# 2.62 fix eos/table command

## 2.62.1 Syntax

```
fix ID group-ID eos/table style file N keyword
```

- ID, group-ID are documented in *fix* command
- eos/table = style name of this fix command
- style = *linear* = method of interpolation
- file = filename containing the tabulated equation of state

- $N$  = use  $N$  values in *linear* tables
- keyword = name of table keyword corresponding to table file

## 2.62.2 Examples

```
fix 1 all eos/table linear eos.table 100000 KEYWORD
```

## 2.62.3 Description

Fix *eos/table* applies a tabulated mesoparticle equation of state to relate the particle internal energy ( $u_i$ ) to the particle internal temperature ( $dPdTheta_i$ ).

Fix *eos/table* creates interpolation tables of length  $N$  from internal energy values listed in a file as a function of internal temperature.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy values at each of  $N$  internal temperatures, and vice versa. During a simulation, these tables are used to interpolate internal energy or temperature values as needed. The interpolation is done with the *linear* style.

For the *linear* style, the internal temperature is used to find 2 surrounding table values from which an internal energy is computed by linear interpolation, and vice versa.

The filename specifies a file containing tabulated internal temperature and internal energy values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# EOS TABLE          (one or more comment or blank lines)

KEYWORD               (keyword is first text on line)
N 500                 (N parameter)
                      (blank)
1   1.00 0.000        (index, internal temperature, internal energy)
2   1.02 0.001
...
500 10.0 0.500
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the fix command.

The next line lists the number of table entries. The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the  $N$  specified in the *fix eos/table* command. Let  $N_{\text{table}} = N$  in the fix command, and  $N_{\text{file}} = “N”$  in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the  $N_{\text{file}}$  tabulated values as nodal points. It uses these to interpolate as needed to generate energy and temperature values at  $N_{\text{table}}$  different points. The resulting tables of length  $N_{\text{table}}$  are then used as described above, when computing energy and temperature relationships. This means that if you want the interpolation tables of length  $N_{\text{table}}$  to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set  $N_{\text{table}} = N_{\text{file}}$ .

Following a blank line, the next  $N$  lines list the tabulated values. On each line, the first value is the index from 1 to  $N$ , the second value is the internal temperature (in temperature units), the third value is the internal energy (in energy units).

Note that the internal temperature and internal energy values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

## 2.62.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command also requires use of the [atom\\_style dpd](#) command.

The equation of state must be a monotonically increasing function.

An error will occur if the internal temperature or internal energies are not within the table cutoffs.

## 2.62.5 Related commands

*fix shadlow, pair dpd/fdt*

## 2.62.6 Default

none

# 2.63 fix eos/table/rx command

Accelerator Variants: *eos/table/rx/kk*

## 2.63.1 Syntax

```
fix ID group-ID eos/table/rx style file1 N keyword ...
```

- ID, group-ID are documented in [fix](#) command
- eos/table/rx = style name of this fix command
- style = *linear* = method of interpolation
- file1 = filename containing the tabulated equation of state
- N = use N values in *linear* tables
- keyword = name of table keyword corresponding to table file
- file2 = filename containing the heats of formation of each species (optional)
- deltaHf = heat of formation for a single species in energy units (optional)
- energyCorr = energy correction in energy units (optional)
- tempCorrCoeff = temperature correction coefficient (optional)

## 2.63.2 Examples

```
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD thermo.table
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD 1.5
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD 1.5 0.025 0.0
```

## 2.63.3 Description

Fix *eos/table/rx* applies a tabulated mesoparticle equation of state to relate the concentration-dependent particle internal energy ( $u_i$ ) to the particle internal temperature ( $\theta_i$ ).

The concentration-dependent particle internal energy ( $u_i$ ) is computed according to the following relation:

$$U_i = \sum_{j=1}^m c_{i,j}(u_j + \Delta H_{f,j}) + \frac{3k_B T}{2} + Nk_B T$$

where  $m$  is the number of species,  $c_{i,j}$  is the concentration of species  $j$  in particle  $i$ ,  $u_j$  is the internal energy of species  $j$ ,  $\Delta H_{f,j}$  is the heat of formation of species  $j$ ,  $N$  is the number of molecules represented by the coarse-grained particle,  $k_B$  is the Boltzmann constant, and  $T$  is the temperature of the system. Additionally, it is possible to modify the concentration-dependent particle internal energy relation by adding an energy correction, temperature-dependent correction, and/or a molecule-dependent correction. An energy correction can be specified as a constant (in energy units). A temperature correction can be specified by multiplying a temperature correction coefficient by the internal temperature. A molecular correction can be specified by multiplying a molecule correction coefficient by the average number of product gas particles in the coarse-grain particle.

Fix *eos/table/rx* creates interpolation tables of length  $N$  from  $m$  internal energy values of each species  $u_j$  listed in a file as a function of internal temperature. During a simulation, these tables are used to interpolate internal energy or temperature values as needed. The interpolation is done with the *linear* style. For the *linear* style, the internal temperature is used to find 2 surrounding table values from which an internal energy is computed by linear interpolation. A secant solver is used to determine the internal temperature from the internal energy.

The first filename specifies a file containing tabulated internal temperature and  $m$  internal energy values for each species  $u_j$ . The keyword specifies a section of the file. The format of this file is described below.

The second filename specifies a file containing heat of formation  $\Delta H_{f,j}$  for each species.

In cases where the coarse-grain particle represents a single molecular species (i.e., no reactions occur and fix *rx* is not present in the input file), fix *eos/table/rx* can be applied in a similar manner to fix *eos/table* within a non-reactive DPD simulation. In this case, the heat of formation filename is replaced with the heat of formation value for the single species. Additionally, the energy correction and temperature correction coefficients may also be specified as fix arguments.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# EOS TABLE          (one or more comment or blank lines)

KEYWORD               (keyword is first text on line)
N 500 h2 no2 n2 ... no (N parameter species1 species2 ... speciesN)
                        (blank)
1 1.00 0.000 ... 0.0000 (index, internal temperature, internal energy of species 1, ..
→., internal energy of species m)
2 1.02 0.001 ... 0.0002
...
500 10.0 0.500 ... 1.0000
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `fix` command.

The next line lists the number of table entries and the species names that correspond with all the species listed in the reaction equations through the `fix rx` command. The parameter “N” is required and its value is the number of table entries that follow. Let `Nfile = “N”` in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the `Nfile` tabulated values as nodal points.

Following a blank line, the next `N` lines list the tabulated values. On each line, the first value is the index from 1 to `N`, the second value is the internal temperature (in temperature units), the third value until the  $m+3$  value are the internal energies of the `m` species (in energy units).

Note that all internal temperature and internal energy values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

The format of a heat of formation file is as follows (without the parenthesized comments):

```
# HEAT OF FORMATION TABLE (one or more comment or blank lines)

                                (blank)
h2      0.00                    (species name, heat of formation)
no2     0.34
n2      0.00
...
no      0.93
```

Note that the species can be listed in any order. The tag that is used as the species name must correspond with the tags used to define the reactions with the `fix rx` command.

Alternatively, corrections to the EOS can be included by specifying three additional columns that correspond to the energy correction, the temperature correction coefficient and molecule correction coefficient. In this case, the format of the file is as follows:

```
# HEAT OF FORMATION TABLE (one or more comment or blank lines)

                                (blank)
h2      0.00 1.23 0.025 0.0 (species name, heat of formation, energy correction,
→temperature correction coefficient, molecule correction coefficient)
no2     0.34 0.00 0.000 -1.76
n2      0.00 0.00 0.000 -1.76
...
no      0.93 0.00 0.000 -1.76
```

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` *command-line switch* when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.63.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command also requires use of the [atom\\_style dpd](#) command.

The equation of state must be a monotonically increasing function.

An error will occur if the internal temperature or internal energies are not within the table cutoffs.

## 2.63.5 Related commands

## 2.63.6 Default

none

# 2.64 fix evaporate command

## 2.64.1 Syntax

```
fix ID group-ID evaporate N M region-ID seed
```

- ID, group-ID are documented in [fix](#) command
- evaporate = style name of this fix command
- N = delete atoms every this many timesteps
- M = number of atoms to delete each time
- region-ID = ID of region within which to perform deletions
- seed = random number seed to use for choosing atoms to delete
- zero or more keyword/value pairs may be appended

keyword = *molecule*

*molecule* value = *no* or *yes*

## 2.64.2 Examples

```
fix 1 solvent evaporate 1000 10 surface 49892
fix 1 solvent evaporate 1000 10 surface 38277 molecule yes
```

## 2.64.3 Description

Remove  $M$  atoms from the simulation every  $N$  steps. This can be used, for example, to model evaporation of solvent particles or molecules (i.e. drying) of a system. Every  $N$  steps, the number of atoms in the fix group and within the specified region are counted.  $M$  of these are chosen at random and deleted. If there are less than  $M$  eligible particles, then all of them are deleted.

If the setting for the *molecule* keyword is *no*, then only single atoms are deleted. In this case, you should ensure you do not delete only a portion of a molecule (only some of its atoms), or LAMMPS will soon generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for deletion have a non-zero molecule ID, but does not check for this at the time of deletion.

If the setting for the *molecule* keyword is *yes*, then when an atom is chosen for deletion, the entire molecule it is part of is deleted. The count of deleted atoms is incremented by the number of atoms in the molecule, which may make it exceed  $M$ . If the molecule ID of the chosen atom is 0, then it is assumed to not be part of a molecule, and just the single atom is deleted.

As an example, if you wish to delete 10 water molecules every  $N$  steps, you should set  $M$  to 30. If only the water's oxygen atoms were in the fix group, then two hydrogen atoms would be deleted when an oxygen atom is selected for deletion, whether the hydrogen atoms are inside the evaporation region or not.

Note that neighbor lists are re-built on timesteps that atoms are removed. Thus you should not remove atoms too frequently or you will incur overhead due to the cost of building neighbor lists.

---

**Note:** If you are monitoring the temperature of a system where the atom count is changing due to evaporation, you typically should use the *compute\_modify dynamic/dof yes* command for the temperature compute you are using.

---

## 2.64.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar, which can be accessed by various *output commands*. The scalar is the cumulative number of deleted atoms. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.64.5 Restrictions

None

## 2.64.6 Related commands

*fix deposit*

## 2.64.7 Default

The option defaults are molecule = no.

## 2.65 fix external command

### 2.65.1 Syntax

```
fix ID group-ID external mode args
```

- ID, group-ID are documented in *fix* command
- external = style name of this fix command
- mode = *pf/callback* or *pf/array*

*pf/callback* args = Ncall Napply

Ncall = make callback every Ncall steps

Napply = apply callback forces every Napply steps

*pf/array* args = Napply

Napply = apply array forces every Napply steps

### 2.65.2 Examples

```
fix 1 all external pf/callback 1 1
fix 1 all external pf/callback 100 1
fix 1 all external pf/array 10
```

### 2.65.3 Description

This fix allows external programs that are running LAMMPS through its *library interface* to modify certain LAMMPS properties on specific timesteps, similar to the way other fixes do. The external driver can be a *C/C++ or Fortran program* or a *Python script*.

If mode is *pf/callback* then the fix will make a callback every *Ncall* timesteps or minimization iterations to the external program. The external program computes forces on atoms by setting values in an array owned by the fix. The fix then adds these forces to each atom in the group, once every *Napply* steps, similar to the way the *fix addforce* command works. Note that if *Ncall* > *Napply*, the force values produced by one callback will persist, and be used multiple times to update atom forces.

The callback function “foo” is invoked by the fix as:

```
foo(void *ptr, bigint timestep, int nlocal, tagint *ids, double **x, double **fexternal);
```

The arguments are as follows:

- *ptr* = pointer provided by and simply passed back to external driver
- *timestep* = current LAMMPS timestep
- *nlocal* = # of atoms on this processor
- *ids* = list of atom IDs on this processor
- *x* = coordinates of atoms on this processor
- *fexternal* = forces to add to atoms on this processor

Note that *timestep* is a “bigint” which is defined in `src/lmptype.h`, typically as a 64-bit integer. And *ids* is a pointer to type “tagint” which is typically a 32-bit integer unless LAMMPS is compiled with `-DLAMMPS_BIGBIG`. For more info please see the [build settings](#) section of the manual. Finally, *fexternal* are the forces returned by the driver program.

The fix has a `set_callback()` method which the external driver can call to pass a pointer to its `foo()` function. See the `couple/lammps_quest/impqst.cpp` file in the LAMMPS distribution for an example of how this is done. This sample application performs classical MD using quantum forces computed by a density functional code [Quest](#).

---

If mode is *pf/array* then the fix simply stores force values in an array. The fix adds these forces to each atom in the group, once every *Napply* steps, similar to the way the [fix addforce](#) command works.

The name of the public force array provided by the `FixExternal` class is

```
double **fexternal;
```

It is allocated by the `FixExternal` class as an (N,3) array where N is the number of atoms owned by a processor. The 3 corresponds to the *fx*, *fy*, *fz* components of force.

It is up to the external program to set the values in this array to the desired quantities, as often as desired. For example, the driver program might perform an MD run in stages of 1000 timesteps each. In between calls to the LAMMPS [run](#) command, it could retrieve atom coordinates from LAMMPS, compute forces, set values in *fexternal*, etc.

---

To use this fix during energy minimization, the energy corresponding to the added forces must also be set so as to be consistent with the added forces. Otherwise the minimization will not converge correctly. Correspondingly, the global virial needs to be updated to be use this fix with variable cell calculations (e.g. [fix box/relax](#) or [fix npt](#)).

This can be done from the external driver by calling these public methods of the `FixExternal` class:

```
void set_energy_global(double eng);  
void set_virial_global(double *virial);
```

where *eng* is the potential energy, and *virial* an array of the 6 stress tensor components. *Eng* is an extensive quantity, meaning it should be the sum over per-atom energies of all affected atoms. It should also be provided in [energy units](#) consistent with the simulation. See the details below for how to ensure this energy setting is used appropriately in a minimization.

Additional public methods that the caller can use to update system properties are:

```
void set_energy_peratom(double *eng);  
void set_virial_peratom(double **virial);  
void set_vector_length(int n);  
void set_vector(int idx, double val);
```

These allow to set per-atom energy contributions, per-atom stress contributions, the length and individual values of a global vector of properties that the caller code may want to communicate to LAMMPS (e.g. for use in [fix ave/time](#) or in [equal-style variables](#) or for [custom thermo output](#)).

## 2.65.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy set by the external driver to both the global potential energy and peratom potential energies of the system as part of *thermodynamic output* or output by the *compute pe/atom* command. The default setting for this fix is *fix\_modify energy yes*. Note that this energy may be a fictitious quantity but it is needed so that the *minimize* command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force.

The *fix\_modify virial* option is supported by this fix to add the contribution computed by the external program to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the potential energy discussed above. The scalar stored by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you **MUST** not disable the *fix\_modify energy* option for this fix.

---

## 2.65.5 Restrictions

none

## 2.65.6 Related commands

none

## 2.65.7 Default

none

# 2.66 fix ffl command

## 2.66.1 Syntax

`fix ID id-group ffl tau Tstart Tstop seed [flip-type]`

- ID, group-ID are documented in *fix* command
- ffl = style name of this fix command
- tau = thermostat parameter (positive real)

- Tstart, Tstop = temperature ramp during the run
- seed = random number seed to use for generating noise (positive integer)
- one more value may be appended

flip-type = determines the flipping type, can be chosen between rescale - no\_flip -  
 → hard - soft, if no flip type is given, rescale will be chosen by default

## 2.66.2 Examples

```
fix 3 boundary ffl 10 300 300 31415
fix 1 all ffl 100 500 500 9265 soft
```

## 2.66.3 Description

Apply a Fast-Forward Langevin Equation (FFL) thermostat as described in ([Hijazi](#)). Contrary to *fix langevin*, this fix performs both thermostating and evolution of the Hamiltonian equations of motion, so it should not be used together with *fix nve* – at least not on the same atom groups.

The time-evolution of a single particle undergoing Langevin dynamics is described by the equations

$$\frac{dq}{dt} = \frac{p}{m},$$

$$\frac{dp}{dt} = -\gamma p + W + F,$$

where  $F$  is the physical force,  $\gamma$  is the friction coefficient, and  $W$  is a Gaussian random force.

The friction coefficient is the inverse of the thermostat parameter :  $\gamma = 1/\tau$ , with  $\tau$  the thermostat parameter *tau*. The thermostat parameter is given in the time units,  $\gamma$  is in inverse time units.

Equilibrium sampling a temperature  $T$  is obtained by specifying the target value as the *Tstart* and *Tstop* arguments, so that the internal constants depending on the temperature are computed automatically.

The random number *seed* must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The flipping type *flip-type* can be chosen between 4 types described in ([Hijazi](#)). The flipping operation occurs during the thermostating step and it flips the momenta of the atoms. If *no\_flip* is chosen, no flip will be executed and the integration will be the same as a standard Langevin thermostat ([Bussi](#)). The other flipping types are : rescale - hard - soft.

## 2.66.4 Restart, fix\_modify, output, run start/stop, minimize info

The instantaneous values of the extended variables are written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Note however that you should use a different seed each time you restart, otherwise the same sequence of random numbers will be used each time, which might lead to stochastic synchronization and subtle artifacts in the sampling.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.66.5 Restrictions

In order to perform constant-pressure simulations please use *fix press/berendsen*, rather than *fix npt*, to avoid duplicate integration of the equations of motion.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.66.6 Related commands

## 2.67 fix filter/corotate command

### 2.67.1 Syntax

```
fix ID group-ID filter/corotate keyword value ...
```

- ID, group-ID are documented in *fix* command
- one or more constraint/value pairs are appended
- constraint = *b* or *a* or *t* or *m*

*b* values = one or more bond types

*a* values = one or more angle types

*t* values = one or more atom types

*m* value = one or more mass values

### 2.67.2 Examples

```
timestep 8
run_style respa 3 2 8 bond 1 pair 2 kspace 3
fix cor all filter/corotate m 1.0

fix cor all filter/corotate b 4 19 a 3 5 2
```

### 2.67.3 Description

This fix implements a corotational filter for a mollified impulse method. In biomolecular simulations, it allows the usage of larger timesteps for long-range electrostatic interactions. For details, see (Fath).

When using *run\_style respa* for a biomolecular simulation with high-frequency covalent bonds, the outer time-step is restricted to below  $\sim 4$ fs due to resonance problems. This fix filters the outer stage of the respa and thus a larger (outer) time-step can be used. Since in large biomolecular simulations the computation of the long-range electrostatic contributions poses a major bottleneck, this can significantly accelerate the simulation.

The filter computes a cluster decomposition of the molecular structure following the criteria indicated by the options a, b, t and m. This process is similar to the approach in *fix shake*, however, the clusters are not kept constrained. Instead, the position is slightly modified only for the computation of long-range forces. A good cluster decomposition constitutes in building clusters which contain the fastest covalent bonds inside clusters.

If the clusters are chosen suitably, the *run\_style respa* is stable for outer timesteps of at least 8fs.

---

### 2.67.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about these fixes is written to *binary restart files*. None of the *fix\_modify* options are relevant to these fixes. No global or per-atom quantities are stored by these fixes for access by various *output commands*. No parameter of these fixes can be used with the *start/stop* keywords of the *run* command. These fixes are not invoked during *energy minimization*.

### 2.67.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Currently, it does not support *molecule templates*.

## 2.68 fix flow/gauss command

### 2.68.1 Syntax

```
fix ID group-ID flow/gauss xflag yflag zflag keyword
```

- ID, group-ID are documented in *fix* command
- flow/gauss = style name of this fix command

- xflag,yflag,zflag = 0 or 1

```
0 = do not conserve current in this dimension
1 = conserve current in this dimension
```

- zero or more keyword/value pairs may be appended
- keyword = *energy*  
*energy* value = *no* or *yes*  
*no* = do not compute work done by this fix  
*yes* = compute work done by this fix

## 2.68.2 Examples

```
fix GD fluid flow/gauss 1 0 0
fix GD fluid flow/gauss 1 1 1 energy yes
```

## 2.68.3 Description

This fix implements the Gaussian dynamics (GD) method to simulate a system at constant mass flux (*Strong*). GD is a nonequilibrium molecular dynamics simulation method that can be used to study fluid flows through pores, pipes, and channels. In its original implementation GD was used to compute the pressure required to achieve a fixed mass flux through an opening. The flux can be conserved in any combination of the directions, x, y, or z, using xflag,yflag,zflag. This fix does not initialize a net flux through a system, it only conserves the center-of-mass momentum that is present when the fix is declared in the input script. Use the *velocity* command to generate an initial center-of-mass momentum.

GD applies an external fluctuating gravitational field that acts as a driving force to keep the system away from equilibrium. To maintain steady state, a profile-unbiased thermostat must be implemented to dissipate the heat that is added by the driving force. *Compute temp/profile* can be used to implement a profile-unbiased thermostat.

A common use of this fix is to compute a pressure drop across a pipe, pore, or membrane. The pressure profile can be computed in LAMMPS with *compute stress/atom* and *fix ave/chunk*, or with the hardy method in *fix atc*. Note that the simple *compute stress/atom* method is only accurate away from inhomogeneities in the fluid, such as fixed wall atoms. Further, the computed pressure profile must be corrected for the acceleration applied by GD before computing a pressure drop or comparing it to other methods, such as the pump method (*Zhu*). The pressure correction is discussed and described in (*Strong*).

For a complete example including the considerations discussed above, see the examples/PACKAGES/flow\_gauss directory.

---

**Note:** Only the flux of the atoms in group-ID will be conserved. If the velocities of the group-ID atoms are coupled to the velocities of other atoms in the simulation, the flux will not be conserved. For example, in a simulation with fluid atoms and harmonically constrained wall atoms, if a single thermostat is applied to group *all*, the fluid atom velocities will be coupled to the wall atom velocities, and the flux will not be conserved. This issue can be avoided by thermostatting the fluid and wall groups separately.

---

Adding an acceleration to atoms does work on the system. This added energy can be optionally subtracted from the potential energy for the thermodynamic output (see below) to check that the timestep is small enough to conserve energy. Since the applied acceleration is fluctuating in time, the work cannot be computed from a potential. As a result, computing the work is slightly more computationally expensive than usual, so it is not performed by default. To invoke the work calculation, use the *energy* keyword. The *fix\_modify energy* option also invokes the work calculation,

and overrides an *energy no* setting here. If neither *energy yes* or *fix\_modify energy yes* are set, the global scalar computed by the fix will return zero.

---

**Note:** In order to check energy conservation, any other fixes that do work on the system must have *fix\_modify energy yes* set as well. This includes thermostat fixes and any constraints that hold the positions of wall atoms fixed, such as *fix spring/self*.

---

If this fix is used in a simulation with the *rRESPA* integrator, the applied acceleration must be computed and applied at the same rRESPA level as the interactions between the flowing fluid and the obstacle. The rRESPA level at which the acceleration is applied can be changed using the *fix\_modify respa* option discussed below. If the flowing fluid and the obstacle interact through multiple interactions that are computed at different rRESPA levels, then there must be a separate flow/gauss fix for each level. For example, if the flowing fluid and obstacle interact through pairwise and long-range Coulomb interactions, which are computed at rRESPA levels 3 and 4, respectively, then there must be two separate flow/gauss fixes, one that specifies *fix\_modify respa 3* and one with *fix\_modify respa 4*.

---

## 2.68.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy added by the fix to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify respa* option is supported by this fix. This allows the user to set at which level of the *rRESPA* integrator the fix computes and adds the external acceleration. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various *output commands*. The scalar is the negative of the work done on the system, see the discussion above. It is only calculated if the *energy* keyword is enabled or *fix\_modify energy yes* is set.

The vector is the total force that this fix applied to the group of atoms on the current timestep. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

## 2.68.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.68.6 Related commands

*fix addforce*, *compute temp/profile*, *velocity*

## 2.68.7 Default

The option default for the *energy* keyword is `energy = no`.

## 2.69 fix freeze command

Accelerator Variants: *freeze/kk*

### 2.69.1 Syntax

```
fix ID group-ID freeze
```

- ID, group-ID are documented in *fix* command
- freeze = style name of this fix command

### 2.69.2 Examples

```
fix 2 bottom freeze
```

### 2.69.3 Description

Zero out the force and torque on a granular particle. This is useful for preventing certain particles from moving in a simulation. The *granular pair styles* also detect if this fix has been defined and compute interactions between frozen and non-frozen particles appropriately, as if the frozen particle has infinite mass. A similar functionality for normal (point) particles can be obtained using *fix setforce*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 2.69.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global 3-vector of forces, which can be accessed by various *output commands*. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.69.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

There can only be a single freeze fix defined. This is because other the *granular pair styles* treat frozen particles differently and need to be able to reference a single group to which this fix is applied.

## 2.69.6 Related commands

*atom\_style sphere, fix setforce*

## 2.69.7 Default

```

### 2.70.3 Description

This fix performs grand canonical Monte Carlo (GCMC) exchanges of atoms or molecules with an imaginary ideal gas reservoir at the specified T and chemical potential ( $\mu$ ) as discussed in (*Frenkel*). It also attempts Monte Carlo (MC) moves (translations and molecule rotations) within the simulation cell or region. If used with the *fix nvt* command, simulations in the grand canonical ensemble ( $\mu$ VT, constant chemical potential, constant volume, and constant temperature) can be performed. Specific uses include computing isotherms in microporous materials, or computing vapor-liquid coexistence curves.

Every N timesteps the fix attempts both GCMC exchanges (insertions or deletions) and MC moves of gas atoms or molecules. On those timesteps, the average number of attempted GCMC exchanges is X, while the average number of attempted MC moves is M. For GCMC exchanges of either molecular or atomic gasses, these exchanges can be either deletions or insertions, with equal probability.

The possible choices for MC moves are translation of an atom, translation of a molecule, and rotation of a molecule. The relative amounts of each are determined by the optional *mcmoves* keyword (see below). The default behavior is as follows. If the *mol* keyword is used, only molecule translations and molecule rotations are performed with equal probability. Conversely, if the *mol* keyword is not used, only atom translations are performed. M should typically be chosen to be approximately equal to the expected number of gas atoms or molecules of the given type within the simulation cell or region, which will result in roughly one MC move per atom or molecule per MC cycle.

All inserted particles are always added to two groups: the default group “all” and the fix group specified in the fix command. In addition, particles are also added to any groups specified by the *group* and *group type* keywords. If inserted particles are individual atoms, they are assigned the atom type given by the *type* argument. If they are molecules, the *type* argument has no effect and must be set to zero. Instead, the type of each atom in the inserted molecule is specified in the file read by the *molecule* command.

---

**Note:** Care should be taken to apply fix gcmc only to a group that contains only those atoms and molecules that you wish to manipulate using Monte Carlo. Hence it is generally not a good idea to specify the default group “all” in the fix command, although it is allowed.

---

This fix cannot be used to perform GCMC insertions of gas atoms or molecules other than the exchanged type, but GCMC deletions, and MC translations, and rotations can be performed on any atom/molecule in the fix group. All atoms in the simulation cell can be moved using regular time integration translations, e.g. via *fix nvt*, resulting in a hybrid GCMC+MD simulation. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the inserted molecules are not well equilibrated.

This command may optionally use the *region* keyword to define an exchange and move volume. The specified region must have been previously defined with a *region* command. It must be defined with *side = in*. Insertion attempts occur only within the specified region. For non-rectangular regions, random trial points are generated within the rectangular bounding box until a point is found that lies inside the region. If no valid point is generated after 1000 trials, no insertion is performed, but it is counted as an attempted insertion. Move and deletion attempt candidates are selected from gas atoms or molecules within the region. If there are no candidates, no move or deletion is performed, but it is counted as an attempt move or deletion. If an attempted move places the atom or molecule center-of-mass outside the specified region, a new attempted move is generated. This process is repeated until the atom or molecule center-of-mass is inside the specified region.

If used with *fix nvt*, the temperature of the imaginary reservoir, T, should be set to be equivalent to the target temperature used in fix nvt. Otherwise, the imaginary reservoir will not be in thermal equilibrium with the simulation cell. Also, it is important that the temperature used by *fix nvt* is dynamically updated, which can be achieved as follows:

```
compute mdtemp mdatoms temp
compute_modify mdtemp dynamic/dof yes
fix mdnvt mdatoms nvt temp 300.0 300.0 10.0
fix_modify mdnvt temp mdtemp
```

Note that neighbor lists are re-built every timestep that this fix is invoked, so you should not set N to be too small. However, periodic rebuilds are necessary in order to avoid dangerous rebuilds and missed interactions. Specifically, avoid performing so many MC translations per timestep that atoms can move beyond the neighbor list skin distance. See the *neighbor* command for details.

When an atom or molecule is to be inserted, its coordinates are chosen at a random position within the current simulation cell or region, and new atom velocities are randomly chosen from the specified temperature distribution given by T. The effective temperature for new atom velocities can be increased or decreased using the optional keyword *tfac\_insert* (see below). Relative coordinates for atoms in a molecule are taken from the template molecule provided by the user. The center of mass of the molecule is placed at the insertion point. The orientation of the molecule is chosen at random by rotating about this point.

Individual atoms are inserted, unless the *mol* keyword is used. It specifies a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc., as well as any bonding and special neighbor information for the molecule can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

When not using the *mol* keyword, you should ensure you do not delete atoms that are bonded to other atoms, or LAMMPS will soon generate an error when it tries to find bonded neighbors. LAMMPS will warn you if any of the atoms eligible for deletion have a non-zero molecule ID, but does not check for this at the time of deletion.

If you wish to insert molecules using the *mol* keyword that will be treated as rigid bodies, use the *rigid* keyword, specifying as its value the ID of a separate *fix rigid/small* command which also appears in your input script.

---

**Note:** If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via *fix rigid/small/nvt* or *fix rigid/small/npt*, then you need to use the *fix\_modify dynamic/dof yes* command for the rigid fix. This is to inform that fix that the molecule count will vary dynamically.

---

If you wish to insert molecules via the *mol* keyword, that will have their bonds or angles constrained via SHAKE, use the *shake* keyword, specifying as its value the ID of a separate *fix shake* command which also appears in your input script.

Optionally, users may specify the relative amounts of different MC moves using the *mcmoves* keyword. The values *Patomtrans*, *Pmoltrans*, *Pmolrotate* specify the average proportion of atom translations, molecule translations, and molecule rotations, respectively. The values must be non-negative integers or real numbers, with at least one non-zero value. For example, (10,30,0) would result in 25% of the MC moves being atomic translations, 75% molecular translations, and no molecular rotations.

Optionally, users may specify the maximum rotation angle for molecular rotations using the *maxangle* keyword and specifying the angle in degrees. Rotations are performed by generating a random point on the unit sphere and a random rotation angle on the range [0,maxangle). The molecule is then rotated by that angle about an axis passing through the molecule center of mass. The axis is parallel to the unit vector defined by the point on the unit sphere. The same procedure is used for randomly rotating molecules when they are inserted, except that the maximum angle is 360 degrees.

Note that fix gcmc does not use configurational bias MC or any other kind of sampling of intramolecular degrees of freedom. Inserted molecules can have different orientations, but they will all have the same intramolecular configuration, which was specified in the molecule command input.

For atomic gasses, inserted atoms have the specified atom type, but deleted atoms are any atoms that have been inserted or that already belong to the fix group. For molecular gasses, exchanged molecules use the same atom types as in the template molecule supplied by the user. In both cases, exchanged atoms/molecules are assigned to two groups: the default group “all” and the fix group (which can also be “all”).

The chemical potential is a user-specified input parameter defined as:

$$\mu = \mu^{id} + \mu^{ex}$$

The second term `mu_ex` is the excess chemical potential due to energetic interactions and is formally zero for the fictitious gas reservoir but is non-zero for interacting systems. So, while the chemical potential of the reservoir and the simulation cell are equal, `mu_ex` is not, and as a result, the densities of the two are generally quite different. The first term `mu_id` is the ideal gas contribution to the chemical potential. `mu_id` can be related to the density or pressure of the fictitious gas reservoir by:

$$\begin{aligned}\mu^{id} &= kT \ln \rho \Lambda^3 \\ &= kT \ln \frac{\phi P \Lambda^3}{k_B T}\end{aligned}$$

where  $k_B$  is the Boltzmann constant,  $T$  is the user-specified temperature,  $\rho$  is the number density,  $P$  is the pressure, and  $\phi$  is the fugacity coefficient. The constant  $\Lambda$  is required for dimensional consistency. For all unit styles except *lj* it is defined as the thermal de Broglie wavelength

$$\Lambda = \sqrt{\frac{h^2}{2\pi m k_B T}}$$

where  $h$  is Planck's constant, and  $m$  is the mass of the exchanged atom or molecule. For unit style *lj*,  $\Lambda$  is simply set to unity. Note that prior to March 2017,  $\Lambda$  for unit style *lj* was calculated using the above formula with  $h$  set to the rather specific value of 0.18292026. Chemical potential under the old definition can be converted to an equivalent value under the new definition by subtracting  $3kT \ln(\Lambda_{old})$ .

As an alternative to specifying `mu` directly, the ideal gas reservoir can be defined by its pressure  $P$  using the *pressure* keyword, in which case the user-specified chemical potential is ignored. The user may also specify the fugacity coefficient  $\phi$  using the *fugacity\_coeff* keyword, which defaults to unity.

The *full\_energy* option means that the fix calculates the total potential energy of the entire simulated system, instead of just the energy of the part that is changed. The total system energy before and after the proposed GCMC exchange or MC move is then used in the Metropolis criterion to determine whether or not to accept the proposed change. By default, this option is off, in which case only partial energies are computed to determine the energy difference due to the proposed change.

The *full\_energy* option is needed for systems with complicated potential energy calculations, including the following:

- long-range electrostatics (*kspace*)
- many-body pair styles
- hybrid pair styles
- eam pair styles
- tail corrections
- need to include potential energy contributions from other fixes

In these cases, LAMMPS will automatically apply the *full\_energy* keyword and issue a warning message.

When the *mol* keyword is used, the *full\_energy* option also includes the intramolecular energy of inserted and deleted molecules, whereas this energy is not included when *full\_energy* is not used. If this is not desired, the *intra\_energy* keyword can be used to define an amount of energy that is subtracted from the final energy when a molecule is inserted, and subtracted from the initial energy when a molecule is deleted. For molecules that have a non-zero intramolecular energy, this will ensure roughly the same behavior whether or not the *full\_energy* option is used.

Inserted atoms and molecules are assigned random velocities based on the specified temperature  $T$ . Because the relative velocity of all atoms in the molecule is zero, this may result in inserted molecules that are systematically too cold. In addition, the intramolecular potential energy of the inserted molecule may cause the kinetic energy of the molecule to quickly increase or decrease after insertion. The *tfac\_insert* keyword allows the user to counteract these effects by changing the temperature used to assign velocities to inserted atoms and molecules by a constant factor. For a particular application, some experimentation may be required to find a value of *tfac\_insert* that results in inserted molecules that equilibrate quickly to the correct temperature.

Some fixes have an associated potential energy. Examples of such fixes include: *efield*, *gravity*, *addforce*, *langevin*, *restrain*, *temp/berendsen*, *temp/rescale*, and *wall fixes*. For that energy to be included in the total potential energy of the system (the quantity used when performing GCMC exchange and MC moves), you MUST enable the *fix\_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

Use the *charge* option to insert atoms with a user-specified point charge. Note that doing so will cause the system to become non-neutral. LAMMPS issues a warning when using long-range electrostatics (kspace) with non-neutral systems. See the *compute group/group* documentation for more details about simulating non-neutral systems with kspace on.

Use of this fix typically will cause the number of atoms to fluctuate, therefore, you will want to use the *compute\_modify dynamic/dof* command to ensure that the current number of atoms is used as a normalizing factor each time temperature is computed. A simple example of this is:

```
compute_modify thermo_temp dynamic/dof yes
```

A more complicated example is listed earlier on this page in the context of NVT dynamics.

---

**Note:** If the density of the cell is initially very small or zero, and increases to a much larger density after a period of equilibration, then certain quantities that are only calculated once at the start (kspace parameters) may no longer be accurate. The solution is to start a new simulation after the equilibrium density has been reached.

---

With some pair\_styles, such as *Buckingham*, *Born-Mayer-Huggins* and *ReaxFF*, two atoms placed close to each other may have an arbitrary large, negative potential energy due to the functional form of the potential. While these unphysical configurations are inaccessible to typical dynamical trajectories, they can be generated by Monte Carlo moves. The *overlap\_cutoff* keyword suppresses these moves by effectively assigning an infinite positive energy to all new configurations that place any pair of atoms closer than the specified overlap cutoff distance.

The *max* and *min* keywords allow for the restriction of the number of atoms in the simulation. They automatically reject all insertion or deletion moves that would take the system beyond the set boundaries. Should the system already be beyond the boundary, only moves that bring the system closer to the bounds may be accepted.

The *group* keyword adds all inserted atoms to the *group* of the group-ID value. The *group\_type* keyword adds all inserted atoms of the specified type to the *group* of the group-ID value.

#### 2.70.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the fix to *binary restart files*. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of MC step attempts and successes etc. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset\_timestep*. The fix will try to detect it and stop with an error.

---

None of the *fix\_modify* options are relevant to this fix.

This fix computes a global vector of length 8, which can be accessed by various *output commands*. The vector values are the following global cumulative quantities:

1. translation attempts
2. translation successes
3. insertion attempts

4. insertion successes
5. deletion attempts
6. deletion successes
7. rotation attempts
8. rotation successes

The vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.70.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

This fix style requires an *atom style* with per atom type masses.

Do not set “neigh\_modify once yes” or else this fix will never be called. Reneighboring is **required**.

Only usable for 3D simulations.

This fix can be run in parallel, but aspects of the GCMC part will not scale well in parallel. Currently, molecule translations and rotations are not supported with more than one MPI process. It is still possible to do parallel molecule exchange without translation and rotation moves by setting MC moves to zero and/or by using the *mcmoves* keyword with *Pmoltrans* = *Pmolrotate* = 0 .

When using fix gcmc in combination with fix shake or fix rigid, only GCMC exchange moves are supported, so the argument *M* must be zero.

When using fix gcmc in combination with fix rigid, deletion of the last remaining molecule is not allowed for technical reasons, and so the molecule count will never drop below 1, regardless of the specified chemical potential.

Note that very lengthy simulations involving insertions/deletions of billions of gas molecules may run out of atom or molecule IDs and trigger an error, so it is better to run multiple shorter-duration simulations. Likewise, very large molecules have not been tested and may turn out to be problematic.

Use of multiple fix gcmc commands in the same input script can be problematic if using a template molecule. The issue is that the user-referenced template molecule in the second fix gcmc command may no longer exist since it might have been deleted by the first fix gcmc command. An existing template molecule will need to be referenced by the user for each subsequent fix gcmc command.

### 2.70.6 Related commands

*fix atom/swap*, *fix nvt*, *neighbor*, *fix deposit*, *fix evaporate*, *delete\_atoms*

## 2.70.7 Default

The option defaults are `mol = no`, `maxangle = 10`, `overlap_cutoff = 0.0`, `fugacity_coeff = 1.0`, `intra_energy = 0.0`, `tfac_insert = 1.0`. (`Patomtrans`, `Pmoltrans`, `Pmolrotate`) = (1, 0, 0) for `mol = no` and (0, 1, 1) for `mol = yes`. `full_energy = no`, except for the situations where `full_energy` is required, as listed above.

(Frenkel) Frenkel and Smit, Understanding Molecular Simulation, Academic Press, London, 2002.

## 2.71 fix gld command

### 2.71.1 Syntax

```
fix ID group-ID gld Tstart Tstop N_k seed series c_1 tau_1 ... c_N_k tau_N_k keyword_
→values ...
```

- ID, group-ID are documented in *fix* command
- gld = style name of this fix command
- Tstart,Tstop = desired temperature at start/end of run (temperature units)
- N\_k = number of terms in the Prony series representation of the memory kernel
- seed = random number seed to use for white noise (positive integer)
- series = *pprony* is presently the only available option
- c\_k = the weight of the kth term in the Prony series (mass per time units)
- tau\_k = the time constant of the kth term in the Prony series (time units)
- zero or more keyword/value pairs may be appended

keyword = *frozen* or *zero*

*frozen* value = *no* or *yes*

*no* = initialize extended variables using values drawn from equilibrium\_

→distribution at Tstart

*yes* = initialize extended variables to zero (i.e., from equilibrium\_

→distribution at zero temperature)

*zero* value = *no* or *yes*

*no* = do not set total random force to zero

*yes* = set total random force to zero

### 2.71.2 Examples

```
fix 1 all gld 1.0 1.0 2 82885 pprony 0.5 1.0 1.0 2.0 frozen yes zero yes
fix 3 rouse gld 7.355 7.355 4 48823 pprony 107.1 0.02415 186.0 0.04294 428.6 0.09661_
→1714 0.38643
```

### 2.71.3 Description

Applies Generalized Langevin Dynamics to a group of atoms, as described in (Baczewski). This is intended to model the effect of an implicit solvent with a temporally non-local dissipative force and a colored Gaussian random force, consistent with the Fluctuation-Dissipation Theorem. The functional form of the memory kernel associated with the temporally non-local force is constrained to be a Prony series.

---

**Note:** While this fix bears many similarities to *fix langevin*, it has one significant difference. Namely, *fix gld* performs time integration, whereas *fix langevin* does NOT. To this end, the specification of another fix to perform time integration, such as *fix nve*, is NOT necessary.

---

With this fix active, the force on the  $j$ th atom is given as

$$\mathbf{F}_j(t) = \mathbf{F}_j^C(t) - \int_0^t \Gamma_j(t-s) \mathbf{v}_j(s) ds + \mathbf{F}_j^R(t)$$

$$\Gamma_j(t-s) = \sum_{k=1}^{N_k} \frac{c_k}{\tau_k} e^{-(t-s)/\tau_k}$$

$$\langle \mathbf{F}_j^R(t), \mathbf{F}_j^R(s) \rangle = k_B T \Gamma_j(t-s)$$

Here, the first term is representative of all conservative (pairwise, bonded, etc) forces external to this fix, the second is the temporally non-local dissipative force given as a Prony series, and the third is the colored Gaussian random force.

The Prony series form of the memory kernel is chosen to enable an extended variable formalism, with a number of exemplary mathematical features discussed in (Baczewski). In particular,  $3N_k$  extended variables are added to each atom, which effect the action of the memory kernel without having to explicitly evaluate the integral over time in the second term of the force. This also has the benefit of requiring the generation of uncorrelated random forces, rather than correlated random forces as specified in the third term of the force.

Presently, the Prony series coefficients are limited to being greater than or equal to zero, and the time constants are limited to being greater than zero. To this end, the value of series MUST be set to *pprony*, for now. Future updates will allow for negative coefficients and other representations of the memory kernel. It is with these updates in mind that the series option was included.

The units of the Prony series coefficients are chosen to be mass per time to ensure that the numerical integration scheme stably approaches the Newtonian and Langevin limits. Details of these limits, and the associated numerical concerns are discussed in (Baczewski).

The desired temperature at each timestep is ramped from *Tstart* to *Tstop* over the course of the next run.

The random # *seed* must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

---

The keyword/value option pairs are used in the following ways.

The keyword *frozen* can be used to specify how the extended variables associated with the GLD memory kernel are initialized. Specifying no (the default), the initial values are drawn at random from an equilibrium distribution at *Tstart*, consistent with the Fluctuation-Dissipation Theorem. Specifying yes, initializes the extended variables to zero.

The keyword *zero* can be used to eliminate drift due to the thermostat. Because the random forces on different atoms are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the center-of-mass of the system undergoes a slow random walk. If the keyword *zero* is set to yes, the total random force is set exactly to zero by subtracting off an equal part of it from each atom in the group. As a result, the center-of-mass of a system with zero initial momentum will not drift over time.

---

## 2.71.4 Restart, fix\_modify, output, run start/stop, minimize info

The instantaneous values of the extended variables are written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.71.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.71.6 Related commands

*fix langevin*, *fix viscous*, *pair\_style dpd/tstat*

## 2.71.7 Default

The option defaults are frozen = no, zero = no.

---

(Baczewski) A.D. Baczewski and S.D. Bond, J. Chem. Phys. 139, 044107 (2013).

## 2.72 fix gle command

### 2.72.1 Syntax

```
fix ID id-group gle Ns Tstart Tstop seed Amatrix [noneq Cmatrix] [every stride]
```

- ID, group-ID are documented in *fix* command
- gle = style name of this fix command
- Ns = number of additional fictitious momenta
- Tstart, Tstop = temperature ramp during the run
- Amatrix = file to read the drift matrix A from
- seed = random number seed to use for generating noise (positive integer)
- zero or more keyword/value pairs may be appended

keyword = *noneq* or *every*  
*noneq* Cmatrix = file to read the non-equilibrium covariance matrix from  
*every* stride = apply the GLE once every time steps. Reduces the accuracy  
of the integration of the GLE, but has *\*no effect\** on the accuracy of *equilibrium*  
sampling. It might change sampling properties when used together with *noneq*.

## 2.72.2 Examples

```
fix 3 boundary gle 6 300 300 31415 smart.A
fix 1 all gle 6 300 300 31415 qt-300k.A noneq qt-300k.C
```

## 2.72.3 Description

Apply a Generalized Langevin Equation (GLE) thermostat as described in ([Ceriotti](#)). The formalism allows one to obtain a number of different effects ranging from efficient sampling of all vibrational modes in the system to inexpensive (approximate) modelling of nuclear quantum effects. Contrary to *fix langevin*, this fix performs both thermostating and evolution of the Hamiltonian equations of motion, so it should not be used together with *fix nve* – at least not on the same atom groups.

Each degree of freedom in the thermostatted group is supplemented with  $N_s$  additional degrees of freedom  $s$ , and the equations of motion become

$$\begin{aligned} dq/dt &= p/m \\ d(p,s)/dt &= (F, \emptyset) - A(p,s) + B dW/dt \end{aligned}$$

where  $F$  is the physical force,  $A$  is the drift matrix (that generalizes the friction in Langevin dynamics),  $B$  is the diffusion term and  $dW/dt$  un-correlated Gaussian random forces. The  $A$  matrix couples the physical  $(q,p)$  dynamics with that of the additional degrees of freedom, and makes it possible to obtain effectively a history-dependent noise and friction kernel.

The drift matrix should be given as an external file *Afile*, as a  $(N_s+1 \times N_s+1)$  matrix in inverse time units. Matrices that are optimal for a given application and the system of choice can be obtained from ([GLE4MD](#)).

Equilibrium sampling a temperature  $T$  is obtained by specifying the target value as the *Tstart* and *Tstop* arguments, so that the diffusion matrix that gives canonical sampling for a given  $A$  is computed automatically. However, the GLE framework also allow for non-equilibrium sampling, that can be used for instance to model inexpensively zero-point energy effects ([Ceriotti2](#)). This is achieved specifying the *noneq* keyword followed by the name of the file that contains the static covariance matrix for the non-equilibrium dynamics. Please note, that the covariance matrix is expected to be given in **temperature units**.

Since integrating GLE dynamics can be costly when used together with simple potentials, one can use the *every* optional keyword to apply the Langevin terms only once every several MD steps, in a multiple time-step fashion. This should be used with care when doing non-equilibrium sampling, but should have no effect on equilibrium averages when using canonical sampling.

The random number *seed* must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

Note also that the Generalized Langevin Dynamics scheme that is implemented by the *fix glt* scheme is closely related to the present one. In fact, it should be always possible to cast the Prony series form of the memory kernel used by GLD into an appropriate input matrix for *fix gle*. While the GLE scheme is more general, the form used by *fix glt* can be more directly related to the representation of an implicit solvent environment.

### 2.72.4 Restart, fix\_modify, output, run start/stop, minimize info

The instantaneous values of the extended variables are written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Note however that you should use a different seed each time you restart, otherwise the same sequence of random numbers will be used each time, which might lead to stochastic synchronization and subtle artifacts in the sampling.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

### 2.72.5 Restrictions

The GLE thermostat in its current implementation should not be used with rigid bodies, SHAKE or RATTLE. It is expected that all the thermostatted degrees of freedom are fully flexible, and the sampled ensemble will not be correct otherwise.

In order to perform constant-pressure simulations please use *fix press/berendsen*, rather than *fix npt*, to avoid duplicate integration of the equations of motion.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 2.72.6 Related commands

## 2.73 fix gravity command

Accelerator Variants: *gravity/omp*, *gravity/kk*

### 2.73.1 Syntax

```
fix ID group gravity magnitude style args
```

- ID, group are documented in *fix* command
  - gravity = style name of this fix command
  - magnitude = size of acceleration (force/mass units)
  - magnitude can be a variable (see below)
  - style = *chute* or *spherical* or *gradient* or *vector*
- chute* args = angle  
 angle = angle in +x away from -z or -y axis in 3d/2d (in degrees)  
 angle can be a variable (see below)
- spherical* args = phi theta  
 phi = azimuthal angle from +x axis (in degrees)  
 theta = angle from +z or +y axis in 3d/2d (in degrees)  
 phi or theta can be a variable (see below)
- vector* args = x y z  
 x y z = vector direction to apply the acceleration  
 x or y or z can be a variable (see below)

### 2.73.2 Examples

```
fix 1 all gravity 1.0 chute 24.0
fix 1 all gravity v_increase chute 24.0
fix 1 all gravity 1.0 spherical 0.0 -180.0
fix 1 all gravity 10.0 spherical v_phi v_theta
fix 1 all gravity 100.0 vector 1 1 0
```

### 2.73.3 Description

Impose an additional acceleration on each particle in the group. This fix is typically used with granular systems to include a “gravity” term acting on the macroscopic particles. More generally, it can represent any kind of driving field, e.g. a pressure gradient inducing a Poiseuille flow in a fluid. Note that this fix operates differently than the *fix addforce* command. The *addforce* fix adds the same force to each atom, independent of its mass. This command imparts the same acceleration to each atom (force/mass).

The *magnitude* of the acceleration is specified in force/mass units. For granular systems (LJ units) this is typically 1.0. See the *units* command for details.

Style *chute* is typically used for simulations of chute flow where the specified *angle* is the chute angle, with flow occurring in the +x direction. For 3d systems, the tilt is away from the z axis; for 2d systems, the tilt is away from the y axis.

Style *spherical* allows an arbitrary 3d direction to be specified for the acceleration vector. *Phi* and *theta* are defined in the usual spherical coordinates. Thus for acceleration acting in the -z direction, *theta* would be 180.0 (or -180.0). *Theta* = 90.0 and *phi* = -90.0 would mean acceleration acts in the -y direction. For 2d systems, *phi* is ignored and *theta* is an angle in the xy plane where *theta* = 0.0 is the y-axis.

Style *vector* imposes an acceleration in the vector direction given by (x,y,z). Only the direction of the vector is important; it’s length is ignored. For 2d systems, the z component is ignored.

Any of the quantities *magnitude*, *angle*, *phi*, *theta*, *x*, *y*, *z* which define the gravitational magnitude and direction, can be specified as an equal-style *variable*. If the value is a variable, it should be specified as *v\_name*, where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the quantity. You should ensure that the variable calculates a result in the appropriate units, e.g. force/mass or degrees.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent gravitational field.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 2.73.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the gravitational potential energy of the system to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various *output commands*. This scalar is the gravitational potential energy of the particles in the defined field, namely  $\text{mass} * (\mathbf{g} \cdot \mathbf{x})$  for each particles, where *x* and *mass* are the particles position and mass, and *g* is the gravitational field. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

#### 2.73.5 Restrictions

none

#### 2.73.6 Related commands

*atom\_style sphere*, *fix addforce*

## 2.73.7 Default

none

## 2.74 fix grem command

### 2.74.1 Syntax

```
fix ID group-ID grem lambda eta H0 thermostat-ID
```

- ID, group-ID are documented in *fix* command
- grem = style name of this fix command
- lambda = intercept parameter of linear effective temperature function
- eta = slope parameter of linear effective temperature function
- H0 = shift parameter of linear effective temperature function
- thermostat-ID = ID of Nose-Hoover thermostat or barostat used in simulation

### 2.74.2 Examples

```
fix          fxgREM all grem 400 -0.01 -300000 fxnpt
thermo_modify press fxgREM_press

fix          fxgREM all grem 502 -0.15 -800000 fxnvt
```

### 2.74.3 Description

This fix implements the molecular dynamics version of the generalized replica exchange method (gREM) originally developed by (Kim), which uses non-Boltzmann ensembles to sample over first order phase transitions. The is done by defining replicas with an enthalpy dependent effective temperature

$$T_{eff} = \lambda + \eta(H - H_0)$$

with  $\eta$  negative and steep enough to only intersect the characteristic microcanonical temperature ( $T_s$ ) of the system once, ensuring a unimodal enthalpy distribution in that replica.  $\lambda$  is the intercept and effects the generalized ensemble similar to how temperature effects a Boltzmann ensemble.  $H_0$  is a reference enthalpy, and is typically set as the lowest desired sampled enthalpy. Further explanation can be found in our recent papers (Malolepsza).

This fix requires a Nose-Hoover thermostat fix reference passed to the grem as *thermostat-ID*. Two distinct temperatures exist in this generalized ensemble, the effective temperature defined above, and a kinetic temperature that controls the velocity distribution of particles as usual. Either constant volume or constant pressure algorithms can be used.

The fix enforces a generalized ensemble in a single replica only. Typically, this ideology is combined with replica exchange with replicas differing by  $\lambda$  only for simplicity, but this is not required. A multi-replica simulation can be run within the LAMMPS environment using the *temper/grem* command. This utilizes LAMMPS partition mode and requires the number of available processors be on the order of the number of desired replicas. A 100-replica simulation would require at least 100 processors (1 per world at minimum). If many replicas are needed on a small

number of processors, multi-replica runs can be run outside of LAMMPS. An example of this can be found in examples/PACKAGES/grem and has no limit on the number of replicas per processor. However, this is very inefficient and error prone and should be avoided if possible.

In general, defining the generalized ensembles is unique for every system. When starting a many-replica simulation without any knowledge of the underlying microcanonical temperature, there are several tricks we have utilized to optimize the process. Choosing a less-steep  $\eta$  yields broader distributions, requiring fewer replicas to map the microcanonical temperature. While this likely struggles from the same sampling problems gREM was built to avoid, it provides quick insight to Ts. Initially using an evenly-spaced  $\lambda$  distribution identifies regions where small changes in enthalpy lead to large temperature changes. Replicas are easily added where needed.

---

#### 2.74.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *thermo\_modify press* option is supported by this fix to add the rescaled kinetic pressure as part of *thermodynamic output*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the effective temperature  $T_{eff}$ . The scalar value calculated by this fix is “intensive”.

#### 2.74.5 Restrictions

This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 2.75 fix halt command

#### 2.75.1 Syntax

`fix ID group-ID halt N attribute operator avalue keyword value ...`

- ID, group-ID are documented in *fix* command
- halt = style name of this fix command
- N = check halt condition every N steps

- attribute = *bondmax* or *tlimit* or *v\_name*  
*bondmax* = length of longest bond in the system (in length units)  
*tlimit* = elapsed CPU time (in seconds)  
*diskfree* = free disk space (in MBytes)  
*v\_name* = name of *equal-style variable*
- operator = "<" or "<=" or ">" or ">=" or "==" or "!=" or "|^"
- avalue = numeric value to compare attribute to
- zero or more keyword/value pairs may be appended
- keyword = *error* or *message* or *path*  
*error* value = *hard* or *soft* or *continue*  
*message* value = *yes* or *no*  
*path* value = path to check for free space (may be in quotes)

## 2.75.2 Examples

```
fix 10 all halt 1 bondmax > 1.5
fix 10 all halt 10 v_myCheck != 0 error soft
fix 10 all halt 100 diskfree < 1000000.0 path "dump storage/."
```

## 2.75.3 Description

Check a condition every *N* steps during a simulation run. *N* must be  $\geq 1$ . If the condition is met, exit the run. In this context a “run” can be dynamics or minimization iterations, as specified by the *run* or *minimize* command.

The specified group-ID is ignored by this fix.

The specified *attribute* can be one of the options listed above, namely *bondmax*, *tlimit*, *diskfree*, or an *equal-style variable* referenced as *v\_name*, where “name” is the name of a variable that has been defined previously in the input script.

The *bondmax* attribute will loop over all bonds in the system, compute their current lengths, and set *attribute* to the longest bond distance.

The *tlimit* attribute queries the elapsed CPU time (in seconds) since the current run began, and sets *attribute* to that value. This is an alternative way to limit the length of a simulation run, similar to the *timer* timeout command. There are two differences in using this method versus the timer command option. The first is that the clock starts at the beginning of the current run (not when the timer or fix command is specified), so that any setup time for the run is not included in the elapsed time. The second is that the timer invocation and syncing across all processors (via MPI\_Allreduce) is not performed once every *N* steps by this command. Instead it is performed (typically) only a small number of times and the elapsed times are used to predict when the end-of-the-run will be. Both of these attributes can be useful when performing benchmark calculations for a desired length of time with minimal overhead. For example, if a run is performing 1000s of timesteps/sec, the overhead for syncing the timer frequently across a large number of processors may be non-negligible.

The *diskfree* attribute will check for available disk space (in MBytes) on supported operating systems. By default it will check the file system of the current working directory. This can be changed with the optional *path* keyword, which will take the path to a file or folder on the file system to be checked as argument. This path must be given with single or double quotes, if it contains blanks or other special characters (like \$).

Equal-style variables evaluate to a numeric value. See the *variable* command for a description. They calculate formulas which can involve mathematical operations, atom properties, group properties, thermodynamic properties, global

values calculated by a *compute* or *fix*, or references to other *variables*. Thus they are a very general means of computing some attribute of the current system. For example, the following “bondmax” variable will calculate the same quantity as the `hstyle = bondmax` option.

```
compute      bdist all bond/local dist
compute      bmax all reduce max c_bdist
variable     bondmax equal c_bmax
```

Thus these two versions of a `fix halt` command will do the same thing:

```
fix 10 all halt 1 bondmax > 1.5
fix 10 all halt 1 v_bondmax > 1.5
```

The version with “bondmax” will just run somewhat faster, due to less overhead in computing bond lengths and not storing them in a separate compute.

A variable can be used to implement a large variety of conditions, including to stop when a specific file exists. Example:

```
variable exit equal is_file(EXIT)
fix 10 all halt 100 v_exit != 0 error soft
```

Will stop the current run command when a file `EXIT` is created in the current working directory. The condition can be cleared by removing the file through the *shell* command.

The choice of operators listed above are the usual comparison operators. The XOR operation (exclusive or) is also included as “|^”. In this context, XOR means that if either the attribute or avalue is 0.0 and the other is non-zero, then the result is “true”. Otherwise it is “false”.

The specified *avalue* must be a numeric value.

The optional *error* keyword determines how the current run is halted. If its value is *hard*, then LAMMPS will stop with an error message.

If its value is *soft*, LAMMPS will exit the current run, but continue to execute subsequent commands in the input script. However, additional *run* or *minimize* commands will be skipped. For example, this allows a script to output the current state of the system, e.g. via a *write\_dump* or *write\_restart* command.

If its value is *continue*, the behavior is the same as for *soft*, except subsequent *run* or *minimize* commands are executed. This allows your script to remedy the condition that triggered the halt, if necessary. Note that you may wish use the *unfix* command on the `fix halt` ID, so that the same condition is not immediately triggered in a subsequent run.

The optional *message* keyword determines whether a message is printed to the screen and logfile when the halt condition is triggered. If *message* is set to yes, a one line message with the values that triggered the halt is printed. If *message* is set to no, no message is printed; the run simply exits. The latter may be desirable for post-processing tools that extract thermodynamic information from log files.

## 2.75.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

## 2.75.5 Restrictions

The *diskfree* attribute is currently only supported on Linux, macOS, and \*BSD.

## 2.75.6 Related commands

*variable*

## 2.75.7 Default

The option defaults are error = soft, message = yes, and path = “.”.

# 2.76 fix heat command

## 2.76.1 Syntax

```
fix ID group-ID heat N eflux
```

- ID, group-ID are documented in *fix* command
- heat = style name of this fix command
- N = add/subtract heat every this many timesteps
- eflux = rate of heat addition or subtraction (energy/time units)
- eflux can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = *region*

*region* value = region-ID

region-ID = ID of region atoms must be in to have added force

## 2.76.2 Examples

```
fix 3 qin heat 1 1.0  
fix 3 qin heat 10 v_flux  
fix 4 qout heat 1 -1.0 region top
```

## 2.76.3 Description

Add non-translational kinetic energy (heat) to a group of atoms in a manner that conserves their aggregate momentum. Two of these fixes can be used to establish a temperature gradient across a simulation domain by adding heat (energy) to one group of atoms (hot reservoir) and subtracting heat from another (cold reservoir). E.g. a simulation sampling from the McDLT ensemble.

If the *region* keyword is used, the atom must be in both the group and the specified geometric *region* in order to have energy added or subtracted to it. If not specified, then the atoms in the group are affected wherever they may move to.

Heat addition/subtraction is performed every N timesteps.

The *eflux* parameter can be specified as a numeric constant or as an equal- or atom-style *variable*. If the value is a variable, it should be specified as *v\_name*, where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its current value(s) used to determine the flux.

If *eflux* is a numeric constant or equal-style variable which evaluates to a scalar value, then *eflux* determines the change in aggregate energy of the entire group of atoms per unit time, e.g. in eV/ps for *metal units*. In this case it is an “extensive” quantity, meaning its magnitude should be scaled with the number of atoms in the group. Note that since *eflux* also has per-time units (i.e. it is a flux), this means that a larger value of *N* will add/subtract a larger amount of energy each time the fix is invoked.

---

**Note:** The heat-exchange (HEX) algorithm implemented by this fix is known to exhibit a pronounced energy drift. An improved algorithm (eHEX) is available as a *fix ehex* command and might be preferable if energy conservation is important.

---

If *eflux* is specified as an atom-style variable (see below), then the variable computes one value per atom. In this case, each value is the energy flux for a single atom, again in units of energy per unit time. In this case, each value is an “intensive” quantity, which need not be scaled with the number of atoms in the group.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent flux.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent flux with optional time-dependence as well.

---

**Note:** If heat is subtracted from the system too aggressively so that the group’s kinetic energy would go to zero, or any individual atom’s kinetic energy would go to zero for the case where *eflux* is an atom-style variable, then LAMMPS will halt with an error message.

---

Fix heat is different from a thermostat such as *fix nvt* or *fix temp/rescale* in that energy is added/subtracted continually. Thus if there is not another mechanism in place to counterbalance this effect, the entire system will heat or cool continuously. You can use multiple heat fixes so that the net energy change is 0.0 or use *fix viscous* to drain energy from the system.

This fix does not change the coordinates of its atoms; it only scales their velocities. Thus you must still use an integration fix (e.g. *fix nve*) on the affected atoms. This fix should not normally be used on atoms that have their temperature controlled by another fix - e.g. *fix nvt* or *fix langevin* fix.

## 2.76.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar which can be accessed by various *output commands*. This scalar is the most recent value by which velocities were scaled. The scalar value calculated by this fix is “intensive”. If *eflux* is specified as an atom-style variable, this fix computes the average value by which the velocities were scaled for all of the atoms that had their velocities scaled.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.76.5 Restrictions

# 2.77 fix heat/flow command

## 2.77.1 Syntax

```
fix ID group-ID heat/flow style values ...
```

- ID, group-ID are documented in *fix* command
- heat/flow = style name of this fix command
- one style with corresponding value(s) needs to be listed

style = *constant* or *type*

constant = *cp*

cp = value of specific heat (energy/(mass \* temperature) units)

type = *cp1 ... cpN*

cpN = value of specific heat for type N (energy/(mass \* temperature) units)

•

## 2.77.2 Examples

```
fix 1 all heat/flow constant 1.0  
fix 1 all heat/flow type 1.0 0.5
```

## 2.77.3 Description

Perform plain time integration to update temperature for atoms in the group each timestep. The specific heat of atoms can be defined using either the *constant* or *type* keywords. For style *constant*, the specific heat is a constant value *cp* for all atoms. For style *type*, *N* different values of the specific heat are defined, one for each of the *N* types of atoms.

---

## 2.77.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.77.5 Restrictions

This pair style is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store temperature and heat flow as defined by the *fix property/atom* command.

# 2.78 fix hyper/global command

## 2.78.1 Syntax

```
fix ID group-ID hyper/global cutbond qfactor Vmax Tequil
```

- ID, group-ID are documented in *fix* command
- hyper/global = style name of this fix command
- cutbond = max distance at which a pair of atoms is considered bonded (distance units)
- qfactor = max strain at which bias potential goes to 0.0 (unitless)
- Vmax = height of bias potential (energy units)
- Tequil = equilibration temperature (temperature units)

## 2.78.2 Examples

```
fix 1 all hyper/global 1.0 0.3 0.8 300.0
```

### 2.78.3 Description

This fix is meant to be used with the *hyper* command to perform a bond-boost global hyperdynamics (GHD) simulation. The role of this fix is to select a single pair of atoms in the system at each timestep to add a global bias potential to, which will alter the dynamics of the system in a manner that effectively accelerates time. This is in contrast to the *fix hyper/local* command, which can be used to perform a local hyperdynamics (LHD) simulation, by adding a local bias potential to multiple pairs of atoms at each timestep. GHD can time accelerate a small simulation with up to a few 100 atoms. For larger systems, LHD is needed to achieve good time acceleration.

For a system that undergoes rare transition events, where one or more atoms move over an energy barrier to a new potential energy basin, the effect of the bias potential is to induce more rapid transitions. This can lead to a dramatic speed-up in the rate at which events occurs, without altering their relative frequencies, thus leading to an overall increase in the elapsed real time of the simulation as compared to running for the same number of timesteps with normal MD. See the *hyper* page for a more general discussion of hyperdynamics and citations that explain both GHD and LHD.

The equations and logic used by this fix and described here to perform GHD follow the description given in (Voter2013). The bond-boost form of a bias potential for HD is due to Miron and Fichthorn as described in (Miron). In LAMMPS we use a simplified version of bond-boost GHD where a single bond in the system is biased at any one timestep.

Bonds are defined between each pair of atoms  $ij$ , whose  $R_{ij}^0$  distance is less than *cutbond*, when the system is in a quenched state (minimum) energy. Note that these are not “bonds” in a covalent sense. A bond is simply any pair of atoms that meet the distance criterion. *Cutbond* is an argument to this fix; it is discussed below. A bond is only formed if one or both of the  $ij$  atoms are in the specified group.

The current strain of bond  $ij$  (when running dynamics) is defined as

$$E_{ij} = \frac{R_{ij} - R_{ij}^0}{R_{ij}^0}$$

where  $R_{ij}$  is the current distance between atoms  $i$  and  $j$ , and  $R_{ij}^0$  is the equilibrium distance in the quenched state.

The bias energy  $V_{ij}$  of any bond between atoms  $i$  and  $j$  is defined as

$$V_{ij} = V^{max} \cdot \left( 1 - \left( \frac{E_{ij}}{q} \right)^2 \right) \text{ for } |E_{ij}| < qfactor \text{ or } 0 \text{ otherwise}$$

where the prefactor  $V^{max}$  and the cutoff *qfactor* are arguments to this fix; they are discussed below. This functional form is an inverse parabola centered at 0.0 with height  $V^{max}$  and which goes to 0.0 at  $\pm qfactor$ .

Let  $E^{max}$  be the maximum of  $|E_{ij}|$  for all  $ij$  bonds in the system on a given timestep. On that step,  $V_{ij}$  is added as a bias potential to only the single bond with strain  $E^{max}$ , call it  $V_{ij}^{max}$ . Note that  $V_{ij}^{max}$  will be 0.0 if  $E^{max} \geq qfactor$  on that timestep. Also note that  $V_{ij}^{max}$  is added to the normal interatomic potential that is computed between all atoms in the system at every step.

The derivative of  $V_{ij}^{max}$  with respect to the position of each atom in the  $E^{max}$  bond gives a bias force  $F_{ij}^{max}$  acting on the bond as

$$F_{ij}^{max} = -\frac{dV_{ij}^{max}}{dE_{ij}} = \frac{2V_{ij}^{max}E_{ij}}{qfactor^2} \text{ for } |E_{ij}| < qfactor \text{ or } 0 \text{ otherwise}$$

which can be decomposed into an equal and opposite force acting on only the two  $ij$  atoms in the  $E^{max}$  bond.

The time boost factor for the system is given each timestep  $I$  by

$$B_i = e^{\beta V_{ij}^{max}}$$

where  $\beta = \frac{1}{kT_{equil}}$ , and  $T_{equil}$  is the temperature of the system and an argument to this fix. Note that  $B_i \geq 1$  at every step.

---

**Note:** To run a GHD simulation, the input script must also use the [fix langevin](#) command to thermostat the atoms at the same  $T_{\text{equil}}$  as specified by this fix, so that the system is running constant-temperature (NVT) dynamics. LAMMPS does not check that this is done.

---

The elapsed time  $t_{\text{hyper}}$  for a GHD simulation running for  $N$  timesteps is simply

$$t_{\text{hyper}} = \sum_{i=1,N} B - i \cdot dt$$

where  $dt$  is the timestep size defined by the [timestep](#) command. The effective time acceleration due to GHD is thus  $t_{\text{hyper}} / N \cdot dt$ , where  $N \cdot dt$  is elapsed time for a normal MD run of  $N$  timesteps.

Note that in GHD, the boost factor varies from timestep to timestep. Likewise, which bond has  $E^{\text{max}}$  strain and thus which pair of atoms the bias potential is added to, will also vary from timestep to timestep. This is in contrast to local hyperdynamics (LHD) where the boost factor is an input parameter; see the [fix hyper/local](#) page for details.

---

Here is additional information on the input parameters for GHD.

The *cutbond* argument is the cutoff distance for defining bonds between pairs of nearby atoms. A pair of  $ij$  atoms in their equilibrium, minimum-energy configuration, which are separated by a distance  $R_{ij} < \text{cutbond}$ , are flagged as a bonded pair. Setting *cutbond* to be ~25% larger than the nearest-neighbor distance in a crystalline lattice is a typical choice for solids, so that bonds exist only between nearest neighbor pairs.

The *qfactor* argument is the limiting strain at which the bias potential goes to 0.0. It is dimensionless, so a value of 0.3 means a bond distance can be up to 30% larger or 30% smaller than the equilibrium (quenched)  $R_{ij}^0$  distance and the two atoms in the bond could still experience a non-zero bias force.

If *qfactor* is set too large, then transitions from one energy basin to another are affected because the bias potential is non-zero at the transition state (e.g. saddle point). If *qfactor* is set too small then little boost is achieved because the  $E_{ij}$  strain of some bond in the system will (nearly) always exceed *qfactor*. A value of 0.3 for *qfactor* is typically reasonable.

The *Vmax* argument is the prefactor on the bias potential. Ideally, it should be set to a value slightly less than the smallest barrier height for an event to occur. Otherwise the applied bias potential may be large enough (when added to the interatomic potential) to produce a local energy basin with a maxima in the center. This can produce artificial energy minima in the same basin that trap an atom. Or if *Vmax* is even larger, it may induce an atom(s) to rapidly transition to another energy basin. Both cases are “bad dynamics” which violate the assumptions of GHD that guarantee an accelerated time-accurate trajectory of the system.

Note that if *Vmax* is set too small, the GHD simulation will run correctly. There will just be fewer events because the hyper time ( $t_{\text{hyper}}$  equation above) will be shorter.

---

**Note:** If you have no physical intuition as to the smallest barrier height in your system, a reasonable strategy to determine the largest *Vmax* you can use for a GHD model, is to run a sequence of simulations with smaller and smaller *Vmax* values, until the event rate does not change (as a function of hyper time).

---

The *Tequil* argument is the temperature at which the system is simulated; see the comment above about the [fix langevin](#) thermostatting. It is also part of the beta term in the exponential factor that determines how much boost is achieved as a function of the bias potential.

In general, the lower the value of *Tequil* and the higher the value of *Vmax*, the more time boost will be achievable by the GHD algorithm.

---

## 2.78.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the energy of the bias potential to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

This fix computes a global scalar and global vector of length 12, which can be accessed by various *output commands*. The scalar is the magnitude of the bias potential (energy units) applied on the current timestep. The vector stores the following quantities:

1. boost factor on this step (unitless)
2. max strain  $E_{ij}$  of any bond on this step (absolute value, unitless)
3. ID of first atom in the max-strain bond
4. ID of second atom in the max-strain bond
5. average # of bonds/atom on this step
6. fraction of timesteps where the biased bond has bias = 0.0 during this run
7. fraction of timesteps where the biased bond has negative strain during this run
8. max drift distance of any atom during this run (distance units)
9. max bond length during this run (distance units)
10. cumulative hyper time since fix was defined (time units)
11. cumulative count of event timesteps since fix was defined
12. cumulative count of atoms in events since fix was defined

The first 5 quantities are for the current timestep. Quantities 6-9 are for the current hyper run. They are reset each time a new hyper run is performed. Quantities 10-12 are cumulative across multiple runs (since the point in the input script the fix was defined).

For value 8, drift is the distance an atom moves between two quenched states when the second quench determines an event has occurred. Atoms involved in an event will typically move the greatest distance since others typically remain near their original quenched position.

For value 11, events are checked for by the *hyper* command once every *Nevent* timesteps. This value is the count of those timesteps on which one (or more) events was detected. It is NOT the number of distinct events, since more than one event may occur in the same *Nevent* time window.

For value 12, each time the *hyper* command checks for an event, it invokes a compute to flag zero or more atoms as participating in one or more events. E.g. atoms that have displaced more than some distance from the previous quench state. Value 11 is the cumulative count of the number of atoms participating in any of the events that were found.

The scalar and vector values calculated by this fix are all “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.78.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the [Build package](#) page for more info.

```

## 2.79.3 Description

This fix is meant to be used with the *hyper* command to perform a bond-boost local hyperdynamics (LHD) simulation. The role of this fix is to select multiple pairs of atoms in the system at each timestep to add a local bias potential to, which will alter the dynamics of the system in a manner that effectively accelerates time. This is in contrast to the *fix hyper/global* command, which can be used to perform a global hyperdynamics (GHD) simulation, by adding a global bias potential to a single pair of atoms at each timestep. GHD can time accelerate a small simulation with up to a few 100 atoms. For larger systems, LHD is needed to achieve good time acceleration.

For a system that undergoes rare transition events, where one or more atoms move over an energy barrier to a new potential energy basin, the effect of the bias potential is to induce more rapid transitions. This can lead to a dramatic speed-up in the rate at which events occurs, without altering their relative frequencies, thus leading to an overall increase in the elapsed real time of the simulation as compared to running for the same number of timesteps with normal MD. See the *hyper* page for a more general discussion of hyperdynamics and citations that explain both GHD and LHD.

The equations and logic used by this fix and described here to perform LHD follow the description given in (Voter2013). The bond-boost form of a bias potential for HD is due to Miron and Fichthorn as described in (Miron).

To understand this description, you should first read the description of the GHD algorithm on the *fix hyper/global* doc page. This description of LHD builds on the GHD description.

The definition of bonds and  $E_{ij}$  are the same for GHD and LHD. The formulas for  $V_{ij}^{max}$  and  $F_{ij}^{max}$  are also the same except for a prefactor  $C_{ij}$ , explained below.

The bias energy  $V_{ij}$  applied to a bond  $ij$  with maximum strain is

$$V_{ij}^{max} = C_{ij} \cdot V^{max} \cdot \left( 1 - \left( \frac{E_{ij}}{q} \right)^2 \right) \text{ for } |E_{ij}| < qfactor \text{ or } 0 \text{ otherwise}$$

The derivative of  $V_{ij}^{max}$  with respect to the position of each atom in the  $ij$  bond gives a bias force  $F_{ij}^{max}$  acting on the bond as

$$F_{ij}^{max} = -\frac{dV_{ij}^{max}}{dE_{ij}} = 2C_{ij}V^{max} \frac{E_{ij}}{qfactor^2} \text{ for } |E_{ij}| < qfactor \text{ or } 0 \text{ otherwise}$$

which can be decomposed into an equal and opposite force acting on only the two atoms  $i$  and  $j$  in the  $ij$  bond.

The key difference is that in GHD a bias energy and force is added (on a particular timestep) to only one bond (pair of atoms) in the system, which is the bond with maximum strain  $E^{max}$ .

In LHD, a bias energy and force can be added to multiple bonds separated by the specified *Dcut* distance or more. A bond  $ij$  is biased if it is the maximum strain bond within its local “neighborhood”, which is defined as the bond  $ij$  plus any neighbor bonds within a distance *Dcut* from  $ij$ . The “distance” between bond  $ij$  and bond  $kl$  is the minimum distance between any of the  $ik$ ,  $il$ ,  $jk$ , and  $jl$  pairs of atoms.

For a large system, multiple bonds will typically meet this requirement, and thus a bias potential  $V_{ij}^{max}$  will be applied to many bonds on the same timestep.

In LHD, all bonds store a  $C_{ij}$  prefactor which appears in the  $V_{ij}^{max}$  and  $F_{ij}^{max}$  equations above. Note that the : *math* : ‘ $C_{ij}$ ’ factor scales the strength of the bias energy and forces whenever bond  $ij$  is the maximum strain bond in its neighborhood.

$C_{ij}$  is initialized to 1.0 when a bond between the  $ij$  atoms is first defined. The specified *Btarget* factor is then used to adjust the  $C_{ij}$  prefactors for each bond every timestep in the following manner.

An instantaneous boost factor  $B_{ij}$  is computed each timestep for each bond, as

$$B_{ij} = e^{\beta V_{kl}^{max}}$$

where  $V_{kl}^{max}$  is the bias energy of the maxstrain bond  $kl$  within bond  $ij$ 's neighborhood,  $\beta = \frac{1}{kT_{equil}}$ , and  $T_{equil}$  is the temperature of the system and an argument to this fix.

---

**Note:** To run an LHD simulation, the input script must also use the [fix langevin](#) command to thermostat the atoms at the same  $T_{equil}$  as specified by this fix, so that the system is running constant-temperature (NVT) dynamics. LAMMPS does not check that this is done.

---

Note that if  $ij == kl$ , then bond  $ij$  is a biased bond on that timestep, otherwise it is not. But regardless, the boost factor  $B_{ij}$  can be thought of an estimate of time boost currently being applied within a local region centered on bond  $ij$ . For LHD, we want this to be the specified  $B_{target}$  value everywhere in the simulation domain.

To accomplish this, if  $B_{ij} < B_{target}$ , the  $C_{ij}$  prefactor for bond  $ij$  is incremented on the current timestep by an amount proportional to the inverse of the specified  $\alpha$  and the difference ( $B_{ij} - B_{target}$ ). Conversely if  $B_{ij} > B_{target}$ ,  $C_{ij}$  is decremented by the same amount. This procedure is termed “boostostatting” in (Voter2013). It drives all of the individual  $C_{ij}$  to values such that when  $V_{ij}^{max}$  is applied as a bias to bond  $ij$ , the resulting boost factor  $B_{ij}$  will be close to  $B_{target}$  on average. Thus the LHD time acceleration factor for the overall system is effectively  $B_{target}$ .

Note that in LHD, the boost factor  $B_{target}$  is specified by the user. This is in contrast to global hyperdynamics (GHD) where the boost factor varies each timestep and is computed as a function of  $V_{max}$ ,  $E_{max}$ , and  $T_{equil}$ ; see the [fix hyper/global](#) page for details.

---

Here is additional information on the input parameters for LHD.

Note that the *cutbond*, *qfactor*, and *Tequil* arguments have the same meaning as for GHD. The *Vmax* argument is slightly different. The *Dcut*, *alpha*, and *Btarget* parameters are unique to LHD.

The *cutbond* argument is the cutoff distance for defining bonds between pairs of nearby atoms. A pair of I,J atoms in their equilibrium, minimum-energy configuration, which are separated by a distance  $R_{ij} < cutbond$ , are flagged as a bonded pair. Setting *cutbond* to be ~25% larger than the nearest-neighbor distance in a crystalline lattice is a typical choice for solids, so that bonds exist only between nearest neighbor pairs.

The *qfactor* argument is the limiting strain at which the bias potential goes to 0.0. It is dimensionless, so a value of 0.3 means a bond distance can be up to 30% larger or 30% smaller than the equilibrium (quenched)  $R_{ij}^0$  distance and the two atoms in the bond could still experience a non-zero bias force.

If *qfactor* is set too large, then transitions from one energy basin to another are affected because the bias potential is non-zero at the transition state (e.g. saddle point). If *qfactor* is set too small then little boost can be achieved because the  $E_{ij}$  strain of some bond in the system will (nearly) always exceed *qfactor*. A value of 0.3 for *qfactor* is typically a reasonable value.

The *Vmax* argument is a fixed prefactor on the bias potential. There is also a dynamic prefactor  $C_{ij}$ , driven by the choice of *Btarget* as discussed above. The product of these should be a value less than the smallest barrier height for an event to occur. Otherwise the applied bias potential may be large enough (when added to the interatomic potential) to produce a local energy basin with a maxima in the center. This can produce artificial energy minima in the same basin that trap an atom. Or if  $C_{ij} \cdot V^{max}$  is even larger, it may induce an atom(s) to rapidly transition to another energy basin. Both cases are “bad dynamics” which violate the assumptions of LHD that guarantee an accelerated time-accurate trajectory of the system.

---

**Note:** It may seem that  $V^{max}$  can be set to any value, and  $C_{ij}$  will compensate to reduce the overall prefactor if necessary. However the  $C_{ij}$  are initialized to 1.0 and the boostostatting procedure typically operates slowly enough that there can

---

be a time period of bad dynamics if  $V^{max}$  is set too large. A better strategy is to set  $V^{max}$  to the slightly smaller than the lowest barrier height for an event (the same as for GHD), so that the  $C_{ij}$  remain near unity.

---

The *Tequil* argument is the temperature at which the system is simulated; see the comment above about the *fix langevin* thermostating. It is also part of the beta term in the exponential factor that determines how much boost is achieved as a function of the bias potential. See the discussion of the *Btarget* argument below.

As discussed above, the *Dcut* argument is the distance required between two locally maxstrain bonds for them to both be selected as biased bonds on the same timestep. Computationally, the larger *Dcut* is, the more work (computation and communication) must be done each timestep within the LHD algorithm. And the fewer bonds can be simultaneously biased, which may mean the specified *Btarget* time acceleration cannot be achieved.

Physically *Dcut* should be a long enough distance that biasing two pairs of atoms that close together will not influence the dynamics of each pair. E.g. something like 2x the cutoff of the interatomic potential. In practice a *Dcut* value of ~10 Angstroms seems to work well for many solid-state systems.

---

**Note:** You should ensure that ghost atom communication is performed for a distance of at least  $Dcut + cutedvent =$  the distance one or more atoms move (between quenched states) to be considered an “event”. It is an argument to the “compute event/displace” command used to detect events. By default the ghost communication distance is set by the *pair\_style* cutoff, which will typically be  $< Dcut$ . The *comm\_modify cutoff* command should be used to override the ghost cutoff explicitly, e.g.

---

`comm_modify cutoff 12.0`

Note that this fix does not know the *cutedvent* parameter, but uses half the *cutbond* parameter as an estimate to warn if the ghost cutoff is not long enough.

As described above the *alpha* argument is a prefactor in the boostostat update equation for each bond’s  $C_{ij}$  prefactor. *Alpha* is specified in time units, similar to other thermostat or barostat damping parameters. It is roughly the physical time it will take the boostostat to adjust a  $C_{ij}$  value from a too high (or too low) value to a correct one. An *alpha* setting of a few ps is typically good for solid-state systems. Note that the *alpha* argument here is the inverse of the alpha parameter discussed in (*Voter2013*).

The *Btarget* argument is the desired time boost factor (a value  $> 1$ ) that all the atoms in the system will experience. The elapsed time *t\_hyper* for an LHD simulation running for *N* timesteps is simply

$$t_{hyper} = B_{target} \cdot N \cdot dt$$

where *dt* is the timestep size defined by the *timestep* command. The effective time acceleration due to LHD is thus  $\frac{t_{hyper}}{N \cdot dt} = B_{target}$ , where  $N \cdot dt$  is the elapsed time for a normal MD run of *N* timesteps.

You cannot choose an arbitrarily large setting for *Btarget*. The maximum value you should choose is

$$B_{target} = e^{\beta V_{small}}$$

where  $V_{small}$  is the smallest event barrier height in your system,  $\beta = \frac{1}{kT_{equil}}$ , and  $T_{equil}$  is the specified temperature of the system (both by this fix and the Langevin thermostat).

Note that if *Btarget* is set smaller than this, the LHD simulation will run correctly. There will just be fewer events because the hyper time (*t\_hyper* equation above) will be shorter.

---

**Note:** If you have no physical intuition as to the smallest barrier height in your system, a reasonable strategy to determine the largest *Btarget* you can use for an LHD model, is to run a sequence of simulations with smaller and smaller *Btarget* values, until the event rate does not change (as a function of hyper time).

---

Here is additional information on the optional keywords for this fix.

The *bound* keyword turns on min/max bounds for bias coefficients  $C_{ij}$  for all bonds.  $C_{ij}$  is a prefactor for each bond on the bias potential of maximum strength  $V^{max}$ . Depending on the choice of *alpha* and *Btarget* and  $V^{max}$ , the boost-ostating can cause individual  $C_{ij}$  values to fluctuate. If the fluctuations are too large  $C_{ij} \cdot V^{max}$  can exceed low barrier heights and induce bad event dynamics. Bounding the  $C_{ij}$  values is a way to prevent this. If *Bfrac* is set to -1 or any negative value (the default) then no bounds are enforced on  $C_{ij}$  values (except they must always be  $\geq 0.0$ ). A *Bfrac* setting  $\geq 0.0$  sets a lower bound of  $1.0 - Bfrac$  and upper bound of  $1.0 + Bfrac$  on each  $C_{ij}$  value. Note that all  $C_{ij}$  values are initialized to 1.0 when a bond is created for the first time. Thus *Bfrac* limits the bias potential height to  $V^{max} \pm Bfrac \cdot V^{max}$ .

The *reset* keyword allow  $V^{max}$  to be adjusted dynamically depending on the average value of all  $C_{ij}$  prefactors. This can be useful if you are unsure what value of  $V^{max}$  will match the *Btarget* boost for the system. The  $C_{ij}$  values will then adjust in aggregate (up or down) so that  $C_{ij} \cdot V^{max}$  produces a boost of *Btarget*, but this may conflict with the *bound* keyword settings. By using *bound* and *reset* together,  $V^{max}$  itself can be reset, and desired bounds still applied to the  $C_{ij}$  values.

A setting for *Rfreq* of -1 (the default) means  $V^{max}$  never changes. A setting of 0 means  $V^{max}$  is adjusted every time an event occurs and bond pairs are recalculated. A setting of  $N > 0$  timesteps means  $V^{max}$  is adjusted on the first time an event occurs on a timestep  $\geq N$  steps after the previous adjustment. The adjustment to  $V^{max}$  is computed as follows. The current average of all  $C_{ij} \cdot V^{max}$  values is computed and the  $V^{max}$  is reset to that value. All  $C_{ij}$  values are changed to new prefactors such the new  $C_{ij} \cdot V^{max}$  is the same as it was previously. If the *bound* keyword was used, those bounds are enforced on the new  $C_{ij}$  values. Henceforth, new bonds are assigned a  $C_{ij} = 1.0$ , which means their bias potential magnitude is the new  $V^{max}$ .

The *check/ghost* keyword turns on extra computation each timestep to compute statistics about ghost atoms used to determine which bonds to bias. The output of these stats are the vector values 14 and 15, described below. If this keyword is not enabled, the output of the stats will be zero.

The *check/bias* keyword turns on extra computation and communication to check if any biased bonds are closer than *Dcut* to each other, which should not be the case if LHD is operating correctly. Thus it is a debugging check. The *Nevery* setting determines how often the check is made. The *error*, *warn*, or *ignore* setting determines what is done if the count of too-close bonds is not zero. Either the code will exit, or issue a warning, or silently tally the count. The count can be output as vector value 17, as described below. If this keyword is not enabled, the output of that statistic will be 0.

Note that both of these computations are costly, hence they are only enabled by these keywords.

---

## 2.79.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the energy of the bias potential to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

This fix computes a global scalar and global vector of length 28, which can be accessed by various *output commands*. The scalar is the magnitude of the bias potential (energy units) applied on the current timestep, summed over all biased bonds. The vector stores the following quantities:

1. average boost for all bonds on this step (unitless)
2. # of biased bonds on this step
3. max strain  $E_{ij}$  of any bond on this step (absolute value, unitless)

4. value of  $V^{max}$  on this step (energy units)
5. average bias coeff for all bonds on this step (unitless)
6. min bias coeff for all bonds on this step (unitless)
7. max bias coeff for all bonds on this step (unitless)
8. average # of bonds/atom on this step
9. average neighbor bonds/bond on this step within  $Dcut$
10. average boost for all bonds during this run (unitless)
11. average # of biased bonds/step during this run
12. fraction of biased bonds with no bias during this run
13. fraction of biased bonds with negative strain during this run
14. max bond length during this run (distance units)
15. average bias coeff for all bonds during this run (unitless)
16. min bias coeff for any bond during this run (unitless)
17. max bias coeff for any bond during this run (unitless)
18. max drift distance of any bond atom during this run (distance units)
19. max distance from proc subbox of any ghost atom with  $maxstrain < qfactor$  during this run (distance units)
20. max distance outside my box of any ghost atom with any  $maxstrain$  during this run (distance units)
21. count of ghost atoms that could not be found on reneighbor steps during this run
22. count of bias overlaps ( $< Dcut$ ) found during this run
23. cumulative hyper time since fix created (time units)
24. cumulative count of event timesteps since fix created
25. cumulative count of atoms in events since fix created
26. cumulative # of new bonds formed since fix created
27. average boost for biased bonds on this step (unitless)
28. # of bonds with absolute strain  $\geq q$  on this step

Quantities 1-9 are for the current timestep. Quantities 10-22 are for the current hyper run. They are reset each time a new hyper run is performed. Quantities 23-26 are cumulative across multiple runs (since the point in the input script the fix was defined).

For value 10, each bond instantaneous boost factor is given by the equation for  $B_{ij}$  above. The total system boost (average across all bonds) fluctuates, but should average to a value close to the specified  $B_{target}$ .

For value 12, the numerator is a count of all biased bonds on each timestep whose bias energy = 0.0 due to  $E_{ij} \geq qfactor$ . The denominator is the count of all biased bonds on all timesteps.

For value 13, the numerator is a count of all biased bonds on each timestep with negative strain. The denominator is the count of all biased bonds on all timesteps.

Values 18-22 are mostly useful for debugging and diagnostic purposes.

For value 18, drift is the distance an atom moves between two quenched states when the second quench determines an event has occurred. Atoms involved in an event will typically move the greatest distance since others typically remain near their original quenched position.

For values 19-21, neighbor atoms in the full neighbor list with cutoff  $D_{cut}$  may be ghost atoms outside a processor's sub-box. Before the next event occurs they may move further than  $D_{cut}$  away from the sub-box boundary. Value 19 is the furthest (from the sub-box) any ghost atom in the neighbor list with  $maxstrain < qfactor$  was accessed during the run. Value 20 is the same except that the ghost atom's  $maxstrain$  may be  $\geq qfactor$ , which may mean it is about to participate in an event. Value 21 is a count of how many ghost atoms could not be found on reneighbor steps, presumably because they moved too far away due to their participation in an event (which will likely be detected at the next quench).

Typical values for 19 and 20 should be slightly larger than  $D_{cut}$ , which accounts for ghost atoms initially at a  $D_{cut}$  distance moving thermally before the next event takes place.

Note that for values 19 and 20 to be computed, the optional keyword *check/ghost* must be specified. Otherwise these values will be zero. This is because computing them incurs overhead, so the values are only computed if requested.

Value 21 should be zero or small. As explained above a small count likely means some ghost atoms were participating in their own events and moved a longer distance. If the value is large, it likely means the communication cutoff for ghosts is too close to  $D_{cut}$  leading to many not-found ghost atoms before the next event. This may lead to a reduced number of bonds being selected for biasing, since the code assumes those atoms are part of highly strained bonds. As explained above, the *comm\_modify cutoff* command can be used to set a longer cutoff.

For value 22, no two bonds should be biased if they are within a  $D_{cut}$  distance of each other. This value should be zero, indicating that no pair of biased bonds are closer than  $D_{cut}$  from each other.

Note that for value 22 to be computed, the optional keyword *check/bias* must be specified and it determines how often this check is performed. This is because performing the check incurs overhead, so if only computed as often as requested.

The result at the end of the run is the cumulative total from every timestep the check was made. Note that the value is a count of atoms in bonds which found other atoms in bonds too close, so it is almost always an over-count of the number of too-close bonds.

Value 23 is simply the specified *boost* factor times the number of timesteps times the timestep size.

For value 24, events are checked for by the *hyper* command once every *Nevent* timesteps. This value is the count of those timesteps on which one (or more) events was detected. It is NOT the number of distinct events, since more than one event may occur in the same *Nevent* time window.

For value 25, each time the *hyper* command checks for an event, it invokes a compute to flag zero or more atoms as participating in one or more events. E.g. atoms that have displaced more than some distance from the previous quench state. Value 25 is the cumulative count of the number of atoms participating in any of the events that were found.

Value 26 tallies the number of new bonds created by the bond reset operation. Bonds between a specific I,J pair of atoms may persist for the entire hyperdynamics simulation if neither I or J are involved in an event.

Value 27 computes the average boost for biased bonds only on this step.

Value 28 is the count of bonds with an absolute value of strain  $\geq q$  on this step.

The scalar value and vector values are all "intensive".

This fix also computes a local vector of length the number of bonds currently in the system. The value for each bond is its  $C_{ij}$  prefactor (bias coefficient). These values can be accessed by various *output commands*. A particularly useful one is the *fix ave/histo* command which can be used to histogram the  $C_{ij}$  values to see if they are distributed reasonably close to 1.0, which indicates a good choice of  $V^{max}$ .

The local values calculated by this fix are unitless.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.79.5 Restrictions

This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) doc page for more info.

## 2.79.6 Related commands

*hyper*, *fix hyper/global*

## 2.79.7 Default

The default settings for optimal keywords are `bounds = -1` and `reset = -1`. The `check/ghost` and `check/bias` keywords are not enabled by default.

# 2.80 fix imd command

## 2.80.1 Syntax

`fix ID group-ID imd trate port keyword values ...`

- ID, group-ID are documented in *fix* command
- imd = style name of this fix command
- port = port number on which the fix listens for an IMD client
- keyword = *unwrap* or *fscale* or *trate* or *nowait*

*unwrap* arg = *on* or *off*

off = coordinates are wrapped back into the principal unit cell (default)

on = "unwrapped" coordinates using the image flags used

*fscale* arg = factor

factor = floating point number to scale IMD forces (default: 1.0)

*trate* arg = transmission rate of coordinate data sets (default: 1)

*nowait* arg = *on* or *off*

off = LAMMPS waits to be connected to an IMD client before continuing (default)

on = LAMMPS listens for an IMD client, but continues with the run

## 2.80.2 Examples

```
fix vmd all imd 5678
fix comm all imd 8888 trate 5 unwrap on fscale 10.0
```

## 2.80.3 Description

This fix implements the “Interactive MD” (IMD) protocol which allows realtime visualization and manipulation of MD simulations through the IMD protocol, as initially implemented in VMD and NAMD. Specifically it allows LAMMPS to connect an IMD client, for example the [VMD visualization program](#), so that it can monitor the progress of the simulation and interactively apply forces to selected atoms.

If LAMMPS is compiled with the pre-processor flag `-DLAMMPS_ASYNC_IMD` then `fix imd` will use POSIX threads to spawn a IMD communication thread on MPI rank 0 in order to offload data reading and writing from the main execution thread and potentially lower the inferred latencies for slow communication links. This feature has only been tested under linux.

The source code for this fix includes code developed by the Theoretical and Computational Biophysics Group in the Beckman Institute for Advanced Science and Technology at the University of Illinois at Urbana-Champaign. We thank them for providing a software interface that allows codes like LAMMPS to hook to [VMD](#).

Upon initialization of the fix, it will open a communication port on the node with MPI task 0 and wait for an incoming connection. As soon as an IMD client is connected, the simulation will continue and the fix will send the current coordinates of the fix’s group to the IMD client at every `trate` MD step. When using `r-RESPA`, `trate` applies to the steps of the outmost `RESPA` level. During a run with an active IMD connection also the IMD client can request to apply forces to selected atoms of the fix group.

The port number selected must be an available network port number. On many machines, port numbers < 1024 are reserved for accounts with system manager privilege and specific applications. If multiple `imd` fixes would be active at the same time, each needs to use a different port number.

The `nowait` keyword controls the behavior of the fix when no IMD client is connected. With the default setting of `off`, LAMMPS will wait until a connection is made before continuing with the execution. Setting `nowait` to `on` will have the LAMMPS code be ready to connect to a client, but continue with the simulation. This can for example be used to monitor the progress of an ongoing calculation without the need to be permanently connected or having to download a trajectory file.

The `trate` keyword allows to select how often the coordinate data is sent to the IMD client. It can also be changed on request of the IMD client through an IMD protocol message. The `unwrap` keyword allows to send “unwrapped” coordinates to the IMD client that undo the wrapping back of coordinates into the principle unit cell, as done by default in LAMMPS. The `fscale` keyword allows to apply a scaling factor to forces transmitted by the IMD client. The IMD protocols stipulates that forces are transferred in kcal/mol/Angstrom under the assumption that coordinates are given in Angstrom. For LAMMPS runs with different units or as a measure to tweak the forces generated by the manipulation of the IMD client, this option allows to make adjustments.

To connect VMD to a listening LAMMPS simulation on the same machine with `fix imd` enabled, one needs to start VMD and load a coordinate or topology file that matches the fix group. When the VMD command prompts appears, one types the command line:

```
imd connect localhost 5678
```

This assumes that `fix imd` was started with 5678 as a port number for the IMD protocol.

The steps to do interactive manipulation of a running simulation in VMD are the following:

In the Mouse menu of the VMD Main window, select “Mouse -> Force -> Atom”. You may alternately select “Residue”, or “Fragment” to apply forces to whole residues or fragments. Your mouse can now be used to apply forces to your

simulation. Click on an atom, residue, or fragment and drag to apply a force. Click quickly without moving the mouse to turn the force off. You can also use a variety of 3D position trackers to apply forces to your simulation. Game controllers or haptic devices with force-feedback such as the Novint Falcon or Sensable PHANTOM allow you to feel the resistance due to inertia or interactions with neighbors that the atoms experience you are trying to move, as if they were real objects. See the [VMD IMD Homepage](#) for more details.

If IMD control messages are received, a line of text describing the message and its effect will be printed to the LAMMPS output screen, if screen output is active.

## 2.80.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global scalar or vector or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.80.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

When used in combination with VMD, a topology or coordinate file has to be loaded, which matches (in number and ordering of atoms) the group the fix is applied to. The fix internally sorts atom IDs by ascending integer value; in VMD (and thus the IMD protocol) those will be assigned 0-based consecutive index numbers.

When using multiple active IMD connections at the same time, each needs to use a different port number.

fix 2 flow indent 10.0 cylinder z 0.0 0.0 10.0 units box

```

## 2.81.3 Description

Insert an indenter within a simulation box. The indenter repels all atoms in the group that touch it, so it can be used to push into a material or as an obstacle in a flow. Alternatively, it can be used as a constraining wall around a simulation; see the discussion of the *side* keyword below.

The *gstyle* keyword selects the geometry of the indenter and it can either have the value of *sphere*, *cylinder*, *cone*, or *plane*.

A spherical indenter (*gstyle* = *sphere*) exerts a force of magnitude

$$F(r) = -K(r - R)^2$$

on each atom where  $K$  is the specified force constant,  $r$  is the distance from the atom to the center of the indenter, and  $R$  is the radius of the indenter. The force is repulsive and  $F(r) = 0$  for  $r > R$ .

A cylindrical indenter (*gstyle = cylinder*) follows the same formula for the force as a sphere, except that  $r$  is defined the distance from the atom to the center axis of the cylinder. The cylinder extends infinitely along its axis.

New in version 17April2024.

A conical indenter (*gstyle = cone*) is similar to a cylindrical indenter except that it has a finite length (between  $lo$  and  $hi$ ), and that two different radii (one at each end,  $radlo$  and  $radhi$ ) can be defined.

Spherical, cylindrical, and conical indenters account for periodic boundaries in two ways. First, the center point of a spherical indenter ( $x,y,z$ ) or axis of a cylindrical/conical indenter ( $c1,c2$ ) is remapped back into the simulation box, if the box is periodic in a particular dimension. This occurs every timestep if the indenter geometry is specified with a variable (see below), e.g. it is moving over time. Second, the calculation of distance to the indenter center or axis accounts for periodic boundaries. Both of these mean that an indenter can effectively move through and straddle one or more periodic boundaries.

A planar indenter (*gstyle = plane*) behaves like an axis-aligned infinite-extent wall with the same force expression on atoms in the system as before, but where  $R$  is the position of the plane and  $r-R$  is the distance of an from the plane. If the *side* parameter of the plane is specified as *lo* then it will indent from the *lo* end of the simulation box, meaning that atoms with a coordinate less than the plane's current position will be pushed towards the *hi* end of the box and atoms with a coordinate higher than the plane's current position will feel no force. Vice versa if *side* is specified as *hi*.

Any of the 4 quantities defining a spherical indenter's geometry can be specified as an equal-style *variable*, namely  $x$ ,  $y$ ,  $z$ , or  $R$ . For a cylindrical indenter, any of the 3 quantities  $c1$ ,  $c2$ , or  $R$ , can be a variable. For a conical indenter, any of the 6 quantities  $c1$ ,  $c2$ ,  $radlo$ ,  $radhi$ ,  $lo$ , or  $hi$  can be a variable. For a planar indenter, the single value  $pos$  can be a variable.

If any of these values is a variable, it should be specified as  $v\_name$ , where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its value used to define the indenter geometry.

Note that equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify indenter properties that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo\_style custom* for details.

For example, if a spherical indenter's  $x$ -position is specified as  $v\_x$ , then this variable definition will keep it's center at a relative position in the simulation box, 1/4 of the way from the left edge to the right edge, even if the box size changes:

```
variable x equal "xlo + 0.25*lx"
```

Similarly, either of these variable definitions will move the indenter from an initial position at 2.5 at a constant velocity of 5:

```
variable x equal "2.5 + 5*elaplong*dt"
variable x equal vdisplace(2.5,5)
```

If a spherical indenter's radius is specified as  $v\_r$ , then these variable definitions will grow the size of the indenter at a specified rate.

```
variable r0 equal 0.0
variable rate equal 1.0
variable r equal "v_r0 + step*dt*v_rate"
```

If the *side* keyword is specified as *out*, which is the default, then particles outside the indenter are pushed away from its outer surface, as described above. This only applies to spherical, cylindrical, and conical indenters. If the *side* keyword is specified as *in*, the action of the indenter is reversed. Particles inside the indenter are pushed away from its inner surface. In other words, the indenter is now a containing wall that traps the particles inside it. If the radius shrinks over time, it will squeeze the particles.

The *units* keyword determines the meaning of the distance units used to define the indenter geometry. A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. The (x,y,z) coords of the indenter position are scaled by the x,y,z lattice spacings respectively. The radius of a spherical or cylindrical indenter is scaled by the x lattice spacing.

Note that the *units* keyword only affects indenter geometry parameters specified directly with numbers, not those specified as variables. In the latter case, you should use the *xlat*, *ylat*, *zlat* keywords of the *thermo\_style* command if you want to include lattice spacings in a variable formula.

The force constant *K* is not affected by the *units* keyword. It is always in force/distance<sup>2</sup> units where force and distance are defined by the *units* command. If you wish *K* to be scaled by the lattice spacing, you can define *K* with a variable whose formula contains *xlat*, *ylat*, *zlat* keywords of the *thermo\_style* command, e.g.

```
variable k equal 100.0/xlat/xlat
fix 1 all indent $k sphere ...
```

### 2.81.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the energy of interaction between atoms and the indenter to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*. The energy of each particle interacting with the indenter is  $K/3 (r - R)^3$ .

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global 3-vector of forces (on the indenter), which can be accessed by various *output commands*. The scalar and vector values calculated by this fix are “extensive”.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command. Note that if you define the indenter geometry with a variable using a time-dependent formula, LAMMPS uses the iteration count in the minimizer as the timestep. But it is almost certainly a bad idea to have the indenter change its position or size during a minimization. LAMMPS does not check if you have done this.

---

**Note:** If you want the atom/indenter interaction energy to be included in the total potential energy of the system (the quantity being minimized), you must enable the *fix\_modify energy* option for this fix.

---

## 2.82 fix ipi command

### 2.82.1 Syntax

```
fix ID group-ID ipi address port [unix] [reset]
```

- ID, group-ID are documented in *fix* command
- ipi = style name of this fix command
- address = internet address (FQDN or IP), or UNIX socket name
- port = port number (ignored for UNIX sockets)
- zero or more keywords may be appended
- keyword = *unix* or *reset*  
*unix* args = none = use a unix socket  
*reset* args = none = reset electrostatics at each call

### 2.82.2 Examples

```
fix 1 all ipi my.server.com 12345  
fix 1 all ipi mysocket 666 unix reset
```

### 2.82.3 Description

This fix enables LAMMPS to be run as a client for the i-PI Python wrapper (*IPI*). i-PI is a universal force engine, designed to perform advanced molecular simulations, with a special focus on path integral molecular dynamics (PIMD) simulation. The philosophy behind i-PI is to separate the evaluation of the energy and forces, which is delegated to the client, and the evolution of the dynamics, that is the responsibility of i-PI. This approach also simplifies combining energies computed from different codes, which can for instance be useful to mix first-principles calculations, empirical force fields or machine-learning potentials. The following publication (*IPI-CPC-2014*) discusses the overall implementation of i-PI, and focuses on path-integral techniques, while a later release (*IPI-CPC-2019*) introduces several additional features and simulation schemes.

The communication between i-PI and LAMMPS takes place using sockets, and is reduced to the bare minimum. All the parameters of the dynamics are specified in the input of i-PI, and all the parameters of the force field must be specified as LAMMPS inputs, preceding the *fix ipi* command.

The server address must be specified by the *address* argument, and can be either the IP address, the fully-qualified name of the server, or the name of a UNIX socket for local, faster communication. In the case of internet sockets, the *port* argument specifies the port number on which i-PI is listening, while the *unix* optional switch specifies that the socket is a UNIX socket.

Note that there is no check of data integrity, or that the atomic configurations make sense. It is assumed that the species in the i-PI input are listed in the same order as in the data file of LAMMPS. The initial configuration is ignored, as it will be substituted with the coordinates received from i-PI before forces are ever evaluated.

A note of caution when using potentials that contain long-range electrostatics, or that contain parameters that depend on box size: all of these options will be initialized based on the cell size in the LAMMPS-side initial configuration and kept constant during the run. This is required to e.g. obtain reproducible and conserved forces. If the cell varies too wildly, it may be advisable to re-initialize these interactions at each call. This behavior can be requested by setting the *reset* switch.

## 2.82.4 Obtaining i-PI

Here are the commands to set up a virtual environment and install i-PI into it with all its dependencies via the PyPI repository and the pip package manager.

```
python -m venv ipienv
source ipienv/bin/activate
pip install --upgrade pip
pip install ipi
```

## 2.82.5 Restart, fix\_modify, output, run start/stop, minimize info

There is no restart information associated with this fix, since all the dynamical parameters are dealt with by i-PI.

## 2.82.6 Restrictions

Using this fix on anything other than all atoms requires particular care, since i-PI will know nothing on atoms that are not those whose coordinates are transferred. However, one could use this strategy to define an external potential acting on the atoms that are moved by i-PI.

Since the i-PI code uses atomic units internally, this fix needs to convert LAMMPS data to and from its *specified units* accordingly when communicating with i-PI. This is not possible for reduced units (“units lj”) and thus *fix ipi* will stop with an error in this case.

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info. Because of the use of UNIX domain sockets, this fix will only work in a UNIX environment.

## 2.83 fix langevin command

Accelerator Variants: *langevin/kk*

### 2.83.1 Syntax

```
fix ID group-ID langevin Tstart Tstop damp seed keyword values ...
```

- ID, group-ID are documented in *fix* command
- langevin = style name of this fix command
- Tstart,Tstop = desired temperature at start/end of run (temperature units)
- Tstart can be a variable (see below)
- damp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- zero or more keyword/value pairs may be appended
- keyword = *angmom* or *gjf* or *omega* or *scale* or *tally* or *zero*

*angmom* value = *no* or *factor*

*no* = do not thermostat rotational degrees of freedom via the angular momentum

*factor* = do thermostat rotational degrees of freedom via the angular momentum and

→ apply numeric scale factor as discussed below

*gjf* value = *no* or *vfull* or *vhalf*

*no* = use standard formulation

*vfull* = use Gronbech-Jensen/Farago formulation

*vhalf* = use 2GJ formulation

*omega* value = *no* or *yes*

*no* = do not thermostat rotational degrees of freedom via the angular velocity

*yes* = do thermostat rotational degrees of freedom via the angular velocity

*scale* values = type ratio

type = atom type (1-N)

ratio = factor by which to scale the damping coefficient

*tally* value = *no* or *yes*

*no* = do not tally the energy added/subtracted to atoms

*yes* = do tally the energy added/subtracted to atoms

*zero* value = *no* or *yes*

*no* = do not set total random force to zero

*yes* = set total random force to zero

### 2.83.2 Examples

```
fix 3 boundary langevin 1.0 1.0 1000.0 699483
fix 1 all langevin 1.0 1.1 100.0 48279 scale 3 1.5
fix 1 all langevin 1.0 1.1 100.0 48279 angmom 3.333
```

### 2.83.3 Description

Apply a Langevin thermostat as described in ([Schneider](#)) to a group of atoms which models an interaction with a background implicit solvent. Used with [fix nve](#), this command performs Brownian dynamics (BD), since the total force on each atom will have the form:

$$\begin{aligned} F &= F_c + F_f + F_r \\ F_f &= -\frac{m}{\text{damp}} v \\ F_r &\propto \sqrt{\frac{k_B T m}{dt \text{ damp}}} \end{aligned}$$

$F_c$  is the conservative force computed via the usual inter-particle interactions ([pair\\_style](#), [bond\\_style](#), etc). The  $F_f$  and  $F_r$  terms are added by this fix on a per-particle basis. See the [pair\\_style dpd/tstat](#) command for a thermostating option that adds similar terms on a pairwise basis to pairs of interacting particles.

$F_f$  is a frictional drag or viscous damping term proportional to the particle's velocity. The proportionality constant for each atom is computed as  $\frac{m}{\text{damp}}$ , where  $m$  is the mass of the particle and  $\text{damp}$  is the damping factor specified by the user.

$F_r$  is a force due to solvent atoms at a temperature  $T$  randomly bumping into the particle. As derived from the fluctuation/dissipation theorem, its magnitude as shown above is proportional to  $\sqrt{\frac{k_B T m}{dt \text{ damp}}}$ , where  $k_B$  is the Boltzmann constant,  $T$  is the desired temperature,  $m$  is the mass of the particle,  $dt$  is the timestep size, and  $\text{damp}$  is the damping factor. Random numbers are used to randomize the direction and magnitude of this force as described in ([Dunweg](#)), where a uniform random number is used (instead of a Gaussian random number) for speed.

Note that unless you use the [omega](#) or [angmom](#) keywords, the thermostat effect of this fix is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles, which have rotational degrees of freedom, are being thermostatted. The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

---

**Note:** Unlike the [fix nvt](#) command which performs Nose/Hoover thermostating AND time integration, this fix does NOT perform time integration. It only modifies forces to effect thermostating. Thus you must use a separate time integration fix, like [fix nve](#) to actually update the velocities and positions of atoms using the modified forces. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by [fix nvt](#) or [fix temp/rescale](#) commands.

---

See the [Howto thermostat](#) page for a discussion of different ways to compute temperature and perform thermostating.

The desired temperature at each timestep is a ramped value during the run from  $T_{\text{start}}$  to  $T_{\text{stop}}$ .

$T_{\text{start}}$  can be specified as an equal-style or atom-style [variable](#). In this case, the  $T_{\text{stop}}$  setting is ignored. If the value is a variable, it should be specified as `v_name`, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include [thermo\\_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent temperature with optional time-dependence as well.

Like other fixes that perform thermostating, this fix can be used with [compute commands](#) that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial [region](#), or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

The *damp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units ( $\tau$  or fs or ps - see the *units* command). The damp factor can be thought of as inversely related to the viscosity of the solvent. I.e. a small relaxation time implies a high-viscosity solvent and vice versa. See the discussion about  $\gamma$  and viscosity in the documentation for the *fix viscous* command for more details.

The random # *seed* must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

---

The keyword/value option pairs are used in the following ways.

The keyword *angmom* and *omega* keywords enable thermostating of rotational degrees of freedom in addition to the usual translational degrees of freedom. This can only be done for finite-size particles.

A simulation using *atom\_style sphere* defines an omega for finite-size spheres. A simulation using *atom\_style ellipsoid* defines a finite size and shape for aspherical particles and an angular momentum. The Langevin formulas for thermostating the rotational degrees of freedom are the same as those above, where force is replaced by torque,  $m$  is replaced by the moment of inertia  $I$ , and  $v$  is replaced by omega (which is derived from the angular momentum in the case of aspherical particles).

The rotational temperature of the particles can be monitored by the *compute temp/sphere* and *compute temp/asphere* commands with their rotate options.

For the *omega* keyword there is also a scale factor of  $\frac{10.0}{3.0}$  that is applied as a multiplier on the  $F_f$  (damping) term in the equation above and of  $\sqrt{\frac{10.0}{3.0}}$  as a multiplier on the  $F_r$  term. This does not affect the thermostating behavior of the Langevin formalism but ensures that the randomized rotational diffusivity of spherical particles is correct.

For the *angmom* keyword a similar scale factor is needed which is  $\frac{10.0}{3.0}$  for spherical particles, but is anisotropic for aspherical particles (e.g. ellipsoids). Currently LAMMPS only applies an isotropic scale factor, and you can choose its magnitude as the specified value of the *angmom* keyword. If your aspherical particles are (nearly) spherical than a value of  $\frac{10.0}{3.0} = 3.\bar{3}$  is a good choice. If they are highly aspherical, a value of 1.0 is as good a choice as any, since the effects on rotational diffusivity of the particles will be incorrect regardless. Note that for any reasonable scale factor, the thermostating effect of the *angmom* keyword on the rotational temperature of the aspherical particles should still be valid.

The keyword *scale* allows the damp factor to be scaled up or down by the specified factor for atoms of that type. This can be useful when different atom types have different sizes or masses. It can be used multiple times to adjust damp for several atom types. Note that specifying a ratio of 2 increases the relaxation time which is equivalent to the solvent's viscosity acting on particles with  $\frac{1}{2}$  the diameter. This is the opposite effect of scale factors used by the *fix viscous* command, since the damp factor in *fix langevin* is inversely related to the  $\gamma$  factor in *fix viscous*. Also note that the damping factor in *fix langevin* includes the particle mass in  $F_f$ , unlike *fix viscous*. Thus the mass and size of different atom types should be accounted for in the choice of ratio values.

The keyword *tally* enables the calculation of the cumulative energy added/subtracted to the atoms as they are thermostatted. Effectively it is the energy exchanged between the infinite thermal reservoir and the particles. As described below, this energy can then be printed out or added to the potential energy of the system to monitor energy conservation.

---

**Note:** This accumulated energy does NOT include kinetic energy removed by the *zero* flag. LAMMPS will print a warning when both options are active.

---

The keyword *zero* can be used to eliminate drift due to the thermostat. Because the random forces on different atoms are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the center-of-mass of the system undergoes a slow random walk. If the keyword *zero* is set to *yes*, the total random force is set exactly to zero by subtracting off an equal part of it from each atom in the group. As a result, the center-of-mass of a system with zero initial momentum will not drift over time.

The keyword *gif* can be used to run the *Gronbech-Jensen/Farago* time-discretization of the Langevin model. As described in the papers cited below, the purpose of this method is to enable longer timesteps to be used (up to the numerical stability limit of the integrator), while still producing the correct Boltzmann distribution of atom positions.

The current implementation provides the user with the option to output the velocity in one of two forms: *vfull* or *vhalf*, which replaces the outdated option *yes*. The *gif* option *vfull* outputs the on-site velocity given in *Gronbech-Jensen/Farago*; this velocity is shown to be systematically lower than the target temperature by a small amount, which grows quadratically with the timestep. The *gif* option *vhalf* outputs the 2GJ half-step velocity given in *Gronbech-Jensen/Gronbech-Jensen*; for linear systems, this velocity is shown to not have any statistical errors for any stable time step. An overview of statistically correct Boltzmann and Maxwell-Boltzmann sampling of true on-site and true half-step velocities is given in *Gronbech-Jensen*. Regardless of the choice of output velocity, the sampling of the configurational distribution of atom positions is the same, and linearly consistent with the target temperature.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 2.83.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a temperature *compute* you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*, but only if the *tally* keyword is set to *yes*. See the *thermo\_style* page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”. Note that calculation of this quantity also requires setting the *tally* keyword to *yes*.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

### 2.83.5 Restrictions

For *gif* do not choose  $\text{damp}=\text{dt}/2$ . *gif* is not compatible with *run\_style respa*.

### 2.83.6 Related commands

*fix nvt*, *fix temp/rescale*, *fix viscous*, *fix nvt*, *pair\_style dpd/tstat*

### 2.83.7 Default

The option defaults are *angmom* = no, *omega* = no, *scale* = 1.0 for all types, *tally* = no, *zero* = no, *gif* = no.

## 2.84 fix langevin/drude command

### 2.84.1 Syntax

```
fix ID group-ID langevin/drude Tcom damp_com seed_com Tdrude damp_drude seed_drude_
→keyword values ...
```

- ID, group-ID are documented in *fix* command
- langevin/drude = style name of this fix command
- Tcom = desired temperature of the centers of mass (temperature units)
- damp\_com = damping parameter for the thermostat on centers of mass (time units)
- seed\_com = random number seed to use for white noise of the thermostat on centers of mass (positive integer)
- Tdrude = desired temperature of the Drude oscillators (temperature units)
- damp\_drude = damping parameter for the thermostat on Drude oscillators (time units)
- seed\_drude = random number seed to use for white noise of the thermostat on Drude oscillators (positive integer)
- zero or more keyword/value pairs may be appended
- keyword = *zero*

zero value = *no* or *yes*

no = do not set total random force on centers of mass to zero

yes = set total random force on centers of mass to zero

## 2.84.2 Examples

```
fix 3 all langevin/drude 300.0 100.0 19377 1.0 20.0 83451
fix 1 all langevin/drude 298.15 100.0 19377 5.0 10.0 83451 zero yes
```

Example input scripts available: examples/PACKAGES/drude

## 2.84.3 Description

Apply two Langevin thermostats as described in ([Jiang1](#)) for thermalizing the reduced degrees of freedom of Drude oscillators. This link describes how to use the *thermalized Drude oscillator model* in LAMMPS and polarizable models in LAMMPS are discussed on the *Howto polarizable* doc page.

Drude oscillators are a way to simulate polarizable atoms, by splitting them into a core and a Drude particle bound by a harmonic bond. The thermalization works by transforming the particles degrees of freedom by these equations. In these equations upper case denotes atomic or center of mass values and lower case denotes Drude particle or dipole values. Primes denote the transformed (reduced) values, while bare letters denote the original values.

Velocities:

$$V' = \frac{M V + m v}{M'}$$

$$v' = v - V$$

Masses:

$$M' = M + m$$

$$m' = \frac{M m}{M'}$$

The Langevin forces are computed as

$$F' = -\frac{M'}{\text{damp}_{\text{com}}} V' + F'_r$$

$$f' = -\frac{m'}{\text{damp}_{\text{drude}}} v' + f'_r$$

$F'_r$  is a random force proportional to  $\sqrt{\frac{2 k_B T_{\text{com}} m'}{dt \text{damp}_{\text{com}}}}$ .  $f'_r$  is a random force proportional to  $\sqrt{\frac{2 k_B T_{\text{drude}} m'}{dt \text{damp}_{\text{drude}}}}$ . Then the real forces acting on the particles are computed from the inverse transform:

$$F = \frac{M}{M'} F' - f'$$

$$f = \frac{m}{M'} F' + f'$$

This fix also thermostats non-polarizable atoms in the group at temperature  $T_{\text{com}}$ , as if they had a massless Drude partner. The Drude particles themselves need not be in the group. The center of mass and the dipole are thermostatted iff the core atom is in the group.

Note that the thermostat effect of this fix is applied to only the translational degrees of freedom of the particles, which is an important consideration if finite-size particles, which have rotational degrees of freedom, are being thermostatted. The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

**Note:** Like the *fix langevin* command, this fix does NOT perform time integration. It only modifies forces to effect thermostating. Thus you must use a separate time integration fix, like *fix nve* or *fix nph* to actually update the velocities

and positions of atoms using the modified forces. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by *fix nvt* or *fix temp/rescale* commands.

---

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

---

This fix requires each atom know whether it is a Drude particle or not. You must therefore use the *fix drude* command to specify the Drude status of each atom type.

---

**Note:** only the Drude core atoms need to be in the group specified for this fix. A Drude electron will be transformed together with its cores even if it is not itself in the group. It is safe to include Drude electrons or non-polarizable atoms in the group. The non-polarizable atoms will simply be thermostatted as if they had a massless Drude partner (electron).

---

**Note:** Ghost atoms need to know their velocity for this fix to act correctly. You must use the *comm\_modify* command to enable this, e.g.

---

`comm_modify vel yes`

---

*Tcom* is the target temperature of the centers of mass, which would be used to thermostat the non-polarizable atoms. *Tdrude* is the (normally low) target temperature of the core-Drude particle pairs (dipoles). *Tcom* and *Tdrude* can be specified as an equal-style *variable*. If the value is a variable, it should be specified as *v\_name*, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Like other fixes that perform thermostatting, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Note: The temperature thermostatting the core-Drude particle pairs should be chosen low enough, so as to mimic as closely as possible the self-consistent minimization. It must however be high enough, so that the dipoles can follow the local electric field exerted by the neighboring atoms. The optimal value probably depends on the temperature of the centers of mass and on the mass of the Drude particles.

*damp\_com* is the characteristic time for reaching thermal equilibrium of the centers of mass. For example, a value of 100.0 means to relax the temperature of the centers of mass in a timespan of (roughly) 100 time units (tau or fs or ps - see the *units* command). *damp\_drude* is the characteristic time for reaching thermal equilibrium of the dipoles. It is typically a few timesteps.

The number *seed\_com* and *seed\_drude* are positive integers. They set the seeds of the Marsaglia random number generators used for generating the random forces on centers of mass and on the dipoles. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

---

The keyword *zero* can be used to eliminate drift due to the thermostat on centers of mass. Because the random forces on different centers of mass are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the momentum of the total center of mass of the system undergoes a slow random walk. If the keyword *zero* is set to *yes*, the total random force on the centers of mass is set exactly to zero by subtracting off an equal part of it from each center of mass in the group. As a result, the total center of mass of a system with zero initial momentum will not drift over time.

The actual temperatures of cores and Drude particles, in center-of-mass and relative coordinates, respectively, can be calculated using the *compute temp/drude* command.

Usage example for rigid bodies in the NPT ensemble:

```
comm_modify vel yes
fix TEMP all langevin/drude 300. 100. 1256 1. 20. 13977 zero yes
fix NPH ATOMS rigid/nph/small molecule iso 1. 1. 500.
fix NVE DRUDES nve
compute TDRUDE all temp/drude
thermo_style custom step cpu etotal ke pe ebond ecoul elong press vol temp c_TDRUDE[1] c_
→TDRUDE[2]
```

Comments:

- Drude particles should not be in the rigid group, otherwise the Drude oscillators will be frozen and the system will lose its polarizability.
- *zero yes* avoids a drift of the center of mass of the system, but is a bit slower.
- Use two different random seeds to avoid unphysical correlations.
- Temperature is controlled by the fix *langevin/drude*, so the time-integration fixes do not thermostat. Don't forget to time-integrate both cores and Drude particles.
- Pressure is time-integrated only once by using *nve* for Drude particles and *nph* for atoms/cores (or vice versa). Do not use *nph* for both.
- The temperatures of cores and Drude particles are calculated by *compute temp/drude*
- Contrary to the alternative thermostating using Nose-Hoover thermostat fix *npt* and fix *drude/transform*, the *fix\_modify* command is not required here, because the fix *nph* computes the global pressure even if its group is *ATOMS*. This is what we want. If we thermostatted *ATOMS* using *npt*, the pressure should be the global one, but the temperature should be only that of the cores. That's why the command *fix\_modify* should be called in that case.

## 2.84.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do "exact" restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a temperature *compute* you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by the compute should include the group of this fix and the Drude particles.

This fix is not invoked during *energy minimization*.

## 2.84.5 Restrictions

none

## 2.84.6 Related commands

*fix langevin, fix drude, fix drude/transform, compute temp/drude, pair\_style thole*

## 2.84.7 Default

The option defaults are zero = no.

keyword = *scale* or *tally* or *zero*

scale values = type ratio

type = atom type (1-N)

ratio = factor by which to scale the damping coefficient

tally values = *no* or *yes*

*no* = do not tally the energy added/subtracted to atoms

*yes* = do tally the energy added/subtracted to atoms

zero value = *no* or *yes*

*no* = do not set total random force to zero

*yes* = set total random force to zero

## 2.85.2 Examples

```
fix 3 boundary langevin/eff 1.0 1.0 10.0 699483
fix 1 all langevin/eff 1.0 1.1 10.0 48279 scale 3 1.5
```

## 2.85.3 Description

Apply a Langevin thermostat as described in (*Schneider*) to a group of nuclei and electrons in the *electron force field* model. Used with *fix nve/eff*, this command performs Brownian dynamics (BD), since the total force on each atom will have the form:

$$F = F_c + F_f + F_r$$

$$F_f = - \frac{m}{\text{damp}} v$$

$$F_r \propto \sqrt{\frac{k_B T m}{dt \text{ damp}}}$$

$F_c$  is the conservative force computed via the usual inter-particle interactions (*pair\_style*). The  $F_f$  and  $F_r$  terms are added by this fix on a per-particle basis.

The operation of this fix is exactly like that described by the *fix langevin* command, except that the thermostating is also applied to the radial electron velocity for electron particles.

## 2.85.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a temperature *compute* you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*, but only if the *tally* keyword is set to *yes*. See the *thermo\_style* page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”. Note that calculation of this quantity also requires setting the *tally* keyword to *yes*.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.85.5 Restrictions

none

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 2.85.6 Related commands

*fix langevin*

## 2.85.7 Default

The option defaults are scale = 1.0 for all types and tally = no.

**(Schneider)** Schneider and Stoll, Phys Rev B, 17, 1302 (1978).

## 2.86 fix langevin/spin command

### 2.86.1 Syntax

```
fix ID group-ID langevin/spin T Tdamp seed
```

- ID, group-ID are documented in *fix* command
- langevin/spin = style name of this fix command
- T = desired temperature of the bath (temperature units, K in metal units)
- Tdamp = transverse magnetic damping parameter (adim)
- seed = random number seed to use for white noise (positive integer)

### 2.86.2 Examples

```
fix 2 all langevin/spin 300.0 0.01 21
```

### 2.86.3 Description

Apply a Langevin thermostat as described in ([Mayergoyz](#)) to the magnetic spins associated to the atoms. Used with *fix nve/spin*, this command performs Brownian dynamics (BD). A random torque and a transverse dissipation are applied to each spin  $i$  according to the following stochastic differential equation:

$$\frac{d\vec{s}_i}{dt} = \frac{1}{(1 + \lambda^2)} ((\vec{\omega}_i + \vec{\eta}) \times \vec{s}_i + \lambda \vec{s}_i \times (\vec{\omega}_i \times \vec{s}_i))$$

with  $\lambda$  the transverse damping, and  $\vec{\eta}$  a random vector. This equation is referred to as the stochastic Landau-Lifshitz (sLL) equation.

The components of  $\eta$  are drawn from a Gaussian probability law. Their amplitude is defined as a proportion of the temperature of the external thermostat T (in K in metal units).

More details about this implementation are reported in ([Tranchida](#)).

Note: due to the form of the sLL equation, this fix has to be defined just before the nve/spin fix (and after all other magnetic fixes). As an example:

```
fix 1 all precession/spin zeeman 0.01 0.0 0.0 1.0
fix 2 all langevin/spin 300.0 0.01 21
fix 3 all nve/spin lattice moving
```

is correct, but defining a force/spin command after the langevin/spin command would give an error message.

Note: The random # *seed* must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

---

## 2.86.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

This fix is not invoked during *energy minimization*.

## 2.86.5 Restrictions

The *langevin/spin* fix is part of the SPIN package. This style is only enabled if LAMMPS was built with this package. See the [Build package](#) page for more info.

The numerical integration has to be performed with *fix nve/spin* when *fix langevin/spin* is enabled.

This fix has to be the last defined magnetic fix before the time integration fix (e.g. *fix nve/spin*).

## 2.86.6 Related commands

*fix nve/spin*, *fix precession/spin*

## 2.86.7 Default

none

## 2.87 fix lb/fluid command

### 2.87.1 Syntax

```
fix ID group-ID lb/fluid nevery viscosity density keyword values ...
```

- ID, group-ID are documented in *fix* command
- lb/fluid = style name of this fix command
- nevery = update the lattice-Boltzmann fluid every this many timesteps (should normally be 1)
- viscosity = the fluid viscosity (units of mass/(time\*length)).
- density = the fluid density.
- zero or more keyword/value pairs may be appended
- keyword = *dx* or *dm* or *noise* or *stencil* or *read\_restart* or *write\_restart* or *zwall\_velocity* or *pressurebcx* or *bodyforce* or *D3Q19* or *dumpxdf* or *linearInit* or *dof* or *scaleGamma* or *a0* or *npits* or *wp* or *sw*

*dx* values = *dx\_LB* = the lattice spacing.

*dm* values = *dm\_LB* = the lattice-Boltzmann mass unit.

*noise* values = Temperature seed

Temperature = fluid temperature.

seed = random number generator seed (positive integer)

*stencil* values = 2 (trilinear stencil, the default), 3 (3-point immersed boundary *↪stencil*), or 4 (4-point Keys' interpolation stencil)

*read\_restart* values = restart file = name of the restart file to use to restart a *↪fluid* run.

*write\_restart* values = N = write a restart file every N MD timesteps.

*zwall\_velocity* values = velocity\_bottom velocity\_top = velocities along the *↪y*-direction of the bottom and top walls (located at z=zmin and z=zmax).

*pressurebcx* values = pgradav = imposes a pressure jump at the (periodic) x-boundary *↪of* pgradav\*Lx\*1000.

*bodyforce* values = bodyforcex bodyforcey bodyforcez = the x,y and z components of a *↪constant* body force added to the fluid.

*D3Q19* values = none (used to switch from the default D3Q15, 15 velocity lattice, to *↪the* D3Q19, 19 velocity lattice).

*dumpxdf* values = N file timeI

N = output the force and torque every N timesteps

file = output file name

timeI = 1 (use simulation time to index xdmf file), 0 (use output frame number *↪to* index xdmf file)

*linearInit* values = none = initialize density and velocity using linear *↪interpolation* (default is uniform density, no velocities)

*dof* values = dof = specify the number of degrees of freedom for temperature *↪calculation*

*scaleGamma* values = type gammaFactor

type = atom type (1-N)

gammaFactor = factor to scale the *setGamma* gamma value by, for the specified *↪atom* type.

*a0* values = *a0\_real* = the square of the speed of sound in the fluid.

*npits* values = npits h\_p l\_p l\_pp l\_e

npits = number of pit regions

h\_p = z-height of pit regions (floor to bottom of slit)

`l_p` = x-length of pit regions  
`l_pp` = x-length of slit regions between consecutive pits  
`l_e` = x-length of slit regions at ends  
`wp` values = `w_p` = y-width of slit regions (defaults to full width if not present or `↪if sw active`)  
`sw` values = none (turns on y-sidewalls (in xz plane) if npits option active)

## 2.87.2 Examples

```

fix 1 all lb/fluid 1 1.0 0.0009982071 dx 1.2 dm 0.001
fix 1 all lb/fluid 1 1.0 0.0009982071 dx 1.2 dm 0.001 noise 300.0 2761
fix 1 all lb/fluid 1 1.0 1.0 dx 4.0 dm 10.0 dumpxdmf 500 fflow 0 pressurebcx 0.01 npits_
↪2 20 40 5 0 wp 30
  
```

## 2.87.3 Description

Changed in version 24Mar2022.

Implement a lattice-Boltzmann fluid on a uniform mesh covering the LAMMPS simulation domain. Note that this fix was updated in 2022 and is not backward compatible with the previous version. If you need the previous version, please download an older version of LAMMPS. The MD particles described by *group-ID* apply a velocity dependent force to the fluid.

The lattice-Boltzmann algorithm solves for the fluid motion governed by the Navier Stokes equations,

$$\begin{aligned}\partial_t \rho + \partial_\beta (\rho u_\beta) &= 0 \\ \partial_t (\rho u_\alpha) + \partial_\beta (\rho u_\alpha u_\beta) &= \partial_\beta \sigma_{\alpha\beta} + F_\alpha + \partial_\beta (\eta_{\alpha\beta\gamma\nu} \partial_\gamma u_\nu)\end{aligned}$$

with,

$$\eta_{\alpha\beta\gamma\nu} = \eta \left[ \delta_{\alpha\gamma} \delta_{\beta\nu} + \delta_{\alpha\nu} \delta_{\beta\gamma} - \frac{2}{3} \delta_{\alpha\beta} \delta_{\gamma\nu} \right] + \Lambda \delta_{\alpha\beta} \delta_{\gamma\nu}$$

where  $\rho$  is the fluid density,  $u$  is the local fluid velocity,  $\sigma$  is the stress tensor,  $F$  is a local external force, and  $\eta$  and  $\Lambda$  are the shear and bulk viscosities respectively. Here, we have implemented

$$\sigma_{\alpha\beta} = -P_{\alpha\beta} = -\rho a_0 \delta_{\alpha\beta}$$

with  $a_0$  set to  $\frac{1}{3} \frac{dx}{dt}^2$  by default. You should not normally need to change this default.

The algorithm involves tracking the time evolution of a set of partial distribution functions which evolve according to a velocity discretized version of the Boltzmann equation,

$$(\partial_t + e_{i\alpha} \partial_\alpha) f_i = -\frac{1}{\tau} (f_i - f_i^{eq}) + W_i$$

where the first term on the right hand side represents a single time relaxation towards the equilibrium distribution function, and  $\tau$  is a parameter physically related to the viscosity. On a technical note, we have implemented a 15 velocity model (D3Q15) as default; however, the user can switch to a 19 velocity model (D3Q19) through the use of the *D3Q19* keyword. Physical variables are then defined in terms of moments of the distribution functions,

$$\begin{aligned}\rho &= \sum_i f_i \\ \rho u_\alpha &= \sum_i f_i e_{i\alpha}\end{aligned}$$

Full details of the lattice-Boltzmann algorithm used can be found in [Denniston et al.](#).

The fluid is coupled to the MD particles described by *group-ID* through a velocity dependent force. The contribution to the fluid force on a given lattice mesh site  $j$  due to MD particle  $\alpha$  is calculated as:

$$\mathbf{F}_{j\alpha} = \gamma (\mathbf{v}_n - \mathbf{u}_f) \zeta_{j\alpha}$$

where  $\mathbf{v}_n$  is the velocity of the MD particle,  $\mathbf{u}_f$  is the fluid velocity interpolated to the particle location, and  $\gamma$  is the force coupling constant. This force, as with most forces in LAMMPS, and hence the velocities, are calculated at the half-time step.  $\zeta$  is a weight assigned to the grid point, obtained by distributing the particle to the nearest lattice sites.

The force coupling constant,  $\gamma$ , is calculated according to

$$\gamma = \frac{2m_u m_v}{m_u + m_v} \left( \frac{1}{\Delta t} \right)$$

Here,  $m_v$  is the mass of the MD particle,  $m_u$  is a representative fluid mass at the particle location, and  $\Delta t$  is the time step. The fluid mass  $m_u$  that the MD particle interacts with is calculated internally. This coupling is chosen to constrain the particle and associated fluid velocity to match at the end of the time step. As with other constraints, such as [shake](#), this constraint can remove degrees of freedom from the simulation which are accounted for internally in the algorithm.

---

**Note:** While this fix applies the force of the particles on the fluid, it does not apply the force of the fluid to the particles. There is only one option to include this hydrodynamic force on the particles, and that is through the use of the [lb/viscous](#) fix. This fix adds the hydrodynamic force to the total force acting on the particles, after which any of the built-in LAMMPS integrators can be used to integrate the particle motion. If the [lb/viscous](#) fix is NOT used to add the hydrodynamic force to the total force acting on the particles, this physically corresponds to a situation in which an infinitely massive particle is moving through the fluid (since collisions between the particle and the fluid do not act to change the particle's velocity). In this case, setting *scaleGamma* to -1 for the corresponding particle type will explicitly take this limit (of infinite particle mass) in computing the force coupling for the fluid force.

---

Physical parameters describing the fluid are specified through *viscosity* and *density*. These parameters should all be given in terms of the mass, distance, and time units chosen for the main LAMMPS run, as they are scaled by the LB timestep, lattice spacing, and mass unit, inside the fix.

The *dx* keyword allows the user to specify a value for the LB grid spacing and the *dm* keyword allows the user to specify the LB mass unit. Inside the fix, parameters are scaled by the lattice-Boltzmann timestep,  $dt_{LB}$ , grid spacing,  $dx_{LB}$ , and mass unit,  $dm_{LB}$ .  $dt_{LB}$  is set equal to  $nevery \cdot dt_{MD}$ , where  $dt_{MD}$  is the MD timestep. By default,  $dm_{LB}$  is set equal to 1.0, and  $dx_{LB}$  is chosen so that  $\frac{\tau}{dt} = \frac{3\eta dt}{\rho dx^2}$  is approximately equal to 1.

---

**Note:** Care must be taken when choosing both a value for  $dx_{LB}$ , and a simulation domain size. This fix uses the same subdivision of the simulation domain among processors as the main LAMMPS program. In order to uniformly cover the simulation domain with lattice sites, the lengths of the individual LAMMPS subdomains must all be evenly divisible by  $dx_{LB}$ . If the simulation domain size is cubic, with equal lengths in all dimensions, and the default value for  $dx_{LB}$  is used, this will automatically be satisfied.

---

If the *noise* keyword is used, followed by a positive temperature value, and a positive integer random number seed, the thermal LB algorithm of [Adhikari et al.](#) is used.

If the keyword *stencil* is used, the value sets the number of interpolation points used in each direction. For this, the user has the choice between a trilinear stencil (*stencil* 2), which provides a support of 8 lattice sites, or the 3-point immersed boundary method stencil (*stencil* 3), which provides a support of 27 lattice sites, or the 4-point Keys' interpolation stencil (*stencil* 4), which provides a support of 64 lattice sites. The trilinear stencil is the default as it is better suited for simulation of objects close to walls or other objects, due to its smaller support. The 3-point stencil provides smoother motion of the lattice and is suitable for particles not likely to be too close to walls or other objects.

If the keyword *write\_restart* is used, followed by a positive integer, N, a binary restart file is printed every N LB timesteps. This restart file only contains information about the fluid. Therefore, a LAMMPS restart file should also be written in order to print out full details of the simulation.

---

**Note:** When a large number of lattice grid points are used, the restart files may become quite large.

---

In order to restart the fluid portion of the simulation, the keyword *read\_restart* is specified, followed by the name of the binary lb\_fluid restart file to be used.

If the *zwall\_velocity* keyword is used y-velocities are assigned to the lower and upper walls. This keyword requires the presence of walls in the z-direction. This is set by assigning fixed boundary conditions in the z-direction. If fixed boundary conditions are present in the z-direction, and this keyword is not used, the walls are assumed to be stationary.

If the *pressurebcx* keyword is used, a pressure jump (implemented by a step jump in density) is imposed at the (periodic) x-boundary. The value set specifies what would be the resulting equilibrium average pressure gradient in the x-direction if the system had a constant cross-section (i.e. resistance to flow). It is converted to a pressure jump by multiplication by the system size in the x-direction. As this value should normally be quite small, it is also assumed to be scaled by 1000.

If the *bodyforce* keyword is used, a constant body force is added to the fluid, defined by it's x, y and z components.

If the keyword *D3Q19* is used, the 19 velocity (D3Q19) lattice is used by the lattice-Boltzmann algorithm. By default, the 15 velocity (D3Q15) lattice is used.

If the *dumpxdmf* keyword is used, followed by a positive integer, N, and a file name, the fluid densities and velocities at each lattice site are output to an xdmf file every N timesteps. This is a binary file format that can be read by visualization packages such as [Paraview](#). The xdmf file format contains a time index for each frame dump and the value *timeI* = 1 uses simulation time while 0 uses the output frame number to index xdmf file. The later can be useful if the *dump vtk* command is used to output the particle positions at the same timesteps and you want to visualize both the fluid and particle data together in [Paraview](#).

The *scaleGamma* keyword allows the user to scale the  $\gamma$  value by a factor, *gammaFactor*, for a given atom type. Setting *scaleGamma* to -1 for the corresponding particle type will explicitly take the limit of infinite particle mass in computing the force coupling for the fluid force (see note above).

If the *a0* keyword is used, the value specified is used for the square of the speed of sound in the fluid. If this keyword is not present, the speed of sound squared is set equal to  $\frac{1}{3} \left( \frac{dx_{LB}}{dt_{LB}} \right)^2$ . Setting  $a0 > \left( \frac{dx_{LB}}{dt_{LB}} \right)^2$  is not allowed, as this may lead to instabilities. As the speed of sound should usually be much larger than any fluid velocity of interest, its value does not normally have a significant impact on the results. As such, it is usually best to use the default for this option.

The *npits* keyword (followed by integer arguments: *npits*, *h\_p*, *l\_p*, *l\_pp*, *l\_e*) sets the fluid domain to the pits geometry. These arguments should only be used if you actually want something more complex than a rectangular/cubic geometry. The *npits* value sets the number of pits regions (arranged along x). The remaining arguments are sizes measured in multiples of *dx\_lb*: *h\_p* is the z-height of the pit regions, *l\_p* is the x-length of the pit regions, *l\_pp* is the length of the region between consecutive pits (referred to as a "slit" region), and *l\_e* is the x-length of the slit regions at each end of the channel. The pit geometry must fill the system in the x-direction but can be longer, in which case it is truncated (which enables asymmetric entrance/exit end sections). The additional *wp* keyword allows the width (in y-direction) of the pit to be specified (the default is full width) and the *sw* keyword indicates that there should be sidewalls in the y-direction (default is periodic in y-direction). These parameters are illustrated below:

Sideview (in xz plane) of pit geometry:

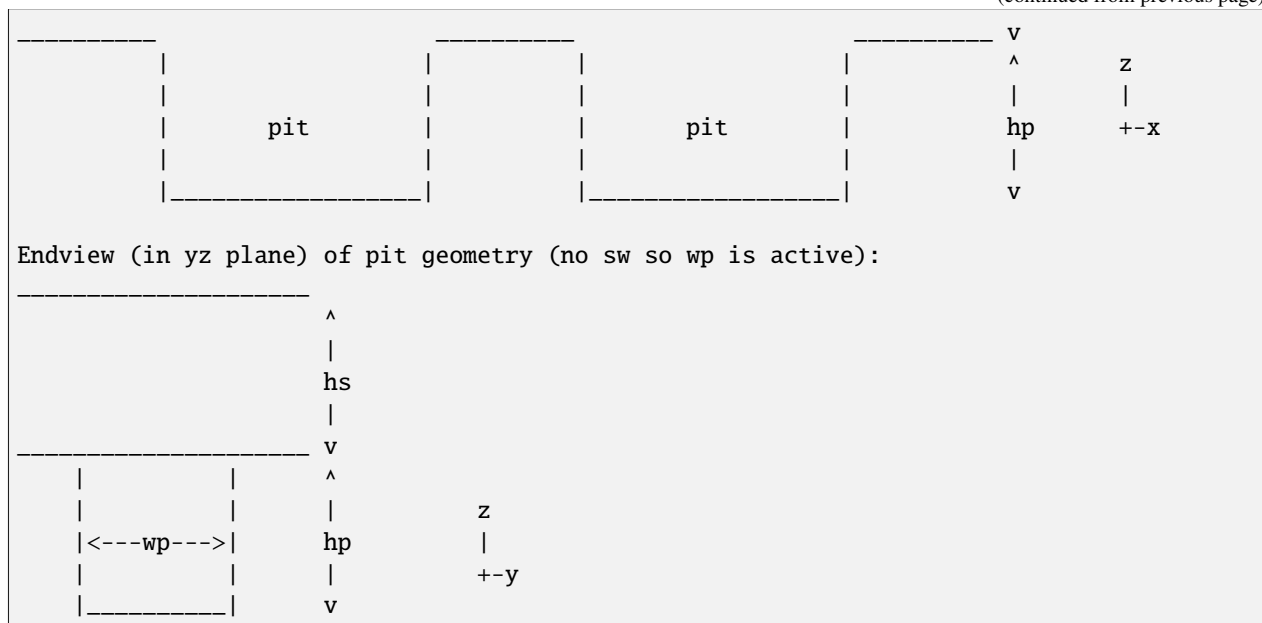

```

slit                slit                slit      ^
|
<---le---><-----lp-----><---lpp---><-----lp-----><---le---> hs = (Nbz-1) - hp
|

```

(continues on next page)

(continued from previous page)

For further details, as well as descriptions and results of several test runs, see [Denniston et al.](#). Please include a citation to this paper if the `lb_fluid` fix is used in work contributing to published research.

## 2.87.4 Restart, fix\_modify, output, run start/stop, minimize info

Due to the large size of the fluid data, this fix writes its own binary restart files, if requested, independent of the main LAMMPS *binary restart files*; no information about `lb_fluid` is written to the main LAMMPS *binary restart files*.

None of the `fix_modify` options are relevant to this fix.

The fix computes a global scalar which can be accessed by various *output commands*. The scalar is the current temperature of the group of particles described by *group-ID* along with the fluid constrained to move with them. The temperature is computed via the kinetic energy of the group and fluid constrained to move with them and the total number of degrees of freedom (calculated internally). If the particles are not integrated independently (such as via *fix NVE*) but have additional constraints imposed on them (such as via integration using *fix rigid*) the degrees of freedom removed from these additional constraints will not be properly accounted for. In this case, the user can specify the total degrees of freedom independently using the *dof* keyword.

The fix also computes a global array of values which can be accessed by various *output commands*. There are 5 entries in the array. The first entry is the temperature of the fluid, the second entry is the total mass of the fluid plus particles, the third through fifth entries give the x, y, and z total momentum of the fluid plus particles.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.87.5 Restrictions

This fix is part of the LATBOLTZ package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix can only be used with an orthogonal simulation domain.

The boundary conditions for the fluid are specified independently to the particles. However, these should normally be specified consistently via the main LAMMPS [boundary](#) command (p p p, p p f, and p f f are the only consistent possibilities). Shrink-wrapped boundary conditions are not permitted with this fix.

This fix must be used before any of [fix lb/viscous](#) and [fix lb/momentum](#) as the fluid needs to be initialized before any of these routines try to access its properties. In addition, in order for the hydrodynamic forces to be added to the particles, this fix must be used in conjunction with the [lb/viscous](#) fix.

This fix needs to be used in conjunction with a standard LAMMPS integrator such as [fix NVE](#) or [fix rigid](#).

## 2.87.6 Related commands

[fix lb/viscous](#), [fix lb/momentum](#)

## 2.87.7 Default

$dx$  is chosen such that  $\frac{\tau}{dt_{LB}} = \frac{3\eta dt_{LB}}{\rho dx_{LB}^2}$  is approximately equal to 1.  $dm$  is set equal to 1.0.  $a0$  is set equal to  $\frac{1}{3} \left( \frac{dx_{LB}}{dt_{LB}} \right)^2$ . The trilinear stencil is used as the default interpolation method. The D3Q15 lattice is used for the lattice-Boltzmann algorithm.

## 2.88 fix lb/momentum command

### 2.88.1 Syntax

```
fix ID group-ID lb/momentum nevery keyword values ...
```

- ID, group-ID are documented in the [fix](#) command
- lb/momentum = style name of this fix command
- nevery = adjust the momentum every this many timesteps
- zero or more keyword/value pairs may be appended
- keyword = *linear*

```
linear values = xflag yflag zflag  
xflag,yflag,zflag = 0/1 to exclude/include each dimension.
```

## 2.88.2 Examples

```
fix 1 sphere lb/momentum  
fix 1 all lb/momentum linear 1 1 0
```

## 2.88.3 Description

This fix is based on the *fix momentum* command, and was created to be used in place of that command, when a lattice-Boltzmann fluid is present.

Zero the total linear momentum of the system, including both the atoms specified by group-ID and the lattice-Boltzmann fluid every nevery timesteps. If there are no atoms specified by group-ID only the fluid momentum is affected. This is accomplished by adjusting the particle velocities and the fluid velocities at each lattice site.

---

**Note:** This fix only considers the linear momentum of the system.

---

By default, the subtraction is performed for each dimension. This can be changed by specifying the keyword *linear*, along with a set of three flags set to 0/1 in order to exclude/ include the corresponding dimension.

## 2.88.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.88.5 Restrictions

Can only be used if a lattice-Boltzmann fluid has been created via the *fix lb/fluid* command, and must come after this command.

This fix is part of the LATBOLTZ package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.88.6 Related commands

*fix momentum*, *fix lb/fluid*

## 2.88.7 Default

Zeros the total system linear momentum in each dimension.

## 2.89 fix lb/viscous command

### 2.89.1 Syntax

```
fix ID group-ID lb/viscous
```

- ID, group-ID are documented in *fix* command
- lb/viscous = style name of this fix command

### 2.89.2 Examples

```
fix 1 flow lb/viscous
```

### 2.89.3 Description

This fix is similar to the *fix viscous* command, and is to be used in place of that command when a lattice-Boltzmann fluid is present using the *fix lb/fluid*. This should be used in conjunction with one of the built-in LAMMPS integrators, such as *fix NVE* or *fix rigid*.

This fix adds a viscous force to each atom to cause it move with the same velocity as the fluid (an equal and opposite force is applied to the fluid via *fix lb/fluid*). When *fix lb/fluid* is called with the noise option, the atoms will also experience random forces which will thermalize them to the same temperature as the fluid. In this way, the combination of this fix with *fix lb/fluid* and a LAMMPS integrator like *fix NVE* is analogous to *fix langevin* except here the fluid is explicit. The temperature of the particles can be monitored via the scalar output of *fix lb/fluid*.

---

For details of this fix, as well as descriptions and results of several test runs, see *Denniston et al.*. Please include a citation to this paper if this fix is used in work contributing to published research.

---

### 2.89.4 Restart, fix\_modify, output, run start/stop, minimize info

As described in the *fix viscous* documentation:

“No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the *min\_style* command for details.”

### 2.89.5 Restrictions

This fix is part of the LATBOLTZ package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Can only be used if a lattice-Boltzmann fluid has been created via the [fix lb/fluid](#) command, and must come after this command.

### 2.89.6 Related commands

[fix lb/fluid](#)

### 2.89.7 Default

**(Denniston et al.)** Denniston, C., Afrasiabian, N., Cole-Andre, M.G., Mackay, F. E., Ollila, S.T.T., and Whitehead, T., LAMMPS lb/fluid fix version 2: Improved Hydrodynamic Forces Implemented into LAMMPS through a lattice-Boltzmann fluid, Computer Physics Communications 275 (2022) [108318](#).

## 2.90 fix lineforce command

### 2.90.1 Syntax

```
fix ID group-ID lineforce x y z
```

- ID, group-ID are documented in [fix](#) command
- lineforce = style name of this fix command
- x y z = direction of line as a 3-vector

### 2.90.2 Examples

```
fix hold boundary lineforce 0.0 1.0 1.0
```

### 2.90.3 Description

Adjust the forces on each atom in the group so that only the component of force along the linear direction specified by the vector (x,y,z) remains. This is done by subtracting out components of force in the plane perpendicular to the line.

If the initial velocity of the atom is 0.0 (or along the line), then it should continue to move along the line thereafter.

## 2.90.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

## 2.90.5 Restrictions

none

## 2.90.6 Related commands

*fix plane-force*

## 2.90.7 Default

none

# 2.91 fix manifoldforce command

## 2.91.1 Syntax

```
fix ID group-ID manifoldforce manifold manifold-args ...
```

- ID, group-ID are documented in *fix* command
- manifold = name of the manifold
- manifold-args = parameters for the manifold

## 2.91.2 Examples

```
fix constrain all manifoldforce sphere 5.0
```

## 2.91.3 Description

This fix subtracts each time step from the force the component along the normal of the specified *manifold*. This can be used in combination with *minimize* to remove overlap between particles while keeping them (roughly) constrained to the given manifold, e.g. to set up a run with *fix nve/manifold/rattle*. I have found that only *hftn* and *quickmin* with a very small time step perform adequately though.

---

## 2.91.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is invoked during *energy minimization*.

---

## 2.91.5 Restrictions

This fix is part of the MANIFOLD package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Only use this with *min\_style hfqn* or *min\_style quickmin*. If not, the constraints will not be satisfied very well at all. A warning is generated if the *min\_style* is incompatible but no error.

---

## 2.91.6 Related commands

fix 1 all mdi/qm
fix 1 all mdi/qm virial yes
fix 1 all mdi/qm add no every 100 elements C C H O
```

## 2.92.3 Description

New in version 3Aug2022.

This command enables LAMMPS to act as a client with another server code that will compute the total energy, per-atom forces, and total virial for atom conformations and simulation box size/shapes that LAMMPS sends it.

Typically the server code will be a quantum mechanics (QM) code, hence the name of the fix. However this is not required, the server code could be another classical molecular dynamics code or LAMMPS itself. The server code must support use of the [MDI Library](#) as explained below.

Typically, to use this fix, the input script should not define any other classical force field components, e.g. a pair style, bond style, etc.

These are example use cases for this fix, discussed further below:

- perform an ab initio MD (AIMD) simulation with quantum forces
- perform an energy minimization with quantum forces
- perform a nudged elastic band (NEB) calculation with quantum forces
- perform a QM calculation for a series of independent systems which LAMMPS reads or generates once
- run a classical MD simulation and calculate QM energy/forces once every N steps on the current configuration

More generally any command which calculates per-atom forces can instead use quantum forces by defining this fix. Examples are the Monte Carlo commands *fix gcmc* and *fix atom/swap*, as well as the *compute born/matrix* command. The only requirement is that internally the command invokes the `post_force()` method of fixes such as this one, which will trigger the quantum calculation.

The code coupling performed by this command is done via the [MDI Library](#). LAMMPS runs as an MDI driver (client), and sends MDI commands to an external MDI engine code (server), e.g. a QM code which has support for MDI. See the [Howto mdi](#) page for more information about how LAMMPS can operate as either an MDI driver or engine.

The `examples/mdi` directory contains input scripts using this fix in the various use cases discussed below. In each case, two instances of LAMMPS are used, once as an MDI driver, once as an MDI engine (surrogate for a QM code). The `examples/mdi/README` file explains how to launch two codes so that they communicate via the MDI library using either MPI or sockets. Any QM code that supports MDI could be used in place of LAMMPS acting as a QM surrogate. See the [Howto mdi](#) page for a current list (March 2022) of such QM codes. The `examples/QUANTUM` directory has examples for coupling LAMMPS to 3 QM codes either via this fix or the *fix mdi/qmmm* command.

Note that an engine code can support MDI in either or both of two modes. It can be used as a stand-alone code, launched at the same time as LAMMPS. Or it can be used as a plugin library, which LAMMPS loads. See the *mdi plugin* command for how to trigger LAMMPS to load a plugin library. The `examples/mdi/README` file and `examples/QUANTUM/QM-code/README` files explain how to launch the two codes in either mode.

The *virial* keyword setting of yes or no determines whether LAMMPS will request the QM code to also compute and return the QM contribution to a stress tensor for the system which LAMMPS will convert to a 6-element symmetric virial tensor.

The *add* keyword setting of *yes* or *no* determines whether the energy and forces and virial returned by the QM code will be added to the LAMMPS internal energy and forces and virial or not. If the setting is *no* then the default *fix\_modify energy* and *fix\_modify virial* settings are also set to *no* and your input scripts should not set them to *yes*. See more details on these *fix\_modify* settings below.

Whatever the setting for the *add* keyword, the QM energy, forces, and virial will be stored by the fix, so they can be accessed by other commands. See details below.

The *every* keyword determines how often the QM code will be invoked during a dynamics run with the current LAMMPS simulation box and configuration of atoms. The QM code will be called once every *Nevery* timesteps. By default *Nevery* = 1.

The *connect* keyword determines whether this fix performs a one-time connection to the QM code. The default is *yes*. The only time a *no* is needed is if this command is used multiple times in an input script and the MDI coupling is between two stand-alone codes (not plugin mode). E.g. if it used inside a loop which also uses the *clear* command to destroy the system (including this fix). See the `examples/mdi/in.series.driver` script as an example of this, where LAMMPS is using the QM code to compute energy and forces for a series of system configurations. In this use case *connect no* is used along with the *mdi connect and exit* command to one-time initiate/terminate the connection outside the loop.

The *elements* keyword allows specification of what element each LAMMPS atom type corresponds to. This is specified by the chemical symbol of the element, e.g. C or Al or Si. A symbol must be specified for each of the ntypes LAMMPS atom types. Multiple LAMMPS types can represent the same element. Ntypes is typically specified via the *create\_box* command or in the data file read by the *read\_data* command.

If this keyword is specified, then this fix will send the MDI ">ELEMENTS" command to the engine, to ensure the two codes are consistent in their definition of atomic species. If this keyword is not specified, then this fix will send the MDI >TYPES command to the engine. This is fine if both the LAMMPS driver and the MDI engine are initialized so that the atom type values are consistent in both codes.

The *mc* keyword enables this fix to be used with a Monte Carlo (MC) fix to calculate before/after quantum energies as part of the MC accept/reject criterion. The *fix gcmc* and *fix atom/swap* commands can be used in this manner. Specify the ID of the MC fix following the *mc* keyword. This allows the two fixes to coordinate when MC events are being calculated versus MD timesteps between the MC events.

---

The following 3 example use cases are illustrated in the `examples/mdi` directory. See its README file for more details.

(1) To run an ab initio MD (AIMD) dynamics simulation, or an energy minimization with QM forces, or a multi-replica NEB calculation, use *add yes* and *every 1* (the defaults). This is so that every time LAMMPS needs energy and forces, the QM code will be invoked.

Both LAMMPS and the QM code should define the same system (simulation box, atoms and their types) in their respective input scripts. Note that on this scenario, it may not be necessary for LAMMPS to define a pair style or use a neighbor list.

LAMMPS will then perform the timestepping or minimization iterations for the simulation. At the point in each timestep or iteration when LAMMPS needs the force on each atom, it communicates with the engine code. It sends the current simulation box size and shape (if they change dynamically, e.g. during an NPT simulation), and the current atom coordinates. The engine code computes quantum forces on each atom and the total energy of the system and returns them to LAMMPS.

Note that if the AIMD simulation is an NPT or NPH model, or the energy minimization includes *fix box relax* to equilibrate the box size/shape, then LAMMPS computes a pressure. This means the *virial* keyword should be set to *yes* so that the QM contribution to the pressure can be included.

(2) To run dynamics with a LAMMPS interatomic potential, and evaluate the QM energy and forces once every 1000 steps, use *add no* and *every 1000*. This could be useful for using an MD run to generate randomized configurations

which are then passed to the QM code to produce training data for a machine learning potential. A *dump custom* command could be invoked every 1000 steps to dump the atom coordinates and QM forces to a file. Likewise the QM energy and virial could be output with the *thermo\_style custom* command.

(3) To do a QM evaluation of energy and forces for a series of  $N$  independent systems (simulation box and atoms), use *add no* and *every 1*. Write a LAMMPS input script which loops over the  $N$  systems. See the *Howto multiple* doc page for details on looping and removing old systems. The series of systems could be initialized by reading them from data files with *read\_data* commands. Or, for example, by using the *lattice*, *create\_atoms*, *delete\_atoms*, and/or *displace\_atoms random* commands to generate a series of different systems. At the end of the loop perform *run 0* and *write\_dump* commands to invoke the QM code and output the QM energy and forces. As in (2) this be useful to produce QM data for training a machine learning potential.

---

#### 2.92.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy computed by the QM code to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy yes*, unless the *add* keyword is set to *no*, in which case the default setting is *no*.

The *fix\_modify virial* option is supported by this fix to add the contribution computed by the QM code to the global pressure of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*, unless the *add* keyword is set to *no*, in which case the default setting is *no*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the energy returned by the QM code. The scalar value calculated by this fix is “extensive”.

This fix also computes a global vector with of length 6 which contains the symmetric virial tensor values returned by the QM code. It can likewise be accessed by various *output commands*.

The ordering of values in the symmetric virial tensor is as follows: vxx, vyy, vzz, vxy, vxz, vyz. The values will be in pressure *units*.

This fix also computes a peratom array with 3 columns which contains the peratom forces returned by the QM code. It can likewise be accessed by various *output commands*.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

Assuming the *add* keyword is set to *yes* (the default), the forces computed by the QM code are used during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the potential energy associated with the QM forces to be included in the total potential energy of the system (the quantity being minimized), you **MUST** not disable the *fix\_modify energy* option for this fix, which means the *add* keyword should also be set to *yes* (the default).

---

## 2.92.5 Restrictions

This fix is part of the MDI package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

To use LAMMPS as an MDI driver in conjunction with other MDI-enabled codes (MD or QM codes), the [units](#) command should be used to specify *real* or *metal* units. This will ensure the correct unit conversions between LAMMPS and MDI units. The other code will also perform similar unit conversions into its preferred units.

LAMMPS can also be used as an MDI driver in other unit choices it supports, e.g. *lj*, but then no unit conversion to MDI units is performed.

If this fix is used in conjunction with a QM code that does not support periodic boundary conditions (more specifically, a QM code that does not support the >CELL MDI command), the LAMMPS system must be fully non-periodic. I.e. no dimension of the system can be periodic.

## 2.92.6 Related commands

*mdi plugin, mdi engine, fix mdi/qmmm*

## 2.92.7 Default

The default for the optional keywords are virial = no, add = yes, every = 1, connect = yes.

# 2.93 fix mdi/qmmm command

## 2.93.1 Syntax

```
fix ID group-ID mdi/qmmm mode keyword value(s) keyword value(s) ...
```

- ID, group-ID are documented in [fix](#) command
- mdi/qmmm = style name of this fix command
- mode = *direct* or *potential*
- zero or more keyword/value pairs may be appended
- keyword = *virial* or *add* or *every* or *connect* or *elements*

*virial* args = *yes* or *no*

yes = request virial tensor from server code

no = do not request virial tensor from server code

*connect* args = *yes* or *no*

yes = perform a one-time connection to the MDI engine code

no = do not perform the connection operation

*elements* args = N\_1 N\_2 ... N\_ntypes

N\_1,N\_2,...N\_ntypes = chemical symbol for each of ntypes LAMMPS atom types

## 2.93.2 Examples

```
fix 1 all mdi/qmmm direct
fix 1 all mdi/qmmm potential virial yes
fix 1 all mdi/qmmm potential virial yes elements 13 29
```

## 2.93.3 Description

New in version 28Mar2023.

This command enables LAMMPS to act as a client with another server code to perform a coupled QM/MM (quantum-mechanics/molecular-mechanics) simulation. LAMMPS will perform classical MD (molecular mechanics or MM) for the (typically larger) MM portion of the system. A quantum mechanics code will calculate quantum energy and forces for the QM portion of the system. The two codes work together to calculate the energy and forces due to the cross interactions between QM and MM atoms. The QM server code must support use of the [MDI Library](#) as explained below.

The partitioning of the system between QM and MM atoms is as follows. Atoms in the specified group are QM atoms; the remaining atoms are MM atoms. The input script should thus define this partitioning. See additional information below about other requirements for an input script to use this fix and perform a QM/MM simulation.

The code coupling performed by this command is done via the [MDI Library](#). LAMMPS runs as an MDI driver (client), and sends MDI commands to an external MDI engine code (server), in this case a QM code which has support for MDI. See the [Howto mdi](#) page for more information about how LAMMPS can operate as either an MDI driver or engine.

