMPRESS package versions *atom/gz*, *custom/gz* and *local/gz*). If set to *yes*, each individual dump file will contain two extra lines at the very beginning with:

```
ITEM: UNITS
<units style>
```

This will output the current selected *units* style to the dump file and thus allows visualization and post-processing tools to determine the choice of units of the data in the dump file. The default setting is *no*.

---

The *unwrap* keyword only applies to the dump *dcd* and *xtc* styles. If set to *yes*, coordinates will be written “unwrapped” by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

---

The *COMPRESS* package offers both GZ and Zstd compression variants of styles *atom*, *custom*, *local*, *cfg*, and *xyz*. When using these styles the compression level can be controlled by the *compression\_level* keyword. File names with these styles have to end in either *.gz* or *.zst*.

GZ supports compression levels from  $-1$  (default), 0 (no compression), and 1 to 9, 9 being the best compression. The *COMPRESS /gz* styles use 9 as default compression level.

Zstd offers a wider range of compression levels, including negative levels that sacrifice compression for performance. 0 is the default, positive levels are 1 to 22, with 22 being the most expensive compression. Zstd promises higher compression/decompression speeds for similar compression ratios. For more details see <https://facebook.github.io/zstd/>.

In addition, Zstd compressed files can include a checksum of the entire contents. The Zstd enabled dump styles enable this feature by default and it can be disabled with the *checksum* keyword.

---

The *VTK* package offers writing dump files in *VTK file formats* that can be read by a variety of visualization tools based on the VTK library. These VTK files follow naming conventions that collide with the LAMMPS convention to append “.bin” to a file name in order to switch to a binary output. Thus for *vtk style dumps* the *dump\_modify* command supports the keyword *binary* which selects between generating text mode and binary style VTK files.

---

## 9.19.4 Restrictions

Not all *dump\_modify* options can be applied to all dump styles. Details are in the discussions of the individual options.

## 9.19.5 Related commands

*dump*, *dump image*, *undump*

## 9.19.6 Default

The option defaults are

- *append* = no
- *balance* = no
- *buffer* = yes for dump styles *atom*, *custom*, *loca*, and *xyz*
- *element* = “C” for every atom type
- *every* = whatever it was set to via the *dump* command
- *fileper* = # of processors

- first = no
- flush = yes
- format = %d and %g for each integer or floating point value
- image = no
- label = ENTRIES
- maxfiles = -1
- nfile = 1
- pad = 0
- pbc = no
- precision = 1000
- region = none
- scale = yes
- sort = off for dump styles *atom*, *custom*, *cfg*, and *local*
- sort = id for dump styles *dcd*, *xtc*, and *xyz*
- thresh = none
- time = no
- triclinic/general = no
- types = numeric
- units = no
- unwrap = no
- compression\_level = 9 (gz variants)
- compression\_level = 0 (zstd variants)
- checksum = yes (zstd variants)

## 9.20 dump molfile command

### 9.20.1 Syntax

```
dump ID group-ID molfile N file format path
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- molfile = style of dump command (other styles *atom* or *cfg* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file = name of file to write to
- format = file format to be used
- path = file path with plugins (optional)

## 9.20.2 Examples

