21.3 Design and Implementation History

The current version of the sweep-line algorithm was written by Baruch Zukerman, based on previous implementations by Ester Ezra and Tali Zvi.

2D Intersection of Curves

Reference Manual

Baruch Zukerman and Ron Wein

This chapter describes three functions implemented using the sweep-line algorithm: given a collection \mathcal{C} of planar curves, compute all intersection points among them, obtain the set of maximal pairwise interior-disjoint subcurves of the curves in \mathcal{C} , or check whether there is at least one pair of curves in \mathcal{C} that intersect in their interior.

The first two operations are performed in an output-sensitive manner.

get_subcurves page [1615](#)

CGAL::get_intersection_points

```
#include <CGAL/Sweep_line_2_algorithms.h>

template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      get_intersection_points( InputIterator curves_begin,
                                           InputIterator curves_end,
                                           OutputIterator points,
                                           bool report_endpoints = false,
                                           Traits traits = Default_traits())
```

given a range of curves, compute all intersection points between two (or more) input curves. If the flag *report_endpoints* is *true*, then the curve endpoints are reported as well. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::Point_2*. The output points are reported in an increasing *xy*-lexicographical order.

CGAL::get_subcurves

```
#include <CGAL/Sweep_line_2_algorithms.h>
```

```
template <class InputIterator, class OutputIterator, class Traits>
OutputIterator      get_subcurves( InputIterator curves_begin,
                                   InputIterator curves_end,
                                   OutputIterator subcurves,
                                   bool multiple_overlaps = false,
                                   Traits traits = Default_traits())
```

given a range of curves, compute all x -monotone subcurves that are pairwise disjoint in their interior, as induced by the input curves. If the flag *multiple_overlaps* is *true*, then a subcurve that represents an overlap of k input curves is reported k times; otherwise, each subcurve is reported only once. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*, and the value-type of *OutputIterator* is *Traits::X_monotone_curve_2*.

CGAL::do_curves_intersect

```
#include <CGAL/Sweep_line_2_algorithms.h>
```

```
template <class InputIterator, class Traits>
```

```
bool do_curves_intersect( InputIterator curves_begin,  
                          InputIterator curves_end,  
                          Traits traits = Default_traits())
```

given a range of curves, check whether there is at least one pair of curves that intersect in their interior. The function returns *true* if such a pair is found, and *false* if all curves are pairwise disjoint in their interior. The *Traits* type must be a model of the *ArrangementTraits_2* concept, such that the value-type of *InputIterator* is *Traits::Curve_2*.

22.1 Introduction

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

Figure 22.1: An arrangement of segments before (a) and after (b) SR (hot pixels are shaded)

22.2 What is Snap Rounding/Iterated Snap Rounding

Given a finite collection S of segments in the plane, the arrangement of S denoted $\mathcal{A}(S)$ is the subdivision of the plane into vertices, edges, and faces induced by S . A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, the SR procedure `snap_rounding_2<Traits,InputIterator,OutputContainer>` proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e , in the same order as they are met by e . Figure 22.1 demonstrates the results of SR.

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. Figure 22.2 depicts the results of SR and ISR on the same input. Conceptually, the ISR procedure is equivalent to repeated application of SR, namely we apply SR to the original set of segments, then we use the output of SR as input to another round of SR and so on until all the vertices are well separated from non-incident edges. Algorithmically we operate differently, as this repeated application of SR would have resulted in an efficient overall process. The algorithmic details are given in [HP02].

22.3 Terms and Software Design

Our package supports both schemes, implementing the algorithm described in [HP02]. Although the paper only describes an algorithm for ISR, it is easy to derive an algorithm for SR, by performing only the first rounding level for each segment.

The input to the program is a set S of n segments, $S = \{s_1, \dots, s_n\}$ and the output is a set G of n polylines, with a polyline g_i for each input segments s_i . An input segment is given by the coordinates of its endpoints. An output polyline is given by the ordered set of vertices v_0, \dots, v_k along the polyline. The polyline consists of the segments $(v_0v_1), \dots, (v_{k-1}v_k)$.

There are three template parameters: *Traits* is the underlying geometry, i.e., the number type used and the coordinate representation. *InputIterator* is the type of the iterators that point to the first and after-the-last elements of the input. Finally, *OutputContainer* is the type of the output container.

Since the algorithm requires kernel functionalities such as the rounding to the center of a pixel, a special traits class must be provided. The precise description of the requirements is given by the concept `SnapRoundingTraits_2`. The class `Snap_rounding_traits_2` is a model of this concept.

22.4 Four Line Segment Example

The following example generates an ISR representation of an arrangement of four line segments. In particular it produces a list of points that are the vertices of the resulting polylines in a plane tiled with one-unit square pixels.

```
#include <CGAL/basic.h>
```

Figure 22.2: An arrangement of segments before (a), after SR (b) and ISR (c) (hot pixels are shaded).

```
#include <CGAL/Cartesian.h>
#include <CGAL/Quotient.h>
#include <CGAL/MP_Float.h>
#include <CGAL/Snap_rounding_traits_2.h>
#include <CGAL/Snap_rounding_2.h>

typedef CGAL::Quotient<CGAL::MP_Float>          Number_type;
typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Snap_rounding_traits_2<Kernel>    Traits;
typedef Kernel::Segment_2                      Segment_2;
typedef Kernel::Point_2                       Point_2;
typedef std::list<Segment_2>                   Segment_list_2;
typedef std::list<Point_2>                    Polyline_2;
typedef std::list<Polyline_2>                 Polyline_list_2;

int main()
{
    Segment_list_2 seg_list;
    Polyline_list_2 output_list;

    seg_list.push_back(Segment_2(Point_2(0, 0), Point_2(10, 10)));
    seg_list.push_back(Segment_2(Point_2(0, 10), Point_2(10, 0)));
    seg_list.push_back(Segment_2(Point_2(3, 0), Point_2(3, 10)));
    seg_list.push_back(Segment_2(Point_2(7, 0), Point_2(7, 10)));

    // Generate an iterated snap-rounding representation, where the centers of
    // the hot pixels bear their original coordinates, using 5 kd trees:
    CGAL::snap_rounding_2<Traits, Segment_list_2::const_iterator, Polyline_list_2>
        (seg_list.begin(), seg_list.end(), output_list, 1.0, true, false, 5);

    int counter = 0;
    Polyline_list_2::const_iterator iter1;
    for (iter1 = output_list.begin(); iter1 != output_list.end(); ++iter1) {
        std::cout << "Polyline number " << ++counter << ":\n";
        Polyline_2::const_iterator iter2;
        for (iter2 = iter1->begin(); iter2 != iter1->end(); ++iter2)
```

```

        std::cout << "      (" << iter2->x() << ":" << iter2->y() << ")\n";
    }

    return(0);
}

```

File: examples/Snap_rounding_2/snap_rounding.cpp

This program generates four polylines, one for each input segment. The exact output follows:

Polyline number 1:

```

(0/4:0/4)
(12/4:12/4)
(20/4:20/4)
(28/4:28/4)
(40/4:40/4)

```

Polyline number 2:

```

(0/4:40/4)
(12/4:28/4)
(20/4:20/4)
(28/4:12/4)
(40/4:0/4)

```

Polyline number 3:

```

(12/4:0/4)
(12/4:12/4)
(12/4:28/4)
(12/4:40/4)

```

Polyline number 4:

```

(28/4:0/4)
(28/4:12/4)
(28/4:28/4)
(28/4:40/4)

```

The package is supplied with a graphical demo program that opens a window, allows the user to edit segments dynamically, applies a selected snap-rounding procedures, and displays the result onto the same window (see `<CGAL_ROOT>/demo/Snap_rounding_2/demo.cpp`).