The `examples/QUANTUM` directory has sub-directories with example input scripts using this fix in tandem with different QM codes. The README files in the sub-directories explain how to download and build the various QM codes. They also explain how to launch LAMMPS and the QM code so that they communicate via the MDI library using either MPI or sockets. Any QM code that supports MDI could be used in addition to those discussed in the sub-directories. See the [Howto mdi](#) page for a current list (March 2022) of such QM codes.

Note that an engine code can support MDI in either or both of two modes. It can be used as a stand-alone code, launched at the same time as LAMMPS. Or it can be used as a plugin library, which LAMMPS loads. See the [mdi plugin](#) command for how to trigger LAMMPS to load a plugin library. The `examples/QUANTUM` sub-directory README files explains how to launch the two codes in either mode.

The *mode* setting determines which QM/MM coupling algorithm is used. LAMMPS currently supports *direct* and *potential* algorithms, based on the *mode* setting. Both algorithms should give reasonably accurate results, but some QM codes support only one of the two modes. E.g. in the `examples/QUANTUM` directory, PySCF supports only *direct*, NWChem supports only *potential*, and LATTE currently supports neither, so it cannot be used for QM/MM simulations using this fix.

The *direct* option passes the coordinates and charges of each MM atom to the quantum code, in addition to the coordinates of each QM atom. The quantum code returns forces on each QM atom as well as forces on each MM atom. The latter is effectively the force on MM atoms due to the QM atoms.

The input script for performing a *direct* mode QM/MM simulation should do the following:

- delete all bonds (angles, dihedrals, etc) between QM atoms
- set the charge on each QM atom to zero
- define no bonds (angles, dihedrals, etc) which involve both QM and MM atoms
- define a force field (pair, bonds, angles, optional kspace) for the entire system

The first two bullet can be performed using the *delete\_bonds* and *set* commands.

The third bullet is required to have a consistent model, but is not checked by LAMMPS.

The fourth bullet implies that non-bonded non-Coulombic interactions (e.g. van der Waals) between QM/QM and QM/MM pairs of atoms are computed by LAMMPS.

See the `examples/QUANTUM/PySCF/in.*` files for examples of input scripts for QM/MM simulations using the *direct* mode.

The *potential* option passes the coordinates of each QM atom and a Coulomb potential for each QM atom to the quantum code. The latter is calculated by performing a Coulombics-only calculation for the entire system, subtracting all QM/QM pairwise Coulombic terms, and dividing the Coulomb energy on each QM atom by the charge of the QM atom. The potential value represents the Coulombic influence of all the MM atoms on each QM atom.

The quantum code returns forces and charge on each QM atom. The new charges on the QM atom are used to recalculate the MM force field, resulting in altered forces on the MM atoms.

The input script for performing a *potential* mode QM/MM simulation should do the following:

- delete all bonds (angles, dihedrals, etc) between QM atoms
- define a hybrid pair style which includes a Coulomb-only pair sub-style
- define no bonds (angles, dihedrals, etc) which involve both QM and MM atoms
- define a force field (pair, bonds, angles, optional kspace) for the entire system

The first operation can be performed using the *delete\_bonds* command. See the `examples/QUANTUM/NWChem/in.*` files for examples of how to do this.

The second operation is necessary so that this fix can calculate the Coulomb potential for the QM atoms.

The third bullet is required to have a consistent model, but is not checked by LAMMPS.

The fourth bullet implies that non-bonded non-Coulombic interactions (e.g. van der Waals) between QM/QM and QM/MM pairs of atoms are computed by LAMMPS. However, some QM codes do not want the MM code (LAMMPS) to compute QM/QM van der Waals interactions. NWChem is an example. In this case, the coefficients for those interactions need to be turned off, which typically requires the atom types for the QM atoms be different than those for the MM atoms.

See the `examples/QUANTUM/NWChem/in.*` files for examples of input scripts for QM/MM simulations using the *potential* mode. Those scripts also illustrate how to turn off QM/QM van der Waals interactions.

---

The *virial* keyword setting of yes or no determines whether LAMMPS will request the QM code to also compute and return the QM contribution to a stress tensor for the system which LAMMPS will convert to a 6-element symmetric virial tensor.

The *connect* keyword determines whether this fix performs a one-time connection to the QM code. The default is *yes*. The only time a *no* is needed is if this command is used multiple times in an input script. E.g. if it used inside a loop which also uses the *clear* command to destroy the system (including this fix). As example would be a script which loop over a series of independent QM/MM simulations, e.g. each with their own data file. In this use case *connect no* could be used along with the *mdi connect and exit* command to one-time initiate/terminate the connection outside the loop.

The *elements* keyword allows specification of what element each LAMMPS atom type corresponds to. This is specified by the chemical symbol of the element, e.g. C or Al or Si. A symbol must be specified for each of the ntypes LAMMPS atom types. Multiple LAMMPS types can represent the same element. Ntypes is typically specified via the *create\_box* command or in the data file read by the *read\_data* command.

If this keyword is specified, then this fix will send the MDI ">ELEMENTS" command to the engine, to insure the two codes are consistent in their definition of atomic species. If this keyword is not specified, then this fix will send the

MDI >TYPES command to the engine. This is fine if both the LAMMPS driver and the MDI engine are initialized so that the atom type values are consistent in both codes.

---

### 2.93.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy computed by the QM code to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy yes*.

The *fix\_modify virial* option is supported by this fix to add the contribution computed by the QM code to the global pressure of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the energy returned by the QM code. The scalar value calculated by this fix is “extensive”.

This fix also computes a global vector with of length 6 which contains the symmetric virial tensor values returned by the QM code. It can likewise be accessed by various *output commands*.

The ordering of values in the symmetric virial tensor is as follows: vxx, vyy, vzz, vxy, vxz, vyz. The values will be in pressure *units*.

This fix also computes a peratom array with 3 columns which contains the peratom forces returned by the QM code. It can likewise be accessed by various *output commands*. Note that for *direct* mode this will be quantum forces on both QM and MM atoms. For *potential* mode it will only be quantum forces on QM atoms; the forces for MM atoms will be zero.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces computed by the QM code are used during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the potential energy associated with the QM forces to be included in the total potential energy of the system (the quantity being minimized), you MUST not disable the *fix\_modify energy* option for this fix.

---

### 2.93.5 Restrictions

This command is part of the MDI package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

To use LAMMPS as an MDI driver in conjunction with other MDI-enabled codes (MD or QM codes), the *units* command should be used to specify *real* or *metal* units. This will ensure the correct unit conversions between LAMMPS and MDI units. The other code will also perform similar unit conversions into its preferred units.

If this fix is used in conjunction with a QM code that does not support periodic boundary conditions (more specifically, a QM code that does not support the >CELL MDI command), the LAMMPS system must be fully non-periodic. I.e. no dimension of the system can be periodic.

fix 2 boundary meso/move variable v_myx v_myy NULL v_VX v_VY NULL
```

### 2.94.3 Description

Perform updates of position, velocity, internal energy and local density for mesoscopic particles in the group each timestep using the specified settings or formulas, without regard to forces on the particles. This can be useful for boundary, solid bodies or other particles, whose movement can influence nearby particles.

The operation of this fix is exactly like that described by the *fix move* command, except that particles' density, internal energy and extrapolated velocity are also updated.

---

**Note:** The particles affected by this fix should not be time integrated by other fixes (e.g. *fix sph*, *fix sph/stationary*), since that will change their positions and velocities twice.

---

---

**Note:** As particles move due to this fix, they will pass through periodic boundaries and be remapped to the other side of the simulation box, just as they would during normal time integration (e.g. via the *fix sph* command). It is up to you to decide whether periodic boundaries are appropriate with the kind of particle motion you are prescribing with this fix.

---

---

**Note:** As discussed below, particles are moved relative to their initial position at the time the fix is specified. These initial coordinates are stored by the fix in “unwrapped” form, by using the image flags associated with each particle. See the *dump custom* command for a discussion of “unwrapped” coordinates. See the Atoms section of the *read\_data* command for a discussion of image flags and how they are set for each particle. You can reset the image flags (e.g. to 0) before invoking this fix by using the *set image* command.

---

The *linear* style moves particles at a constant velocity, so that their position  $X = (x,y,z)$  as a function of time is given in vector notation as

$$X(t) = X_0 + V * \text{delta}$$

where  $X_0 = (x_0,y_0,z_0)$  is their position at the time the fix is specified,  $V$  is the specified velocity vector with components  $(V_x,V_y,V_z)$ , and  $\text{delta}$  is the time elapsed since the fix was specified. This style also sets the velocity of each particle to  $V = (V_x,V_y,V_z)$ . If any of the velocity components is specified as NULL, then the position and velocity of that component is time integrated the same as the *fix sph* command would perform, using the corresponding force component on the particle.

Note that the *linear* style is identical to using the *variable* style with an *equal-style variable* that uses the *vdisplace()* function. E.g.

```
variable V equal 10.0
variable x equal vdisplace(0.0,$V)
fix 1 boundary move variable v_x NULL NULL v_V NULL NULL
```

The *wiggle* style moves particles in an oscillatory fashion, so that their position  $X = (x,y,z)$  as a function of time is given in vector notation as

$$X(t) = X_0 + A \sin(\omega * \text{delta})$$

where  $X_0 = (x_0,y_0,z_0)$  is their position at the time the fix is specified,  $A$  is the specified amplitude vector with components  $(A_x,A_y,A_z)$ ,  $\omega$  is  $2 \text{ PI} / \text{period}$ , and  $\text{delta}$  is the time elapsed since the fix was specified. This style also sets the velocity of each particle to the time derivative of this expression. If any of the amplitude components is specified as NULL, then the position and velocity of that component is time integrated the same as the *fix sph* command would perform, using the corresponding force component on the particle.

Note that the *wiggle* style is identical to using the *variable* style with *equal-style variables* that use the `swiggle()` and `cwiggle()` functions. E.g.

```
variable A equal 10.0
variable T equal 5.0
variable omega equal 2.0*PI/$T
variable x equal swiggle(0.0,$A,$T)
variable v equal v_omega*($A-cwiggle(0.0,$A,$T))
fix 1 boundary move variable v_x NULL NULL v_v NULL NULL
```

The *rotate* style rotates particles around a rotation axis  $R = (R_x, R_y, R_z)$  that goes through a point  $P = (P_x, P_y, P_z)$ . The *period* of the rotation is also specified. The direction of rotation for the particles around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along  $R$ , then your fingers wrap around the axis in the direction of rotation.

This style also sets the velocity of each particle to  $(\omega \times R_{\text{perp}})$  where  $\omega$  is its angular velocity around the rotation axis and  $R_{\text{perp}}$  is a perpendicular vector from the rotation axis to the particle.

The *variable* style allows the position and velocity components of each particle to be set by formulas specified via the *variable* command. Each of the 6 variables is specified as an argument to the `fix` as `v_name`, where `name` is the variable name that is defined elsewhere in the input script.

Each variable must be of either the *equal* or *atom* style. *Equal*-style variables compute a single numeric quantity, that can be a function of the timestep as well as of other simulation values. *Atom*-style variables compute a numeric quantity for each particle, that can be a function per-atom quantities, such as the particle's position, as well as of the timestep and other simulation values. Note that this `fix` stores the original coordinates of each particle (see note below) so that per-atom quantity can be used in an atom-style variable formula. See the *variable* command for details.

The first 3 variables (`v_dx`, `v_dy`, `v_dz`) specified for the *variable* style are used to calculate a displacement from the particle's original position at the time the `fix` was specified. The second 3 variables (`v_vx`, `v_vy`, `v_vz`) specified are used to compute a velocity for each particle.

Any of the 6 variables can be specified as `NULL`. If both the displacement and velocity variables for a particular  $x, y, z$  component are specified as `NULL`, then the position and velocity of that component is time integrated the same as the *fix sph* command would perform, using the corresponding force component on the particle. If only the velocity variable for a component is specified as `NULL`, then the displacement variable will be used to set the position of the particle, and its velocity component will not be changed. If only the displacement variable for a component is specified as `NULL`, then the velocity variable will be used to set the velocity of the particle, and the position of the particle will be time integrated using that velocity.

The *units* keyword determines the meaning of the distance units used to define the *linear* velocity and *wiggle* amplitude and *rotate* origin. This setting is ignored for the *variable* style. A *box* value selects standard units as defined by the *units* command, e.g. velocity in Angstroms/fs and amplitude and position in Angstroms for `units = real`. A *lattice* value means the velocity units are in lattice spacings per time and the amplitude and position are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. Each of these 3 quantities may be dependent on the  $x, y, z$  dimension, since the lattice spacings can be different in  $x, y, z$ .

## 2.94.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the original coordinates of moving particles to *binary restart files*, as well as the initial timestep, so that the motion can be continuous in a restarted simulation. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** Because the move positions are a function of the current timestep and the initial timestep, you cannot reset the timestep to a different value after reading a restart file, if you expect a fix move command to work in an uninterrupted fashion.

---

None of the *fix\_modify* options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various *output commands*. The number of columns for each atom is 3, and the columns store the original unwrapped x,y,z coords of each particle. The per-atom values can be accessed on any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

## 2.94.5 Restrictions

This fix is part of the DPD-SMOOTH package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store density and internal energy as defined by the *atom\_style sph* command.

All particles in the group must be mesoscopic SPH/SDPD particles.

Changed in version 29Aug2024.

This fix is incompatible with deformation controls that remap velocity, for instance the *remap v* option of *fix deform*.

## 2.94.6 Related commands

*fix move*, *fix sph*, *displace\_atoms*

## 2.94.7 Default

The option default is units = lattice.

# 2.95 fix\_modify AtC commands

## 2.95.1 fix\_modify AtC add\_molecule command

### Syntax

```
fix_modify <AtC fixID> add_molecule <small|large> <tag> <group-ID>
```

- AtC fixID = ID of *fix atc* instance
- add\_molecule = name of the AtC sub-command

- *small* or *large* = can be *small* if molecule size < cutoff radius, must be *large* otherwise
- tag = tag for tracking a molecule
- *group-ID* = LAMMPS defined group-ID

## Examples

```
group WATERGROUP type 1 2
fix_modify AtC add_molecule small water WATERGROUP
```

## Description

Associates a tag with all molecules corresponding to a specified group.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC add\_species*
- *fix\_modify AtC remove\_species*
- *fix\_modify AtC remove\_molecule*

## Default

None.

## 2.95.2 fix\_modify AtC add\_species command

### Syntax

```
fix_modify <AtC fixID> add_species <tag> <group|type> <ID>
```

- AtC fixID = ID of *fix atc* instance
- add\_species = name of the AtC sub-command
- tag = tag for tracking a species
- *group* or *type* = LAMMPS defined group or type of atoms
- ID = name of group or type number

## Examples

```
fix_modify AtC add_species gold type 1
group GOLDGROUP type 1
fix_modify AtC add_species gold group GOLDGROUP
```

## Description

Associates a tag with all atoms of a specified type or within a specified group.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC add\_molecule*
- *fix\_modify AtC remove\_species*
- *fix\_modify AtC remove\_molecule*

## Default

None.

## 2.95.3 fix\_modify AtC atom\_element\_map command

### Syntax

```
fix_modify <AtC fixID> atom_element_map <eulerian|lagrangian> [<frequency>]
```

- AtC fixID = ID of *fix atc* instance
- atom\_element\_map = name of the AtC sub-command
- *eulerian* or *lagrangian* = frame of reference
- frequency = frequency of updating atom-to-continuum maps based on the current configuration - (only for eulerian)

## Examples

```
fix_modify AtC atom_element_map eulerian 100
```

## Description

Changes frame of reference from *eulerian* to *lagrangian* or vice versa and sets the frequency for which the map from atoms to elements is reformed and all the attendant data is recalculated.

## Restrictions

Cannot change map type after initialization.

## Related AtC commands

- [\*fix\\_modify AtC command overview\*](#)

## Default

*lagrangian*

## 2.95.4 fix\_modify AtC atom\_weight command

### Syntax

```
fix_modify <AtC fixID> atom_weight <method> <args>
```

- AtC fixID = ID of *fix atc* instance
- atom\_weight = name of the AtC sub-command
- method = *constant* or *lattice* or *element* or *region* or *group* or *read\_in*
  - *constant* <group-ID> <value>: atoms in specified group are assigned the constant value given
  - *lattice*: volume per atom for specified lattice type (e.g. fcc) and parameter
  - *element*: element volume divided among atoms within element
  - *region*: volume per atom determined based on the atom count in the MD regions and their volumes. Note: meaningful only if atoms completely fill all the regions.
  - *group*: volume per atom determined based on the atom count in a group and its volume
  - *node*: (undocumented)
  - *node\_element*: (undocumented)
  - *read\_in*<filename>: list of values for atoms are read-in from specified file

## Examples

```
fix_modify AtC atom_weight constant myatoms 11.8
fix_modify AtC atom_weight lattice
fix_modify AtC atom_weight read-in atm_wt_file.txt
```

## Description

Command for assigning the value of atomic weights used for atomic integration in atom-continuum coupled simulations.

## Restrictions

The use of the lattice option requires a lattice type and parameter is already specified.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

*lattice*

## 2.95.5 fix\_modify AtC atomic\_charge command

### Syntax

```
fix_modify <AtC fixID> <include|omit> atomic_charge
```

- AtC fixID = ID of *fix atc* instance
- *include* or *omit* = switch to activate/deactivate inclusion of intrinsic atomic charge in ATC
- atomic\_charge = name of the AtC sub-command

## Examples

```
fix_modify AtC include atomic_charge
```

## Description

Determines whether AtC tracks the total charge as a finite element field.

## Restrictions

Required for: *electrostatics*

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

If the atom charge is defined, default is on, otherwise default is off.

## 2.95.6 fix\_modify AtC boundary\_dynamics command

### Syntax

```
fix_modify <AtC fixID> boundary_dynamics <on|damped_harmonic|prescribed|coupled|none>
```

- AtC fixID = ID of *fix atc* instance
- boundary\_dynamics = name of the AtC sub-command
- *on* or *damped\_harmonic* *prescribed* *coupled* *none*

## Description

Sets different schemes for controlling boundary atoms. *on* will integrate the boundary atoms using the velocity-verlet algorithm. *damped\_harmonic* uses a mass/spring/dashpot for the boundary atoms with added arguments of the damping and spring constants followed by the ratio of the boundary type mass to the desired mass. *prescribed* forces the boundary atoms to follow the finite element displacement. *coupled* does the same.

## Restrictions

Boundary atoms must be specified. When using swaps between internal and boundary atoms, the initial configuration must have already correctly partitioned the two.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

*prescribed on*

## 2.95.7 fix\_modify AtC boundary\_faceset command

### Syntax

```
fix_modify <AtC fixID> boundary_faceset <is|add> <faceset_name>
```

- AtC fixID = ID of *fix atc* instance
- boundary\_faceset = name of the AtC sub-command
- *is* or *add* = select whether to select or add a faceset
- faceset\_name = name of the faceset

### Examples

```
fix_modify AtC boundary_faceset is obndy
```

### Description

This command species the faceset name when using a faceset to compute the MD/FE boundary fluxes. The faceset must already exist.

### Restrictions

This is only valid when *fe\_md\_boundary* is set to *faceset*.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC fe\_md\_boundary*
- *fix\_modify AtC mesh create\_faceset box*
- *fix\_modify AtC mesh create\_faceset plane*

## Default

None.

## 2.95.8 fix\_modify AtC boundary type command

### Syntax

```
fix_modify <AtC fixID> boundary type <atom-type-id>
```

- AtC fixID = ID of *fix atc* instance
- boundary type = name of the AtC sub-command
- atom-type-id = type id for atoms that represent a fictitious boundary internal to the FE mesh

### Examples

```
fix_modify AtC boundary type ghost_atoms
```

### Description

Command to define the atoms that represent the fictitious boundary internal to the FE mesh. For fully overlapped MD/FE domains with periodic boundary conditions no boundary atoms should be defined.

### Restrictions

None.

### Related AtC commands

- *fix\_modify AtC command overview*

## Default

None.

## 2.95.9 fix\_modify AtC consistent\_fe\_initialization command

### Syntax

```
fix_modify <AtC fixID> consistent_fe_initialization <on|off>
```

- AtC fixID = ID of *fix atc* instance
- consistent\_fe\_initialization = name of the AtC sub-command
- *on* or *off* = switch to activate/deactivate the initial setting of the FE intrinsic field to match the projected MD field

## Examples

```
fix_modify AtC consistent_fe_initialization on
```

## Description

Determines whether AtC initializes FE intrinsic fields (e.g., temperature) to match the projected MD values. This is particularly useful for fully overlapping simulations.

## Restrictions

Can be used with: *thermal*, *two\_temperature*. Cannot be used with time filtering on. Does not include boundary nodes.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

Default is *off*

## 2.95.10 fix\_modify AtC control localized\_lambda command

### Syntax

```
fix_modify <AtC fixID> control localized_lambda <on|off>
```

- AtC fixID = ID of *fix atc* instance
- control localized\_lambda = name of the AtC sub-command
- *on* or *off* = Toggles state of localization algorithm

## Examples

```
fix_modify AtC control localized_lambda on
```

## Description

Turns the localization algorithms *on* or *off* for control algorithms to restrict the influence of FE coupling or boundary conditions to a region near the boundary of the MD region. Control algorithms will not affect atoms in elements not possessing faces on the boundary of the region. Flux-based control is localized via row-sum lumping while quantity control is done by solving a truncated matrix equation.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

off

## 2.95.11 fix\_modify AtC control momentum command

### Syntax

```
fix_modify <AtC fixID> control <physics_type> <solution_parameter> <value>
fix_modify AtC control momentum none
fix_modify AtC control momentum rescale <frequency>
fix_modify AtC control momentum glc_displacement
fix_modify AtC control momentum glc_velocity
fix_modify AtC control momentum hoover
fix_modify AtC control momentum flux [faceset face_set_id, interpolate]
```

- AtC fixID = ID of *fix atc* instance
- control = name of the AtC sub-command
- physics\_type = *thermal* or *momentum*
- solution\_parameter = *max\_iterations* or *tolerance*
- value = solution\_parameter value
- momentum option = *none* or *rescale* or *glc\_displacement* or *glc\_velocity* *hoover* or *flux*
- frequency = time step frequency for applying displacement and velocity rescaling
- faceset\_id = id of boundary face set (optional, only for *faceset*)

### Examples

```
fix_modify AtC control momentum none
fix_modify AtC control momentum flux faceset bndy_faces
fix_modify AtC control momentum glc_velocity
```

## Description

The general version of *control* sets the numerical parameters for the matrix solvers used in the specified control algorithm. Many solution approaches require iterative solvers, and these methods enable users to provide the maximum number of iterations and the relative tolerance.

The *control momentum* version sets the momentum exchange mechanism from the finite elements to the atoms, managed through a control algorithm. *rescale* computes a scale factor for each atom to match the finite element temperature. *hoover* is a Gaussian least-constraint isokinetic thermostat enforces that the nodal restricted atomic temperature matches the finite element temperature. *flux* is a similar mode, but rather adds energy to the atoms based on conservation of energy.

*correction\_max\_iterations* sets the maximum number of iterations to compute the second order in time correction term for lambda with the fractional step method. The method uses the same tolerance as the controller's matrix solver.

## Restrictions

Only for be used with the specific controllers *thermal* or *momentum*. They are ignored if a lumped solution is requested.

*control momentum* is only for be used with specific transfers: elastic *rescale* not valid with time filtering activated

## Related AtC commands

- [fix\\_modify AtC command overview](#)
- [fix\\_modify AtC control thermal](#)

## Default

- *max\_iterations* is the number of rows in the matrix.
- *tolerance* is 1.0e-10.

## 2.95.12 fix\_modify AtC control thermal command

### Syntax

```
fix_modify <AtC fixID> control <physics_type> <solution_parameter> <value>
fix_modify <AtC fixID> control thermal <control_type> <optional_args>
fix_modify <AtC fixID> control thermal rescale <frequency>
fix_modify <AtC fixID> control thermal flux <boundary_integration_type> <faceset_id>
fix_modify <AtC fixID> control thermal correction_max_iterations <max_iterations>
```

- AtC fixID = ID of *fix atc* instance
- control = name of the AtC sub-command
- physics\_type = *thermal* or *momentum*
- solution\_parameter = *max\_iterations* or *tolerance*
- value = solution\_parameter value
- thermal control\_type = *none* or *rescale* or *hoover* or *flux*
- frequency = time step frequency for applying velocity rescaling

- `boundary_integration_type` = *faceset* or *interpolate* (optional)
- `faceset_id` = id of boundary face set (optional, only for *faceset*)
- `correction_max_iterations` = maximum number of iterations that will be used by iterative matrix solvers for *thermal* physics type

## Examples

```
fix_modify AtC control thermal none
fix_modify AtC control thermal rescale 10
fix_modify AtC control thermal hoover
fix_modify AtC control thermal flux
fix_modify AtC control thermal flux faceset bndy_faces
fix_modify AtC control thermal correction_max_iterations 10
```

## Description

The general version of *control* sets the numerical parameters for the matrix solvers used in the specified control algorithm. Many solution approaches require iterative solvers, and these methods enable users to provide the maximum number of iterations and the relative tolerance.

The *control thermal* version sets the energy exchange mechanism from the finite elements to the atoms, managed through a control algorithm. *rescale* computes a scale factor for each atom to match the finite element temperature. *hoover* is a Gaussian least-constraint isokinetic thermostat enforces that the nodal restricted atomic temperature matches the finite element temperature. *flux* is a similar mode, but rather adds energy to the atoms based on conservation of energy. *hoover* and *flux* allow the prescription of sources or fixed temperatures on the atoms.

*correction\_max\_iterations* sets the maximum number of iterations to compute the second order in time correction term for lambda with the fractional step method. The method uses the same tolerance as the controller's matrix solver.

## Restrictions

Only for be used with the specific controllers *thermal* or *momentum*. They are ignored if a lumped solution is requested.

*control thermal* is only for be used with specific transfers: *thermal (rescale, hoover, flux)*, *two\_temperature (flux)*. *rescale* not valid with time filtering activated

*correction\_max\_iterations* is only for use with *thermal* physics using the fractional step method.

## Related AtC commands

- [\*fix\\_modify AtC command overview\*](#)
- [\*fix\\_modify AtC control momentum\*](#)

## Default

- *max\_iterations* is the number of rows in the matrix.
- *tolerance* is 1.0e-10.
- *rescale* frequency is 1
- *flux* boundary\_integration\_type is *interpolate*
- *correction\_max\_iterations* is 20

## 2.95.13 fix\_modify AtC decomposition command

### Syntax

```
fix_modify <AtC fixID> decomposition <type>
```

- AtC fixID = ID of *fix atc* instance
- decomposition = name of the AtC sub-command
- type = *replicated\_memory* or *distributed\_memory*

### Examples

```
fix_modify AtC decomposition distributed_memory
```

### Description

Command for assigning the distribution of work and memory for parallel runs. With *replicated\_memory* the nodal information is replicated on each processor, and with *distributed\_memory* only the owned nodal information kept on each processor. The *replicated\_memory* option is most appropriate for simulations where the number of nodes is much smaller than the number of atoms.

### Restrictions

None.

### Related AtC commands

- *fix\_modify AtC command overview*

## Default

replicated\_memory

### 2.95.14 fix\_modify AtC extrinsic electron\_integration command

#### Syntax

```
fix_modify <AtC fixID> extrinsic electron_integration <integration_type> [<num_subcycle_
→steps>]
```

- AtC fixID = ID of *fix atc* instance
- extrinsic electron\_integration = name of the AtC sub-command
- integration\_type = *explicit* or *implicit* or *steady*
- num\_subcycle\_steps = number of subcycle steps for the electron time integration (optional)

#### Examples

```
fix_modify AtC extrinsic electron_integration implicit
fix_modify AtC extrinsic electron_integration explicit 100
```

#### Description

Switches between integration schemes for the electron temperature. The number of subcycling steps used to integrate the electron temperature for one LAMMPS timestep can be manually adjusted to capture fast electron dynamics.

#### Restrictions

For use only with the two\_temperature type of the AtC fix (see *fix atc* command)

#### Related AtC commands

- *fix\_modify AtC command overview*

#### Default

*implicit* and *subcycle\_steps* = 1

## 2.95.15 `fix_modify AtC equilibrium_start` command

### Syntax

```
fix_modify <AtC fixID> equilibrium_start <on|off>
```

- AtC fixID = ID of *fix atc* instance
- equilibrium\_start = name of the AtC sub-command
- *exponential* or *step* or *no\_filter* = select type of filter

### Examples

```
fix_modify AtC equilibrium_start on
```

### Description

Starts filtered calculations assuming they start in equilibrium, i.e. perfect finite element force balance.

### Restrictions

Only for use with these specific transfers: thermal, two\_temperature

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC filter*
- *fix\_modify AtC filter scale*

### Default

None.

## 2.95.16 `fix_modify AtC extrinsic exchange` command

### Syntax

```
fix_modify <AtC fixID> extrinsic exchange <on|off>
```

- AtC fixID = ID of *fix atc* instance
- extrinsic exchange = name of the AtC sub-command
- *on* or *off* = set state of energy exchange

## Examples

```
fix_modify AtC extrinsic exchange on
```

## Description

Switches energy exchange between the MD system and the electron system on or off

## Restrictions

For use only with the two\_temperature type of the AtC fix (see *fix atc* command)

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

*on*

## 2.95.17 fix\_modify AtC fe\_md\_boundary command

### Syntax

```
fix_modify <AtC fixID> fe_md_boundary <faceset|interpolate|no_boundary>
```

- AtC fixID = ID of *fix atc* instance
- fe\_md\_boundary = name of the AtC sub-command
- *faceset* or *interpolate* or *no\_boundary*

## Examples

```
fix_modify AtC fe_md_boundary interpolate
```

## Description

Specifies different methods for computing fluxes between the MD and FE integration regions. Faceset defines a faceset separating the MD and FE regions and uses finite element face quadrature to compute the flux. Interpolate uses a reconstruction scheme to approximate the flux, which is more robust but less accurate if the MD/FE boundary does correspond to a faceset. No boundary results in no fluxes between the systems being computed.

## Restrictions

If *faceset* is used, all the AtC non-boundary atoms must lie within and completely fill the domain enclosed by the faceset.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create\_faceset box*
- *fix\_modify AtC mesh create\_faceset plane*

## Default

*interpolate*

## 2.95.18 fix\_modify AtC filter scale command

### Syntax

```
fix_modify <AtC fixID> filter scale <scale>
```

- AtC fixID = ID of *fix atc* instance
- filter scale = name of the AtC sub-command
- scale = characteristic times scale of the filter

### Examples

```
fix_modify AtC filter scale 10.0
```

### Description

Sets the time scale for MD dynamics filter to construct a more appropriate continuous field.

### Restrictions

Only for use with these specific transfers: thermal, two\_temperature

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC filter*
- *fix\_modify AtC filter type*

### Default

0.0

## 2.95.19 fix\_modify AtC filter type command

### Syntax

```
fix_modify <AtC fixID> filter type <exponential|step|no_filter>
```

- AtC fixID = ID of *fix atc* instance
- filter type = name of the AtC sub-command
- *exponential* or *step* or *no\_filter* = select type of filter

### Examples

```
fix_modify AtC filter type exponential
```

### Description

Specifies the type of time filter used.

### Restrictions

Only for use with these specific transfers: thermal, two\_temperature

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC filter*
- *fix\_modify AtC filter scale*

## Default

None.

## 2.95.20 fix\_modify AtC fix command

### Syntax

```
fix_modify <AtC fixID> fix <field> <nodeset> <constant|function>
```

- AtC fixID = ID of *fix atc* instance
- fix = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron\_temperature*
- nodeset = name of set of nodes to apply boundary condition
- *constant* or *function* = value or name of function followed by its parameters

### Examples

```
fix_modify AtC fix temperature groupNAME 10.
fix_modify AtC fix temperature groupNAME 0 0 0 10.0 0 0 1.0
```

### Description

Creates a constraint on the values of the specified field at specified nodes.

### Restrictions

The keyword *all* is reserved and thus not available as nodeset name.

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC unfix*

## Default

None.

### 2.95.21 `fix_modify AtC fix_flux` command

#### Syntax

```
fix_modify <AtC fixID> fix_flux <field> <face_set> <value|function>
```

- AtC fixID = ID of *fix atc* instance
- fix\_flux = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron\_temperature*
- face\_set = name of set of element faces
- *value* or *function* = value or name of function followed by its parameters

#### Examples

```
fix_modify AtC fix_flux temperature faceSet 10.0
```

#### Description

Command for fixing normal fluxes e.g. heat\_flux. This command only prescribes the normal component of the physical flux, e.g. heat (energy) flux. The units are in AtC units, i.e. derived from the LAMMPS length, time, and mass scales.

#### Restrictions

Only normal fluxes (Neumann data) can be prescribed.

#### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC unfix\_flux*

#### Default

None.

### 2.95.22 `fix_modify AtC computes` command

#### Syntax

```
fix_modify <AtC fixID> computes <add|delete> <per-atom compute-ID> <volume|number>
```

- AtC fixID = ID of *fix atc* instance
- computes = name of the AtC sub-command
- *add* or *delete* = add or delete the calculation of an equivalent continuum field for the specified per-atom compute as volume or number density quantity

- per-atom compute-ID = ID of a per-atom compute; fields can be calculated for all per-atom computes available in LAMMPS
- *volume* or *number* = select whether the created field is a per-unit-volume quantity or a per-atom quantity as weighted by kernel functions

## Examples

```
compute virial all stress/atom
fix_modify AtC computes add virial volume
fix_modify AtC computes delete virial

compute centrosymmetry all centro/atom
fix_modify AtC computes add centrosymmetry number
```

## Description

Calculates continuum fields corresponding to specified per-atom *computes* created by LAMMPS.

## Restrictions

Must be used with *fix atc hardy*. The per-atom compute must be specified before the corresponding continuum field can be requested.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC fields*
- *compute*

## Default

None.

## 2.95.23 fix\_modify AtC fields command

### Syntax

```
fix_modify <AtC fixID> fields <all|none>
fix_modify <AtC fixID> fields <add|delete> <list_of_fields>
```

- AtC fixID = ID of *fix atc* instance
- fields = name of the AtC sub-command
- *all* or *none* = output all or no fields
- *add* or *delete* = add or delete the listed output fields
- list\_of\_fields = one or more of the fields listed below:

- density : mass per unit volume
- displacement : displacement vector
- momentum : momentum per unit volume
- velocity : defined by momentum divided by density
- projected\_velocity : simple kernel estimation of atomic velocities
- temperature : temperature derived from the relative atomic kinetic energy
- kinetic\_temperature : temperature derived from the full kinetic energy
- number\_density : simple kernel estimation of number of atoms per unit volume
- stress : Cauchy stress tensor for eulerian analysis (atom\_element\_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
- transformed\_stress : first Piola-Kirchhoff stress tensor for eulerian analysis (atom\_element\_map), or Cauchy stress tensor for lagrangian analysis
- heat\_flux : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
- potential\_energy : potential energy per unit volume
- kinetic\_energy : kinetic energy per unit volume
- thermal\_energy : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
- internal\_energy : total internal energy (potential + thermal) per unit volume
- energy : total energy (potential + kinetic) per unit volume
- number\_density : number of atoms per unit volume
- eshelby\_stress : configurational stress (energy-momentum) tensor defined by (*Eshelby*)
- vacancy\_concentration : volume fraction of vacancy content
- type\_concentration : volume fraction of a specific atom type

## Examples

```
fix_modify AtC fields add velocity temperature
```

## Description

Allows modification of the fields calculated and output by the AtC transfer class. The commands are cumulative, e.g.:

```
fix_modify AtC fields none
fix_modify AtC fields add velocity temperature
```

will only output the velocity and temperature fields.

## Restrictions

Must be used with *fix atc hardy*. Currently, the stress and heat flux formulas are only correct for central force potentials, e.g. Lennard-Jones and EAM but not Stillinger-Weber.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC gradients*
- *fix\_modify AtC rates*
- *fix\_modify AtC computes*

## Default

By default, no fields are output.

## References

(Eshelby) J.D. Eshelby, Philos. Trans. Royal Soc. London A, Math. Phys. Sci., Vol. 244, No. 877 (1951) pp. 87-112; J. Elasticity, Vol. 5, Nos. 3-4 (1975) pp. 321-335]

## 2.95.24 fix\_modify AtC gradients command

### Syntax

```
fix_modify <AtC fixID> gradients <add|delete> <list_of_fields>
```

- AtC fixID = ID of *fix atc* instance
- gradients = name of the AtC sub-command
- *add* or *delete* = select whether to add or delete calculation of gradients for the listed output fields
- list\_of\_fields = one or more of the fields listed below:
  - density : mass per unit volume
  - displacement : displacement vector
  - momentum : momentum per unit volume
  - velocity : defined by momentum divided by density
  - projected\_velocity : simple kernel estimation of atomic velocities
  - temperature : temperature derived from the relative atomic kinetic energy
  - kinetic\_temperature : temperature derived from the full kinetic energy
  - number\_density : simple kernel estimation of number of atoms per unit volume
  - stress : Cauchy stress tensor for eulerian analysis (atom\_element\_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
  - transformed\_stress : first Piola-Kirchhoff stress tensor for eulerian analysis (atom\_element\_map), or Cauchy stress tensor for lagrangian analysis

- `heat_flux` : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
- `potential_energy` : potential energy per unit volume
- `kinetic_energy` : kinetic energy per unit volume
- `thermal_energy` : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
- `internal_energy` : total internal energy (potential + thermal) per unit volume
- `energy` : total energy (potential + kinetic) per unit volume
- `number_density` : number of atoms per unit volume
- `eshelby_stress` : configurational stress (energy-momentum) tensor defined by (*Eshelby*)
- `vacancy_concentration` : volume fraction of vacancy content
- `type_concentration` : volume fraction of a specific atom type

## Examples

```
fix_modify AtC gradients add temperature velocity stress
fix_modify AtC gradients delete velocity
```

## Description

Requests calculation and output of gradients of the fields from the AtC transfer class. These gradients will be with regard to spatial or material coordinate for Eulerian or Lagrangian analysis, respectively, as specified by *fix\_modify AtC atom\_element\_map*

## Restrictions

Must be used with *fix atc hardy*.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC atom\_element\_map*
- *fix\_modify AtC fields*
- *fix\_modify AtC rates*

## Default

None.

## References

(Eshelby) J.D. Eshelby, Philos. Trans. Royal Soc. London A, Math. Phys. Sci., Vol. 244, No. 877 (1951) pp. 87-112; J. Elasticity, Vol. 5, Nos. 3-4 (1975) pp. 321-335]

### 2.95.25 fix\_modify AtC kernel command

#### Syntax

```
fix_modify <AtC fixID> kernel <type> <parameters>
```

- AtC fixID = ID of *fix atc* instance
- kernel = name of the AtC sub-command
- type = *step* or *cell* or *cubic\_bar* or *cubic\_cylinder* or *cubic\_sphere* or *quartic\_bar* or *quartic\_cylinder* or *quartic\_sphere*
- the following parameter(s) are required for each kernel:
  - *step* : <radius>
  - *cell* : <hx> <hy> <hz> or <h>
  - *cubic\_bar* : <half\_width>
  - *cubic\_cylinder* : <radius>
  - *cubic\_sphere* : <radius>
  - *quartic\_bar* : <half\_width>
  - *quartic\_cylinder* : <radius>
  - *quartic\_sphere* : <radius>

#### Examples

```
fix_modify AtC kernel cell 1.0 1.0 1.0
fix_modify AtC kernel quartic_sphere 10.0
```

#### Description

Sets the localization kernel type and parameters for *fix atc hardy*.

#### Restrictions

Must be used with *fix atc hardy*. For bar kernel types, half-width oriented along x-direction. For cylinder kernel types, cylindrical axis is assumed to be in z-direction.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC fields*
- *fix\_modify AtC gradients*
- *fix\_modify AtC rates*
- *fix\_modify AtC computes*

## Default

None.

## 2.95.26 fix\_modify AtC on\_the\_fly command

### Syntax

```
fix_modify <AtC fixID> on_the_fly <bond|kernel> <on|off>
```

- AtC fixID = ID of *fix atc* instance
- on\_the\_fly = name of the AtC sub-command
- *bond* or *kernel* = specifies on-the-fly calculation of *bond* or *kernel* matrix elements
- *on* or *off* = activate or discontinue on-the-fly mode

### Examples

```
fix_modify AtC on_the_fly bond on  
fix_modify AtC on_the_fly kernel  
fix_modify AtC on_the_fly kernel off
```

### Description

Overrides normal mode of pre-calculating and storing bond pair-to-node and kernel atom-to-node matrices. If activated, it will calculate elements of these matrices during repeated calls of field computations (i.e. “on-the-fly”) and not store them for future use. The *on* flag is optional - if omitted, *on\_the\_fly* will be activated for the specified matrix. Can be deactivated using the *off* flag.

## Restrictions

Must be used with *fix atc hardy*.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

By default, on-the-fly calculation is not active (i.e. off). However, THE code does a memory allocation check to determine if it can store all needed bond and kernel matrix elements. If this allocation fails, on-the-fly will be activated.

## 2.95.27 fix\_modify AtC rates command

### Syntax

```
fix_modify <AtC fixID> rates <add|delete> <list_of_fields>
```

- AtC fixID = ID of *fix atc* instance
- rates = name of the AtC sub-command
- *add* or *delete* = select whether to add or delete calculation of rates for the listed output fields
- list\_of\_fields = one or more of the fields listed below:
  - density : mass per unit volume
  - displacement : displacement vector
  - momentum : momentum per unit volume
  - velocity : defined by momentum divided by density
  - projected\_velocity : simple kernel estimation of atomic velocities
  - temperature : temperature derived from the relative atomic kinetic energy
  - kinetic\_temperature : temperature derived from the full kinetic energy
  - number\_density : simple kernel estimation of number of atoms per unit volume
  - stress : Cauchy stress tensor for eulerian analysis (atom\_element\_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
  - transformed\_stress : first Piola-Kirchhoff stress tensor for eulerian analysis (atom\_element\_map), or Cauchy stress tensor for lagrangian analysis
  - heat\_flux : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
  - potential\_energy : potential energy per unit volume
  - kinetic\_energy : kinetic energy per unit volume
  - thermal\_energy : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
  - internal\_energy : total internal energy (potential + thermal) per unit volume
  - energy : total energy (potential + kinetic) per unit volume

- `number_density` : number of atoms per unit volume
- `eshelby_stress` : configurational stress (energy-momentum) tensor defined by (*Eshelby*)
- `vacancy_concentration` : volume fraction of vacancy content
- `type_concentration` : volume fraction of a specific atom type

## Examples

```
fix_modify AtC rates add temperature velocity stress
fix_modify AtC rates delete stress
```

## Description

Requests calculation and output of rates (time derivatives) of the fields from the AtC transfer class. For Eulerian analysis (see *fix\_modify AtC atom\_element\_map*) these rates are the partial time derivatives of the nodal fields, not the full (material) time derivatives.

## Restrictions

Must be used with *fix atc hardy*.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC atom\_element\_map*
- *fix\_modify AtC fields*
- *fix\_modify AtC fields*

## Default

None.

## References

(**Eshelby**) J.D. Eshelby, Philos. Trans. Royal Soc. London A, Math. Phys. Sci., Vol. 244, No. 877 (1951) pp. 87-112; J. Elasticity, Vol. 5, Nos. 3-4 (1975) pp. 321-335]

## 2.95.28 `fix_modify` AtC initial command

### Syntax

```
fix_modify <AtC fixID> initial <field> <nodeset> <constant|function>
```

- AtC fixID = ID of *fix atc* instance
- initial = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron\_temperature*
- nodeset = name of set of nodes to apply initial condition
- *constant* or *function* = value or name of function followed by its parameters

### Examples

```
fix_modify AtC initial temperature groupNAME 10.
```

### Description

Sets the initial values for the specified field at the specified nodes.

### Restrictions

The keyword *all* is reserved and thus not available as nodeset name.

### Related AtC commands

- *fix\_modify AtC command overview*

### Default

None.

## 2.95.29 `fix_modify` AtC internal\_element\_set command

### Syntax

```
fix_modify <AtC fixID> internal_element_set <element_set_name>
```

- AtC fixID = ID of *fix atc* instance
- internal\_element\_set = name of the AtC sub-command
- element\_set\_name = name of element set defining internal region, or *off*

## Examples

```
fix_modify AtC internal_element_set myElementSet
fix_modify AtC internal_element_set off
```

## Description

Enables AtC to base the region for internal atoms to be an element set. If no ghost atoms are used, all the AtC atoms must be constrained to remain in this element set by the user, e.g., with walls. If boundary atoms are used in conjunction with Eulerian atom maps AtC will partition all atoms of a boundary or internal type to be of type internal if they are in the internal region or to be of type boundary otherwise.

## Restrictions

If boundary atoms are used in conjunction with Eulerian atom maps, the Eulerian reset frequency must be an integer multiple of the LAMMPS reneighbor frequency.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC atom\_element\_map*
- *fix\_modify AtC boundary type*

## Default

*off*

## 2.95.30 fix\_modify AtC internal\_quadrature command

### Syntax

```
fix_modify <AtC fixID> internal_quadrature <on|off> [region]
```

- AtC fixID = ID of *fix atc* instance
- internal\_quadrature = name of the AtC sub-command
- on or off = select whether internal quadrature is enabled or not
- region = treat finite elements as within MD region (optional)

## Examples

```
fix_modify AtC internal_quadrature off
```

## Description

Command to use or not use atomic quadrature on internal elements fully filled with atoms. By turning the internal quadrature off these elements do not contribute to the governing PDE and the fields at the internal nodes follow the weighted averages of the atomic data.

Optional region tag specifies which finite element nodes will be treated as being within the MD region. This option is only valid with internal\_quadrature off.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

on.

## 2.95.31 fix\_modify AtC kernel\_bandwidth command

### Syntax

```
fix_modify <AtC fixID> kernel_bandwidth <value>
```

- AtC fixID = ID of *fix atc* instance
- kernel\_bandwidth = name of the AtC sub-command
- value = new bandwidth value

## Examples

```
fix_modify AtC kernel_bandwidth 8
```

## Description

Sets a maximum parallel bandwidth for the kernel functions during parallel communication. If the command is not issued, the default will be to assume the bandwidth of the kernel matrix corresponds to the number of sampling locations.

## Restrictions

Only is used if kernel functions are being used.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

Number of sample locations.

## 2.95.32 fix\_modify AtC control lumped\_lambda\_solve command

### Syntax

```
fix_modify <AtC fixID> control lumped_lambda_solve <on|off>
```

- AtC fixID = ID of *fix atc* instance
- control lumped\_lambda\_solve = name of the AtC sub-command
- *on* or *off* = Toggles state of lumped matrix

### Examples

```
fix_modify AtC control lumped_lambda_solve on
```

### Description

Command select whether to use or not use lumped matrix for lambda solve.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

off

### 2.95.33 fix\_modify AtC control mask\_direction command

#### Syntax

```
fix_modify <AtC fixID> control mask_direction <direction> <on|off>
```

- AtC fixID = ID of *fix atc* instance
- control mask\_direction = name of the AtC sub-command
- direction = select direction
- *on* or *off* = Toggles state

#### Examples

```
fix_modify AtC control mask_direction 0 on
```

#### Description

Command to mask out certain dimensions from the atomic regulator

#### Restrictions

None.

#### Related AtC commands

- *fix\_modify AtC command overview*

### 2.95.34 fix\_modify AtC mass\_matrix command

#### Syntax

```
fix_modify <AtC fixID> mass_matrix <fe|md_fe>
```

- AtC fixID = ID of *fix atc* instance
- mass\_matrix = name of the AtC sub-command
- *fe* or *md\_fe* = activate/deactivate using the FE mass matrix in the MD region

## Examples

```
fix_modify AtC mass_matrix fe
```

## Description

Determines whether AtC uses the FE mass matrix based on Gaussian quadrature or based on atomic quadrature in the MD region. This is useful for fully overlapping simulations to improve efficiency.

## Restrictions

Should not be used unless the FE region is contained within the MD region, otherwise the method will be unstable and inaccurate.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

*md\_fe*

## 2.95.35 fix\_modify AtC material command

### Syntax

```
fix_modify <AtC fixID> material <elementset_name> <material_id>
```

- AtC fixID = ID of *fix atc* instance
- material = name of the AtC sub-command
- elementset\_name = name of the elementset
- material\_id = ID of the material

## Examples

```
fix_modify AtC material gap_region 1
```

## Description

Sets the material model in *elementset\_name* to be of type *material\_id*.

## Restrictions

The element set must already be created and the material must be specified in the material file given the the atc fix on construction

## Related AtC commands

- [\*fix\\_modify AtC command overview\*](#)

## Default

All elements default to the first material in the material file.

## 2.95.36 fix\_modify AtC mesh add\_to\_nodeset command

### Syntax

```
fix_modify <AtC fixID> mesh add_to_nodeset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- AtC fixID = ID of *fix atc* instance
- mesh create\_nodeset = name of the AtC sub-command
- id = id to assign to the collection of FE nodes
- <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> = coordinates of the bounding box that contains the desired nodes to be added

## Examples

```
fix_modify AtC mesh add_to_nodeset lbc -12.1 -11.9 -12 12 -12 12
```

## Description

Command to add nodes to an already existing FE nodeset.

## Restrictions

None

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create\_nodeset*

## Default

Coordinates are assumed to be in lattice units.

## 2.95.37 fix\_modify AtC mesh create command

### Syntax

```
fix_modify <AtC fixID> mesh create <nx> <ny> <nz> <region-ID> <f|p> <f|p> <f|p>
```

- AtC fixID = ID of *fix atc* instance
- mesh create = name of the AtC sub-command
- nx ny nz = number of elements in x-, y-, and z-direction
- region-ID = ID of region that is to be meshed
- f or p = periodicity flags for x-, y-, and z-direction

### Examples

```
fix_modify AtC mesh create 10 1 1 feRegion p p p
```

### Description

Creates a uniform mesh in a rectangular region.

### Restrictions

Creates only uniform rectangular grids in a rectangular region

## Related AtC commands

- [fix\\_modify AtC command overview](#)
- [fix\\_modify AtC mesh quadrature](#)

## Default

When created, the mesh defaults to gauss2 (2-point Gaussian) quadrature. Use the [fix\\_modify AtC mesh quadrature](#) command to change the quadrature style.

## 2.95.38 fix\_modify AtC mesh create\_elementset command

### Syntax

```
fix_modify <AtC fixID> mesh create_elementset <id> <xmin> <xmax> <ymin> <ymax> <zmin>
→<zmax>
```

- AtC fixID = ID of *fix atc* instance
- mesh create\_elementset = name of the AtC sub-command
- id = id to assign to the collection of FE nodes
- <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> = coordinates of the bounding box that contains only the desired elements

### Examples

```
fix_modify AtC mesh create_elementset middle -4.1 4.1 -100 100 -100 1100
```

### Description

Command to assign an id to a set of FE elements to be used subsequently in defining material and mesh-based operations.

### Restrictions

Only viable for rectangular grids.

## Related AtC commands

- [fix\\_modify AtC command overview](#)
- [fix\\_modify AtC mesh delete\\_elements](#)
- [fix\\_modify AtC mesh nodeset\\_to\\_elementset](#)

## Default

Coordinates are assumed to be in lattice units.

### 2.95.39 `fix_modify AtC mesh create_faceset box` command

#### Syntax

```
fix_modify <AtC fixID> mesh create_faceset <id> box <xmin> <xmax> <ymin> <ymax> <zmin>  
↪<zmax> <in|out> [units]
```

- AtC fixID = ID of *fix atc* instance
- mesh create\_faceset = name of the AtC sub-command
- id = id to assign to the collection of FE faces
- box = use bounding box to define FE faces
- <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> = coordinates of the bounding box that is coincident with the desired FE faces
- <in|out> = “in” gives inner faces to the box, “out” gives the outer faces to the box
- units = option to specify real as opposed to lattice units

#### Examples

```
fix_modify AtC mesh create_faceset obndy box -4.0 4.0 -12 12 -12 12 out
```

#### Description

Command to assign an id to a set of FE faces.

#### Restrictions

Only viable for rectangular grids.

#### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create\_faceset plane*

## Default

The default options are units = lattice and the use of outer faces.

## 2.95.40 fix\_modify AtC mesh create\_faceset plane command

### Syntax

```
fix_modify <AtC fixID> mesh create_faceset <id> plane <x|y|z> <val1> <x|y|z> <lval2>  
→<uval2> [units]
```

- AtC fixID = ID of *fix atc* instance
- mesh create\_faceset = name of the AtC sub-command
- id = id to assign to the collection of FE faces
- plane = use plane to define faceset
- <val1>,<lval2>,<uval2> = plane is specified as the x|y|z=val1 plane bounded by the segments x|y|z = [lval2,uval2]
- units = option to specify real as opposed to lattice units

### Examples

```
fix_modify AtC mesh create_faceset xyplane plane y 0 x -4 0
```

### Description

Command to assign an id to a set of FE faces.

### Restrictions

Only viable for rectangular grids.

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create\_faceset box*

## Default

The default options are units = lattice.

## 2.95.41 `fix_modify AtC mesh create_nodeset` command

### Syntax

```
fix_modify <AtC fixID> mesh create_nodeset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- AtC fixID = ID of *fix atc* instance
- mesh create\_nodeset = name of the AtC sub-command
- id = id to assign to the collection of FE nodes
- <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> = coordinates of the bounding box that contains only the desired nodes

### Examples

```
fix_modify AtC mesh create_nodeset lbc -12.1 -11.9 -12 12 -12 12
```

### Description

Command to assign an id to a set of FE nodes to be used subsequently in defining boundary conditions.

### Restrictions

None

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh add\_to\_nodeset*

### Default

Coordinates are assumed to be in lattice units.

## 2.95.42 `fix_modify AtC mesh delete_elements` command

### Syntax

```
fix_modify <AtC fixID> mesh delete_elements <id>
```

- AtC fixID = ID of *fix atc* instance
- mesh create\_elementsset = name of the AtC sub-command
- id = id of the element set

## Examples

```
fix_modify AtC mesh delete_elements gap
```

## Description

Deletes a group of elements from the mesh.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create\_elementset*
- *fix\_modify AtC mesh nodeset\_to\_elementset*

## Default

None.

## 2.95.43 fix\_modify AtC mesh nodeset\_to\_elementset command

### Syntax

```
fix_modify <AtC fixID> mesh nodeset_to_elementset <nodeset_id> <elementset_id> <max/min>
```

- AtC fixID = ID of *fix atc* instance
- mesh nodeset\_to\_elementset = name of the AtC sub-command
- nodeset\_id = id of desired nodeset from which to create the elementset
- elementset\_id = id to assign to the collection of FE elements
- <max/min> = flag to choose either the maximal or minimal elementset

## Examples

```
fix_modify AtC mesh nodeset_to_elementset myNodeset myElementset min
```

## Description

Command to create an elementset from an existing nodeset. Either the minimal element set of elements with all nodes in the set, or maximal element set with all elements with at least one node in the set, can be created.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create\_elementset*
- *fix\_modify AtC mesh delete\_elements*

## Default

Unless specified, the maximal element set is created.

## 2.95.44 fix\_modify AtC mesh output command

### Syntax

```
fix_modify <AtC fixID> mesh output <file_prefix>
```

- AtC fixID = ID of *fix atc* instance
- mesh output = name of the AtC sub-command
- file\_prefix = prefix of various generated output files

### Examples

```
fix_modify AtC mesh output meshData
```

## Description

Command to output mesh and associated data: nodesets, facesets, and elementsets. This data is only output once upon initialization since currently the mesh is static. Creates binary (EnSight, “gold” format) output of mesh data.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

None.

## 2.95.45 fix\_modify AtC mesh quadrature command

### Syntax

```
fix_modify <AtC fixID> mesh quatration <quad>
```

- AtC fixID = ID of *fix atc* instance
- mesh quadrature = name of the AtC sub-command
- quad = *nodal* or *gauss1* or *gauss2* or *gauss3* or *face*

### Examples

```
fix_modify AtC mesh quadrature face
```

### Description

(Re-)assigns the quadrature style for an existing mesh. When a mesh is created its quadrature method defaults to gauss2. Use this call to change it after the fact.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create*

## Default

None.

## 2.95.46 `fix_modify` AtC mesh read command

### Syntax

```
fix_modify <AtC fixID> mesh read <f|p> <f|p> <f|p>
```

- AtC fixID = ID of *fix atc* instance
- mesh read = name of the AtC sub-command
- filename = name of the file containing the mesh to be read
- f or p = periodicity flags for x-, y-, and z-direction (optional)

### Examples

```
fix_modify AtC mesh read myComponent.mesh p p p  
fix_modify AtC mesh read myOtherComponent.exo
```

### Description

Reads a mesh from a text or exodus file, and assigns periodic boundary conditions if needed.

### Restrictions

None

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create*
- *fix\_modify AtC mesh write*

### Default

Periodicity flags are set to false (f) by default.

## 2.95.47 fix\_modify AtC mesh write command

### Syntax

```
fix_modify <AtC fixID> mesh write <f|p> <f|p> <f|p>
```

- AtC fixID = ID of *fix atc* instance
- mesh write = name of the AtC sub-command
- filename = name of the file containing the mesh to be write

### Examples

```
fix_modify AtC mesh write myMesh.mesh
```

### Description

Writes a mesh to a text file.

### Restrictions

None

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC mesh create*
- *fix\_modify AtC mesh read*

### Default

None.

## 2.95.48 fix\_modify AtC output command

### Syntax

```
fix_modify <AtC fixID> output <filename_prefix> <frequency> [text|full_  
→text|binary|vector_components|tensor_components]  
fix_modify <AtC fixID> output index [step|time]
```

- AtC fixID = ID of *fix atc* instance
- *output* or *output index* = name of the AtC sub-command
- filename\_prefix = prefix for data files (for *output*)
- frequency = frequency of output in timesteps (for *output*)

- optional keywords for *output*:
  - text = creates text output of index, step and nodal variable values for unique nodes
  - full\_text = creates text output index, nodal id, step, nodal coordinates and nodal variable values for unique and image nodes
  - binary = creates binary EnSight output
  - vector\_components = outputs vectors as scalar components
  - tensor\_components = outputs tensor as scalar components (for use with ParaView)
- *step* or *time* = index output by step or by time (for *output index*)

## Examples

```
fix_modify AtC output heatFE 100
fix_modify AtC output hardyFE 1 text tensor_components
fix_modify AtC output hardyFE 10 text binary tensor_components
fix_modify AtC output index step
```

## Description

Creates text and/or binary (EnSight, “gold” format) output of nodal/mesh data which is transfer/physics specific. Output indexing by step or time is possible.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix atc command*

## Default

No default format. Output indexed by time.

## 2.95.49 fix\_modify AtC output boundary\_integral command

### Syntax

```
fix_modify <AtC fixID> output boundary_integral <fieldname> faceset [name]
```

- AtC fixID = ID of *fix atc* instance
- output boundary\_integral = name of the AtC sub-command
- fieldname = name of hardy field

- faceset = required keyword
- name= name of faceset

## Examples

```
fix_modify AtC output boundary_integral stress faceset loop1
```

## Description

Calculates a surface integral of the given field dotted with the outward normal of the faces and puts output in the “GLOBALS” file.

## Restrictions

Must be used with the hardy/field type of *fix atc*

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

None.

## 2.95.50 fix\_modify AtC output contour\_integral command

### Syntax

```
fix_modify <AtC fixID> output contour_integral <fieldname> faceset <name> [axis [x|y|z]]
```

- AtC fixID = ID of *fix atc* instance
- output contour\_integral = name of the AtC sub-command
- fieldname = name of hardy field
- faceset = required keyword
- name = name of faceset
- axis x or axis y or axis z = (optional)

## Examples

```
fix_modify AtC output contour_integral stress faceset loop1
```

## Description

Calculates a surface integral of the given field dotted with the outward normal of the faces and puts output in the “GLOBALS” file.

## Restrictions

Must be used with the hardy/field type of *fix atc*

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

None.

## 2.95.51 fix\_modify AtC output nodeset command

### Syntax

```
fix_modify <AtC fixID> output nodeset <nodeset_name> <operation>
```

- AtC fixID = ID of *fix atc* instance
- output nodeset = name of the AtC sub-command
- nodeset\_name= name of nodeset to be operated on
- operation = *sum*
  - *sum* = creates nodal sum over nodes in specified nodeset

## Examples

```
fix_modify AtC output nodeset nset1 sum
```

## Description

Performs operation over the nodes belonging to specified nodeset and outputs resulting variable values to GLOBALS file.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix atc command*

## Default

None.

## 2.95.52 fix\_modify AtC output volume\_integral command

### Syntax

```
fix_modify <AtC fixID> output volume_integral <elementset_name> <field>
```

- AtC fixID = ID of *fix atc* instance
- output volume\_integral = name of the AtC sub-command
- elementset\_name= name of elementset to be integrated over
- fieldname = name of field to integrate

### Examples

```
fix_modify AtC output volume_integral eset1 mass_density
```

## Description

Performs volume integration of specified field over elementset and outputs resulting variable values to GLOBALS file.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix atc command*

## Default

None.

### 2.95.53 fix\_modify AtC pair\_interactions command

### 2.95.54 fix\_modify AtC bond\_interactions command

## Syntax

```
fix_modify <AtC fixID> pair_interactions <on|off>  
fix_modify <AtC fixID> bond_interactions <on|off>
```

- AtC fixID = ID of *fix atc* instance
- *pair\_interactions* or *bond\_interactions* = name of the AtC sub-command
- *on* or *off* = activate or deactivate

## Examples

```
fix_modify AtC pair_interactions off  
fix_modify AtC bond_interactions on
```

## Description

Include bonds and/or pairs in stress and heat flux computations.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

*pair\_interactions*: on, *bond\_interactions*: off

## 2.95.55 fix\_modify AtC poisson\_solver command

### Syntax

```
fix_modify <AtC fixID> poisson_solver mesh create <nx> <ny> <nz> <region-ID> <f|p> <f|p>
→<f|p>
```

- AtC fixID = ID of *fix atc* instance
- poisson\_solver = name of the AtC sub-command
- *nx ny nz* = number of elements in x, y, and z
- region-id = id of region to be meshed
- *f* or *p* = periodicity flags for x, y, and z

### Examples

```
fix_modify AtC poisson_solver mesh create 10 1 1 feRegion p p p
```

### Description

Creates a uniform mesh in a rectangular region.

### Restrictions

Creates only uniform rectangular grids in rectangular regions.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

None.

## 2.95.56 `fix_modify AtC read_restart` command

### Syntax

```
fix_modify <AtC fixID> read_restart <file_name>
```

- AtC fixID = ID of *fix atc* instance
- read\_restart = name of the AtC sub-command
- file\_name = name of AtC restart file

### Examples

```
fix_modify AtC read_restart restart.mydata.AtC
```

### Description

Reads the current state of the AtC fields from a named text-based restart file.

### Restrictions

The restart file only contains fields and their time derivatives. The reference positions of the atoms and the commands that initialize the fix are not saved e.g. an identical mesh containing the same atoms will have to be recreated.

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC write\_restart*

## Default

None.

## 2.95.57 `fix_modify AtC remove_molecule` command

### Syntax

```
fix_modify <AtC fixID> remove_molecule <tag>
```

- AtC fixID = ID of *fix atc* instance
- remove\_molecule = name of the AtC sub-command
- tag = tag for tracking a molecule

## Examples

```
fix_modify AtC remove_molecule water
```

## Description

Removes tag designated for tracking a specified set of molecules.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC add\_species*
- *fix\_modify AtC add\_molecule*
- *fix\_modify AtC remove\_species*

## Default

None.

## 2.95.58 fix\_modify AtC remove\_source command

### Syntax

```
fix_modify <AtC fixID> remove_source <field> <element_set>
```

- AtC fixID = ID of *fix atc* instance
- remove\_source = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron\_temperature*
- element\_set = name of set of elements

## Examples

```
fix_modify AtC remove_source temperature groupNAME
```

## Description

Remove a domain source.

## Restrictions

The keyword *all* is reserved and thus not available as element\_set name.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC source*

## Default

None.

## 2.95.59 fix\_modify AtC remove\_species command

### Syntax

```
fix_modify <AtC fixID> remove_species <tag>
```

- AtC fixID = ID of *fix atc* instance
- remove\_species = name of the AtC sub-command
- tag = tag for tracking a species

### Examples

```
fix_modify AtC remove_species gold
```

## Description

Removes tag designated for tracking a specified species.

## Restrictions

None.

### Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC add\_species*
- *fix\_modify AtC add\_molecule*
- *fix\_modify AtC remove\_molecule*

### Default

None.

## 2.95.60 fix\_modify AtC reset\_atomic\_reference\_positions command

### Syntax

```
fix_modify <AtC fixID> reset_atomic_reference_positions
```

- AtC fixID = ID of *fix atc* instance
- reset\_atomic\_reference\_positions = name of the AtC sub-command

### Examples

```
fix_modify AtC reset_atomic_reference_positions
```

### Description

Resets the atomic positions ATC uses to perform point to field operations. In can be used to use perfect lattice sites in ATC but a thermalized or deformed lattice in LAMMPS.

### Restrictions

None.

### Related AtC commands

- *fix\_modify AtC command overview*

## Default

None

### 2.95.61 `fix_modify AtC reset_time` command

#### Syntax

```
fix_modify <AtC fixID> reset_time <value>
```

- AtC fixID = ID of *fix atc* instance
- reset\_time = name of the AtC sub-command
- value = new time value

#### Examples

```
fix_modify AtC reset_time 0.0
```

#### Description

Resets the simulation time counter.

#### Restrictions

None.

#### Related AtC commands

- *fix\_modify AtC command overview*

## Default

None

### 2.95.62 `fix_modify AtC sample_frequency` command

#### Syntax

```
fix_modify <AtC fixID> sample_frequency <freq>
```

- AtC fixID = ID of *fix atc* instance
- sample\_frequency = name of the AtC sub-command
- freq = frequency to sample fields in number of steps

## Examples

```
fix_modify AtC sample_frequency 10
```

## Description

Specifies a frequency at which fields are computed for the case where time filters are being applied.

## Restrictions

Must be used with *fix atc hardy* and is only relevant when time filters are being used.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

None.

## 2.95.63 fix\_modify AtC set reference\_potential\_energy command

### Syntax

```
fix_modify <AtC fixID> set reference_potential_energy [<value|filename>]
```

- AtC fixID = ID of *fix atc* instance
- set reference\_potential\_energy = name of the AtC sub-command
- value = optional user specified zero point for PE in native LAMMPS energy units
- filename = optional user specified string for file of nodal PE values to be read-in

## Examples

```
fix_modify AtC set reference_potential_energy
fix_modify AtC set reference_potential_energy -0.05
fix_modify AtC set reference_potential_energy myPEvalues
```

## Description

Used to set various quantities for the post-processing algorithms. It sets the zero point for the potential energy density using the value provided for all nodes, or from the current configuration of the lattice if no value is provided, or values provided within the specified filename.

## Restrictions

Must be used with *fix atc hardy* or *fix atc field*.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

Defaults to the LAMMPS zero point i.e. isolated atoms.

## 2.95.64 fix\_modify AtC source command

### Syntax

```
fix_modify <AtC fixID> source <field> <element_set> <value|function>
```

- AtC fixID = ID of *fix atc* instance
- source = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron\_temperature*
- element\_set = name of set of elements
- *value* or *function* = value or name of function followed by its parameters

### Examples

```
fix_modify AtC source temperature middle temporal_ramp 10.0 0.0
```

## Description

Add domain sources to the mesh. The units are consistent with LAMMPS's units for mass, length and time and are defined by the PDE being solved, e.g. for thermal transfer the balance equation is for energy and source is energy per time.

## Restrictions

The keyword *all* is reserved and thus not available as `element_set` name.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC remove\_source*

## Default

None.

## 2.95.65 fix\_modify AtC source\_integration command

### Syntax

```
fix_modify <AtC fixID> source_integration <fe|atom>
```

- AtC `fixID` = ID of *fix atc* instance
- `source_integration` = name of the AtC sub-command
- *fe* or *atom* = (undocumented)

### Examples

```
fix_modify AtC source_integration atom
```

### Description

(undocumented)

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

Default is *fe*

## 2.95.66 `fix_modify AtC temperature_definition` command

### Syntax

```
fix_modify <AtC fixID> temperature_definition <kinetic|total>
```

- AtC fixID = ID of *fix atc* instance
- temperature\_definition = name of the AtC sub-command
- *kinetic* or *total* = (undocumented)

### Examples

```
fix_modify AtC temperature_definition kinetic
```

### Description

Change the definition for the atomic temperature used to create the finite element temperature. The kinetic option is based only on the kinetic energy of the atoms while the total option uses the total energy (kinetic + potential) of an atom.

### Restrictions

This command is only valid when using thermal coupling. Also, while not a formal restriction, the user should ensure that associating a potential energy with each atom makes physical sense for the total option to be meaningful.

### Related AtC commands

- *fix\_modify AtC command overview*

## Default

*kinetic*

## 2.95.67 `fix_modify AtC filter` command

### Syntax

```
fix_modify <AtC fixID> filter <on|off|equilibrate>
```

- AtC fixID = ID of *fix atc* instance
- filter = name of the AtC sub-command

- *on* or *off* or *equilibrate* = Select state of filter

## Examples

```
fix_modify AtC filter on
```

## Description

Filters the MD dynamics to construct a more appropriate continuous field. Equilibrating first filters the time derivatives without changing the dynamics to provide a better initial condition to the filtered dynamics.

## Restrictions

Only for use with these specific transfers: thermal, two\_temperature

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC filter scale*
- *fix\_modify AtC equilibrium\_start*

## Default

off

## 2.95.68 fix\_modify AtC time\_integration command

### Syntax

```
fix_modify <AtC fixID> time_integration <descriptor>
```

- AtC fixID = ID of *fix atc* instance
- time\_integration = name of the AtC sub-command
- descriptor = *gear* or *fractional\_step* or *verlet*

## Examples

```
fix_modify AtC time_integration fractional_step
```

## Description

Command to select the thermal or momentum time integration.

---

Options for thermal time integration:

### *gear*

atomic velocity update with second order Verlet, nodal temperature update with third or fourth order Gear, thermostats based on controlling power

### *fractional\_step*

atomic velocity update with second order Verlet, mixed nodal temperature update, 3/4 Gear for continuum and 2 Verlet for atomic contributions, thermostats based on controlling discrete energy changes

---

Options for momentum time integration:

### *verlet*

atomic velocity update with second order Verlet, nodal temperature update with second order Verlet, kinetostats based on controlling force

### *fractional\_step*

atomic velocity update with second order Verlet, mixed nodal momentum update, second order Verlet for continuum and exact second order Verlet for atomic contributions, kinetostats based on controlling discrete momentum changes

### *gear*

atomic velocity update with second order Verlet, nodal temperature update with third or fourth order Gear, kinetostats based on controlling power.

---

## Restrictions

None.

## Related AtC commands

- [\*fix\\_modify AtC command overview\*](#)

## Default

None.

## 2.95.69 fix\_modify AtC track\_displacement command

### Syntax

```
fix_modify <AtC fixID> track_displacement <on|off>
```

- AtC fixID = ID of *fix atc* instance
- track\_displacement = name of the AtC sub-command
- *on* or *off* = (undocumented)

## Examples

```
fix_modify AtC track_displacement on
```

## Description

Determines whether displacement is tracked or not. For solids problems this is a useful quantity, but for fluids it is not relevant.

## Restrictions

Some constitutive models require the displacement field.

## Related AtC commands

- *fix\_modify AtC command overview*

## Default

*on*

## 2.95.70 fix\_modify AtC unfix command

### Syntax

```
fix_modify <AtC fixID> unfix <field> <nodeset>
```

- AtC fixID = ID of *fix atc* instance
- unfix = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron\_temperature*
- nodeset = name of set of nodes to apply boundary condition

## Examples

```
fix_modify AtC unfix temperature groupNAME
```

## Description

Removes constraint on field values for specified nodes.

## Restrictions

The keyword *all* is reserved and thus not available as nodeset name.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC fix*

## Default

None.

## 2.95.71 fix\_modify AtC unfix\_flux command

### Syntax

```
fix_modify <AtC fixID> unfix_flux <field> <face_set> <value|function>
```

- AtC fixID = ID of *fix atc* instance
- unfix\_flux = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron\_temperature*
- face\_set = name of set of element faces

### Examples

```
fix_modify AtC unfix_flux temperature faceSet
```

### Description

Command for removing prescribed normal fluxes e.g. heat\_flux, stress.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC fix\_flux*

## Default

None.

## 2.95.72 `fix_modify AtC write_atom_weights` command

### Syntax

```
fix_modify <AtC fixID> write_atom_weights <filename> <frequency>
```

- AtC fixID = ID of *fix atc* instance
- write\_atom\_weights = name of the AtC sub-command
- filename = name of file that atomic weights are written to
- frequency = how often writes will occur

### Examples

```
fix_modify AtC write_atom_weights atm_wt_file.txt 10
```

### Description

Command for writing the values of atomic weights to a specified file.

### Restrictions

None.

### Related AtC commands

- *fix\_modify AtC command overview*

## Default

None

## 2.95.73 `fix_modify AtC write_restart` command

### Syntax

```
fix_modify <AtC fixID> write_restart <file_name>
```

- AtC fixID = ID of *fix atc* instance
- write\_restart = name of the AtC sub-command
- file\_name = name of AtC restart file

## Examples

```
fix_modify AtC write_restart restart.mydata.AtC
```

## Description

Dumps the current state of the fields to a named text-based restart file. This done when the command is invoked and not repeated, unlike the otherwise similar LAMMPS command.

## Restrictions

None.

## Related AtC commands

- *fix\_modify AtC command overview*
- *fix\_modify AtC read\_restart*

## Default

None.

# 2.96 fix mol/swap command

## 2.96.1 Syntax

```
fix ID group-ID mol/swap N X itype jtype seed T keyword value ...
```

- ID, group-ID are documented in *fix* command
- atom/swap = style name of this fix command
- N = invoke this fix every N steps
- X = number of swaps to attempt every N steps
- itype,jtype = two atom types (1-Ntypes or type label) to swap with each other
- seed = random # seed (positive integer)
- T = scaling temperature of the MC swaps (temperature units)
- zero or more keyword/value pairs may be appended to args
- keyword = *ke*  
    *ke* value = *no* or *yes*  
        *no* = no conservation of kinetic energy after atom swaps  
        *yes* = kinetic energy is conserved after atom swaps

## 2.96.2 Examples

```
fix 2 all mol/swap 100 1 2 3 29494 300.0 ke no
fix mySwap fluid mol/swap 500 10 1 2 482798 1.0

labelmap atom 1 A 2 B
fix mySwap fluid mol/swap 500 10 A B 482798 1.0
```

## 2.96.3 Description

This fix performs Monte Carlo swaps of two specified atom types within a randomly selected molecule. Two possible use cases are as follows.

First, consider a mixture of some molecules with atoms of itype and other molecules with atoms of jtype. The fix will select a random molecule and attempt to swap all the itype atoms to jtype for the first kind of molecule, or all the jtype atoms to itype for the second kind. Because the swap will only take place if it is energetically favorable, the fix can be used to determine the miscibility of 2 different kinds of molecules much more quickly than just dynamics would do it.

Second, consider diblock co-polymers with two types of monomers itype and jtype. The fix will select a random molecule and attempt to do a itype <=> jtype swap of all those monomers within the molecule. Thus the fix can be used to find the energetically favorable fractions of two flavors of diblock co-polymers.

Intra-molecular swaps of atom types are attempted every N timesteps. On that timestep, X swaps are attempted. For each attempt a single molecule ID is randomly selected. The range of possible molecule IDs from loID to hiID is pre-computed before each run begins. The loID/hiID is set for the molecule with the smallest/largest ID which has any itype or jtype atoms in it. Note that if you define a system with many molecule IDs between loID and hiID which have no itype or jtype atoms, then the fix will be inefficient at performing swaps. Also note that if atoms with molecule ID = 0 exist, they are not considered molecules by this fix; they are assumed to be solvent atoms or molecules.

Candidate atoms for swapping must also be in the fix group. Atoms within the selected molecule which are not itype or jtype are ignored.

When an atom is swapped from itype to jtype (or vice versa), if charges are defined, the charge values for itype versus jtype atoms are also swapped. This requires that all itype atoms in the system have the same charge value. Likewise all jtype atoms in the system must have the same charge value. If this is not the case, LAMMPS issues a warning that it cannot swap charge values.

If the *ke* keyword is set to yes, which is the default, and the masses of itype and jtype atoms are different, then when a swap occurs, the velocity of the swapped atom is rescaled by the sqrt of the mass ratio, so as to conserve the kinetic energy of the atom.

The potential energy of the entire system is computed before and after each swap is performed within a single molecule. The specified temperature T is used in the Metropolis criterion to accept or reject the attempted swap. If the swap is rejected all swapped values are reversed.

The potential energy calculations can include systems and models with the following features:

- manybody pair styles, including EAM
- hybrid pair styles
- long-range electrostatics (k-space)
- triclinic systems
- potential energy contributions from other fixes

For the last bullet point, fixes can have an associated potential energy. Examples of such fixes include: *efield*, *gravity*, *addforce*, *langevin*, *restrain*, *temp/berendsen*, *temp/rescale*, and *wall fixes*. For that energy to be included in the total potential energy of the system (the quantity used for the swap accept/reject decision), you MUST enable the *fix\_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

---

**Note:** One comment on computational efficiency. If the cutoff lengths defined for the pair style are different for itype versus jtype atoms (for any of their interactions with any other atom type), then a new neighbor list needs to be generated for every attempted swap. This is potentially expensive if N is small or X is large.

---

## 2.96.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the fix to *binary restart files*. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of exchange attempts and successes etc. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset\_timestep*. The fix will try to detect it and stop with an error.

---

None of the *fix\_modify* options are relevant to this fix.

This fix computes a global vector of length 2, which can be accessed by various *output commands*. The vector values are the following global cumulative quantities:

1. swap attempts
2. swap accepts

The vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.96.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

## 2.96.6 Related commands

*fix atom/swap*, *fix gcmc*

## 2.96.7 Default

The option default is `ke = yes`.

## 2.97 fix momentum command

Accelerator Variants: *momentum/kk*

## 2.98 fix momentum/chunk command

### 2.98.1 Syntax

```
fix ID group-ID momentum N keyword values ...
```

- ID, group-ID are documented in *fix* command
- momentum = style name of this fix command
- N = adjust the momentum every this many timesteps one or more keyword/value pairs may be appended

```
fix ID group-ID momentum/chunk N chunkID keyword values ...
```

- ID, group-ID are documented in *fix* command
- momentum/chunk = style name of this fix command
- N = adjust the momentum per chunk every this many timesteps
- chunkID = ID of *compute chunk/atom* command
  - one or more keyword/value settings may be appended to each of the fix commands:
- keyword = *linear* or *angular* or *rescale*
  - linear* values = xflag yflag zflag
    - xflag,yflag,zflag = 0/1 to exclude/include each dimension
  - angular* values = none
  - rescale* values = none

### 2.98.2 Examples

```
fix 1 all momentum 1 linear 1 1 0
fix 1 all momentum 1 linear 1 1 1 rescale
fix 1 all momentum 100 linear 1 1 1 angular
fix 1 all momentum/chunk 100 molchunk linear 1 1 1 angular
```

### 2.98.3 Description

Fix momentum zeroes the linear and/or angular momentum of the group of atoms every N timesteps by adjusting the velocities of the atoms. Fix momentum/chunk works equivalently, but operates on a per-chunk basis.

One (or both) of the *linear* or *angular* keywords **must** be specified.

If the *linear* keyword is used, the linear momentum is zeroed by subtracting the center-of-mass velocity of the group or chunk from each atom. This does not change the relative velocity of any pair of atoms. One or more dimensions can be excluded from this operation by setting the corresponding flag to 0.

If the *angular* keyword is used, the angular momentum is zeroed by subtracting a rotational component from each atom.

This command can be used to ensure the entire collection of atoms (or a subset of them) does not drift or rotate during the simulation due to random perturbations (e.g. *fix langevin* thermostating).

The *rescale* keyword enables conserving the kinetic energy of the group or chunk of atoms by rescaling the velocities after the momentum was removed.

Note that the *velocity* command can be used to create initial velocities with zero aggregate linear and/or angular momentum.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 2.98.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.98.5 Restrictions

Fix momentum/chunk is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.98.6 Related commands

fix 3 boundary move transrot 0.1 0.1 0.0 0.0 0.0 0.0 0.0 1.0 5.0 units box
```

## 2.99.3 Description

Perform updates of position and velocity for atoms in the group each timestep using the specified settings or formulas, without regard to forces on the atoms. This can be useful for boundary or other atoms, whose movement can influence nearby atoms.

---

**Note:** The atoms affected by this fix should not normally be time integrated by other fixes (e.g. *fix nve*, *fix nvt*), since that will change their positions and velocities twice.

---

---

**Note:** As atoms move due to this fix, they will pass through periodic boundaries and be remapped to the other side of the simulation box, just as they would during normal time integration (e.g. via the *fix nve* command). It is up to you to decide whether periodic boundaries are appropriate with the kind of atom motion you are prescribing with this fix.

---

---

**Note:** As discussed below, atoms are moved relative to their initial position at the time the fix is specified. These initial coordinates are stored by the fix in “unwrapped” form, by using the image flags associated with each atom. See the *dump custom* command for a discussion of “unwrapped” coordinates. See the Atoms section of the *read\_data* command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this fix by using the *set image* command.

---

The *linear* style moves atoms at a constant velocity, so that their position  $X = (x,y,z)$  as a function of time is given in vector notation as

$$X(t) = X0 + V * \text{delta}$$

where  $X0 = (x0,y0,z0)$  is their position at the time the fix is specified,  $V$  is the specified velocity vector with components  $(Vx,Vy,Vz)$ , and  $\text{delta}$  is the time elapsed since the fix was specified. This style also sets the velocity of each atom to  $V = (Vx,Vy,Vz)$ . If any of the velocity components is specified as NULL, then the position and velocity of that component is time integrated the same as the *fix nve* command would perform, using the corresponding force component on the atom.

Note that the *linear* style is identical to using the *variable* style with an *equal-style variable* that uses the *vdisplace()* function. E.g.

```
variable V equal 10.0
variable x equal vdisplace(0.0,$V)
fix 1 boundary move variable v_x NULL NULL v_V NULL NULL
```

The *wiggle* style moves atoms in an oscillatory fashion, so that their position  $X = (x,y,z)$  as a function of time is given in vector notation as

$$X(t) = X0 + A \sin(\omega * \text{delta})$$

where  $X0 = (x0,y0,z0)$  is their position at the time the fix is specified,  $A$  is the specified amplitude vector with components  $(Ax,Ay,Az)$ ,  $\omega$  is  $2\pi / \text{period}$ , and  $\delta$  is the time elapsed since the fix was specified. This style also sets the velocity of each atom to the time derivative of this expression. If any of the amplitude components is specified as NULL, then the position and velocity of that component is time integrated the same as the *fix nve* command would perform, using the corresponding force component on the atom.

Note that the *wiggle* style is identical to using the *variable* style with *equal-style variables* that use the *swiggle()* and *cwiggle()* functions. E.g.

```
variable A equal 10.0
variable T equal 5.0
variable omega equal 2.0*PI/$T
variable x equal swiggle(0.0,$A,$T)
variable v equal v_omega*($A-cwiggle(0.0,$A,$T))
fix 1 boundary move variable v_x NULL NULL v_v NULL NULL
```

The *rotate* style rotates atoms around a rotation axis  $R = (Rx,Ry,Rz)$  that goes through a point  $P = (Px,Py,Pz)$ . The *period* of the rotation is also specified. The direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along  $R$ , then your fingers wrap around the axis in the direction of rotation.

This style also sets the velocity of each atom to  $(\omega \text{ cross } R_{\text{perp}})$  where  $\omega$  is its angular velocity around the rotation axis and  $R_{\text{perp}}$  is a perpendicular vector from the rotation axis to the atom. If the defined *atom\_style* assigns an angular velocity or angular momentum or orientation to each atom (*atom styles* sphere, ellipsoid, line, tri, body), then those properties are also updated appropriately to correspond to the atom's motion and rotation over time.

The *transrot* style combines the effects of *rotate* and *linear* so that it is possible to prescribe a rotating group of atoms that also moves at a constant velocity. The arguments are for the translation first and then for the rotation. Since the rotation affects all coordinate components, it is not possible to set any of the translation vector components to NULL.

The *variable* style allows the position and velocity components of each atom to be set by formulas specified via the *variable* command. Each of the 6 variables is specified as an argument to the fix as *v\_name*, where name is the variable name that is defined elsewhere in the input script.

Each variable must be of either the *equal* or *atom* style. *Equal-style* variables compute a single numeric quantity, that can be a function of the timestep as well as of other simulation values. *Atom-style* variables compute a numeric quantity for each atom, that can be a function per-atom quantities, such as the atom's position, as well as of the timestep and other simulation values. Note that this fix stores the original coordinates of each atom (see note below) so that per-atom quantity can be used in an atom-style variable formula. See the *variable* command for details.

The first 3 variables (*v\_dx,v\_dy,v\_dz*) specified for the *variable* style are used to calculate a displacement from the atom's original position at the time the fix was specified. The second 3 variables (*v\_vx,v\_vy,v\_vz*) specified are used to compute a velocity for each atom.

Any of the 6 variables can be specified as NULL. If both the displacement and velocity variables for a particular x,y,z component are specified as NULL, then the position and velocity of that component is time integrated the same as the *fix nve* command would perform, using the corresponding force component on the atom. If only the velocity variable for a component is specified as NULL, then the displacement variable will be used to set the position of the atom, and its velocity component will not be changed. If only the displacement variable for a component is specified as NULL, then the velocity variable will be used to set the velocity of the atom, and the position of the atom will be time integrated using that velocity.

The *units* keyword determines the meaning of the distance units used to define the *linear* velocity and *wiggle* amplitude and *rotate* origin. This setting is ignored for the *variable* style. A *box* value selects standard units as defined by the *units* command, e.g. velocity in Angstroms/fs and amplitude and position in Angstroms for *units = real*. A *lattice* value means the velocity units are in lattice spacings per time and the amplitude and position are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. Each of these 3 quantities may be dependent on the x,y,z dimension, since the lattice spacings can be different in x,y,z.

## 2.99.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the original coordinates of moving atoms to *binary restart files*, as well as the initial timestep, so that the motion can be continuous in a restarted simulation. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** Because the move positions are a function of the current timestep and the initial timestep, you cannot reset the timestep to a different value after reading a restart file, if you expect a fix move command to work in an uninterrupted fashion.

---

None of the *fix\_modify* options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various *output commands*. The number of columns for each atom is 3, and the columns store the original unwrapped x,y,z coords of each atom. The per-atom values can be accessed on any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

For *rRESPA time integration*, this fix adjusts the position and velocity of atoms on the outermost rRESPA level.

## 2.99.5 Restrictions

## 2.99.6 Related commands

*fix nve, displace\_atoms*

## 2.99.7 Default

none

The option default is units = lattice.

# 2.100 fix msst command

## 2.100.1 Syntax

**fix** ID group-ID msst dir shockvel keyword value ...

- ID, group-ID are documented in *fix* command
- msst = style name of this fix
- dir = x or y or z
- shockvel = shock velocity (strictly positive, distance/time units)

- zero or more keyword value pairs may be appended
- keyword = *q* or *mu* or *p0* or *v0* or *e0* or *tscale* or *beta* or *dftb*
  - q* value = cell mass-like parameter ( $\text{mass}^2/\text{distance}^4$  units)
  - mu* value = artificial viscosity ( $\text{mass}/\text{length}/\text{time}$  units)
  - p0* value = initial pressure in the shock equations (pressure units)
  - v0* value = initial simulation cell volume in the shock equations ( $\text{distance}^3$  units)
  - e0* value = initial total energy (energy units)
  - tscale* value = reduction in initial temperature (unitless fraction between 0.0 and 1.0)
  - dftb* value = yes or no for whether using MSST in conjunction with DFTB+
  - beta* value = scale factor for improved energy conservation

## 2.100.2 Examples

```
fix 1 all msst y 100.0 q 1.0e5 mu 1.0e5
fix 2 all msst z 50.0 q 1.0e4 mu 1.0e4 v0 4.3419e+03 p0 3.7797e+03 e0 -9.72360e+02
→tscale 0.01
fix 1 all msst y 100.0 q 1.0e5 mu 1.0e5 dftb yes beta 0.5
```

## 2.100.3 Description

This command performs the Multi-Scale Shock Technique (MSST) integration to update positions and velocities each timestep to mimic a compressive shock wave passing over the system. See [\(Reed\)](#) for a detailed description of this method. The MSST varies the cell volume and temperature in such a way as to restrain the system to the shock Hugoniot and the Rayleigh line. These restraints correspond to the macroscopic conservation laws dictated by a shock front. *shockvel* determines the steady shock velocity that will be simulated.

To perform a simulation, choose a value of *q* that provides volume compression on the timescale of 100 fs to 1 ps. If the volume is not compressing, either the shock speed is chosen to be below the material sound speed or *p0* has been chosen inaccurately. Volume compression at the start can be sped up by using a non-zero value of *tscale*. Use the smallest value of *tscale* that results in compression.

Under some special high-symmetry conditions, the pressure (volume) and/or temperature of the system may oscillate for many cycles even with an appropriate choice of mass-like parameter *q*. Such oscillations have physical significance in some cases. The optional *mu* keyword adds an artificial viscosity that helps break the system symmetry to equilibrate to the shock Hugoniot and Rayleigh line more rapidly in such cases.

The keyword *tscale* is a factor between 0 and 1 that determines what fraction of thermal kinetic energy is converted to compressive strain kinetic energy at the start of the simulation. Setting this parameter to a non-zero value may assist in compression at the start of simulations where it is slow to occur.

If keywords *e0*, *p0*, or *v0* are not supplied, these quantities will be calculated on the first step, after the energy specified by *tscale* is removed. The value of *e0* is not used in the dynamical equations, but is used in calculating the deviation from the Hugoniot.

The keyword *beta* is a scaling term that can be added to the MSST ionic equations of motion to account for drift in the conserved quantity during long timescale simulations, similar to a Berendsen thermostat. See [\(Reed\)](#) and [\(Goldman\)](#) for more details. The value of *beta* must be between 0.0 and 1.0 inclusive. A value of 0.0 means no contribution, a value of 1.0 means a full contribution.

Values of *shockvel* less than a critical value determined by the material response will not have compressive solutions. This will be reflected in lack of significant change of the volume in the MSST.

For all pressure styles, the simulation box stays orthogonal in shape. Parrinello-Rahman boundary conditions (tilted box) are supported by LAMMPS, but are not implemented for MSST.

This fix computes a temperature and pressure and potential energy each timestep. To do this, the fix creates its own computes of style “temp” “pressure”, and “pe”, as if these commands had been issued:

```
compute fix-ID_MSST_temp all temp
compute fix-ID_MSST_press all pressure fix-ID_MSST_temp

compute fix-ID_MSST_pe all pe
```

See the [compute temp](#) and [compute pressure](#) commands for details. Note that the IDs of the new computes are the fix-ID + “\_MSST\_temp” or “\_MSST\_press” or “\_MSST\_pe”. The group for the new computes is “all”.

---

The *dftb* keyword is to allow this fix to be used when LAMMPS is being driven by DFTB+, a density-functional tight-binding code. If the keyword *dftb* is used with a value of *yes*, then the MSST equations are altered to account for the electron entropy contribution to the Hugoniot relations and total energy. See ([Reed2](#)) and ([Goldman](#)) for details on this contribution. In this case, you must define a [fix external](#) command in your input script, which is used to callback to DFTB+ during the LAMMPS timestepping. DFTB+ will communicate its info to LAMMPS via that fix.

---

## 2.100.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of all internal variables to *binary restart files*. See the [read\\_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The cumulative energy change in the system imposed by this fix is included in the [thermodynamic output](#) keywords *ecouple* and *econserve*. See the [thermo\\_style](#) doc page for details.

This fix computes a global scalar which can be accessed by various [output commands](#). The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

The progress of the MSST can be monitored by printing the global scalar and global vector quantities computed by the fix.

As mentioned above, the scalar is the cumulative energy change due to the fix. By monitoring the thermodynamic *econserve* output, this can be used to test if the MD timestep is sufficiently small for accurate integration of the dynamic equations.

The global vector contains four values in the following order. The vector values output by this fix are “intensive”.

[*dhugoniot*, *drayleigh*, *lagrangian\_speed*, *lagrangian\_position*]

1. *dhugoniot* is the departure from the Hugoniot (temperature units).
2. *drayleigh* is the departure from the Rayleigh line (pressure units).
3. *lagrangian\_speed* is the laboratory-frame Lagrangian speed (particle velocity) of the computational cell (velocity units).
4. *lagrangian\_position* is the computational cell position in the reference frame moving at the shock speed. This is usually a good estimate of distance of the computational cell behind the shock front.

To print these quantities to the log file with descriptive column headers, the following LAMMPS commands are suggested:

```

fix                msst all msst z
variable dhug      equal f_msst[1]
variable dray      equal f_msst[2]
variable lgr_vel   equal f_msst[3]
variable lgr_pos   equal f_msst[4]
thermo_style       custom step temp ke pe lz pzz econserve v_dhug v_dray v_lgr_vel v_lgr_
→pos f_msst

```

## 2.100.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

All cell dimensions must be periodic. This fix can not be used with a triclinic cell. The MSST fix has been tested only for the group-ID all.

## 2.100.6 Related commands

*fix nphug, fix deform*

## 2.100.7 Default

The keyword defaults are  $q = 10$ ,  $\mu = 0$ ,  $t_{\text{scale}} = 0.01$ ,  $d_{\text{ftb}} = \text{no}$ ,  $\beta = 0.0$ . Note that  $p_0$ ,  $v_0$ , and  $e_0$  are calculated on the first timestep.

## 2.101 fix mvv/dpd command

## 2.102 fix mvv/edpd command

## 2.103 fix mvv/tdpd command

### 2.103.1 Syntax

```

fix ID group-ID mvv/dpd lambda
fix ID group-ID mvv/edpd lambda
fix ID group-ID mvv/tdpd lambda

```

- ID, group-ID are documented in *fix* command

- mvv/dpd, mvv/edpd, mvv/tdpd = style name of this fix command
- lambda = (optional) relaxation parameter (unitless)

## 2.103.2 Examples

```
fix 1 all mvv/dpd
fix 1 all mvv/dpd 0.5
fix 1 all mvv/edpd
fix 1 all mvv/edpd 0.5
fix 1 all mvv/tdpd
fix 1 all mvv/tdpd 0.5
```

## 2.103.3 Description

Perform time integration using the modified velocity-Verlet (MVV) algorithm to update position and velocity (fix mvv/dpd), or position, velocity and temperature (fix mvv/edpd), or position, velocity and concentration (fix mvv/tdpd) for particles in the group each timestep.

The modified velocity-Verlet (MVV) algorithm aims to improve the stability of the time integrator by using an extrapolated version of the velocity for the force evaluation:

$$\begin{aligned}v(t + \frac{\Delta t}{2}) &= v(t) + \frac{\Delta t}{2} \cdot a(t) \\r(t + \Delta t) &= r(t) + \Delta t \cdot v(t + \frac{\Delta t}{2}) \\a(t + \Delta t) &= \frac{1}{m} \cdot F[r(t + \Delta t), v(t) + \lambda \cdot \Delta t \cdot a(t)] \\v(t + \Delta t) &= v(t + \frac{\Delta t}{2}) + \frac{\Delta t}{2} \cdot a(t + \Delta t)\end{aligned}$$

where the parameter  $\lambda$  depends on the specific choice of DPD parameters, and needs to be tuned on a case-by-case basis. Specification of a *lambda* value is optional. If specified, the setting must be from 0.0 to 1.0. If not specified, a default value of 0.5 is used, which effectively reproduces the standard velocity-Verlet (VV) scheme. For more details, see [Groot](#).

Fix *mvv/dpd* updates the position and velocity of each atom. It can be used with the *pair\_style mdpd* command or other pair styles such as *pair dpd*.

Fix *mvv/edpd* updates the per-atom temperature, in addition to position and velocity, and must be used with the *pair\_style edpd* command.

Fix *mvv/tdpd* updates the per-atom chemical concentration, in addition to position and velocity, and must be used with the *pair\_style tdpd* command.

---

## 2.103.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.103.5 Restrictions

These fixes are part of the DPD-MESO package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Changed in version 29Aug2024.

This fix is incompatible with deformation controls that remap velocity, for instance the *remap v* option of *fix deform*.

## 2.103.6 Related commands

*pair\_style mdpd*, *pair\_style edpd*, *pair\_style tdpd*

## 2.103.7 Default

The default value for the optional *lambda* parameter is 0.5.

## 2.104 fix neb command

### 2.104.1 Syntax

```
fix ID group-ID neb Kspring keyword value
```

- ID, group-ID are documented in *fix* command
- neb = style name of this fix command
- Kspring = spring constant for parallel nudging force (force/distance units or force units, see parallel keyword)
- zero or more keyword/value pairs may be appended
- keyword = *parallel* or *perp* or *end*

*parallel* value = *neigh* or *ideal* or *equal*

*neigh* = parallel nudging force based on distance to neighbor replicas (Kspring = force/↪distance units)

*ideal* = parallel nudging force based on interpolated ideal position (Kspring = force,↪units)

*equal* = parallel nudging force based on interpolated ideal position before climbing,↪then interpolated ideal energy whilst climbing (Kspring = force units)

*perp* value = *Kspring2*

*Kspring2* = spring constant for perpendicular nudging force (force/distance units)

*end* values = *estyle* Kspring3

```

estyle = first or last or last/efirst or last/efirst/middle
  first = apply force to first replica
  last = apply force to last replica
  last/efirst = apply force to last replica and set its target energy to that of first_
→replica
  last/efirst/middle = same as last/efirst plus prevent middle replicas having lower_
→energy than first replica
  Kspring3 = spring constant for target energy term (1/distance units)

```

## 2.104.2 Examples

```

fix 1 active neb 10.0
fix 2 all neb 1.0 perp 1.0 end last
fix 2 all neb 1.0 perp 1.0 end first 1.0 end last 1.0
fix 1 all neb 1.0 parallel ideal end last/efirst 1

```

## 2.104.3 Description

Add nudging forces to atoms in the group for a multi-replica simulation run via the `neb` command to perform a nudged elastic band (NEB) calculation for finding the transition state. Hi-level explanations of NEB are given with the `neb` command and on the [Howto replica](#) doc page. The `fix neb` command must be used with the “neb” command and defines how inter-replica nudging forces are computed. A NEB calculation is divided in two stages. In the first stage  $n$  replicas are relaxed toward a MEP until convergence. In the second stage, the climbing image scheme (see [\(Henkelman2\)](#)) is enabled, so that the replica having the highest energy relaxes toward the saddle point (i.e. the point of highest energy along the MEP), and a second relaxation is performed.

A key purpose of the nudging forces is to keep the replicas equally spaced. During the NEB calculation, the  $3N$ -length vector of interatomic force  $F_i = -\nabla V$  for each replica  $i$  is altered. For all intermediate replicas (i.e. for  $1 < i < N$ , except the climbing replica) the force vector becomes:

$$F_i = -\nabla V + (\nabla V \cdot T')T' + F_{\parallel} + F_{\perp}$$

$T'$  is the unit “tangent” vector for replica  $i$  and is a function of  $R_i, R_{i-1}, R_{i+1}$ , and the potential energy of the 3 replicas; it points roughly in the direction of  $R_{i+1} - R_{i-1}$ ; see the [\(Henkelman1\)](#) paper for details.  $R_i$  are the atomic coordinates of replica  $i$ ;  $R_{i-1}$  and  $R_{i+1}$  are the coordinates of its neighbor replicas. The term  $\nabla V \cdot T'$  is used to remove the component of the gradient parallel to the path which would tend to distribute the replica unevenly along the path.  $F_{\parallel}$  is an artificial nudging force which is applied only in the tangent direction and which maintains the equal spacing between replicas (see below for more information).  $F_{\perp}$  is an optional artificial spring which is applied in a direction perpendicular to the tangent direction and which prevent the paths from forming acute kinks (see below for more information).

In the second stage of the NEB calculation, the interatomic force  $F_i$  for the climbing replica (the replica of highest energy after the first stage) is changed to:

$$F_i = -\nabla V + 2(\nabla V \cdot T')T' + F_{\perp}$$

and the relaxation procedure is continued to a new converged MEP.

The keyword `parallel` specifies how the parallel nudging force is computed. With a value of `neigh`, the parallel nudging force is computed as in [\(Henkelman1\)](#) by connecting each intermediate replica with the previous and the next image:

$$F_{\parallel} = Kspring \cdot (|R_{i+1} - R_i| - |R_i - R_{i-1}|)$$

Note that in this case the specified *Kspring* is in force/distance units.

With a value of *ideal*, the spring force is computed as suggested in (WeinanE)

$$F_{\parallel} = -K_{spring} \cdot (RD - RD_{ideal}) / (2 \cdot meanDist)$$

where *RD* is the “reaction coordinate” see *neb* section, and *RD<sub>ideal</sub>* is the ideal *RD* for which all the images are equally spaced. I.e.  $RD_{ideal} = (i - 1) \cdot meanDist$  when the climbing replica is off, where *i* is the replica number). The *meanDist* is the average distance between replicas. Note that in this case the specified *Kspring* is in force units. When the climbing replica is on, *RD<sub>ideal</sub>* and *meanDist* are calculated separately each side of the climbing image. Note that the *ideal* form of nudging can often be more effective at keeping the replicas equally spaced before climbing, then equally spaced either side of the climbing image whilst climbing.

With a value of *equal* the spring force is computed as for *ideal* when the climbing replica is off, promoting equidistance. When the climbing replica is on, the spring force is computed to promote equidistant absolute differences in energy, rather than distance, each side of the climbing image:

$$F_{\parallel} = -K_{spring} \cdot (ED - ED_{ideal}) / (2 \cdot meanEDist)$$

where *ED* is the cumulative sum of absolute energy differences:

$$ED = \sum_{i < N} |E(R_{i+1}) - E(R_i)|,$$

*meanEDist* is the average absolute energy difference between replicas up to the climbing image or from the climbing image to the final image, for images before or after the climbing image respectively. *ED<sub>ideal</sub>* is the corresponding cumulative sum of average absolute energy differences in each case, in close analogy to *ideal*. This form of nudging is to aid schemes which integrate forces along, or near to, NEB pathways such as *fix\_pafi*.

The keyword *perp* specifies if and how a perpendicular nudging force is computed. It adds a spring force perpendicular to the path in order to prevent the path from becoming too strongly kinked. It can significantly improve the convergence of the NEB calculation when the resolution is poor. I.e. when few replicas are used; see (Maras) for details.

The perpendicular spring force is given by

$$F_{\perp} = K_{spring2} \cdot F(R_{i-1}, R_i, R_{i+1})(R_{i+1} + R_{i-1} - 2R_i)$$

where *Kspring2* is the specified value.  $F(R_{i-1}, R_i, R_{i+1})$  is a smooth scalar function of the angle  $R_{i-1}R_iR_{i+1}$ . It is equal to 0.0 when the path is straight and is equal to 1 when the angle  $R_{i-1}R_iR_{i+1}$  is acute.  $F(R_{i-1}, R_i, R_{i+1})$  is defined in (Jonsson).

If *Kspring2* is set to 0.0 (the default) then no perpendicular spring force is added.

By default, no additional forces act on the first and last replicas during the NEB relaxation, so these replicas simply relax toward their respective local minima. By using the key word *end*, additional forces can be applied to the first and/or last replicas, to enable them to relax toward a MEP while constraining their energy *E* to the target energy *E<sub>Target</sub>*.

If  $E_{Target} > E$ , the interatomic force  $F_i$  for the specified replica becomes:

$$\begin{aligned} F_i &= -\nabla V + (\nabla V \cdot T' + (E - E_{Target}) \cdot K_{spring3})T', & \text{when } \nabla V \cdot T' < 0 \\ F_i &= -\nabla V + (\nabla V \cdot T' + (E_{Target} - E) \cdot K_{spring3})T', & \text{when } \nabla V \cdot T' > 0 \end{aligned}$$

The “spring” constant on the difference in energies is the specified *Kspring3* value.

When *estyle* is specified as *first*, the force is applied to the first replica. When *estyle* is specified as *last*, the force is applied to the last replica. Note that the *end* keyword can be used twice to add forces to both the first and last replicas.

For both these *estyle* settings, the target energy *E<sub>Target</sub>* is set to the initial energy of the replica (at the start of the NEB calculation).

If the *estyle* is specified as *last/efirst* or *last/efirst/middle*, force is applied to the last replica, but the target energy *E<sub>Target</sub>* is continuously set to the energy of the first replica, as it evolves during the NEB relaxation.

The difference between these two *estyle* options is as follows. When *estyle* is specified as *last/efirst*, no change is made to the inter-replica force applied to the intermediate replicas (neither first or last). If the initial path is too far from the MEP, an intermediate replica may relax “faster” and reach a lower energy than the last replica. In this case the intermediate replica will be relaxing toward its own local minima. This behavior can be prevented by specifying *estyle* as *last/efirst/middle* which will alter the inter-replica force applied to intermediate replicas by removing the contribution of the gradient to the inter-replica force. This will only be done if a particular intermediate replica has a lower energy than the first replica. This should effectively prevent the intermediate replicas from over-relaxing.

After converging a NEB calculation using an *estyle* of *last/efirst/middle*, you should check that all intermediate replicas have a larger energy than the first replica. If this is not the case, the path is probably not a MEP.

Finally, note that the last replica may never reach the target energy if it is stuck in a local minima which has a larger energy than the target energy.

#### 2.104.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, as invoked by the *minimize* command via the *neb* command.

#### 2.104.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the *Build package* doc page for more info.

#### 2.104.6 Related commands

*neb*

#### 2.104.7 Default

The option defaults are parallel = neigh, perp = 0.0, ends is not specified (no inter-replica force on the end replicas).

## 2.105 fix neb/spin command

### 2.105.1 Syntax

```
fix ID group-ID neb/spin Kspring
```

- ID, group-ID are documented in *fix* command
- neb/spin = style name of this fix command

Kspring = spring constant for parallel nudging force  
(force/distance units or force units, see parallel keyword)

### 2.105.2 Examples

```
fix 1 active neb/spin 1.0
```

### 2.105.3 Description

Add nudging forces to spins in the group for a multi-replica simulation run via the *neb/spin* command to perform a geodesic nudged elastic band (GNEB) calculation for finding the transition state. Hi-level explanations of GNEB are given with the *neb/spin* command and on the *Howto replica* doc page. The fix *neb/spin* command must be used with the “neb/spin” command and defines how inter-replica nudging forces are computed. A GNEB calculation is divided in two stages. In the first stage *n* replicas are relaxed toward a MEP until convergence. In the second stage, the climbing image scheme is enabled, so that the replica having the highest energy relaxes toward the saddle point (i.e. the point of highest energy along the MEP), and a second relaxation is performed.

The nudging forces are calculated as explained in (*Bessarab*). See this reference for more explanation about their expression.

### 2.105.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, as invoked by the *minimize* command via the *neb/spin* command.

### 2.105.5 Restrictions

This command can only be used if LAMMPS was built with the SPIN package. See the *Build package* doc page for more info.

## 2.105.6 Related commands

*neb\_spin*

## 2.105.7 Default

none

```

## 2.108.3 Description

These commands perform time integration on Nose-Hoover style non-Hamiltonian equations of motion which are designed to generate positions and velocities sampled from the canonical (nvt), isothermal-isobaric (npt), and isenthalpic (npb) ensembles. This updates the position and velocity for atoms in the group each timestep.

The thermostating and barostating is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostating) and simulation domain dimensions (barostating). In addition to basic thermostating and barostating, these fixes can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the xy, xz and yz tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by Tstart/Tstop and Pstart/Pstop.

The equations of motion used are those of Shinoda et al in ([Shinoda](#)), which combine the hydrostatic equations of Martyna, Tobias and Klein in ([Martyna](#)) with the strain energy proposed by Parrinello and Rahman in ([Parrinello](#)). The time integration schemes closely follow the time-reversible measure-preserving Verlet and rRESPA integrators derived by Tuckerman et al in ([Tuckerman](#)).

The thermostat parameters for fix styles *nvt* and *npt* are specified using the *temp* keyword. Other thermostat-related keywords are *tchain*, *tloop* and *drag*, which are discussed below.

The thermostat is applied to only the translational degrees of freedom for the particles. The translational degrees of freedom can also have a bias velocity removed before thermostating takes place; see the description below. The desired temperature at each timestep is a ramped value during the run from *Tstart* to *Tstop*. The *Tdamp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g.  $\tau$  or fs or ps - see the *units* command). The atoms in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration.

---

**Note:** A Nose-Hoover thermostat will not work well for arbitrary values of *Tdamp*. If *Tdamp* is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good choice for many models is a *Tdamp* of around 100 timesteps. Note that this is NOT the same as 100 time units for most *units* settings. A simple way to ensure this, is via using an *immediate variable* expression accessing the thermo property 'dt', which is the length of the time step. Example:

---

```
fix 1 all nvt temp 300.0 300.0 $(100.0*dt)
```

---

The barostat parameters for fix styles *npt* and *nph* is specified using one or more of the *iso*, *aniso*, *tri*, *x*, *y*, *z*, *xy*, *xz*, *yz*, and *couple* keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation.

Other barostat-related keywords are *pchain*, *mtk*, *ploop*, *nreset*, *drag*, and *dilate*, which are discussed below.

Orthogonal simulation boxes have 3 adjustable dimensions (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (x,y,z,xy,xz,yz). The *create\_box*, *read\_data*, and *read\_restart* commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

The target pressures for each of the 6 components of the stress tensor can be specified independently via the *x*, *y*, *z*, *xy*, *xz*, *yz* keywords, which correspond to the 6 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from *Pstart* to *Pstop*. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the *y* keyword is used, the y-box length will change. If the *xy* keyword is used, the xy tilt factor will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the *fix deform* command.

Note that in order to use the *xy*, *xz*, or *yz* keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

For all barostat keywords, the *Pdamp* parameter operates like the *Tdamp* parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g.  $\tau$  or fs or ps - see the *units* command).

---

**Note:** A Nose-Hoover barostat will not work well for arbitrary values of *Pdamp*. If *Pdamp* is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a *Pdamp* of around 1000 timesteps. However, note that *Pdamp* is specified in time units, and that timesteps are NOT the same as time units for most *units* settings.

---

The relaxation rate of the barostat is set by its inertia  $W$ :

$$W = (N + 1)k_B T_{\text{target}} P_{\text{damp}}^2$$

where  $N$  is the number of atoms,  $k_B$  is the Boltzmann constant, and  $T_{\text{target}}$  is the target temperature of the barostat (*Martyna*). If a thermostat is defined,  $T_{\text{target}}$  is the target temperature of the thermostat. If a thermostat is not defined,  $T_{\text{target}}$  is set to the current temperature of the system when the barostat is initialized. If this temperature is too low the simulation will quit with an error. Note: in previous versions of LAMMPS,  $T_{\text{target}}$  would default to a value of 1.0 for *lj* units and 300.0 otherwise if the system had a temperature of exactly zero.

If a thermostat is not specified by this fix,  $T_{\text{target}}$  can be manually specified using the *Ptemp* parameter. This may be useful if the barostat is initialized when the current temperature does not reflect the steady state temperature of the system. This keyword may also be useful in athermal simulations where the temperature is not well defined.

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword *dilate* is specified with a *dilate-group-ID* for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin. Also note that for atoms not in the fix group, a separate time integration fix like *fix nve* or *fix nvt* can be used on them, independent of whether they are dilated or not.

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, *xz* means the  $P_{xx}$  and  $P_{zz}$  components of the stress tensor are coupled. *xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The *Pstart*, *Pstop*, *Pdamp* parameters for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the *z* dimension is simply ignored.

The *iso*, *aniso*, and *tri* keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “*iso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
```

The keyword *aniso* means *x*, *y*, and *z* dimensions are controlled independently using the  $P_{xx}$ ,  $P_{yy}$ , and  $P_{zz}$  components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “*aniso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple none
```

The keyword *tri* means *x*, *y*, *z*, *xy*, *xz*, and *yz* dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “*tri Pstart Pstop Pdamp*” is the same as specifying these 7 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
xy 0.0 0.0 Pdamp
yz 0.0 0.0 Pdamp
xz 0.0 0.0 Pdamp
couple none
```

In some cases (e.g. for solids) the pressure (volume) and/or temperature of the system can oscillate undesirably when a Nose/Hoover barostat and thermostat is applied. The optional *drag* keyword will damp these oscillations, although it alters the Nose/Hoover equations. A value of 0.0 (no drag) leaves the Nose/Hoover formalism unchanged. A non-zero value adds a drag term; the larger the value specified, the greater the damping effect. Performing a short run and monitoring the pressure and temperature is the best way to determine if the drag term is working. Typically a value between 0.2 to 2.0 is sufficient to damp oscillations after a few periods. Note that use of the drag keyword will interfere with energy conservation and will also change the distribution of positions and velocities so that they do not correspond to the nominal NVT, NPT, or NPH ensembles.

An alternative way to control initial oscillations is to use chain thermostats. The keyword *tchain* determines the number of thermostats in the particle thermostat. A value of 1 corresponds to the original Nose-Hoover thermostat. The keyword *pchain* specifies the number of thermostats in the chain thermostating the barostat degrees of freedom. A value of 0 corresponds to no thermostating of the barostat variables.

The *mtk* keyword controls whether or not the correction terms due to Martyna, Tuckerman, and Klein are included in the equations of motion (*Martyna*). Specifying *no* reproduces the original Hoover barostat, whose volume probability distribution function differs from the true NPT and NPH ensembles by a factor of  $1/V$ . Hence using *yes* is more correct, but in many cases the difference is negligible.

The keyword *tloop* can be used to improve the accuracy of integration scheme at little extra cost. The initial and final updates of the thermostat variables are broken up into *tloop* sub-steps, each of length  $dt/tloop$ . This corresponds to using a first-order Suzuki-Yoshida scheme (*Tuckerman*). The keyword *ploop* does the same thing for the barostat thermostat.

The keyword *nreset* controls how often the reference dimensions used to define the strain energy are reset. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. If the simulation domain changes significantly during the simulation, then the final average pressure tensor will differ significantly from the specified values of the external stress tensor. A value of *nstep* means that every *nstep* timesteps, the reference dimensions are set to those of the current simulation domain.

The *scaleyz*, *scalexz*, and *scalexy* keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when barostatting triclinic periodic cells. The default values *yes* will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing *no* ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to *no*.

The *flip* keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed below. If the *flip* value is set to *yes*, the bound is enforced by flipping the box when it is exceeded. If the *flip* value is set to *no*, the tilt will continue to change without flipping. Note that if applied stress induces large deformations (e.g. in a liquid), this means the box shape can tilt dramatically and LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor's irregular-shaped subdomain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The *fixedpoint* keyword specifies the fixed point for barostat volume changes. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to *fixedpoint*, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle trajectories are unaffected by the chosen value, except for a time-dependent constant translation of positions.

If the *update* keyword is used with the *dipole* value, then the orientation of the dipole moment of each particle is also updated during the time integration. This option should be used for models where a dipole moment is assigned to finite-size particles, e.g. spheroids via use of the *atom\_style hybrid sphere dipole* command.

The default dipole orientation integrator can be changed to the Dullweber-Leimkuhler-McLachlan integration scheme (*Dullweber*) when using *update* with the value *dipole/dlm*. This integrator is symplectic and time-reversible, giving better energy conservation and allows slightly longer timesteps at only a small additional computational cost.

---

**Note:** Using a barostat coupled to tilt dimensions *xy*, *xz*, *yz* can sometimes result in arbitrarily large values of the tilt dimensions, i.e. a dramatically deformed simulation box. LAMMPS allows the tilt factors to grow a small amount beyond the normal limit of half the box length (0.6 times the box length), and then performs a box “flip” to an equivalent periodic cell. See the discussion of the *flip* keyword above, to allow this bound to be exceeded, if desired.

---

The flip operation is described in more detail in the page for *fix deform*. Both the barostat dynamics and the atom trajectories are unaffected by this operation. However, if a tilt factor is incremented by a large amount (1.5 times the box length) on a single timestep, LAMMPS can not accommodate this event and will terminate the simulation with an error. This error typically indicates that there is something badly wrong with how the simulation was constructed, such as specifying values of *Pstart* that are too far from the current stress value, or specifying a timestep that is too large. Triclinic barostatting should be used with care. This also is true for other barostat styles, although they tend to be more forgiving of insults. In particular, it is important to recognize that equilibrium liquids can not support a shear stress and that equilibrium solids can not support shear stresses that exceed the yield stress.

One exception to this rule is if the first dimension in the tilt factor (*x* for *xy*) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

---

**Note:** Unlike the *fix temp/berendsen* command which performs thermostatting but NO time integration, these fixes perform thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as *fix nve* on atoms to which this fix is applied. Likewise, *fix nvt* and *fix npt* should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by *fix langevin* or *fix temp/rescale* commands.

---

See the *Howto thermostat* and *Howto barostat* doc pages for a discussion of different ways to compute temperature and perform thermostatting and barostatting.

---

These fixes compute a temperature and pressure each timestep. To do this, the thermostat and barostat fixes create their own computes of style “temp” and “pressure”, as if one of these sets of commands had been issued:

For *fix nvt*:

```
compute fix-ID_temp group-ID temp
```

For *fix npt* and *fix nph*:

```
compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

For *fix nvt*, the group for the new temperature compute is the same as the *fix* group. For *fix npt* and *fix nph*, the group for both the new temperature and pressure compute is “all” since pressure is computed for the entire system. In the case of *fix nph*, the temperature compute is not used for thermostatting, but just for a kinetic-energy contribution to the pressure. See the *compute temp* and *compute pressure* commands for details. Note that the IDs of the new computes are the *fix-ID* + underscore + “temp” or *fix-ID* + underscore + “press”.

Note that these are NOT the computes used by thermodynamic output (see the [thermo\\_style](#) command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of these fix's temperature or pressure via the [compute\\_modify](#) command. Or you can print this temperature or pressure during thermodynamic output via the [thermo\\_style custom](#) command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with [compute commands](#) that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the [fix\\_modify](#) command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual [compute temp commands](#) to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

These fixes can be used with either the *verlet* or *respa* [integrators](#). When using one of the barostat fixes with *respa*, LAMMPS uses an integrator constructed according to the following factorization of the Liouville propagator (for two rRESPA levels):

$$\begin{aligned} \exp(iL\Delta t) = & \hat{E} \exp\left(iL_{T\text{-baro}}\frac{\Delta t}{2}\right) \exp\left(iL_{T\text{-part}}\frac{\Delta t}{2}\right) \exp\left(iL_{\epsilon,2}\frac{\Delta t}{2}\right) \exp\left(iL_2^{(2)}\frac{\Delta t}{2}\right) \\ & \times \left[ \exp\left(iL_2^{(1)}\frac{\Delta t}{2n}\right) \exp\left(iL_{\epsilon,1}\frac{\Delta t}{2n}\right) \exp\left(iL_1\frac{\Delta t}{n}\right) \exp\left(iL_{\epsilon,1}\frac{\Delta t}{2n}\right) \exp\left(iL_2^{(1)}\frac{\Delta t}{2n}\right) \right]^n \\ & \times \exp\left(iL_2^{(2)}\frac{\Delta t}{2}\right) \exp\left(iL_{\epsilon,2}\frac{\Delta t}{2}\right) \exp\left(iL_{T\text{-part}}\frac{\Delta t}{2}\right) \exp\left(iL_{T\text{-baro}}\frac{\Delta t}{2}\right) \\ & + \mathcal{O}(\Delta t^3) \end{aligned}$$

This factorization differs somewhat from that of Tuckerman et al, in that the barostat is only updated at the outermost rRESPA level, whereas Tuckerman's factorization requires splitting the pressure into pieces corresponding to the forces computed at each rRESPA level. In theory, the latter method will exhibit better numerical stability. In practice, because Pdamp is normally chosen to be a large multiple of the outermost rRESPA timestep, the barostat dynamics are not the limiting factor for numerical stability. Both factorizations are time-reversible and can be shown to preserve the phase space measure of the underlying non-Hamiltonian equations of motion.

---

**Note:** This implementation has been shown to conserve linear momentum up to machine precision under NVT dynamics. Under NPT dynamics, for a system with zero initial total linear momentum, the total momentum fluctuates close to zero. It may occasionally undergo brief excursions to non-negligible values, before returning close to zero. Over long simulations, this has the effect of causing the center-of-mass to undergo a slow random walk. This can be mitigated by resetting the momentum at infrequent intervals using the [fix momentum](#) command.

---

The fix npt and fix nph commands can be used with rigid bodies or mixtures of rigid bodies and non-rigid particles (e.g. solvent). But there are also [fix rigid/npt](#) and [fix rigid/nph](#) commands, which are typically a more natural choice. See the page for those commands for more discussion of the various ways to do this.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.108.4 Restart, fix\_modify, output, run start/stop, minimize info

These fixes writes the state of all the thermostat and barostat variables to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by these fixes. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostating procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

**Note:** If both the *temp* and *press* keywords are used in a single *thermo\_modify* command (or in two separate commands), then the order in which the keywords are specified is important. Note that a *pressure compute* defines its own temperature compute as an argument when it is specified. The *temp* keyword will override this (for the pressure compute being used by fix npt), but only if the *temp* keyword comes after the *press* keyword. If the *temp* keyword comes before the *press* keyword, then the new pressure compute specified by the *press* keyword will be unaffected by the *temp* setting.

The cumulative energy change in the system imposed by these fixes, via either thermostating and/or barostating, is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* page for details.

These fixes compute a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

These fixes compute also compute a global vector of quantities, which can be accessed by various *output commands*. The vector values are “intensive”.

The vector stores internal Nose/Hoover thermostat and barostat variables. The number and meaning of the vector values depends on which fix is used and the settings for keywords *tchain* and *pchain*, which specify the number of Nose/Hoover chains for the thermostat and barostat. If no thermostating is done, then *tchain* is 0. If no barostating is done, then *pchain* is 0. In the following list, “ndof” is 0, 1, 3, or 6, and is the number of degrees of freedom in the barostat. Its value is 0 if no barostat is used, else its value is 6 if any off-diagonal stress tensor component is barostatted, else its value is 1 if *couple xyz* is used or *couple xy* for a 2d simulation, otherwise its value is 3.

The order of values in the global vector and their meaning is as follows. The notation means there are *tchain* values for *eta*, followed by *tchain* for *eta\_dot*, followed by *ndof* for *omega*, etc:

- *eta[tchain]* = particle thermostat displacements (unitless)
- *eta\_dot[tchain]* = particle thermostat velocities (1/time units)
- *omega[ndof]* = barostat displacements (unitless)
- *omega\_dot[ndof]* = barostat velocities (1/time units)
- *etap[pchain]* = barostat thermostat displacements (unitless)
- *etap\_dot[pchain]* = barostat thermostat velocities (1/time units)
- *PE\_eta[tchain]* = potential energy of each particle thermostat displacement (energy units)

- KE\_eta\_dot[tchain] = kinetic energy of each particle thermostat velocity (energy units)
- PE\_omega[ndof] = potential energy of each barostat displacement (energy units)
- KE\_omega\_dot[ndof] = kinetic energy of each barostat velocity (energy units)
- PE\_etap[pchain] = potential energy of each barostat thermostat displacement (energy units)
- KE\_etap\_dot[pchain] = kinetic energy of each barostat thermostat velocity (energy units)
- PE\_strain[1] = scalar strain energy (energy units)

These fixes can ramp their external temperature and pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

These fixes are not invoked during *energy minimization*.

---

## 2.108.5 Restrictions

X, y, z cannot be barostatted if the associated dimension is not periodic. Xy, xz, and yz can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword (y dimension in xy) is periodic. Z, xz, and yz, cannot be barostatted for 2D simulations. The *create\_box*, *read\_data*, and *read\_restart* commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

For the *temp* keyword, the final Tstop cannot be 0.0 since it would make the external T = 0.0 at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The *scaleyz yes* and *scalexz yes* keyword/value pairs can not be used for 2D simulations. *scaleyz yes*, *scalexz yes*, and *scalexy yes* options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords *tri*, *yz*, *xz*, and *xy*.

These fixes can be used with dynamic groups as defined by the *group* command. Likewise they can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

## 2.108.6 Related commands

*fix nve*, *fix\_modify*, *run\_style*

## 2.108.7 Default

The keyword defaults are tchain = 3, pchain = 3, mtk = yes, tloop = 1, ploop = 1, nreset = 0, drag = 0.0, dilate = all, couple = none, flip = yes, scaleyz = scalexz = scalexy = yes if periodic in second dimension and not coupled to barostat, otherwise no.

```

### 2.111.3 Description

These commands perform time integration on Nose-Hoover style non-Hamiltonian equations of motion for nuclei and electrons in the group for the *electron force field* model. The fixes are designed to generate positions and velocities sampled from the canonical (nvt), isothermal-isobaric (npt), and isenthalpic (nph) ensembles. This is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostatting) and simulation domain dimensions (barostatting). In addition to basic thermostatting and barostatting, these fixes can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the *xy*, *xz* and *yz* tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by Tstart/Tstop and Pstart/Pstop.

The operation of these fixes is exactly like that described by the *fix nvt*, *npt*, and *nph* commands, except that the radius and radial velocity of electrons are also updated. Likewise the temperature and pressure calculated by the fix, using the computes it creates (as discussed in the *fix nvt*, *npt*, and *nph* doc page), are performed with computes that include the eFF contribution to the temperature or kinetic energy from the electron radial velocity.

---

**Note:** there are two different pressures that can be reported for eFF when defining the *pair\_style* (see *pair eff/cut* to understand these settings), one (default) that considers electrons do not contribute radial virial components (i.e. electrons treated as incompressible ‘rigid’ spheres) and one that does. The radial electronic contributions to the virials are only tallied if the flexible pressure option is set, and this will affect both global and per-atom quantities. In principle, the true pressure of a system is somewhere in between the rigid and the flexible eFF pressures, but, for most cases, the difference between these two pressures will not be significant over long-term averaged runs (i.e. even though the energy partitioning changes, the total energy remains similar).

---

---

**Note:** currently, there is no available option for the user to set or create temperature distributions that include the radial electronic degrees of freedom with the *velocity* command, so the user must allow for these degrees of freedom to equilibrate (i.e. equi-partitioning of energy) through time integration.

---

### 2.111.4 Restart, fix\_modify, output, run start/stop, minimize info

See the page for the *fix nvt*, *npt*, and *nph* commands for details.

### 2.111.5 Restrictions

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Other restriction discussed on the page for the *fix nvt*, *npt*, and *nph* commands also apply.

---

**Note:** The temperature for systems (regions or groups) with only electrons and no nuclei is 0.0 (i.e. not defined) in the current temperature calculations, a practical example would be a uniform electron gas or a very hot plasma, where electrons remain delocalized from the nuclei. This is because, even though electron virials are included in the temperature calculation, these are averaged over the nuclear degrees of freedom only. In such cases a corrective term must be added to the pressure to get the correct kinetic contribution.

---

fix biax_npt all npt/uef temp 400 400 100 erate -0.00001 0.000005 x 1 1 3000
```

## 2.113.3 Description

These fixes can be used to simulate non-equilibrium molecular dynamics (NEMD) under diagonal flow fields, including uniaxial and bi-axial flow. Simulations under continuous extensional flow may be carried out for an indefinite amount of time. It is an implementation of the boundary conditions from ([Dobson](#)), and also uses numerical lattice reduction as was proposed by ([Hunt](#)). The lattice reduction algorithm is from ([Semaev](#)). The fix is intended for simulations of homogeneous flows, and integrates the SLLOD equations of motion, originally proposed by Hoover and Ladd (see ([Evans and Morriss](#))). Additional detail about this implementation can be found in ([Nicholson and Rutledge](#)).

Note that NEMD simulations of a continuously strained system can be performed using the *fix deform*, *fix nvt/sllod*, and *compute temp/deform* commands.

The applied flow field is set by the *erate* keyword. The values *edot\_x* and *edot\_y* correspond to the strain rates in the *xx* and *yy* directions. It is implicitly assumed that the flow field is traceless, and therefore the strain rate in the *zz* direction is equal to  $-(edot_x + edot_y)$ .

**Note:** Due to an instability in the SLLOD equations under extension, *fix momentum* should be used to regularly reset the linear momentum.

The boundary conditions require a simulation box that does not have a consistent alignment relative to the applied flow field. Since LAMMPS utilizes an upper-triangular simulation box, it is not possible to express the evolving simulation box in the same coordinate system as the flow field. These fixes keep track of two coordinate systems: the flow frame, and the upper triangular LAMMPS frame. The coordinate systems are related to each other through the QR decomposition, as is illustrated in the image below.

During most molecular dynamics operations, the system is represented in the LAMMPS frame. Only when the positions and velocities are updated is the system rotated to the flow frame, and it is rotated back to the LAMMPS frame immediately afterwards. For this reason, all vector-valued quantities (except for the tensors from `compute pressure/uef` and `compute temp/uef`) will be computed in the LAMMPS frame. Rotationally invariant scalar quantities like the temperature and hydrostatic pressure are frame-invariant and will be computed correctly. Additionally, the system is in the LAMMPS frame during all of the output steps, and therefore trajectory files made using the dump command will be in the LAMMPS frame unless the `dump cfg/uef` command is used.

Temperature control is achieved with the default Nose-Hoover style thermostat documented in `fix nvt`. When this fix is active, only the peculiar velocity of each atom is stored, defined as the velocity relative to the streaming velocity. This is in contrast to `fix nvt/sllod`, which uses a lab-frame velocity, and removes the contribution from the streaming velocity in order to compute the temperature.

Pressure control is achieved using the default Nose-Hoover barostat documented in `fix npt`. There are two ways to control the pressure using this fix. The first method involves using the `ext` keyword along with the `iso` pressure style. With this method, the pressure is controlled by scaling the simulation box isotropically to achieve the average pressure only in the directions specified by `ext`. For example, if the `ext` value is set to `xy`, the average pressure  $(P_{xx}+P_{yy})/2$  will be controlled.

This example command will control the total hydrostatic pressure under uniaxial tension:

```
fix f1 all npt/uef temp 0.7 0.7 0.5 iso 1 1 5 erate -0.5 -0.5 ext xyz
```

This example command will control the average stress in compression directions, which would typically correspond to free surfaces under drawing with uniaxial tension:

```
fix f2 all npt/uef temp 0.7 0.7 0.5 iso 1 1 5 erate -0.5 -0.5 ext xy
```

The second method for pressure control involves setting the normal stresses using the `x`, `y`, and/or `z` keywords. When using this method, the same pressure must be specified via `Pstart` and `Pstop` for all dimensions controlled. Any choice of pressure conditions that would cause LAMMPS to compute a deviatoric stress are not permissible and will result in an error. Additionally, all dimensions with controlled stress must have the same applied strain rate. The `ext` keyword must be set to the default value (`xyz`) when using this method.

For example, the following commands will work:

```
fix f3 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 y 1 1 5 erate -0.5 -0.5
fix f4 all npt/uef temp 0.7 0.7 0.5 z 1 1 5 erate 0.5 0.5
```

The following commands will not work:

```
fix f5 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 z 1 1 5 erate -0.5 -0.5
fix f6 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 z 2 2 5 erate 0.5 0.5
```

These fixes compute a temperature and pressure each timestep. To do this, they create their own computes of style “temp/uef” and “pressure/uef”, as if one of these two sets of commands had been issued:

```
compute fix-ID_temp group-ID temp/uef
compute fix-ID_press group-ID pressure/uef fix-ID_temp

compute fix-ID_temp all temp/uef
compute fix-ID_press all pressure/uef fix-ID_temp
```

See the `compute temp/uef` and `compute pressure/uef` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix\_ID + underscore + “press”.

### 2.113.4 Restart, fix\_modify, output, run start/stop, minimize info

The fix writes the state of all the thermostat and barostat variables, as well as the cumulative strain applied, to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** It is not necessary to set the *strain* keyword when resuming a run from a restart file. Only for resuming from data files, which do not contain the cumulative applied strain, will this keyword be necessary.

---

These fixes can be used with the *fix\_modify temp* and *press* options. The temperature and pressure computes used must be of type *temp/uef* and *pressure/uef*.

These fixes compute the same global scalar and vector quantities as *fix nvt andnpt*.

These fixes are not invoked during *energy minimization*.

### 2.113.5 Restrictions

These fixes are part of the UEF package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Due to requirements of the boundary conditions, when the *strain* keyword is set to zero (or unset), the initial simulation box must be cubic and have style triclinic. If the box is initially of type ortho, use *change\_box* before invoking the fix.

### 2.113.6 Related commands

*fix nvt*, *fix npt*, *fix nvt/sllod*, *compute temp/uef*, *compute pressure/uef*, *dump cfg/uef*

### 2.113.7 Default

The default keyword values specific to these fixes are *exy = xyz*, *strain = 0 0*. The remaining defaults are the same as for *fix nvt or npt* except *tchain = 1*. The reason for this change is given in *fix nvt/sllod*.

---

## 2.114 fix nonaffine/displacement command

### 2.114.1 Syntax

```
fix ID group nonaffine/displacement style args reference/style nstep keyword values
```

- ID, group are documented in *fix* command
- nonaffine/displacement = style name of this fix command
- nevery = calculate nonaffine displacement every this many timesteps
- style = *d2min* or *integrated*
  - d2min* args = cutoff args
    - cutoff = *type* or *radius* or *custom*
      - type* args = none, cutoffs determined by atom types
      - radius* args = none, cutoffs determined based on atom diameters (atom style *→sphere*)
      - custom* args = *rmax*, cutoff set by a constant numeric value *rmax* (distance units)
    - integrated* args = none
- reference/style = *fixed* or *update* or *offset*
  - fixed* = use a fixed reference frame at *nstep*
  - update* = update the reference frame every *nstep* timesteps
  - offset* = update the reference frame *nstep* timesteps before calculating the *→nonaffine* displacement
- zero or more keyword/value pairs may be appended
  - z/min* values = *zmin*
    - zmin* = minimum coordination number to calculate D2min

### 2.114.2 Examples

```
fix 1 all nonaffine/displacement 100 integrated update 100
fix 1 all nonaffine/displacement 1000 d2min type fixed 0
fix 1 all nonaffine/displacement 1000 d2min custom 2.0 offset 100
```

### 2.114.3 Description

New in version 7Feb2024.

This fix computes different metrics of the nonaffine displacement of particles. The first metric, *d2min* calculates the  $D_{\min}^2$  nonaffine displacement by Falk and Langer in (*Falk*). For each atom, the fix computes the two tensors

$$X = \sum_{\text{neighbors}} \vec{r} (\vec{r}_0)^T$$

and

$$Y = \sum_{\text{neighbors}} \vec{r}_0 (\vec{r}_0)^T$$

where the neighbors include all other atoms within the distance criterion set by the cutoff option, discussed below,  $\vec{r}$  is the current displacement between particles, and  $\vec{r}_0$  is the reference displacement. A deformation gradient tensor is then calculated as  $F = XY^{-1}$  from which

$$D_{\min}^2 = \sum_{\text{neighbors}} |\vec{r} - F\vec{r}_0|^2$$

and a strain tensor is calculated  $E = FF^T - I$  where  $I$  is the identity tensor. This calculation is only performed on timesteps that are a multiple of *nevery* (including timestep zero). Data accessed before this occurs will simply be zeroed.

For particles with low coordination numbers, calculations of  $D_{\min}^2$  may not be accurate. An optional minimum coordination number can be defined using the *z/min* keyword. If any particle has fewer than the specified number of particles in the cutoff distance or in contact, the above calculations will be skipped and the corresponding peratom array entries will be zero.

The *integrated* style simply integrates the velocity of particles every timestep to calculate a displacement. This style only works if used in conjunction with another fix that deforms the box and displaces atom positions such as *fix deform* with *remap x*, *fix press/berendsen*, or *fix nh*.

Both of these methods require defining a reference state. With the *fixed* reference style, the user picks a specific timestep *nstep* at which particle positions are saved. If peratom data is accessed from this compute prior to this timestep, it will simply be zeroed. The *update* reference style implies the reference state will be updated every *nstep* timesteps. The *offset* reference will update the reference state *nstep* timesteps before a multiple of *nevery* timesteps.

---

#### 2.114.4 Restart, fix\_modify, output, run start/stop, minimize info

The reference state is saved to *binary restart files*.

None of the *fix\_modify* options are relevant to this fix.

This fix computes a peratom array with 3 columns, which can be accessed by indices 1-3 using any command that uses per-atom values from a fix as input.

For the *integrated* style, the three columns are the nonaffine displacements in the x, y, and z directions. For the *d2min* style, the three columns are the calculated  $\sqrt{D_{\min}^2}$ , the volumetric strain, and the deviatoric strain.

#### 2.114.5 Restrictions

This compute is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 2.114.6 Related commands

## 2.115 fix npn/asphere command

Accelerator Variants: *nph/asphere/omp*

### 2.115.1 Syntax

```
fix ID group-ID npn/asphere args keyword value ...
```

- ID, group-ID are documented in *fix* command
- npn/asphere = style name of this fix command
- additional barostat related keyword/value pairs from the *fix npn* command can be appended

### 2.115.2 Examples

```
fix 1 all npn/asphere iso 0.0 0.0 1000.0
fix 2 all npn/asphere x 5.0 5.0 1000.0
fix 2 all npn/asphere x 5.0 5.0 1000.0 drag 0.2
fix 2 water npn/asphere aniso 0.0 0.0 1000.0 dilate partial
```

### 2.115.3 Description

Perform constant NPH integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the *fix npn* command, which assumes point particles and only updates their position and velocity.

Additional parameters affecting the barostat are specified by keywords and values documented with the *fix npn* command. See, for example, discussion of the *aniso*, and *dilate* keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/asphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/asphere
compute fix-ID_press all pressure fix-ID_temp
```

See the *compute temp/asphere* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix\_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.115.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostating procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nph* command.

This fix can ramp its target pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.115.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the [atom\\_style ellipsoid](#) command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

## 2.115.6 Related commands

fix 2 water nph/body aniso 0.0 0.0 1000.0 dilate partial
```

## 2.116.3 Description

Perform constant NPH integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the [fix nph](#) command, which assumes point particles and only updates their position and velocity.

Additional parameters affecting the barostat are specified by keywords and values documented with the [fix nph](#) command. See, for example, discussion of the [aniso](#), and [dilate](#) keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

---

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/body” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/body
compute fix-ID_press all pressure fix-ID_temp
```

See the *compute temp/body* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix\_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.116.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostating procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nph* command.

This fix can ramp its target pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.116.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the [atom\\_style body](#) command.

## 2.116.7 Default

none

## 2.117 fix nph/sphere command

Accelerator Variants: *nph/sphere/omp*

### 2.117.1 Syntax

```
fix ID group-ID nph/sphere args keyword value ...
```

- ID, group-ID are documented in *fix* command
- nph/sphere = style name of this fix command
- keyword = *disc*  
*disc* value = none = treat particles as 2d discs, not spheres
- additional barostat related keyword/value pairs from the *fix nph* command can be appended

### 2.117.2 Examples

```
fix 1 all nph/sphere iso 0.0 0.0 1000.0
fix 2 all nph/sphere x 5.0 5.0 1000.0
fix 2 all nph/sphere x 5.0 5.0 1000.0 disc
fix 2 all nph/sphere x 5.0 5.0 1000.0 drag 0.2
fix 2 water nph/sphere aniso 0.0 0.0 1000.0 dilate partial
```

### 2.117.3 Description

Perform constant NPH integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the [fix \*nph\*](#) command, which assumes point particles and only updates their position and velocity.

If the *disc* keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the [dimension](#) keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the barostat are specified by keywords and values documented with the [fix \*nph\*](#) command. See, for example, discussion of the *aniso*, and *dilate* keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

---

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/sphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/sphere
compute fix-ID_press all pressure fix-ID_temp
```

See the [compute \*temp/sphere\*](#) and [compute \*pressure\*](#) commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix\_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the [thermo\\_style](#) command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the [compute\\_modify](#) command or print this temperature or pressure during thermodynamic output via the [thermo\\_style custom](#) command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 2.117.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nph* command.

This fix can ramp its target pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.117.5 Restrictions

This fix requires that atoms store torque and angular velocity ( $\omega$ ) and a radius as defined by the *atom\_style sphere* command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the *disc* keyword is only allowed for 2d simulations, as defined by the *dimension* keyword.

```

## 2.118.3 Description

This command is a variant of the Nose-Hoover *fix npt* fix style. It performs time integration of the Hugoniostat equations of motion developed by Ravelo et al. (*Ravelo*). These equations compress the system to a state with average axial stress or pressure equal to the specified target value and that satisfies the Rankine-Hugoniot (RH) jump conditions for steady shocks.

The compression can be performed either hydrostatically (using keyword *iso*, *aniso*, or *tri*) or uniaxially (using keywords *x*, *y*, or *z*). In the hydrostatic case, the cell dimensions change dynamically so that the average axial stress in all three directions converges towards the specified target value. In the uniaxial case, the chosen cell dimension changes dynamically so that the average axial stress in that direction converges towards the target value. The other two cell dimensions are kept fixed (zero lateral strain).

This leads to the following additional restrictions on the keywords:

- One and only one of the following keywords should be used: *iso*, *aniso*, *tri*, *x*, *y*, *z*
- The specified initial and final target pressures must be the same.
- The keywords *xy*, *xz*, *yz* may not be used.
- The only admissible value for the *couple* keyword is *xyz*, which has the same effect as keyword *iso*
- The *temp* keyword must be used to specify the time constant for kinetic energy relaxation, but initial and final target temperature values are ignored.

Essentially, a Hugoniosat simulation is an NPT simulation in which the user-specified target temperature is replaced with a time-dependent target temperature  $T_t$  obtained from the following equation:

$$T_t - T = \frac{\left(\frac{1}{2} (P + P_0) (V_0 - V) + E_0 - E\right)}{N_{\text{dof}} k_B} = \Delta$$

where  $T$  and  $T_t$  are the instantaneous and target temperatures,  $P$  and  $P_0$  are the instantaneous and reference pressures or axial stresses, depending on whether hydrostatic or uniaxial compression is being performed,  $V$  and  $V_0$  are the instantaneous and reference volumes,  $E$  and  $E_0$  are the instantaneous and reference internal energy (potential plus kinetic),  $N_{\text{dof}}$  is the number of degrees of freedom used in the definition of temperature, and  $k_B$  is the Boltzmann constant.  $\Delta$  is the negative deviation of the instantaneous temperature from the target temperature. When the system reaches a stable equilibrium, the value of  $\Delta$  should fluctuate about zero.

The values of  $E_0$ ,  $V_0$ , and  $P_0$  are the instantaneous values at the start of the simulation. These can be overridden using the `fix_modify` keywords `e0`, `v0`, and `p0` described below.

---

**Note:** Unlike the `fix temp/berendsen` command which performs thermostating but NO time integration, this fix performs thermostating/barostatting AND time integration. Thus you should not use any other time integration fix, such as `fix nve` on atoms to which this fix is applied. Likewise, this fix should not be used on atoms that have their temperature controlled by another fix - e.g. by `fix langevin` or `fix temp/rescale` commands.

---

This fix computes a temperature and pressure at each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if one of these two sets of commands had been issued:

```
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp

compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

See the `compute temp` and `compute pressure` commands for details. Note that the IDs of the new computes are the `fix-ID` + underscore + “temp” or `fix-ID` + underscore + “press”. The group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

---

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.118.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the values of  $E_0$ ,  $V_0$ , and  $P_0$ , as well as the state of all the thermostat and barostat variables to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify* *e0*, *v0* and *p0* keywords can be used to define the values of  $E_0$ ,  $V_0$ , and  $P_0$ . Note the the values for *e0* and *v0* are extensive, and so must correspond to the total energy and volume of the entire system, not energy and volume per atom. If any of these quantities are not specified, then the instantaneous value in the system at the start of the simulation is used.

The *fix\_modify* *temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostating procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details. Note that this energy is *\*not\** included in the definition of internal energy  $E$  when calculating the value of  $\Delta$  in the above equation.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix also computes a global vector of quantities, which can be accessed by various *output commands*. The scalar The vector values are “intensive”.

The vector stores three quantities unique to this fix ( $\Delta$ ,  $U_s$ , and  $u_p$ ), followed by all the internal Nose/Hoover thermostat and barostat variables defined for *fix npt*.  $\Delta$  is the deviation of the temperature from the target temperature, given by the above equation.  $U_s$  and  $u_p$  are the shock and particle velocity corresponding to a steady shock calculated from the RH conditions. They have units of distance/time.

## 2.118.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

All the usual restrictions for *fix npt* apply, plus the additional ones mentioned above.

## 2.118.6 Related commands

*fix msst*, *fix npt*, *fix\_modify*

## 2.118.7 Default

The keyword defaults are the same as those for *fix npt*

## 2.119 fix npt/asphere command

Accelerator Variants: *npt/asphere/omp*

### 2.119.1 Syntax

```
fix ID group-ID npt/asphere keyword value ...
```

- ID, group-ID are documented in *fix* command
- npt/asphere = style name of this fix command
- additional thermostat and barostat related keyword/value pairs from the *fix npt* command can be appended

### 2.119.2 Examples

```
fix 1 all npt/asphere temp 300.0 300.0 100.0 iso 0.0 0.0 1000.0
fix 2 all npt/asphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0
fix 2 all npt/asphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0 drag 0.2
fix 2 water npt/asphere temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```

### 2.119.3 Description

Perform constant NPT integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the *fix npt* command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the aspherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the *fix npt* command. See, for example, discussion of the *temp*, *iso*, *aniso*, and *dilate* keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/asphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/asphere
compute fix-ID_press all pressure fix-ID_temp
```

See the [compute temp/asphere](#) and [compute pressure](#) commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix\_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the [thermo\\_style](#) command) with ID = [thermo\\_temp](#) and [thermo\\_press](#). This means you can change the attributes of this fix’s temperature or pressure via the [compute\\_modify](#) command or print this temperature or pressure during thermodynamic output via the [thermo\\_style custom](#) command using the appropriate compute-ID. It also means that changing attributes of [thermo\\_temp](#) or [thermo\\_press](#) will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with [compute commands](#) that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial [region](#), or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the [fix\\_modify](#) command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual [compute temp commands](#) to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a [gpu](#), [intel](#), [kk](#), [omp](#), or [opt](#) suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 2.119.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to [binary restart files](#). See the [read\\_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The [fix\\_modify temp](#) and [press](#) options are supported by this fix. You can use them to assign a [compute](#) you have defined to this fix which will be used in its thermostating or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the [thermodynamic output](#) keywords [ecouple](#) and [econserve](#). See the [thermo\\_style](#) doc page for details.

This fix computes the same global scalar and global vector of quantities as does the [fix npt](#) command.

This fix can ramp its target temperature and pressure over multiple runs, using the [start](#) and [stop](#) keywords of the [run](#) command. See the [run](#) command for details of how to do this.

This fix is not invoked during [energy minimization](#).

## 2.119.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the [atom\\_style ellipsoid](#) command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

fix 2 water npt/body temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```

## 2.120.3 Description

Perform constant NPT integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the [fix npt](#) command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the body particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the *fix npt* command. See, for example, discussion of the *temp*, *iso*, *aniso*, and *dilate* keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

---

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/body” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/body
compute fix-ID_press all pressure fix-ID_temp
```

See the *compute temp/body* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix\_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.120.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix npt* command.

This fix can ramp its target temperature and pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.120.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the *atom\_style body* command.

```

## 2.121.3 Description

This command performs time integration on Nose-Hoover style non-Hamiltonian equations of motion which are designed to generate positions and velocities sampled from the isothermal-isobaric (npt) ensembles. This updates the position and velocity for atoms in the group each timestep and the box dimensions.

The thermostating and barostating is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostating) and simulation domain dimensions (barostating). In addition to basic thermostating and barostating, this fix can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the *xy*, *xz* and *yz* tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by Tstart/Tstop and Pstart/Pstop.

The equations of motion used are those of Shinoda et al in ([Shinoda](#)), which combine the hydrostatic equations of Martyna, Tobias and Klein in ([Martyna](#)) with the strain energy proposed by Parrinello and Rahman in ([Parrinello](#)). The time integration schemes closely follow the time-reversible measure-preserving Verlet and rRESPA integrators derived by Tuckerman et al in ([Tuckerman](#)).

---

The thermostat parameters are specified using the *temp* keyword. Other thermostat-related keywords are *tchain*, *tloop* and *drag*, which are discussed below.

The thermostat is applied to only the translational degrees of freedom for the particles. The translational degrees of freedom can also have a bias velocity removed before thermostating takes place; see the description below. The desired temperature at each timestep is a ramped value during the run from *Tstart* to *Tstop*. The *Tdamp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g.  $\tau$  or fs or ps - see the [units](#) command). The atoms in the *fix* group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration.

---

**Note:** A Nose-Hoover thermostat will not work well for arbitrary values of *Tdamp*. If *Tdamp* is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good choice for many models is a *Tdamp* of around 100 timesteps. Note that this is NOT the same as 100 time units for most [units](#) settings.

---

The barostat parameters are specified using one or more of the *iso*, *aniso*, *tri*, *x*, *y*, *z*, *xy*, *xz*, *yz*, and *couple* keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation.

Other barostat-related keywords are *pchain*, *mtk*, *ploop*, *nreset*, *drag*, and *dilate*, which are discussed below.

Orthogonal simulation boxes have 3 adjustable dimensions (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (x,y,z,xy,xz,yz). The [create\\_box](#), [read\\_data](#), and [read\\_restart](#) commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

The target pressures for each of the 6 components of the stress tensor can be specified independently via the *x*, *y*, *z*, *xy*, *xz*, *yz* keywords, which correspond to the 6 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from *Pstart* to *Pstop*. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the *y* keyword is used, the y-box length will change. If the *xy* keyword is used, the xy tilt factor will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the [fix deform](#) command.

Note that in order to use the *xy*, *xz*, or *yz* keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

For all barostat keywords, the *Pdamp* parameter operates like the *Tdamp* parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g.  $\tau$  or fs or ps - see the [units](#) command).

---

**Note:** A Nose-Hoover barostat will not work well for arbitrary values of *Pdamp*. If *Pdamp* is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a *Pdamp* of around 1000 timesteps. However, note that *Pdamp* is specified in time units, and that timesteps are NOT the same as time units for most [units](#) settings.

---

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword *dilate* is specified with a *dilate-group-ID* for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin. Also note that for atoms not in the fix group, a separate time integration fix like *fix nve* or *fix nvt* can be used on them, independent of whether they are dilated or not.

---

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, *xz* means the  $P_{xx}$  and  $P_{zz}$  components of the stress tensor are coupled. *xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The *Pstart*, *Pstop*, *Pdamp* parameters for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the *z* dimension is simply ignored.

---

The *iso*, *aniso*, and *tri* keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “*iso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
```

The keyword *aniso* means *x*, *y*, and *z* dimensions are controlled independently using the  $P_{xx}$ ,  $P_{yy}$ , and  $P_{zz}$  components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “*aniso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple none
```

The keyword *tri* means *x*, *y*, *z*, *xy*, *xz*, and *yz* dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “*tri Pstart Pstop Pdamp*” is the same as specifying these 7 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
xy 0.0 0.0 Pdamp
yz 0.0 0.0 Pdamp
xz 0.0 0.0 Pdamp
couple none
```

---

In some cases (e.g. for solids) the pressure (volume) and/or temperature of the system can oscillate undesirably when a Nose/Hoover barostat and thermostat is applied. The optional *drag* keyword will damp these oscillations, although it alters the Nose/Hoover equations. A value of 0.0 (no drag) leaves the Nose/Hoover formalism unchanged. A non-zero value adds a drag term; the larger the value specified, the greater the damping effect. Performing a short run and

monitoring the pressure and temperature is the best way to determine if the drag term is working. Typically a value between 0.2 to 2.0 is sufficient to damp oscillations after a few periods. Note that use of the `drag` keyword will interfere with energy conservation and will also change the distribution of positions and velocities so that they do not correspond to the nominal NVT, NPT, or NPH ensembles.

An alternative way to control initial oscillations is to use chain thermostats. The keyword *tchain* determines the number of thermostats in the particle thermostat. A value of 1 corresponds to the original Nose-Hoover thermostat. The keyword *pchain* specifies the number of thermostats in the chain thermostating the barostat degrees of freedom. A value of 0 corresponds to no thermostating of the barostat variables.

The *mtk* keyword controls whether or not the correction terms due to Martyna, Tuckerman, and Klein are included in the equations of motion (*Martyna*). Specifying *no* reproduces the original Hoover barostat, whose volume probability distribution function differs from the true NPT and NPH ensembles by a factor of  $1/V$ . Hence using *yes* is more correct, but in many cases the difference is negligible.

The keyword *tloop* can be used to improve the accuracy of integration scheme at little extra cost. The initial and final updates of the thermostat variables are broken up into *tloop* sub-steps, each of length  $dt/tloop$ . This corresponds to using a first-order Suzuki-Yoshida scheme (*Tuckerman*). The keyword *ploop* does the same thing for the barostat thermostat.

The keyword *nreset* controls how often the reference dimensions used to define the strain energy are reset. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. If the simulation domain changes significantly during the simulation, then the final average pressure tensor will differ significantly from the specified values of the external stress tensor. A value of *nstep* means that every *nstep* timesteps, the reference dimensions are set to those of the current simulation domain.

The *scaleyz*, *scalexz*, and *scalexy* keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when barostatting triclinic periodic cells. The default values *yes* will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing *no* ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to *no*.

The *flip* keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed below. If the *flip* value is set to *yes*, the bound is enforced by flipping the box when it is exceeded. If the *flip* value is set to *no*, the tilt will continue to change without flipping. Note that if applied stress induces large deformations (e.g. in a liquid), this means the box shape can tilt dramatically and LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor's irregular-shaped subdomain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The *fixedpoint* keyword specifies the fixed point for barostat volume changes. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to *fixedpoint*, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle trajectories are unaffected by the chosen value, except for a time-dependent constant translation of positions.

---

**Note:** Using a barostat coupled to tilt dimensions *xy*, *xz*, *yz* can sometimes result in arbitrarily large values of the tilt dimensions, i.e. a dramatically deformed simulation box. LAMMPS allows the tilt factors to grow a small amount beyond the normal limit of half the box length (0.6 times the box length), and then performs a box “flip” to an equivalent periodic cell. See the discussion of the *flip* keyword above, to allow this bound to be exceeded, if desired.

---

The flip operation is described in more detail in the page for *fix deform*. Both the barostat dynamics and the atom trajectories are unaffected by this operation. However, if a tilt factor is incremented by a large amount (1.5 times the box length) on a single timestep, LAMMPS can not accommodate this event and will terminate the simulation with an error. This error typically indicates that there is something badly wrong with how the simulation was constructed, such as specifying values of *Pstart* that are too far from the current stress value, or specifying a timestep that is too large.

Triclinic barostatting should be used with care. This also is true for other barostat styles, although they tend to be more forgiving of insults. In particular, it is important to recognize that equilibrium liquids can not support a shear stress and that equilibrium solids can not support shear stresses that exceed the yield stress.

One exception to this rule is if the first dimension in the tilt factor (x for xy) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

---

**Note:** Unlike the *fix temp/berendsen* command which performs thermostating but NO time integration, this fix performs thermostating/barostatting AND time integration. Thus you should not use any other time integration fix, such as *fix nve* on atoms to which this fix is applied. Likewise, *fix npt/cauchy* should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by *fix langevin* or *fix temp/rescale* commands.

---

See the *Howto thermostat* and *Howto barostat* doc pages for a discussion of different ways to compute temperature and perform thermostating and barostatting.