```
dump mf1 all molfile 10 melt1.xml hoond
dump mf2 all molfile 10 melt2-*.pdb pdb .
dump mf3 all molfile 50 melt3.xyz xyz ./home/akohlmeier/vmd/plugins/LINUX/molfile
```

## 9.20.3 Description

Dump a snapshot of atom coordinates and selected additional quantities to one or more files every N timesteps in one of several formats. Only information for atoms in the specified group is dumped. This specific dump style uses molfile plugins that are bundled with the [VMD](#) molecular visualization and analysis program.

Unless the filename contains a \* character, the output will be written to one single file with the specified format. Otherwise there will be one file per snapshot and the \* will be replaced by the time step number when the snapshot is written.

---

**Note:** Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

---

The molfile plugin API has a few restrictions that have to be honored by this dump style: the number of atoms must not change, the atoms must be sorted, outside of the coordinates no change in atom properties (like type, mass, charge) will be recorded.

---

The *format* keyword determines what format is used to write out the dump. For this to work, LAMMPS must be able to find and load a compatible molfile plugin that supports this format. Settings made via the *dump\_modify* command can alter per atom properties like element names.

The *path* keyword determines which directories. This is a “path” like other search paths, i.e. it can contain multiple directories separated by a colon (or semicolon on Windows). This keyword is optional and default to “.”, the current directory.

The *unwrap* option of the *dump\_modify* command allows coordinates to be written “unwrapped” by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

---

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the *dump\_modify first* command, which can be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the *dump\_modify every* command. The *dump\_modify every* command also allows a variable to be used to determine the sequence of timesteps on which dump files are written.

---

## 9.20.4 Restrictions

The *molfile* dump style is part of the MOLFILE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Molfile plugins provide a consistent programming interface to read and write file formats commonly used in molecular simulations. The MOLFILE package only provides the interface code, not the plugins. These can be obtained from a VMD installation which has to match the platform that you are using to compile LAMMPS for. By adding plugins to VMD, support for new file formats can be added to LAMMPS (or VMD or other programs that use them) without having to re-compile the application itself. The plugins are installed in the directory: <VMD-HOME>/plugins/<VMDARCH>/molfile

---

**Note:** while the programming interface (API) to the plugins is backward compatible, the binary interface (ABI) has been changing over time, so it is necessary to compile this package with the plugin header files from VMD that match the binary plugins. These header files in the directory: <VMDHOME>/plugins/include For convenience, the package ships with a set of header files that are compatible with VMD 1.9 and 1.9.1 (June 2012)

---

## 9.20.5 Related commands

*dump*, *dump\_modify*, *undump*

## 9.20.6 Default

The default path is “.”. All other properties have to be specified.

## 9.21 dump netcdf command

## 9.22 dump netcdf/mpiio command

### 9.22.1 Syntax

```
dump ID group-ID netcdf N file args
dump ID group-ID netcdf/mpiio N file args
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be imaged
- *netcdf* or *netcdf/mpiio* = style of dump command (other styles *atom* or *cfd* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)
- N = dump every this many timesteps
- file = name of file to write dump info to
- args = list of atom attributes, same as for [dump\\_style custom](#)

## 9.22.2 Examples

```
dump 1 all netcdf 100 traj.nc type x y z vx vy vz
dump_modify 1 append yes at -1 thermo yes
dump 1 all netcdf/mpiio 1000 traj.nc id type x y z
dump 1 all netcdf 1000 traj.*.nc id type x y z
```

## 9.22.3 Description

Dump a snapshot of atom coordinates every N timesteps in Amber-style NetCDF file format. NetCDF files are binary, portable and self-describing. This dump style will write only one file on the root node. The dump style *netcdf* uses the [standard NetCDF library](#). All data is collected on one processor and then written to the dump file. Dump style *netcdf/mpiio* uses the [parallel NetCDF library](#) and MPI-IO to write to the dump file in parallel; it has better performance on a larger number of processors. Note that style *netcdf* outputs all atoms sorted by atom tag while style *netcdf/mpiio* outputs atoms in order of their MPI rank.

NetCDF files can be directly visualized via the following tools:

- Ovito (<https://www.ovito.org/>). Ovito supports the AMBER convention and all extensions of this dump style.
- VMD (<https://www.ks.uiuc.edu/Research/vmd/>).

In addition to per-atom data, *thermo* data can be included in the dump file. The data included in the dump file is identical to the data specified by *thermo\_style*.

---

## 9.22.4 Restrictions

The *netcdf* and *netcdf/mpiio* dump styles are part of the NETCDF package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The *netcdf* and *netcdf/mpiio* dump styles currently cannot dump string properties or properties from variables.

---

## 9.22.5 Related commands

*dump*, *dump\_modify*, *undump*

## 9.23 dump vtk command

### 9.23.1 Syntax

```
dump ID group-ID vtk N file args
```

- ID = user-assigned name for the dump
- group-ID = ID of the group of atoms to be dumped
- vtk = style of dump command (other styles such as *atom* or *cfd* or *dcd* or *xtc* or *xyz* or *local* or *custom* are discussed on the [dump](#) doc page)

- $N$  = dump every this many timesteps
- file = name of file to write dump info to
- args = same as arguments for *dump\_style custom*

### 9.23.2 Examples

```
dump dmpvtk all vtk 100 dump*.myforce.vtk id type vx fx
dump dmpvtp flow vtk 100 dump*%displace.vtp id type c_myD[1] c_myD[2] c_myD[3] v_ke
```

### 9.23.3 Description

Dump a snapshot of atom quantities to one or more files every  $N$  timesteps in a format readable by the [VTK visualization toolkit](#) or other visualization tools that use it, such as [ParaView](#). The time steps on which dump output is written can also be controlled by a variable; see the *dump\_modify every* command for details.