CGAL::snap_rounding_2

Definition

Snap Rounding (SR, for short) is a well known method for converting arbitrary-precision arrangements of segments into a fixed-precision representation [GGHT97, GM98, Hob99]. In the study of robust geometric computing, it can be classified as a finite precision approximation technique. Iterated Snap Rounding (ISR, for short) is a modification of SR in which each vertex is at least half-the-width-of-a-pixel away from any non-incident edge [HP02]. This package supports both methods. Algorithmic details and experimental results are given in [HP02].

Given a finite collection \mathcal{S} of segments in the plane, the arrangement of \mathcal{S} denoted $\mathcal{A}(\mathcal{S})$ is the subdivision of the plane into vertices, edges, and faces induced by \mathcal{S} . A *vertex* of the arrangement is either a segment endpoint or the intersection of two segments. Given an arrangement of segments whose vertices are represented with arbitrary-precision coordinates, SR proceeds as follows. We tile the plane with a grid of unit squares, *pixels*, each centered at a point with integer coordinates. A pixel is *hot* if it contains a vertex of the arrangement. Each vertex of the arrangement is replaced by the center of the hot pixel containing it and each edge e is replaced by the polygonal chain through the centers of the hot pixels met by e , in the same order as they are met by e .

In a snap-rounded arrangement, the distance between a vertex and a non-incident edge can be extremely small compared with the width of a pixel in the grid used for rounding. ISR is a modification of SR which makes a vertex and a non-incident edge well separated (the distance between each is at least half-the-width-of-a-pixel). However, the guaranteed quality of the approximation in ISR degrades. For more details on ISR see [HP02].

The traits used here must support (arbitrary-precision) rational number type as this is a basic requirement of SR.

```
#include <CGAL/Snap_rounding_2.h>
```

```
template < class Traits, class InputIterator, class OutputContainer >
void      snap_rounding_2( InputIterator begin,
                          InputIterator end,
                          OutputContainer& output_container,
                          typename Traits::FT pixel_size,
                          bool do_isr = true,
                          bool int_output = true,
                          unsigned int number_of_kd_trees = 1)
```

The first two parameters denote the first and after-the-last iterators of the input segments. The third parameter is a reference to a container of the output polylines. Since a polyline is composed of a sequence of points, a polyline is a container itself. The fifth parameter determines whether to apply ISR or SR.

The forth parameter denotes the pixel size w . The plane will be tiled with square pixels of width w such that the origin is the center of a pixel. The sixth parameter denotes the output representation. If the value of the sixth parameter is *true* then the centers of pixels constitute the integer grid, and hence the vertices of the output polylines will be integers. For example, the coordinates of the center of the pixel to the right of the pixel containing the origin will be $(1,0)$ regardless of the pixel width. If the value of the sixth parameter is *false*, then the centers of hot pixels (and hence the vertices of the output polylines) will bear their original coordinates, which may not necessarily be integers. In the latter case, the coordinates of the center of the pixel to the right of the pixel containing the origin, for example, will be $(w,0)$.

The seventh (and last) parameter is briefly described next; for a detailed description see [HP02].

A basic query used in the algorithm is to report the hot pixels of size w that a certain segment s intersects. An alternative way to do the same is to query the hot pixels' centers contained in a Minkowski sum of s with a pixel of width w centered at the origin; we denote this Minkowski sum by $M(s)$. Since efficiently implementing this kind of query is difficult, we use an orthogonal range-search structure instead. We query with the bounding box $B(M(s))$ of $M(s)$ in a two-dimensional kd-tree which stores the centers of hot pixels. Since $B(M(s))$ in general is larger than $M(s)$, we still need to filter out the hot pixels which do not intersect s .

While this approach is easy to implement with CGAL, it may incur considerable overhead since the area of $B(M(s))$ may be much larger than the area of $M(s)$, possibly resulting in many redundant hot pixels to filter out. Our heuristic solution, which we describe next, is to use a cluster of kd-trees rather than just one. The cluster includes several kd-trees, each has the plane, and hence the centers of hot pixels, rotated by a different angle in the first quadrant of the plane; for our purpose, a rotation by angles outside this quadrant is symmetric to a rotation by an angle in the first quadrant.

Given a parameter c , the angles of rotation are $(i-1)\frac{\pi}{2c}$, $i = 1, \dots, c$, and we construct a kd-tree corresponding to each of these angles. Then for a query segment s , we choose the kd-tree for which the area of $B(M(s))$ is the smallest, in order to (potentially) get less hot pixels to filter out. Since constructing many kd-trees may be costly, our algorithm avoids building a kd-tree which it expects to be queried a relatively small number of times (we estimate this number in advance). How many kd-trees should be used? It is difficult to provide a simple answer for that. There are inputs for which the time to build more than one kd-tree is far greater than the time saved by having to filter out less hot pixels (sparse arrangements demonstrate this behavior), and there are inputs which benefit from using several kd-trees. Thus, the user can control the number of kd-trees with the parameter *number_of_kd_trees*. Typically, but not always, one kd-tree (the default) is sufficient.

Precondition: *pixel_size* must have a positive value and *number_of_kd_trees* must be a positive integer.

SnapRoundingTraits_2

Definition

The concept `SnapRoundingTraits_2` lists the set of requirements that must be fulfilled by an instance of the *Traits* template-parameter of the function `snap_rounding_2<Traits, InputIterator, OutputContainer>()`. This concept provides the types of the geometric primitives used in this class and some function object types for the required predicates on those primitives.

Refines

This concept refines the standard concepts `DefaultConstructible`, `Assignable` and `CopyConstructible`. It also refines the concept *SweepLineTraits_2* (page ??). An instance of this concept is used as the traits class for the *Sweep_line_2.get_intersection_points()* operation. The requirements listed below are induced by components of the `snap_rounding_2()` function other than the call to *Sweep_line_2.get_intersection_points()*. Naturally, some of them may already be listed in *SweepLineTraits_2*.