---

This fix compute a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if one of these sets of commands had been issued:

```
compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

The group for both the new temperature and pressure compute is “all” since pressure is computed for the entire system. See the *compute temp* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix-ID + underscore + “press”.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of these fix’s temperature or pressure via the *compute\_modify* command. Or you can print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

This fix can be used with either the *verlet* or *respa integrators*. When using this fix with *respa*, LAMMPS uses an integrator constructed according to the following factorization of the Liouville propagator (for two rRESPA levels):

$$\begin{aligned} \exp(iL\Delta t) = & \hat{E} \exp\left(iL_{T\text{-baro}}\frac{\Delta t}{2}\right) \exp\left(iL_{T\text{-part}}\frac{\Delta t}{2}\right) \exp\left(iL_{\epsilon,2}\frac{\Delta t}{2}\right) \exp\left(iL_2^{(2)}\frac{\Delta t}{2}\right) \\ & \times \left[ \exp\left(iL_2^{(1)}\frac{\Delta t}{2n}\right) \exp\left(iL_{\epsilon,1}\frac{\Delta t}{2n}\right) \exp\left(iL_1\frac{\Delta t}{n}\right) \exp\left(iL_{\epsilon,1}\frac{\Delta t}{2n}\right) \exp\left(iL_2^{(1)}\frac{\Delta t}{2n}\right) \right]^n \\ & \times \exp\left(iL_2^{(2)}\frac{\Delta t}{2}\right) \exp\left(iL_{\epsilon,2}\frac{\Delta t}{2}\right) \exp\left(iL_{T\text{-part}}\frac{\Delta t}{2}\right) \exp\left(iL_{T\text{-baro}}\frac{\Delta t}{2}\right) \\ & + \mathcal{O}(\Delta t^3) \end{aligned}$$

This factorization differs somewhat from that of Tuckerman et al, in that the barostat is only updated at the outermost rRESPA level, whereas Tuckerman’s factorization requires splitting the pressure into pieces corresponding to the forces computed at each rRESPA level. In theory, the latter method will exhibit better numerical stability. In practice, because Pdamp is normally chosen to be a large multiple of the outermost rRESPA timestep, the barostat dynamics are not the limiting factor for numerical stability. Both factorizations are time-reversible and can be shown to preserve the phase space measure of the underlying non-Hamiltonian equations of motion.

---

**Note:** Under NPT dynamics, for a system with zero initial total linear momentum, the total momentum fluctuates close to zero. It may occasionally undergo brief excursions to non-negligible values, before returning close to zero. Over long simulations, this has the effect of causing the center-of-mass to undergo a slow random walk. This can be mitigated by resetting the momentum at infrequent intervals using the *fix momentum* command.

---

#### 2.121.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of all the thermostat and barostat variables to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostatting procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

---

**Note:** If both the *temp* and *press* keywords are used in a single thermo\_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a *pressure compute* defines its own temperature compute as an argument when it is specified. The *temp* keyword will override this (for the pressure compute being used by fix npt), but only if the *temp* keyword comes after the *press* keyword. If the *temp* keyword comes before the *press* keyword, then the new pressure compute specified by the *press* keyword will be unaffected by the *temp* setting.

---

The cumulative energy change in the system imposed by this fix, due to thermostating and/or barostatting, is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix also computes a global vector of quantities, which can be accessed by various *output commands*. The vector values are “intensive”.

The vector stores internal Nose/Hoover thermostat and barostat variables. The number and meaning of the vector values depends on which fix is used and the settings for keywords *tchain* and *pchain*, which specify the number of Nose/Hoover chains for the thermostat and barostat. If no thermostating is done, then *tchain* is 0. If no barostatting is done, then *pchain* is 0. In the following list, “ndof” is 0, 1, 3, or 6, and is the number of degrees of freedom in the barostat. Its value is 0 if no barostat is used, else its value is 6 if any off-diagonal stress tensor component is barostatted, else its value is 1 if *couple xyz* is used or *couple xy* for a 2d simulation, otherwise its value is 3.

The order of values in the global vector and their meaning is as follows. The notation means there are *tchain* values for eta, followed by *tchain* for eta\_dot, followed by *ndof* for omega, etc:

- eta[tchain] = particle thermostat displacements (unitless)
- eta\_dot[tchain] = particle thermostat velocities (1/time units)

- `omega[ndof]` = barostat displacements (unitless)
- `omega_dot[ndof]` = barostat velocities (1/time units)
- `etap[pchain]` = barostat thermostat displacements (unitless)
- `etap_dot[pchain]` = barostat thermostat velocities (1/time units)
- `PE_eta[tchain]` = potential energy of each particle thermostat displacement (energy units)
- `KE_eta_dot[tchain]` = kinetic energy of each particle thermostat velocity (energy units)
- `PE_omega[ndof]` = potential energy of each barostat displacement (energy units)
- `KE_omega_dot[ndof]` = kinetic energy of each barostat velocity (energy units)
- `PE_etap[pchain]` = potential energy of each barostat thermostat displacement (energy units)
- `KE_etap_dot[pchain]` = kinetic energy of each barostat thermostat velocity (energy units)
- `PE_strain[1]` = scalar strain energy (energy units)

This fix can ramp its external temperature and pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

---

## 2.121.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

X, y, z cannot be barostatted if the associated dimension is not periodic. Xy, xz, and yz can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword (y dimension in xy) is periodic. Z, xz, and yz, cannot be barostatted for 2D simulations. The *create\_box*, *read\_data*, and *read\_restart* commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

For the *temp* keyword, the final Tstop cannot be 0.0 since it would make the external T = 0.0 at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The *scaleyz yes* and *scalexz yes* keyword/value pairs can not be used for 2D simulations. *scaleyz yes*, *scalexz yes*, and *scalexy yes* options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords *tri*, *yz*, *xz*, and *xy*.

The *alpha* keyword modifies the barostat as per Miller et al. (Miller)\_"#nc-Miller" so that the Cauchy stress is controlled. *alpha* is the non-dimensional parameter, typically set to 0.001 or 0.01 that determines how aggressively the algorithm drives the system towards the set Cauchy stresses. Larger values of *alpha* will modify the system more quickly, but can lead to instabilities. Smaller values will lead to longer convergence time. Since *alpha* also influences how much the stress fluctuations deviate from the equilibrium fluctuations, it should be set as small as possible.

A *continue* value of *yes* indicates that the fix is subsequent to a previous run with the *npt/cauchy* fix, and the intention is to continue from the converged stress state at the end of the previous run. This may be required, for example, when implementing a multi-step loading/unloading sequence over several fixes.

Setting *alpha* to zero is not permitted. To “turn off” the cauchystat control and thus restore the equilibrium stress fluctuations, two subsequent fixes should be used. In the first, fix *npt/cauchy* is used and the simulation box equilibrates to the correct shape for the desired stresses. In the second, *fix npt* is used instead which uses the original Parrinello-Rahman algorithm, but now with the corrected simulation box shape from using fix *npt/cauchy*.

This fix can be used with dynamic groups as defined by the *group* command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the

thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

## 2.121.6 Related commands

*fix nve, fix\_modify, run\_style*

## 2.121.7 Default

The keyword defaults are tchain = 3, pchain = 3, mtk = yes, tloop = ploop = 1, nreset = 0, drag = 0.0, dilate = all, couple = none, cauchystat = no, scaleyz = scalexz = scalexy = yes if periodic in second dimension and not coupled to barostat, otherwise no.

## 2.122 fix npt/sphere command

Accelerator Variants: *npt/sphere/omp*

### 2.122.1 Syntax

```
fix ID group-ID npt/sphere keyword value ...
```

- ID, group-ID are documented in *fix* command npt/sphere = style name of this fix command zero or more keyword/value pairs may be appended
- keyword = *disc*

*disc* value = none = treat particles as 2d discs, not spheres

- NOTE: additional thermostat and barostat and dipole related keyword/value pairs from the *fix npt* command can be appended

### 2.122.2 Examples

```
fix 1 all npt/sphere temp 300.0 300.0 100.0 iso 0.0 0.0 1000.0
fix 2 all npt/sphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0
fix 2 all npt/sphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0 disc
fix 2 all npt/sphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0 drag 0.2
fix 2 all npt/sphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0 update dipole
fix 2 water npt/sphere temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```

### 2.122.3 Description

Perform constant NPT integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the *fix npt* command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the spherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

If the *disc* keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the *dimension* keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the *fix npt* command. See, for example, discussion of the *temp*, *iso*, *aniso*, and *dilate* keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

---

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/sphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/sphere
compute fix-ID_press all pressure fix-ID_temp
```

See the *compute temp/sphere* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix-ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 2.122.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its thermostating or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix npt* command.

This fix can ramp its target temperature and pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

#### 2.122.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the *atom\_style sphere* command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the *disc* keyword is only allowed for 2d simulations, as defined by the *dimension* keyword.

#### 2.122.6 Related commands

*fix nvt\_sphere*, *fix npt\_asphere*, *fix\_modify*

#### 2.122.7 Default

none

## 2.123 fix numdiff command

### 2.123.1 Syntax

```
fix ID group-ID numdiff Nevery delta
```

- ID, group-ID are documented in *fix* command
- numdiff = style name of this fix command
- Nevery = calculate force by finite difference every this many timesteps
- delta = size of atom displacements (distance units)

### 2.123.2 Examples

```
fix 1 all numdiff 10 1e-6  
fix 1 movegroup numdiff 100 0.01
```

### 2.123.3 Description

Calculate forces through finite difference calculations of energy versus position. These forces can be compared to analytic forces computed by pair styles, bond styles, etc. This can be useful for debugging or other purposes.

The group specified with the command means only atoms within the group have their averages computed. Results are set to 0.0 for atoms not in the group.

This fix performs a loop over all atoms in the group. For each atom and each component of force it adds *delta* to the position, and computes the new energy of the entire system. It then subtracts *delta* from the original position and again computes the new energy of the system. It then restores the original position. That component of force is calculated as the difference in energy divided by two times *delta*.

---

**Note:** It is important to choose a suitable value for delta, the magnitude of atom displacements that are used to generate finite difference approximations to the exact forces. For typical systems, a value in the range of 1 part in 1e4 to 1e5 of the typical separation distance between atoms in the liquid or solid state will be sufficient. However, the best value will depend on a multitude of factors including the stiffness of the interatomic potential, the thermodynamic state of the material being probed, and so on. The only way to be sure that you have made a good choice is to do a sensitivity study on a representative atomic configuration, sweeping over a wide range of values of delta. If delta is too small, the output forces will vary erratically due to truncation effects. If delta is increased beyond a certain point, the output forces will start to vary smoothly with delta, due to growing contributions from higher order derivatives. In between these two limits, the numerical force values should be largely independent of delta.

---

---

**Note:** The cost of each energy evaluation is essentially the cost of an MD timestep. Thus invoking this fix once for a 3d system has a cost of 6N timesteps, where N is the total number of atoms in the system. So this fix can be very expensive to use for large systems. One expedient alternative is to define the fix for a group containing only a few atoms.

---

The *Nevery* argument specifies on what timesteps the force will be used calculated by finite difference.

The *delta* argument specifies the size of the displacement each atom will undergo.

---

### 2.123.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various *output commands*, which stores the components of the force on each atom as calculated by finite difference. The per-atom values can only be accessed on timesteps that are multiples of *Nevery* since that is when the finite difference forces are calculated. See the examples in *examples/numdiff* directory to see how this fix can be used to directly compare with the analytic forces computed by LAMMPS.

The array values calculated by this compute will be in force *units*.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is invoked during *energy minimization*.

### 2.123.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 2.123.6 Related commands

## 2.124 fix numdiff/virial command

### 2.124.1 Syntax

```
fix ID group-ID numdiff/virial Nevery delta
```

- ID, group-ID are documented in *fix* command
- numdiff/virial = style name of this fix command
- Nevery = calculate virial by finite difference every this many timesteps
- delta = magnitude of strain fields (dimensionless)

## 2.124.2 Examples

```
fix 1 all numdiff/stress 10 1e-6
```

## 2.124.3 Description

New in version 17Feb2022.

Calculate the virial stress tensor through a finite difference calculation of energy versus strain. These values can be compared to the analytic virial tensor computed by pair styles, bond styles, etc. This can be useful for debugging or other purposes. The specified group must be “all”.

This fix applies linear strain fields of magnitude *delta* to all the atoms relative to a point at the center of the box. The strain fields are in six different directions, corresponding to the six Cartesian components of the stress tensor defined by LAMMPS. For each direction it applies the strain field in both the positive and negative senses, and the new energy of the entire system is calculated after each. The difference in these two energies divided by two times *delta*, approximates the corresponding component of the virial stress tensor, after applying a suitable unit conversion.

---

**Note:** It is important to choose a suitable value for delta, the magnitude of strains that are used to generate finite difference approximations to the exact virial stress. For typical systems, a value in the range of 1 part in 1e5 to 1e6 will be sufficient. However, the best value will depend on a multitude of factors including the stiffness of the interatomic potential, the thermodynamic state of the material being probed, and so on. The only way to be sure that you have made a good choice is to do a sensitivity study on a representative atomic configuration, sweeping over a wide range of values of delta. If delta is too small, the output values will vary erratically due to truncation effects. If delta is increased beyond a certain point, the output values will start to vary smoothly with delta, due to growing contributions from higher order derivatives. In between these two limits, the numerical virial values should be largely independent of delta.

---

The *Nevery* argument specifies on what timesteps the force will be used calculated by finite difference.

The *delta* argument specifies the size of the displacement each atom will undergo.

---

## 2.124.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix produces a global vector which can be accessed by various *output commands*, which stores the components of the virial stress tensor as calculated by finite difference. The global vector can only be accessed on timesteps that are multiples of *Nevery* since that is when the finite difference virial is calculated. See the examples in *examples/numdiff* directory to see how this fix can be used to directly compare with the analytic virial stress tensor computed by LAMMPS.

The order of the virial stress tensor components is *xx*, *yy*, *zz*, *yz*, *xz*, and *xy*, consistent with Voigt notation. Note that the vector produced by *compute pressure* uses a different ordering, with *yz* and *xy* swapped.

The vector values calculated by this compute are “intensive”. The vector values will be in pressure *units*.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is invoked during *energy minimization*.

## 2.124.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 2.125 fix nve command

Accelerator Variants: *nve/gpu*, *nve/intel*, *nve/kk*, *nve/omp*

### 2.125.1 Syntax

```
fix ID group-ID nve
```

- ID, group-ID are documented in *fix* command
- nve = style name of this fix command

### 2.125.2 Examples

```
fix 1 all nve
```

### 2.125.3 Description

Perform plain time integration to update position and velocity for atoms in the group each timestep. This creates a system trajectory consistent with the microcanonical ensemble (NVE) provided there are (full) periodic boundary conditions and no other “manipulations” of the system (e.g. fixes that modify forces or velocities).

This fix invokes the velocity form of the Stoermer-Verlet time integration algorithm (velocity-Verlet). Other time integration options can be invoked using the *run\_style* command.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 2.125.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 2.126.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the *atom\_style ellipsoid* command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

### 2.126.6 Related commands

*fix nve*, *fix nve/sphere*

### 2.126.7 Default

none

## 2.127 fix nve/asphere/noforce command

### 2.127.1 Syntax

```
fix ID group-ID nve/asphere/noforce
```

- ID, group-ID are documented in *fix* command
- nve/asphere/noforce = style name of this fix command

### 2.127.2 Examples

```
fix 1 all nve/asphere/noforce
```

### 2.127.3 Description

Perform updates of position and orientation, but not velocity or angular momentum for atoms in the group each timestep. In other words, the force and torque on the atoms is ignored and their velocity and angular momentum are not updated. The atom velocities and angular momenta are used to update their positions and orientation.

This is useful as an implicit time integrator for Fast Lubrication Dynamics, since the velocity and angular momentum are updated by the *pair\_style lubricateU* command.

---

### 2.127.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.127.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the *atom\_style ellipsoid* command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

# 2.128 fix nve/awpmd command

## 2.128.1 Syntax

```
fix ID group-ID nve/awpmd
```

- ID, group-ID are documented in *fix* command
- nve/awpmd = style name of this fix command

## 2.128.2 Examples

```
fix 1 all nve/awpmd
```

## 2.128.3 Description

Perform constant NVE integration to update position and velocity for nuclei and electrons in the group for the *Antisymmetrized Wave Packet Molecular Dynamics* model. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble.

The operation of this fix is exactly like that described by the *fix nve* command, except that the width and width-velocity of the electron wave functions are also updated.

---

## 2.128.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.128.5 Restrictions

This fix is part of the AWPMD package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 2.128.6 Related commands

*fix nve*

# 2.130 fix nve/bpm/sphere command

## 2.130.1 Syntax

```
fix ID group-ID nve/bpm/sphere
```

- ID, group-ID are documented in [fix](#) command
- nve/bpm/sphere = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = *disc*  
*disc* value = none = treat particles as 2d discs, not spheres

## 2.130.2 Examples

```
fix 1 all nve/bpm/sphere
fix 1 all nve/bpm/sphere disc
```

## 2.130.3 Description

New in version 4May2022.

Perform constant NVE integration to update position, velocity, angular velocity, and quaternion orientation for finite-size spherical particles in the group each timestep. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble.

This fix differs from the [fix nve](#) command, which assumes point particles and only updates their position and velocity. It also differs from the [fix nve/sphere](#) command which assumes finite-size spheroid particles which do not store a quaternion. It thus does not update a particle's orientation or quaternion.

If the *disc* keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the *dimension* keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

---

#### 2.130.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

#### 2.130.5 Restrictions

This fix is part of the BPM package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store torque, angular velocity (omega), a radius, and a quaternion as defined by the *atom\_style bpm/sphere* command.

All particles in the group must be finite-size spheres with quaternions. They cannot be point particles.

Use of the *disc* keyword is only allowed for 2d simulations, as defined by the *dimension* keyword.

### 2.131 fix nve/dot command

#### 2.131.1 Syntax

```
fix ID group-ID nve/dot
```

- ID, group-ID are documented in *fix* command
- nve/dot = style name of this fix command

## 2.131.2 Examples

```
fix 1 all nve/dot
```

## 2.131.3 Description

Apply a rigid-body integrator as described in ([Davidchack](#)) to a group of atoms, but without Langevin dynamics. This command performs Molecular dynamics (MD) via a velocity-Verlet algorithm and an evolution operator that rotates the quaternion degrees of freedom, similar to the scheme outlined in ([Miller](#)).

This command is the equivalent of the *fix nve/dotc/langevin* without damping and noise and can be used to determine the stability range in a NVE ensemble prior to using the Langevin-type DOTC-integrator (see also *fix nve/dotc/langevin*). The command is equivalent to the *fix nve*. The particles are always considered to have a finite size.

An example input file can be found in /examples/PACKAGES/cgdn/examples/duplex1/. Further details of the implementation and stability of the integrator are contained in ([Henrich](#)). The preprint version of the article can be found [here](#).

## 2.131.4 Restrictions

These pair styles can only be used if LAMMPS was built with the *CG-DNA* package and the MOLECULE and ASPHERE package. See the *Build package* page for more info.

## 2.131.5 Related commands

*fix nve/dotc/langevin*, *fix nve*

## 2.132 fix nve/dotc/langevin command

### 2.132.1 Syntax

```
fix ID group-ID nve/dotc/langevin Tstart Tstop damp seed keyword value
```

- ID, group-ID are documented in *fix* command
- nve/dotc/langevin = style name of this fix command

- Tstart,Tstop = desired temperature at start/end of run (temperature units)
- damp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- keyword = *angmom*

*angmom* value = factor

factor = do thermostat rotational degrees of freedom via the angular momentum and  
→ apply numeric scale factor as discussed below

## 2.132.2 Examples

```
fix 1 all nve/dotc/langevin 1.0 1.0 0.03 457145 angmom 10
fix 1 all nve/dotc/langevin 0.1 0.1 78.9375 457145 angmom 10
```

## 2.132.3 Description

Apply a rigid-body Langevin-type integrator of the kind “Langevin C” as described in ([Davidchack](#)) to a group of atoms, which models an interaction with an implicit background solvent. This command performs Brownian dynamics (BD) via a technique that splits the integration into a deterministic Hamiltonian part and the Ornstein-Uhlenbeck process for noise and damping. The quaternion degrees of freedom are updated though an evolution operator which performs a rotation in quaternion space, preserves the quaternion norm and is akin to ([Miller](#)).

In terms of syntax this command has been closely modelled on the *fix langevin* and its *angmom* option. But it combines the *fix nve* and the *fix langevin* in one single command. The main feature is improved stability over the standard integrator, permitting slightly larger timestep sizes.

---

**Note:** Unlike the *fix langevin* this command performs also time integration of the translational and quaternion degrees of freedom.

---

The total force on each atom will have the form:

$$\begin{aligned} F &= F_c + F_f + F_r \\ F_f &= -\frac{m}{\text{damp}} v \\ F_r &\propto \sqrt{\frac{k_B T m}{dt \text{ damp}}} \end{aligned}$$

$F_c$  is the conservative force computed via the usual inter-particle interactions (*pair\_style*, *bond\_style*, etc). The  $F_f$  and  $F_r$  terms are implicitly taken into account by this fix on a per-particle basis.

$F_f$  is a frictional drag or viscous damping term proportional to the particle’s velocity. The proportionality constant for each atom is computed as  $\frac{m}{\text{damp}}$ , where  $m$  is the mass of the particle and damp is the damping factor specified by the user.

$F_r$  is a force due to solvent atoms at a temperature  $T$  randomly bumping into the particle. As derived from the fluctuation/dissipation theorem, its magnitude as shown above is proportional to  $\sqrt{\frac{k_B T m}{dt \text{ damp}}}$ , where  $k_B$  is the Boltzmann constant,  $T$  is the desired temperature,  $m$  is the mass of the particle,  $dt$  is the timestep size, and damp is the damping factor. Random numbers are used to randomize the direction and magnitude of this force as described in ([Dunweg](#)), where a uniform random number is used (instead of a Gaussian random number) for speed.

*Tstart* and *Tstop* have to be constant values, i.e. they cannot be variables. If used together with the oxDNA force field for coarse-grained simulation of DNA please note that  $T = 0.1$  in oxDNA units corresponds to  $T = 300$  K.

The *damp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 0.03 means to relax the temperature in a timespan of (roughly) 0.03 time units  $\tau$  (see the *units* command). The damp factor can be thought of as inversely related to the viscosity of the solvent, i.e. a small relaxation time implies a high-viscosity solvent and vice versa. See the discussion about gamma and viscosity in the documentation for the *fix viscous* command for more details. Note that the value 78.9375 in the second example above corresponds to a diffusion constant, which is about an order of magnitude larger than realistic ones. This has been used to sample configurations faster in Brownian dynamics simulations.

The random # *seed* must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword/value option has to be used in the following way:

This fix has to be used together with the *angmom* keyword. The particles are always considered to have a finite size. The keyword *angmom* enables thermostating of the rotational degrees of freedom in addition to the usual translational degrees of freedom.

The scale factor after the *angmom* keyword gives the ratio of the rotational to the translational friction coefficient.

An example input file can be found in examples/PACKAGES/cgdna/examples/duplex2/. Further details of the implementation and stability of the integrators are contained in ([Henrich](#)). The preprint version of the article can be found [here](#).

---

## 2.132.4 Restrictions

These pair styles can only be used if LAMMPS was built with the *CG-DNA* package and the MOLECULE and ASPHERE package. See the [Build package](#) page for more info.

## 2.133 fix nve/eff command

### 2.133.1 Syntax

```
fix ID group-ID nve/eff
```

- ID, group-ID are documented in *fix* command
- nve/eff = style name of this fix command

### 2.133.2 Examples

```
fix 1 all nve/eff
```

### 2.133.3 Description

Perform constant NVE integration to update position and velocity for nuclei and electrons in the group for the *electron force field* model. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble.

The operation of this fix is exactly like that described by the *fix nve* command, except that the radius and radial velocity of electrons are also updated.

### 2.133.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.133.5 Restrictions

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 2.133.6 Related commands

*fix nve*, *fix nvt/eff*, *fix npt/eff*

### 2.133.7 Default

none

## 2.134 fix nve/limit command

### 2.134.1 Syntax

```
fix ID group-ID nve/limit xmax
```

- ID, group-ID are documented in *fix* command
- nve = style name of this fix command
- xmax = maximum distance an atom can move in one timestep (distance units)

### 2.134.2 Examples

```
fix 1 all nve/limit 0.1
```

### 2.134.3 Description

Perform constant NVE updates of position and velocity for atoms in the group each timestep. A limit is imposed on the maximum distance an atom can move in one timestep. This is useful when starting a simulation with a configuration containing highly overlapped atoms. Normally this would generate huge forces which would blow atoms out of the simulation box, causing LAMMPS to stop with an error.

Using this fix can overcome that problem. Forces on atoms must still be computable (which typically means two atoms must have a separation distance  $> 0.0$ ). But large velocities generated by large forces are reset to a value that corresponds to a displacement of length  $x_{max}$  in a single timestep.  $x_{max}$  is specified in distance units; see the *units* command for details. The value of  $x_{max}$  should be consistent with the neighbor skin distance and the frequency of neighbor list re-building, so that pairwise interactions are not missed on successive timesteps as atoms move. See the *neighbor* and *neigh\_modify* commands for details.

Note that if a velocity reset occurs the integrator will not conserve energy. On steps where no velocity resets occur, this integrator is exactly like the *fix nve* command. Since forces are unaltered, pressures computed by thermodynamic output will still be very large for overlapped configurations.

---

**Note:** You should not use *fix shake* in conjunction with this fix. That is because fix shake applies constraint forces based on the predicted positions of atoms after the next timestep. It has no way of knowing the timestep may change due to this fix, which will cause the constraint forces to be invalid. A better strategy is to turn off fix shake when performing initial dynamics that need this fix, then turn fix shake on when doing normal dynamics with a fixed-size timestep.

---

### 2.134.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the count of how many updates of atom's velocity/position were limited by the maximum distance criterion. This should be roughly the number of atoms so affected, except that updates occur at both the beginning and end of a timestep in a velocity Verlet timestepping algorithm. This is a cumulative quantity for the current run, but is re-initialized to zero each time a run is performed. The scalar value calculated by this fix is "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.134.5 Restrictions

none

# 2.135 fix nve/line command

## 2.135.1 Syntax

```
fix ID group-ID nve/line
```

- ID, group-ID are documented in *fix* command
- nve/line = style name of this fix command

## 2.135.2 Examples

```
fix 1 all nve/line
```

## 2.135.3 Description

Perform constant NVE integration to update position, velocity, orientation, and angular velocity for line segment particles in the group each timestep. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble. See [Howto spherical](#) page for an overview of using line segment particles.

This fix differs from the *fix nve* command, which assumes point particles and only updates their position and velocity.

## 2.135.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.135.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix requires that particles be line segments as defined by the [atom\\_style line](#) command.

## 2.135.6 Related commands

*fix nve*, *fix nve/asphere*

## 2.135.7 Default

none

# 2.136 fix nve/manifold/rattle command

## 2.136.1 Syntax

```
fix ID group-ID nve/manifold/rattle tol maxit manifold manifold-args keyword value ...
```

- ID, group-ID are documented in [fix](#) command
- nve/manifold/rattle = style name of this fix command
- tol = tolerance to which Newton iteration must converge
- maxit = maximum number of iterations to perform
- manifold = name of the manifold
- manifold-args = parameters for the manifold
- one or more keyword/value pairs may be appended

keyword = *every*

every values = N

N = print info about iteration every N steps. N = 0 means no output

## 2.136.2 Examples

```
fix 1 all nve/manifold/rattle 1e-4 10 sphere 5.0
fix step all nve/manifold/rattle 1e-8 100 ellipsoid 2.5 2.5 5.0 every 25
```

### 2.136.3 Description

Perform constant NVE integration to update position and velocity for atoms constrained to a curved surface (manifold) in the group each timestep. The constraint is handled by RATTLE ([Andersen](#)) written out for the special case of single-particle constraints as explained in ([Paquay](#)). V is volume; E is energy. This way, the dynamics of particles constrained to curved surfaces can be studied. If combined with [fix langevin](#), this generates Brownian motion of particles constrained to a curved surface. For a list of currently supported manifolds and their parameters, see the [Howto manifold](#) doc page.

Note that the particles must initially be close to the manifold in question. If not, RATTLE will not be able to iterate until the constraint is satisfied, and an error is generated. For simple manifolds this can be achieved with *region* and *create\_atoms* commands, but for more complex surfaces it might be more useful to write a script.

The manifold args may be equal-style variables, like so:

```
variable R equal "ramp(5.0,3.0)"
fix shrink_sphere all nve/manifold/rattle 1e-4 10 sphere v_R
```

In this case, the manifold parameter will change in time according to the variable. This is not a problem for the time integrator as long as the change of the manifold is slow with respect to the dynamics of the particles. Note that if the manifold has to exert work on the particles because of these changes, the total energy might not be conserved.

---

### 2.136.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

---

### 2.136.5 Restrictions

## 2.137 fix nve/noforce command

### 2.137.1 Syntax

```
fix ID group-ID nve
```

- ID, group-ID are documented in *fix* command
- nve/noforce = style name of this fix command

### 2.137.2 Examples

```
fix 3 wall nve/noforce
```

### 2.137.3 Description

Perform updates of position, but not velocity for atoms in the group each timestep. In other words, the force on the atoms is ignored and their velocity is not updated. The atom velocities are used to update their positions.

This can be useful for wall atoms, when you set their velocities, and want the wall to move (or stay stationary) in a prescribed fashion.

This can also be accomplished via the *fix setforce* command, but with fix nve/noforce, the forces on the wall atoms are unchanged, and can thus be printed by the *dump* command or queried with an equal-style *variable* that uses the fcm() group function to compute the total force on the group of atoms.

### 2.137.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.137.5 Restrictions

none

### 2.137.6 Related commands

*fix nve*

## 2.137.7 Default

none

## 2.138 fix nve/sphere command

Accelerator Variants: *nve/sphere/omp*, *nve/sphere/kk*

### 2.138.1 Syntax

```
fix ID group-ID nve/sphere
```

- ID, group-ID are documented in *fix* command
- nve/sphere = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = *update* or *disc*
  - update* value = *dipole* or *dipole/dlm*
    - dipole* = update orientation of dipole moment during integration
    - dipole/dlm* = use DLM integrator to update dipole orientation
  - disc* value = none = treat particles as 2d discs, not spheres

### 2.138.2 Examples

```
fix 1 all nve/sphere
fix 1 all nve/sphere update dipole
fix 1 all nve/sphere disc
fix 1 all nve/sphere update dipole/dlm
```

### 2.138.3 Description

Perform constant NVE integration to update position, velocity, and angular velocity for finite-size spherical particles in the group each timestep. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble.

This fix differs from the *fix nve* command, which assumes point particles and only updates their position and velocity.

If the *update* keyword is used with the *dipole* value, then the orientation of the dipole moment of each particle is also updated during the time integration. This option should be used for models where a dipole moment is assigned to finite-size particles, e.g. spheroids via use of the *atom\_style hybrid sphere dipole* command.

The default dipole orientation integrator can be changed to the Dullweber-Leimkuhler-McLachlan integration scheme (*Dullweber*) when using *update* with the value *dipole/dlm*. This integrator is symplectic and time-reversible, giving better energy conservation and allows slightly longer timesteps at only a small additional computational cost.

If the *disc* keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the *dimension* keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.138.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to [binary restart files](#). None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various [output commands](#). No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during [energy minimization](#).

## 2.138.5 Restrictions

This fix requires that atoms store torque and angular velocity (*omega*) and a radius as defined by the [atom\\_style sphere](#) command. If the *dipole* keyword is used, then they must also store a dipole moment as defined by the [atom\\_style dipole](#) command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the *disc* keyword is only allowed for 2d simulations, as defined by the [dimension](#) keyword.

## 2.138.6 Related commands

*fix nve*, *fix nve/asphere*

## 2.138.7 Default

none

# 2.139 fix nve/spin command

## 2.139.1 Syntax

**fix** ID group-ID nve/spin keyword values

- ID, group-ID are documented in [fix](#) command
- nve/spin = style name of this fix command

- keyword = *lattice*

*lattice* value = *moving* or *frozen*

*moving* = integrate both spin and atomic degrees of freedom

*frozen* = integrate spins on a fixed lattice

## 2.139.2 Examples

```
fix 3 all nve/spin lattice moving
fix 1 all nve/spin lattice frozen
```

## 2.139.3 Description

Perform a symplectic integration for the spin or spin-lattice system.

The *lattice* keyword defines if the spins are integrated on a lattice of fixed atoms (*lattice* = *frozen*), or if atoms are moving (*lattice* = *moving*). The first case corresponds to a spin dynamics calculation, and the second to a spin-lattice calculation. By default a spin-lattice integration is performed (*lattice* = *moving*).

The *nve/spin* fix applies a Suzuki-Trotter decomposition to the equations of motion of the spin lattice system, following the scheme:

according to the implementation reported in ([Omelyan](#)).

A sectoring method enables this scheme for parallel calculations. The implementation of this sectoring algorithm is reported in ([Tranchida](#)).

---

## 2.139.4 Restrictions

This fix style can only be used if LAMMPS was built with the SPIN package. See the [Build package](#) page for more info.

To use the spin algorithm, it is necessary to define a map with the atom\_modify command. Typically, by adding the command:

```
atom_modify map array
```

before you create the simulation box. Note that the keyword “hash” instead of “array” is also valid.

## 2.139.5 Related commands

*atom\_style spin, fix nve*

## 2.139.6 Default

The option default is lattice = moving.

## 2.140 fix nve/tri command

### 2.140.1 Syntax

```
fix ID group-ID nve/tri
```

- ID, group-ID are documented in *fix* command
- nve/tri = style name of this fix command

### 2.140.2 Examples

```
fix 1 all nve/tri
```

### 2.140.3 Description

Perform constant NVE integration to update position, velocity, orientation, and angular momentum for triangular particles in the group each timestep. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble. See the [Howto spherical](#) page for an overview of using triangular particles.

This fix differs from the *fix nve* command, which assumes point particles and only updates their position and velocity.

## 2.140.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.140.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that particles be triangles as defined by the *atom\_style tri* command.

## 2.140.6 Related commands

*fix nve*, *fix nve/asphere*

## 2.140.7 Default

none

# 2.141 fix nvk command

## 2.141.1 Syntax

```
fix ID group-ID nvk
```

- ID, group-ID are documented in *fix* command
- nvk = style name of this fix command

## 2.141.2 Examples

```
fix 1 all nvk
```

## 2.141.3 Description

Perform constant kinetic energy integration using the Gaussian thermostat to update position and velocity for atoms in the group each timestep. V is volume; K is kinetic energy. This creates a system trajectory consistent with the isokinetic ensemble.

The equations of motion used are those of Minary et al in (*Minary*), a variant of those initially given by Zhang in (*Zhang*).

The kinetic energy will be held constant at its value given when fix nvk is initiated. If a different kinetic energy is desired, the *velocity* command should be used to change the kinetic energy prior to this fix.

## 2.141.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.141.5 Restrictions

The Gaussian thermostat only works when it is applied to all atoms in the simulation box. Therefore, the group must be set to all.

This fix has not yet been implemented to work with the RESPA integrator.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.141.6 Related commands

## 2.142 fix nvt/asphere command

Accelerator Variants: *nvt/asphere/omp*

### 2.142.1 Syntax

**fix** ID group-ID nvt/asphere keyword value ...

- ID, group-ID are documented in *fix* command
- nvt/asphere = style name of this fix command
- additional thermostat related keyword/value pairs from the *fix nvt* command can be appended

## 2.142.2 Examples

```
fix 1 all nvt/asphere temp 300.0 300.0 100.0
fix 1 all nvt/asphere temp 300.0 300.0 100.0 drag 0.2
```

## 2.142.3 Description

Perform constant NVT integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the [fix nvt](#) command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the aspherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

Additional parameters affecting the thermostat are specified by keywords and values documented with the [fix nvt](#) command. See, for example, discussion of the [temp](#) and [drag](#) keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/asphere”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/asphere
```

See the [compute temp/asphere](#) command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the [thermo\\_style](#) command) with ID = [thermo\\_temp](#). This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the [compute\\_modify](#) command or print this temperature during thermodynamic output via the [thermo\\_style custom](#) command using the appropriate compute-ID. It also means that changing attributes of [thermo\\_temp](#) will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with [compute commands](#) that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial [region](#), or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the [fix\\_modify](#) command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual [compute temp commands](#) to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a [gpu](#), [intel](#), [kk](#), [omp](#), or [opt](#) suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the [-suffix command-line switch](#) when you invoke LAMMPS, or you can use the [suffix](#) command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 2.142.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a *compute* you have defined to this fix which will be used in its thermostating procedure.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nvt* command.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.142.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the *atom\_style ellipsoid* command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

## 2.142.6 Related commands

## 2.142.7 Default

none

# 2.143 fix nvt/body command

## 2.143.1 Syntax

```
fix ID group-ID nvt/body keyword value ...
```

- ID, group-ID are documented in *fix* command
- nvt/body = style name of this fix command
- additional thermostat related keyword/value pairs from the *fix nvt* command can be appended

## 2.143.2 Examples

```
fix 1 all nvt/body temp 300.0 300.0 100.0
fix 1 all nvt/body temp 300.0 300.0 100.0 drag 0.2
```

## 2.143.3 Description

Perform constant NVT integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover temperature thermostat. *V* is volume; *T* is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the *fix nvt* command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the body particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

Additional parameters affecting the thermostat are specified by keywords and values documented with the *fix nvt* command. See, for example, discussion of the *temp* and *drag* keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/body”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/body
```

See the *compute temp/body* command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp*. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command or print this temperature during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.143.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a *compute* you have defined to this fix which will be used in its thermostating procedure.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nvt* command.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.143.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the *atom\_style body* command.

# 2.144 fix nvt/manifold/rattle command

## 2.144.1 Syntax

```
fix ID group-ID nvt/manifold/rattle tol maxit manifold manifold-args keyword value ...
```

- ID, group-ID are documented in *fix* command
- nvt/manifold/rattle = style name of this fix command
- tol = tolerance to which Newton iteration must converge
- maxit = maximum number of iterations to perform
- manifold = name of the manifold
- manifold-args = parameters for the manifold
- one or more keyword/value pairs may be appended

keyword = *temp* or *tchain* or *every*  
  *temp* values = Tstart Tstop Tdamp  
    Tstart, Tstop = external temperature at start/end of run  
    Tdamp = temperature damping parameter (time units)  
  *tchain* value = N  
    N = length of thermostat chain (1 = single thermostat)  
  *every* value = N  
    N = print info about iteration every N steps. N = 0 means no output

## 2.144.2 Examples

```
fix 1 all nvt/manifold/rattle 1e-4 10 cylinder 3.0 temp 1.0 1.0 10.0
```

## 2.144.3 Description

This fix combines the RATTLE-based (*Andersen*) time integrator of *fix nve/manifold/rattle* (*Paquay*) with a Nose-Hoover-chain thermostat to sample the canonical ensemble of particles constrained to a curved surface (manifold). This sampling does suffer from discretization bias of  $O(dt)$ . For a list of currently supported manifolds and their parameters, see the *Howto manifold* doc page.

---

## 2.144.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

---

## 2.144.5 Restrictions

This fix is part of the MANIFOLD package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.145 fix nvt/sllod command

Accelerator Variants: *nvt/sllod/intel*, *nvt/sllod/omp*, *nvt/sllod/kk*

### 2.145.1 Syntax

```
fix ID group-ID nvt/sllod keyword value ...
```

- ID, group-ID are documented in *fix* command
- nvt/sllod = style name of this fix command
- zero or more keyword/value pairs may be appended

keyword = *psllod*

*psllod* value = *no* or *yes* = use SLLOD or p-SLLOD variant, respectively

- additional thermostat related keyword/value pairs from the *fix nvt* command can be appended

### 2.145.2 Examples

```
fix 1 all nvt/sllod temp 300.0 300.0 100.0
fix 1 all nvt/sllod temp 300.0 300.0 100.0 drag 0.2
```

### 2.145.3 Description

Perform constant NVT integration to update positions and velocities each timestep for atoms in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This thermostat is used for a simulation box that is changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the *fix deform* command, so each point in the simulation box can be thought of as having a “streaming” velocity. This position-dependent streaming velocity is subtracted from each atom’s actual velocity to yield a thermal velocity which is used for temperature computation and thermostating. For example, if the box is being sheared in x, relative to y, then points at the bottom of the box (low y) have a small x velocity, while points at the top of the box (hi y) have a large x velocity. These velocities do not contribute to the thermal “temperature” of the atom.

**Note:** *Fix deform* has an option for remapping either atom coordinates or velocities to the changing simulation box. To use *fix nvt/sllod*, *fix deform* should NOT remap atom positions, because *fix nvt/sllod* adjusts the atom positions and velocities to create a velocity profile that matches the changing box size/shape. *Fix deform* SHOULD remap atom velocities when atoms cross periodic boundaries since that is consistent with maintaining the velocity profile created by *fix nvt/sllod*. LAMMPS will give an error if this setting is not consistent.

The SLLOD equations of motion, originally proposed by Hoover and Ladd (see (*Evans and Morriss*)), were proven to be equivalent to Newton’s equations of motion for shear flow by (*Evans and Morriss*). They were later shown to generate the desired velocity gradient and the correct production of work by stresses for all forms of homogeneous flow by (*Daivis and Todd*).

Changed in version 8Feb2023.

For the default (*psllod = no*), the LAMMPS implementation adheres to the standard SLLOD equations of motion, as defined by (*Evans and Morriss*). The option *psllod = yes* invokes the slightly different SLLOD variant first introduced by (*Tuckerman et al.*) as g-SLLOD and later by (*Edwards*) as p-SLLOD. In all cases, the equations of motion are coupled to a Nose/Hoover chain thermostat in a velocity Verlet formulation, closely following the implementation used for the *fix nvt* command.

---

**Note:** A recent (2017) book by (*Todd and Daivis*) discusses use of the SLLOD method and non-equilibrium MD (NEMD) thermostating generally, for both simple and complex fluids, e.g. molecular systems. The latter can be tricky to do correctly.

---

Additional parameters affecting the thermostat are specified by keywords and values documented with the *fix nvt* command. See, for example, discussion of the *temp* and *drag* keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/deform”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/deform
```

See the *compute temp/deform* command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp*. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command or print this temperature during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.145.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a *compute* you have defined to this fix which will be used in its thermostating procedure.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nvt* command.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.145.5 Restrictions

This fix works best without Nose-Hoover chain thermostats, i.e. using *tchain* = 1. Setting *tchain* to larger values can result in poor equilibration.

## 2.145.6 Related commands

*fix nve*, *fix nvt*, *fix temp/rescale*, *fix langevin*, *fix\_modify*, *compute temp/deform*

## 2.145.7 Default

Same as *fix nvt*, except *tchain* = 1, *psllod* = *no*.

## 2.146 fix nvt/sllod/eff command

### 2.146.1 Syntax

```
fix ID group-ID nvt/sllod/eff keyword value ...
```

- ID, group-ID are documented in *fix* command
- nvt/sllod/eff = style name of this fix command

- zero or more keyword/value pairs may be appended

keyword = *psllod*

*psllod* value = *no* or *yes* = use SLLOD or p-SLLOD variant, respectively

- additional thermostat related keyword/value pairs from the *fix nvt/eff* command may be appended, too.

## 2.146.2 Examples

```
fix 1 all nvt/sllod/eff temp 300.0 300.0 0.1
fix 1 all nvt/sllod/eff temp 300.0 300.0 0.1 drag 0.2
```

## 2.146.3 Description

Perform constant NVT integration to update positions and velocities each timestep for nuclei and electrons in the group for the *electron force field* model, using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

The operation of this fix is exactly like that described by the *fix nvt/sllod* command, except that the radius and radial velocity of electrons are also updated and thermostatted. Likewise the temperature calculated by the fix, using the compute it creates (as discussed in the *fix nvt*, *npt*, and *nph* doc page), is performed with a *compute temp/deform/eff* command that includes the eFF contribution to the temperature from the electron radial velocity.

## 2.146.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a *compute* you have defined to this fix which will be used in its thermostating procedure.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nvt/eff* command.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.146.5 Restrictions

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix works best without Nose-Hoover chain thermostats, i.e. using *tchain* = 1. Setting *tchain* to larger values can result in poor equilibration.

## 2.146.6 Related commands

*fix nve/eff*, *fix nvt/eff*, *fix langevin/eff*, *fix nvt/sllod*, *fix\_modify*, *compute temp/deform/eff*

## 2.146.7 Default

Same as *fix nvt/eff*, except *tchain* = 1.

---

## 2.147 fix nvt/sphere command

Accelerator Variants: *nvt/sphere/omp*

### 2.147.1 Syntax

```
fix ID group-ID nvt/sphere keyword value ...
```

- ID, group-ID are documented in *fix* command
- nvt/sphere = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = *disc*  
*disc* value = none = treat particles as 2d discs, not spheres
- NOTE: additional thermostat and dipole related keyword/value pairs from the *fix nvt* command can be appended

### 2.147.2 Examples

```
fix 1 all nvt/sphere temp 300.0 300.0 100.0
fix 1 all nvt/sphere temp 300.0 300.0 100.0 disc
fix 1 all nvt/sphere temp 300.0 300.0 100.0 drag 0.2
fix 1 all nvt/sphere temp 300.0 300.0 100.0 update dipole
```

### 2.147.3 Description

Perform constant NVT integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the *fix nvt* command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the spherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

If the *disc* keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the *dimension* keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the thermostat are specified by keywords and values documented with the *fix nvt* command. See, for example, discussion of the *temp* and *drag* keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/sphere”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/sphere
```

See the *compute temp/sphere* command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp*. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command or print this temperature during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

#### 2.147.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a *compute* you have defined to this fix which will be used in its thermostating procedure.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes the same global scalar and global vector of quantities as does the *fix nvt* command.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.147.5 Restrictions

This fix requires that atoms store torque and angular velocity ( $\omega$ ) and a radius as defined by the *atom\_style sphere* command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the *disc* keyword is only allowed for 2d simulations, as defined by the *dimension* keyword.

## 2.147.6 Related commands

# 2.148 fix oneway command

## 2.148.1 Syntax

```
fix ID group-ID oneway N region-ID direction
```

- ID, group-ID are documented in *fix* command
- oneway = style name of this fix command
- N = apply this fix every this many timesteps
- region-ID = ID of region where fix is active
- direction = x or -x or y or -y or z or -z = coordinate and direction of the oneway constraint

## 2.148.2 Examples

```
fix 1 ions oneway 10 semi -x
fix 2 all oneway 1 left -z
fix 3 all oneway 1 right z
```

### 2.148.3 Description

Enforce that particles in the group and in a given region can only move in one direction. This is done by reversing a particle's velocity component, if it has the wrong sign in the specified dimension. The effect is that the particle moves in one direction only.

This can be used, for example, as a simple model of a semi-permeable membrane, or as an implementation of Maxwell's demon.

---

### 2.148.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.148.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.149 fix orient/fcc command

## 2.150 fix orient/bcc command

### 2.150.1 Syntax

```
fix ID group-ID orient/fcc nstats dir alat dE cutlo cuthi file0 file1
fix ID group-ID orient/bcc nstats dir alat dE cutlo cuthi file0 file1
```

- ID, group-ID are documented in *fix* command
- nstats = print stats every this many steps, 0 = never
- dir = 0/1 for which crystal is used as reference
- alat = fcc/bcc cubic lattice constant (distance units)
- dE = energy added to each atom (energy units)
- cutlo,cuthi = values between 0.0 and 1.0, cutlo < cuthi
- file0,file1 = files that specify orientation of each grain

## 2.150.2 Examples

```
fix gb all orient/fcc 0 1 4.032008 0.001 0.25 0.75 xi.vec chi.vec
fix gb all orient/bcc 0 1 2.882 0.001 0.25 0.75 ngb.left ngb.right
```

## 2.150.3 Description

The fix applies an orientation-dependent force to atoms near a planar grain boundary which can be used to induce grain boundary migration (in the direction perpendicular to the grain boundary plane). The motivation and explanation of this force and its application are described in ([Janssens](#)). The adaptation to bcc crystals is described in ([Wicaksono1](#)). The computed force is only applied to atoms in the fix group.

The basic idea is that atoms in one grain (on one side of the boundary) have a potential energy  $dE$  added to them. Atoms in the other grain have 0.0 potential energy added. Atoms near the boundary (whose neighbor environment is intermediate between the two grain orientations) have an energy between 0.0 and  $dE$  added. This creates an effective driving force to reduce the potential energy of atoms near the boundary by pushing them towards one of the grain orientations. For  $dir = 1$  and  $dE > 0$ , the boundary will thus move so that the grain described by file0 grows and the grain described by file1 shrinks. Thus this fix is designed for simulations of two-grain systems, either with one grain boundary and free surfaces parallel to the boundary, or a system with periodic boundary conditions and two equal and opposite grain boundaries. In either case, the entire system can displace during the simulation, and such motion should be accounted for in measuring the grain boundary velocity.

The potential energy added to atom I is given by these formulas

$$\xi_i = \sum_{j=1}^{12} |\mathbf{r}_j - \mathbf{r}_i^I| \quad (1)$$

$$\xi_{IJ} = \sum_{j=1}^{12} |\mathbf{r}_j^J - \mathbf{r}_i^I| \quad (2)$$

$$\xi_{\text{low}} = \text{cutlo } \xi_{IJ} \quad (3)$$

$$\xi_{\text{high}} = \text{cuthi } \xi_{IJ} \quad (4)$$

$$\omega_i = \frac{\pi}{2} \frac{\xi_i - \xi_{\text{low}}}{\xi_{\text{high}} - \xi_{\text{low}}} \quad (5)$$

$$\begin{aligned} u_i &= 0 & \text{for } \xi_i < \xi_{\text{low}} \\ &= dE \frac{1 - \cos(2\omega_i)}{2} & \text{for } \xi_{\text{low}} < \xi_i < \xi_{\text{high}} \\ &= dE & \text{for } \xi_{\text{high}} < \xi_i \end{aligned} \quad (6)$$

which are fully explained in ([Janssens](#)). For fcc crystals this order parameter  $\xi_i$  for atom I in equation (1) is a sum over the 12 nearest neighbors of atom I. For bcc crystals it is the corresponding sum of the 8 nearest neighbors.  $\mathbf{r}_j$  is the vector from atom I to its neighbor J, and  $\mathbf{r}_j^I$  is a vector in the reference (perfect) crystal. That is, if  $dir = 0/1$ , then  $\mathbf{r}_j^I$  is a vector to an atom coord from file 0/1. Equation (2) gives the expected value of the order parameter  $\xi_{IJ}$  in the other grain.  $\xi_{\text{hi}}$  and  $\xi_{\text{lo}}$  cutoffs are defined in equations (3) and (4), using the input parameters *cutlo* and *cuthi* as thresholds to avoid adding grain boundary energy when the deviation in the order parameter from 0 or 1 is small (e.g. due to thermal fluctuations in a perfect crystal). The added potential energy  $U_i$  for atom I is given in equation (6) where it is interpolated between 0 and  $dE$  using the two threshold  $\xi_i$  values and the  $W_i$  value of equation (5).

The derivative of this energy expression gives the force on each atom which thus depends on the orientation of its neighbors relative to the 2 grain orientations. Only atoms near the grain boundary feel a net force which tends to drive them to one of the two grain orientations.

In equation (1), the reference vector used for each neighbor is the reference vector closest to the actual neighbor position. This means it is possible two different neighbors will use the same reference vector. In such cases, the atom in question is far from a perfect orientation and will likely receive the full  $dE$  addition, so the effect of duplicate reference vector usage is small.

The *dir* parameter determines which grain wants to grow at the expense of the other. A value of 0 means the first grain will shrink; a value of 1 means it will grow. This assumes that  $dE$  is positive. The reverse will be true if  $dE$  is negative.

The *alat* parameter is the cubic lattice constant for the fcc or bcc material and is only used to compute a cutoff distance of  $1.57 * alat / \sqrt{2}$  for finding the 12 or 8 nearest neighbors of each atom (which should be valid for an fcc or bcc crystal). A longer/shorter cutoff can be imposed by adjusting *alat*. If a particular atom has less than 12 or 8 neighbors within the cutoff, the order parameter of equation (1) is effectively multiplied by 12 or 8 divided by the actual number of neighbors within the cutoff.

The  $dE$  parameter is the maximum amount of additional energy added to each atom in the grain which wants to shrink.

The *cutlo* and *cuthi* parameters are used to reduce the force added to bulk atoms in each grain far away from the boundary. An atom in the bulk surrounded by neighbors at the ideal grain orientation would compute an order parameter of 0 or 1 and have no force added. However, thermal vibrations in the solid will cause the order parameters to be greater than 0 or less than 1. The cutoff parameters mask this effect, allowing forces to only be added to atoms with order-parameters between the cutoff values.

*File0* and *file1* are filenames for the two grains which each contain 6 vectors (6 lines with 3 values per line) which specify the grain orientations. Each vector is a displacement from a central atom (0,0,0) to a nearest neighbor atom in an fcc lattice at the proper orientation. The vector lengths should all be identical since an fcc lattice has a coordination number of 12. Only 6 are listed due to symmetry, so the list must include one from each pair of equal-and-opposite neighbors. A pair of orientation files for a Sigma=5 tilt boundary are shown below. A tutorial that can help for writing the orientation files is given in ([Wicaksono2](#))

## 2.150.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy of atom interactions with the grain boundary driving force to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify respa* option is supported by these fixes. This allows to set at which level of the *r-RESPA* integrator a fix is adding its forces. Default is the outermost level.

This fix calculates a global scalar which can be accessed by various *output commands*. The scalar is the potential energy change due to this fix. The scalar value calculated by this fix is “extensive”.

This fix also calculates a per-atom array which can be accessed by various *output commands*. The array stores the order parameter  $\Xi$  and normalized order parameter (0 to 1) for each atom. The per-atom values can be accessed on any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

## 2.150.5 Restrictions

These fixes are part of the ORIENT package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These fixes should only be used with fcc or bcc lattices.

## 2.150.6 Related commands

*fix\_modify*

## 2.151 fix orient/eco command

```
fix ID group-ID orient/eco u0 eta cutoff orientationsFile
```

- ID, group-ID are documented in fix command
- u0 = energy added to each atom (energy units)
- eta = cutoff value (usually 0.25)

- cutoff = cutoff radius for orientation parameter calculation
- orientationsFile = file that specifies orientation of each grain

### 2.151.1 Examples

```
fix gb all orient/eco 0.08 0.25 3.524 sigma5.ori
```

### 2.151.2 Description

The fix applies a synthetic driving force to a grain boundary which can be used for the investigation of grain boundary motion. The affiliation of atoms to either of the two grains forming the grain boundary is determined from an orientation-dependent order parameter as described in (Ulomek). The potential energy of atoms is either increased by an amount of  $0.5*u0$  or  $-0.5*u0$  according to the orientation of the surrounding crystal. This creates a potential energy gradient which pushes atoms near the grain boundary to orient according to the energetically favorable grain orientation. This fix is designed for applications in bicrystal system with one grain boundary and open ends, or two opposite grain boundaries in a periodic system. In either case, the entire system can experience a displacement during the simulation which needs to be accounted for in the evaluation of the grain boundary velocity. While the basic method is described in (Ulomek), the implementation follows the efficient implementation from (Schratt & Mohles). The synthetic potential energy added to an atom  $j$  is given by the following formulas

$$w(|\vec{r}_{jk}|) = w_{jk} = \begin{cases} \frac{|\vec{r}_{jk}|^4}{r_{\text{cut}}^4} - 2 \frac{|\vec{r}_{jk}|^2}{r_{\text{cut}}^2} + 1, & |\vec{r}_{jk}| < r_{\text{cut}} \\ 0, & |\vec{r}_{jk}| \geq r_{\text{cut}} \end{cases}$$

$$\chi_j = \frac{1}{N} \sum_{l=1}^3 \left[ |\psi_l^I(\vec{r}_j)|^2 - |\psi_l^{II}(\vec{r}_j)|^2 \right]$$

$$\psi_l^X(\vec{r}_j) = \sum_{k \in \mathbf{I}} w_{jk} \exp(i\vec{r}_{jk} \cdot \vec{q}_l^X)$$

$$u(\chi_j) = \frac{u_0}{2} \begin{cases} 1, & \chi_j \geq \eta \\ \sin\left(\frac{\pi\chi_j}{2\eta}\right), & -\eta < \chi_j < \eta \\ -1, & \chi_j \leq -\eta \end{cases}$$

which are fully explained in (Ulomek) and (Schratt & Mohles).

The force on each atom is the negative gradient of the synthetic potential energy. It depends on the surrounding of this atom. An atom far from the grain boundary does not experience a synthetic force as its surrounding is that of an oriented single crystal and thermal fluctuations are masked by the parameter *eta*. Near the grain boundary however, the gradient is nonzero and synthetic force terms are computed. The orientationsFile specifies the perfect oriented crystal basis vectors for the two adjoining crystals. The first three lines (line=row vector) for the energetically penalized and the last three lines for the energetically favored grain assuming  $u0$  is positive. For negative  $u0$ , this is reversed. With the *cutoff* parameter, the size of the region around each atom which is used in the order parameter computation is defined. The cutoff must be smaller than the interaction range of the MD potential. It should at least include the nearest neighbor shell. For high temperatures or low angle grain boundaries, it might be beneficial to increase the cutoff in order to get a more precise identification of the atoms surrounding. However, computation time will increase as more atoms are considered in the order parameter and force computation. It is also worth noting that the cutoff radius must not exceed the communication distance for ghost atoms in LAMMPS. With orientationsFile, the 6 oriented crystal basis vectors is specified. Each line of the input file contains the three components of a primitive lattice vector oriented according to the grain orientation in the simulation box. The first (last) three lines correspond to the primitive lattice vectors of the first (second) grain. An example for a  $\Sigma(001)$  mis-orientation is given at the end.

If no synthetic energy difference between the grains is created,  $u0 = 0$ , the force computation is omitted. In this case, still, the order parameter of the driving force is computed and can be used to track the grain boundary motion throughout the simulation.

### 2.151.3 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy of atom interactions with the grain boundary driving force to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

This fix calculates a per-atom array with 2 columns, which can be accessed by indices 1-1 by any command that uses per-atom values from a fix as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The first column is the order parameter for each atom; the second is the thermal masking value for each atom. Both are described above.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 2.151.4 Restrictions

This fix is part of the ORIENT package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 2.151.5 Related commands

*fix\_modify*

*fix\_orient*

### 2.151.6 Default

## 2.152 fix pafi command

### 2.152.1 Syntax

```
fix ID group-ID pafi compute-ID Temp Tdamp seed keyword values...
```

- ID, group-ID are documented in *fix* command
- pafi = style name of this fix command
- compute-ID = ID of a *compute property/atom* that holds data used by this fix
- Temp = desired temperature (temperature units)
- Tdamp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- keyword = *overdamped* or *com*
  - overdamped* value = yes or no or 1 or 0
    - yes or 1 = Brownian (overdamped) integration in hyperplane
    - no or 0 = Langevin integration in hyperplane
  - com* value = yes or no or 1 or 0
    - yes or 1 = zero linear momentum, fixing center of mass (recommended)
    - no or 0 = do not zero linear momentum, allowing center of mass drift

### 2.152.2 Examples

```
compute pa all property/atom d_nx d_ny d_nz d_dnx d_dny d_dnz d_ddnx d_ddny d_ddnz
run 0 post no
fix hp all pafi pa 500.0 0.01 434 overdamped yes
```

### 2.152.3 Description

Perform Brownian or Langevin integration whilst constraining the system to lie in some hyperplane, which is expected to be the tangent plane to some reference pathway in a solid state system. The instantaneous value of a modified force projection is also calculated, whose time integral can be shown to be equal to the true free energy gradient along the minimum free energy path local to the reference pathway. A detailed discussion of the projection technique can be found in (*Swinburne*).

This fix can be used with LAMMPS as demonstrated in examples/PACKAGES/pafi, though it is primarily intended to be coupled with the PAFI C++ code, developed at <https://github.com/tomswinburne/pafi>, which distributes multiple LAMMPS workers in parallel to compute and collate hyperplane-constrained averages, allowing the calculation of free energy barriers and pathways.

A *compute property/atom* must be provided with 9 fields per atom coordinate, which in order are the x,y,z coordinates of a configuration on the reference path, the x,y,z coordinates of the path tangent (derivative of path position with path coordinate) and the x,y,z coordinates of the change in tangent (derivative of path tangent with path coordinate).

A 4-element vector is also calculated by this fix. The 4 components are the modified projected force, its square, the expected projection of the minimum free energy path tangent on the reference path tangent and the minimum image distance between the current configuration and the reference configuration, projected along the path tangent. This latter value should be essentially zero.

---

**Note:** When `com=yes/1`, which is recommended, the provided tangent vector must also have zero center of mass. This can be achieved by subtracting from each coordinate of the path tangent the average `x,y,z` value. The PAFI C++ code (see above) can generate these paths for use in LAMMPS.

---

---

**Note:** When `overdamped=yes/1`, the `Tdamp` parameter should be around 5-10 times smaller than that used in typical Langevin integration. See [fix langevin](#) for typical values.

---

## 2.152.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix produces a global vector each timestep which can be accessed by various *output commands*.

## 2.152.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 2.152.6 Default

The option defaults are `com = yes`, `overdamped = no`

# 2.153 fix pair command

## 2.153.1 Syntax

```
fix ID group-ID pair N pstyle name flag ...
```

- ID, group-ID are documented in *fix* command
- pair = style name of this fix command
- N = invoke this fix once every N timesteps
- pstyle = name of pair style to extract info from (e.g. eam)
- one or more name/flag pairs can be listed
- name = name of quantity the pair style allows extraction of
- flag = 1 if pair style needs to be triggered to produce data for name, 0 if not

## 2.153.2 Examples

```
fix request all pair 100 eam rho 0
fix request all pair 100 amoeba uind 0 uinp 0
```

## 2.153.3 Description

New in version 15Sep2022.

Extract per-atom quantities from a pair style and store them in this fix so they can be accessed by other LAMMPS commands, e.g. by a *dump* command or by another *fix*, *compute*, or *variable* command.

These are example use cases:

- extract per-atom density from *pair\_style eam* to a dump file
- extract induced dipoles from *pair\_style amoeba* to a dump file
- extract accuracy metrics from a machine-learned potential to trigger output when a condition is met (see the *dump\_modify skip* command)

The *N* argument determines how often the fix is invoked.

The *pstyle* argument is the name of the pair style. It can be a sub-style used in a *pair\_style hybrid* command. If there are multiple sub-styles using the same pair style, then *pstyle* should be specified as “style:N”, where *N* is the number of the instance of the pair style you wish monitor (e.g., the first or second). For example, *pstyle* could be specified as “pace/extrapolation” or “amoeba” or “eam:1” or “eam:2”.

One or more *name/flag* pairs of arguments follow. Each *name* is a per-atom quantity which the pair style must recognize as an extraction request. See the doc pages for individual *pair\_styles* to see what fix pair requests (if any) they support.

The *flag* setting determines whether this fix will also trigger the pair style to compute the named quantity so it can be extracted. If the quantity is always computed by the pair style, no trigger is needed; specify *flag* = 0. If the quantity is not always computed (e.g. because it is expensive to calculate), then specify *flag* = 1. This will trigger the quantity to be calculated only on timesteps it is needed. Again, see the doc pages for individual *pair\_styles* to determine which fix pair requests (if any) need to be triggered with a *flag* = 1 setting.

The per-atom data extracted from the pair style is stored by this fix as either a per-atom vector or array. If there is only one *name* argument specified and the pair style computes a single value for each atom, then this fix stores it as a per-atom vector. Otherwise a per-atom array is created, with its data in the order of the *name* arguments.

For example, *pair\_style amoeba* allows extraction of two named quantities: “uind” and “uinp”, both of which are 3-vectors for each atom, i.e. dipole moments. In the example below a 6-column per-atom array will be created. Columns 1-3 will store the “uind” values; columns 4-6 will store the “uinp” values.

```
pair_style amoeba
fix ex all pair 10 amoeba uind 0 uinp 0
```

## 2.153.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

As explained above, this fix produces a per-atom vector or array which can be accessed by various *output commands*. If an array is produced, the number of columns is the sum of the number of per-atom quantities produced by each *name* argument requested from the pair style.

## 2.153.5 Restrictions

none

# 2.154 fix phonon command

## 2.154.1 Syntax

```
fix ID group-ID phonon N Noutput Nwait map_file prefix keyword values ...
```

- ID, group-ID are documented in *fix* command
- phonon = style name of this fix command
- N = measure the Green's function every this many timesteps
- Noutput = output the dynamical matrix every this many measurements
- Nwait = wait this many timesteps before measuring
- map\_file = *file* or *GAMMA*

*file* is the file that contains the mapping info between atom ID and the lattice<sub>→</sub>indices.

*GAMMA* flags to treat the whole simulation box as a unit cell, so that the mapping info can be generated internally. In this case, dynamical matrix at only the<sub>→</sub>gamma-point will/can be evaluated.

- prefix = prefix for output files
- one or none keyword/value pairs may be appended
- keyword = *sysdim* or *nasr*

```
sysdim value = d
  d = dimension of the system, usually the same as the MD model dimension
nasr value = n
  n = number of iterations to enforce the acoustic sum rule
```

## 2.154.2 Examples

```
fix 1 all phonon 20 5000 2000000 map.in LJ1D sysdim 1
fix 1 all phonon 20 5000 2000000 map.in EAM3D
fix 1 all phonon 10 5000 5000000 GAMMA EAM0D nasr 100
```

## 2.154.3 Description

Calculate the dynamical matrix from molecular dynamics simulations based on fluctuation-dissipation theory for a group of atoms.

Consider a crystal with  $N$  unit cells in three dimensions labeled  $l = (l_1, l_2, l_3)$  where  $l_i$  are integers. Each unit cell is defined by three linearly independent vectors  $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$  forming a parallelepiped, containing  $K$  basis atoms labeled  $k$ .

Based on fluctuation-dissipation theory, the force constant coefficients of the system in reciprocal space are given by (*Campana*, *Kong*)

$$\mathbf{K}_{k\alpha,k'\beta}(\mathbf{q}) = k_B T \mathbf{G}_{k\alpha,k'\beta}^{-1}(\mathbf{q})$$

where  $\mathbf{G}$  is the Green's functions coefficients given by

$$\mathbf{G}_{k\alpha,k'\beta}(\mathbf{q}) = \langle \mathbf{u}_{k\alpha}(\mathbf{q}) \bullet \mathbf{u}_{k'\beta}^*(\mathbf{q}) \rangle$$

where  $\langle \dots \rangle$  denotes the ensemble average, and

$$\mathbf{u}_{k\alpha}(\mathbf{q}) = \sum_l \mathbf{u}_{lk\alpha} \exp(i\mathbf{q}\mathbf{r}_l)$$

is the  $\alpha$  component of the atomic displacement for the  $k$ th atom in the unit cell in reciprocal space at  $\mathbf{q}$ . In practice, the Green's functions coefficients can also be measured according to the following formula,

$$\mathbf{G}_{k\alpha,k'\beta}(\mathbf{q}) = \langle \mathbf{R}_{k\alpha}(\mathbf{q}) \bullet \mathbf{R}_{k'\beta}^*(\mathbf{q}) \rangle - \langle \mathbf{R} \rangle_{k\alpha}(\mathbf{q}) \bullet \langle \mathbf{R} \rangle_{k'\beta}^*(\mathbf{q})$$

where  $\mathbf{R}$  is the instantaneous positions of atoms, and  $\langle \mathbf{R} \rangle$  is the averaged atomic positions. It gives essentially the same results as the displacement method and is easier to implement in an MD code.

Once the force constant matrix is known, the dynamical matrix  $\mathbf{D}$  can then be obtained by

$$\mathbf{D}_{k\alpha,k'\beta}(\mathbf{q}) = (m_k m_{k'})^{-\frac{1}{2}} \mathbf{K}_{k\alpha,k'\beta}(\mathbf{q})$$

whose eigenvalues are exactly the phonon frequencies at  $\mathbf{q}$ .

This fix uses positions of atoms in the specified group and calculates two-point correlations. To achieve this, the positions of the atoms are examined every *Nevery* steps and are Fourier-transformed into reciprocal space, where the averaging process and correlation computation is then done. After every *Noutput* measurements, the matrix  $\mathbf{G}(\mathbf{q})$  is calculated and inverted to obtain the elastic stiffness coefficients. The dynamical matrices are then constructed and written to *prefix.bin.timestep* files in binary format and to the file *prefix.log* for each wave-vector  $\mathbf{q}$ .

A detailed description of this method can be found in (*Kong2011*).

The *sysdim* keyword is optional. If specified with a value smaller than the dimensionality of the LAMMPS simulation, its value is used for the dynamical matrix calculation. For example, using LAMMPS to model a 2D or 3D system, the phonon dispersion of a 1D atomic chain can be computed using *sysdim* = 1.

The *nasr* keyword is optional. An iterative procedure is employed to enforce the acoustic sum rule on  $\Phi$  at  $\Gamma$ , and the number provided by keyword *nasr* gives the total number of iterations. For a system whose unit cell has only one atom, *nasr* = 1 is sufficient; for other systems, *nasr* = 10 is typically sufficient.

The *map\_file* contains the mapping information between the lattice indices and the atom IDs, which tells the code which atom sits at which lattice point; the lattice indices start from 0. An auxiliary code, *latgen*, can be employed to generate the compatible map file for various crystals.

In case one simulates a non-periodic system, where the whole simulation box is treated as a unit cell, one can set *map\_file* as *GAMMA*, so that the mapping info will be generated internally and a file is not needed. In this case, the dynamical matrix at only the gamma-point will/can be evaluated. Please keep in mind that fix-phonon is designed for crystals, it will be inefficient and even degrade the performance of LAMMPS in case the unit cell is too large.

The calculated dynamical matrix elements are written out in *energy/distance<sup>2</sup>/mass* units. The coordinates for *q* points in the log file is in the units of the basis vectors of the corresponding reciprocal lattice.

#### 2.154.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify temp* option is supported by this fix. You can use it to change the temperature compute from thermo\_temp to the one that reflects the true temperature of atoms in the group.

No global scalar or vector or per-atom quantities are stored by this fix for access by various *output commands*.

Instead, this fix outputs its initialization information (including mapping information) and the calculated dynamical matrices to the file *prefix.log*, with the specified *prefix*. The dynamical matrices are also written to files *prefix.bin.timestep* in binary format. These can be read by the post-processing tool in tools/phonon to compute the phonon density of states and/or phonon dispersion curves.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

#### 2.154.5 Restrictions

This fix assumes a crystalline system with periodical lattice. The temperature of the system should not exceed the melting temperature to keep the system in its solid state.

This fix is part of the PHONON package. It is only enabled if LAMMPS was built with that package. This fix also requires LAMMPS to be built with 3d-FFT support which is included in the KSPACE package. See the *Build package* page for more info.

## 2.154.6 Related commands

*compute msd, dynamical\_matrix*

## 2.154.7 Default

The option defaults are sysdim = the same dimension as specified by the *dimension* command, and nasr = 20.

```

## 2.156.3 Description

Changed in version 28Mar2023.

Fix pimd was renamed to fix *pimd/nvt* and fix *pimd/langevin* was added.

These fix commands perform quantum molecular dynamics simulations based on the Feynman path-integral to include effects of tunneling and zero-point motion. In this formalism, the isomorphism of a quantum partition function for the original system to a classical partition function for a ring-polymer system is exploited, to efficiently sample configurations from the canonical ensemble (*Feynman*).

The classical partition function and its components are given by the following equations:

$$\begin{aligned}
 Z &= \int d\mathbf{q}d\mathbf{p} \cdot \exp[-\beta H_{eff}] \\
 H_{eff} &= \left( \sum_{i=1}^P \frac{p_i^2}{2M_i} \right) + V_{eff} \\
 V_{eff} &= \sum_{i=1}^P \left[ \frac{mP}{2\beta^2 \hbar^2} (q_i - q_{i+1})^2 + \frac{1}{P} V(q_i) \right]
 \end{aligned}$$

$M_i$  is the fictitious mass of the  $i$ -th mode, and  $m$  is the actual mass of the atoms.

The interested user is referred to any of the numerous references on this methodology, but briefly, each quantum particle in a path integral simulation is represented by a ring-polymer of  $P$  quasi-beads, labeled from 1 to  $P$ . During the simulation, each quasi-bead interacts with beads on the other ring-polymers with the same imaginary time index (the second term in the effective potential above). The quasi-beads also interact with the two neighboring quasi-beads through the spring potential in imaginary-time space (first term in effective potential). To sample the canonical ensemble, any thermostat can be applied.

Fix *pimd/nvt* applies a Nose-Hoover massive chain thermostat ([Tuckerman](#)). With the massive chain algorithm, a chain of NH thermostats is coupled to each degree of freedom for each quasi-bead. The keyword *temp* sets the target temperature for the system and the keyword *nhc* sets the number  $N_c$  of thermostats in each chain. For example, for a simulation of  $N$  particles with  $P$  beads in each ring-polymer, the total number of NH thermostats would be  $3 \times N \times P \times N_c$ .

Fix *pimd/langevin* implements a Langevin thermostat in the normal mode representation, and also provides a barostat to sample the NPH/NPT ensembles.

---

**Note:** Both these *fix* styles implement a complete velocity-verlet integrator combined with a thermostat, so no other time integration fix should be used.

---

The *method* keyword determines what style of PIMD is performed. A value of *pimd* is standard PIMD. A value of *nmpimd* is for normal-mode PIMD. A value of *cmd* is for centroid molecular dynamics (CMD). The difference between the styles is as follows.

In standard PIMD, the value used for a bead's fictitious mass is arbitrary. A common choice is to use  $M_i = m/P$ , which results in the mass of the entire ring-polymer being equal to the real quantum particle. But it can be difficult to efficiently integrate the equations of motion for the stiff harmonic interactions in the ring polymers.

A useful way to resolve this issue is to integrate the equations of motion in a normal mode representation, using Normal Mode Path-Integral Molecular Dynamics (NMPIMD) ([Cao1](#)). In NMPIMD, the NH chains are attached to each normal mode of the ring-polymer and the fictitious mass of each mode is chosen as  $M_k = \text{the eigenvalue of the } K\text{th normal mode for } k > 0$ . The  $k = 0$  mode, referred to as the zero-frequency mode or centroid, corresponds to overall translation of the ring-polymer and is assigned the mass of the real particle.

---

**Note:** Motion of the centroid can be effectively uncoupled from the other normal modes by scaling the fictitious masses to achieve a partial adiabatic separation. This is called a Centroid Molecular Dynamics (CMD) approximation ([Cao2](#)). The time-evolution (and resulting dynamics) of the quantum particles can be used to obtain centroid time correlation functions, which can be further used to obtain the true quantum correlation function for the original system. The CMD method also uses normal modes to evolve the system, except only the  $k > 0$  modes are thermostatted, not the centroid degrees of freedom.

---

New in version 21Nov2023: Mode *pimd* added to fix *pimd/langevin*.

Fix *pimd/langevin* supports the *method* values *nmpimd* and *pimd*. The default value is *nmpimd*. If *method* is *nmpimd*, the normal mode representation is used to integrate the equations of motion. The exact solution of harmonic oscillator is used to propagate the free ring polymer part of the Hamiltonian. If *method* is *pimd*, the Cartesian representation is used to integrate the equations of motion. The harmonic force is added to the total force of the system, and the numerical integrator is used to propagate the Hamiltonian.

The keyword *integrator* specifies the Trotter splitting method used by fix *pimd/langevin*. See ([Liu](#)) for a discussion on the OBABO and BAOAB splitting schemes. Typically either of the two should work fine.

The keyword *fmass* sets a further scaling factor for the fictitious masses of beads, which can be used for the Partial Adiabatic CMD ([Hone](#)), or to be set as  $P$ , which results in the fictitious masses to be equal to the real particle masses.

The keyword *fmmode* of fix *pimd/langevin* determines the mode of fictitious mass preconditioning. There are two options: *physical* and *normal*. If *fmmode* is *physical*, then the physical mass of the particles are used (and then multiplied by *fmass*). If *fmmode* is *normal*, then the physical mass is first multiplied by the eigenvalue of each normal mode, and then multiplied by *fmass*. More precisely, the fictitious mass of fix *pimd/langevin* is determined by two factors: *fmmode* and *fmass*. If *fmmode* is *physical*, then the fictitious mass is

$$M_i = \text{fmass} \times m$$

If *fmmode* is *normal*, then the fictitious mass is

$$M_i = \text{fmass} \times \lambda_i \times m$$

where  $\lambda_i$  is the eigenvalue of the  $i$ -th normal mode.

---

**Note:** Fictitious mass is only used in the momentum of the equation of motion ( $\mathbf{p}_i = M_i \mathbf{v}_i$ ), and not used in the spring elastic energy ( $\sum_{i=1}^P \frac{1}{2} m \omega_p^2 (q_i - q_{i+1})^2$ ,  $m$  is always the actual mass of the particles).

---

The keyword *sp* is a scaling factor on Planck's constant, which can be useful for debugging or other purposes. The default value of 1.0 is appropriate for most situations.

The keyword *ensemble* for fix style *pimd/langevin* determines which ensemble is it going to sample. The value can be *nve* (microcanonical), *nvt* (canonical), *nph* (isoenthalpic), and *npt* (isothermal-isobaric).

The keyword *temp* specifies temperature parameter for fix styles *pimd/nvt* and *pimd/langevin*. It should read a positive floating-point number.

---

**Note:** For *pimd* simulations, a temperature values should be specified even for *nve* ensemble. Temperature will make a difference for *nve pimd*, since the spring elastic frequency between the beads will be affected by the temperature.

---

The keyword *thermostat* reads *style* and *seed* of thermostat for fix style *pimd/langevin*. *style* can only be *PILE\_L* (path integral Langevin equation local thermostat, as described in [Cerioti](#)), and *seed* should a positive integer number, which serves as the seed of the pseudo random number generator.

---

**Note:** The fix style *pimd/langevin* uses the stochastic *PILE\_L* thermostat to control temperature. This thermostat works on the normal modes of the ring polymer. The *tau* parameter controls the centroid mode, and the *scale* parameter controls the non-centroid modes.

---

The keyword *tau* specifies the thermostat damping time parameter for fix style *pimd/langevin*. It is in time unit. It only works on the centroid mode.

The keyword *scale* specifies a scaling parameter for the damping times of the non-centroid modes for fix style *pimd/langevin*. The default damping time of the non-centroid mode  $i$  is  $\frac{P}{\beta \hbar} \sqrt{\lambda_i} \times \text{fmass}$  (*fmmode* is *physical*) or  $\frac{P}{\beta \hbar} \sqrt{\text{fmass}}$  (*fmmode* is *normal*). The damping times of all non-centroid modes are the default values divided by *scale*.

The barostat parameters for fix style *pimd/langevin* with *npt* or *nph* ensemble is specified using one of *iso* and *aniso* keywords. A *pressure* value should be given with pressure unit. The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. The keyword *aniso* means x, y, and z dimensions are controlled independently using the Pxx, Pyy, and Pzz components of the stress tensor as the driving forces, and the specified scalar external pressure.

The keyword *barostat* reads *style* of barostat for fix style *pimd/langevin*. *style* can be *BZP* (Bussi-Zykova-Parrinello, as described in [Bussi](#)) or *MTTK* (Martyna-Tuckerman-Tobias-Klein, as described in [Martyna1](#) and [Martyna2](#)).

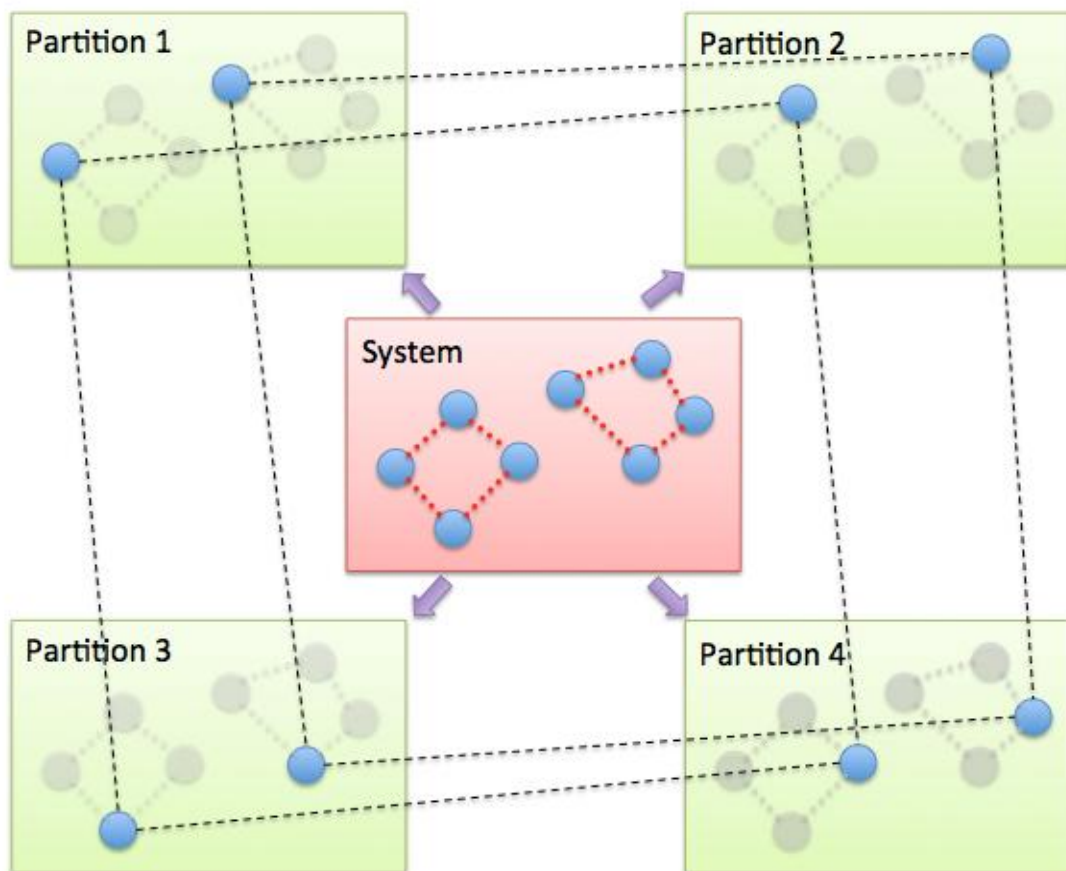

The keyword *taup* specifies the barostat damping time parameter for fix style *pimd/langevin*. It is in time unit.

The keyword *fixcom* specifies whether the center-of-mass of the extended ring-polymer system is fixed during the *pimd* simulation. Once *fixcom* is set to be *yes*, the center-of-mass velocity will be distracted from the centroid-mode velocities in each step.

The keyword *lj* should be used if *lj units* is used for fix *pimd/langevin*. Typically one may want to use reduced units to run the simulation, and then convert the results into some physical units (for example, [metal units](#)). In this case, the 5 quantities in the physical mass units are needed: epsilon (energy scale), sigma (length scale), mass, Planck's constant, mvv2e (mass \* velocity^2 to energy conversion factor). Planck's constant and mvv2e can be found in `src/update.cpp`.

If there is no need to convert reduced units to physical units, you can omit the keyword *lj* and these five values will be set to 1.

The PIMD algorithm in LAMMPS is implemented as a hyper-parallel scheme as described in [Calhoun](#). In LAMMPS this is done by using *multi-replica feature* in LAMMPS, where each quasi-particle system is stored and simulated on a separate partition of processors. The following diagram illustrates this approach. The original system with 2 ring polymers is shown in red. Since each ring has 4 quasi-beads (imaginary time slices), there are 4 replicas of the system, each running on one of the 4 partitions of processors. Each replica (shown in green) owns one quasi-bead in each ring.

To run a PIMD simulation with  $M$  quasi-beads in each ring polymer using  $N$  MPI tasks for each partition's domain-decomposition, you would use  $P = M \times N$  processors (cores) and run the simulation as follows:

```
mpirun -np P lmp_mpi -partition MxN -in script
```

Note that in the LAMMPS input script for a multi-partition simulation, it is often very useful to define a *uloop-style variable* such as

```
variable ibead uloop M pad
```

where  $M$  is the number of quasi-beads (partitions) used in the calculation. The uloop variable can then be used to manage I/O related tasks for each of the partitions, e.g.

```
dump dcd all dcd 10 system_${ibead}.dcd
dump 1 all custom 100 ${ibead}.xyz id type x y z vx vy vz ix iy iz fx fy fz
restart 1000 system_${ibead}.restart1 system_${ibead}.restart2
```

(continues on next page)

(continued from previous page)

```
read_restart system_${i bead}.restart2
```

**Note:** Fix *pimd/langevin* dumps the Cartesian coordinates, but dumps the velocities and forces in the normal mode representation. If the Cartesian velocities and forces are needed, it is easy to perform the transformation when doing post-processing.

It is recommended to dump the image flags (*ix iy iz*) for fix *pimd/langevin*. It will be useful if you want to calculate some estimators during post-processing.

Major differences of fix *pimd/nvt* and fix *pimd/langevin* are:

1. Fix *pimd/nvt* includes Cartesian *pimd*, normal mode *pimd*, and centroid *md*. Fix *pimd/langevin* only intends to support normal mode *pimd*, as it is commonly enough for thermodynamic sampling.
2. Fix *pimd/nvt* uses Nose-Hoover chain thermostat. Fix *pimd/langevin* uses Langevin thermostat.
3. Fix *pimd/langevin* provides barostat, so the *npt* ensemble can be sampled. Fix *pimd/nvt* only support *nvt* ensemble.
4. Fix *pimd/langevin* provides several quantum estimators in output.
5. Fix *pimd/langevin* allows multiple processes for each bead. For fix *pimd/nvt*, there is a large chance that multi-process tasks for each bead may fail.
6. The dump of fix *pimd/nvt* are all Cartesian. Fix *pimd/langevin* dumps normal-mode velocities and forces, and Cartesian coordinates.

Initially, the inter-replica communication and normal mode transformation parts of fix *pimd/langevin* are written based on those of fix *pimd/nvt*, but are significantly revised.

## 2.156.4 Restart, fix\_modify, output, run start/stop, minimize info

Fix *pimd/nvt* writes the state of the Nose/Hoover thermostat over all quasi-beads to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

Fix *pimd/langevin* writes the state of the barostat overall beads to *binary restart files*. Since it uses a stochastic thermostat, the state of the thermostat is not written. However, the state of the system can be restored by reading the restart file, except that it will re-initialize the random number generator.

None of the *fix\_modify* options are relevant to fix *pimd/nvt*.

Fix *pimd/nvt* computes a global 3-vector, which can be accessed by various *output commands*. The three quantities in the global vector are:

1. the total spring energy of the quasi-beads,
2. the current temperature of the classical system of ring polymers,
3. the current value of the scalar virial estimator for the kinetic energy of the quantum system (*Herman*).

The vector values calculated by fix *pimd/nvt* are “extensive”, except for the temperature, which is “intensive”.

Fix *pimd/langevin* computes a global vector of quantities, which can be accessed by various *output commands*. Note that it outputs multiple log files, and different log files contain information about different beads or modes (see detailed explanations below). If *ensemble* is *nve* or *nvt*, the vector has 10 values:

1. kinetic energy of the normal mode

2. spring elastic energy of the normal mode
3. potential energy of the bead
4. total energy of all beads (conserved if *ensemble* is *nve*)
5. primitive kinetic energy estimator
6. virial energy estimator
7. centroid-virial energy estimator
8. primitive pressure estimator
9. thermodynamic pressure estimator
10. centroid-virial pressure estimator

The first 3 are different for different log files, and the others are the same for different log files.

If *ensemble* is *nph* or *npt*, the vector stores internal variables of the barostat. If *iso* is used, the vector has 15 values:

1. kinetic energy of the normal mode
2. spring elastic energy of the normal mode
3. potential energy of the bead
4. total energy of all beads (conserved if *ensemble* is *nve*)
5. primitive kinetic energy estimator
6. virial energy estimator
7. centroid-virial energy estimator
8. primitive pressure estimator
9. thermodynamic pressure estimator
10. centroid-virial pressure estimator
11. barostat velocity
12. barostat kinetic energy
13. barostat potential energy
14. barostat cell Jacobian
15. enthalpy of the extended system (sum of 4, 12, 13, and 14; conserved if *ensemble* is *nph*)

If *aniso* or *x* or *y* or *z* is used for the barostat, the vector has 17 values:

1. kinetic energy of the normal mode
2. spring elastic energy of the normal mode
3. potential energy of the bead
4. total energy of all beads (conserved if *ensemble* is *nve*)
5. primitive kinetic energy estimator
6. virial energy estimator
7. centroid-virial energy estimator
8. primitive pressure estimator
9. thermodynamic pressure estimator

10. centroid-virial pressure estimator
11. x component of barostat velocity
12. y component of barostat velocity
13. z component of barostat velocity
14. barostat kinetic energy
15. barostat potential energy
16. barostat cell Jacobian
17. enthalpy of the extended system (sum of 4, 14, 15, and 16; conserved if *ensemble* is *nph*)

No parameter of `fix pimd/nvt` or `pimd/langevin` can be used with the *start/stop* keywords of the `run` command. `fix pimd/nvt` or `pimd/langevin` is not invoked during *energy minimization*.

## 2.156.5 Restrictions

These fixes are part of the REPLICA package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

`fix pimd/nvt` cannot be used with *lj units*. `fix pimd/langevin` can be used with *lj units*. See the above part for how to use it.

A PIMD simulation can be initialized with a single data file read via the `read_data` command. However, this means all quasi-beads in a ring polymer will have identical positions and velocities, resulting in identical trajectories for all quasi-beads. To avoid this, users can simply initialize velocities with different random number seeds assigned to each partition, as defined by the `uloop` variable, e.g.

```
velocity all create 300.0 1234${ibead} rot yes dist gaussian
```

## 2.156.6 Default

The keyword defaults for `fix pimd/nvt` are `method = pimd`, `fmass = 1.0`, `sp = 1.0`, `temp = 300.0`, and `nhc = 2`.

## 2.157 fix plane force command

### 2.157.1 Syntax

```
fix ID group-ID plane force x y z
```

- ID, group-ID are documented in *fix* command
- plane force = style name of this fix command
- x y z = 3-vector that is normal to the plane

### 2.157.2 Examples

```
fix hold boundary plane force 1.0 0.0 0.0
```

### 2.157.3 Description

Adjust the forces on each atom in the group so that only the components of force in the plane specified by the normal vector (x,y,z) remain. This is done by subtracting out the component of force perpendicular to the plane.

If the initial velocity of the atom is 0.0 (or in the plane), then it should continue to move in the plane thereafter.

### 2.157.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

### 2.157.5 Restrictions

none

### 2.157.6 Related commands

*fix line force*

### 2.157.7 Default

none

## 2.158 fix plumed command

### 2.158.1 Syntax

```
fix ID group-ID plumed keyword value ...
```

- ID, group-ID are documented in *fix* command
- plumed = style name of this fix command
- keyword = *plumedfile* or *outfile*

*plumedfile* arg = name of PLUMED input file to use (default: NULL)

*outfile* arg = name of file on which to write the PLUMED log (default: NULL)

### 2.158.2 Examples

```
fix pl all plumed plumedfile plumed.dat outfile p.log
```

### 2.158.3 Description

This fix instructs LAMMPS to call the **PLUMED** library, which allows one to perform various forms of trajectory analysis on the fly and to also use methods such as umbrella sampling and metadynamics to enhance the sampling of phase space.

The documentation included here only describes the fix plumed command itself. This command is LAMMPS specific, whereas most of the functionality implemented in PLUMED will work with a range of MD codes, and when PLUMED is used as a stand alone code for analysis. The full [documentation for PLUMED](#) is available online and included in the PLUMED source code. The PLUMED library development is hosted at <https://github.com/plumed/plumed2> A detailed discussion of the code can be found in (*Tribello*).

There is an example input for using this package with LAMMPS in the examples/PACKAGES/plumed directory.

The command to make LAMMPS call PLUMED during a run requires two keyword value pairs pointing to the PLUMED input file and an output file for the PLUMED log. The user must specify these arguments every time PLUMED is to be used. Furthermore, the fix plumed command should appear in the LAMMPS input file **after** relevant input parameters (e.g. the timestep) have been set.

The *group-ID* entry is ignored. LAMMPS will always pass all the atoms to PLUMED and there can only be one instance of the plumed fix at a time. The way the plumed fix is implemented ensures that the minimum amount of information required is communicated. Furthermore, PLUMED supports multiple, completely independent collective variables, multiple independent biases and multiple independent forms of analysis. There is thus really no restriction in functionality by only allowing only one plumed fix in the LAMMPS input.

The *plumedfile* keyword allows the user to specify the name of the PLUMED input file. Instructions as to what should be included in a plumed input file can be found in the [documentation for PLUMED](#)

The *outfile* keyword allows the user to specify the name of a file in which to output the PLUMED log. This log file normally just repeats the information that is contained in the input file to confirm it was correctly read and parsed. The names of the files in which the results are stored from the various analysis options performed by PLUMED will be specified by the user in the PLUMED input file.

## 2.158.4 Restart, fix\_modify, output, run start/stop, minimize info

When performing a restart of a calculation that involves PLUMED you must include a RESTART command in the PLUMED input file as detailed in the [PLUMED documentation](#). When the restart command is found in the PLUMED input PLUMED will append to the files that were generated in the run that was performed previously. No part of the PLUMED restart data is included in the LAMMPS restart files. Furthermore, any history dependent bias potentials that were accumulated in previous calculations will be read in when the RESTART command is included in the PLUMED input.

The *fix\_modify energy* option is supported by this fix to add the energy change from the biasing force added by PLUMED to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy yes*.

The *fix\_modify virial* option is supported by this fix to add the contribution from the biasing force to the global pressure of the system via the *compute pressure* command. This can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the PLUMED energy mentioned above. The scalar value calculated by this fix is “extensive”.

Note that other quantities of interest can be output by commands that are native to PLUMED.

## 2.158.5 Restrictions

This fix is part of the PLUMED package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

There can only be one fix plumed command active at a time.

## 2.158.6 Related commands

*fix smd fix colvars*

## 2.158.7 Default

The default options are plumedfile = NULL and outfile = NULL

## 2.159 fix poems command

### 2.159.1 Syntax

**fix** ID group-ID poems keyword values

- ID, group-ID are documented in *fix* command
- poems = style name of this fix command
- keyword = *group* or *file* or *molecule*

```

group values = list of group IDs
molecule values = none
file values = filename

```

## 2.159.2 Examples

```

fix 3 fluid poems group clump1 clump2 clump3
fix 3 fluid poems file cluster.list

```

## 2.159.3 Description

Treats one or more sets of atoms as coupled rigid bodies. This means that each timestep the total force and torque on each rigid body is computed and the coordinates and velocities of the atoms are updated so that the collection of bodies move as a coupled set. This can be useful for treating a large biomolecule as a collection of connected, coarse-grained particles.

The coupling, associated motion constraints, and time integration is performed by the software package *Parallelizable Open source Efficient Multibody Software (POEMS)* which computes the constrained rigid-body motion of articulated (jointed) multibody systems ([Anderson](#)). POEMS was written and is distributed by Prof Kurt Anderson, his graduate student Rudranarayan Mukherjee, and other members of his group at Rensselaer Polytechnic Institute (RPI). Rudranarayan developed the LAMMPS/POEMS interface. For copyright information on POEMS and other details, please refer to the documents in the poems directory distributed with LAMMPS.

This fix updates the positions and velocities of the rigid atoms with a constant-energy time integration, so you should not update the same atoms via other fixes (e.g. nve, nvt, npt, temp/rescale, langevin).

Each body must have a non-degenerate inertia tensor, which means it must contain at least 3 non-collinear atoms. Which atoms are in which bodies can be defined via several options.

For option *group*, each of the listed groups is treated as a rigid body. Note that only atoms that are also in the fix group are included in each rigid body.

For option *molecule*, each set of atoms in the group with a different molecule ID is treated as a rigid body.

For option *file*, sets of atoms are read from the specified file and each set is treated as a rigid body. Each line of the file specifies a rigid body in the following format:

```
ID type atom1-ID atom2-ID atom3-ID ...
```

ID as an integer from 1 to M (the number of rigid bodies). Type is any integer; it is not used by the fix poems command. The remaining arguments are IDs of atoms in the rigid body, each typically from 1 to N (the number of atoms in the system). Only atoms that are also in the fix group are included in each rigid body. Blank lines and lines that begin with '#' are skipped.

A connection between a pair of rigid bodies is inferred if one atom is common to both bodies. The POEMS solver treats that atom as a spherical joint with 3 degrees of freedom. Currently, a collection of bodies can only be connected by joints as a linear chain. The entire collection of rigid bodies can represent one or more chains. Other connection topologies (tree, ring) are not allowed, but will be added later. Note that if no joints exist, it is more efficient to use the *fix rigid* command to simulate the system.

When the poems fix is defined, it will print out statistics on the total # of clusters, bodies, joints, atoms involved. A cluster in this context means a set of rigid bodies connected by joints.

For computational efficiency, you should turn off pairwise and bond interactions within each rigid body, as they no longer contribute to the motion. The "neigh\_modify exclude" and "delete\_bonds" commands can be used to do this if each rigid body is a group.

For computational efficiency, you should only define one fix poems which includes all the desired rigid bodies. LAMMPS will allow multiple poems fixes to be defined, but it is more expensive.

The degrees-of-freedom removed by coupled rigid bodies are accounted for in temperature and pressure computations. Similarly, the rigid body contribution to the pressure virial is also accounted for. The latter is only correct if forces within the bodies have been turned off, and there is only a single fix poems defined.

## 2.159.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the added forces and torques on atoms to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*.

The *fix\_modify bodyforces* option is supported by this fix style to set whether per-body forces and torques are computed early or late in a timestep, i.e. at the post-force stage or at the final-integrate stage, respectively.

No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.159.5 Restrictions

This fix is part of the *POEMS* package. It is only enabled if LAMMPS was built with that package, which also requires the POEMS library be built and linked with LAMMPS. See the *Build package* page for more info.

## 2.159.6 Related commands

*fix rigid*, *delete\_bonds*, *neigh\_modify* exclude

## 2.159.7 Default

none

## 2.160 fix polarize/bem/gmres command

## 2.161 fix polarize/bem/icc command

## 2.162 fix polarize/functional command

### 2.162.1 Syntax

```
fix ID group-ID style nevery tolerance
```

- ID, group-ID are documented in *fix* command
- style = *polarize/bem/gmres* or *polarize/bem/icc* or *polarize/functional*
- nevery = this fixed is invoked every this many timesteps
- tolerance = the relative tolerance for the iterative solver to stop

## 2.162.2 Examples

```
fix 2 interface polarize/bem/gmres 5 0.0001
fix 1 interface polarize/bem/icc 1 0.0001
fix 3 interface polarize/functional 1 0.0001
```

Used in input scripts:

```
examples/PACKAGES/dielectric/in.confined
examples/PACKAGES/dielectric/in.nopbc
```

## 2.162.3 Description

These fixes compute induced charges at the interface between two impermeable media with different dielectric constants. The interfaces need to be discretized into vertices, each representing a boundary element. The vertices are treated as if they were regular atoms or particles. *atom\_style dielectric* should be used since it defines the additional properties of each interface particle such as interface normal vectors, element areas, and local dielectric mismatch. These fixes also require the use of *pair\_style* and *kpace\_style* with the *dielectric* suffix. At every time step, given a configuration of the physical charges in the system (such as atoms and charged particles) these fixes compute and update the charge of the interface particles. The interfaces are allowed to move during the simulation if the appropriate time integrators are also set (for example, with *fix\_rigid*).

Consider an interface between two media: one with dielectric constant of 78 (water), the other of 4 (silica). The interface is discretized into 2000 boundary elements, each represented by an interface particle. Suppose that each interface particle has a normal unit vector pointing from the silica medium to water. The dielectric difference along the normal vector is then  $78 - 4 = 74$ , the mean dielectric value is  $(78 + 4) / 2 = 41$ . Each boundary element also has its area and the local mean curvature, which is used by these fixes for computing a correction term in the local electric field. To model charged interfaces, an interface particle will have a non-zero charge value, coming from its area and surface charge density, and its local dielectric constant set to the mean dielectric value.

For non-interface particles such as atoms and charged particles, the interface normal vectors, element area, and dielectric mismatch are irrelevant and unused. Their local dielectric value is used internally to rescale their given charge when computing the Coulombic interactions. For instance, to simulate a cation carrying a charge of +2 (in simulation charge units) in an implicit solvent with a dielectric constant of 40, the cation's charge should be set to +2 and its local dielectric constant property (defined in the *atom\_style dielectric*) should be set to 40; there is no need to manually rescale charge. This will produce the proper force for any *pair\_style* with the *dielectric* suffix. It is assumed that the particles cannot pass through the interface during the simulation because the value of the local dielectric constant property does not change.

There are some example scripts for using these fixes with LAMMPS in the `examples/PACKAGES/dielectric` directory. The README file therein contains specific details on the system setup. Note that the example data files show the additional fields (columns) needed for *atom\_style dielectric* beyond the conventional fields *id*, *mol*, *type*, *q*, *x*, *y*, and *z*.

For fix *polarize/bem/gmres* and fix *polarize/bem/icc* the induced charges of the atoms in the specified group, which are the vertices on the interface, are computed using the equation:

$$\sigma_b(\mathbf{s}) = \frac{1 - \bar{\epsilon}}{\bar{\epsilon}} \sigma_f(\mathbf{s}) - \epsilon_0 \frac{\Delta\epsilon}{\bar{\epsilon}} \mathbf{E}(\mathbf{s}) \cdot \mathbf{n}(\mathbf{s})$$

- $\sigma_b$  is the induced charge density at the interface vertex  $\mathbf{s}$ .
- $\bar{\epsilon}$  is the mean dielectric constant at the interface vertex:  $\bar{\epsilon} = (\epsilon_1 + \epsilon_2)/2$ .
- $\Delta\epsilon$  is the dielectric constant difference at the interface vertex:  $\Delta\epsilon = \epsilon_1 - \epsilon_2$
- $\sigma_f$  is the free charge density at the interface vertex
- $\mathbf{E}(\mathbf{s})$  is the electrical field at the vertex
- $\mathbf{n}(\mathbf{s})$  is the unit normal vector at the vertex pointing from medium with  $\epsilon_2$  to that with  $\epsilon_1$

Fix *polarize/bem/gmres* employs the Generalized Minimum Residual (GMRES) as described in ([Barros](#)) to solve  $\sigma_b$ .

Fix *polarize/bem/icc* employs the successive over-relaxation algorithm as described in ([Tyagi](#)) to solve  $\sigma_b$ .

The iterative solvers would terminate either when the maximum relative change in the induced charges in consecutive iterations is below the set tolerance, or when the number of iterations reaches *iter\_max* (see below).

Fix *polarize/functional* employs the energy functional variation approach as described in ([Jadhao](#)) to solve  $\sigma_b$ .

The induced charges computed by these fixes are stored in the *q\_scaled* field, and can be accessed as in the following example:

```
compute qs all property/atom q_scaled
dump 1 all custom 1000 all.txt id type q x y z c_qs
```

Note that the *q* field is the regular atom charges, which do not change during the simulation. For interface particles, *q\_scaled* is the sum of the real charge, divided by the local dielectric constant *epsilon*, and their induced charges. For non-interface particles, *q\_scaled* is the real charge, divided by the local dielectric constant *epsilon*.

More details on the implementation of these fixes and their recommended use are described in ([NguyenTD](#)).

## 2.162.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify* command provides the ability to modify certain settings:

```
itr_max arg
  arg = maximum number of iterations for convergence
dielectrics ediff emean epsilon area charge
  ediff = dielectric difference or NULL
  emean = dielectric mean or NULL
  epsilon = local dielectric value or NULL
  area = element area or NULL
  charge = real interface charge or NULL
kspace arg = yes or no
rand max seed
  max = range of random induced charges to be generated
  seed = random number seed to use when generating random charge
mr arg
  arg = maximum number of q-vectors to use when solving (GMRES only)
omega arg
  arg = relaxation parameter to use when iterating (ICC only)
```

The *itr\_max* keyword sets the max number of iterations to be used for solving each step.

The *dielectrics* keyword allows properties of the atoms in group *group-ID* to be modified. Values passed to any of the arguments (*ediff*, *emean*, *epsilon*, *area*, *charge*) will override existing values for all atoms in the group *group-ID*. Passing NULL to any of these arguments will preserve the existing value. Note that setting the properties of the interface this way will change the properties of all atoms associated with the fix (all atoms in *group-ID*), so multiple fix and fix\_modify commands would be needed to change the properties of two different interfaces to different values (one fix and fix\_modify for each interface group).

The *kpace* keyword turns on long range interactions.

If the arguments of the *rand* keyword are set, then the atoms subject to this fix will be assigned a random initial charge in a uniform distribution from  $-max/2$  to  $max/2$ , using random number seed *seed*.

The *mr* keyword only applies to *style = polarize/bem/gmres*. It is the maximum number of q-vectors to use when solving for the surface charge.

The *omega* keyword only applies when using *style = polarize/bem/icc*. It is a relaxation parameter defined in (Tyagi) that should generally be set between 0 and 2.

Note that the local dielectric constant (epsilon) can also be set independently using the *set* command.

---

*polarize/bem/gmres* or *polarize/bem/icc* compute a global 2-element vector which can be accessed by various *output commands*. The first element is the number of iterations when the solver terminates (of which the upper bound is set by *itr\_max*). The second element is the RMS error.

## 2.162.5 Restrictions

These fixes are part of the DIELECTRIC package. They are only enabled if LAMMPS was built with that package, which requires that also the KSPACE package is installed. See the *Build package* page for more info.

Note that the *polarize/bem/gmres* and *polarize/bem/icc* fixes only support *units lj, real, metal, si* and *nano* at the moment.

Note that *polarize/functional* does not yet support charged interfaces.

## 2.162.6 Related commands

*pair\_coeff*, *fix polarize*, *read\_data*, *pair\_style lj/cut/coul/long/dielectric*, *kpace\_style pppm/dielectric*, *compute efield/atom*

## 2.162.7 Default

*itr\_max* = 50

*kpace* = yes

*omega* = 0.7 (ICC only)

*mr* = # atoms in group *group-ID* minus 1 (GMRES only)

No random charge initialization happens by default.

```

## 2.163.3 Description

Insert finite-size particles or molecules into the simulation box every few timesteps within a specified region until N particles or molecules have been inserted. This is typically used to model the pouring of granular particles into a container under the influence of gravity. For the remainder of this doc page, a single inserted atom or molecule is referred to as a “particle”.

If inserted particles are individual atoms, they are assigned the specified atom type. If they are molecules, the type of each atom in the inserted molecule is specified in the file read by the *molecule* command, and those values are added to the specified atom type. E.g. if the file specifies atom types 1,2,3, and those are the atom types you want for inserted molecules, then specify *type* = 0. If you specify *type* = 2, the in the inserted molecule will have atom types 3,4,5.

All atoms in the inserted particle are assigned to two groups: the default group “all” and the group specified in the fix pour command (which can also be “all”).

This command must use the *region* keyword to define an insertion volume. The specified region must have been previously defined with a *region* command. It must be of type *block* or a z-axis *cylinder* and must be defined with side = *in*. The cylinder style of region can only be used with 3d simulations.

Individual atoms are inserted, unless the *mol* keyword is used. It specifies a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. The coordinates, atom types, center-of-mass, moments of inertia, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

If the molecule template contains more than one molecule, the relative probability of depositing each molecule can be specified by the *molfrac* keyword. N relative probabilities, each from 0.0 to 1.0, are specified, where N is the number of molecules in the template. Each time a molecule is inserted, a random number is used to sample from the list of relative probabilities. The N values must sum to 1.0.

If you wish to insert molecules via the *mol* keyword, that will be treated as rigid bodies, use the *rigid* keyword, specifying as its value the ID of a separate *fix rigid/small* command which also appears in your input script.

---

**Note:** If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via *fix rigid/small/nvt* or *fix rigid/small/npt*, then you need to use the *fix\_modify dynamic/dof yes* command for the rigid fix. This is to inform that fix that the molecule count will vary dynamically.

---

If you wish to insert molecules via the *mol* keyword, that will have their bonds or angles constrained via SHAKE, use the *shake* keyword, specifying as its value the ID of a separate *fix shake* command which also appears in your input script.

Each timestep particles are inserted, they are placed randomly inside the insertion volume so as to mimic a stream of poured particles. If they are molecules they are also oriented randomly. Each atom in the particle is tested for overlaps with existing particles, including effects due to periodic boundary conditions if applicable. If an overlap is detected, another random insertion attempt is made; see the *vol* keyword discussion below. The larger the volume of the insertion region, the more particles that can be inserted at any one timestep. Particles are inserted again after enough time has elapsed that the previously inserted particles fall out of the insertion volume under the influence of gravity. Insertions continue every so many timesteps until the desired # of particles has been inserted.

---

**Note:** If you are monitoring the temperature of a system where the particle count is changing due to adding particles, you typically should use the *compute\_modify dynamic/dof yes* command for the temperature compute you are using.

---

All other keywords are optional with defaults as shown below.

The *diam* option is only used when inserting atoms and specifies the diameters of inserted particles. There are 3 styles: *one*, *range*, or *poly*. For *one*, all particles will have diameter *D*. For *range*, the diameter of each particle will be chosen randomly and uniformly between the specified *Dlo* and *Dhi* bounds. For *poly*, a series of *Npoly* diameters is specified. For each diameter a percentage value from 0.0 to 1.0 is also specified. The *Npoly* percentages must sum to 1.0. For the example shown above with “*diam 2 0.7 0.4 1.5 0.6*”, all inserted particles will have a diameter of 0.7 or 1.5. 40% of the particles will be small; 60% will be large.

Note that for molecule insertion, the diameters of individual atoms in the molecule can be specified in the file read by the *molecule* command. If not specified, the diameter of each atom in the molecule has a default diameter of 1.0.

The *id* option has two settings which are used to determine the atom or molecule IDs to assign to inserted particles/molecules. In both cases a check is done of the current system to find the maximum current atom and molecule ID of any existing particle. Newly inserted particles and molecules are assigned IDs that increment those max values. For the *max* setting, which is the default, this check is done at every insertion step, which allows for particles to leave the system, and their IDs to potentially be re-used. For the *next* setting this check is done only once when the fix is specified, which can be more efficient if you are sure particles will not be added in some other way.

The *vol* option specifies what volume fraction of the insertion volume will be filled with particles. For particles with a size specified by the *diam range* keyword, they are assumed to all be of maximum diameter *Dhi* for purposes of computing their contribution to the volume fraction.

The higher the volume fraction value, the more particles are inserted each timestep. Since inserted particles cannot overlap, the maximum volume fraction should be no higher than about 0.6. Each timestep particles are inserted, LAMMPS will make up to a total of *M* tries to insert the new particles without overlaps, where *M* = # of inserted particles \* *Nattempt*. If LAMMPS is unsuccessful at completing all insertions, it prints a warning.

The *dens* and *vel* options enable inserted particles to have a range of densities or xy velocities. The specific values for a particular inserted particle will be chosen randomly and uniformly between the specified bounds. Internally, the density value for a particle is converted to a mass, based on the radius (volume) of the particle. The *vz* or *vy* value for option *vel* assigns a z-velocity (3d) or y-velocity (2d) to each inserted particle.

The *rate* option moves the insertion volume in the z direction (3d) or y direction (2d). This enables pouring particles from a successively higher height over time.

The *ignore* option is useful when running a simulation that used line segment (2d) or triangle (3d) particles, typically to define boundaries for spherical granular particles to interact with. See the *atom\_style line or tri* command for details. Lines and triangles store their size, and if the size is large it may overlap (in a spherical sense) with the insertion region, even if the line/triangle is oriented such that there is no actual overlap. This can prevent particles from being inserted.

The *ignore* keyword causes the overlap check to skip any line or triangle particles. Obviously you should only use it if there is in fact no overlap of the line or triangle particles with the insertion region.

## 2.163.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. This means you must be careful when restarting a pouring simulation, when the restart file was written in the middle of the pouring operation. Specifically, you should use a new fix pour command in the input script for the restarted simulation that continues the operation. You will need to adjust the arguments of the original fix pour command to do this.

Also note that because the state of the random number generator is not saved in restart files, you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior if you adjust the fix pour parameters appropriately.

None of the *fix\_modify* options are relevant to this fix. This fix computes a global scalar, which can be accessed by various output commands. The scalar is the cumulative number of insertions. The scalar value calculated by this fix is “intensive”. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.163.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

For 3d simulations, a gravity fix in the -z direction must be defined for use in conjunction with this fix. For 2d simulations, gravity must be defined in the -y direction.

The specified insertion region cannot be a “dynamic” region, as defined by the *region* command.

## 2.163.6 Related commands

*fix deposit*, *fix gravity*, *region*

## 2.163.7 Default

Insertions are performed for individual particles, i.e. no *mol* setting is defined. If the *mol* keyword is used, the default for *molfrac* is an equal probabilities for all molecules in the template. Additional option defaults are diam = one 1.0, dens = 1.0 1.0, vol = 0.25 50, rate = 0.0, vel = 0.0 0.0 0.0 0.0 0.0 (for 3d), vel = 0.0 0.0 0.0 (for 2d), and id = max.

# 2.164 fix precession/spin command

## 2.164.1 Syntax

```
fix ID group precession/spin style args
```

- ID, group are documented in *fix* command
- precession/spin = style name of this fix command
- style = *zeeman* or *anisotropy* or *cubic* or *stt*

```

zeeman args = H x y z
  H = intensity of the magnetic field (in Tesla)
  x y z = vector direction of the field
anisotropy args = K x y z
  K = intensity of the magnetic anisotropy (in eV)
  x y z = vector direction of the anisotropy
cubic args = K1 K2c nlx nly nlx n2x n2y n2z n3x n3y n3z
  K1 and K2c = intensity of the magnetic anisotropy (in eV)
  nlx to n3z = three direction vectors of the cubic anisotropy
stt args = J x y z
  J = intensity of the spin-transfer torque field
  x y z = vector direction of the field

```

## 2.164.2 Examples

```

fix 1 all precession/spin zeeman 0.1 0.0 0.0 1.0 anisotropy 0.001 0.0 0.0 1.0

```

## 2.164.3 Description

This fix applies a precession torque to each magnetic spin in the group.

Style *zeeman* is used for the simulation of the interaction between the magnetic spins in the defined group and an external magnetic field:

$$H_{Zeeman} = -g \sum_{i=0}^N \mu_i \vec{s}_i \cdot \vec{B}_{ext}$$

with:

- $\vec{B}_{ext}$  the external magnetic field (in T)
- $g$  the Lande factor (hard-coded as  $g = 2.0$ )
- $\vec{s}_i$  the unitary vector describing the orientation of spin  $i$
- $\mu_i$  the atomic moment of spin  $i$  given as a multiple of the Bohr magneton  $\mu_B$  (for example,  $\mu_i \approx 2.2$  in bulk iron).

The field value in Tesla is multiplied by the gyromagnetic ratio,  $g \cdot \mu_B / \hbar$ , converting it into a precession frequency in rad.THz (in metal units and with  $\mu_B = 5.788 \cdot 10^{-5}$  eV/T).

As a comparison, the figure below displays the simulation of a single spin (of norm  $\mu_i = 1.0$ ) submitted to an external magnetic field of  $|B_{ext}| = 10.0$  Tesla (and oriented along the z axis). The upper plot shows the average magnetization along the external magnetic field axis and the lower plot the Zeeman energy, both as a function of temperature. The reference result is provided by the plot of the Langevin function for the same parameters.

The temperature effects are accounted for by connecting the spin  $i$  to a thermal bath using a Langevin thermostat (see [fix langevin/spin](#) for the definition of this thermostat).

Style *anisotropy* is used to simulate an easy axis or an easy plane for the magnetic spins in the defined group:

$$H_{aniso} = - \sum_{i=1}^N K_{an}(\mathbf{r}_i) (\vec{s}_i \cdot \vec{n}_i)^2$$

with  $n$  defining the direction of the anisotropy, and  $K$  (in eV) its intensity. If  $K > 0$ , an easy axis is defined, and if  $K < 0$ , an easy plane is defined.

Style *cubic* is used to simulate a cubic anisotropy, with three possible easy axis for the magnetic spins in the defined group:

$$H_{cubic} = - \sum_{i=1}^N K_1 \left[ (\vec{s}_i \cdot \vec{n}_1)^2 (\vec{s}_i \cdot \vec{n}_2)^2 + (\vec{s}_i \cdot \vec{n}_2)^2 (\vec{s}_i \cdot \vec{n}_3)^2 + (\vec{s}_i \cdot \vec{n}_1)^2 (\vec{s}_i \cdot \vec{n}_3)^2 \right] + K_2^{(c)} (\vec{s}_i \cdot \vec{n}_1)^2 (\vec{s}_i \cdot \vec{n}_2)^2 (\vec{s}_i \cdot \vec{n}_3)^2$$

with  $K_1$  and  $K_{2c}$  (in eV) the intensity coefficients and  $\vec{n}_1$ ,  $\vec{n}_2$  and  $\vec{n}_3$  defining the three anisotropic directions defined by the command (from  $n1x$  to  $n3z$ ). For  $\vec{n}_1 = (100)$ ,  $\vec{n}_2 = (010)$ , and  $\vec{n}_3 = (001)$ ,  $K_1 < 0$  defines an iron type anisotropy (easy axis along the (001)-type cube edges), and  $K_1 > 0$  defines a nickel type anisotropy (easy axis along the (111)-type cube diagonals).  $K_2^{(c)} > 0$  also defines easy axis along the (111)-type cube diagonals. See chapter 2 of ([Skomski](#)) for more details on cubic anisotropies.

Style *stt* is used to simulate the interaction between the spins and a spin-transfer torque. See equation (7) of ([Chirac](#)) for more details about the implemented spin-transfer torque term.

In all cases, the choice of ( $xyz$ ) only imposes the vector directions for the forces. Only the direction of the vector is important; its length is ignored (the entered vectors are normalized).

Those styles can be combined within one single command line.

---

**Note:** The norm of all vectors defined with the precession/spin command have to be non-zero. For example, defining “fix 1 all precession/spin zeeman 0.1 0.0 0.0 0.0” would result in an error message. Since those vector components are used to compute the inverse of the field (or anisotropy) vector norm, setting a zero-vector would result in a division by zero.

---

## 2.164.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the energy associated with the spin precession torque to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the potential energy (in energy units) discussed in the previous paragraph. The scalar value is an “extensive” quantity.

No information about this fix is written to *binary restart files*.

## 2.164.5 Restrictions

The *precession/spin* style is part of the SPIN package. This style is only enabled if LAMMPS was built with this package, and if the atom\_style “spin” was declared. See the *Build package* page for more info.

## 2.164.6 Related commands

*atom\_style spin*

## 2.164.7 Default

none

## 2.165 fix press/berendsen command

### 2.165.1 Syntax

**fix** ID group-ID press/berendsen keyword value ...

- ID, group-ID are documented in *fix* command
- press/berendsen = style name of this fix command

one or more keyword value pairs may be appended  
 keyword = *iso* or *aniso* or *x* or *y* or *z* or *couple* or *dilate* or *modulus*  
*iso* or *aniso* values = *Pstart Pstop Pdamp*  
*Pstart,Pstop* = scalar external pressure at start/end of run (pressure units)  
*Pdamp* = pressure damping parameter (time units)  
*x* or *y* or *z* values = *Pstart Pstop Pdamp*  
*Pstart,Pstop* = external stress tensor component at start/end of run (pressure\_→units)  
*Pdamp* = stress damping parameter (time units)  
*couple* = *none* or *xyz* or *xy* or *yz* or *xz*  
*modulus* value = bulk modulus of system (pressure units)  
*dilate* value = *all* or *partial*

## 2.165.2 Examples

```
fix 1 all press/berendsen iso 0.0 0.0 1000.0
fix 2 all press/berendsen aniso 0.0 0.0 1000.0 dilate partial
```

## 2.165.3 Description

Reset the pressure of the system by using a Berendsen barostat ([Berendsen](#)), which rescales the system volume and (optionally) the atoms coordinates within the simulation box every timestep.

Regardless of what atoms are in the fix group, a global pressure is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the atoms in the fix group are re-scaled. The latter can be useful for leaving the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

---

**Note:** Unlike the [fix npt](#) or [fix npb](#) commands which perform Nose/Hoover barostatting AND time integration, this fix does NOT perform time integration. It only modifies the box size and atom coordinates to effect barostatting. Thus you must use a separate time integration fix, like [fix nve](#) or [fix nvt](#) to actually update the positions and velocities of atoms. This fix can be used in conjunction with thermostating fixes to control the temperature, such as [fix nvt](#) or [fix langevin](#) or [fix temp/berendsen](#).

---

See the [Howto barostat](#) page for a discussion of different ways to perform barostatting.

---

The barostat is specified using one or more of the *iso*, *aniso*, *x*, *y*, *z*, and *couple* keywords. These keywords give you the ability to specify the 3 diagonal components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation. Unlike the [fix npt](#) and [fix npb](#) commands, this fix cannot be used with triclinic (non-orthogonal) simulation boxes to control all 6 components of the general pressure tensor.

The target pressures for each of the 3 diagonal components of the stress tensor can be specified independently via the *x*, *y*, *z*, keywords, which correspond to the 3 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from *Pstart* to *Pstop*. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the *y* keyword is used, the y-box length will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the [fix deform](#) command.

For all barostat keywords, the *Pdamp* parameter determines the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (tau or fs or ps - see the *units* command).

---

**Note:** A Berendsen barostat will not work well for arbitrary values of *Pdamp*. If *Pdamp* is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a *Pdamp* of around 1000 timesteps. However, note that *Pdamp* is specified in time units, and that timesteps are NOT the same as time units for most *units* settings.

---

---

**Note:** The relaxation time is actually also a function of the bulk modulus of the system (inverse of isothermal compressibility). The bulk modulus has units of pressure and is the amount of pressure that would need to be applied (isotropically) to reduce the volume of the system by a factor of 2 (assuming the bulk modulus was a constant, independent of density, which it's not). The bulk modulus can be set via the keyword *modulus*. The *Pdamp* parameter is effectively multiplied by the bulk modulus, so if the pressure is relaxing faster than expected or desired, increasing the bulk modulus has the same effect as increasing *Pdamp*. The converse is also true. LAMMPS does not attempt to guess a correct value of the bulk modulus; it just uses 10.0 as a default value which gives reasonable relaxation for a Lennard-Jones liquid, but will be way off for other materials and way too small for solids. Thus you should experiment to find appropriate values of *Pdamp* and/or the *modulus* when using this fix.

---

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, *xz* means the  $P_{xx}$  and  $P_{zz}$  components of the stress tensor are coupled. *xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The *Pstart*, *Pstop*, *Pdamp* parameters for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the *z* dimension is simply ignored.

---

The *iso* and *aniso* keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “*iso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
```

The keyword *aniso* means *x*, *y*, and *z* dimensions are controlled independently using the  $P_{xx}$ ,  $P_{yy}$ , and  $P_{zz}$  components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “*aniso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple none
```

---

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp
```

See the *compute temp* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix-ID + underscore + “press”, and the group for the new computes is the same as the fix group.

Note that these are NOT the computes used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp* and *thermo\_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

## 2.165.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify temp* and *press* options are supported by this fix. You can use them to assign a *compute* you have defined to this fix which will be used in its temperature and pressure calculations. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

No global or per-atom quantities are stored by this fix for access by various *output commands*.

This fix can ramp its target pressure over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.165.5 Restrictions

Any dimension being adjusted by this fix must be periodic.

## 2.165.6 Related commands

*fix nve*, *fix nph*, *fix npt*, *fix temp/berendsen*, *fix\_modify*

## 2.165.7 Default

The keyword defaults are dilate = all, modulus = 10.0 in units of pressure for whatever *units* are defined.

**(Berendsen)** Berendsen, Postma, van Gunsteren, DiNola, Haak, J Chem Phys, 81, 3684 (1984).

## 2.166 fix press/langevin command

### 2.166.1 Syntax

```
fix ID group-ID press/langevin keyword value ...
```

- ID, group-ID are documented in *fix* command
- press/langevin = style name of this fix command

one or more keyword value pairs may be appended

keyword = *iso* or *aniso* or *tri* or *x* or *y* or *z* or *xy* or *xz* or *yz* or *couple* or *dilate* ↵

↵or *modulus* or *temp* or *flip*

*iso* or *aniso* or *tri* values = Pstart Pstop Pdamp

Pstart,Pstop = scalar external pressure at start/end of run (pressure units)

Pdamp = pressure damping parameter (time units)

*x* or *y* or *z* or *xy* or *xz* or *yz* values = Pstart Pstop Pdamp

Pstart,Pstop = external stress tensor component at start/end of run (pressure ↵  
↵units)

Pdamp = pressure damping parameter

*flip* value = *yes* or *no* = allow or disallow box flips when it becomes highly skewed

*couple* = *none* or *xyz* or *xy* or *yz* or *xz*

*friction* value = Friction coefficient for the barostat (time units)

*temp* values = Tstart, Tstop, seed

Tstart, Tstop = target temperature used for the barostat at start/end of run

seed = seed of the random number generator

*dilate* value = *all* or *partial*

### 2.166.2 Examples

```
fix 1 all press/langevin iso 0.0 0.0 1000.0 temp 300 300 487374
fix 2 all press/langevin aniso 0.0 0.0 1000.0 temp 100 300 238 dilate partial
```

### 2.166.3 Description

Adjust the pressure of the system by using a Langevin stochastic barostat (*Gronbech*), which rescales the system volume and (optionally) the atoms coordinates within the simulation box every timestep.

The Langevin barostat couple each direction  $L$  with a pseudo-particle that obeys the Langevin equation such as:

$$\begin{aligned}
 f_P &= \frac{Nk_B T_{target}}{V} + \frac{1}{Vd} \sum_{i=1}^N \vec{r}_i \cdot \vec{f}_i - P_{target} \\
 Q\ddot{L} + \alpha\dot{L} &= f_P + \beta(t) \\
 L^{n+1} &= L^n + bdt\dot{L}^n + \frac{bdt^2}{2Q} \\
 \dot{L}^{n+1} &= \alpha\dot{L}^n + \frac{dt}{2Q} (af_P^n + f_P^{n+1}) + \frac{b}{Q}\beta^{n+1} \\
 a &= \frac{1 - \frac{\alpha dt}{2Q}}{1 + \frac{\alpha dt}{2Q}} \\
 b &= \frac{1}{1 + \frac{\alpha dt}{2Q}} \\
 \langle \beta(t)\beta(t') \rangle &= 2\alpha k_B T dt
 \end{aligned}$$

Where  $dt$  is the timestep  $\dot{L}$  and  $\ddot{L}$  the first and second derivatives of the coupled direction with regard to time,  $\alpha$  is a friction coefficient,  $\beta$  is a random gaussian variable and  $Q$  the effective mass of the coupled pseudoparticle. The two first terms on the right-hand side of the first equation are the virial expression of the canonical pressure. It is to be noted that the temperature used to compute the pressure is not based on the atom velocities but rather on the canonical target temperature directly. This temperature is specified using the *temp* keyword parameter and should be close to the expected target temperature of the system.

Regardless of what atoms are in the fix group, a global pressure is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the atoms in the fix group are re-scaled. The latter can be useful for leaving the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

---

**Note:** Unlike the *fix npt* or *fix npb* commands which perform Nose-Hoover barostatting AND time integration, this fix does NOT perform time integration of the atoms but only of the barostat coupled coordinate. It then only modifies the box size and atom coordinates to effect barostatting. Thus you must use a separate time integration fix, like *fix nve* or *fix nvt* to actually update the positions and velocities of atoms. This fix can be used in conjunction with thermostating fixes to control the temperature, such as *fix nvt* or *fix langevin* or *fix temp/berendsen*.

---

See the [Howto barostat](#) page for a discussion of different ways to perform barostatting.

---

The barostat is specified using one or more of the *iso*, *aniso*, *tri x*, *y*, *z*, *xy*, *xz*, *yz*, and *couple* keywords. These keywords give you the ability to specify the 3 diagonal components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation.

The target pressures for each of the 6 diagonal components of the stress tensor can be specified independently via the *x*, *y*, *z*, keywords, which correspond to the 3 simulation box dimensions, and the *xy*, *xz* and *yz* keywords which corresponds to the 3 simulation box tilt factors. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from *Pstart* to *Pstop*. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the *y* keyword is used, the *y*-box length will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the *fix deform* command.

The *Pdamp* parameter can be seen in the same way as a Nose-Hoover parameter as it is used to compute the mass of the fictitious particle. Without friction, the barostat can be compared to a single particle Nose-Hoover barostat and should follow a similar decay in time. The mass of the barostat is linked to *Pdamp* by the relation  $Q = (N_{at} + 1) \cdot k_B T_{target} \cdot P_{damp}^2$ . Note that *Pdamp* should be expressed in time units.

**Note:** As for Berendsen barostat, a Langevin barostat will not work well for arbitrary values of *Pdamp*. If *Pdamp* is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a *Pdamp* of around 1000 timesteps. However, note that *Pdamp* is specified in time units, and that timesteps are NOT the same as time units for most *units* settings.

---

The *temp* keyword sets the temperature to use in the equation of motion of the barostat. This value is used to compute the value of the force  $f_P$  in the equation of motion. It is important to note that this value is not the instantaneous temperature but a target temperature that ramps from *Tstart* to *Tstop*. Also the required argument *seed* sets the seed for the random number generator used in the generation of the random forces.

---

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, *xz* means the  $P_{xx}$  and  $P_{zz}$  components of the stress tensor are coupled. *Xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The *Pstart*, *Pstop*, *Pdamp* parameters for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the *z* dimension is simply ignored.

---

The *iso*, *aniso* and *tri* keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “*iso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
```

The keyword *aniso* means *x*, *y*, and *z* dimensions are controlled independently using the  $P_{xx}$ ,  $P_{yy}$ , and  $P_{zz}$  components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “*aniso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple none
```

The keyword *tri* is the same as *aniso* but also adds the control on the shear pressure coupled with the tilt factors.

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
xy Pstart Pstop Pdamp
xz Pstart Pstop Pdamp
yz Pstart Pstop Pdamp
couple none
```

The *flip* keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed below. If the *flip* value is set to *yes*, the bound is enforced by flipping the box when it is exceeded. If the *flip*

value is set to *no*, the tilt will continue to change without flipping. Note that if applied stress induces large deformations (e.g. in a liquid), this means the box shape can tilt dramatically and LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor's irregular-shaped subdomain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The *friction* keyword sets the friction parameter  $\alpha$  in the equations of motion of the barostat. For each barostat direction, the value of  $\alpha$  depends on both *Pdamp* and *friction*. The value given as a parameter is the Langevin characteristic time  $\tau_L = \frac{\eta}{\alpha}$  in time units. The langevin time can be understood as a decorrelation time for the pressure. A long Langevin time value will make the barostat act as an underdamped oscillator while a short value will make it act as an overdamped oscillator. The ideal configuration would be to find the critical parameter of the barostat. Empirically this is observed to occur for  $\tau_L \approx P_{damp}$ . For this reason, if the *friction* keyword is not used, the default value *Pdamp* is used for each barostat direction.

This fix computes pressure each timestep. To do this, the fix creates its own computes of style “pressure”, as if this command had been issued:

```
compute fix-ID_press group-ID pressure NULL virial
```

The kinetic contribution to the pressure is taken as the ensemble value  $\frac{Nk_bT}{V}$  and computed by the fix itself.

See the *compute pressure* command for details. Note that the IDs of the new compute is the fix-ID + underscore + “press” and the group for the new computes is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_press*. This means you can change the attributes of this fix's pressure via the *compute\_modify* command or print this temperature or pressure during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* or *thermo\_press* will have no effect on this fix.

## 2.166.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify press* option is supported by this fix. You can use it to assign a *compute* you have defined to this fix which will be used in its pressure calculations.

No global or per-atom quantities are stored by this fix for access by various *output commands*.

This fix can ramp its target pressure and temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this. It is recommended that the ramped temperature is the same as the effective temperature of the thermostatted system. That is, if the system's temperature is ramped by other commands, it is recommended to do the same with this pressure control.

This fix is not invoked during *energy minimization*.

## 2.166.5 Restrictions

Any dimension being adjusted by this fix must be periodic.

## 2.166.6 Related commands

*fix press/berendsen*, *fix nve*, *fix npb*, *fix npt*, *fix langevin*, *fix\_modify*

## 2.166.7 Default

The keyword defaults are *dilate* = all, *flip* = yes, and *friction* = *Pdamp*.

---

(Gronbech) Gronbech-Jensen, Farago, J Chem Phys, 141, 194108 (2014).

# 2.167 fix print command

## 2.167.1 Syntax

```
fix ID group-ID print N string keyword value ...
```

- ID, group-ID are documented in *fix* command
- print = style name of this fix command
- N = print every N steps; N can be a variable (see below)
- string = text string to print with optional variable names
- zero or more keyword/value pairs may be appended
- keyword = *file* or *append* or *screen* or *title*

*file* value = filename

*append* value = filename

*screen* value = yes or no

*title* value = string

string = text to print as 1st line of output file

## 2.167.2 Examples

```
fix extra all print 100 "Coords of marker atom = $x $y $z"  
fix extra all print 100 "Coords of marker atom = $x $y $z" file coord.txt
```

### 2.167.3 Description

Print a text string every N steps during a simulation run. This can be used for diagnostic purposes or as a debugging tool to monitor some quantity during a run. The text string must be a single argument, so it should be enclosed in single or double quotes if it is more than one word. If it contains variables it must be enclosed in double quotes to ensure they are not evaluated when the input script line is read, but will instead be evaluated each time the string is printed.

New in version 15Jun2023: support for vector style variables

See the [variable](#) command for a description of *equal* and *vector* style variables which are typically the most useful ones to use with the print command. Equal- and vector-style variables can calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a [compute](#) or [fix](#), or references to other [variables](#). Vector-style variables are printed in a bracketed, comma-separated format, e.g. [1,2,3,4] or [12.5,2,4.6,10.1].

---

**Note:** As discussed on the [Commands parse](#) doc page, the text string can use “immediate” variables, specified as \$(formula) with parenthesis, where the numeric formula has the same syntax as equal-style variables described on the [variable](#) doc page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then use that variable in the text string. The formula can include a trailing colon and format string which determines the precision with which the numeric value is output. This is also explained on the [Commands parse](#) doc page.

---

Instead of a numeric value, N can be specified as an *equal-style variable*, which should be specified as v\_name, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the **next** timestep at which the string will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for *equal-style variables*, as examples of useful functions to use in this context. For example, the following commands will print output at timesteps 10,20,30,100,200,300,1000,2000,etc:

```
variable          s equal logfreq(10,3,10)
fix extra all print v_s "Coords of marker atom = $x $y $z"
```

The specified group-ID is ignored by this fix.

If the *file* or *append* keyword is used, a filename is specified to which the output generated by this fix will be written. If *file* is used, then the filename is overwritten if it already exists. If *append* is used, then the filename is appended to if it already exists, or created if it does not exist.

If the *screen* keyword is used, output by this fix to the screen and logfile can be turned on or off as desired.

The *title* keyword allow specification of the string that will be printed as the first line of the output file, assuming the *file* keyword was used. By default, the title line is as follows:

```
# Fix print output for fix ID
```

where ID is replaced with the fix-ID.

## 2.167.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.167.5 Restrictions

none

## 2.167.6 Related commands

*variable, print*

## 2.167.7 Default

The option defaults are no file output, screen = yes, and title string as described above.

# 2.168 fix propel/self command

## 2.168.1 Syntax

```
fix ID group-ID propel/self mode magnitude keyword values
```

- ID, group-ID are documented in *fix* command
- propel/self = style name of this fix command
- mode = *dipole* or *velocity* or *quat*
- magnitude = magnitude of self-propulsion force
- zero or one keyword/value pairs may be appended
- keyword = *qvector*  
    *qvector* value = direction of force in ellipsoid frame  
    *sx*, *sy*, *sz* = components of *qvector*

## 2.168.2 Examples

```
fix active all propel/self dipole 40.0  
fix active all propel/self velocity 10.0  
fix active all propel/self quat 15.7 qvector 1.0 0.0 0.0
```

### 2.168.3 Description

Add a force to each atom in the group due to a self-propulsion force. The force is given by

$$F_i = f_P e_i$$

where  $i$  is the particle the force is being applied to,  $f_P$  is the magnitude of the force, and  $e_i$  is the vector direction of the force. The specification of  $e_i$  is based on which of the three keywords (*dipole* or *velocity* or *quat*) one selects.

For mode *dipole*,  $e_i$  is just equal to the dipole vectors of the atoms in the group. Therefore, if the dipoles are not unit vectors, the  $e_i$  will not be unit vectors.

---

**Note:** If another command changes the magnitude of the dipole, this force will change accordingly (since  $|e_i|$  will change, which is physically equivalent to re-scaling  $f_P$  while keeping  $|e_i|$  constant), and no warning will be provided by LAMMPS. This is almost never what you want, so ensure you are not changing dipole magnitudes with another LAMMPS fix or pair style. Furthermore, self-propulsion forces (almost) always set  $e_i$  to be a unit vector for all times, so it's best to set all the dipole magnitudes to 1.0 unless you have a good reason not to (see the [set](#) command on how to do this).

---

For mode *velocity*,  $e_i$  points in the direction of the current velocity (a unit-vector). This can be interpreted as a velocity-dependent friction, as proposed by e.g. ([Erdmann](#)).

For mode *quat*,  $e_i$  points in the direction of a unit vector, oriented in the coordinate frame of the ellipsoidal particles, which defaults to point along the x-direction. This default behavior can be changed by via the *quatvec* keyword.

The optional *quatvec* keyword specifies the direction of self-propulsion via a unit vector (sx,sy,sz). The arguments sx, sy, and sz, are defined within the coordinate frame of the atom's ellipsoid. For instance, for an ellipsoid with long axis along its x-direction, if one wanted the self-propulsion force to also be along this axis, set sx equal to 1 and sy, sz both equal to zero. This keyword may only be specified for mode *quat*.

---

**Note:** In using keyword *quatvec*, the three arguments sx, sy, and sz will be automatically normalized to components of a unit vector internally to avoid users having to explicitly do so themselves. Therefore, in mode *quat*, the vectors  $e_i$  will always be of unit length.

---

Along with adding a force contribution, this fix can also contribute to the virial (pressure) of the system, defined as  $f_P \sum_i \langle e_i \cdot r_i \rangle / (dV)$ , where  $r_i$  is the *unwrapped* coordinate of particle i in the case of periodic boundary conditions. See ([Winkler](#)) for a discussion of this active pressure contribution.

For modes *dipole* and *quat*, this fix is by default included in pressure computations.

For mode *velocity*, this fix is by default not included in pressure computations.

---

**Note:** In contrast to equilibrium systems, pressure of active systems in general depends on the geometry of the container. The active pressure contribution as calculated in this fix is only valid for certain boundary conditions (spherical walls, rectangular walls, or periodic boundary conditions). For other geometries, the pressure must be measured via explicit calculation of the force per unit area on a wall, and so one must not calculate it using this fix. (Use [fix\\_modify](#) as described below to turn off the virial contribution of this fix). Again, see ([Winkler](#)) for discussion of why this is the case.

Furthermore, when dealing with active systems, the temperature is no longer well defined. Therefore, one should ensure that the *virial* flag is used in the [compute pressure](#) command (turning off temperature contributions).

---

## 2.168.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the added forces on atoms to the system's virial as part of *thermodynamic output*. The default is *virial yes* for keywords *dipole* and *quat*. The default is *virial no* for keyword *velocity*.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

## 2.168.5 Restrictions

With keyword *dipole*, this fix only works when the DIPOLE package is enabled. See the *Build package* page for more info.

This fix is part of the BROWNIAN package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

## 2.168.6 Related commands

*fix efield* , *fix setforce*, *fix addforce*

## 2.168.7 Default

none

## 2.169 fix property/atom command

Accelerator Variants: *property/atom/kk*

### 2.169.1 Syntax

**fix** ID group-ID property/atom name1 name2 ... keyword value ...

- ID, group-ID are documented in *fix* command
- property/atom = style name of this fix command
- name1,name2,... = *mol* or *q* or *rmass* or *i\_name* or *d\_name* or *i2\_name* or *d2\_name*

*mol* = molecule IDs

*q* = charge

*rmass* = per-atom mass

*temperature* = internal temperature of atom

*heatflow* = internal heat flow of atom

*i\_name* = new integer vector referenced by name

*d\_name* = new floating-point vector referenced by name

```
i2_name = new integer array referenced by name
  i2_name arg = N = number of columns in the array
d2_name = new floating-point array referenced by name
  d2_name arg = N = number of columns in the array
```

- zero or more keyword/value pairs may be appended
- keyword = *ghost*

*ghost* value = *no* or *yes* for whether ghost atom info is communicated

## 2.169.2 Examples

```
fix 1 all property/atom mol
fix 1 all property/atom i_myflag1 i_myflag2
fix 1 all property/atom d2_sxyz 3 ghost yes
```

## 2.169.3 Description

Create one or more additional per-atom vectors or arrays to store information about atoms and to use during a simulation. The specified *group-ID* is ignored by this fix.

The atom style used for a simulation defines a set of per-atom properties, as explained on the [atom\\_style](#) and [read\\_data](#) doc pages. The latter command defines these properties for each atom in the system when a data file is read. This fix augments the set of per-atom properties with new custom ones. This can be useful in several scenarios.

If the atom style does not define molecule IDs, per-atom charge, per-atom mass, internal temperature, or internal heat flow, they can be added using the *mol*, *q*, *rmass*, *temperature*, or *heatflow* keywords. This could be useful to define “molecules” to use as rigid bodies with the [fix rigid](#) command, or to carry around an extra flag with atoms (stored as a molecule ID) that can be used by various commands like [compute chunk/atom](#) to group atoms without having to use the group command (which is limited to a total of 32 groups including *all*). For finite-size particles, an internal temperature and heat flow can be used to model heat conduction as in the [GRANULAR package](#).

Another application is to use the *rmass* flag in order to have per-atom masses instead of per-type masses. This could be used to study isotope effects with partial isotope substitution. [See below](#) for an example of simulating a mixture of light and heavy water with the TIP4P water potential.

An alternative to using [fix property/atom](#) for these examples is to use an atom style that does define molecule IDs or charge or per-atom mass (indirectly via diameter and density) or to use a hybrid atom style that combines two or more atom styles to provide the union of all their atom properties. However, this has two practical drawbacks: first, it typically necessitates changing the format of the Atoms section in the data file and second, it may define additional properties that are not needed such as bond lists, which incurs some overhead when there are no bonds.

In the future, we may add additional existing per-atom properties to [fix property/atom](#), similar to *mol*, *q*, *rmass*, *temperature*, or *heatflow* which “turn-on” specific properties defined by some atom styles, so they can be easily used by atom styles that do not define them.

More generally, the *i\_name* and *d\_name* options allow one or more new custom per-atom vectors to be defined. Likewise the *i2\_name* and *d2\_name* options allow one or more custom per-atom arrays to be defined. The *i2\_name* and *d2\_name* options take an argument *N* which specifies the number of columns in the per-atom array, i.e. the number of attributes associated with each atom. *N* >= 1 is required.

Each name must be unique and can use alphanumeric or underscore characters. These vectors and arrays can store whatever values you decide are useful in your simulation. As explained below there are several ways to initialize, access, and output these values, via input script commands, data files, and in new code you add to LAMMPS.

This is effectively a simple way to add per-atom properties to a model without needing to write code for a new *atom style* that defines the properties. Note however that implementing a new atom style allows new atom properties to be more tightly and seamlessly integrated with the rest of the code.

The new atom properties encode values that migrate with atoms to new processors and are written to restart files. If you want the new properties to also be defined for ghost atoms, then use the *ghost* keyword with a value of *yes*. This will invoke extra communication when ghost atoms are created (at every re-neighboring) to ensure the new properties are also defined for the ghost atoms.

---

### Properties on ghost atoms

If you use the *mol*, *q* or *rmass* names, you most likely want to set *ghost* yes, since these properties are stored with ghost atoms if you use an *atom style* that defines them. Many LAMMPS operations that use molecule IDs or charge, such as neighbor lists and pair styles, will expect ghost atoms to have these values. LAMMPS will issue a warning if you define those vectors but do not set *ghost* yes.

---

---

### Limitations on ghost atom properties

The specified properties for ghost atoms are not updated every timestep, but only once every few steps when neighbor lists are re-built. Thus the *ghost* keyword is suitable for static properties, like molecule IDs, but not for dynamic properties that change every step. For the latter, the code you add to LAMMPS to change the properties will also need to communicate their new values to/from ghost atoms, an operation that can be invoked from within a *pair style* or *fix* or *compute* that you write.

---

This fix is one of a small number that can be defined in an input script before the simulation box is created or atoms are defined. This is so it can be used with the *read\_data* command as described next.

Per-atom properties that are defined by the *atom style* are initialized when atoms are created, e.g. by the *read\_data* or *create\_atoms* commands. The per-atom properties defined by this fix are not. So you need to initialize them explicitly. One way to do this is *read\_data* command, using its *fix* keyword and passing it the fix-ID of this fix.

Thus these commands:

```
fix prop all property/atom mol d_flag
read_data data.txt fix prop NULL Molecules
```

would allow a data file to have a section like this:

```
Molecules
1 4 1.5
2 4 3.0
3 10 1.0
4 10 1.0
5 10 1.0
...
N 763 4.5
```

where N is the number of atoms, the first field on each line is the atom-ID, the next two are a molecule-ID and a floating point value that will be stored in a new property called “flag”. If a per-atom array was specified in the fix property/atom command then the *N* values for that array must be specified consecutively for that property on each line. Note that the order of values on each line corresponds to the order of custom names in the fix property/atom command.

Note that the the lines of per-atom properties can be listed in any order. Also note that all the per-atom properties specified by the fix ID (prop in this case) must be included on each line in the specified data file section (Molecules in this case).

Another way of initializing the new properties is via the *set* command. For example, if you wanted molecules defined for every set of 10 atoms, based on their atom-IDs, these commands could be used:

```
fix prop all property/atom mol
variable cluster atom ((id-1)/10)+1
set atom * mol v_cluster
```

The *atom-style variable* will create values for atoms with IDs 31,32,33,...40 that are 4.0,4.1,4.2,...,4.9. When the *set* commands assigns them to the molecule ID for each atom, they will be truncated to an integer value, so atoms 31-40 will all be assigned a molecule ID of 4.

Note that *atomfile-style variables* can also be used in place of atom-style variables, which means in this case that the molecule IDs could be read-in from a separate file and assigned by the *set* command. This allows you to initialize new per-atom properties in a completely general fashion.

For new atom properties specified as *i\_name*, *d\_name*, *i2\_name*, or *d2\_name*, the *dump custom* and *compute property/atom* commands can access their values. This means that the values can be used accessed by fixes like *fix ave/atom*, accessed by other computes like *compute reduce*, or used in *atom-style variables*.

For example, these commands will output both the instantaneous and time-averaged values of two new properties to a custom dump file:

```
fix myprops all property/atom i_flag1 d_flag2
compute 1 all property/atom i_flag1 d_flag2
fix 1 all ave/atom 10 10 100 c_1[1] c_1[2]
dump 1 all custom 100 tmp.dump id x y z i_flag1 d_flag2 f_1[1] f_1[2]
```

If you wish to add new *pair styles*, *fixes*, or *computes* that use the per-atom properties defined by this fix, see the *Modify atom* doc page which has details on how the custom properties of this fix can be accessed from added classes.

Here is an example of using per-atom masses with TIP4P water to study isotope effects. When setting up simulations with the *TIP4P pair styles* for water, you have to provide exactly one atom type each to identify the water oxygen and hydrogen atoms. Since the atom mass is normally tied to the atom type, this makes it impossible to study multiple isotopes in the same simulation. With *fix property/atom rmass* however, the per-type masses are replaced by per-atom masses. Asuming you have a working input deck for regular TIP4P water, where water oxygen is atom type 1 and water hydrogen is atom type 2, the following lines of input script convert this to using per-atom masses:

```
fix Isotopes all property/atom rmass ghost yes
set type 1 mass 15.9994
set type 2 mass 1.008
```

When writing out the system data with the *write\_data* command, there will be a new section named with the fix-ID (i.e. *Isotopes* in this case). Alternatively, you can take an existing data file and just add this *Isotopes* section with one line per atom containing atom-ID and mass. Either way, the extended data file can be read back with:

```
fix Isotopes all property/atom rmass ghost yes
read_data tip4p-isotopes.data fix Isotopes NULL Isotopes
```

Please note that the first *Isotopes* refers to the fix-ID and the second to the name of the section. The following input script code will now change the first 100 water molecules in this example to heavy water:

```
group hwat id 2:300:3
group hwat id 3:300:3
set group hwat mass 2.0141018
```

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.169.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the per-atom values it stores to [binary restart files](#), so that the values can be restored when a simulation is restarted. See the [read\\_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Warning:** When reading data from a restart file, this fix command has to be specified **after** the *read\_restart* command and **exactly** the same was in the input script that created the restart file. LAMMPS will only check whether a fix is of the same style and has the same fix ID and in case of a match will then try to initialize the fix with the data stored in the binary restart file. If the names and associated data types in the new fix property/atom command do not match the old one exactly, data can be corrupted or LAMMPS may crash. If the fix is specified **before** the *read\_restart* command its data will not be restored.

None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various [output commands](#). No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during [energy minimization](#).

## 2.169.5 Restrictions

none

## 2.169.6 Related commands

*read\_data, set, compute property/atom*

## 2.169.7 Default

The default keyword value is `ghost = no`.

## 2.170 fix python/invoke command

### 2.170.1 Syntax

```
fix ID group-ID python/invoke N callback function_name
```

- ID, group-ID are ignored by this fix
- python/invoke = style name of this fix command
- N = execute every N steps
- callback = *post\_force* or *end\_of\_step*

*post\_force* = callback after force computations on atoms every N time steps

*end\_of\_step* = callback after every N time steps

### 2.170.2 Examples

```
python post_force_callback here """
from lammps import lammps

def post_force_callback(lammps_ptr, vflag):
    lmp = lammps(ptr=lammps_ptr)
    # access LAMMPS state using Python interface
    """

python end_of_step_callback here """
def end_of_step_callback(lammps_ptr):
    lmp = lammps(ptr=lammps_ptr)
    # access LAMMPS state using Python interface
    """

fix pf all python/invoke 50 post_force post_force_callback
fix eos all python/invoke 50 end_of_step end_of_step_callback
```

### 2.170.3 Description

This fix allows you to call a Python function during a simulation run. The callback is either executed after forces have been applied to atoms or at the end of every N time steps.

Callback functions must be declared in the global scope of the active Python interpreter. This can either be done by defining it inline using the `python` command or by importing functions from other Python modules. If LAMMPS is driven using the library interface from Python, functions defined in the driving Python interpreter can also be executed.

Each callback is given a pointer object as first argument. This can be used to initialize an instance of the lammps Python interface, which gives access to the LAMMPS state from Python.

**Warning:** While you can access the state of LAMMPS via library functions from these callbacks, trying to execute input script commands will in the best case not work or in the worst case result in undefined behavior.

### 2.170.4 Restrictions

This fix is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Building LAMMPS with the PYTHON package will link LAMMPS with the Python library on your system. Settings to enable this are in the `lib/python/Makefile.lammps` file. See the `lib/python/README` file for information on those settings.

### 2.170.5 Related commands

*python command*

## 2.171 fix python/move command

### 2.171.1 Syntax

```
fix python/move pmodule.CLASS
```

pmodule.CLASS = use class **CLASS** in module/file **pmodule** to compute how to move atoms

### 2.171.2 Examples

```
fix 1 all python/move py_nve.NVE
fix 1 all python/move py_nve.NVE_OPT
```

### 2.171.3 Description

The *python/move* fix style provides a way to define ways how particles are moved during an MD run from python script code, that is loaded from a file into LAMMPS and executed at the various steps where other fixes can be executed. This python script must contain specific python class definitions.

This allows to implement complex position updates and also modified time integration methods. Due to python being an interpreted language, however, the performance of this fix can be moderately to significantly slower than the corresponding C++ code. For specific cases, this performance penalty can be limited through effective use of NumPy.

The python module file has to start with the following code:

```
from __future__ import print_function
import lammps
import ctypes
import traceback
import numpy as np
#
class LAMMPSFix(object):
    def __init__(self, ptr, group_name="all"):
        self.lmp = lammps.lammps(ptr=ptr)
        self.group_name = group_name
#
class LAMMPSFixMove(LAMMPSFix):
    def __init__(self, ptr, group_name="all"):
        super(LAMMPSFixMove, self).__init__(ptr, group_name)
#
    def init(self):
        pass
#
    def initial_integrate(self, vflag):
        pass
#
    def final_integrate(self):
        pass
#
    def initial_integrate_respa(self, vflag, ilevel, iloop):
        pass
#
    def final_integrate_respa(self, ilevel, iloop):
        pass
#
    def reset_dt(self):
        pass
```

Any classes implementing new atom motion functionality have to be derived from the **LAMMPSFixMove** class, overriding the available methods as needed.

Examples for how to do this are in the *examples/python* folder.

## 2.171.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.171.5 Restrictions

This pair style is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

# 2.172 fix qbmsst command

## 2.172.1 Syntax

```
fix ID group-ID qbmsst dir shockvel keyword value ...
```

- ID, group-ID are documented in *fix* command
- qbmsst = style name of this fix
- dir = x or y or z
- shockvel = shock velocity (strictly positive, velocity units)
- zero or more keyword/value pairs may be appended
- keyword = *q* or *mu* or *p0* or *v0* or *e0* or *tscale* or *damp* or *seed* or *f\_max* or *N\_f* or *eta* or *beta* or *T\_init*

*q* value = cell mass-like parameter ( $\text{mass}^2/\text{distance}^4$  units)

*mu* value = artificial viscosity ( $\text{mass}/\text{distance}/\text{time}$  units)

*p0* value = initial pressure in the shock equations (pressure units)

*v0* value = initial simulation cell volume in the shock equations ( $\text{distance}^3$  units)

*e0* value = initial total energy (energy units)

*tscale* value = reduction in initial temperature (unitless fraction between 0.0 and 1.0)

*damp* value = damping parameter (time units) inverse of friction *gamma*

*seed* value = random number seed (positive integer)

*f\_max* value = upper cutoff frequency of the vibration spectrum ( $1/\text{time}$  units)

*N\_f* value = number of frequency bins (positive integer)

*eta* value = coupling constant between the shock system and the quantum thermal bath (positive unitless)

*beta* value = the quantum temperature is updated every beta time steps (positive integer)

$T_{init}$  value = quantum temperature for the initial state (temperature units)

## 2.172.2 Examples

```
# (liquid methane modeled with the REAX force field, real units)
fix 1 all qbmsst z 0.122 q 25 mu 0.9 tscale 0.01 damp 200 seed 35082 f_max 0.3 N_f 100
→eta 1 beta 400 T_init 110
# (quartz modeled with the BKS force field, metal units)
fix 2 all qbmsst z 72 q 40 tscale 0.05 damp 1 seed 47508 f_max 120.0 N_f 100 eta 1.0
→beta 500 T_init 300
```

Two example input scripts are given, including shocked  $\alpha$ -quartz and shocked liquid methane. The input script first equilibrates an initial state with the quantum thermal bath at the target temperature and then applies *fix qbmsst* to simulate shock compression with quantum nuclear correction. The following two figures plot relevant quantities for shocked  $\alpha$ -quartz.

Figure 1. Classical temperature  $T_{cl} = \sum \frac{m_i v_i^2}{3Nk_B}$  vs. time for coupling the  $\alpha$ -quartz initial state with the quantum thermal bath at target quantum temperature  $T^{qm} = 300K$ . The NpH ensemble is used for time integration while QTB provides the colored random force.  $T^{cl}$  converges at the timescale of *damp* which is set to be 1 ps.

Figure 2. Quantum temperature and pressure vs. time for simulating shocked  $\alpha$ -quartz with *fix qbmsst*. The shock propagates along the *z* direction. Restart of the *fix qbmsst* command is demonstrated in the example input script. Thermodynamic quantities stay continuous before and after the restart.

### 2.172.3 Description

This command performs the Quantum-Bath coupled Multi-Scale Shock Technique (QBMSST) integration. See (Qi) for a detailed description of this method. QBMSST provides description of the thermodynamics and kinetics of shock processes while incorporating quantum nuclear effects. The *shockvel* setting determines the steady shock velocity that will be simulated along direction *dir*.

Quantum nuclear effects (*fix qtb*) can be crucial especially when the temperature of the initial state is below the classical limit or there is a great change in the zero point energies between the initial and final states. Theoretical post processing quantum corrections of shock compressed water and methane have been reported as much as 30% of the temperatures (Goldman). A self-consistent method that couples the shock to a quantum thermal bath described by a colored noise Langevin thermostat has been developed by Qi et al (Qi) and applied to shocked methane. The onset of chemistry is reported to be at a pressure on the shock Hugoniot that is 40% lower than observed with classical molecular dynamics.

It is highly recommended that the system be already in an equilibrium state with a quantum thermal bath at temperature of  $T_{init}$ . The *fix* command *fix qtb* at constant temperature  $T_{init}$  could be used before applying this command to introduce self-consistent quantum nuclear effects into the initial state.

The parameters *q*, *mu*, *e0*, *p0*, *v0* and *tscale* are described in the command *fix msst*. The values of *e0*, *p0*, or *v0* will be calculated on the first step if not specified. The parameter of *damp*, *f\_max*, and *N\_f* are described in the command *fix qtb*.

The *fix qbmsst* command couples the shock system to a quantum thermal bath with a rate that is proportional to the change of the total energy of the shock system,  $E^{tot} - E_0^{tot}$ . Here  $E^{tot}$  consists of both the system energy and a thermal term, see (Qi), and  $E_0^{tot} = e0$  is the initial total energy.

The *eta* ( $\eta$ ) parameter is a unitless coupling constant between the shock system and the quantum thermal bath. A small  $\eta$  value cannot adjust the quantum temperature fast enough during the temperature ramping period of shock compression while large  $\eta$  leads to big temperature oscillation. A value of  $\eta$  between 0.3 and 1 is usually appropriate for simulating most systems under shock compression. We observe that different values of  $\eta$  lead to almost the same final thermodynamic state behind the shock, as expected.

The quantum temperature is updated every *beta* ( $\beta$ ) steps with an integration time interval  $\beta$  times longer than the simulation time step. In that case,  $E^{tot}$  is taken as its average over the past  $\beta$  steps. The temperature of the quantum thermal bath  $T^{qm}$  changes dynamically according to the following equation where  $\Delta_t$  is the MD time step and  $\gamma$  is the friction constant which is equal to the inverse of the *damp* parameter.

$$\frac{dT^{qm}}{dt} = \gamma \eta \sum_{l=1}^{\beta} \frac{E^{tot}(t - l\Delta_t) - E_0^{tot}}{3\beta N k_B}$$

The parameter  $T_{init}$  is the initial temperature of the quantum thermal bath and the system before shock loading.

For all pressure styles, the simulation box stays orthorhombic in shape. Parrinello-Rahman boundary conditions (tilted box) are supported by LAMMPS, but are not implemented for QBMSST.

---

### 2.172.4 Restart, fix\_modify, output, run start/stop, minimize info

Because the state of the random number generator is not written to *binary restart files*, this *fix* cannot be restarted “exactly” in an uninterrupted fashion. However, in a statistical sense, a restarted simulation should produce similar behaviors of the system as if it is not interrupted. To achieve such a restart, one should write explicitly the same value for *q*, *mu*, *damp*, *f\_max*, *N\_f*, *eta*, and *beta* and set *tscale* = 0 if the system is compressed during the first run.

The cumulative energy change in the system imposed by this *fix* is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes a global scalar which can be accessed by various [output commands](#). The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

The progress of the QBMSST can be monitored by printing the global scalar and global vector quantities computed by the fix.

As mentioned above, the scalar is the cumulative energy change due to the fix. By monitoring the thermodynamic *econserve* output, this can be used to test if the MD timestep is sufficiently small for accurate integration of the dynamic equations.

The global vector contains five values in the following order. The vector values output by this fix are “intensive”.

[*dhugoniot*, *drayleigh*, *lagrangian\_speed*, *lagrangian\_position*, *quantum\_temperature*]

1. *dhugoniot* is the departure from the Hugoniot (temperature units).
2. *drayleigh* is the departure from the Rayleigh line (pressure units).
3. *lagrangian\_speed* is the laboratory-frame Lagrangian speed (particle velocity) of the computational cell (velocity units).
4. *lagrangian\_position* is the computational cell position in the reference frame moving at the shock speed. This is the distance of the computational cell behind the shock front.
5. *quantum\_temperature* is the temperature of the quantum thermal bath  $T^{qm}$ .

To print these quantities to the log file with descriptive column headers, the following LAMMPS commands are suggested.

```
fix          fix_id all msst z
variable     dhug      equal f_fix_id[1]
variable     dray      equal f_fix_id[2]
variable     lgr_vel   equal f_fix_id[3]
variable     lgr_pos   equal f_fix_id[4]
variable     T_qm      equal f_fix_id[5]
thermo_style custom step temp ke pe lz pzz econserve v_dhug v_dray v_lgr_vel v_lgr_
→pos v_T_qm f_fix_id
```

It is worth noting that the temp keyword for the *thermo\_style* command prints the instantaneous classical temperature  $T^{cl}$  as described by the [fix qtb](#) command.

## 2.172.5 Restrictions

This fix style is part of the QTB package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

All cell dimensions must be periodic. This fix can not be used with a triclinic cell. The QBMSST fix has been tested only for the group-ID all.

## 2.172.6 Related commands

*fix qtb*, *fix msst*

---

### 2.172.7 Default

The keyword defaults are  $q = 10$ ,  $\mu = 0$ ,  $t_{\text{scale}} = 0.01$ ,  $\text{damp} = 1$ ,  $\text{seed} = 880302$ ,  $f_{\text{max}} = 200.0$ ,  $N_{\text{f}} = 100$ ,  $\text{eta} = 1.0$ ,  $\text{beta} = 100$ , and  $T_{\text{init}} = 300.0$ .  $e_0$ ,  $p_0$ , and  $v_0$  are calculated on the first step.

```

## 2.177.3 Description

Perform the charge equilibration (QEq) method as described in (*Rappe and Goddard*) and formulated in (*Nakano*) (also known as the matrix inversion method) and in (*Rick and Stuart*) (also known as the extended Lagrangian method) based on the electronegativity equilization principle.

These fixes can be used with any *pair style* in LAMMPS, so long as per-atom charges are defined. The most typical use-case is in conjunction with a *pair style* that performs charge equilibration periodically (e.g. every timestep), such as the ReaxFF or Streitz-Mintmire potential. But these fixes can also be used with potentials that normally assume per-atom charges are fixed, e.g. a *Buckingham* or *LJ/Coulombic* potential.

Because the charge equilibration calculation is effectively independent of the pair style, these fixes can also be used to perform a one-time assignment of charges to atoms. For example, you could define the QEq fix, perform a zero-timestep run via the *run* command without any pair style defined which would set per-atom charges (based on the current atom configuration), then remove the fix via the *unfix* command before performing further dynamics.

---

**Note:** Computing and using charge values different from published values defined for a fixed-charge potential like Buckingham or CHARMM or AMBER, can have a strong effect on energies and forces, and produces a different model than the published versions.

---

---

**Note:** The *fix qeq/comb* command must still be used to perform charge equilibration with the *COMB potential*. The *fix qeq/reaxff* command can be used to perform charge equilibration with the *ReaxFF force field*, although *fix qeq/shielded* yields the same results as *fix qeq/reaxff* if *Nevery*, *cutoff*, and *tolerance* are the same. Eventually the *fix qeq/reaxff* command will be deprecated.

---

The QEq method minimizes the electrostatic energy of the system (or equalizes the derivative of energy with respect to charge of all the atoms) by adjusting the partial charge on individual atoms based on interactions with their neighbors within *cutoff*. It requires a few parameters in the appropriate units for each atom type which are read from a file specified by *qfile*. The file has the following format

```
1 chi eta gamma zeta qcore
2 chi eta gamma zeta qcore
...
Ntype chi eta gamma zeta qcore
```

There have to be parameters given for every atom type. Wildcard entries are possible using the same type range syntax as for “coeff” commands (i.e., *n\*m*, *n\**, *\*m*, *\**). Later entries will overwrite previous ones. Empty lines or any text following the pound sign (#) are ignored. Each line starts with the atom type followed by five parameters. Only a subset

of the parameters is used by each QEq style as described below, thus the others can be set to 0.0 if desired, but all five entries per line are required.

- *chi* = electronegativity in energy units
- *eta* = self-Coulomb potential in energy units
- *gamma* = shielded Coulomb constant defined by *ReaxFF force field* in distance units
- *zeta* = Slater type orbital exponent defined by the *Streitz-Mintmire* potential in reverse distance units
- *qcore* = charge of the nucleus defined by the *Streitz-Mintmire potential* potential in charge units

The fix qeq styles will print a warning if the charges are not equilibrated within *tolerance* by *maxiter* steps, unless the *warn* keyword is used with “no” as argument. This latter option may be useful for testing and benchmarking purposes, as it allows to use a fixed number of QEq iterations when *tolerance* is set to a small enough value to always reach the *maxiter* limit. Turning off warnings will avoid the excessive output in that case.

The *qeq/point* style describes partial charges on atoms as point charges. Interaction between a pair of charged particles is  $1/r$ , which is the simplest description of the interaction between charges. Only the *chi* and *eta* parameters from the *qfile* file are used. Note that Coulomb catastrophe can occur if repulsion between the pair of charged particles is too weak. This style solves partial charges on atoms via the matrix inversion method. A tolerance of  $1.0\text{e-}6$  is usually a good number.

The *qeq/shielded* style describes partial charges on atoms also as point charges, but uses a shielded Coulomb potential to describe the interaction between a pair of charged particles. Interaction through the shielded Coulomb is given by equation (13) of the *ReaxFF force field* paper. The shielding accounts for charge overlap between charged particles at small separation. This style is the same as *fix qeq/reaxff*, and can be used with *pair\_style reaxff*. Only the *chi*, *eta*, and *gamma* parameters from the *qfile* file are used. When using the string *reaxff* as filename, these parameters are extracted directly from an active *reaxff* pair style. This style solves partial charges on atoms via the matrix inversion method. A tolerance of  $1.0\text{e-}6$  is usually a good number.

The *qeq/slater* style describes partial charges on atoms as spherical charge densities centered around atoms via the Slater  $1s$  orbital, so that the interaction between a pair of charged particles is the product of two Slater  $1s$  orbitals. The expression for the Slater  $1s$  orbital is given under equation (6) of the *Streitz-Mintmire* paper. Only the *chi*, *eta*, *zeta*, and *qcore* parameters from the *qfile* file are used. When using the string *coul/streitz* as filename, these parameters are extracted directly from an active *coul/streitz* pair style. This style solves partial charges on atoms via the matrix inversion method. A tolerance of  $1.0\text{e-}6$  is usually a good number. Keyword *alpha* can be used to change the Slater type orbital exponent.

The *qeq/dynamic* style describes partial charges on atoms as point charges that interact through  $1/r$ , but the extended Lagrangian method is used to solve partial charges on atoms. Only the *chi* and *eta* parameters from the *qfile* file are used. Note that Coulomb catastrophe can occur if repulsion between the pair of charged particles is too weak. A tolerance of  $1.0\text{e-}3$  is usually a good number. Keyword *qdamp* can be used to change the damping factor, while keyword *qstep* can be used to change the time step size.

The *\*qeq/fire\** style describes the same charge model and charge solver as the *qeq/dynamic* style, but employs a FIRE minimization algorithm to solve for equilibrium charges. Keyword *qdamp* can be used to change the damping factor, while keyword *qstep* can be used to change the time step size.

Note that *qeq/point*, *qeq/shielded*, and *qeq/slater* describe different charge models, whereas the matrix inversion method and the extended Lagrangian method (*qeq/dynamic* and *qeq/fire*) are different solvers.

Note that *qeq/point*, *qeq/dynamic* and *qeq/fire* styles all describe charges as point charges that interact through  $1/r$  relationship, but solve partial charges on atoms using different solvers. These three styles should yield comparable results if the QEq parameters and *Nevery*, *cutoff*, and *tolerance* are the same. Style *qeq/point* is typically faster, *qeq/dynamic* scales better on larger sizes, and *qeq/fire* is faster than *qeq/dynamic*.

---

**Note:** In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also

satisfy this constraint. LAMMPS will print a warning if that is not the case.

---

**Note:** Developing QEq parameters (chi, eta, gamma, zeta, and qcore) is non-trivial. Charges on atoms are not guaranteed to equilibrate with arbitrary choices of these parameters. We do not develop these QEq parameters. See the `examples/qeq` directory for some examples.

---

#### 2.177.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about these fixes is written to *binary restart files*. No global scalar or vector or per-atom quantities are stored by these fixes for access by various *output commands*. No parameter of these fixes can be used with the *start/stop* keywords of the *run* command.

These fixes are invoked during *energy minimization*.

#### 2.177.5 Restrictions

These fixes are part of the QEq package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These qeq fixes will ignore electric field contributions from *fix efield*.

#### 2.177.6 Related commands

## 2.178 fix qeq/comb command

Accelerator Variants: *qeq/comb/omp*

### 2.178.1 Syntax

```
fix ID group-ID qeq/comb Nevery precision keyword value ...
```

- ID, group-ID are documented in *fix* command
- qeq/comb = style name of this fix command
- Nevery = perform charge equilibration every this many steps
- precision = convergence criterion for charge equilibration
- zero or more keyword/value pairs may be appended
- keyword = *file*
  - file* value = filename
  - filename = name of file to write QEQ equilibration info to

### 2.178.2 Examples

```
fix 1 surface qeq/comb 10 0.0001
```

### 2.178.3 Description

Perform charge equilibration (QeQ) in conjunction with the COMB (Charge-Optimized Many-Body) potential as described in (*COMB\_1*) and (*COMB\_2*). It performs the charge equilibration portion of the calculation using the so-called QEq method, whereby the charge on each atom is adjusted to minimize the energy of the system. This fix can only be used with the COMB potential; see the *fix qeq/reaxff* command for a QeQ calculation that can be used with any potential.

Only charges on the atoms in the specified group are equilibrated. The fix relies on the pair style (COMB in this case) to calculate the per-atom electronegativity (effective force on the charges). An electronegativity equalization calculation (or QEq) is performed in an iterative fashion, which in parallel requires communication at each iteration for processors to exchange charge information about nearby atoms with each other. See *Rappe\_and\_Goddard* and *Rick\_and\_Stuart* for details.

During a run, charge equilibration is performed every *Nevery* time steps. Charge equilibration is also always enforced on the first step of each run. The *precision* argument controls the tolerance for the difference in electronegativity for all atoms during charge equilibration. *Precision* is a trade-off between the cost of performing charge equilibration (more iterations) and accuracy.

If the *file* keyword is used, then information about each equilibration calculation is written to the specified file.

---

**Note:** In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.178.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is performing charge equilibration. Default is the outermost level.

This fix produces a per-atom vector which can be accessed by various *output commands*. The vector stores the gradient of the charge on each atom. The per-atom values be accessed on any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix can be invoked during *energy minimization*.

## 2.178.5 Restrictions

This fix command currently only supports *pair style \*comb\**.

## 2.178.6 Related commands

*pair\_style comb*

## 2.178.7 Default

No file output is performed.

## 2.179 fix qeq/reaxff command

Accelerator Variants: *qeq/reaxff/kk*, *qeq/reaxff/omp*

### 2.179.1 Syntax

```
fix ID group-ID qeq/reaxff Nevery cutlo cuthi tolerance params args
```

- ID, group-ID are documented in *fix* command
- qeq/reaxff = style name of this fix command
- Nevery = perform QEq every this many steps
- cutlo,cuthi = lo and hi cutoff for Taper radius
- tolerance = precision to which charges will be equilibrated
- params = reaxff or a filename
- one or more keywords or keyword/value pairs may be appended

keyword = *dual* or *maxiter* or *nowarn*

*dual* = process S and T matrix in parallel (only for qeq/reaxff/omp)

*maxiter* N = limit the number of iterations to N

*nowarn* = do not print a warning message if the maximum number of iterations was reached

### 2.179.2 Examples

```
fix 1 all qeq/reaxff 1 0.0 10.0 1.0e-6 reaxff
fix 1 all qeq/reaxff 1 0.0 10.0 1.0e-6 param.qeq maxiter 500
```

### 2.179.3 Description

Perform the charge equilibration (QEq) method as described in (*Rappe and Goddard*) and formulated in (*Nakano*). It is typically used in conjunction with the ReaxFF force field model as implemented in the *pair\_style reaxff* command, but it can be used with any potential in LAMMPS, so long as it defines and uses charges on each atom. The *fix qeq/comb* command should be used to perform charge equilibration with the *COMB potential*. For more technical details about the charge equilibration performed by fix qeq/reaxff, see the (*Aktulga*) paper.