This dump style is similar to *dump\_style custom* but uses the VTK library to write data to VTK simple legacy or XML format, depending on the filename extension specified for the dump file. This can be either \*.vtk for the legacy format or \*.vtp and \*.vtu, respectively, for XML format; see the [VTK homepage](#) for a detailed description of these formats. Since this naming convention conflicts with the way binary output is usually specified (see below), the *dump\_modify binary* command allows setting of a binary option for this dump style explicitly.

Only information for atoms in the specified group is dumped. The *dump\_modify thresh and region* commands can also alter what atoms are included; see details below.

As described below, special characters ("\*", "%") in the filename determine the kind of output.

**Warning:** Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

**Warning:** Unless the *dump\_modify sort* option is invoked, the lines of atom information written to dump files will be in an indeterminate order for each snapshot. This is even true when running on a single processor, if the *atom\_modify sort* option is on, which it is by default. In this case atoms are re-ordered periodically during a simulation, due to spatial sorting. It is also true when running in parallel, because data for a single snapshot is collected from multiple processors, each of which owns a subset of the atoms.

For the *vtk* style, sorting is off by default. See the *dump\_modify* page for details.

The dimensions of the simulation box are written to a separate file for each snapshot (either in legacy VTK or XML format depending on the format of the main dump file) with the suffix *\_boundingBox* appended to the given dump filename.

For an orthogonal simulation box this information is saved as a rectilinear grid (legacy .vtk or .vtr XML format).

Triclinic simulation boxes (non-orthogonal) are saved as hexahedrons in either legacy .vtk or .vtu XML format.

Style *vtk* allows you to specify a list of atom attributes to be written to the dump file for each atom. The list of possible attributes is the same as for the *dump\_style custom* command; see its documentation page for a listing and an explanation of each attribute.

**Note:** Since position data is required to write VTK files the atom attributes “x y z” do not have to be specified explicitly; they will be included in the dump file regardless. Also, in contrast to the *custom* style, the specified *vtk* attributes are rearranged to ensure correct ordering of vector components (except for computes and fixes - these have to be given in the right order) and duplicate entries are removed.

---

The VTK format uses a single snapshot of the system per file, thus a wildcard “\*” must be included in the filename, as discussed below. Otherwise the dump files will get overwritten with the new snapshot each time.

---

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the *dump\_modify first* command, which can also be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the *dump\_modify every* command. The *dump\_modify every* command also allows a variable to be used to determine the sequence of timesteps on which dump files are written. In this mode a dump on the first timestep of a run will also not be written unless the *dump\_modify first* command is used.

Dump filenames can contain two wildcard characters. If a “\*” character appears in the filename, then one file per snapshot is written and the “\*” character is replaced with the timestep value. For example, tmp.dump\*.vtk becomes tmp.dump0.vtk, tmp.dump10000.vtk, tmp.dump20000.vtk, etc. Note that the *dump\_modify pad* command can be used to ensure all timestep numbers are the same length (e.g. 00010), which can make it easier to read a series of dump files in order with some post-processing tools.

If a “%” character appears in the filename, then each of P processors writes a portion of the dump file, and the “%” character is replaced with the processor ID from 0 to P-1 preceded by an underscore character. For example, tmp.dump%.vtp becomes tmp.dump\_0.vtp, tmp.dump\_1.vtp, ... tmp.dump\_P-1.vtp, etc. This creates smaller files and can be a fast mode of output on parallel machines that support parallel I/O for output.

By default, P = the number of processors meaning one file per processor, but P can be set to a smaller value via the *nfile* or *fileper* keywords of the *dump\_modify* command. These options can be the most efficient way of writing out dump files when running on large numbers of processors.

For the legacy VTK format “%” is ignored and P = 1, i.e., only processor 0 does write files.

Note that using the “\*” and “%” characters together can produce a large number of small dump files!

If *dump\_modify binary* is used, the dump file (or files, if “\*” or “%” is also used) is written in binary format. A binary dump file will be about the same size as a text version, but will typically write out much faster.

---

## 9.23.4 Restrictions

The *vtk* style does not support writing of gzipped dump files.

The *vtk* dump style is part of the VTK package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

To use this dump style, you also must link to the VTK library. See the info in lib/vtk/README and ensure the Makefile.lammps file in that directory is appropriate for your machine.

The *vtk* dump style supports neither buffering or custom format strings.

### 9.23.5 Related commands

*dump*, *dump image*, *dump\_modify*, *undump*

### 9.23.6 Default

By default, files are written in ASCII format. If the file extension is not one of .vtk, .vtp or .vtu, the legacy VTK file format is used.