Types

<i>SnapRoundingTraits_2:: FT</i>	The number type. This type must fulfill the requirements on <i>FieldNumberType</i>
<i>SnapRoundingTraits_2:: Point_2</i>	The point type.
<i>SnapRoundingTraits_2:: Segment_2</i>	The segment type.
<i>SnapRoundingTraits_2:: Iso_rectangle_2</i>	The iso-rectangle type.
<i>SnapRoundingTraits_2:: Construct_vertex_2</i>	Function object. Must provide the operator <i>Point_2 operator()(Segment_2 seg, int i)</i> , which returns the source or target of <i>seg</i> . If <i>i</i> modulo 2 is 0, the source is returned, otherwise the target is returned.
<i>SnapRoundingTraits_2:: Construct_segment_2</i>	Function object. Must provide the operator <i>Segment_2 operator()(Point_2 p, Point_2 q)</i> , which introduces a segment with source <i>p</i> and target <i>q</i> . The segment is directed from the source towards the target.
<i>SnapRoundingTraits_2:: Construct_iso_rectangle_2</i>	Function object. Must provide the operator <i>Iso_rectangle_2 operator()(Point_2 left, Point_2 right, Point_2 bottom, Point_2 top)</i> , which introduces an iso-oriented rectangle for whose minimal <i>x</i> coordinate is the one of <i>left</i> , the maximal <i>x</i> coordinate is the one of <i>right</i> , the minimal <i>y</i> coordinate is the one of <i>bottom</i> , the maximal <i>y</i> coordinate is the one of <i>top</i> .
<i>SnapRoundingTraits_2:: To_double</i>	Function object. Must provide the operator <i>double operator()(FT)</i> , which computes an approximation of a given number of type <i>FT</i> . The precision of this operation is of not high significance, as it is only used in the implementation of the heuristic technique to exploit a cluster of kd-trees rather than just one.

<i>SnapRoundingTraits_2:: Compare_x_2</i>	Function object. Must provide the operator <i>Comparison_result operator()(Point_2 p, Point_2 q)</i> which returns <i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i> according to the <i>x</i> -ordering of points <i>p</i> and <i>q</i> .
<i>SnapRoundingTraits_2:: Compare_y_2</i>	Function object. Must provide the operator <i>Comparison_result operator()(Point_2 p, Point_2 q)</i> which returns <i>SMALLER</i> , <i>EQUAL</i> or <i>LARGER</i> according to the <i>y</i> -ordering of points <i>p</i> and <i>q</i> .
<i>SnapRoundingTraits_2:: Snap_2</i>	Rounds a point to a center of a pixel (unit square) in the grid used by the Snap Rounding algorithm. Note that no conversion to an integer grid is done yet. Must have the syntax <i>void operator()(Point_2 p, FT pixel_size, FT &x, FT &y)</i> where <i>p</i> is the input point, <i>pixel_size</i> is the size of the pixel of the grid, and <i>x</i> and <i>y</i> are the <i>x</i> and <i>y</i> -coordinates of the rounded point respectively.
<i>SnapRoundingTraits_2:: Integer_grid_point_2</i>	Convert coordinates into an integer representation where one unit is equal to pixel size. For instance, if a point has the coordinates (3.7, 5.3) and the pixel size is 0.5, then the new point will have the coordinates of (7, 10). Note, however, that the number type remains the same here, although integers are represented. Must have the syntax <i>Point_2 operator()(Point_2 p, NT pixel_size)</i> where <i>p</i> is the converted point and <i>pixel_size</i> is the size of the pixel of the grid.
<i>SnapRoundingTraits_2:: Minkowski_sum_with_pixel_2</i>	Returns the vertices of a polygon, which is the Minkowski sum of a segment and a square centered at the origin with edge size <i>pixel edge</i> . Must have the syntax <i>void operator()(std::list<Point_2>& vertices_list, Segment_2 s, NT unit_square)</i> where <i>vertices_list</i> is the list of the vertices of the Minkowski sum polygon, <i>s</i> is the input segment and <i>unit_square</i> is the edge size of the pixel.

Creation

This concept refines the standard concepts `DefaultConstructible`, `Assignable` and `CopyConstructible`.

Operations

The following functions construct the required function objects occasionally referred as functors listed above.

<i>Construct_vertex_2</i>	<i>traits.construct_vertex_2_object()</i>
<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_iso_rectangle_2</i>	<i>traits.construct_iso_rectangle_2_object()</i>
<i>Compare_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Compare_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Snap_2</i>	<i>traits.snap_2_object()</i>
<i>Integer_grid_point_2</i>	<i>traits.integer_grid_point_2_object()</i>
<i>Minkowski_sum_with_pixel_2</i>	<i>traits.minkowski_sum_with_pixel_2_object()</i>

Has Models

CGAL::Snap_rounding_traits<Kernel>

See Also

CGAL::Snap_rounding_2<Traits>

CGAL::Snap_rounding_traits_2<Kernel>

The class *Snap_rounding_traits_2<Kernel>* is a model of the *SnapRoundingTraits_2* concept, and is the only traits class supplied with the package. This class should be instantiated with an exact geometric kernel that conforms to the CGAL kernel-concept, such as the *Cartesian<gmpq>* kernel.

This geometric kernel must provide an (arbitrary-precision) rational number type (*FT*), *Point_2*, *Segment_2* and *Iso_rectangle_2*. It should be possible to cast numbers of the number type *FT* to double-precision representation. That is, the function *CGAL::to_double(FT)* must be supported.

The *CGAL::to_double()* function is used to implement the operation that rounds the coordinates of a point to a center of a pixel. This operation is one of the traits-concept requirement. The coordinates are converted to double, rounded down to the nearest grid point, and finally adjusted to lie on a center of a pixel. Notice that if *CGAL::to_double()* returns the closet value, then when it rounds up a given coordinate, the resulting ISR, may be imprecise, and the distance between some vertex and a non-incident edge can be slightly less than the guaranteed half-the width-of-a-pixel.

Figure 23.1: The lower envelope of a set of line segments and hyperbolic arc.

23.1 Introduction

A continuous curve C in \mathbb{R}^2 is called *x-monotone*, if every vertical line intersects it at a single point at most. For example, the circle $x^2 + y^2 = 1$ is *not* *xy-monotone* as the vertical line $x = 0$ intersects it at $(0, -1)$ and at $(0, 1)$; however, it is possible to split the circle into an upper part and a lower part, such that both of these parts are

x -monotone. We consider vertical segments as *weakly* x -monotone, to properly handle inputs that contain such vertical curves.

An x -monotone curve can be represented as a univariate function $y = C(x)$, defined over some continuous range $R_C \subseteq \mathbb{R}$. Given a set $C = \{C_1, C_2, \dots, C_n\}$ of x -monotone curves, their *lower envelope* is defined as the point-wise minimum of all curves. Namely, the lower envelope of the set C can be defined as the following function:

$$\mathcal{L}_C(x) = \min_{1 \leq k \leq n} \overline{C}_k(x) ,$$

where we define $\overline{C}_k(x) = C_k(x)$ for $x \in R_{C_k}$, and $\overline{C}_k(x) = \infty$ otherwise.

Similarly, the *upper envelope* of C is the point-wise maximum of the x -monotone curves in the set:

$$\mathcal{U}_C(x) = \max_{1 \leq k \leq n} \underline{C}_k(x) ,$$

where in this case $\underline{C}_k(x) = -\infty$ for $x \notin R_{C_k}$.

Given a set of x -monotone curves C , the *minimization diagram* of C is a subdivision of the x -axis into cells, such that the identity of the curves that induce the lower envelope over a specific cell of the subdivision (an edge or a vertex) is the same. In non-degenerate situations, an edge — which represents a continuous interval on the x -axis — is induced by a single curve (or by no curves at all, if there are no x -monotone curves defined over the interval), and a vertex is induced by a single curve and corresponds to one of its endpoints, or by two curves and corresponds to their intersection point. The *maximization diagram* is symmetrically defined for upper envelopes. In the rest of this chapter, we refer to both these diagrams as *envelope diagrams*.