The QEq method minimizes the electrostatic energy of the system by adjusting the partial charge on individual atoms based on interactions with their neighbors. It requires some parameters for each atom type. If the *params* setting above is the word “reaxff”, then these are extracted from the *pair\_style reaxff* command and the ReaxFF force field file it reads in. If a file name is specified for *params*, then the parameters are taken from the specified file and the file must contain one line for each atom type. The latter form must be used when performing Qeq with a non-ReaxFF potential. Each line should be formatted as follows:

```
itype chi eta gamma
```

where *itype* is the atom type from 1 to Ntypes, *chi* denotes the electronegativity in eV, *eta* denotes the self-Coulomb potential in eV, and *gamma* denotes the valence orbital exponent. Note that these 3 quantities are also in the ReaxFF potential file, except that eta is defined here as twice the eta value in the ReaxFF file. Note that unlike the rest of LAMMPS, the units of this fix are hard-coded to be A, eV, and electronic charge.

The optional *dual* keyword allows to perform the optimization of the S and T matrices in parallel. This is only supported for the *qeq/reaxff/omp* style. Otherwise they are processed separately. The *qeq/reaxff/kk* style always solves the S and T matrices in parallel.

The optional *maxiter* keyword allows changing the max number of iterations in the linear solver. The default value is 200.

The optional *nowarn* keyword silences the warning message printed when the maximum number of iterations was reached. This can be useful for comparing serial and parallel results where having the same fixed number of QEq iterations is desired, which can be achieved by using a very small tolerance and setting *maxiter* to the desired number of iterations.

---

**Note:** In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.

---

## 2.179.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. This fix computes a global scalar (the number of iterations) for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is invoked during *energy minimization*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 2.179.5 Restrictions

This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix does not correctly handle interactions involving multiple periodic images of the same atom. Hence, it should not be used for periodic cell dimensions less than 10 Angstroms.

This fix may be used in combination with *fix efield* and will apply the external electric field during charge equilibration, but there may be only one fix efield instance used and the electric field vector may only have components in non-periodic directions. Equal-style variables can be used for electric field vector components without any further settings. Atom-style variables can be used for spatially-varying electric field vector components, but the resulting electric potential must be specified as an atom-style variable using the *potential* keyword for *fix efield*.

## 2.180 fix qmmm command

### 2.180.1 Syntax

```
fix ID group-ID qmmm
```

- ID, group-ID are documented in *fix* command
- qmmm = style name of this fix command

### 2.180.2 Examples

```
fix 1 qmol qmmm
```

### 2.180.3 Description

This fix provides functionality to enable a quantum mechanics/molecular mechanics (QM/MM) coupling of LAMMPS to a quantum mechanical code. The current implementation only supports an ONIOM style mechanical coupling to the [Quantum ESPRESSO](#) plane wave DFT package. Electrostatic coupling is in preparation and the interface has been written in a manner that coupling to other QM codes should be possible without changes to LAMMPS itself.

The interface code for this is in the lib/qmmm directory of the LAMMPS distribution and is being made available at this early stage of development in order to encourage contributions for interfaces to other QM codes. This will allow the LAMMPS side of the implementation to be adapted if necessary before being finalized.

Details about how to use this fix are currently documented in the description of the QM/MM interface code itself in lib/qmmm/README.

## 2.180.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global scalar or vector or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.180.5 Restrictions

This fix is part of the QMMM package. It is only enabled if LAMMPS was built with that package. It also requires building a library provided with LAMMPS. See the *Build package* page for more info.

The fix is only functional when LAMMPS is built as a library and linked with a compatible QM program and a QM/MM front end into a QM/MM executable. See the lib/qmmm/README file for details.

# 2.181 fix qtb command

## 2.181.1 Syntax

```
fix ID group-ID qtb keyword value ...
```

- ID, group-ID are documented in *fix* command
- qtb = style name of this fix
- zero or more keyword/value pairs may be appended
- keyword = *temp* or *damp* or *seed* or *f\_max* or *N\_f*
  - temp* value = target quantum temperature (temperature units)
  - damp* value = damping parameter (time units) inverse of friction *gamma*
  - seed* value = random number seed (positive integer)
  - f\_max* value = upper cutoff frequency of the vibration spectrum (1/time units)
  - N\_f* value = number of frequency bins (positive integer)

## 2.181.2 Examples

```
# (liquid methane modeled with the REAX force field, real units)
fix 1 all nve
fix 1 all qtb temp 110 damp 200 seed 35082 f_max 0.3 N_f 100
# (quartz modeled with the BKS force field, metal units)
fix 2 all nph iso 1.01325 1.01325 1
fix 2 all qtb temp 300 damp 1 seed 47508 f_max 120.0 N_f 100
```

## 2.181.3 Description

This command performs the quantum thermal bath scheme proposed by (*Dammak*) to include self-consistent quantum nuclear effects, when used in conjunction with the *fix nve* or *fix nph* commands.

Classical molecular dynamics simulation does not include any quantum nuclear effect. Quantum treatment of the vibrational modes will introduce zero point energy into the system, alter the energy power spectrum and bias the heat capacity from the classical limit. Missing all the quantum nuclear effects, classical MD cannot model systems at temperatures lower than their classical limits. This effect is especially important for materials with a large population of hydrogen atoms and thus higher classical limits.

The equation of motion implemented by this command follows a Langevin form:

$$m_i a_i = f_i + R_i - m_i \gamma v_i$$

Here  $m_i$ ,  $a_i$ ,  $f_i$ ,  $R_i$ ,  $\gamma$ , and  $v_i$  represent in this order mass, acceleration, force exerted by all other atoms, random force, frictional coefficient (the inverse of damping parameter damp), and velocity. The random force  $R_i$  is “colored” so that any vibrational mode with frequency  $\omega$  will have a temperature-sensitive energy  $\theta(\omega, T)$  which resembles the energy expectation for a quantum harmonic oscillator with the same natural frequency:

$$\theta(\omega T) = \frac{\hbar}{2} + \hbar \omega \left[ \exp\left(\frac{\hbar \omega}{k_B T}\right) - 1 \right]^{-1}$$

To efficiently generate the random forces, we employ the method of (*Barrat*), that circumvents the need to generate all random forces for all times before the simulation. The memory requirement of this approach is less demanding and independent of the simulation duration. Since the total random force  $R_{tot}$  does not necessarily vanish for a finite number of atoms,  $R_i$  is replaced by  $R_i - \frac{R_{tot}}{N_{tot}}$  to avoid collective motion of the system.

The *temp* parameter sets the target quantum temperature. LAMMPS will still have an output temperature in its thermo style. That is the instantaneous classical temperature  $T^{cl}$  derived from the atom velocities at thermal equilibrium. A non-zero  $T^{cl}$  will be present even when the quantum temperature approaches zero. This is associated with zero-point energy at low temperatures.

$$T^{cl} = \sum \frac{m_i v_i^2}{3Nk_B}$$

The *damp* parameter is specified in time units, and it equals the inverse of the frictional coefficient  $\gamma$ .  $\gamma$  should be as small as possible but slightly larger than the timescale of anharmonic coupling in the system which is about 10 ps to 100 ps. When  $\gamma$  is too large, it gives an energy spectrum that differs from the desired Bose-Einstein spectrum. When  $\gamma$  is too small, the quantum thermal bath coupling to the system will be less significant than anharmonic effects, reducing to a classical limit. We find that setting  $\gamma$  between 5 THz and 1 THz could be appropriate depending on the system.

The random number *seed* is a positive integer used to initiate a Marsaglia random number generator. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The *f\_max* parameter truncate the noise frequency domain so that vibrational modes with frequencies higher than *f\_max* will not be modulated. If we denote  $\Delta t$  as the time interval for the MD integration, *f\_max* is always reset by the code to

make  $\alpha = (int)(2 f_{max} \Delta t)^{-1}$  a positive integer and print out relative information. An appropriate value for the cutoff frequency  $f_{max}$  would be around  $2\sim 3 f_D$ , where  $f_D$  is the Debye frequency.

The  $N_f$  parameter is the frequency grid size, the number of points from 0 to  $f_{max}$  in the frequency domain that will be sampled.  $3*2N_f$  per-atom random numbers are required in the random force generation and there could be as many atoms as in the whole simulation that can migrate into every individual processor. A larger  $N_f$  provides a more accurate sampling of the spectrum while consumes more memory. With fixed  $f_{max}$  and  $\gamma$ ,  $N_f$  should be big enough to converge the classical temperature  $T^{cl}$  as a function of target quantum bath temperature. Memory usage per processor could be from 10 to 100 MBytes.

---

**Note:** Unlike the *fix nvt* command which performs Nose/Hoover thermostating AND time integration, this fix does NOT perform time integration. It only modifies forces to a colored thermostat. Thus you must use a separate time integration fix, like *fix nve* or *fix nph* to actually update the velocities and positions of atoms (as shown in the examples). Likewise, this fix should not normally be used with other fixes or commands that also specify system temperatures , e.g. *fix nvt* and *fix temp/rescale*.

---

## 2.181.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix. However, in a statistical sense, a restarted simulation should produce similar behaviors of the system.

This fix is not invoked during *energy minimization*.

---

## 2.181.5 Restrictions

This fix style is part of the QTB package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

---

## 2.181.6 Related commands

*fix nve*, *fix nph*, *fix langevin*, *fix qbmsst*

---

## 2.181.7 Default

The keyword defaults are temp = 300, damp = 1, seed = 880302, f\_max=200.0 and N\_f = 100.

---

**(Dammak)** Dammak, Chalopin, Laroche, Hayoun, and Greffet, Phys Rev Lett, 103, 190601 (2009).

**(Barrat)** Barrat and Rodney, J. Stat. Phys, 144, 679 (2011).

## 2.182 fix reaxff/bonds command

Accelerator Variants: *reaxff/bonds/kk*

### 2.182.1 Syntax

```
fix ID group-ID reaxff/bonds Nevery filename
```

- ID, group-ID are documented in *fix* command
- reax/bonds = style name of this fix command
- Nevery = output interval in timesteps
- filename = name of output file

### 2.182.2 Examples

```
fix 1 all reaxff/bonds 100 bonds.reaxff
```

### 2.182.3 Description

Write out the bond information computed by the ReaxFF potential specified by *pair\_style reaxff* in the exact same format as the original stand-alone ReaxFF code of Adri van Duin. The bond information is written to *filename* on timesteps that are multiples of *Nevery*, including timestep 0. For time-averaged chemical species analysis, please see the *fix reaxff/species* command.

The specified group-ID is ignored by this fix.

The format of the output file should be reasonably self-explanatory. The meaning of the column header abbreviations is as follows:

- id = atom id
- type = atom type
- nb = number of bonds
- id\_1 = atom id of first bond
- id\_nb = atom id of Nth bond
- mol = molecule id
- bo\_1 = bond order of first bond
- bo\_nb = bond order of Nth bond
- abo = atom bond order (sum of all bonds)
- nlp = number of lone pairs
- q = atomic charge

If the filename ends with “.gz”, the output file is written in gzipped format. A gzipped dump file will be about 3x smaller than the text version, but will also take longer to write.

## 2.182.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.182.5 Restrictions

The fix reaxff/bonds command requires that the *pair\_style reaxff* is invoked. This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

To write gzipped bond files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option.

## 2.182.6 Related commands

*pair\_style reaxff*, *fix reaxff/species*

## 2.182.7 Default

none

## 2.183 fix reaxff/species command

Accelerator Variants: *reaxff/species/kk*

### 2.183.1 Syntax

```
fix ID group-ID reaxff/species Nevery Nrepeat Nfreq filename keyword value ...
```

- ID, group-ID are documented in *fix* command
- reaxff/species = style name of this command
- Nevery = sample bond-order every this many timesteps
- Nrepeat = # of bond-order samples used for calculating averages

- *Nfreq* = calculate average bond-order every this many timesteps
- *filename* = name of output file
- zero or more keyword/value pairs may be appended
- *keyword* = *cutoff* or *element* or *position* or *delete* or *delete\_rate\_limit*

```

cutoff value = I J Cutoff
  I, J = atom types (see asterisk form below)
  Cutoff = Bond-order cutoff value for this pair of atom types
element value = Element1, Element2, ...
position value = posfreq filepos
  posfreq = write position files every this many timestep
  filepos = name of position output file
delete value = filedel keyword value
  filedel = name of delete species output file
  keyword = specieslist or masslimit
    specieslist value = Nspecies Species1 Species2 ...
      Nspecies = number of species in list
    masslimit value = massmin massmax
      massmin = minimum molecular weight of species to delete
      massmax = maximum molecular weight of species to delete
delete_rate_limit value = Nlimit Nsteps
  Nlimit = maximum number of deletions allowed to occur within interval
  Nsteps = the interval (number of timesteps) over which to count deletions

```

## 2.183.2 Examples

```

fix 1 all reaxff/species 10 10 100 species.out
fix 1 all reaxff/species 1 2 20 species.out cutoff 1 1 0.40 cutoff 1 2*3 0.55
fix 1 all reaxff/species 1 100 100 species.out element Au O H position 1000 AuOH.pos
fix 1 all reaxff/species 1 100 100 species.out delete species.del masslimit 0 50

```

## 2.183.3 Description

Write out the chemical species information computed by the ReaxFF potential specified by *pair\_style reaxff*. Bond-order values (either averaged or instantaneous, depending on value of *Nrepeat*) are used to determine chemical bonds. Every *Nfreq* timesteps, chemical species information is written to *filename* as a two line output. The first line is a header containing labels. The second line consists of the following: timestep, total number of molecules, total number of distinct species, number of molecules of each species. In this context, “species” means a unique molecule. The chemical formula of each species is given in the first line.

**Warning:** In order to compute averaged data, it is required that there are no neighbor list rebuilds for at least *Nrepeat*\**Nevery* steps preceding each *Nfreq* step. For that reason, fix *reaxff/species* may change your neighbor list settings. Reneighboring will occur no more frequently than every *Nrepeat*\**Nevery* timesteps, and will occur less frequently if *Nfreq* is not a multiple of *Nrepeat*\**Nevery*. There will be a warning message showing the new settings. Having a *Nfreq* setting that is larger than what is required for correct computation of the ReaxFF force field interactions, in combination with certain *Nrepeat* and *Nevery* settings, can thus lead to incorrect results. For typical ReaxFF calculations, reneighboring only every 100 steps is already quite a low frequency.

If the filename ends with “.gz”, the output file is written in gzipped format. A gzipped dump file will be about 3x smaller than the text version, but will also take longer to write.

New in version 15Jun2023: Support for wildcards added

Optional keyword *cutoff* can be assigned to change the minimum bond-order values used in identifying chemical bonds between pairs of atoms. Bond-order cutoffs should be carefully chosen, as bond-order cutoffs that are too small may include too many bonds (which will result in an error), while cutoffs that are too large will result in fragmented molecules. The default cutoff of 0.3 usually gives good results. A wildcard asterisk can be used in place of or in conjunction with the I,J arguments to set the bond-order cutoff for multiple pairs of atom types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *n* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive).

The optional keyword *element* can be used to specify the chemical symbol printed for each LAMMPS atom type. The number of symbols must match the number of LAMMPS atom types and each symbol must consist of 1 or 2 alphanumeric characters. By default, these symbols are the same as the chemical identity of each LAMMPS atom type, as specified by the *ReaxFF pair\_coeff* command and the ReaxFF force field file.

The optional keyword *position* writes center-of-mass positions of each identified molecules to file *filepos* every *posfreq* timesteps. The first line contains information on timestep, total number of molecules, total number of distinct species, and box dimensions. The second line is a header containing labels. From the third line downward, each molecule writes a line of output containing the following information: molecule ID, number of atoms in this molecule, chemical formula, total charge, and center-of-mass xyz positions of this molecule. The xyz positions are in fractional coordinates relative to the box dimensions.

For the keyword *position*, the *filepos* is the name of the output file. It can contain the wildcard character “\*”. If the “\*” character appears in *filepos*, then one file per snapshot is written at *posfreq* and the “\*” character is replaced with the timestep value. For example, AuO.pos.\* becomes AuO.pos.0, AuO.pos.1000, etc.

New in version 3Aug2022.

The optional keyword *delete* enables the periodic removal of molecules from the system (*Gissinger*). Criteria for deletion can be either a list of specific chemical formulae or a range of molecular weights. Molecules are deleted every *Nfreq* timesteps, and bond connectivity is determined using the *Nevery* and *Nrepeat* keywords. The *filedel* argument is the name of the output file that records the species that are removed from the system. The *specieslist* keyword permits specific chemical species to be deleted. The *Nspecies* argument specifies how many species are eligible for deletion and is followed by a list of chemical formulae, whose strings are compared to species identified by this fix. For example, “specieslist 2 CO CO2” deletes molecules that are identified as “CO” and “CO2” in the species output file. When using the *specieslist* keyword, the *filedel* file has the following format: the first line lists the chemical formulae eligible for deletion, and each additional line contains the timestep on which a molecule deletion occurs and the number of each species deleted on that timestep. The *masslimit* keyword permits deletion of molecules with molecular weights between *massmin* and *massmax*. When using the *masslimit* keyword, each line of the *filedel* file contains the timestep on which deletions occurs, followed by how many of each species are deleted (with quantities preceding chemical formulae). The *specieslist* and *masslimit* keywords cannot both be used in the same *reaxff/species* fix. The *delete\_rate\_limit* keyword can enforce an upper limit on the overall rate of molecule deletion. The number of deletion occurrences is limited to *Nlimit* within an interval of *Nsteps* timesteps. *Nlimit* can be specified with an equal-style *variable*. When using the *delete\_rate\_limit* keyword, no deletions are permitted to occur within the first *Nsteps* timesteps of the first run (after reading a either a data or restart file).

The *Nevery*, *Nrepeat*, and *Nfreq* arguments specify on what timesteps the bond-order values are sampled to get the average bond order. The species analysis is performed using the average bond-order on timesteps that are a multiple of *Nfreq*. The average is over *Nrepeat* bond-order samples, computed in the preceding portion of the simulation every *Nevery* timesteps. *Nfreq* must be a multiple of *Nevery* and *Nevery* must be non-zero even if *Nrepeat* is 1. Also, the timesteps contributing to the average bond-order cannot overlap, i.e. *Nrepeat*\**Nevery* can not exceed *Nfreq*.

For example, if `Nevery=2`, `Nrepeat=6`, and `Nfreq=100`, then bond-order values on timesteps 90,92,94,96,98,100 will be used to compute the average bond-order for the species analysis output on timestep 100.

---

## 2.183.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes both a global vector of length 2 and a per-atom vector, either of which can be accessed by various *output commands*. The values in the global vector are “intensive”.

The 2 values in the global vector are as follows:

1. total number of molecules
2. total number of distinct species

The per-atom vector stores the molecule ID for each atom as identified by the fix. If an atom is not in a molecule, its ID will be 0. For atoms in the same molecule, the molecule ID for all of them will be the same and will be equal to the smallest atom ID of any atom in the molecule.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 2.183.5 Restrictions

The “fix reaxff/species” requires that *pair\_style reaxff* is used. This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

To write gzipped species files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option.

## 2.183.6 Related commands

*pair\_style reaxff*, *fix reaxff/bonds*

## 2.183.7 Default

The default values for bond-order cutoffs are 0.3 for all I-J pairs. The default element symbols are taken from the ReaxFF pair\_coeff command. Position files are not written by default.

**(Gissinger)** Jacob R. Gissinger, Scott R. Zavada, Joseph G. Smith, Josh Kemppainen, Ivan Gallegos, Gregory M. Odegard, Emilie J. Siochi, and Kristopher E. Wise, Carbon, 202, 336-347 (2023).

## 2.184 fix recenter command

### 2.184.1 Syntax

```
fix ID group-ID recenter x y z keyword value ...
```

- ID, group-ID are documented in *fix* command
- recenter = style name of this fix command
- x,y,z = constrain center-of-mass to these coords (distance units), any coord can also be NULL or INIT (see below)
- zero or more keyword/value pairs may be appended
- keyword = *shift* or *units*

*shift* value = group-ID

group-ID = group of atoms whose coords are shifted

*units* value = *box* or *lattice* or *fraction*

### 2.184.2 Examples

```
fix 1 all recenter 0.0 0.5 0.0
fix 1 all recenter INIT INIT NULL
fix 1 all recenter INIT 0.0 0.0 units box
```

### 2.184.3 Description

Constrain the center-of-mass position of a group of atoms by adjusting the coordinates of the atoms every timestep. This is simply a small shift that does not alter the dynamics of the system or change the relative coordinates of any pair of atoms in the group. This can be used to ensure the entire collection of atoms (or a portion of them) do not drift during the simulation due to random perturbations (e.g. *fix langevin* thermostating).

Distance units for the x,y,z values are determined by the setting of the *units* keyword, as discussed below. One or more x,y,z values can also be specified as NULL, which means exclude that dimension from this operation. Or it can be specified as INIT which means to constrain the center-of-mass to its initial value at the beginning of the run.

The center-of-mass (COM) is computed for the group specified by the fix. If the current COM is different than the specified x,y,z, then a group of atoms has their coordinates shifted by the difference. By default the shifted group is also the group specified by the fix. A different group can be shifted by using the *shift* keyword. For example, the COM could be computed on a protein to keep it in the center of the simulation box. But the entire system (protein + water) could be shifted.

If the *units* keyword is set to *box*, then the distance units of x,y,z are defined by the *units* command - e.g. Angstroms for *real* units. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. A *fraction* value means a fractional distance between the lo/hi box boundaries, e.g. 0.5 = middle of the box. The default is to use lattice units.

Note that the *velocity* command can be used to create velocities with zero aggregate linear and/or angular momentum.

---

**Note:** This fix performs its operations at the same point in the timestep as other time integration fixes, such as *fix nve*, *fix nvt*, or *fix npt*. Thus fix recenter should normally be the last such fix specified in the input script, since the adjustments it makes to atom coordinates should come after the changes made by time integration. LAMMPS will warn you if your fixes are not ordered this way.

---

---

**Note:** If you use this fix on a small group of atoms (e.g. a molecule in solvent) without using the *shift* keyword to adjust the positions of all atoms in the system, then the results can be unpredictable. For example, if the molecule is pushed consistently in one direction by a flowing solvent, its velocity will increase. But its coordinates will be re-centered, meaning it is moved back towards the force. Thus over time, the velocity and effective temperature of the molecule could become very large, though it won't actually be moving due to the re-centering. If you are thermostating the entire system, then the solvent would be cooled to compensate. A better solution for this simulation scenario is to use the *fix spring* command to tether the molecule in place.

---

## 2.184.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the distance the group is moved by fix recenter.

This fix also computes global 3-vector which can be accessed by various *output commands*. The 3 quantities in the vector are xyz components of displacement applied to the group of atoms by the fix.

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.184.5 Restrictions

This fix should not be used with an x,y,z setting that causes a large shift in the system on the first timestep, due to the requested COM being very different from the initial COM. This could cause atoms to be lost, especially in parallel. Instead, use the *displace\_atoms* command, which can be used to move atoms a large distance.

## 2.184.6 Related commands

*fix momentum, velocity*

## 2.184.7 Default

The option defaults are shift = fix group-ID, and units = lattice.

## 2.185 fix restrain command

### 2.185.1 Syntax

```
fix ID group-ID restrain keyword args ...
```

- ID, group-ID are documented in *fix* command
- restrain = style name of this fix command
- one or more keyword/arg pairs may be appended
- keyword = *bond* or *lbound* or *angle* or *dihedral*

*bond* args = atom1 atom2 Kstart Kstop r0start (r0stop)

atom1,atom2 = IDs of two atoms in bond

Kstart,Kstop = restraint coefficients at start/end of run (energy units)

r0start = equilibrium bond distance at start of run (distance units)

r0stop = equilibrium bond distance at end of run (optional) (distance units). If   
→not

specified it is assumed to be equal to r0start

*lbound* args = atom1 atom2 Kstart Kstop r0start (r0stop)

atom1,atom2 = IDs of two atoms in bond

Kstart,Kstop = restraint coefficients at start/end of run (energy units)

r0start = equilibrium bond distance at start of run (distance units)

r0stop = equilibrium bond distance at end of run (optional) (distance units). If   
→not

specified it is assumed to be equal to r0start

*angle* args = atom1 atom2 atom3 Kstart Kstop theta0

atom1,atom2,atom3 = IDs of three atoms in angle, atom2 = middle atom

Kstart,Kstop = restraint coefficients at start/end of run (energy units)

theta0 = equilibrium angle theta (degrees)

*dihedral* args = atom1 atom2 atom3 atom4 Kstart Kstop phi0 keyword/value

atom1,atom2,atom3,atom4 = IDs of 4 atoms in dihedral in linear order

Kstart,Kstop = restraint coefficients at start/end of run (energy units)

phi0 = equilibrium dihedral angle phi (degrees)

keyword/value = optional keyword value pairs. supported keyword/value pairs:

mult n = dihedral multiplicity n (integer >= 0, default = 1)

### 2.185.2 Examples

```
fix holdem all restrain bond 45 48 2000.0 2000.0 2.75
fix holdem all restrain lbound 45 48 2000.0 2000.0 2.75
fix holdem all restrain dihedral 1 2 3 4 2000.0 2000.0 120.0
fix holdem all restrain bond 45 48 2000.0 2000.0 2.75 dihedral 1 2 3 4 2000.0 2000.0 120.
→0
fix texas_holdem all restrain dihedral 1 2 3 4 0.0 2000.0 120.0 dihedral 1 2 3 5 0.0
→2000.0 -120.0 dihedral 1 2 3 6 0.0 2000.0 0.0
```

### 2.185.3 Description

Restrain the motion of the specified sets of atoms by making them part of a bond or angle or dihedral interaction whose strength can vary over time during a simulation. This is functionally similar to creating a bond or angle or dihedral for the same atoms in a data file, as specified by the `read_data` command, albeit with a time-varying prefactor coefficient, and except for exclusion rules, as explained below.

For the purpose of force field parameter-fitting or mapping a molecular potential energy surface, this fix reduces the hassle and risk associated with modifying data files. In other words, use this fix to temporarily force a molecule to adopt a particular conformation. To create a permanent bond or angle or dihedral, you should modify the data file.

---

**Note:** Adding a bond/angle/dihedral with this command does not apply the exclusion rules and weighting factors specified by the `special_bonds` command to atoms in the restraint that are now bonded (1-2,1-3,1-4 neighbors) as a result. If they are close enough to interact in a `pair_style` sense (non-bonded interaction), then the bond/angle/dihedral restraint interaction will simply be superposed on top of that interaction.

---

The group-ID specified by this fix is ignored.

The second example above applies a restraint to hold the dihedral angle formed by atoms 1, 2, 3, and 4 near 120 degrees using a constant restraint coefficient. The fourth example applies similar restraints to multiple dihedral angles using a restraint coefficient that increases from 0.0 to 2000.0 over the course of the run.

---

**Note:** Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the `run` command, this energy can be added to the system's potential energy for thermodynamic output (see below). For energy minimization via the `minimize` command, this energy must be added to the system's potential energy to formulate a self-consistent minimization problem (see below).

---

In order for a restraint to be effective, the restraint force must typically be significantly larger than the forces associated with conventional force field terms. If the restraint is applied during a dynamics run (as opposed to during an energy minimization), a large restraint coefficient can significantly reduce the stable timestep size, especially if the atoms are initially far from the preferred conformation. You may need to experiment to determine what value of  $K$  works best for a given application.

For the case of finding a minimum energy structure for a single molecule with particular restraints (e.g. for fitting force field parameters or constructing a potential energy surface), commands such as the following may be useful:

```
# minimize molecule energy with restraints
velocity all create 600.0 8675309 mom yes rot yes dist gaussian
fix NVE all nve
fix TFIX all langevin 600.0 0.0 100 24601
fix REST all restrain dihedral 2 1 3 8 0.0 5000.0 ${angle1} dihedral 3 1 2 9 0.0 5000.0 $
→{angle2}
fix_modify REST energy yes
run 10000
fix TFIX all langevin 0.0 0.0 100 24601
fix REST all restrain dihedral 2 1 3 8 5000.0 5000.0 ${angle1} dihedral 3 1 2 9 5000.0.
→5000.0 ${angle2}
fix_modify REST energy yes
run 10000
# sanity check for convergence
minimize 1e-6 1e-9 1000 1000000
# report unrestrained energies
```

(continues on next page)

(continued from previous page)

```
unfix REST
run 0
```

The *bond* keyword applies a bond restraint to the specified atoms using the same functional form used by the *bond\_style harmonic* command. The potential associated with the restraint is

$$E = K(r - r_0)^2$$

with the following coefficients:

- $K$  (energy/distance<sup>2</sup>)
- $r_0$  (distance)

$K$  and  $r_0$  are specified with the fix. Note that the usual 1/2 factor is included in  $K$ .

The *lbond* keyword applies a lower bound bond restraint to the specified atoms using the same functional form used by the *bond\_style harmonic* command if the distance between the atoms is smaller than the equilibrium bond distance and 0 otherwise. The potential associated with the restraint is

$$E = K(r - r_0)^2, \text{ if } r < r_0$$

$$E = 0, \text{ if } r \geq r_0$$

with the following coefficients:

- $K$  (energy/distance<sup>2</sup>)
- $r_0$  (distance)

$K$  and  $r_0$  are specified with the fix. Note that the usual 1/2 factor is included in  $K$ .

The *angle* keyword applies an angle restraint to the specified atoms using the same functional form used by the *angle\_style harmonic* command. The potential associated with the restraint is

$$E = K(\theta - \theta_0)^2$$

with the following coefficients:

- $K$  (energy)
- $\theta_0$  (degrees)

$K$  and  $\theta_0$  are specified with the fix.  $\theta_0$  is specified in degrees, but LAMMPS converts it to radians internally; hence  $K$  is effectively energy per radian<sup>2</sup>. Note that the usual 1/2 factor is included in  $K$ .

The *dihedral* keyword applies a dihedral restraint to the specified atoms using a simplified form of the function used by the *dihedral\_style charmm* command. The potential associated with the restraint is

$$E = K[1 + \cos(n\phi - d)]$$

with the following coefficients:

- $K$  (energy)

- $n$  (multiplicity,  $\geq 0$ )
- $d$  (degrees) =  $\phi_0 + 180$

$K$  and  $\phi_0$  are specified with the fix. Note that the value of the dihedral multiplicity  $n$  is set by default to 1. You can use the optional *mult* keyword to set it to a different positive integer. Also note that the energy will be a minimum when the current dihedral angle  $\phi$  is equal to  $\phi_0$ .

---

## 2.185.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy associated with this fix to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

---

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you **MUST** enable the *fix\_modify energy* option for this fix.

---

This fix computes a global scalar and a global vector of length 3, which can be accessed by various *output commands*. The scalar is the total potential energy for *all* the restraints as discussed above. The vector values are the sum of contributions to the following individual categories:

1. bond energy
2. angle energy
3. dihedral energy

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

## 2.185.5 Restrictions

none

## 2.185.6 Related commands

none

## 2.185.7 Default

none

## 2.186 fix rheo command

### 2.186.1 Syntax

```
fix ID group-ID rheo cut kstyle zmin keyword values...
```

- ID, group-ID are documented in *fix* command
- rheo = style name of this fix command
- cut = cutoff for the kernel (distance)
- kstyle = *quintic* or *RK0* or *RK1* or *RK2*
- zmin = minimal number of neighbors for reproducing kernels
- zero or more keyword/value pairs may be appended to args
- **keyword** = *thermal* or *interface/reconstruct* or *surface/detection* or *shift* or *rho/sum* or *density* or *self/mass* or *speed/sound*

*thermal* values = none, turns on thermal evolution

*interface/reconstruct* values = none, reconstructs interfaces with solid particles

*surface/detection* values = *sdstyle limit limit/splash*

*sdstyle* = *coordination* or *divergence*

*limit* = threshold for surface particles

*limit/splash* = threshold for splash particles

*shift* values = none, turns on velocity shifting

*rho/sum* values = none, uses the kernel to compute the density of particles

*self/mass* values = none, a particle uses its own mass in a rho summation

*density* values = *rho01*, ... *rho0N* (density)

*speed/sound* values = *cs0*, ... *csN* (velocity)

### 2.186.2 Examples

```
fix 1 all rheo 3.0 quintic 0 thermal density 0.1 0.1 speed/sound 10.0 1.0
fix 1 all rheo 3.0 RK1 10 shift surface/detection coordination 40
```

### 2.186.3 Description

New in version 29Aug2024.

Perform time integration for RHEO particles, updating positions, velocities, and densities. For an overview of other features available in the RHEO package, see [the RHEO howto](#).

The type of kernel is specified using *kstyle* and the cutoff is *cut*. Four kernels are currently available. The *quintic* kernel is a standard quintic spline function commonly used in SPH. The other options, *RK0*, *RK1*, and *RK2*, are zeroth, first, and second order reproducing. To generate a reproducing kernel, a particle must have sufficient neighbors inside the kernel cutoff distance (a coordination number) to accurately calculate moments. This threshold is set by *zmin*. If reproducing kernels are requested but a particle has fewer neighbors, then it will revert to a non-reproducing quintic kernel until it gains more neighbors.

To model temperature evolution, one must specify the *thermal* keyword, define a separate instance of *fix rheo/thermal*, and use atom style *rheo/thermal*.

By default, the density of solid RHEO particles does not evolve and forces with fluid particles are calculated using the current velocity of the solid particle. If the *interface/reconstruct* keyword is used, then the density and velocity of solid particles are alternatively reconstructed for every fluid-solid interaction to ensure no-slip and pressure-balanced boundaries. This is done by estimating the location of the fluid-solid interface and extrapolating fluid particle properties across the interface to calculate a temporary apparent density and velocity for a solid particle.

A modified form of Fickian particle shifting can be enabled with the *shift* keyword. This effectively shifts particle positions to generate a more uniform spatial distribution. Shifting currently does not consider the type of a particle and therefore may be inappropriate in systems consisting of multiple fluid phases.

In systems with free surfaces, the *surface/detection* keyword can be used to classify the location of particles as being within the bulk fluid, on a free surface, or isolated from other particles in a splash or droplet. Shifting is then disabled in the normal direction away from the free surface to prevent particles from diffusing away. Surface detection can also be used to control surface-nucleated effects like oxidation when used in combination with *fix rheo/oxidation*. Surface detection is not performed on solid bodies.

The *surface/detection* keyword takes three arguments: *sdstyle*, *limit*, and *limit/splash*. The first, *sdstyle*, specifies whether surface particles are identified using a coordination number (*coordination*) or the divergence of the local particle positions (*divergence*). The threshold value for a surface particle for either of these criteria is set by the numerical value of *limit*. Additionally, if a particle's coordination number is too low, i.e. if it has separated off from the bulk in a droplet, it is not possible to define surfaces and the particle is classified as a splash. The coordination threshold for this classification is set by the numerical value of *limit/splash*.

By default, RHEO integrates particles' densities using a mass diffusion equation. Alternatively, one can update densities every timestep by performing a kernel summation of the masses of neighboring particles by specifying the *rho/sum* keyword.

The *self/mass* keyword modifies the behavior of the density summation in *rho/sum*. Typically, the density  $\rho$  of a particle is calculated as the sum over neighbors

$$\rho_i = \sum_j W_{ij} M_j$$

where  $W_{ij}$  is the kernel, and  $M_j$  is the mass of particle  $j$ . The *self/mass* keyword augments this expression by replacing  $M_j$  with  $M_i$ . This may be useful in simulations of multiple fluid phases with large differences in density, ([Hu](#)).

The *density* keyword is used to specify the equilibrium density of each of the  $N$  particle types. It must be followed by  $N$  numerical values specifying each type's equilibrium density *rho0*.

The *speed/sound* keyword is used to specify the speed of sound of each of the  $N$  particle types. It must be followed by  $N$  numerical values specifying each type's speed of sound *cs*.

## 2.186.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.186.5 Restrictions

This fix must be used with atom style *rheo* or *rheo/thermal*. This fix must be used in conjunction with *fix rheo/pressure* and *fix rheo/viscosity*. If the *thermal* setting is used, there must also be an instance of *fix rheo/thermal*. The fix group must be set to all. Only one instance of fix *rheo* may be defined and it must be defined prior to all other RHEO fixes in the input script.

This fix is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.186.6 Related commands

*fix rheo/viscosity*, *fix rheo/pressure*, *fix rheo/thermal*, *pair rheo*, *compute rheo/property/atom*

## 2.186.7 Default

*rho0* and *cs* are set to 1.0 for all atom types.

## 2.187 fix rheo/oxidation command

### 2.187.1 Syntax

```
fix ID group-ID rheo/oxidation cut btype rsurf
```

- ID, group-ID are documented in *fix* command
- rheo/oxidation = style name of this fix command
- cut = maximum bond length (distance units)
- btype = type of bonds created
- rsurf = distance from surface to create bonds (distance units)

## 2.187.2 Examples

```
fix 1 all rheo/oxidation 1.5 2 0.0
fix 1 all rheo/oxidation 1.0 1 2.0
```

## 2.187.3 Description

New in version 29Aug2024.

This fix dynamically creates bonds on the surface of fluids to represent physical processes such as oxidation. It is intended for use with bond style *bond rheo/shell*.

Every timestep, particles check neighbors within a distance of *cut*. This distance must be smaller than the kernel length defined in *fix rheo*. Bonds of type *btype* are created between a fluid particle and either a fluid or solid neighbor. The fluid particles must also be on the fluid surface, or within a distance of *rsurf* from the surface. This process is further described in (Clemmer).

If used in conjunction with solid bodies, such as those generated by the *react* option of *fix rheo/thermal*, it is recommended to use a *hybrid bond style* with different bond types for solid and oxide bonds.

## 2.187.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.187.5 Restrictions

This fix must be used with the bond style *rheo/shell* and *fix rheo* with surface detection enabled.

This fix is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.188 fix rheo/pressure command

### 2.188.1 Syntax

```
fix ID group-ID rheo/pressure type1 pstyle1 args1 ... typeN pstyleN argsN
```

- ID, group-ID are documented in *fix* command
- rheo/pressure = style name of this fix command
- one or more types and pressure styles must be appended
- types = lists of types (see below)
- pstyle = *linear* or *taitwater* or *cubic*  
*linear* args = none  
*taitwater* args = none  
*cubic* args = cubic prefactor  $A_3$  (pressure/density<sup>2</sup>)

### 2.188.2 Examples

```
fix 1 all rheo/pressure * linear
fix 1 all rheo/pressure 1 linear 2 cubic 10.0
```

### 2.188.3 Description

New in version 29Aug2024.

This fix defines a pressure equation of state for RHEO particles. One can define different equations of state for different atom types. An equation must be specified for every atom type.

One first defines the atom *types*. A wild-card asterisk can be used in place of or in conjunction with the *types* argument to set the coefficients for multiple pairs of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the number of atom types, then an asterisk with no numeric values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $m$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive).

The *types* definition is followed by the pressure style, *pstyle*. Current options *linear*, *taitwater*, and *cubic*. Style *linear* is a linear equation of state with a particle pressure  $P$  calculated as

$$P = c(\rho - \rho_0)$$

where  $c$  is the speed of sound,  $\rho_0$  is the equilibrium density, and  $\rho$  is the current density of a particle. The numerical values of  $c$  and  $\rho_0$  are set in *fix rheo*. Style *cubic* is a cubic equation of state which has an extra argument  $A_3$ ,

$$P = c((\rho - \rho_0) + A_3(\rho - \rho_0)^3).$$

Style *taitwater* is Tait’s equation of state:

$$P = \frac{c^2 \rho_0}{7} \left[ \left( \frac{\rho}{\rho_0} \right)^7 - 1 \right].$$

## 2.188.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.188.5 Restrictions

This fix must be used with an atom style that includes density such as atom\_style rheo or rheo/thermal. This fix must be used in conjunction with *fix rheo*. The fix group must be set to all. Only one instance of fix rheo/pressure can be defined.

This fix is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

→specific/heat * constant 1.0

```

## 2.189.3 Description

New in version 29Aug2024.

This fix performs time integration of temperature for atom style rheo/thermal. In addition, it defines multiple thermal properties of particles and handles melting/solidification, if applicable. For more details on phase transitions in RHEO, see [the RHEO howto](#).

Note that the temperature of a particle is always derived from the energy. This implies the *temperature* attribute of [the set command](#) does not affect particles. Instead, one should use the *sph/e* attribute.

For each atom type, one can define expressions for the *conductivity*, *specific/heat*, *latent/heat*, and critical temperature (*Tfreeze*). The conductivity and specific heat must be defined for all atom types. The latent heat and critical temperature are optional. However, a critical temperature must be defined to specify a latent heat.

Note, if shifting is turned on in [fix rheo](#), the gradient of the energy is used to shift energies. This may be inappropriate in systems with multiple atom types with different specific heats.

For each property, one must first define a list of atom types. A wild-card asterisk can be used in place of or in conjunction with the *types* argument to set the coefficients for multiple pairs of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *m* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive).

The *types* definition for each property is followed by the style. Currently, the only option is *constant*. Style *constant* simply applies a constant value of respective property to each particle of the assigned type.

The *react* keyword controls whether bonds are created/deleted when particles transition between a fluid and solid state. This option only applies to atom types that have a defined value of *Tfreeze*. When a fluid particle’s temperature drops below *Tfreeze*, bonds of type *btype* are created between nearby solid particles within a distance of *cut*. The particle’s status also swaps to a solid state. When a solid particle’s temperature rises above *Tfreeze*, all bonds of type *btype* are broken and the particle’s status swaps to a fluid state.

## 2.189.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.189.5 Restrictions

This fix must be used with an atom style that includes temperature, heatflow, and conductivity such as *atom\_style rheo/thermal*. This fix must be used in conjunction with *fix rheo* with the *thermal* setting. The fix group must be set to all. Only one instance of fix rheo/pressure can be defined.

This fix is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

```

## 2.190.3 Description

New in version 29Aug2024.

This fix defines a viscosity for RHEO particles. One can define different viscosities for different atom types, but a viscosity must be specified for every atom type.

One first defines the atom *types*. A wild-card asterisk can be used in place of or in conjunction with the *types* argument to set the coefficients for multiple pairs of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the number of atom types, then an asterisk with no numeric values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $m$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive).

The *types* definition is followed by the viscosity style, *vstyle*. Two options are available, *constant* and *power*. Style *constant* simply applies a constant value of the viscosity *eta* to each particle of the assigned type. Style *power* is a Herschel-Bulkley constitutive equation for the stress  $\tau$

$$\tau = \left( \frac{\tau_0}{\dot{\gamma}} + K \dot{\gamma}^{n-1} \right) \dot{\gamma}, \tau \geq \tau_0$$

where  $\dot{\gamma}$  is the strain rate and  $\tau_0$  is the critical yield stress, below which  $\dot{\gamma} = 0.0$ . To avoid divergences, this expression is regularized by defining a critical strain rate *gd0*. If the local strain rate on a particle falls below this limit, a constant viscosity of *eta* is assigned. This implies a value of

$$\tau_0 = \eta \dot{\gamma}_0 - K \dot{\gamma}_0^N$$

## 2.190.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.190.5 Restrictions

This fix must be used with an atom style that includes viscosity such as atom\_style rheo or rheo/thermal. This fix must be used in conjunction with *fix rheo*. The fix group must be set to all. Only one instance of fix rheo/viscosity can be defined.

This fix is part of the RHEO package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.190.6 Related commands

*fix rheo*, *pair rheo*, *compute rheo/property/atom*

## 2.190.7 Default

none

## 2.191 fix rhok command

### 2.191.1 Syntax

```
fix ID group-ID rhok nx ny nz K a
```

- ID, group-ID are documented in *fix* command
- nx, ny, nz = k-vector of collective density field
- K = spring constant of bias potential
- a = anchor point of bias potential

### 2.191.2 Examples

```
fix bias all rhok 16 0 0 4.0 16.0
fix 1 all npt temp 0.8 0.8 4.0 z 2.2 2.2 8.0
# output of 4 values from fix rhok: U_bias rho_k_RE rho_k_IM \rho_k\
thermo_style custom step temp pzz lz f_bias f_bias[1] f_bias[2] f_bias[3]
```

### 2.191.3 Description

The fix applies a force to atoms given by the potential

$$U = \frac{1}{2} K (|\rho_{\vec{k}}| - a)^2$$
$$\rho_{\vec{k}} = \sum_j^N \exp(-i\vec{k} \cdot \vec{r}_j) / \sqrt{N}$$
$$\vec{k} = (2\pi n_x / L_x, 2\pi n_y / L_y, 2\pi n_z / L_z)$$

as described in ([Pedersen](#)).

This field, which biases configurations with long-range order, can be used to study crystal-liquid interfaces and determine melting temperatures ([Pedersen](#)).

An example of using the interface pinning method is located in the *examples/PACKAGES/rhok* directory.

## 2.191.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the potential energy calculated by the fix to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the potential energy discussed in the preceding paragraph. The scalar stored by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

## 2.191.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.201.3 Description

Treat one or more sets of atoms as independent rigid bodies. This means that each timestep the total force and torque on each rigid body is computed as the sum of the forces and torques on its constituent particles. The coordinates, velocities, and orientations of the atoms in each body are then updated so that the body moves and rotates as a single entity. This is implemented by creating internal data structures for each rigid body and performing time integration on these data structures. Positions, velocities, and orientations of the constituent particles are regenerated from the rigid body data structures in every time step. This restricts which operations and fixes can be applied to rigid bodies. See below for a detailed discussion.

Examples of large rigid bodies are a colloidal particle, or portions of a biomolecule such as a protein.

Example of small rigid bodies are patchy nanoparticles, such as those modeled in [this paper](#) by Sharon Glotzer's group, clumps of granular particles, lipid molecules consisting of one or more point dipoles connected to other spheroids or ellipsoids, irregular particles built from line segments (2d) or triangles (3d), and coarse-grain models of nano or colloidal particles consisting of a small number of constituent particles. Note that the *fix shake* command can also be used to rigidify small molecules of 2, 3, or 4 atoms, e.g. water molecules. That fix treats the constituent atoms as point masses.

These fixes also update the positions and velocities of the atoms in each rigid body via time integration, in the NVE, NVT, NPT, or NPH ensemble, as described below.

There are two main variants of this fix, *fix rigid* and *fix rigid/small*. The NVE/NVT/NPT/NHT versions belong to one of the two variants, as their style names indicate.

---

**Note:** Not all of the *bodystyle* options and keyword/value options are available for both the *rigid* and *rigid/small* variants. See details below.

---

The *rigid* styles are typically the best choice for a system with a small number of large rigid bodies, each of which can extend across the domain of many processors. It operates by creating a single global list of rigid bodies, which all processors contribute to. MPI\_Allreduce operations are performed each timestep to sum the contributions from each processor to the force and torque on all the bodies. This operation will not scale well in parallel if large numbers of rigid bodies are simulated.

The *rigid/small* styles are typically best for a system with a large number of small rigid bodies. Each body is assigned to the atom closest to the geometrical center of the body. The fix operates using local lists of rigid bodies owned by each processor and information is exchanged and summed via local communication between neighboring processors when ghost atom info is accumulated.

---

**Note:** To use the *rigid/small* styles the ghost atom cutoff must be large enough to span the distance between the atom that owns the body and every other atom in the body. This distance value is printed out when the rigid bodies are defined. If the *pair\_style* cutoff plus neighbor skin does not span this distance, then you should use the *comm\_modify cutoff* command with a setting epsilon larger than the distance.

---

Which of the two variants is faster for a particular problem is hard to predict. The best way to decide is to perform a short test run. Both variants should give identical numerical answers for short runs. Long runs should give statistically

similar results, but round-off differences may accumulate to produce divergent trajectories.

---

**Note:** You should not update the atoms in rigid bodies via other time-integration fixes (e.g. *fix nve*, *fix nvt*, *fix npt*, *fix move*), or you will have conflicting updates to positions and velocities resulting in unphysical behavior in most cases. When performing a hybrid simulation with some atoms in rigid bodies, and some not, a separate time integration fix like *fix nve* or *fix nvt* should be used for the non-rigid particles.

---

---

**Note:** These fixes are overkill if you simply want to hold a collection of atoms stationary or have them move with a constant velocity. A simpler way to hold atoms stationary is to not include those atoms in your time integration fix. E.g. use “fix 1 mobile nve” instead of “fix 1 all nve”, where “mobile” is the group of atoms that you want to move. You can move atoms with a constant velocity by assigning them an initial velocity (via the *velocity* command), setting the force on them to 0.0 (via the *fix setforce* command), and integrating them as usual (e.g. via the *fix nve* command).

---

**Warning:** The aggregate properties of each rigid body are calculated at the start of a simulation run and are maintained in internal data structures. The properties include the position and velocity of the center-of-mass of the body, its moments of inertia, and its angular momentum. This is done using the properties of the constituent atoms of the body at that point in time (or see the *infile* keyword option). Thereafter, changing these properties of individual atoms in the body will have no effect on a rigid body’s dynamics, unless they effect any computation of per-atom forces or torques. If the keyword *reinit* is set to *yes* (the default), the rigid body data structures will be recreated at the beginning of each *run* command; if the keyword *reinit* is set to *no*, the rigid body data structures will be built only at the very first *run* command and maintained for as long as the rigid fix is defined. For example, you might think you could displace the atoms in a body or add a large velocity to each atom in a body to make it move in a desired direction before a second run is performed, using the *set* or *displace\_atoms* or *velocity* commands. But these commands will not affect the internal attributes of the body unless *reinit* is set to *yes*. With *reinit* set to *no* (or using the *infile* option, which implies *reinit no*) the position and velocity of individual atoms in the body will be reset when time integration starts again.

---

Each rigid body must have two or more atoms. An atom can belong to at most one rigid body. Which atoms are in which bodies can be defined via several options.

---

**Note:** With the *rigid/small* styles, which require that *bodystyle* be specified as *molecule* or *custom*, you can define a system that has no rigid bodies initially. This is useful when you are using the *mol* keyword in conjunction with another fix that is adding rigid bodies on-the-fly as molecules, such as *fix deposit* or *fix pour*.

---

For *bodystyle single* the entire fix group of atoms is treated as one rigid body. This option is only allowed for the *rigid* styles.

For *bodystyle molecule*, atoms are grouped into rigid bodies by their respective molecule IDs: each set of atoms in the fix group with the same molecule ID is treated as a different rigid body. This option is allowed for both the *rigid* and *rigid/small* styles. Note that atoms with a molecule ID = 0 will be treated as a single rigid body. For a system with atomic solvent (typically this is atoms with molecule ID = 0) surrounding rigid bodies, this may not be what you want. Thus you should be careful to use a fix group that only includes atoms you want to be part of rigid bodies.

*Bodystyle custom* is similar to *bodystyle molecule* except that it is more flexible in using other per-atom properties to define the sets of atoms that form rigid bodies. A custom per-atom integer vector defined by the *fix property/atom* command can be used. Or an *atom-style* or *atomfile-style variable* can be used; the floating-point value produced by the variable is rounded to an integer. As with *bodystyle molecule*, each set of atoms in the fix groups with the same integer value is treated as a different rigid body. Since *fix property/atom* custom vectors and *atom-style* variables produce

values for all atoms, you should be careful to use a fix group that only includes atoms you want to be part of rigid bodies.

---

**Note:** To compute the initial center-of-mass position and other properties of each rigid body, the image flags for each atom in the body are used to “unwrap” the atom coordinates. Thus you must ensure that these image flags are consistent so that the unwrapping creates a valid rigid body (one where the atoms are close together), particularly if the atoms in a single rigid body straddle a periodic boundary. This means the input data file or restart file must define the image flags for each atom consistently or that you have used the *set* command to specify them correctly. If a dimension is non-periodic then the image flag of each atom must be 0 in that dimension, else an error is generated.

---

The *force* and *torque* keywords discussed next are only allowed for the *rigid* styles.

By default, each rigid body is acted on by other atoms which induce an external force and torque on its center of mass, causing it to translate and rotate. Components of the external center-of-mass force and torque can be turned off by the *force* and *torque* keywords. This may be useful if you wish a body to rotate but not translate, or vice versa, or if you wish it to rotate or translate continuously unaffected by interactions with other particles. Note that if you expect a rigid body not to move or rotate by using these keywords, you must ensure its initial center-of-mass translational or angular velocity is 0.0. Otherwise the initial translational or angular momentum the body has will persist.

An xflag, yflag, or zflag set to *off* means turn off the component of force or torque in that dimension. A setting of *on* means turn on the component, which is the default. Which rigid body(s) the settings apply to is determined by the first argument of the *force* and *torque* keywords. It can be an integer M from 1 to Nbody, where Nbody is the number of rigid bodies defined. A wild-card asterisk can be used in place of, or in conjunction with, the M argument to set the flags for multiple rigid bodies. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If N = the number of rigid bodies, then an asterisk with no numeric values means all bodies from 1 to N. A leading asterisk means all bodies from 1 to n (inclusive). A trailing asterisk means all bodies from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that you can use the *force* or *torque* keywords as many times as you like. If a particular rigid body has its component flags set multiple times, the settings from the final keyword are used.

---

**Note:** For computational efficiency, you may wish to turn off pairwise and bond interactions within each rigid body, as they no longer contribute to the motion. The *neigh\_modify exclude* and *delete\_bonds* commands are used to do this. If the rigid bodies have strongly overlapping atoms, you may need to turn off these interactions to avoid numerical problems due to large equal/opposite intra-body forces swamping the contribution of small inter-body forces.

---

For computational efficiency, you should typically define one fix rigid or fix rigid/small command which includes all the desired rigid bodies. LAMMPS will allow multiple rigid fixes to be defined, but it is more expensive.

---

The constituent particles within a rigid body can be point particles (the default in LAMMPS) or finite-size particles, such as spheres or ellipsoids or line segments or triangles. See the *atom\_style sphere and ellipsoid and line and tri* commands for more details on these kinds of particles. Finite-size particles contribute differently to the moment of inertia of a rigid body than do point particles. Finite-size particles can also experience torque (e.g. due to *frictional granular interactions*) and have an orientation. These contributions are accounted for by these fixes.

Forces between particles within a body do not contribute to the external force or torque on the body. Thus for computational efficiency, you may wish to turn off pairwise and bond interactions between particles within each rigid body. The *neigh\_modify exclude* and *delete\_bonds* commands are used to do this. For finite-size particles this also means the particles can be highly overlapped when creating the rigid body.

---

The *rigid*, *rigid/nve*, *rigid/small*, and *rigid/small/nve* styles perform constant NVE time integration. They are referred to below as the 4 NVE rigid styles. The only difference is that the *rigid* and *rigid/small* styles use an integration technique

based on Richardson iterations. The *rigid/nve* and *rigid/small/nve* styles uses the methods described in the paper by [Miller](#), which are thought to provide better energy conservation than an iterative approach.

The *rigid/nvt* and *rigid/nvt/small* styles performs constant NVT integration using a Nose/Hoover thermostat with chains as described originally in ([Hoover](#)) and ([Martyna](#)), which thermostats both the translational and rotational degrees of freedom of the rigid bodies. They are referred to below as the 2 NVT rigid styles. The rigid-body algorithm used by *rigid/nvt* is described in the paper by [Kamberaj](#).

The *rigid/npt*, *rigid/nph*, *rigid/npt/small*, and *rigid/nph/small* styles perform constant NPT or NPH integration using a Nose/Hoover barostat with chains. They are referred to below as the 4 NPT and NPH rigid styles. For the NPT case, the same Nose/Hoover thermostat is also used as with *rigid/nvt* and *rigid/nvt/small*.

The barostat parameters are specified using one or more of the *iso*, *aniso*, *x*, *y*, *z* and *couple* keywords. These keywords give you the ability to specify 3 diagonal components of the external stress tensor, and to couple these components together so that the dimensions they represent are varied together during a constant-pressure simulation. The effects of these keywords are similar to those defined in [fix npt/nph](#)

---

**Note:** Currently the *rigid/npt*, *rigid/nph*, *rigid/npt/small*, and *rigid/nph/small* styles do not support triclinic (non-orthogonal) boxes.

---

The target pressures for each of the 6 components of the stress tensor can be specified independently via the *x*, *y*, *z* keywords, which correspond to the 3 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from *Pstart* to *Pstop*. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the *y* keyword is used, the y-box length will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the [fix deform](#) command.

For all barostat keywords, the *Pdamp* parameter operates like the *Tdamp* parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g.  $\tau$  or fs or ps - see the [units](#) command).

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword *dilate* is specified with a *dilate-group-ID* for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. Another example is a system consisting of rigid bodies and point particles where the barostat is only coupled with the rigid bodies. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin.

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, *xz* means the *Pxx* and *Pzz* components of the stress tensor are coupled. *xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The *Pstart*, *Pstop*, *Pdamp* parameters for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the *z* dimension is simply ignored.

The *iso* and *aniso* keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso Pstart Pstop Pdamp” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
```

The keyword *aniso* means *x*, *y*, and *z* dimensions are controlled independently using the *Pxx*, *Pyy*, and *Pzz* components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “*aniso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple none
```

---

The keyword/value option pairs are used in the following ways.

The *reinit* keyword determines, whether the rigid body properties are re-initialized between run commands. With the option *yes* (the default) this is done, with the option *no* this is not done. Turning off the re-initialization can be helpful to protect rigid bodies against unphysical manipulations between runs or when properties cannot be easily re-computed (e.g. when read from a file). When using the *infile* keyword, the *reinit* option is automatically set to *no*.

The *langevin* and *temp* and *tparam* keywords perform thermostating of the rigid bodies, altering both their translational and rotational degrees of freedom. What is meant by “temperature” of a collection of rigid bodies and how it can be monitored via the fix output is discussed below.

The *langevin* keyword applies a Langevin thermostat to the constant NVE time integration performed by any of the 4 NVE rigid styles: *rigid*, *rigid/nve*, *rigid/small*, *rigid/small/nve*. It cannot be used with the 2 NVT rigid styles: *rigid/nvt*, *rigid/small/nvt*. The desired temperature at each timestep is a ramped value during the run from *Tstart* to *Tstop*. The *Tdamp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units ( $\tau$  or fs or ps - see the [units](#) command). The random # *seed* must be a positive integer.

The way that Langevin thermostating operates is explained on the [fix langevin](#) doc page. If you wish to simply viscously damp the rotational motion without thermostating, you can set *Tstart* and *Tstop* to 0.0, which means only the viscous drag term in the Langevin thermostat will be applied. See the discussion on the [fix viscous](#) page for details.

---

**Note:** When the *langevin* keyword is used with fix rigid versus fix rigid/small, different dynamics will result for parallel runs. This is because of the way random numbers are used in the two cases. The dynamics for the two cases should be statistically similar, but will not be identical, even for a single timestep.

---

The *temp* and *tparam* keywords apply a Nose/Hoover thermostat to the NVT time integration performed by the 2 NVT rigid styles. They cannot be used with the 4 NVE rigid styles. The desired temperature at each timestep is a ramped value during the run from *Tstart* to *Tstop*. The *Tdamp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (tau or fs or ps - see the [units](#) command).

Nose/Hoover chains are used in conjunction with this thermostat. The *tparam* keyword can optionally be used to change the chain settings used. *Tchain* is the number of thermostats in the Nose Hoover chain. This value, along with *Tdamp* can be varied to dampen undesirable oscillations in temperature that can occur in a simulation. As a rule of thumb, increasing the chain length should lead to smaller oscillations. The keyword *pchain* specifies the number of thermostats in the chain thermostating the barostat degrees of freedom.

---

**Note:** There are alternate ways to thermostat a system of rigid bodies. You can use [fix langevin](#) to treat the individual particles in the rigid bodies as effectively immersed in an implicit solvent, e.g. a Brownian dynamics model. For hybrid systems with both rigid bodies and solvent particles, you can thermostat only the solvent particles that surround one or more rigid bodies by appropriate choice of groups in the compute and fix commands for temperature and thermostating. The solvent interactions with the rigid bodies should then effectively thermostat the rigid body temperature as well without use of the Langevin or Nose/Hoover options associated with the fix rigid commands.

---

The *mol* keyword can only be used with the *rigid/small* styles. It must be used when other commands, such as *fix deposit* or *fix pour*, add rigid bodies on-the-fly during a simulation. You specify a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. You must use the same *template-ID* that the other fix which is adding rigid bodies uses. The coordinates, atom types, atom diameters, center-of-mass, and moments of inertia can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule, in which case the molecule command calculates the other quantities itself.

Note that these other fixes create new rigid bodies, in addition to those defined initially by this fix via the *bodystyle* setting.

Also note that when using the *mol* keyword, extra restart information about all rigid bodies is written out whenever a restart file is written out. See the NOTE in the next section for details.

The *infile* keyword allows a file of rigid body attributes to be read in from a file, rather than having LAMMPS compute them. There are 5 such attributes: the total mass of the rigid body, its center-of-mass position, its 6 moments of inertia, its center-of-mass velocity, and the 3 image flags of the center-of-mass position. For rigid bodies consisting of point particles or non-overlapping finite-size particles, LAMMPS can compute these values accurately.

However, for rigid bodies consisting of finite-size particles which overlap each other, LAMMPS will ignore the overlaps when computing these 4 attributes, which means the dynamics of the bodies will be incorrect. The amount of error this induces depends on the amount of overlap. To avoid this issue, the values can be pre-computed (e.g. using Monte Carlo integration).

The format of the file is as follows. Note that the file does not have to list attributes for every rigid body integrated by fix rigid. Only bodies which the file specifies will have their computed attributes overridden. The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 masstotal xcm ycm zcm ixm iym izz ixz iyz vxcm vyxm vzcm lx ly lz ixcm iycm izcm
ID2 masstotal xcm ycm zcm ixm iym izz ixz iyz vxcm vyxm vzcm lx ly lz ixcm iycm izcm
...
IDN masstotal xcm ycm zcm ixm iym izz ixz iyz vxcm vyxm vzcm lx ly lz ixcm iycm izcm
```

The rigid body IDs are all positive integers. For the *single* bodystyle, only an ID of 1 can be used. For the *group* bodystyle, IDs from 1 to Ng can be used where Ng is the number of specified groups. For the *molecule* bodystyle, use the molecule ID for the atoms in a specific rigid body as the rigid body ID.

The masstotal and center-of-mass coordinates (xcm,ycm,zcm) are self-explanatory. The center-of-mass should be consistent with what is calculated for the position of the rigid body with all its atoms unwrapped by their respective image flags. If this produces a center-of-mass that is outside the simulation box, LAMMPS wraps it back into the box.

The 6 moments of inertia (ixm,iym,izz,ixz,iyz) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

The (vxcm,vyxm,vzcm) values are the velocity of the center of mass. The (lx,ly,lz) values are the angular momentum of the body. The (vxcm,vyxm,vzcm) and (lx,ly,lz) values can simply be set to 0 if you wish the body to have no initial motion.

The (ixcm,iycm,izcm) values are the image flags of the center of mass of the body. For periodic dimensions, they specify which image of the simulation box the body is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid bodies cross periodic boundaries during the simulation.

**Note:** If you use the *infile* or *mol* keywords and write restart files during a simulation, then each time a restart file is written, the fix also write an auxiliary restart file with the name *rfile.rigid*, where “*rfile*” is the name of the restart file, e.g. *tmp.restart.10000* and *tmp.restart.10000.rigid*. This auxiliary file is in the same format described above. Thus it can be used in a new input script that restarts the run and re-specifies a rigid fix using an *infile* keyword and the appropriate filename. Note that the auxiliary file will contain one line for every rigid body, even if the original file only listed a subset of the rigid bodies.

---

If the system has rigid bodies with finite-size overlapping particles and the model uses the *fix gravity* command to apply a gravitational force to the rigid bodies, then the *gravity* keyword should be used in the following manner.

First, the group specified for the *fix gravity* command should not include any atoms in rigid bodies which have overlapping particles. It can be empty (see the *group empty* command) or only contain single particles not in rigid bodies, e.g. background particles.

Second, the *infile* keyword should be used to specify the total mass and other properties of the rigid bodies with overlaps, so that their dynamics will be modeled correctly, as explained above.

Third, the *gravity* keyword should be used with the ID of the *fix gravity* command as its argument. The rigid fixes will access the gravity fix to extract the current direction of the gravity vector at each timestep (which can be static or dynamic). A gravity force will then be applied to each rigid body at its center-of-mass position using its total mass.

---

If you use a *temperature compute* with a group that includes particles in rigid bodies, the degrees-of-freedom removed by each rigid body are accounted for in the temperature (and pressure) computation, but only if the temperature group includes all the particles in a particular rigid body.

A 3d rigid body has 6 degrees of freedom (3 translational, 3 rotational), except for a collection of point particles lying on a straight line, which has only 5, e.g. a dimer. A 2d rigid body has 3 degrees of freedom (2 translational, 1 rotational).

---

**Note:** You may wish to explicitly subtract additional degrees-of-freedom if you use the *force* and *torque* keywords to eliminate certain motions of one or more rigid bodies. LAMMPS does not do this automatically.

---

The rigid body contribution to the pressure of the system (virial) is also accounted for by this fix.

---

If your simulation is a hybrid model with a mixture of rigid bodies and non-rigid particles (e.g. solvent) there are several ways these rigid fixes can be used in tandem with *fix nve*, *fix nvt*, *fix npt*, and *fix nph*.

If you wish to perform NVE dynamics (no thermostatting or barostatting), use one of 4 NVE rigid styles to integrate the rigid bodies, and *fix nve* to integrate the non-rigid particles.

If you wish to perform NVT dynamics (thermostatting, but no barostatting), you can use one of the 2 NVT rigid styles for the rigid bodies, and any thermostatting fix for the non-rigid particles (*fix nvt*, *fix langevin*, *fix temp/berendsen*). You can also use one of the 4 NVE rigid styles for the rigid bodies and thermostat them using *fix langevin* on the group that contains all the particles in the rigid bodies. The net force added by *fix langevin* to each rigid body effectively thermostats its translational center-of-mass motion. Not sure how well it does at thermostatting its rotational motion.

If you wish to perform NPT or NPH dynamics (barostatting), you cannot use both *fix npt* and the NPT or NPH rigid styles. This is because there can only be one fix which monitors the global pressure and changes the simulation box dimensions. So you have 3 choices:

1. Use one of the 4 NPT or NPH styles for the rigid bodies. Use the *dilate* all option so that it will dilate the positions of the non-rigid particles as well. Use *fix nvt* (or any other thermostat) for the non-rigid particles.
2. Use *fix npt* for the group of non-rigid particles. Use the *dilate* all option so that it will dilate the center-of-mass positions of the rigid bodies as well. Use one of the 4 NVE or 2 NVT rigid styles for the rigid bodies.

3. Use *fix press/berendsen* to compute the pressure and change the box dimensions. Use one of the 4 NVE or 2 NVT rigid styles for the rigid bodies. Use *fix nvt* (or any other thermostat) for the non-rigid particles.

In all case, the rigid bodies and non-rigid particles both contribute to the global pressure and the box is scaled the same by any of the barostatting fixes.

You could even use the second and third options for a non-hybrid simulation consisting of only rigid bodies, assuming you give *fix npt* an empty group, though it's an odd thing to do. The barostatting fixes (*fix npt* and *fix press/berendsen*) will monitor the pressure and change the box dimensions, but not time integrate any particles. The integration of the rigid bodies will be performed by *fix rigid/nvt*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.201.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about the 4 NVE rigid styles is written to *binary restart files*. The exception is if the *infile* or *mol* keyword is used, in which case an auxiliary file is written out with rigid body information each time a restart file is written, as explained above for the *infile* keyword. For the 2 NVT rigid styles, the state of the Nose/Hoover thermostat is written to *binary restart files*. Ditto for the 4 NPT and NPH rigid styles, and the state of the Nose/Hoover barostat. See the [read\\_restart](#) command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify temp* and *press* options are supported by the 4 NPT and NPH rigid styles to change the computes used to calculate the instantaneous pressure tensor. Note that the 2 NVT rigid fixes do not use any external compute to compute instantaneous temperature.

The *fix\_modify bodyforces* option is supported by all rigid styles to set whether per-body forces and torques are computed early or late in a timestep, i.e. at the post-force stage or at the final-integrate stage or the timestep, respectively.

The cumulative energy change in the system imposed by the 6 NVT, NPT, NPH rigid fixes, via either thermostating and/or barostatting, is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the [thermo\\_style](#) doc page for details.

The 2 NVE rigid fixes compute a global scalar which can be accessed by various [output commands](#). The scalar value calculated by these fixes is “intensive”. The scalar is the current temperature of the collection of rigid bodies. This is averaged over all rigid bodies and their translational and rotational degrees of freedom. The translational energy of a rigid body is  $\frac{1}{2} m v^2$ , where  $m$  = total mass of the body and  $v$  = the velocity of its center of mass. The rotational energy of a rigid body is  $\frac{1}{2} I \omega^2$ , where  $I$  = the moment of inertia tensor of the body and  $\omega$  = its angular velocity. Degrees of freedom constrained by the *force* and *torque* keywords are removed from this calculation, but only for the *rigid* and *rigid/nve* fixes.

The 6 NVT, NPT, NPH rigid fixes compute a global scalar which can be accessed by various [output commands](#). The scalar is the same cumulative energy change due to these fixes described above. The scalar value calculated by this fix is “extensive”.

The *fix\_modify virial* option is supported by these fixes to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial yes*.

All of the *rigid* styles (but not the *rigid/small* styles) compute a global array of values which can be accessed by various *output commands*. Similar information about the bodies defined by the *rigid/small* styles can be accessed via the *compute rigid/local* command.

The number of rows in the array is equal to the number of rigid bodies. The number of columns is 15. Thus for each rigid body, 15 values are stored: the xyz coords of the center of mass (COM), the xyz components of the COM velocity, the xyz components of the force acting on the COM, the xyz components of the torque acting on the COM, and the xyz image flags of the COM.

The center of mass (COM) for each body is similar to unwrapped coordinates written to a dump file. It will always be inside (or slightly outside) the simulation box. The image flags have the same meaning as image flags for atom positions (see the “dump” command). This means you can calculate the unwrapped COM by applying the image flags to the COM, the same as when unwrapped coordinates are written to a dump file.

The force and torque values in the array are not affected by the *force* and *torque* keywords in the fix rigid command; they reflect values before any changes are made by those keywords.

The ordering of the rigid bodies (by row in the array) is as follows. For the *single* keyword there is just one rigid body. For the *molecule* keyword, the bodies are ordered by ascending molecule ID. For the *group* keyword, the list of group IDs determines the ordering of bodies.

The array values calculated by these fixes are “intensive”, meaning they are independent of the number of atoms in the simulation.

No parameter of these fixes can be used with the *start/stop* keywords of the *run* command. These fixes are not invoked during *energy minimization*.

---

## 2.201.5 Restrictions

These fixes are all part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Assigning a temperature via the *velocity create* command to a system with *rigid bodies* may not have the desired outcome for two reasons. First, the velocity command can be invoked before the rigid-body fix is invoked or initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a *run 0* command, which ensures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

```
velocity all create 300.0 12345
run 0                                # temperature may not be 300K
velocity all scale 300.0             # now it should be
```

## 2.201.6 Related commands

*delete\_bonds*, *neigh\_modify* *exclude*, *fix shake*

## 2.201.7 Default

The option defaults are force \* on on on and torque \* on on on, meaning all rigid bodies are acted on by center-of-mass force and torque. Also Tchain = Pchain = 10, Titer = 1, Torder = 3, reinit = yes.

## 2.202 fix rigid/meso command

### 2.202.1 Syntax

```
fix ID group-ID rigid/meso bodystyle args keyword values ...
```

- ID, group-ID are documented in *fix* command
- rigid/meso = style name of this fix command
- bodystyle = *single* or *molecule* or *group*

*single* args = none

*molecule* args = none

*custom* args = *i\_propname* or *v\_varname*

*i\_propname* = an integer property defined via *fix property/atom*

*v\_varname* = an atom-style or atomfile-style variable

*group* args = N groupID1 groupID2 ...

N = # of groups

groupID1, groupID2, ... = list of N group IDs

- zero or more keyword/value pairs may be appended
- keyword = *reinit* or *force* or *torque* or *infile*

*reinit* = yes or no

*force* values = M xflag yflag zflag

M = which rigid body from 1-Nbody (see asterisk form below)

xflag,yflag,zflag = off/on if component of center-of-mass force is active

*torque* values = M xflag yflag zflag

M = which rigid body from 1-Nbody (see asterisk form below)

xflag,yflag,zflag = off/on if component of center-of-mass torque is active

*infile* filename

filename = file with per-body values of mass, center-of-mass, moments of inertia

## 2.202.2 Examples

```
fix 1 ellipsoid rigid/meso single
fix 1 rods      rigid/meso molecule
fix 1 spheres   rigid/meso single force 1 off off on
fix 1 particles rigid/meso molecule force 1*5 off off off force 6*10 off off on
fix 2 spheres   rigid/meso group 3 sphere1 sphere2 sphere3 torque * off off off
```

## 2.202.3 Description

Treat one or more sets of mesoscopic SPH/SDPD particles as independent rigid bodies. This means that each timestep the total force and torque on each rigid body is computed as the sum of the forces and torques on its constituent particles. The coordinates and velocities of the particles in each body are then updated so that the body moves and rotates as a single entity using the methods described in the paper by (Miller). Density and internal energy of the particles will also be updated. This is implemented by creating internal data structures for each rigid body and performing time integration on these data structures. Positions and velocities of the constituent particles are regenerated from the rigid body data structures in every time step. This restricts which operations and fixes can be applied to rigid bodies. See below for a detailed discussion.

The operation of this fix is exactly like that described by the *fix rigid/nve* command, except that particles' density, internal energy and extrapolated velocity are also updated.

---

**Note:** You should not update the particles in rigid bodies via other time-integration fixes (e.g. *fix sph*, *fix sph/stationary*), or you will have conflicting updates to positions and velocities resulting in unphysical behavior in most cases. When performing a hybrid simulation with some atoms in rigid bodies, and some not, a separate time integration fix like *fix sph* should be used for the non-rigid particles.

---

---

**Note:** These fixes are overkill if you simply want to hold a collection of particles stationary or have them move with a constant velocity. To hold particles stationary use *fix sph/stationary* instead. If you would like to move particles with a constant velocity use *fix meso/move*.

---

**Warning:** The aggregate properties of each rigid body are calculated at the start of a simulation run and are maintained in internal data structures. The properties include the position and velocity of the center-of-mass of the body, its moments of inertia, and its angular momentum. This is done using the properties of the constituent particles of the body at that point in time (or see the *infile* keyword option). Thereafter, changing these properties of individual particles in the body will have no effect on a rigid body's dynamics, unless they effect any computation of per-particle forces or torques. If the keyword *reinit* is set to *yes* (the default), the rigid body data structures will be recreated at the beginning of each *run* command; if the keyword *reinit* is set to *no*, the rigid body data structures will be built only at the very first *run* command and maintained for as long as the rigid fix is defined. For example, you might think you could displace the particles in a body or add a large velocity to each particle in a body to make it move in a desired direction before a second run is performed, using the *set* or *displace\_atoms* or *velocity* commands. But these commands will not affect the internal attributes of the body unless *reinit* is set to *yes*. With *reinit* set to *no* (or using the *infile* option, which implies *reinit no*) the position and velocity of individual particles in the body will be reset when time integration starts again.

---

Each rigid body must have two or more particles. A particle can belong to at most one rigid body. Which particles are in which bodies can be defined via several options.

For bodystyle *single* the entire fix group of particles is treated as one rigid body.

For bodystyle *molecule*, particles are grouped into rigid bodies by their respective molecule IDs: each set of particles in the fix group with the same molecule ID is treated as a different rigid body. Note that particles with a molecule ID = 0 will be treated as a single rigid body. For a system with solvent (typically this is particles with molecule ID = 0) surrounding rigid bodies, this may not be what you want. Thus you should be careful to use a fix group that only includes particles you want to be part of rigid bodies.

Bodystyle *custom* is similar to bodystyle *molecule* except that it is more flexible in using other per-atom properties to define the sets of particles that form rigid bodies. An integer vector defined by the *fix property/atom* command can be used. Or an *atom-style* or *atomfile-style* variable can be used; the floating-point value produced by the variable is rounded to an integer. As with bodystyle *molecule*, each set of particles in the fix groups with the same integer value is treated as a different rigid body. Since fix property/atom vectors and atom-style variables produce values for all particles, you should be careful to use a fix group that only includes particles you want to be part of rigid bodies.

For bodystyle *group*, each of the listed groups is treated as a separate rigid body. Only particles that are also in the fix group are included in each rigid body.

---

**Note:** To compute the initial center-of-mass position and other properties of each rigid body, the image flags for each particle in the body are used to “unwrap” the particle coordinates. Thus you must ensure that these image flags are consistent so that the unwrapping creates a valid rigid body (one where the particles are close together), particularly if the particles in a single rigid body straddle a periodic boundary. This means the input data file or restart file must define the image flags for each particle consistently or that you have used the *set* command to specify them correctly. If a dimension is non-periodic then the image flag of each particle must be 0 in that dimension, else an error is generated.

---

By default, each rigid body is acted on by other particles which induce an external force and torque on its center of mass, causing it to translate and rotate. Components of the external center-of-mass force and torque can be turned off by the *force* and *torque* keywords. This may be useful if you wish a body to rotate but not translate, or vice versa, or if you wish it to rotate or translate continuously unaffected by interactions with other particles. Note that if you expect a rigid body not to move or rotate by using these keywords, you must ensure its initial center-of-mass translational or angular velocity is 0.0. Otherwise the initial translational or angular momentum, the body has, will persist.

An xflag, yflag, or zflag set to *off* means turn off the component of force or torque in that dimension. A setting of *on* means turn on the component, which is the default. Which rigid body(s) the settings apply to is determined by the first argument of the *force* and *torque* keywords. It can be an integer M from 1 to Nbody, where Nbody is the number of rigid bodies defined. A wild-card asterisk can be used in place of, or in conjunction with, the M argument to set the flags for multiple rigid bodies. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If N = the number of rigid bodies, then an asterisk with no numeric values means all bodies from 1 to N. A leading asterisk means all bodies from 1 to n (inclusive). A trailing asterisk means all bodies from n to N (inclusive). A middle asterisk means all bodies from m to n (inclusive). Note that you can use the *force* or *torque* keywords as many times as you like. If a particular rigid body has its component flags set multiple times, the settings from the final keyword are used.

For computational efficiency, you should typically define one fix rigid/meso command which includes all the desired rigid bodies. LAMMPS will allow multiple rigid/meso fixes to be defined, but it is more expensive.

---

The keyword/value option pairs are used in the following ways.

The *reinit* keyword determines, whether the rigid body properties are re-initialized between run commands. With the option *yes* (the default) this is done, with the option *no* this is not done. Turning off the re-initialization can be helpful to protect rigid bodies against unphysical manipulations between runs or when properties cannot be easily re-computed (e.g. when read from a file). When using the *infile* keyword, the *reinit* option is automatically set to *no*.

---

The *infile* keyword allows a file of rigid body attributes to be read in from a file, rather than having LAMMPS compute them. There are 5 such attributes: the total mass of the rigid body, its center-of-mass position, its 6 moments of inertia,

its center-of-mass velocity, and the 3 image flags of the center-of-mass position. For rigid bodies consisting of point particles or non-overlapping finite-size particles, LAMMPS can compute these values accurately. However, for rigid bodies consisting of finite-size particles which overlap each other, LAMMPS will ignore the overlaps when computing these 4 attributes. The amount of error this induces depends on the amount of overlap. To avoid this issue, the values can be pre-computed (e.g. using Monte Carlo integration).

The format of the file is as follows. Note that the file does not have to list attributes for every rigid body integrated by fix rigid. Only bodies which the file specifies will have their computed attributes overridden. The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 masstotal xcm ycm zcm ixm iym izz ixz iyz vxcm vyxm vzcm lx ly lz ixcm iycm izcm
ID2 masstotal xcm ycm zcm ixm iym izz ixz iyz vxcm vyxm vzcm lx ly lz ixcm iycm izcm
...
IDN masstotal xcm ycm zcm ixm iym izz ixz iyz vxcm vyxm vzcm lx ly lz ixcm iycm izcm
```

The rigid body IDs are all positive integers. For the *single* bodystyle, only an ID of 1 can be used. For the *group* bodystyle, IDs from 1 to Ng can be used where Ng is the number of specified groups. For the *molecule* bodystyle, use the molecule ID for the atoms in a specific rigid body as the rigid body ID.

The masstotal and center-of-mass coordinates (xcm,ycm,zcm) are self-explanatory. The center-of-mass should be consistent with what is calculated for the position of the rigid body with all its atoms unwrapped by their respective image flags. If this produces a center-of-mass that is outside the simulation box, LAMMPS wraps it back into the box.

The 6 moments of inertia (ixm,iym,izz,ixz,iyz) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

The (vxcm,vyxm,vzcm) values are the velocity of the center of mass. The (lx,ly,lz) values are the angular momentum of the body. The (vxcm,vyxm,vzcm) and (lx,ly,lz) values can simply be set to 0 if you wish the body to have no initial motion.

The (ixcm,iycm,izcm) values are the image flags of the center of mass of the body. For periodic dimensions, they specify which image of the simulation box the body is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid bodies cross periodic boundaries during the simulation.

---

**Note:** If you use the *infile* keyword and write restart files during a simulation, then each time a restart file is written, the fix also write an auxiliary restart file with the name rfile.rigid, where “rfile” is the name of the restart file, e.g. tmp.restart.10000 and tmp.restart.10000.rigid. This auxiliary file is in the same format described above. Thus it can be used in a new input script that restarts the run and re-specifies a rigid fix using an *infile* keyword and the appropriate filename. Note that the auxiliary file will contain one line for every rigid body, even if the original file only listed a subset of the rigid bodies.

---

## 2.202.4 Restart, fix\_modify, output, run start/stop, minimize info

No information is written to *binary restart files*. If the *infile* keyword is used, an auxiliary file is written out with rigid body information each time a restart file is written, as explained above for the *infile* keyword.

None of the *fix\_modify* options are relevant to this fix.

This fix computes a global array of values which can be accessed by various *output commands*.

The number of rows in the array is equal to the number of rigid bodies. The number of columns is 28. Thus for each rigid body, 28 values are stored: the xyz coords of the center of mass (COM), the xyz components of the COM velocity, the xyz components of the force acting on the COM, the components of the 4-vector quaternion representing the orientation of the rigid body, the xyz components of the angular velocity of the body around its COM, the xyz components of the torque acting on the COM, the 3 principal components of the moment of inertia, the xyz components of the angular momentum of the body around its COM, and the xyz image flags of the COM.

The center of mass (COM) for each body is similar to unwrapped coordinates written to a dump file. It will always be inside (or slightly outside) the simulation box. The image flags have the same meaning as image flags for particle positions (see the “dump” command). This means you can calculate the unwrapped COM by applying the image flags to the COM, the same as when unwrapped coordinates are written to a dump file.

The force and torque values in the array are not affected by the *force* and *torque* keywords in the fix rigid command; they reflect values before any changes are made by those keywords.

The ordering of the rigid bodies (by row in the array) is as follows. For the *single* keyword there is just one rigid body. For the *molecule* keyword, the bodies are ordered by ascending molecule ID. For the *group* keyword, the list of group IDs determines the ordering of bodies.

The array values calculated by this fix are “intensive”, meaning they are independent of the number of particles in the simulation.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

---

## 2.202.5 Restrictions

This fix is part of the DPD-SMOOTH package and also depends on the RIGID package. It is only enabled if LAMMPS was built with both packages. See the *Build package* page for more info.

This fix requires that atoms store density and internal energy as defined by the *atom\_style sph* command.

All particles in the group must be mesoscopic SPH/SDPD particles.

Changed in version 29Aug2024.

This fix is incompatible with deformation controls that remap velocity, for instance the *remap v* option of *fix deform*.

## 2.202.6 Related commands

*fix meso/move, fix rigid, neigh\_modify exclude*

## 2.202.7 Default

The option defaults are force \* on on on and torque \* on on on, meaning all rigid bodies are acted on by center-of-mass force and torque. Also reinit = yes.

---

(Miller) Miller, Eleftheriou, Pattnaik, Ndirango, and Newns, J Chem Phys, 116, 8649 (2002).

## 2.203 fix rx command

Accelerator Variants: *rx/kk*

### 2.203.1 Syntax

```
fix ID group-ID rx file localTemp matrix solver minSteps ...
```

- ID, group-ID are documented in *fix* command
- rx = style name of this fix command
- file = filename containing the reaction kinetic equations and Arrhenius parameters
- localTemp = *none*, *lucy* = no local temperature averaging or local temperature defined through Lucy weighting function
- matrix = *sparse*, *dense* format for the stoichiometric matrix
- solver = *lammps\_rk4*, *rkf45* = rk4 is an explicit fourth order Runge-Kutta method; rkf45 is an adaptive fourth-order Runge-Kutta-Fehlberg method
- minSteps = # of steps for rk4 solver or minimum # of steps for rkf45 (rk4 or rkf45)
- maxSteps = maximum number of steps for the rkf45 solver (rkf45 only)
- relTol = relative tolerance for the rkf45 solver (rkf45 only)
- absTol = absolute tolerance for the rkf45 solver (rkf45 only)
- diag = Diagnostics frequency for the rkf45 solver (optional, rkf45 only)

### 2.203.2 Examples

```
fix 1 all rx kinetics.rx none dense lammps_rk4
fix 1 all rx kinetics.rx none sparse lammps_rk4 1
fix 1 all rx kinetics.rx lucy sparse lammps_rk4 10
fix 1 all rx kinetics.rx none dense rkf45 1 100 1e-6 1e-8
fix 1 all rx kinetics.rx none dense rkf45 1 100 1e-6 1e-8 -1
```

### 2.203.3 Description

Fix *rx* solves the reaction kinetic ODEs for a given reaction set that is defined within the file associated with this command.

For a general reaction such that

the reaction rate equation is defined to be of the form

$$r = k(T)[A]^{v_A}[B]^{v_B}$$

In the current implementation, the exponents are defined to be equal to the stoichiometric coefficients. A given reaction set consisting of  $n$  reaction equations will contain a total of  $m$  species. A set of  $m$  ordinary differential equations (ODEs) that describe the change in concentration of a given species as a function of time are then constructed based on the  $n$  reaction rate equations.

The ODE systems are solved over the full DPD timestep  $dt$  using either a fourth order Runge-Kutta *rk4* method with a fixed step-size  $h$ , specified by the *lammmps\_rk4* keyword, or a fourth order Runge-Kutta-Fehlberg (rkf45) method with an adaptive step-size for  $h$ . The number of ODE steps per DPD timestep for the rk4 method is optionally specified immediately after the rk4 keyword. The ODE step-size is set as  $dt/num\_steps$ . Smaller step-sizes tend to yield more accurate results but there is not control on the error. For error control, use the rkf45 ODE solver.

The rkf45 method adjusts the step-size so that the local truncation error is held within the specified absolute and relative tolerances. The initial step-size  $h0$  can be specified by the user or estimated internally. It is recommended that the user specify  $h0$  since this will generally reduced the number of ODE integration steps required.  $h0$  is defined as  $dt/min\_steps$  if  $min\_steps \geq 1$ . If  $min\_steps == 0$ ,  $h0$  is estimated such that an explicit Euler method would likely produce an acceptable solution. This is generally overly conservative for the fourth-order method and users are advised to specify  $h0$  as some fraction of the DPD timestep. For small DPD timesteps, only one step may be necessary depending upon the tolerances. Note that more than  $min\_steps$  ODE steps may be taken depending upon the ODE stiffness but no more than  $max\_steps$  will be taken. If  $max\_steps$  is reached, an error warning is printed and the simulation is stopped.

After each ODE step, the solution error  $e$  is tested and weighted using the *absTol* and *relTol* values. The error vector is weighted as  $e / (relTol * |u| + absTol)$  where  $u$  is the solution vector. If the norm of the error is  $\leq 1$ , the solution is accepted,  $h$  is increased by a proportional amount, and the next ODE step is begun. Otherwise,  $h$  is shrunk and the ODE step is repeated.

Run-time diagnostics are available for the rkf45 ODE solver. The frequency (in timesteps) that diagnostics are reported is controlled by the last (optional) 12th argument. A negative frequency means that diagnostics are reported once at the end of each run. A positive value  $N$  means that the diagnostics are reported once per  $N$  timesteps.

The diagnostics report the average # of integrator steps and RHS function evaluations and run-time per ODE as well as the average/RMS/min/max per process. If the reporting frequency is 1, the RMS/min/max per ODE are also reported. The per ODE statistics can be used to adjust the tolerance and min/max step parameters. The statistics per MPI process can be useful to examine any load imbalance caused by the adaptive ODE solver. (Some DPD particles can take longer to solve than others. This can lead to an imbalance across the MPI processes.)

The filename specifies a file that contains the entire set of reaction kinetic equations and corresponding Arrhenius parameters. The format of this file is described below.

There is no restriction on the total number or reaction equations that are specified. The species names are arbitrary string names that are associated with the species concentrations. Each species in a given reaction must be preceded by it's stoichiometric coefficient. The only delimiters that are recognized between the species are either a + or = character. The = character corresponds to an irreversible reaction. After specifying the reaction, the reaction rate constant is determined through the temperature dependent Arrhenius equation:

$$k = AT^n e^{\frac{-E_a}{k_B T}}$$

where  $A$  is the Arrhenius factor in time units or concentration/time units,  $n$  is the unitless exponent of the temperature dependence, and  $E_a$  is the activation energy in energy units. The temperature dependence can be removed by specifying the exponent as zero.

The internal temperature of the coarse-grained particles can be used in constructing the reaction rate constants at every DPD timestep by specifying the keyword *none*. Alternatively, the keyword *lucy* can be specified to compute a local-average particle internal temperature for use in the reaction rate constant expressions. The local-average particle internal temperature is defined as:

$$\theta_i^{-1} = \frac{\sum_{j=1} \omega_{Lucy}(r_{ij}) \theta_j^{-1}}{\sum_{j=1} \omega_{Lucy}(r_{ij})}$$

where the Lucy function is expressed as:

$$\omega_{Lucy}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_c}\right) \left(1 - \frac{r_{ij}}{r_c}\right)^3$$

The self-particle interaction is included in the above equation.

The stoichiometric coefficients for the reaction mechanism are stored in either a sparse or dense matrix format. The dense matrix should only be used for small reaction mechanisms. The sparse matrix should be used when there are many reactions (e.g., more than 5). This allows the number of reactions and species to grow while keeping the computational cost tractable. The matrix format can be specified as using either the *sparse* or *dense* keywords. If all stoichiometric coefficients for a reaction are small integers (whole numbers  $\leq 3$ ), a fast exponential function is used. This can save significant computational time so users are encouraged to use integer coefficients where possible.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Rxn equations and parameters (one or more comment or blank lines)

1.0 hcn + 1.0 no2 = 1.0 no + 0.5 n2 + 0.5 h2 + 1.0 co 2.49E+01 0.0 1.34 (rxn equation, A, n, Ea)
1.0 hcn + 1.0 no = 1.0 co + 1.0 n2 + 0.5 h2 2.16E+00 0.0 1.52
...
1.0 no + 1.0 co = 0.5 n2 + 1.0 co2 1.66E+06 0.0 0.69
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections.

Following a blank line, the next  $N$  lines list the  $N$  reaction equations. Each species within the reaction equation is specified through its stoichiometric coefficient and a species tag. Reactant species are specified on the left-hand side of the equation and product species are specified on the right-hand side of the equation. After specifying the reactant and product species, the final three arguments of each line represent the Arrhenius parameter  $A$ , the temperature exponent  $n$ , and the activation energy  $E_a$ .

Note that the species tags that are defined in the reaction equations are used by the *fix eos/table/rx* command to define the thermodynamic properties of each species. Furthermore, the number of species molecules (i.e., concentration) can be specified either with the *set* command using the “d\_” prefix or by reading directly the concentrations from a data file. For the latter case, the *read\_data* command with the *fix* keyword should be specified, where the fix-ID will be the “fix rx`ID with a <SPECIES>”\_ suffix, e.g.

```
fix foo all rx reaction.file ... read_data data.dpd fix foo_SPECIES NULL Species
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages*

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

## 2.203.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command also requires use of the *atom\_style dpd* command.

This command can only be used with a constant energy or constant enthalpy DPD simulation.

## 2.203.5 Related commands

*fix eos/table/rx, fix shadlow, pair dpd/fdt/energy*

## 2.203.6 Default

none

# 2.204 fix saed/vtk command

## 2.204.1 Syntax

```
fix ID group-ID saed/vtk Nevery Nrepeat Nfreak c_ID attribute args ... keyword args ...
```

- ID, group-ID are documented in *fix* command
- saed/vtk = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreak = calculate averages every this many timesteps
- c\_ID = saed compute ID

keyword = *file* or *ave* or *start* or *file* or *overwrite:l*

ave args = *one* or *running* or *window M*

one = output a new average value every Nfreak steps

running = output cumulative average of all previous Nfreak steps

window M = output average of M most recent Nfreak steps

start args = Nstart

Nstart = start averaging on this timestep

```
file arg = filename
filename = name of file to output time averages to
```

## 2.204.2 Examples

```
compute 1 all saed 0.0251 Al 0 Kmax 1.70 Zone 0 0 1 dR_Ewald 0.01 c 0.5 0.5 0.5
compute 2 all saed 0.0251 Ni Kmax 1.70 Zone 0 0 0 c 0.05 0.05 0.05 manual echo

fix 1 all saed/vtk 1 1 1 c_1 file Al203_001.saed
fix 2 all saed/vtk 1 1 1 c_2 file Ni_000.saed
```

## 2.204.3 Description

Time average computed intensities from *compute saed* and write output to a file in the third generation vtk image data format for visualization directly in parallelized visualization software packages like ParaView and VisIt. Note that if no time averaging is done, this command can be used as a convenient way to simply output diffraction intensities at a single snapshot.

To produce output in the image data vtk format ghost data is added outside the *Kmax* range assigned in the *compute saed*. The ghost data is assigned a value of -1 and can be removed setting a minimum isovolume of 0 within the visualization software. SAED images can be created by visualizing a spherical slice of the data that is centered at  $R\_Ewald \cdot [h \ k \ l] / \text{norm}([h \ k \ l])$ , where  $R\_Ewald = 1/\lambda$ .

The group specified within this command is ignored. However, note that specified values may represent calculations performed by *saed* computes which store their own “group” definitions.

Fix *saed/vtk* is designed to work only with *compute saed* values, e.g.

```
compute 3 top saed 0.0251 Al 0
fix saed/vtk 1 1 1 c_3 file Al203_001.saed
```

The *Nevery*, *Nrepeat*, and *Nfreq* arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of *Nfreq*. The average is over *Nrepeat* quantities, computed in the preceding portion of the simulation every *Nevery* timesteps. *Nfreq* must be a multiple of *Nevery* and *Nevery* must be non-zero even if *Nrepeat* is 1. Also, the timesteps contributing to the average value cannot overlap, i.e.  $Nrepeat \cdot Nevery$  can not exceed *Nfreq*.

For example, if *Nevery*=2, *Nrepeat*=6, and *Nfreq*=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If *Nrepeat*=1 and *Nfreq* = 100, then no time averaging is done; values are simply generated on timesteps 100,200,etc.

The output for *fix ave/time/saed* is a file written with the third generation vtk image data formatting. The filename assigned by the *file* keyword is appended with *\_N.vtk* where *N* is an index (0,1,2,...) to account for multiple diffraction intensity outputs.

By default the header contains the following information (with example data):

```
# vtk DataFile Version 3.0 c_SAED
Image data set
ASCII
DATASET STRUCTURED_POINTS
```

(continues on next page)

(continued from previous page)

```

DIMENSIONS 337 219 209
ASPECT_RATIO 0.00507953 0.00785161 0.00821458
ORIGIN -0.853361 -0.855826 -0.854316
POINT_DATA 15424827
SCALARS intensity float
LOOKUP_TABLE default
...data

```

In this example, kspace is sampled across a 337 x 219 x 209 point mesh where the mesh spacing is approximately 0.005, 0.007, and 0.008 inv(length) units in the k1, k2, and k3 directions, respectively. The data is shifted by -0.85, -0.85, -0.85 inv(length) units so that the origin will lie at 0, 0, 0. Here, 15,424,827 kspace points are sampled in total.

Additional optional keywords also affect the operation of this fix.

The *ave* keyword determines how the values produced every *Nfreq* steps are averaged with values produced on previous steps that were multiples of *Nfreq*, before they are accessed by another output command or written to a file.

If the *ave* setting is *one*, then the values produced on timesteps that are multiples of *Nfreq* are independent of each other; they are output as-is without further averaging.

If the *ave* setting is *running*, then the values produced on timesteps that are multiples of *Nfreq* are summed and averaged in a cumulative sense before being output. Each output value is thus the average of the value produced on that timestep with all preceding values. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the *unfix* command, or by re-defining the fix by re-specifying it.

If the *ave* setting is *window*, then the values produced on timesteps that are multiples of *Nfreq* are summed and averaged within a moving “window” of time, so that the last M values are used to produce the output. E.g. if M = 3 and *Nfreq* = 1000, then the output on step 10000 will be the average of the individual values on steps 8000,9000,10000. Outputs on early steps will average over less than M values if they are not available.

The *start* keyword specifies what timestep averaging will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting *start* to a larger value can avoid including a 0.0 in a running or windowed average.

The *file* keyword allows a filename to be specified. Every *Nfreq* steps, the vector of saed intensity data is written to a new file using the third generation vtk format. The base of each file is assigned by the *file* keyword and this string is appended with *\_N.vtk* where N is an index (0,1,2...) to account for situations with multiple diffraction intensity outputs.

## 2.204.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix is part of the DIFFRACTION package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.204.5 Restrictions

The attributes for `fix_saed_vtk` must match the values assigned in the associated `compute_saed` command.

## 2.204.6 Related commands

`compute_saed`

## 2.204.7 Default

The option defaults are `ave = one`, `start = 0`, no file output.

---

(Coleman) Coleman, Spearot, Capolungo, MSMSE, 21, 055020 (2013).

## 2.205 fix setforce command

Accelerator Variants: `setforce/kk`

## 2.206 fix setforce/spin command

### 2.206.1 Syntax

```
fix ID group-ID setforce fx fy fz keyword value ...
```

- ID, group-ID are documented in `fix` command
- setforce = style name of this fix command
- fx,fy,fz = force component values
- any of fx,fy,fz can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = `region`

`region value = region-ID`

`region-ID = ID of region atoms must be in to have added force`

### 2.206.2 Examples

```
fix freeze indenter setforce 0.0 0.0 0.0
fix 2 edge setforce NULL 0.0 0.0
fix 1 edge setforce/spin 0.0 0.0 0.0
fix 2 edge setforce NULL 0.0 v_oscillate
```

### 2.206.3 Description

Set each component of force on each atom in the group to the specified values *fx,fy,fz*. This erases all previously computed forces on the atom, though additional fixes could add new forces. This command can be used to freeze certain atoms in the simulation by zeroing their force, either for running dynamics or performing an energy minimization. For dynamics, this assumes their initial velocity is also zero.

Any of the *fx,fy,fz* values can be specified as NULL which means do not alter the force component in that dimension.

Any of the 3 quantities defining the force components can be specified as an equal-style or atom-style *variable*, namely *fx,fy,fz*. If the value is a variable, it should be specified as *v\_name*, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the *region* keyword is used, the atom must also be in the specified geometric *region* in order to have force added to it.

---

Style *spin* suffix sets the components of the magnetic precession vectors instead of the mechanical forces. This also erases all previously computed magnetic precession vectors on the atom, though additional magnetic fixes could add new forces.

This command can be used to freeze the magnetic moment of certain atoms in the simulation by zeroing their precession vector.

All options defined above remain valid, they just apply to the magnetic precession vectors instead of the forces.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

**Note:** The *region* keyword is supported by Kokkos, but a Kokkos-enabled region must be used. See the *region region* command for more information.

---

## 2.206.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is setting the forces to the desired values; on all other levels, the force is set to 0.0 for the atoms in the fix group, so that setforce values are not counted multiple times. Default is to override forces at the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various *output commands*. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command, but you cannot set forces to any value besides zero when performing a minimization. Use the *fix addforce* command if you want to apply a non-zero force to atoms during a minimization.

## 2.206.5 Restrictions

Fix *setforce/spin* is part of the SPIN package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.206.6 Related commands

*fix addforce*, *fix aveforce*

## 2.206.7 Default

none

# 2.207 fix sgcmc command

## 2.207.1 Syntax

```
fix ID group-ID sgcmc every_nsteps swap_fraction temperature deltamu ...
```

- ID, group-ID are documented in *fix* command
- sgcmc = style name of this fix command
- every\_nsteps = number of MD steps between MC cycles
- swap\_fraction = fraction of a full MC cycle carried out at each call (a value of 1.0 will perform as many trial moves as there are atoms)
- temperature = temperature that enters Boltzmann factor in Metropolis criterion (usually the same as MD temperature)
- deltamu =  $N$ -1 chemical potential differences  $\mu_1 - \mu_2, \dots, \mu_1 - \mu_N$  ( $N$  is the number of atom types)
- Zero or more keyword/value pairs may be appended to fix definition line:

```

keyword = variance or randseed or window_moves or window_size
variance kappa conc1 [conc2] ... [concN]
    kappa = variance constraint parameter
    c_2, c_3, ..., c_N = N-1 target concentration fractions
randseed N
    N = seed for pseudo random number generator
window_moves N
    N = number of times sampling window is moved during one MC cycle
window_size frac
    frac = size of sampling window (must be between 0.5 and 1.0)

```

## 2.207.2 Examples

```

fix mc all sgcmc 50 0.1 400.0 -0.55
fix vc all sgcmc 20 0.2 700.0 -0.7 randseed 324234 variance 2000.0 0.05
fix 2 all sgcmc 20 0.1 700.0 -0.7 window_moves 20

```

## 2.207.3 Description

New in version 22Dec2022.

This command allows to carry out parallel hybrid molecular dynamics/Monte Carlo (MD/MC) simulations using the algorithms described in ([Sadigh1](#)). Simulations can be carried out in either the semi-grand canonical (SGC) or variance constrained semi-grand canonical (VC-SGC) ensemble ([Sadigh2](#)). Only atom type swaps are performed by the SGCMC fix. Relaxations are accounted for by the molecular dynamics integration steps.

This fix can be used with standard multi-element EAM potentials (*pair styles eam/alloy or eam/fs*)

The SGCMC fix can handle Finnis/Sinclair type EAM potentials where  $\rho(r)$  is atom-type specific, such that different elements can contribute differently to the total electron density at an atomic site depending on the identity of the element at that atomic site.

If this fix is applied, the regular MD simulation will be interrupted in defined intervals to carry out a fraction of a Monte Carlo (MC) cycle. The interval is set using the parameter *every\_nsteps* which determines how many MD integrator steps are taken between subsequent calls to the MC routine.

It is possible to carry out pure lattice MC simulations by setting *every\_nsteps* to 1 and not defining an integration fix such as NVE, NPT etc. In that case, the particles will not move and only the MC routine will be called to perform atom type swaps.

The parameter *swap\_fraction* determines how many MC trial steps are carried out every time the MC routine is entered. It is measured in units of full MC cycles where one full cycle, *swap\_fraction=1*, corresponds to as many MC trial steps as there are atoms.

The parameter *temperature* specifies the temperature that is used to evaluate the Metropolis acceptance criterion. While it usually should be set to the same value as the MD temperature there are cases when it can be useful to use two different values for at least part of the simulation, e.g., to speed up equilibration at low temperatures.

The parameter *deltamu* is used to set the chemical potential differences in the SGC MC algorithm (see Eq. 16 in [Sadigh1](#)). The *N-1* differences are defined as  $\mu_1 - \mu_2, \dots, \mu_1 - \mu_N$ , where *N* is the number of atom types.

The variance-constrained SGC MC algorithm is activated if the keyword *variance* is used. In that case the fix parameter *deltamu* determines the effective average constraint in the parallel VC-SGC MC algorithm (parameter  $\delta\mu_0$  in Eq. (20) of [Sadigh1](#)). The parameter *kappa* specifies the variance constraint (see Eqs. (20-21) in [Sadigh1](#)). The parameter *conc* sets the  $N-1$  target atomic concentration fractions (parameter  $c_0$  in Eqs. (20-21) of [Sadigh1](#))  $0 \leq c_2, \dots, c_N \leq 1$ , with  $c_1 = 1 - \sum_{i=2}^N c_i$ . When the simulation includes  $N$  atom types (elements),  $N-1$  concentration values must be specified.

---

There are several technical parameters that can be set via optional flags.

*randseed* is expected to be a positive integer number and is used to initialize the random number generator on each processor.

*window\_size* controls the size of the sampling window in a parallel MC simulation. The size has to lie between 0.5 and 1.0. Normally, this parameter should be left unspecified which instructs the code to choose the optimal window size automatically (see Sect. III.B and Figure 6 in [Sadigh1](#) for details).

The number of times the window is moved during a MC cycle is set using the parameter *window\_moves* (see Sect. III.B in [Sadigh1](#) for details).

---

## 2.207.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to restart files.

The MC routine keeps track of the global concentration(s) as well as the number of accepted and rejected trial swaps during each MC step. These values are provided by the *sgcmc* fix in the form of a global vector that can be accessed by various *output commands* components of the vector represent the following quantities:

- 1 = The absolute number of accepted trial swaps during the last MC step
- 2 = The absolute number of rejected trial swaps during the last MC step
- 3 = Current global concentration  $c_1$  (= number of atoms of type 1 / total number of atoms)
- 4 = Current global concentration  $c_2$  (= number of atoms of type 2 / total number of atoms)
- ...
- $N+2$  = Current global concentration  $c_N$  (= number of atoms of type  $N$  / total number of atoms)

The vector values calculated by this fix are “intensive”.

## 2.207.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix style requires an *atom style* with per atom type masses.

At present the fix provides optimized subroutines for EAM type potentials (see above) that calculate potential energy changes due to *local* atom type swaps very efficiently. Other potentials are supported by using the generic potential functions. This, however, will lead to exceedingly slow simulations since it implies that the energy of the *entire* system is recomputed at each MC trial step. If other potentials are to be used it is strongly recommended to modify and optimize the existing generic potential functions for this purpose. Also, the generic energy calculation can not be used for parallel execution i.e. it only works with a single MPI process.

---

## 2.207.6 Default

The optional parameters default to the following values:

- *randseed* = 324234
- *window\_moves* = 8
- *window\_size* = automatic

## 2.208 fix shake command

Accelerator Variants: *shake/kk*

## 2.209 fix rattle command

### 2.209.1 Syntax

```
fix ID group-ID style tol iter N constraint values ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- style = shake or rattle = style name of this fix command
- tol = accuracy tolerance of SHAKE solution
- iter = max # of iterations in each SHAKE solution
- N = print SHAKE statistics every this many timesteps (0 = never)
- one or more constraint/value pairs are appended
- constraint = *b* or *a* or *t* or *m*
  - b* values = one or more bond types (may use type labels)
  - a* values = one or more angle types (may use type labels)
  - t* values = one or more atom types (may use type labels)
  - m* value = one or more mass values

- zero or more keyword/value pairs may be appended
- keyword = *mol* or *kbond*

*mol* value = template-ID

template-ID = ID of molecule template specified in a separate *molecule* command

*kbond* value = force constant

force constant = force constant used to apply a restraint force when used during *minimization*

## 2.209.2 Examples

```
fix 1 sub shake 0.0001 20 10 b 4 19 a 3 5 2
fix 1 sub shake 0.0001 20 10 t 5 6 m 1.0 a 31
fix 1 sub shake 0.0001 20 10 t 5 6 m 1.0 a 31 mol myMol
fix 1 sub rattle 0.0001 20 10 t 5 6 m 1.0 a 31
fix 1 sub rattle 0.0001 20 10 t 5 6 m 1.0 a 31 mol myMol
```

## 2.209.3 Description

Apply bond and angle constraints to specified bonds and angles in the simulation by either the SHAKE or RATTLE algorithms. This typically enables a longer timestep. The SHAKE or RATTLE constraint algorithms, however, can *only* be applied during molecular dynamics runs.

Changed in version 15Sep2022.

These fixes may now also be used during minimization. In that case the constraints are *approximated* by strong harmonic restraints.

### SHAKE vs RATTLE:

The SHAKE algorithm was invented for schemes such as standard Verlet timestepping, where only the coordinates are integrated and the velocities are approximated as finite differences to the trajectories (*Ryckaert et al. (1977)*). If the velocities are integrated explicitly, as with velocity Verlet which is what LAMMPS uses as an integration method, a second set of constraining forces is required in order to eliminate velocity components along the bonds (*Andersen (1983)*).

In order to formulate individual constraints for SHAKE and RATTLE, focus on a single molecule whose bonds are constrained. Let  $\mathbf{R}_i$  and  $\mathbf{V}_i$  be the position and velocity of atom  $i$  at time  $n$ , for  $i=1,\dots,N$ , where  $N$  is the number of sites of our reference molecule. The distance vector between sites  $i$  and  $j$  is given by

$$\mathbf{r}_{ij}^{n+1} = \mathbf{r}_j^n - \mathbf{r}_i^n$$

The constraints can then be formulated as

$$\begin{aligned} \mathbf{r}_{ij}^{n+1} \cdot \mathbf{r}_{ij}^{n+1} &= d_{ij}^2 \quad \text{and} \\ \mathbf{v}_{ij}^{n+1} \cdot \mathbf{r}_{ij}^{n+1} &= 0 \end{aligned}$$

The SHAKE algorithm satisfies the first condition, i.e. the sites at time  $n+1$  will have the desired separations  $D_{ij}$  immediately after the coordinates are integrated. If we also enforce the second condition, the velocity components along the bonds will vanish. RATTLE satisfies both conditions. As implemented in LAMMPS, *fix rattle* uses *fix shake* for satisfying the coordinate constraints. Therefore the settings and optional keywords are the same for both fixes, and all the information below about SHAKE is also relevant for RATTLE.

### SHAKE:

Each timestep the specified bonds and angles are reset to their equilibrium lengths and angular values via the SHAKE algorithm (*Ryckaert et al. (1977)*). This is done by applying an additional constraint force so that the new positions preserve the desired atom separations. The equations for the additional force are solved via an iterative method that typically converges to an accurate solution in a few iterations. The desired tolerance (e.g.  $1.0\text{e-}4 = 1$  part in 10000) and maximum # of iterations are specified as arguments. Setting the N argument will print statistics to the screen and log file about regarding the lengths of bonds and angles that are being constrained. Small delta values mean SHAKE is doing a good job.

In LAMMPS, only small clusters of atoms can be constrained. This is so the constraint calculation for a cluster can be performed by a single processor, to enable good parallel performance. A cluster is defined as a central atom connected to others in the cluster by constrained bonds. LAMMPS allows for the following kinds of clusters to be constrained:

one central atom bonded to 1 or 2 or 3 atoms, or one central atom bonded to 2 others and the angle between the three atoms also constrained. This means water molecules or CH<sub>2</sub> or CH<sub>3</sub> groups may be constrained, but not all the C-C backbone bonds of a long polymer chain.

The *b* constraint lists bond types that will be constrained. The *t* constraint lists atom types. All bonds connected to an atom of the specified type will be constrained. The *m* constraint lists atom masses. All bonds connected to atoms of the specified masses will be constrained (within a fudge factor of MASSDELTA specified in `src/RIGID/fix_shake.cpp`). The *a* constraint lists angle types. If both bonds in the angle are constrained then the angle will also be constrained if its type is in the list.

Changed in version 29Aug2024.

The types may be given as type labels *only* if there is no atom, bond, or angle type label named *b*, *a*, *t*, or *m* defined in the simulation. If that is the case, type labels cannot be used as constraint type index with these two fixes, because the type labels would be incorrectly treated as a new type of constraint instead. Thus, LAMMPS will print a warning and type label handling is disabled and numeric types must be used.

For all constraints, a particular bond is only constrained if *both* atoms in the bond are in the group specified with the SHAKE fix.

The degrees-of-freedom removed by SHAKE bonds and angles are accounted for in temperature and pressure computations. Similarly, the SHAKE contribution to the pressure of the system (virial) is also accounted for.

---

**Note:** This command works by using the current forces on atoms to calculate an additional constraint force which when added will leave the atoms in positions that satisfy the SHAKE constraints (e.g. bond length) after the next time integration step. If you define fixes (e.g. *fix efield*) that add additional force to the atoms after *fix shake* operates, then this fix will not take them into account and the time integration will typically not satisfy the SHAKE constraints. The solution for this is to make sure that *fix shake* is defined in your input script after any other fixes which add or change forces (to atoms that *fix shake* operates on).

---

The *mol* keyword should be used when other commands, such as *fix deposit* or *fix pour*, add molecules on-the-fly during a simulation, and you wish to constrain the new molecules via SHAKE. You specify a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. You must use the same *template-ID* that the command adding molecules uses. The coordinates, atom types, special bond restrictions, and SHAKE info can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file (by this command) are the SHAKE info of atoms in the molecule.

The *kbond* keyword sets the restraint force constant when *fix shake* or *fix rattle* are used during minimization. In that case the constraint algorithms are *not* applied and restraint forces are used instead to maintain the geometries similar to the constraints. How well the geometries are maintained and how quickly a minimization converges, depends largely on the force constant *kbond*: larger values will reduce the deviation from the desired geometry, but can also lead to slower convergence of the minimization or lead to instabilities depending on the minimization algorithm requiring to reduce the value of *timestep*. Even though the restraints will not preserve the bond lengths and angles as closely as the constraints during the MD, they are generally close enough so that the constraints will be fulfilled to the desired accuracy within a few MD steps following the minimization. The default value for *kbond* depends on the *units* setting and is 1.0e6\*k\_B.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## RATTLE:

The velocity constraints lead to a linear system of equations which can be solved analytically. The implementation of the algorithm in LAMMPS closely follows (*Andersen (1983)*).

---

**Note:** The *fix rattle* command modifies forces and velocities and thus should be defined after all other integration fixes in your input script. If you define other fixes that modify velocities or forces after *fix rattle* operates, then *fix rattle* will not take them into account and the overall time integration will typically not satisfy the RATTLE constraints. You can check whether the constraints work correctly by setting the value of RATTLE\_DEBUG in *src/RIGID/fix\_rattle.cpp* to 1 and recompiling LAMMPS.

---

## 2.209.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about these fixes is written to *binary restart files*.

Both *fix shake* and *fix rattle* behave differently during a minimization in comparison to a molecular dynamics run:

- When used during a minimization, the SHAKE or RATTLE constraint algorithms themselves are **not** applied. Instead the constraints are replaced by harmonic restraint forces. The energy and virial contributions due to the restraint forces are tallied into global and per-atom accumulators. The total restraint energy is also accessible as a global scalar property of the fix.
- During molecular dynamics runs, however, the fixes do apply the requested SHAKE or RATTLE constraint algorithms.

The *fix\_modify virial* option is supported by these fixes to add the contribution due to the added constraint forces on atoms to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*.

The default setting for this fix is *fix\_modify virial yes*. No global or per-atom quantities are stored by these fixes for access by various *output commands* during an MD run. No parameter of these fixes can be used with the *start/stop* keywords of the *run* command.

## 2.209.5 Restrictions

These fixes are part of the RIGID package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

For computational efficiency, there can only be one shake or rattle fix defined in a simulation.

If you use a tolerance that is too large or a max-iteration count that is too small, the constraints will not be enforced very strongly, which can lead to poor energy conservation. You can test for this in your system by running a constant NVE simulation with a particular set of SHAKE parameters and monitoring the energy versus time.

SHAKE or RATTLE should not be used to constrain an angle at 180 degrees (e.g. a linear CO<sub>2</sub> molecule). This causes a divergence when solving the constraint equations numerically. You can use *fix rigid* or *fix rigid/small* instead to make a linear molecule rigid.

When used during minimization choosing a too large value of the *kbond* can make minimization very inefficient and also cause stability problems with some minimization algorithms. Sometimes those can be avoided by reducing the *timestep*.

## 2.210 fix shardlow command

Accelerator Variants: *shardlow/kk*

### 2.210.1 Syntax

```
fix ID group-ID shardlow
```

- ID, group-ID are documented in *fix* command
- shardlow = style name of this fix command

### 2.210.2 Examples

```
fix 1 all shardlow
```

### 2.210.3 Description

Specifies that the Shardlow splitting algorithm (SSA) is to be used to integrate the DPD equations of motion. The SSA splits the integration into a stochastic and deterministic integration step. The fix *shardlow* performs the stochastic integration step and must be used in conjunction with a deterministic integrator (e.g. *fix nve* or *fix nph*). The stochastic integration of the dissipative and random forces is performed prior to the deterministic integration of the conservative force. Further details regarding the method are provided in (*Lisal*) and (*Larentzos1*).

The fix *shardlow* must be used with the *pair\_style dpd/fdt* or *pair\_style dpd/fdt/energy* command to properly initialize the fluctuation-dissipation theorem parameter(s) sigma (and kappa, if necessary).

Note that numerous variants of DPD can be specified by choosing an appropriate combination of the integrator and *pair\_style dpd/fdt* command. DPD under isothermal conditions can be specified by using fix *shardlow*, fix *nve* and pair\_style *dpd/fdt*. DPD under isoenergetic conditions can be specified by using fix *shardlow*, fix *nve* and pair\_style *dpd/fdt/energy*. DPD under isobaric conditions can be specified by using fix *shardlow*, fix *nph* and pair\_style *dpd/fdt*.

DPD under isoenthalpic conditions can be specified by using `fix shardlow`, `fix nph` and `pair_style dpd/fdt/energy`. Examples of each DPD variant are provided in the `examples/PACKAGES/dpd-react` directory.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.210.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This fix is currently limited to orthogonal simulation cell geometries.

This fix must be used with an additional fix that specifies time integration, e.g. *fix nve* or *fix nph*.

The Shardlow splitting algorithm requires the sizes of the subdomain lengths to be larger than twice the cutoff+skin. Generally, the domain decomposition is dependent on the number of processors requested.

## 2.210.5 Related commands

*pair\_style dpd/fdt*, *fix eos/cv*

## 2.210.6 Default

none

## 2.211 fix smd command

### 2.211.1 Syntax

```
fix ID group-ID smd type values keyword values
```

- ID, group-ID are documented in *fix* command
- smd = style name of this fix command
- mode = *cvel* or *cfor* to select constant velocity or constant force SMD
  - cvel* values = K vel  
 K = spring constant (force/distance units)  
 vel = velocity of pulling (distance/time units)
  - cfor* values = force  
 force = pulling force (force units)
- keyword = *tether* or *couple*
  - tether* values = x y z R0  
 x,y,z = point to which spring is tethered  
 R0 = distance of end of spring from tether point (distance units)
  - couple* values = group-ID2 x y z R0  
 group-ID2 = 2nd group to couple to fix group with a spring  
 x,y,z = direction of spring, automatically computed with 'auto'  
 R0 = distance of end of spring (distance units)

### 2.211.2 Examples

```
fix pull cterm smd cvel 20.0 -0.00005 tether NULL NULL 100.0 0.0
fix pull cterm smd cvel 20.0 -0.0001 tether 25.0 25 25.0 0.0
fix stretch cterm smd cvel 20.0 0.0001 couple nterm auto auto auto 0.0
fix pull cterm smd cfor 5.0 tether 25.0 25.0 25.0 0.0
```

### 2.211.3 Description

This fix implements several options of steered MD (SMD) as reviewed in (*Izrailev*), which allows to induce conformational changes in systems and to compute the potential of mean force (PMF) along the assumed reaction coordinate (*Park*) based on Jarzynski's equality (*Jarzynski*). This fix borrows a lot from *fix spring* and *fix setforce*.

You can apply a moving spring force to a group of atoms (*tether* style) or between two groups of atoms (*couple* style). The spring can then be used in either constant velocity (*cvel*) mode or in constant force (*cfor*) mode to induce transitions in your systems. When running in *tether* style, you may need some way to fix some other part of the system (e.g. via *fix spring/self*)

The *tether* style attaches a spring between a point at a distance of R0 away from a fixed point x,y,z and the center of mass of the fix group of atoms. A restoring force of magnitude  $K (R - R0) M_i / M$  is applied to each atom in the group where  $K$  is the spring constant,  $M_i$  is the mass of the atom, and  $M$  is the total mass of all atoms in the group. Note that  $K$  thus represents the total force on the group of atoms, not a per-atom force.

In *cvel* mode the distance R is incremented or decremented monotonously according to the pulling (or pushing) velocity. In *cfor* mode a constant force is added and the actual distance in direction of the spring is recorded.

The *couple* style links two groups of atoms together. The first group is the fix group; the second is specified by group-ID2. The groups are coupled together by a spring that is at equilibrium when the two groups are displaced by a vector in direction  $x,y,z$  with respect to each other and at a distance  $R0$  from that displacement. Note that  $x,y,z$  only provides a direction and will be internally normalized. But since it represents the *absolute* displacement of group-ID2 relative to the fix group, (1,1,0) is a different spring than (-1,-1,0). For each vector component, the displacement can be described with the *auto* parameter. In this case the direction is re-computed in every step, which can be useful for steering a local process where the whole object undergoes some other change. When the relative positions and distance between the two groups are not in equilibrium, the same spring force described above is applied to atoms in each of the two groups.

For both the *tether* and *couple* styles, any of the  $x,y,z$  values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

For constant velocity pulling (*cvel* mode), the running integral over the pulling force in direction of the spring is recorded and can then later be used to compute the potential of mean force (PMF) by averaging over multiple independent trajectories along the same pulling path.

#### 2.211.4 Restart, fix\_modify, output, run start/stop, minimize info

The fix stores the direction of the spring, current pulling target distance and the running PMF to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a vector list of 7 quantities, which can be accessed by various *output commands*. The quantities in the vector are in this order: the x-, y-, and z-component of the pulling force, the total force in direction of the pull, the equilibrium distance of the spring, the distance between the two reference points, and finally the accumulated PMF (the sum of pulling forces times displacement).

The force is the total force on the group of atoms by the spring. In the case of the *couple* style, it is the force on the fix group (group-ID) or the negative of the force on the second group (group-ID2). The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

#### 2.211.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.212 fix smd/adjust\_dt command

### 2.212.1 Syntax

```
fix ID group-ID smd/adjust_dt arg
```

- ID, group-ID are documented in *fix* command
- smd/adjust\_dt = style name of this fix command
- arg = *s\_fact*  
*s\_fact* = safety factor

### 2.212.2 Examples

```
fix 1 all smd/adjust_dt 0.1
```

### 2.212.3 Description

The fix calculates a new stable time increment for use with the SMD time integrators.

The stable time increment is based on multiple conditions. For the SPH pair styles, a CFL criterion (Courant, Friedrichs & Lewy, 1928) is evaluated, which determines the speed of sound cannot propagate further than a typical spacing between particles within a single time step to ensure no information is lost. For the contact pair styles, a linear analysis of the pair potential determines a stable maximum time step.

This fix inquires the minimum stable time increment across all particles contained in the group for which this fix is defined. An additional safety factor *s\_fact* is applied to the time increment.

See [this PDF guide](#) to use Smooth Mach Dynamics in LAMMPS.

## 2.212.4 Restart, fix\_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization.

## 2.212.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 2.212.6 Related commands

*smd/tlsph\_dt*

## 2.212.7 Default

none

# 2.213 fix smd/integrate\_tlsph command

## 2.213.1 Syntax

```
fix ID group-ID smd/integrate_tlsph keyword values
```

- ID, group-ID are documented in *fix* command
- smd/integrate\_tlsph = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = *limit\_velocity*

*limit\_velocity* value = max\_vel

max\_vel = maximum allowed velocity

## 2.213.2 Examples

```
fix 1 all smd/integrate_tlsph  
fix 1 all smd/integrate_tlsph limit_velocity 1000
```

## 2.213.3 Description

The fix performs explicit time integration for particles which interact according with the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

The *limit\_velocity* keyword will control the velocity, scaling the norm of the velocity vector to max\_vel in case it exceeds this velocity limit.

## 2.213.4 Restart, fix\_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. This fix has no outputs.

## 2.213.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Changed in version 29Aug2024.

This fix is incompatible with deformation controls that remap velocity, for instance the *remap v* option of *fix deform*.

## 2.213.6 Related commands

*smd/integrate\_ulsph*

## 2.213.7 Default

none

# 2.214 fix smd/integrate\_ulsph command

## 2.214.1 Syntax

```
fix ID group-ID smd/integrate_ulsph keyword
```

- ID, group-ID are documented in *fix* command
- smd/integrate\_ulsph = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = adjust\_radius or limit\_velocity

**adjust\_radius values = adjust\_radius\_factor min\_nn max\_nn**

adjust\_radius\_factor = factor which scale the smooth/kernel radius  
min\_nn = minimum number of neighbors  
max\_nn = maximum number of neighbors

**limit\_velocity values = max\_velocity**

max\_velocity = maximum allowed velocity.

## 2.214.2 Examples

```
fix 1 all smd/integrate_ulsph adjust_radius 1.02 25 50
fix 1 all smd/integrate_ulsph limit_velocity 1000
```

### 2.214.3 Description

The fix performs explicit time integration for particles which interact with the updated Lagrangian SPH pair style.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

The *adjust\_radius* keyword activates dynamic adjustment of the per-particle SPH smoothing kernel radius such that the number of neighbors per particles remains within the interval *min\_nn* to *max\_nn*. The parameter *adjust\_radius\_factor* determines the amount of adjustment per timestep. Typical values are *adjust\_radius\_factor* = 1.02, *min\_nn* = 15, and *max\_nn* = 20.

The *limit\_velocity* keyword will control the velocity, scaling the norm of the velocity vector to *max\_vel* in case it exceeds this velocity limit.

### 2.214.4 Restart, fix\_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. This fix has no outputs.

### 2.214.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Changed in version 29Aug2024.

This fix is incompatible with deformation controls that remap velocity, for instance the *remap v* option of *fix deform*.

### 2.214.6 Related commands

### 2.214.7 Default

none

## 2.215 fix smd/move\_tri\_surf command

### 2.215.1 Syntax

**fix** ID group-ID smd/move\_tri\_surf keyword

- ID, group-ID are documented in *fix* command
- smd/move\_tri\_surf keyword = style name of this fix command
- keyword = *\*LINEAR* or *\*WIGGLE* or *\*ROTATE*
  - \*LINEAR* args = Vx Vy Vz  
Vx,Vy,Vz = components of velocity vector (velocity units), any component can be [specified as NULL](#)
  - \*WIGGLE* args = Vx Vy Vz max\_travel

$v_x, v_y, v_z$  = components of velocity vector (velocity units), any component can be `NULL`  
 $\rightarrow$  specified as `NULL`  
`max_travel` = wiggle amplitude  
`*ROTATE` args = `Px Py Pz Rx Ry Rz period`  
`Px,Py,Pz` = origin point of axis of rotation (distance units)  
`Rx,Ry,Rz` = axis of rotation vector  
`period` = period of rotation (time units)

## 2.215.2 Examples

```

fix 1 tool smd/move_tri_surf *LINEAR 20 20 10
fix 2 tool smd/move_tri_surf *WIGGLE 20 20 10
fix 2 tool smd/move_tri_surf *ROTATE 0 0 0 5 2 1
  
```

## 2.215.3 Description

This fix applies only to rigid surfaces read from .STL files via fix [smd/wall\\_surface](#). It updates position and velocity for the particles in the group each timestep without regard to forces on the particles. The rigid surfaces can thus be moved along simple trajectories during the simulation.

The `*LINEAR` style moves particles with the specified constant velocity vector  $V = (V_x, V_y, V_z)$ . This style also sets the velocity of each particle to  $V = (V_x, V_y, V_z)$ .

The `*WIGGLE` style moves particles in an oscillatory fashion. Particles are moved along  $(v_x, v_y, v_z)$  with constant velocity until a displacement of `max_travel` is reached. Then, the velocity vector is reversed. This process is repeated.

The `*ROTATE` style rotates particles around a rotation axis  $R = (R_x, R_y, R_z)$  that goes through a point  $P = (P_x, P_y, P_z)$ . The period of the rotation is also specified. This style also sets the velocity of each particle to  $(\omega \times R_{\text{perp}})$  where  $\omega$  is its angular velocity around the rotation axis and  $R_{\text{perp}}$  is a perpendicular vector from the rotation axis to the particle.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

## 2.215.4 Restart, fix\_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. This fix has no outputs.

## 2.215.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

## 2.215.6 Related commands

*smd/triangle\_mesh\_vertices*, *smd/wall\_surface*

## 2.215.7 Default

none

## 2.216 fix smd/setvel command

### 2.216.1 Syntax

```
fix ID group-ID smd/setvel vx vy vz keyword value ...
```

- ID, group-ID are documented in *fix* command
- smd/setvel = style name of this fix command
- vx,vy,vz = velocity component values
- any of vx,vy,vz can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = *region*

*region* value = region-ID

region-ID = ID of region particles must be in to have their velocities set

### 2.216.2 Examples

```
fix top_velocity top_group smd/setvel 1.0 0.0 0.0
```

### 2.216.3 Description

Set each component of velocity on each particle in the group to the specified values vx,vy,vz, regardless of the forces acting on the particle. This command can be used to impose velocity boundary conditions.

Any of the vx,vy,vz values can be specified as NULL which means do not alter the velocity component in that dimension.

This fix is indented to be used together with a time integration fix.

Any of the 3 quantities defining the velocity components can be specified as an equal-style or atom-style *variable*, namely vx, vy, vz. If the value is a variable, it should be specified as v\_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent velocity field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field with optional time-dependence as well.

If the *region* keyword is used, the particle must also be in the specified geometric *region* in order to have its velocity set by this command.

---

## 2.216.4 Restart, fix\_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global 3-vector of forces, which can be accessed by various *output commands*. This is the total force on the group of atoms. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

## 2.216.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.216.6 Related commands

none

## 2.216.7 Default

none

# 2.217 fix smd/wall\_surface command

## 2.217.1 Syntax

**fix** ID group-ID smd/wall\_surface arg type mol-ID

- ID, group-ID are documented in *fix* command
- smd/wall\_surface = style name of this fix command
- arg = *file*  
*file* = file name of a triangular mesh in stl format
- type = particle type to be given to the new particles created by this fix
- mol-ID = molecule-ID to be given to the new particles created by this fix (must be  $\geq 65535$ )

## 2.217.2 Examples

```
fix stl_surf all smd/wall_surface tool.stl 2 65535
```

## 2.217.3 Description

This fix creates reads a triangulated surface from a file in .STL format. For each triangle, a new particle is created which stores the barycenter of the triangle and the vertex positions. The radius of the new particle is that of the minimum circle which encompasses the triangle vertices.

The triangulated surface can be used as a complex rigid wall via the *smd/tri\_surface* pair style. It is possible to move the triangulated surface via the *smd/move\_tri\_surf* fix style.

Immediately after a .STL file has been read, the simulation needs to be run for 0 timesteps in order to properly register the new particles in the system. See the “funnel\_flow” example in the MACHDYN examples directory.

See [this PDF guide](#) to use Smooth Mach Dynamics in LAMMPS.

## 2.217.4 Restart, fix\_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. This fix has no outputs.

## 2.217.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The molecule ID given to the particles created by this fix have to be equal to or larger than 65535.

Within each .STL file, only a single triangulated object must be present, even though the STL format allows for the possibility of multiple objects in one file.

fix longitudinal pore spring couple ion 100.0 NULL NULL -20.0 0.0
fix radial pore spring couple ion 100.0 0.0 0.0 NULL 5.0
```

## 2.220.3 Description

Apply a spring force to a group of atoms or between two groups of atoms. This is useful for applying an umbrella force to a small molecule or lightly tethering a large group of atoms (e.g. all the solvent or a large molecule) to the center of the simulation box so that it does not wander away over the course of a long simulation. It can also be used to hold the centers of mass of two groups of atoms at a given distance or orientation with respect to each other.

The *tether* style attaches a spring between a fixed point  $x,y,z$  and the center of mass of the fix group of atoms. The equilibrium position of the spring is  $R0$ . At each timestep the distance  $R$  from the center of mass of the group of atoms to the tethering point is computed, taking account of wrap-around in a periodic simulation box. A restoring force of magnitude  $K (R - R0) M_i / M$  is applied to each atom in the group where  $K$  is the spring constant,  $M_i$  is the mass of the atom, and  $M$  is the total mass of all atoms in the group. Note that  $K$  thus represents the spring constant for the total force on the group of atoms, not for a spring applied to each atom.

The *couple* style links two groups of atoms together. The first group is the fix group; the second is specified by group-ID2. The groups are coupled together by a spring that is at equilibrium when the two groups are displaced by a vector  $x,y,z$  with respect to each other and at a distance  $R0$  from that displacement. Note that  $x,y,z$  is the equilibrium displacement of group-ID2 relative to the fix group. Thus (1,1,0) is a different spring than (-1,-1,0). When the relative positions and distance between the two groups are not in equilibrium, the same spring force described above is applied to atoms in each of the two groups.

For both the *tether* and *couple* styles, any of the  $x,y,z$  values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

The first example above pulls the ligand towards the point (0,0,0). The second example holds the ligand near the surface of a sphere of radius 5 around the point (0,0,0). The third example holds the ligand a distance 3 away from the  $z=2$  plane (on either side).

The fourth example holds 2 bilayers a distance 10 apart in  $z$ . For the last two examples, imagine a pore (a slab of atoms with a cylindrical hole cut out) oriented with the pore axis along  $z$ , and an ion moving within the pore. The fifth example holds the ion a distance of -20 below the  $z = 0$  center plane of the pore (umbrella sampling). The last example holds the ion a distance 5 away from the pore axis (assuming the center-of-mass of the pore in  $x,y$  is the pore axis).

---

**Note:** The center of mass of a group of atoms is calculated in “unwrapped” coordinates using atom image flags, which means that the group can straddle a periodic boundary. See the [dump](#) doc page for a discussion of unwrapped coordinates. It also means that a spring connecting two groups or a group and the tether point can cross a periodic boundary and its length be calculated correctly.

---

## 2.220.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the energy stored in the spring to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the spring energy  $= 0.5 * K * r^2$ .

This fix also computes global 4-vector which can be accessed by various *output commands*. The first 3 quantities in the vector are xyz components of the total force added to the group of atoms by the spring. In the case of the *couple* style, it is the force on the fix group (group-ID) or the negative of the force on the second group (group-ID2). The fourth quantity in the vector is the magnitude of the force added by the spring, as a positive value if  $(r-R0) > 0$  and a negative value if  $(r-R0) < 0$ . This sign convention can be useful when using the spring force to compute a potential of mean force (PMF).

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix\_modify energy* option for this fix.

---

## 2.220.5 Restrictions

# 2.221 fix spring/chunk command

## 2.221.1 Syntax

**fix** ID group-ID spring/chunk K chunkID comID

- ID, group-ID are documented in *fix* command
- spring/chunk = style name of this fix command
- K = spring constant for each chunk (force/distance units)

- chunkID = ID of *compute chunk/atom* command
- comID = ID of *compute com/chunk* command

## 2.221.2 Examples

```
fix restrain all spring/chunk 100 chunkID comID
```

## 2.221.3 Description

Apply a spring force to the center-of-mass (COM) of chunks of atoms as defined by the *compute chunk/atom* command. Chunks can be molecules or spatial bins or other groupings of atoms. This is a way of tethering each chunk to its initial COM coordinates.

The *chunkID* is the ID of a *compute chunk/atom* command defined in the input script. It is used to define the chunks. The *comID* is the ID of a *compute com/chunk* command defined in the input script. It is used to compute the COMs of each chunk.

At the beginning of the first *run* or *minimize* command after this fix is defined, the initial COM of each chunk is calculated and stored as  $R_{0M}$ , where  $M$  is the chunk number. Thereafter, at every timestep (or minimization iteration), the current COM of each chunk is calculated as  $R_M$ . A restoring force of magnitude  $K (R_M - R_{0M}) M_i / M_m$  is applied to each atom in each chunk where  $K$  is the specified spring constant,  $M_i$  is the mass of the atom, and  $M_m$  is the total mass of all atoms in the chunk. Note that  $K$  thus represents the spring constant for the total force on each chunk of atoms, not for a spring applied to each atom.

## 2.221.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the locations of the initial per-chunk center of mass coordinates to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion. Since this fix depends on an instance of *compute chunk/atom* it will check when reading the restart if the chunk still exists and will define the same number of chunks. The restart data is only applied when the number of chunks matches. Otherwise the center of mass coordinates are recomputed.

The *fix\_modify energy* option is supported by this fix to add the energy stored in all the springs to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the energy of all the springs, i.e.  $0.5 * K * r^2$  per-spring.

The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the spring energies to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix\_modify energy* option for this fix.

---

*fix spring*, *fix spring/self*, *fix spring/rg*

## 2.221.7 Default

none

# 2.222 fix spring/rg command

## 2.222.1 Syntax

```
fix ID group-ID spring/rg K RG0
```

- ID, group-ID are documented in *fix* command
- spring/rg = style name of this fix command
- K = harmonic force constant (force/distance units)
- RG0 = target radius of gyration to constrain to (distance units)

```
if RG0 = NULL, use the current RG as the target value
```

## 2.222.2 Examples

```
fix 1 protein spring/rg 5.0 10.0  
fix 2 micelle spring/rg 5.0 NULL
```

## 2.222.3 Description

Apply a harmonic restraining force to atoms in the group to affect their central moment about the center of mass (radius of gyration). This fix is useful to encourage a protein or polymer to fold/unfold and also when sampling along the radius of gyration as a reaction coordinate (i.e. for protein folding).

The radius of gyration is defined as RG in the first formula. The energy of the constraint and associated force on each atom is given by the second and third formulas, when the group is at a different RG than the target value RG0.

$$R_G^2 = \frac{1}{M} \sum_i^N m_i \left( x_i - \frac{1}{M} \sum_j^N m_j x_j \right)^2$$
$$E = K (R_G - R_{G0})^2$$
$$F_i = 2K \frac{m_i}{M} \left( 1 - \frac{R_{G0}}{R_G} \right) \left( x_i - \frac{1}{M} \sum_j^N m_j x_j \right)$$

The ( $x_i$  - center-of-mass) term is computed taking into account periodic boundary conditions,  $m_i$  is the mass of the atom, and  $M$  is the mass of the entire group. Note that  $K$  is thus a force constant for the aggregate force on the group of atoms, not a per-atom force.

If  $R_{G0}$  is specified as NULL, then the RG of the group is computed at the time the fix is specified, and that value is used as the target.

## 2.222.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the currently used reference RG ( $R_{G0}$ ) to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the reference radius of gyration  $R_{G0}$  used by the fix. energy change due to this fix. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

## 2.222.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.222.6 Related commands

*fix spring*, *fix spring/self* *fix drag*, *fix smd*

## 2.223 fix spring/self command

### 2.223.1 Syntax

```
fix ID group-ID spring/self K dir
```

- ID, group-ID are documented in *fix* command
- spring/self = style name of this fix command
- K = spring constant (force/distance units)
- dir = xyz, xy, xz, yz, x, y, or z (optional, default: xyz)

## 2.223.2 Examples

```
fix tether boundary-atoms spring/self 10.0
fix zrest move spring/self 10.0 z
```

## 2.223.3 Description

Apply a spring force independently to each atom in the group to tether it to its initial position. The initial position for each atom is its location at the time the fix command was issued. At each timestep, the magnitude of the force on each atom is  $-Kr$ , where  $r$  is the displacement of the atom from its current position to its initial position. The distance  $r$  correctly takes into account any crossings of periodic boundary by the atom since it was in its initial position.

With the (optional) `dir` flag, one can select in which direction the spring force is applied. By default, the restraint is applied in all directions, but it can be limited to the `xy`-, `xz`-, `yz`-plane and the `x`-, `y`-, or `z`-direction, thus restraining the atoms to a line or a plane, respectively.

## 2.223.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the original coordinates of tethered atoms to *binary restart files*, so that the spring effect will be the same in a restarted simulation. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify energy* option is supported by this fix to add the energy stored in the per-atom springs to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is an energy which is the sum of the spring energy for each atom, where the per-atom energy is  $0.5 * K * r^2$ . The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the per-atom spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix\_modify energy* option for this fix.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.224.3 Description

Treat a group of particles as stochastic rotation dynamics (SRD) particles that serve as a background solvent when interacting with big (colloidal) particles in groupbig-ID. The SRD formalism is described in ([Hecht](#)). The same methodology is also called multi-particle collision dynamics (MPCD) in the literature.

The key idea behind using SRD particles as a cheap coarse-grained solvent is that SRD particles do not interact with each other, but only with the solute particles, which in LAMMPS can be spheroids, ellipsoids, or line segments, or triangles, or rigid bodies containing multiple spheroids or ellipsoids or line segments or triangles. The collision and rotation properties of the model imbue the SRD particles with fluid-like properties, including an effective viscosity. Thus simulations with large solute particles can be run more quickly, to measure solute properties like diffusivity and viscosity in a background fluid. The usual LAMMPS fixes for such simulations, such as *fix deform*, *fix viscosity*, and *fix nvt/sllod*, can be used in conjunction with the SRD model.

These 3 papers give more details on how the SRD model is implemented in LAMMPS. ([Petersen](#)) describes pure SRD fluid systems. ([Bolintineanu1](#)) describes models where pure SRD fluids interact with boundary walls. ([Bolintineanu2](#)) describes mixture models where large colloidal particles are solvated by an SRD fluid. See the `examples/srd` directory for sample input scripts.

This fix does two things:

1. It advects the SRD particles, performing collisions between SRD and big particles or walls every timestep, imparting force and torque to the big particles. Collisions also change the position and velocity of SRD particles.
2. It resets the velocity distribution of SRD particles via random rotations every N timesteps.

SRD particles have a mass, temperature, characteristic timestep  $dt_{SRD}$ , and mean free path between collisions ( $\lambda$ ). The fundamental equation relating these 4 quantities is

$$\lambda = dt_{SRD} \sqrt{\frac{k_B T_{SRD}}{m}}$$

The mass  $m$  of SRD particles is set by the *mass* command elsewhere in the input script. The SRD timestep  $dt_{SRD}$  is N times the step  $dt$  defined by the *timestep* command. Big particles move in the normal way via a time integration *fix* with a short timestep  $dt$ . SRD particles advect with a large timestep  $dt_{SRD} \geq dt$ .

If the *lamda* keyword is not specified, the SRD temperature  $T_{SRD}$  is used in the above formula to compute  $\lambda$ . If the *lamda* keyword is specified, then the *Tsrd* setting is ignored and the above equation is used to compute the SRD temperature.

The characteristic length scale for the SRD fluid is set by *hgrid* which is used to bin SRD particles for purposes of resetting their velocities. Normally *hgrid* is set to be 1/4 of the big particle diameter or smaller, to adequately resolve fluid properties around the big particles.

$\lambda$  cannot be smaller than  $0.6 * hgrid$ , else an error is generated (unless the *shift* keyword is used, see below). The velocities of SRD particles are bounded by  $V_{max}$ , which is set so that an SRD particle will not advect further than  $D_{max} = 4\lambda$  in  $dt_{SRD}$ . This means that roughly speaking,  $D_{max}$  should not be larger than a big particle diameter, else SRDs may pass through big particles without colliding. A warning is generated if this is the case.

Collisions between SRD particles and big particles or walls are modeled as a lightweight SRD point particle hitting a heavy big particle of given diameter or a wall at a point on its surface and bouncing off with a new velocity. The collision changes the momentum of the SRD particle. It imparts a force and torque to the big particle. It imparts a force to a wall. Static or moving SRD walls are setup via the *fix wall/srd* command. For the remainder of this doc page, a collision of an SRD particle with a wall can be viewed as a collision with a big particle of infinite radius and mass.

The *collision* keyword sets the style of collisions. The *slip* style means that the tangential component of the SRD particle momentum is preserved. Thus a force is imparted to a big particle, but no torque. The normal component of the new SRD velocity is sampled from a Gaussian distribution at temperature *Tsrd*.

For the *noslip* style, both the normal and tangential components of the new SRD velocity are sampled from a Gaussian distribution at temperature *Tsrd*. Additionally, a new tangential direction for the SRD velocity is chosen randomly. This collision style imparts torque to a big particle. Thus a time integrator *fix* that rotates the big particles appropriately should be used.

The *overlap* keyword should be set to *yes* if two (or more) big particles can ever overlap. This depends on the pair potential interaction used for big-big interactions, or could be the case if multiple big particles are held together as rigid bodies via the *fix rigid* command. If the *overlap* keyword is *no* and big particles do in fact overlap, then SRD/big collisions can generate an error if an SRD ends up inside two (or more) big particles at once. How this error is treated is determined by the *inside* keyword. Running with *overlap* set to *no* allows for faster collision checking, so it should only be set to *yes* if needed.

The *inside* keyword determines how a collision is treated if the computation determines that the timestep started with the SRD particle already inside a big particle. If the setting is *error* then this generates an error message and LAMMPS stops. If the setting is *warn* then this generates a warning message and the code continues. If the setting is *ignore* then no message is generated. One of the output quantities logged by the *fix* (see below) tallies the number of such events, so it can be monitored. Note that once an SRD particle is inside a big particle, it may remain there for several steps until it drifts outside the big particle.

The *exact* keyword determines how accurately collisions are computed. A setting of *yes* computes the time and position of each collision as SRD and big particles move together. A setting of *no* estimates the position of each collision based on the end-of-timestep positions of the SRD and big particle. If *overlap* is set to *yes*, the setting of the *exact* keyword is ignored since time-accurate collisions are needed.

The *radius* keyword scales the effective size of big particles. If big particles will overlap as they undergo dynamics, then this keyword can be used to scale down their effective collision radius by an amount *rfactor*, so that SRD particle will only collide with one big particle at a time. For example, in a Lennard-Jones system at a temperature of 1.0 (in reduced LJ units), the minimum separation between two big particles is as small as about 0.88 sigma. Thus an *rfactor* value of 0.85 should prevent dual collisions.

The *bounce* keyword can be used to limit the maximum number of collisions an SRD particle undergoes in a single timestep as it bounces between nearby big particles. Note that if the limit is reached, the SRD can be left inside a big particle. A setting of 0 is the same as no limit.

There are 2 kinds of bins created and maintained when running an SRD simulation. The first are “SRD bins” which are used to bin SRD particles and reset their velocities, as discussed above. The second are “search bins” which are used to identify SRD/big particle collisions.

The *search* keyword can be used to choose a search bin size for identifying SRD/big particle collisions. The default is to use the *hgrid* parameter for SRD bins as the search bin size. Choosing a smaller or large value may be more efficient, depending on the problem. But, in a statistical sense, it should not change the simulation results.

The *cubic* keyword can be used to generate an error or warning when the bin size chosen by LAMMPS creates SRD bins that are non-cubic or different than the requested value of *hgrid* by a specified *tolerance*. Note that using non-cubic SRD bins can lead to undetermined behavior when rotating the velocities of SRD particles, hence LAMMPS tries to protect you from this problem.

LAMMPS attempts to set the SRD bin size to exactly *hgrid*. However, there must be an integer number of bins in each dimension of the simulation box. Thus the actual bin size will depend on the size and shape of the overall simulation box. The actual bin size is printed as part of the SRD output when a simulation begins.

If the actual bin size is non-cubic by an amount exceeding the tolerance, an error or warning is printed, depending on the style of the *cubic* keyword. Likewise, if the actual bin size differs from the requested *hgrid* value by an amount exceeding the tolerance, then an error or warning is printed. The *tolerance* is a fractional difference. E.g. a tolerance setting of 0.01 on the shape means that if the ratio of any 2 bin dimensions exceeds (1 +/- tolerance) then an error or warning is generated. Similarly, if the ratio of any bin dimension with *hgrid* exceeds (1 +/- tolerance), then an error or warning is generated.

---

**Note:** The *fix srd* command can be used with simulations where the size and/or shape of the simulation box changes. This can be due to non-periodic boundary conditions or the use of fixes such as the *fix deform* or *fix wall/srd* commands to impose a shear on an SRD fluid or an interaction with an external wall. If the box size changes then the size of SRD bins must be recalculated every reneighboring. This is not necessary if only the box shape changes. This re-binning is always done so as to fit an integer number of bins in the current box dimension, whether it be a fixed, shrink-wrapped, or periodic boundary, as set by the *boundary* command. If the box size or shape changes, then the size of the search bins must be recalculated every reneighboring. Note that changing the SRD bin size may alter the properties of the SRD fluid, such as its viscosity.

---

The *shift* keyword determines whether the coordinates of SRD particles are randomly shifted when binned for purposes of rotating their velocities. When no shifting is performed, SRD particles are binned and the velocity distribution of the set of SRD particles in each bin is adjusted via a rotation operator. This is a statistically valid operation if SRD particles move sufficiently far between successive rotations. This is determined by their mean-free path  $\lambda$ . If  $\lambda$  is less than 0.6 of the SRD bin size, then shifting is required. A shift means that all of the SRD particles are shifted by a vector whose coordinates are chosen randomly in the range  $[-1/2 \text{ bin size}, 1/2 \text{ bin size}]$ . Note that all particles are shifted by the same vector. The specified random number *shiftseed* is used to generate these vectors. This operation sufficiently randomizes which SRD particles are in the same bin, even if *lambda* is small.

If the *shift* flag is set to *no*, then no shifting is performed, but bin data will be communicated if bins overlap processor boundaries. An error will be generated if  $\lambda < 0.6$  of the SRD bin size. If the *shift* flag is set to *possible*, then shifting is performed only if  $\lambda < 0.6$  of the SRD bin size. A warning is generated to let you know this is occurring. If the *shift* flag is set to *yes* then shifting is performed regardless of the magnitude of  $\lambda$ . Note that the *shiftseed* is not used if the *shift* flag is set to *no*, but must still be specified.

Note that shifting of SRD coordinates requires extra communication, hence it should not normally be enabled unless required.

The *tstat* keyword will thermostat the SRD particles to the specified *Tsrd*. This is done every N timesteps, during the velocity rotation operation, by rescaling the thermal velocity of particles in each SRD bin to the desired temperature. If there is a streaming velocity associated with the system, e.g. due to use of the *fix deform* command to perform a simulation undergoing shear, then that is also accounted for. The mean velocity of each bin of SRD particles is set to the position-dependent streaming velocity, based on the coordinates of the center of the SRD bin. Note that collisions of SRD particles with big particles or walls has a thermostating effect on the colliding particles, so it may not be necessary to thermostat the SRD particles on a bin by bin basis in that case. Also note that for streaming simulations, if no thermostating is performed (the default), then it may take a long time for the SRD fluid to come to equilibrium with a velocity profile that matches the simulation box deformation.

The *rescale* keyword enables rescaling of an SRD particle's velocity if it would travel more than 4 mean-free paths in an SRD timestep. If an SRD particle exceeds this velocity it is possible it will be lost when migrating to other processors or that collisions with big particles will be missed, either of which will generate errors. Thus the safest mode is to run

with rescaling enabled. However rescaling removes kinetic energy from the system (the particle's velocity is reduced). The latter will not typically be a problem if thermostatting is enabled via the *tstat* keyword or if SRD collisions with big particles or walls effectively thermostat the system. If you wish to turn off rescaling (on is the default), e.g. for a pure SRD system with no thermostatting so that the temperature does not decline over time, the *rescale* keyword can be used. The *no* value turns rescaling off during collisions and the per-bin velocity rotation operation. The *collide* and *rotate* values turn it on for one of the operations and off for the other.

---

**Note:** This fix is normally used for simulations with a huge number of SRD particles relative to the number of big particles, e.g. 100 to 1. In this scenario, computations that involve only big particles (neighbor list creation, communication, time integration) can slow down dramatically due to the large number of background SRD particles.

---

Three other input script commands will largely overcome this effect, speeding up an SRD simulation by a significant amount. These are the *atom\_modify first*, *neigh\_modify include*, and *comm\_modify group* commands. Each takes a group-ID as an argument, which in this case should be the group-ID of the big solute particles.

Additionally, when a *pair\_style* for big/big particle interactions is specified, the *pair\_coeff* command should be used to turn off big/SRD interactions, e.g. by setting their epsilon or cutoff length to 0.0.

The “delete\_atoms overlap” command may be useful in setting up an SRD simulation to ensure there are no initial overlaps between big and SRD particles.

---

#### 2.224.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix tabulates several SRD statistics which are stored in a vector of length 12, which can be accessed by various *output commands*. The vector values calculated by this fix are “intensive”, meaning they do not scale with the size of the simulation. Technically, the first 8 do scale with the size of the simulation, but treating them as intensive means they are not scaled when printed as part of thermodynamic output.

These are the 12 quantities. All are values for the current timestep, except for quantity 5 and the last three, each of which are cumulative quantities since the beginning of the run.

- (1) # of SRD/big collision checks performed
- (2) # of SRDs which had a collision
- (3) # of SRD/big collisions (including multiple bounces)
- (4) # of SRD particles inside a big particle
- (5) # of SRD particles whose velocity was rescaled to be < Vmax
- (6) # of bins for collision searching
- (7) # of bins for SRD velocity rotation
- (8) # of bins in which SRD temperature was computed
- (9) SRD temperature
- (10) # of SRD particles which have undergone max # of bounces
- (11) max # of bounces any SRD particle has had in a single step
- (12) # of reneighborings due to SRD particles moving too far

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.224.5 Restrictions

This command can only be used if LAMMPS was built with the SRD package. See the [Build package](#) doc page for more info.

## 2.224.6 Related commands

*fix wall/srd*

## 2.224.7 Default

The option defaults are: *lamda* ( $\lambda$ ) is inferred from *Tsrd*, collision = noslip, overlap = no, inside = error, exact = yes, radius = 1.0, bounce = 0, search = hgrid, cubic = error 0.01, shift = no, tstat = no, and rescale = yes.

## 2.225 fix store/force command

### 2.225.1 Syntax

```
fix ID group-ID store/force
```

- ID, group-ID are documented in *fix* command
- store/force = style name of this fix command

### 2.225.2 Examples

```
fix 1 all store/force
```

### 2.225.3 Description

Store the forces on atoms in the group at the point during each timestep when the fix is invoked, as described below. This is useful for storing forces before constraints or other boundary conditions are computed which modify the forces, so that unmodified forces can be *written to a dump file* or accessed by other *output commands* that use per-atom quantities.

This fix is invoked at the point in the velocity-Verlet timestepping immediately after *pair*, *bond*, *angle*, *dihedral*, *improper*, and *long-range* forces have been calculated. It is the point in the timestep when various fixes that compute constraint forces are calculated and potentially modify the force on each atom. Examples of such fixes are *fix shake*, *fix wall*, and *fix indent*.

**Note:** The order in which various fixes are applied which operate at the same point during the timestep, is the same as the order they are specified in the input script. Thus normally, if you want to store per-atom forces due to force field interactions, before constraints are applied, you should list this fix first within that set of fixes, i.e. before other fixes that apply constraints. However, if you wish to include certain constraints (e.g. fix shake) in the stored force, then it could be specified after some fixes and before others.

## 2.225.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various *output commands*. The number of columns for each atom is 3, and the columns store the x,y,z forces on each atom. The per-atom values be accessed on any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

```
fix 1 all store/state 0 x y z
fix 1 all store/state 0 xu yu zu com yes
fix 2 all store/state 1000 vx vy vz
```

### 2.226.3 Description

Define a fix that stores attributes for each atom in the group at the time the fix is defined. If  $N$  is 0, then the values are never updated, so this is a way of archiving an atom attribute at a given time for future use in a calculation or output. See the discussion of *output commands* that take fixes as inputs.

If  $N$  is not zero, then the attributes will be updated every  $N$  steps.

---

**Note:** Actually, only atom attributes specified by keywords like *xu* or *vy* or *radius* are initially stored immediately at the point in your input script when the fix is defined. Attributes specified by a compute, fix, or variable are not initially stored until the first run following the fix definition begins. This is because calculating those attributes may require quantities that are not defined in between runs.

---

The list of possible attributes is the same as that used by the *dump custom* command, which describes their meaning.

If the *com* keyword is set to *yes* then the *xu*, *yu*, and *zu* inputs store the position of each atom relative to the center-of-mass of the group of atoms, instead of storing the absolute position.

The requested values are stored in a per-atom vector or array as discussed below. Zeroes are stored for atoms not in the specified group.

### 2.226.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the per-atom values it stores to *binary restart files*, so that the values can be restored when a simulation is restarted. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Warning:** When reading data from a restart file, this fix command has to be specified **exactly** the same way as before. LAMMPS will only check whether a fix is of the same style and has the same fix ID and in case of a match will then try to initialize the fix with the data stored in the binary restart file. If the fix store/state command does not match exactly, data can be corrupted or LAMMPS may crash.

None of the *fix\_modify* options are relevant to this fix.

If a single input is specified, this fix produces a per-atom vector. If multiple inputs are specified, a per-atom array is produced where the number of columns for each atom is the number of inputs. These can be accessed by various *output commands*. The per-atom values be accessed on any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.226.5 Restrictions

none

## 2.226.6 Related commands

*dump custom, compute property/atom, fix property/atom, variable*

## 2.226.7 Default

The option default is com = no.

## 2.227 fix temp/berendsen command

Accelerator Variants: *temp/berendsen/kk*

### 2.227.1 Syntax

```
fix ID group-ID temp/berendsen Tstart Tstop Tdamp
```

- ID, group-ID are documented in *fix* command
- temp/berendsen = style name of this fix command
- Tstart,Tstop = desired temperature at start/end of run

Tstart can be a variable (see below)

- Tdamp = temperature damping parameter (time units)

### 2.227.2 Examples

```
fix 1 all temp/berendsen 300.0 300.0 100.0
```

### 2.227.3 Description

Reset the temperature of a group of atoms by using a Berendsen thermostat (*Berendsen*), which rescales their velocities every timestep.

The thermostat is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles which have rotational degrees of freedom are being thermostatted with this fix. The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

The desired temperature at each timestep is a ramped value during the run from *Tstart* to *Tstop*. The *Tdamp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (tau or fs or ps - see the *units* command).

*Tstart* can be specified as an equal-style *variable*. In this case, the *Tstop* setting is ignored. If the value is a variable, it should be specified as *v\_name*, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

---

**Note:** This thermostat will generate an error if the current temperature is zero at the end of a timestep. It cannot rescale a zero temperature.

---

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

---

**Note:** Unlike the *fix nvt* command which performs Nose/Hoover thermostating AND time integration, this fix does NOT perform time integration. It only modifies velocities to effect thermostating. Thus you must use a separate time integration fix, like *fix nve* to actually update the positions of atoms using the modified velocities. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by *fix nvt* or *fix langevin* commands.

---

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostating.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the *compute temp* command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp*. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command or print this temperature during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 2.227.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the cumulative global energy change to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a temperature *compute* you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.227.5 Restrictions

This fix can be used with dynamic groups as defined by the *group* command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

## 2.227.6 Related commands

## 2.228 fix temp/csvr command

## 2.229 fix temp/csld command

### 2.229.1 Syntax

```
fix ID group-ID temp/csvr Tstart Tstop Tdamp seed
fix ID group-ID temp/csld Tstart Tstop Tdamp seed
```

- ID, group-ID are documented in *fix* command
- temp/csvr or temp/csld = style name of this fix command
- Tstart,Tstop = desired temperature at start/end of run

`Tstart` can be a variable (see below)

- `Tdamp` = temperature damping parameter (time units)
- `seed` = random number seed to use for white noise (positive integer)

## 2.229.2 Examples

```
fix 1 all temp/csvr 300.0 300.0 100.0 54324
fix 1 all temp/csld 100.0 300.0 10.0 123321
```

## 2.229.3 Description

Adjust the temperature with a canonical sampling thermostat that uses global velocity rescaling with Hamiltonian dynamics (*temp/csvr*) ([Bussi1](#)), or Langevin dynamics (*temp/csld*) ([Bussi2](#)). In the case of *temp/csvr* the thermostat is similar to the empirical Berendsen thermostat in *temp/berendsen*, but chooses the actual scaling factor from a suitably chosen (gaussian) distribution rather than having it determined from the time constant directly. In the case of *temp/csld* the velocities are updated to a linear combination of the current velocities with a gaussian distribution of velocities at the desired temperature. Both thermostats are applied every timestep.

The thermostat is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles which have rotational degrees of freedom are being thermostatted with these fixes. The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

The desired temperature at each timestep is a ramped value during the run from *Tstart* to *Tstop*. The *Tdamp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (tau or fs or ps - see the *units* command).

*Tstart* can be specified as an equal-style *variable*. In this case, the *Tstop* setting is ignored. If the value is a variable, it should be specified as *v\_name*, where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

---

**Note:** Unlike the *fix nvt* command which performs Nose/Hoover thermostating AND time integration, these fixes do NOT perform time integration. They only modify velocities to effect thermostating. Thus you must use a separate time integration fix, like *fix nve* to actually update the positions of atoms using the modified velocities. Likewise, these fixes should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by *fix nvt* or *fix langevin* commands.

---

See the [Howto thermostat](#) page for a discussion of different ways to compute temperature and perform thermostating.

These fixes compute a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the *compute temp* command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp*. This means you can change the attributes of this fix's temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command or print this temperature during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

An important feature of these thermostats is that they have an associated effective energy that is a constant of motion. The effective energy is the total energy (kinetic + potential) plus the accumulated kinetic energy changes due to the thermostat. The latter quantity is the global scalar computed by these fixes. This feature is useful to check the integration of the equations of motion against discretization errors. In other words, the conservation of the effective energy can be used to choose an appropriate integration *timestep*. This is similar to the usual paradigm of checking the conservation of the total energy in the microcanonical ensemble.

---

## 2.229.4 Restart, fix\_modify, output, run start/stop, minimize info

These fixes write the cumulative global energy change and the random number generator states to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the selected fix continues in an uninterrupted fashion. The random number generator state can only be restored when the number of processors remains unchanged from what is recorded in the restart file.

The *fix\_modify temp* option is supported by these fixes. You can use it to assign a temperature *compute* you have defined to these fixes which will be used in its thermostating procedure, as described above. For consistency, the group used by these fixes and by the compute should be the same.

The cumulative energy change in the system imposed by these fixes is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

These fixes compute a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

These fixes can ramp their target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

These fixes are not invoked during *energy minimization*.

## 2.229.5 Restrictions

Fix *temp/csld* is not compatible with *fix shake*.

These fixes are part of the EXTRA-FIX package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These fixes can be used with dynamic groups as defined by the *group* command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

## 2.230 fix temp/rescale command

Accelerator Variants: *temp/rescale/kk*

### 2.230.1 Syntax

```
fix ID group-ID temp/rescale N Tstart Tstop window fraction
```

- ID, group-ID are documented in *fix* command
- temp/rescale = style name of this fix command
- N = perform rescaling every N steps
- Tstart, Tstop = desired temperature at start/end of run (temperature units)

Tstart can be a variable (see below)

- window = only rescale if temperature is outside this window (temperature units)
- fraction = rescale to target temperature by this fraction

### 2.230.2 Examples

```
fix 3 flow temp/rescale 100 1.0 1.1 0.02 0.5
fix 3 boundary temp/rescale 1 1.0 1.5 0.05 1.0
fix 3 boundary temp/rescale 1 1.0 1.5 0.05 1.0
```

### 2.230.3 Description

Reset the temperature of a group of atoms by explicitly rescaling their velocities.

The rescaling is applied to only the translational degrees of freedom for the particles, which is an important consideration if finite-size particles which have rotational degrees of freedom are being thermostatted with this fix. The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

Rescaling is performed every N timesteps. The target temperature is a ramped value between the *Tstart* and *Tstop* temperatures at the beginning and end of the run.

**Note:** This thermostat will generate an error if the current temperature is zero at the end of a timestep it is invoked on. It cannot rescale a zero temperature.

---

*Tstart* can be specified as an equal-style *variable*. In this case, the *Tstop* setting is ignored. If the value is a variable, it should be specified as *v\_name*, where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Rescaling is only performed if the difference between the current and desired temperatures is greater than the *window* value. The amount of rescaling that is applied is a *fraction* (from 0.0 to 1.0) of the difference between the actual and desired temperature. E.g. if *fraction* = 1.0, the temperature is reset to exactly the desired value.

---

**Note:** Unlike the *fix nvt* command which performs Nose/Hoover thermostating AND time integration, this fix does NOT perform time integration. It only modifies velocities to effect thermostating. Thus you must use a separate time integration fix, like *fix nve* to actually update the positions of atoms using the modified velocities. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by *fix nvt* or *fix langevin* commands.

---

See the [Howto thermostat](#) page for a discussion of different ways to compute temperature and perform thermostating.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if one of this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the [compute temp](#) for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the *thermo\_style* command) with ID = *thermo\_temp*. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the *compute\_modify* command or print this temperature during thermodynamic output via the *thermo\_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo\_temp* will have no effect on this fix.

Like other fixes that perform thermostating, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial *region*, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix\_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

## 2.230.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the cumulative global energy change to *binary restart files*. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a temperature *compute* you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.230.5 Restrictions

# 2.231 fix temp/rescale/eff command

## 2.231.1 Syntax

```
fix ID group-ID temp/rescale/eff N Tstart Tstop window fraction
```

- ID, group-ID are documented in *fix* command
- temp/rescale/eff = style name of this fix command
- N = perform rescaling every N steps
- Tstart,Tstop = desired temperature at start/end of run (temperature units)
- window = only rescale if temperature is outside this window (temperature units)

- fraction = rescale to target temperature by this fraction

## 2.231.2 Examples

```
fix 3 flow temp/rescale/eff 10 1.0 100.0 0.02 1.0
```

## 2.231.3 Description

Reset the temperature of a group of nuclei and electrons in the *electron force field* model by explicitly rescaling their velocities.

The operation of this fix is exactly like that described by the *fix temp/rescale* command, except that the rescaling is also applied to the radial electron velocity for electron particles.

## 2.231.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify temp* option is supported by this fix. You can use it to assign a temperature *compute* you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the *thermodynamic output* keywords *ecouple* and *econserve*. See the *thermo\_style* doc page for details.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.231.5 Restrictions

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

fix 1 all tfmc 0.05 600.0 658943 com 1 1 0
fix 1 all tfmc 0.1 750.0 387068 com 1 1 1 rot
```

### 2.232.3 Description

Perform uniform-acceptance force-bias Monte Carlo (fbMC) simulations, using the time-stamped force-bias Monte Carlo (tfMC) algorithm described in (*Mees*) and (*Bal*).

One successful use case of force-bias Monte Carlo methods is that they can be used to extend the time scale of atomistic simulations, in particular when long time scale relaxation effects must be considered; some interesting examples are given in the review by (*Neyts*). An example of a typical use case would be the modelling of chemical vapor deposition (CVD) processes on a surface, in which impacts by gas-phase species can be performed using MD, but subsequent relaxation of the surface is too slow to be done using MD only. Using tfMC can allow for a much faster relaxation of the surface, so that higher fluxes can be used, effectively extending the time scale of the simulation. (Such an alternating simulation approach could be set up using a *loop*.)

The initial version of tfMC algorithm in (*Mees*) contained an estimation of the effective time scale of such a simulation, but it was later shown that the speed-up one can gain from a tfMC simulation is system- and process-dependent, ranging from none to several orders of magnitude. In general, solid-state processes such as (re)crystallization or growth can be accelerated by up to two or three orders of magnitude, whereas diffusion in the liquid phase is not accelerated at all. The observed pseudodynamics when using the tfMC method is not the actual dynamics one would obtain using MD, but the relative importance of processes can match the actual relative dynamics of the system quite well, provided

*Delta* is chosen with care. Thus, the system's equilibrium is reached faster than in MD, along a path that is generally roughly similar to a typical MD simulation (but not necessarily so). See (*Bal*) for details.

Each step, all atoms in the selected group are displaced using the stochastic tfMC algorithm, which is designed to sample the canonical (NVT) ensemble at the temperature *Temp*. Although tfMC is a Monte Carlo algorithm and thus strictly speaking does not perform time integration, it is similar in the sense that it uses the forces on all atoms in order to update their positions. Therefore, it is implemented as a time integration fix, and no other fixes of this type (such as *fix nve*) should be used at the same time. Because velocities do not play a role in this kind of Monte Carlo simulations, instantaneous temperatures as calculated by *temperature computes* or *thermodynamic output* have no meaning: the only relevant temperature is the sampling temperature *Temp*. Similarly, performing tfMC simulations does not require setting a *timestep* and the *simulated time* as calculated by LAMMPS is meaningless.

The critical parameter determining the success of a tfMC simulation is *Delta*, the maximal displacement length of the lightest element in the system: the larger it is, the longer the effective time scale of the simulation will be (there is an approximately quadratic dependence). However, *Delta* must also be chosen sufficiently small in order to comply with detailed balance; in general values between 5 and 10 % of the nearest neighbor distance are found to be a good choice. For a more extensive discussion with specific examples, please refer to (*Bal*), which also describes how the code calculates element-specific maximal displacements from *Delta*, based on the fourth root of their mass.

Because of the uncorrelated movements of the atoms, the center-of-mass of the fix group will not necessarily be stationary, just like its orientation. When the *com* keyword is used, all atom positions will be shifted (after every tfMC iteration) in order to fix the position of the center-of-mass along the included directions, by setting the corresponding flag to 1. The *rot* keyword does the same for the rotational component of the tfMC displacements after every iteration.

---

**Note:** the *com* and *rot* keywords should not be used if an external force is acting on the specified fix group, along the included directions. This can be either a true external force (e.g. through *fix wall*) or forces due to the interaction with atoms not included in the fix group. This is because in such cases, translations or rotations of the fix group could be induced by these external forces, and removing them will lead to a violation of detailed balance.

---

## 2.232.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

None of the *fix\_modify* options are relevant to this fix.

This fix is not invoked during *energy minimization*.

## 2.232.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

This fix is not compatible with *fix shake*.

```

Example input scripts available: `examples/PACKAGES/drude`

## 2.234.3 Description

These commands are variants of the Nose-Hoover fix styles `fix nvt` and `fix npt` for thermalized Drude polarizable models. They apply temperature-grouped Nose-Hoover thermostat (TGNH) proposed by (Son). When there are fast vibrational modes with frequencies close to Drude oscillators (e.g. double bonds or out-of-plane torsions), this thermostat can provide better kinetic energy equipartitioning.

The difference between TGNH and the original Nose-Hoover thermostat is that, TGNH separates the kinetic energy of the group into three contributions: molecular center of mass (COM) motion, motion of COM of atom-Drude pairs or non-polarizable atoms relative to molecular COM, and relative motion of atom-Drude pairs. An independent Nose-Hoover chain is applied to each type of motion. The temperatures for these three types of motion are denoted as molecular translational temperature ( $T_M$ ), real atomic temperature ( $T_R$ ) and Drude temperature ( $T_D$ ), which are defined in terms of their associated degrees of freedom (DOF):

$$\begin{aligned}
 T_M &= \frac{\sum_i^{N_{\text{mol}}} M_i V_i^2}{3 \left( N_{\text{mol}} - \frac{N_{\text{mol}}}{N_{\text{mol,sys}}} \right) k_B} \\
 T_R &= \frac{\sum_i^{N_{\text{real}}} m_i (v_i - v_{M,i})^2}{(N_{\text{DOF}} - 3N_{\text{mol}} + 3 \frac{N_{\text{mol}}}{N_{\text{mol,sys}}} - 3N_{\text{drude}}) k_B} \\
 T_D &= \frac{\sum_i^{N_{\text{drude}}} m'_i v_i'^2}{3N_{\text{drude}} k_B}
 \end{aligned}$$

Here  $N_{\text{mol}}$  and  $N_{\text{mol,sys}}$  are the numbers of molecules in the group and in the whole system, respectively.  $N_{\text{real}}$  is the number of atom-Drude pairs and non-polarizable atoms in the group.  $N_{\text{drude}}$  is the number of Drude particles in the group.  $N_{\text{DOF}}$  is the DOF of the group.  $M_i$  and  $V_i$  are the mass and the COM velocity of the  $i$ -th molecule.  $m_i$  is the mass of the  $i$ -th atom-Drude pair or non-polarizable atom.  $v_i$  is the velocity of COM of  $i$ -th atom-Drude pair or non-polarizable atom.  $v_{M,i}$  is the COM velocity of the molecule the  $i$ -th atom-Drude pair or non-polarizable atom belongs to.  $m'_i$  and  $v_i'$  are the reduced mass and the relative velocity of the  $i$ -th atom-Drude pair.

**Note:** These fixes require that each atom knows whether it is a Drude particle or not. You must therefore use the `fix drude` command to specify the Drude status of each atom type.

Because the TGNH thermostat thermostats the molecular COM motion, all atoms belonging to the same molecule must be in the same group. That is, these fixes can not be applied to a subset of a molecule.

For this fix to act correctly, ghost atoms need to know their velocity. You must use the [comm\\_modify](#) command to enable this.

These fixes assume that the translational DOF of the whole system is removed. It is therefore recommended to invoke [fix\\_momentum](#) command so that the  $T_M$  is calculated correctly.

The thermostat parameters are specified using the *temp* keyword. The thermostat is applied to only the translational DOF for the particles. The translational DOF can also have a bias velocity removed before thermostating takes place; see the description below. The desired temperature for molecular and real atomic motion is a ramped value during the run from *Tstart* to *Tstop*. The *Tdamp* parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g.  $\tau$  or fs or ps - see the [units](#) command). The parameter *Tdrude* is the desired temperature for Drude motion at each timestep. Similar to *Tdamp*, the *Tdamp\_drude* parameter determines the relaxation speed for Drude motion. Fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration. Other thermostat-related keywords are *tchain* and *tloop*, which are detailed in [fix nvt](#).

**Note:** A Nose-Hoover thermostat will not work well for arbitrary values of *Tdamp*. If *Tdamp* is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good choice for many models is a *Tdamp* of around 100 timesteps. A smaller *Tdamp\_drude* value would be required to maintain Drude motion at low temperature.

```
fix 1 all nvt temp 300.0 300.0 $(100.0*dt) 1.0 $(20.0*dt)
```

The barostat parameters for fix style *tnpt/drude* is specified using one or more of the *iso*, *aniso*, *tri*, *x*, *y*, *z*, *xy*, *xz*, *yz*, and *couple* keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation. Other barostat-related keywords are *pchain*, *mtk*, *ploop*, *nreset*, *scalexy*, *scaleyz*, *scalexz*, *flip* and *fixedpoint*. The meaning of barostat parameters are detailed in [fix npt](#).

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions.

**Note:** Unlike the [fix temp/berendsen](#) command which performs thermostating but NO time integration, these fixes perform thermostating/barostatting AND time integration. Thus you should not use any other time integration fix, such as [fix nve](#) on atoms to which this fix is applied. Likewise, these fixes should not be used on atoms that also have their temperature controlled by another fix - e.g. by [fix langevin/drude](#) command.

See the [Howto thermostat](#) and [Howto barostat](#) doc pages for a discussion of different ways to compute temperature and perform thermostating and barostatting.

Like other fixes that perform thermostating, this fix can be used with [compute commands](#) that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial [region](#), or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the [fix\\_modify](#) command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual [compute temp commands](#) to determine which ones include

a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostating is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

**Note:** However, not all temperature compute commands are valid to be used with these fixes. Precisely, only temperature compute that does not modify the DOF of the group can be used. E.g. `compute temp/ramp` and `compute viscosity/cos` compute the kinetic energy after remove a velocity gradient without affecting the DOF of the group, then they can be invoked in this way. In contrast, `compute temp/partial` may remove the DOF at one or more dimensions, therefore it cannot be used with these fixes.

---

#### 2.234.4 Restart, fix\_modify, output, run start/stop, minimize info

These fixes writes the state of all the thermostat and barostat variables to *binary restart files*. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify temp` and `press` options are supported by these fixes. You can use them to assign a `compute` you have defined to this fix which will be used in its thermostating or barostating procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

---

**Note:** If both the `temp` and `press` keywords are used in a single `thermo_modify` command (or in two separate commands), then the order in which the keywords are specified is important. Note that a `pressure compute` defines its own temperature compute as an argument when it is specified. The `temp` keyword will override this (for the pressure compute being used by fix npt), but only if the `temp` keyword comes after the `press` keyword. If the `temp` keyword comes before the `press` keyword, then the new pressure compute specified by the `press` keyword will be unaffected by the `temp` setting.

---

The cumulative energy change in the system imposed by these fixes, due to thermostating and/or barostating, are included in the *thermodynamic output* keywords `ecouple` and `econserve`. See the *thermo\_style* page for details.

These fixes compute a global scalar which can be accessed by various *output commands*. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

These fixes also compute a global vector of quantities, which can be accessed by various *output commands*. The vector values are “intensive”. The vector stores the three temperatures  $T_M$ ,  $T_R$  and  $T_D$ .

These fixes can ramp their external temperature and pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

These fixes are not invoked during *energy minimization*.

---

## 2.234.5 Restrictions

These fixes are only available when LAMMPS was built with the DRUDE package. These fixes cannot be used with dynamic groups as defined by the *group* command. These fixes cannot be used in 2D simulations.

$X$ ,  $y$ ,  $z$  cannot be barostatted if the associated dimension is not periodic.  $Xy$ ,  $xz$ , and  $yz$  can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword ( $y$  dimension in  $xy$ ) is periodic. The *create\_box*, *read\_data*, and *read\_restart* commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the  $xy, xz, yz$  tilt factors.

For the *temp* keyword, the final *Tstop* cannot be 0.0 since it would make the external  $T = 0.0$  at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The *scaleyz yes*, *scalexz yes*, and *scalexy yes* options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords *tri*, *yz*, *xz*, and *xy*.

## 2.234.6 Related commands

*fix drude*, *fix nvt*, *fix npt*, *fix\_modify*

## 2.234.7 Default

The keyword defaults are *tchain* = 3, *pchain* = 3, *mtk* = yes, *tloop* = 1, *ploop* = 1, *nreset* = 0, *couple* = none, *flip* = yes, *scaleyz* = *scalexz* = *scalexy* = yes if periodic in second dimension and not coupled to barostat, otherwise no.

## 2.235 fix thermal/conductivity command

### 2.235.1 Syntax

```
fix ID group-ID thermal/conductivity N edim Nbin keyword value ...
```

- ID, group-ID are documented in *fix* command
- thermal/conductivity = style name of this fix command
- N = perform kinetic energy exchange every N steps
- edim =  $x$  or  $y$  or  $z$  = direction of kinetic energy transfer
- Nbin = # of layers in edim direction (must be even number)
- zero or more keyword/value pairs may be appended
- keyword = *swap*  
     *swap* value = Nswap = number of swaps to perform every N steps

## 2.235.2 Examples

```
fix 1 all thermal/conductivity 100 z 20
fix 1 all thermal/conductivity 50 z 20 swap 2
```

## 2.235.3 Description

Use the Muller-Plathe algorithm described in [this paper](#) to exchange kinetic energy between two particles in different regions of the simulation box every N steps. This induces a temperature gradient in the system. As described below this enables the thermal conductivity of a material to be calculated. This algorithm is sometimes called a reverse non-equilibrium MD (reverse NEMD) approach to computing thermal conductivity. This is because the usual NEMD approach is to impose a temperature gradient on the system and measure the response as the resulting heat flux. In the Muller-Plathe method, the heat flux is imposed, and the temperature gradient is the system's response.

See the `compute heat/flux` command for details on how to compute thermal conductivity in an alternate way, via the Green-Kubo formalism.

The simulation box is divided into *Nbin* layers in the *edim* direction, where the layer 1 is at the low end of that dimension and the layer *Nbin* is at the high end. Every N steps, *Nswap* pairs of atoms are chosen in the following manner. Only atoms in the fix group are considered. The hottest *Nswap* atoms in layer 1 are selected. Similarly, the coldest *Nswap* atoms in the “middle” layer (see below) are selected. The two sets of *Nswap* atoms are paired up and their velocities are exchanged. This effectively swaps their kinetic energies, assuming their masses are the same. If the masses are different, an exchange of velocities relative to center of mass motion of the two atoms is performed, to conserve kinetic energy. Over time, this induces a temperature gradient in the system which can be measured using commands such as the following, which writes the temperature profile (assuming *z* = *edim*) to the file `tmp.profile`:

```
compute ke all ke/atom
variable temp atom c_ke/1.5
compute layers all chunk/atom bin/1d z lower 0.05 units reduced
fix 3 all ave/chunk 10 100 1000 layers v_temp file tmp.profile
```

Note that by default, *Nswap* = 1, though this can be changed by the optional `swap` keyword. Setting this parameter appropriately, in conjunction with the swap rate N, allows the heat flux to be adjusted across a wide range of values, and the kinetic energy to be exchanged in large chunks or more smoothly.

The “middle” layer for velocity swapping is defined as the *Nbin*/2 + 1 layer. Thus if *Nbin* = 20, the two swapping layers are 1 and 11. This should lead to a symmetric temperature profile since the two layers are separated by the same distance in both directions in a periodic sense. This is why *Nbin* is restricted to being an even number.

As described below, the total kinetic energy transferred by these swaps is computed by the fix and can be output. Dividing this quantity by time and the cross-sectional area of the simulation box yields a heat flux. The ratio of heat flux to the slope of the temperature profile is proportional to the thermal conductivity of the fluid, in appropriate units. See the [Muller-Plathe paper](#) for details.

---

**Note:** If your system is periodic in the direction of the heat flux, then the flux is going in 2 directions. This means the effective heat flux in one direction is reduced by a factor of 2. You will see this in the equations for thermal conductivity ( $\kappa$ ) in the Muller-Plathe paper. LAMMPS is simply tallying kinetic energy which does not account for whether or not your system is periodic; you must use the value appropriately to yield a  $\kappa$  for your system.

---

---

**Note:** After equilibration, if the temperature gradient you observe is not linear, then you are likely swapping energy too frequently and are not in a regime of linear response. In this case you cannot accurately infer a thermal conductivity and should try increasing the *Nevery* parameter.

---

## 2.235.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global scalar which can be accessed by various *output commands*. The scalar is the cumulative kinetic energy transferred between the bottom and middle of the simulation box (in the *edim* direction) is stored as a scalar quantity by this fix. This quantity is zeroed when the fix is defined and accumulates thereafter, once every N steps. The units of the quantity are energy; see the *units* command for details. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.235.5 Restrictions

Swaps conserve both momentum and kinetic energy, even if the masses of the swapped atoms are not equal. Thus you should not need to thermostat the system. If you do use a thermostat, you may want to apply it only to the non-swapped dimensions (other than *vdim*).

LAMMPS does not check, but you should not use this fix to swap the kinetic energy of atoms that are in constrained molecules, e.g. via *fix shake* or *fix rigid*. This is because application of the constraints will alter the amount of transferred momentum. You should, however, be able to use flexible molecules. See the *Zhang paper* for a discussion and results of this idea.

When running a simulation with large, massive particles or molecules in a background solvent, you may want to only exchange kinetic energy between solvent particles.

## 2.235.6 Related commands

*fix ehex*, *fix heat*, *fix ave/chunk*, *fix viscosity*, *compute heat/flux*

## 2.235.7 Default

The option defaults are `swap = 1`.

## 2.236 fix ti/spring command

### 2.236.1 Syntax

```
fix ID group-ID ti/spring k t_s t_eq keyword value ...
```

- ID, group-ID are documented in *fix* command
- ti/spring = style name of this fix command
- k = spring constant (force/distance units)
- t\_eq = number of steps for the equilibration procedure

- `t_s` = number of steps for the switching procedure
- zero or more keyword/value pairs may be appended to args
- keyword = *function*

*function* value = function-ID  
 function-ID = ID of the switching function (1 or 2)

## 2.236.2 Example

```
fix 1 all ti/spring 50.0 2000 1000 function 2
```

## 2.236.3 Description

This fix allows you to compute the free energy of crystalline solids by performing a nonequilibrium thermodynamic integration between the solid of interest and an Einstein crystal. A detailed explanation of how to use this command and choose its parameters for optimal performance and accuracy is given in the paper by [Freitas](#). The paper also presents a short summary of the theory of nonequilibrium thermodynamic integration.

The thermodynamic integration procedure is performed by rescaling the force on each atom. Given an atomic configuration the force ( $F$ ) on each atom is given by

$$F = (1 - \lambda) F_{\text{solid}} + \lambda F_{\text{harm}}$$

where  $F_{\text{solid}}$  is the force that acts on an atom due to an interatomic potential (*e.g.* EAM potential),  $F_{\text{harm}}$  is the force due to the Einstein crystal harmonic spring, and  $\lambda$  is the coupling parameter of the thermodynamic integration. An Einstein crystal is a solid where each atom is attached to its equilibrium position by a harmonic spring with spring constant  $k$ . With this fix a spring force is applied independently to each atom in the group defined by the fix to tether it to its initial position. The initial position of each atom is its position at the time the fix command was issued.

The fix acts as follows: during the first  $t_{eq}$  steps after the fix is defined the value of  $\lambda$  is zero. This is the period to equilibrate the system in the  $\lambda = 0$  state. After this the value of  $\lambda$  changes dynamically during the simulation from 0 to 1 according to the function defined using the keyword *function* (described below), this switching from  $\lambda$  from 0 to 1 is done in  $t_s$  steps. Then comes the second equilibration period of  $t_{eq}$  to equilibrate the system in the  $\lambda = 1$  state. After that, the switching back to the  $\lambda = 0$  state is made using  $t_s$  timesteps and following the same switching function. After this period the value of  $\lambda$  is kept equal to zero and the fix has no other effect on the dynamics of the system.

The processes described above is known as nonequilibrium thermodynamic integration and is has been shown ([Freitas](#)) to present a much superior efficiency when compared to standard equilibrium methods. The reason why the switching it is made in both directions (potential to Einstein crystal and back) is to eliminate the dissipated heat due to the nonequilibrium process. Further details about nonequilibrium thermodynamic integration and its implementation in LAMMPS is available in [Freitas](#).

The *function* keyword allows the use of two different  $\lambda$  paths. Option 1 results in a constant rate of change of  $\lambda$  with time:

$$\lambda(\tau) = \tau$$

where  $\tau$  is the scaled time variable  $t/t_s$ . The option 2 performs the  $\lambda$  switching at a rate defined by the following switching function

$$\lambda(\tau) = \tau^5 (70\tau^4 - 315\tau^3 + 540\tau^2 - 420\tau + 126)$$

This function has zero slope as lambda approaches its extreme values (0 and 1), according to *de Koning* this results in smaller fluctuations on the integral to be computed on the thermodynamic integration. The use of option 2 is recommended since it results in better accuracy and less dissipation without any increase in computational resources cost.

---

**Note:** As described in *Freitas*, it is important to keep the center-of-mass fixed during the thermodynamic integration. A nonzero total velocity will result in divergences during the integration due to the fact that the atoms are ‘attached’ to their equilibrium positions by the Einstein crystal. Check the option *zero* of *fix langevin* and *velocity*. The use of the Nose-Hoover thermostat (*fix nvt*) is *NOT* recommended due to its well documented issues with the canonical sampling of harmonic degrees of freedom (notice that the *chain* option will *NOT* solve this problem). The Langevin thermostat (*fix langevin*) correctly thermostats the system and we advise its usage with *ti/spring* command.

---

## 2.236.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the original coordinates of tethered atoms to *binary restart files*, so that the spring effect will be the same in a restarted simulation. See the *read restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The *fix\_modify energy* option is supported by this fix to add the energy stored in the per-atom springs to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

This fix computes a global scalar and a global vector quantities which can be accessed by various *output commands*. The scalar is an energy which is the sum of the spring energy for each atom, where the per-atom energy is  $0.5 \cdot k \cdot r^2$ . The vector stores 2 values. The first value is the coupling parameter lambda. The second value is the derivative of lambda with respect to the integer timestep *s*, i.e.  $\frac{d\lambda}{ds}$ . In order to obtain  $\frac{d\lambda}{dt}$ , where *t* is simulation time, this 2nd value needs to be divided by the timestep size (e.g. 0.5 fs). The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the per-atom spring energy to be included in the total potential energy of the system (the quantity being minimized), you *MUST* enable the *fix modify energy* option for this fix.

---

## 2.236.5 Related commands

*fix spring*, *fix adapt*

## 2.236.6 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 2.236.7 Default

The keyword default is function = 1.

## 2.237 fix tmd command

### 2.237.1 Syntax

```
fix ID group-ID tmd rho_final file1 N file2
```

- ID, group-ID are documented in *fix* command
- tmd = style name of this fix command
- rho\_final = desired value of rho at the end of the run (distance units)
- file1 = filename to read target structure from
- N = dump TMD statistics every this many timesteps, 0 = no dump
- file2 = filename to write TMD statistics to (only needed if N > 0)

### 2.237.2 Examples

```
fix 1 all nve
fix 2 tmdatoms tmd 1.0 target_file 100 tmd_dump_file
```

### 2.237.3 Description

Perform targeted molecular dynamics (TMD) on a group of atoms. A holonomic constraint is used to force the atoms to move towards (or away from) the target configuration. The parameter “rho” is monotonically decreased (or increased) from its initial value to rho\_final at the end of the run.

Rho has distance units and is a measure of the root-mean-squared distance (RMSD) between the current configuration of the atoms in the group and the target coordinates listed in file1. Thus a value of rho\_final = 0.0 means move the atoms all the way to the final structure during the course of the run.

The target file1 can be ASCII text or a gzipped text file (detected by a .gz suffix). The format of the target file1 is as follows:

```
0.0 25.0 xlo xhi
0.0 25.0 ylo yhi
0.0 25.0 zlo zhi
125    24.97311    1.69005    23.46956 0 0 -1
126    1.94691    2.79640    1.92799 1 0 0
127    0.15906    3.46099    0.79121 1 0 0
...
```

The first 3 lines may or may not be needed, depending on the format of the atoms to follow. If image flags are included with the atoms, the first 3 lo/hi lines **must** appear in the file. If image flags are not included, the first 3 lines **must not** appear. The 3 lines contain the simulation box dimensions for the atom coordinates, in the same format as in a LAMMPS data file (see the [read\\_data](#) command).

The remaining lines each contain an atom ID and its target x,y,z coordinates. The atom lines (all or none of them) can optionally be followed by 3 integer values: nx,ny,nz. For periodic dimensions, they specify which image of the box the atom is considered to be in, i.e. a value of N (positive or negative) means add N times the box length to the coordinate to get the true value. Those 3 integers either must be given for all atoms or none.

The atom lines can be listed in any order, but every atom in the group must be listed in the file. Atoms not in the fix group may also be listed; they will be ignored.

Comments starting with '#' and empty lines may be included as well.

TMD statistics are written to file2 every N timesteps, unless N is specified as 0, which means no statistics.

The atoms in the fix tmd group should be integrated (via a fix nve, nvt, npt) along with other atoms in the system.

Restarts can be used with a fix tmd command. For example, imagine a 10000 timestep run with a rho\_initial = 11 and a rho\_final = 1. If a restart file was written after 2000 time steps, then the configuration in the file would have a rho value of 9. A new 8000 time step run could be performed with the same rho\_final = 1 to complete the conformational change at the same transition rate. Note that for restarted runs, the name of the TMD statistics file should be changed to prevent it being overwritten.

For more information about TMD, see ([Schlitter1](#)) and ([Schlitter2](#)).

## 2.237.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*.

This fix can ramp its rho parameter over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this.

This fix is not invoked during *energy minimization*.

## 2.237.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

All TMD fixes must be listed in the input script after all integrator fixes (nve, nvt, npt) are applied. This ensures that atoms are moved before their positions are corrected to comply with the constraint.

Atoms that have a TMD fix applied should not be part of a group to which a SHAKE fix is applied. This is because LAMMPS assumes there are not multiple competing holonomic constraints applied to the same atoms.

To read gzipped target files, you must compile LAMMPS with the -DLAMMPS\_GZIP option. See the [Build settings](#) doc page for details.

fix 4 all ttm/mod 34277 parameters.txt 5 5 5 infile T_init outfile 10 T_out

```

Example input scripts using these commands can be found in `examples/ttm`.

## 2.240.3 Description

Use a two-temperature model (TTM) to represent heat transfer through and between electronic and atomic subsystems. LAMMPS models the atomic subsystem as usual with a molecular dynamics model and the classical force field specified by the user. The electronic subsystem is modeled as a continuum, or a background “gas”, on a regular grid which overlays the simulation domain. Energy can be transferred spatially within the grid representing the electrons. Energy can also be transferred between the electronic and atomic subsystems. The algorithm underlying this fix was derived by D. M. Duffy and A. M. Rutherford and is discussed in two J Physics: Condensed Matter papers: ([Duffy](#)) and ([Rutherford](#)). They used this algorithm in cascade simulations where a primary knock-on atom (PKA) was initialized with a high velocity to simulate a radiation event.

The description in this subsection applies to all 3 fix styles: *ttm*, *ttm/grid*, and *ttm/mod*.

Fix *ttm/grid* distributes the regular grid across processors consistent with the subdomains of atoms owned by each processor, but is otherwise identical to fix *ttm*. Note that fix *ttm* stores a copy of the grid on each processor, which is acceptable when the overall grid is reasonably small. For larger grids you should use fix *ttm/grid* instead.

Fix *ttm/mod* adds options to account for external heat sources (e.g. at a surface) and for specifying parameters that allow the electronic heat capacity to depend strongly on electronic temperature. It is more expensive computationally than fix *ttm* because it treats the thermal diffusion equation as non-linear. More details on fix *ttm/mod* are given below.

Heat transfer between the electronic and atomic subsystems is carried out via an inhomogeneous Langevin thermostat. Only atoms in the fix group contribute to and are affected by this heat transfer.

This thermostatting differs from the regular Langevin thermostat ([fix langevin](#)) in three important ways. First, the Langevin thermostat is applied uniformly to all atoms in the user-specified group for a single target temperature, whereas the TTM fixes apply Langevin thermostatting locally to atoms within the volumes represented by the user-specified grid points with a target temperature specific to that grid point. Second, the Langevin thermostat couples the temperature of the atoms to an infinite heat reservoir, whereas the heat reservoir for the TTM fixes is finite and represents the local electrons. Third, the TTM fixes allow users to specify not just one friction coefficient, but rather two independent friction coefficients: one for the electron-ion interactions (*gamma\_p*), and one for electron stopping (*gamma\_s*).

When the friction coefficient due to electron stopping, *gamma\_s*, is non-zero, electron stopping effects are included for atoms moving faster than the electron stopping critical velocity, *v\_0*. For further details about this algorithm, see ([Duffy](#)) and ([Rutherford](#)).

Energy transport within the electronic subsystem is solved according to the heat diffusion equation with added source

terms for heat transfer between the subsystems:

$$C_e \rho_e \frac{\partial T_e}{\partial t} = \nabla(\kappa_e \nabla T_e) - g_p(T_e - T_a) + g_s T'_a$$

where  $C_e$  is the specific heat,  $\rho_e$  is the density,  $\kappa_e$  is the thermal conductivity,  $T$  is temperature, the “e” and “a” subscripts represent electronic and atomic subsystems respectively,  $g_p$  is the coupling constant for the electron-ion interaction, and  $g_s$  is the electron stopping coupling parameter.  $C_e$ ,  $\rho_e$ , and  $\kappa_e$  are specified as parameters to the fix *ttm* or *ttm/grid*. The other quantities are derived. The form of the heat diffusion equation used here is almost the same as that in equation 6 of (Duffy), with the exception that the electronic density is explicitly represented, rather than being part of the specific heat parameter.

Currently, the TTM fixes assume that none of the user-supplied parameters will vary with temperature. Note that (Duffy) used a tanh() functional form for the temperature dependence of the electronic specific heat, but ignored temperature dependencies of any of the other parameters. See more discussion below for fix *ttm/mod*.

---

**Note:** These fixes do not perform time integration of the atoms in the fix group, they only rescale their velocities. Thus a time integration fix such as *fix nve* should be used in conjunction with these fixes. These fixes should not normally be used on atoms that have their temperature controlled by another thermostating fix, e.g. *fix nvt* or *fix langevin*.

---

---

**Note:** These fixes require use of an orthogonal 3d simulation box with periodic boundary conditions in all dimensions. They also require that the size and shape of the simulation box do not vary dynamically, e.g. due to use of the *fix npt* command. Likewise, the size/shape of processor subdomains cannot vary due to dynamic load-balancing via use of the *fix balance* command. It is possible however to load balance before the simulation starts using the *balance* command, so that each processor has a different size subdomain.

---

Periodic boundary conditions are also used in the heat equation solve for the electronic subsystem. This varies from the approach of (Rutherford) where the atomic subsystem was embedded within a larger continuum representation of the electronic subsystem.

The *set* keyword specifies a *Tinit* temperature value to initialize the value stored on all grid points. By default the temperatures are all zero when the grid is created.

The *infile* keyword specifies an input file of electronic temperatures for each grid point to be read in to initialize the grid, as an alternative to using the *set* keyword.

The input file is a text file which may have comments starting with the ‘#’ character. Each line contains four numeric columns: ix,iy,iz,Temperature. Empty or comment-only lines will be ignored. The number of lines must be equal to the number of user-specified grid points (Nx by Ny by Nz). The ix,iy,iz are grid point indices ranging from 1 to Nxyz inclusive in each dimension. The lines can appear in any order. For example, the initial electronic temperatures on a 1 by 2 by 3 grid could be specified in the file as follows:

```
# UNITS: metal COMMENT: initial electron temperature
1 1 1 1.0
1 1 2 1.0
1 1 3 1.0
1 2 1 2.0
1 2 2 2.0
1 2 3 2.0
```

where the electronic temperatures along the y=0 plane have been set to 1.0, and the electronic temperatures along the y=1 plane have been set to 2.0. If all the grid point values are not specified, LAMMPS will generate an error. LAMMPS will check if a “UNITS:” tag is in the first line and stop with an error, if there is a mismatch with the current units used.

---

**Note:** The electronic temperature at each grid point must be a non-zero positive value, both initially, and as the temperature evolves over time. Thus you must use either the *set* or *infile* keyword or be restarting a simulation that used this fix previously.

---

The *outfile* keyword has 2 values. The first value *Nout* triggers output of the electronic temperatures for each grid point every *Nout* timesteps. The second value is the filename for output, which will be suffixed by the timestep. The format of each output file is exactly the same as the input temperature file. It will contain a comment in the first line reporting the date the file was created, the LAMMPS units setting in use, grid size and the current timestep.

---

**Note:** The fix *ttm/grid* command does not support the *outfile* keyword. Instead you can use the *dump grid* command to output the electronic temperature on the distributed grid to a dump file or the *restart* command which creates a file specific to this fix which the *read restart* command reads. The file has the same format as the file the *infile* option reads.

---

For the fix *ttm* and fix *ttm/mod* commands, the corresponding atomic temperature for atoms in each grid cell can be computed and output by the *fix ave/chunk* command using the *compute chunk/atom* command to create a 3d array of chunks consistent with the grid used by this fix.

For the fix *ttm/grid* command the same thing can be done using the *fix ave/grid* command and its per-grid values can be output via the *dump grid* command.

---

### Additional details for fix *ttm/mod*

Fix *ttm/mod* uses the heat diffusion equation with possible external heat sources (e.g. laser heating in ablation simulations):

$$C_e \rho_e \frac{\partial T_e}{\partial t} = \nabla(\kappa_e \nabla T_e) - g_p(T_e - T_a) + g_s T'_a + \theta(x - x_{surface}) I_0 \exp(-x/l_{skin})$$

where  $\theta$  is the Heaviside step function,  $I_0$  is the (absorbed) laser pulse intensity for ablation simulations,  $l_{skin}$  is the depth of the skin-layer, and all other designations have the same meaning as in the former equation. The duration of the pulse is set by the parameter *tau* in the *init\_file*.

Fix *ttm/mod* also allows users to specify the dependencies of  $C_e$  and  $\kappa_e$  on the electronic temperature. The specific heat is expressed as

$$C_e = C_0 + (a_0 + a_1 X + a_2 X^2 + a_3 X^3 + a_4 X^4) \exp(-(AX)^2)$$

where  $X = \frac{T_e}{1000}$ , and the thermal conductivity is defined as  $\kappa_e = D_e \cdot \rho_e \cdot C_e$ , where  $D_e$  is the thermal diffusion coefficient.

Electronic pressure effects are included in the TTM model to account for the blast force acting on ions because of electronic pressure gradient (see (Chen), (Norman)). The total force acting on an ion is:

$$\vec{F}_i = -\partial U / \partial \vec{r}_i + \vec{F}_{langevin} - \nabla P_e / n_{ion}$$

where  $F_{langevin}$  is a force from Langevin thermostat simulating electron-phonon coupling, and  $\nabla P_e / n_{ion}$  is the electron blast force.

The electronic pressure is taken to be  $P_e = B \cdot \rho_e \cdot C_e \cdot T_e$

The current fix *ttm/mod* implementation allows TTM simulations with a vacuum. The vacuum region is defined as the grid cells with zero electronic temperature. The numerical scheme does not allow energy exchange with such cells. Since the material can expand to previously unoccupied region in some simulations, the vacuum border can be allowed to move. It is controlled by the *surface\_movement* parameter in the *init\_file*. If it is set to 1, then “vacuum” cells can be

changed to “electron-filled” cells with the temperature  $T_{e\_min}$  if atoms move into them (currently only implemented for the case of 1-dimensional motion of a flat surface normal to the X axis). The initial locations of the interfaces of the electron density to the vacuum can be set in the *init\_file* via *lsurface* and *rsurface* parameters. In this case, electronic pressure gradient is calculated as

$$\nabla_x P_e = \left[ \frac{C_e T_e(x) \lambda}{(x + \lambda)^2} + \frac{x}{x + \lambda} \frac{(C_e T_e)_{x+\Delta x} - (C_e T_e)_x}{\Delta x} \right]$$

where  $\lambda$  is the electron mean free path (see (*Norman*), (*Pisarev*))

The fix *ttm/mod* parameter file *init\_file* has the following syntax. Every line with an odd number is considered as a comment and ignored. The lines with the even numbers are treated as follows:

```
a_0, energy/(temperature*electron) units
a_1, energy/(temperature^2*electron) units
a_2, energy/(temperature^3*electron) units
a_3, energy/(temperature^4*electron) units
a_4, energy/(temperature^5*electron) units
C_0, energy/(temperature*electron) units
A, 1/temperature units
rho_e, electrons/volume units
D_e, length^2/time units
gamma_p, mass/time units
gamma_s, mass/time units
v_0, length/time units
I_0, energy/(time*length^2) units
lsurface, electron grid units (positive integer)
rsurface, electron grid units (positive integer)
l_skin, length units
tau, time units
B, dimensionless
lambda, length units
n_ion, ions/volume units
surface_movement: 0 to disable tracking of surface motion, 1 to enable
T_e_min, temperature units
```

---

## 2.240.4 Restart, fix\_modify, output, run start/stop, minimize info

The fix *ttm* and fix *ttm/mod* commands write the state of the electronic subsystem and the energy exchange between the subsystems to *binary restart files*. The fix *ttm/grid* command does not yet support writing of its distributed grid to a restart file.

See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion. Note that the restart script must define the same size grid as the original script.

The fix *ttm/grid* command also outputs an auxiliary file each time a restart file is written, with the electron temperatures for each grid cell. The format of this file is the same as that read by the *infile* option explained above. The filename is the same as the restart filename with “.ttm” appended. This auxiliary file can be read in for a restarted run by using the *infile* option for the fix *ttm/grid* command, following the *read\_restart* command.

None of the *fix\_modify* options are relevant to these fixes.

These fixes compute 2 output quantities stored in a vector of length 2, which can be accessed by various *output commands*. The first quantity is the total energy of the electronic subsystem. The second quantity is the energy transferred

from the electronic to the atomic subsystem on that timestep. Note that the velocity verlet integrator applies the fix ttm forces to the atomic subsystem as two half-step velocity updates: one on the current timestep and one on the subsequent timestep. Consequently, the change in the atomic subsystem energy is lagged by half a timestep relative to the change in the electronic subsystem energy. As a result of this, users may notice slight fluctuations in the sum of the atomic and electronic subsystem energies reported at the end of the timestep.

The vector values calculated are “extensive”.

The fix ttm/grid command also outputs a per-grid vector which stores the electron temperature for each grid cell in temperature *units*. which can be accessed by various *output commands*. The length of the vector (distributed across all processors) is  $N_x * N_y * N_z$ . For access by other commands, the name of the single grid produced by fix ttm/grid is “grid”. The name of its per-grid data is “data”.

No parameter of the fixes can be used with the *start/stop* keywords of the *run* command. The fixes are not invoked during *energy minimization*.

## 2.240.5 Restrictions

All these fixes are part of the EXTRA-FIX package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

As mentioned above, these fixes require 3d simulations and orthogonal simulation boxes periodic in all 3 dimensions.

These fixes used a random number generator to Langevin thermostat the electron temperature. This means you will not get identical answers when running on different numbers of processors or when restarting a simulation (even on the same number of processors). However, in a statistical sense, simulations on different processor counts and restarted simulation should produce results which are statistically the same.

## 2.240.6 Related commands

## 2.241 fix tune/kspace command

### 2.241.1 Syntax

```
fix ID group-ID tune/kspace N
```

- ID, group-ID are documented in *fix* command
- tune/kspace = style name of this fix command
- N = invoke this fix every N steps

### 2.241.2 Examples

```
fix 2 all tune/kspace 100
```

### 2.241.3 Description

This fix tests each kspace style (Ewald, PPPM, and MSM), and automatically selects the fastest style to use for the remainder of the run. If the fastest style is Ewald or PPPM, the fix also adjusts the Coulombic cutoff towards optimal speed. Future versions of this fix will automatically select other kspace parameters to use for maximum simulation speed. The kspace parameters may include the style, cutoff, grid points in each direction, order, Ewald parameter, MSM parallelization cut-point, MPI tasks to use, etc.

The rationale for this fix is to provide the user with as-fast-as-possible simulations that include long-range electrostatics (kspace) while meeting the user-prescribed accuracy requirement. A simple heuristic could never capture the optimal combination of parameters for every possible run-time scenario. But by performing short tests of various kspace parameter sets, this fix allows parameters to be tailored specifically to the user's machine, MPI ranks, use of threading or accelerators, the simulated system, and the simulation details. In addition, it is possible that parameters could be evolved with the simulation on-the-fly, which is useful for systems that are dynamically evolving (e.g. changes in box size/shape or number of particles).

When this fix is invoked, LAMMPS will perform short timed tests of various parameter sets to determine the optimal parameters. Tests are performed on-the-fly, with a new test initialized every N steps. N should be chosen large enough so that adequate CPU time lapses between tests, thereby providing statistically significant timings. But N should not be chosen to be so large that an unfortunate parameter set test takes an inordinate amount of wall time to complete. An N of 100 for most problems seems reasonable. Once an optimal parameter set is found, that set is used for the remainder of the run.

This fix uses heuristics to guide it's selection of parameter sets to test, but the actual timed results will be used to decide which set to use in the simulation.

It is not necessary to discard trajectories produced using sub-optimal parameter sets, or a mix of various parameter sets, since the user-prescribed accuracy will have been maintained throughout. However, some users may prefer to use this fix only to discover the optimal parameter set for a given setup that can then be used on subsequent production runs.

This fix starts with kspace parameters that are set by the user with the *kspace\_style* and *kspace\_modify* commands. The prescribed accuracy will be maintained by this fix throughout the simulation.

None of the *fix\_modify* options are relevant to this fix.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.241.4 Restrictions

This fix is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Do not set “neigh\_modify once yes” or else this fix will never be called. Reneighboring is required.

This fix is not compatible with a hybrid pair style, long-range dispersion, TIP4P water support, or long-range point dipole support.

## 2.241.5 Related commands

*kspace\_style*, *boundary kspace\_modify*, *pair\_style lj/cut/coul/long*, *pair\_style lj/charmm/coul/long*, *pair\_style lj/long*, *pair\_style lj/long/coul/long*, *pair\_style buck/coul/long*

## 2.241.6 Default

# 2.242 fix vector command

## 2.242.1 Syntax

```
fix ID group-ID vector Nevery value1 value2 ... keyword args ...
```

- ID, group-ID are documented in *fix* command
- vector = style name of this fix command
- Nevery = use input values every this many timesteps
- one or more input values can be listed
- value = c\_ID, c\_ID[N], f\_ID, f\_ID[N], v\_name

```
c_ID = global scalar calculated by a compute with ID
c_ID[I] = Ith component of global vector calculated by a compute with ID
f_ID = global scalar calculated by a fix with ID
f_ID[I] = Ith component of global vector calculated by a fix with ID
v_name = value calculated by an equal-style variable with name
v_name[I] = Ith component of vector-style variable with name
```

- zero or more keyword/args pairs may be appended
- keyword = *nmax*  
*nmax* length = set maximal length of vector to <length>

## 2.242.2 Examples

```
fix 1 all vector 100 c_myTemp
fix 1 all vector 5 c_myTemp v_integral
fix 1 all vector 50 c_myTemp nmax 200
```

## 2.242.3 Description

Use one or more global values as inputs every few timesteps, and simply store them as a sequence. For a single specified value, the values are stored as a global vector of growing length. For multiple specified values, they are stored as rows in a global array, whose number of rows is growing. The resulting vector or array can be used by other *output commands*.

The optional *nmax* keyword can be used to restrict the length of the vector to the given *length* value. Once the restricted vector is filled, the oldest entry will be discarded when a entry is added.

One way to use this command is to accumulate a vector that is numerically integrated using the *variable trap()* function. For example, the velocity auto-correlation function (VACF) can be integrated, to yield a diffusion coefficient, as follows:

```
compute      2 all vacf
fix          5 all vector 1 c_2[4]
variable     diff equal dt*trap(f_5)
thermo_style custom step v_diff
```

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a *compute* or *fix* or the evaluation of an equal-style or vector-style *variable*. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. And the global quantity must be a scalar, not a vector or array.

*Computes* that produce global quantities are those which do not have the word *atom* in their style name. Only a few *fixes* produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. *Variables* of style *equal* or *vector* are the only ones that can be used with this fix. Variables of style *atom* cannot be used, since they produce per-atom values.

The *Nevery* argument specifies on what timesteps the input values will be used in order to be stored. Only timesteps that are a multiple of *Nevery*, including timestep 0, will contribute values.

---

### Note:

If *Nevery* is a small number and the simulation runs for many steps, the accumulated vector or array can become very large and thus consume a lot of memory. The implementation limit is about 2 billion entries. Using the *nmax* keyword mentioned above can avoid that by limiting the size of the vector.

---

Note that if you perform multiple runs, using the “pre no” option of the *run* command to avoid initialization on subsequent runs, then you need to use the *stop* keyword with the first *run* command with a timestep value that encompasses all the runs. This is so that the vector or array stored by this fix can be allocated to a sufficient size.

---

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the *i*th element of the global vector calculated by the compute is used.

Note that there is a *compute reduce* command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix vector. Or it can be a compute defined not in your input script, but by *thermodynamic output* or other fixes such as *fix nvt* or *fix temp/rescale*. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and *add them to LAMMPS*.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used.

Note that some fixes only produce their values on certain timesteps, which must be compatible with *Nevery*, else an error will result. Users can also write code for their own fix styles and *add them to LAMMPS*.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. An equal-style or vector-style variable can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. See the *variable* command for details. Note that variables of style *equal* and *vector* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to be stored by fix vector.

---

## 2.242.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix produces a global vector or global array which can be accessed by various *output commands*. The values can only be accessed on timesteps that are multiples of *Nevery*.

A vector is produced if only a single input value is specified. An array is produced if multiple input values are specified. The length of the vector or the number of rows in the array grows by 1 every *Nevery* timesteps.

If the fix produces a vector, then the entire vector will be either “intensive” or “extensive”, depending on whether the values stored in the vector are “intensive” or “extensive”. If the fix produces an array, then all elements in the array must be the same, either “intensive” or “extensive”. If a compute or fix provides the value stored, then the compute or fix determines whether the value is intensive or extensive; see the page for that compute or fix for further info. Values produced by a variable are treated as intensive.

This fix can allocate storage for stored values accumulated over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this. If using the *run pre no* command option, this is required to allow the fix to allocate sufficient storage for stored values.

This fix is not invoked during *energy minimization*.

## 2.242.5 Restrictions

none

## 2.242.6 Related commands

*compute, variable*

## 2.242.7 Defaults

The default value of *nmax* is deduced from the number of steps in a run (or multiple runs when using the *start* and *stop* keywords of the *run command*) divided by the choice of *Nevery* plus 1.

## 2.243 fix viscosity command

### 2.243.1 Syntax

```
fix ID group-ID viscosity N vdim pdim Nbin keyword value ...
```

- ID, group-ID are documented in *fix* command
- viscosity = style name of this fix command
- N = perform momentum exchange every N steps
- vdim = *x* or *y* or *z* = which momentum component to exchange
- pdim = *x* or *y* or *z* = direction of momentum transfer
- Nbin = # of layers in pdim direction (must be even number)
- zero or more keyword/value pairs may be appended
- keyword = *swap* or *vtarget*

*swap* value = *Nswap* = number of swaps to perform every N steps

*vtarget* value = *V* or *INF* = target velocity of swap partners (velocity units)

### 2.243.2 Examples

```
fix 1 all viscosity 100 x z 20
fix 1 all viscosity 50 x z 20 swap 2 vtarget 1.5
```

### 2.243.3 Description

Use the Muller-Plathe algorithm described in [this paper](#) to exchange momenta between two particles in different regions of the simulation box every N steps. This induces a shear velocity profile in the system. As described below this enables a viscosity of the fluid to be calculated. This algorithm is sometimes called a reverse non-equilibrium MD (reverse NEMD) approach to computing viscosity. This is because the usual NEMD approach is to impose a shear velocity profile on the system and measure the response via an off-diagonal component of the stress tensor, which is proportional to the momentum flux. In the Muller-Plathe method, the momentum flux is imposed, and the shear velocity profile is the system's response.

The simulation box is divided into *Nbin* layers in the *pdim* direction, where the layer 1 is at the low end of that dimension and the layer *Nbin* is at the high end. Every N steps, *Nswap* pairs of atoms are chosen in the following manner. Only atoms in the fix group are considered. *Nswap* atoms in layer 1 with positive velocity components in the *vdim* direction closest to the target value *V* are selected. Similarly, *Nswap* atoms in the “middle” layer (see below) with negative

velocity components in the *vdim* direction closest to the negative of the target value *V* are selected. The two sets of *Nswap* atoms are paired up and their *vdim* momenta components are swapped within each pair. This resets their velocities, typically in opposite directions. Over time, this induces a shear velocity profile in the system which can be measured using commands such as the following, which writes the profile to the file *tmp.profile*:

```
compute layers all chunk/atom bin/1d z lower 0.05 units reduced
fix f1 all ave/chunk 100 10 1000 layers vx file tmp.profile
```

Note that by default, *Nswap* = 1 and *vtarget* = INF, though this can be changed by the optional *swap* and *vtarget* keywords. When *vtarget* = INF, one or more atoms with the most positive and negative velocity components are selected. Setting these parameters appropriately, in conjunction with the swap rate *N*, allows the momentum flux rate to be adjusted across a wide range of values, and the momenta to be exchanged in large chunks or more smoothly.

The “middle” layer for momenta swapping is defined as the  $N_{bin}/2 + 1$  layer. Thus if *Nbin* = 20, the two swapping layers are 1 and 11. This should lead to a symmetric velocity profile since the two layers are separated by the same distance in both directions in a periodic sense. This is why *Nbin* is restricted to being an even number.

As described below, the total momentum transferred by these velocity swaps is computed by the *fix* and can be output. Dividing this quantity by time and the cross-sectional area of the simulation box yields a momentum flux. The ratio of momentum flux to the slope of the shear velocity profile is proportional to the viscosity of the fluid, in appropriate units. See the [Muller-Plathe paper](#) for details.

---

**Note:** If your system is periodic in the direction of the momentum flux, then the flux is going in 2 directions. This means the effective momentum flux in one direction is reduced by a factor of 2. You will see this in the equations for viscosity in the Muller-Plathe paper. LAMMPS is simply tallying momentum which does not account for whether or not your system is periodic; you must use the value appropriately to yield a viscosity for your system.

---

---

**Note:** After equilibration, if the velocity profile you observe is not linear, then you are likely swapping momentum too frequently and are not in a regime of linear response. In this case you cannot accurately infer a viscosity and should try increasing the *Nevery* parameter.

---

An alternative method for calculating a viscosity is to run a NEMD simulation, as described on the [Howto nemd](#) doc page. NEMD simulations deform the simulation box via the *fix deform* command.

Some features or combination of settings in LAMMPS do not support non-orthogonal boxes. Using *fix viscosity* keeps the box orthogonal; thus it does not suffer from these limitations.

#### 2.243.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this *fix* is written to *binary restart files*. None of the *fix\_modify* options are relevant to this *fix*.

This *fix* computes a global scalar which can be accessed by various *output commands*. The scalar is the cumulative momentum transferred between the bottom and middle of the simulation box (in the *pdim* direction) is stored as a scalar quantity by this *fix*. This quantity is zeroed when the *fix* is defined and accumulates thereafter, once every *N* steps. The units of the quantity are momentum = mass\*velocity. The scalar value calculated by this *fix* is “intensive”.

No parameter of this *fix* can be used with the *start/stop* keywords of the *run* command. This *fix* is not invoked during *energy minimization*.

## 2.243.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Swaps conserve both momentum and kinetic energy, even if the masses of the swapped atoms are not equal. Thus you should not need to thermostat the system. If you do use a thermostat, you may want to apply it only to the non-swapped dimensions (other than *vdim*).

LAMMPS does not check, but you should not use this fix to swap velocities of atoms that are in constrained molecules, e.g. via *fix shake* or *fix rigid*. This is because application of the constraints will alter the amount of transferred momentum. You should, however, be able to use flexible molecules. See the [Maginn paper](#) for an example of using this algorithm in a computation of alcohol molecule properties.

When running a simulation with large, massive particles or molecules in a background solvent, you may want to only exchange momenta between solvent particles.

## 2.243.6 Related commands

*fix ave/chunk*, *fix thermal/conductivity*

## 2.243.7 Default

The option defaults are `swap = 1` and `vtarget = INF`.

## 2.244 fix viscous command

Accelerator Variants: *viscous/kk*

### 2.244.1 Syntax

```
fix ID group-ID viscous gamma keyword values ...
```

- ID, group-ID are documented in *fix* command
- viscous = style name of this fix command
- gamma = damping coefficient (force/velocity units)
- zero or more keyword/value pairs may be appended

keyword = *scale*

scale values = type ratio

type = atom type (1-N)

ratio = factor to scale the damping coefficient by

## 2.244.2 Examples

```
fix 1 flow viscous 0.1
fix 1 damp viscous 0.5 scale 3 2.5
```

## 2.244.3 Description

Add a viscous damping force to atoms in the group that is proportional to the velocity of the atom. The added force can be thought of as a frictional interaction with implicit solvent, i.e. the no-slip Stokes drag on a spherical particle. In granular simulations this can be useful for draining the kinetic energy from the system in a controlled fashion. If used without additional thermostating (to add kinetic energy to the system), it has the effect of slowly (or rapidly) freezing the system; hence it can also be used as a simple energy minimization technique.

The damping force  $F_i$  is given by  $F_i = -\gamma v_i$ . The larger the coefficient, the faster the kinetic energy is reduced. If the optional keyword *scale* is used,  $\gamma$  can be scaled up or down by the specified factor for atoms of that type. It can be used multiple times to adjust  $\gamma$  for several atom types.

---

**Note:** You should specify gamma in force/velocity units. This is not the same as mass/time units, at least for some of the LAMMPS *units* options like “real” or “metal” that are not self-consistent.

---

In a Brownian dynamics context,  $\gamma = \frac{k_B T}{D}$ , where  $k_B$  = Boltzmann’s constant,  $T$  = temperature, and  $D$  = particle diffusion coefficient.  $D$  can be written as  $\frac{k_B T}{3\pi\eta d}$ , where  $\eta$  = dynamic viscosity of the frictional fluid and  $d$  = diameter of particle. This means  $\gamma = 3\pi\eta d$ , and thus is proportional to the viscosity of the fluid and the particle diameter.

In the current implementation, rather than have the user specify a viscosity,  $\gamma$  is specified directly in force/velocity units. If needed,  $\gamma$  can be adjusted for atoms of different sizes (i.e.  $\sigma$ ) by using the *scale* keyword.

Note that Brownian dynamics models also typically include a randomized force term to thermostat the system at a chosen temperature. The *fix langevin* command does this. It has the same viscous damping term as *fix viscous* and adds a random force to each atom. The random force term is proportional to the square root of the chosen thermostating temperature. Thus if you use *fix langevin* with a target  $T = 0$ , its random force term is zero, and you are essentially performing the same operation as *fix viscous*. Also note that the gamma of *fix viscous* is related to the damping parameter of *fix langevin*, however the former is specified in units of force/velocity and the latter in units of time, so that it can more easily be used as a thermostat.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.244.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is modifying forces. Default is the outermost level.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the *min\_style* command for details.

## 2.244.5 Restrictions

- gamma = damping coefficient (torque/angular velocity units)
- zero or more keyword/value pairs may be appended

keyword = *scale*

scale values = *type ratio* or *v\_name*

type = atom type (1-N)

ratio = factor to scale the damping coefficients by

v\_name = reference to atom style variable *name*

## 2.245.2 Examples

```
fix 1 flow viscous/sphere 0.1
fix 1 damp viscous/sphere 0.5 scale 3 2.5
fix 1 damp viscous/sphere 0.5 scale v_radscale
```

## 2.245.3 Description

Add a viscous damping torque to finite-size spherical particles in the group that is proportional to the angular velocity of the atom. In granular simulations this can be useful for draining the rotational kinetic energy from the system in a controlled fashion. If used without additional thermostating (to add kinetic energy to the system), it has the effect of slowly (or rapidly) freezing the system; hence it can also be used as a simple energy minimization technique.

The damping torque  $T_i$  is given by  $T_i = -\gamma\omega_i$ . The larger the coefficient, the faster the rotational kinetic energy is reduced.

If the optional keyword *scale* is used,  $\gamma$  can be scaled up or down by the specified factor for atoms. This factor can be set for different atom types and thus the *scale* keyword used multiple times followed by the atom type and the associated scale factor. Alternately the scaling factor can be computed for each atom (e.g. based on its radius) by using an *atom-style variable*.

---

**Note:** You should specify gamma in torque/angular velocity units. This is not the same as mass/time units, at least for some of the LAMMPS *units* options like “real” or “metal” that are not self-consistent.

---

In the current implementation, rather than have the user specify a viscosity,  $\gamma$  is specified directly in torque/angular velocity units. If needed,  $\gamma$  can be adjusted for atoms of different sizes (i.e.  $\sigma$ ) by using the *scale* keyword.

---

## 2.245.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is modifying torques. Default is the outermost level.

The torques due to this fix are imposed during an energy minimization, invoked by the *minimize* command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the *min\_style* command for details.

## 2.245.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the *atom\_style sphere* command.

All particles in the group must be finite-size spheres. They cannot be point particles.

```

## 2.253.3 Description

Bound the simulation domain on one or more of its faces with a flat wall that interacts with the atoms in the group by generating a force on the atom in a direction perpendicular to the wall. The energy of wall-particle interactions depends on the style.

For style *wall/lj93*, the energy  $E$  is given by the 9-3 Lennard-Jones potential:

$$E = \varepsilon \left[ \frac{2}{15} \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^3 \right] \quad r < r_c$$

For style *wall/lj126*, the energy  $E$  is given by the 12-6 Lennard-Jones potential:

$$E = 4\varepsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

For style *wall/lj1043*, the energy  $E$  is given by the 10-4-3 Lennard-Jones potential:

$$E = 2\pi\varepsilon \left[ \frac{2}{5} \left( \frac{\sigma}{r} \right)^{10} - \left( \frac{\sigma}{r} \right)^4 - \frac{\sqrt{2}\sigma^3}{3(r + (0.61/\sqrt{2})\sigma)^3} \right] \quad r < r_c$$

For style *wall/colloid*, the energy  $E$  is given by an integrated form of the *pair\_style colloid* potential:

$$E = \varepsilon \left[ \frac{\sigma^6}{7560} \left( \frac{6R - D}{D^7} + \frac{D + 8R}{(D + 2R)^7} \right) - \frac{1}{6} \left( \frac{2R(D + R) + D(D + 2R) [\ln D - \ln(D + 2R)]}{D(D + 2R)} \right) \right] \quad r < r_c$$

For style *wall/harmonic*, the energy  $E$  is given by a repulsive-only harmonic spring potential:

$$E = \varepsilon (r - r_c)^2 \quad r < r_c$$

For style *wall/morse*, the energy  $E$  is given by a Morse potential:

$$E = D_0 [e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)}] \quad r < r_c$$

New in version 28Mar2023.

For style *wall/lepton*, the energy  $E$  is provided as an Lepton expression string using “ $r$ ” as the distance variable. The [Lepton library](#), that the *wall/lepton* style interfaces with, evaluates this expression string at run time to compute the wall-particle energy. It also creates an analytical representation of the first derivative of this expression with respect to “ $r$ ” and then uses that to compute the force between the wall and atoms in the fix group. The Lepton expression must be either enclosed in quotes or must not contain any whitespace so that LAMMPS recognizes it as a single keyword.

Optionally, the expression may use “ $rc$ ” to refer to the cutoff distance for the given wall. Further constants in the expression can be defined in the same string as additional expressions separated by semicolons. The expression “ $k*(r-rc)^2;k=100.0$ ” represents a repulsive-only harmonic spring as in fix *wall/harmonic* with a force constant  $K$  (same as  $\epsilon$  above) of 100 energy units. More details on the Lepton expression strings are given below.

New in version 28Mar2023.

For style *wall/table*, the energy  $E$  and forces are determined from interpolation tables listed in one or more files as a function of distance. The interpolation tables are used to evaluate energy and forces between particles and the wall similar to how analytic formulas are used for the other wall styles.

The interpolation tables are created as a pre-computation by fitting cubic splines to the file values and interpolating energy and force values at each of  $N$  distances. During a simulation, the tables are used to interpolate energy and force values as needed for each wall and particle separated by a distance  $R$ . The interpolation is done in one of two styles: *linear* or *spline*.

For the *linear* style, the distance  $R$  is used to find the 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the *spline* style, cubic spline coefficients are computed and stored for each of the  $N$  values in the table, one set of splines for energy, another for force. Note that these splines are different than the ones used to pre-compute the  $N$  values. Those splines were fit to the  $N_{file}$  values in the tabulated file, where often  $N_{file} < N$ . The distance  $R$  is used to find the appropriate set of spline coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For each wall a filename and a keyword must be provided as in the examples above. The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The format of this file is described below.

In all cases,  $r$  is the distance from the particle to the wall at position *coord*, and  $r_c$  is the *cutoff* distance at which the particle and wall no longer interact. The energy of the wall potential is shifted so that the wall-particle interaction energy is 0.0 at the cutoff distance.

Up to 6 walls or faces can be specified in a single command: *xlo, xhi, ylo, yhi, zlo, zhi*. A *lo* face interacts with particles near the lower side of the simulation box in that dimension. A *hi* face interacts with particles near the upper side of the simulation box in that dimension.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (x, y, or z). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as *v\_name*, where name is an [equal-style variable](#) name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include [thermo\\_style](#) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position. See examples below.

For the *wall/lj93* and *wall/lj126* and *wall/lj1043* styles,  $\epsilon$  and  $\sigma$  are the usual Lennard-Jones parameters, which determine the strength and size of the particle as it interacts with the wall. Epsilon has energy units. Note that this  $\epsilon$  and  $\sigma$  may be different than any  $\epsilon$  or  $\sigma$  values defined for a pair style that computes particle-particle interactions.

The *wall/lj93* interaction is derived by integrating over a 3d half-lattice of Lennard-Jones 12/6 particles. The *wall/lj126* interaction is effectively a harder, more repulsive wall interaction. The *wall/lj1043* interaction is yet a different form of

wall interaction, described in Magda et al in ([Magda](#)).

For the *wall/colloid* style,  $R$  is the radius of the colloid particle,  $D$  is the distance from the surface of the colloid particle to the wall ( $r-R$ ), and  $\sigma$  is the size of a constituent LJ particle inside the colloid particle and wall. Note that the cutoff distance  $R_c$  in this case is the distance from the colloid particle center to the wall. The prefactor  $\epsilon$  can be thought of as an effective Hamaker constant with energy units for the strength of the colloid-wall interaction. More specifically, the  $\epsilon$  prefactor is  $4\pi^2\rho_{\text{wall}}\rho_{\text{colloid}}\epsilon\sigma^6$ , where  $\epsilon$  and  $\sigma$  are the LJ parameters for the constituent LJ particles.  $\rho_{\text{wall}}$  and  $\rho_{\text{colloid}}$  are the number density of the constituent particles, in the wall and colloid respectively, in units of 1/volume.

The *wall/colloid* interaction is derived by integrating over constituent LJ particles of size  $\sigma$  within the colloid particle and a 3d half-lattice of Lennard-Jones 12/6 particles of size  $\sigma$  in the wall. As mentioned in the preceding paragraph, the density of particles in the wall and colloid can be different, as specified by the  $\epsilon$  prefactor.

For the *wall/harmonic* style,  $\epsilon$  is effectively the spring constant  $K$ , and has units (energy/distance<sup>2</sup>). The input parameter  $\sigma$  is ignored. The minimum energy position of the harmonic spring is at the *cutoff*. This is a repulsive-only spring since the interaction is truncated at the *cutoff*.

For the *wall/morse* style, the three parameters are in this order:  $D_0$  the depth of the potential,  $\alpha$  the width parameter, and  $r_0$  the location of the minimum.  $D_0$  has energy units,  $\alpha$  inverse distance units, and  $r_0$  distance units.

For any wall that supports them, the  $\epsilon$  and/or  $\sigma$  and/or  $\alpha$  parameter can be specified as an *equal-style variable*, in which case it should be specified as *v\_name*, where name is the variable name. As with a variable wall position, the variable is evaluated each timestep and the result becomes the current epsilon or sigma of the wall. Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall interaction.

---

**Note:** For all of the styles, you must ensure that  $r$  is always  $> 0$  for all particles in the group, or LAMMPS will generate an error. This means you cannot start your simulation with particles at the wall position *coord* ( $r = 0$ ) or with particles on the wrong side of the wall ( $r < 0$ ). For the *wall/lj93* and *wall/lj126* styles, the energy of the wall/particle interaction (and hence the force on the particle) blows up as  $r \rightarrow 0$ . The *wall/colloid* style is even more restrictive, since the energy blows up as  $D = r-R \rightarrow 0$ . This means the finite-size particles of radius  $R$  must be a distance larger than  $R$  from the wall position *coord*. The *harmonic* style is a softer potential and does not blow up as  $r \rightarrow 0$ , but you must use a large enough  $\epsilon$  that particles always remain on the correct side of the wall ( $r > 0$ ).

---

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant or variable is used. It is not relevant when *EDGE* is used to specify a face position. In the variable case, the variable is assumed to produce a value compatible with the *units* setting you specify.

A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

The *fld* keyword can be used with a *yes* setting to invoke the wall constraint before pairwise interactions are computed. This allows an implicit FLD model using *pair\_style lubricateU* to include the wall force in its calculations. If the setting is *no*, wall forces are imposed after pairwise interactions, in the usual manner.

The *pbc* keyword can be used with a *yes* setting to allow walls to be specified in a periodic dimension. See the *boundary* command for options on simulation box boundaries. The default for *pbc* is *no*, which means the system must be non-periodic when using a wall. But you may wish to use a periodic box. E.g. to allow some particles to interact with the wall via the fix group-ID, and others to pass through it and wrap around a periodic box. In this case you should ensure that the wall is sufficiently far enough away from the box boundary. If you do not, then particles may interact with both the wall and with periodic images on the other side of the box, which is probably not what you want.

---

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style *variables*. The wall interaction parameters (epsilon, sigma) could be varied with additional variable definitions.

```

variable ramp equal ramp(0,10)
fix 1 all wall xlo v_ramp 1.0 1.0 2.5

variable linear equal vdisplace(0,20)
fix 1 all wall xlo v_linear 1.0 1.0 2.5

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall xlo v_wiggle 1.0 1.0 2.5

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall xlo v_wiggle 1.0 1.0 2.5

```

The *ramp(lo,hi)* function adjusts the wall position linearly from *lo* to *hi* over the course of a run. The *vdisplace(c0,velocity)* function does something similar using the equation  $position = c0 + velocity * delta$ , where *delta* is the elapsed time.

The *swiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, where  $\omega = 2 \pi / period$ :

$$position = c0 + A \sin(\omega * delta)$$

The *cwiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

$$position = c0 + A (1 - \cos(\omega * delta))$$

## 2.253.4 Lepton expression syntax and features

Lepton supports the following operators in expressions:

+	Add	-	Subtract	*	Multiply	/	Divide	^	Power
---	-----	---	----------	---	----------	---	--------	---	-------

The following mathematical functions are available:

sqrt(x)	Square root	exp(x)	Exponential
log(x)	Natural logarithm	sin(x)	Sine (angle in radians)
cos(x)	Cosine (angle in radians)	sec(x)	Secant (angle in radians)
csc(x)	Cosecant (angle in radians)	tan(x)	Tangent (angle in radians)
cot(x)	Cotangent (angle in radians)	asin(x)	Inverse sine (in radians)
acos(x)	Inverse cosine (in radians)	atan(x)	Inverse tangent (in radians)
sinh(x)	Hyperbolic sine	cosh(x)	Hyperbolic cosine
tanh(x)	Hyperbolic tangent	erf(x)	Error function
erfc(x)	Complementary Error function	abs(x)	Absolute value
min(x,y)	Minimum of two values	max(x,y)	Maximum of two values
delta(x)	delta(x) is 1 for $x = 0$ , otherwise 0	step(x)	step(x) is 0 for $x < 0$ , otherwise 1

Numbers may be given in either decimal or exponential form. All of the following are valid numbers: 5, -3.1, 1e6, and 3.12e-2.

As an extension to the standard Lepton syntax, it is also possible to use LAMMPS *variables* in the format “v\_name”. Before evaluating the expression, “v\_name” will be replaced with the value of the variable “name”. This is compatible

with all kinds of scalar variables, but not with vectors, arrays, local, or per-atom variables. If necessary, a custom scalar variable needs to be defined that can access the desired (single) item from a non-scalar variable. As an example, the following lines will instruct LAMMPS to ramp the force constant for a harmonic bond from 100.0 to 200.0 during the next run:

```
variable fconst equal ramp(100.0, 200)
bond_style lepton
bond_coeff 1 1.5 "v_fconst * (r^2)"
```

An expression may be followed by definitions for intermediate values that appear in the expression. A semicolon “;” is used as a delimiter between value definitions. For example, the expression:

```
a^2+a*b+b^2; a=a1+a2; b=b1+b2
```

is exactly equivalent to

```
(a1+a2)^2+(a1+a2)*(b1+b2)+(b1+b2)^2
```

The definition of an intermediate value may itself involve other intermediate values. Whitespace and quotation characters (” and ‘”) are ignored. All uses of a value must appear *before* that value’s definition. For efficiency reasons, the expression string is parsed, optimized, and then stored in an internal, pre-parsed representation for evaluation.

Evaluating a Lepton expression is typically between 2.5 and 5 times slower than the corresponding compiled and optimized C++ code. If additional speed or GPU acceleration (via GPU or KOKKOS) is required, the interaction can be represented as a table. Suitable table files can be created either internally using the *pair\_write* or *bond\_write* command or through the Python scripts in the *tools/tabulate* folder.

## 2.253.5 Table file format

Suitable tables for use with fix *wall/table* can be created by the Python code in the *tools/tabulate* folder of the LAMMPS source code distribution.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Tabulated wall potential UNITS: real

HARMONIC                                (keyword is the first text on a line)
N 100 FP 200 200

1 0.04 1568.16 792.00                    (blank line)
2 0.08 1536.64 784.00                    (index, distance to wall, energy, force)
3 0.12 1505.44 776.00
...
99 3.96 0.16 8.00
100 4.00 0 0
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the fix *wall/table* command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the *N* specified in the fix *wall/table* command. Let *Ntable* = *N* in the fix command, and *Nfile* = “N” in the tabulated file.

What LAMMPS does is a preliminary interpolation by creating splines using the *Nfile* tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at *Ntable* different points. The resulting tables of length *Ntable* are then used as described above, when computing energy and force for wall-particle interactions. This means that if you want the interpolation tables of length *Ntable* to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set *Ntable* = *Nfile*.

---

### 2.253.6 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the energy of interaction between atoms and all the specified walls to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the interaction between atoms and all the specified walls to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global vector of forces, which can be accessed by various *output commands*. Note that the scalar energy is the sum of interactions with all defined walls. If you want the energy on a per-wall basis, you need to use multiple fix wall commands. The length of the vector is equal to the number of walls defined by the fix. Each vector value is the normal force on a specific wall. Note that an outward force on a wall will be a negative value for *lo* walls and a positive value for *hi* walls. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix\_modify energy* option for this fix.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

## 2.253.7 Restrictions

Fix *wall/lepton* is part of the LEPTON package and only enabled if LAMMPS was built with this package. See the *Build package* page for more info.

## 2.253.8 Related commands

*fix wall/reflect*, *fix wall/gran*, *fix wall/region*

## 2.253.9 Default

The option defaults units = lattice, fld = no, and pbc = no.

## 2.254 fix wall/body/polygon command

### 2.254.1 Syntax

**fix** ID group-ID wall/body/polygon k\_n c\_n c\_t wallstyle args keyword values ...

- ID, group-ID are documented in *fix* command
- wall/body/polygon = style name of this fix command
- k\_n = normal repulsion strength (force/distance or pressure units)
- c\_n = normal damping coefficient (force/distance or pressure units)
- c\_t = tangential damping coefficient (force/distance or pressure units)
- wallstyle = *xplane* or *yplane* or *zcylinder*
- args = list of arguments for a particular style
  - xplane* or *yplane* args = lo hi  
lo,hi = position of lower and upper plane (distance units), either can be NULL)
  - zcylinder* args = radius  
radius = cylinder radius (distance units)
- zero or more keyword/value pairs may be appended to args
- keyword = *wiggle*
  - wiggle* values = dim amplitude period  
dim = x or y or z  
amplitude = size of oscillation (distance units)  
period = time of oscillation (time units)

## 2.254.2 Examples

```
fix 1 all wall/body/polygon 1000.0 20.0 5.0 xplane -10.0 10.0
```

## 2.254.3 Description

This fix is for use with 2d models of body particles of style *rounded/polygon*. It bounds the simulation domain with wall(s). All particles in the group interact with the wall when they are close enough to touch it. The nature of the interaction between the wall and the polygon particles is the same as that between the polygon particles themselves, which is similar to a Hookean potential. See the [Howto body](#) page for more details on using body particles.

The parameters *k\_n*, *c\_n*, *c\_t* have the same meaning and units as those specified with the *pair\_style body/rounded/polygon* command.

The *wallstyle* can be planar or cylindrical. The 2 planar options specify a pair of walls in a dimension. Wall positions are given by *lo* and *hi*. Either of the values can be specified as NULL if a single wall is desired. For a *zcylinder* wallstyle, the cylinder's axis is at  $x = y = 0.0$ , and the radius of the cylinder is specified.

Optionally, the wall can be moving, if the *wiggle* keyword is appended.

For the *wiggle* keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the *fix move* command. This is useful in packing simulations of particles. The arguments to the *wiggle* keyword specify a dimension for the motion, as well as its *amplitude* and *period*. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion. A *zcylinder* wall can only be wiggled in the *z* dimension.

Each timestep, the position of a wiggled wall in the appropriate *dim* is set according to this equation:

$$\text{position} = \text{coord} + A - A \cos(\omega * \text{delta})$$

where *coord* is the specified initial position of the wall, *A* is the *amplitude*, *omega* is  $2 \text{ PI} / \text{period}$ , and *delta* is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.

## 2.254.4 Restart, fix\_modify, output, run start/stop, minimize info

None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.254.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Any dimension (xy) that has a wall must be non-periodic.

## 2.254.6 Related commands

# 2.255 fix wall/body/polyhedron command

## 2.255.1 Syntax

```
fix ID group-ID wall/body/polyhedron k_n c_n c_t wallstyle args keyword values ...
```

- ID, group-ID are documented in *fix* command
- wall/body/polyhedron = style name of this fix command
- k\_n = normal repulsion strength (force/distance units or pressure units - see discussion below)
- c\_n = normal damping coefficient (force/distance units or pressure units - see discussion below)
- c\_t = tangential damping coefficient (force/distance units or pressure units - see discussion below)
- wallstyle = *xplane* or *yplane* or *zplane*
- args = list of arguments for a particular style

```
xplane or yplane or zplane args = lo hi
lo,hi = position of lower and upper plane (distance units), either can be NULL)
```
- zero or more keyword/value pairs may be appended to args
- keyword = *wiggle*

```
wiggle values = dim amplitude period
dim = x or y or z
amplitude = size of oscillation (distance units)
period = time of oscillation (time units)
```

## 2.255.2 Examples

```
fix 1 all wall/body/polyhedron 1000.0 20.0 5.0 xplane -10.0 10.0
```

### 2.255.3 Description

This fix is for use with 3d models of body particles of style *rounded/polyhedron*. It bounds the simulation domain with wall(s). All particles in the group interact with the wall when they are close enough to touch it. The nature of the interaction between the wall and the polygon particles is the same as that between the polygon particles themselves, which is similar to a Hookean potential. See the [Howto body](#) page for more details on using body particles.

The parameters *k\_n*, *c\_n*, *c\_t* have the same meaning and units as those specified with the *pair\_style body/rounded/polyhedron* command.

The *wallstyle* can be planar or cylindrical. The 3 planar options specify a pair of walls in a dimension. Wall positions are given by *lo* and *hi*. Either of the values can be specified as NULL if a single wall is desired.

Optionally, the wall can be moving, if the *wiggle* keyword is appended.

For the *wiggle* keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the *fix move* command. This is useful in packing simulations of particles. The arguments to the *wiggle* keyword specify a dimension for the motion, as well as its *amplitude* and *period*. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion.

Each timestep, the position of a wiggled wall in the appropriate *dim* is set according to this equation:

$$\text{position} = \text{coord} + A - A \cos(\omega * \text{delta})$$

where *coord* is the specified initial position of the wall, *A* is the *amplitude*, *omega* is  $2 \pi / \text{period}$ , and *delta* is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.

### 2.255.4 Restart, fix\_modify, output, run start/stop, minimize info

None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 2.255.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Any dimension (xyz) that has a wall must be non-periodic.

```

### 2.257.3 Description

Fix *wall/ees* bounds the simulation domain on one or more of its faces with a flat wall that interacts with the ellipsoidal atoms in the group by generating a force on the atom in a direction perpendicular to the wall and a torque parallel with the wall. The energy of wall-particle interactions  $E$  is given by:

$$E = \varepsilon \left[ \frac{2\sigma_{LJ}^{12} (7r^5 + 14r^3\sigma_n^2 + 3r\sigma_n^4)}{945 (r^2 - \sigma_n^2)^7} - \frac{\sigma_{LJ}^6 (2r\sigma_n^3 + \sigma_n^2 (r^2 - \sigma_n^2) \log \left[ \frac{r - \sigma_n}{r + \sigma_n} \right])}{12\sigma_n^5 (r^2 - \sigma_n^2)} \right] \quad \sigma_n < r < r_c$$

Introduced by Babadi and Ejtehadi in (Babadi2). Here,  $r$  is the distance from the particle to the wall at position *coord*, and  $R_c$  is the *cutoff* distance at which the particle and wall no longer interact. Also,  $\sigma_n$  is the distance between center of ellipsoid and the nearest point of its surface to the wall as shown below.

Details of using this command and specifications are the same as fix/wall command. You can also find an example in USER/ees/ under examples/ directory.

The prefactor  $\varepsilon$  can be thought of as an effective Hamaker constant with energy units for the strength of the ellipsoid-wall interaction. More specifically, the  $\varepsilon$  prefactor is

$$8\pi^2 \rho_{wall} \rho_{ellipsoid} \varepsilon \sigma_a \sigma_b \sigma_c$$

where  $\varepsilon$  is the LJ energy parameter for the constituent LJ particles and  $\sigma_a$ ,  $\sigma_b$ , and  $\sigma_c$  are the radii of the ellipsoidal particles.  $\rho_{wall}$  and  $\rho_{ellipsoid}$  are the number density of the constituent particles, in the wall and ellipsoid respectively, in units of 1/volume.

**Note:** You must ensure that  $r$  is always bigger than  $\sigma_n$  for all particles in the group, or LAMMPS will generate an error. This means you cannot start your simulation with particles touching the wall position *coord* ( $r = \sigma_n$ ) or with particles penetrating the wall ( $0 \leq r < \sigma_n$ ) or with particles on the wrong side of the wall ( $r < 0$ ).

Fix *wall/region/ees* treats the surface of the geometric region defined by the *region-ID* as a bounding wall which interacts with nearby ellipsoidal particles according to the EES potential introduced above.

Other details of this command are the same as for the *fix wall/region* command. One may also find an example of using this fix in the examples/PACKAGES/ees/ directory.

## 2.257.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about these fixes are written to *binary restart files*.

The *fix\_modify energy* option is supported by these fixes to add the energy of interaction between atoms and all the specified walls or region wall to the global potential energy of the system as part of *thermodynamic output*. The default settings for these fixes are *fix\_modify energy no*.

The *fix\_modify respa* option is supported by these fixes. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

These fixes computes a global scalar and a global vector of forces, which can be accessed by various *output commands*. See the *fix wall* command for a description of the scalar and vector.

No parameter of these fixes can be used with the *start/stop* keywords of the *run* command.

The forces due to these fixes are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix\_modify energy* option for this fix.

---

## 2.257.5 Restrictions

These fixes are part of the EXTRA-FIX package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These fixes requires that atoms be ellipsoids as defined by the *atom\_style ellipsoid* command.

## 2.258 fix wall/flow command

Accelerator Variants: *wall/flow/kk*

## 2.258.1 Syntax

```
fix ID group-ID wall/flow axis vflow T seed N coords ... keyword value
```

- ID, group-ID are documented in *fix* command
- wall/flow = style name of this fix command
- axis = flow axis (x, y, or z)
- vflow = generated flow velocity in *axis* direction (velocity units)
- T = flow temperature (temperature units)
- seed = random seed for stochasticity (positive integer)
- N = number of walls
- coords = list of N wall positions along the *axis* direction in ascending order (distance units)
- zero or more keyword/value pairs may be appended
- keyword = *units*

*units* value = *lattice* or *box*

*lattice* = wall positions are defined in lattice units

*box* = the wall positions are defined in simulation box units

## 2.258.2 Examples

```
fix 1 all wall/flow x 0.4 1.5 593894 4 2.0 4.0 6.0 8.0
```

## 2.258.3 Description

New in version 17Apr2024.

This fix implements flow boundary conditions (FBC) introduced in ([Pavlov1](#)) and ([Pavlov2](#)). The goal is to generate a stationary flow with a shifted Maxwell velocity distribution:

$$f_a(v_a) \propto \exp\left(-\frac{m(v_a - v_{\text{flow}})^2}{2kBT}\right)$$

where  $v_a$  is the component of velocity along the specified *axis* argument (a = x,y,z),  $v_{\text{flow}}$  is the flow velocity specified as the *vflow* argument,  $T$  is the specified flow temperature,  $m$  is the particle mass, and  $kB$  is the Boltzmann constant.

This is achieved by defining a series of  $N$  transparent walls along the flow *axis* direction. Each wall is at the specified position listed in the *coords* argument. Note that an additional transparent wall is defined by the code at the boundary of the (periodic) simulation domain in the *axis* direction. So there are effectively  $N+1$  walls.

Each time a particle in the specified group passes through one of the transparent walls, its velocity is re-assigned. Particles not in the group do not interact with the wall. This can be used, for example, to add obstacles composed of atoms, or to simulate a solution of complex molecules in a one-atom liquid (note that the fix has been tested for one-atom systems only).

Conceptually, the velocity re-assignment represents creation of a new particle within the system with simultaneous removal of the particle which passed through the wall. The velocity components in directions parallel to the wall

are re-assigned according to the standard Maxwell velocity distribution for the specified temperature  $T$ . The velocity component perpendicular to the wall is re-assigned according to the shifted Maxwell distribution defined above:

$$f_a^{\text{generated}}(v_a) \propto v_a f_a(v_a)$$

It can be shown that for an ideal-gas scenario this procedure makes the velocity distribution of particles between walls exactly as desired.

Since in most cases simulated systems are not an ideal gas, multiple walls can be defined, since a single wall may not be sufficient for maintaining a stationary flow without “congestion” which can manifest itself as regions in the flow with increased particle density located upstream from static obstacles.

For the same reason, the actual temperature and velocity of the generated flow may differ from what is requested. The degree of discrepancy is determined by how different from an ideal gas the simulated system is. Therefore, a calibration procedure may be required for such a system as described in (Pavlov).

Note that the interactions between particles on different sides of a transparent wall are not disabled or neglected. Likewise particle positions are not altered by the velocity reassignment. This removes the need to modify the force field to work correctly in cases when a particle is close to a wall.

For example, if particle positions were uniformly redistributed across the surface of a wall, two particles could end up too close to each other, potentially causing the simulation to explode. However due to this compromise, some collective phenomena such as regions with increased/decreased density or collective movements are not fully removed when particles cross a wall. This unwanted consequence can also be potentially mitigated by using more multiple walls.

---

**Note:** When the specified flow has a high velocity, a lost atoms error can occur (see [error messages](#)). If this happens, you should ensure the checks for neighbor list rebuilds, set via the [neigh\\_modify](#) command, are as conservative as possible (every timestep if needed). Those are the default settings.

---

## 2.258.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

None of the [fix\\_modify](#) options are relevant to this fix.

No global or per-atom quantities are stored by this fix for access by various *output commands*.

No parameter of this fix can be used with the *start/stop* keywords of the [run](#) command.

This fix is not invoked during *energy minimization*.

## 2.258.5 Restrictions

Fix *wall\_flow* is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Flow boundary conditions should not be used with rigid bodies such as those defined by a “fix rigid” command.

This fix can only be used with periodic boundary conditions along the flow axis. The size of the box in this direction must not change. Also, the fix is designed to work only in an orthogonal simulation box.

## 2.258.6 Related commands

*fix wall/reflect* command

## 2.258.7 Default

The default for the units keyword is lattice.

## 2.259 fix wall/gran command

Accelerator Variants: *wall/gran/kk*

### 2.259.1 Syntax

```
fix ID group-ID wall/gran fstyle fstyle_params wallstyle args keyword values ...
```

- ID, group-ID are documented in *fix* command
- wall/gran = style name of this fix command
- fstyle = style of force interactions between particles and wall

possible choices: hooke, hooke/history, hertz/history, granular

- fstyle\_params = parameters associated with force interaction style

For *hooke*, *hooke/history*, and *hertz/history*, *fstyle\_params* are:

Kn = elastic constant for normal particle repulsion (force/distance units or  
→pressure units - see discussion below)  
Kt = elastic constant for tangential contact (force/distance units or  
→pressure units - see discussion below)  
gamma\_n = damping coefficient for collisions in normal direction (1/time  
→units or 1/time-distance units - see discussion below)  
gamma\_t = damping coefficient for collisions in tangential direction (1/time  
→units or 1/time-distance units - see discussion below)  
xmu = static yield criterion (unitless value between 0.0 and 1.0e4)  
dampflag = 0 or 1 if tangential damping force is excluded or included  
optional keyword = *limit\_damping*, limit damping to prevent attractive  
→interaction

For *granular*, *fstyle\_params* are set using the same syntax as for the *pair\_coeff*  
→command of *pair\_style granular*

- wallstyle = *xplane* or *yplane* or *zplane* or *zcylinder*
- args = list of arguments for a particular style

*xplane* or *yplane* or *zplane* args = lo hi  
 lo,hi = position of lower and upper plane (distance units), either can be NULL)  
*zcylinder* args = radius  
 radius = cylinder radius (distance units)

- zero or more keyword/value pairs may be appended to args
- keyword = *wiggle* or *shear* or *contacts* or *temperature*

*wiggle* values = dim amplitude period  
 dim = x or y or z  
 amplitude = size of oscillation (distance units)  
 period = time of oscillation (time units)  
*shear* values = dim vshear  
 dim = x or y or z  
 vshear = magnitude of shear velocity (velocity units)  
*contacts* value = none  
 generate contact information for each particle  
*temperature* value = temperature  
 specify temperature of wall

## 2.259.3 Description

Bound the simulation domain of a granular system with a frictional wall. All particles in the group interact with the wall when they are close enough to touch it.

The nature of the wall/particle interactions are determined by the *fstyle* setting. It can be any of the styles defined by the *pair\_style gran/\** or the more general *pair\_style granular* commands. Currently the options are *hooke*, *hooke/history*, or *hertz/history* for the former, and *granular* with all the possible options of the associated *pair\_coeff* command for the latter. The equation for the force between the wall and particles touching it is the same as the corresponding equation on the *pair\_style gran/\** and *pair\_style granular* doc pages, in the limit of one of the two particles going to infinite radius and mass (flat wall). Specifically,  $\delta = \text{radius} - r = \text{overlap of particle with wall}$ ,  $m_{\text{eff}} = \text{mass of particle}$ , and the effective radius of contact  $= RiRj/Ri+Rj$  is set to the radius of the particle.

The parameters *Kn*, *Kt*, *gamma\_n*, *gamma\_t*, *xmu*, *dampflag*, and the optional keyword *limit\_damping* have the same meaning and units as those specified with the *pair\_style gran/\** commands. This means a NULL can be used for either *Kt* or *gamma\_t* as described on that page. If a NULL is used for *Kt*, then a default value is used where  $Kt = 2/7 Kn$ . If a NULL is used for *gamma\_t*, then a default value is used where  $\gamma_t = 1/2 \gamma_n$ .

All the model choices for cohesion, tangential friction, rolling friction and twisting friction supported by the *pair\_style granular* through its *pair\_coeff* command are also supported for walls. These are discussed in greater detail on the doc page for *pair\_style granular*.

**Note:** When *fstyle granular* is specified, the associated *fstyle\_params* are taken as those for a wall/particle interaction. For example, for the *hertz/material* normal contact model with  $E = 960$  and  $\nu = 0.2$ , the effective Young's modulus for a wall/particle interaction is computed as  $E_{eff} = \frac{960}{2(1-0.2^2)} = 500$ . Any pair coefficients defined by *pair\_style granular* are not taken into consideration. To model different wall/particle interactions for particles of different material types, the user may define multiple *fix wall/gran* commands operating on separate groups (e.g. based on particle type) each with a different wall/particle effective Young's modulus.

Note that you can choose a different force styles and/or different values for the wall/particle coefficients than for particle/particle interactions. E.g. if you wish to model the wall as a different material.

**Note:** As discussed on the page for *pair\_style gran/\**, versions of LAMMPS before 9Jan09 used a different equation for Hertzian interactions. This means Hertzian wall/particle interactions have also changed. They now include a  $\sqrt{\text{radius}}$  term which was not present before. Also the previous versions used *Kn* and *Kt* from the pairwise interaction and hardcoded *dampflag* to 1, rather than letting them be specified directly. This means you can set the values of the wall/particle coefficients appropriately in the current code to reproduce the results of a previous Hertzian monodisperse calculation. For example, for the common case of a monodisperse system with particles of diameter 1, *Kn*, *Kt*, *gamma\_n*, and *gamma\_s* should be set  $\sqrt{2.0}$  larger than they were previously.

The effective mass  $m_{eff}$  in the formulas listed on the *pair\_style granular* page is the mass of the particle for particle/wall interactions (mass of wall is infinite). If the particle is part of a rigid body, its mass is replaced by the mass of the rigid body in those formulas. This is determined by searching for a *fix rigid* command (or its variants).

The *wallstyle* can be planar or cylindrical. The 3 planar options specify a pair of walls in a dimension. Wall positions are given by *lo* and *hi*. Either of the values can be specified as NULL if a single wall is desired. For a *zcylinder* wallstyle, the cylinder's axis is at  $x = y = 0.0$ , and the radius of the cylinder is specified.

Optionally, the wall can be moving, if the *wiggle* or *shear* keywords are appended. Both keywords cannot be used together.

For the *wiggle* keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the *fix move* command. This is useful in packing simulations of granular particles. The arguments to the *wiggle* keyword specify a dimension for the motion, as well as its *amplitude* and *period*. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion. A *zcylinder* wall can only be wiggled in the *z* dimension.

Each timestep, the position of a wiggled wall in the appropriate *dim* is set according to this equation:

$$\text{position} = \text{coord} + A - A \cos(\omega * \text{delta})$$

where *coord* is the specified initial position of the wall, *A* is the *amplitude*,  $\omega$  is  $2 \pi / \text{period}$ , and *delta* is the time elapsed since the *fix* was specified. The velocity of the wall is set to the derivative of this expression.

For the *shear* keyword, the wall moves continuously in the specified dimension with velocity *vshear*. The dimension must be tangential to walls with a planar *wallstyle*, e.g. in the *y* or *z* directions for an *xplane* wall. For *zcylinder* walls, a dimension of *z* means the cylinder is moving in the *z*-direction along its axis. A dimension of *x* or *y* means the cylinder is spinning around the *z*-axis, either in the clockwise direction for *vshear* > 0 or counter-clockwise for *vshear* < 0. In this case, *vshear* is the tangential velocity of the wall at whatever *radius* has been defined.

The *temperature* keyword is used to assign a temperature to the wall. The following value can either be a numeric value or an equal-style *variable*. If the value is a variable, it should be specified as *v\_name*, where *name* is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the temperature. This

option must be used in conjunction with a heat conduction model defined in *pair\_style granular*, *fix property/atom* to store temperature and a heat flow, and *fix heat/flow* to integrate heat flow.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 2.259.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the shear friction state of atoms interacting with the wall to *binary restart files*, so that a simulation can continue correctly if granular potentials with shear “history” effects are being used. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

If the *contacts* option is used, this fix generates a per-atom array with 8 columns as output, containing the contact information for owned particles (nlocal on each processor). All columns in this per-atom array will be zero if no contact has occurred. The values of these columns are listed in the following table:

Index	Value	Units
1	1.0 if particle is in contact with wall, 0.0 otherwise	
2	Force $f_x$ exerted by the wall	force units
3	Force $f_y$ exerted by the wall	force units
4	Force $f_z$ exerted by the wall	force units
5	$x$ -coordinate of contact point on wall	distance units
6	$y$ -coordinate of contact point on wall	distance units
7	$z$ -coordinate of contact point on wall	distance units
8	Radius $r$ of atom	distance units

None of the *fix\_modify* options are relevant to this fix. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

#### 2.259.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Any dimension (xyz) that has a granular wall must be non-periodic.

## 2.259.6 Related commands

## 2.260 fix wall/gran/region command

### 2.260.1 Syntax

```
fix ID group-ID wall/gran/region fstyle fstyle_params wallstyle regionID keyword values .
→ ..
```

- ID, group-ID are documented in *fix* command
- wall/region = style name of this fix command
- fstyle = style of force interactions between particles and wall

possible choices: hooke, hooke/history, hertz/history, granular

- fstyle\_params = parameters associated with force interaction style

For *hooke*, *hooke/history*, and *hertz/history*, *fstyle\_params* are:

Kn = elastic constant for normal particle repulsion (force/distance units or  
→pressure units - see discussion below)  
Kt = elastic constant for tangential contact (force/distance units or  
→pressure units - see discussion below)  
gamma\_n = damping coefficient for collisions in normal direction (1/time  
→units or 1/time-distance units - see discussion below)  
gamma\_t = damping coefficient for collisions in tangential direction (1/time  
→units or 1/time-distance units - see discussion below)  
xmu = static yield criterion (unitless value between 0.0 and 1.0e4)  
dampflag = 0 or 1 if tangential damping force is excluded or included

For *granular*, *fstyle\_params* are set using the same syntax as for the *pair\_coeff*  
→command of *pair\_style granular*

- wallstyle = region (see *fix wall/gran* for options for other kinds of walls)
- region-ID = region whose boundary will act as wall
- keyword = *contacts* or *temperature*

## 2.260.3 Description

Treat the surface of the geometric region defined by the *region-ID* as a bounding frictional wall which interacts with nearby finite-size granular particles when they are close enough to touch the wall. See the *fix wall/region* and *fix wall/gran* commands for related kinds of walls for non-granular particles and simpler wall geometries, respectively.

Here are snapshots of example models using this command. Corresponding input scripts can be found in `examples/granregion`. Movies of these simulations are [here on the Movies page](#) of the LAMMPS website.

The distance between a particle and the region boundary is the distance to the nearest point on the region surface. The force the wall exerts on the particle is along the direction between that point and the particle center, which is the direction normal to the surface at that point. Note that if the region surface is comprised of multiple “faces”, then each face can exert a force on the particle if it is close enough. E.g. for *region\_style block*, a particle in the interior, near a corner of the block, could feel wall forces from 1, 2, or 3 faces of the block.

Regions are defined using the *region* command. Note that the region volume can be interior or exterior to the bounding surface, which will determine in which direction the surface interacts with particles, i.e. the direction of the surface

normal. The exception to this is if one or more *open* options are specified for the region command, in which case particles interact with both the interior and exterior surfaces of regions.

Regions can either be primitive shapes (block, sphere, cylinder, etc) or combinations of primitive shapes specified via the *union* or *intersect* region styles. These latter styles can be used to construct particle containers with complex shapes.

Regions can also move dynamically via the *region* command keywords (*move*) and *rotate*, or change their shape by use of variables as inputs to the *region* command. If such a region is used with this fix, then the region surface will move in time in the corresponding manner.

---

**Note:** As discussed on the *region* command doc page, regions in LAMMPS do not get wrapped across periodic boundaries. It is up to you to ensure that the region location with respect to periodic or non-periodic boundaries is specified appropriately via the *region* and *boundary* commands when using a region as a wall that bounds particle motion.

---

---

**Note:** For primitive regions with sharp corners and/or edges (e.g. a block or cylinder), wall/particle forces are computed accurately for both interior and exterior regions. For *union* and *intersect* regions, additional sharp corners and edges may be present due to the intersection of the surfaces of 2 or more primitive volumes. These corners and edges can be of two types: concave or convex. Concave points/edges are like the corners of a cube as seen by particles in the interior of a cube. Wall/particle forces around these features are computed correctly. Convex points/edges are like the corners of a cube as seen by particles exterior to the cube, i.e. the points jut into the volume where particles are present. LAMMPS does NOT compute the location of these convex points directly, and hence wall/particle forces in the cutoff volume around these points suffer from inaccuracies. The basic problem is that the outward normal of the surface is not continuous at these points. This can cause particles to feel no force (they don't "see" the wall) when in one location, then move a distance epsilon, and suddenly feel a large force because they now "see" the wall. In a worst-case scenario, this can blow particles out of the simulation box. Thus, as a general rule you should not use the fix wall/gran/region command with *union* or *intersect* regions that have convex points or edges resulting from the union/intersection (convex points/edges in the union/intersection due to a single sub-region are still OK).

---

---

**Note:** Similarly, you should not define *union* or *intersect* regions for use with this command that share an overlapping common face that is part of the overall outer boundary (interior boundary is OK), even if the face is smooth. E.g. two regions of style block in a *union* region, where the two blocks overlap on one or more of their faces. This is because LAMMPS discards points that are part of multiple sub-regions when calculating wall/particle interactions, to avoid double-counting the interaction. Having two coincident faces could cause the face to become invisible to the particles. The solution is to make the two faces differ by epsilon in their position.

---

The nature of the wall/particle interactions are determined by the *fstyle* setting. It can be any of the styles defined by the *pair\_style gran/\** or the more general *pair\_style granular* commands. Currently the options are *hooke*, *hooke/history*, or *hertz/history* for the former, and *granular* with all the possible options of the associated *pair\_coeff* command for the latter. The equation for the force between the wall and particles touching it is the same as the corresponding equation on the *pair\_style gran/\** and *pair\_style granular* doc pages, but the effective radius is calculated using the radius of the particle and the radius of curvature of the wall at the contact point.

Specifically,  $\delta = \text{radius} - r = \text{overlap of particle with wall}$ ,  $m_{\text{eff}} = \text{mass of particle}$ , and  $R_i R_j / (R_i + R_j)$  is the effective radius, with  $R_j$  replaced by the radius of curvature of the wall at the contact point. The radius of curvature can be negative for a concave wall section, e.g. the interior of cylinder. For a flat wall,  $\delta = \text{radius} - r = \text{overlap of particle with wall}$ ,  $m_{\text{eff}} = \text{mass of particle}$ , and the effective radius of contact is just the radius of the particle.

The parameters *Kn*, *Kt*, *gamma\_n*, *gamma\_t*, *xmu*, *dampflag*, and the optional keyword *limit\_damping* have the same meaning and units as those specified with the *pair\_style gran/\** commands. This means a NULL can be used for either *Kt* or *gamma\_t* as described on that page. If a NULL is used for *Kt*, then a default value is used where  $Kt = 2/7 Kn$ . If a NULL is used for *gamma\_t*, then a default value is used where  $\gamma_t = 1/2 \gamma_n$ .

All the model choices for cohesion, tangential friction, rolling friction and twisting friction supported by the *pair\_style granular* through its *pair\_coeff* command are also supported for walls. These are discussed in greater detail on the doc page for *pair\_style granular*.

Note that you can choose a different force styles and/or different values for the 6 wall/particle coefficients than for particle/particle interactions. E.g. if you wish to model the wall as a different material.

The *temperature* keyword is used to assign a temperature to the wall. The following value can either be a numeric value or an equal-style *variable*. If the value is a variable, it should be specified as *v\_name*, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the temperature. This option must be used in conjunction with a heat conduction model defined in *pair\_style granular*, *fix property/atom* to store temperature and a heat flow, and *fix heat/flow* to integrate heat flow.

## 2.260.4 Restart, fix\_modify, output, run start/stop, minimize info

Similar to *fix wall/gran* command, this fix writes the shear friction state of atoms interacting with the wall to *binary restart files*, so that a simulation can continue correctly if granular potentials with shear “history” effects are being used. This fix also includes info about a moving region in the restart file. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** Information about region definitions is NOT included in restart files, as discussed on the *read\_restart* doc page. So you must re-define your region and if it is a moving region, define its motion attributes in a way that is consistent with the simulation that wrote the restart file. In particular, if you want to change the region motion attributes (e.g. its velocity), then you should ensure the position/orientation of the region at the initial restart timestep is the same as it was on the timestep the restart file was written. If this is not possible, you may need to ignore info in the restart file by defining a new *fix wall/gran/region* command in your restart script, e.g. with a different fix ID. Or if you want to keep the shear history info but discard the region motion information, you can use the same fix ID for *fix wall/gran/region*, but assign it a region with a different region ID.

---

If the *contacts* option is used, this fix generates a per-atom array with 8 columns as output, containing the contact information for owned particles (nlocal on each processor). All columns in this per-atom array will be zero if no contact has occurred. The values of these columns are listed in the following table:

Index	Value	Units
1	1.0 if particle is in contact with wall, 0.0 otherwise	
2	Force $f_x$ exerted by the wall	force units
3	Force $f_y$ exerted by the wall	force units
4	Force $f_z$ exerted by the wall	force units
5	$x$ -coordinate of contact point on wall	distance units
6	$y$ -coordinate of contact point on wall	distance units
7	$z$ -coordinate of contact point on wall	distance units
8	Radius $r$ of atom	distance units

None of the *fix\_modify* options are relevant to this fix. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.260.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

fix xwalls all wall/piston zlo
fix walls all wall/piston zlo pos 1.0 vel 10.0 units box
fix top all wall/piston zlo vel 10.0 ramp
```

## 2.261.3 Description

Bound the simulation with a moving wall which reflect particles in the specified group and drive the system with an effective infinite-mass piston capable of driving shock waves.

A momentum mirror technique is used, which means that if an atom (or the wall) moves such that an atom is outside the wall on a timestep by a distance delta (e.g. due to *fix nve*), then it is put back inside the face by the same delta, and the velocity relative to the moving wall is flipped in z. For instance, a stationary particle hit with a piston wall with velocity  $v_z$ , will end the timestep with a velocity of  $2*v_z$ .

Currently the *face* keyword can only be *zlo*. This creates a piston moving in the positive z direction. Particles with z coordinate less than the wall position are reflected to a z coordinate greater than the wall position. If the piston velocity is  $v_{pz}$  and the particle velocity before reflection is  $v_{zi}$ , the particle velocity after reflection is  $-v_{zi} + 2*v_{pz}$ .

The initial position of the wall can be specified by the *pos* keyword.

The final velocity of the wall can be specified by the *vel* keyword

The *ramp* keyword will cause the wall/piston to adjust the velocity linearly from zero velocity to *vel* over the course of the run. If the *ramp* keyword is omitted then the wall/piston moves at a constant velocity defined by *vel*.

The *temp* keyword will cause the region immediately in front of the wall/piston to be thermostatted with a Langevin thermostat. This region moves with the piston. The damping and kicking are measured in the reference frame of the piston. So, a temperature of zero would mean all particles were moving at exactly the speed of the wall/piston.

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used.

A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

---

## 2.261.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.261.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The face that has the wall/piston must be boundary type ‘s’ (shrink-wrapped). The opposing face can be any boundary type other than periodic.

A wall/piston should not be used with rigid bodies such as those defined by a “fix rigid” command. This is because the wall/piston displaces atoms directly rather than exerting a force on them.

## 2.261.6 Related commands

[fix wall/reflect](#) command, [fix append/atoms](#) command

fix top all wall/reflect zhi v_pressdown
```

## 2.262.3 Description

Bound the simulation with one or more walls which reflect particles in the specified group when they attempt to move through them.

Reflection means that if an atom moves outside the wall on a timestep by a distance delta (e.g. due to *fix nve*), then it is put back inside the face by the same delta, and the sign of the corresponding component of its velocity is flipped.

When used in conjunction with *fix nve* and *run\_style verlet*, the resultant time-integration algorithm is equivalent to the primitive splitting algorithm (PSA) described by *Bond*. Because each reflection event divides the corresponding timestep asymmetrically, energy conservation is only satisfied to  $O(dt)$ , rather than to  $O(dt^2)$  as it would be for velocity-Verlet integration without reflective walls.

Up to 6 walls or faces can be specified in a single command: *xlo*, *xhi*, *ylo*, *yhi*, *zlo*, *zhi*. A *lo* face reflects particles that move to a coordinate less than the wall position, back in the *hi* direction. A *hi* face reflects particles that move to a coordinate higher than the wall position, back in the *lo* direction.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (x, y, or z). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as *v\_name*, where name is an *equal-style variable* name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position.

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant or variable is used. It is not relevant when EDGE is used to specify a face position. In the variable case, the variable is assumed to produce a value compatible with the *units* setting you specify.

A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

---

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style variables.

```
variable ramp equal ramp(0,10)
fix 1 all wall/reflect xlo v_ramp

variable linear equal vdisplace(0,20)
fix 1 all wall/reflect xlo v_linear

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall/reflect xlo v_wiggle

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall/reflect xlo v_wiggle
```

The *ramp(lo,hi)* function adjusts the wall position linearly from *lo* to *hi* over the course of a run. The *vdisplace(c0,velocity)* function does something similar using the equation  $position = c0 + velocity * delta$ , where *delta* is the elapsed time.

The *swiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, where  $\omega = 2 \pi / period$ :

$$position = c0 + A \sin(\omega * delta)$$

The *cwiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

$$position = c0 + A (1 - \cos(\omega * delta))$$

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

## 2.262.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.262.5 Restrictions

Any dimension (xyz) that has a reflecting wall must be non-periodic.

A reflecting wall should not be used with rigid bodies such as those defined by a “fix rigid” command. This is because the wall/reflect displaces atoms directly rather than exerts a force on them. For rigid bodies, use a soft wall instead, such as *fix wall/lj93*. LAMMPS will flag the use of a rigid fix with fix wall/reflect with a warning, but will not generate an error.

## 2.262.6 Related commands

*fix wall/lj93*, *fix oneway*

## 2.262.7 Default

The default for the units keyword is lattice.

```

### 2.263.3 Description

Bound the simulation with one or more walls which reflect particles in the specified group when they attempt to move through them.

Reflection means that if an atom moves outside the wall on a timestep (e.g. due to the *fix nve* command), then it is put back inside the wall with a changed velocity.

This fix models treats the wall as a moving solid boundary with a finite temperature, which can exchange energy with particles that collide with it. This is different than the simpler *fix wall/reflect* command which models mirror reflection. For this fix, the post collision velocity of each particle is treated stochastically. The randomness can come from many sources: thermal motion of the wall atoms, surface roughness, etc. Three stochastic reflection models are currently implemented.

For *rstyle diffusive*, particles are reflected diffusively. Their velocity distribution corresponds to an equilibrium distribution of particles at the wall temperature. No accommodation coefficients are specified.

For *rstyle maxwell*, particle reflection is Maxwellian which means partially diffusive and partially specular (*Maxwell*). A single accommodation coeff is specified which must be between 0.0 and 1.0 inclusive. It determines the fraction of the collision which is diffusive versus specular. An accommodation coefficient of 1.0 is fully diffusive; a coefficient of 0.0 is fully specular.

For *rstyle cll*, particle collisions are computed by the Cercignani/Lampis model. See *CL* and *To* for details. Three accommodations coefficient are specified. Each must be between 0.0 and 1.0 inclusive. Two are velocity accommodation coefficients; one is a normal kinetic energy accommodation. The normal coeff is the one corresponding to the normal of the wall itself. For example if the wall is *ylo* or *yhi*, *accomx* and *accomz* are the tangential velocity accommodation coefficients, and *accomy* is the normal kinetic energy accommodation coefficient.

The optional *units* keyword determines the distance units used to define a wall position. A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

---

### 2.263.4 Restrictions

This fix has the same limitations as the *fix wall/reflect* command. Any dimension (xyz) that has a wall must be non-periodic. It should not be used with rigid bodies such as those defined by the *fix rigid* command. The wall velocity must lie on the same plane as the wall itself.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

```

### 2.264.3 Description

Treat the surface of the geometric region defined by the *region-ID* as a bounding wall which interacts with nearby particles according to the specified style.

The distance between a particle and the surface is the distance to the nearest point on the surface and the force the wall exerts on the particle is along the direction between that point and the particle, which is the direction normal to the surface at that point. Note that if the region surface is comprised of multiple “faces”, then each face can exert a force on the particle if it is close enough. E.g. for *region\_style block*, a particle in the interior, near a corner of the block, could feel wall forces from 1, 2, or 3 faces of the block.

Regions are defined using the *region* command. Note that the region volume can be interior or exterior to the bounding surface, which will determine in which direction the surface interacts with particles, i.e. the direction of the surface normal. The surface of the region only exerts forces on particles “inside” the region; if a particle is “outside” the region it will generate an error, because it has moved through the wall.

Regions can either be primitive shapes (block, sphere, cylinder, etc) or combinations of primitive shapes specified via the *union* or *intersect* region styles. These latter styles can be used to construct particle containers with complex shapes. Regions can also change over time via the *region* command keywords (move) and *rotate*. If such a region is used with this fix, then the of region surface will move over time in the corresponding manner.

---

**Note:** As discussed on the *region* command doc page, regions in LAMMPS do not get wrapped across periodic boundaries. It is up to you to ensure that periodic or non-periodic boundaries are specified appropriately via the *boundary* command when using a region as a wall that bounds particle motion. This also means that if you embed a region in your simulation box and want it to repulse particles from its surface (using the “side out” option in the *region* command), that its repulsive force will not be felt across a periodic boundary.

---

---

**Note:** For primitive regions with sharp corners and/or edges (e.g. a block or cylinder), wall/particle forces are computed accurately for both interior and exterior regions. For *union* and *intersect* regions, additional sharp corners and edges may be present due to the intersection of the surfaces of 2 or more primitive volumes. These corners and edges can be of two types: concave or convex. Concave points/edges are like the corners of a cube as seen by particles in the interior of a cube. Wall/particle forces around these features are computed correctly. Convex points/edges are like the corners of a cube as seen by particles exterior to the cube, i.e. the points jut into the volume where particles are present. LAMMPS does NOT compute the location of these convex points directly, and hence wall/particle forces in the cutoff volume around these points suffer from inaccuracies. The basic problem is that the outward normal of the surface is not continuous at these points. This can cause particles to feel no force (they don’t “see” the wall) when in one location, then move a distance epsilon, and suddenly feel a large force because they now “see” the wall. In a worst-case scenario, this can blow particles out of the simulation box. Thus, as a general rule you should not use the fix wall/gran/region command with *union* or *intersect* regions that have convex points or edges resulting from the union/intersection (convex points/edges in the union/intersection due to a single sub-region are still OK).

---

---

**Note:** Similarly, you should not define *union* or *intersect* regions for use with this command that share an overlapping common face that is part of the overall outer boundary (interior boundary is OK), even if the face is smooth. E.g. two regions of style block in a *union* region, where the two blocks overlap on one or more of their faces. This is because LAMMPS discards points that are part of multiple sub-regions when calculating wall/particle interactions, to avoid double-counting the interaction. Having two coincident faces could cause the face to become invisible to the particles. The solution is to make the two faces differ by epsilon in their position.

---

The energy of wall-particle interactions depends on the specified style.

For style *lj93*, the energy  $E$  is given by the 9/3 potential:

$$E = \epsilon \left[ \frac{2}{15} \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^3 \right] \quad r < r_c$$

For style *lj126*, the energy  $E$  is given by the 12/6 potential:

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

For style *wall/lj1043*, the energy  $E$  is given by the 10/4/3 potential:

$$E = 2\pi\epsilon \left[ \frac{2}{5} \left( \frac{\sigma}{r} \right)^{10} - \left( \frac{\sigma}{r} \right)^4 - \frac{\sqrt{2}\sigma^3}{3(r + (0.61/\sqrt{2})\sigma)^3} \right] \quad r < r_c$$

For style *colloid*, the energy  $E$  is given by an integrated form of the *pair\_style colloid* potential:

$$E = \epsilon \left[ \frac{\sigma^6}{7560} \left( \frac{6R - D}{D^7} + \frac{D + 8R}{(D + 2R)^7} \right) - \frac{1}{6} \left( \frac{2R(D + R) + D(D + 2R)[\ln D - \ln(D + 2R)]}{D(D + 2R)} \right) \right] \quad r < r_c$$

For style *wall/harmonic*, the energy  $E$  is given by a harmonic spring potential (the distance parameter is ignored):

$$E = \epsilon (r - r_c)^2 \quad r < r_c$$

For style *wall/morse*, the energy  $E$  is given by the Morse potential:

$$E = D_0 [e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)}] \quad r < r_c$$

Unlike other styles, this requires three parameters ( $D_0$ ,  $\alpha$ , and  $r_0$  in this order) instead of two like for the other wall styles.

In all cases,  $r$  is the distance from the particle to the region surface, and  $R_c$  is the *cutoff* distance at which the particle and surface no longer interact. The cutoff is always the last argument. The energy of the wall potential is shifted so that the wall-particle interaction energy is 0.0 at the cutoff distance.

For a full description of these wall styles, see `fix_style wall`

## 2.264.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix\_modify energy* option is supported by this fix to add the energy of interaction between atoms and the region wall to the global potential energy of the system as part of *thermodynamic output*. The default setting for this fix is *fix\_modify energy no*.

The *fix\_modify virial* option is supported by this fix to add the contribution due to the interaction between atoms and the region wall to both the global pressure and per-atom stress of the system via the *compute pressure* and *compute stress/atom* commands. The former can be accessed by *thermodynamic output*. The default setting for this fix is *fix\_modify virial no*.

The *fix\_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global 3-length vector of forces, which can be accessed by various *output commands*. The scalar energy is the sum of energy interactions for all particles interacting with the wall represented

by the region surface. The 3 vector quantities are the x,y,z components of the total force acting on the wall due to the particles. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

The forces due to this fix are imposed during an energy minimization, invoked by the *minimize* command.

---

**Note:** If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix\_modify energy* option for this fix.

---

## 2.265 fix wall/srd command

### 2.265.1 Syntax

```
fix ID group-ID wall/srd face arg ... keyword value ...
```

- ID, group-ID are documented in *fix* command
- wall/srd = style name of this fix command
- one or more face/arg pairs may be appended
- face = *xlo* or *xhi* or *ylo* or *yhi* or *zlo* or *zhi*

*xlo,ylo,zlo* arg = EDGE or constant or variable

EDGE = current lo edge of simulation box

constant = number like 0.0 or -30.0 (distance units)

variable = *equal-style variable* like v\_x or v\_wiggle

*xhi,yhi,zhi* arg = EDGE or constant or variable

EDGE = current hi edge of simulation box

constant = number like 50.0 or 100.3 (distance units)

variable = *equal-style variable* like v\_x or v\_wiggle

- zero or more keyword/value pairs may be appended
- keyword = *units*

*units* value = *lattice* or *box*

*lattice* = the wall position is defined in lattice units

*box* = the wall position is defined in simulation box units

## 2.265.2 Examples

```
fix xwalls all wall/srd xlo EDGE xhi EDGE
fix walls all wall/srd xlo 0.0 ylo 10.0 units box
fix top all wall/srd zhi v_pressdown
```

## 2.265.3 Description

Bound the simulation with one or more walls which interact with stochastic reaction dynamics (SRD) particles as slip (smooth) or no-slip (rough) flat surfaces. The wall interaction is actually invoked via the *fix srd* command, only on the group of SRD particles it defines, so the group setting for the *fix wall/srd* command is ignored.

A particle/wall collision occurs if an SRD particle moves outside the wall on a timestep. This alters the position and velocity of the SRD particle and imparts a force to the wall.

The *collision* and *Tsrd* settings specified via the *fix srd* command affect the SRD/wall collisions. A *slip* setting for the *collision* keyword means that the tangential component of the SRD particle momentum is preserved. Thus only a normal force is imparted to the wall. The normal component of the new SRD velocity is sampled from a Gaussian distribution at temperature *Tsrd*.

For a *noslip* setting of the *collision* keyword, both the normal and tangential components of the new SRD velocity are sampled from a Gaussian distribution at temperature *Tsrd*. Additionally, a new tangential direction for the SRD velocity is chosen randomly. This collision style imparts both a normal and tangential force to the wall.

Up to 6 walls or faces can be specified in a single command: *xlo*, *xhi*, *ylo*, *yhi*, *zlo*, *zhi*. A *lo* face reflects particles that move to a coordinate less than the wall position, back in the *hi* direction. A *hi* face reflects particles that move to a coordinate higher than the wall position, back in the *lo* direction.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (x, y, or z). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as *v\_name*, where name is an *equal-style variable* name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include *thermo\_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position.

---

**Note:** Because the trajectory of the SRD particle is tracked as it collides with the wall, you must ensure that  $r$  = distance of the particle from the wall, is always  $> 0$  for SRD particles, or LAMMPS will generate an error. This means you cannot start your simulation with SRD particles at the wall position *coord* ( $r = 0$ ) or with particles on the wrong side of the wall ( $r < 0$ ).

---

---

**Note:** If you have 2 or more walls that come together at an edge or corner (e.g. walls in the x and y dimensions), then be sure to set the *overlap* keyword to *yes* in the *fix srd* command, since the walls effectively overlap when SRD particles collide with them. LAMMPS will issue a warning if you do not do this.

---

---

**Note:** The walls of this *fix* only interact with SRD particles, as defined by the *fix srd* command. If you are simulating a mixture containing other kinds of particles, then you should typically use *another wall command* to act on the other particles. Since SRD particles will be colliding both with the walls and the other particles, it is important to ensure

that the other particle's finite extent does not overlap an SRD wall. If you do not do this, you may generate errors when SRD particles end up "inside" another particle or a wall at the beginning of a collision step.

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. It is not relevant when EDGE or a variable is used to specify a face position.

A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style *variables*.

```
variable ramp equal ramp(0,10)
fix 1 all wall/srd xlo v_ramp

variable linear equal vdisplace(0,20)
fix 1 all wall/srd xlo v_linear

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall/srd xlo v_wiggle

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall/srd xlo v_wiggle
```

The *ramp(lo,hi)* function adjusts the wall position linearly from *lo* to *hi* over the course of a run. The *vdisplace(c0,velocity)* function does something similar using the equation  $position = c0 + velocity * delta$ , where *delta* is the elapsed time.

The *swiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, where  $\omega = 2 \pi / period$ :

$$position = c0 + A \sin(\omega * delta)$$

The *cwiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

$$position = c0 + A (1 - \cos(\omega * delta))$$

## 2.265.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix\_modify* options are relevant to this fix.

This fix computes a global array of values which can be accessed by various *output commands*. The number of rows in the array is equal to the number of walls defined by the fix. The number of columns is 3, for the x,y,z components of force on each wall.

Note that an outward normal force on a wall will be a negative value for *lo* walls and a positive value for *hi* walls. The array values calculated by this fix are "extensive".

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.265.5 Restrictions

Any dimension (xyz) that has an SRD wall must be non-periodic.

# 2.266 fix widom command

## 2.266.1 Syntax

```
fix ID group-ID widom N M type seed T keyword values ...
```

- ID, group-ID are documented in *fix* command
- widom = style name of this fix command
- N = invoke this fix every N steps
- M = number of Widom insertions to attempt every N steps
- type = atom type (1-Ntypes or type label) for inserted atoms (must be 0 if mol keyword used)
- seed = random # seed (positive integer)
- T = temperature of the system (temperature units)
- zero or more keyword/value pairs may be appended to args

keyword = *mol*, *region*, *full\_energy*, *charge*, *intra\_energy*

*mol* value = template-ID

template-ID = ID of molecule template specified in a separate *molecule* command

*region* value = region-ID

region-ID = ID of region where Widom insertions are allowed

*full\_energy* = compute the entire system energy when performing Widom insertions

*charge* value = charge of inserted atoms (charge units)

*intra\_energy* value = intramolecular energy (energy units)

## 2.266.2 Examples

```
fix 2 gas widom 1 50000 1 19494 2.0
fix 3 water widom 1000 100 0 29494 300.0 mol h2omol full_energy

labelmap atom 1 Li
fix 2 ion widom 1 50000 Li 19494 2.0
```

### 2.266.3 Description

This fix performs Widom insertions of atoms or molecules at the given temperature as discussed in (Frenkel). Specific uses include computation of Henry constants of small molecules in microporous materials or amorphous systems.

Every N timesteps the fix attempts M number of Widom insertions of atoms or molecules.

If the *mol* keyword is used, only molecule insertions are performed. Conversely, if the *mol* keyword is not used, only atom insertions are performed.

This command may optionally use the *region* keyword to define an insertion volume. The specified region must have been previously defined with a *region* command. It must be defined with *side = in*. Insertion attempts occur only within the specified region. For non-rectangular regions, random trial points are generated within the rectangular bounding box until a point is found that lies inside the region. If no valid point is generated after 1000 trials, no insertion is performed. If an attempted insertion places the atom or molecule center-of-mass outside the specified region, a new attempted insertion is generated. This process is repeated until the atom or molecule center-of-mass is inside the specified region.

Note that neighbor lists are re-built every timestep that this fix is invoked, so you should not set N to be too small. See the *neighbor* command for details.

When an atom or molecule is to be inserted, its coordinates are chosen at a random position within the current simulation cell or region. Relative coordinates for atoms in a molecule are taken from the template molecule provided by the user. The center of mass of the molecule is placed at the insertion point. The orientation of the molecule is chosen at random by rotating about this point.

Individual atoms are inserted, unless the *mol* keyword is used. It specifies a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc., as well as any bonding and special neighbor information for the molecule can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

Note that fix widom does not use configurational bias MC or any other kind of sampling of intramolecular degrees of freedom. Inserted molecules can have different orientations, but they will all have the same intramolecular configuration, which was specified in the molecule command input.

For atoms, inserted particles have the specified atom type. For molecules, they use the same atom types as in the template molecule supplied by the user.

The excess chemical potential  $\mu_{ex}$  is defined as:

$$\mu_{ex} = -kT \ln(\langle \exp(-(U_{N+1} - U_N)/k_B T) \rangle)$$

where  $k_B$  is the Boltzmann constant,  $T$  is the user-specified temperature,  $U_N$  and  $U_{N+1}$  is the potential energy of the system with  $N$  and  $N + 1$  particles.

The *full\_energy* option means that the fix calculates the total potential energy of the entire simulated system, instead of just the energy of the part that is changed. By default, this option is off, in which case only partial energies are computed to determine the energy difference due to the proposed change.

The *full\_energy* option is needed for systems with complicated potential energy calculations, including the following:

- long-range electrostatics (kspace)
- many-body pair styles
- hybrid pair styles
- eam pair styles
- tail corrections
- need to include potential energy contributions from other fixes

In these cases, LAMMPS will automatically apply the *full\_energy* keyword and issue a warning message.

When the *mol* keyword is used, the *full\_energy* option also includes the intramolecular energy of inserted and deleted molecules, whereas this energy is not included when *full\_energy* is not used. If this is not desired, the *intra\_energy* keyword can be used to define an amount of energy that is subtracted from the final energy when a molecule is inserted, and subtracted from the initial energy when a molecule is deleted. For molecules that have a non-zero intramolecular energy, this will ensure roughly the same behavior whether or not the *full\_energy* option is used.

Some fixes have an associated potential energy. Examples of such fixes include: *efield*, *gravity*, *addforce*, *restrain*, and *wall fixes*. For that energy to be included in the total potential energy of the system (the quantity used when performing Widom insertions), you MUST enable the *fix\_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

Use the *charge* option to insert atoms with a user-specified point charge. Note that doing so will cause the system to become non-neutral. LAMMPS issues a warning when using long-range electrostatics (kspace) with non-neutral systems. See the *compute group/group* documentation for more details about simulating non-neutral systems with kspace on.

## 2.266.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the state of the fix to *binary restart files*. This includes information about the random number generator seed, the next timestep for Widom insertions etc. See the *read\_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

---

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset\_timestep*. The fix will try to detect it and stop with an error.

---

None of the *fix\_modify* options are relevant to this fix.

This fix computes a global vector of length 3, which can be accessed by various *output commands*. The vector values are the following global cumulative quantities:

1. average excess chemical potential on each timestep
2. average difference in potential energy on each timestep
3. volume of the insertion region

The vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

## 2.266.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

Do not set “neigh\_modify once yes” or else this fix will never be called. Reneighboring is **required**.

This fix style requires an *atom style* with per atom type masses.

Can be run in parallel, but some aspects of the insertion procedure will not scale well in parallel. Only usable for 3D simulations.

## 2.266.6 Related commands

*fix gcmc fix atom/swap, neighbor, fix deposit, fix evaporate,*

## 2.266.7 Default

The option defaults are mol = no, intra\_energy = 0.0 and full\_energy = no, except for the situations where full\_energy is required, as listed above.

---

## COMPUTES

### 3.1 compute ackland/atom command

#### 3.1.1 Syntax

```
compute ID group-ID ackland/atom keyword/value
```

- ID, group-ID are documented in *compute* command
- ackland/atom = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *legacy*

*legacy* args = *yes* or *no* = use (*yes*) or do not use (*no*) legacy Ackland algorithm.  
→ implementation

#### 3.1.2 Examples

```
compute 1 all ackland/atom  
compute 1 all ackland/atom legacy yes
```

#### 3.1.3 Description

Defines a computation that calculates the local lattice structure according to the formulation given in (*Ackland*). Historically, LAMMPS had two, slightly different implementations of the algorithm from the paper. With the *legacy* keyword, it is possible to switch between the pre-2015 (*legacy yes*) and post-2015 implementation (*legacy no*). The post-2015 variant is the default.

In contrast to the *centro-symmetry parameter* this method is stable against temperature boost, because it is based not on the distance between particles but the angles. Therefore statistical fluctuations are averaged out a little more. A comparison with the Common Neighbor Analysis metric is made in the paper.

The result is a number which is mapped to the following different lattice structures:

- 0 = UNKNOWN
- 1 = BCC
- 2 = FCC
- 3 = HCP

- 4 = ICO

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each of which computes this quantity.-

### 3.1.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

### 3.1.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The per-atom vector values will be unitless since they are the integers defined above.

### 3.1.6 Related commands

*compute centro/atom*

### 3.1.7 Default

The keyword *legacy* defaults to *no*.

compute 1 fluid adf 32 1*2 1*2 1*2 0.5 3.5
compute 1 fluid adf 32
```

### 3.2.3 Description

Define a computation that calculates one or more angular distribution functions (ADF) for a group of particles. Each ADF is calculated in histogram form by measuring the angle formed by a central atom and two neighbor atoms and binning these angles into *Nbin* bins. Only neighbors for which  $R_{inner} < R < R_{outer}$  are counted, where *Rinner* and *Router* are specified separately for the first and second neighbor atom in each requested ADF.

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses a neighbor list, it also means those pairs will not be included in the ADF. This does not apply when using long-range coulomb interactions (*coul/long*, *coul/msm*, *coul/wolf* or similar. One way to get around this would be to set *special\_bond* scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the *rerun* command to compute the ADF for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

**Note:** If you request any outer cutoff  $R_{outer} > \text{force cutoff}$ , or if no pair style is defined, e.g. the *rerun* command is being used to post-process a dump file of snapshots you must ensure ghost atom information out to the largest value of  $R_{outer} + \text{skin}$  is communicated, via the *comm\_modify cutoff* command, else the ADF computation cannot be performed, and LAMMPS will give an error message. The *skin* value is what is specified with the *neighbor* command.

The *itypeN*, *jtypeN*, *ktypeN* settings can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a wild-card asterisk can be used to specify a range of atom types as in the second example above. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

If *itypeN*, *jtypeN*, and *ktypeN* are single values, as in the first example above, this means that the ADF is computed where atoms of type *itypeN* are the central atom, and neighbor atoms of type *jtypeN* and *ktypeN* are forming the angle. If any of *itypeN*, *jtypeN*, or *ktypeN* represent a range of values via the wild-card asterisk, as in the second example above, this means that the ADF is computed where atoms of any of the range of types represented by *itypeN* are the

central atom, and the angle is formed by two neighbors, one neighbor in the range of types represented by *jtypeN* and another neighbor in the range of types represented by *ktypeN*.

If no *itypeN*, *jtypeN*, *ktypeN* settings are specified, then LAMMPS will generate a single ADF for all atoms in the group. The inner cutoff is set to zero and the outer cutoff is set to the force cutoff. If no *pair\_style* is specified, there is no force cutoff and LAMMPS will give an error message. Note that in most cases, generating an ADF for all atoms is not a good thing. Such an ADF is both uninformative and extremely expensive to compute. For example, with liquid water with a 10 Å force cutoff, there are 80,000 angles per atom. In addition, most of the interesting angular structure occurs for neighbors that are the closest to the central atom, involving just a few dozen angles.

Angles for each ADF are generated by double-looping over the list of neighbors of each central atom I, just as they would be in the force calculation for a three-body potential such as *Stillinger-Weber*. The angle formed by central atom I and neighbor atoms J and K is included in an ADF if the following criteria are met:

- atoms I,J,K are all in the specified compute group
- the distance between atoms I,J is between *Rjinner* and *Rjouter*
- the distance between atoms I,K is between *Rkinner* and *Rkouter*
- the type of the I atom matches *itypeN* (one or a range of types)
- atoms I,J,K are distinct
- the type of the J atom matches *jtypeN* (one or a range of types)
- the type of the K atom matches *ktypeN* (one or a range of types)

Each unique angle satisfying the above criteria is counted only once, regardless of whether either or both of the neighbor atoms making up the angle appear in both the J and K lists. It is OK if a particular angle is included in more than one individual histogram, due to the way the *itypeN*, *jtypeN*, *ktypeN* arguments are specified.

The first ADF value for a bin is calculated from the histogram count by dividing by the total number of triples satisfying the criteria, so that the integral of the ADF w.r.t. angle is 1, i.e. the ADF is a probability density function.

The second ADF value is reported as a cumulative sum of all bins up to the current bins, averaged over atoms of type *itypeN*. It represents the number of angles per central atom with angle less than or equal to the angle of the current bin, analogous to the coordination number radial distribution function.

The *ordinate* optional keyword determines whether the bins are of uniform angular size from zero to 180 (*degree*), zero to Pi (*radian*), or the cosine of the angle uniform in the range [-1,1] (*cosine*). *cosine* has the advantage of eliminating the *acos()* function call, which speeds up the compute by 2-3x, and it is also preferred on physical grounds, because the for uniformly distributed particles in 3D, the angular probability density w.r.t *dtheta* is  $\sin(\theta)/2$ , while for  $d(\cos(\theta))$ , it is 1/2. Regardless of which ordinate is chosen, the first column of ADF values is normalized w.r.t. the range of that ordinate, so that the integral is 1.

The simplest way to output the results of the compute adf calculation to a file is to use the *fix ave/time* command, for example:

```
compute myADF all adf 32 2 2 2 0.5 3.5 0.5 3.5
fix 1 all ave/time 100 1 100 c_myADF[*] file tmp.adf mode vector
```

### 3.2.4 Output info

This compute calculates a global array with the number of rows =  $N_{bins}$  and the number of columns =  $1 + 2 \times N_{triples}$ , where  $N_{triples}$  is the number of I,J,K triples specified. The first column has the bin coordinate (angle-related ordinate at midpoint of bin). Each subsequent column has the two ADF values for a specific set of ( $itypeN, jtypeN, ktypeN$ ) interactions, as described above. These values can be used by any command that uses a global values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The array values calculated by this compute are all “intensive”.

The first column of array values is the angle-related ordinate, either the angle in degrees or radians, or the cosine of the angle. Each subsequent pair of columns gives the first and second kinds of ADF for a specific set of ( $itypeN, jtypeN, ktypeN$ ). The values in the first ADF column are normalized numbers  $\geq 0.0$ , whose integral w.r.t. the ordinate is 1, i.e. the first ADF is a normalized probability distribution. The values in the second ADF column are also numbers  $\geq 0.0$ . They are the cumulative density distribution of angles per atom. By definition, this ADF is monotonically increasing from zero to a maximum value equal to the average total number of angles per atom satisfying the ADF criteria.

### 3.2.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

By default, the ADF is not computed for distances longer than the largest force cutoff, since the neighbor list creation will only contain pairs up to that distance (plus neighbor list skin). If you use outer cutoffs larger than that, you must use *neighbor style 'bin' or 'nsq'*.

If you want an ADF for a larger outer cutoff, you can also use the *rerun* command to post-process a dump file, use *pair style zero* and set the force cutoff to be larger in the rerun script. Note that in the rerun context, the force cutoff is arbitrary and with pair style zero you are not computing any forces, and since you are not running dynamics you are not changing the model that generated the trajectory.

The ADF is not computed for neighbors outside the force cutoff, since processors (in parallel) don't know about atom coordinates for atoms further away than that distance. If you want an ADF for larger distances, you can use the *rerun* command to post-process a dump file and set the cutoff for the potential to be longer in the rerun script. Note that in the rerun context, the force cutoff is arbitrary, since you are not running dynamics and thus are not changing your model.

### 3.2.6 Related commands

*compute rdf, fix ave/time, compute\_modify*

### 3.2.7 Default

The keyword default is ordinate = degree.

## 3.3 compute angle command

### 3.3.1 Syntax

```
compute ID group-ID angle
```

- ID, group-ID are documented in *compute* command
- angle = style name of this compute command

### 3.3.2 Examples

```
compute 1 all angle
```

### 3.3.3 Description

Define a computation that extracts the angle energy calculated by each of the angle sub-styles used in the *angle\_style hybrid* command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using *angle\_style hybrid* if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

### 3.3.4 Output info

This compute calculates a global vector of length  $N$ , where  $N$  is the number of sub\_styles defined by the *angle\_style hybrid* command, which can be accessed by indices 1 through  $N$ . These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy *units*.

### 3.3.5 Restrictions

none

### 3.3.6 Related commands

*compute pe, compute pair*

### 3.3.7 Default

none

## 3.4 compute angle/local command

### 3.4.1 Syntax

```
compute ID group-ID angle/local value1 value2 ... keyword args ...
```

- ID, group-ID are documented in *compute* command
- angle/local = style name of this compute command
- one or more values may be appended
- value = *theta* or *eng* or *v\_name*  
*theta* = tabulate angles  
*eng* = tabulate angle energies  
*v\_name* = equal-style variable with name (see below)
- zero or more keyword/args pairs may be appended
- keyword = *set*  
*set* args = *theta* name  
*theta* = only currently allowed arg  
name = name of variable to set with *theta*

### 3.4.2 Examples

```
compute 1 all angle/local theta
compute 1 all angle/local eng theta
compute 1 all angle/local theta v_cos set theta t
```

### 3.4.3 Description

Define a computation that calculates properties of individual angle interactions. The number of datums generated, aggregated across all processors, equals the number of angles in the system, modified by the group parameter as explained below.

The value *theta* is the angle for the three atoms in the interaction.

The value *eng* is the interaction energy for the angle.

The value *v\_name* can be used together with the *set* keyword to compute a user-specified function of the angle *theta*. The *name* specified for the *v\_name* value is the name of an *equal-style variable* which should evaluate a formula based on a variable which will store the angle *theta*. This other variable must be an *internal-style variable* defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The *set* keyword is used to identify the name of this other variable associated with *theta*.

Note that the value of *theta* for each angle which stored in the internal variable is in radians, not degrees.

As an example, these commands can be added to the bench/in.rhodo script to compute the cosine and cosine-squared of every angle in the system and output the statistics in various ways:

```
variable t internal 0.0
variable cos equal cos(v_t)
variable cossq equal cos(v_t)*cos(v_t)

compute 1 all property/local aatom1 aatom2 aatom3 atype
compute 2 all angle/local eng theta v_cos v_cossq set theta t
dump 1 all local 100 tmp.dump c_1[*] c_2[*]

compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]

fix 10 all ave/histo 10 10 100 -1 1 20 c_2[3] mode vector file tmp.histo
```

The *dump local* command will output the potential energy ( $\phi$ ), the angle ( $\theta$ ),  $\cos(\theta)$ , and  $\cos^2(\theta)$  for every angle  $\theta$  in the system. The *thermo\_style* command will print the average of those quantities via the *compute reduce* command with thermo output. And the *fix ave/histo* command will histogram the  $\cos(\theta)$  values and write them to a file.

---

The local data stored by this command is generated by looping over all the atoms owned on a processor and their angles. An angle will only be included if all three atoms in the angle are in the specified compute group. Any angles that have been broken (see the *angle\_style* command) by setting their angle type to 0 are not included. Angles that have been turned off (see the *fix shake* or *delete\_bonds* commands) by setting their angle type negative are written into the file, but their energy will be 0.0.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, angle output from the *compute property/local* command can be combined with data from this command and output by the *dump local* command in a consistent way.

Here is an example of how to do this:

```
compute 1 all property/local atype aatom1 aatom2 aatom3
compute 2 all angle/local theta eng
dump 1 all local 1000 tmp.dump index c_1[1] c_1[2] c_1[3] c_1[4] c_2[1] c_2[2]
```

### 3.4.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of angles. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The output for *theta* will be in degrees. The output for *eng* will be in energy *units*.

### 3.4.5 Restrictions

none

### 3.4.6 Related commands

*dump local*, *compute property/local*

### 3.4.7 Default

none

## 3.5 compute angmom/chunk command

### 3.5.1 Syntax

```
compute ID group-ID angmom/chunk chunkID
```

- ID, group-ID are documented in *compute* command
- angmom/chunk = style name of this compute command
- chunkID = ID of *compute chunk/atom* command

### 3.5.2 Examples

```
compute 1 fluid angmom/chunk molchunk
```

### 3.5.3 Description

Define a computation that calculates the angular momentum of multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 3 components of the angular momentum vector for each chunk, due to the velocity/momentum of the individual atoms in the chunk around the center-of-mass of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The *compute chunk/atom* command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

---

**Note:** The coordinates of an atom contribute to the chunk’s angular momentum in “unwrapped” form, by using the image flags associated with each atom. See the *dump custom* command for a discussion of “unwrapped” coordinates.

See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the [set image](#) command.

---

The simplest way to output the results of the compute angmom/chunk calculation to a file is to use the [fix ave/time](#) command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all angmom/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.5.4 Output info

This compute calculates a global array where the number of rows = the number of chunks *Nchunk* as calculated by the specified [compute chunk/atom](#) command. The number of columns = 3 for the three (*x*, *y*, *z*) components of the angular momentum for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in mass-velocity-distance [units](#).

### 3.5.5 Restrictions

## 3.6 compute ave/sphere/atom command

Accelerator Variants: *ave/sphere/atom/kk*

### 3.6.1 Syntax

```
compute ID group-ID ave/sphere/atom keyword values ...
```

- ID, group-ID are documented in [compute](#) command
- ave/sphere/atom = style name of this compute command
- one or more keyword/value pairs may be appended

keyword = *cutoff*  
cutoff value = distance cutoff

### 3.6.2 Examples

```
compute 1 all ave/sphere/atom

compute 1 all ave/sphere/atom cutoff 5.0
comm_modify cutoff 5.0
```

### 3.6.3 Description

New in version 7Jan2022.

Define a computation that calculates the local mass density and temperature for each atom based on its neighbors inside a spherical cutoff. If an atom has  $M$  neighbors, then its local mass density is calculated as the sum of its mass and its  $M$  neighbor masses, divided by the volume of the cutoff sphere (or circle in 2d). The local temperature of the atom is calculated as the temperature of the collection of  $M + 1$  atoms, after subtracting the center-of-mass velocity of the  $M + 1$  atoms from each of the  $M + 1$  atom's velocities. This is effectively the thermal velocity of the neighborhood of the central atom, similar to [compute temp/com](#).

The optional keyword *cutoff* defines the distance cutoff used when searching for neighbors. The default value is the cutoff specified by the pair style. If no pair style is defined, then a cutoff must be defined using this keyword. If the specified cutoff is larger than that of the pair\_style plus neighbor skin (or no pair style is defined), the *comm\_modify cutoff* option must also be set to match that of the *cutoff* keyword.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

---

**Note:** If you have a bonded system, then the settings of [special\\_bonds](#) command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the [special\\_bonds](#) command, and means those pairwise interactions do not appear in the neighbor list. Because this compute uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the [rerun](#) command to compute the order parameter for snapshots in the dump file. The rerun script can use a [special\\_bonds](#) command that includes all pairs in the neighbor list.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 3.6.4 Output info

This compute calculates a per-atom array with two columns: mass density in density *units* and temperature in temperature *units*.

These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

### 3.6.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This compute requires *neighbor styles* 'bin' or 'nsq'.

### 3.6.6 Related commands

*comm\_modify*

### 3.6.7 Default

The option defaults are *cutoff* = pair style cutoff.

## 3.7 compute basal/atom command

### 3.7.1 Syntax

```
compute ID group-ID basal/atom
```

- ID, group-ID are documented in *compute* command
- basal/atom = style name of this compute command

### 3.7.2 Examples

```
compute 1 all basal/atom
```

### 3.7.3 Description

Defines a computation that calculates the hexagonal close-packed “c” lattice vector for each atom in the group. It does this by calculating the normal unit vector to the basal plane for each atom. The results enable efficient identification and characterization of twins and grains in hexagonal close-packed structures.

The output of the compute is thus the 3 components of a unit vector associated with each atom. The components are set to 0.0 for atoms not in the group.

Details of the calculation are given in (*Barrett*).

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each of which computes this quantity.

An example input script that uses this compute is provided in `examples/PACKAGES/basal`.

### 3.7.4 Output info

This compute calculates a per-atom array with three columns, which can be accessed by indices 1–3 by any command that uses per-atom values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The per-atom vector values are unitless since the three columns represent components of a unit vector.

### 3.7.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The output of this compute will be meaningless unless the atoms are on (or near) hcp lattice sites, since the calculation assumes a well-defined basal plane.

### 3.7.6 Related commands

*compute centro/atom*, *compute ackland/atom*

### 3.7.7 Default

none

---

(Barrett) Barrett, Tschopp, El Kadiri, Scripta Mat. 66, p.666 (2012).

## 3.8 compute body/local command

### 3.8.1 Syntax

```
compute ID group-ID body/local input1 input2 ...
```

- ID, group-ID are documented in [compute](#) command
- body/local = style name of this compute command
- one or more keywords may be appended
- keyword = *id* or *type* or *integer*
  - id* = atom ID of the body particle
  - type* = atom type of the body particle
  - integer* = 1,2,3,etc = index of fields defined by body style

### 3.8.2 Examples

```
compute 1 all body/local type 1 2 3
compute 1 all body/local 3 6
```

### 3.8.3 Description

Define a computation that calculates properties of individual body sub-particles. The number of data generated, aggregated across all processors, equals the number of body sub-particles plus the number of non-body particles in the system, modified by the *group* parameter as explained below. See the [Howto body](#) page for more details on using body particles.

The local data stored by this command is generated by looping over all the atoms. An atom will only be included if it is in the group. If the atom is a body particle, then its  $N$  sub-particles will be looped over, and it will contribute  $N$  data to the count of data. If it is not a body particle, it will contribute 1 datum.

For both body particles and non-body particles, the *id* keyword will store the ID of the particle.

For both body particles and non-body particles, the *type* keyword will store the type of the particle.

The *integer* keywords mean different things for body and non-body particles. If the atom is not a body particle, only its  $x, y, z$  coordinates can be referenced, using the *integer* keywords 1,2,3. Note that this means that if you want to access more fields than this for body particles, then you cannot include non-body particles in the group.

For a body particle, the *integer* keywords refer to fields calculated by the body style for each sub-particle. The body style, as specified by the *atom\_style body*, determines how many fields exist and what they are. See the [Howto\\_body](#) doc page for details of the different styles.

Here is an example of how to output body information using the *dump local* command with this compute. If fields 1, 2, and 3 for the body sub-particles are  $(x, y, z)$  coordinates, then the dump file will be formatted similar to the output of a *dump atom or custom* command.

```
compute 1 all body/local type 1 2 3
dump 1 all local 1000 tmp.dump index c_1[1] c_1[2] c_1[3] c_1[4]
```

### 3.8.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of data as described above. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The *units* for output values depend on the body style.

### 3.8.5 Restrictions

none

### 3.8.6 Related commands

*dump local*

## 3.9 compute bond command

### 3.9.1 Syntax

```
compute ID group-ID bond
```

- ID, group-ID are documented in *compute* command
- bond = style name of this compute command

### 3.9.2 Examples

```
compute 1 all bond
```

### 3.9.3 Description

Define a computation that extracts the bond energy calculated by each of the bond sub-styles used in the *bond\_style hybrid* command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using *bond\_style hybrid* if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

### 3.9.4 Output info

This compute calculates a global vector of length  $N$ , where  $N$  is the number of sub\_styles defined by the *bond\_style hybrid* command, which can be accessed by indices 1 through  $N$ . These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy *units*.

## 3.10 compute bond/local command

### 3.10.1 Syntax

```
compute ID group-ID bond/local value1 value2 ... keyword args ...
```

- ID, group-ID are documented in *compute* command
- bond/local = style name of this compute command
- one or more values may be appended
- value = *dist* or *dx* or *dy* or *dz* or *engpot* or *force* or *fx* or *fy* or *fz* or *engvib* or *engrot* or *engtrans* or *omega* or *velvib* or *v\_name* or *bN*

*dist* = bond distance

*engpot* = bond potential energy

*force* = bond force

*dx,dy,dz* = components of pairwise distance

*fx,fy,fz* = components of bond force

*engvib* = bond kinetic energy of vibration

*engrot* = bond kinetic energy of rotation

*engtrans* = bond kinetic energy of translation

*omega* = magnitude of bond angular velocity

*velvib* = vibrational velocity along the bond length

*v\_name* = equal-style variable with name (see below)

*bN* = bond style specific quantities for allowed N values

- zero or more keyword/args pairs may be appended
- keyword = *set*

*set args* = *dist* name

*dist* = only currently allowed arg

name = name of variable to set with distance (*dist*)

### 3.10.2 Examples

```
compute 1 all bond/local engpot
compute 1 all bond/local dist engpot force

compute 1 all bond/local dist fx fy fz b1 b2

compute 1 all bond/local dist v_distsq set dist d
```

### 3.10.3 Description

Define a computation that calculates properties of individual bond interactions. The number of datums generated, aggregated across all processors, equals the number of bonds in the system, modified by the group parameter as explained below.

All these properties are computed for the pair of atoms in a bond, whether the two atoms represent a simple diatomic molecule, or are part of some larger molecule.

The value *dist* is the current length of the bond. The values *dx*, *dy*, and *dz* are the xyz components of the *distance* between the pair of atoms. This value is always the distance from the atom of lower to the one with the higher id.

The value *engpot* is the potential energy for the bond, based on the current separation of the pair of atoms in the bond.

The value *force* is the magnitude of the force acting between the pair of atoms in the bond.

The values *fx*, *fy*, and *fz* are the xyz components of *force* between the pair of atoms in the bond. For bond styles that apply non-central forces, such as *bond\_style bpm/rotational*, these values only include the (x,y,z) components of the normal force component.

The remaining properties are all computed for motion of the two atoms relative to the center of mass (COM) velocity of the two atoms in the bond.

The value *engvib* is the vibrational kinetic energy of the two atoms in the bond, which is simply  $\frac{1}{2}m_1v_1^2 + \frac{1}{2}m_2v_2^2$ , where  $v_1$  and  $v_2$  are the magnitude of the velocity of the two atoms along the bond direction, after the COM velocity has been subtracted from each.

The value *engrot* is the rotational kinetic energy of the two atoms in the bond, which is simply  $\frac{1}{2}m_1v_1^2 + \frac{1}{2}m_2v_2^2$ , where  $v_1$  and  $v_2$  are the magnitude of the velocity of the two atoms perpendicular to the bond direction, after the COM velocity has been subtracted from each.

The value *engtrans* is the translational kinetic energy associated with the motion of the COM of the system itself, namely  $\frac{1}{2}(m_1 + m_2)V_{cm}^2$ , where  $V_{cm}$  = magnitude of the velocity of the COM.

Note that these three kinetic energy terms are simply a partitioning of the summed kinetic energy of the two atoms themselves. That is, the total kinetic energy is  $\frac{1}{2}m_1v_1^2 + \frac{1}{2}m_2v_2^2 = \text{engvib} + \text{engrot} + \text{engtrans}$ , where  $v_1$  and  $v_2$  are the magnitude of the velocities of the two atoms, without any adjustment for the COM velocity.

The value *omega* is the magnitude of the angular velocity of the two atoms around their COM position.

The value *velvib* is the magnitude of the relative velocity of the two atoms in the bond towards each other. A negative value means the two atoms are moving toward each other; a positive value means they are moving apart.

The value *v\_name* can be used together with the *set* keyword to compute a user-specified function of the bond distance. The *name* specified for the *v\_name* value is the name of an *equal-style variable* which should evaluate a formula based on a variable which will store the bond distance. This other variable must be an *internal-style variable* defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The *set* keyword is used to identify the name of this other variable associated with theta.

As an example, these commands can be added to the bench/in.rhodo script to compute the length<sup>2</sup> of every bond in the system and output the statistics in various ways:

```
variable d internal 0.0
variable dsq equal v_d*v_d

compute 1 all property/local batom1 batom2 btype
compute 2 all bond/local engpot dist v_dsq set dist d
dump 1 all local 100 tmp.dump c_1[*] c_2[*]

compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]

fix 10 all ave/histo 10 10 100 0 6 20 c_2[3] mode vector file tmp.histo
```

The *dump local* command will output the energy, length, and length<sup>2</sup> for every bond in the system. The *thermo\_style* command will print the average of those quantities via the *compute reduce* command with thermo output, and the *fix ave/histo* command will histogram the length<sup>2</sup> values and write them to a file.

A bond style may define additional bond quantities which can be accessed as *b1* to *bN*, where *N* is defined by the bond style. Most bond styles do not define any additional quantities, so *N* = 0. An example of ones that do are the *BPM bond styles* which store the reference state between two particles. See individual bond styles for details.

When using *bN* with bond style *hybrid*, the output will be the *N*th quantity from the sub-style that computes the bonded interaction (based on bond type). If that sub-style does not define a *bN*, the output will be 0.0. The maximum allowed *N* is the maximum number of quantities provided by any sub-style.

---

The local data stored by this command is generated by looping over all the atoms owned on a processor and their bonds. A bond will only be included if both atoms in the bond are in the specified compute group. Any bonds that have been broken (see the *bond\_style* command) by setting their bond type to 0 are not included. Bonds that have been turned off (see the *fix shake* or *delete\_bonds* commands) by setting their bond type negative are written into the file, but their energy will be 0.0.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, bond output from the *compute property/local* command can be combined with data from this command and output by the *dump local* command in a consistent way.

Here is an example of how to do this:

```
compute 1 all property/local btype batom1 batom2
compute 2 all bond/local dist engpot
dump 1 all local 1000 tmp.dump index c_1[*] c_2[*]
```

### 3.10.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of bonds. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The output for *dist* will be in distance *units*. The output for *velvib* will be in velocity *units*. The output for *omega* will be in velocity/distance *units*. The output for *engtrans*, *engvib*, *engrot*, and *engpot* will be in energy *units*. The output for *force* will be in force *units*.

## 3.11 compute born/matrix command

### 3.11.1 Syntax

```
compute ID group-ID born/matrix keyword value ...
```

- ID, group-ID are documented in [compute](#) command
- born/matrix = style name of this compute command
- zero or more keywords or keyword/value pairs may be appended

keyword = *numdiff* or *pair* or *bond* or *angle* or *dihedral* or *improper*

*numdiff* values = delta virial-ID

delta = magnitude of strain (dimensionless)

virial-ID = ID of pressure compute for virial (string)

(*numdiff* cannot be used with any other keyword)

*pair* = compute pair-wise contributions

*bond* = compute bonding contributions

*angle* = compute angle contributions

*dihedral* = compute dihedral contributions

*improper* = compute improper contributions

### 3.11.2 Examples

```
compute 1 all born/matrix
compute 1 all born/matrix bond angle
compute 1 all born/matrix numdiff 1.0e-4 myvirial
```

### 3.11.3 Description

New in version 4May2022.

Define a compute that calculates  $\frac{\partial^2 U}{\partial \epsilon_i \partial \epsilon_j}$ , the second derivatives of the potential energy  $U$  with respect to the strain tensor  $\epsilon$  elements. These values are related to:

$$C_{i,j}^B = \frac{1}{V} \frac{\partial^2 U}{\partial \epsilon_i \partial \epsilon_j}$$

also called the Born term of elastic constants in the stress-stress fluctuation formalism. This quantity can be used to compute the elastic constant tensor. Using the symmetric Voigt notation, the elastic constant tensor can be written as a 6x6 symmetric matrix:

$$C_{i,j} = \langle C_{i,j}^B \rangle + \frac{V}{k_B T} (\langle \sigma_i \sigma_j \rangle - \langle \sigma_i \rangle \langle \sigma_j \rangle) + \frac{N k_B T}{V} (\delta_{i,j} + (\delta_{1,i} + \delta_{2,i} + \delta_{3,i}) * (\delta_{1,j} + \delta_{2,j} + \delta_{3,j}))$$

In the above expression,  $\sigma$  stands for the virial stress tensor,  $\delta$  is the Kronecker delta and the usual notation apply for the number of particle, the temperature and volume respectively  $N$ ,  $T$  and  $V$ .  $k_B$  is the Boltzmann constant.

The Born term is a symmetric 6x6 matrix, as is the matrix of second derivatives of potential energy w.r.t strain, whose 21 independent elements are output in this order:

$$\begin{bmatrix} C_1 & C_7 & C_8 & C_9 & C_{10} & C_{11} \\ C_7 & C_2 & C_{12} & C_{13} & C_{14} & C_{15} \\ \vdots & C_{12} & C_3 & C_{16} & C_{17} & C_{18} \\ \vdots & C_{13} & C_{16} & C_4 & C_{19} & C_{20} \\ \vdots & \vdots & \vdots & C_{19} & C_5 & C_{21} \\ \vdots & \vdots & \vdots & \vdots & C_{21} & C_6 \end{bmatrix}$$

in this matrix the indices of  $C_k$  value are the corresponding element  $k$  in the global vector output by this compute. Each term comes from the sum of the derivatives of every contribution to the potential energy in the system as explained in ([VanWorkum](#)).

The output can be accessed using usual Lammmps routines:

```
compute 1 all born/matrix
compute 2 all pressure NULL virial
variable S1 equal -c_2[1]
variable S2 equal -c_2[2]
variable S3 equal -c_2[3]
variable S4 equal -c_2[4]
variable S5 equal -c_2[5]
variable S6 equal -c_2[6]
fix 1 all ave/time 1 1 1 v_S1 v_S2 v_S3 v_S4 v_S5 v_S6 c_1[*] file born.out
```

In this example, the file *born.out* will contain the information needed to compute the first and second terms of the elastic constant matrix in a post processing procedure. The other required quantities can be accessed using any other *LAMMPS* usual method. Several examples of this method are provided in the examples/ELASTIC\_T/BORN\_MATRIX directory described on the [Examples](#) doc page.

NOTE: In the above  $C_{i,j}$  computation, the fluctuation term involving the virial stress tensor  $\sigma$  is the covariance between each elements. In a solid the stress fluctuations can vary rapidly, while average fluctuations can be slow to converge. A detailed analysis of the convergence rate of all the terms in the elastic tensor is provided in the paper by Clavier et al. ([Clavier](#)).

Two different computation methods for the Born matrix are implemented in this compute and are mutually exclusive.

The first one is a direct computation from the analytical formula from the different terms of the potential used for the simulations ([VanWorkum](#)). However, the implementation of such derivations must be done for every potential form. This has not been done yet and can be very complicated for complex potentials. At the moment a warning message is displayed for every term that is not supporting the compute at the moment. This method is the default for now.

The second method uses finite differences of energy to numerically approximate the second derivatives ([Zhen](#)). This is useful when using interaction styles for which the analytical second derivatives have not been implemented. In this cases, the compute applies linear strain fields of magnitude *delta* to all the atoms relative to a point at the center of the box. The strain fields are in six different directions, corresponding to the six Cartesian components of the stress tensor defined by LAMMPS. For each direction it applies the strain field in both the positive and negative senses, and the new stress virial tensor of the entire system is calculated after each. The difference in these two virials divided by two times *delta*, approximates the corresponding components of the second derivative, after applying a suitable unit conversion.

---

**Note:** It is important to choose a suitable value for delta, the magnitude of strains that are used to generate finite difference approximations to the exact virial stress. For typical systems, a value in the range of 1 part in 1e5 to 1e6 will be sufficient. However, the best value will depend on a multitude of factors including the stiffness of the interatomic potential, the thermodynamic state of the material being probed, and so on. The only way to be sure that you have made a good choice is to do a sensitivity study on a representative atomic configuration, sweeping over a wide range of values of delta. If delta is too small, the output values will vary erratically due to truncation effects. If delta is increased beyond a certain point, the output values will start to vary smoothly with delta, due to growing contributions from higher order derivatives. In between these two limits, the numerical virial values should be largely independent of delta.

---

The keyword requires the additional arguments *delta* and *virial-ID*. *delta* gives the size of the applied strains. *virial-ID* gives the ID string of the pressure compute that provides the virial stress tensor, requiring that it use the virial keyword e.g.

```
compute myvirial all pressure NULL virial
compute 1 all born/matrix numdiff 1.0e-4 myvirial
```

#### Output info:

This compute calculates a global vector with 21 values that are the second derivatives of the potential energy with respect to strain. The values are in energy units. The values are ordered as explained above. These values can be used by any command that uses global values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The array values calculated by this compute are all “extensive”.

### 3.11.4 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info. LAMMPS was built with that package. See the [Build package](#) page for more info.

The Born term can be decomposed as a product of two terms. The first one is a general term which depends on the configuration. The second one is specific to every interaction composing your force field (non-bonded, bonds, angle, ...). Currently not all LAMMPS interaction styles implement the *born\_matrix* method giving first and second order derivatives and LAMMPS will exit with an error if this compute is used with such interactions unless the *numdiff* option is also used. The *numdiff* option cannot be used with any other keyword. In this situation, LAMMPS will also exit with an error.

## 3.12 compute centro/atom command

### 3.12.1 Syntax

`compute ID group-ID centro/atom lattice keyword value ...`

- ID, group-ID are documented in [compute](#) command
- centro/atom = style name of this compute command
- lattice = *fcc* or *bcc* or N = # of neighbors per atom to include
- zero or more keyword/value pairs may be appended
- keyword = *axes*

axes value = *no* or *yes*

no = do not calculate 3 symmetry axes

yes = calculate 3 symmetry axes

### 3.12.2 Examples

```
compute 1 all centro/atom fcc
```

```
compute 1 all centro/atom 8
```

### 3.12.3 Description

Define a computation that calculates the centro-symmetry parameter for each atom in the group, for either FCC or BCC lattices, depending on the choice of the *lattice* argument. In solid-state systems the centro-symmetry parameter is a useful measure of the local lattice disorder around an atom and can be used to characterize whether the atom is part of a perfect lattice, a local defect (e.g. a dislocation or stacking fault), or at a surface.

The value of the centro-symmetry parameter will be 0.0 for atoms not in the specified compute group.

This parameter is computed using the following formula from (*Kelchner*)

$$CS = \sum_{i=1}^{N/2} |\vec{R}_i + \vec{R}_{i+N/2}|^2$$

where the  $N$  nearest neighbors of each atom are identified and  $\vec{R}_i$  and  $\vec{R}_{i+N/2}$  are vectors from the central atom to a particular pair of nearest neighbors. There are  $N(N-1)/2$  possible neighbor pairs that can contribute to this formula. The quantity in the sum is computed for each, and the  $N/2$  smallest are used. This will typically be for pairs of atoms in symmetrically opposite positions with respect to the central atom; hence the  $i + N/2$  notation.

$N$  is an input parameter, which should be set to correspond to the number of nearest neighbors in the underlying lattice of atoms. If the keyword *fcc* or *bcc* is used,  $N$  is set to 12 and 8 respectively. More generally,  $N$  can be set to a positive, even integer.

For an atom on a lattice site, surrounded by atoms on a perfect lattice, the centro-symmetry parameter will be 0. It will be near 0 for small thermal perturbations of a perfect lattice. If a point defect exists, the symmetry is broken, and the parameter will be a larger positive value. An atom at a surface will have a large positive parameter. If the atom does not have  $N$  neighbors (within the potential cutoff), then its centro-symmetry parameter is set to 0.0.

If the keyword *axes* has the setting *yes*, then this compute also estimates three symmetry axes for each atom's local neighborhood. The first two of these are the vectors joining the two pairs of neighbor atoms with smallest contributions to the centrosymmetry parameter, i.e. the two most symmetric pairs of atoms. The third vector is normal to the first two by the right-hand rule. All three vectors are normalized to unit length. For FCC crystals, the first two vectors will lie along a  $\langle 110 \rangle$  direction, while the third vector will lie along either a  $\langle 100 \rangle$  or  $\langle 111 \rangle$  direction. For HCP crystals, the first two vectors will lie along  $\langle 1000 \rangle$  directions, while the third vector will lie along  $\langle 0001 \rangle$ . This provides a simple way to measure local orientation in HCP structures. In general, the *axes* keyword can be used to estimate the orientation of symmetry axes in the neighborhood of any atom.

Only atoms within the cutoff of the pairwise neighbor list are considered as possible neighbors. Atoms not in the compute group are included in the  $N$  neighbors used in this calculation.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g., each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a *centro/atom* style.

### 3.12.4 Output info

By default, this compute calculates the centrosymmetry value for each atom as a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

If the *axes* keyword setting is *yes*, then a per-atom array is calculated. The first column is the centrosymmetry parameter. The next three columns are the *x*, *y*, and *z* components of the first symmetry axis, followed by the second, and third symmetry axes in columns 5–7 and 8–10.

The centrosymmetry values are unitless values  $\geq 0.0$ . Their magnitude depends on the lattice style due to the number of contributing neighbor pairs in the summation in the formula above. And it depends on the local defects surrounding the central atom, as described above. For the *axes yes* case, the vector components are also unitless, since they represent spatial directions.

Here are typical centro-symmetry values, from a nanoindentation simulation into gold (FCC). These were provided by Jon Zimmerman (Sandia):

```
Bulk lattice = 0
Dislocation core ~ 1.0 (0.5 to 1.25)
Stacking faults ~ 5.0 (4.0 to 6.0)
Free surface ~ 23.0
```

These values are **not** normalized by the square of the lattice parameter. If they were, normalized values would be:

```
Bulk lattice = 0
Dislocation core ~ 0.06 (0.03 to 0.075)
Stacking faults ~ 0.3 (0.24 to 0.36)
Free surface ~ 1.38
```

For BCC materials, the values for dislocation cores and free surfaces would be somewhat different, due to their being only 8 neighbors instead of 12.

### 3.12.5 Restrictions

none

### 3.12.6 Related commands

*compute cna/atom*

### 3.12.7 Default

The default value for the optional keyword is *axes = no*.

compute 1 all chunk/atom bin/cylinder z lower 2 10 10 2.0 5.0 3 discard yes
compute 1 all chunk/atom c_cluster

```

### 3.13.3 Description

Define a computation that calculates an integer chunk ID from 1 to `Nchunk` for each atom in the group. Values of chunk IDs are determined by the *style* of chunk, which can be based on atom type or molecule ID or spatial binning or a per-atom property or value calculated by another [compute](#), [fix](#), or [atom-style variable](#). Per-atom chunk IDs can be used by other computes with “chunk” in their style name, such as [compute com/chunk](#) or [compute msd/chunk](#). Or they can be used by the [fix ave/chunk](#) command to sum and time average a variety of per-atom properties over the atoms in each chunk. Or they can simply be accessed by any command that uses per-atom values from a compute as input, as discussed on the [Howto output](#) doc page.