Lower and upper envelopes can be efficiently computed using a divide-and-conquer approach. First, note that the envelope diagram for a single x -monotone curve C_k is trivial to compute: we project the boundary of its range of definition R_{C_k} onto the x -axis and label the features it induces accordingly. Given a set \mathcal{D} of (non necessarily x -monotone) curves in \mathbb{R}^2 , we subdivide each curve into a finite number of weakly x -monotone curves, and obtain the set C . Then, we split the set into two disjoint subsets C_1 and C_2 , and we compute their envelope diagrams recursively. Finally, we merge the diagrams in linear time by traversing both diagrams in parallel.

23.2 The Envelope Diagram

The package basically contains two sets of free functions: *lower_envelope_x_monotone_2* (*begin*, *end*, *diag*) (similarly *upper_envelope_x_monotone_2*()) construct the envelope diagram for a given range of x -monotone curves, while *lower_envelope_2* (*begin*, *end*, *diag*) (similarly *upper_envelope_2*()) construct the envelope diagram for a range of *arbitrary* (not necessarily x -monotone) curves. In this section we explain more on the structure of the envelope diagram these functions output.

A minimization diagram or a maximization diagram is represented by a model of the concept *EnvelopeDiagram_1*. This concept defines the structure of the subdivision of the x -axis into 0-dimensional cells called *vertices*, and 1-dimensional cells called *edges*. The important property of this subdivision is that the identity of the curves that induce the lower envelope (or the upper envelope) over each cell is fixed.

Figure 23.2 shows the lower envelope of a set of eight line segments, and sketches the structure of their minimization diagram. Each diagram vertex v is associated with a point p_v on the envelope, which corresponds to either a curve endpoint or to an intersection point of two (or more) curves. The vertex is therefore associated with a set of x -monotone curves that induce the envelope over p_v . Each vertex is incident to two edges, one lying to its left and the other to its right.

An edge in the envelope diagram represents a continuous portion of the x -axis, and is associated with a set of x -monotone curves that induce the envelope over this interval. Note that this set may be empty if no x -monotone

Figure 23.2: The lower envelope of eight line segments, labeled A, \dots, H , as constructed in *ex_envelope_segments.cpp*. The minimization diagram is shown at the bottom, where each diagram vertex points to the point associated with it, and the labels of the segment that induce a diagram edge are displayed below this edge. Note that there exists one edge that represents an overlap (i.e., there are two segments that induce it), and there are also a few edges that represent empty intervals.

curves are defined over this interval. In degenerate situations where curves overlap, there may be more than a single curve that induces the envelope over the interval the edge represents. An envelop diagram of a set of curves either consists of a single unbounded edge (in case the curve set is empty or if the envelope contains a single unbounded curve that is below or above all other curves), or at least one vertex and two unbounded edges, while each additional vertex comes along with an additional edge. It is possible to directly access the *leftmost* edge, representing the unbounded interval that starts at $-\infty$, and the *rightmost* edge, representing the unbounded interval that ends at ∞ . (In the example depicted in Figure 23.2 we have only bounded curves, so the leftmost and rightmost edges represent empty intervals. This is not the case when we deal, for example, with envelopes of sets of lines.)

Any model of the concept must define a geometric traits class, which in turn defines the *Point_2* and *X_monotone_curve_2* types defined with the diagram features. The geometric traits class must be a model of the *ArrangementXMonotoneTraits_2* concept in case we construct envelopes of x -monotone curves. If we are interested in handling arbitrary (not necessarily x -monotone) curves, the traits class must be a model of the *ArrangementTraits_2* concept. This concepts refined the *ArrangementXMonotoneTraits_2* concept; a traits class that models this concepts must also defines a *Curve_2* type, representing an arbitrary planar curve, and provide a functor for subdividing such curves into x -monotone subcurves.

23.3 Examples

23.3.1 Example for Envelope of Line Segments

The following example demonstrates how to compute and traverse the minimization diagram of line segments, as illustrated in Figure 23.2. We use the curve-data traits instantiated by the *Arr_segment_traits_2* class, in order to attach a label (a *char* in this case) to each input segment. We use these labels when we print the minimization diagram:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Env_default_diagram_1.h>
#include <CGAL/envelope_2.h>

#include <list>
#include <iostream>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>             Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>        Segment_traits_2;
typedef Segment_traits_2::X_monotone_curve_2      Segment_2;
typedef CGAL::Arr_curve_data_traits_2<Segment_traits_2,
                                         char>      Traits_2;
typedef Traits_2::Point_2                        Point_2;
typedef Traits_2::X_monotone_curve_2              Labeled_segment_2;
typedef CGAL::Env_default_diagram_1<Traits_2>      Diagram_1;

int main ()
{
    // Construct the input segments and label them 'A' ... 'H'.
    std::list<Labeled_segment_2> segments;

    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (0, 1),
                                                         Point_2 (2, 3)), 'A'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (1, 2),
                                                         Point_2 (4, 5)), 'B'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (1, 5),
                                                         Point_2 (7, 2)), 'C'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (4, 2),
                                                         Point_2 (6, 4)), 'D'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (8, 3),
                                                         Point_2 (8, 6)), 'E'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (9, 2),
                                                         Point_2 (12, 4)), 'F'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (10, 2),
                                                         Point_2 (12, 1)), 'G'));
    segments.push_back (Labeled_segment_2 (Segment_2 (Point_2 (11, 0),
                                                         Point_2 (11, 5)), 'H'));

    // Compute the minimization diagram that represents their lower envelope.
    Diagram_1 min_diag;
```

```

lower_envelope_x_monotone_2 (segments.begin(), segments.end(),
                             min_diag);

// Print the minimization diagram.
Diagram_1::Edge_const_handle e = min_diag.leftmost();
Diagram_1::Vertex_const_handle v;
Diagram_1::Curve_const_iterator cit;

while (e != min_diag.rightmost())
{
    std::cout << "Edge:";
    if (! e->is_empty())
    {
        for (cit = e->curves_begin(); cit != e->curves_end(); ++cit)
            std::cout << ' ' << cit->data();
    }
    else
        std::cout << " [empty]";
    std::cout << std::endl;

    v = e->right();
    std::cout << "Vertex (" << v->point() << "):";
    for (cit = v->curves_begin(); cit != v->curves_end(); ++cit)
        std::cout << ' ' << cit->data();
    std::cout << std::endl;

    e = v->right();
}
CGAL_assertion (e->is_empty());
std::cout << "Edge: [empty]" << std::endl;

return (0);
}

```

23.3.2 Example for Computing the Convex Hull with Envelopes

The next example computes the convex hull of a set of input points by constructing envelopes of unbounded curves, in our case lines that are dual to the input points. Here we use the *Arr_linear_traits_2* class to compute the lower envelope of the set of dual lines. We read a set of points $\mathcal{P} = p_1, \dots, p_n$ from an input file, and construct the corresponding dual lines $\mathcal{P}^* = p_1^*, \dots, p_n^*$, where the line p^* dual to a point $p = (p_x, p_y)$ is given by $y = p_x x - p_y$. We then compute the convex hull of the point-set \mathcal{P} , using the fact that the lines that form the lower envelope of \mathcal{P}^* are dual to the points along the *upper* part of \mathcal{P} 's convex hull, and the lines that form the upper envelope of \mathcal{P}^* are dual to the points along the *lower* part of the convex hull; see, e.g., [dBvKOS00, Section 11.4] for more details. Note that the leftmost edge of the minimization diagram is associated with the same line as the rightmost edge of the maximization diagram, and vice-versa. We can therefore skip the rightmost edges of both diagrams:

```
#include <CGAL/Gmpq.h>
```

```

#include <CGAL/Cartesian.h>
#include <CGAL/Arr_linear_traits_2.h>
#include <CGAL/Arr_curve_data_traits_2.h>
#include <CGAL/Env_default_diagram_1.h>
#include <CGAL/envelope_2.h>
#include <vector>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>             Kernel;
typedef CGAL::Arr_linear_traits_2<Kernel>         Linear_traits_2;
typedef Linear_traits_2::Point_2                 Point_2;
typedef Linear_traits_2::Line_2                  Line_2;
typedef CGAL::Arr_curve_data_traits_2<Linear_traits_2,
                                         unsigned int> Traits_2;
typedef Traits_2::X_monotone_curve_2             Dual_line_2;
typedef CGAL::Env_default_diagram_1<Traits_2>     Diagram_1;

int main (int argc, char **argv)
{
    // Get the name of the input file from the command line, or use the default
    // points.dat file if no command-line parameters are given.
    const char *filename = "ch_points.dat";

    if (argc > 1)
        filename = argv[1];

    // Open the input file.
    std::ifstream in_file (filename);

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open " << filename << " ..." << std::endl;
        return (1);
    }

    // Read the points from the file, and construct their dual lines.
    unsigned int      n;
    int               px, py;
    std::vector<Point_2> points;
    Line_2            line;

23.3.3 Example for Envelope of Non-Linear Curves

We conclude by an example of envelopes of non-linear curves. We use the *Arr_circle_segment_traits_2* class to construct the lower and the upper envelopes of a set of four circles, as depicted in Figure 23.3. Note that unlike the two previous examples, here our curves are not *x*-monotone, so we use the functions that compute envelopes of arbitrary curves:

```
#include <CGAL/Gmpq.h>
```

Figure 23.3: A set of four circles, as constructed in *ex_envelope_circles.cpp*. The lower envelope and the upper envelope are shown using thick dashed lines of different colors respectively.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_circle_segment_traits_2.h>
#include <CGAL/Arrangement_2.h>
#include <CGAL/Env_default_diagram_1.h>
#include <CGAL/envelope_2.h>

typedef CGAL::Gmpq                                     Number_type;
typedef CGAL::Cartesian<Number_type>                   Kernel;
typedef Kernel::Point_2                                 Kernel_point_2;
typedef Kernel::Circle_2                                Circle_2;
typedef CGAL::Arr_circle_segment_traits_2<Kernel>       Traits_2;
typedef Traits_2::Curve_2                               Curve_2;
typedef CGAL::Env_default_diagram_1<Traits_2>           Diagram_1;

/*! Print the given envelope diagram. */
void print_diagram (const Diagram_1& diag)
{
    Diagram_1::Edge_const_handle    e = diag.leftmost();
    Diagram_1::Vertex_const_handle  v;

    while (e != diag.rightmost())
    {
        std::cout << "Edge: ";
        if (! e->is_empty())
        {
            Circle_2    circ = e->curve().supporting_circle();
            std::cout << " (x - " << CGAL::to_double(circ.center().x()) << ")^2 + "
                      << " (y - " << CGAL::to_double(circ.center().y()) << ")^2 = "
                      << CGAL::to_double(circ.squared_radius()) << std::endl;
        }
        else
            std::cout << " [empty]" << std::endl;

        v = e->right();
    }
}
```

```

        std::cout << "Vertex (" << CGAL::to_double(v->point().x()) << ' '
            << CGAL::to_double(v->point().y()) << ') ' << std::endl;

        e = v->right();
    }
    CGAL_assertion (e->is_empty());
    std::cout << "Edge: [empty]" << std::endl;

    return;
}

/*! The main program. */
int main ()

Envelopes of Curves in 2D

Reference Manual

Ron Wein

Introduction

This package consists of functions that compute the lower (or upper) envelope of a set of arbitrary curves in 2D. The output is represented as an envelope diagram, namely a subdivision of the x -axis into intervals, such that the identity of the curves that induce the envelope over each interval is unique.

CGAL::lower_envelope_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>
```

```
void lower_envelope_2( InputIterator begin, InputIterator end, EnvelopeDiagram& diag)
```

Computes the lower envelope of a set of curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.

Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::Traits_2::Curve_2*.

CGAL::upper_envelope_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>
```

```
void upper_envelope_2( InputIterator begin, InputIterator end, EnvelopeDiagram& diag)
```

Computes the upper envelope of a set of curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The upper envelope is represented using the output maximization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.

Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::Traits_2::Curve_2*.

CGAL::lower_envelope_x_monotone_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>  
void lower_envelope_x_monotone_2( InputIterator begin,  
                                  InputIterator end,  
                                  EnvelopeDiagram& diag)
```

Computes the lower envelope of a set of x -monotone curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept.
Precondition: The value-type of *InputIterator* is *EnvelopeDiagram::X_monotone_curve_2*.

CGAL::upper_envelope_x_monotone_2