See the [Howto chunk](#) page for an overview of how this compute can be used with a variety of other commands to tabulate properties of a simulation. The page gives several examples of input script commands that can be used to calculate interesting properties.

Conceptually it is important to realize that this compute does two simple things. First, it sets the value of `Nchunk` = the number of chunks, which can be a constant value or change over time. Second, it assigns each atom to a chunk via a chunk ID. Chunk IDs range from 1 to `Nchunk` inclusive; some chunks may have no atoms assigned to them. Atoms that do not belong to any chunk are assigned a value of 0. Note that the two operations are not always performed together. For example, spatial bins can be setup once (which sets `Nchunk`), and atoms assigned to those bins many times thereafter (setting their chunk IDs).

All other commands in LAMMPS that use chunk IDs assume there are *Nchunk* number of chunks, and that every atom is assigned to one of those chunks, or not assigned to any chunk.

There are many options for specifying for how and when *Nchunk* is calculated, and how and when chunk IDs are assigned to atoms. The details depend on the chunk *style* and its *args*, as well as optional keyword settings. They can also depend on whether a *fix ave/chunk* command is using this compute, since that command requires *Nchunk* to remain static across windows of timesteps it specifies, while it accumulates per-chunk averages.

The details are described below.

The different chunk styles operate as follows. For each style, how it calculates *Nchunk* and assigns chunk IDs to atoms is explained. Note that using the optional keywords can change both of those actions, as described further below where the keywords are discussed.

The *binning* styles perform a spatial binning of atoms, and assign an atom the chunk ID corresponding to the bin number it is in. *Nchunk* is set to the number of bins, which can change if the simulation box size changes. This also depends on the setting of the *units* keyword (e.g., for *reduced* units the number of chunks may not change even if the box size does).

The *bin/1d*, *bin/2d*, and *bin/3d* styles define bins as 1d layers (slabs), 2d pencils, or 3d boxes. The *dim*, *origin*, and *delta* settings are specified 1, 2, or 3 times. For 2d or 3d bins, there is no restriction on specifying *dim* = *x* before *dim* = *y* or *z*, or *dim* = *y* before *dim* = *z*. Bins in a particular *dim* have a bin size in that dimension given by *delta*. In each dimension, bins are defined relative to a specified *origin*, which may be the lower/upper edge of the simulation box (in that dimension), or its center point, or a specified coordinate value. Starting at the origin, sufficient bins are created in both directions to completely span the simulation box or the bounds specified by the optional *bounds* keyword.

For orthogonal simulation boxes, the bins are layers, pencils, or boxes aligned with the xyz coordinate axes. For triclinic (non-orthogonal) simulation boxes, the bin faces are parallel to the tilted faces of the simulation box. See the [Howto triclinic](#) page for a discussion of the geometry of triclinic boxes in LAMMPS. As described there, a tilted simulation box has edge vectors  $\vec{a}$ ,  $\vec{b}$ , and  $\vec{c}$ . In that nomenclature, bins in the *x* dimension have faces with normals in the  $\vec{b} \times \vec{c}$  direction, bins in *y* have faces normal to the  $\vec{a} \times \vec{c}$  direction, and bins in *z* have faces normal to the  $\vec{a} \times \vec{b}$  direction. Note that in order to define the size and position of these bins in an unambiguous fashion, the *units* option must be set to *reduced* when using a triclinic simulation box, as noted below.

The meaning of *origin* and *delta* for triclinic boxes is as follows. Consider a triclinic box with bins that are 1d layers or slabs in the *x* dimension. No matter how the box is tilted, an *origin* of 0.0 means start layers at the lower  $\vec{b} \times \vec{c}$  plane of the simulation box and an *origin* of 1.0 means to start layers at the upper  $\vec{b} \times \vec{c}$  face of the box. A *delta* value of 0.1 in *reduced* units means there will be 10 layers from 0.0 to 1.0, regardless of the current size or shape of the simulation box.

The *bin/sphere* style defines a set of spherical shell bins around the origin (*xorig*,*yorig*,*zorig*), using *nsbin* bins with radii equally spaced between *srmin* and *srmax*. This is effectively a 1d vector of bins. For example, if *srmin* = 1.0 and *srmax* = 10.0 and *nsbin* = 9, then the first bin spans  $1.0 < r < 2.0$ , and the last bin spans  $9.0 < r < 10.0$ . The geometry of the bins is the same whether the simulation box is orthogonal or triclinic (i.e., the spherical shells are not tilted or scaled differently in different dimensions to transform them into ellipsoidal shells).

The *bin/cylinder* style defines bins for a cylinder oriented along the axis *dim* with the axis coordinates in the other two radial dimensions at (*c1*,*c2*). For *dim* = *x*,  $c_1/c_2 = y/z$ ; for *dim* = *y*,  $c_1/c_2 = x/z$ ; for *dim* = *z*,  $c_1/c_2 = x/y$ . This is effectively a 2d array of bins. The first dimension is along the cylinder axis, the second dimension is radially outward from the cylinder axis. The bin size and positions along the cylinder axis are specified by the *origin* and *delta* values, the same as for the *bin/1d*, *bin/2d*, and *bin/3d* styles. There are *ncbin* concentric circle bins in the radial direction from the cylinder axis with radii equally spaced between *crmin* and *crmax*. For example, if *crmin* = 1.0 and *crmax* = 10.0 and *ncbin* = 9, then the first bin spans  $1.0 < r < 2.0$  and the last bin spans  $9.0 < r < 10.0$ . The geometry of the bins in the radial dimensions is the same whether the simulation box is orthogonal or triclinic (i.e., the concentric circles are not tilted or scaled differently in the two different dimensions to transform them into ellipses).

The created bins (and hence the chunk IDs) are numbered consecutively from 1 to the number of bins = *Nchunk*. For *bin2d* and *bin3d*, the numbering varies most rapidly in the first dimension (which could be *x*, *y*, or *z*), next rapidly in the second dimension, and most slowly in the third dimension. For *bin/sphere*, the bin with smallest radii is chunk 1 and the bin with largest radii is chunk *Nchunk* = *ncbin*. For *bin/cylinder*, the numbering varies most rapidly in the dimension along the cylinder axis and most slowly in the radial direction.

Each time this compute is invoked, each atom is mapped to a bin based on its current position. Note that between reneighboring timesteps, atoms can move outside the current simulation box. If the box is periodic (in that dimension) the atom is remapping into the periodic box for purposes of binning. If the box is not periodic, the atom may have moved outside the bounds of all bins. If an atom is not inside any bin, the *discard* keyword is used to determine how a chunk ID is assigned to the atom.

---

The *type* style uses the atom type as the chunk ID. *Nchunk* is set to the number of atom types defined for the simulation (e.g., via the *create\_box* or *read\_data* commands).

---

The *molecule* style uses the molecule ID of each atom as its chunk ID. *Nchunk* is set to the largest chunk ID. Note that this excludes molecule IDs for atoms which are not in the specified group or optional region.

There is no requirement that all atoms in a particular molecule are assigned the same chunk ID (zero or non-zero), though you probably want that to be the case, if you wish to compute a per-molecule property. LAMMPS will issue a warning if that is not the case, but only the first time that *Nchunk* is calculated.

Note that atoms with a molecule ID = 0, which may be non-molecular solvent atoms, have an out-of-range chunk ID. These atoms are discarded (not assigned to any chunk) or assigned to *Nchunk*, depending on the value of the *discard* keyword.

---

The *compute/fix/variable* styles set the chunk ID of each atom based on a quantity calculated and stored by a compute, fix, or variable. In each case, it must be a per-atom quantity. In each case the referenced floating point values are converted to an integer chunk ID as follows. The floating point value is truncated (rounded down) to an integer value. If the integer value is  $\leq 0$ , then a chunk ID of 0 is assigned to the atom. If the integer value is  $> 0$ , it becomes the chunk ID to the atom. *Nchunk* is set to the largest chunk ID. Note that this excludes atoms which are not in the specified group or optional region.

If the style begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the *I*th column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*.

If the style begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the *I*th column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with the timestep on which this compute accesses the fix, else an error results. Users can also write code for their own fix styles and *add them to LAMMPS*.

If a value begins with “v\_”, a variable name for an *atom* or *atomfile* style *variable* must follow which has been previously defined in the input script. Variables of style *atom* can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to treat as a chunk ID.

---

Normally, *Nchunk* = the number of chunks, is re-calculated every time this fix is invoked, though the value may or may not change. As explained below, the *nchunk* keyword can be set to *once* which means *Nchunk* will never change.

If a *fix ave/chunk* command uses this compute, it can also turn off the re-calculation of *Nchunk* for one or more windows of timesteps. The extent of the windows, during which *Nchunk* is held constant, are determined by the *Nevery*, *Nrepeat*, *Nfreq* values and the *ave* keyword setting that are used by the *fix ave/chunk* command.

Specifically, if *ave* = *one*, then for each span of *Nfreq* timesteps, *Nchunk* is held constant between the first timestep when averaging is done (within the *Nfreq*-length window), and the last timestep when averaging is done (multiple of *Nfreq*). If *ave* = *running* or *window*, then *Nchunk* is held constant forever, starting on the first timestep when the *fix ave/chunk* command invokes this compute.

Note that multiple *fix ave/chunk* commands can use the same compute chunk/atom compute. However, the time windows they induce for holding *Nchunk* constant must be identical, else an error will be generated.

---

The various optional keywords operate as follows. Note that some of them function differently or are ignored by different chunk styles. Some of them also have different default values, depending on the chunk style, as listed below.

The *region* keyword applies to all chunk styles. If used, an atom must be in both the specified group and the specified geometric *region* to be assigned to a chunk.

---

The *nchunk* keyword applies to all chunk styles. It specifies how often *Nchunk* is recalculated, which in turn can affect the chunk IDs assigned to individual atoms.

If *nchunk* is set to *once*, then *Nchunk* is only calculated once, the first time this compute is invoked. If *nchunk* is set to *every*, then *Nchunk* is re-calculated every time the compute is invoked. Note that, as described above, the use of this compute by the *fix ave/chunk* command can override the *every* setting.

The default values for *nchunk* are listed below and depend on the chunk style and other system and keyword settings. They attempt to represent typical use cases for the various chunk styles. The *nchunk* value can always be set explicitly if desired.

---

The *limit* keyword can be used to limit the calculated value of *Nchunk* = the number of chunks. The limit is applied each time *Nchunk* is calculated, which also limits the chunk IDs assigned to any atom. The *limit* keyword is used by all chunk styles except the *binning* styles, which ignore it. This is because the number of bins can be tailored using the *bound* keyword (described below) which effectively limits the size of *Nchunk*.

If *limit* is set to *Nc* = 0, then no limit is imposed on *Nchunk*, though the *compress* keyword can still be used to reduce *Nchunk*, as described below.

If *Nc* > 0, then the effect of the *limit* keyword depends on whether the *compress* keyword is also used with a setting of *yes*, and whether the *compress* keyword is specified before the *limit* keyword or after.

In all cases, *Nchunk* is first calculated in the usual way for each chunk style, as described above.

First, here is what occurs if *compress yes* is not set. If *limit* is set to *Nc max*, then *Nchunk* is reset to the smaller of *Nchunk* and *Nc*. If *limit* is set to *Nc exact*, then *Nchunk* is reset to *Nc*, whether the original *Nchunk* was larger or smaller than *Nc*. If *Nchunk* shrank due to the *limit* setting, then atom chunk IDs > *Nchunk* will be reset to 0 or *Nchunk*, depending on the setting of the *discard* keyword. If *Nchunk* grew, there will simply be some chunks with no atoms assigned to them.

If *compress yes* is set, and the *compress* keyword comes before the *limit* keyword, the compression operation is performed first, as described below, which resets *Nchunk*. The *limit* keyword is then applied to the new *Nchunk* value, exactly as described in the preceding paragraph. Note that in this case, all atoms will end up with chunk IDs ≤ *Nc*, but their original values (e.g., molecule ID or compute/fix/variable) may have been > *Nc*, because of the compression operation.

If *compress yes* is set, and the *compress* keyword comes after the *limit* keyword, then the *limit* value of *Nc* is applied first to the uncompressed value of *Nchunk*, but only if *Nc* < *Nchunk* (whether *Nc max* or *Nc exact* is used). This effectively

means all atoms with chunk IDs  $> N_c$  have their chunk IDs reset to 0 or  $N_c$ , depending on the setting of the *discard* keyword. The compression operation is then performed, which may shrink *Nchunk* further. If the new *Nchunk*  $< N_c$  and *limit* = *Nc exact* is specified, then *Nchunk* is reset to  $N_c$ , which results in extra chunks with no atoms assigned to them. Note that in this case, all atoms will end up with chunk IDs  $\leq N_c$ , and their original values (e.g., molecule ID or compute/fix/variable value) will also have been  $\leq N_c$ .

---

The *ids* keyword applies to all chunk styles. If the setting is *once* then the chunk IDs assigned to atoms the first time this compute is invoked will be permanent, and never be re-computed.

If the setting is *nfreq* and if a *fix ave/chunk* command is using this compute, then in each of the *Nchunk* = constant time windows (discussed above), the chunk ID's assigned to atoms on the first step of the time window will persist until the end of the time window.

If the setting is *every*, which is the default, then chunk IDs are re-calculated on any timestep this compute is invoked.

---

**Note:** If you want the persistent chunk-IDs calculated by this compute to be continuous when running from a *restart file*, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with chunk IDs from the restart file.

---

The *compress* keyword applies to all chunk styles and affects how *Nchunk* is calculated, which in turn affects the chunk IDs assigned to each atom. It is useful for converting a “sparse” set of chunk IDs (with many IDs that have no atoms assigned to them), into a “dense” set of IDs, where every chunk has one or more atoms assigned to it.

Two possible use cases are as follows. If a large simulation box is mostly empty space, then the *binning* style may produce many bins with no atoms. If *compress* is set to *yes*, only bins with atoms will contribute to *Nchunk*. Likewise, the *molecule* or *compute/fix/variable* styles may produce large *Nchunk* values. For example, the *compute cluster/atom* command assigns every atom an atom ID for one of the atoms it is clustered with. For a million-atom system with 5 clusters, there would only be 5 unique chunk IDs, but the largest chunk ID might be 1 million, resulting in *Nchunk* = 1 million. If *compress* is set to *yes*, *Nchunk* will be reset to 5.

If *compress* is set to *no*, which is the default, no compression is done. If it is set to *yes*, all chunk IDs with no atoms are removed from the list of chunk IDs, and the list is sorted. The remaining chunk IDs are renumbered from 1 to *Nchunk* where *Nchunk* is the new length of the list. The chunk IDs assigned to each atom reflect the new renumbering from 1 to *Nchunk*.

The original chunk IDs (before renumbering) can be accessed by the *compute property/chunk* command and its *id* keyword, or by the *fix ave/chunk* command which outputs the original IDs as one of the columns in its global output array. For example, using the “compute cluster/atom” command discussed above, the original 5 unique chunk IDs might be atom IDs (27,4982,58374,857838,1000000). After compression, these will be renumbered to (1,2,3,4,5). The original values (27,...,1000000) can be output to a file by the *fix ave/chunk* command, or by using the *fix ave/time* command in conjunction with the *compute property/chunk* command.

---

**Note:** The compression operation requires global communication across all processors to share their chunk ID values. It can require large memory on every processor to store them, even after they are compressed, if there are a large number of unique chunk IDs with atoms assigned to them. It uses a STL map to find unique chunk IDs and store them in sorted order. Each time an atom is assigned a compressed chunk ID, it must access the STL map. All of this means that compression can be expensive, both in memory and CPU time. The use of the *limit* keyword in conjunction with the *compress* keyword can affect these costs, depending on which keyword is used first. So use this option with care.

---

The *discard* keyword applies to all chunk styles. It affects what chunk IDs are assigned to atoms that do not match one of the valid chunk IDs from 1 to *Nchunk*. Note that it does not apply to atoms that are not in the specified group or optionally specified region. Those atoms are always assigned a chunk ID = 0.

If the calculated chunk ID for an atom is not within the range 1 to *Nchunk* then it is a “discard” atom. Note that *Nchunk* may have been shrunk by the *limit* keyword. Or the *compress* keyword may have eliminated chunk IDs that were valid before the compression took place, and are now not in the compressed list. Also note that for the *molecule* chunk style, if new molecules are added to the system, their chunk IDs may exceed a previously calculated *Nchunk*. Likewise, evaluation of a compute/fix/variable on a later timestep may return chunk IDs that are invalid for the previously calculated *Nchunk*.

All the chunk styles except the *binning* styles, must use *discard* set to either *yes* or *no*. If *discard* is set to *yes*, which is the default, then every “discard” atom has its chunk ID set to 0. If *discard* is set to *no*, every “discard” atom has its chunk ID set to *Nchunk*. I.e. it becomes part of the last chunk.

The *binning* styles use the *discard* keyword to decide whether to discard atoms outside the spatial domain covered by bins, or to assign them to the bin they are nearest to.

For the *bin/1d*, *bin/2d*, *bin/3d* styles the details are as follows. If *discard* is set to *yes*, an out-of-domain atom will have its chunk ID set to 0. If *discard* is set to *no*, the atom will have its chunk ID set to the first or last bin in that dimension. If *discard* is set to *mixed*, which is the default, it will only have its chunk ID set to the first or last bin if bins extend to the simulation box boundary in that dimension. This is the case if the *bound* keyword settings are *lower* and *upper*, which is the default. If the *bound* keyword settings are numeric values, then the atom will have its chunk ID set to 0 if it is outside the bounds of any bin. Note that in this case, it is possible that the first or last bin extends beyond the numeric *bounds* settings, depending on the specified *origin*. If this is the case, the chunk ID of the atom is only set to 0 if it is outside the first or last bin, not if it is simply outside the numeric *bounds* setting.

For the *bin/sphere* style the details are as follows. If *discard* is set to *yes*, an out-of-domain atom will have its chunk ID set to 0. If *discard* is set to *no* or *mixed*, the atom will have its chunk ID set to the first or last bin, i.e. the innermost or outermost spherical shell. If the distance of the atom from the origin is less than *rmin*, it will be assigned to the first bin. If the distance of the atom from the origin is greater than *rmax*, it will be assigned to the last bin.

For the *bin/cylinder* style the details are as follows. If *discard* is set to *yes*, an out-of-domain atom will have its chunk ID set to 0. If *discard* is set to *no*, the atom will have its chunk ID set to the first or last bin in both the radial and axis dimensions. If *discard* is set to *mixed*, which is the default, the radial dimension is treated the same as for *discard* = *no*. But for the axis dimension, it will only have its chunk ID set to the first or last bin if bins extend to the simulation box boundary in the axis dimension. This is the case if the *bound* keyword settings are *lower* and *upper*, which is the default. If the *bound* keyword settings are numeric values, then the atom will have its chunk ID set to 0 if it is outside the bounds of any bin. Note that in this case, it is possible that the first or last bin extends beyond the numeric *bounds* settings, depending on the specified *origin*. If this is the case, the chunk ID of the atom is only set to 0 if it is outside the first or last bin, not if it is simply outside the numeric *bounds* setting.

If *discard* is set to *no* or *mixed*, the atom will have its chunk ID set to the first or last bin, i.e. the innermost or outermost spherical shell. If the distance of the atom from the origin is less than *rmin*, it will be assigned to the first bin. If the distance of the atom from the origin is greater than *rmax*, it will be assigned to the last bin.

---

The *bound* keyword only applies to the *bin/1d*, *bin/2d*, *bin/3d* styles and to the axis dimension of the *bin/cylinder* style; otherwise it is ignored. It can be used one or more times to limit the extent of bin coverage in a specified dimension, i.e. to only bin a portion of the box. If the *lo* setting is *lower* or the *hi* setting is *upper*, the bin extent in that direction extends to the box boundary. If a numeric value is used for *lo* and/or *hi*, then the bin extent in the *lo* or *hi* direction extends only to that value, which is assumed to be inside (or at least near) the simulation box boundaries, though LAMMPS does not check for this. Note that using the *bound* keyword typically reduces the total number of bins and thus the number of chunks *Nchunk*.

The *pbc* keyword only applies to the *bin/sphere* and *bin/cylinder* styles. If set to *yes*, the distance an atom is from the sphere origin or cylinder axis is calculated in a minimum image sense with respect to periodic dimensions, when determining which bin the atom is in. I.e. if *x* is a periodic dimension and the distance between the atom and the sphere

center in the  $x$  dimension is greater than  $0.5 * \text{simulation box length in } x$ , then a box length is subtracted to give a distance  $< 0.5 * \text{simulation box length}$ . This allows the sphere or cylinder center to be near a box edge, and atoms on the other side of the periodic box will still be close to the center point/axis. Note that with a setting of *yes*, the outer sphere or cylinder radius must also be  $\leq 0.5 * \text{simulation box length}$  in any periodic dimension except for the cylinder axis dimension, or an error is generated.

The *units* keyword only applies to the *binning* styles; otherwise it is ignored. For the *bin/1d*, *bin/2d*, *bin/3d* styles, it determines the meaning of the distance units used for the bin sizes *delta* and for *origin* and *bounds* values if they are coordinate values. For the *bin/sphere* style it determines the meaning of the distance units used for *xorig*, *yorig*, *zorig* and the radii *srmin* and *srmax*. For the *bin/cylinder* style it determines the meaning of the distance units used for *delta*, *c1*, *c2* and the radii *crmin* and *crmax*.

For orthogonal simulation boxes, any of the 3 options may be used. For non-orthogonal (triclinic) simulation boxes, only the *reduced* option may be used.

A *box* value selects standard distance units as defined by the *units* command (e.g., Å for *units = real* or *metal*). A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. A *reduced* value means normalized unitless values between 0 and 1, which represent the lower and upper faces of the simulation box respectively. Thus an *origin* value of 0.5 means the center of the box in any dimension. A *delta* value of 0.1 means 10 bins span the box in that dimension.

Note that for the *bin/sphere* style, the radii *srmin* and *srmax* are scaled by the lattice spacing or reduced value of the  $x$  dimension.

Note that for the *bin/cylinder* style, the radii *crmin* and *crmax* are scaled by the lattice spacing or reduced value of the first dimension perpendicular to the cylinder axis (e.g.,  $y$  for an  $x$ -axis cylinder,  $x$  for a  $y$ -axis cylinder, and  $z$  for a  $z$ -axis cylinder).

---

### 3.13.4 Output info

This compute calculates a per-atom vector (the chunk ID), which can be accessed by any command that uses per-atom values from a compute as input. It also calculates a global scalar (the number of chunks), which can be similarly accessed everywhere outside of a per-atom context. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values are unitless chunk IDs, ranging from 1 to *Nchunk* (inclusive) for atoms assigned to chunks, and 0 for atoms not belonging to a chunk. The scalar contains the value of *Nchunk*.

### 3.13.5 Restrictions

Even if the *nchunk* keyword is set to *once*, the chunk IDs assigned to each atom are not stored in a restart files. This means you cannot expect those assignments to persist in a restarted simulation. Instead you must re-specify this command and assign atoms to chunks when the restarted simulation begins.

### 3.13.6 Related commands

*fix ave/chunk, compute global/atom*

### 3.13.7 Default

The option defaults are as follows:

- region = none
- nchunk = every, if compress is yes, overriding other defaults listed here
- nchunk = once, for type style
- nchunk = once, for mol style if region is none
- nchunk = every, for mol style if region is set
- nchunk = once, for binning style if the simulation box size is static or units = reduced
- nchunk = every, for binning style if the simulation box size is dynamic and units is lattice or box
- nchunk = every, for compute/fix/variable style
- limit = 0
- ids = every
- compress = no
- discard = yes, for all styles except binning
- discard = mixed, for binning styles
- bound = lower and upper in all dimensions
- pbc = no
- units = lattice

## 3.14 compute chunk/spread/atom command

### 3.14.1 Syntax

```
compute ID group-ID chunk/spread/atom chunkID input1 input2 ...
```

- ID, group-ID are documented in *compute* command
- chunk/spread/atom = style name of this compute command
- chunkID = ID of *compute chunk/atom* command
- one or more inputs can be listed
- input = c\_ID, c\_ID[N], f\_ID, f\_ID[N]

```
c_ID = global vector calculated by a compute with ID
c_ID[I] = Ith column of global array calculated by a compute with ID, I can include
→wildcard (see below)
f_ID = global vector calculated by a fix with ID
```

(continues on next page)

(continued from previous page)

```
f_ID[I] = Ith column of global array calculated by a fix with ID, I can include_  
→wildcard (see below)
```

### 3.14.2 Examples

```
compute 1 all chunk/spread/atom mychunk c_com[*] c_gyration
```

### 3.14.3 Description

Define a calculation that “spreads” one or more per-chunk values to each atom in the chunk. This can be useful in several scenarios:

- For creating a *dump file* where each atom lists info about the chunk it is in, e.g. for post-processing purposes.
- To access chunk value in *atom-style variables* that need info about the chunk each atom is in.
- To use the *fix ave/chunk* command to spatially average per-chunk values calculated by a per-chunk compute.

Examples are given below.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as *chunkID*. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

For inputs that are computes, they must be a compute that calculates per-chunk values. These are computes whose style names end in “/chunk”.

For inputs that are fixes, they should be a fix that calculates per-chunk values. For example, *fix ave/chunk* or *fix ave/time* (assuming it is time-averaging per-chunk data).

For each atom, this compute accesses its chunk ID from the specified *chunkID* compute, then accesses the per-chunk value in each input. Those values are copied to this compute to become the output for that atom.

The values generated by this compute will be 0.0 for atoms not in the specified compute group *group-ID*. They will also be 0.0 if the atom is not in a chunk, as assigned by the *chunkID* compute. They will also be 0.0 if the current chunk ID for the atom is out-of-bounds with respect to the number of chunks stored by a particular input compute or fix.

---

**Note:** LAMMPS does not check that a compute or fix which calculates per-chunk values uses the same definition of chunks as this compute. It’s up to you to be consistent. Likewise, for a fix input, LAMMPS does not check that it is per-chunk data. It only checks that the fix produces a global vector or array.

---

Each listed input is operated on independently.

If a bracketed index *I* is used, it can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\**n*” or “*n*\*” or “*m*\**n*”. If *N* = the number of columns in the array, then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute *chunk/spread/atom* commands are equivalent, since the *compute com/chunk* command creates a per-atom array with 3 columns:

```
compute com all com/chunk mychunk
compute 10 all chunk/spread/atom mychunk c_com[*]
compute 10 all chunk/spread/atom mychunk c_com[1] c_com[2] c_com[3]
```

Here is an example of writing a dump file the with the center-of-mass (COM) for the chunk each atom is in. The commands below can be added to the bench/in.chain script.

```
compute      cmol all chunk/atom molecule
compute      com all com/chunk cmol
compute      comchunk all chunk/spread/atom cmol c_com[*]
dump         1 all custom 50 tmp.dump id mol type x y z c_comchunk[*]
dump_modify  1 sort id
```

The same per-chunk data for each atom could be used to define per-atom forces for the *fix addforce* command. In this example the forces act to pull atoms of an extended polymer chain towards its COM in an attractive manner.

```
compute      prop all property/atom xu yu zu
variable     k equal 0.1
variable     fx atom v_k*(c_comchunk[1]-c_prop[1])
variable     fy atom v_k*(c_comchunk[2]-c_prop[2])
variable     fz atom v_k*(c_comchunk[3]-c_prop[3])
fix          3 all addforce v_fx v_fy v_fz
```

Note that *compute property/atom* is used to generate unwrapped coordinates for use in the per-atom force calculation, so that the effect of periodic boundaries is accounted for properly.

Over time this applied force could shrink each polymer chain's radius of gyration in a polymer mixture simulation. Here is output from the bench/in.chain script. Thermo output is shown for 1000 steps, where the last column is the average radius of gyration over all 320 chains in the 32000 atom system:

```
compute      gyr all gyration/chunk cmol
variable     ave equal ave(c_gyr)
thermo_style  custom step etotal press v_ave
```

400	22.557196	4.9492211	4.7937849
500	22.571017	4.9161853	4.7412008
600	22.573944	5.0229708	4.6931243
700	22.581804	5.0541301	4.6440647
800	22.584683	4.9691734	4.6000016
900	22.59128	5.0247538	4.5611513
1000	22.586832	4.94697	4.5238362

Here is an example for using one set of chunks, defined for molecules, to compute the dipole moment vector for each chunk. E.g. for water molecules. Then spreading those values to each atom in each chunk. Then defining a second set of chunks based on spatial bins. And finally, using the *fix ave/chunk* command to calculate an average dipole moment vector per spatial bin.

```
compute      cmol all chunk/atom molecule
compute      dipole all dipole/chunk cmol
compute      spread all chunk/spread/atom cmol c_dipole[1] c_dipole[2] c_dipole[3]
compute      cspatial all chunk/atom bin/1d z lower 0.1 units reduced
fix          ave all ave/chunk 100 10 1000 cspatial c_spread[*]
```

Note that the *fix ave/chunk* command requires per-atom values as input. That is why the compute chunk/spread/atom command is used to assign per-chunk values to each atom in the chunk. If a molecule straddles bin boundaries, each of its atoms contributes in a weighted manner to the average dipole moment of the spatial bin it is in.

---

### 3.14.4 Output info

This compute calculates a per-atom vector or array, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The output is a per-atom vector if a single input value is specified, otherwise a per-atom array is output. The number of columns in the array is the number of inputs provided. The per-atom values for the vector or each column of the array will be in whatever *units* the corresponding input value is in.

The vector or array values are “intensive”.

### 3.14.5 Restrictions

none

### 3.14.6 Related commands

### 3.14.7 Default

none

## 3.15 compute cluster/atom command

## 3.16 compute fragment/atom command

## 3.17 compute aggregate/atom command

### 3.17.1 Syntax

```
compute ID group-ID cluster/atom cutoff
compute ID group-ID fragment/atom keyword value ...
compute ID group-ID aggregate/atom cutoff
```

- ID, group-ID are documented in *compute* command
- *cluster/atom* or *fragment/atom* or *aggregate/atom* = style name of this compute command
- cutoff = distance within which to label atoms as part of same cluster (distance units)
- zero or more keyword/value pairs may be appended to *fragment/atom*
- keyword = *single*

*single* value = yes or no to treat single atoms (no bonds) as fragments

### 3.17.2 Examples

```
compute 1 all cluster/atom 3.5
compute 1 all fragment/atom
compute 1 all fragment/atom single no
compute 1 all aggregate/atom 3.5
```

### 3.17.3 Description

Define a computation that assigns each atom a cluster, fragment, or aggregate ID. Only atoms in the compute group are clustered and assigned cluster IDs. Atoms not in the compute group are assigned an ID = 0.

A cluster is defined as a set of atoms, each of which is within the cutoff distance from one or more other atoms in the cluster. If an atom has no neighbors within the cutoff distance, then it is a 1-atom cluster.

A fragment is similarly defined as a set of atoms, each of which has a bond to another atom in the fragment. Bonds can be defined initially via the *data file* or *create\_bonds* commands, or dynamically by fixes which create or break bonds like *fix bond/react*, *fix bond/create*, *fix bond/swap*, or *fix bond/break*. The cluster ID or fragment ID of every atom in the cluster will be set to the smallest atom ID of any atom in the cluster or fragment, respectively.

For the *fragment/atom* style, the *single* keyword determines whether single atoms (not bonded to another atom) are treated as one-atom fragments or not, based on the *yes* or *no* setting. If the setting is *no* (the default), their fragment IDs are set to 0.

An aggregate is defined by combining the rules for clusters and fragments (i.e., a set of atoms, where each of them is within the cutoff distance from one or more atoms within a fragment that is part of the same cluster). This measure can be used to track molecular assemblies like micelles.

For computes *cluster/atom* and *aggregate/atom* a neighbor list needed to compute cluster IDs is constructed each time the compute is invoked. Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple *cluster/atom* or *aggregate/atom* style computes.

---

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included when computing the clusters. This does not apply when using long-range coulomb (*coul/long*, *coul/msm*, *coul/wolf* or similar. One way to get around this would be to set *special\_bond* scaling factors to very tiny numbers that are not exactly zero (e.g.,  $1.0 \times 10^{-50}$ ). Another workaround is to write a dump file and use the *rerun* command to compute the clusters for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

---

---

**Note:** For the compute fragment/atom style, each fragment is identified using the current bond topology. This will not account for bonds broken by the *bond\_style* *quartic* command because it does not perform a full update of the bond topology data structures within LAMMPS.

---

### 3.17.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-atom vector values will be an ID > 0, as explained above.

### 3.17.5 Restrictions

none

### 3.17.6 Related commands

*compute coord/atom*

### 3.17.7 Default

The default for fragment/atom is single=no.

## 3.18 compute cna/atom command

### 3.18.1 Syntax

```
compute ID group-ID cna/atom cutoff
```

- ID, group-ID are documented in *compute* command
- cna/atom = style name of this compute command
- cutoff = cutoff distance for nearest neighbors (distance units)

### 3.18.2 Examples

```
compute 1 all cna/atom 3.08
```

### 3.18.3 Description

Define a computation that calculates the CNA (Common Neighbor Analysis) pattern for each atom in the group. In solid-state systems the CNA pattern is a useful measure of the local crystal structure around an atom. The CNA methodology is described in ([Faken](#)) and ([Tsuzuki](#)).

Currently, there are five kinds of CNA patterns LAMMPS recognizes:

- fcc = 1
- hcp = 2
- bcc = 3
- icosahedral = 4
- unknown = 5

The value of the CNA pattern will be 0 for atoms not in the specified compute group. Note that normally a CNA calculation should only be performed on mono-component systems.

The CNA calculation can be sensitive to the specified cutoff value. You should ensure the appropriate nearest neighbors of an atom are found within the cutoff distance for the presumed crystal structure (e.g., 12 nearest neighbor for perfect FCC and HCP crystals, 14 nearest neighbors for perfect BCC crystals). These formulas can be used to obtain a good cutoff distance:

$$r_c^{\text{fcc}} = \frac{1}{2} \left( \frac{\sqrt{2}}{2} + 1 \right) a \approx 0.8536a$$

$$r_c^{\text{bcc}} = \frac{1}{2} (\sqrt{2} + 1) a \approx 1.207a$$

$$r_c^{\text{hcp}} = \frac{1}{2} \left( 1 + \sqrt{\frac{4 + 2x^2}{3}} \right) a$$

where  $a$  is the lattice constant for the crystal structure concerned and in the HCP case,  $x = (c/a)/1.633$ , where 1.633 is the ideal  $c/a$  for HCP crystals.

Also note that since the CNA calculation in LAMMPS uses the neighbors of an owned atom to find the nearest neighbors of a ghost atom, the following relation should also be satisfied:

$$r_c + r_s > 2 * \text{cutoff}$$

where  $r_c$  is the cutoff distance of the potential,  $r_s$  is the skin distance as specified by the [neighbor](#) command, and cutoff is the argument used with the compute cna/atom command. LAMMPS will issue a warning if this is not the case.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a *cna/atom* style.

### 3.18.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be a number from 0 to 5, as explained above.

## 3.19 compute cnp/atom command

### 3.19.1 Syntax

```
compute ID group-ID cnp/atom cutoff
```

- ID, group-ID are documented in *compute* command
- cnp/atom = style name of this compute command
- cutoff = cutoff distance for nearest neighbors (distance units)

### 3.19.2 Examples

```
compute 1 all cnp/atom 3.08
```

### 3.19.3 Description

Define a computation that calculates the Common Neighborhood Parameter (CNP) for each atom in the group. In solid-state systems the CNP is a useful measure of the local crystal structure around an atom and can be used to characterize whether the atom is part of a perfect lattice, a local defect (e.g., a dislocation or stacking fault), or at a surface.

The value of the CNP parameter will be 0.0 for atoms not in the specified compute group. Note that normally a CNP calculation should only be performed on single component systems.

This parameter is computed using the following formula from (*Tsuzuki*)

$$Q_i = \frac{1}{n_i} \sum_{j=1}^{n_i} \left\| \sum_{k=1}^{n_{ij}} \vec{R}_{ik} + \vec{R}_{jk} \right\|^2$$

where the index  $j$  goes over the  $n_i$  nearest neighbors of atom  $i$ , and the index  $k$  goes over the  $n_{ij}$  common nearest neighbors between atom  $i$  and atom  $j$ .  $\vec{R}_{ik}$  and  $\vec{R}_{jk}$  are the vectors connecting atom  $k$  to atoms  $i$  and  $j$ . The quantity in the double sum is computed for each atom.

The CNP calculation is sensitive to the specified cutoff value. You should ensure that the appropriate nearest neighbors of an atom are found within the cutoff distance for the presumed crystal structure. E.g. 12 nearest neighbor for perfect FCC and HCP crystals, 14 nearest neighbors for perfect BCC crystals. These formulas can be used to obtain a good cutoff distance:

$$r_c^{\text{fcc}} = \frac{1}{2} \left( \frac{\sqrt{2}}{2} + 1 \right) a \approx 0.8536a$$

$$r_c^{\text{bcc}} = \frac{1}{2} (\sqrt{2} + 1) a \approx 1.207a$$

$$r_c^{\text{hcp}} = \frac{1}{2} \left( 1 + \sqrt{\frac{4 + 2x^2}{3}} \right) a$$

where  $a$  is the lattice constant for the crystal structure concerned and in the HCP case,  $x = (c/a)/1.633$ , where 1.633 is the ideal  $c/a$  for HCP crystals.

Also note that since the CNP calculation in LAMMPS uses the neighbors of an owned atom to find the nearest neighbors of a ghost atom, the following relation should also be satisfied:

$$r_c + r_s > 2 * \text{cutoff}$$

where  $r_c$  is the cutoff distance of the potential,  $r_s$  is the skin distance as specified by the [neighbor](#) command, and cutoff is the argument used with the compute cnp/atom command. LAMMPS will issue a warning if this is not the case.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g., each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a *cnp/atom* style.

### 3.19.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be real positive numbers. Some typical CNP values:

```
FCC lattice = 0.0
BCC lattice = 0.0
HCP lattice = 4.4

FCC (111) surface = 13.0
FCC (100) surface = 26.5
FCC dislocation core = 11
```

### 3.19.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.19.6 Related commands

*compute cna/atom compute centro/atom*

### 3.19.7 Default

## 3.20 compute com command

### 3.20.1 Syntax

```
compute ID group-ID com
```

- ID, group-ID are documented in *compute* command
- com = style name of this compute command

### 3.20.2 Examples

```
compute 1 all com
```

### 3.20.3 Description

Define a computation that calculates the center-of-mass of the group of atoms, including all effects due to atoms passing through periodic boundaries.

A vector of three quantities is calculated by this compute, which are the (x, y, z) coordinates of the center of mass.

---

**Note:** The coordinates of an atom contribute to the center-of-mass in “unwrapped” form, by using the image flags associated with each atom. See the *dump custom* command for a discussion of “unwrapped” coordinates. See the Atoms section of the *read\_data* command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the *set image* command.

---

### 3.20.4 Output info

This compute calculates a global vector of length 3, which can be accessed by indices 1–3 by any command that uses global vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in distance *units*.

### 3.20.5 Restrictions

none

### 3.20.6 Related commands

*compute com/chunk*

### 3.20.7 Default

none

## 3.21 compute com/chunk command

### 3.21.1 Syntax

```
compute ID group-ID com/chunk chunkID
```

- ID, group-ID are documented in *compute* command
- com/chunk = style name of this compute command
- chunkID = ID of *compute chunk/atom* command

### 3.21.2 Examples

```
compute 1 fluid com/chunk molchunk
```

### 3.21.3 Description

Define a computation that calculates the center-of-mass for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the  $(x, y, z)$  coordinates of the center of mass for each chunk, which includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The *compute chunk/atom* command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

---

**Note:** The coordinates of an atom contribute to the chunk’s center-of-mass in “unwrapped” form, by using the image flags associated with each atom. See the *dump custom* command for a discussion of “unwrapped” coordinates. See the Atoms section of the *read\_data* command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the *set image* command.

---

The simplest way to output the results of the compute com/chunk calculation to a file is to use the *fix ave/time* command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all com/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.21.4 Output info

This compute calculates a global array where the number of rows = the number of chunks *Nchunk* as calculated by the specified *compute chunk/atom* command. The number of columns is 3 for the (x,y,z) center-of-mass coordinates of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in distance *units*.

### 3.21.5 Restrictions

none

### 3.21.6 Related commands

## 3.22 compute composition/atom command

Accelerator Variants: *composition/atom/kk*

### 3.22.1 Syntax

```
compute ID group-ID composition/atom keyword values ...
```

- ID, group-ID are documented in *compute* command
- composition/atom = style name of this compute command
- one or more keyword/value pairs may be appended

keyword = *cutoff*  
*cutoff* value = distance cutoff

### 3.22.2 Examples

```
compute 1 all composition/atom

compute 1 all composition/atom cutoff 9.0
comm_modify cutoff 9.0
```

### 3.22.3 Description

New in version 21Nov2023.

Define a computation that calculates a local composition vector for each atom. For a central atom with  $M$  neighbors within the neighbor cutoff sphere, composition is defined as the number of atoms of a given type (including the central atom) divided by  $(M + 1)$ . For a given central atom, the sum of all compositions equals one.

---

**Note:** This compute uses the number of atom types, not chemical species, assigned in *pair\_coeff* command. If an interatomic potential has two species (i.e., Cu and Ni) assigned to four different atom types in *pair\_coeff* (i.e., ‘Cu Cu Ni Ni’), the compute will output four fractional values. In those cases, the user may desire an extra calculation step to consolidate per-type fractions into per-species fractions. This calculation can be conducted within LAMMPS using another compute such as *compute reduce*, an atom-style *variable command*, or as a post-processing step.

---

The optional keyword *cutoff* defines the distance cutoff used when searching for neighbors. The default value is the cutoff specified by the pair style. If no pair style is defined, then a cutoff must be defined using this keyword. If the specified cutoff is larger than that of the pair\_style plus neighbor skin (or no pair style is defined), the *comm\_modify cutoff* option must also be set to match that of the *cutoff* keyword.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

---

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this compute uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the *rerun* command to compute the order parameter for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

---

### 3.22.4 Output info

This compute calculates a per-atom array with  $1 + N$  columns, where  $N$  is the number of atom types. The first column is a count of the number of atoms used to calculate composition (including the central atom), and each subsequent column indicates the fraction of that atom type within the cutoff sphere.

These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

### 3.22.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This compute requires *neighbor styles* 'bin' or 'nsq'.

### 3.22.6 Related commands

*comm\_modify*

### 3.22.7 Default

The option defaults are *cutoff* = pair style cutoff.

## 3.23 compute contact/atom command

### 3.23.1 Syntax

```
compute ID group-ID contact/atom group2-ID
```

- ID, group-ID are documented in *compute* command
- contact/atom = style name of this compute command
- group2-ID = optional argument to restrict which atoms to consider for contacts (see below)

### 3.23.2 Examples

```
compute 1 all contact/atom
compute 1 all contact/atom mygroup
```

### 3.23.3 Description

Define a computation that calculates the number of contacts for each atom in a group.

The contact number is defined for finite-size spherical particles as the number of neighbor atoms which overlap the central particle, meaning that their distance of separation is less than or equal to the sum of the radii of the two particles.

The value of the contact number will be 0.0 for atoms not in the specified compute group.

The optional *group2-ID* argument allows to specify from which group atoms contribute to the coordination number. Default setting is group 'all'.

### 3.23.4 Output info

This compute calculates a per-atom vector, whose values can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be a number  $\geq 0.0$ , as explained above.

### 3.23.5 Restrictions

This compute is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This compute requires that atoms store a radius as defined by the [atom\\_style sphere](#) command.

### 3.23.6 Related commands

*compute coord/atom*

### 3.23.7 Default

*group2-ID* = all

## 3.24 compute coord/atom command

Accelerator Variants: *coord/atom/kk*

### 3.24.1 Syntax

```
compute ID group-ID coord/atom style args ...
```

- ID, group-ID are documented in [compute](#) command
- coord/atom = style name of this compute command
- style = *cutoff* or *orientorder*

```
cutoff args = cutoff [group group2-ID] typeN
    cutoff = distance within which to count coordination neighbors (distance units)
    group group2-ID = select group-ID to restrict which atoms to consider for
    ↪ coordination number (optional)
    typeN = atom type for Nth coordination count (see asterisk form below)
orientorder args = orientorderID threshold
    orientorderID = ID of an orientorder/atom compute
    threshold = minimum value of the product of two "connected" atoms
```

### 3.24.2 Examples

```
compute 1 all coord/atom cutoff 2.0
compute 1 all coord/atom cutoff 6.0 1 2
compute 1 all coord/atom cutoff 6.0 2*4 5*8 *
compute 1 solute coord/atom cutoff 2.0 group solvent
compute 1 all coord/atom orientorder 2 0.5
```

### 3.24.3 Description

This compute performs calculations between neighboring atoms to determine a coordination value. The specific calculation and the meaning of the resulting value depend on the *cstyle* keyword used.

The *cutoff* *cstyle* calculates one or more traditional coordination numbers for each atom. A coordination number is defined as the number of neighbor atoms with specified atom type(s), and optionally within the specified group, that are within the specified cutoff distance from the central atom. The compute group selects only the central atoms; all neighboring atoms, unless selected by type, type range, or group option, are included in the coordination number tally.

The optional *group* keyword allows to specify from which group atoms contribute to the coordination number. Default setting is group ‘all.’

The *typeN* keywords allow specification of which atom types contribute to each coordination number. One coordination number is computed for each of the *typeN* keywords listed. If no *typeN* keywords are listed, a single coordination number is calculated, which includes atoms of all types (same as the “\*” format, see below).

The *typeN* keywords can be specified in one of two ways. An explicit numeric value can be used, as in the second example above. Or a wild-card asterisk can be used to specify a range of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *m* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive).

The *orientorder* *cstyle* calculates the number of “connected” neighbor atoms *j* around each central atom *i*. For this *cstyle*, connected is defined by the orientational order parameter calculated by the [compute orientorder/atom](#) command. This *cstyle* thus allows one to apply the ten Wolde’s criterion to identify crystal-like atoms in a system, as discussed in [ten Wolde](#).

The ID of the previously specified [compute orientorder/atom](#) command is specified as *orientorderID*. The compute must invoke its *components* option to calculate components of the *Ybar\_lm* vector for each atoms, as described in its documentation. Note that *orientorder/atom* compute defines its own criteria for identifying neighboring atoms. If the scalar product (*Ybar\_lm(i)*, *Ybar\_lm(j)*), calculated by the *orientorder/atom* compute is larger than the specified *threshold*, then *i* and *j* are connected, and the coordination value of *i* is incremented by one.

For all *cstyle* settings, all coordination values will be 0.0 for atoms not in the specified compute group.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e., each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

---

**Note:** If you have a bonded system, then the settings of [special\\_bonds](#) command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the [special\\_bonds](#) command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the coordination count. One way to get around this, is to write a dump file, and use the [rerun](#) command to compute the coordination for snapshots in the dump file. The rerun script can use a [special\\_bonds](#) command that includes all pairs in the neighbor list.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 3.24.4 Output info

For *cstyle* cutoff, this compute can calculate a per-atom vector or array. If single *type1* keyword is specified (or if none are specified), this compute calculates a per-atom vector. If multiple *typeN* keywords are specified, this compute calculates a per-atom array, with *N* columns.

For *cstyle* orientorder, this compute calculates a per-atom vector.

These values can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The per-atom vector or array values will be a number  $\geq 0.0$ , as explained above.

## 3.25 compute count/type command

### 3.25.1 Syntax

`compute ID group-ID count/type mode`

- ID, group-ID are documented in [compute](#) command
- count/type = style name of this compute command
- mode = *atom* or *bond* or *angle* or *dihedral* or *improper*

### 3.25.2 Examples

```
compute 1 all count/type atom
compute 1 flowmols count/type bond
```

### 3.25.3 Description

New in version 15Jun2023.

Define a computation that counts the current number of atoms for each atom type. Or the number of bonds (angles, dihedrals, impropers) for each bond (angle, dihedral, improper) type.

The former can be useful if atoms are added to or deleted from the system in random ways, e.g. via the *fix deposit*, *fix pour*, or *fix evaporate* commands. The latter can be useful in reactive simulations where molecular bonds are broken or created, as well as angles, dihedrals, impropers.

Note that for this command, bonds (angles, etc) are the topological kind enumerated in a data file, initially read by the *read\_data* command or defined by the *molecule* command. They do not refer to implicit bonds defined on-the-fly by bond-order or reactive pair styles based on the current conformation of small clusters of atoms.

These commands can turn off topological bonds (angles, etc) by setting their bond (angle, etc) types to negative values. This command includes the turned-off bonds (angles, etc) in the count for each type:

- *fix shake*
- *delete\_bonds*

These commands can create and/or break topological bonds (angles, etc). In the case of breaking, they remove the bond (angle, etc) from the system, so that they no longer exist (*bond\_style quartic* and *BPM bond styles* are exceptions, see the discussion below). Thus they are not included in the counts for each type:

- *delete\_bonds remove*
- *bond\_style quartic*
- *fix bond/react*
- *fix bond/create*
- *fix bond/break*
- *BPM package* bond styles

---

If the *mode* setting is *atom* then the count of atoms for each atom type is tallied. Only atoms in the specified group are counted.

The atom count for each type can be normalized by the total number of atoms like so:

```
compute typevec all count/type atom # number of atoms of each type
variable normtypes vector c_typevec/atoms # divide by total number of atoms
variable ntypes equal extract_setting(ntypes) # number of atom types
thermo_style custom step v_normtypes[*${ntypes}] # vector variable needs upper limit
```

Similarly, bond counts can be normalized by the total number of bonds. The same goes for angles, dihedrals, and impropers (see below).

If the *mode* setting is *bond* then the count of bonds for each bond type is tallied. Only bonds with both atoms in the specified group are counted.

For *mode* = *bond*, broken bonds with a bond type of zero are also counted. The *bond\_style quartic* and *BPM bond styles* break bonds by doing this. See the *Howto broken bonds* doc page for more details. Note that the group setting is ignored for broken bonds; all broken bonds in the system are counted.

If the *mode* setting is *angle* then the count of angles for each angle type is tallied. Only angles with all 3 atoms in the specified group are counted.

If the *mode* setting is *dihedral* then the count of dihedrals for each dihedral type is tallied. Only dihedrals with all 4 atoms in the specified group are counted.

If the *mode* setting is *improper* then the count of improper for each improper type is tallied. Only improper with all 4 atoms in the specified group are counted.

---

### 3.25.4 Output info

This compute calculates a global vector of counts. If the mode is *atom* or *bond* or *angle* or *dihedral* or *improper*, then the vector length is the number of atom types or bond types or angle types or dihedral types or improper types, respectively.

If the mode is *bond* this compute also calculates a global scalar which is the number of broken bonds with type = 0, as explained above.

These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are both “intensive”.

### 3.25.5 Restrictions

none

### 3.25.7 Default

none

## 3.26 compute damage/atom command

### 3.26.1 Syntax

**compute** ID group-ID damage/atom

- ID, group-ID are documented in *compute* command
- damage/atom = style name of this compute command

### 3.26.2 Examples

```
compute 1 all damage/atom
```

### 3.26.3 Description

Define a computation that calculates the per-atom damage for each atom in a group. This is a quantity relevant for *Peridynamics models*. See [this document](#) for an overview of LAMMPS commands for Peridynamics modeling.

The “damage” of a Peridynamics particles is based on the bond breakage between the particle and its neighbors. If all the bonds are broken the particle is considered to be fully damaged.

See the *Peridynamics Howto* for a formal definition of “damage” and more details about Peridynamics as it is implemented in LAMMPS.

This command can be used with all the Peridynamic pair styles.

The damage value will be 0.0 for atoms not in the specified compute group.

### 3.26.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers (damage)  $\geq 0.0$ .

### 3.26.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.26.6 Related commands

*compute dilatation/atom, compute plasticity/atom*

### 3.26.7 Default

## 3.27 compute dihedral command

### 3.27.1 Syntax

```
compute ID group-ID dihedral
```

- ID, group-ID are documented in *compute* command
- dihedral = style name of this compute command

### 3.27.2 Examples

```
compute 1 all dihedral
```

### 3.27.3 Description

Define a computation that extracts the dihedral energy calculated by each of the dihedral sub-styles used in the *dihedral\_style hybrid* command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using *dihedral\_style hybrid* if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

### 3.27.4 Output info

This compute calculates a global vector of length  $N$ , where  $N$  is the number of sub\_styles defined by the *dihedral\_style hybrid* command, which can be accessed by the indices 1 through  $N$ . These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy *units*.

### 3.27.5 Restrictions

none

## 3.28 compute dihedral/local command

### 3.28.1 Syntax

```
compute ID group-ID dihedral/local value1 value2 ... keyword args ...
```

- ID, group-ID are documented in *compute* command
- dihedral/local = style name of this compute command
- one or more values may be appended
- value = *phi* or *v\_name*  
*phi* = tabulate dihedral angles  
*v\_name* = equal-style variable with name (see below)

- zero or more keyword/args pairs may be appended
- keyword = *set*
  - set args = phi name
  - phi = only currently allowed arg
  - name = name of variable to set with phi

### 3.28.2 Examples

```
compute 1 all dihedral/local phi
compute 1 all dihedral/local phi v_cos set phi p
```

### 3.28.3 Description

Define a computation that calculates properties of individual dihedral interactions. The number of datums generated, aggregated across all processors, equals the number of dihedral angles in the system, modified by the group parameter as explained below.

The value *phi* ( $\phi$ ) is the dihedral angle, as defined in the diagram on the [dihedral\\_style](#) doc page.

The value *v\_name* can be used together with the *set* keyword to compute a user-specified function of the dihedral angle  $\phi$ . The *name* specified for the *v\_name* value is the name of an [equal-style variable](#) which should evaluate a formula based on a variable which will store the angle  $\phi$ . This other variable must be an [internal-style variable](#) defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The *set* keyword is used to identify the name of this other variable associated with  $\phi$ .

Note that the value of  $\phi$  for each angle which stored in the internal variable is in radians, not degrees.

As an example, these commands can be added to the bench/in.rhodo script to compute the  $\cos \phi$  and  $\cos^2 \phi$  of every dihedral angle in the system and output the statistics in various ways:

```
variable p internal 0.0
variable cos equal cos(v_p)
variable cossq equal cos(v_p)*cos(v_p)

compute 1 all property/local datum1 datum2 datum3 datum4 dtype
compute 2 all dihedral/local phi v_cos v_cossq set phi p
dump 1 all local 100 tmp.dump c_1[*] c_2[*]

compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]

fix 10 all ave/histo 10 10 100 -1 1 20 c_2[2] mode vector file tmp.histo
```

The *dump local* command will output the angle ( $\phi$ ),  $\cos(\phi)$ , and  $\cos^2(\phi)$  for every dihedral in the system. The *thermo\_style* command will print the average of those quantities via the [compute reduce](#) command with thermo output. And the *fix ave/histo* command will histogram the cosine(angle) values and write them to a file.

---

The local data stored by this command is generated by looping over all the atoms owned on a processor and their dipoles. A dihedral will only be included if all four atoms in the dihedral are in the specified compute group.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a

particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, dihedral output from the *compute property/local* command can be combined with data from this command and output by the *dump local* command in a consistent way.

Here is an example of how to do this:

```
compute 1 all property/local dtype datom1 datom2 datom3 datom4
compute 2 all dihedral/local phi
dump 1 all local 1000 tmp.dump index c_1[1] c_1[2] c_1[3] c_1[4] c_1[5] c_2[1]
```

### 3.28.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of dihedrals. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns is equal to the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The output for *phi* will be in degrees.

### 3.28.5 Restrictions

none

### 3.28.6 Related commands

*dump local*, *compute property/local*

### 3.28.7 Default

## 3.29 compute dilatation/atom command

### 3.29.1 Syntax

```
compute ID group-ID dilatation/atom
```

- ID, group-ID are documented in compute command
- dilatation/atom = style name of this compute command

### 3.29.2 Examples

```
compute 1 all dilatation/atom
```

### 3.29.3 Description

Define a computation that calculates the per-atom dilatation for each atom in a group. This is a quantity relevant for *Peridynamics models*. See [this document](#) for an overview of LAMMPS commands for Peridynamics modeling.

For small deformation, dilatation of is the measure of the volumetric strain.

The dilatation  $\theta$  for each peridynamic particle  $i$  is calculated as a sum over its neighbors with unbroken bonds, where the contribution of the  $ij$  pair is a function of the change in bond length (versus the initial length in the reference state), the volume fraction of the particles and an influence function. See the *Peridynamics Howto* for a formal definition of dilatation.

This command can only be used with a subset of the Peridynamic *pair styles*: *peri/lps*, *peri/ves*, and *peri/eps*.

The dilatation value will be 0.0 for atoms not in the specified compute group.

### 3.29.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers ( $\theta \geq 0.0$ ).

### 3.29.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.29.6 Related commands

*compute damage/atom*, *compute plasticity/atom*

### 3.29.7 Default

none

## 3.30 compute dipole command

## 3.31 compute dipole/tip4p command

### 3.31.1 Syntax

```
compute ID group-ID style arg
```

- ID, group-ID are documented in *compute* command
- style = *dipole* or *dipole/tip4p*
- arg = *mass* or *geometry* = use COM or geometric center for charged chunk correction (optional)

### 3.31.2 Examples

```
compute 1 fluid dipole
compute dw water dipole geometry
compute dw water dipole/tip4p
```

### 3.31.3 Description

Define a computation that calculates the dipole vector and total dipole for a group of atoms.

These computes calculate the x,y,z coordinates of the dipole vector and the total dipole moment for the atoms in the compute group. This includes all effects due to atoms passing through periodic boundaries. For a group with a net charge the resulting dipole is made position independent by subtracting the position vector of the center of mass or geometric center times the net charge from the computed dipole vector. Both per-atom charges and per-atom dipole moments, if present, contribute to the computed dipole.

New in version 28Mar2023.

Compute *dipole/tip4p* includes adjustments for the charge carrying point M in molecules with TIP4P water geometry. The corresponding parameters are extracted from the pair style.

---

**Note:** The coordinates of an atom contribute to the dipole in “unwrapped” form, by using the image flags associated with each atom. See the *dump custom* command for a discussion of “unwrapped” coordinates. See the Atoms section of the *read\_data* command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the *set image* command.

---

### 3.31.4 Output info

These computes calculate a global scalar containing the magnitude of the computed dipole moment and a global vector of length 3 with the dipole vector. See the *Howto output* page for an overview of LAMMPS output options.

The computed values are “intensive”. The array values will be in dipole units (i.e., charge *units* times distance *units*).

### 3.31.5 Restrictions

Compute style *dipole/tip4p* is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Compute style *dipole/tip4p* can only be used with tip4p pair styles.

### 3.31.6 Related commands

*compute dipole/chunk*

### 3.31.7 Default

Using the center of mass is the default setting for the net charge correction.

## 3.32 compute dipole/chunk command

## 3.33 compute dipole/tip4p/chunk command

### 3.33.1 Syntax

```
compute ID group-ID style chunkID arg
```

- ID, group-ID are documented in *compute* command
- style = *dipole/chunk* or *dipole/tip4p/chunk*
- chunkID = ID of *compute chunk/atom* command
- arg = *mass* or *geometry* = use COM or geometric center for charged chunk correction (optional)

### 3.33.2 Examples

```
compute 1 fluid dipole/chunk molchunk  
compute dw water dipole/chunk 1 geometry
```

### 3.33.3 Description

Define a computation that calculates the dipole vector and total dipole for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

These computes calculate the  $(x, y, z)$  coordinates of the dipole vector and the total dipole moment for each chunk, which includes all effects due to atoms passing through periodic boundaries. For chunks with a net charge the resulting dipole is made position independent by subtracting the position vector of the center of mass or geometric center times the net charge from the computed dipole vector. Both per-atom charges and per-atom dipole moments, if present, contribute to the computed dipole.

New in version 28Mar2023.

Compute *dipole/tip4p/chunk* includes adjustments for the charge carrying point M in molecules with TIP4P water geometry. The corresponding parameters are extracted from the pair style.

Note that only atoms in the specified group contribute to the calculation. The *compute chunk/atom* command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk,

and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

**Note:** The coordinates of an atom contribute to the chunk’s dipole in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

The simplest way to output the results of the compute com/chunk calculation to a file is to use the [fix ave/time](#) command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all dipole/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.33.4 Output info

These computes calculate a global array where the number of rows = the number of chunks *Nchunk* as calculated by the specified [compute chunk/atom](#) command. The number of columns is 4 for the (x, y, z) dipole vector components and the total dipole of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in dipole units (i.e., charge [units](#) times distance [units](#)).

### 3.33.5 Restrictions

Compute style *dipole/tip4p/chunk* is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Compute style *dipole/tip4p/chunk* can only be used with tip4p pair styles.

### 3.33.6 Related commands

[compute com/chunk](#), [compute dipole](#)

### 3.33.7 Default

Using the center of mass is the default setting for the net charge correction.

## 3.34 compute displace/atom command

### 3.34.1 Syntax

```
compute ID group-ID displace/atom
```

- ID, group-ID are documented in [compute](#) command
- displace/atom = style name of this compute command

- zero or more keyword/arg pairs may be appended
- keyword = *refresh*  
*refresh* arg = name of per-atom variable

### 3.34.2 Examples

```
compute 1 all displace/atom
compute 1 all displace/atom refresh myVar
```

### 3.34.3 Description

Define a computation that calculates the current displacement of each atom in the group from its original (reference) coordinates, including all effects due to atoms passing through periodic boundaries.

A vector of four quantities per atom is calculated by this compute. The first three elements of the vector are the ( $dx$ ,  $dy$ ,  $dz$ ) displacements. The fourth component is the total displacement (i.e.,  $\sqrt{dx^2 + dy^2 + dz^2}$ ).

The displacement of an atom is from its original position at the time the compute command was issued. The value of the displacement will be 0.0 for atoms not in the specified compute group.

---

**Note:** Initial coordinates are stored in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

---

---

**Note:** If you want the quantities calculated by this compute to be continuous when running from a [restart file](#), then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with time = 0 atom coordinates from the restart file.

---

The *refresh* option can be used in conjunction with the “dump\_modify refresh” command to generate incremental dump files.

The definition and motivation of an incremental dump file is as follows. Instead of outputting all atoms at each snapshot (with some associated values), you may only wish to output the subset of atoms with a value that has changed in some way compared to the value the last time that atom was output. In some scenarios this can result in a dramatically smaller dump file. If desired, by post-processing the sequence of snapshots, the values for all atoms at all timesteps can be inferred.

A concrete example using this compute, is a simulation of atom diffusion in a solid, represented as atoms on a lattice. Diffusive hops are rare. Imagine that when a hop occurs an atom moves more than a distance *Dhop*. For any snapshot we only want to output atoms that have hopped since the last snapshot. This can be accomplished with something like the following commands:

```
write_dump      all custom tmp.dump id type x y z      # see comment below
variable        Dhop equal 0.6
variable        check atom "c_dsp[4] > v_Dhop"
```

(continues on next page)

(continued from previous page)

```

compute      dsp all displace/atom refresh check
dump         1 all custom 100 tmp.dump id type x y z
dump_modify  1 append yes thresh c_dsp[4] > ${Dhop} &
              refresh c_dsp delay 100

```

The *dump\_modify thresh* command will only output atoms that have displaced more than 0.6 Å on each snapshot (assuming metal units). The *dump\_modify refresh* option triggers a call to this compute at the end of every dump.

The *refresh* argument for this compute is the ID of an *atom-style variable* which calculates a Boolean value (0 or 1) based on the same criterion used by *dump\_modify thresh*. This compute evaluates the atom-style variable. For each atom that returns 1 (true), the original (reference) coordinates of the atom (stored by this compute) are updated.

The effect of these commands is that a particular atom will only be output in the dump file on the snapshot after it makes a diffusive hop. It will not be output again until it makes another hop.

Note that in the first snapshot of a subsequent run, no atoms will be typically be output. That is because the initial displacement for all atoms is 0.0. If an initial dump snapshot is desired, containing the initial reference positions of all atoms, one way to do this is illustrated above. An initial *write\_dump* command can be used before the first run. It will contain the positions of all the atoms, Options in the *dump\_modify* command above will append new output to that same file and delay the output until a later timestep. The *delay* setting avoids a second time = 0 snapshot which would be empty.

### 3.34.4 Output info

This compute calculates a per-atom array with four columns, which can be accessed by indices 1–4 by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The per-atom array values will be in distance *units*.

This compute supports the *refresh* option as explained above, for use in conjunction with *dump\_modify refresh* to generate incremental dump files.

### 3.34.5 Restrictions

none

## 3.35 compute dpd command

### 3.35.1 Syntax

```
compute ID group-ID dpd
```

- ID, group-ID are documented in *compute* command
- dpd = style name of this compute command

### 3.35.2 Examples

```
compute 1 all dpd
```

### 3.35.3 Description

Define a computation that accumulates the total internal conductive energy ( $U^{\text{cond}}$ ), the total internal mechanical energy ( $U^{\text{mech}}$ ), the total chemical energy ( $U^{\text{chem}}$ ) and the *harmonic* average of the internal temperature ( $\theta_{\text{avg}}$ ) for the entire system of particles. See the *compute dpd/atom* command if you want per-particle internal energies and internal temperatures.

The system internal properties are computed according to the following relations:

$$\begin{aligned}U^{\text{cond}} &= \sum_{i=1}^N u_i^{\text{cond}} \\U^{\text{mech}} &= \sum_{i=1}^N u_i^{\text{mech}} \\U^{\text{chem}} &= \sum_{i=1}^N u_i^{\text{chem}} \\U &= \sum_{i=1}^N (u_i^{\text{cond}} + u_i^{\text{mech}} + u_i^{\text{chem}}) \\\theta_{\text{avg}} &= \left( \frac{1}{N} \sum_{i=1}^N \frac{1}{\theta_i} \right)^{-1}\end{aligned}$$

where  $N$  is the number of particles in the system.

---

### 3.35.4 Output info

This compute calculates a global vector of length 5 ( $U^{\text{cond}}$ ,  $U^{\text{mech}}$ ,  $U^{\text{chem}}$ ,  $\theta_{\text{avg}}$ ,  $N$ ), which can be accessed by indices 1 through 5. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector values will be in energy and temperature *units*.

### 3.35.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command also requires use of the [atom\\_style dpd](#) command.

## 3.36 compute dpd/atom command

### 3.36.1 Syntax

```
compute ID group-ID dpd/atom
```

- ID, group-ID are documented in [compute](#) command
- dpd/atom = style name of this compute command

### 3.36.2 Examples

```
compute 1 all dpd/atom
```

### 3.36.3 Description

Define a computation that accesses the per-particle internal conductive energy ( $u^{\text{cond}}$ ), internal mechanical energy ( $u^{\text{mech}}$ ), internal chemical energy ( $u^{\text{chem}}$ ) and internal temperatures ( $\theta$ ) for each particle in a group. See the [compute dpd](#) command if you want the total internal conductive energy, the total internal mechanical energy, the total chemical energy and average internal temperature of the entire system or group of dpd particles.

### 3.36.4 Output info

This compute calculates a per-particle array with four columns ( $u^{\text{cond}}$ ,  $u^{\text{mech}}$ ,  $u^{\text{chem}}$ ,  $\theta$ ), which can be accessed by indices 1–4 by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle array values will be in energy ( $u^{\text{cond}}$ ,  $u^{\text{mech}}$ ,  $u^{\text{chem}}$ ) and temperature ( $\theta$ ) *units*.

### 3.36.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command also requires use of the [atom\\_style dpd](#) command.

### 3.36.6 Related commands

## 3.37 compute edpd/temp/atom command

### 3.37.1 Syntax

```
compute ID group-ID edpd/temp/atom
```

- ID, group-ID are documented in [compute](#) command
- edpd/temp/atom = style name of this compute command

### 3.37.2 Examples

```
compute 1 all edpd/temp/atom
```

### 3.37.3 Description

Define a computation that calculates the per-atom temperature for each eDPD particle in a group.

The temperature is a local temperature derived from the internal energy of each eDPD particle based on the local equilibrium hypothesis. For more details please see ([Espanol1997](#)) and ([Li2014](#)).

### 3.37.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in temperature *units*.

### 3.37.5 Restrictions

This compute is part of the DPD-MESO package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.37.6 Related commands

*pair\_style edpd*

### 3.37.7 Default

none

## 3.38 compute efield/atom command

### 3.38.1 Syntax

```
compute ID group-ID efield/atom keyword val
```

- ID, group-ID are documented in [compute](#) command
- efield/atom = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *pair* or *kpace*

*pair* args = *yes* or *no*  
*kpace* args = *yes* or *no*

### 3.38.2 Examples

```
compute 1 all efield/atom  
compute 1 all efield/atom pair yes kspace no
```

Used in input scripts:

```
examples/PACKAGES/dielectric/in.confined  
examples/PACKAGES/dielectric/in.nopbc
```

### 3.38.3 Description

Define a computation that calculates the electric field at each atom in a group. The compute should only be enabled with *pair* and *kpace* styles that are provided by the DIELECTRIC package because only these styles compute the per-atom electric field at every time step.

The electric field is a 3-component vector. The value of the electric field components will be 0.0 for atoms not in the specified compute group.

---

The keyword/value option pairs are used in the following ways.

For the *pair* and *kpace* keywords, the real-space and reciprocal-space contributions to the electric field can be turned off and on.

### 3.38.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in electric field *units*.

### 3.38.5 Restrictions

This compute is part of the DIELECTRIC package. It is only enabled if LAMMPS was built with that package.

### 3.38.6 Related commands

*dump custom*

### 3.38.7 Default

The option defaults are pair = yes and kspace = yes.

## 3.39 compute efield/wolf/atom command

### 3.39.1 Syntax

```
compute ID group-ID efield/wolf/atom alpha keyword val
```

- ID, group-ID are documented in [compute](#) command
- efield/atom/wolf = style name of this compute command
- alpha = damping parameter (inverse distance units)
- zero or more keyword/value pairs may be appended
- keyword = *limit* or *cutoff*

*limit* group2-ID = limit computing the electric field contributions to a group.  
 → (default: all)

*cutoff* value = set cutoff for computing contributions to this value (default: 10.0)  
 → maximum cutoff of pair style)

### 3.39.2 Examples

```
compute 1 all efield/wolf/atom 0.2
compute 1 mols efield/wolf/atom 0.25 limit water cutoff 10.0
```

### 3.39.3 Description

New in version 8Feb2023.

Define a computation that approximates the electric field at each atom in a group.

$$\vec{E}_i = \frac{\vec{F}_{coul_i}}{q_i} = \sum_{j \neq i} \frac{q_j}{r_{ij}^2} \quad r < r_c$$

The electric field at the position of the atom  $i$  is the coulomb force on a unit charge at that point, which is equivalent to dividing the Coulomb force by the charge of the individual atom.

In this compute the electric field is approximated as the derivative of the potential energy using the Wolf summation method, described in [Wolf](#), given by:

$$E_i = \frac{1}{2} \sum_{j \neq i} \frac{q_i q_j \text{erfc}(\alpha r_{ij})}{r_{ij}} + \frac{1}{2} \sum_{j \neq i} \frac{q_i q_j \text{erf}(\alpha r_{ij})}{r_{ij}} \quad r < r_c$$

where  $\alpha$  is the damping parameter, and  $\text{erf}()$  and  $\text{erfc}()$  are error-function and complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, force-shifted, pairwise  $1/r$  summation. With a manipulation of adding and subtracting a self term (for  $i = j$ ) to the first and second term on the right-hand-side, respectively, and a small enough  $\alpha$  damping parameter, the second term shrinks and the potential becomes a

rapidly-converging real-space summation. With a long enough cutoff and small enough  $\alpha$  parameter, the electric field calculated by the Wolf summation method approaches that computed using the Ewald sum.

The value of the electric field components will be 0.0 for atoms not in the specified compute group.

When the *limit* keyword is used, only contributions from atoms in the selected group will be considered, otherwise contributions from all atoms within the cutoff are included.

When the *cutoff* keyword is used, the cutoff used for the electric field approximation can be set explicitly. By default it is the largest cutoff of any pair style force computation.

---

### Computational Efficiency

This compute will loop over a full neighbor list just like a pair style does when computing forces, thus it can be quite time-consuming and slow down a calculation significantly when its data is used in every time step. The *compute efield/atom* command of the DIELECTRIC package is more efficient in comparison, since the electric field data is collected and stored as part of the force computation at next to no extra computational cost.

---

## 3.39.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector contains 3 values per atom which are the x-, y-, and z-direction electric field components in force units.

## 3.39.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package.

This compute requires *neighbor styles 'bin' or 'nsq'*.

## 3.39.6 Related commands

*pair\_style coul/wolf*, *compute efield/atom*

## 3.39.7 Default

The option defaults are *limit* = all and *cutoff* = largest cutoff for pair styles.

---

(Wolf) D. Wolf, P. Keflin, S. R. Phillpot, J. Eggebrecht, J Chem Phys, 110, 8254 (1999).

## 3.40 compute entropy/atom command

### 3.40.1 Syntax

```
compute ID group-ID entropy/atom sigma cutoff keyword value ...
```

- ID, group-ID are documented in *compute* command
- entropy/atom = style name of this compute command
- sigma = width of Gaussians used in the  $g(r)$  smoothing
- cutoff = cutoff for the  $g(r)$  calculation
- one or more keyword/value pairs may be appended

keyword = *avg* or *local*

avg args = neigh cutoff2

neigh value = *yes* or *no* = whether to average the pair entropy over neighbors

cutoff2 = cutoff for the averaging over neighbors

local arg = *yes* or *no* = use the local density around each atom to normalize the  $g(r)$

### 3.40.2 Examples

```
compute 1 all entropy/atom 0.25 5.
compute 1 all entropy/atom 0.25 5. avg yes 5.
compute 1 all entropy/atom 0.125 7.3 avg yes 5.1 local yes
```

### 3.40.3 Description

Define a computation that calculates the pair entropy fingerprint for each atom in the group. The fingerprint is useful to distinguish between ordered and disordered environments, for instance liquid and solid-like environments, or glassy and crystalline-like environments. Some applications could be the identification of grain boundaries, a melt-solid interface, or a solid cluster emerging from the melt. The advantage of this parameter over others is that no a priori information about the solid structure is required.

This parameter for atom  $i$  is computed using the following formula from (Piaggi) and (Nettleton),

$$s_S^i = -2\pi\rho k_B \int_0^{r_m} [g(r) \ln g(r) - g(r) + 1] r^2 dr$$

where  $r$  is a distance,  $g(r)$  is the radial distribution function of atom  $i$ , and  $\rho$  is the density of the system. The  $g(r)$  computed for each atom  $i$  can be noisy and therefore it is smoothed using

$$g_m^i(r) = \frac{1}{4\pi\rho r^2} \sum_j \frac{1}{\sqrt{2\pi\sigma^2}} e^{-(r-r_{ij})^2/(2\sigma^2)}$$

where the sum over  $j$  goes through the neighbors of atom  $i$  and  $\sigma$  is a parameter to control the smoothing.

The input parameters are *sigma* the smoothing parameter  $\sigma$ , and the *cutoff* for the calculation of  $g(r)$ .

If the keyword *avg* has the setting *yes*, then this compute also averages the parameter over the neighbors of atom  $i$  according to

$$\langle s_S^i \rangle = \frac{\sum_j s_S^j + s_S^i}{N + 1},$$

where the sum over  $j$  goes over the neighbors of atom  $i$  and  $N$  is the number of neighbors. This procedure provides a sharper distinction between order and disorder environments. In this case the input parameter *cutoff2* is the cutoff for the averaging over the neighbors and must also be specified.

If the *avg yes* option is used, the effective cutoff of the neighbor list should be *cutoff+cutoff2* and therefore it might be necessary to increase the skin of the neighbor list with:

```
neighbor <skin distance> bin
```

See *neighbor* for details.

If the *local yes* option is used, the  $g(r)$  is normalized by the local density around each atom, that is to say the density around each atom is the number of neighbors within the neighbor list cutoff divided by the corresponding volume. This option can be useful when dealing with inhomogeneous systems such as those that have surfaces.

Here are typical input parameters for fcc aluminum (lattice constant 4.05 Å),

```
compute 1 all entropy/atom 0.25 5.7 avg yes 3.7
```

and for bcc sodium (lattice constant 4.23 Å),

```
compute 1 all entropy/atom 0.25 7.3 avg yes 5.1
```

### 3.40.4 Output info

By default, this compute calculates the pair entropy value for each atom as a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The pair entropy values have units of the Boltzmann constant. They are always negative, and lower values (lower entropy) correspond to more ordered environments.

### 3.40.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.40.6 Related commands

*compute cna/atom compute centro/atom*

### 3.40.7 Default

The default values for the optional keywords are *avg = no* and *local = no*.

---

(Nettleton) Nettleton and Green, J Chem Phys, 29, 6 (1958).

## 3.41 compute erotate/asphere command

### 3.41.1 Syntax

```
compute ID group-ID erotate/asphere
```

- ID, group-ID are documented in [compute](#) command
- erotate/asphere = style name of this compute command

### 3.41.2 Examples

```
compute 1 all erotate/asphere
```

### 3.41.3 Description

Define a computation that calculates the rotational kinetic energy of a group of aspherical particles. The aspherical particles can be ellipsoids, or line segments, or triangles. See the [atom\\_style](#) and [read\\_data](#) commands for descriptions of these options.

For all 3 types of particles, the rotational kinetic energy is computed as  $\frac{1}{2}I\omega^2$ , where  $I$  is the inertia tensor for the aspherical particle and  $\omega$  is its angular velocity, which is computed from its angular momentum if needed.

---

**Note:** For *2d models*, ellipsoidal particles are treated as ellipsoids, not ellipses, meaning their moments of inertia will be the same as in 3d.

---

### 3.41.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

### 3.41.5 Restrictions

This compute requires that ellipsoidal particles atoms store a shape and quaternion orientation and angular momentum as defined by the [atom\\_style ellipsoid](#) command.

This compute requires that line segment particles atoms store a length and orientation and angular velocity as defined by the [atom\\_style line](#) command.

This compute requires that triangular particles atoms store a size and shape and quaternion orientation and angular momentum as defined by the [atom\\_style tri](#) command.

All particles in the group must be of finite size. They cannot be point particles.

### 3.41.6 Related commands

none

*compute erotate/sphere*

### 3.41.7 Default

none

## 3.42 compute erotate/rigid command

### 3.42.1 Syntax

```
compute ID group-ID erotate/rigid fix-ID
```

- ID, group-ID are documented in *compute* command
- erotate/rigid = style name of this compute command
- fix-ID = ID of rigid body fix

### 3.42.2 Examples

```
compute 1 all erotate/rigid myRigid
```

### 3.42.3 Description

Define a computation that calculates the rotational kinetic energy of a collection of rigid bodies, as defined by one of the *fix rigid* command variants.

The rotational energy of each rigid body is computed as  $\frac{1}{2}I\omega_{\text{body}}^2$ , where  $I$  is the inertia tensor for the rigid body and  $\omega_{\text{body}}$  is its angular velocity vector. Both  $I$  and  $\omega_{\text{body}}$  are in the frame of reference of the rigid body (i.e.,  $I$  is diagonal).

The *fix-ID* should be the ID of one of the *fix rigid* commands which defines the rigid bodies. The group specified in the compute command is ignored. The rotational energy of all the rigid bodies defined by the fix rigid command is included in the calculation.

### 3.42.4 Output info

This compute calculates a global scalar (the summed rotational energy of all the rigid bodies). This value can be used by any command that uses a global scalar value from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

### 3.42.5 Restrictions

This compute is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.42.6 Related commands

*compute ke/rigid*

### 3.42.7 Default

none

## 3.43 compute erotate/sphere command

Accelerator Variants: *erotate/sphere/kk*

### 3.43.1 Syntax

```
compute ID group-ID erotate/sphere
```

- ID, group-ID are documented in *compute* command
- erotate/sphere = style name of this compute command

### 3.43.2 Examples

```
compute 1 all erotate/sphere
```

### 3.43.3 Description

Define a computation that calculates the rotational kinetic energy of a group of spherical particles.

The rotational energy is computed as  $\frac{1}{2}I\omega^2$ , where  $I$  is the moment of inertia for a sphere and  $\omega$  is the particle's angular velocity.

---

**Note:** For *2d models*, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3d.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 3.43.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

### 3.43.5 Restrictions

This compute requires that atoms store a radius and angular velocity (omega) as defined by the *atom\_style sphere* command.

All particles in the group must be finite-size spheres or point particles. They cannot be aspherical. Point particles will not contribute to the rotational energy.

### 3.43.6 Related commands

*compute erotate/asphere*

### 3.43.7 Default

none

## 3.44 compute erotate/sphere/atom command

### 3.44.1 Syntax

```
compute ID group-ID erotate/sphere/atom
```

- ID, group-ID are documented in *compute* command
- erotate/sphere/atom = style name of this compute command

### 3.44.2 Examples

```
compute 1 all erotate/sphere/atom
```

### 3.44.3 Description

Define a computation that calculates the rotational kinetic energy for each particle in a group.

The rotational energy is computed as  $\frac{1}{2}I\omega^2$ , where  $I$  is the moment of inertia for a sphere and  $\omega$  is the particle's angular velocity.

---

**Note:** For *2d models*, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3d.

---

The value of the rotational kinetic energy will be 0.0 for atoms not in the specified compute group or for point particles with a radius of 0.0.

### 3.44.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-atom vector values will be in energy *units*.

### 3.44.5 Restrictions

none

### 3.44.6 Related commands

*dump custom*

### 3.44.7 Default

none

## 3.45 compute event/displace command

### 3.45.1 Syntax

```
compute ID group-ID event/displace threshold
```

- ID, group-ID are documented in *compute* command
- event/displace = style name of this compute command
- threshold = minimum distance any particle must move to trigger an event (distance units)

### 3.45.2 Examples

```
compute 1 all event/displace 0.5
```

### 3.45.3 Description

Define a computation that flags an “event” if any particle in the group has moved a distance greater than the specified threshold distance when compared to a previously stored reference state (i.e., the previous event). This compute is typically used in conjunction with the *prd* and *tad* commands, to detect if a transition to a new minimum energy basin has occurred.

This value calculated by the compute is equal to 0 if no particle has moved far enough, and equal to 1 if one or more particles have moved further than the threshold distance.

---

**Note:** If the system is undergoing significant center-of-mass motion, due to thermal motion, an external force, or an initial net momentum, then this compute will not be able to distinguish that motion from local atom displacements and may generate “false positives”.

---

### 3.45.4 Output info

This compute calculates a global scalar (the flag). This value can be used by any command that uses a global scalar value from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The scalar value will be a 0 or 1 as explained above.

### 3.45.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the [Build package](#) doc page for more info.

### 3.45.6 Related commands

*prd*, *tad*

### 3.45.7 Default

## 3.46 compute fabric command

### 3.46.1 Syntax

```
compute ID group-ID fabric cutoff attribute ... keyword values ...
```

- ID, group-ID are documented in [compute](#) command
- fabric = style name of this compute command

- cutoff = *type* or *radius*  
*type* = cutoffs determined based on atom types  
*radius* = cutoffs determined based on atom diameters (atom style sphere)
- one or more attributes may be appended
- attribute = *contact* or *branch* or *force/normal* or *force/tangential*  
*contact* = contact tensor  
*branch* = branch tensor  
*force/normal* = normal force tensor  
*force/tangential* = tangential force tensor
- zero or more keyword/value pairs may be appended
- keyword = *type/include*  
*type/include* value = arg1 arg2  
arg = separate lists of types (see below)

### 3.46.2 Examples

```
compute 1 all fabric type contact force/normal type/include 1,2 3*4
compute 1 all fabric radius force/normal force/tangential
```

### 3.46.3 Description

Define a compute that calculates various fabric tensors for pairwise interaction (*Ouadfel*). Fabric tensors are commonly used to quantify the anisotropy or orientation of granular contacts but can also be used to characterize the direction of pairwise interactions in general systems. The *type* and *radius* settings are used to select whether interactions cutoffs are determined by atom types or by the sum of atomic radii (atom style sphere), respectively. Calling this compute is roughly the cost of a pair style invocation as it involves a loop over the neighbor list. If the normal or tangential force tensors are requested, it will be more expensive than a pair style invocation as it will also recalculate all pair forces.

Four fabric tensors are available: the contact, branch, normal force, or tangential force tensor. The contact tensor is calculated as

$$C_{ab} = \frac{15}{2}(\phi_{ab} - \frac{1}{3}\text{Tr}(\phi)\delta_{ab})$$

where  $a$  and  $b$  are the  $x, y, z$  directions,  $\delta_{ab}$  is the Kronecker delta function, and the tensor  $\phi$  is defined as

$$\phi_{ab} = \sum_{n=1}^{N_p} \frac{r_a r_b}{r^2}$$

where  $n$  loops over the  $N_p$  pair interactions in the simulation,  $r_a$  is the  $a$  component of the radial vector between the two pairwise interacting particles, and  $r$  is the magnitude of the radial vector.

The branch tensor is calculated as

$$B_{ab} = \frac{15}{2\text{Tr}(D)}(D_{ab} - \frac{1}{3}\text{Tr}(D)\delta_{ab})$$

where the tensor  $D$  is defined as

$$D_{ab} = \sum_{n=1}^{N_p} \frac{1}{N_c(r^2 + C_{cd}r_c r_d)} \frac{r_a r_b}{r}$$

where  $N_c$  is the total number of contacts in the system and the subscripts  $c$  and  $d$  indices are summed according to Einstein notation.

The normal force fabric tensor is calculated as

$$F_{ab}^n = \frac{15}{2\text{Tr}(N)}(N_{ab} - \frac{1}{3}\text{Tr}(N)\delta_{ab})$$

where the tensor  $N$  is defined as

$$N_{ab} = \sum_{n=1}^{N_p} \frac{1}{N_c(r^2 + C_{cd}r_cr_d)} \frac{r_ar_b}{r^2} f_n$$

and  $f_n$  is the magnitude of the normal, central-body force between the two atoms.

Finally, the tangential force fabric tensor is only defined for pair styles that apply tangential forces to particles, namely granular pair styles. It is calculated as

$$F_{ab}^t = \frac{5}{\text{Tr}(N)}(T_{ab} - \frac{1}{3}\text{Tr}(T)\delta_{ab})$$

where the tensor  $T$  is defined as

$$T_{ab} = \sum_{n=1}^{N_p} \frac{1}{N_c(r^2 + C_{cd}r_cr_d)} \frac{r_ar_b}{r^2} f_t$$

and  $f_t$  is the magnitude of the tangential force between the two atoms.

The *type/include* keyword filters interactions based on the types of the two atoms. Interactions between two atoms are only included in calculations if the atom types are in the two lists. Each list consists of a series of type ranges separated by commas. The range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. For example, if  $M$  is the number of atom types, then an asterisk with no numeric values means all types from 1 to  $M$ . A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to  $M$  (inclusive). A middle asterisk means all types from m to n (inclusive). Multiple *type/include* keywords may be added.

### 3.46.4 Output info

This compute calculates a global vector of doubles and a global scalar. The vector stores the unique components of the first requested tensor in the order  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$  followed by the same components for all subsequent tensors. The length of the vector is therefore six times the number of requested tensors. The scalar output is the number of pairwise interactions included in the calculation of the fabric tensor.

### 3.46.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) doc page for more info.

Currently, compute *fabric* does not support pair styles with many-body interactions. It also does not support models with long-range Coulombic or dispersion forces, i.e. the `kspace_style` command in LAMMPS. It also does not support the following fixes which add rigid-body constraints: *fix shake*, *fix rattle*, *fix rigid*, *fix rigid/small*. It does not support granular pair styles that extend beyond the contact of atomic radii (e.g., JKR and DMT).

atom args = aparam I v_delta
  aparam = charge = parameter to perturb
  I = type to set parameter for
  v_delta = variable with perturbation to apply (in the units of the parameter)
```

- zero or more keyword/value pairs may be appended
- keyword = *tail* or *volume*

```
tail value = no or yes
  no = ignore tail correction to pair energies (usually small in fep)
  yes = include tail correction to pair energies
volume value = no or yes
  no = ignore volume changes (e.g., in NVE or NVT trajectories)
  yes = include volume changes (e.g., in NPT trajectories)
```

### 3.47.2 Examples

```
compute 1 all fep 298 pair lj/cut epsilon 1 * v_delta pair lj/cut sigma 1 * v_delta
→volume yes
compute 1 all fep 300 atom charge 2 v_delta
```

Example input scripts available: examples/PACKAGES/fep

### 3.47.3 Description

Apply a perturbation to parameters of the interaction potential and recalculate the pair potential energy without changing the atomic coordinates from those of the reference, unperturbed system. This compute can be used to calculate free energy differences using several methods, such as free-energy perturbation (FEP), finite-difference thermodynamic integration (FDTI) or Bennet's acceptance ratio method (BAR).

The potential energy of the system is decomposed in three terms: a background term corresponding to interaction sites whose parameters remain constant, a reference term  $U_0$  corresponding to the initial interactions of the atoms that will undergo perturbation, and a term  $U_1$  corresponding to the final interactions of these atoms:

$$U(\lambda) = U_{\text{bg}} + U_1(\lambda) + U_0(\lambda)$$

A coupling parameter  $\lambda$  varying from 0 to 1 connects the reference and perturbed systems:

$$\begin{aligned}\lambda = 0 &\Rightarrow U = U_{\text{bg}} + U_0 \\ \lambda = 1 &\Rightarrow U = U_{\text{bg}} + U_1\end{aligned}$$

It is possible but not necessary that the coupling parameter (or a function thereof) appears as a multiplication factor of the potential energy. Therefore, this compute can apply perturbations to interaction parameters that are not directly proportional to the potential energy (e.g.,  $\sigma$  in Lennard-Jones potentials).

This command can be combined with *fix adapt* to perform multistage free-energy perturbation calculations along step-wise alchemical transformations during a simulation run:

$$\Delta_0^1 A = \sum_{i=0}^{n-1} \Delta_{\lambda_i}^{\lambda_{i+1}} A = -k_B T \sum_{i=0}^{n-1} \ln \left\langle \exp \left( -\frac{U(\lambda_{i+1}) - U(\lambda_i)}{k_B T} \right) \right\rangle_{\lambda_i}$$

This compute is suitable for the finite-difference thermodynamic integration (FDTI) method (*Mezei*), which is based on an evaluation of the numerical derivative of the free energy by a perturbation method using a very small  $\delta$ :

$$\Delta_0^1 A = \int_{\lambda=0}^{\lambda=1} \left( \frac{\partial A(\lambda)}{\partial \lambda} \right)_{\lambda} d\lambda \approx \sum_{i=0}^{n-1} w_i \frac{A(\lambda_i + \delta) - A(\lambda_i)}{\delta}$$

where  $w_i$  are weights of a numerical quadrature. The *fix adapt* command can be used to define the stages of  $\lambda$  at which the derivative is calculated and averaged.

The compute fep calculates the exponential Boltzmann term and also the potential energy difference  $U_1 - U_0$ . By choosing a very small perturbation  $\delta$  the thermodynamic integration method can be implemented using a numerical evaluation of the derivative of the potential energy with respect to  $\lambda$ :

$$\Delta_0^1 A = \int_{\lambda=0}^{\lambda=1} \left\langle \frac{\partial U(\lambda)}{\partial \lambda} \right\rangle_{\lambda} d\lambda \approx \sum_{i=0}^{n-1} w_i \left\langle \frac{U(\lambda_i + \delta) - U(\lambda_i)}{\delta} \right\rangle_{\lambda_i}$$

Another technique to calculate free energy differences is the acceptance ratio method (*Bennet*), which can be implemented by calculating the potential energy differences with  $\delta = 1.0$  on both the forward and reverse routes:

$$\left\langle \frac{1}{1 + \exp [(U_1 - U_0 - \Delta_0^1 A) / k_B T]} \right\rangle_0 = \left\langle \frac{1}{1 + \exp [(U_0 - U_1 + \Delta_0^1 A) / k_B T]} \right\rangle_1$$

The value of the free energy difference is determined by numerical root finding to establish the equality.

Concerning the choice of how the atomic parameters are perturbed in order to setup an alchemical transformation route, several strategies are available, such as single-topology or double-topology strategies ([Pearlman](#)). The latter does not require modification of bond lengths, angles or other internal coordinates.

NOTES: This compute command does not take kinetic energy into account, therefore the masses of the particles should not be modified between the reference and perturbed states, or along the alchemical transformation route. This compute command does not change bond lengths or other internal coordinates ([Boresch](#), [Karplus](#)).

The *pair* attribute enables various parameters of potentials defined by the *pair\_style* and *pair\_coeff* commands to be changed, if the pair style supports it.

The *pstyle* argument is the name of the pair style. For example, *pstyle* could be specified as “lj/cut”. The *pparam* argument is the name of the parameter to change. This is a list of pair styles and parameters that can be used with this compute. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

<i>born</i>	a,b,c	type pairs
<i>buck</i> , <i>buck/coul/cut</i> , <i>buck/coul/long</i> , <i>buck/coul/msm</i>	a,c	type pairs
<i>buck/mdf</i>	a,c	type pairs
<i>coul/cut</i>	scale	type pairs
<i>coul/cut/soft</i>	lambda	type pairs
<i>coul/long</i> , <i>coul/msm</i>	scale	type pairs
<i>coul/long/soft</i>	scale, lambda	type pairs
<i>eam</i>	scale	type pairs
<i>gauss</i>	a	type pairs
<i>lennard/mdf</i>	a,b	type pairs
<i>lj/class2</i>	epsilon,sigma	type pairs
<i>lj/class2/coul/cut</i> , <i>lj/class2/coul/long</i>	epsilon,sigma	type pairs
<i>lj/cut</i>	epsilon,sigma	type pairs
<i>lj/cut/soft</i>	epsilon,sigma,lambda	type pairs
<i>lj/cut/coul/cut</i> , <i>lj/cut/coul/long</i> , <i>lj/cut/coul/msm</i>	epsilon,sigma	type pairs
<i>lj/cut/coul/cut/soft</i> , <i>lj/cut/coul/long/soft</i>	epsilon,sigma,lambda	type pairs
<i>lj/cut/tip4p/cut</i> , <i>lj/cut/tip4p/long</i>	epsilon,sigma	type pairs
<i>lj/cut/tip4p/long/soft</i>	epsilon,sigma,lambda	type pairs
<i>lj/expand</i>	epsilon,sigma,delta	type pairs
<i>lj/mdf</i>	epsilon,sigma	type pairs
<i>lj/sf/dipole/sf</i>	epsilon,sigma,scale	type pairs
<i>mie/cut</i>	epsilon,sigma,gamR,gamA	type pairs
<i>morse</i> , <i>morse/smooth/linear</i>	d0,r0,alpha	type pairs
<i>morse/soft</i>	d0,r0,alpha,lambda	type pairs
<i>nm/cut</i>	e0,r0,nn,mm	type pairs
<i>nm/cut/coul/cut</i> , <i>nm/cut/coul/long</i>	e0,r0,nn,mm	type pairs
<i>ufm</i>	epsilon,sigma,scale	type pairs
<i>soft</i>	a	type pairs

Note that it is easy to add new potentials and their parameters to this list. All it typically takes is adding an `extract()` method to the `pair_*.cpp` file associated with the potential.

Similar to the *pair\_coeff* command, I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above.  $I \leq J$  is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values. A wild-card asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types

from 1 to n (inclusive). A trailing asterisk means all types from m to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with  $I \leq J$  are considered; if asterisks imply type pairs where  $J < I$ , they are ignored.

If *pair\_style hybrid* or *hybrid/overlay* is being used, then the *pstyle* will be a sub-style name. You must specify I,J arguments that correspond to type pair values defined (via the *pair\_coeff* command) for that sub-style.

The *v\_name* argument for keyword *pair* is the name of an *equal-style variable* which will be evaluated each time this compute is invoked. It should be specified as *v\_name*, where name is the variable name.

---

The *atom* attribute enables atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be used with this compute:

- charge = charge on particle

The *v\_name* argument for keyword *pair* is the name of an *equal-style variable* which will be evaluated each time this compute is invoked. It should be specified as *v\_name*, where name is the variable name.

---

The *tail* keyword controls the calculation of the tail correction to “van der Waals” pair energies beyond the cutoff, if this has been activated via the *pair\_modify* command. If the perturbation is small, the tail contribution to the energy difference between the reference and perturbed systems should be negligible.

If the keyword *volume = yes*, then the Boltzmann term is multiplied by the volume so that correct ensemble averaging can be performed over trajectories during which the volume fluctuates or changes (*Allen and Tildesley*):

$$\Delta_0^1 A = -k_B T \sum_{i=0}^{n-1} \ln \frac{\left\langle V \exp \left( -\frac{U(\lambda_{i+1}) - U(\lambda_i)}{k_B T} \right) \right\rangle_{\lambda_i}}{\langle V \rangle_{\lambda_i}}$$

---

### 3.47.4 Output info

This compute calculates a global vector of length 3 which contains the energy difference (  $U_1 - U_0$  ) as *c\_ID*[1], the Boltzmann factor  $\exp(-(U_1 - U_0)/k_B T)$ , or  $V \exp(-(U_1 - U_0)/k_B T)$ , as *c\_ID*[2] and the volume of the simulation box  $V$  as *c\_ID*[3].  $U_1$  is the pair potential energy obtained with the perturbed parameters and  $U_0$  is the pair potential energy obtained with the unperturbed parameters. The energies include kspace terms if these are used in the simulation.

These output results can be used by any command that uses a global scalar or vector from a compute as input. See the *Howto output* page for an overview of LAMMPS output options. For example, the computed values can be averaged using *fix ave/time*.

The values calculated by this compute are “extensive”.

### 3.47.5 Restrictions

This compute is distributed as the FEP package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.47.6 Related commands

*fix adapt/fep, fix ave/time, pair\_style .../soft*

### 3.47.7 Default

The option defaults are *tail = no*, *volume = no*.

## 3.48 compute fep/ta command

### 3.48.1 Syntax

```
compute ID group-ID fep/ta temp plane scale_factor keyword value ...
```

- ID, group-ID are documented in the *compute* command
- fep/ta = name of this compute command
- temp = external temperature (as specified for constant-temperature run)
- plane = xy or xz or yz
- scale\_factor = multiplicative factor for change in plane area
- zero or more keyword/value pairs may be appended
- keyword = *tail*

*tail* value = *no* or *yes*

*no* = ignore tail correction to pair energies (usually small in fep)

*yes* = include tail correction to pair energies

### 3.48.2 Examples

```
compute 1 all fep/ta 298 xy 1.0005
```

### 3.48.3 Description

New in version 4May2022.

Define a computation that calculates the change in the free energy due to a test-area (TA) perturbation (*Gloor*). The test-area approach can be used to determine the interfacial tension of the system in a single simulation:

$$\gamma = \lim_{\Delta A \rightarrow 0} \left( \frac{\Delta A_{0 \rightarrow 1}}{\Delta A} \right)_{N,V,T} = -\frac{k_B T}{\Delta A} \ln \left\langle \exp \left( \frac{-(U_1 - U_0)}{k_B T} \right) \right\rangle_0$$

During the perturbation, both axes of *plane* are scaled by multiplying  $\sqrt{\text{scale\_factor}}$ , while the other axis divided by  $\text{scale\_factor}$  such that the overall volume of the system is maintained.

The *tail* keyword controls the calculation of the tail correction to “van der Waals” pair energies beyond the cutoff, if this has been activated via the *pair\_modify* command. If the perturbation is small, the tail contribution to the energy difference between the reference and perturbed systems should be negligible.

---

### 3.48.4 Output info

This compute calculates a global vector of length 3 which contains the energy difference ( $U_1 - U_0$ ) as c\_ID[1], the Boltzmann factor  $\exp(-(U_1 - U_0)/k_B T)$ , as c\_ID[2] and the change in the *plane* area  $\Delta A$  as c\_ID[3].  $U_1$  is the potential energy of the perturbed state and  $U_0$  is the potential energy of the reference state. The energies include kspace terms if these are used in the simulation.

These output results can be used by any command that uses a global scalar or vector from a compute as input. See the *Howto output* page for an overview of LAMMPS output options. For example, the computed values can be averaged using *fix ave/time*.

### 3.48.5 Restrictions

Constraints, like fix shake, may lead to incorrect values for energy difference.

This compute is distributed as the FEP package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.48.6 Related commands

*compute fep*

### 3.48.7 Default

The option defaults are *tail = no*.

## 3.49 compute global/atom command

### 3.49.1 Syntax

```
compute ID group-ID style index input1 input2 ...
```

- ID, group-ID are documented in *compute* command
- global/atom = style name of this compute command
- index = c\_ID, c\_ID[N], f\_ID, f\_ID[N], v\_name

```
c_ID = per-atom vector calculated by a compute with ID
c_ID[I] = Ith column of per-atom array calculated by a compute with ID
f_ID = per-atom vector calculated by a fix with ID
f_ID[I] = Ith column of per-atom array calculated by a fix with ID
v_name = per-atom vector calculated by an atom-style variable with name
```

- one or more inputs can be listed
- input = c\_ID, c\_ID[N], f\_ID, f\_ID[N], v\_name

```
c_ID = global vector calculated by a compute with ID
c_ID[I] = Ith column of global array calculated by a compute with ID, I can include ↵
↵wildcard (see below)
f_ID = global vector calculated by a fix with ID
f_ID[I] = Ith column of global array calculated by a fix with ID, I can include ↵
↵wildcard (see below)
v_name = global vector calculated by a vector-style variable with name
```

### 3.49.2 Examples

```
compute 1 all global/atom c_chunk c_com[1] c_com[2] c_com[3]
compute 1 all global/atom c_chunk c_com[*]
```

### 3.49.3 Description

Define a calculation that assigns global values to each atom from vectors or arrays of global values. The specified *index* parameter is used to determine which global value is assigned to each atom.

The *index* parameter must reference a per-atom vector or array from a *compute* or *fix* or the evaluation of an atom-style *variable*. Each *input* value must reference a global vector or array from a *compute* or *fix* or the evaluation of an vector-style *variable*. Details are given below.

The *index* value for an atom is used as an index  $I$  (from 1 to  $N$ , where  $N$  is the number of atoms) into the vector associated with each of the input values. The  $I$ th value from the input vector becomes one output value for that atom. If the atom is not in the specified group, or the index  $I < 1$  or  $I > M$ , where  $M$  is the actual length of the input vector, then an output value of 0.0 is assigned to the atom.

An example of how this command is useful, is in the context of “chunks” which are static or dynamic subsets of atoms. The *compute chunk/atom* command assigns unique chunk IDs to each atom. Its output can be used as the *index* parameter for this command. Various other computes with “chunk” in their style name, such as *compute com/chunk* or *compute msd/chunk*, calculate properties for each chunk. The output of these commands are global vectors or arrays,

with one or more values per chunk, and can be used as input values for this command. This command will then assign the global chunk value to each atom in the chunk, producing a per-atom vector or per-atom array as output. The per-atom values can then be output to a dump file or used by any command that uses per-atom values from a compute as input, as discussed on the [Howto output](#) doc page.

As a concrete example, these commands will calculate the displacement of each atom from the center-of-mass of the molecule it is in, and dump those values to a dump file. In this case, each molecule is a chunk.

```
compute cc1 all chunk/atom molecule
compute myChunk all com/chunk cc1
compute prop all property/atom xu yu zu
compute glob all global/atom c_cc1 c_myChunk[*]
variable dx atom c_prop[1]-c_glob[1]
variable dy atom c_prop[2]-c_glob[2]
variable dz atom c_prop[3]-c_glob[3]
variable dist atom sqrt(v_dx*v_dx+v_dy*v_dy+v_dz*v_dz)
dump 1 all custom 100 tmp.dump id xu yu zu c_glob[1] c_glob[2] c_glob[3] &
      v_dx v_dy v_dz v_dist
dump_modify 1 sort id
```

You can add these commands to the bench/in.chain script to see how they work.

---

Note that for input values from a compute or fix, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *m* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. For example, the following two compute global/atom commands are equivalent, since the [compute com/chunk](#) command creates a global array with three columns:

```
compute cc1 all chunk/atom molecule
compute com all com/chunk cc1
compute 1 all global/atom c_cc1 c_com[1] c_com[2] c_com[3]
compute 1 all global/atom c_cc1 c_com[*]
```

---

This section explains the *index* parameter. Note that it must reference per-atom values, as contrasted with the *input* values, which must reference global values.

Note that all of these options generate floating point values. When they are used as an index into the specified input vectors, they are simply rounded down to convert the value to integer indices. The final values should range from 1 to *N* (inclusive), since they are used to access values from *N*-length vectors.

If *index* begins with “c\_”, a compute ID must follow which has been previously defined in the input script. The compute must generate per-atom quantities. See the individual [compute](#) doc page for details. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the *I*th column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and [add them to LAMMPS](#). See the discussion above for how *I* can be specified with a wildcard asterisk to effectively specify multiple values.

If *index* begins with “f\_”, a fix ID must follow which has been previously defined in the input script. The Fix must generate per-atom quantities. See the individual [fix](#) page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute global/atom references the values, else an error

results. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the fix is used. Users can also write code for their own fix style and [add them to LAMMPS](#). See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If *index* begins with “v\_”, a variable name must follow which has been previously defined in the input script. It must be an *atom-style variable*. Atom-style variables can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to use as *index*.

---

This section explains the kinds of *input* values that can be used. Note that inputs reference global values, as contrasted with the *index* parameter which must reference per-atom values.

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. The compute must generate a global vector or array. See the individual [compute](#) doc page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the array calculated by the compute is used. Users can also write code for their own compute styles and [add them to LAMMPS](#). See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. The fix must generate a global vector or array. See the individual [fix](#) doc page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute global/atom references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the array calculated by the fix is used. Users can also write code for their own fix style and [add them to LAMMPS](#). See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. It must be a *vector-style variable*. Vector-style variables can reference thermodynamic keywords and various other attributes of atoms, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating a vector of global quantities which the *index* parameter will reference for assignment of global values to atoms.

---

### 3.49.4 Output info

If a single input is specified this compute produces a per-atom vector. If multiple inputs are specified, this compute produces a per-atom array values, where the number of columns is equal to the number of inputs specified. These values can be used by any command that uses per-atom vector or array values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector or array values will be in whatever units the corresponding input values are in.

## 3.50 compute group/group command

### 3.50.1 Syntax

```
compute ID group-ID group/group group2-ID keyword value ...
```

- ID, group-ID are documented in *compute* command
- group/group = style name of this compute command
- group2-ID = group ID of second (or same) group
- zero or more keyword/value pairs may be appended
- keyword = *pair* or *kpace* or *boundary* or *molecule*

*pair* value = *yes* or *no*

*kpace* value = *yes* or *no*

*boundary* value = *yes* or *no*

*molecule* value = *off* or *inter* or *intra*

### 3.50.2 Examples

```
compute 1 lower group/group upper  
compute 1 lower group/group upper kspace yes  
compute mine fluid group/group wall
```

### 3.50.3 Description

Define a computation that calculates the total energy and force interaction between two groups of atoms: the compute group and the specified group2. The two groups can be the same.

If the *pair* keyword is set to *yes*, which is the default, then the the interaction energy will include a pair component which is defined as the pairwise energy between all pairs of atoms where one atom in the pair is in the first group and the other is in the second group. Likewise, the interaction force calculated by this compute will include the force on the compute group atoms due to pairwise interactions with atoms in the specified group2.

---

**Note:** The energies computed by the *pair* keyword do not include tail corrections, even if they are enabled via the *pair\_modify* command.

---

If the *molecule* keyword is set to *inter* or *intra* than an additional check is made based on the molecule IDs of the two atoms in each pair before including their pairwise interaction energy and force. For the *inter* setting, the two atoms must be in different molecules. For the *intra* setting, the two atoms must be in the same molecule.

If the *kpace* keyword is set to *yes*, which is not the default, and if a *kpace\_style* is defined, then the interaction energy will include a Kspace component which is the long-range Coulombic energy between all the atoms in the first group and all the atoms in the second group. Likewise, the interaction force calculated by this compute will include the force on the compute group atoms due to long-range Coulombic interactions with atoms in the specified group2.

Normally the long-range Coulombic energy converges only when the net charge of the unit cell is zero. However, one can assume the net charge of the system is neutralized by a uniform background plasma, and a correction to the system energy can be applied to reduce artifacts. For more information see (*Bogusz*). If the *boundary* keyword is set to *yes*, which is the default, and *kpace* contributions are included, then this energy correction term will be added to the total group-group energy. This correction term does not affect the force calculation and will be zero if one or both of the groups are charge neutral. This energy correction term is the same as that included in the regular Ewald and PPPM routines.

---

**Note:** The *molecule* setting only affects the group/group contributions calculated by the *pair* keyword. It does not affect the group/group contributions calculated by the *kpace* keyword.

---

This compute does not calculate any bond or angle or dihedral or improper interactions between atoms in the two groups.

---

The pairwise contributions to the group-group interactions are calculated by looping over a neighbor list. The Kspace contribution to the group-group interactions require essentially the same amount of work (FFTs, Ewald summation) as computing long-range forces for the entire system. Thus it can be costly to invoke this compute too frequently.

---

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this compute uses a neighbor list, it also means those pairs will not be included in the group/group interaction. This does not apply when using long-range Coulomb interactions (*coul/long*, *coul/msm*, *coul/wolf* or similar). One way to get around this would be to set *special\_bond* scaling factors to very tiny numbers that are not exactly zero (e.g.,  $1.0 \times 10^{-50}$ ). Another workaround would be to write a dump file and use the *rerun* command to compute the group/group interactions for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

---

If you desire a breakdown of the interactions into a pairwise and Kspace component, simply invoke the compute twice with the appropriate yes/no settings for the *pair* and *kpace* keywords. This is no more costly than using a single compute with both keywords set to *yes*. The individual contributions can be summed in a *variable* if desired.

This [document](#) describes how the long-range group-group calculations are performed.

---

### 3.50.4 Output info

This compute calculates a global scalar (the energy) and a global vector of length 3 (force), which can be accessed by indices 1–3. These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

Both the scalar and vector values calculated by this compute are “extensive”. The scalar value will be in energy *units*. The vector values will be in force *units*.

### 3.50.5 Restrictions

Not all pair styles can be evaluated in a pairwise mode as required by this compute. For example, three-body and other many-body potentials, such as *Tersoff* and *Stillinger-Weber* cannot be used. *EAM* potentials will re-use previously computed embedding term contributions, so the computed pairwise forces and energies are based on the whole system and not valid if particles have been moved since.

Not all *Kspace styles* support the calculation of group/group interactions. The regular *ewald* and *pppm* styles do.

### 3.50.6 Related commands

Bogusz et al, J Chem Phys, 108, 7070 (1998)

## 3.51 compute gyration command

### 3.51.1 Syntax

```
compute ID group-ID gyration
```

- ID, group-ID are documented in *compute* command
- gyration = style name of this compute command

### 3.51.2 Examples

```
compute 1 molecule gyration
```

### 3.51.3 Description

Define a computation that calculates the radius of gyration  $R_g$  of the group of atoms, including all effects due to atoms passing through periodic boundaries.

$R_g$  is a measure of the size of the group of atoms, and is computed as the square root of the  $R_g^2$  value in this formula

$$R_g^2 = \frac{1}{M} \sum_i m_i (r_i - r_{\text{cm}})^2$$

where  $M$  is the total mass of the group,  $r_{\text{cm}}$  is the center-of-mass position of the group, and the sum is over all atoms in the group.

A  $R_g^2$  tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that  $(r_i - r_{\text{cm}})^2$  is replaced by  $(r_{i,x} - r_{\text{cm},x}) \cdot (r_{i,y} - r_{\text{cm},y})$  for the  $xy$  component, and so on. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ . Note that unlike the scalar  $R_g$ , each of the six values of the tensor is effectively a “squared” value, since the cross-terms may be negative and taking a square root would be invalid.

---

**Note:** The coordinates of an atom contribute to  $R_g$  in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

---

### 3.51.4 Output info

This compute calculates a global scalar ( $R_g$ ) and a global vector of length 6 ( $R_g^2$  tensor), which can be accessed by indices 1–6. These values can be used by any command that uses a global scalar value or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are “intensive”. The scalar and vector values will be in distance and distance<sup>2</sup> *units*, respectively.

### 3.51.5 Restrictions

## 3.52 compute gyration/chunk command

### 3.52.1 Syntax

```
compute ID group-ID gyration/chunk chunkID keyword value ...
```

- ID, group-ID are documented in *compute* command
- gyration/chunk = style name of this compute command
- chunkID = ID of *compute chunk/atom* command
- zero or more keyword/value pairs may be appended
- keyword = *tensor*  
*tensor* value = none

### 3.52.2 Examples

```
compute 1 molecule gyration/chunk molchunk
compute 2 molecule gyration/chunk molchunk tensor
```

### 3.52.3 Description

Define a computation that calculates the radius of gyration  $R_g$  for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the radius of gyration  $R_g$  for each chunk, which includes all effects due to atoms passing through periodic boundaries.

$R_g$  is a measure of the size of a chunk, and is computed by the formula

$$R_g^2 = \frac{1}{M} \sum_i m_i (r_i - r_{\text{cm}})^2$$

where  $M$  is the total mass of the chunk,  $r_{\text{cm}}$  is the center-of-mass position of the chunk, and the sum is over all atoms in the chunk.

Note that only atoms in the specified group contribute to the calculation. The *compute chunk/atom* command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

If the *tensor* keyword is specified, then the scalar  $R_g$  value is not calculated, but an  $R_g$  tensor is instead calculated for each chunk. The formula for the components of the tensor is the same as the above formula, except that  $(r_i - r_{\text{cm}})^2$  is replaced by  $(r_{i,x} - r_{\text{cm},x}) \cdot (r_{i,y} - r_{\text{cm},y})$  for the  $xy$  component, and so on. The six components of the tensor are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ .

**Note:** The coordinates of an atom contribute to  $R_g$  in “unwrapped” form, by using the image flags associated with each atom. See the *dump custom* command for a discussion of “unwrapped” coordinates. See the Atoms section of the

[read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

The simplest way to output the results of the compute gyration/chunk calculation to a file is to use the [fix ave/time](#) command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all gyration/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk file tmp.out mode vector
```

### 3.52.4 Output info

This compute calculates a global vector if the *tensor* keyword is not specified and a global array if it is. The length of the vector or number of rows in the array = the number of chunks *Nchunk* as calculated by the specified [compute chunk/atom](#) command. If the *tensor* keyword is specified, the global array has six columns. The vector or array can be accessed by any command that uses global values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

All the vector or array values calculated by this compute are “intensive”. The vector or array values will be in distance *units*, since they are the square root of values represented by the formula above.

### 3.52.5 Restrictions

## 3.53 compute gyration/shape command

### 3.53.1 Syntax

```
compute ID group-ID gyration/shape compute-ID
```

- ID, group-ID are documented in [compute](#) command
- gyration/shape = style name of this compute command
- compute-ID = ID of [compute gyration](#) command

### 3.53.2 Examples

```
compute 1 molecule gyration/shape pe
```

### 3.53.3 Description

Define a computation that calculates the eigenvalues of the gyration tensor of a group of atoms and three shape parameters. The computation includes all effects due to atoms passing through periodic boundaries.

The three computed shape parameters are the asphericity,  $b$ , the acylindricity,  $c$ , and the relative shape anisotropy,  $k$ , viz.,

$$\begin{aligned}b &= l_z - \frac{1}{2}(l_y + l_x) \\c &= l_y - l_x \\k &= \frac{3}{2} \frac{l_x^2 + l_y^2 + l_z^2}{(l_x + l_y + l_z)^2} - \frac{1}{2}\end{aligned}$$

where  $l_x \leq l_y \leq l_z$  are the three eigenvalues of the gyration tensor. A general description of these parameters is provided in ([Mattice](#)) while an application to polymer systems can be found in ([Theodorou](#)). The asphericity is always non-negative and zero only when the three principal moments are equal. This zero condition is met when the distribution of particles is spherically symmetric (hence the name asphericity) but also whenever the particle distribution is symmetric with respect to the three coordinate axes (e.g., when the particles are distributed uniformly on a cube, tetrahedron or other Platonic solid). The acylindricity is always non-negative and zero only when the two principal moments are equal. This zero condition is met when the distribution of particles is cylindrically symmetric (hence the name, acylindricity), but also whenever the particle distribution is symmetric with respect to the two coordinate axes (e.g., when the particles are distributed uniformly on a regular prism). The relative shape anisotropy is bounded between zero (if all points are spherically symmetric) and one (if all points lie on a line).

---

**Note:** The coordinates of an atom contribute to the gyration tensor in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

---

### 3.53.4 Output info

This compute calculates a global vector of length 6, which can be accessed by indices 1–6. The first three values are the eigenvalues of the gyration tensor followed by the asphericity, the acylindricity and the relative shape anisotropy. The computed values can be used by any command that uses global vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector values calculated by this compute are “intensive”. The first five vector values will be in distance2 [units](#) while the sixth one is dimensionless.

### 3.53.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

- compute-ID = ID of *compute gyration/chunk* command

### 3.54.2 Examples

```
compute 1 molecule gyration/shape/chunk pe
```

### 3.54.3 Description

Define a computation that calculates the eigenvalues of the gyration tensor and three shape parameters of multiple chunks of atoms. The computation includes all effects due to atoms passing through periodic boundaries.

The three computed shape parameters are the asphericity,  $b$ , the acylindricity,  $c$ , and the relative shape anisotropy,  $k$ , viz.,

$$b = l_z - \frac{1}{2}(l_y + l_x)$$

$$c = l_y - l_x$$

$$k = \frac{3}{2} \frac{l_x^2 + l_y^2 + l_z^2}{(l_x + l_y + l_z)^2} - \frac{1}{2}$$

where  $l_x \leq l_y \leq l_z$  are the three eigenvalues of the gyration tensor. A general description of these parameters is provided in ([Mattice](#)) while an application to polymer systems can be found in ([Theodorou](#)). The asphericity is always non-negative and zero only when the three principal moments are equal. This zero condition is met when the distribution of particles is spherically symmetric (hence the name asphericity) but also whenever the particle distribution is symmetric with respect to the three coordinate axes (e.g., when the particles are distributed uniformly on a cube, tetrahedron, or other Platonic solid). The acylindricity is always non-negative and zero only when the two principal moments are equal. This zero condition is met when the distribution of particles is cylindrically symmetric (hence the name, acylindricity), but also whenever the particle distribution is symmetric with respect to the two coordinate axes (e.g., when the particles are distributed uniformly on a regular prism). The relative shape anisotropy is bounded between 0 (if all points are spherically symmetric) and 1 (if all points lie on a line).

The tensor keyword must be specified in the compute gyration/chunk command.

---

**Note:** The coordinates of an atom contribute to the gyration tensor in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

---

### 3.54.4 Output info

## 3.55 compute heat/flux command

### 3.55.1 Syntax

```
compute ID group-ID heat/flux ke-ID pe-ID stress-ID
```

- ID, group-ID are documented in [compute](#) command
- heat/flux = style name of this compute command
- ke-ID = ID of a compute that calculates per-atom kinetic energy
- pe-ID = ID of a compute that calculates per-atom potential energy
- stress-ID = ID of a compute that calculates per-atom stress

### 3.55.2 Examples

```
compute myFlux all heat/flux myKE myPE myStress
```

### 3.55.3 Description

Define a computation that calculates the heat flux vector based on contributions from atoms in the specified group. This can be used by itself to measure the heat flux through a set of atoms (e.g., a region between two thermostatted reservoirs held at different temperatures), or to calculate a thermal conductivity using the equilibrium Green-Kubo formalism.

For other non-equilibrium ways to compute a thermal conductivity, see the [Howto kappa](#) doc page. These include use of the [fix thermal/conductivity](#) command for the Muller-Plathe method. Or the [fix heat](#) command which can add or subtract heat from groups of atoms.

The compute takes three arguments which are IDs of other [computes](#). One calculates per-atom kinetic energy (*ke-ID*), one calculates per-atom potential energy (*pe-ID*), and the third calculates per-atom stress (*stress-ID*).

**Note:** These other computes should provide values for all the atoms in the group this compute specifies. That means the other computes could use the same group as this compute, or they can just use group “all” (or any group whose atoms are superset of the atoms in this compute’s group). LAMMPS does not check for this.

In case of two-body interactions, the heat flux  $\mathbf{J}$  is defined as

$$\begin{aligned}\mathbf{J} &= \frac{1}{V} \left[ \sum_i e_i \mathbf{v}_i - \sum_i \mathbf{S}_i \mathbf{v}_i \right] \\ &= \frac{1}{V} \left[ \sum_i e_i \mathbf{v}_i + \sum_{i < j} (\mathbf{F}_{ij} \cdot \mathbf{v}_j) \mathbf{r}_{ij} \right] \\ &= \frac{1}{V} \left[ \sum_i e_i \mathbf{v}_i + \frac{1}{2} \sum_{i < j} (\mathbf{F}_{ij} \cdot (\mathbf{v}_i + \mathbf{v}_j)) \mathbf{r}_{ij} \right]\end{aligned}$$

$e_i$  in the first term of the equation is the per-atom energy (potential and kinetic). This is calculated by the computes *ke-ID* and *pe-ID*.  $\mathbf{S}_i$  in the second term is the per-atom stress tensor calculated by the compute *stress-ID*. See [compute stress/atom](#) and [compute centroid/stress/atom](#) for possible definitions of atomic stress  $\mathbf{S}_i$  in the case of bonded and many-body interactions. The tensor multiplies  $\mathbf{v}_i$  by a  $3 \times 3$  matrix to yield a vector. Note that as discussed below, the

1/V scaling factor in the equation for **J** is **not** included in the calculation performed by these computes; you need to add it for a volume appropriate to the atoms included in the calculation.

---

**Note:** The `compute pe/atom` and `compute stress/atom` commands have options for which terms to include in their calculation (pair, bond, etc). The heat flux calculation will thus include exactly the same terms. Normally you should use `compute stress/atom virial` or `compute centroid/stress/atom virial` so as not to include a kinetic energy term in the heat flux.

---

**Warning:** The compute `heat/flux` has been reported to produce unphysical values for angle, dihedral, improper and constraint force contributions when used with `compute stress/atom`, as discussed in (Surblys2019), (Boone) and (Surblys2021). You are strongly advised to use `compute centroid/stress/atom`, which has been implemented specifically for such cases.

**Warning:** Due to an implementation detail, the y and z components of heat flux from `fix rigid` contribution when computed via `compute stress/atom` are highly unphysical and should not be used.

The Green–Kubo formulas relate the ensemble average of the auto-correlation of the heat flux **J** to the thermal conductivity  $\kappa$ :

$$\kappa = \frac{V}{k_B T^2} \int_0^\infty \langle J_x(0) J_x(t) \rangle dt = \frac{V}{3k_B T^2} \int_0^\infty \langle \mathbf{J}(0) \cdot \mathbf{J}(t) \rangle dt$$

---

The heat flux can be output every so many timesteps (e.g., via the `thermo_style custom` command). Then as a post-processing operation, an auto-correlation can be performed, its integral estimated, and the Green–Kubo formula above evaluated.

The `fix ave/correlate` command can calculate the auto-correlation. The `trap()` function in the `variable` command can calculate the integral.

An example LAMMPS input script for solid argon is appended below. The result should be an average conductivity  $\approx 0.29 \text{ W/m} \cdot \text{K}$ .

---

### 3.55.4 Output info

This compute calculates a global vector of length 6. The first three components are the *x*, *y*, and *z* components of the full heat flux vector (i.e.,  $J_x$ ,  $J_y$ , and  $J_z$ ). The next three components are the *x*, *y*, and *z* components of just the convective portion of the flux (i.e., the first term in the equation for **J**). Each component can be accessed by indices 1–6. These values can be used by any command that uses global vector values from a compute as input. See the [Howto output](#) documentation for an overview of LAMMPS output options.

The vector values calculated by this compute are “extensive”, meaning they scale with the number of atoms in the simulation. They can be divided by the appropriate volume to get a flux, which would then be an “intensive” value, meaning independent of the number of atoms in the simulation. Note that if the compute group is “all”, then the appropriate volume to divide by is the simulation box volume. However, if a group with a subset of atoms is used, it should be the volume containing those atoms.

The vector values will be in energy\*velocity *units*. Once divided by a volume the units will be that of flux, namely energy/area/time *units*

## 3.56 compute hexorder/atom command

### 3.56.1 Syntax

```
compute ID group-ID hexorder/atom keyword values ...
```

- ID, group-ID are documented in *compute* command
- hexorder/atom = style name of this compute command
- one or more keyword/value pairs may be appended

keyword = *degree* or *nnn* or *cutoff*

*cutoff* value = distance cutoff

*nnn* value = number of nearest neighbors

*degree* value = degree *n* of order parameter

### 3.56.2 Examples

```
compute 1 all hexorder/atom
compute 1 all hexorder/atom degree 4 nnn 4 cutoff 1.2
```

### 3.56.3 Description

Define a computation that calculates  $q_n$  the bond-orientational order parameter for each atom in a group. The hexatic ( $n = 6$ ) order parameter was introduced by [Nelson and Halperin](#) as a way to detect hexagonal symmetry in two-dimensional systems. For each atom,  $q_n$  is a complex number (stored as two real numbers) defined as follows:

$$q_n = \frac{1}{nnn} \sum_{j=1}^{nnn} e^{ni\theta(r_{ij})}$$

where the sum is over the  $nnn$  nearest neighbors of the central atom. The angle  $\theta$  is formed by the bond vector  $r_{ij}$  and the  $x$  axis.  $\theta$  is calculated only using the  $x$  and  $y$  components, whereas the distance from the central atom is calculated using all three  $x$ ,  $y$ , and  $z$  components of the bond vector. Neighbor atoms not in the group are included in the order parameter of atoms in the group.

The optional keyword *cutoff* defines the distance cutoff used when searching for neighbors. The default value, also the maximum allowable value, is the cutoff specified by the pair style.

The optional keyword *nnn* defines the number of nearest neighbors used to calculate  $q_n$ . The default value is 6. If the value is NULL, then all neighbors up to the distance cutoff are used.

The optional keyword *degree* sets the degree  $n$  of the order parameter. The default value is 6. For a perfect hexagonal lattice with  $nnn = 6$ ,  $q_6 = e^{6i\phi}$  for all atoms, where the constant  $0 < \phi < \frac{\pi}{3}$  depends only on the orientation of the lattice relative to the  $x$  axis. In an isotropic liquid, local neighborhoods may still exhibit weak hexagonal symmetry, but because the orientational correlation decays quickly with distance, the value of  $\phi$  will be different for different atoms, and so when  $q_6$  is averaged over all the atoms in the system,  $|\langle q_6 \rangle| \ll 1$ .

The value of  $q_n$  is set to zero for atoms not in the specified compute group, as well as for atoms that have less than  $nnn$  neighbors within the distance cutoff.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

---

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the *rerun* command to compute the order parameter for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

---

### 3.56.4 Output info

This compute calculates a per-atom array with 2 columns, giving the real and imaginary parts  $q_n$ , a complex number restricted to the unit disk of the complex plane (i.e.,  $\Re(q_n)^2 + \Im(q_n)^2 \leq 1$ ).

These values can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

### 3.56.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.56.6 Related commands

*compute orientorder/atom, compute coord/atom, compute centro/atom*

### 3.56.7 Default

The option defaults are *cutoff* = pair style cutoff, *nnn* = 6, *degree* = 6

## 3.57 compute hma command

### 3.57.1 Syntax

`compute ID group-ID hma temp-ID keyword ...`

- ID, group-ID are documented in [compute](#) command
- hma = style name of this compute command
- temp-ID = ID of fix that specifies the set temperature during canonical simulation
- one or more keywords or keyword/argument pairs must be appended
- keyword = *anharmonic* or *u* or *p* or *cv*

*anharmonic* = compute will return anharmonic property values

*u* = compute will return potential energy

*p* value = Pharm = compute will return pressure

Pharm = difference between the harmonic pressure and lattice pressure  
as described below

*cv* = compute will return the heat capacity

### 3.57.2 Examples

```
compute 2 all hma 1 u
compute 2 all hma 1 anharmonic u p 0.9
compute 2 all hma 1 u cv
```

### 3.57.3 Description

Define a computation that calculates the properties of a solid (potential energy, pressure or heat capacity), using the harmonically-mapped averaging (HMA) method. This command yields much higher precision than the equivalent compute commands (*compute pe*, *compute pressure*, etc.) commands during a canonical simulation of an atomic crystal. Specifically, near melting HMA can yield averages of a given precision an order of magnitude faster than conventional methods, and this only improves as the temperatures is lowered. This is particularly important for evaluating the free energy by thermodynamic integration, where the low-temperature contributions are the greatest source of statistical uncertainty. Moreover, HMA has other advantages, including smaller potential-truncation effects, finite-size effects, smaller timestep inaccuracy, faster equilibration and shorter decorrelation time.

HMA should not be used if atoms are expected to diffuse. It is also restricted to simulations in the NVT ensemble. While this compute may be used with any potential in LAMMPS, it will provide inaccurate results for potentials that do not go to 0 at the truncation distance; *pair\_style lj/smooth/linear* and Ewald summation should work fine, while *pair\_style lj/cut* will perform poorly unless the potential is shifted (via *pair\_modify* shift) or the cutoff is large. Furthermore, computation of the heat capacity with this compute is restricted to those that implement the *single\_hessian* method in Pair. Implementing *single\_hessian* in additional pair styles is simple. Please contact Andrew Schultz (ajs42 at buffalo.edu) and David Kofke (kofke at buffalo.edu) if your desired pair style does not have this method. This is the list of pair styles that currently implement *single\_hessian*:

- *pair\_style lj/smooth/linear*

In this method, the analytically known harmonic behavior of a crystal is removed from the traditional ensemble averages, which leads to an accurate and precise measurement of the anharmonic contributions without contamination by noise produced by the already-known harmonic behavior. A detailed description of this method can be found in (Moustafa). The potential energy is computed by the formula:

$$\langle U \rangle_{\text{HMA}} = \frac{d}{2}(N-1)k_B T + \left\langle U + \frac{1}{2} \vec{F} \cdot \Delta \vec{r} \right\rangle$$

where  $N$  is the number of atoms in the system,  $k_B$  is Boltzmann's constant,  $T$  is the temperature,  $d$  is the dimensionality of the system (2 or 3 for 2d/3d),  $\vec{F} \cdot \Delta \vec{r}$  is the sum of dot products of the atomic force vectors and displacement (from lattice sites) vectors, and  $U$  is the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix energies.

The pressure is computed by the formula:

$$\langle P \rangle_{\text{HMA}} = \Delta \hat{P} + \left\langle P_{\text{vir}} + \frac{\beta \Delta \hat{P} - \rho}{d(N-1)} \vec{F} \cdot \Delta \vec{r} \right\rangle$$

where  $\rho$  is the number density of the system,  $\Delta \hat{P}$  is the difference between the harmonic and lattice pressure,  $P_{\text{vir}}$  is the virial pressure computed as the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix contributions to the force on each atom, and  $k_B = 1/k_B T$ . Although the method will work for any value of  $\Delta \hat{P}$  specified (use pressure *units*), the precision of the resultant pressure is sensitive to  $\Delta \hat{P}$ ; the precision tends to be best when  $\Delta \hat{P}$  is the actual the difference between the lattice pressure and harmonic pressure.

$$\langle C_V \rangle_{\text{HMA}} = \frac{d}{2}(N-1)k_B + \frac{1}{k_B T^2} \left( \langle U_{\text{HMA}}^2 \rangle - \langle U_{\text{HMA}} \rangle^2 \right) + \frac{1}{4T} \left\langle \vec{F} \cdot \Delta \vec{r} + \Delta r \cdot \Phi \cdot \Delta \vec{r} \right\rangle$$

where  $\Phi$  is the Hessian matrix. The compute hma command computes the full expression for  $C_V$  except for the  $\langle U_{\text{HMA}} \rangle^2$  in the variance term, which can be obtained by passing the *u* keyword; you must add this extra contribution to the  $C_V$

value reported by this compute. The variance term can cause significant round-off error when computing  $C_V$ . To address this, the *anharmonic* keyword can be passed and/or the output format can be specified with more digits.

```
thermo_modify format float '%22.15e'
```

The *anharmonic* keyword will instruct the compute to return anharmonic properties rather than the full properties, which include lattice, harmonic and anharmonic contributions. When using this keyword, the compute must be first active (it must be included via a *thermo\_style custom* command) while the atoms are still at their lattice sites (before equilibration).

The temp-ID specified with compute hma command should be same as the fix-ID of the Nose-Hoover (*fix nvt*) or Berendsen (*fix temp/berendsen*) thermostat used for the simulation. While using this command, the Langevin thermostat (*fix langevin*) should be avoided as its extra forces interfere with the HMA implementation.

---

**Note:** Compute hma command should be used right after the energy minimization, when the atoms are at their lattice sites. The simulation should not be started before this command has been used in the input script.

---

The following example illustrates the placement of this command in the input script:

```
min_style cg
minimize 1e-35 1e-15 50000 500000
compute 1 all hma thermostaid u
fix thermostaid all nvt temp 600.0 600.0 100.0
```

---

**Note:** Compute hma should be used when the atoms of the solid do not diffuse. Diffusion will reduce the precision in the potential energy computation.

---

---

**Note:** The *fix\_modify energy yes* command must also be specified if a fix is to contribute potential energy to this command.

---

An example input script that uses this compute is included in examples/PACKAGES/hma/ along with corresponding LAMMPS output showing that the HMA properties fluctuate less than the corresponding conventional properties.

### 3.57.4 Output info

This compute calculates a global vector that includes the *n* properties requested as arguments to the command (the potential energy, pressure and/or heat capacity). The elements of the vector can be accessed by indices 1–*n* by any command that uses global vector values as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector values calculated by this compute are “extensive”. The scalar value will be in energy *units*.

### 3.57.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is enabled only if LAMMPS was built with that package. See the [Build package](#) page for more info.

Usage restricted to canonical (NVT) ensemble simulation only.

### 3.57.6 Related commands

*compute pe*, *compute pressure*

*dynamical matrix* provides a finite difference formulation of the Hessian provided by Pair’s `single_hessian`, which is used by this compute.

### 3.57.7 Default

none

## 3.58 compute improper command

### 3.58.1 Syntax

```
compute ID group-ID improper
```

- ID, group-ID are documented in [compute](#) command
- improper = style name of this compute command

### 3.58.2 Examples

```
compute 1 all improper
```

### 3.58.3 Description

Define a computation that extracts the improper energy calculated by each of the improper sub-styles used in the *improper\_style hybrid* command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using *improper\_style hybrid* if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

### 3.58.4 Output info

This compute calculates a global vector of length  $N$ , where  $N$  is the number of sub\_styles defined by the *improper\_style hybrid* command. These styles can be accessed by the indices 1 through  $N$ . These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy *units*.

### 3.58.5 Restrictions

none

### 3.58.6 Related commands

*compute pe, compute pair*

### 3.58.7 Default

none

## 3.59 compute improper/local command

### 3.59.1 Syntax

```
compute ID group-ID improper/local value1 value2 ...
```

- ID, group-ID are documented in *compute* command
- improper/local = style name of this compute command
- one or more values may be appended
- value = *chi*  
*chi* = tabulate improper angles

### 3.59.2 Examples

```
compute 1 all improper/local chi
```

### 3.59.3 Description

Define a computation that calculates properties of individual improper interactions. The number of datums generated, aggregated across all processors, equals the number of impropers in the system, modified by the group parameter as explained below.

The value *chi* is the improper angle, as defined in the doc pages for the individual improper styles listed on *improper\_style* doc page.

The local data stored by this command is generated by looping over all the atoms owned on a processor and their impropers. An improper will only be included if all four atoms in the improper are in the specified compute group.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, improper output from the *compute property/local* command can be combined with data from this command and output by the *dump local* command in a consistent way.

Here is an example of how to do this:

```
compute 1 all property/local itype iatom1 iatom2 iatom3 iatom4
compute 2 all improper/local chi
dump 1 all local 1000 tmp.dump index c_1[1] c_1[2] c_1[3] c_1[4] c_1[5] c_2[1]
```

### 3.59.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of impropers. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The output for *chi* will be in degrees.

### 3.59.5 Restrictions

none

### 3.59.6 Related commands

*dump local*, *compute property/local*

### 3.59.7 Default

none

## 3.60 compute inertia/chunk command

### 3.60.1 Syntax

```
compute ID group-ID inertia/chunk chunkID
```

- ID, group-ID are documented in [compute](#) command
- inertia/chunk = style name of this compute command
- chunkID = ID of [compute chunk/atom](#) command

### 3.60.2 Examples

```
compute 1 fluid inertia/chunk molchunk
```

### 3.60.3 Description

Define a computation that calculates the inertia tensor for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a [compute chunk/atom](#) command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the [compute chunk/atom](#) and [Howto chunk](#) doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the six components of the symmetric inertia tensor for each chunk, ordered  $I_{xx}, I_{yy}, I_{zz}, I_{xy}, I_{yz}, I_{xz}$ . The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The [compute chunk/atom](#) command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

---

**Note:** The coordinates of an atom contribute to the chunk’s inertia tensor in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

---

The simplest way to output the results of the compute inertia/chunk calculation to a file is to use the [fix ave/time](#) command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all inertia/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.60.4 Output info

This compute calculates a global array where the number of rows = the number of chunks *Nchunk* as calculated by the specified *compute chunk/atom* command. The number of columns is 6, one for each of the 6 components of the inertia tensor for each chunk, ordered as listed above. These values can be accessed by any command that uses global array values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in mass\*distance<sup>2</sup> *units*.

## 3.61 compute ke command

### 3.61.1 Syntax

```
compute ID group-ID ke
```

- ID, group-ID are documented in *compute* command
- ke = style name of this compute command

### 3.61.2 Examples

```
compute 1 all ke
```

### 3.61.3 Description

Define a computation that calculates the translational kinetic energy of a group of particles.

The kinetic energy of each particle is computed as  $\frac{1}{2}mv^2$ , where *m* and *v* are the mass and velocity of the particle, respectively.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the *ke* or *etotal* keyword used in thermodynamic output, as specified by the *thermo\_style* command. For this compute, kinetic energy is “translational” kinetic energy, calculated by the simple formula above. For thermodynamic output, the *ke* keyword infers kinetic energy from the temperature of the system with  $\frac{1}{2}k_B T$  of energy for each degree of freedom. For the default temperature computation via the *compute temp* command, these are the same. However, different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc.).

### 3.61.4 Output info

This compute calculates a global scalar (the summed KE). This value can be used by any command that uses a global scalar value from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

## 3.62 compute ke/atom command

### 3.62.1 Syntax

```
compute ID group-ID ke/atom
```

- ID, group-ID are documented in *compute* command
- ke/atom = style name of this compute command

### 3.62.2 Examples

```
compute 1 all ke/atom
```

### 3.62.3 Description

Define a computation that calculates the per-atom translational kinetic energy for each atom in a group.

The kinetic energy is simply  $\frac{1}{2}mv^2$ , where  $m$  is the mass and  $v$  is the velocity of each atom.

The value of the kinetic energy will be 0.0 for atoms not in the specified compute group.

### 3.62.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in energy *units*.

### 3.62.5 Restrictions

none

### 3.62.6 Related commands

*dump custom*

## 3.63 compute ke/atom/eff command

### 3.63.1 Syntax

```
compute ID group-ID ke/atom/eff
```

- ID, group-ID are documented in [compute](#) command
- ke/atom/eff = style name of this compute command

### 3.63.2 Examples

```
compute 1 all ke/atom/eff
```

### 3.63.3 Description

Define a computation that calculates the per-atom translational (nuclei and electrons) and radial kinetic energy (electron only) in a group. The particles are assumed to be nuclei and electrons modeled with the [electronic force field](#).

The kinetic energy for each nucleus is computed as  $\frac{1}{2}mv^2$ , where  $m$  corresponds to the corresponding nuclear mass, and the kinetic energy for each electron is computed as  $\frac{1}{2}(m_e v^2 + \frac{3}{4}m_e s^2)$ , where  $m_e$  and  $v$  correspond to the mass and translational velocity of each electron, and  $s$  to its radial velocity, respectively.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the *ke* or *etotal* keyword used in thermodynamic output, as specified by the [thermo\\_style](#) command. For this compute, kinetic energy is “translational” plus electronic “radial” kinetic energy, calculated by the simple formula above. For thermodynamic output, the *ke* keyword infers kinetic energy from the temperature of the system with  $\frac{1}{2}k_B T$  of energy for each (nuclear-only) degree of freedom in eFF.

**Note:** The temperature in eFF should be monitored via the `compute temp/eff` command, which can be printed with thermodynamic output by using the `thermo_modify` command, as shown in the following example:

---

```
compute      effTemp all temp/eff
thermo_style  custom step etotal pe ke temp press
thermo_modify temp effTemp
```

The value of the kinetic energy will be 0.0 for atoms (nuclei or electrons) not in the specified compute group.

### 3.63.4 Output info

This compute calculates a scalar quantity for each atom, which can be accessed by any command that uses per-atom computes as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in energy *units*.

### 3.63.5 Restrictions

This compute is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

```

- ID, group-ID are documented in `compute` command
- ke/eff = style name of this compute command

### 3.64.2 Examples

```
compute 1 all ke/eff
```

### 3.64.3 Description

Define a computation that calculates the kinetic energy of motion of a group of eFF particles (nuclei and electrons), as modeled with the *electronic force field*.

The kinetic energy for each nucleus is computed as  $\frac{1}{2}mv^2$  and the kinetic energy for each electron is computed as  $\frac{1}{2}(m_e v^2 + \frac{3}{4}m_e s^2)$ , where  $m$  corresponds to the nuclear mass,  $m_e$  to the electron mass,  $v$  to the translational velocity of each particle, and  $s$  to the radial velocity of the electron, respectively.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the *ke* or *etotal* keyword used in thermodynamic output, as specified by the *thermo\_style* command. For this compute, kinetic energy is “translational” and “radial” (only for electrons) kinetic energy, calculated by the simple formula above. For thermodynamic output, the *ke* keyword infers kinetic energy from the temperature of the system with  $\frac{1}{2}k_B T$  of energy for each degree of freedom. For the eFF temperature computation via the *compute temp\_eff* command, these are the same. But different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include other degrees of freedom.

**Warning:** The temperature in eFF models should be monitored via the *compute temp/eff* command, which can be printed with thermodynamic output by using the *thermo\_modify* command, as shown in the following example:

```
compute      effTemp all temp/eff
thermo_style custom step etotal pe ke temp press
thermo_modify temp effTemp
```

See *compute temp/eff*.

### 3.64.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

### 3.64.5 Restrictions

## 3.65 compute ke/rigid command

### 3.65.1 Syntax

```
compute ID group-ID ke/rigid fix-ID
```

- ID, group-ID are documented in *compute* command
- ke = style name of this compute command
- fix-ID = ID of rigid body fix

### 3.65.2 Examples

```
compute 1 all ke/rigid myRigid
```

### 3.65.3 Description

Define a computation that calculates the translational kinetic energy of a collection of rigid bodies, as defined by one of the *fix rigid* command variants.

The kinetic energy of each rigid body is computed as  $\frac{1}{2}MV_{\text{cm}}^2$ , where  $M$  is the total mass of the rigid body, and  $V_{\text{cm}}$  is its center-of-mass velocity.

The *fix-ID* should be the ID of one of the *fix rigid* commands which defines the rigid bodies. The group specified in the compute command is ignored. The kinetic energy of all the rigid bodies defined by the fix rigid command is included in the calculation.

### 3.65.4 Output info

This compute calculates a global scalar (the summed KE of all the rigid bodies). This value can be used by any command that uses a global scalar value from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

### 3.65.5 Restrictions

## 3.66 compute mliap command

### 3.66.1 Syntax

```
compute ID group-ID mliap ... keyword values ...
```

- ID, group-ID are documented in *compute* command
  - mliap = style name of this compute command
  - two or more keyword/value pairs must be appended
  - keyword = *model* or *descriptor* or *gradgradflag*
- model* values = style  
 style = *linear* or *quadratic* or *mliappy*  
*descriptor* values = style filename  
 style = *sna* or *ace*  
 filename = name of file containing descriptor definitions  
*gradgradflag* value = 0/1  
 toggle gradgrad method for force gradient

### 3.66.2 Examples

```
compute mliap model linear descriptor sna Ta06A.mliap.descriptor
compute mliap model linear descriptor ace H_N_O_ccs.yace gradgradflag 1
```

### 3.66.3 Description

Compute style *mliap* provides a general interface to the gradient of machine-learning interatomic potentials with respect to model parameters. It is used primarily for calculating the gradient of energy, force, and stress components with respect to model parameters, which is useful when training *mliap pair\_style* models to match target data. It provides separate definitions of the interatomic potential functional form (*model*) and the geometric quantities that characterize the atomic positions (*descriptor*). By defining *model* and *descriptor* separately, it is possible to use many different models with a given descriptor, or many different descriptors with a given model. Currently, the compute supports

*linear* and *quadratic* SNAP descriptor computes used in *pair\_style snap*, *linear* SO3 descriptor computes, and *linear* ACE descriptor computes used in *pair\_style pace*, and it is straightforward to add new descriptor styles.

The compute *mliap* command must be followed by two keywords *model* and *descriptor* in either order.

The *model* keyword is followed by the model style (*linear*, *quadratic* or *mliappy*). The *mliappy* model is only available if LAMMPS is built with the *mliappy* Python module. There are [specific installation instructions](#) for that module. For the *mliap* compute, specifying a *linear* model will compute the specified descriptors and gradients with respect to linear model parameters whereas *quadratic* will do the same, but for the quadratic products of descriptors.

The *descriptor* keyword is followed by a descriptor style, and additional arguments. The compute currently supports three descriptor styles: *sna*, *so3*, and *ace*, but it is straightforward to add additional descriptor styles. The SNAP descriptor style *sna* is the same as that used by *pair\_style snap*, including the linear, quadratic, and chem variants. A single additional argument specifies the descriptor filename containing the parameters and setting used by the SNAP descriptor. The descriptor filename usually ends in the *.mliap.descriptor* extension. The format of this file is identical to the descriptor file in the *pair\_style mliap*, and is described in detail there.

The ACE descriptor style *ace* is the same as *pair\_style pace*. A single additional argument specifies the *ace* descriptor filename that contains parameters and settings for the ACE descriptors. This file format differs from the SNAP or SO3 descriptor files, and has a *.pace* or *.ace* extension. However, as with other *mliap* descriptor styles, this file is identical to the *ace* descriptor file in *pair\_style mliap*, where it is described in further detail.

---

**Note:** The number of LAMMPS atom types (and the value of *nelems* in the model) must match the value of *nelems* in the descriptor file.

---

Compute *mliap* calculates a global array containing gradient information. The number of columns in the array is *nelems*  $\times$  *nparams* + 1. The first row of the array contain the derivative of potential energy with respect to. to each parameter and each element. The last six rows of the array contain the corresponding derivatives of the virial stress tensor, listed in Voigt notation: *pxx*, *pyy*, *pzz*, *pyz*, *pxz*, and *pxy*. In between the energy and stress rows are the *3N* rows containing the derivatives of the force components. See section below on output for a detailed description of how rows and columns are ordered.

The element in the last column of each row contains the potential energy, force, or stress, according to the row. These quantities correspond to the user-specified reference potential that must be subtracted from the target data when training a model. The potential energy calculation uses the built in compute *thermo\_pe*. The stress calculation uses a compute called *mliap\_press* that is automatically created behind the scenes, according to the following command:

```
compute mliap_press all pressure NULL virial
```

See section below on output for a detailed explanation of the data layout in the global array.

The optional keyword *gradgradflag* controls how the force gradient is calculated. A value of 1 requires that the model provide the matrix of double gradients of energy with respect to both parameters and descriptors. For the linear and quadratic models this matrix is sparse and so is easily calculated and stored. For other models, this matrix may be prohibitively expensive to calculate and store. A value of 0 requires that the descriptor provide the derivative of the descriptors with respect to the position of every neighbor atom. This is not optimal for linear and quadratic models, but may be a better choice for more complex models.

Atoms not in the group do not contribute to this compute. Neighbor atoms not in the group do not contribute to this compute. The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e., each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

---

**Note:** If the user-specified reference potentials includes bonded and non-bonded pairwise interactions, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the calculation.

---

The *rerun* command is not an option here, since the reference potential is required for the last column of the global array. A work-around is to prevent pairwise interactions from being removed by explicitly adding a *tiny* positive value for every pairwise interaction that would otherwise be set to zero in the *special\_bonds* command.

### 3.66.4 Output info

Compute *mliap* evaluates a global array. The columns are arranged into *nelems* blocks, listed in order of element *I*. Each block contains one column for each of the *nparams* model parameters. A final column contains the corresponding energy, force component on an atom, or virial stress component. The rows of the array appear in the following order:

- 1 row: Derivatives of potential energy with respect to each parameter of each element.
- $3N$  rows: Derivatives of force components; the *x*, *y*, and *z* components of the force on atom *i* appear in consecutive rows. The atoms are sorted based on atom ID.
- 6 rows: Derivatives of the virial stress tensor with respect to each parameter of each element. The ordering of the rows follows Voigt notation: *pxx*, *pyy*, *pzz*, *pyz*, *pxz*, *pxy*.

These values can be accessed by any command that uses a global array from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options. To see how this command can be used within a Python workflow to train machine-learning interatomic potentials, see the examples in [FitSNAP](#).

### 3.66.5 Restrictions

This compute is part of the ML-IAP package. It is only enabled if LAMMPS was built with that package. In addition, building LAMMPS with the ML-IAP package requires building LAMMPS with the ML-SNAP package. The *mli-appy* model also requires building LAMMPS with the PYTHON package. The *ace* descriptor also requires building LAMMPS with the ML-PACE package. See the [Build package](#) page for more info. Note that *kk* (KOKKOS) accelerated variants of SNAP and ACE descriptors are not compatible with *mliap descriptor*.

### 3.66.6 Related commands

*pair\_style mliap*

### 3.66.7 Default

The keyword defaults are `gradgradflag = 1`

## 3.67 compute momentum command

### 3.67.1 Syntax

```
compute ID group-ID momentum
```

- ID, group-ID are documented in [compute](#) command
- momentum = style name of this compute command

### 3.67.2 Examples

```
compute 1 all momentum
```

### 3.67.3 Description

Define a computation that calculates the translational momentum  $p$  of a group of particles. It is computed as the sum  $\vec{p} = \sum_i m_i \cdot \vec{v}_i$  over all particles in the compute group, where  $m$  and  $v$  are the mass and velocity vector of the particle, respectively.

### 3.67.4 Output info

This compute calculates a global vector (the summed momentum) of length 3. This value can be used by any command that uses a global vector value from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector value calculated by this compute is “extensive”. The vector value will be in mass\*velocity *units*.

### 3.67.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.67.6 Related commands

### 3.67.7 Default

none

## 3.68 compute msd command

### 3.68.1 Syntax

```
compute ID group-ID msd keyword values ...
```

- ID, group-ID are documented in [compute](#) command
- msd = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *com* or *average*
  - com* value = *yes* or *no*
  - average* value = *yes* or *no*

### 3.68.2 Examples

```
compute 1 all msd
compute 1 upper msd com yes average yes
```

### 3.68.3 Description

Define a computation that calculates the mean-squared displacement (MSD) of the group of atoms, including all effects due to atoms passing through periodic boundaries. For computation of the non-Gaussian parameter of mean-squared displacement, see the [compute msd/nongauss](#) command.

A vector of four quantities is calculated by this compute. The first three elements of the vector are the squared  $dx$ ,  $dy$ , and  $dz$  displacements, summed and averaged over atoms in the group. The fourth element is the total squared displacement (i.e.,  $dx^2 + dy^2 + dz^2$ ), summed and averaged over atoms in the group.

The slope of the mean-squared displacement (MSD) versus time is proportional to the diffusion coefficient of the diffusing atoms.

The displacement of an atom is from its reference position. This is normally the original position at the time the compute command was issued, unless the *average* keyword is set to *yes*. The value of the displacement will be 0.0 for atoms not in the specified compute group.

If the *com* option is set to *yes* then the effect of any drift in the center-of-mass of the group of atoms is subtracted out before the displacement of each atom is calculated.

If the *average* option is set to *yes* then the reference position of an atom is based on the average position of that atom, corrected for center-of-mass motion if requested. The average position is a running average over all previous calls to the compute, including the current call. So on the first call it is current position, on the second call it is the arithmetic average of the current position and the position on the first call, and so on. Note that when using this option, the precise value of the mean square displacement will depend on the number of times the compute is called. So, for example, changing the frequency of thermo output may change the computed displacement. Also, the precise values will be changed if a single simulation is broken up into two parts, using either multiple run commands or a restart file. It only makes sense to use this option if the atoms are not diffusing, so that their average positions relative to the center of mass of the system are stationary. The most common case is crystalline solids undergoing thermal motion.

---

**Note:** Initial coordinates are stored in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the [set image](#) command.

---

---

**Note:** If you want the quantities calculated by this compute to be continuous when running from a [restart file](#), then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with atom reference positions from the restart file. When *average* is set to *yes*, then the atom reference positions are restored correctly, but not the number of samples used obtain them. As a result, the reference positions from the restart file are combined with subsequent positions as if they were from a single sample, instead of many, which will change the values of msd somewhat.

---

### 3.68.4 Output info

This compute calculates a global vector of length 4, which can be accessed by indices 1–4 by any command that uses global vector values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in distance<sup>2</sup> *units*.

### 3.68.5 Restrictions

Compute *msd* cannot be used with a dynamic group.

### 3.68.6 Related commands

*compute msd/nongauss*, *compute displace\_atom*, *fix store/state*, *compute msd/chunk*

### 3.68.7 Default

The option default are com = no, average = no.

## 3.69 compute msd/chunk command

### 3.69.1 Syntax

```
compute ID group-ID msd/chunk chunkID
```

- ID, group-ID are documented in [compute](#) command
- msd/chunk = style name of this compute command
- chunkID = ID of [compute chunk/atom](#) command

### 3.69.2 Examples

```
compute 1 all msd/chunk molchunk
```

### 3.69.3 Description

Define a computation that calculates the mean-squared displacement (MSD) for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a [compute chunk/atom](#) command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the [compute chunk/atom](#) and [Howto chunk](#) doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

Four quantities are calculated by this compute for each chunk. The first 3 quantities are the squared *dx*, *dy*, and *dz* displacements of the center-of-mass. The fourth component is the total squared displacement (i.e.,  $dx^2 + dy^2 + dz^2$ ) of the center-of-mass. These calculations include all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The slope of the mean-squared displacement (MSD) versus time is proportional to the diffusion coefficient of the diffusing chunks.

The displacement of the center-of-mass of the chunk is from its original center-of-mass position, calculated on the timestep this compute command was first invoked.

---

**Note:** The number of chunks *Nchunk* calculated by the `compute chunk/atom` command must remain constant each time this compute is invoked, so that the displacement for each chunk from its original position can be computed consistently. If *Nchunk* does not remain constant, an error will be generated. If needed, you can enforce a constant *Nchunk* by using the *nchunk once* or *ids once* options when specifying the `compute chunk/atom` command.

---

---

**Note:** This compute stores the original position (of the center-of-mass) of each chunk. When a displacement is calculated on a later timestep, it is assumed that the same atoms are assigned to the same chunk ID. However LAMMPS has no simple way to ensure this is the case, though you can use the *ids once* option when specifying the `compute chunk/atom` command. Note that if this is not the case, the MSD calculation does not have a sensible meaning.

---

---

**Note:** The initial coordinates of the atoms in each chunk are stored in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the `set image` command.

---

---

**Note:** If you want the quantities calculated by this compute to be continuous when running from a *restart file*, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-chunk quantities will also have the same ID, and thus be initialized correctly with chunk reference positions from the restart file.

---

The simplest way to output the results of the compute msd/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all msd/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.69.4 Output info

This compute calculates a global array where the number of rows = the number of chunks *Nchunk* as calculated by the specified `compute chunk/atom` command. The number of columns = 4 for *dx*, *dy*, *dz*, and the total displacement. These values can be accessed by any command that uses global array values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in distance<sup>2</sup> *units*.

### 3.69.5 Restrictions

none

### 3.69.6 Related commands

*compute msd*

### 3.69.7 Default

## 3.70 compute msd/nongauss command

### 3.70.1 Syntax

```
compute ID group-ID msd/nongauss keyword values ...
```

- ID, group-ID are documented in *compute* command
- msd/nongauss = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *com*

*com* value = *yes* or *no*

### 3.70.2 Examples

```
compute 1 all msd/nongauss  
compute 1 upper msd/nongauss com yes
```

### 3.70.3 Description

Define a computation that calculates the mean-squared displacement (MSD) and non-Gaussian parameter (NGP) of the group of atoms, including all effects due to atoms passing through periodic boundaries.

A vector of three quantities is calculated by this compute. The first element of the vector is the total squared displacement,  $dr^2 = dx^2 + dy^2 + dz^2$ , of the atoms, and the second is the fourth power of these displacements,  $dr^4 = (dx^2 + dy^2 + dz^2)^2$ , summed and averaged over atoms in the group. The third component is the non-Gaussian diffusion parameter NGP,

$$\text{NGP}(t) = \frac{3 \langle (r(t) - r(0))^4 \rangle}{5 \langle (r(t) - r(0))^2 \rangle^2} - 1.$$

The NGP is a commonly used quantity in studies of dynamical heterogeneity. Its minimum theoretical value (−0.4) occurs when all atoms have the same displacement magnitude. NGP = 0 for Brownian diffusion, while NGP > 0 when some mobile atoms move faster than others.

If the *com* option is set to *yes* then the effect of any drift in the center-of-mass of the group of atoms is subtracted out before the displacement of each atom is calculated.

See the [compute msd](#) page for further important NOTES, which also apply to this compute.

### 3.70.4 Output info

This compute calculates a global vector of length 3, which can be accessed by indices 1–3 by any command that uses global vector values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The first vector value will be in distance<sup>2</sup> *units*, the second is in distance<sup>4</sup> units, and the third is dimensionless.

### 3.70.5 Restrictions

Compute *msd/nongauss* cannot be used with a dynamic group.

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.70.6 Related commands

*compute msd*

### 3.70.7 Default

The option default is *com = no*.

## 3.71 compute nbond/atom command

### 3.71.1 Syntax

```
compute ID group-ID nbond/atom keyword value
```

- ID, group-ID are documented in [compute](#) command
- nbond/atom = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *bond/type*

*bond/type* value = *btype*

*btype* = bond type included in count

### 3.71.2 Examples

```
compute 1 all nbond/atom
compute 1 all nbond/atom bond/type 2
```

### 3.71.3 Description

New in version 4May2022.

Define a computation that computes the number of bonds each atom is part of. Bonds which are broken are not counted in the tally. See the [Howto broken bonds](#) page for more information. The number of bonds will be zero for atoms not in the specified compute group. This compute does not depend on Newton bond settings.

If the keyword *bond/type* is specified, only bonds of *btype* are counted.

### 3.71.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

### 3.71.5 Restrictions

This compute is part of the BPM package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.71.6 Related commands

### 3.71.7 Default

none

## 3.72 compute omega/chunk command

### 3.72.1 Syntax

```
compute ID group-ID omega/chunk chunkID
```

- ID, group-ID are documented in [compute](#) command
- omega/chunk = style name of this compute command
- chunkID = ID of [compute chunk/atom](#) command

### 3.72.2 Examples

```
compute 1 fluid omega/chunk molchunk
```

### 3.72.3 Description

Define a computation that calculates the angular velocity ( $\omega$ ) of multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a [compute chunk/atom](#) command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the [compute chunk/atom](#) and [Howto chunk](#) doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the three components of the angular velocity vector for each chunk via the formula  $\vec{L} = \mathbf{I} \cdot \vec{\omega}$ , where  $\vec{L}$  is the angular momentum vector of the chunk,  $\mathbf{I}$  is its moment of inertia tensor, and  $\vec{\omega}$  is the angular velocity of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The [compute chunk/atom](#) command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

---

**Note:** The coordinates of an atom contribute to the chunk’s angular velocity in “unwrapped” form, by using the image flags associated with each atom. See the [dump custom](#) command for a discussion of “unwrapped” coordinates. See the Atoms section of the [read\\_data](#) command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the [set image](#) command.

---

The simplest way to output the results of the compute omega/chunk calculation to a file is to use the [fix ave/time](#) command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all omega/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.72.4 Output info

This compute calculates a global array where the number of rows is the number of chunks  $N_{chunk}$  as calculated by the specified [compute chunk/atom](#) command. The number of columns is 3 for the three (x, y, z) components of the angular velocity for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in velocity/distance *units*.

## 3.73 compute orientorder/atom command

Accelerator Variants: *orientorder/atom/kk*

### 3.73.1 Syntax

```
compute ID group-ID orientorder/atom keyword values ...
```

- ID, group-ID are documented in *compute* command
- orientorder/atom = style name of this compute command
- one or more keyword/value pairs may be appended

keyword = *cutoff* or *nnn* or *degrees* or *wl* or *wl/hat* or *components* or *chunksize*

*cutoff* value = distance cutoff

*nnn* value = number of nearest neighbors

*degrees* values = nlvalues, l1, l2,...

*wl* value = *yes* or *no*

*wl/hat* value = *yes* or *no*

*components* value = ldegree

*chunksize* value = number of atoms in each pass

### 3.73.2 Examples

```
compute 1 all orientorder/atom
compute 1 all orientorder/atom degrees 5 4 6 8 10 12 nnn NULL cutoff 1.5
compute 1 all orientorder/atom wl/hat yes
compute 1 all orientorder/atom components 6
```

### 3.73.3 Description

Define a computation that calculates a set of bond-orientational order parameters  $Q_\ell$  for each atom in a group. These order parameters were introduced by [Steinhardt et al.](#) as a way to characterize the local orientational order in atomic structures. For each atom,  $Q_\ell$  is a real number defined as follows:

$$\bar{Y}_{\ell m} = \frac{1}{nnn} \sum_{j=1}^{nnn} Y_{\ell m}(\theta(\mathbf{r}_{ij}), \phi(\mathbf{r}_{ij}))$$

$$Q_\ell = \sqrt{\frac{4\pi}{2\ell+1} \sum_{m=-\ell}^{\ell} \bar{Y}_{\ell m} \bar{Y}_{\ell m}^*}$$

The first equation defines the local order parameters as averages of the spherical harmonics  $Y_{\ell m}$  for each neighbor. These are complex number components of the 3D analog of the 2D order parameter  $q_n$ , which is implemented as LAMMPS compute [hexorder/atom](#). The summation is over the *nnn* nearest neighbors of the central atom. The angles  $\theta$  and  $\phi$  are the standard spherical polar angles defining the direction of the bond vector  $\mathbf{r}_{ij}$ . The phase and sign of  $Y_{\ell m}$  follow the standard conventions, so that  $\text{sign}(Y_{\ell\ell}(0,0)) = (-1)^\ell$ . The second equation defines  $Q_\ell$ , which is a rotationally invariant non-negative amplitude obtained by summing over all the components of degree  $\ell$ .

The optional keyword *cutoff* defines the distance cutoff used when searching for neighbors. The default value, also the maximum allowable value, is the cutoff specified by the pair style.

The optional keyword *nnn* defines the number of nearest neighbors used to calculate  $Q_\ell$ . The default value is 12. If the value is NULL, then all neighbors up to the specified distance cutoff are used.

The optional keyword *degrees* defines the list of order parameters to be computed. The first argument *nvalues* is the number of order parameters. This is followed by that number of non-negative integers giving the degree of each order parameter. Because  $Q_2$  and all odd-degree order parameters are zero for atoms in cubic crystals (see [Steinhardt](#)), the default order parameters are  $Q_4$ ,  $Q_6$ ,  $Q_8$ ,  $Q_{10}$ , and  $Q_{12}$ . For the FCC crystal with *nnn*=12,

$$Q_4 = \sqrt{\frac{7}{192}} \approx 0.19094$$

The numerical values of all order parameters up to  $Q_{12}$  for a range of commonly encountered high-symmetry structures are given in Table I of [Mickel et al.](#), and these can be reproduced with this compute.

The optional keyword *wl* will output the third-order invariants  $W_\ell$  (see Eq. 1.4 in [Steinhardt](#)) for the same degrees as for the  $Q_\ell$  parameters. For the FCC crystal with *nnn* = 12,

$$W_4 = -\sqrt{\frac{14}{143}} \left( \frac{49}{4096} \right) \pi^{-3/2} \approx -0.0006722136$$

The optional keyword *wl/hat* will output the normalized third-order invariants  $\hat{W}_\ell$  (see Eq. 2.2 in [Steinhardt](#)) for the same degrees as for the  $Q_\ell$  parameters. For the FCC crystal with *nnn*=12,

$$\hat{W}_4 = -\frac{7}{3} \sqrt{\frac{2}{429}} \approx -0.159317$$

The numerical values of  $\hat{W}_\ell$  for a range of commonly encountered high-symmetry structures are given in Table I of [Steinhardt](#), and these can be reproduced with this keyword.

The optional keyword *components* will output the components of the *normalized* complex vector  $\hat{Y}_{\ell m} = \bar{Y}_{\ell m}/|\bar{Y}_{\ell m}|$  of degree *ldegree*, which must be included in the list of order parameters to be computed. This option can be used in conjunction with [compute coord\\_atom](#) to calculate the ten Wolde's criterion to identify crystal-like particles, as discussed in [ten Wolde](#).

The optional keyword *chunksize* is only applicable when using the the KOKKOS package and is ignored otherwise. This keyword controls the number of atoms in each pass used to compute the bond-orientational order parameters and

is used to avoid running out of memory. For example if there are 32768 atoms in the simulation and the *chunksize* is set to 16384, the parameter calculation will be broken up into two passes.

The value of  $Q_\ell$  is set to zero for atoms not in the specified compute group, as well as for atoms that have less than *nnn* neighbors within the distance cutoff, unless *nnn* is NULL.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e., each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

---

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the *rerun* command to compute the order parameter for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 3.73.4 Output info

This compute calculates a per-atom array with *nvalues* columns, giving the  $Q_\ell$  values for each atom, which are real numbers in the range  $0 \leq Q_\ell \leq 1$ .

If the keyword *wl* is set to yes, then the  $W_\ell$  values for each atom will be added to the output array, which are real numbers.

If the keyword *wl/hat* is set to yes, then the  $\hat{W}_\ell$  values for each atom will be added to the output array, which are real numbers.

If the keyword *components* is set, then the real and imaginary parts of each component of *normalized*  $\hat{Y}_{\ell m}$  will be added to the output array in the following order:  $\Re(\hat{Y}_{-m})$ ,  $\Im(\hat{Y}_{-m})$ ,  $\Re(\hat{Y}_{-m+1})$ ,  $\Im(\hat{Y}_{-m+1})$ , ...,  $\Re(\hat{Y}_m)$ ,  $\Im(\hat{Y}_m)$ .

In summary, the per-atom array will contain *nvalues* columns, followed by an additional *nvalues* columns if *wl* is set to yes, followed by an additional *nvalues* columns if *wl/hat* is set to yes, followed by an additional  $2*(2* ldegree+1)$  columns if the *components* keyword is set.

These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

```
compute pace all pace coupling_coefficients.yace
compute pace all pace coupling_coefficients.yace 0 1
compute pace all pace coupling_coefficients.yace 1 1
```

### 3.74.3 Description

New in version 7Feb2024.

This compute calculates a set of quantities related to the atomic cluster expansion (ACE) descriptors of the atoms in a group. ACE descriptors are highly general atomic descriptors, encoding the radial and angular distribution of neighbor atoms, up to arbitrary bond order (rank). The detailed mathematical definition is given in the paper by (Drautz). These descriptors are used in the *pace pair\_style*. Quantities obtained from *compute pace* are related to those used in *pace pair\_style* to evaluate atomic energies, forces, and stresses for linear ACE models.

For example, the energy for a linear ACE model is calculated as:  $E = \sum_i^{N_{atoms}} \sum_v c_v B_{i,v}$ . The ACE descriptors for atom  $i$   $B_{i,v}$ , and  $c_v$  are linear model parameters. The detailed definition and indexing convention for ACE descriptors is given in (Drautz). In short, body order  $N$ , angular character, radial character, and chemical elements in the  $N$ -body descriptor are encoded by  $v$ . In the *pace pair\_style*, the linear model parameters and the ACE descriptors are combined for efficient evaluation of energies and forces. The details and benefits of this efficient implementation are given in (Lysogorskiy), but the combined descriptors and linear model parameters for the purposes of *compute pace* may be expressed in terms of the ACE descriptors mentioned above.

$$c_v B_{i,v} = \sum_{v' \in v} [c_v C(v')] A_{i,v'}$$

where the bracketed terms on the right-hand side are the combined functions with linear model parameters typically provided in the `<name>.yace` potential file for *pace pair\_style*. When these bracketed terms are multiplied by the products of the atomic base from (Drautz),  $A_{i,v'}$ , the ACE descriptors are recovered but they are also scaled by linear model parameters. The generalized coupling coefficients, written in short-hand here as  $C(v')$ , are the generalized Clebsch-Gordan or generalized Wigner symbols. It may be desirable to reverse the combination of these descriptors and the linear model parameters so that the ACE descriptors themselves may be used. The ACE descriptors and their gradients are often used when training ACE models, performing custom data analysis, generalizing ACE model forms, and other tasks that involve direct computation of descriptors. The key utility of *compute pace* is that it can compute the ACE descriptors and gradients so that these tasks can be performed during a LAMMPS simulation or so that LAMMPS can be used as a driver for tasks like ACE model parameterization. To see how this command can be used within a Python workflow to train ACE potentials, see the examples in FitSNAP. Examples on using outputs from this compute to construct general ACE potential forms are demonstrated in (Goff). The various keywords and inputs to *compute pace* determine what ACE descriptors and related quantities are returned in a compute array.

The coefficient file, `<name>.yace`, ultimately defines the number of ACE descriptors to be computed, their maximum body-order, the degree of angular character they have, the degree of radial character they have, the chemical character (which element-element interactions are encoded by descriptors), and other hyper-parameters defined in (Drautz). These may be modeled after the potential files in *pace pair\_style*, and have the same format. Details on how to generate the coefficient files to train ACE models may be found in FitSNAP.

The keyword *bikflag* determines whether or not to list the descriptors of each atom separately, or sum them together and list in a single row. If *bikflag* is set to 0 then a single descriptor row is used, which contains the per-atom ACE descriptors  $B_{i,v}$  summed over all atoms  $i$  to produce  $B_v$ . If *bikflag* is set to 1 this is replaced by a separate per-atom ACE descriptor row for each atom. In this case, the entries in the final column for these rows are set to zero.

The keyword *dgradflag* determines whether to sum atom gradients or list them separately. If *dgradflag* is set to 0, the ACE descriptor gradients w.r.t. atom  $j$  are summed over all atoms  $i$  of, which may be useful when training linear ACE models on atomic forces. If *dgradflag* is set to 1, gradients are listed separately for each pair of atoms. Each row corresponds to a single term  $\frac{\partial B_{i,v}}{\partial r_j^a}$  where  $r_j^a$  is the  $a$ -th position coordinate of the atom with global index  $j$ . This also changes the number of columns to be equal to the number of ACE descriptors, with 3 additional columns representing the indices  $i$ ,  $j$ , and  $a$ , as explained more in the Output info section below. The option *dgradflag=1* requires that *bikflag=1*.

**Note:** It is noted here that in contrast to *pace pair\_style*, the *.yace* file for *compute pace* typically should not contain linear parameters for an ACE potential. If  $c_v$  are included, the value of the descriptor will not be returned in the *compute* array, but instead, the energy contribution from that descriptor will be returned. Do not do this unless it is the desired

behavior. In short, you should not plug in a `.yace` for a `pace` potential into this compute to evaluate descriptors.

---

**Note:** Generalized Clebsch-Gordan or Generalized Wigner symbols (with appropriate factors) must be used to evaluate ACE descriptors with this compute. There are multiple ways to define the generalized coupling coefficients. Because of this, this compute will not revert your potential file to a coupling coefficient file. Instead this compute allows the user to supply coupling coefficients that follow any convention.

---

---

**Note:** Using `dgradflag = 1` produces a global array with  $N + 3N^2 + 1$  rows which becomes expensive for systems with more than 1000 atoms.

---

---

**Note:** If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the calculation. One way to get around this, is to write a dump file, and use the `rerun` command to compute the ACE descriptors for snapshots in the dump file. The rerun script can use a `special_bonds` command that includes all pairs in the neighbor list.

---

### 3.74.4 Output info

Compute `pace` evaluates a global array. The columns are arranged into `ntypes` blocks, listed in order of atom type  $I$ . Each block contains one column for each ACE descriptor, the same as for compute `sna/atomin` `compute snap`. A final column contains the corresponding energy, force component on an atom, or virial stress component. The rows of the array appear in the following order:

- 1 row: `pace` average descriptor values for all atoms of type  $I$
- $3*n$  force rows: quantities, with derivatives w.r.t.  $x$ ,  $y$ , and  $z$  coordinate of atom  $i$  appearing in consecutive rows. The atoms are sorted based on atom ID and run up to the total number of atoms,  $n$ .
- 6 rows: `virial` quantities summed for all atoms of type  $I$

For example, if  $\# B_{i,v} = 30$  and `ntypes=1`, the number of columns in the The number of columns in the global array generated by `pace` are 31, and 931, respectively, while the number of rows is  $1+3*n+6$ , where  $n$  is the total number of atoms.

If the `bik` keyword is set to 1, the structure of the `pace` array is expanded. The first  $N$  rows of the `pace` array correspond to  $\# B_{i,v}$  instead of a single row summed over atoms  $i$ . In this case, the entries in the final column for these rows are set to zero. Also, each row contains only non-zero entries for the columns corresponding to the type of that atom. This is not true in the case of `dgradflag` keyword = 1 (see below).

If the `dgradflag` keyword is set to 1, this changes the structure of the global array completely. Here the per-atom quantities are replaced with rows corresponding to descriptor gradient components on single atoms:

$$\frac{\partial B_{i,v}}{\partial r_j^a}$$

where  $r_j^a$  is the  $a$ -th position coordinate of the atom with global index  $j$ . The rows are organized in chunks, where each chunk corresponds to an atom with global index  $j$ . The rows in an atom  $j$  chunk correspond to atoms with global index  $i$ . The total number of rows for these descriptor gradients is therefore  $3N^2$ . The number of columns is equal to the number of ACE descriptors, plus 3 additional left-most columns representing the global atom indices  $i$ ,  $j$ , and

Cartesian direction  $a$  (0, 1, 2, for x, y, z). The first 3 columns of the first  $N$  rows belong to the reference potential force components. The remaining  $K$  columns contain the  $B_{i,v}$  per-atom descriptors corresponding to the non-zero entries obtained when  $bikflag = 1$ . The first column of the last row, after the first  $N + 3N^2$  rows, contains the reference potential energy. The virial components are not used with this option. The total number of rows is therefore  $N + 3N^2 + 1$  and the number of columns is  $K + 3$ .

These values can be accessed by any command that uses global values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

### 3.74.5 Restrictions

These computes are part of the ML-PACE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.74.6 Related commands

*pair\_style pace pair\_style snap compute snap*

### 3.74.7 Default

The optional keyword defaults are  $bikflag = 0$ ,  $dgradflag = 0$

## 3.75 compute pair command

### 3.75.1 Syntax

`compute ID group-ID pair pstyle [nstyle] [evaluate]`

- ID, group-ID are documented in [compute](#) command
- pair = style name of this compute command
- pstyle = style name of a pair style that calculates additional values
- nsub =  $n$ -instance of a sub-style, if a pair style is used multiple times in a hybrid style
- evaluate = *epair* or *evdwl* or *ecoul* or blank (optional)

### 3.75.2 Examples

```
compute 1 all pair gauss
compute 1 all pair lj/cut/coul/cut ecoul
compute 1 all pair tersoff 2 epair
compute 1 all pair reaxff
```

### 3.75.3 Description

Define a computation that extracts additional values calculated by a pair style, and makes them accessible for output or further processing by other commands.

---

**Note:** The group specified for this command is **ignored**.

---

The specified *pstyle* must be a pair style used in your simulation either by itself or as a sub-style in a *pair\_style hybrid* or *hybrid/overlay* command. If the sub-style is used more than once, an additional number *nsub* has to be specified in order to choose which instance of the sub-style will be used by the compute. Not specifying the number in this case will cause the compute to fail.

The *evaluate* setting is optional. All pair styles tally a potential energy *epair* which may be broken into two parts: *evdwl* and *ecoul* such that  $epair = evdwl + ecoul$ . If the pair style calculates Coulombic interactions, their energy will be tallied in *ecoul*. Everything else (whether it is a Lennard-Jones style van der Waals interaction or not) is tallied in *evdwl*. If *evaluate* is blank or specified as *epair*, then *epair* is stored as a global scalar by this compute. This is useful when using *pair\_style hybrid* if you want to know the portion of the total energy contributed by one sub-style. If *evaluate* is specified as *evdwl* or *ecoul*, then just that portion of the energy is stored as a global scalar.

---

**Note:** The energy returned by the *evdwl* keyword does not include tail corrections, even if they are enabled via the *pair\_modify* command.

---

Some pair styles tally additional quantities, e.g. a breakdown of potential energy into 14 components is tallied by the *pair\_style reaxff* command. These values (1 or more) are stored as a global vector by this compute. See the page for *individual pair styles* for info on these values.

### 3.75.4 Output info

This compute calculates a global scalar which is *epair* or *evdwl* or *ecoul*. If the pair style supports it, it also calculates a global vector of length  $\geq 1$ , as determined by the pair style. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are “extensive”.

The scalar value will be in energy *units*. The vector values will typically also be in energy *units*, but see the page for the pair style for details.

### 3.75.5 Restrictions

none

### 3.75.6 Related commands

*compute pe, compute bond, fix pair*

### 3.75.7 Default

The keyword defaults are *eval* = *epair*, *nsub* = 0.

## 3.76 compute pair/local command

### 3.76.1 Syntax

```
compute ID group-ID pair/local value1 value2 ... keyword args ...
```

- ID, group-ID are documented in *compute* command
- pair/local = style name of this compute command
- one or more values may be appended
- value = *dist* or *dx* or *dy* or *dz* or *eng* or *force* or *fx* or *fy* or *fz* or *p1* or *p2* or ...
  - dist* = pairwise distance
  - dx,dy,dz* = components of pairwise distance
  - eng* = pairwise energy
  - force* = pairwise force
  - fx,fy,fz* = components of pairwise force
  - p1, p2, ...* = pair style specific quantities for allowed N values
- zero or more keyword/arg pairs may be appended
- keyword = *cutoff*
  - cutoff arg* = *type* or *radius*

### 3.76.2 Examples

```
compute 1 all pair/local eng
compute 1 all pair/local dist eng force
compute 1 all pair/local dist eng fx fy fz
compute 1 all pair/local dist fx fy fz p1 p2 p3
```

### 3.76.3 Description

Define a computation that calculates properties of individual pairwise interactions. The number of datums generated, aggregated across all processors, equals the number of pairwise interactions in the system.

The local data stored by this command is generated by looping over the pairwise neighbor list. Info about an individual pairwise interaction will only be included if both atoms in the pair are in the specified compute group, and if the current pairwise distance is less than the force cutoff distance for that interaction, as defined by the *pair\_style* and *pair\_coeff* commands.

The value *dist* is the distance between the pair of atoms. The values *dx*, *dy*, and *dz* are the  $(x, y, z)$  components of the *distance* between the pair of atoms. This value is always the distance from the atom of higher to the one with the lower atom ID.

The value *eng* is the interaction energy for the pair of atoms.

The value *force* is the force acting between the pair of atoms, which is positive for a repulsive force and negative for an attractive force. The values *fx*, *fy*, and *fz* are the  $(x, y, z)$  components of *force* on atom I. For pair styles that apply non-central forces, such as *granular pair styles*, these values only include the  $(x, y, z)$  components of the normal force component.

A pair style may define additional pairwise quantities which can be accessed as *p1* to *pN*, where *N* is defined by the pair style. Most pair styles do not define any additional quantities, so *N* = 0. An example of ones that do are the *granular pair styles* which calculate the tangential force between two particles and return its components and magnitude acting on atom *I* for  $N \in \{1, 2, 3, 4\}$ . See individual pair styles for details.

When using *pN* with pair style *hybrid*, the output will be the *N*th quantity from the sub-style that computes the pairwise interaction (based on atom types). If that sub-style does not define a *pN*, the output will be 0.0. The maximum allowed *N* is the maximum number of quantities provided by any sub-style.

When using *pN* with pair style *hybrid/overlay* the quantities from all sub-styles that provide them are concatenated together into one long list. For example, if there are 3 sub-styles and 2 of them have additional output (with 3 and 4 quantities, respectively), then 7 values (*p1* up to *p7*) are defined. The values *p1* to *p3* refer to quantities defined by the first of the two sub-styles. Values *p4* to *p7* refer to quantities from the second of the two sub-styles. If the referenced *pN* is not computed for the specific pairwise interaction (based on atom types), then the output will be 0.0.

The value *dist*, *dx*, *dy* and *dz* will be in distance *units*. The value *eng* will be in energy *units*. The values *force*, *fx*, *fy*, and *fz* will be in force *units*. The values *pN* will be in whatever units the pair style defines.

The optional *cutoff* keyword determines how the force cutoff distance for an interaction is determined. For the default setting of *type*, the pairwise cutoff defined by the *pair\_style* command for the types of the two atoms is used. For the *radius* setting, the sum of the radii of the two particles is used as a cutoff. For example, this is appropriate for granular particles which only interact when they are overlapping, as computed by *granular pair styles*. Note that if a granular model defines atom types such that all particles of a specific type are monodisperse (same diameter), then the two settings are effectively identical.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, pair output from the *compute property/local* command can be combined with data from this command and output by the *dump local* command in a consistent way.

Here is an example of how to do this:

```
compute 1 all property/local patom1 patom2
compute 2 all pair/local dist eng force
dump 1 all local 1000 tmp.dump index c_1[1] c_1[2] c_2[1] c_2[2] c_2[3]
```

**Note:** For pairs, if two atoms I,J are involved in 1–2, 1–3, and 1–4 interactions within the molecular topology, their pairwise interaction may be turned off, and thus they may not appear in the neighbor list, and will not be part of the local data created by this command. More specifically, this will be true of I,J pairs with a weighting factor of 0.0; pairs with a non-zero weighting factor are included. The weighting factors for 1–2, 1–3, and 1–4 pairwise interactions are set by the *special\_bonds* command. An exception is if long-range Coulombics are being computed via the *kspace\_style* command, then atom pairs with weighting factors of zero are still included in the neighbor list, so that a portion of the long-range interaction contribution can be computed in the pair style. Hence in that case, those atom pairs will be part of the local data created by this command.

---

### 3.76.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of pairs. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The output for *dist* will be in distance *units*. The output for *eng* will be in energy *units*. The output for *force*, *fx*, *fy*, and *fz* will be in force *units*. The output for *pN* will be in whatever units the pair style defines.

### 3.76.5 Restrictions

none

### 3.76.6 Related commands

*dump local*, *compute property/local*

### 3.76.7 Default

The keyword default is *cutoff* = type.

## 3.77 compute pe command

### 3.77.1 Syntax

```
compute ID group-ID pe keyword ...
```

- ID, group-ID are documented in *compute* command
- pe = style name of this compute command
- zero or more keywords may be appended
- keyword = *pair* or *bond* or *angle* or *dihedral* or *improper* or *kspace* or *fix*

### 3.77.2 Examples

```
compute 1 all pe
compute molPE all pe bond angle dihedral improper
```

### 3.77.3 Description

Define a computation that calculates the potential energy of the entire system of atoms. The specified group must be “all”. See the [compute pe/atom](#) command if you want per-atom energies. These per-atom values could be summed for a group of atoms via the [compute reduce](#) command.

The energy is calculated by the various pair, bond, etc. potentials defined for the simulation. If no extra keywords are listed, then the potential energy is the sum of pair, bond, angle, dihedral, improper, *k*-space (long-range), and fix energy (i.e., it is as though all the keywords were listed). If any extra keywords are listed, then only those components are summed to compute the potential energy.

The *k*-space contribution requires 1 extra FFT each timestep the energy is calculated, if using the PPPM solver via the [kpace\\_style pppm](#) command. Thus it can increase the cost of the PPPM calculation if it is needed on a large fraction of the simulation timesteps.

Various fixes can contribute to the total potential energy of the system if the *fix* contribution is included. See the doc pages for [individual fixes](#) for details of which ones compute a potential energy.

---

**Note:** The [fix\\_modify energy yes](#) command must also be specified if a fix is to contribute potential energy to this command.

---

A compute of this style with the ID of “thermo\_pe” is created when LAMMPS starts up, as if this command were in the input script:

```
compute thermo_pe all pe
```

See the “thermo\_style” command for more details.

---

### 3.77.4 Output info

This compute calculates a global scalar (the potential energy). This value can be used by any command that uses a global scalar value from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

### 3.77.5 Restrictions

none

### 3.77.6 Related commands

*compute pe/atom*

### 3.77.7 Default

none

## 3.78 compute pe/atom command

### 3.78.1 Syntax

```
compute ID group-ID pe/atom keyword ...
```

- ID, group-ID are documented in *compute* command
- pe/atom = style name of this compute command
- zero or more keywords may be appended
- keyword = *pair* or *bond* or *angle* or *dihedral* or *improper* or *kpace* or *fix*

### 3.78.2 Examples

```
compute 1 all pe/atom  
compute 1 all pe/atom pair  
compute 1 all pe/atom pair bond
```

### 3.78.3 Description

Define a computation that computes the per-atom potential energy for each atom in a group. See the *compute pe* command if you want the potential energy of the entire system.

The per-atom energy is calculated by the various pair, bond, etc potentials defined for the simulation. If no extra keywords are listed, then the potential energy is the sum of pair, bond, angle, dihedral, improper, *k*-space (long-range), and fix energy (i.e., it is as though all the keywords were listed). If any extra keywords are listed, then only those components are summed to compute the potential energy.

Note that the energy of each atom is due to its interaction with all other atoms in the simulation, not just with other atoms in the group.

For an energy contribution produced by a small set of atoms (e.g., 4 atoms in a dihedral or 3 atoms in a Tersoff 3-body interaction), that energy is assigned in equal portions to each atom in the set (e.g., 1/4 of the dihedral energy to each of the four atoms).

The *dihedral\_style charmm* style calculates pairwise interactions between 1–4 atoms. The energy contribution of these terms is included in the pair energy, not the dihedral energy.

The KSpace contribution is calculated using the method in (Heyes) for the Ewald method and a related method for PPPM, as specified by the *kpace\_style ppm* command. For PPPM, the calculation requires 1 extra FFT each timestep that per-atom energy is calculated. This document describes how the long-range per-atom energy calculation is performed.

Various fixes can contribute to the per-atom potential energy of the system if the *fix* contribution is included. See the doc pages for *individual fixes* for details of which ones compute a per-atom potential energy.

---

**Note:** The *fix\_modify energy yes* command must also be specified if a fix is to contribute per-atom potential energy to this command.

---

As an example of per-atom potential energy compared to total potential energy, these lines in an input script should yield the same result in the last 2 columns of thermo output:

```
compute      peratom all pe/atom
compute      pe all reduce sum c_peratom
thermo_style  custom step temp etotal press pe c_pe
```

---

**Note:** The per-atom energy does not include any Lennard-Jones tail corrections to the energy added by the *pair\_modify tail yes* command, since those are contributions to the global system energy.

---

### 3.78.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-atom vector values will be in energy *units*.

### 3.78.5 Restrictions

### 3.78.6 Related commands

## 3.79 compute plasticity/atom command

### 3.79.1 Syntax

```
compute ID group-ID plasticity/atom
```

- ID, group-ID are documented in compute command
- plasticity/atom = style name of this compute command

### 3.79.2 Examples

```
compute 1 all plasticity/atom
```

### 3.79.3 Description

Define a computation that calculates the per-atom plasticity for each atom in a group. This is a quantity relevant for *Peridynamics models*. See [this document](#) for an overview of LAMMPS commands for Peridynamics modeling.

The plasticity for a Peridynamic particle is the so-called consistency parameter ( $\lambda$ ). For elastic deformation,  $\lambda = 0$ , otherwise  $\lambda > 0$  for plastic deformation. For details, see [\(Mitchell\)](#) and the PDF doc included in the LAMMPS distribution in `doc/PDF/PDLammps_EPS.pdf`.

This command can be invoked for one of the Peridynamic *pair styles*: `peri/eps`.

The plasticity value will be 0.0 for atoms not in the specified compute group.

### 3.79.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers  $\lambda \geq 0.0$ .

### 3.79.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.79.6 Related commands

compute d all pod/atom Ta_param.pod Ta_coefficients.pod
compute dd all podd/atom Ta_param.pod Ta_coefficients.pod
compute ldd all pod/local Ta_param.pod Ta_coefficients.pod
compute gdd all podd/global Ta_param.pod Ta_coefficients.pod
```

### 3.83.3 Description

New in version 27June2024.

Define a computation that calculates a set of quantities related to the POD descriptors of the atoms in a group. These computes are used primarily for calculating the dependence of energy and force components on the linear coefficients in the *pod pair\_style*, which is useful when training a POD potential to match target data. POD descriptors of an atom are characterized by the radial and angular distribution of neighbor atoms. The detailed mathematical definition is given in the papers by (Nguyen and Rohskopf), (Nguyen2023), (Nguyen2024), and (Nguyen and Sema).

Compute *pod/atom* calculates the per-atom POD descriptors.

Compute *podd/atom* calculates derivatives of the per-atom POD descriptors with respect to atom positions.

Compute *pod/local* calculates the per-atom POD descriptors and their derivatives with respect to atom positions.

Compute *pod/global* calculates the global POD descriptors and their derivatives with respect to atom positions.

Examples how to use Compute POD commands are found in the directory `examples/PACKAGES/pod`.

**Warning:** All of these compute styles produce *very* large per-atom output arrays that scale with the total number of atoms in the system. This will result in *very* large memory consumption for systems with a large number of atoms.

---

### 3.83.4 Output info

Compute *pod/atom* produces an 2D array of size  $N \times M$ , where  $N$  is the number of atoms and  $M$  is the number of descriptors. Each column corresponds to a particular POD descriptor.

Compute *podd/atom* produces an 2D array of size  $N \times (M * 3N)$ . Each column corresponds to a particular derivative of a POD descriptor.

Compute *pod/local* produces an 2D array of size  $(1 + 3N) \times (M * N)$ . The first row contains the per-atom descriptors, and the last  $3N$  rows contain the derivatives of the per-atom descriptors with respect to atom positions.

Compute *pod/global* produces an 2D array of size  $(1 + 3N) \times (M)$ . The first row contains the global descriptors, and the last  $3N$  rows contain the derivatives of the global descriptors with respect to atom positions.

### 3.83.5 Restrictions

These computes are part of the ML-POD package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.83.6 Related commands

*fitpod*, *pair\_style pod*

## 3.84 compute pressure command

### 3.84.1 Syntax

```
compute ID group-ID pressure temp-ID keyword ...
```

- ID, group-ID are documented in *compute* command
- pressure = style name of this compute command
- temp-ID = ID of compute that calculates temperature, can be NULL if not needed
- zero or more keywords may be appended
- keyword = *ke* or *pair* or *bond* or *angle* or *dihedral* or *improper* or *kpace* or *fix* or *virial* or *pair/hybrid*

### 3.84.2 Examples

```
compute 1 all pressure thermo_temp
compute 1 all pressure NULL pair bond
compute 1 all pressure NULL pair/hybrid lj/cut
```

### 3.84.3 Description

Define a computation that calculates the pressure of the entire system of atoms. The specified group must be “all”. See the *compute stress/atom* command if you want per-atom pressure (stress). These per-atom values could be summed for a group of atoms via the *compute reduce* command.

The pressure is computed by the formula

$$P = \frac{Nk_B T}{V} + \frac{1}{Vd} \sum_{i=1}^{N'} \vec{r}_i \cdot \vec{f}_i$$

where  $N$  is the number of atoms in the system (see discussion of DOF below),  $k_B$  is the Boltzmann constant,  $T$  is the temperature,  $d$  is the dimensionality of the system (2 for 2d, 3 for 3d), and  $V$  is the system volume (or area in 2d). The second term is the virial, equal to  $-dU/dV$ , computed for all pairwise as well as 2-body, 3-body, 4-body, many-body, and long-range interactions, where  $\vec{r}_i$  and  $\vec{f}_i$  are the position and force vector of atom  $i$ , and the dot indicates the dot product (scalar product). This is computed in parallel for each subdomain and then summed over all parallel processes. Thus  $N'$  necessarily includes atoms from neighboring subdomains (so-called ghost atoms) and the position and force vectors of ghost atoms are thus included in the summation. Only when running in serial and without periodic boundary

conditions is  $N' = N$  the number of atoms in the system. *Fixes* that impose constraints (e.g., the *fix shake* command) may also contribute to the virial term.

A symmetric pressure tensor, stored as a 6-element vector, is also calculated by this compute. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ . The equation for the  $(I, J)$  components (where  $I$  and  $J$  are  $x$ ,  $y$ , or  $z$ ) is similar to the above formula, except that the first term uses components related to the kinetic energy tensor and the second term uses components of the virial tensor:

$$P_{IJ} = \frac{1}{V} \sum_{k=1}^N m_k v_{k_i} v_{k_j} + \frac{1}{V} \sum_{k=1}^{N'} r_{k_i} f_{k_j}.$$

If no extra keywords are listed, the entire equations above are calculated. This includes a kinetic energy (temperature) term and the virial as the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix contributions to the force on each atom. If any extra keywords are listed, then only those components are summed to compute temperature or ke and/or the virial. The *virial* keyword means include all terms except the kinetic energy *ke*.

The *pair/hybrid* keyword means to only include contribution from a sub-style in a *hybrid* or *hybrid/overlay* pair style.

Details of how LAMMPS computes the virial efficiently for the entire system, including for many-body potentials and accounting for the effects of periodic boundary conditions are discussed in (*Thompson*).

The temperature and kinetic energy tensor are not calculated by this compute, but rather by the temperature compute specified with the command. See the doc pages for individual compute temp variants for an explanation of how they calculate temperature and a symmetric tensor (6-element vector) whose components are twice that of the traditional KE tensor. That tensor is what appears in the pressure tensor formula above.

If the kinetic energy is not included in the pressure, then the temperature compute is not used and can be specified as NULL. Normally the temperature compute used by compute pressure should calculate the temperature of all atoms for consistency with the virial term, but any compute style that calculates temperature can be used (e.g., one that excludes frozen atoms or other degrees of freedom).

Note that if desired the specified temperature compute can be one that subtracts off a bias to calculate a temperature using only the thermal velocity of the atoms (e.g., by subtracting a background streaming velocity). See the doc pages for individual *compute commands* to determine which ones include a bias.

Also note that the  $N$  in the first formula above is really degrees-of-freedom divided by  $d = \text{dimensionality}$ , where the DOF value is calculated by the temperature compute. See the various *compute temperature* styles for details.

A compute of this style with the ID of thermo\_press is created when LAMMPS starts up, as if this command were in the input script:

```
compute thermo_press all pressure thermo_temp
```

where thermo\_temp is the ID of a similarly defined compute of style “temp”. See the *thermo\_style* command for more details.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 3.84.4 Output info

This compute calculates a global scalar (the pressure) and a global vector of length 6 (pressure tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The ordering of values in the symmetric pressure tensor is as follows:  $p_{xx}$ ,  $p_{yy}$ ,  $p_{zz}$ ,  $p_{xy}$ ,  $p_{xz}$ ,  $p_{yz}$ .

The scalar and vector values calculated by this compute are “intensive”. The scalar and vector values will be in pressure *units*.

### 3.84.5 Restrictions

none

### 3.84.6 Related commands

*compute temp*, *compute stress/atom*, *thermo\_style*, *fix numdiff/virial*,

### 3.84.7 Default

By default the compute includes contributions from the keywords: ke pair bond angle dihedral improper kspace fix

## 3.85 compute pressure/alchemy command

### 3.85.1 Syntax

```
compute ID group-ID pressure/alchemy fix-ID
```

- ID, group-ID are documented in *compute* command
- pressure/alchemy = style name of this compute command
- fix-ID = ID of *fix alchemy* command

### 3.85.2 Examples

```
fix trans all alchemy
compute mixed all pressure/alchemy trans
thermo_modify press mixed
```

### 3.85.3 Description

New in version 28Mar2023.

Define a compute style that makes the “mixed” system pressure available for a system that uses the *fix alchemy* command to transform one topology to another. This can be used in combination with either *thermo\_modify press* or *fix\_modify press* to output and access a pressure consistent with the simulated combined two topology system.

The actual pressure is determined with *compute pressure* commands that are internally used by *fix alchemy* for each topology individually and then combined. This command just extracts the information from the fix.

The `examples/PACKAGES/alchemy` folder contains an example input for this command.

---

### 3.85.4 Output info

This compute calculates a global scalar (the pressure) and a global vector of length 6 (the pressure tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The ordering of values in the symmetric pressure tensor is as follows:  $p_{xx}$ ,  $p_{yy}$ ,  $p_{zz}$ ,  $p_{xy}$ ,  $p_{xz}$ ,  $p_{yz}$ .

The scalar and vector values calculated by this compute are “intensive”. The scalar and vector values will be in pressure *units*.

### 3.85.5 Restrictions

This compute is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.85.6 Related commands

*fix alchemy*, *compute pressure*, *thermo\_modify*, *fix\_modify*

### 3.85.7 Default

none

## 3.86 compute pressure/uef command

### 3.86.1 Syntax

```
compute ID group-ID pressure/uef temp-ID keyword ...
```

- ID, group-ID are documented in *compute* command
- pressure/uef = style name of this compute command
- temp-ID = ID of compute that calculates temperature, can be NULL if not needed
- zero or more keywords may be appended
- keyword = *ke* or *pair* or *bond* or *angle* or *dihedral* or *improper* or *kspace* or *fix* or *virial*

### 3.86.2 Examples

```
compute 1 all pressure/uef my_temp_uef
compute 2 all pressure/uef my_temp_uef virial
```

### 3.86.3 Description

This command is used to compute the pressure tensor in the reference frame of the applied flow field when *fix nvt/uef* or *fix npt/uef* is used. It is not necessary to use this command to compute the scalar value of the pressure. A *compute pressure* may be used for that purpose.

The keywords and output information are documented in *compute\_pressure*.

### 3.86.4 Restrictions

This fix is part of the UEF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This command can only be used when *fix nvt/uef* or *fix npt/uef* is active.

The kinetic contribution to the pressure tensor will be accurate only when the compute specified by *temp-ID* is a *compute temp/uef*.

### 3.86.5 Related commands

*compute pressure*, *fix nvt/uef*, *compute temp/uef*

### 3.86.6 Default

none

## 3.87 compute property/atom command

### 3.87.1 Syntax

```
compute ID group-ID property/atom input1 input2 ...
```

- ID, group-ID are documented in *compute* command
- property/atom = style name of this compute command
- input = one or more atom attributes

```
possible attributes = id, mol, proc, type, mass,

eravel = electron radial velocity
erforce = electron radial force

```

```

SPH package per-atom properties:
rho = density of SPH particles
drho = change in density
e = energy
de = change in thermal energy
cv = heat capacity

```

## 3.87.2 Examples

```

compute 1 all property/atom xs vx fx mux
compute 2 all property/atom type
compute 1 all property/atom ix iy iz
compute 3 all property/atom sp spx spy spz
compute 1 all property/atom i_myFlag d_Sxyz[1] d_Sxyz[3]

```

## 3.87.3 Description

Define a computation that simply stores atom attributes for each atom in the group. This is useful so that the values can be used by other *output commands* that take computes as inputs. See for example, the *compute reduce*, *fix ave/atom*, *fix ave/histo*, *fix ave/chunk*, and *atom-style variable* commands.

The list of possible attributes is essentially the same as that used by the *dump custom* command, which describes their meaning, with some additional quantities that are only defined for certain *atom styles*. The goal of this augmented list gives an input script access to any per-atom quantity stored by LAMMPS.

The values are stored in a per-atom vector or array as discussed below. Zeroes are stored for atoms not in the specified group or for quantities that are not defined for a particular particle in the group (e.g., *shapex* if the particle is not an ellipsoid).

Attributes *i\_name*, *d\_name*, *i2\_name*, *d2\_name* refer to custom per-atom integer and floating-point vectors or arrays that have been added via the *fix property/atom* command. When that command is used specific names are given to each attribute which are the “name” portion of these attributes. For arrays *i2\_name* and *d2\_name*, the column of the array must also be included following the name in brackets (e.g., *d2\_xyz[2]* or *i2\_mySpin[3]*).

The additional quantities only accessible via this command, and not directly via the *dump custom* command, are as follows.

*Nbonds* is available for all molecular atom styles and refers to the number of explicit bonds assigned to an atom. Note that if the *newton bond* command is set to *on*, which is the default, then every bond in the system is assigned to only one of the two atoms in the bond. Thus a bond between atoms *I* and *J* may be tallied for either atom *I* or atom *J*. If *newton bond off* is set, it will be tallied with both atom *I* and atom *J*.

The quantities *shapex*, *shapey*, and *shapex* are defined for ellipsoidal particles and define the 3d shape of each particle.

The quantities *quatw*, *quati*, *quatj*, and *quatk* are defined for ellipsoidal particles and body particles and store the 4-vector quaternion representing the orientation of each particle. See the *set* command for an explanation of the quaternion vector.

*End1x*, *end1y*, *end1z*, *end2x*, *end2y*, *end2z*, are defined for line segment particles and define the end points of each line segment.

*Corner1x, corner1y, corner1z, corner2x, corner2y, corner2z, corner3x, corner3y, corner3z*, are defined for triangular particles and define the corner points of each triangle.

In addition, the various per-atom quantities listed above for specific packages are only accessible by this command.

Changed in version 15Sep2022: The *espin* property was previously called *spin*.

### 3.87.4 Output info

This compute calculates a per-atom vector or per-atom array depending on the number of input values. If a single input is specified, a per-atom vector is produced. If two or more inputs are specified, a per-atom array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector or array values will be in whatever [units](#) the corresponding attribute is in (e.g., velocity units for *vx*, charge units for *q*).

For the spin quantities, *sp* is in the units of the Bohr magneton; *spx*, *spy*, and *spz* are unitless quantities; and *fmx*, *fmy*, and *fmz* are given in rad/THz.

### 3.87.5 Restrictions

none

### 3.87.6 Related commands

*dump custom, compute reduce, fix ave/atom, fix ave/chunk, fix property/atom*

### 3.87.7 Default

none

## 3.88 compute property/chunk command

### 3.88.1 Syntax

```
compute ID group-ID property/chunk chunkID input1 input2 ...
```

- ID, group-ID are documented in [compute](#) command
- property/chunk = style name of this compute command
- chunkID = ID of [compute chunk/atom](#) command that defines the chunks
- input1,etc = one or more attributes

attributes = count, id, coord1, coord2, coord3

count = # of atoms in chunk

id = original chunk IDs before compression by [compute chunk/atom](#)

coord123 = coordinates for spatial bins calculated by [compute chunk/atom](#)

### 3.88.2 Examples

```
compute 1 all property/chunk bin2d id count
compute 1 all property/chunk myChunks id coord1
```

### 3.88.3 Description

Define a computation that stores the specified attributes of chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates and stores the specified attributes of chunks as global data so they can be accessed by other *output commands* and used in conjunction with other commands that generate per-chunk data, such as *compute com/chunk* or *compute msd/chunk*.

Note that only atoms in the specified group contribute to the calculation of the *count* attribute. The *compute chunk/atom* command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The *count* attribute is the number of atoms in the chunk.

The *id* attribute stores the original chunk ID for each chunk. It can only be used if the *compress* keyword was set to *yes* for the *compute chunk/atom* command referenced by chunkID. This means that the original chunk IDs (e.g., molecule IDs) will have been compressed to remove chunk IDs with no atoms assigned to them. Thus a compressed chunk ID of 3 may correspond to an original chunk ID (molecule ID in this case) of 415. The *id* attribute will then be 415 for the third chunk.

The *coordN* attributes can only be used if a *binning* style was used

in the *compute chunk/atom* command referenced by chunkID. For *bin/1d*, *bin/2d*, and *bin/3d* styles the attribute is the center point of the bin in the corresponding dimension. Style *bin/1d* only defines a *coord1* attribute. Style *bin/2d* adds a *coord2* attribute. Style *bin/3d* adds a *coord3* attribute.

Note that if the value of the *units* keyword used in the *compute chunk/atom command* is *box* or *lattice*, the *coordN* attributes will be in distance *units*. If the value of the *units* keyword is *reduced*, the *coordN* attributes will be in unitless reduced units (0-1).

The simplest way to output the results of the compute property/chunk calculation to a file is to use the *fix ave/time* command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk1 all property/chunk cc1 count
compute myChunk2 all com/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk1 c_myChunk2[*] file tmp.out mode vector
```

### 3.88.4 Output info

This compute calculates a global vector or global array depending on the number of input values. The length of the vector or number of rows in the array is the number of chunks.

This compute calculates a global vector or global array where the number of rows = the number of chunks *Nchunk* as calculated by the specified *compute chunk/atom* command. If a single input is specified, a global vector is produced. If two or more inputs are specified, a global array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses global values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array values are “intensive”. The values will be unitless or in the units discussed above.

### 3.88.5 Restrictions

none

### 3.88.6 Related commands

## 3.89 compute property/grid command

### 3.89.1 Syntax

```
compute ID group-ID property/grid Nx Ny Nz input1 input2 ...
```

- ID, group-ID are documented in *compute* command
- property/grid = style name of this compute command
- Nx, Ny, Nz = grid size in each dimension
- input1,etc = one or more attributes

```
attributes = id, ix, iy, iz, x, y, z, xs, ys, zs, xc, yc, zc, xsc, ysc, zsc
  id = ID of grid cell, x fastest, y next, z slowest
  proc = processor ID (0 to Nprocs-1) which owns the grid cell
  ix,iy,iz = grid indices in each dimension (1 to N inclusive)
  x,y,z = coords of lower left corner of grid cell
  xs,ys,zs = scaled coords of lower left corner of grid cell (0.0 to 1.0)
  xc,yc,zc = coords of center point of grid cell
  xsc,ysc,zsc = scaled coords of center point of grid cell (0.0 to 1.0)
```

### 3.89.2 Examples

```
compute 1 all property/grid 10 10 20 id ix iy iz
compute 1 all property/grid 100 100 1 id xc yc zc
```

### 3.89.3 Description

Define a computation that stores the specified attributes of a distributed grid. In LAMMPS, distributed grids are regular 2d or 3d grids which overlay a 2d or 3d simulation domain. Each processor owns the grid cells whose center points lie within its subdomain. See the [Howto grid](#) doc page for details of how distributed grids can be defined by various commands and referenced.

This compute stores the specified attributes of grids as per-grid data so they can be accessed by other *output commands* such as *dump grid*.

$N_x$ ,  $N_y$ , and  $N_z$  define the size of the grid. For a 2d simulation  $N_z$  must be 1. When this compute is used by *dump grid*, to output per-grid values from other computes of fixes, the grid size specified for this command must be consistent with the grid sizes used by the other commands.

The *id* attribute is the grid ID for each grid cell. For a global grid of size  $N_x$  by  $N_y$  by  $N_z$  (in 3d simulations) the grid IDs range from 1 to  $N_x*N_y*N_z$ . They are ordered with the X index of the 3d grid varying fastest, then Y, then Z slowest. For 2d grids (in 2d simulations), the grid IDs range from 1 to  $N_x*N_y$ , with X varying fastest and Y slowest.

New in version 21Nov2023.

The *proc* attribute is the ID of the processor which owns the grid cell. Processor IDs range from 0 to  $N_{procs} - 1$ , where  $N_{procs}$  is the number of processors the simulation is running on. Each grid cell is owned by a single processor.

The *ix*, *iy*, *iz* attributes are the indices of a grid cell in each dimension. They range from 1 to  $N_x$  inclusive in the X dimension, and similar for Y and Z.

The *x*, *y*, *z* attributes are the coordinates of the lower left corner point of each grid cell.

The *xs*, *ys*, *zs* attributes are also coordinates of the lower left corner point of each grid cell, except in scaled coordinates, where the lower-left corner of the entire simulation box is (0,0,0) and the upper right corner is (1,1,1).

The *xc*, *yc*, *zc* attributes are the coordinates of the center point of each grid cell.

The *xsc*, *ysc*, *zsc* attributes are also coordinates of the center point each grid cell, except in scaled coordinates, where the lower-left corner of the entire simulation box is (0,0,0) and the upper right corner is (1,1,1).

For *triclinic simulation boxes*, the grid point coordinates for (x,y,z) and (xc,yc,zc) will reflect the triclinic geometry. For (xs,ys,zs) and (xsc,ysc,zsc), the coordinates are the same for orthogonal versus triclinic boxes.

### 3.89.4 Output info

This compute calculates a per-grid vector or array depending on the number of input values. The length of the vector or number of array rows (distributed across all processors) is  $N_x * N_y * N_z$ . For access by other commands, the name of the single grid produced by this command is "grid". The name of its per-grid data is "data".

The (x,y,z) and (xc,yc,zc) coordinates are in distance *units*.

### 3.89.5 Restrictions

For 2d simulations, the attributes which refer to the Z dimension cannot be used.

### 3.89.6 Related commands

*dump grid*

### 3.89.7 Default

none

## 3.90 compute property/local command

### 3.90.1 Syntax

```
compute ID group-ID property/local attribute1 attribute2 ... keyword args ...
```

- ID, group-ID are documented in *compute* command
- property/local = style name of this compute command
- one or more attributes of the same type (neighbor, pair, bond, angle, dihedral, or improper) may be appended

```
possible attributes = natom1, natom2, ntype1, ntype2,  
                      patom1, patom2, ptype1, ptype2,  
                      batom1, batom2, btype,  
                      aatom1, aatom2, aatom3, atype,  
                      datom1, datom2, datom3, datom4, dtype,  
                      iatom1, iatom2, iatom3, iatom4, itype
```

– Neighbor attributes

```
natom1, natom2 = store IDs of two atoms in each pair (within neighbor cutoff)  
ntype1, ntype2 = store types of two atoms in each pair (within neighbor cutoff)
```

– Pair attributes

```
patom1, patom2 = store IDs of two atoms in each pair (within force cutoff)  
ptype1, ptype2 = store types of two atoms in each pair (within force cutoff)
```

– Bond attributes

```
batom1, batom2 = store IDs of two atoms in each bond  
btype = store bond type of each bond
```

– Angle attributes

```
aatom1, aatom2, aatom3 = store IDs of three atoms in each angle  
atype = store angle type of each angle
```

– Dihedral attributes

```

datom1, datom2, datom3, datom4 = store IDs of 4 atoms in each dihedral
dtype = store dihedral type of each dihedral

```

– Improper attributes

```

iatom1, iatom2, iatom3, iatom4 = store IDs of 4 atoms in each improper
itype = store improper type of each improper

```

- zero or more keyword/arg pairs may be appended
- keyword = *cutoff*  
*cutoff* arg = *type* or *radius*

### 3.90.2 Examples

```

compute 1 all property/local btype batom1 batom2
compute 1 all property/local atype aatom2

```

### 3.90.3 Description

Define a computation that stores the specified attributes as local data so it can be accessed by other *output commands*. If the input attributes refer to bond information, then the number of datums generated, aggregated across all processors, equals the number of bonds in the system. Ditto for pairs, angles, etc.

If multiple attributes are specified then they must all generate the same amount of information, so that the resulting local array has the same number of rows for each column. This means that only bond attributes can be specified together, or angle attributes, etc. Bond and angle attributes cannot be mixed in the same compute property/local command.

If the inputs are pair attributes, the local data is generated by looping over the pairwise neighbor list. Info about an individual pairwise interaction will only be included if both atoms in the pair are in the specified compute group. For *natom1* and *natom2*, all atom pairs in the neighbor list are considered (out to the neighbor cutoff = force cutoff + *neighbor skin*). For *patom1* and *patom2*, the distance between the atoms must be less than the force cutoff distance for that pair to be included, as defined by the *pair\_style* and *pair\_coeff* commands.

The optional *cutoff* keyword determines how the force cutoff distance for an interaction is determined for the *patom1* and *patom2* attributes. For the default setting of *type*, the pairwise cutoff defined by the *pair\_style* command for the types of the two atoms is used. For the *radius* setting, the sum of the radii of the two particles is used as a cutoff. For example, this is appropriate for granular particles which only interact when they are overlapping, as computed by *granular pair styles*. Note that if a granular model defines atom types such that all particles of a specific type are monodisperse (same diameter), then the two settings are effectively identical.

If the inputs are bond, angle, etc attributes, the local data is generated by looping over all the atoms owned on a processor and extracting bond, angle, etc info. For bonds, info about an individual bond will only be included if both atoms in the bond are in the specified compute group. Likewise for angles, dihedrals, etc.

For bonds and angles, a bonds/angles that have been broken by setting their bond/angle type to 0 will not be included. Bonds/angles that have been turned off (see the *fix shake* or *delete\_bonds* commands) by setting their bond/angle type negative are written into the file. This is consistent with the *compute bond/local* and *compute angle/local* commands

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, output from the *compute bond/local* command can be combined with bond atom indices from this command and output by the *dump local* command in a consistent way.

The *natom1* and *natom2* or *patom1* and *patom2* attributes refer to the atom IDs of the two atoms in each pairwise interaction computed by the *pair\_style* command. The *ntype1* and *ntype2* or *ptype1* and *ptype2* attributes refer to the atom types of the two atoms in each pairwise interaction.

---

**Note:** For pairs, if two atoms *I, J* are involved in 1–2, 1–3, 1–4 interactions within the molecular topology, their pairwise interaction may be turned off, and thus they may not appear in the neighbor list, and will not be part of the local data created by this command. More specifically, this may be true of *I, J* pairs with a weighting factor of 0.0; pairs with a non-zero weighting factor are included. The weighting factors for 1–2, 1–3, and 1–4 pairwise interactions are set by the *special\_bonds* command.

---

The *batom1* and *batom2* attributes refer to the atom IDs of the 2 atoms in each *bond*. The *btype* attribute refers to the type of the bond, from 1 to *Nbtypes* = # of bond types. The number of bond types is defined in the data file read by the *read\_data* command.

The attributes that start with “a”, “d”, and “i” refer to similar values for *angles*, *dihedrals*, and *impropers*.

### 3.90.4 Output info

This compute calculates a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of bonds, angles, etc. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array values will be integers that correspond to the specified attribute.

### 3.90.5 Restrictions

none

### 3.90.6 Related commands

*dump local*, *compute reduce*

### 3.90.7 Default

The keyword default is *cutoff = type*.

## 3.91 compute ptm/atom command

### 3.91.1 Syntax

`compute ID group-ID ptm/atom structures threshold group2-ID`

- ID, group-ID are documented in *compute* command
- ptm/atom = style name of this compute command

- `structures` = *default* or *all* or any hyphen-separated combination of *fcc*, *hcp*, *bcc*, *ico*, *sc*, *dcub*, *dhex*, or *graphene* = structure types to search for
- `threshold` = lattice distortion threshold (RMSD)
- `group2-ID` determines which group is used for neighbor selection (optional, default “all”)

### 3.91.2 Examples

```
compute 1 all ptm/atom default 0.1 all
compute 1 all ptm/atom fcc-hcp-dcub-dhex 0.15 all
compute 1 all ptm/atom all 0
```

### 3.91.3 Description

Define a computation that determines the local lattice structure around an atom using the PTM (Polyhedral Template Matching) method. The PTM method is described in [\(Larsen\)](#).

Currently, there are seven lattice structures PTM recognizes:

- `fcc` = 1
- `hcp` = 2
- `bcc` = 3
- `ico` (icosahedral) = 4
- `sc` (simple cubic) = 5
- `dcub` (diamond cubic) = 6
- `dhex` (diamond hexagonal) = 7
- `graphene` = 8

The value of the PTM structure will be 0 for unknown types and  $-1$  for atoms not in the specified compute group. The choice of structures to search for can be specified using the “structures” argument, which is a hyphen-separated list of structure keywords. Two convenient pre-set options are provided:

- `default`: `fcc-hcp-bcc-ico`
- `all`: `fcc-hcp-bcc-ico-sc-dcub-dhex-graphene`

The ‘default’ setting detects the same structures as the Common Neighbor Analysis method. The ‘all’ setting searches for all structure types. A performance penalty is incurred for the diamond and graphene structures, so it is not recommended to use this option if it is known that the simulation does not contain these structures.

PTM identifies structures using two steps. First, a graph isomorphism test is used to identify potential structure matches. Next, the deviation is computed between the local structure (in the simulation) and a template of the ideal lattice structure. The deviation is calculated as:

$$\text{RMSD}(\mathbf{u}, \mathbf{v}) = \min_{s, \mathbf{Q}} \sqrt{\frac{1}{N} \sum_{i=1}^N \|s[\vec{u}_i - \vec{\mathbf{u}}] - \mathbf{Q} \cdot \vec{v}_i\|^2}$$

Here,  $\vec{u}$  and  $\vec{v}$  contain the coordinates of the local and ideal structures respectively,  $s$  is a scale factor, and  $\mathbf{Q}$  is a rotation. The best match is identified by the lowest RMSD value, using the optimal scaling, rotation, and correspondence between the points.

The *threshold* keyword sets an upper limit on the maximum permitted deviation before a local structure is identified as disordered. Typical values are in the range 0.1–0.15, but larger values may be desirable at higher temperatures. A value of 0 is equivalent to infinity and can be used if no threshold is desired.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g., each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a *ptm/atom* style. By default the compute processes **all** neighbors unless the optional *group2-ID* argument is given, then only members of that group are considered as neighbors.

### 3.91.4 Output info

This compute calculates a per-atom array, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

Results are stored in the per-atom array in the following order:

- type
- rmsd
- interatomic distance
- qw
- qx
- qy
- qz

The type is a number from  $-1$  to 8. The rmsd is a positive real number. The interatomic distance is computed from the scale factor in the RMSD equation. The (*qw*, *qx*, *qy*, *qz*) parameters represent the orientation of the local structure in quaternion form. The reference coordinates for each template (from which the orientation is determined) can be found in the *ptm\_constants.h* file in the PTM source directory. For atoms that are not within the compute group-ID, all values are set to zero.

### 3.91.5 Restrictions

This fix is part of the PTM package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.91.6 Related commands

**(Larsen)** Larsen, Schmidt, Schiotz, Modelling Simul Mater Sci Eng, 24, 055007 (2016).

## 3.92 compute rattlers/atom command

### 3.92.1 Syntax

```
compute ID group-ID rattlers/atom cutoff zmin ntries
```

- ID, group-ID are documented in *compute* command
- rattlers/atom = style name of this compute command
- cutoff = *type* or *radius*  
*type* = cutoffs determined based on atom types  
*radius* = cutoffs determined based on atom diameters (atom style sphere)
- zmin = minimum coordination for a non-rattler atom
- ntries = maximum number of iterations to remove rattlers

### 3.92.2 Examples

```
compute 1 all rattlers/atom type 4 10
```

### 3.92.3 Description

New in version 7Feb2024.

Define a compute that identifies rattlers in a system. Rattlers are often identified in granular or glassy packings as under-coordinated atoms that do not have the required number of contacts to constrain their translational degrees of freedom. Such atoms are not considered rigid and can often freely rattle around in the system. This compute identifies rattlers which can be helpful for excluding them from analysis or providing extra damping forces to accelerate relaxation processes.

Rattlers are identified using an interactive approach. The coordination number of all atoms is first calculated. The *type* and *radius* settings are used to select whether interaction cutoffs are determined by atom types or by the sum of atomic radii (atom style sphere), respectively. Rattlers are then identified as atoms with a coordination number less than *zmin* and are removed from consideration. Atomic coordination numbers are then recalculated, excluding previously identified rattlers, to identify a new set of rattlers. This process is iterated up to a maximum of *ntries* or until no new rattlers are identified and the remaining atoms form a stable network of contacts.

In dense homogeneous systems where the average atom coordination number is expected to be larger than *zmin*, this process usually only takes a few iterations and a value of *ntries* around ten may be sufficient. In systems with significant heterogeneity or average coordination numbers less than *zmin*, an appropriate value of *ntries* depends heavily on the specific system. For instance, a linear chain of N rattler atoms with a *zmin* of 2 would take N/2 iterations to identify that all the atoms are rattlers.

### 3.92.4 Output info

This compute calculates a per-atom vector and a global scalar. The vector designates which atoms are rattlers, indicated by a value 1. Non-rattlers have a value of 0. The global scalar returns the total number of rattlers in the system. See the [Howto output](#) page for an overview of LAMMPS output options.

### 3.92.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The *radius* cutoff option requires that atoms store a radius as defined by the [atom\\_style sphere](#) or similar commands.

### 3.92.6 Related commands

*compute coord/atom compute contact/atom*

### 3.92.7 Default

none

## 3.93 compute rdf command

### 3.93.1 Syntax

```
compute ID group-ID rdf Nbin itype1 jtype1 itype2 jtype2 ... keyword/value ...
```

- ID, group-ID are documented in [compute](#) command
- rdf = style name of this compute command
- Nbin = number of RDF bins
- itypeN = central atom type for Nth RDF histogram (integer, type label, or asterisk form)
- jtypeN = distribution atom type for Nth RDF histogram (integer, type label, or asterisk form)
- zero or more keyword/value pairs may be appended
- keyword = *cutoff*  
*cutoff* value = Rcut  
Rcut = cutoff distance for RDF computation (distance units)

### 3.93.2 Examples

```
compute 1 all rdf 100
compute 1 all rdf 100 1 1
compute 1 all rdf 100 * 3 cutoff 5.0
compute 1 fluid rdf 500 1 1 1 2 2 1 2 2
compute 1 fluid rdf 500 1*3 2 5 *10 cutoff 3.5
```

### 3.93.3 Description

Define a computation that calculates the radial distribution function (RDF), also called  $g(r)$ , and the coordination number for a group of particles. Both are calculated in histogram form by binning pairwise distances into  $N_{bin}$  bins from 0.0 to the maximum force cutoff defined by the *pair\_style* command or the cutoff distance  $R_{cut}$  specified via the *cutoff* keyword. The bins are of uniform size in radial distance. Thus a single bin encompasses a thin shell of distances in 3d and a thin ring of distances in 2d.

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses a neighbor list, it also means those pairs will not be included in the RDF. This does not apply when using long-range coulomb interactions (*coul/long*, *coul/msm*, *coul/wolf* or similar). One way to get around this would be to set *special\_bond* scaling factors to very tiny numbers that are not exactly zero (e.g.,  $1.0 \times 10^{-50}$ ). Another workaround is to write a dump file, and use the *rerun* command to compute the RDF for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

By default the RDF is computed out to the maximum force cutoff defined by the *pair\_style* command. If the *cutoff* keyword is used, then the RDF is computed accurately out to the  $R_{cut} > 0.0$  distance specified.

**Note:** Normally, you should only use the *cutoff* keyword if no pair style is defined (e.g., the *rerun* command is being used to post-process a dump file of snapshots) or if you really want the RDF for distances beyond the *pair\_style* force cutoff and cannot easily post-process a dump file to calculate it. This is because using the *cutoff* keyword incurs extra computation and possibly communication, which may slow down your simulation. If you specify  $R_{cut} \leq$  force cutoff, you will force an additional neighbor list to be built at every timestep this command is invoked (or every reneighboring timestep, whichever is less frequent), which is inefficient. LAMMPS will warn you if this is the case. If you specify a  $R_{cut} >$  force cutoff, you must ensure ghost atom information out to  $R_{cut} + skin$  is communicated, via the *comm\_modify cutoff* command, else the RDF computation cannot be performed, and LAMMPS will give an error message. The *skin* value is what is specified with the *neighbor* command. In this case, you are forcing a large neighbor list to be built just for the RDF computation, and extra communication to be performed every timestep.

The *itypeN* and *jtypeN* arguments are optional. These arguments must come in pairs. If no pairs are listed, then a single histogram is computed for  $g(r)$  between all atom types. If one or more pairs are listed, then a separate histogram is generated for each *itype.jtype* pair.

The *itypeN* and *jtypeN* settings can be specified in one of three ways. One or both of the types in the I,J pair can be a *type label*. Or an explicit numeric value can be used, as in the fourth example above. Or a wild-card asterisk can be used to specify a range of atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If  $N$  is the number of atom types, then an asterisk with no numeric values means all types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $m$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive).

If both *itypeN* and *jtypeN* are single values, as in the fourth example above, this means that a  $g(r)$  is computed where

atoms of type *itypeN* are the central atom, and atoms of type *jtypeN* are the distribution atom. If either *itypeN* and *jtypeN* represent a range of values via the wild-card asterisk, as in the fifth example above, this means that a  $g(r)$  is computed where atoms of any of the range of types represented by *itypeN* are the central atom, and atoms of any of the range of types represented by *jtypeN* are the distribution atom.

Pairwise distances are generated by looping over a pairwise neighbor list, just as they would be in a *pair\_style* computation. The distance between two atoms *I* and *J* is included in a specific histogram if the following criteria are met:

- atoms *I* and *J* are both in the specified compute group
- the distance between atoms *I* and *J* is less than the maximum force cutoff
- the type of the *I* atom matches *itypeN* (one or a range of types)
- the type of the *J* atom matches *jtypeN* (one or a range of types)

It is OK if a particular pairwise distance is included in more than one individual histogram, due to the way the *itypeN* and *jtypeN* arguments are specified.

The  $g(r)$  value for a bin is calculated from the histogram count by scaling it by the idealized number of how many counts there would be if atoms of type *jtypeN* were uniformly distributed. Thus it involves the count of *itypeN* atoms, the count of *jtypeN* atoms, the volume of the entire simulation box, and the volume of the bin's thin shell in 3d (or the area of the bin's thin ring in 2d).

A coordination number  $\text{coord}(r)$  is also calculated, which is the number of atoms of type *jtypeN* within the current bin or closer, averaged over atoms of type *itypeN*. This is calculated as the area- or volume-weighted sum of  $g(r)$  values over all bins up to and including the current bin, multiplied by the global average volume density of atoms of type *jtypeN*.

The simplest way to output the results of the compute rdf calculation to a file is to use the *fix ave/time* command, for example:

```
compute myRDF all rdf 50
fix 1 all ave/time 100 1 100 c_myRDF[*] file tmp.rdf mode vector
```

### 3.93.4 Output info

This compute calculates a global array in which the number of rows is  $N_{\text{bins}}$  and the number of columns is  $1 + 2N_{\text{pairs}}$ , where  $N_{\text{pairs}}$  is the number of *I, J* pairings specified. The first column has the bin coordinate (center of the bin), and each successive set of two columns has the  $g(r)$  and  $\text{coord}(r)$  values for a specific set of *itypeN* versus *jtypeN* interactions, as described above. These values can be used by any command that uses a global values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The array values calculated by this compute are all “intensive”.

The first column of array values will be in distance *units*. The  $g(r)$  columns of array values are normalized numbers  $\geq 0.0$ . The coordination number columns of array values are also numbers  $\geq 0.0$ .

### 3.93.5 Restrictions

By default, the RDF is not computed for distances longer than the largest force cutoff, since the neighbor list creation will only contain pairs up to that distance (plus neighbor list skin). This distance can be increased using the *cutoff* keyword but this keyword is only valid with *neighbor styles 'bin' and 'nsq'*.

If you want an RDF for larger distances, you can also use the *rerun* command to post-process a dump file, use *pair style zero* and set the force cutoff to be longer in the rerun script. Note that in the rerun context, the force cutoff is arbitrary and with pair style zero you are not computing any forces, and you are not running dynamics you are not changing the model that generated the trajectory.

The definition of  $g(r)$  used by LAMMPS is only appropriate for characterizing atoms that are uniformly distributed throughout the simulation cell. In such cases, the coordination number is still correct and meaningful. As an example, if a large simulation cell contains only one atom of type *itypeN* and one of *jtypeN*, then  $g(r)$  will register an arbitrarily large spike at whatever distance they happen to be at, and zero everywhere else. The function  $\text{coord}(r)$  will show a step change from zero to one at the location of the spike in  $g(r)$ .

---

**Note:** `compute rdf` can handle dynamic groups and systems where atoms are added or removed, but this causes that certain normalization parameters need to be re-computed in every step and include collective communication operations. This will reduce performance and limit parallel efficiency and scaling. For systems, where only the type of atoms changes (e.g., when using *fix atom/swap*), you need to explicitly request the dynamic normalization updates via *compute\_modify dynamic/dof yes*

---

### 3.93.6 Related commands

*fix ave/time*, *compute\_modify*, *compute adf*

### 3.93.7 Default

The keyword defaults are `cutoff = 0.0` (use the pairwise force cutoff).

## 3.94 compute reaxff/atom command

Accelerator Variants: *reaxff/atom/kk*

### 3.94.1 Syntax

```
compute ID group-ID reaxff/atom attribute args ... keyword value ...
```

- ID, group-ID are documented in *compute* command
- reaxff/atom = name of this compute command
- attribute = *pair*  
 $\text{pair args} = \text{nsub}$   
 $\text{nsub} = n\text{-instance of a sub-style, if a pair style is used multiple times in a}$   
 $\rightarrow \text{hybrid style}$
- keyword = *bonds*

```
bonds value = no or yes
no = ignore list of local bonds
yes = include list of local bonds
```

### 3.94.2 Examples

```
compute 1 all reaxff/atom bonds yes
```

### 3.94.3 Description

New in version 7Feb2024.

Define a computation that extracts bond information computed by the ReaxFF potential specified by *pair\_style reaxff*.

By default, it produces per-atom data that includes the following columns:

- abo = atom bond order (sum of all bonds)
- nlp = number of lone pairs
- nb = number of bonds

Bonds will only be included if its atoms are in the group.

In addition, if **bonds** is set to **yes**, the compute will also produce a local array of all bonds on the current processor whose atoms are in the group. The columns of each entry of this local array are:

- id\_i = atom i id of bond
- id\_j = atom j id of bond
- bo = bond order of bond

### 3.94.4 Output info

This compute calculates a per-atom array and local array depending on the number of keywords. The number of rows in the local array is the number of bonds as described above. Both per-atom and local array have 3 columns.

The arrays can be accessed by any command that uses local and per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 3.94.5 Restrictions

The `compute reaxff/atom` command requires that the *pair\_style reaxff* is invoked. This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.94.6 Related commands

*pair\_style reaxff*

### 3.94.7 Default

The option defaults are *bonds = no*.

## 3.95 compute reduce command

## 3.96 compute reduce/region command

### 3.96.1 Syntax

```
compute ID group-ID style arg mode input1 input2 ... keyword args ...
```

- ID, group-ID are documented in *compute* command
- style = *reduce* or *reduce/region*
  - reduce* arg = none
  - reduce/region* arg = region-ID
  - region-ID = ID of region to use for choosing atoms
- mode = *sum* or *min* or *minabs* or *max* or *maxabs* or *ave* or *sumsq* or *avesq* or *sumabs* or *aveabs*
- one or more inputs can be listed
- input = *x* or *y* or *z* or *vx* or *vy* or *vz* or *fx* or *fy* or *fz* or *c\_ID* or *c\_ID[N]* or *f\_ID* or *f\_ID[N]* or *v\_name*
  - x, y, z, vx, vy, vz, fx, fy, fz* = atom attribute (position, velocity, force component)
  - c\_ID* = per-atom or local vector calculated by a compute with ID
  - c\_ID[I]* = Ith column of per-atom or local array calculated by a compute with ID, I can include wildcard (see below)
  - f\_ID* = per-atom or local vector calculated by a fix with ID
  - f\_ID[I]* = Ith column of per-atom or local array calculated by a fix with ID, I can include wildcard (see below)
  - v\_name* = per-atom vector calculated by an atom-style variable with name
- zero or more keyword/args pairs may be appended
- keyword = *replace* or *inputs*
  - replace* args = *vec1 vec2*
    - vec1* = reduced value from this input vector will be replaced
    - vec2* = replace it with *vec1[N]* where N is index of max/min value from *vec2*
  - inputs* arg = *peratom* or *local*
    - peratom* = all inputs are per-atom quantities (default)
    - local* = all input are local quantities

### 3.96.2 Examples

```
compute 1 all reduce sum c_force
compute 1 all reduce/region subbox sum c_force

```

### 3.96.3 Description

Define a calculation that “reduces” one or more vector inputs into scalar values, one per listed input. For the compute reduce command, the inputs can be either per-atom or local quantities and must all be of the same kind (per-atom or local); see discussion of the optional *inputs* keyword below. The compute reduce/region command can only be used with per-atom inputs.

Atom attributes are per-atom quantities, *computes* and *fixes* can generate either per-atom or local quantities, and *atom-style variables* generate per-atom quantities. See the *variable* command and its special functions which can perform the same reduction operations as the compute reduce command on global vectors.

The reduction operation is specified by the *mode* setting. The *sum* option adds the values in the vector into a global total. The *min* or *max* options find the minimum or maximum value across all vector values. The *minabs* or *maxabs* options find the minimum or maximum value across all absolute vector values. The *ave* setting adds the vector values into a global total, then divides by the number of values in the vector. The *sumsq* option sums the square of the values in the vector into a global total. The *avesq* setting does the same as *sumsq*, then divides the sum of squares by the number of values. The last two options can be useful for calculating the variance of some quantity (e.g., variance =  $\text{sumsq} - \text{ave}^2$ ). The *sumabs* option sums the absolute values in the vector into a global total. The *aveabs* setting does the same as *sumabs*, then divides the sum of absolute values by the number of values.

Each listed input is operated on independently. For per-atom inputs, the group specified with this command means only atoms within the group contribute to the result. Likewise for per-atom inputs, if the compute reduce/region command is used, the atoms must also currently be within the region. Note that an input that produces per-atom quantities may define its own group which affects the quantities it returns. For example, if a compute is used as an input which generates a per-atom vector, it will generate values of 0.0 for atoms that are not in the group specified for that compute.

Each listed input can be an atom attribute (position, velocity, force component) or can be the result of a *compute* or *fix* or the evaluation of an atom-style *variable*.

Note that for values from a compute or fix, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *m* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. For example, the following two compute reduce commands are equivalent, since the *compute stress/atom* command creates a per-atom array with six columns:

```
compute myPress all stress/atom NULL
compute 2 all reduce min c_myPress[*]
compute 2 all reduce min c_myPress[1] c_myPress[2] c_myPress[3] &
                           c_myPress[4] c_myPress[5] c_myPress[6]
```

The atom attribute values ( $x$ ,  $y$ ,  $z$ ,  $vx$ ,  $vy$ ,  $vz$ ,  $fx$ ,  $fy$ , and  $fz$ ) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the `compute property/atom` command and then specifying an input value from that compute.

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. Valid computes can generate per-atom or local quantities. See the individual `compute` page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the  $I$ th column of the array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. Valid fixes can generate per-atom or local quantities. See the individual `fix` page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute reduce references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the  $I$ th column of the array calculated by the fix is used. Users can also write code for their own fix style and *add them to LAMMPS*. See the discussion above for how  $I$  can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. It must be an *atom-style variable*. Atom-style variables can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to reduce.

If the `replace` keyword is used, two indices `vec1` and `vec2` are specified, where each index ranges from 1 to the number of input values. The `replace` keyword can only be used if the `mode` is `min` or `max`. It works as follows. A min/max is computed as usual on the `vec2` input vector. The index  $N$  of that value within `vec2` is also stored. Then, instead of performing a min/max on the `vec1` input vector, the stored index is used to select the  $N$ th element of the `vec1` vector.

Thus, for example, if you wish to use this compute to find the bond with maximum stretch, you can do it as follows:

```
compute 1 all property/local batom1 batom2
compute 2 all bond/local dist
compute 3 all reduce max c_1[1] c_1[2] c_2 replace 1 3 replace 2 3
thermo_style custom step temp c_3[1] c_3[2] c_3[3]
```

The first two input values in the compute reduce command are vectors with the IDs of the two atoms in each bond, using the `compute property/local` command. The last input value is bond distance, using the `compute bond/local` command. Instead of taking the max of the two atom ID vectors, which does not yield useful information in this context, the `replace` keywords will extract the atom IDs for the two atoms in the bond of maximum stretch. These atom IDs and the bond stretch will be printed with thermodynamic output.

New in version 21Nov2023.

The `inputs` keyword allows selection of whether all the inputs are per-atom or local quantities. As noted above, all the inputs must be the same kind (per-atom or local). Per-atom is the default setting. If a compute or fix is specified as an input, it must produce per-atom or local data to match this setting. If it produces both, e.g. for the `compute voronoi/atom` command, then this keyword selects between them.

If a single input is specified this compute produces a global scalar value. If multiple inputs are specified, this compute produces a global vector of values, the length of which is equal to the number of inputs specified.

As discussed below, for the `sum`, `sumabs`, and `sumsq` modes, the value(s) produced by this compute are all “extensive”, meaning their value scales linearly with the number of atoms involved. If normalized values are desired, this compute can be accessed by the `thermo_style custom` command with `thermo_modify norm yes` set as an option. Or it can be accessed by a *variable* that divides by the appropriate atom count.

### 3.96.4 Output info

This compute calculates a global scalar if a single input value is specified or a global vector of length  $N$ , where  $N$  is the number of inputs, and which can be accessed by indices 1 to  $N$ . These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

All the scalar or vector values calculated by this compute are “intensive”, except when the *sum*, *sumabs*, or *sumsq* modes are used on per-atom or local vectors, in which case the calculated values are “extensive”.

The scalar or vector values will be in whatever *units* the quantities being reduced are in.

### 3.96.5 Restrictions

As noted above, the compute reduce/region command can only be used with per-atom inputs.

### 3.96.6 Related commands

*compute*, *fix*, *variable*

### 3.96.7 Default

The default value for the *inputs* keyword is peratom.

## 3.97 compute reduce/chunk command

### 3.97.1 Syntax

```
compute ID group-ID reduce/chunk chunkID mode input1 input2 ...
```

- ID, group-ID are documented in [compute](#) command
- reduce/chunk = style name of this compute command
- chunkID = ID of [compute chunk/atom](#) command
- mode = *sum* or *min* or *max*
- one or more inputs can be listed
- input = c\_ID, c\_ID[N], f\_ID, f\_ID[N], v\_ID

```
c_ID = per-atom vector calculated by a compute with ID
c_ID[I] = Ith column of per-atom array calculated by a compute with ID, I can
→include wildcard (see below)
f_ID = per-atom vector calculated by a fix with ID
f_ID[I] = Ith column of per-atom array calculated by a fix with ID, I can include
→wildcard (see below)
v_name = per-atom vector calculated by an atom-style variable with name
```

### 3.97.2 Examples

```
compute 1 all reduce/chunk mychunk min c_cluster
```

### 3.97.3 Description

Define a calculation that reduces one or more per-atom vectors into per-chunk values. This can be useful for diagnostic output. Or when used in conjunction with the [compute chunk/spread/atom](#) command it can be used to create per-atom values that induce a new set of chunks with a second [compute chunk/atom](#) command. An example is given below.

In LAMMPS, chunks are collections of atoms defined by a [compute chunk/atom](#) command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as *chunkID*. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the [compute chunk/atom](#) and [Howto chunk](#) doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

For each atom, this compute accesses its chunk ID from the specified *chunkID* compute. The per-atom value from an input contributes to a per-chunk value corresponding the the chunk ID.

The reduction operation is specified by the *mode* setting and is performed over all the per-atom values from the atoms in each chunk. The *sum* option adds the pre-atom values to a per-chunk total. The *min* or *max* options find the minimum or maximum value of the per-atom values for each chunk.

Note that only atoms in the specified group contribute to the reduction operation. If the *chunkID* compute returns a 0 for the chunk ID of an atom (i.e., the atom is not in a chunk defined by the [compute chunk/atom](#) command), that atom will also not contribute to the reduction operation. An input that is a compute or fix may define its own group which affects the quantities it returns. For example, a compute with return a zero value for atoms that are not in the group specified for that compute.

Each listed input is operated on independently. Each input can be the result of a [compute](#) or [fix](#) or the evaluation of an atom-style [variable](#).

Note that for values from a compute or fix, the bracketed index *I* can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the size of the vector (for *mode* = scalar) or the number of columns in the array (for *mode* = vector), then an asterisk with no numeric values means all indices from 1 to *N*. A leading asterisk means all indices from 1 to *n* (inclusive). A trailing asterisk means all indices from *n* to *N* (inclusive). A middle asterisk means all indices from *m* to *n* (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. For example, the following two compute reduce/chunk commands are equivalent, since the [compute property/chunk](#) command creates a per-atom array with 3 columns:

```
compute prop all property/atom vx vy vz
compute 10 all reduce/chunk mychunk max c_prop[*]
compute 10 all reduce/chunk mychunk max c_prop[1] c_prop[2] c_prop[3]
```

Here is an example of using this compute, in conjunction with the [compute chunk/spread/atom](#) command to identify self-assembled micelles. The commands below can be added to the examples/in.micelle script.

Imagine a collection of polymer chains or small molecules with hydrophobic end groups. All the hydrophobic (HP) atoms are assigned to a group called “phobic”.

These commands will assign a unique cluster ID to all HP atoms within a specified distance of each other. A cluster will contain all HP atoms in a single molecule, but also the HP atoms in nearby molecules (e.g., molecules that have clumped to form a micelle due to the attraction induced by the hydrophobicity). The output of the chunk/reduce command will be a cluster ID per chunk (molecule). Molecules with the same cluster ID are in the same micelle.

```
group phobic type 4      # specific to in.micelle model
compute cluster phobic cluster/atom 2.0
compute cmol all chunk/atom molecule
compute reduce phobic reduce/chunk cmol min c_cluster
```

This per-chunk info could be output in at least two ways:

```
fix 10 all ave/time 1000 1 1000 c_reduce file tmp.phobic mode vector

compute spread all chunk/spread/atom cmol c_reduce
dump 1 all custom 1000 tmp.dump id type mol x y z c_cluster c_spread
dump_modify 1 sort id
```

In the first case, each snapshot in the tmp.phobic file will contain one line per molecule. Molecules with the same value are in the same micelle. In the second case each dump snapshot contains all atoms, each with a final field with the cluster ID of the micelle that the HP atoms of that atom's molecule belong to.

The result from compute chunk/spread/atom can be used to define a new set of chunks, where all the atoms in all the molecules in the same micelle are assigned to the same chunk (i.e., one chunk per micelle).

```
compute micelle all chunk/atom c_spread compress yes
```

Further analysis on a per-micelle basis can now be performed using any of the per-chunk computes listed on the [Howto chunk](#) doc page (e.g., count the number of atoms in each micelle, calculate its center or mass, shape/moments of inertia, and radius of gyration).

```
compute prop all property/chunk micelle count
fix 20 all ave/time 1000 1 1000 c_prop file tmp.micelle mode vector
```

Each snapshot in the tmp.micelle file will have one line per micelle with its count of atoms, plus a first line for a chunk with all the solvent atoms. By the time 50000 steps have elapsed, there are a handful of large micelles.

---

### 3.97.4 Output info

This compute calculates a global vector if a single input value is specified, otherwise a global array is output. The number of columns in the array is the number of inputs provided. The length of the vector or the number of vector elements or array rows = the number of chunks *Nchunk* as calculated by the specified [compute chunk/atom](#) command. The vector or array can be accessed by any command that uses global values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom values for the vector or each column of the array will be in whatever [units](#) the corresponding input value is in. The vector or array values are “intensive”.

### 3.97.5 Restrictions

none

### 3.97.6 Related commands

*compute chunk/atom, compute reduce, compute chunk/spread/atom*

### 3.97.7 Default

```

### 3.98.2 Examples

```
compute 1 all rheo/property/atom phase surface/r surface/n/* pressure
compute 2 all rheo/property/atom shift/v/x grad/v/xx stress/v/*
```

### 3.98.3 Description

New in version 29Aug2024.

Define a computation that stores atom attributes specific to the RHEO package for each atom in the group. This is useful so that the values can be used by other *output commands* that take computes as inputs. See for example, the *compute reduce*, *fix ave/atom*, *fix ave/histo*, *fix ave/chunk*, and *atom-style variable* commands.

For vector attributes, e.g. *shift/v/ $\alpha$* , one must specify  $\alpha$  as the  $x$ ,  $y$ , or  $z$  component, e.g. *shift/v/ $x$* . Alternatively, a wild card *\** will include all components,  $x$  and  $y$  in 2D or  $x$ ,  $y$ , and  $z$  in 3D.

For tensor attributes, e.g. *grad/v/ $\alpha\beta$* , one must specify both  $\alpha$  and  $\beta$  as  $x$ ,  $y$ , or  $z$ , e.g. *grad/v/ $xy$* . Alternatively, a wild card *\** will include all components. In 2D, this includes  $xx$ ,  $xy$ ,  $yx$ , and  $yy$ . In 3D, this includes  $xx$ ,  $xy$ ,  $xz$ ,  $yx$ ,  $yy$ ,  $yz$ ,  $zx$ ,  $zy$ , and  $zz$ .

Many properties require their respective fixes, listed below in related commands, be defined. For instance, the *viscosity* attribute is the viscosity of a particle calculated by *fix rheo/viscous*. The meaning of less obvious properties is described below.

The *phase* property indicates whether the particle is in a fluid state, a value of 0, or a solid state, a value of 1.

The *surface* property indicates the surface designation produced by the *interface/reconstruct* option of *fix rheo*. Bulk particles have a value of 0, surface particles have a value of 1, and splash particles have a value of 2. The *surface/r* property is the distance from the surface, up to the kernel cutoff length. Surface particles have a value of 0. The *surface/n/ $\alpha$*  properties are the components of the surface normal vector.

The *shift/v/ $\alpha$*  properties are the components of the shifting velocity produced by the *shift* option of *fix rheo*.

The *nbond/shell* property is the number of shell bonds that have been activated from *bond style rheo/shell*.

The values are stored in a per-atom vector or array as discussed below. Zeroes are stored for atoms not in the specified group or for quantities that are not defined for a particular particle in the group

### 3.98.4 Output info

This compute calculates a per-atom vector or per-atom array depending on the number of input values. Generally, if a single input is specified, a per-atom vector is produced. If two or more inputs are specified, a per-atom array is produced where the number of columns = the number of inputs. However, if a wild card *\** is used for a vector or tensor, then the number of inputs is considered to be incremented by the dimension or the dimension squared, respectively. The vector or array can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array values will be in whatever *units* the corresponding attribute is in (e.g., density units for *rho*).

### 3.98.5 Restrictions

none

### 3.98.6 Related commands

*dump custom*, *compute reduce*, *fix ave/atom*, *fix ave/chunk*, *fix rheo/viscosity*, *fix rheo/pressure*, *fix rheo/thermal*, *fix rheo/oxidation*, *fix rheo*

## 3.99 compute rigid/local command

### 3.99.1 Syntax

```
compute ID group-ID rigid/local rigidID input1 input2 ...
```

- ID, group-ID are documented in *compute* command
- rigid/local = style name of this compute command
- rigidID = ID of fix rigid/small command or one of its variants
- input = one or more rigid body attributes

```
possible attributes = id, mol, mass,
                    x, y, z, xu, yu, zu, ix, iy, iz
                    vx, vy, vz, fx, fy, fz,
                    omegax, omegay, omegaz,
                    angmomx, angmomy, angmomz,
                    quatw, quati, quatj, quatk,
                    tqx, tqy, tqz,
                    inertiax, inertiy, inertiaz
```

id = atom ID of atom within body which owns body properties  
mol = molecule ID used to define body in *fix rigid/small* command  
mass = total mass of body  
x,y,z = center of mass coords of body  
xu,yu,zu = unwrapped center of mass coords of body  
ix,iy,iz = box image that the center of mass is in  
vx,vy,vz = center of mass velocities  
fx,fy,fz = force of center of mass  
omegax,omegay,omegaz = angular velocity of body  
angmomx,angmomy,angmomz = angular momentum of body  
quatw,quati,quatj,quatk = quaternion components for body  
tqx,tqy,tqz = torque on body  
inertiax,inertiy,inertiaz = diagonalized moments of inertia of body

### 3.99.2 Examples

```
compute 1 all rigid/local myRigid mol x y z
```

### 3.99.3 Description

Define a computation that simply stores rigid body attributes for rigid bodies defined by the *fix rigid/small* command or one of its NVE, NVT, NPT, NPH variants. The data is stored as local data so it can be accessed by other *output commands* that process local data, such as the *compute reduce* or *dump local* commands.

Note that this command only works with the *fix rigid/small* command or its variants, not the *fix rigid* command and its variants. The ID of the *fix rigid/small* command used to define rigid bodies must be specified as *rigidID*. The *fix rigid* command is typically used to define a handful of (potentially very large) rigid bodies. It outputs similar per-body information as this command directly from the *fix* as global data; see the *fix rigid* page for details

The local data stored by this command is generated by looping over all the atoms owned on a processor. If the atom is not in the specified *group-ID* or is not part of a rigid body it is skipped. If it is not the atom within a body that is assigned to store the body information it is skipped (only one atom per body is so assigned). If it is the assigned atom, then the info for that body is output. This means that information for *N* bodies is generated. *N* may be less than the number of bodies defined by the *fix rigid* command, if the atoms in some bodies are not in the *group-ID*.

---

**Note:** Which atom in a body owns the body info is determined internal to LAMMPS; it's the one nearest the geometric center of the body. Typically you should avoid this complication, by defining the group associated with this *fix* to include/exclude entire bodies.

---

Note that as atoms and bodies migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next.

Here is an example of how to use this compute to dump rigid body info to a file:

```
compute 1 all rigid/local myRigid mol x y z fx fy fz
dump 1 all local 1000 tmp.dump index c_1[1] c_1[2] c_1[3] c_1[4] c_1[5] c_1[6] c_1[7]
```

---

This section explains the rigid body attributes that can be specified.

The *id* attribute is the atom-ID of the atom which owns the rigid body, which is assigned by the *fix rigid/small* command.

The *mol* attribute is the molecule ID of the rigid body. It should be the molecule ID which all of the atoms in the body belong to, since that is how the *fix rigid/small* command defines its rigid bodies.

The *mass* attribute is the total mass of the rigid body.

There are two options for outputting the coordinates of the center of mass (COM) of the body. The *x*, *y*, *z* attributes write the COM “unscaled”, in the appropriate distance *units* (Å, σ, etc). Use *xu*, *yu*, *zu* if you want the COM “unwrapped” by the image flags for each body. Unwrapped means that if the body COM has passed through a periodic boundary one or more times, the value is generated what the COM coordinate would be if it had not been wrapped back into the periodic box.

The image flags for the body can be generated directly using the *ix*, *iy*, *iz* attributes. For periodic dimensions, they specify which image of the simulation box the COM is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid body COMs cross periodic boundaries during the simulation.

The *vx*, *vy*, *vz*, *fx*, *fy*, *fz* attributes are components of the COM velocity and force on the COM of the body.

The *omegax*, *omegay*, and *omegaz* attributes are the angular velocity components of the body in the system frame around its COM.

The *angmomx*, *angmomy*, and *angmomz* attributes are the angular momentum components of the body in the system frame around its COM.

The *quatw*, *quati*, *quatj*, and *quatk* attributes are the components of the 4-vector quaternion representing the orientation of the rigid body. See the [set](#) command for an explanation of the quaternion vector.

The *txx*, *txy*, *txz* attributes are components of the torque acting on the body around its COM.

The *inertiax*, *inertiay*, *inertiaz* attributes are components of diagonalized inertia tensor for the body (i.e., the three moments of inertia for the body around its principal axes), as computed internally by LAMMPS.

---

### 3.99.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of rigid bodies. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector or array values will be in whatever [units](#) the corresponding attribute is in:

- id,mol = unitless
- mass = mass units
- x,y,z and xy,yu,zu = distance units
- vx,vy,vz = velocity units
- fx,fy,fz = force units
- omegax,omegay,omegaz = radians/time units
- angmomx,angmomy,angmomz = mass\*distance<sup>2</sup>/time units
- quatw,quati,quatj,quatk = unitless
- txx,txy,txz = torque units
- inertiax,inertiay,inertiaz = mass\*distance<sup>2</sup> units

### 3.99.5 Restrictions

This compute is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.99.6 Related commands

*dump local*, *compute reduce*

### 3.99.7 Default

none

## 3.100 compute saed command

### 3.100.1 Syntax

```
compute ID group-ID saed lambda type1 type2 ... typeN keyword value ...
```

- ID, group-ID are documented in *compute* command
- saed = style name of this compute command
- lambda = wavelength of incident radiation (length units)
- type1 type2 ... typeN = chemical symbol of each atom type (see valid options below)
- zero or more keyword/value pairs may be appended
- keyword = *Kmax* or *Zone* or *dR\_Ewald* or *c* or *manual* or *echo*

*Kmax* value = Maximum distance explored from reciprocal space origin  
(inverse length units)

*Zone* values = z1 z2 z3

z1,z2,z3 = Zone axis of incident radiation. If z1=z2=z3=0 all  
reciprocal space will be meshed up to *Kmax*

*dR\_Ewald* value = Thickness of Ewald sphere slice intercepting  
reciprocal space (inverse length units)

*c* values = c1 c2 c3

c1,c2,c3 = parameters to adjust the spacing of the reciprocal  
lattice nodes in the h, k, and l directions respectively

*manual* = flag to use manual spacing of reciprocal lattice points  
based on the values of the *c* parameters

*echo* = flag to provide extra output for debugging purposes

### 3.100.2 Examples

```
compute 1 all saed 0.0251 Al 0 Kmax 1.70 Zone 0 0 1 dR_Ewald 0.01 c 0.5 0.5 0.5
compute 2 all saed 0.0251 Ni Kmax 1.70 Zone 0 0 0 c 0.05 0.05 0.05 manual echo
```

```
fix 1 all saed/vtk 1 1 1 c_1 file Al203_001.saed
```

```
fix 2 all saed/vtk 1 1 1 c_2 file Ni_000.saed
```

### 3.100.3 Description

Define a computation that calculates electron diffraction intensity as described in (Coleman) on a mesh of reciprocal lattice nodes defined by the entire simulation domain (or manually) using simulated radiation of wavelength lambda.

The electron diffraction intensity  $I$  at each reciprocal lattice point is computed from the structure factor  $F$  using the equations:

$$I = \frac{F^* F}{N}$$

$$F(\mathbf{k}) = \sum_{j=1}^N f_j(\theta) \exp(2\pi i \mathbf{k} \cdot \mathbf{r}_j)$$

Here,  $\mathbf{K}$  is the location of the reciprocal lattice node,  $\mathbf{r}_j$  is the position of each atom,  $f_j$  are atomic scattering factors.

Diffraction intensities are calculated on a three-dimensional mesh of reciprocal lattice nodes. The mesh spacing is defined either (a) by the entire simulation domain or (b) manually using selected values as shown in the 2D diagram below.

For a mesh defined by the simulation domain, a rectilinear grid is constructed with spacing  $c^* \text{inv}(A)$  along each reciprocal lattice axis. Where  $A$  are the vectors corresponding to the edges of the simulation cell. If one or two directions has non-periodic boundary conditions, then the spacing in these directions is defined from the average of the (inversed) box lengths with periodic boundary conditions. Meshes defined by the simulation domain must contain at least one periodic boundary.

If the *manual* flag is included, the mesh of reciprocal lattice nodes will be defined using the  $c$  values for the spacing along each reciprocal lattice axis. Note that manual mapping of the reciprocal space mesh is good for comparing diffraction results from multiple simulations; however it can reduce the likelihood that Bragg reflections will be satisfied unless small spacing parameters ( $< 0.05 \text{ \AA}^{-1}$ ) are implemented. Meshes with manual spacing do not require a periodic boundary.

The limits of the reciprocal lattice mesh are determined by the use of the  $K_{max}$ ,  $Zone$ , and  $dR\_Ewald$  parameters. The rectilinear mesh created about the origin of reciprocal space is terminated at the boundary of a sphere of radius  $K_{max}$  centered at the origin. If  $Zone$  parameters  $z1 = z2 = z3 = 0$  are used, diffraction intensities are computed throughout the entire spherical volume - note this can greatly increase the cost of computation. Otherwise,  $Zone$  parameters will denote the  $z1 = h$ ,  $z2 = k$ , and  $z3 = \ell$  (in a global sense) zone axis of an intersecting Ewald sphere. Diffraction

intensities will only be computed at the intersection of the reciprocal lattice mesh and a  $dR_{Ewald}$  thick surface of the Ewald sphere. See the example 3D intensity data and the intersection of a [010] zone axis in the below image.

The atomic scattering factors,  $f_j$ , accounts for the reduction in diffraction intensity due to Compton scattering. Compute saed uses analytical approximations of the atomic scattering factors that vary for each atom type (type1 type2 ... typeN) and angle of diffraction. The analytic approximation is computed using the formula ([Brown](#)):

$$f_j \left( \frac{\sin(\theta)}{\lambda} \right) = \sum_i^5 a_i \exp \left( -b_i \frac{\sin^2(\theta)}{\lambda^2} \right)$$

Coefficients parameterized by ([Fox](#)) are assigned for each atom type designating the chemical symbol and charge of each atom type. Valid chemical symbols for compute saed are:

H	He	Li	Be	B	C	N	O	F	Ne	Na	Mg	Al	Si	P	S	Cl	Ar	K	Ca
Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn	Ga	Ge	As	Se	Br	Kr	Rb	Sr	Y	Zr
Nb	Mo	Tc	Ru	Rh	Pd	Ag	Cd	In	Sn	Sb	Te	I	Xe	Cs	Ba	La	Ce	Pr	Nd
Pm	Sm	Eu	Gd	Tb	Dy	Ho	Er	Tm	Yb	Lu	Hf	Ta	W	Re	Os	Ir	Pt	Au	Hg
Tl	Pb	Bi	Po	At	Rn	Fr	Ra	Ac	Th	Pa	U	Np	Pu	Am	Cm	Bk	Cf		

If the *echo* keyword is specified, compute saed will provide extra reporting information to the screen.

### 3.100.4 Output info

This compute calculates a global vector. The length of the vector is the number of reciprocal lattice nodes that are explored by the mesh. The entries of the global vector are the computed diffraction intensities as described above.

The vector can be accessed by any command that uses global values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

All array values calculated by this compute are “intensive”.

### 3.100.5 Restrictions

This compute is part of the DIFFRACTION package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The compute\_saed command does not work for triclinic cells.

### 3.100.6 Related commands

*fix saed\_vtk*, *compute xrd*

### 3.100.7 Default

The option defaults are Kmax = 1.70, Zone 1 0 0, c 1 1 1, dR\_Ewald = 0.01.

## 3.101 compute slcsa/atom command

### 3.101.1 Syntax

```
compute ID group-ID slcsa/atom twojmax nclasses db_mean_descriptor_file lda_file lr_
→decision_file lr_bias_file maha_file value
```

- ID, group-ID are documented in [compute](#) command
- slcsa/atom = style name of this compute command
- twojmax = band limit for bispectrum components (non-negative integer)
- nclasses = number of crystal structures used in the database for the classifier SL-CSA
- db\_mean\_descriptor\_file = file name of file containing the database mean descriptor
- lda\_file = file name of file containing the linear discriminant analysis matrix for dimension reduction
- lr\_decision\_file = file name of file containing the scaling matrix for logistic regression classification
- lr\_bias\_file = file name of file containing the bias vector for logistic regression classification

- maha\_file = file name of file containing for each crystal structure: the Mahalanobis distance threshold for sanity check purposes, the average reduced descriptor and the inverse of the corresponding covariance matrix
- c\_ID[\*] = compute ID of previously required *compute sna/atom* command

### 3.101.2 Examples

```
compute b1 all sna/atom 9.0 0.99363 8 0.5 1.0 rmin0 0.0 nnn 24 wmode 1 delta 0.3
compute b2 all slcsa/atom 8 4 mean_descriptors.dat lda_scalings.dat lr_decision.dat lr_
→bias.dat maha_thresholds.dat c_b1[*]
```

### 3.101.3 Description

New in version 7Feb2024.

Define a computation that performs the Supervised Learning Crystal Structure Analysis (SL-CSA) from ([Lafourcade](#)) for each atom in the group. The SL-CSA tool takes as an input a per-atom descriptor (bispectrum) that is computed through the *compute sna/atom* command and then proceeds to a dimension reduction step followed by a logistic regression in order to assign a probable crystal structure to each atom in the group. The SL-CSA tool is pre-trained on a database containing  $C$  distinct crystal structures from which a crystal structure classifier is derived and a tutorial to build such a tool is available at [SL-CSA](#).

The first step of the SL-CSA tool consists in performing a dimension reduction of the per-atom descriptor  $\mathbf{B}^i \in \mathbb{R}^D$  through the Linear Discriminant Analysis (LDA) method, leading to a new projected descriptor  $\mathbf{x}^i = \mathbf{P}_{\text{LDA}}(\mathbf{B}^i) : \mathbb{R}^D \rightarrow \mathbb{R}^{d=C-1}$ .

$$\mathbf{x}^i = \mathbf{C}_{\text{LDA}}^T \cdot (\mathbf{B}^i - \mu_{\text{db}}^{\mathbf{B}})$$

where  $\mathbf{C}_{\text{LDA}}^T \in \mathbb{R}^{D \times d}$  is the reduction coefficients matrix of the LDA model read in file *lda\_file*,  $\mathbf{B}^i \in \mathbb{R}^D$  is the bispectrum of atom  $i$  and  $\mu_{\text{db}}^{\mathbf{B}} \in \mathbb{R}^D$  is the average descriptor of the entire database. The latter is computed from the average descriptors of each crystal structure read from the file *mean\_descriptors\_file*.

The new projected descriptor with dimension  $d = C - 1$  allows for a good separation of different crystal structures fingerprints in the latent space.

Once the dimension reduction step is performed by means of LDA, the new descriptor  $\mathbf{x}^i \in \mathbb{R}^{d=C-1}$  is taken as an input for performing a multinomial logistic regression (LR) which provides a score vector  $\mathbf{s}^i = \mathbf{P}_{\text{LR}}(\mathbf{x}^i) : \mathbb{R}^d \rightarrow \mathbb{R}^C$  defined as:

$$\mathbf{s}^i = \mathbf{b}_{\text{LR}} + \mathbf{D}_{\text{LR}} \cdot \mathbf{x}^{iT}$$

with  $\mathbf{b}_{\text{LR}} \in \mathbb{R}^C$  and  $\mathbf{D}_{\text{LR}} \in \mathbb{R}^{C \times d}$  the bias vector and decision matrix of the LR model after training both read in files *lr\_file1* and *lr\_file2* respectively.

Finally, a probability vector  $\mathbf{p}^i = \mathbf{P}_{\text{LR}}(\mathbf{x}^i) : \mathbb{R}^d \rightarrow \mathbb{R}^C$  is defined as:

$$\mathbf{p}^i = \frac{\exp(\mathbf{s}^i)}{\sum_j \exp(\mathbf{s}_j^i)}$$

from which the crystal structure assigned to each atom with descriptor  $\mathbf{B}^i$  and projected descriptor  $\mathbf{x}^i$  is computed as the *argmax* of the probability vector  $\mathbf{p}^i$ . Since the logistic regression step systematically attributes a crystal structure to each atom, a sanity check is needed to avoid misclassification. To this end, a per-atom Mahalanobis distance to each crystal structure  $CS$  present in the database is computed:

$$d_{\text{Mahalanobis}}^{i \rightarrow CS} = \sqrt{(\mathbf{x}^i - \mu_{CS}^{\mathbf{x}})^T \cdot \mathbf{\Sigma}_{CS}^{-1} \cdot (\mathbf{x}^i - \mu_{CS}^{\mathbf{x}})}$$

where  $\mu_{CS}^x \in \mathbb{R}^d$  is the average projected descriptor of crystal structure  $CS$  in the database and where  $\Sigma_{CS} \in \mathbb{R}^{d \times d}$  is the corresponding covariance matrix. Finally, if the Mahalanobis distance to crystal structure  $CS$  for atom  $i$  is greater than the pre-determined threshold, no crystal structure is assigned to atom  $i$ . The Mahalanobis distance thresholds are read in file *maha\_file* while the covariance matrices are read in file *covmat\_file*.

The [SL-CSA](#) framework provides an automatic computation of the different matrices and thresholds required for a proper classification and writes down all the required files for calling the `compute slcsa/atom` command.

The `compute slcsa/atom` command requires that the `compute sna/atom` command is called before as it takes the resulting per-atom bispectrum as an input. In addition, it is crucial that the value *twojmax* is set to the same value of the value *twojmax* used in the `compute sna/atom` command, as well as that the value *nclasses* is set to the number of crystal structures used in the database to train the SL-CSA tool.

### 3.101.4 Output info

By default, this compute computes the Mahalanobis distances to the different crystal structures present in the database in addition to assigning a crystal structure for each atom as a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

### 3.101.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.101.6 Related commands

`compute sna/atom`

### 3.101.7 Default

## 3.102 compute slice command

### 3.102.1 Syntax

```
compute ID group-ID slice Nstart Nstop Nskip input1 input2 ...
```

- ID, group-ID are documented in [compute](#) command
- slice = style name of this compute command
- Nstart = starting index within input vector(s)
- Nstop = stopping index within input vector(s)

- Nskip = extract every Nskip elements from input vector(s)
- input = c\_ID, c\_ID[N], f\_ID, f\_ID[N]

```
c_ID = global vector calculated by a compute with ID
c_ID[I] = Ith column of global array calculated by a compute with ID
f_ID = global vector calculated by a fix with ID
f_ID[I] = Ith column of global array calculated by a fix with ID
v_name = vector calculated by an vector-style variable with name
```

### 3.102.2 Examples

```
compute 1 all slice 1 100 10 c_msdmol[4]
compute 1 all slice 301 400 1 c_msdmol[4] v_myVec
```

### 3.102.3 Description

Define a calculation that “slices” one or more vector inputs into smaller vectors, one per listed input. The inputs can be global quantities; they cannot be per-atom or local quantities. *Computes* and *fixes* and vector-style *variables* can generate such global quantities. The group specified with this command is ignored.

The values extracted from the input vector(s) are determined by the *Nstart*, *Nstop*, and *Nskip* parameters. The elements of an input vector of length N are indexed from 1 to N. Starting at element *Nstart*, every Mth element is extracted, where  $M = Nskip$ , until element *Nstop* is reached. The extracted quantities are stored as a vector, which is typically shorter than the input vector.

Each listed input is operated on independently to produce one output vector. Each listed input must be a global vector or column of a global array calculated by another *compute* or *fix*.

If an input value begins with “c\_”, a compute ID must follow which has been previously defined in the input script and which generates a global vector or array. See the individual *compute* doc page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script and which generates a global vector or array. See the individual *fix* page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute slice references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the array calculated by the fix is used. Users can also write code for their own fix style and *add them to LAMMPS*.

If an input value begins with “v\_”, a variable name must follow which has been previously defined in the input script. Only vector-style variables can be referenced. See the *variable* command for details. Note that variables of style *vector* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to slice.

If a single input is specified this compute produces a global vector, even if the length of the vector is 1. If multiple inputs are specified, then a global array of values is produced, with the number of columns equal to the number of inputs specified.

### 3.102.4 Output info

This compute calculates a global vector if a single input value is specified or a global array with N columns where N is the number of inputs. The length of the vector or the number of rows in the array is equal to the number of values extracted from each input vector. These values can be used by any command that uses global vector or array values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The vector or array values calculated by this compute are simply copies of values generated by computes or fixes or variables that are input vectors to this compute. If there is a single input vector of intensive and/or extensive values, then each value in the vector of values calculated by this compute will be “intensive” or “extensive”, depending on the corresponding input value. If there are multiple input vectors, and all the values in them are intensive, then the array values calculated by this compute are “intensive”. If there are multiple input vectors, and any value in them is extensive, then the array values calculated by this compute are “extensive”. Values produced by a variable are treated as intensive.

The vector or array values will be in whatever *units* the input quantities are in.

## 3.103 compute smd/contact/radius command

### 3.103.1 Syntax

```
compute ID group-ID smd/contact/radius
```

- ID, group-ID are documented in *compute* command
- smd/contact/radius = style name of this compute command

### 3.103.2 Examples

```
compute 1 all smd/contact/radius
```

### 3.103.3 Description

Define a computation which outputs the contact radius, i.e., the radius used to prevent particles from penetrating each other. The contact radius is used only to prevent particles belonging to different physical bodies from penetrating each other. It is used by the contact pair styles, e.g., `smd/hertz` and `smd/tri_surface`.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

The value of the contact radius will be 0.0 for particles not in the specified compute group.

### 3.103.4 Output info

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle vector values will be in distance *units*.

### 3.103.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.103.6 Related commands

*dump custom* `smd/hertz` `smd/tri_surface`

## 3.104 compute smd/damage command

### 3.104.1 Syntax

```
compute ID group-ID smd/damage
```

- ID, group-ID are documented in *compute* command
- smd/damage = style name of this compute command

### 3.104.2 Examples

```
compute 1 all smd/damage
```

### 3.104.3 Description

Define a computation that calculates the damage status of SPH particles according to the damage model which is defined via the SMD SPH pair styles, e.g., the maximum plastic strain failure criterion.

See [this PDF guide](#) to use Smooth Mach Dynamics in LAMMPS.

#### Output Info:

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle values are dimensionless and in the range of zero to one.

### 3.104.4 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the “Build

### 3.104.5 Related commands

## 3.105 compute smd/hourglass/error command

### 3.105.1 Syntax

```
compute ID group-ID smd/hourglass/error
```

- ID, group-ID are documented in [compute](#) command
- smd/hourglass/error = style name of this compute command

### 3.105.2 Examples

```
compute 1 all smd/hourglass/error
```

### 3.105.3 Description

Define a computation which outputs the error of the approximated relative separation with respect to the actual relative separation of the particles *i* and *j*. Ideally, if the deformation gradient is exact, and there exists a unique mapping between all particles' positions within the neighborhood of the central node and the deformation gradient, the approximated relative separation will coincide with the actual relative separation of the particles *i* and *j* in the deformed configuration. This compute is only really useful for debugging the hourglass control mechanism which is part of the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to use Smooth Mach Dynamics in LAMMPS.

#### Output Info:

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle vector values will be dimensionless. See [units](#).

### 3.105.4 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This quantity will be computed only for particles which interact with *tlsph* pair style.

### 3.105.5 Related commands

- smd/tlsph/defgrad = style name of this compute command

## 3.110.2 Examples

```
compute 1 all smd/tlsph/defgrad
```

## 3.110.3 Description

Define a computation that calculates the deformation gradient. It is only meaningful for particles which interact according to the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to use Smooth Mach Dynamics in LAMMPS.

## 3.110.4 Output info

This compute outputs a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The per-particle vector values will be given dimensionless. See [units](#). The per-particle vector has 10 entries. The first nine entries correspond to the xx, xy, xz, yx, yy, yz, zx, zy, zz components of the asymmetric deformation gradient tensor. The tenth entry is the determinant of the deformation gradient.

## 3.110.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info. This compute can only be used for particles which interact via the total Lagrangian SPH pair style.

- smd/tlsph/dt = style name of this compute command

### 3.111.2 Examples

```
compute 1 all smd/tlsph/dt
```

### 3.111.3 Description

Define a computation that outputs the CFL-stable time increment per particle. This time increment is essentially given by the speed of sound, divided by the SPH smoothing length. Because both the speed of sound and the smoothing length typically change during the course of a simulation, the stable time increment needs to be re-computed every time step. This calculation is performed automatically in the relevant SPH pair styles and this compute only serves to make the stable time increment accessible for output purposes.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

### 3.111.4 Output info

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle values will be given in *units* of time.

### 3.111.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This compute can only be used for particles interacting with the Total-Lagrangian SPH pair style.

### 3.111.6 Related commands

*smd/adjust/dt*

### 3.111.7 Default

none

## 3.112 compute smd/tlsph/num/neighs command

### 3.112.1 Syntax

```
compute ID group-ID smd/tlsph/num/neighs
```

- ID, group-ID are documented in [compute](#) command
- smd/tlsph/num/neighs = style name of this compute command

### 3.112.2 Examples

```
compute 1 all smd/tlsph/num/neighs
```

### 3.112.3 Description

Define a computation that calculates the number of particles inside of the smoothing kernel radius for particles interacting via the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

### 3.112.4 Output info

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle values are dimensionless. See [units](#).

### 3.112.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This quantity will be computed only for particles which interact with the Total-Lagrangian pair style.

### 3.112.6 Related commands

*smd/ulsph/num/neighs*

### 3.112.7 Default

none

## 3.113 compute smd/tlsph/shape command

### 3.113.1 Syntax

```
compute ID group-ID smd/tlsph/shape
```

- ID, group-ID are documented in [compute](#) command
- smd/tlsph/shape = style name of this compute command

### 3.113.2 Examples

```
compute 1 all smd/tlsph/shape
```

### 3.113.3 Description

Define a computation that outputs the current shape of the volume associated with a particle as a rotated ellipsoid. It is only meaningful for particles which interact according to the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to use Smooth Mach Dynamics in LAMMPS.

### 3.113.4 Output info

This compute calculates a per-particle vector of vectors, which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle vector has 7 entries. The first three entries correspond to the lengths of the ellipsoid's axes and have units of length. These axis values are computed as the contact radius times the xx, yy, or zz components of the Green-Lagrange strain tensor associated with the particle. The next 4 values are quaternions (order: q, x, y, z) which describe the spatial rotation of the particle relative to its initial state.

### 3.113.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This quantity will be computed only for particles which interact with the Total-Lagrangian SPH pair style.

### 3.113.6 Related commands

*smd/contact/radius*

## 3.114 compute smd/tlsph/strain command

### 3.114.1 Syntax

```
compute ID group-ID smd/tlsph/strain
```

- ID, group-ID are documented in [compute](#) command
- smd/tlsph/strain = style name of this compute command

### 3.114.2 Examples

```
compute 1 all smd/tlsph/strain
```

### 3.114.3 Description

Define a computation that calculates the Green-Lagrange strain tensor for particles interacting via the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

### 3.114.4 Output info

This compute calculates a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The per-particle tensor values will be given dimensionless. See [units](#).

The per-particle vector has 6 entries, corresponding to the xx, yy, zz, xy, xz, yz components of the symmetric strain tensor.

### 3.114.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This quantity will be computed only for particles which interact with the Total-Lagrangian SPH pair style.

### 3.114.6 Related commands

*smd/tlsph/strain/rate, smd/tlsph/stress*

### 3.114.7 Default

none

## 3.115 compute smd/tlsph/strain/rate command

### 3.115.1 Syntax

```
compute ID group-ID smd/tlsph/strain/rate
```

- ID, group-ID are documented in [compute](#) command
- smd/tlsph/strain/rate = style name of this compute command

### 3.115.2 Examples

```
compute 1 all smd/tlsph/strain/rate
```

### 3.115.3 Description

Define a computation that calculates the rate of the strain tensor for particles interacting via the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

### 3.115.4 Output info

This compute calculates a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The values will be given in [units](#) of one over time.

The per-particle vector has 6 entries, corresponding to the xx, yy, zz, xy, xz, yz components of the symmetric strain rate tensor.

### 3.115.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This quantity will be computed only for particles which interact with Total-Lagrangian SPH pair style.

### 3.115.6 Related commands

*compute smd/tlsph/strain, compute smd/tlsph/stress*

### 3.115.7 Default

none

## 3.116 compute smd/tlsph/stress command

### 3.116.1 Syntax

```
compute ID group-ID smd/tlsph/stress
```

- ID, group-ID are documented in [compute](#) command
- smd/tlsph/stress = style name of this compute command

### 3.116.2 Examples

```
compute 1 all smd/tlsph/stress
```

### 3.116.3 Description

Define a computation that outputs the Cauchy stress tensor for particles interacting via the Total-Lagrangian SPH pair style.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

### 3.116.4 Output info

This compute calculates a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The values will be given in [units](#) of pressure.

The per-particle vector has 7 entries. The first six entries correspond to the xx, yy, zz, xy, xz and yz components of the symmetric Cauchy stress tensor. The seventh entry is the second invariant of the stress tensor, i.e., the von Mises equivalent stress.

### 3.116.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This quantity will be computed only for particles which interact with the Total-Lagrangian SPH pair style.

### 3.116.6 Related commands

*compute smd/tlsph/strain, cmopute smd/tlsph/strain/rate*

### 3.116.7 Default

none

## 3.117 compute smd/triangle/vertices command

### 3.117.1 Syntax

```
compute ID group-ID smd/triangle/vertices
```

- ID, group-ID are documented in [compute](#) command
- smd/triangle/vertices = style name of this compute command

### 3.117.2 Examples

```
compute 1 all smd/triangle/vertices
```

### 3.117.3 Description

Define a computation that returns the coordinates of the vertices corresponding to the triangle-elements of a mesh created by the *fix smd/wall\_surface*.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

### 3.117.4 Output info

This compute returns a per-particle vector of vectors, which can be accessed by any command that uses per-particle values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-particle vector has nine entries, (x1/y1/z1), (x2/y2/z2), and (x3/y3/z3) corresponding to the first, second, and third vertex of each triangle.

It is only meaningful to use this compute for a group of particles which is created via the *fix smd/wall\_surface* command.

The output of this compute can be used with the `dump2vtk_tris` tool to generate a VTK representation of the `smd/wall_surface` mesh for visualization purposes.

The values will be given in *units* of distance.

### 3.117.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.117.6 Related commands

*fix smd/move/tri/surf*, *fix smd/wall\_surface*

none

## 3.118 compute smd/ulsph/effm command

### 3.118.1 Syntax

```
compute ID group-ID smd/ulsph/effm
```

- ID, group-ID are documented in *compute* command
- smd/ulsph/effm = style name of this compute command

### 3.118.2 Examples

```
compute 1 all smd/ulsph/effm
```

### 3.118.3 Description

Define a computation that outputs the effective shear modulus for particles interacting via the updated Lagrangian SPH pair style.

See [this PDF guide](#) to using Smooth Mach Dynamics in LAMMPS.

### 3.118.4 Output info

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-particle vector contains the current effective per atom shear modulus as computed by the *pair smd/ulsph* pair style.

### 3.118.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info. This compute can only be used for particles which interact with the updated Lagrangian SPH pair style.

### 3.118.6 Related commands

### 3.129.3 Description

Define a computation that calculates a set of quantities related to the bispectrum components of the atoms in a group. These computes are used primarily for calculating the dependence of energy, force, and stress components on the linear coefficients in the *snap pair\_style*, which is useful when training a SNAP potential to match target data.

Bispectrum components of an atom are order parameters characterizing the radial and angular distribution of neighbor atoms. The detailed mathematical definition is given in the paper by Thompson et al. ([Thompson](#))

The position of a neighbor atom  $i'$  relative to a central atom  $i$  is a point within the 3D ball of radius  $R_{ii'} = r_{cut} fac$  ( $R_i + R_{i'}$ )

Bartok et al. ([Bartok](#)), proposed mapping this 3D ball onto the 3-sphere, the surface of the unit ball in a four-dimensional space. The radial distance  $r$  within  $R_{ii'}$  is mapped on to a third polar angle  $\theta_0$  defined by,

$$\theta_0 = r_{fac} 0 \frac{r - r_{min0}}{R_{ii'} - r_{min0}} \pi$$

In this way, all possible neighbor positions are mapped on to a subset of the 3-sphere. Points south of the latitude  $\theta_0 = r_{fac} 0 \pi$  are excluded.

The natural basis for functions on the 3-sphere is formed by the representatives of  $SU(2)$ , the matrices  $U_{m,m'}^j(\theta, \phi, \theta_0)$ . These functions are better known as  $D_{m,m'}^j$ , the elements of the Wigner  $D$ -matrices ([Meremianin](#), [Varshalovich](#), [Mason](#)) The density of neighbors on the 3-sphere can be written as a sum of Dirac-delta functions, one for each neighbor, weighted by species and radial distance. Expanding this density function as a generalized Fourier series in the basis functions, we can write each Fourier coefficient as

$$u_{m,m'}^j = U_{m,m'}^j(0, 0, 0) + \sum_{r_{ii'} < R_{ii'}} f_c(r_{ii'}) w_{\mu_{i'}} U_{m,m'}^j(\theta_0, \theta, \phi)$$

The  $w_{\mu_{i'}}$  neighbor weights are dimensionless numbers that depend on  $\mu_{i'}$ , the SNAP element of atom  $i'$ , while the central atom is arbitrarily assigned a unit weight. The function  $f_c(r)$  ensures that the contribution of each neighbor atom goes smoothly to zero at  $R_{ii'}$ :

$$f_c(r) = \frac{1}{2} (\cos(\pi \frac{r - r_{min0}}{R_{ii'} - r_{min0}}) + 1), r \leq R_{ii'}$$

$$= 0, r > R_{ii'}$$

The expansion coefficients  $u_{m,m'}^j$  are complex-valued and they are not directly useful as descriptors, because they are not invariant under rotation of the polar coordinate frame. However, the following scalar triple products of expansion coefficients can be shown to be real-valued and invariant under rotation ([Bartok](#)).

$$B_{j_1, j_2, j} = \sum_{m_1, m'_1 = -j_1}^{j_1} \sum_{m_2, m'_2 = -j_2}^{j_2} \sum_{m, m' = -j}^j (u_{m, m'}^j)^* H_{j_1 m_1 m'_1, j_2 m_2 m'_2}^{j m m'} u_{m_1, m'_1}^{j_1} u_{m_2, m'_2}^{j_2}$$

The constants  $H_{j_1 m_1 m'_1, j_2 m_2 m'_2}^{j m m'}$  are coupling coefficients, analogous to Clebsch-Gordan coefficients for rotations on the 2-sphere. These invariants are the components of the bispectrum and these are the quantities calculated by the compute *sna/atom*. They characterize the strength of density correlations at three points on the 3-sphere. The  $j_2=0$  subset form the power spectrum, which characterizes the correlations of two points. The lowest-order components describe the coarsest features of the density function, while higher-order components reflect finer detail. Each bispectrum component contains terms that depend on the positions of up to 4 atoms (3 neighbors and the central atom).

Compute *sna/atom* calculates the derivative of the bispectrum components summed separately for each LAMMPS atom type:

$$- \sum_{i' \in I} \frac{\partial B_{j_1, j_2, j}^{i'}}{\partial \mathbf{r}_i}$$

The sum is over all atoms  $i'$  of atom type  $I$ . For each atom  $i$ , this compute evaluates the above expression for each direction, each atom type, and each bispectrum component. See section below on output for a detailed explanation.

Compute *snav/atom* calculates the virial contribution due to the derivatives:

$$-\mathbf{r}_i \otimes \sum_{i' \in I} \frac{\partial B'_{j_1, j_2, j}}{\partial \mathbf{r}_i}$$

Again, the sum is over all atoms  $i'$  of atom type  $I$ . For each atom  $i$ , this compute evaluates the above expression for each of the six virial components, each atom type, and each bispectrum component. See section below on output for a detailed explanation.

Compute *snap* calculates a global array containing information related to all three of the above per-atom computes *sna/atom*, *snad/atom*, and *snav/atom*. The first row of the array contains the summation of *sna/atom* over all atoms, but broken out by type. The last six rows of the array contain the summation of *snav/atom* over all atoms, broken out by type. In between these are  $3*N$  rows containing the same values computed by *snad/atom* (these are already summed over all atoms and broken out by type). The element in the last column of each row contains the potential energy, force, or stress, according to the row. These quantities correspond to the user-specified reference potential that must be subtracted from the target data when fitting SNAP. The potential energy calculation uses the built in compute *thermo\_pe*. The stress calculation uses a compute called *snap\_press* that is automatically created behind the scenes, according to the following command:

```
compute snap_press all pressure NULL virial
```

See section below on output for a detailed explanation of the data layout in the global array.

New in version 3Aug2022.

The compute *sna/grid* and *sna/grid/local* commands calculate bispectrum components for a regular grid of points. These are calculated from the local density of nearby atoms  $i'$  around each grid point, as if there was a central atom  $i$  at the grid point. This is useful for characterizing fine-scale structure in a configuration of atoms, and it is used in the [MALA package](#) to build machine-learning surrogates for finite-temperature Kohn-Sham density functional theory (*Ellis et al.*) Neighbor atoms not in the group do not contribute to the bispectrum components of the grid points. The distance cutoff  $R_{ii'}$  assumes that  $i$  has the same type as the neighbor atom  $i'$ .

Compute *sna/grid* calculates a global array containing bispectrum components for a regular grid of points. The grid is aligned with the current box dimensions, with the first point at the box origin, and forming a regular 3d array with  $nx$ ,  $ny$ , and  $nz$  points in the x, y, and z directions. For triclinic boxes, the array is congruent with the periodic lattice vectors  $a$ ,  $b$ , and  $c$ . The array contains one row for each of the  $nx \times ny \times nz$  grid points, looping over the index for  $ix$  fastest, then  $iy$ , and  $iz$  slowest. Each row of the array contains the x, y, and z coordinates of the grid point, followed by the bispectrum components. See section below on output for a detailed explanation of the data layout in the global array.

Compute *sna/grid/local* calculates bispectrum components of a regular grid of points similarly to compute *sna/grid* described above. However, because the array is local, it contains only rows for grid points that are local to the processor subdomain. The global grid of  $nx \times ny \times nz$  points is still laid out in space the same as for *sna/grid*, but grid points are strictly partitioned, so that every grid point appears in one and only one local array. The array contains one row for each of the local grid points, looping over the global index  $ix$  fastest, then  $iy$ , and  $iz$  slowest. Each row of the array contains the global indexes  $ix$ ,  $iy$ , and  $iz$  first, followed by the x, y, and z coordinates of the grid point, followed by the bispectrum components. See section below on output for a detailed explanation of the data layout in the global array.

The value of all bispectrum components will be zero for atoms not in the group. Neighbor atoms not in the group do not contribute to the bispectrum of atoms in the group.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

The argument *rcutfac* is a scale factor that controls the ratio of atomic radius to radial cutoff distance.

The argument *rfac0* and the optional keyword *rmin0* define the linear mapping from radial distance to polar angle *theta0* on the 3-sphere, given above.

The argument *twojmax* defines which bispectrum components are generated. See section below on output for a detailed explanation of the number of bispectrum components and the ordered in which they are listed.

The keyword *switchflag* can be used to turn off the switching function  $f_c(r)$ .

The keyword *bzeroflag* determines whether or not  $B0$ , the bispectrum components of an atom with no neighbors, are subtracted from the calculated bispectrum components. This optional keyword normally only affects compute *sna/atom*. However, when *quadraticflag* is on, it also affects *snad/atom* and *snav/atom*.

The keyword *quadraticflag* determines whether or not the quadratic combinations of bispectrum quantities are generated. These are formed by taking the outer product of the vector of bispectrum components with itself. See section below on output for a detailed explanation of the number of quadratic terms and the ordered in which they are listed.

The keyword *chem* activates the explicit multi-element variant of the SNAP bispectrum components. The argument *nelements* specifies the number of SNAP elements that will be handled. This is followed by *elementlist*, a list of integers of length *ntypes*, with values in the range  $[0, nelements)$ , which maps each LAMMPS type to one of the SNAP elements. Note that multiple LAMMPS types can be mapped to the same element, and some elements may be mapped by no LAMMPS type. However, in typical use cases (training SNAP potentials) the mapping from LAMMPS types to elements is one-to-one.

The explicit multi-element variant invoked by the *chem* keyword partitions the density of neighbors into partial densities for each chemical element. This is described in detail in the paper by [Cusentino et al.](#) The bispectrum components are indexed on ordered triplets of elements:

$$B_{j_1, j_2, j}^{\kappa\lambda\mu} = \sum_{m_1, m'_1 = -j_1}^{j_1} \sum_{m_2, m'_2 = -j_2}^{j_2} \sum_{m, m' = -j}^j (u_{j, m, m'}^\mu)^* H_{j_1 m_1 m'_1}^{j m m'} u_{j_1, m_1, m'_1}^\kappa u_{j_2, m_2, m'_2}^\lambda$$

where  $u_{j, m, m'}^\mu$  is an expansion coefficient for the partial density of neighbors of element  $\mu$

$$u_{j, m, m'}^\mu = w_{\mu_i \mu}^{self} U^{j, m, m'}(0, 0, 0) + \sum_{r_{ii'} < R_{ii'}} \delta_{\mu \mu'} f_c(r_{ii'}) w_{\mu_i'} U^{j, m, m'}(\theta_0, \theta, \phi)$$

where  $w_{\mu_i \mu}^{self}$  is the self-contribution, which is either 1 or 0 (see keyword *wselfallflag* below),  $\delta_{\mu \mu'}$  indicates that the sum is only over neighbor atoms of element  $\mu$ , and all other quantities are the same as those appearing in the original equation for  $u_{m, m'}^j$  given above.

The keyword *wselfallflag* defines the rule used for the self-contribution. If *wselfallflag* is on, then  $w_{\mu_i \mu}^{self} = 1$ . If it is off then  $w_{\mu_i \mu}^{self} = 0$ , except in the case of  $\mu_i = \mu$ , when  $w_{\mu_i \mu}^{self} = 1$ . When the *chem* keyword is not used, this keyword has no effect.

The keyword *bnormflag* determines whether or not the bispectrum component  $B_{j_1, j_2, j}$  is divided by a factor of  $2j + 1$ . This normalization simplifies force calculations because of the following symmetry relation

$$\frac{B_{j_1, j_2, j}}{2j + 1} = \frac{B_{j, j_2, j_1}}{2j_1 + 1} = \frac{B_{j_1, j, j_2}}{2j_2 + 1}$$

This option is typically used in conjunction with the *chem* keyword, and LAMMPS will generate a warning if both *chem* and *bnormflag* are not both set or not both unset.

The keyword *switchinnerflag* with value 1 activates an additional radial switching function similar to  $f_c(r)$  above, but acting to switch off smoothly contributions from neighbor atoms at short separation distances. This is useful when SNAP is used in combination with a simple repulsive potential. For a neighbor atom at distance  $r$ , its contribution is scaled by a multiplicative factor  $f_{inner}(r)$  defined as follows:

$$\begin{aligned} &= 0, r \leq S_{inner} - D_{inner} \\ f_{inner}(r) &= \frac{1}{2} \left( 1 - \cos\left(\frac{\pi}{2} \left( 1 + \frac{r - S_{inner}}{D_{inner}} \right) \right) \right), S_{inner} - D_{inner} < r \leq S_{inner} + D_{inner} \\ &= 1, r > S_{inner} + D_{inner} \end{aligned}$$

where the switching region is centered at  $S_{inner}$  and it extends a distance  $D_{inner}$  to the left and to the right of this. With this option, additional keywords *sinner* and *dinner* must be used, each followed by *ntypes* values for  $S_{inner}$  and  $D_{inner}$ , respectively. When the central atom and the neighbor atom have different types, the values of  $S_{inner}$  and  $D_{inner}$  are the arithmetic means of the values for both types.

The keywords *bikflag* and *dgradflag* are only used by compute *snap*. The keyword *bikflag* determines whether or not to list the descriptors of each atom separately, or sum them together and list in a single row. If *bikflag* is set to 0 then a single bispectrum row is used, which contains the per-atom bispectrum descriptors  $B_{i,k}$  summed over all atoms  $i$  to produce  $B_k$ . If *bikflag* is set to 1 this is replaced by a separate per-atom bispectrum row for each atom. In this case, the entries in the final column for these rows are set to zero.

The keyword *dgradflag* determines whether to sum atom gradients or list them separately. If *dgradflag* is set to 0, the bispectrum descriptor gradients w.r.t. atom  $j$  are summed over all atoms  $i'$  of type  $I$  (similar to *snad/atom* above). If *dgradflag* is set to 1, gradients are listed separately for each pair of atoms. Each row corresponds to a single term  $\frac{\partial B_{i,k}}{\partial r_j^a}$  where  $r_j^a$  is the  $a$ -th position coordinate of the atom with global index  $j$ . This also changes the number of columns to be equal to the number of bispectrum components, with 3 additional columns representing the indices  $i$ ,  $j$ , and  $a$ , as explained more in the Output info section below. The option *dgradflag*=1 requires that *bikflag*=1.

---

**Note:** Using *dgradflag* = 1 produces a global array with  $N + 3N^2 + 1$  rows which becomes expensive for systems with more than 1000 atoms.

---

---

**Note:** If you have a bonded system, then the settings of *special\_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special\_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the calculation. One way to get around this, is to write a dump file, and use the *rerun* command to compute the bispectrum components for snapshots in the dump file. The rerun script can use a *special\_bonds* command that includes all pairs in the neighbor list.

---

The keyword *nnn* allows for the calculation of the bispectrum over a specific target number of neighbors. This option is only implemented for the compute *snad/atom*. An optimal cutoff radius for defining the neighborhood of the central atom is calculated by means of a dichotomy algorithm. This iterative process allows to assign weights to neighboring atoms in order to match the total sum of weights with the target number of neighbors. Depending on the radial weight function used in that process, the cutoff radius can fluctuate a lot in the presence of thermal noise. Therefore, in addition to the *nnn* keyword, the keyword *wmode* allows to choose whether a Heaviside (*wmode* = 0) function or a Hyperbolic tangent function (*wmode* = 1) should be used. If the Heaviside function is used, the cutoff radius exactly matches the distance between the central atom and its *nnn*'th neighbor. However, in the case of the hyperbolic tangent function, the dichotomy algorithm allows to span the weights over a distance *delta* in order to reduce fluctuations in the resulting local atomic environment fingerprint. The detailed formalism is given in the paper by Lafourcade et al. ([Lafourcade](#)).

---

### 3.129.4 Output info

Compute *snad/atom* calculates a per-atom array, each column corresponding to a particular bispectrum component. The total number of columns and the identity of the bispectrum component contained in each column depend of the value of *twojmax*, as described by the following piece of python code:

```
for j1 in range(0,twojmax+1):
    for j2 in range(0,j1+1):
        for j in range(j1-j2,min(twojmax,j1+j2)+1,2):
            if (j>=j1): print j1/2.,j2/2.,j/2.
```

There are  $m(m+1)/2$  descriptors with last index  $j$ , where  $m = \lfloor j \rfloor + 1$ . Hence, for even  $twojmax = 2(m-1)$ ,  $K = m(m+1)(2m+1)/6$ , the  $m$ -th pyramidal number, and for odd  $twojmax = 2m-1$ ,  $K = m(m+1)(m+2)/3$ , twice the  $m$ -th tetrahedral number.

---

**Note:** the *diagonal* keyword allowing other possible choices for the number of bispectrum components was removed in 2019, since all potentials use the value of 3, corresponding to the above set of bispectrum components.

---

Compute *snad/atom* evaluates a per-atom array. The columns are arranged into *ntypes* blocks, listed in order of atom type  $I$ . Each block contains three sub-blocks corresponding to the  $x$ ,  $y$ , and  $z$  components of the atom position. Each of these sub-blocks contains  $K$  columns for the  $K$  bispectrum components, the same as for compute *sna/atom*

Compute *snav/atom* evaluates a per-atom array. The columns are arranged into *ntypes* blocks, listed in order of atom type  $I$ . Each block contains six sub-blocks corresponding to the  $xx$ ,  $yy$ ,  $zz$ ,  $yz$ ,  $xz$ , and  $xy$  components of the virial tensor in Voigt notation. Each of these sub-blocks contains  $K$  columns for the  $K$  bispectrum components, the same as for compute *sna/atom*

Compute *snap* evaluates a global array. The columns are arranged into *ntypes* blocks, listed in order of atom type  $I$ . Each block contains one column for each bispectrum component, the same as for compute *sna/atom*. A final column contains the corresponding energy, force component on an atom, or virial stress component. The rows of the array appear in the following order:

- 1 row: *sna/atom* quantities summed for all atoms of type  $I$
- $3*N$  rows: *snad/atom* quantities, with derivatives w.r.t.  $x$ ,  $y$ , and  $z$  coordinate of atom  $i$  appearing in consecutive rows. The atoms are sorted based on atom ID.
- 6 rows: *snav/atom* quantities summed for all atoms of type  $I$

For example, if  $K=30$  and *ntypes*=1, the number of columns in the per-atom arrays generated by *sna/atom*, *snad/atom*, and *snav/atom* are 30, 90, and 180, respectively. With *quadratic* value=1, the numbers of columns are 930, 2790, and 5580, respectively. The number of columns in the global array generated by *snap* are 31, and 931, respectively, while the number of rows is  $1+3*N+6$ , where  $N$  is the total number of atoms.

Compute *sna/grid* evaluates a global array. The array contains one row for each of the  $n_x \times n_y \times n_z$  grid points, looping over the index for  $ix$  fastest, then  $iy$ , and  $iz$  slowest. Each row of the array contains the  $x$ ,  $y$ , and  $z$  coordinates of the grid point, followed by the bispectrum components.

Compute *sna/grid/local* evaluates a local array. The array contains one row for each of the local grid points, looping over the global index  $ix$  fastest, then  $iy$ , and  $iz$  slowest. Each row of the array contains the global indexes  $ix$ ,  $iy$ , and  $iz$  first, followed by the  $x$ ,  $y$ , and  $z$  coordinates of the grid point, followed by the bispectrum components.

If the *quadratic* keyword value is set to 1, then additional columns are generated, corresponding to the products of all distinct pairs of bispectrum components. If the number of bispectrum components is  $K$ , then the number of distinct pairs is  $K(K+1)/2$ . For compute *sna/atom* these columns are appended to existing  $K$  columns. The ordering of quadratic terms is upper-triangular,  $(1,1),(1,2)\dots(1,K),(2,1)\dots(K-1,K-1),(K-1,K),(K,K)$ . For computes *snad/atom* and *snav/atom* each set of  $K(K+1)/2$  additional columns is inserted directly after each of sub-block of linear terms i.e. linear and quadratic terms are contiguous. So the nesting order from inside to outside is bispectrum component, linear then quadratic, vector/tensor component, type.

If the *chem* keyword is used, then the data is arranged into  $N_{elem}^3$  sub-blocks, each sub-block corresponding to a particular chemical labeling  $\kappa\lambda\mu$  with the last label changing fastest. Each sub-block contains  $K$  bispectrum components. For the purposes of handling contributions to force, virial, and quadratic combinations, these  $N_{elem}^3$  sub-blocks are treated as a single block of  $KN_{elem}^3$  columns.

If the *bik* keyword is set to 1, the structure of the *snap* array is expanded. The first  $N$  rows of the *snap* array correspond to  $B_{i,k}$  instead of a single row summed over atoms  $i$ . In this case, the entries in the final column for these rows are set to zero. Also, each row contains only non-zero entries for the columns corresponding to the type of that atom. This is not true in the case of *dgradflag* keyword = 1 (see below).

If the *dgradflag* keyword is set to 1, this changes the structure of the global array completely. Here the *snad/atom* quantities are replaced with rows corresponding to descriptor gradient components on single atoms:

$$\frac{\partial B_{i,k}}{\partial r_j^a}$$

where  $r_j^a$  is the  $a$ -th position coordinate of the atom with global index  $j$ . The rows are organized in chunks, where each chunk corresponds to an atom with global index  $j$ . The rows in an atom  $j$  chunk correspond to atoms with global index  $i$ . The total number of rows for these descriptor gradients is therefore  $3N^2$ . The number of columns is equal to the number of bispectrum components, plus 3 additional left-most columns representing the global atom indices  $i$ ,  $j$ , and Cartesian direction  $a$  (0, 1, 2, for x, y, z). The first 3 columns of the first  $N$  rows belong to the reference potential force components. The remaining  $K$  columns contain the  $B_{i,k}$  per-atom descriptors corresponding to the non-zero entries obtained when *bikflag* = 1. The first column of the last row, after the first  $N + 3N^2$  rows, contains the reference potential energy. The virial components are not used with this option. The total number of rows is therefore  $N + 3N^2 + 1$  and the number of columns is  $K + 3$ .

These values can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options. To see how this command can be used within a Python workflow to train SNAP potentials, see the examples in [FitSNAP](#).

### 3.129.5 Restrictions

These computes are part of the ML-SNAP package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.129.6 Related commands

*pair\_style snap compute slcsa/atom*

### 3.129.7 Default

The optional keyword defaults are *rmin0* = 0, *switchflag* = 1, *bzeroflag* = 1, *quadraticflag* = 0, *bnormflag* = 0, *wselfallflag* = 0, *switchinnerflag* = 0, *nnn* = -1, *wmode* = 0, *delta* = 1.e-3

## 3.130 compute sph/e/atom command

### 3.130.1 Syntax

```
compute ID group-ID sph/e/atom
```

- ID, group-ID are documented in *compute* command
- sph/e/atom = style name of this compute command

### 3.130.2 Examples

```
compute 1 all sph/e/atom
```

### 3.130.3 Description

Define a computation that calculates the per-atom internal energy for each atom in a group.

The internal energy is the energy associated with the internal degrees of freedom of an SPH particle, i.e. a Smooth-Particle Hydrodynamics particle.

See [this PDF guide](#) to using SPH in LAMMPS.

The value of the internal energy will be 0.0 for atoms not in the specified compute group.

### 3.130.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in energy *units*.

### 3.130.5 Restrictions

This compute is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.130.6 Related commands

*dump custom*

### 3.130.7 Default

none

## 3.131 compute sph/rho/atom command

### 3.131.1 Syntax

```
compute ID group-ID sph/rho/atom
```

- ID, group-ID are documented in [compute](#) command
- sph/rho/atom = style name of this compute command

### 3.131.2 Examples

```
compute 1 all sph/rho/atom
```

### 3.131.3 Description

Define a computation that calculates the per-atom SPH density for each atom in a group, i.e. a Smooth-Particle Hydrodynamics density.

The SPH density is the mass density of an SPH particle, calculated by kernel function interpolation using “pair style sph/rhosum”.

See [this PDF guide](#) to using SPH in LAMMPS.

The value of the SPH density will be 0.0 for atoms not in the specified compute group.

### 3.131.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in mass/volume [units](#).

### 3.131.5 Restrictions

This compute is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.131.6 Related commands

*dump custom*

### 3.131.7 Default

none

## 3.132 compute sph/t/atom command

### 3.132.1 Syntax

```
compute ID group-ID sph/t/atom
```

- ID, group-ID are documented in *compute* command
- sph/t/atom = style name of this compute command

### 3.132.2 Examples

```
compute 1 all sph/t/atom
```

### 3.132.3 Description

Define a computation that calculates the per-atom internal temperature for each atom in a group.

The internal temperature is the ratio of internal energy over the heat capacity associated with the internal degrees of freedom of an SPH particles, i.e. a Smooth-Particle Hydrodynamics particle.

$$T_{int} = E_{int} / C_{v,int}$$

See [this PDF guide](#) to using SPH in LAMMPS.

The value of the internal energy will be 0.0 for atoms not in the specified compute group.

### 3.132.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in temperature *units*.

### 3.132.5 Restrictions

This compute is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.132.6 Related commands

*dump custom*

### 3.132.7 Default

none

## 3.133 compute spin command

### 3.133.1 Syntax

```
compute ID group-ID spin
```

- ID, group-ID are documented in [compute](#) command
- spin = style name of this compute command

### 3.133.2 Examples

```
compute out_mag all spin
```

### 3.133.3 Description

Define a computation that calculates magnetic quantities for a system of atoms having spins.

This compute calculates the following 6 magnetic quantities:

- the three first quantities are the x,y and z coordinates of the total magnetization,
- the fourth quantity is the norm of the total magnetization,
- The fifth quantity is the magnetic energy (in eV),
- The sixth one is referred to as the spin temperature, according to the work of ([Nurdin](#)).

The simplest way to output the results of the compute spin calculation is to define some of the quantities as variables, and to use the thermo and thermo\_style commands, for example:

```
compute out_mag      all spin

variable mag_z        equal c_out_mag[3]
variable mag_norm      equal c_out_mag[4]
variable temp_mag      equal c_out_mag[6]
```

(continues on next page)

(continued from previous page)

```
thermo 10
thermo_style custom step v_mag_z v_mag_norm v_temp_mag
```

This series of commands evaluates the total magnetization along z, the norm of the total magnetization, and the magnetic temperature. Three variables are assigned to those quantities. The `thermo` and `thermo_style` commands print them every 10 timesteps.

### 3.133.4 Output info

The array values are “intensive”. The array values will be in metal units (*units*).

### 3.133.5 Restrictions

The *spin* compute is part of the SPIN package. This compute is only enabled if LAMMPS was built with this package. See the [Build package](#) page for more info. The `atom_style` has to be “spin” for this compute to be valid.

## 3.134 compute stress/atom command

## 3.135 compute centroid/stress/atom command

### 3.135.1 Syntax

```
compute ID group-ID style temp-ID keyword ...
```

- ID, group-ID are documented in [compute](#) command
- style = *stress/atom* or *centroid/stress/atom*
- temp-ID = ID of compute that calculates temperature, can be NULL if not needed
- zero or more keywords may be appended
- keyword = *ke* or *pair* or *bond* or *angle* or *dihedral* or *improper* or *kpace* or *fix* or *virial*

### 3.135.2 Examples

```
compute 1 mobile stress/atom NULL
compute 1 mobile stress/atom myRamp
compute 1 all stress/atom NULL pair bond
compute 1 all centroid/stress/atom NULL bond dihedral improper
```

### 3.135.3 Description

Define a computation that computes per-atom stress tensor for each atom in a group. In case of compute *stress/atom*, the tensor for each atom is symmetric with 6 components and is stored as a 6-element vector in the following order: *xx*, *yy*, *zz*, *xy*, *xz*, *yz*. In case of compute *centroid/stress/atom*, the tensor for each atom is asymmetric with 9 components and is stored as a 9-element vector in the following order: *xx*, *yy*, *zz*, *xy*, *xz*, *yz*, *yx*, *zx*, *zy*. See the [compute pressure](#) command if you want the stress tensor (pressure) of the entire system.

The stress tensor for atom *I* is given by the following formula, where *a* and *b* take on values *x*, *y*, *z* to generate the components of the tensor:

$$S_{ab} = -mv_a v_b - W_{ab}$$

The first term is a kinetic energy contribution for atom *I*. See details below on how the specified *temp-ID* can affect the velocities used in this calculation. The second term is the virial contribution due to intra and intermolecular interactions, where the exact computation details are determined by the compute style.

In case of compute *stress/atom*, the virial contribution is:

$$\begin{aligned} W_{ab} = & \frac{1}{2} \sum_{n=1}^{N_p} (r_{1a} F_{1b} + r_{2a} F_{2b}) + \frac{1}{2} \sum_{n=1}^{N_b} (r_{1a} F_{1b} + r_{2a} F_{2b}) \\ & + \frac{1}{3} \sum_{n=1}^{N_a} (r_{1a} F_{1b} + r_{2a} F_{2b} + r_{3a} F_{3b}) + \frac{1}{4} \sum_{n=1}^{N_d} (r_{1a} F_{1b} + r_{2a} F_{2b} + r_{3a} F_{3b} + r_{4a} F_{4b}) \\ & + \frac{1}{4} \sum_{n=1}^{N_i} (r_{1a} F_{1b} + r_{2a} F_{2b} + r_{3a} F_{3b} + r_{4a} F_{4b}) + \text{Kspace}(r_{ia}, F_{ib}) + \sum_{n=1}^{N_f} r_{ia} F_{ib} \end{aligned}$$

The first term is a pairwise energy contribution where *n* loops over the *N<sub>p</sub>* neighbors of atom *I*, *r<sub>1</sub>* and *r<sub>2</sub>* are the positions of the two atoms in the pairwise interaction, and *F<sub>1</sub>* and *F<sub>2</sub>* are the forces on the two atoms resulting from the pairwise interaction. The second term is a bond contribution of similar form for the *N<sub>b</sub>* bonds which atom *I* is part of. There are similar terms for the *N<sub>a</sub>* angle, *N<sub>d</sub>* dihedral, and *N<sub>i</sub>* improper interactions atom *I* is part of. There is also a term for the KSpace contribution from long-range Coulombic interactions, if defined. Finally, there is a term for the *N<sub>f</sub>* *fixes* that apply internal constraint forces to atom *I*. Currently, only the *fix shake* and *fix rigid* commands contribute to this term. As the coefficients in the formula imply, a virial contribution produced by a small set of atoms (e.g. 4 atoms in a dihedral or 3 atoms in a Tersoff 3-body interaction) is assigned in equal portions to each atom in the set. E.g. 1/4 of the dihedral virial to each of the 4 atoms, or 1/3 of the fix virial due to SHAKE constraints applied to atoms in a water molecule via the *fix shake* command. As an exception, the virial contribution from constraint forces in *fix rigid* on each atom is computed from the constraint force acting on the corresponding atom and its position, i.e. the total virial is not equally distributed.

In case of compute *centroid/stress/atom*, the virial contribution is:

$$\begin{aligned} W_{ab} = & \sum_{n=1}^{N_p} r_{I0a} F_{Ib} + \sum_{n=1}^{N_b} r_{I0a} F_{Ib} + \sum_{n=1}^{N_a} r_{I0a} F_{Ib} + \sum_{n=1}^{N_d} r_{I0a} F_{Ib} + \sum_{n=1}^{N_i} r_{I0a} F_{Ib} \\ & + \text{Kspace}(r_{ia}, F_{ib}) + \sum_{n=1}^{N_f} r_{ia} F_{ib} \end{aligned}$$

As with compute *stress/atom*, the first, second, third, fourth and fifth terms are pairwise, bond, angle, dihedral and improper contributions, but instead of assigning the virial contribution equally to each atom, only the force  $\mathbf{F}_I$  acting on atom  $I$  due to the interaction and the relative position  $\mathbf{r}_{I0}$  of the atom  $I$  to the geometric center of the interacting atoms, i.e. centroid, is used. As the geometric center is different for each interaction, the  $\mathbf{r}_{I0}$  also differs. The sixth term, Kspace contribution, is computed identically to compute *stress/atom*. The seventh term is handed differently depending on if the constraint forces are due to *fix shake* or *fix rigid*. In case of SHAKE constraints, each distance constraint is handed as a pairwise interaction. E.g. in case of a water molecule, two OH and one HH distance constraints are treated as three pairwise interactions. In case of *fix rigid*, all constraint forces in the molecule are treated as a single many-body interaction with a single centroid position. In case of water molecule, the formula expression would become identical to that of the three-body angle interaction. Although the total system virial is the same as compute *stress/atom*, compute *centroid/stress/atom* is known to result in more consistent heat flux values for angle, dihedrals, improper and constraint force contributions when computed via *compute heat/flux*.

If no extra keywords are listed, the kinetic contribution *and* all of the virial contribution terms are included in the per-atom stress tensor. If any extra keywords are listed, only those terms are summed to compute the tensor. The *virial* keyword means include all terms except the kinetic energy *ke*.

Note that the stress for each atom is due to its interaction with all other atoms in the simulation, not just with other atoms in the group.

Details of how compute *stress/atom* obtains the virial for individual atoms for either pairwise or many-body potentials, and including the effects of periodic boundary conditions is discussed in (Thompson). The basic idea for many-body potentials is to treat each component of the force computation between a small cluster of atoms in the same manner as in the formula above for bond, angle, dihedral, etc interactions. Namely the quantity  $\mathbf{r} \cdot \mathbf{F}$  is summed over the atoms in the interaction, with the  $\mathbf{r}$  vectors unwrapped by periodic boundaries so that the cluster of atoms is close together. The total contribution for the cluster interaction is divided evenly among those atoms.

Details of how compute *centroid/stress/atom* obtains the virial for individual atoms are given in (Surblys2019) and (Surblys2021), where the idea is that the virial of the atom  $I$  is the result of only the force  $\mathbf{F}_I$  on the atom due to the interaction and its positional vector  $\mathbf{r}_{I0}$ , relative to the geometric center of the interacting atoms, regardless of the number of participating atoms. The periodic boundary treatment is identical to that of compute *stress/atom*, and both of them reduce to identical expressions for two-body interactions, i.e. computed values for contributions from bonds and two-body pair styles, such as *Lennard-Jones*, will be the same, while contributions from angles, dihedrals and impropers will be different.

The *dihedral\_style charmm* style calculates pairwise interactions between 1-4 atoms. The virial contribution of these terms is included in the pair virial, not the dihedral virial.

The KSpace contribution is calculated using the method in (Heyes) for the Ewald method and by the methodology described in (Sirk) for PPPM. The choice of KSpace solver is specified by the *kspace\_style pppm* command. Note that for PPPM, the calculation requires 6 extra FFTs each timestep that per-atom stress is calculated. Thus it can significantly increase the cost of the PPPM calculation if it is needed on a large fraction of the simulation timesteps.

The *temp-ID* argument can be used to affect the per-atom velocities used in the kinetic energy contribution to the total stress. If the kinetic energy is not included in the stress, then the temperature compute is not used and can be specified as NULL. If the kinetic energy is included and you wish to use atom velocities as-is, then *temp-ID* can also be specified as NULL. If desired, the specified temperature compute can be one that subtracts off a bias to leave each atom with only a thermal velocity to use in the formula above, e.g. by subtracting a background streaming velocity. See the doc pages for individual *compute commands* to determine which ones include a bias.

Note that as defined in the formula, per-atom stress is the negative of the per-atom pressure tensor. It is also really a stress\*volume formulation, meaning the computed quantity is in units of pressure\*volume. It would need to be divided by a per-atom volume to have units of stress (pressure), but an individual atom's volume is not well defined or easy to compute in a deformed solid or a liquid. See the *compute voronoi/atom* command for one possible way to estimate a per-atom volume.

Thus, if the diagonal components of the per-atom stress tensor are summed for all atoms in the system and the sum is divided by  $dV$ , where  $d$  = dimension and  $V$  is the volume of the system, the result should be  $-P$ , where  $P$  is the total pressure of the system.

These lines in an input script for a 3d system should yield that result. I.e. the last 2 columns of thermo output will be the same:

```
compute      peratom all stress/atom NULL
compute      p all reduce sum c_peratom[1] c_peratom[2] c_peratom[3]
variable      press equal -(c_p[1]+c_p[2]+c_p[3])/(3*vol)
thermo_style  custom step temp etotal press v_press
```

---

**Note:** The per-atom stress does not include any Lennard-Jones tail corrections to the pressure added by the *pair\_modify tail yes* command, since those are contributions to the global system pressure.

---

The compute stress/atom can be used in a number of ways. Here is an example to compute a 1-d pressure profile in x-direction across the complete simulation box. You will need to adjust the number of bins and the selections for time averaging to your specific simulation. This assumes that the dimensions of the simulation cell does not change.

```
# set number of bins
variable nbins index 20
variable fraction equal 1.0/v_nbins
# define bins as chunks
compute cchunk all chunk/atom bin/1d x lower ${fraction} units reduced
compute stress all stress/atom NULL
# apply conversion to pressure early since we have no variable style for processing.
→chunks
variable press atom -(c_stress[1]+c_stress[2]+c_stress[3])/(3.0*vol*${fraction})
compute binpress all reduce/chunk cchunk sum v_press
fix avg all ave/time 10 40 400 c_binpress mode vector file ave_stress.txt
```

### 3.135.4 Output info

Compute *stress/atom* calculates a per-atom array with 6 columns, which can be accessed by indices 1-6 by any command that uses per-atom values from a compute as input. Compute *centroid/stress/atom* produces a per-atom array with 9 columns, but otherwise can be used in an identical manner to compute *stress/atom*. See the [Howto output](#) page for an overview of LAMMPS output options.

The ordering of the 6 columns for *stress/atom* is as follows: xx, yy, zz, xy, xz, yz. The ordering of the 9 columns for *centroid/stress/atom* is as follows: xx, yy, zz, xy, xz, yz, yx, zx, zy.

The per-atom array values will be in pressure\*volume *units* as discussed above.

### 3.135.5 Restrictions

Currently, compute *centroid/stress/atom* does not support pair styles with many-body interactions (*EAM* is an exception, since its computations are performed pairwise), nor granular pair styles with pairwise forces which are not aligned with the vector between the pair of particles. All bond styles are supported. All angle, dihedral, improper styles are supported with the exception of INTEL and KOKKOS variants of specific styles. It also does not support models with long-range Coulombic or dispersion forces, i.e. the *kpace\_style* command in LAMMPS. It also does not implement the following fixes which add rigid-body constraints: *fix rigid/\** and the OpenMP accelerated version of *fix rigid/small*, while all other *fix rigid/\*small* are implemented.

LAMMPS will generate an error if one of these options is included in your model. Extension of centroid stress calculations to these force and fix styles is planned for the future.

### 3.135.6 Related commands

*compute pe*, *compute pressure*

### 3.135.7 Default

By default the compute includes contributions from the keywords: `ke pair bond angle dihedral improper kspace fix`

## 3.136 compute stress/cartesian command

### 3.136.1 Syntax

```
compute ID group-ID stress/cartesian args
```

- ID, group-ID are documented in *compute* command
- args = argument specific to the compute style

```
stress/cartesian args = dim1 bin_width1 dim2 bin_width2 keyword
```

```
dim1 = x or y or z
```

```
bin_width1 = width of the bin
```

```
dim2 = x or y or z or NULL
```

```
bin_width2 = width of the bin
```

```
keyword = ke or pair or bond
```

### 3.136.2 Examples

```
compute 1 all stress/cartesian x 0.1 NULL 0
compute 1 all stress/cartesian y 0.1 z 0.1
compute 1 all stress/cartesian x 0.1 NULL 0 ke pair
```

### 3.136.3 Description

Compute *stress/cartesian* defines computations that calculate profiles of the diagonal components of the local stress tensor over one or two Cartesian dimensions, as described in (*Ikeshoji*). The stress tensor is split into a kinetic contribution  $P^k$  and a virial contribution  $P^v$ . The sum gives the total stress tensor  $P = P^k + P^v$ . This compute obeys momentum balance through fluid interfaces. They use the Irving–Kirkwood contour, which is the straight line between particle pairs.

New in version 15Jun2023: Added support for bond styles

This compute only supports pair and bond (no angle, dihedral, improper, or kspace) forces. By default, if no extra keywords are specified, all supported contributions to the stress are included (ke, pair, bond). If any keywords are specified, then only those components are summed.

### 3.136.4 Output info

The output columns for *stress/cartesian* are the position of the center of the local volume in the first and second dimensions, number density,  $P_{xx}^k$ ,  $P_{yy}^k$ ,  $P_{zz}^k$ ,  $P_{xx}^v$ ,  $P_{yy}^v$ , and  $P_{zz}^v$ . There are 8 columns when one dimension is specified and 9 columns when two dimensions are specified. The number of bins (rows) is  $(L_1/b_1)(L_2/b_2)$ , where  $L_1$  and  $L_2$  are the lengths of the simulation box in the specified dimensions and  $b_1$  and  $b_2$  are the specified bin widths. When only one dimension is specified, the number of bins (rows) is  $L_1/b_1$ .

This array can be output with *fix ave/time*,

```
compute p all stress/cartesian x 0.1
fix 2 all ave/time 100 1 100 c_p[*] file dump_p.out mode vector
```

The values calculated by this compute are “intensive”. The stress values will be in pressure *units*. The number density values are in inverse volume *units*.

NOTE 1: The local stress does not include any Lennard-Jones tail corrections to the stress added by the *pair\_modify tail yes* command, since those are contributions to the global system pressure.

NOTE 2: The local stress profiles generated by these computes are similar to those obtained by the *method-of-planes (MOP)*. A key difference is that compute *stress/mop/profile* considers particles crossing a set of planes, while *stress/cartesian* computes averages for a set of small volumes. Moreover, this compute computes the diagonal components of the stress tensor  $P_{xx}$ ,  $P_{yy}$ , and  $P_{zz}$ , while *stress/mop/profile* computes the components  $P_{ix}$ ,  $P_{iy}$ , and  $P_{iz}$ , where  $i$  is the direction normal to the plane.

More information on the similarities and differences can be found in (*Ikeshoji*).

### 3.136.5 Restrictions

These computes calculate the stress tensor contributions for pair and bond forces only (no angle, dihedral, improper, or kspace force). It requires pairwise force calculations not available for most many-body pair styles.

These computes are part of the EXTRA-COMPUTE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) doc page for more info.

### 3.136.6 Related commands

*compute stress/atom*, *compute pressure*, *compute stress/mop/profile*, *compute stress/spherical*, *compute stress/cylinder*

(Ikeshoji) Ikeshoji, Hafskjold, Furuholt, Mol Sim, 29, 101-109, (2003).

## 3.137 compute stress/cylinder command

## 3.138 compute stress/spherical command

### 3.138.1 Syntax

```
compute ID group-ID style args
```

- ID, group-ID are documented in *compute* command
- style = stress/spherical or stress/cylinder
- args = argument specific to the compute style

*stress/cylinder* args = zlo zh Rmax bin\_width keyword

zlo = minimum z-boundary for cylinder

zhi = maximum z-boundary for cylinder

Rmax = maximum radius to perform calculation to

bin\_width = width of radial bins to use for calculation

keyword = ke (zero or one can be specified)

ke = yes or no

*stress/spherical*

x0, y0, z0 = origin of the spherical coordinate system

bin\_width = width of spherical shells

Rmax = maximum radius of spherical shells

### 3.138.2 Examples

```
compute 1 all stress/cylinder -10.0 10.0 15.0 0.25
compute 1 all stress/cylinder -10.0 10.0 15.0 0.25 ke no
compute 1 all stress/spherical 0 0 0 0.1 10
```

### 3.138.3 Description

Compute *stress/cylinder*, and compute *stress/spherical* define computations that calculate profiles of the diagonal components of the local stress tensor in the specified coordinate system. The stress tensor is split into a kinetic contribution  $P^k$  and a virial contribution  $P^v$ . The sum gives the total stress tensor  $P = P^k + P^v$ . These computes can for example be used to calculate the diagonal components of the local stress tensor of surfaces with cylindrical or spherical symmetry. These computes obeys momentum balance through fluid interfaces. They use the Irving–Kirkwood contour, which is the straight line between particle pairs.

The compute *stress/cylinder* computes the stress profile along the radial direction in cylindrical coordinates, as described in ([Addington](#)). The compute *stress/spherical* computes the stress profile along the radial direction in spherical coordinates, as described in ([Ikeshoji](#)).

### 3.138.4 Output info

The default output columns for *stress/cylinder* are the radius to the center of the cylindrical shell, number density,  $P_{rr}^k$ ,  $P_{\phi\phi}^k$ ,  $P_{zz}^k$ ,  $P_{rr}^v$ ,  $P_{\phi\phi}^v$ , and  $P_{zz}^v$ . When the keyword *ke* is set to *no*, the kinetic contributions are not calculated, and consequently there are only 5 columns: the position of the center of the cylindrical shell, the number density,  $P_{rr}^v$ ,  $P_{\phi\phi}^v$ , and  $P_{zz}^v$ . The number of bins (rows) is  $R_{\max}/b$ , where  $b$  is the specified bin width.

The output columns for *stress/spherical* are the position of the center of the spherical shell, the number density,  $P_{rr}^k$ ,  $P_{\theta\theta}^k$ ,  $P_{\phi\phi}^k$ ,  $P_{rr}^v$ ,  $P_{\theta\theta}^v$ , and  $P_{\phi\phi}^v$ . There are 8 columns and the number of bins (rows) is  $R_{\max}/b$ , where  $b$  is the specified bin width.

This array can be output with *fix ave/time*,

```
compute 1 all stress/spherical 0 0 0 0.1 10
fix 2 all ave/time 100 1 100 c_p[*] file dump_p.out mode vector
```

The values calculated by this compute are “intensive”. The stress values will be in pressure *units*. The number density values are in inverse volume *units*.

NOTE 1: The local stress does not include any Lennard-Jones tail corrections to the stress added by the *pair\_modify tail yes* command, since those are contributions to the global system pressure.

### 3.138.5 Restrictions

These computes calculate the stress tensor contributions for pair styles only (i.e., no bond, angle, dihedral, etc. contributions, and in the presence of bonded interactions, the result may be incorrect due to exclusions for *special bonds* excluding pairs of atoms completely). It requires pairwise force calculations not available for most many-body pair styles. Note that  $k$ -space calculations are also excluded.

These computes are part of the EXTRA-COMPUTE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) doc page for more info.

### 3.138.6 Related commands

*compute stress/atom*, *compute pressure*, *compute stress/mop/profile*, *compute stress/cartesian*

### 3.138.7 Default

The keyword default for ke in style *stress/cylinder* is yes.

(Ikeshoji) Ikeshoji, Hafskjold, Furuholt, Mol Sim, 29, 101-109, (2003).

(Addington) Addington, Long, Gubbins, J Chem Phys, 149, 084109 (2018).

## 3.139 compute stress/mop command

### 3.140 compute stress/mop/profile command

#### 3.140.1 Syntax

```
compute ID group-ID style dir args keywords ...
```

- ID, group-ID are documented in *compute* command
- style = *stress/mop* or *stress/mop/profile*
- dir = x or y or z is the direction normal to the plane
- args = argument specific to the compute style
- keywords = *kin* or *conf* or *total* or *pair* or *bond* or *angle* or *dihedral* (one or more can be specified)

*stress/mop* args = pos

pos = *lower* or *center* or *upper* or coordinate value (distance units) is the position of the plane

*stress/mop/profile* args = origin delta

origin = *lower* or *center* or *upper* or coordinate value (distance units) is the position of the first plane

delta = value (distance units) is the distance between planes

#### 3.140.2 Examples

```
compute 1 all stress/mop x lower total
compute 1 liquid stress/mop z 0.0 kin conf
fix 1 all ave/time 10 1000 10000 c_1[*] file mop.time
fix 1 all ave/time 10 1000 10000 c_1[2] file mop.time

compute 1 all stress/mop/profile x lower 0.1 total
compute 1 liquid stress/mop/profile z 0.0 0.25 kin conf
fix 1 all ave/time 500 20 10000 c_1[*] ave running overwrite file mopp.time mode vector
```

### 3.140.3 Description

Compute *stress/mop* and compute *stress/mop/profile* define computations that calculate components of the local stress tensor using the method of planes (*Todd*). Specifically in compute *stress/mop* calculates 3 components are computed in directions *dir,x*; *dir,y*; and *dir,z*; where *dir* is the direction normal to the plane, while in compute *stress/mop/profile* the profile of the stress is computed.

Contrary to methods based on histograms of atomic stress (i.e., using *compute stress/atom*), the method of planes is compatible with mechanical balance in heterogeneous systems and at interfaces (*Todd*).

The stress tensor is the sum of a kinetic term and a configurational term, which are given respectively by Eq. (21) and Eq. (16) in (*Todd*). For the kinetic part, the algorithm considers that atoms have crossed the plane if their positions at times  $t - \Delta t$  and  $t$  are one on either side of the plane, and uses the velocity at time  $t - \Delta t/2$  given by the velocity Verlet algorithm.

New in version 15Jun2023: contributions from bond, angle and dihedral potentials

Between one and seven keywords can be used to indicate which contributions to the stress must be computed: total stress (total), kinetic stress (kin), configurational stress (conf), stress due to bond stretching (bond), stress due to angle bending (angle), stress due to dihedral terms (dihedral) and/or due to pairwise non-bonded interactions (pair).

NOTE 1: The configurational stress is computed considering all pairs of atoms where at least one atom belongs to group group-ID.

NOTE 2: The local stress does not include any Lennard-Jones tail corrections to the stress added by the *pair\_modify tail yes* command, since those are contributions to the global system pressure.

NOTE 3: The local stress profile generated by compute *stress/mop/profile* is similar to that obtained by compute *stress/cartesian*. A key difference is that compute *stress/mop/profile* considers particles crossing a set of planes, while *stress/cartesian* computes averages for a set of small volumes. Moreover, *stress/cartesian* compute computes the diagonal components of the stress tensor  $P_{xx}$ ,  $P_{yy}$ , and  $P_{zz}$ , while *stress/mop/profile* computes the components  $P_{ix}$ ,  $P_{iy}$ , and  $P_{iz}$ , where  $i$  is the direction normal to the plane.