```
#include <CGAL/envelope_2.h>
```

```
template<class InputIterator, class EnvelopeDiagram>
void      upper_envelope_x_monotone_2( InputIterator begin,
                                       InputIterator end,
                                       EnvelopeDiagram& diag)
```

Computes the upper envelope of a set of x -monotone curves in \mathbb{R}^2 , as given by the range $[begin, end)$. The upper envelope is represented using the output maximization diagram *diag*, which must be a model of the *EnvelopeDiagram_1* concept. *Precondition:* The value-type of *InputIterator* is *EnvelopeDiagram::X_monotone_curve_2*.

EnvelopeDiagram_1

Definition

This concept defines the representation of an envelope diagram of a set of planar curve. The *envelope diagram* is a subdivision of the x -axis into 0-dimensional cells (*vertices*) and 1-dimensional cells (*edges*), such that the identity of the curves that induce the lower envelope (or the upper envelope) over each cell is fixed.

A vertex in an envelope diagram is therefore associated with a point on the envelope, and corresponds to either a curve endpoint or to an intersection point of two (or more) curves. Therefore each vertex is associated with a set of x -monotone curves that induce the envelope over this point. Each vertex is incident to two edges, one lying to its left and the other to its right.

An edge in the envelope diagram represents a continuous portion of the x -axis, and is associated with a (possibly empty) set of curves that induce the envelope over this portion of the x -axis. An edge may be bounded by two vertices, one to its left and the other to its right. However, the diagram contains two unbounded edges, its *leftmost* edge, representing the interval $(-\infty, x_l)$, and its *rightmost* edge, representing the interval (x_r, ∞) , where x_l and x_r are the x -coordinates of the leftmost and the rightmost vertices in the diagram, respectively. Note that a diagram may contain no vertices at all, in which case it comprises a single edge.

Note that any model of the EnvelopeDiagram_1 concept must define a geometric traits class, which in turn defines the *Point_2* and *X_monotone_curve_2* types defined with the diagram features.

Types

<i>EnvelopeDiagram_1:: Traits_2</i>	the geometric traits class.
<i>typedef Traits_2:: Point_2</i>	
<i>Point_2;</i>	the point type.
<i>typedef Traits_2:: X_monotone_curve_2</i>	
<i>X_monotone_curve_2;</i>	the x -monotone curve type.
<i>EnvelopeDiagram_1:: Size</i>	the size type (convertible to <i>size_t</i>).
<i>EnvelopeDiagram_1:: Curve_const_iterator</i>	an iterator for the x -monotone curves that induce a diagram feature. Its value-type is <i>X_monotone_curve_2</i> .
<i>EnvelopeDiagram_1:: Vertex</i>	the vertex type, a model of the concept <i>EnvelopeDiagramVertex</i> .
<i>EnvelopeDiagram_1:: Edge</i>	the edge type, a model of the concept <i>EnvelopeDiagramEdge</i> .
<i>EnvelopeDiagram_1:: Vertex_handle</i>	a handle to a diagram vertex.
<i>EnvelopeDiagram_1:: Vertex_const_handle</i>	a non-mutable handle to a diagram vertex.

<i>EnvelopeDiagram_1:: Edge_handle</i>	a handle to a diagram edge.
<i>EnvelopeDiagram_1:: Edge_const_handle</i>	a non-mutable handle to a diagram edge.

Creation

<i>EnvelopeDiagram_1 diag;</i>	constructs an empty diagram containing one unbounded edge, which corresponds to the entire plane and has no x -monotone curves that are associated with it.
--------------------------------	---

<i>EnvelopeDiagram_1 diag(Self other);</i>	copy constructor.
---	-------------------

Access Functions

<i>Edge_const_handle</i>	<i>diag.leftmost()</i>	returns the leftmost edge of the diagram (a non-const version is also available).
--------------------------	------------------------	---

<i>Edge_const_handle</i>	<i>diag.rightmost()</i>	returns the rightmost edge of the diagram (a non-const version is also available).
--------------------------	-------------------------	--

Modifiers

<i>void</i>	<i>diag.set_leftmost(Edge_const_handle e)</i>	sets the leftmost edge of the diagram to be e .
-------------	--	---

<i>void</i>	<i>diag.set_rightmost(Edge_const_handle e)</i>	sets the rightmost edge of the diagram to be e .
-------------	---	--

<i>Vertex_handle</i>	<i>diag.new_vertex(Point_2 p)</i>	creates a new diagram vertex, associated with the point p .
----------------------	------------------------------------	---

<i>Edge_handle</i>	<i>diag.new_edge()</i>	creates a new diagram edge.
--------------------	------------------------	-----------------------------

<i>void</i>	<i>diag.delete_vertex(Vertex_handle v)</i>	deletes the given vertex v .
-------------	---	--------------------------------

<i>void</i>	<i>diag.delete_edge(Edge_handle e)</i>	deletes the given edge e .
-------------	---	------------------------------

EnvelopeDiagramVertex

Definition

A vertex record in an envelope diagram. It is always associated with a point on the lower (upper) envelope of a non-empty set of curves. A vertex is also associated with a set of x -monotone curves that induce the envelope over this point. It is incident to two edges, one lying to its left and the other to its right.

Types

<i>EnvelopeDiagramVertex:: Size</i>	the size type (convertible to <i>size_t</i>).
<i>EnvelopeDiagramVertex:: Edge</i>	the corresponding diagram-edge type.
<i>EnvelopeDiagramVertex:: Point_2</i>	the point type associated with the vertex.
<i>EnvelopeDiagramVertex:: X_monotone_curve_2</i>	the x -monotone curve type.

Creation

<i>EnvelopeDiagramVertex v;</i>	default constructor.
<i>EnvelopeDiagramVertex v(other);</i>	copy constructor.
<i>EnvelopeDiagramVertex v(Point_2 p);</i>	constructs a vertex associated with the given point p .

Access Functions

<i>Point_2</i>	<i>v.point()</i>	returns the point associated with v .
<i>Size</i>	<i>v.number_of_curves()</i>	returns the number of x -monotone curves associated with v .
<i>Curve_const_iterator</i>	<i>v.curves_begin()</i>	return an iterator for the first x -monotone curve associated with v .
<i>Curve_const_iterator</i>	<i>v.curves_end()</i>	return a past-the-end iterator for the x -monotone curves associated with v .
<i>Edge_const_handle</i>	<i>v.left()</i>	returns the edge lying to v 's left.
<i>Edge_const_handle</i>	<i>v.right()</i>	returns the edge lying to v 's right.

Modifiers

<i>void</i>	<i>v.set_point(Point_2 p)</i>	associates the point <i>p</i> with <i>v</i> .
<i>void</i>	<i>v.clear_curves()</i>	clears the set of curves associated with <i>v</i> .
<i>void</i>	<i>v.add_curve(X_monotone_curve_2 cv)</i>	adds the <i>x</i> -monotone curve <i>cv</i> to the set of curves associated with <i>v</i> .
<i>void</i>	<i>v.add_curves(Curve_const_iterator begin, Curve_const_iterator end)</i>	adds the given range of <i>x</i> -monotone curves to the set of curves associated with <i>v</i> .
<i>void</i>	<i>v.set_left(Edge_const_handle e)</i>	sets the edge lying to the left of <i>v</i> to be <i>e</i> .
<i>void</i>	<i>v.set_right(Edge_const_handle e)</i>	sets the edge lying to the right of <i>v</i> to be <i>e</i> .

EnvelopeDiagramEdge

Definition

An edge record in an envelope diagram, which represents a continuous portion of the x -axis. It is associated with a (possibly empty) set of curves that induce the envelope over this portion of the x -axis. Note that all curves in this set overlap over the interval represented by the edge.

Types

<i>EnvelopeDiagramEdge:: Size</i>	the size type (convertible to <i>size_t</i>).
<i>EnvelopeDiagramEdge:: Vertex</i>	the corresponding diagram-vertex type.
<i>EnvelopeDiagramEdge:: X_monotone_curve_2</i>	the x -monotone curve type.

Creation

<i>EnvelopeDiagramEdge e;</i>	default constructor.
<i>EnvelopeDiagramEdge e(other);</i>	copy constructor.

Access Functions

<i>Size</i>	<i>e.number_of_curves()</i>	returns the number of x -monotone curves associated with e .
<i>bool</i>	<i>e.is_empty()</i>	returns whether e represents an empty interval — namely, whether the set of x -monotone curves associated with it is empty.
<i>X_monotone_curve_2</i>	<i>e.curve()</i>	returns a representative x -monotone curve associated with e . <i>Precondition:</i> e does not represent an empty interval.
<i>Curve_const_iterator</i>	<i>e.curves_begin()</i>	return an iterator for the first x -monotone curve associated with e .
<i>Curve_const_iterator</i>	<i>e.curves_end()</i>	return a past-the-end iterator for the x -monotone curves associated with e .
<i>Vertex_const_handle</i>	<i>e.left()</i>	returns the vertex lying to e 's left. <i>Precondition:</i> e is not the leftmost edge in the diagram.
<i>Vertex_const_handle</i>	<i>e.right()</i>	returns the vertex lying to e 's right. <i>Precondition:</i> e is not the rightmost edge in the diagram.

Modifiers

<i>void</i>	<i>e.clear_curves()</i>	clears the set of curves associated with <i>e</i> .
<i>void</i>	<i>e.add_curve(X_monotone_curve_2 cv)</i>	
		adds the <i>x</i> -monotone curve <i>cv</i> to the set of curves associated with <i>e</i> .
<i>void</i>	<i>e.add_curves(Curve_const_iterator begin, Curve_const_iterator end)</i>	
		adds the given range of <i>x</i> -monotone curves to the set of curves associated with <i>e</i> .
<i>void</i>	<i>e.set_left(Vertex_const_handle v)</i>	
		sets the vertex lying to the left of <i>e</i> to be <i>v</i> .
<i>void</i>	<i>e.set_right(Vertex_const_handle v)</i>	
		sets the vertex lying to the right of <i>e</i> to be <i>v</i> .

CGAL::Env_default_diagram_1<Traits>

Definition

This class is the default envelope-diagram class used by envelope functions to represent the minimization or the maximization diagram of a set of curves. It represents the diagram as a doubly-linked list of interleaved vertices and edges. Thus, all operations provided by the envelope diagram take constant time, and the space needed to store the diagram class is linear in the complexity of the envelope.

The envelope-diagram class is parameterized by a traits class, which is a model of the *ArrangementXMonotoneTraits_2* concept, in case we handle only envelopes of *x*-monotone curves, or of the refined *ArrangementTraits_2* concept in case we handle arbitrary planar curves.