### 3.140.4 Output info

Compute *stress/mop* calculates a global vector (indices starting at 1), with 3 values for each declared keyword (in the order the keywords have been declared). For each keyword, the stress tensor components are ordered as follows: stress\_dir,x, stress\_dir,y, and stress\_dir,z.

Compute *stress/mop/profile* instead calculates a global array, with 1 column giving the position of the planes where the stress tensor was computed, and with 3 columns of values for each declared keyword (in the order the keywords have been declared). For each keyword, the profiles of stress tensor components are ordered as follows: stress\_dir,x; stress\_dir,y; and stress\_dir,z.

The values are in pressure *units*.

The values produced by this compute can be accessed by various *output commands*. For instance, the results can be written to a file using the *fix ave/time* command. Please see the example in the examples/PACKAGES/mop folder.

### 3.140.5 Restrictions

These styles are part of the EXTRA-COMPUTE package. They are only enabled if LAMMPS is built with that package. See the *Build package* doc page on for more info.

The method is implemented for orthogonal simulation boxes whose size does not change in time, and axis-aligned planes.

The method only works with two-body pair interactions, because it requires the class method `Pair::single()` to be implemented, which is not possible for manybody potentials. In particular, compute *stress/mop/profile* and *stress/mop* do not work with more than two-body pair interactions, long range (kspace) interactions and improper intramolecular interactions.

The impact of fixes that affect the stress (e.g. fix langevin) is also not included in the stress computed here.

### 3.140.6 Related commands

### 3.146.2 Examples

```
compute 1 lower force/tally upper
compute 1 left pe/tally right
compute 1 lower stress/tally lower
compute 1 subregion heat/flux/tally all
compute 1 liquid heat/flux/virial/tally solid
```

### 3.146.3 Description

Define a computation that calculates properties between two groups of atoms by accumulating them from pairwise non-bonded computations. Except for *heat/flux/virial/tally*, the two groups can be the same. This is similar to *compute group/group* only that the data is accumulated directly during the non-bonded force computation. The computes *force/tally*, *pe/tally*, *stress/tally*, and *heat/flux/tally* are primarily provided as example how to program additional, more sophisticated computes using the tally callback mechanism. Compute *pe/mol/tally* is one such style, that can—through using this mechanism—separately tally intermolecular and intramolecular energies. Something that would otherwise be impossible without integrating this as a core functionality into the base classes of LAMMPS.

Compute *heat/flux/tally* obtains the heat flux (strictly speaking, heat flow) inside the first group, which is the sum of the convective contribution due to atoms in the first group and the virial contribution due to interaction between the first and second groups:

$$\mathbf{Q} = \sum_{i \in \text{group 1}} e_i \mathbf{v}_i + \frac{1}{2} \sum_{i \in \text{group 1}} \sum_{\substack{j \in \text{group 2} \\ j \neq i}} (\mathbf{F}_{ij} \cdot \mathbf{v}_j) \mathbf{r}_{ij}$$

When the second group in *heat/flux/tally* is set to “all”, the resulting values will be identical to that obtained by *compute heat/flux*, provided only pairwise interactions exist.

Compute *heat/flux/virial/tally* obtains the total virial heat flux (strictly speaking, heat flow) into the first group due to interaction with the second group, and is defined as:

$$Q = \frac{1}{2} \sum_{i \in \text{group 1}} \sum_{j \in \text{group 2}} \mathbf{F}_{ij} \cdot (\mathbf{v}_i + \mathbf{v}_j)$$

Although, the *heat/flux/virial/tally* compute does not include the convective term, it can be used to obtain the total heat flux over control surfaces, when there are no particles crossing over, such as is often in solid–solid and solid–liquid interfaces. This would be identical to the method of planes method. Note that the *heat/flux/virial/tally* compute is distinctly different from the *heat/flux* and *heat/flux/tally* computes, that are essentially volume averaging methods. The following example demonstrates the difference:

```
# System with only pairwise interactions.
# Non-periodic boundaries in the x direction.
# Has LeftLiquid and RightWall groups along x direction.

# Heat flux over the solid-liquid interface
compute hflow_hfvt RightWall heat/flux/virial/tally LeftLiquid
variable hflux_hfvt equal c_hflow_hfvt/(ly*lz)
```

(continues on next page)

(continued from previous page)

```

# x component of approximate heat flux vector inside the liquid region,
# two approaches.
#
compute myKE all ke/atom
compute myPE all pe/atom
compute myStress all stress/atom NULL virial
compute hflow_hf LeftLiquid heat/flux myKE myPE myStress
variable hflux_hf equal c_hflow_hf[1]/${volLiq}
#
compute hflow_hft LeftLiquid heat/flux/tally all
variable hflux_hft equal c_hflow_hft[1]/${volLiq}

# Pressure over the solid-liquid interface, three approaches.
#
compute force_gg RightWall group/group LeftLiquid
variable press_gg equal c_force_gg[1]/(ly*lz)
#
compute force_ft RightWall force/tally LeftLiquid
compute rforce_ft RightWall reduce sum c_force_ft[1]
variable press_ft equal c_rforce_ft/(ly*lz)
#
compute rforce_hfvt all reduce sum c_hflow_hfvt[1]
variable press_hfvt equal c_rforce_hfvt/(ly*lz)

```

The pairwise contributions are computing via a callback that the compute registers with the non-bonded pairwise force computation. This limits the use to systems that have no bonds, no Kspace, and no many-body interactions. On the other hand, the computation does not have to compute forces or energies a second time and thus can be much more efficient. The callback mechanism allows to write more complex pairwise property computations.

### 3.146.4 Output info

- Compute *pe/tally* calculates a global scalar (the energy) and a per atom scalar (the contributions of the single atom to the global scalar).
- Compute *pe/mol/tally* calculates a global four-element vector containing (in this order): *evdwl* and *ecoul* for intramolecular pairs and *evdwl* and *ecoul* for intermolecular pairs. Since molecules are identified by their molecule IDs, the partitioning does not have to be related to molecules, but the energies are tallied into the respective slots depending on whether the molecule IDs of a pair are the same or different.
- Compute *force/tally* calculates a global scalar (the force magnitude) and a per atom 3-element vector (force contribution from each atom).
- Compute *stress/tally* calculates a global scalar (average of the diagonal elements of the stress tensor) and a per atom vector (the six elements of stress tensor contributions from the individual atom).
- As in *compute heat/flux*, compute *heat/flux/tally* calculates a global vector of length 6, where the first three components are the x, y, z components of the full heat flow vector, and the next three components are the corresponding components of just the convective portion of the flow (i.e., the first term in the equation for **Q**).
- Compute *heat/flux/virial/tally* calculates a global scalar (heat flow) and a per atom three-element vector (contribution to the force acting over atoms in the first group from individual atoms in both groups).

Both the scalar and vector values calculated by this compute are “extensive”.

### 3.146.5 Restrictions

This compute is part of the TALLY package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Not all pair styles can be evaluated in a pairwise mode as required by this compute. For example, 3-body and other many-body potentials, such as [Tersoff](#) and [Stillinger-Weber](#) cannot be used. [EAM](#) potentials only include the pair potential portion of the EAM interaction when used by this compute, not the embedding term. Also bonded or Kspace interactions do not contribute to this compute.

These computes are not compatible with accelerated pair styles from the GPU, INTEL, KOKKOS, or OPENMP packages. They will either create an error or print a warning when required data was not tallied in the required way and thus the data acquisition functions from these computes not called.

When used with dynamic groups, a [run 0](#) command needs to be inserted in order to initialize the dynamic groups before accessing the computes.

## 3.147 compute tdpd/cc/atom command

### 3.147.1 Syntax

```
compute ID group-ID tdpd/cc/atom index
```

- ID, group-ID are documented in [compute](#) command
- tdpd/cc/atom = style name of this compute command
- index = index of chemical species (1 to Nspecies)

### 3.147.2 Examples

```
compute 1 all tdpd/cc/atom 2
```

### 3.147.3 Description

Define a computation that calculates the per-atom chemical concentration of a specified species for each tDPD particle in a group.

The chemical concentration of each species is defined as the number of molecules carried by a tDPD particle for dilute solution. For more details see ([Li2015](#)).

### 3.147.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The per-atom vector values will be in the units of chemical species per unit mass.

### 3.147.5 Restrictions

This compute is part of the DPD-MESO package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.147.6 Related commands

## 3.148 compute temp command

Accelerator Variants: *temp/kk*

### 3.148.1 Syntax

**compute** ID group-ID temp

- ID, group-ID are documented in [compute](#) command
- temp = style name of this compute command

### 3.148.2 Examples

```
compute 1 all temp
compute myTemp mobile temp
```

### 3.148.3 Description

Define a computation that calculates the temperature of a group of atoms. A compute of this style can be used by any command that computes a temperature, e.g. *thermo\_modify*, *fix temp/rescale*, *fix npt*, etc.

The temperature is calculated by the formula

$$T = \frac{2E_{\text{kin}}}{N_{\text{DOF}}k_B} \quad \text{with} \quad E_{\text{kin}} = \sum_{i=1}^{N_{\text{atoms}}} \frac{1}{2} m_i v_i^2 \quad \text{and} \quad N_{\text{DOF}} = n_{\text{dim}} N_{\text{atoms}} - n_{\text{dim}} - N_{\text{fixDOFs}}$$

where  $E_{\text{kin}}$  is the total kinetic energy of the group of atoms,  $n_{\text{dim}}$  is the dimensionality of the simulation (i.e. either 2 or 3),  $N_{\text{atoms}}$  is the number of atoms in the group,  $N_{\text{fixDOFs}}$  is the number of degrees of freedom removed by fix commands (see below),  $k_B$  is the Boltzmann constant, and  $T$  is the resulting computed temperature.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the  $xy$  component, and so on. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute\_modify* command if this is not the case.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute\_modify* command. By default this *extra* component is initialized to  $n_{\text{dim}}$  (as shown in the formula above) to represent the degrees of freedom removed from a system due to its translation invariance due to periodic boundary conditions.

A compute of this style with the ID of “thermo\_temp” is created when LAMMPS starts up, as if this command were in the input script:

```
compute thermo_temp all temp
```

See the “thermo\_style” command for more details.

See the [Howto thermostat](#) page for a discussion of different ways to compute temperature and perform thermostatting.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

### 3.148.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length six (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

### 3.149.2 Examples

```
compute 1 all temp/asphere
compute myTemp mobile temp/asphere bias tempCOM
compute myTemp mobile temp/asphere dof rotate
```

### 3.149.3 Description

Define a computation that calculates the temperature of a group of aspherical particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual `compute temp` command, which assumes point particles with only translational kinetic energy.

Only finite-size particles (aspherical or spherical) can be included in the group. For 3d finite-size particles, each has six degrees of freedom (three translational, three rotational). For 2d finite-size particles, each has three degrees of freedom (two translational, one rotational).

---

**Note:** This choice for degrees of freedom (DOF) assumes that all finite-size aspherical or spherical particles in your model will freely rotate, sampling all their rotational DOF. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are fewer DOF and you should use the `compute_modify extra/dof` command to adjust the DOF accordingly.

---

For example, an aspherical particle with all three of its shape parameters the same is a sphere. If it does not rotate, then it should have 3 DOF instead of 6 in 3d (or two instead of three in 2d). A uniaxial aspherical particle has two of its three shape parameters the same. If it does not rotate around the axis perpendicular to its circular cross section, then it should have 5 DOF instead of 6 in 3d. The latter is the case for uniaxial ellipsoids in a *GayBerne model* since there is no induced torque around the optical axis. It will also be the case for biaxial ellipsoids when exactly two of the semiaxes have the same length and the corresponding relative well depths are equal.

The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as  $\frac{1}{2}I\omega^2$ , where  $I$  is the inertia tensor for the aspherical particle and  $\omega$  is its angular velocity, which is computed from its angular momentum.

---

**Note:** For *2d models*, particles are treated as ellipsoids, not ellipses, meaning their moments of inertia will be the same as in 3d.

---

A kinetic energy tensor, stored as a six-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that  $v^2$  and  $\omega^2$  are replaced by  $v_x v_y$  and  $\omega_x \omega_y$  for the  $xy$  component, and the appropriate elements of the moment of inertia tensor are used. The six components of the vector are ordered  $xx, yy, zz, xy, xz, yz$ .

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the `compute pressue` command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  and  $\omega^2$  are replaced by  $v_x v_y$  and  $\omega_x \omega_y$  for the  $xy$  component, and so on. And the appropriate elements of the moment of inertia tensor are used. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx, yy, zz, xy, xz, yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic/dof` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed

correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra/dof* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

---

The keyword/value option pairs are used in the following ways.

For the *bias* keyword, *bias-ID* refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows compute temp/sphere to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way (e.g., to remove a flow velocity profile). Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostatting for more details.

For the *dof* keyword, a setting of *all* calculates a temperature that includes both translational and rotational degrees of freedom. A setting of *rotate* calculates a temperature that includes only rotational degrees of freedom.

---

### 3.149.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

### 3.149.5 Restrictions

This compute is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This compute requires that atoms store angular momentum and a quaternion as defined by the *atom\_style ellipsoid* command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

compute myTemp mobile temp/body dof rotate
```

### 3.150.3 Description

Define a computation that calculates the temperature of a group of body particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual *compute temp* command, which assumes point particles with only translational kinetic energy.

Only body particles can be included in the group. For 3d particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d body particles, each has 3 degrees of freedom (2 translational, 1 rotational).

---

**Note:** This choice for degrees of freedom (DOF) assumes that all body particles in your model will freely rotate, sampling all their rotational DOF. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less DOF and you should use the *compute\_modify extra/dof* command to adjust the DOF accordingly.

---

The translational kinetic energy is computed the same as is described by the *compute temp* command. The rotational kinetic energy is computed as  $\frac{1}{2}I\omega^2$ , where  $I$  is the moment of inertia tensor for the aspherical particle and  $\omega$  is its angular velocity, which is computed from its angular momentum.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  and  $\omega^2$  are replaced by  $v_x v_y$  and  $\omega_x \omega_y$  for the  $xy$  component, and so on. And the appropriate elements of the moment of inertia tensor are used. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic/dof* option of the *compute\_modify* command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra/dof* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

---

The keyword/value option pairs are used in the following ways.

For the *bias* keyword, *bias-ID* refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows compute temp/sphere to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way (e.g., to remove a flow velocity profile). Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostatting for more details.

For the *dof* keyword, a setting of *all* calculates a temperature that includes both translational and rotational degrees of freedom. A setting of *rotate* calculates a temperature that includes only rotational degrees of freedom.

---

### 3.150.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. ```

### 3.151.3 Description

Define a computation that calculates the temperature of a group of atoms that are also in chunks, after optionally subtracting out the center-of-mass velocity of each chunk. By specifying optional values, it can also calculate the per-chunk temperature or energies of the multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a *compute chunk/atom* command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the *compute chunk/atom* and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

The temperature is calculated by the formula

$$KE = \frac{DOF}{2} k_B T,$$

where KE is the total kinetic energy of all atoms assigned to chunks (sum of  $\frac{1}{2}mv^2$ ), DOF is the the total number of degrees of freedom for those atoms,  $k_B$  is Boltzmann constant, and  $T$  is the absolute temperature.

The DOF is calculated as  $N \times adof + N_{\text{chunk}} \times cdof$ , where  $N$  is the number of atoms contributing to the kinetic energy,  $adof$  is the number of degrees of freedom per atom, and  $cdof$  is the number of degrees of freedom per chunk. By default,  $adof = 2$  or  $3 =$  dimensionality of system, as set via the [dimension](#) command, and  $cdof = 0.0$ . This gives the usual formula for temperature.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the  $1/2$  factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the  $xy$  component, and so on. Note that because it lacks the  $1/2$  factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx, yy, zz, xy, xz, yz$ .

Note that the number of atoms contributing to the temperature is calculated each time the temperature is evaluated since it is assumed the atoms may be dynamically assigned to chunks. Thus there is no need to use the *dynamic* option of the [compute\\_modify](#) command for this compute style.

If any optional values are specified, then per-chunk quantities are also calculated and stored in a global array, as described below.

The *temp* value calculates the temperature for each chunk by the formula

$$\text{KE} = \frac{\text{DOF}}{2} k_B T,$$

where KE is the total kinetic energy of the chunk of atoms (sum of  $\frac{1}{2}mv^2$ ), DOF is the total number of degrees of freedom for all atoms in the chunk,  $k_B$  is the Boltzmann constant, and  $T$  is the absolute temperature.

The number of degrees of freedom (DOF) in this case is calculated as  $N \times adof + cdof$ , where  $N$  is the number of atoms in the chunk,  $adof$  is the number of degrees of freedom per atom, and  $cdof$  is the number of degrees of freedom per chunk. By default,  $cdof = 2$  or  $3 =$  dimensionality of system, as set via the [dimension](#) command, and  $cdof = 0.0$ . This gives the usual formula for temperature.

The *kecom* value calculates the kinetic energy of each chunk as if all its atoms were moving with the velocity of the center-of-mass of the chunk.

The *internal* value calculates the internal kinetic energy of each chunk. The internal KE is summed over the atoms in the chunk using an internal “thermal” velocity for each atom, which is its velocity minus the center-of-mass velocity of the chunk.

Note that currently the global and per-chunk temperatures calculated by this compute only include translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as [compute temp/partial](#), or [fix shake](#) or [fix rigid](#). This is because those degrees of freedom (e.g., a constrained bond) could apply to sets of atoms that are both included and excluded from a specific chunk, and hence the concept is somewhat ill-defined. In some cases, you can use the *adof* and *cdof* keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Note that the per-chunk temperature calculated by this compute and the [fix ave/chunk temp](#) command can be different. This compute calculates the temperature for each chunk for a single snapshot. [fix ave/chunk](#) can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the chunk on different timesteps were collected together as one set of atoms to calculate their temperature. This compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; [fix ave/chunk](#) does not.

**Note:** Only atoms in the specified group contribute to the calculations performed by this compute. The [compute chunk/atom](#) command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying

they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

---

The simplest way to output the per-chunk results of the compute temp/chunk calculation to a file is to use the *fix ave/time* command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all temp/chunk cc1 temp
fix 1 all ave/time 100 1 100 c_myChunk[1] file tmp.out mode vector
```

---

The keyword/value option pairs are used in the following ways.

The *com* keyword can be used with a value of *yes* to subtract the velocity of the center-of-mass for each chunk from the velocity of the atoms in that chunk, before calculating either the global or per-chunk temperature. This can be useful if the atoms are streaming or otherwise moving collectively, and you wish to calculate only the thermal temperature.

For the *bias* keyword, *bias-ID* refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This also allows calculation of the global or per-chunk temperature using only the thermal temperature of atoms in each chunk after the translational kinetic energy components have been altered in a prescribed way (e.g., to remove a velocity profile). It also applies to the calculation of the other per-chunk values, such as *kecom* or *internal*, which involve the center-of-mass velocity of each chunk, which is calculated after the velocity bias is removed from each atom. Note that the temperature compute will apply its bias globally to the entire system, not on a per-chunk basis.

The *adof* and *cdof* keywords define the values used in the degree of freedom (DOF) formulas used for the global or per-chunk temperature, as described above. They can be used to calculate a more appropriate temperature for some kinds of chunks. Here are three examples:

If spatially binned chunks contain some number of water molecules and *fix shake* is used to make each molecule rigid, then you could calculate a temperature with six degrees of freedom (DOF) (three translational, three rotational) per molecule by setting *adof* to 2.0.

If *compute temp/partial* is used with the *bias* keyword to only allow the x component of velocity to contribute to the temperature, then *adof* = 1.0 would be appropriate.

If each chunk consists of a large molecule, with some number of its bonds constrained by *fix shake* or the entire molecule by *fix rigid/small*, *adof* = 0.0 and *cdof* could be set to the remaining degrees of freedom for the entire molecule (entire chunk in this case; i.e., 6 for 3d, or 3 for 2d, for a rigid molecule).

---

### 3.151.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

This compute also optionally calculates a global array, if one or more of the optional values are specified. The number of rows in the array is the number of chunks *Nchunk* as calculated by the specified *compute chunk/atom* command. The number of columns is the number of specified values (1 or more). These values can be accessed by any command that uses global array values from a compute as input. Again, see the *Howto output* doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*. The array values will be in temperature *units* for the *temp* value, and in energy *units* for the *kecom* and *internal* values.

### 3.151.5 Restrictions

The *com* and *bias* keywords cannot be used together.

### 3.151.6 Related commands

*compute temp*, *fix ave/chunk temp*

### 3.151.7 Default

The option defaults are *com* no, no *bias*, *adof* = dimensionality of the system (2 or 3), and *cdof* = 0.0.

## 3.152 compute temp/com command

### 3.152.1 Syntax

```
compute ID group-ID temp/com
```

- ID, group-ID are documented in *compute* command
- temp/com = style name of this compute command

### 3.152.2 Examples

```
compute 1 all temp/com
compute myTemp mobile temp/com
```

### 3.152.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out the center-of-mass velocity of the group. This is useful if the group is expected to have a non-zero net velocity for some reason. A compute of this style can be used by any command that computes a temperature, (e.g., *thermo\_modify*, *fix temp/rescale*, *fix npt*).

After the center-of-mass velocity has been subtracted from each atom, the temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ), *dim* = 2 or 3 is the dimensionality of the simulation, *N* is number of atoms in the group, *k<sub>B</sub>* is the Boltzmann constant, and *T* is the absolute temperature.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for *E<sub>kin</sub>*, except that the 1/2 factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the *xy* component, and so on. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered *xx*, *yy*, *zz*, *xy*, *xz*, *yz*.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute\_modify* command if this is not the case.

The removal of the center-of-mass velocity by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include *fix nvt*, *fix temp/rescale*, *fix temp/berendsen*, and *fix langevin*.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostating.

### 3.152.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values is in energy *units*.

### 3.152.5 Restrictions

none

### 3.152.6 Related commands

*compute temp*

### 3.152.7 Default

none

## 3.153 compute temp/cs command

### 3.153.1 Syntax

`compute ID group-ID temp/cs group1 group2`

- ID, group-ID are documented in *compute* command
- temp/cs = style name of this compute command
- group1 = group-ID of either cores or shells
- group2 = group-ID of either shells or cores

### 3.153.2 Examples

```
compute oxygen_c-s all temp/cs O_core O_shell
compute core_shells all temp/cs cores shells
```

### 3.153.3 Description

Define a computation that calculates the temperature of a system based on the center-of-mass velocity of atom pairs that are bonded to each other. This compute is designed to be used with the adiabatic core/shell model of ([Mitchell and Fincham](#)). See the [Howto coreshell](#) page for an overview of the model as implemented in LAMMPS. Specifically, this compute enables correct temperature calculation and thermostating of core/shell pairs where it is desirable for the internal degrees of freedom of the core/shell pairs to not be influenced by a thermostat. A compute of this style can be used by any command that computes a temperature via [fix\\_modify](#) (e.g., [fix temp/rescale](#), [fix npt](#)).

Note that this compute does not require all ions to be polarized, hence defined as core/shell pairs. One can mix core/shell pairs and ions without a satellite particle if desired. The compute will consider the non-polarized ions according to the physical system.

For this compute, core and shell particles are specified by two respective group IDs, which can be defined using the [group](#) command. The number of atoms in the two groups must be the same and there should be one bond defined between a pair of atoms in the two groups. Non-polarized ions which might also be included in the treated system should not be included into either of these groups, they are taken into account by the *group-ID* (second argument) of the compute.

The temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ),  $\text{dim} = 2$  or  $3$  is the dimensionality of the simulation,  $N$  is the number of atoms in the group,  $k_B$  is the Boltzmann constant, and  $T$  is the absolute temperature. Note that the velocity of each core or shell atom used in the KE calculation is the velocity of the center-of-mass (COM) of the core/shell pair the atom is part of.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the [compute pressue](#) command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the  $1/2$  factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the  $xy$  component, and so on. Note that because it lacks the  $1/2$  factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx, yy, zz, xy, xz, yz$ .

The change this fix makes to core/shell atom velocities is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. This “bias” is the velocity of the atom relative to the center-of-mass velocity of the core/shell pair. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining center-of-mass velocity will be performed, and the bias will be added back in. This means the thermostating will effectively be performed on the core/shell pairs, instead of on the individual core and shell atoms. Thermostating fixes that work in this way include [fix nvt](#), [fix temp/rescale](#), [fix temp/berendsen](#), and [fix langevin](#).

The internal energy of core/shell pairs can be calculated by the [compute temp/chunk](#) command, if chunks are defined as core/shell pairs. See the [Howto coreshell](#) doc page for more discussion on how to do this.

### 3.153.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

### 3.153.5 Restrictions

The number of core/shell pairs contributing to the temperature is assumed to be constant for the duration of the run. No fixes should be used which generate new molecules or atoms during a simulation.

### 3.153.6 Related commands

*compute temp*, *compute temp/chunk*

### 3.153.7 Default

## 3.154 compute temp/deform command

Accelerator Variants: *temp/deform/kk*

### 3.154.1 Syntax

```
compute ID group-ID temp/deform
```

- ID, group-ID are documented in *compute* command
- temp/deform = style name of this compute command

### 3.154.2 Examples

```
compute myTemp all temp/deform
```

### 3.154.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a streaming velocity induced by the simulation box changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the *fix deform* command. A compute of this style is created by the *fix nvt/sllod* command to compute the thermal temperature of atoms for thermostating purposes. A compute of this style can also be used by any command that computes a temperature (e.g., *thermo\_modify*, *fix temp/rescale*, *fix npt*).

The deformation fix changes the box size and/or shape over time, so each atom in the simulation box can be thought of as having a “streaming” velocity. For example, if the box is being sheared in  $x$ , relative to  $y$ , then atoms at the bottom of the box (low  $y$ ) have a small  $x$  velocity, while atoms at the top of the box (high  $y$ ) have a large  $x$  velocity. This position-dependent streaming velocity is subtracted from each atom’s actual velocity to yield a thermal velocity, which is then used to compute the temperature.

---

**Note:** *Fix deform* has an option for remapping either atom coordinates or velocities to the changing simulation box. When using this compute in conjunction with a deforming box, fix deform should NOT remap atom positions, but rather should let atoms respond to the changing box by adjusting their own velocities (or let *fix deform* remap the atom velocities; see its remap option). If fix deform does remap atom positions, then they appear to move with the box but their velocity is not changed, and thus they do NOT have the streaming velocity assumed by this compute. LAMMPS will warn you if fix deform is defined and its remap setting is not consistent with this compute.

---

After the streaming velocity has been subtracted from each atom, the temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ,  $\text{dim} = 2$  or  $3$  is the dimensionality of the simulation,  $N$  is the number of atoms in the group,  $k_B$  is the Boltzmann constant, and  $T$  is the temperature. Note that  $v$  in the kinetic energy formula is the atom’s velocity.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the  $1/2$  factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the  $xy$  component, and so on. Note that because it lacks the  $1/2$  factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute\_modify* command if this is not the case.

The removal of the box deformation velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include *fix nvt*, *fix temp/rescale*, *fix temp/berendsen*, and *fix langevin*.

---

**Note:** The temperature calculated by this compute is only accurate if the atoms are indeed moving with a stream velocity profile that matches the box deformation. If not, then the compute will subtract off an incorrect stream velocity, yielding a bogus thermal temperature. You should **not** assume that your atoms are streaming at the same rate the box is deforming. Rather, you should monitor their velocity profiles (e.g., via the *fix ave/chunk* command). You can also compare the results of this compute to *compute temp/profile*, which actually calculates the stream profile before subtracting it. If the two computes do not give roughly the same temperature, then your atoms are not streaming consistent with the box deformation. See the *fix deform* command for more details on ways to get atoms to stream consistently with the box deformation.

---

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

### 3.154.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

### 3.155.2 Examples

```
compute myTemp all temp/deform/eff
```

### 3.155.3 Description

Define a computation that calculates the temperature of a group of nuclei and electrons in the *electron force field* model, after subtracting out a streaming velocity induced by the simulation box changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the *fix deform* command. A compute of this style is created by the *fix nvt/sllod/eff* command to compute the thermal temperature of atoms for thermostatting purposes. A compute of this style can also be used by any command that computes a temperature (e.g., *thermo\_modify*, *fix npt/eff*).

The calculation performed by this compute is exactly like that described by the *compute temp/deform* command, except that the formulas for the temperature (scalar) and diagonal components of the symmetric tensor (vector) include the radial electron velocity contributions, as discussed by the *compute temp/eff* command. Note that only the translational degrees of freedom for each nuclei or electron are affected by the streaming velocity adjustment. The radial velocity component of the electrons is not affected.

### 3.155.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

### 3.155.5 Restrictions

This compute is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.156.2 Examples

```
compute TDRUDE all temp/drude
```

Example input scripts available: `examples/PACKAGES/drude`.

### 3.156.3 Description

Define a computation that calculates the temperatures of core–Drude pairs. This compute is designed to be used with the *thermalized Drude oscillator model*. Polarizable models in LAMMPS are described on the *Howto polarizable* doc page.

Drude oscillators consist of a core particle and a Drude particle connected by a harmonic bond, and the relative motion of these Drude oscillators is usually maintained cold by a specific thermostat that acts on the relative motion of the core–Drude particle pairs. Therefore, because LAMMPS considers Drude particles as normal atoms in its default temperature compute (*compute temp* command), the reduced temperature of the core–Drude particle pairs is not calculated correctly.

By contrast, this compute calculates the temperature of the cores using center-of-mass velocities of the core–Drude pairs, and the reduced temperature of the Drude particles using the relative velocities of the Drude particles with respect to their cores. Non-polarizable atoms are considered as cores. Their velocities contribute to the temperature of the cores.

### 3.156.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6, which can be accessed by indices 1–6, whose components are

1. temperature of the centers of mass (temperature units)
2. temperature of the dipoles (temperature units)
3. number of degrees of freedom of the centers of mass
4. number of degrees of freedom of the dipoles
5. kinetic energy of the centers of mass (energy units)
6. kinetic energy of the dipoles (energy units)

These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

Both the scalar value and the first two values of the vector calculated by this compute are “intensive”. The other four vector values are “extensive”.

### 3.156.5 Restrictions

The number of degrees of freedom contributing to the temperature is assumed to be constant for the duration of the run unless the *fix\_modify* command sets the option *dynamic/dof yes*.

## 3.157 compute temp/eff command

### 3.157.1 Syntax

```
compute ID group-ID temp/eff
```

- ID, group-ID are documented in *compute* command
- temp/eff = style name of this compute command

### 3.157.2 Examples

```
compute 1 all temp/eff
compute myTemp mobile temp/eff
```

### 3.157.3 Description

Define a computation that calculates the temperature of a group of nuclei and electrons in the *electron force field* model. A compute of this style can be used by commands that compute a temperature (e.g., *thermo\_modify, fix npt/eff*).

The temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$  for nuclei and sum of  $\frac{1}{2}(mv^2 + \frac{3}{4}ms^2)$  for electrons, where  $s$  includes the radial electron velocity contributions),  $\text{dim} = 2$  or  $3$  is the dimensionality of the simulation,  $N$  is the number of atoms (only total number of nuclei in the eFF (see the *pair\_eff* command) in the group,  $k_B$  is the Boltzmann constant, and  $T$  is the absolute temperature. This expression is summed over all nuclear and electronic degrees of freedom, essentially by setting the kinetic contribution to the heat capacity to  $\frac{3}{2}k$  (where only nuclei contribute). This subtlety is valid for temperatures well below the Fermi temperature, which for densities two to five times the density of liquid hydrogen ranges from 86,000 to 170,000 K.

**Note:** For eFF models, in order to override the default temperature reported by LAMMPS in the thermodynamic quantities reported via the *thermo* command, the user should apply a *thermo\_modify* command, as shown in the following example:

```
compute          effTemp all temp/eff
thermo_style      custom step etotal pe ke temp press
thermo_modify     temp effTemp
```

A six-component kinetic energy tensor is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that  $v^2$  is replaced by  $v_x v_y$  for the  $xy$  component, etc. For the eFF, again, the radial electronic velocities are also considered.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the `compute_modify` command if this is not the case.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the `compute_modify` command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

### 3.157.4 Output info

The scalar value calculated by this compute is “intensive”, meaning it is independent of the number of atoms in the simulation. The vector values are “extensive”, meaning they scale with the number of atoms in the simulation.

### 3.157.5 Restrictions

This compute is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 3.157.6 Related commands

*compute temp/partial, compute temp/region, compute pressure*

### 3.157.7 Default

none

## 3.158 compute temp/partial command

### 3.158.1 Syntax

```
compute ID group-ID temp/partial xflag yflag zflag
```

- ID, group-ID are documented in *compute* command
- temp/partial = style name of this compute command
- xflag,yflag,zflag = 0/1 for whether to exclude/include this dimension

### 3.158.2 Examples

```
compute newT flow temp/partial 1 1 0
```

### 3.158.3 Description

Define a computation that calculates the temperature of a group of atoms, after excluding one or more velocity components. A compute of this style can be used by any command that computes a temperature (e.g. *thermo\_modify*, *fix temp/rescale*, *fix npt*).

The temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ), dim = 2 or 3 is the dimensionality of the simulation,  $N$  is the number of atoms in the group,  $k_B$  is the Boltzmann constant, and  $T$  = temperature. The calculation of KE excludes the  $x$ ,  $y$ , or  $z$  dimensions if *xflag*, *yflag*, or *zflag* is 0. The dim parameter is adjusted to give the correct number of degrees of freedom.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the  $xy$  component, and so on. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute\_modify* command if this is not the case.

The removal of velocity components by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include *fix nvt*, *fix temp/rescale*, *fix temp/berendsen*, and *fix langevin*.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostating.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 3.158.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

```
compute myTemp flow temp/profile 1 1 1 x 10
compute myTemp flow temp/profile 1 1 1 x 10 out bin
compute myTemp flow temp/profile 0 1 1 xyz 20 20 20
```

### 3.159.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a spatially-averaged center-of-mass velocity field, before computing the kinetic energy. This can be useful for thermostating a collection of atoms undergoing a complex flow (e.g. via a profile-unbiased thermostat (PUT) as described in (Evans)). A compute of this style can be used by any command that computes a temperature (e.g. *thermo\_modify*, *fix temp/rescale*, *fix npt*).

The *xflag*, *yflag*, *zflag* settings determine which components of average velocity are subtracted out.

The *binstyle* setting and its *Nx*, *Ny*, *Nz* arguments determine how bins are setup to perform spatial averaging. “Bins” can be 1d slabs, 2d pencils, or 3d bricks depending on which *binstyle* is used. The simulation box is partitioned conceptually into  $N_x \times N_y \times N_z$  bins. Depending on the *binstyle*, you may only specify one or two of these values; the others are effectively set to 1 (no binning in that dimension). For non-orthogonal (triclinic) simulation boxes, the bins are “tilted” slabs or pencils or bricks that are parallel to the tilted faces of the box. See the *region prism* command for a discussion of the geometry of tilted boxes in LAMMPS.

When a temperature is computed, the center-of-mass velocity for the set of atoms that are both in the compute group and in the same spatial bin is calculated. This bias velocity is then subtracted from the velocities of individual atoms in the bin to yield a thermal velocity for each atom. Note that if there is only one atom in the bin, its thermal velocity will thus be 0.0.

After the spatially-averaged velocity field has been subtracted from each atom, the temperature is calculated by the formula

$$KE = \left( \frac{\text{dim}}{N} - N_s N_x N_y N_z - \text{extra} \right) \frac{k_B T}{2},$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ; *dim* = 2 or 3 is the dimensionality of the simulation;  $N_s$  = 0, 1, 2, or 3 for streaming velocity subtracted in 0, 1, 2, or 3 dimensions, respectively; *extra* is the number of extra degrees of freedom; *N* is the number of atoms in the group;  $k_B$  is the Boltzmann constant, and *T* is the absolute temperature. The  $N_s N_x N_y N_z$  term is the number of degrees of freedom subtracted to adjust for the removal of the center-of-mass velocity in each direction of the  $N_x * N_y * N_z$  bins, as discussed in the (Evans) paper. The extra term defaults to *dim* −  $N_s$  and accounts for overall conservation of center-of-mass velocity across the group in directions where streaming velocity is *not* subtracted. This can be altered using the *extra* option of the *compute\_modify* command.

If the *out* keyword is used with a *tensor* value, which is the default, then a symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressure* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the *xy* component, and so on. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered *xx*, *yy*, *zz*, *xy*, *xz*, *yz*.

If the *out* keyword is used with a *bin* value, the count of atoms and computed temperature for each bin are stored for output, as an array of values, as described below. The temperature of each bin is calculated as described above, where the bias velocity is subtracted and only the remaining thermal velocity of atoms in the bin contributes to the temperature. See the note below for how the temperature is normalized by the degrees-of-freedom of atoms in the bin.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute\_modify* command if this is not the case.

The removal of the spatially-averaged velocity field by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include *fix nvt*, *fix temp/rescale*, *fix temp/berendsen*, and *fix langevin*.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute\_modify* command.

---

**Note:** When using the *out* keyword with a value of *bin*, the calculated temperature for each bin includes the degrees-of-freedom adjustment described in the preceding paragraph for fixes that constrain molecular motion, as well as the adjustment due to the *extra* option (which defaults to *dim - Ns* as described above), by fractionally applying them based on the fraction of atoms in each bin. As a result, the bin degrees-of-freedom summed over all bins exactly equals the degrees-of-freedom used in the scalar temperature calculation,  $\sum N_{\text{DOF}_i} = N_{\text{DOF}}$  and the corresponding relation for temperature is also satisfied ( $\sum N_{\text{DOF}_i} T_i = N_{\text{DOF}} T$ ). These relations will break down in cases for which the adjustment exceeds the actual number of degrees of freedom in a bin. This could happen if a bin is empty or in situations in which rigid molecules are non-uniformly distributed, in which case the reported temperature within a bin may not be accurate.

---

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostating. Using this compute in conjunction with a thermostating fix, as explained there, will effectively implement a profile-unbiased thermostat (PUT), as described in (*Evans*).

### 3.159.4 Output info

This compute calculates a global scalar (the temperature). Depending on the setting of the *out* keyword, it also calculates a global vector or array. For *out = tensor*, it calculates a vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. For *out = bin* it calculates a global array which has 2 columns and *N* rows, where *N* is the number of bins. The first column contains the number of atoms in that bin. The second contains the temperature of that bin, calculated as described above. The ordering of rows in the array is as follows. Bins in *x* vary fastest, then *y*, then *z*. Thus for a  $10 \times 10 \times 10$  3d array of bins, there will be 1000 rows. The bin with indices  $(i_x, i_y, i_z) = (2, 3, 4)$  would map to row  $M = 10^2(i_z - 1) + 10(i_y - 1) + i_x = 322$ , where the rows are numbered from 1 to 1000 and the bin indices are numbered from 1 to 10 in each dimension.

These values can be used by any command that uses global scalar or vector or array values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*. The first column of array values are counts; the values in the second column will be in temperature *units*.

### 3.159.5 Restrictions

You should not use too large a velocity-binning grid, especially in 3d. In the current implementation, the binned velocity averages are summed across all processors, so this will be inefficient if the grid is too large, and the operation is performed every timestep, as it will be for most thermostats.

### 3.159.6 Related commands

*compute temp, compute temp/ramp, compute temp/deform, compute pressure*

### 3.159.7 Default

The option default is out = tensor.

(Evans) Evans and Morriss, Phys Rev Lett, 56, 2172-2175 (1986).

## 3.160 compute temp/ramp command

### 3.160.1 Syntax

```
compute ID group-ID temp/ramp vdim vlo vhi dim clo chi keyword value ...
```

- ID, group-ID are documented in *compute* command
- temp/ramp = style name of this compute command
- vdim = vx or vy or vz
- vlo,vhi = subtract velocities between vlo and vhi (velocity units)
- dim = x or y or z
- clo,chi = lower and upper bound of domain to subtract from (distance units)
- zero or more keyword/value pairs may be appended
- keyword = *units*

*units* value = *lattice* or *box*

### 3.160.2 Examples

```
compute 2nd middle temp/ramp vx 0 8 y 2 12 units lattice
```

### 3.160.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out an ramped velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature (e.g. *thermo\_modify*, *fix temp/rescale*, *fix npt*).

The meaning of the arguments for this command which define the velocity ramp are the same as for the *velocity ramp* command which was presumably used to impose the velocity.

After the ramp velocity has been subtracted from the specified dimension for each atom, the temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ),  $\text{dim} = 2$  or  $3$  is the dimensionality of the simulation,  $N$  is the number of atoms in the group,  $k_B$  is the Boltzmann constant, and  $T$  is the absolute temperature.

The *units* keyword determines the meaning of the distance units used for coordinates (*clo*, *chi*) and velocities (*vlo*, *vhi*). A *box* value selects standard distance units as defined by the *units* command (e.g., Å for units = real or metal). A *lattice* value means the distance units are in lattice spacings (i.e., velocity in lattice spacings per unit time). The *lattice* command must have been previously used to define the lattice spacing.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressure* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the  $1/2$  factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the *xy* component, and so on. Note that because it lacks the  $1/2$  factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered *xx*, *yy*, *zz*, *xy*, *xz*, *yz*.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute\_modify* command if this is not the case.

The removal of the ramped velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include *fix nvt*, *fix temp/rescale*, *fix temp/berendsen*, and *fix langevin*.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostating.

### 3.160.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

*compute temp*, *compute temp/profile*, *compute temp/deform*, *compute pressure*

### 3.160.7 Default

The option default is units = lattice.

## 3.161 compute temp/region command

### 3.161.1 Syntax

```
compute ID group-ID temp/region region-ID
```

- ID, group-ID are documented in *compute* command
- temp/region = style name of this compute command
- region-ID = ID of region to use for choosing atoms

### 3.161.2 Examples

```
compute mine flow temp/region boundary
```

### 3.161.3 Description

Define a computation that calculates the temperature of a group of atoms in a geometric region. This can be useful for thermostating one portion of the simulation box. For example, a McDLT simulation where one side is cooled, and the other side is heated. A compute of this style can be used by any command that computes a temperature (e.g., *thermo\_modify*, *fix temp/rescale*).

Note that a *region*-style temperature can be used to thermostat with *fix temp/rescale* or *fix langevin*, but should probably not be used with Nose–Hoover style fixes (*fix nvt*, *fix npt*, or *fix nph*) if the degrees of freedom included in the computed temperature vary with time.

The temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE = is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ), dim = 2 or 3 is the dimensionality of the simulation,  $N$  is the number of atoms in both the group and region,  $k_B$  is the Boltzmann constant, and  $T$  temperature.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the *xy* component, and so on. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered *xx*, *yy*, *zz*, *xy*, *xz*, *yz*.

The number of atoms contributing to the temperature is calculated each time the temperature is evaluated since it is assumed atoms can enter/leave the region. Thus there is no need to use the *dynamic* option of the *compute\_modify* command for this compute style.

The removal of atoms outside the region by this fix is essentially computing the temperature after a “bias” has been removed, which in this case is the velocity of any atoms outside the region. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include *fix*

*nvt*, *fix temp/rescale*, *fix temp/berendsen*, and *fix langevin*. This means that when this compute is used to calculate the temperature for any of the thermostating fixes via the *fix modify temp* command, the thermostat will operate only on atoms that are currently in the geometric region.

Unlike other compute styles that calculate temperature, this compute does not subtract out degrees-of-freedom due to fixes that constrain motion, such as *fix shake* and *fix rigid*. This is because those degrees of freedom (e.g., a constrained bond) could apply to sets of atoms that straddle the region boundary, and hence the concept is somewhat ill-defined. If needed the number of subtracted degrees of freedom can be set explicitly using the *extra* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostating.

### 3.161.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

## 3.163 compute temp/rotate command

### 3.163.1 Syntax

```
compute ID group-ID temp/rotate
```

- ID, group-ID are documented in *compute* command
- temp/rotate = style name of this compute command

### 3.163.2 Examples

```
compute Tbead bead temp/rotate
```

### 3.163.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out the center-of-mass velocity and angular velocity of the group. This is useful if the group is expected to have a non-zero net velocity and/or global rotation motion for some reason. A compute of this style can be used by any command that computes a temperature (e.g., *thermo\_modify*, *fix temp/rescale*, *fix npt*).

After the center-of-mass velocity and angular velocity has been subtracted from each atom, the temperature is calculated by the formula

$$KE = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ),  $\text{dim} = 2$  or  $3$  is the dimensionality of the simulation,  $N$  is the number of atoms in the group,  $k_B$  is the Boltzmann constant, and  $T$  is the absolute temperature.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the  $1/2$  factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the  $xy$  component, and so on. Note that because it lacks the  $1/2$  factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute\_modify* command if this is not the case.

The removal of the center-of-mass velocity and angular velocity by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include *fix nvt*, *fix temp/rescale*, *fix temp/berendsen*, and *fix langevin*.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute\_modify* command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostating.

### 3.163.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

### 3.163.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.163.6 Related commands

*compute temp*

### 3.163.7 Default

none

## 3.164 compute temp/sphere command

### 3.164.1 Syntax

```
compute ID group-ID temp/sphere keyword value ...
```

- ID, group-ID are documented in *compute* command
- temp/sphere = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *bias* or *dof*
  - bias* value = bias-ID  
bias-ID = ID of a temperature compute that removes a velocity bias
  - dof* value = *all* or *rotate*  
all = compute temperature of translational and rotational degrees of freedom  
rotate = compute temperature of just rotational degrees of freedom

### 3.164.2 Examples

```
compute 1 all temp/sphere
compute myTemp mobile temp/sphere bias tempCOM
compute myTemp mobile temp/sphere dof rotate
```

### 3.164.3 Description

Define a computation that calculates the temperature of a group of spherical particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual *compute temp* command, which assumes point particles with only translational kinetic energy.

Both point and finite-size particles can be included in the group. Point particles do not rotate, so they have only three translational degrees of freedom. For 3d spherical particles, each has six degrees of freedom (three translational, three rotational). For 2d spherical particles, each has three degrees of freedom (two translational, one rotational).

**Note:** This choice for degrees of freedom (DOF) assumes that all finite-size spherical particles in your model will freely rotate, sampling all their rotational DOF. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less DOF and you should use the `compute_modify extra/dof` command to adjust the DOF accordingly.

---

The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as  $\frac{1}{2}I\omega^2$ , where  $I$  is the moment of inertia for a sphere and  $\omega$  is the particle's angular velocity.

---

**Note:** For *2d models*, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3d.

---

A kinetic energy tensor, stored as a six-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formulas, except that  $v^2$  and  $\omega^2$  are replaced by  $v_x v_y$  and  $\omega_x \omega_y$  for the  $xy$  component. The six components of the vector are ordered  $xx, yy, zz, xy, xz, yz$ .

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the `compute pressue` command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  and  $\omega^2$  are replaced by  $v_x v_y$  and  $\omega_x \omega_y$  for the  $xy$  component, and so on. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx, yy, zz, xy, xz, yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees of freedom can be altered using the `extra/dof` option of the `compute_modify` command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

---

The keyword/value option pairs are used in the following ways.

For the *bias* keyword, *bias-ID* refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows compute temp/sphere to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way (e.g., to remove a flow velocity profile). Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostatting for more details.

For the *dof* keyword, a setting of *all* calculates a temperature that includes both translational and rotational degrees of freedom. A setting of *rotate* calculates a temperature that includes only rotational degrees of freedom.

---

### 3.164.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (symmetric tensor), which can be accessed by indices 1–6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value is in temperature *units*. The vector values are in energy *units*.

### 3.164.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the [atom\\_style sphere](#) command.

All particles in the group must be finite-size spheres, or point particles with radius = 0.0.

### 3.164.6 Related commands

*compute temp*, *compute temp/asphere*

### 3.164.7 Default

The option defaults are no bias and dof = all.

## 3.165 compute temp/uef command

### 3.165.1 Syntax

```
compute ID group-ID temp/uef
```

- ID, group-ID are documented in [compute](#) command
- temp/uef = style name of this compute command

### 3.165.2 Examples

```
compute 1 all temp/uef
compute 2 sel temp/uef
```

### 3.165.3 Description

This command is used to compute the kinetic energy tensor in the reference frame of the applied flow field when *fix nvt/uef* or *fix npt/uef* is used. It is not necessary to use this command to compute the scalar value of the temperature. A *compute temp* may be used for that purpose.

Output information for this command can be found in the documentation for *compute temp*.

### 3.165.4 Restrictions

This fix is part of the UEF package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This command can only be used when *fix nvt/uef* or *fix npt/uef* is active.

### 3.165.5 Related commands

*compute temp*, *fix nvt/uef*, *compute pressure/uef*

### 3.165.6 Default

compute 1 all ti lj/cut 1*3 v_lj v_dlj coul/long * v_c v_dc kspace * v_ks v_dks
```

### 3.166.3 Description

Define a computation that calculates the derivative of the interaction potential with respect to *lambda*, the coupling parameter used in a thermodynamic integration. This derivative can be used to infer a free energy difference resulting from an alchemical simulation, as described in *Eike*.

Typically this compute will be used in conjunction with the *fix adapt* command which can perform alchemical transformations by adjusting the strength of an interaction potential as a simulation runs, as defined by one or more *pair\_style* or *kspace\_style* commands. This scaling is done via a prefactor on the energy, forces, virial calculated by the pair or *k*-space style. The prefactor is often a function of a *lambda* parameter which may be adjusted from 0 to 1 (or vice versa) over the course of a *run*. The time-dependent adjustment is what the *fix adapt* command does.

Assume that the unscaled energy of a *pair\_style* or *kspace\_style* is given by *U*. Then the scaled energy is

$$U_s = f(\lambda)U$$

where *f* is some function of  $\lambda$ . What this compute calculates is

$$\frac{dU_s}{d\lambda} = U \frac{df(\lambda)}{d\lambda} = \frac{U_s}{f(\lambda)} \frac{df(\lambda)}{d\lambda},$$

which is the derivative of the system's scaled potential energy  $U_s$  with respect to  $\lambda$ .

To perform this calculation, you provide one or more atom types as *atype*. The variable *atype* can be specified in one of two ways. An explicit numeric value can be used, as in the first example above, or a wildcard asterisk can be used in place of or in conjunction with the *atype* argument to select multiple atom types. This takes the form “\*” or “\*n” or “m\*” or “m\*n”. If *N* is the number of atom types, then an asterisk with no numeric values means all types from 1 to *N*. A leading asterisk means all types from 1 to *n* (inclusive). A trailing asterisk means all types from *m* to *N* (inclusive). A middle asterisk means all types from *m* to *n* (inclusive).

You also specify two functions, as *equal-style variables*. The first is specified as *v\_name1*, where *name1* is the name of the variable, and is  $f(\lambda)$  in the notation above. The second is specified as *v\_name2*, where *name2* is the name of the variable, and is  $df(\lambda)/d\lambda$  in the notation above (i.e., it is the analytic derivative of *f* with respect to  $\lambda$ ). Note that the *name1* variable is also typically given as an argument to the *fix adapt* command.

An alchemical simulation may use several pair potentials together, invoked via the *pair\_style hybrid* or *hybrid/overlay* command. The total  $dU_s/d\lambda$  for the overall system is calculated as the sum of each contributing term as listed by the keywords in the *compute ti* command. Individual pair potentials can be listed, which will be sub-styles in the hybrid case. You can also include a *k*-space term via the *kspace* keyword. You can also include a pairwise long-range tail correction to the energy via the *tail* keyword.

For each term, you can specify a different (or the same) scale factor by the two variables that you list. Again, these will typically correspond to the scale factors applied to these various potentials and the *k*-space contribution via the *fix adapt* command.

More details about the exact functional forms for the computation of  $du/dl$  can be found in the paper by *Eike*.

### 3.166.4 Output info

This compute calculates a global scalar, namely  $dU_s/d\lambda$ . This value can be used by any command that uses a global scalar value from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”.

The scalar value will be in energy *units*.

### 3.166.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 3.166.6 Related commands

*fix adapt*

### 3.166.7 Default

## 3.167 compute torque/chunk command

### 3.167.1 Syntax

```
compute ID group-ID torque/chunk chunkID
```

- ID, group-ID are documented in [compute](#) command
- torque/chunk = style name of this compute command
- chunkID = ID of [compute chunk/atom](#) command

### 3.167.2 Examples

```
compute 1 fluid torque/chunk molchunk
```

### 3.167.3 Description

Define a computation that calculates the torque on multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as `chunkID`. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and *Howto chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the three components of the torque vector for each chunk, due to the forces on the individual atoms in the chunk around the center-of-mass of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

---

**Note:** The coordinates of an atom contribute to the chunk’s torque in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the `set image` command.

---

The simplest way to output the results of the compute torque/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all torque/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.167.4 Output info

This compute calculates a global array where the number of rows is equal to the number of chunks *Nchunk* as calculated by the specified `compute chunk/atom` command. The number of columns is three for the *x*, *y*, and *z* components of the torque for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in force-distance *units*.

### 3.167.5 Restrictions

none

### 3.167.6 Related commands

*variable torque()* function

### 3.167.7 Default

none

## 3.168 compute vacf command

### 3.168.1 Syntax

```
compute ID group-ID vacf
```

- ID, group-ID are documented in *compute* command
- vacf = style name of this compute command

### 3.168.2 Examples

```
compute 1 all vacf
compute 1 upper vacf
```

### 3.168.3 Description

Define a computation that calculates the velocity auto-correlation function (VACF), averaged over a group of atoms. Each atom's contribution to the VACF is its current velocity vector dotted into its initial velocity vector at the time the compute was specified.

A vector of four quantities is calculated by this compute. The first three elements of the vector are  $v_x v_{x,0}$  (and similar for the y and z components), summed and averaged over atoms in the group, where  $v_x$  is the current x-component of the velocity of the atom and  $v_{x,0}$  is the initial x-component of the velocity of the atom. The fourth element of the vector is the total VACF (i.e.,  $(v_x v_{x,0} + v_y v_{y,0} + v_z v_{z,0})$ ), summed and averaged over atoms in the group.

The integral of the VACF versus time is proportional to the diffusion coefficient of the diffusing atoms. This can be computed in the following manner, using the *variable trap()* function:

```
compute      2 all vacf
fix          5 all vector 1 c_2[4]
variable     diff equal dt*trap(f_5)
thermo_style custom step v_diff
```

---

**Note:** If you want the quantities calculated by this compute to be continuous when running from a *restart file*, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with time=0 atom velocities from the restart file.

---

### 3.168.4 Output info

This compute calculates a global vector of length 4, which can be accessed by indices 1–4 by any command that uses global vector values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in velocity<sup>2</sup> *units*.

## 3.169 compute vcm/chunk command

### 3.169.1 Syntax

```
compute ID group-ID vcm/chunk chunkID
```

- ID, group-ID are documented in [compute](#) command
- vcm/chunk = style name of this compute command
- chunkID = ID of [compute chunk/atom](#) command

### 3.169.2 Examples

```
compute 1 fluid vcm/chunk molchunk
```

### 3.169.3 Description

Define a computation that calculates the center-of-mass velocity for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a [compute chunk/atom](#) command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the [compute chunk/atom](#) and [Howto chunk](#) doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the (*x*, *y*, *z*) components of the center-of-mass velocity for each chunk. This is done by summing mass\*velocity for each atom in the chunk and dividing the sum by the total mass of the chunk.

Note that only atoms in the specified group contribute to the calculation. The [compute chunk/atom](#) command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk,

and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The simplest way to output the results of the compute vcm/chunk calculation to a file is to use the *fix ave/time* command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all vcm/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 3.169.4 Output info

This compute calculates a global array where the number of rows is the number of chunks *Nchunk* as calculated by the specified *compute chunk/atom* command. The number of columns is 3 for the  $(x, y, z)$  center-of-mass velocity coordinates of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in velocity *units*.

variable   reciprocalViscosity equal v_V/$(A)/v_density*39.4784/v_lz/v_lz*100 # 1/(Pa*s)

```

### 3.170.3 Description

Define a computation that calculates the velocity amplitude of a group of atoms with an cosine-shaped velocity profile and the temperature of them after subtracting out the velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature (e.g., *thermo\_modify*, *fix npt*).

This command together with *fix accelerate/cos* enables viscosity calculation with periodic perturbation method, as described by *Hess*. An acceleration along the  $x$ -direction is applied to the simulation system by using *fix accelerate/cos* command. The acceleration is a periodic function along the  $z$ -direction:

$$a_x(z) = A \cos\left(\frac{2\pi z}{l_z}\right)$$

where  $A$  is the acceleration amplitude,  $l_z$  is the  $z$ -length of the simulation box. At steady state, the acceleration generates a velocity profile:

$$v_x(z) = V \cos\left(\frac{2\pi z}{l_z}\right)$$

The generated velocity amplitude  $V$  is related to the shear viscosity  $\eta$  by

$$V = \frac{A\rho}{\eta} \left(\frac{l_z}{2\pi}\right)^2,$$

and it can be obtained from ensemble average of the velocity profile via

$$V = \frac{\sum_i 2m_i v_{i,x} \cos\left(\frac{2\pi z_i}{l_z}\right)}{\sum_i m_i}$$

where  $m_i$ ,  $v_{i,x}$  and  $z_i$  are the mass,  $x$ -component velocity, and  $z$ -coordinate of a particle, respectively.

After the cosine-shaped collective velocity in the  $x$ -direction has been subtracted for each atom, the temperature is calculated by the formula

$$\text{KE} = \frac{\text{dim}}{2} N k_B T,$$

where KE is the total kinetic energy of the group of atoms (sum of  $\frac{1}{2}mv^2$ ), dim = 2 or 3 is the dimensionality of the simulation,  $N$  is the number of atoms in the group,  $k_B$  is the Boltzmann constant, and  $T$  is the absolute temperature.

A symmetric tensor, stored as a six-element vector, is also calculated by this compute for use in the computation of a pressure tensor by the *compute pressue* command. The formula for the components of the tensor is the same as the above expression for  $E_{\text{kin}}$ , except that the 1/2 factor is NOT included and the  $v_i^2$  is replaced by  $v_{i,x}v_{i,y}$  for the  $xy$  component, and so on. Note that because it lacks the 1/2 factor, these tensor components are twice those of the traditional kinetic energy tensor. The six components of the vector are ordered  $xx$ ,  $yy$ ,  $zz$ ,  $xy$ ,  $xz$ ,  $yz$ .

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the `compute_modify` command if this is not the case. However, in order to get meaningful results, the group ID of this compute should be all.

The removal of the cosine-shaped velocity component by this command is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees of freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means that the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees of freedom can be altered using the *extra* option of the `compute_modify` command.

See the [Howto thermostat](#) page for a discussion of different ways to compute temperature and perform thermostating.

---

### 3.170.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 7, which can be accessed by indices 1–7. The first six elements of the vector are those of the symmetric tensor discussed above. The seventh is the cosine-shaped velocity amplitude  $V$ , which can be used to calculate the reciprocal viscosity, as shown in the example. These values can be used by any command that uses global scalar or vector values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The first six elements of vector values are “extensive”, and the seventh element of vector values is “intensive”.

The scalar value is in temperature *units*. The first six elements of vector values are in energy *units*. The seventh element of vector value is in velocity *units*.

### 3.170.5 Restrictions

This compute is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Since this compute depends on `fix accelerate/cos` which can only work for 3d systems, it cannot be used for 2d systems.

### 3.170.6 Related commands

`fix accelerate/cos`

## 3.171 compute voronoi/atom command

### 3.171.1 Syntax

```
compute ID group-ID voronoi/atom keyword arg ...
```

- ID, group-ID are documented in *compute* command
- voronoi/atom = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *only\_group* or *occupation* or *surface* or *radius* or *edge\_histo* or *edge\_threshold* or *face\_threshold* or *neighbors*

*only\_group* = no arg

*occupation* = no arg

*surface* arg = sgroup-ID

sgroup-ID = compute the dividing surface between group-ID and sgroup-ID

this keyword adds a third column to the compute output

*radius* arg = v\_r

v\_r = radius atom style variable for a poly-disperse Voronoi tessellation

*edge\_histo* arg = maxedge

maxedge = maximum number of Voronoi cell edges to be accounted in the histogram

*edge\_threshold* arg = minlength

minlength = minimum length for an edge to be counted

*face\_threshold* arg = minarea

minarea = minimum area for a face to be counted

*neighbors* value = yes or no = store list of all neighbors or no

### 3.171.2 Examples

```
compute 1 all voronoi/atom
compute 2 precipitate voronoi/atom surface matrix
compute 3b precipitate voronoi/atom radius v_r
compute 4 solute voronoi/atom only_group
compute 5 defects voronoi/atom occupation
compute 6 all voronoi/atom neighbors yes
```

### 3.171.3 Description

Define a computation that calculates the Voronoi tessellation of the atoms in the simulation box. The tessellation is calculated using all atoms in the simulation, but non-zero values are only stored for atoms in the group.

Two per-atom quantities are calculated by this compute. The first is the volume of the Voronoi cell around each atom. Any point in an atom's Voronoi cell is closer to that atom than any other. The second is the number of faces of the Voronoi cell. This is equal to the number of nearest neighbors of the central atom, plus any exterior faces (see note below).

If the *only\_group* keyword is specified the tessellation is performed only with respect to the atoms contained in the compute group. This is equivalent to deleting all atoms not contained in the group prior to evaluating the tessellation.

If the *surface* keyword is specified a third quantity per atom is computed: the Voronoi cell surface of the given atom. *surface* takes a group ID as an argument. If a group other than *all* is specified, only the Voronoi cell facets facing a neighbor atom from the specified group are counted towards the surface area.

In the example above, a precipitate embedded in a matrix, only atoms at the surface of the precipitate will have non-zero surface area, and only the outward facing facets of the Voronoi cells are counted (the hull of the precipitate). The total surface area of the precipitate can be obtained by running a “reduce sum” compute on `c_2[3]`.

If the *radius* keyword is specified with an atom style variable as the argument, a poly-disperse Voronoi tessellation is performed. Examples for radius variables are

```
variable r1 atom (type==1)*0.1+(type==2)*0.4
compute radius all property/atom radius
variable r2 atom c_radius
```

Here `v_r1` specifies a per-type radius of 0.1 units for type 1 atoms and 0.4 units for type 2 atoms, and `v_r2` accesses the radius property present in `atom_style sphere` for granular models.

The *edge\_histo* keyword activates the compilation of a histogram of number of edges on the faces of the Voronoi cells in the compute group. The argument *maxedge* of the this keyword is the largest number of edges on a single Voronoi cell face expected to occur in the sample. This keyword generates output of a global vector by this compute with *maxedge*+1 entries. The last entry in the vector contains the number of faces with more than *maxedge* edges. Since the polygon with the smallest amount of edges is a triangle, entries 1 and 2 of the vector will always be zero.

The *edge\_threshold* and *face\_threshold* keywords allow the suppression of edges below a given minimum length and faces below a given minimum area. Ultra short edges and ultra small faces can occur as artifacts of the Voronoi tessellation. These keywords will affect the neighbor count and edge histogram outputs.

If the *occupation* keyword is specified the tessellation is only performed for the first invocation of the compute and then stored. For all following invocations of the compute the number of atoms in each Voronoi cell in the stored tessellation is counted. In this mode the compute returns a per-atom array with 2 columns. The first column is the number of atoms currently in the Voronoi volume defined by this atom at the time of the first invocation of the compute (note that the atom may have moved significantly). The second column contains the total number of atoms sharing the Voronoi cell of the stored tessellation at the location of the current atom. Numbers in column one can be any positive integer including zero, while column two values will always be greater than zero. Column one data can be used to locate vacancies (the coordinates are given by the atom coordinates at the time step when the compute was first invoked), while column two data can be used to identify interstitial atoms.

If the *neighbors* value is set to yes, then this compute also creates a local array with 3 columns. There is one row for each face of each Voronoi cell. The 3 columns are the atom ID of the atom that owns the cell, the atom ID of the atom in the neighboring cell (or zero if the face is external), and the area of the face. The array can be accessed by any command that uses local values from a compute as input. See the [Howto output](#) page for an overview of LAMMPS output options. More specifically, the array can be accessed by a *dump local* command to write a file containing all the Voronoi neighbors in a system:

```
compute 6 all voronoi/atom neighbors yes
dump d2 all local 1 dump.neighbors index c_6[1] c_6[2] c_6[3]
```

If the *face\_threshold* keyword is used, then only faces with areas greater than the threshold are stored.

---

The Voronoi calculation is performed by the freely available [Voro++ package](#), written by Chris Rycroft at UC Berkeley and LBL, which must be installed on your system when building LAMMPS for use with this compute. See instructions on obtaining and installing the Voro++ software in the `src/VORONOI/README` file.

---

**Note:** The calculation of Voronoi volumes is performed by each processor for the atoms it owns, and includes the effect of ghost atoms stored by the processor. This assumes that the Voronoi cells of owned atoms are not affected

by atoms beyond the ghost atom cut-off distance. This is usually a good assumption for liquid and solid systems, but may lead to underestimation of Voronoi volumes in low density systems. By default, the set of ghost atoms stored by each processor is determined by the cutoff used for *pair\_style* interactions. The cutoff can be set explicitly via the *comm\_modify cutoff* command. The Voronoi cells for atoms adjacent to empty regions will extend into those regions up to the communication cutoff in *x*, *y*, or *z*. In that situation, an exterior face is created at the cutoff distance normal to the *x*, *y*, or *z* direction. For triclinic systems, the exterior face is parallel to the corresponding reciprocal lattice vector.

---

**Note:** The Voro++ package performs its calculation in 3d. This will still work for a 2d LAMMPS simulation, provided all the atoms have the same *z*-coordinate. The Voronoi cell of each atom will be a columnar polyhedron with constant cross-sectional area along the *z*-direction and two exterior faces at the top and bottom of the simulation box. If the atoms do not all have the same *z*-coordinate, then the columnar cells will be accordingly distorted. The cross-sectional area of each Voronoi cell can be obtained by dividing its volume by the *z* extent of the simulation box. Note that you define the *z* extent of the simulation box for 2d simulations when using the *create\_box* or *read\_data* commands.

---

### 3.171.4 Output info

Deprecated since version 21Nov2023: The *peratom* keyword was removed as it is no longer required.

This compute calculates a per-atom array with two columns. In regular dynamic tessellation mode the first column is the Voronoi volume, the second is the neighbor count, as described above (read above for the output data in case the *occupation* keyword is specified). These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

If the *edge\_histo* keyword is used, then this compute generates a global vector of length *maxedge*+1, containing a histogram of the number of edges per face.

If the *neighbors* value is set to *yes*, then this compute calculates a local array with three columns. There is one row for each face of each Voronoi cell.

The Voronoi cell volume will be in distance *units* cubed. The Voronoi face area will be in distance *units* squared.

### 3.171.5 Restrictions

This compute is part of the VORONOI package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

It also requires you have a copy of the Voro++ library built and installed on your system. See instructions on obtaining and installing the Voro++ software in the src/VORONOI/README file.

### 3.171.6 Related commands

*dump custom*, *dump local*

### 3.171.7 Default

The default for the neighbors keyword is no.

## 3.172 compute xrd command

### 3.172.1 Syntax

```
compute ID group-ID xrd lambda type1 type2 ... typeN keyword value ...
```

- ID, group-ID are documented in *compute* command
- xrd = style name of this compute command
- lambda = wavelength of incident radiation (length units)
- type1 type2 ... typeN = chemical symbol of each atom type (see valid options below)
- zero or more keyword/value pairs may be appended
- keyword = *2Theta* or *c* or *LP* or *manual* or *echo*
  - 2Theta* values = Min2Theta Max2Theta  
Min2Theta,Max2Theta = minimum and maximum 2 theta range to explore (radians or degrees)
  - c* values = c1 c2 c3  
c1,c2,c3 = parameters to adjust the spacing of the reciprocal lattice nodes in the h, k, and l directions respectively
  - LP* value = switch to apply Lorentz-polarization factor  
0/1 = off/on
  - manual* = flag to use manual spacing of reciprocal lattice points  
based on the values of the c parameters
  - echo* = flag to provide extra output for debugging purposes

### 3.172.2 Examples

```
compute 1 all xrd 1.541838 Al O 2Theta 0.087 0.87 c 1 1 1 LP 1 echo

fix 2 all ave/histo/weight 1 1 1 10 100 250 c_2[1] c_2[2] mode vector file Deg2Theta.xrd
```

### 3.172.3 Description

Define a computation that calculates X-ray diffraction intensity as described in (Coleman) on a mesh of reciprocal lattice nodes defined by the entire simulation domain (or manually) using a simulated radiation of wavelength  $\lambda$ .

The X-ray diffraction intensity,  $I$ , at each reciprocal lattice point,  $\mathbf{k}$ , is computed from the structure factor,  $F$ , using the equations:

$$I = L_p(\theta) \frac{F^* F}{N}$$

$$F(\mathbf{k}) = \sum_{j=1}^N f_j(\theta) \exp(2\pi i \mathbf{k} \cdot \mathbf{r}_j)$$

$$L_p(\theta) = \frac{1 + \cos^2(2\theta)}{\cos(\theta) \sin^2(\theta)}$$

$$\frac{\sin(\theta)}{\lambda} = \frac{\|\mathbf{k}\|}{2}$$

Here,  $\mathbf{k}$  is the location of the reciprocal lattice node,  $\mathbf{r}_j$  is the position of each atom,  $f_j$  are atomic scattering factors,  $L_p$  is the Lorentz-polarization factor, and  $\theta$  is the scattering angle of diffraction. The Lorentz-polarization factor can be turned off using the optional *LP* keyword.

Diffraction intensities are calculated on a three-dimensional mesh of reciprocal lattice nodes. The mesh spacing is defined either (a) by the entire simulation domain or (b) manually using selected values as shown in the 2D diagram below.

For a mesh defined by the simulation domain, a rectilinear grid is constructed with spacing  $cA^{-1}$  along each reciprocal lattice axis, where  $A$  is a matrix containing the vectors corresponding to the edges of the simulation cell. If one or two directions has non-periodic boundary conditions, then the spacing in these directions is defined from the average of the (inversed) box lengths with periodic boundary conditions. Meshes defined by the simulation domain must contain at least one periodic boundary.

If the *manual* flag is included, the mesh of reciprocal lattice nodes will be defined using the  $c$  values for the spacing along each reciprocal lattice axis. Note that manual mapping of the reciprocal space mesh is good for comparing diffraction results from multiple simulations; however, it can reduce the likelihood that Bragg reflections will be satisfied unless

small spacing parameters ( $< 0.05 \text{ \AA}^{-1}$ ) are implemented. Meshes with manual spacing do not require a periodic boundary.

The limits of the reciprocal lattice mesh are determined by range of scattering angles explored. The *2Theta* parameter allows the user to reduce the scattering angle range to only the region of interest which reduces the cost of the computation.

The atomic scattering factor,  $f_j$ , accounts for the reduction in diffraction intensity due to Compton scattering. Compute xrd uses analytical approximations of the atomic scattering factors that vary for each atom type (type1 type2 ... typeN) and angle of diffraction. The analytic approximation is computed using the formula (*Colliex*):

$$f_j \left( \frac{\sin(\theta)}{\lambda} \right) = \sum_{i=1}^4 a_i \exp \left( -b_i \frac{\sin^2(\theta)}{\lambda^2} \right) + c$$

Coefficients parameterized by (*Peng*) are assigned for each atom type designating the chemical symbol and charge of each atom type. Valid chemical symbols for compute xrd are:

H	He1-	He	Li	Li1+
Be	Be2+	B	C	Cval
N	O	O1-	F	F1-

If the *echo* keyword is specified, compute xrd will provide extra reporting information to the screen.

### 3.172.4 Output info

This compute calculates a global array. The number of rows in the array is the number of reciprocal lattice nodes that are explored which by the mesh. The global array has two columns.

The first column contains the diffraction angle in the units (radians or degrees) provided with the *2Theta* values. The second column contains the computed diffraction intensities as described above.

The array can be accessed by any command that uses global values from a compute as input. See the [Howto output](#) doc page for an overview of LAMMPS output options.

All array values calculated by this compute are “intensive”.

### 3.172.5 Restrictions

This compute is part of the DIFFRACTION package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The compute\_xrd command does not work for triclinic cells.

### 3.172.6 Related commands

*fix ave/histo*, *compute saed*

### 3.172.7 Default

The option defaults are *2Theta* = 1 179 (degrees), *c* = 1 1 1, *LP* = 1, no manual flag, no echo flag.

## PAIR STYLES

### 4.1 pair\_style adp command

Accelerator Variants: *adp/kk*, *adp/omp*

#### 4.1.1 Syntax

```
pair_style adp
```

#### 4.1.2 Examples

```
pair_style adp
pair_coeff * * Ta.adp Ta
pair_coeff * * ../potentials/AlCu.adp Al Al Cu
```

#### 4.1.3 Description

Style *adp* computes pairwise interactions for metals and metal alloys using the angular dependent potential (ADP) of (*Mishin*), which is a generalization of the *embedded atom method (EAM) potential*. The LAMMPS implementation is discussed in (*Singh*). The total energy  $E_i$  of an atom  $I$  is given by

$$\begin{aligned}
 E_i &= F_\alpha \left( \sum_{j \neq i} \rho_\beta(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij}) + \frac{1}{2} \sum_s (\mu_i^s)^2 + \frac{1}{2} \sum_{s,t} (\lambda_i^{st})^2 - \frac{1}{6} v_i^2 \\
 \mu_i^s &= \sum_{j \neq i} u_{\alpha\beta}(r_{ij}) r_{ij}^s \\
 \lambda_i^{st} &= \sum_{j \neq i} w_{\alpha\beta}(r_{ij}) r_{ij}^s r_{ij}^t \\
 v_i &= \sum_s \lambda_i^{ss}
 \end{aligned}$$

where  $F$  is the embedding energy which is a function of the atomic electron density  $\rho$ ,  $\phi$  is a pair potential interaction,  $\alpha$  and  $\beta$  are the element types of atoms  $I$  and  $J$ , and  $s$  and  $t = 1, 2, 3$  and refer to the cartesian coordinates. The  $\mu$  and  $\lambda$  terms represent the dipole and quadruple distortions of the local atomic environment which extend the original EAM framework by introducing angular forces.

Note that unlike for other potentials, cutoffs for ADP potentials are not set in the `pair_style` or `pair_coeff` command; they are specified in the ADP potential files themselves. Likewise, the ADP potential files list atomic masses; thus you do not need to use the *mass* command to specify them.

**ADP potentials are available from:**

- The NIST WWW site at <https://www.ctcms.nist.gov/potentials>. Note that ADP potentials obtained from NIST must be converted into the extended DYNAMO *setfl* format discussed below.
- The OpenKIM Project at <https://openkim.org/browse/models/by-type> provides ADP potentials that can be used directly in LAMMPS with the *kim command* interface.

Only a single `pair_coeff` command is used with the *adp* style which specifies an extended DYNAMO *setfl* file, which contains information for  $M$  elements. These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the `pair_coeff` command, where  $N$  is the number of LAMMPS atom types:

- filename
- $N$  element names = mapping of extended *setfl* elements to atom types

See the *pair\_coeff* page for alternate ways to specify the path for the potential file.

As an example, the potentials/AlCu.adp file, included in the potentials directory of the LAMMPS distribution, is an extended *setfl* file which has tabulated ADP values for w elements and their alloy interactions: Cu and Al. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Al, and the fourth to be Cu, you would use the following `pair_coeff` command:

```
pair_coeff * * AlCu.adp Al Al Al Cu
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The first three Al arguments map LAMMPS atom types 1,2,3 to the Al element in the extended *setfl* file. The final Cu argument maps LAMMPS atom type 4 to the Al element in the extended *setfl* file. Note that there is no requirement that your simulation use all the elements specified by the extended *setfl* file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an *adp* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

*Adp* files in the *potentials* directory of the LAMMPS distribution have an “.adp” suffix. A DYNAMO *setfl* file extended for ADP is formatted as follows. Basically it is the standard *setfl* format with additional tabulated functions u and w added to the file after the tabulated pair potentials. See the *pair\_eam* command for further details on the *setfl* format.

- lines 1,2,3 = comments (ignored)
- line 4:  $N_{\text{elements}}$  Element1 Element2 ... ElementN
- line 5:  $N_p$ ,  $d_p$ ,  $N_r$ ,  $d_r$ , cutoff

Following the 5 header lines are  $N_{\text{elements}}$  sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function  $F(\rho)$  ( $N_p$  values)
- density function  $\rho(r)$  ( $N_r$  values)

Following the  $N_{\text{elements}}$  sections,  $N_r$  values for each pair potential  $\phi(r)$  array are listed for all  $i, j$  element pairs in the same format as other arrays. Since these interactions are symmetric ( $i, j = j, i$ ) only  $\phi$  arrays with  $i \geq j$  are listed, in the following order:

$$i, j = (1, 1), (2, 1), (2, 2), (3, 1), (3, 2), (3, 3), (4, 1), \dots, (N_{\text{elements}}, N_{\text{elements}}).$$

The tabulated values for each  $\phi$  function are listed as  $r * \phi$  (in units of eV-Angstroms), since they are for atom pairs, the same as for *other EAM files*.

After the  $\phi(r)$  arrays, each of the  $u(r)$  arrays are listed in the same order with the same assumptions of symmetry. Directly following the  $u(r)$ , the  $w(r)$  arrays are listed. Note that  $\phi(r)$  is the only array tabulated with a scaling by  $r$ .

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.1.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , where types  $I$  and  $J$  correspond to two different element types, no special mixing rules are needed, since the ADP potential files specify alloy interactions explicitly.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in tabulated potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.1.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

#### 4.1.6 Related commands

*pair\_coeff*, *pair\_eam*

#### 4.1.7 Default

none

## 4.2 pair\_style agni command

Accelerator Variants: *agni/omp*

### 4.2.1 Syntax

```
pair_style agni
```

### 4.2.2 Examples

```
pair_style      agni
pair_coeff      * * Al.agni Al
```

### 4.2.3 Description

Style *agni* style computes the many-body vectorial force components for an atom as

$$F_i^u = \sum_t^{N_t} \alpha_t \cdot \exp \left[ -\frac{(d_{i,t}^u)^2}{2l^2} \right]$$

$$d_{i,t}^u = ||V_i^u(\eta) - V_t^u(\eta)||$$

$$V_i^u(\eta) = \sum_{j \neq i} \frac{r_{ij}^u}{r_{ij}} \cdot e^{-\left(\frac{r_{ij}}{\eta}\right)^2} \cdot f_d(r_{ij})$$

$$f_d(r_{ij}) = \frac{1}{2} \left[ \cos \left( \frac{\pi r_{ij}}{R_c} \right) + 1 \right]$$

$u$  labels the individual components, i.e.  $x$ ,  $y$  or  $z$ , and  $V$  is the corresponding atomic fingerprint.  $d$  is the Euclidean distance between any two atomic fingerprints. A total of  $N_t$  reference atomic environments are considered to construct the force field file.  $\alpha_t$  and  $l$  are the weight coefficients and length scale parameter of the non-linear regression model.

The method implements the recently proposed machine learning access to atomic forces as discussed extensively in the following publications - (*Botu1*) and (*Botu2*). The premise of the method is to map the atomic environment numerically into a fingerprint, and use machine learning methods to create a mapping to the vectorial atomic forces.

Only a single `pair_coeff` command is used with the *agni* style which specifies an AGNI potential file containing the parameters of the force field for the needed elements. These are mapped to LAMMPS atom types by specifying  $N$  additional arguments after the filename in the `pair_coeff` command, where  $N$  is the number of LAMMPS atom types:

- filename
- $N$  element names = mapping of AGNI elements to atom types

See the [pair\\_coeff](#) page for alternate ways to specify the path for the force field file.

An AGNI force field is fully specified by the filename which contains the parameters of the force field, i.e., the reference training environments used to construct the machine learning force field. Example force field and input files are provided in the `examples/PACKAGES/agni` directory.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#).

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.2.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.2.5 Restrictions

Currently, only elemental systems are implemented. Also, the method only provides access to the forces and not energies or stresses. The lack of potential energy data makes this pair style incompatible with several of the *minimizer algorithms* like *cg* or *sd*. It should work with damped dynamics based minimizers like *fire* or *quickmin*. However, one can access the energy via thermodynamic integration of the forces as discussed in ([Botu3](#)). This pair style is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

The AGNI force field files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the AGNI potential with any LAMMPS units, but you would need to create your own AGNI potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

#### 4.2.6 Related commands

```

### 4.3.3 Description

New in version 15Jun2023.

The *aip/water/2dm* style computes the anisotropic interfacial potential (AIP) potential for interfaces of water with two-

dimensional (2D) materials as described in ([Feng1](#)) and ([Feng2](#)).

$$\begin{aligned}
 E &= \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \\
 V_{ij} &= \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta-1)} [\varepsilon + f(\rho_{ij}) + f(\rho_{ji})] - \frac{1}{1 + e^{-d[(r_{ij}/(s_R \cdot r_{eff})) - 1]}} \cdot \frac{C_6}{r_{ij}^6} \right\} \\
 \rho_{ij}^2 &= r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_i)^2 \\
 \rho_{ji}^2 &= r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_j)^2 \\
 f(\rho) &= C e^{-(\rho/\delta)^2} \\
 \text{Tap}(r_{ij}) &= 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1
 \end{aligned}$$

Where  $\text{Tap}(r_{ij})$  is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than  $r_c$  [pair\\_style ilp\\_graphene\\_hbn](#).

---

**Note:** This pair style uses the atomic normal vector definition from ([Feng1](#)), where the atomic normal vectors of the hydrogen atoms are assumed to lie along the corresponding oxygen-hydrogen bonds and the normal vector of the central oxygen atom is defined as their average.

---

The provided parameter file, `CBNOH.aip.water.2dm`, is intended for use with *metal units*, with energies in meV. Two additional parameters,  $S$ , and  $rcut$  are included in the parameter file.  $S$  is designed to facilitate scaling of energies;  $rcut$  is the cutoff for an internal, short distance neighbor list that is generated for speeding up the calculation of the normals for all atom pairs.

---

**Note:** The parameters presented in the provided parameter file, `CBNOH.aip.water.2dm`, are fitted with the taper function enabled by setting the cutoff equal to 16.0 Angstrom. Using a different cutoff or taper function setting should be carefully checked as they can lead to significant errors. These parameters provide a good description in both short- and long-range interaction regimes. This is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance).

---

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using [pair\\_coeff settings](#) with the pair style set to *none*.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the [compute pair](#) command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1.  $E_{vdW}$  = vdW (attractive) energy
2.  $E_{Rep}$  = Repulsive energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```

compute 0 all pair aip/water/2dm
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw

```

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#)

page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.3.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair\_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair\_style and pair\_coeff commands in an input script that reads a restart file.

#### 4.3.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the newton setting to be *on* for pair interactions.

The CBN0H.aip.water.2dm potential file provided with LAMMPS is parameterized for *metal* units. You can use this pair style with any LAMMPS units, but you would need to create your own potential file with parameters in the appropriate units, if your simulation does not use *metal* units.

#### 4.3.6 Related commands

*pair\_coeff*, *pair\_none*, *pair\_style hybrid/overlay*, *pair\_style drip*, *pair\_style ilp\_tmd*, *pair\_style saip\_metal*, *pair\_style ilp\_graphene\_hbn*, *pair\_style pair\_kolmogorov\_crespi\_z*, *pair\_style pair\_kolmogorov\_crespi\_full*, *pair\_style pair\_lebedeva\_z*, *pair\_style pair\_coul\_shield*.

#### 4.3.7 Default

tap\_flag = 1

## 4.4 pair\_style airebo command

Accelerator Variants: *airebo/intel*, *airebo/omp*

## 4.5 pair\_style airebo/morse command

Accelerator Variants: *airebo/morse/intel*, *airebo/morse/omp*

## 4.6 pair\_style rebo command

Accelerator Variants: *rebo/intel*, *rebo/omp*

### 4.6.1 Syntax

```
pair_style style cutoff LJ_flag TORSION_flag cutoff_min
```

- style = *airebo* or *airebo/morse* or *rebo*
- cutoff = LJ or Morse cutoff ( $\sigma$  scale factor) (AIREBO and AIREBO-M only)
- LJ\_flag = 0/1 to turn off/on the LJ or Morse term (AIREBO and AIREBO-M only, optional)
- TORSION\_flag = 0/1 to turn off/on the torsion term (AIREBO and AIREBO-M only, optional)
- cutoff\_min = Start of the transition region of cutoff ( $\sigma$  scale factor) (AIREBO and AIREBO-M only, optional)

### 4.6.2 Examples

```
pair_style airebo 3.0
pair_style airebo 2.5 1 0
pair_coeff * * ../potentials/CH.airebo H C

pair_style airebo/morse 3.0
pair_coeff * * ../potentials/CH.airebo-m H C

pair_style rebo
pair_coeff * * ../potentials/CH.rebo H C
```

### 4.6.3 Description

The *airebo* pair style computes the Adaptive Intermolecular Reactive Empirical Bond Order (AIREBO) Potential of (*Stuart*) for a system of carbon and/or hydrogen atoms. Note that this is the initial formulation of AIREBO from 2000, not the later formulation.

The *airebo/morse* pair style computes the AIREBO-M potential, which is equivalent to AIREBO, but replaces the LJ term with a Morse potential. The Morse potentials are parameterized by high-quality quantum chemistry (MP2) calculations and do not diverge as quickly as particle density increases. This allows AIREBO-M to retain accuracy to much higher pressures than AIREBO (up to 40 GPa for Polyethylene). Details for this potential and its parameterization are given in (*O’Conner*).

The *rebo* pair style computes the Reactive Empirical Bond Order (REBO) Potential of (Brenner). Note that this is the so-called second generation REBO from 2002, not the original REBO from 1990. As discussed below, second generation REBO is closely related to the initial AIREBO; it is just a subset of the potential energy terms with a few slightly different parameters

The AIREBO potential consists of three terms:

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} \left[ E_{ij}^{\text{REBO}} + E_{ij}^{\text{LJ}} + \sum_{k \neq i, j} \sum_{l \neq i, j, k} E_{kijl}^{\text{TORSION}} \right]$$

By default, all three terms are included. For the *airebo* style, if the first two optional flag arguments to the `pair_style` command are included, the LJ and torsional terms can be turned off. Note that both or neither of the flags must be included. If both of the LJ and torsional terms are turned off, it becomes the second-generation REBO potential, with a small caveat on the spline fitting procedure mentioned below. This can be specified directly as `pair_style rebo` with no additional arguments.

The detailed formulas for this potential are given in (Stuart); here we provide only a brief description.

The  $E^{\text{REBO}}$  term has the same functional form as the hydrocarbon REBO potential developed in (Brenner). The coefficients for  $E^{\text{REBO}}$  in AIREBO are essentially the same as Brenner's potential, but a few fitted spline values are slightly different. For most cases the  $E^{\text{REBO}}$  term in AIREBO will produce the same energies, forces and statistical averages as the original REBO potential from which it was derived. The  $E^{\text{REBO}}$  term in the AIREBO potential gives the model its reactive capabilities and only describes short-ranged C-C, C-H and H-H interactions ( $r < 2\text{\AA}$ ). These interactions have strong coordination-dependence through a bond order parameter, which adjusts the attraction between the I, J atoms based on the position of other nearby atoms and thus has 3- and 4-body dependence.

The  $E^{\text{LJ}}$  term adds longer-ranged interactions ( $2 < r < \text{cutoff}$ ) using a form similar to the standard *Lennard Jones potential*. The  $E^{\text{LJ}}$  term in AIREBO contains a series of switching functions so that the short-ranged LJ repulsion ( $1/r^{12}$ ) does not interfere with the energetics captured by the  $E^{\text{REBO}}$  term. The extent of the  $E^{\text{LJ}}$  interactions is determined by the *cutoff* argument to the `pair_style` command which is a scale factor. For each type pair (C-C, C-H, H-H) the cutoff is obtained by multiplying the scale factor by the sigma value defined in the potential file for that type pair. In the standard AIREBO potential,  $\sigma_{\text{CC}} = 3.4\text{\AA}$ , so with a scale factor of 3.0 (the argument in `pair_style`), the resulting  $E^{\text{LJ}}$  cutoff would be  $10.2\text{\AA}$ .

By default, the longer-ranged interaction is smoothly switched off between  $2.16$  and  $3.0 \sigma$ . By specifying *cutoff\_min* in addition to *cutoff*, the switching can be configured to take place between *cutoff\_min* and *cutoff*. *cutoff\_min* can only be specified if all optional arguments are given.

The  $E^{\text{TORSION}}$  term is an explicit 4-body potential that describes various dihedral angle preferences in hydrocarbon configurations.

Only a single `pair_coeff` command is used with the *airebo*, *airebo* or *rebo* style which specifies an AIREBO, REBO, or AIREBO-M potential file with parameters for C and H. Note that as of LAMMPS version 15 May 2019 the *rebo* style in LAMMPS uses its own potential file (CH.rebo). These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of AIREBO elements to atom types

See the *pair\_coeff* page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C, and the fourth to be H, you would use the following `pair_coeff` command:

```
pair_coeff * * CH.airebo C C C H
```

The first 2 arguments must be \* \* so as to span all LAMMPS atom types. The first three C arguments map LAMMPS atom types 1,2,3 to the C element in the AIREBO file. The final H argument maps LAMMPS atom type 4 to the H element in the AIREBO file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *airebo* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the AIREBO potentials are listed in the CH.airebo file to agree with the original ([Stuart](#)) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously.

Similarly the parameters/coefficients for the AIREBO-M potentials are listed in the CH.airebo-m file to agree with the ([O'Connor](#)) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously. The AIREBO-M Morse potentials were parameterized using a cutoff of 3.0 ( $\sigma$ ). Modifying this cutoff may impact simulation accuracy.

This pair style tallies a breakdown of the total AIREBO potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 3. The 3 values correspond to the following sub-categories:

1.  $E_{\text{REBO}}$  = REBO energy
2.  $E_{\text{LJ}}$  = Lennard-Jones energy
3.  $E_{\text{TORSION}}$  = Torsion energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute 0 all pair airebo
variable REBO      equal c_0[1]
variable LJ        equal c_0[2]
variable TORSION   equal c_0[3]
thermo_style custom step temp epair v_REBO v_LJ v_TORSION
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

#### 4.6.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support the *pair\_modify* mix, shift, table, and tail options.

These pair styles do not write their information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

### 4.6.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

These pair potentials require the *newton* setting to be “on” for pair interactions.

The CH.airebo and CH.airebo-m potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the pair styles with *any* LAMMPS units, but you would need to create your own AIREBO or AIREBO-M potential file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

The pair styles provided here **only** support potential files parameterized for the elements carbon and hydrogen (designated with “C” and “H” in the *pair\_coeff* command. Using potential files for other elements will trigger an error.

### 4.6.6 Related commands

*pair\_coeff*

### 4.6.7 Default

none

## 4.7 pair\_style amoeba command

Accelerator Variants: *amoeba/gpu*

## 4.8 pair\_style hippo command

Accelerator Variants: *hippo/gpu*

### 4.8.1 Syntax

**pair\_style** style

- style = *amoeba* or *hippo*

## 4.8.2 Examples

```
pair_style amoeba
pair_coeff * * protein.prm.amoeba protein.key.amoeba
```

```
pair_style hippo
pair_coeff * * water.prm.hippo water.key.hippo
```

## 4.8.3 Additional info

- [Howto amoeba](#)
- [examples/amoeba](#)
- [tools/amoeba](#)
- [potentials/\\*.amoeba](#)
- [potentials/\\*.hippo](#)

## 4.8.4 Description

The *amoeba* style computes the AMOEBA polarizable field formulated by Jay Ponder's group at the U Washington at St Louis ([Ren](#)), ([Shi](#)). The *hippo* style computes the HIPPO polarizable force field, an extension to AMOEBA, formulated by Josh Rackers and collaborators in the Ponder group ([Rackers](#)).

These force fields can be used when polarization effects are desired in simulations of water, organic molecules, and biomolecules including proteins, provided that parameterizations (Tinker PRM force field files) are available for the systems you are interested in. Files in the LAMMPS potentials directory with a “amoeba” or “hippo” suffix can be used. The Tinker distribution and website have additional force field files as well.

As discussed on the [Howto amoeba](#) doc page, the intermolecular (non-bonded) portion of the AMOEBA force field contains these terms:

$$U_{amoeba} = U_{multipole} + U_{polar} + U_{hal}$$

while the HIPPO force field contains these terms:

$$U_{hippo} = U_{multipole} + U_{polar} + U_{qxfer} + U_{repulsion} + U_{dispersion}$$

Conceptually, these terms compute the following interactions:

- $U_{hal}$  = buffered 14-7 van der Waals with offsets applied to hydrogen atoms
- $U_{repulsion}$  = Pauli repulsion due to rearrangement of electron density
- $U_{dispersion}$  = dispersion between correlated, instantaneous induced dipole moments
- $U_{multipole}$  = electrostatics between permanent point charges, dipoles, and quadrupoles
- $U_{polar}$  = electronic polarization between induced point dipoles
- $U_{qxfer}$  = charge transfer effects

Note that the AMOEBA versus HIPPO force fields typically compute the same term differently using their own formulas. The references on this doc page give full details for both force fields.

The formulas for the AMOEBA energy terms are:

$$U_{hal} = \epsilon_{ij} \left( \frac{1.07}{\rho_{ij} + 0.07} \right)^7 \left( \frac{1.12}{\rho_{ij}^7 + 0.12} - 2 \right)$$

$$U_{multipole} = \vec{M}_i T_{ij} \vec{M}_j, \quad \text{with} \quad \vec{M} = (q, \vec{\mu}_{perm}, \Theta)$$

$$U_{polar} = \frac{1}{2} \vec{\mu}_i^{ind} \vec{E}_i^{perm}$$

The formulas for the HIPPO energy terms are:

$$U_{multipole} = Z_i \frac{1}{r_{ij}} Z_j + Z_i T_{ij}^{damp} \vec{M}_j + Z_j T_{ji}^{damp} \vec{M}_i + \vec{M}_i T_{ij}^{damp} \vec{M}_j, \quad \text{with} \quad \vec{M} = (q, \vec{\mu}_{perm}, \Theta)$$

$$U_{polar} = \frac{1}{2} \vec{\mu}_i^{ind} \vec{E}_i^{perm}$$

$$U_{qxfer} = \epsilon_i e^{-\eta_j r_{ij}} + \epsilon_j e^{-\eta_i r_{ij}}$$

$$U_{repulsion} = \frac{K_i K_j}{r_{ij}^2} S^2 = \left( \int \phi_i \phi_j dv \right)^2 = \vec{M}_i T_{ij}^{repulsion} \vec{M}_j$$

$$U_{dispersion} = - \frac{C_6^i C_6^j}{r_{ij}^6} \left( f_{damp}^{dispersion} \right)_{ij}^2$$

**Note:** The AMOEBA and HIPPO force fields compute long-range charge, dipole, and quadrupole interactions as well as long-range dispersion effects. However, unlike other models with long-range interactions in LAMMPS, this does not require use of a KSpace style via the `kpace_style` command. That is because for AMOEBA and HIPPO the long-range computations are intertwined with the pairwise computations. So these pair style include both short- and long-range computations. This means the energy and virial computed by the pair style as well as the “Pair” timing reported by LAMMPS will include the long-range calculations.

The implementation of the AMOEBA and HIPPO force fields in LAMMPS was done using F90 code provided by the Ponder group from their [Tinker MD code](#).

The current implementation (July 2022) of AMOEBA in LAMMPS matches the version discussed in ([Ponder](#)), ([Ren](#)), and ([Shi](#)). Likewise the current implementation of HIPPO in LAMMPS matches the version discussed in ([Rackers](#)).

New in version 8Feb2023.

Accelerator support via the GPU package is available.

Only a single `pair_coeff` command is used with either the *amoeba* and *hippo* styles which specifies two Tinker files, a PRM and KEY file.

```
pair_coeff * * ../potentials/protein.prm.amoeba ../potentials/protein.key.amoeba
pair_coeff * * ../potentials/water.prm.hippo ../potentials/water.key.hippo
```

Examples of the PRM files are in the potentials directory with an \*.amoeba or \*.hippo suffix. The examples/amoeba directory has examples of both PRM and KEY files.

A Tinker PRM file is composed of sections, each of which has multiple lines. A Tinker KEY file is composed of lines, each of which has a keyword followed by zero or more parameters.

The list of PRM sections and KEY keywords which LAMMPS recognizes are listed on the [Howto amoeba](#) doc page. If not recognized, the section or keyword is skipped.

Note that if the KEY file is specified as NULL, then no file is required; default values for various AMOEBA/HIPPO settings are used. The [Howto amoeba](#) doc page also gives the default settings.

New in version 3Nov2022.

The *amoeba* and *hippo* pair styles support extraction of two per-atom quantities by the *fix pair* command. This allows the quantities to be output to files by the *dump* or otherwise processed by other LAMMPS commands.

The names of the two quantities are “uind” and “uinp” for the induced dipole moments for each atom. Neither quantity needs to be triggered by the *fix pair* command in order for these pair styles to calculate it.

---

## 4.8.5 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support the *pair\_modify* mix, shift, table, and tail options.

These pair styles do not write their information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

**Note:** Using the GPU accelerated pair styles ‘amoeba/gpu’ or ‘hippo/gpu’ when compiling the GPU package for OpenCL has a few known issues when running on integrated GPUs and the calculation may crash.

The GPU accelerated pair styles are also not (yet) compatible with single precision FFTs.

---

## 4.8.6 Restrictions

These pair styles are part of the AMOEBA package. They are only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

The AMOEBA and HIPPO potential (PRM) and KEY files provided with LAMMPS in the potentials and examples/amoeba directories are Tinker files parameterized for Tinker units. Their numeric parameters are converted by LAMMPS to its real units *units*. Thus you can only use these pair styles with real units.

These potentials do not yet calculate per-atom energy or virial contributions.

As explained on the *AMOEBA and HIPPO howto* page, use of these pair styles to run a simulation with the AMOEBA or HIPPO force fields requires several things.

---

The first is a data file generated by the tools/tinker/tinker2lmp.py conversion script which uses Tinker file force field file input to create a data file compatible with LAMMPS.

The second is use of these commands:

- *atom\_style amoeba*
- *fix property/atom*
- *special\_bonds one/five*

And third, depending on the model being simulated, these commands for intramolecular interactions may also be required:

- *bond\_style class2*
  - *angle\_style amoeba*
  - *dihedral\_style fourier*
  - *improper\_style amoeba*
  - *fix amoeba/pitortion*
  - *fix amoeba/bitortion*
- 

## 4.8.7 Related commands

*atom\_style amoeba*, *bond\_style class2*, *angle\_style amoeba*, *dihedral\_style fourier*, *improper\_style amoeba*, *fix amoeba/pitortion*, *fix amoeba/bitortion*, *special\_bonds one/five*, *fix property/atom*

## 4.9 pair\_style atm command

### 4.9.1 Syntax

```
pair_style atm cutoff cutoff_triple
```

- cutoff = cutoff for each pair in 3-body interaction (distance units)
- cutoff\_triple = additional cutoff applied to product of 3 pairwise distances (distance units)

## 4.9.2 Examples

```
pair_style atm 4.5 2.5
pair_coeff * * * 0.072

pair_style hybrid/overlay lj/cut 6.5 atm 4.5 2.5
pair_coeff * * lj/cut 1.0 1.0
pair_coeff 1 1 atm 1 0.064
pair_coeff 1 1 atm 2 0.080
pair_coeff 1 2 atm 2 0.100
pair_coeff 2 2 atm 2 0.125
```

## 4.9.3 Description

The *atm* style computes a 3-body *Axilrod-Teller-Muto* potential for the energy  $E$  of a system of atoms as

$$E = v \frac{1 + 3 \cos \gamma_1 \cos \gamma_2 \cos \gamma_3}{r_{12}^3 r_{23}^3 r_{31}^3}$$

where  $v$  is the three-body interaction strength. The distances between pairs of atoms  $r_{12}$ ,  $r_{23}$ ,  $r_{31}$  and the angles  $\gamma_1$ ,  $\gamma_2$ ,  $\gamma_3$  are as shown in this diagram:

Note that for the interaction between a triplet of atoms  $I, J, K$ , there is no “central” atom. The interaction is symmetric with respect to permutation of the three atoms. Thus the  $v$  value is the same for all those permutations of the atom types of  $I, J, K$  and needs to be specified only once, as discussed below.

The *atm* potential is typically used in combination with a two-body potential using the *pair\_style hybrid/overlay* command as in the example above.

The potential for a triplet of atom is calculated only if all 3 distances  $r_{12}$ ,  $r_{23}$ ,  $r_{31}$  between the three atoms satisfy  $r_{IJ} < \text{cutoff}$ . In addition, the product of the 3 distances  $r_{12}r_{23}r_{31} < \text{cutoff\_triple}^3$  is required, which excludes from calculation the triplets with small contribution to the interaction.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the restart files read by the *read\_restart* commands:

- $K$  = atom type of the third atom (1 to  $N_{\text{types}}$ )
- $v$  = prefactor (energy/distance<sup>9</sup> units)

$K$  can be specified in one of two ways. An explicit numeric value or type label can be used, as in the second example above. LAMMPS sets the coefficients for the other 5 symmetric interactions to the same values. E.g. if  $I = 1$ ,  $J = 2$ ,  $K = 3$ , then these 6 values are set to the specified  $v$ :  $v_{123}$ ,  $v_{132}$ ,  $v_{213}$ ,  $v_{231}$ ,  $v_{312}$ ,  $v_{321}$ . This enforces the symmetry discussed above.

A wildcard asterisk can be used for  $K$  to set the coefficients for multiple triplets of atom types. This takes the form “\*” or “\*n” or “n\*” or “m\*n”. If  $N$  equals the number of atom types, then an asterisk with no numeric values means all

types from 1 to  $N$ . A leading asterisk means all types from 1 to  $n$  (inclusive). A trailing asterisk means all types from  $n$  to  $N$  (inclusive). A middle asterisk means all types from  $m$  to  $n$  (inclusive). Note that only type triplets with  $J \leq K$  are considered; if asterisks imply type triplets where  $K < J$ , they are ignored.

Note that a `pair_coeff` command can override a previous setting for the same  $I, J, K$  triplet. For example, these commands set  $v$  for all  $I, J, K$  triplets, then overwrite  $nu$  for just the  $I, J, K = 2, 3, 4$  triplet:

```
pair_coeff * * * 0.25
pair_coeff 2 3 4 0.1
```

Note that for a simulation with a single atom type, only a single entry is required, e.g.

```
pair_coeff 1 1 1 0.25
```

For a simulation with two atom types, four `pair_coeff` commands will specify all possible  $nu$  values:

```
pair_coeff 1 1 1 nu1
pair_coeff 1 1 2 nu2
pair_coeff 1 2 2 nu3
pair_coeff 2 2 2 nu4
```

For a simulation with three atom types, ten `pair_coeff` commands will specify all possible  $nu$  values:

```
pair_coeff 1 1 1 nu1
pair_coeff 1 1 2 nu2
pair_coeff 1 1 3 nu3
pair_coeff 1 2 2 nu4
pair_coeff 1 2 3 nu5
pair_coeff 1 3 3 nu6
pair_coeff 2 2 2 nu7
pair_coeff 2 2 3 nu8
pair_coeff 2 3 3 nu9
pair_coeff 3 3 3 nu10
```

By default the  $v$  value for all triplets is set to 0.0. Thus it is not required to provide `pair_coeff` commands that enumerate triplet interactions for all  $K$  types. If some  $I, J, K$  combination is not specified, then there will be no 3-body ATM interactions for that combination and all its permutations. However, as with all pair styles, it is required to specify a `pair_coeff` command for all  $I, J$  combinations, else an error will result.

---

#### 4.9.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style do not support the `pair_modify` mix, shift, table, and tail options.

This pair style writes its information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file. However, if the *atm* potential is used in combination with other potentials using the `pair_style hybrid/overlay` command then `pair_coeff` commands need to be re-specified in the restart input script.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the *inner*, *middle*, and *outer* keywords.

---

## 4.9.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

## 4.9.6 Related commands

*pair\_coeff*

## 4.9.7 Default

## 4.10 pair\_style awpmd/cut command

### 4.10.1 Syntax

```
pair_style awpmd/cut Rc keyword value ...
```

- Rc = global cutoff, -1 means cutoff of half the shortest box length
- zero or more keyword/value pairs may be appended
- keyword = *hartree* or *dproduct* or *uhf* or *free* or *pb*c or *fix* or *harm* or *erm*scale or *flex\_press*

*hartree* value = none

*dproduct* value = none

*uhf* value = none

*free* value = none

*pb*c value = Plen

Plen = periodic width of electron = -1 or positive value (distance units)

*fix* value = Flen

Flen = fixed width of electron = -1 or positive value (distance units)

*harm* value = width

width = harmonic width constraint

*erm*scale value = factor

factor = scaling between electron mass and width variable mass

*flex\_press* value = none

## 4.10.2 Examples

```

pair_style awpmd/cut 40.0 uhf free
pair_coeff * *
pair_coeff 2 2 20.0
```

## 4.10.3 Description

This pair style contains an implementation of the Antisymmetrized Wave Packet Molecular Dynamics (AWPMD) method. Need citation here. Need basic formulas here. Could be links to other documents.

Rc is the cutoff.

The `pair_style` command allows for several optional keywords to be specified.

The *hartree*, *dproduct*, and *uhf* keywords specify the form of the initial trial wave function for the system. If the *hartree* keyword is used, then a Hartree multielectron trial wave function is used. If the *dproduct* keyword is used, then a trial function which is a product of two determinants for each spin type is used. If the *uhf* keyword is used, then an unrestricted Hartree-Fock trial wave function is used.

The *free*, *pbc*, and *fix* keywords specify a width constraint on the electron wave packets. If the *free* keyword is specified, then there is no constraint. If the *pbc* keyword is used and *Plen* is specified as -1, then the maximum width is half the shortest box length. If *Plen* is a positive value, then the value is the maximum width. If the *fix* keyword is used and *Flen* is specified as -1, then electrons have a constant width that is read from the data file. If *Flen* is a positive value, then the constant width for all electrons is set to *Flen*.

The *harm* keyword allow oscillations in the width of the electron wave packets. More details are needed.

The *ermyscale* keyword specifies a unitless scaling factor between the electron masses and the width variable mass. More details needed.

If the *flex\_press* keyword is used, then a contribution from the electrons is added to the total virial and pressure of the system.

This potential is designed to be used with *atom\_style wavepacket* definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- cutoff (distance units)

For *awpmd/cut*, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the *pair\_style* command is used.

#### 4.10.4 Mixing, shift, table, tail correction, restart, rRESPA info

The *pair\_modify* mix, shift, table, and tail options are not relevant for this pair style.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.10.5 Restrictions

none

#### 4.10.6 Related commands

*pair\_coeff*

#### 4.10.7 Default

These are the defaults for the *pair\_style* keywords: *hartree* for the initial wave function, *free* for the wave packet width.

### 4.11 pair\_style beck command

Accelerator Variants: *beck/gpu*, *beck/omp*

#### 4.11.1 Syntax

```
pair_style beck Rc
```

- Rc = cutoff for interactions (distance units)

#### 4.11.2 Examples

```
pair_style beck 8.0
pair_coeff * * 399.671876712 0.0000867636112694 0.675 4.390 0.0003746
pair_coeff 1 1 399.671876712 0.0000867636112694 0.675 4.390 0.0003746 6.0
```

### 4.11.3 Description

Style *beck* computes interactions based on the potential by (*Beck*), originally designed for simulation of Helium. It includes truncation at a cutoff distance  $r_c$ .

$$E(r) = A \exp [-\alpha r - \beta r^6] - \frac{B}{(r^2 + a^2)^3} \left( 1 + \frac{2.709 + 3a^2}{r^2 + a^2} \right) \quad r < r_c$$

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands.

- $A$  (energy units)
- $B$  (energy-distance<sup>6</sup> units)
- $a$  (distance units)
- $\alpha$  (1/distance units)
- $\beta$  (1/distance<sup>6</sup> units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff  $r_c$  is used.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

### 4.11.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , coefficients must be specified. No default mixing rules are used.

This pair style does not support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.11.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.11.6 Related commands

*pair\_coeff*

### 4.11.7 Default

## 4.12 pair\_style body/nparticle command

### 4.12.1 Syntax

```
pair_style body/nparticle cutoff
```

cutoff = global cutoff for interactions (distance units)

### 4.12.2 Examples

```
pair_style body/nparticle 3.0
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5
```

### 4.12.3 Description

Style *body/nparticle* is for use with body particles and calculates pairwise body/body interactions as well as interactions between body and point-particles. See the [Howto body](#) doc page for more details on using body particles.

This pair style is designed for use with the “nparticle” body style, which is specified as an argument to the “atom-style body” command. See the [Howto body](#) page for more details about the body styles LAMMPS supports. The “nparticle” style treats a body particle as a rigid body composed of N sub-particles.

The coordinates of a body particle are its center-of-mass (COM). If the COMs of a pair of body particles are within the cutoff (global or type-specific, as specified above), then all interactions between pairs of sub-particles in the two body particles are computed. E.g. if the first body particle has 3 sub-particles, and the second has 10, then 30 interactions are computed and summed to yield the total force and torque on each body particle.

---

**Note:** In the example just described, all 30 interactions are computed even if the distance between a particular pair of sub-particles is greater than the cutoff. Likewise, no interaction between two body particles is computed if the two

COMs are further apart than the cutoff, even if the distance between some pairs of their sub-particles is within the cutoff. Thus care should be used in defining the cutoff distances for body particles, depending on their shape and size.

---

Similar rules apply for a body particle interacting with a point particle. The distance between the two particles is calculated using the COM of the body particle and the position of the point particle. If the distance is within the cutoff and the body particle has  $N$  sub-particles, then  $N$  interactions with the point particle are computed and summed. If the distance is not within the cutoff, no interactions between the body and point particle are computed.

The interaction between two sub-particles, or a sub-particle and point particle, or between two point particles is computed as a Lennard-Jones interaction, using the standard formula

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < R_c$$

where  $R_c$  is the cutoff. As explained above, an interaction involving one or two body sub-particles may be computed even for  $r > R_c$ .

For style *body*, the following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

---

#### 4.12.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of this pair style can be mixed. The default mix value is *geometric*. See the *pair\_modify* command for details.

This pair style does not support the *pair\_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.12.5 Restrictions

This style is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Defining particles to be bodies so they participate in body/body or body/particle interactions requires the use of the *atom\_style body* command.

# 4.13 pair\_style body/rounded/polygon command

## 4.13.1 Syntax

```
pair_style body/rounded/polygon c_n c_t mu delta_ua cutoff
```

c\_n = normal damping coefficient  
 c\_t = tangential damping coefficient  
 mu = normal friction coefficient during gross sliding  
 delta\_ua = multiple contact scaling factor  
 cutoff = global separation cutoff for interactions (distance units), see below for [definition](#)

## 4.13.2 Examples

```
pair_style body/rounded/polygon 20.0 5.0 0.0 1.0 0.5
pair_coeff * * 100.0 1.0
pair_coeff 1 1 100.0 1.0
```

## 4.13.3 Description

Style *body/rounded/polygon* is for use with 2d models of body particles of style *rounded/polygon*. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex circular disks with a specified diameter. See the [Howto body](#) page for more details on using body rounded/polygon particles.

This pairwise interaction between rounded polygons is described in [Fraige](#), where a polygon does not have sharp corners, but is rounded at its vertices by circles centered on each vertex with a specified diameter. The edges of the polygon are defined between pairs of adjacent vertices. The circle diameter for each polygon is specified in the data file read by the [read data](#) command. This is a 2d discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polygon particle is displaced outward from each of its vertices and edges by half its circle diameter (as in the diagram below of a gray and yellow square particle). The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices and edges themselves.

This means that the specified cutoff in the *pair\_style* command is the cutoff distance,  $r_c$ , for the surface separation,  $\delta_n$  (see figure below). This is the distance at which two particles no longer interact. If  $r_c$  is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If  $r_c > 0.0$ , then the force between two particles will be attractive for surface separations from 0 to  $r_c$ , and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the  $r_c$  cutoff.

The forces between vertex-vertex, vertex-edge, and edge-edge overlaps are given by:

$$F_n = \begin{cases} k_n \delta_n - c_n v_n & \delta_n \leq 0 \\ -k_{na} \delta_n - c_n v_n & 0 < \delta_n \leq r_c \\ 0 & \delta_n > r_c \end{cases}$$

$$F_t = \begin{cases} \mu k_n \delta_n - c_t v_t & \delta_n \leq 0 \\ 0 & \delta_n > 0 \end{cases}$$

Note that  $F_n$  and  $F_t$  are functions of the surface separation  $\delta_n = d - (R_i + R_j)$ . In this model, when  $(R_i + R_j) < d <$

$(R_i + R_j) + r_c$ , that is,  $0 < \delta_n < r_c$ , the cohesive region of the two surfaces overlap and the two surfaces are attractive to each other.

In *Fraige*, the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e. static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e. we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file read by the *read\_data* command:

- $k_n$  (energy/distance<sup>2</sup> units)
- $k_{na}$  (energy/distance<sup>2</sup> units)

Effectively,  $k_n$  and  $k_{na}$  are the slopes of the red lines in the plot above for force versus surface separation, for  $\delta_n < 0$  and  $0 < \delta_n < r_c$  respectively.

#### 4.13.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.13.5 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

#### 4.13.6 Related commands

## 4.14 pair\_style body/rounded/polyhedron command

### 4.14.1 Syntax

```
pair_style body/rounded/polyhedron c_n c_t mu delta_ua cutoff
```

```
c_n = normal damping coefficient
c_t = tangential damping coefficient
mu = normal friction coefficient during gross sliding
delta_ua = multiple contact scaling factor
cutoff = global separation cutoff for interactions (distance units), see below for definition
```

### 4.14.2 Examples

```
pair_style body/rounded/polyhedron 20.0 5.0 0.0 1.0 0.5
pair_coeff * * 100.0 1.0
pair_coeff 1 1 100.0 1.0
```

### 4.14.3 Description

Style *body/rounded/polyhedron* is for use with 3d models of body particles of style *rounded/polyhedron*. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex spheres with a specified diameter. See the [Howto body](#) page for more details on using body rounded/polyhedron particles.

This pairwise interaction between the rounded polyhedra is described in [Wang](#), where a polyhedron does not have sharp corners and edges, but is rounded at its vertices and edges by spheres centered on each vertex with a specified diameter. The edges of the polyhedron are defined between pairs of adjacent vertices. Its faces are defined by a loop of edges. The sphere diameter for each polygon is specified in the data file read by the [read data](#) command. This is a discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polyhedron particle is displaced outward from each of its vertices, edges, and faces by half its sphere diameter. The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices, edges, and faces themselves.

This means that the specified cutoff in the `pair_style` command is the cutoff distance,  $r_c$ , for the surface separation,  $\delta_n$  (see figure below). This is the distance at which two particles no longer interact. If  $r_c$  is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If  $r_c > 0.0$ , then the force between two particles will be attractive for surface separations from 0 to  $r_c$ , and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the  $r_c$  cutoff.

The forces between vertex-vertex, vertex-edge, vertex-face, edge-edge, and edge-face overlaps are given by:

$$F_n = \begin{cases} k_n \delta_n - c_n v_n, & \delta_n \leq 0 \\ -k_{na} \delta_n - c_n v_n & 0 < \delta_n \leq r_c \\ 0 & \delta_n > r_c \end{cases}$$

$$F_t = \begin{cases} \mu k_n \delta_n - c_t v_t & \delta_n \leq 0 \\ 0 & \delta_n > 0 \end{cases}$$

In [Wang](#), the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e. static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e. we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file read by the *read\_data* command:

- $k_n$  (energy/distance<sup>2</sup> units)
- $k_{na}$  (energy/distance<sup>2</sup> units)

Effectively,  $k_n$  and  $k_{na}$  are the slopes of the red lines in the plot above for force versus surface separation, for  $\delta_n < 0$  and  $0 < \delta_n < r_c$  respectively.

#### 4.14.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*. Thus, you need to re-specify the *pair\_style* and *pair\_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

#### 4.14.5 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style requires the *newton* setting to be “on” for pair interactions.

### 4.15 pair\_style bop command

#### 4.15.1 Syntax

```
pair_style bop keyword ...
```

- zero or more keywords may be appended
- keyword = *save*

```
save = pre-compute and save some values
```

## 4.15.2 Examples

```
pair_style bop
pair_coeff * * ../potentials/CdTe_bop Cd Te
pair_style bop save
pair_coeff * * ../potentials/CdTe.bop.table Cd Te Te
comm_modify cutoff 14.70
```

## 4.15.3 Description

The *bop* pair style computes Bond-Order Potentials (BOP) based on quantum mechanical theory incorporating both  $\sigma$  and  $\pi$  bonding. By analytically deriving the BOP from quantum mechanical theory its transferability to different phases can approach that of quantum mechanical methods. This potential is similar to the original BOP developed by Pettifor ([Pettifor\\_1](#), [Pettifor\\_2](#), [Pettifor\\_3](#)) and later updated by Murdick, Zhou, and Ward ([Murdick](#), [Ward](#)). Currently, BOP potential files for these systems are provided with LAMMPS: AlCu, CCu, CdTe, CdTeSe, CdZnTe, CuH, GaAs. A system with only a subset of these elements, including a single element (e.g. C or Cu or Al or Ga or Zn or CdZn), can also be modeled by using the appropriate alloy file and assigning all atom types to the single element or subset of elements via the `pair_coeff` command, as discussed below.

The BOP potential consists of three terms:

$$E = \frac{1}{2} \sum_{i=1}^N \sum_{j=i_1}^{i_N} \phi_{ij}(r_{ij}) - \sum_{i=1}^N \sum_{j=i_1}^{i_N} \beta_{\sigma,ij}(r_{ij}) \cdot \Theta_{\sigma,ij} - \sum_{i=1}^N \sum_{j=i_1}^{i_N} \beta_{\pi,ij}(r_{ij}) \cdot \Theta_{\pi,ij} + U_{prom}$$

where  $\phi_{ij}(r_{ij})$  is a short-range two-body function representing the repulsion between a pair of ion cores,  $\beta_{\sigma,ij}(r_{ij})$  and  $\beta_{\pi,ij}(r_{ij})$  are respectively sigma and  $\pi$  bond integrals,  $\Theta_{\sigma,ij}$  and  $\Theta_{\pi,ij}$  are  $\sigma$  and  $\pi$  bond-orders, and  $U_{prom}$  is the promotion energy for sp-valent systems.

The detailed formulas for this potential are given in Ward ([Ward](#)); here we provide only a brief description.

The repulsive energy  $\phi_{ij}(r_{ij})$  and the bond integrals  $\beta_{\sigma,ij}(r_{ij})$  and  $\beta_{\pi,ij}(r_{ij})$  are functions of the interatomic distance  $r_{ij}$  between atom  $i$  and  $j$ . Each of these potentials has a smooth cutoff at a radius of  $r_{cut,ij}$ . These smooth cutoffs ensure stable behavior at situations with high sampling near the cutoff such as melts and surfaces.

The bond-orders can be viewed as environment-dependent local variables that are ij bond specific. The maximum value of the  $\sigma$  bond-order ( $\Theta_{\sigma}$  is 1, while that of the  $\pi$  bond-order ( $\Theta_{\pi}$ ) is 2, attributing to a maximum value of the total bond-order ( $\Theta_{\sigma} + \Theta_{\pi}$ ) of 3. The  $\sigma$  and  $\pi$  bond-orders reflect the ubiquitous single-, double-, and triple- bond behavior of chemistry. Their analytical expressions can be derived from tight-binding theory by recursively expanding an inter-site Green's function as a continued fraction. To accurately represent the bonding with a computationally efficient potential formulation suitable for MD simulations, the derived BOP only takes (and retains) the first two levels of the recursive representations for both the  $\sigma$  and the  $\pi$  bond-orders. Bond-order terms can be understood in terms of molecular orbital hopping paths based upon the Cyrot-Lackmann theorem ([Pettifor\\_1](#)). The  $\sigma$  bond-order with a half-full valence shell is used to interpolate the bond-order expression that incorporated explicit valance band filling. This  $\pi$  bond-order expression also contains a three-member ring term that allows implementation of an asymmetric density of states, which helps to either stabilize or destabilize close-packed structures. The  $\pi$  bond-order includes hopping paths of length 4. This enables the incorporation of dihedral angles effects.

---

**Note:** Note that unlike for other potentials, cutoffs for BOP potentials are not set in the `pair_style` or `pair_coeff` command; they are specified in the BOP potential files themselves. Likewise, the BOP potential files list atomic masses; thus you do not need to use the `mass` command to specify them. Note that for BOP potentials with hydrogen, you will likely want to set the mass of H atoms to be 10x or 20x larger to avoid having to use a tiny timestep. You can do this by using the `mass` command after using the `pair_coeff` command to read the BOP potential file.

---

One option can be specified as a keyword with the `pair_style` command.

The *save* keyword gives you the option to calculate in advance and store a set of distances, angles, and derivatives of angles. The default is to not do this, but to calculate them on-the-fly each time they are needed. The former may be faster, but takes more memory. The latter requires less memory, but may be slower. It is best to test this option to optimize the speed of BOP for your particular system configuration.

---

Only a single `pair_coeff` command is used with the *bop* style which specifies a BOP potential file, with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of BOP elements to atom types

As an example, imagine the `CdTe.bop` file has BOP values for Cd and Te. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Cd, and the fourth to be Te, you would use the following `pair_coeff` command:

```
pair_coeff * * CdTe Cd Cd Cd Te
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The first three Cd arguments map LAMMPS atom types 1,2,3 to the Cd element in the BOP file. The final Te argument maps LAMMPS atom type 4 to the Te element in the BOP file.

BOP files in the *potentials* directory of the LAMMPS distribution have a “.bop” suffix. The potentials are in tabulated form containing pre-tabulated pair functions for  $\phi_{ij}(r_{ij})$ ,  $\beta_{(\sigma,ij)}(r_{ij})$ , and  $\beta_{\pi,ij}(r_{ij})$ .

The parameters/coefficients format for the different kinds of BOP files are given below with variables matching the formulation of Ward (*Ward*) and Zhou (*Zhou*). Each header line containing a “:” is preceded by a blank line.

---

#### No angular table file format:

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of  $g$  is given below with variables matching the formulation of Ward (*Ward*). This format also assumes the angular functions have the formulation of (*Ward*).

- Line 1: # elements N

The first line is followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: `nr, nBOt` (`nr` is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; `nBOt` is the number of divisions for the tabulated values of  $\text{THETA}_{(S,ij)}$ )
- Line 2: `delta_1-delta_7` (if all are not used in the particular
- formulation, set unused values to 0.0)

Following this N lines for `e_1-e_N` containing `p_pi`.

- Line 3: `p_pi` (for `e_1`)
- Line 4: `p_pi` (for `e_2` and continues to `e_N`)

The next section contains several pair constants for the number of interaction types `e_i-e_j`, with  $i=1 \rightarrow N, j=i \rightarrow N$

- Line 1: `r_cut` (for `e_1-e_1` interactions)
- Line 2: `c_sigma, a_sigma, c_pi, a_pi`
- Line 3: `delta_sigma, delta_pi`

- Line 4: `f_sigma`, `k_sigma`, `delta_3` (This `delta_3` is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type `e_j-e_i-e_k` with `i=0->N`, `j=0->N`, `k=j->N`

- Line 1: `g_(sigma0)`, `g_(sigma1)`, `g_(sigma2)` (These are coefficients for `g_(sigma,jik)(THETA_ijk)` for `e_1-e_1-e_1` interaction. *Ward* contains the full expressions for the constants as functions of `b_(sigma,ijk)`, `p_(sigma,ijk)`, `u_(sigma,ijk)`)
- Line 2: `g_(sigma0)`, `g_(sigma1)`, `g_(sigma2)` (for `e_1-e_1-e_2`)

The next section contains a block for each interaction type for the `phi_ij(r_ij)`. Each block has `nr` entries with 5 entries per line.

- Line 1: `phi(r1)`, `phi(r2)`, `phi(r3)`, `phi(r4)`, `phi(r5)` (for the `e_1-e_1` interaction type)
- Line 2: `phi(r6)`, `phi(r7)`, `phi(r8)`, `phi(r9)`, `phi(r10)` (this continues until `nr`)
- ...
- Line `nr/5_1`: `phi(r1)`, `phi(r2)`, `phi(r3)`, `phi(r4)`, `phi(r5)`, (for the `e_1-e_1` interaction type)

The next section contains a block for each interaction type for the `beta_(sigma,ij)(r_ij)`. Each block has `nr` entries with 5 entries per line.

- Line 1: `beta_sigma(r1)`, `beta_sigma(r2)`, `beta_sigma(r3)`, `beta_sigma(r4)`, `beta_sigma(r5)` (for the `e_1-e_1` interaction type)
- Line 2: `beta_sigma(r6)`, `beta_sigma(r7)`, `beta_sigma(r8)`, `beta_sigma(r9)`, `beta_sigma(r10)` (this continues until `nr`)
- ...
- Line `nr/5+1`: `beta_sigma(r1)`, `beta_sigma(r2)`, `beta_sigma(r3)`, `beta_sigma(r4)`, `beta_sigma(r5)` (for the `e_1-e_2` interaction type)

The next section contains a block for each interaction type for `beta_(pi,ij)(r_ij)`. Each block has `nr` entries with 5 entries per line.

- Line 1: `beta_pi(r1)`, `beta_pi(r2)`, `beta_pi(r3)`, `beta_pi(r4)`, `beta_pi(r5)` (for the `e_1-e_1` interaction type)
- Line 2: `beta_pi(r6)`, `beta_pi(r7)`, `beta_pi(r8)`, `beta_pi(r9)`, `beta_pi(r10)` (this continues until `nr`)
- ...
- Line `nr/5+1`: `beta_pi(r1)`, `beta_pi(r2)`, `beta_pi(r3)`, `beta_pi(r4)`, `beta_pi(r5)` (for the `e_1-e_2` interaction type)

The next section contains a block for each interaction type for the `THETA_(S,ij)((THETA_(sigma,ij))^(1/2), f_(sigma,ij))`. Each block has `nBOt` entries with 5 entries per line.

- Line 1: `THETA_(S,ij)(r1)`, `THETA_(S,ij)(r2)`, `THETA_(S,ij)(r3)`, `THETA_(S,ij)(r4)`, `THETA_(S,ij)(r5)` (for the `e_1-e_2` interaction type)
- Line 2: `THETA_(S,ij)(r6)`, `THETA_(S,ij)(r7)`, `THETA_(S,ij)(r8)`, `THETA_(S,ij)(r9)`, `THETA_(S,ij)(r10)` (this continues until `nBOt`)
- ...
- Line `nBOt/5+1`: `THETA_(S,ij)(r1)`, `THETA_(S,ij)(r2)`, `THETA_(S,ij)(r3)`, `THETA_(S,ij)(r4)`, `THETA_(S,ij)(r5)` (for the `e_1-e_2` interaction type)

The next section contains a block of `N` lines for `e_1-e_N`

- Line 1: `delta^mu` (for `e_1`)
- Line 2: `delta^mu` (for `e_2` and repeats to `e_N`)

The last section contains more constants for  $e_i$ - $e_j$  interactions with  $i=0 \rightarrow N$ ,  $j=i \rightarrow N$

- Line 1:  $(A_{ij})^{(\mu * \nu)}$  (for  $e_1$ - $e_1$ )
  - Line 2:  $(A_{ij})^{(\mu * \nu)}$  (for  $e_1$ - $e_2$  and repeats as above)
- 

#### Angular spline table file format:

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of  $g$  is given below with variables matching the formulation of Ward (*Ward*). This format also assumes the angular functions have the formulation of (*Zhou*).

- Line 1: # elements  $N$

The first line is followed by  $N$  lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1:  $nr$ ,  $ntheta$ ,  $nBOt$  ( $nr$  is the number of divisions the radius is broken into for function tables and MUST be a factor of 5;  $ntheta$  is the power of the spline used to fit the angular function;  $nBOt$  is the number of divisions for the tabulated values of  $THETA_{(S,ij)}$ )
- Line 2:  $\delta_1$ - $\delta_7$  (if all are not used in the particular formulation, set unused values to 0.0)

Following this  $N$  lines for  $e_1$ - $e_N$  containing  $p_{pi}$ .

- Line 3:  $p_{pi}$  (for  $e_1$ )
- Line 4:  $p_{pi}$  (for  $e_2$  and continues to  $e_N$ )

The next section contains several pair constants for the number of interaction types  $e_i$ - $e_j$ , with  $i=1 \rightarrow N$ ,  $j=i \rightarrow N$

- Line 1:  $r_{cut}$  (for  $e_1$ - $e_1$  interactions)
- Line 2:  $c_{sigma}$ ,  $a_{sigma}$ ,  $c_{pi}$ ,  $a_{pi}$
- Line 3:  $\delta_{sigma}$ ,  $\delta_{pi}$
- Line 4:  $f_{sigma}$ ,  $k_{sigma}$ ,  $\delta_3$  (This  $\delta_3$  is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type  $e_j$ - $e_i$ - $e_k$  with  $i=0 \rightarrow N$ ,  $j=0 \rightarrow N$ ,  $k=j \rightarrow N$

- Line 1:  $g_0$ ,  $g_1$ ,  $g_2 \dots$  (These are coefficients for the angular spline of the  $g_{(sigma,jik)}(THETA_{ijk})$  for  $e_1$ - $e_1$ - $e_1$  interaction. The function can contain up to 10 term thus 10 constants. The first line can contain up to five constants. If the spline has more than five terms the second line will contain the remaining constants The following lines will then contain the constants for the remaining  $g_0$ ,  $g_1$ ,  $g_2 \dots$  (for  $e_1$ - $e_1$ - $e_2$ ) and the other three body interactions

The rest of the table has the same structure as the previous section (see above).

---

#### Angular no-spline table file format:

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of  $g$  is given below with variables matching the formulation of Ward (*Ward*). This format also assumes the angular functions have the formulation of (*Zhou*).

- Line 1: # elements  $N$

The first two lines are followed by  $N$  lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

---

- Line 1: nr, ntheta, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; ntheta is the number of divisions for the tabulated values of the g angular function; nBOt is the number of divisions for the tabulated values of THETA\_(S,ij))
- Line 2: delta\_1-delta\_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e\_1-e\_N containing p\_pi.

- Line 3: p\_pi (for e\_1)
- Line 4: p\_pi (for e\_2 and continues to e\_N)

The next section contains several pair constants for the number of interaction types e\_i-e\_j, with i=1->N, j=i->N

- Line 1: r\_cut (for e\_1-e\_1 interactions)
- Line 2: c\_sigma, a\_sigma, c\_pi, a\_pi
- Line 3: delta\_sigma, delta\_pi
- Line 4: f\_sigma, k\_sigma, delta\_3 (This delta\_3 is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e\_j-e\_i-e\_k with i=0->N, j=0->N, k=j->N

- Line 1: g(theta1), g(theta2), g(theta3), g(theta4), g(theta5) (for the e\_1-e\_1-e\_1 interaction type)
- Line 2: g(theta6), g(theta7), g(theta8), g(theta9), g(theta10) (this continues until ntheta)
- ...
- Line ntheta/5+1: g(theta1), g(theta2), g(theta3), g(theta4), g(theta5), (for the e\_1-e\_1-e\_2 interaction type)

The rest of the table has the same structure as the previous section (see above).

---

#### 4.15.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair\_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the pair\_style and pair\_coeff commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.15.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

These pair potentials require the *newton* setting to be “on” for pair interactions.

Pair style bop is not compatible with being used as a sub-style with doc:hybrid pair styles <pair\_hybrid>. Pair style bop is also not compatible with *multi-cutoff neighbor lists* or *multi-cutoff communication*.

The .bop.table potential files provided with LAMMPS (see the potentials directory) are parameterized for metal *units*. You can use the BOP potential with any LAMMPS units, but you would need to create your own BOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

### 4.15.6 Related commands

*pair\_coeff*

### 4.15.7 Default

non-tabulated potential file, a\_0 is non-zero.

### 4.20.3 Description

The *born* style computes the Born-Mayer-Huggins or Tosi/Fumi potential described in (*Fumi and Tosi*), given by

$$E = A \exp\left(\frac{\sigma - r}{\rho}\right) - \frac{C}{r^6} + \frac{D}{r^8} \quad r < r_c$$

where  $\sigma$  is an interaction-dependent length parameter,  $\rho$  is an ionic-pair dependent length parameter, and  $r_c$  is the cutoff.

The styles with *coul/long* or *coul/msm* add a Coulombic term as described for the *lj/cut* pair styles. An additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kpspace\_style* command and its *ewald* or *pppm* or *msm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

If one cutoff is specified for the *born/coul/long* and *born/coul/msm* style, it is used for both the A,C,D and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C,D terms, and the second is the cutoff for the Coulombic term.

The *born/coul/wolf* style adds a Coulombic term as described for the Wolf potential in the *coul/wolf* pair style.

The *born/coul/dsf* style computes the Coulomb contribution with the damped shifted force model as in the *coul/dsf* style.

Note that these potentials are related to the *Buckingham potential*.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- A (energy units)
- $\rho$  (distance units)
- $\sigma$  (distance units)
- C (energy units \* distance units<sup>6</sup>)
- D (energy units \* distance units<sup>8</sup>)
- cutoff (distance units)

The second coefficient, rho, must be greater than zero.

The last coefficient is optional. If not specified, the global A,C,D cutoff specified in the *pair\_style* command is used.

For *born/coul/long*, *born/coul/wolf* and *born/coul/dsf* no Coulombic cutoff can be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the *pair\_style* command.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.20.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These styles support the *pair\_modify* shift option for the energy of the  $\exp()$ ,  $1/r^6$ , and  $1/r^8$  portion of the pair interaction.

The *born/coul/long* pair style supports the *pair\_modify* table option to tabulate the short-range portion of the long-range Coulombic interaction.

These styles support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These styles write their information to binary *restart* files, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

#### 4.20.5 Restrictions

The *born/coul/long* style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The *born/coul/dsf* and *born/coul/wolf* pair styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.20.6 Related commands

### 4.21 pair\_style born/gauss command

#### 4.21.1 Syntax

```
pair_style born/gauss cutoff
```

- *born/gauss* = name of the pair style
- *cutoff* = global cutoff (distance units)

### 4.21.2 Examples

```
pair_style born/gauss 10.0
pair_coeff 1 1 8.2464e13 12.48 0.042644277 0.44 3.56
```

### 4.21.3 Description

New in version 28Mar2023.

Pair style *born/gauss* computes pairwise interactions from a combination of a Born-Mayer repulsive term and a Gaussian attractive term according to (*Bomont*):

$$E = A_0 \exp(-\alpha r) - A_1 \exp[-\beta (r - r_0)^2] \quad r < r_c$$

$r_c$  is the cutoff.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- $A_0$  (energy units)
- $\alpha$  (1/distance units)
- $A_1$  (energy units)
- $\beta$  (1/(distance units)<sup>2</sup>)
- $r_0$  (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

---

### 4.21.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style supports the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table options are not relevant for this pair style.

This pair style does not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

### 4.21.5 Restrictions

This pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the [Build package](#) page for more info.

### 4.21.6 Related commands

*pair\_coeff*, *pair\_style born*

### 4.21.7 Default

## 4.22 pair\_style bpm/spring command

### 4.22.1 Syntax

```
pair_style bpm/spring
```

### 4.22.2 Examples

```
pair_style bpm/spring
pair_coeff * * 1.0 1.0 1.0
pair_coeff 1 1 1.0 1.0 1.0
```

### 4.22.3 Description

New in version 4May2022.

Style *bpm/spring* computes pairwise forces with the formula

$$F = k(r - r_c)$$

where  $k$  is a stiffness and  $r_c$  is the cutoff length. An additional damping force is also applied to interacting particles. The force is proportional to the difference in the normal velocity of particles

$$F_D = -\gamma w(\hat{r} \bullet \vec{v})$$

where  $\gamma$  is the damping strength,  $\hat{r}$  is the radial normal vector,  $\vec{v}$  is the velocity difference between the two particles, and  $w$  is a smoothing factor. This smoothing factor is constructed such that damping forces go to zero as particles come out of contact to avoid discontinuities. It is given by

$$w = 1.0 - \left(\frac{r}{r_c}\right)^8.$$

This pair style is designed for use in a spring-based bonded particle model. It mirrors the construction of the *bpm/spring* bond style.

This pair interaction is always applied to pairs of non-bonded particles that are within the interaction distance. For pairs of bonded particles that are within the interaction distance, there is the option to either include this pair interaction and overlay the pair force over the bond force or to exclude this pair interaction such that the two particles only interact via the bond force. See discussion of the *overlay/pair* option for BPM bond styles and the *special\_bonds* command in the *how to* page on BPMs for more details.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $k$  (force/distance units)
  - $r_c$  (distance units)
  - $\gamma$  (force/velocity units)
- 

#### 4.22.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the  $A$  coefficient and cutoff distance for this pair style can be mixed.  $A$  is always mixed via a *geometric* rule. The cutoff is mixed according to the *pair\_modify* mix value. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

This pair style does not support the *pair\_modify* shift option, since the pair interaction goes to 0.0 at the cutoff.

The *pair\_modify* table and tail options are not relevant for this pair style.

This pair style writes its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run\_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

---

#### 4.22.5 Restrictions

This pair style is part of the BPM package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 4.22.6 Related commands

## 4.23 pair\_style brownian command

Accelerator Variants: *brownian/omp*

## 4.24 pair\_style brownian/poly command

Accelerator Variants: *brownian/poly/omp*

### 4.24.1 Syntax

```
pair_style style mu flaglog flagfld cutinner cutoff t_target seed flagHI flagVF
```

- *style* = *brownian* or *brownian/poly*
- *mu* = dynamic viscosity (dynamic viscosity units)
- *flaglog* = 0/1 log terms in the lubrication approximation on/off
- *flagfld* = 0/1 to include/exclude Fast Lubrication Dynamics effects
- *cutinner* = inner cutoff distance (distance units)
- *cutoff* = outer cutoff for interactions (distance units)
- *t\_target* = target temp of the system (temperature units)
- *seed* = seed for the random number generator (positive integer)
- *flagHI* (optional) = 0/1 to include/exclude 1/r hydrodynamic interactions
- *flagVF* (optional) = 0/1 to include/exclude volume fraction corrections in the long-range isotropic terms

### 4.24.2 Examples

```
pair_style brownian 1.5 1 1 2.01 2.5 2.0 5878567 # (assuming radius = 1)
pair_coeff 1 1 2.05 2.8
pair_coeff * *
```

### 4.24.3 Description

Styles *brownian* and *brownian/poly* compute Brownian forces and torques on finite-size spherical particles. The former requires monodisperse spherical particles; the latter allows for polydisperse spherical particles.

These pair styles are designed to be used with either the *pair\_style lubricate* or *pair\_style lubricateU* commands to provide thermostating when dissipative lubrication forces are acting. Thus the parameters *mu*, *flaglog*, *flagfld*, *cutinner*, and *cutoff* should be specified consistent with the settings in the lubrication pair styles. For details, refer to either of the lubrication pair styles.

The *t\_target* setting is used to specify the target temperature of the system. The random number *seed* is used to generate random numbers for the thermostating procedure.

The *flagHI* and *flagVF* settings are optional. Neither should be used, or both must be defined.

---

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- cutinner (distance units)
- cutoff (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the *pair\_style* command are used. Otherwise both must be specified.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.24.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs *I,J* and *I != J*, the two cutoff distances for these pair styles can be mixed. The default mix value is *geometric*. See the “*pair\_modify*” command for details.

These pair styles do not support the *pair\_modify* shift option for the energy of the pair interaction.

The *pair\_modify* table option is not relevant for these pair styles.

These pair styles do not support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

---

### 4.24.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

Only spherical monodisperse particles are allowed for pair\_style brownian.

Only spherical particles are allowed for pair\_style brownian/poly.

These pair styles are only compatible with the following wall fixes: doc:fix wall/lj93, fix wall/lj126, fix wall/lj1043, fix wall/colloid, fix wall/harmonic, fix wall/lepton, fix wall/morse, fix wall/table <fix\_wall>.

### 4.24.6 Related commands

*pair\_coeff*, *pair\_style lubricate*, *pair\_style lubricateU*

### 4.24.7 Default

The default settings for the optional args are flagHI = 1 and flagVF = 1.

## 4.25 pair\_style buck command

Accelerator Variants: *buck/gpu*, *buck/intel*, *buck/kk*, *buck/omp*

pair_coeff 1 1 100.0 1.5 200.0 9.0

```

## 4.28.3 Description

The *buck* style computes a Buckingham potential ( $\exp/6$  instead of Lennard-Jones  $12/6$ ) given by

$$E = Ae^{-r/\rho} - \frac{C}{r^6} \quad r < r_c$$

where  $\rho$  is an ionic-pair dependent length parameter, and  $r_c$  is the cutoff on both terms.

The styles with *coul/cut* or *coul/long* or *coul/msm* add a Coulombic term as described for the *lj/cut* pair styles. For *buck/coul/long* and *buc/coul/msm*, an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kpspace\_style* command and its *ewald* or *pppm* or *msm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

If one cutoff is specified for the *born/coul/cut* and *born/coul/long* and *born/coul/msm* styles, it is used for both the A,C and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C terms, and the second is the cutoff for the Coulombic term.

Note that these potentials are related to the *Born-Mayer-Huggins potential*.

---

**Note:** For all these pair styles, the terms with A and C are always cutoff. The additional Coulombic term can be cutoff or long-range (no cutoff) depending on whether the style name includes coul/cut or coul/long or coul/msm. If you wish the  $C/r^6$  term to be long-range (no cutoff), then see the *pair\_style buck/long/coul/long* command.

---

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- A (energy units)
- $\rho$  (distance units)
- C (energy-distance<sup>6</sup> units)
- cutoff (distance units)
- cutoff2 (distance units)

The second coefficient,  $\rho$ , must be greater than zero. The coefficients A,  $\rho$ , and C can be written as analytical expressions of  $\epsilon$  and  $\sigma$ , in analogy to the Lennard-Jones potential (*Khrapak*).

The latter 2 coefficients are optional. If not specified, the global A,C and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both A,C and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the A,C and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style *buck*, since it has no Coulombic terms. For *buck/coul/long* only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the *pair\_style* command.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

---

#### 4.28.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These styles support the *pair\_modify* shift option for the energy of the exp() and  $1/r^6$  portion of the pair interaction.

The *buck/coul/long* pair style supports the *pair\_modify* table option to tabulate the short-range portion of the long-range Coulombic interaction.

These styles support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure for the A,C terms in the pair interaction.

These styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the *pair* keyword of the *run\_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

### 4.28.5 Restrictions

The *buck/coul/long* style is part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 4.28.6 Related commands

pair_coeff 1 1 1030. 3.061 457.179 4.521 0.608
```

### 4.30.3 Description

The *buck6d/coul/gauss* styles evaluate vdW and Coulomb interactions following the MOF-FF force field after (Schmid). The vdW term of the *buck6d* styles computes a dispersion damped Buckingham potential:

$$E = Ae^{-\kappa r} - \frac{C}{r^6} \cdot \frac{1}{1 + Dr^{14}} \quad r < r_c$$

where A and C are a force constant,  $\kappa$  is an ionic-pair dependent reciprocal length parameter, D is a dispersion correction parameter, and the cutoff  $r_c$  truncates the interaction distance. The first term in the potential corresponds to the Buckingham repulsion term and the second term to the dispersion attraction with a damping correction analog to the Grimme correction used in DFT. The latter corrects for artifacts occurring at short distances which become an issue for soft vdW potentials.

The *buck6d* styles include a smoothing function which is invoked according to the global smoothing parameter within the specified cutoff. Hereby a parameter of i.e. 0.9 invokes the smoothing within 90% of the cutoff. No smoothing is applied at a value of 1.0. For the *gauss/dsf* style this smoothing is only applicable for the dispersion damped Buckingham potential. For the *gauss/long* styles the smoothing function can also be invoked for the real space coulomb interactions which enforce continuous energies and forces at the cutoff.

Both styles *buck6d/coul/gauss/dsf* and *buck6d/coul/gauss/long* evaluate a Coulomb potential using spherical Gaussian type charge distributions which effectively dampen electrostatic interactions for high charges at close distances. The electrostatic potential is thus evaluated as:

$$E = \frac{C_{q_i q_j}}{\epsilon r_{ij}} \operatorname{erf}(\alpha_{ij} r_{ij}) \quad r < r_c$$

where C is an energy-conversion constant,  $q_i$  and  $q_j$  are the charges on the two atoms, epsilon is the dielectric constant which can be set by the *dielectric* command,  $\alpha$  is the ion pair dependent damping parameter and erf() is the error-function. The cutoff  $r_c$  truncates the interaction distance.

The style *buck6d/coul/gauss/dsf* computes the Coulomb interaction via the damped shifted force model described in (Fennell) approximating an Ewald sum similar to the *pair coul/dsf* styles. In *buck6d/coul/gauss/long* an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kpace\_style* command and its *ewald* or *pppm* options. The Coulombic cutoff in this case separates the real and reciprocal space evaluation of the Ewald sum.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- A (energy units)
- $\rho$  (distance<sup>-1</sup> units)
- C (energy-distance<sup>6</sup> units)
- D (distance<sup>14</sup> units)
- $\alpha$  (distance<sup>-1</sup> units)
- cutoff (distance units)

The second coefficient,  $\rho$ , must be greater than zero. The latter coefficient is optional. If not specified, the global vdW cutoff is used.

#### 4.30.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These styles do not support the *pair\_modify* shift option for the energy. Instead the smoothing function should be applied by setting the global smoothing parameter to a value  $< 1.0$ .

These styles write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

#### 4.30.5 Restrictions

These styles are part of the MOFFF package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.31 pair\_style buck/long/coul/long command

Accelerator Variants: *buck/long/coul/long/omp*

#### 4.31.1 Syntax

`pair_style` buck/long/coul/long flag\_buck flag\_coul cutoff (cutoff2)

- `flag_buck` = *long* or *cut*  
*long* = use Kspace long-range summation for the dispersion term  $1/r^6$   
*cut* = use a cutoff
- `flag_coul` = *long* or *off*  
*long* = use Kspace long-range summation for the Coulombic term  $1/r$   
*off* = omit the Coulombic term
- `cutoff` = global cutoff for Buckingham (and Coulombic if only 1 cutoff) (distance units)
- `cutoff2` = global cutoff for Coulombic (optional) (distance units)

### 4.31.2 Examples

```
pair_style buck/long/coul/long cut off 2.5
pair_style buck/long/coul/long cut long 2.5 4.0
pair_style buck/long/coul/long long long 4.0
pair_coeff * * 1 1
pair_coeff 1 1 1 3 4
```

### 4.31.3 Description

The *buck/long/coul/long* style computes a Buckingham potential (exp/6 instead of Lennard-Jones 12/6) and Coulombic potential, given by

$$E = Ae^{-r/\rho} - \frac{C}{r^6} \quad r < r_c$$

$$E = \frac{Cq_iq_j}{\epsilon r} \quad r < r_c$$

$r_c$  is the cutoff. If one cutoff is specified in the *pair\_style* command, it is used for both the Buckingham and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the Buckingham and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive  $1/r^6$  Buckingham and Coulombic  $1/r$  interactions. This is done by use of the *flag\_buck* and *flag\_coul* settings. The *Ismail* paper has more details on when it is appropriate to include long-range  $1/r^6$  interactions, using this potential.

If *flag\_buck* is set to *long*, no cutoff is used on the Buckingham  $1/r^6$  dispersion term. The long-range portion can be calculated by using the *kpace\_style ewald/disp* or *pppm/disp* commands. The specified Buckingham cutoff then determines which portion of the Buckingham interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If *flag\_buck* is set to *cut*, the Buckingham interactions are simply cutoff, as with *pair\_style buck*.

If *flag\_coul* is set to *long*, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several *kpace\_style* command options such as *pppm* or *ewald*. Note that if *flag\_buck* is also set to *long*, then the *ewald/disp* or *pppm/disp* Kspace style needs to be used to perform the long-range calculations for both the Buckingham and Coulombic interactions. If *flag\_coul* is set to *off*, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atom types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands:

- A (energy units)
- rho (distance units)
- C (energy-distance<sup>6</sup> units)
- cutoff (distance units)
- cutoff2 (distance units)

The second coefficient, rho, must be greater than zero.

The latter 2 coefficients are optional. If not specified, the global Buckingham and Coulombic cutoffs specified in the *pair\_style* command are used. If only one cutoff is specified, it is used as the cutoff for both Buckingham and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the Buckingham and Coulombic cutoffs for this type pair. Note that if you are using *flag\_buck* set to *long*, you cannot specify a Buckingham cutoff for an atom type pair, since only one global Buckingham cutoff is allowed. Similarly, if you are using *flag\_coul* set to *long*, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.31.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style supports the *pair\_modify* shift option for the energy of the  $\exp()$  and  $1/r^6$  portion of the pair interaction, assuming *flag\_buck* is *cut*.

This pair style does not support the *pair\_modify* shift option for the energy of the Buckingham portion of the pair interaction.

This pair style supports the *pair\_modify* table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.

This pair style write its information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the *run\_style* command for details.

---

#### 4.31.5 Restrictions

This style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

#### 4.31.6 Related commands

### 4.37.3 Description

These pair styles compute Lennard Jones (LJ) and Coulombic interactions with additional switching or shifting functions that ramp the energy and/or force smoothly to zero between an inner and outer cutoff. They implement the widely used CHARMM force field, see [Howto discussion on biomolecular force fields](#) for details.

The styles with *charmm* (not *charmmfsw* or *charmmfsh*) in their name are the older, original LAMMPS implementations. They compute the LJ and Coulombic interactions with an energy switching function which ramps the energy smoothly to zero between the inner and outer cutoff. This can cause irregularities in pairwise forces (due to the discontinuous second derivative of energy at the boundaries of the switching region), which in some cases can result in detectable artifacts in an MD simulation.

The newer styles with *charmmfsw* or *charmmfsh* in their name replace the energy switching with force switching (fsw) and force shifting (fsh) functions, for LJ and Coulombic interactions respectively.

---

**Note:** The newer *charmmfsw* or *charmmfsh* styles were released in March 2017. We recommend they be used instead of the older *charmm* styles. This includes the newer *dihedral\_style charmmfsw* command. Eventually code from the new styles will propagate into the related pair styles (e.g. implicit, accelerator, free energy variants).

---

---

**Note:** The newest CHARMM pair styles reset the Coulombic energy conversion factor used internally in the code, from the LAMMPS value to the CHARMM value, as if it were effectively a parameter of the force field. This is because the CHARMM code uses a slightly different value for the this conversion factor in *real units* (kcal/mol), namely CHARMM = 332.0716, LAMMPS = 332.06371. This is to enable more precise agreement by LAMMPS with the CHARMM force field energies and forces, when using one of these two CHARMM pair styles.

---

When using the *lj/charmm/coul/charmm* styles, both the LJ and Coulombic terms require an inner and outer cutoff. They can be the same for both formulas or different depending on whether 2 or 4 arguments are used in the *pair\_style* command. For the *lj/charmmfsw/coul/charmmfsh* style, the LJ term requires both an inner and outer cutoff, while the Coulombic term requires only one cutoff. If the Coulombic cutoff is not specified (2 instead of 3 arguments), the LJ outer cutoff is used for the Coulombic cutoff. In all cases where an inner and outer cutoff are specified, the inner cutoff distance must be less than the outer cutoff. It is typical to make the difference between the inner and outer cutoffs about 2.0 Angstroms.

Style *lj/charmm/coul/charmm/implicit* computes the same formulas as style *lj/charmm/coul/charmm* except that an additional  $1/r$  term is included in the Coulombic formula. The Coulombic energy thus varies as  $1/r^2$ . This is effectively a distance-dependent dielectric term which is a simple model for an implicit solvent with additional screening. It is designed for use in a simulation of an unsolvated biomolecule (no explicit water molecules).

Styles *lj/charmm/coul/long* and *lj/charmm/coul/msm* compute the same formulas as style *lj/charmm/coul/charmm* and style *lj/charmmfsw/coul/long* computes the same formulas as style *lj/charmmfsw/coul/charmmfsh*, except that an additional damping factor is applied to the Coulombic term, so it can be used in conjunction with the *kpace\_style* command and its *ewald* or *pppm* or *msm* option. Only one Coulombic cutoff is specified for these styles; if only 2 arguments are used in the *pair\_style* command, then the outer LJ cutoff is used as the single Coulombic cutoff. The Coulombic cutoff specified for these styles means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- $\epsilon_{14}$  (energy units)
- $\sigma_{14}$  (distance units)

Note that  $\sigma$  is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at  $2^{1/6}\sigma$ .

The latter 2 coefficients are optional. If they are specified, they are used in the LJ formula between two atoms of these types which are also first and fourth atoms in any dihedral. No cutoffs are specified because the CHARMM force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the *pair\_style* command.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* [command-line switch](#) when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.37.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon, sigma, epsilon\_14, and sigma\_14 coefficients for all of the *lj/charmm* pair styles can be mixed. The default mix value is *arithmetic* to coincide with the usual settings for the CHARMM force field. See the “*pair\_modify*” command for details.

None of the *lj/charmm* or *lj/charmmfsw* pair styles support the *pair\_modify* shift option, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

The *lj/charmm/coul/long* and *lj/charmmfsw/coul/long* styles support the *pair\_modify* table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

None of the *lj/charmm* or *lj/charmmfsw* pair styles support the *pair\_modify* tail option for adding long-range tail corrections to energy and pressure, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

All of the *lj/charmm* and *lj/charmmfsw* pair styles write their information to *binary restart files*, so *pair\_style* and *pair\_coeff* commands do not need to be specified in an input script that reads a restart file.

The *lj/charmm/coul/long* and *lj/charmmfsw/coul/long* pair styles support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the *pair* keyword of *run\_style respa*. See the *run\_style* command for details.

---

#### 4.37.5 Restrictions

All the styles with *coul/charmm* or *coul/charmmfsh* styles are part of the MOLECULE package. All the styles with *coul/long* style are part of the KSPACE package. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) doc page for more info.

## 4.38 pair\_style lj/class2 command

Accelerator Variants: *lj/class2/gpu*, *lj/class2/kk*, *lj/class2/omp*

## 4.39 pair\_style lj/class2/coul/cut command

Accelerator Variants: *lj/class2/coul/cut/kk*, *lj/class2/coul/cut/omp*

## 4.40 pair\_style lj/class2/coul/long command

Accelerator Variants: *lj/class2/coul/long/gpu*, *lj/class2/coul/long/kk*, *lj/class2/coul/long/omp*

### 4.40.1 Syntax

```
pair_style style args
```

- style = *lj/class2* or *lj/class2/coul/cut* or *lj/class2/coul/long*
- args = list of arguments for a particular style

```
lj/class2 args = cutoff
```

```
cutoff = global cutoff for class 2 interactions (distance units)
```

```
lj/class2/coul/cut args = cutoff (cutoff2)
```

```
cutoff = global cutoff for class 2 (and Coulombic if only 1 arg) (distance units)
```

```
cutoff2 = global cutoff for Coulombic (optional) (distance units)
```

```
lj/class2/coul/long args = cutoff (cutoff2)
```

```
cutoff = global cutoff for class 2 (and Coulombic if only 1 arg) (distance units)
```

```
cutoff2 = global cutoff for Coulombic (optional) (distance units)
```

### 4.40.2 Examples

```
pair_style lj/class2 10.0
pair_coeff * * 100.0 2.5
pair_coeff 1 2* 100.0 2.5 9.0

pair_style lj/class2/coul/cut 10.0
pair_style lj/class2/coul/cut 10.0 8.0
pair_coeff * * 100.0 3.0
pair_coeff 1 1 100.0 3.5 9.0
pair_coeff 1 1 100.0 3.5 9.0 9.0

pair_style lj/class2/coul/long 10.0
pair_style lj/class2/coul/long 10.0 8.0
pair_coeff * * 100.0 3.0
pair_coeff 1 1 100.0 3.5 9.0
```

### 4.40.3 Description

The *lj/class2* styles compute a 6/9 Lennard-Jones potential given by

$$E = \epsilon \left[ 2 \left( \frac{\sigma}{r} \right)^9 - 3 \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

$r_c$  is the cutoff.

The *lj/class2/coul/cut* and *lj/class2/coul/long* styles add a Coulombic term as described for the *lj/cut* pair styles.

See ([Sun](#)) for a description of the COMPASS class2 force field.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $\epsilon$  (energy units)
- $\sigma$  (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global class 2 and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both class 2 and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the class 2 and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style *lj/class2*, since it has no Coulombic terms.

For *lj/class2/coul/long* only the class 2 cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the *pair\_style* command.

---

If the *pair\_coeff* command is not used to define coefficients for a particular I != J type pair, the mixing rule for  $\epsilon$  and  $\sigma$  for all class2 potentials is to use the *sixthpower* formulas documented by the *pair\_modify* command. The *pair\_modify mix* setting is thus ignored for class2 potentials for epsilon and sigma. However it is still followed for mixing the cutoff distance.

---

A version of these styles with a soft core, *lj/cut/soft*, suitable for use in free energy calculations, is part of the FEP package and is documented with the *pair\_style \*/soft* styles. The version with soft core is only available if LAMMPS was built with that package. See the [Build package](#) page for more info.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the [Accelerator packages](#) page for more instructions on how to use the accelerated styles effectively.

---

#### 4.40.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs  $I, J$  and  $I \neq J$ , the epsilon and sigma coefficients and cutoff distance for all of the `lj/class2` pair styles can be mixed. Epsilon and sigma are always mixed with the value *sixthpower*. The cutoff distance is mixed by whatever option is set by the `pair_modify` command (default = geometric). See the “`pair_modify`” command for details.

All of the `lj/class2` pair styles support the *pair\_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction.

The `lj/class2/coul/long` pair style does not support the *pair\_modify* table option since a tabulation capability has not yet been added to this potential.

All of the `lj/class2` pair styles support the *pair\_modify* tail option for adding a long-range tail correction to the energy and pressure of the Lennard-Jones portion of the pair interaction.

All of the `lj/class2` pair styles write their information to *binary restart files*, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

Only the `lj/class2` and `lj/class2/coul/long` pair styles support the use of the *inner*, *middle*, and *outer* keywords of the *run\_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the *pair* keyword of *run\_style respa*. See the *run\_style* command for details.

#### 4.40.5 Restrictions

These styles are part of the CLASS2 package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 4.41 pair\_style colloid command

Accelerator Variants: *colloid/gpu*, *colloid/omp*

#### 4.41.1 Syntax

```
pair_style colloid cutoff
```

- cutoff = global cutoff for colloidal interactions (distance units)

### 4.41.2 Examples

```
pair_style colloid 10.0
pair_coeff * * 25 1.0 10.0 10.0
pair_coeff 1 1 144 1.0 0.0 0.0 3.0
pair_coeff 1 2 75.398 1.0 0.0 10.0 9.0
pair_coeff 2 2 39.478 1.0 10.0 10.0 25.0
```

### 4.41.3 Description

Style *colloid* computes pairwise interactions between large colloidal particles and small solvent particles using 3 formulas. A colloidal particle has a size > sigma; a solvent particle is the usual Lennard-Jones particle of size sigma.

The colloid-colloid interaction energy is given by

$$U_A = -\frac{A_{cc}}{6} \left[ \frac{2a_1a_2}{r^2 - (a_1 + a_2)^2} + \frac{2a_1a_2}{r^2 - (a_1 - a_2)^2} + \ln \left( \frac{r^2 - (a_1 + a_2)^2}{r^2 - (a_1 - a_2)^2} \right) \right]$$

$$U_R = \frac{A_{cc}}{37800} \frac{\sigma^6}{r} \left[ \frac{r^2 - 7r(a_1 + a_2) + 6(a_1^2 + 7a_1a_2 + a_2^2)}{(r - a_1 - a_2)^7} \right. \\ + \frac{r^2 + 7r(a_1 + a_2) + 6(a_1^2 + 7a_1a_2 + a_2^2)}{(r + a_1 + a_2)^7} \\ - \frac{r^2 + 7r(a_1 - a_2) + 6(a_1^2 - 7a_1a_2 + a_2^2)}{(r + a_1 - a_2)^7} \\ \left. - \frac{r^2 - 7r(a_1 - a_2) + 6(a_1^2 - 7a_1a_2 + a_2^2)}{(r - a_1 + a_2)^7} \right]$$

$$U = U_A + U_R, \quad r < r_c$$

where  $A_{cc}$  is the Hamaker constant,  $a_1$  and  $a_2$  are the radii of the two colloidal particles, and  $r_c$  is the cutoff. This equation results from describing each colloidal particle as an integrated collection of Lennard-Jones particles of size sigma and is derived in (Everaers).

The colloid-solvent interaction energy is given by

$$U = \frac{2a^3\sigma^3A_{cs}}{9(a^2 - r^2)^3} \left[ 1 - \frac{(5a^6 + 45a^4r^2 + 63a^2r^4 + 15r^6)\sigma^6}{15(a - r)^6(a + r)^6} \right], \quad r < r_c$$

where  $A_{cs}$  is the Hamaker constant,  $a$  is the radius of the colloidal particle, and  $r_c$  is the cutoff. This formula is derived from the colloid-colloid interaction, letting one of the particle sizes go to zero.

The solvent-solvent interaction energy is given by the usual Lennard-Jones formula

$$U = \frac{A_{ss}}{36} \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right], \quad r < r_c$$

with  $A_{ss}$  set appropriately, which results from letting both particle sizes go to zero.

When used in combination with *pair\_style yukawa/colloid*, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.

The following coefficients must be defined for each pair of atoms types via the *pair\_coeff* command as in the examples above, or in the data file or restart files read by the *read\_data* or *read\_restart* commands, or by mixing as described below:

- $A$  (energy units)
- $\sigma$  (distance units)
- $d1$  (distance units)
- $d2$  (distance units)
- cutoff (distance units)

$A$  is the Hamaker energy prefactor and should typically be set as follows:

- $A_{cc} = \text{colloid/colloid} = 4\pi^2 = 39.5$
- $A_{cs} = \text{colloid/solvent} = \sqrt{A_{cc}A_{ss}}$
- $A_{ss} = \text{solvent/solvent} = 144$  (assuming  $\epsilon = 1$ , so that  $144/36 = 4$ )

$\sigma$  is the size of the solvent particle or the constituent particles integrated over in the colloidal particle and should typically be set as follows:

- $\sigma_{cc} = \text{colloid/colloid} = 1.0$
- $\sigma_{cs} = \text{colloid/solvent} = \text{arithmetic mixing between colloid } \sigma \text{ and solvent } \sigma$
- $\sigma_{ss} = \text{solvent/solvent} = 1.0$  or whatever size the solvent particle is

Thus typically  $\sigma_{cs} = 1.0$ , unless the solvent particle's size  $\neq 1.0$ .

$d1$  and  $d2$  are particle diameters, so that  $d1 = 2*a1$  and  $d2 = 2*a2$  in the formulas above. Both  $d1$  and  $d2$  must be values  $\geq 0$ . If  $d1 > 0$  and  $d2 > 0$ , then the pair interacts via the colloid-colloid formula above. If  $d1 = 0$  and  $d2 = 0$ , then the pair interacts via the solvent-solvent formula. I.e. a  $d$  value of 0 is a Lennard-Jones particle of size  $\sigma$ . If either  $d1 = 0$  or  $d2 = 0$  and the other is larger, then the pair interacts via the colloid-solvent formula.

Note that the diameter of a particular particle type may appear in multiple `pair_coeff` commands, as it interacts with other particle types. You should ensure the particle diameter is specified consistently each time it appears.

The last coefficient is optional. If not specified, the global cutoff specified in the `pair_style` command is used. However, you typically want different cutoffs for interactions between different particle sizes. E.g. if colloidal particles of diameter 10 are used with solvent particles of diameter 1, then a solvent-solvent cutoff of 2.5 would correspond to a colloid-colloid cutoff of 25. A good rule-of-thumb is to use a colloid-solvent cutoff that is half the big diameter + 4 times the small diameter. I.e.  $9 = 5 + 4$  for the colloid-solvent cutoff in this case.

---

**Note:** When using `pair_style colloid` for a mixture with 2 (or more) widely different particles sizes (e.g.  $\sigma=10$  colloids in a background  $\sigma=1$  LJ fluid), you will likely want to use these commands for efficiency: [\*neighbor multi\*](#) and [\*comm\\_modify multi\*](#).

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [\*Accelerator packages\*](#) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [\*Build package\*](#) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.