24.1 Introduction

A continuous surface S in \mathbb{R}^3 is called *xy-monotone*, if every line parallel to the z -axis intersects it at a single point at most. For example, the sphere $x^2 + y^2 + z^2 = 1$ is *not* *xy-monotone* as the z -axis intersects it at $(0, 0, -1)$ and at $(0, 0, 1)$; however, if we use the xy -plane to split it to an upper hemisphere and a lower hemisphere, these two hemispheres are *xy-monotone*.

An *xy-monotone* surface can therefore be represented as a bivariate function $z = S(x, y)$, defined over some continuous range $R_S \subseteq \mathbb{R}^2$. Given a set $\mathcal{S} = \{S_1, S_2, \dots, S_n\}$ of *xy-monotone* surfaces, their *lower envelope* is defined as the point-wise minimum of all surfaces. Namely, the lower envelope of the set \mathcal{S} can be defined as the following function:

$$\mathcal{L}_{\mathcal{S}}(x, y) = \min_{1 \leq k \leq n} \bar{S}_k(x, y) ,$$

where we define $\bar{S}_k(x, y) = S_k(x, y)$ for $(x, y) \in R_{S_k}$, and $\bar{S}_k(x, y) = \infty$ otherwise.

Similarly, the *upper envelope* of \mathcal{S} is the point-wise maximum of the *xy-monotone* surfaces in the set:

$$\mathcal{U}_{\mathcal{S}}(x, y) = \max_{1 \leq k \leq n} \underline{S}_k(x, y) ,$$

where in this case $\underline{S}_k(x, y) = -\infty$ for $(x, y) \notin R_{S_k}$.

Given a set of *xy-monotone* surfaces \mathcal{S} , the *minimization diagram* of \mathcal{S} is a subdivision of the xy -plane into cells, such that the identity of the surfaces that induce the lower diagram over a specific cell of the subdivision (be it a

Figure 24.1: (a) The spheres S_1 and S_2 have only one two-dimensional point p in their common xy -definition range. They do not necessarily intersect over this point, and the envelope-construction algorithm needs to determine their relative z -order over p . (b) The z -order of the surfaces S_1 and S_2 should be determined over the x -monotone curve c . The comparison is performed over the *interior* of c , excluding its endpoints.

face, an edge, or a vertex) is the same. In non-degenerate situation, a face is induced by a single surface (or by no surfaces at all, if there are no xy -monotone surfaces defined over it), an edge is induced by a single surface and corresponds to its projected boundary, or by two surfaces and corresponds to their projected intersection curve, and a vertex is induced by a single surface and corresponds to its projected boundary point, or by three surfaces and corresponds to their projected intersection point. The *maximization diagram* is symmetrically defined for upper envelopes. In the rest of this chapter, we refer to both these diagrams as *envelope diagrams*.

It is easy to see that an envelope diagram is no more than a planar arrangement (see Chapter 20), represented using an extended DCEL structure, such that every DCEL record (namely each face, halfedge and vertex) stores an additional container of its originators: the xy -monotone surfaces that induce this feature.

Lower and upper envelopes can be efficiently computed using a divide-and-conquer approach. First note that the envelope diagram for a single xy -monotone curve S_k is trivial to compute: we project the boundary of its range of definition R_{S_k} onto the xy -plane, and label the faces it induces accordingly. Given a set \mathcal{D} of (non necessarily xy -monotone) surfaces in \mathbb{R}^3 , we subdivide each surface into a finite number of weakly xy -monotone surfaces,¹ and obtain the set \mathcal{S} . Then, we split the set into two disjoint subsets S_1 and S_2 , and we compute their envelope diagrams recursively. Finally, we merge the diagrams, and we do this by overlaying them and then applying some post-processing on the resulting diagram. The post-processing stage is non-trivial and involves the projection of intersection curves onto the xy -plane — see [Mey06] for more details.

24.2 The Envelope-Traits Concept

The implementation of the envelope-computation algorithm is generic and can handle arbitrary surfaces. It is parameterized with a traits class, which defines the geometry of surfaces it handles, and supports all the necessary functionality on these surfaces, and on their projections onto the xy -plane. The traits class must model the *EnvelopeTraits_3* concept, the details of which are given below.

As the representation of envelope diagrams is based on 2D arrangements, and the envelop-computation algorithm employs overlay of planar arrangements, the *EnvelopeTraits_3* refines the *ArrangementXMonotoneTraits_2* concept. Namely, a model of this concept must define the planar types *Point_2* and *X_monotone_curve_2* and support basic operations on them, as listed in Section 20.6. Moreover, it must define the spacial types *Surface_3* and *Xy_monotone_surface_3* (in practice, these two types may be the same). Any model of the envelope-traits concept must also support the following operations on these spacial types:

¹We consider *vertical* surfaces, namely patches of planes that are perpendicular to the xy -plane, as *weakly* xy -monotone, to handle degenerate inputs properly.

- Subdivide a given surface into continuous xy -monotone surfaces. It is possible to disregard xy -monotone surfaces that do not contribute to the surface envelope at this stage (for example, if we are given a sphere, it is possible to return just its lower hemisphere if we are interested in the lower envelope; the upper hemisphere is obviously redundant).
- Given an xy -monotone surface S , construct all planar curves that form the boundary of the vertical projection S 's boundary onto the xy -plane.

This operation is used at the bottom of the recursion to build the minimization diagram of a single xy -monotone surface.

- Construct all geometric entities that comprise the projection (onto the xy -plane) of the intersection between two xy -monotone surfaces S_1 and S_2 . These entities may be:
 - A planar curve, which is the projection of an 3D intersection curve of S_1 and S_2 (for example, the intersection curve between two spheres is a 3D circle, which becomes an ellipse when projected onto the xy -plane). In many cases it is also possible to indicate the multiplicity of the intersection: if it is odd, the two surfaces intersect transversely and change their relative z -positions on either side of the intersection curve; if it the multiplicity is even, they maintain their relative z -position. Providing the multiplicity information is optional. When provided, it is used by the algorithm to determine the relative order of S_1 and S_2 on one side of their intersection curve when their order on the other side of that curve is known, thus improving the performance of the algorithm.
 - A point, induces by the projection of a tangency point of S_1 and S_2 , *or* by the projection of a vertical intersection curve onto the xy -plane.

Needless to say, the set of intersection entities may be empty in case S_1 and S_2 do not intersect.

- Given two xy -monotone surfaces S_1 and S_2 , and a planar point $p = (x_0, y_0)$ that lies in their common xy -definition range, determine the z -order of S_1 and S_2 over p , namely compare $S_1(x_0, y_0)$ and $S_2(x_0, y_0)$. This operation is used only in degenerate situations, in order to determine the surface inducing the envelope over a vertex (see Figure 24.1(a) for an illustration of a situation when this operation is used).
- Given two xy -monotone surfaces S_1 and S_2 , and a planar x -monotone curve c , which is a part of their projected intersection, determine the z -order of S_1 and S_2 immediately above (or, similarly, immediately below) the curve c . Note that c is a planar x -monotone curve, and we refer to the region above (or below) it in the *plane*. If c is a vertical curve, we regard the region to its left as lying above it, and the region to its right as lying below it.

This operation is used by the algorithm to determine the surface that induce the envelope over a face incident to c .

- Given two xy -monotone surfaces S_1 and S_2 , and a planar x -monotone curve c , which fully lies in their common xy -definition range, and such that S_1 and S_2 do not intersect over the interior of c , determine the relative z -order of s_1 and s_2 over the interior of c . Namely, we compare $S_1(x_0, y_0)$ and $S_2(x_0, y_0)$ for some point (x_0, y_0) on c .

This operation is used by the algorithm to determine which surface induce the envelope over an edge associated with the x -monotone curve c , or of a face incident to c , in situations where the previous predicate cannot be used, as c is *not* an intersection curve of S_1 and S_2 (see Figure 24.1(b) for an illustration of a situation where this operation is used).

The package currently contains a traits class for named *Env_triangle_traits_3*<Kenrel> handling 3D triangles, and another named *Env_sphere_traits_3*<ConicTraits> for 3D spheres, based on geometric operations on conic curves (ellipses). In addition, the package includes a traits-class decorator that enables users to attach external (non-geometric) data to surfaces. The usage of the various traits classes is demonstrated in the next section.

Figure 24.2: (a) Two triangles in \mathbb{R}^3 , as given in *ex_envelope_triangles.cpp*. (b) Their lower envelope. (c) Their upper envelope.

24.3 Examples

24.3.1 Example for Envelope of Triangles

The following example shows how to use the `envelope-traits` class for 3D triangles and how to traverse the envelope diagram. It constructs the lower and upper envelopes of the two triangles, as depicted in Figure 24.2(a) and prints the triangles that induce each face and each edge in the output diagrams. For convenience, we use the traits-class decorator `Env_surface_data_traits_3` to label the triangles. When printing the diagrams, we just output the labels of the triangles:

```
#include <CGAL/Gmpq.h>
#include <CGAL/Cartesian.h>
#include <CGAL/Env_triangle_traits_3.h>
#include <CGAL/Env_surface_data_traits_3.h>
#include <CGAL/envelope_3.h>
#include <iostream>
#include <list>

typedef CGAL::Gmpq                               Number_type;
typedef CGAL::Cartesian<Number_type>              Kernel;
typedef CGAL::Env_triangle_traits_3<Kernel>        Traits_3;
typedef Kernel::Point_3                           Point_3;
typedef Traits_3::Surface_3                        Triangle_3;
typedef CGAL::Env_surface_data_traits_3<Traits_3, char> Data_traits_3;
typedef Data_traits_3::Surface_3                   Data_triangle_3;
typedef CGAL::Envelope_diagram_2<Data_traits_3>    Envelope_diagram_2;

/* Auxiliary function - print the features of the given envelope diagram. */
void print_diagram (const Envelope_diagram_2& diag)
{
    // Go over all arrangement faces.
    Envelope_diagram_2::Face_const_iterator    fit;
    Envelope_diagram_2::Ccb_halfedge_const_circulator ccb;
    Envelope_diagram_2::Surface_const_iterator sit;
}
```

```

for (fit = diag.faces_begin(); fit != diag.faces_end(); ++fit)
{
    // Print the face boundary.
    if (fit->is_unbounded())
    {
        std::cout << "[Unbounded face]";
    }
    else
    {
        // Print the vertices along the outer boundary of the face.
        ccb = fit->outer_ccb();
        std::cout << "[Face]  ";
        do
        {
            std::cout << '(' << ccb->target()->point() << "  ";
            ++ccb;
        } while (ccb != fit->outer_ccb());
    }

    // Print the labels of the triangles that induce the envelope on this face.
    std::cout << "-->  " << fit->number_of_surfaces()
               << " triangles:";

    for (sit = fit->surfaces_begin(); sit != fit->surfaces_end(); ++sit)
        std::cout << ' ' << sit->data();
    std::cout << std::endl;
}

// Go over all arrangement edges.
Envelope_diagram_2::Edge_const_iterator      eit;

for (eit = diag.edges_begin(); eit != diag.edges_end(); ++eit)
{
    // Print the labels of the triangles that induce the envelope on this edge.
    std::cout << "[Edge]  (" << eit->source()->point()
               << "  (" << eit->target()->point()
               << "  -->  " << eit->number_of_surfaces()
               << " triangles:";

    for (sit = eit->surfaces_begin(); sit != eit->surfaces_end(); ++sit)
        std::cout << ' ' << sit->data();
    std::cout << std::endl;
}

return;
}

/* The main program: */
int main ()
{
    // Construct the input triangles, makred A and B.
    std::list<Data_triangle_3>  triangles;

    triangles.push_back (Data_triangle_3 (Triangle_3 (Point_3 (0, 0, 0),

```

```

Point_3 (0, 6, 0),
Point_3 (5, 3, 4)),
        'A'));
triangles.push_back (Data_triangle_3 (Triangle_3 (Point_3 (6, 0, 0),
Point_3 (6, 6, 0),
Point_3 (1, 3, 4)),
        'B'));

// Compute and print the minimization diagram.
Envelope_diagram_2      min_diag;

CGAL::lower_envelope_3 (triangles.begin(), triangles.end(),
                        min_diag);

std::cout << std::endl << "The minimization diagram:" << std::endl;
print_diagram (min_diag);

// Compute and print the maximization diagram.
Envelope_diagram_2      max_diag;

CGAL::upper_envelope_3 (triangles.begin(), triangles.end(),
                        max_diag);

std::cout << std::endl << "The maximization diagram:" << std::endl;
print_diagram (max_diag);

return (0);
}

```

24.3.2 Example for Envelope of Spheres

The next example demonstrates how to instantiate and use the envelope-traits class for spheres, based on the *Arr_conic_traits_2* class that handles the projected intersection curves. The program reads a set of spheres from an input file and constructs their lower envelope:

```

#include <CGAL/basic.h>

#ifndef CGAL_USE_CORE
#include <iostream>
int main()
{
    std::cout << "Sorry, this example needs CORE ..." << std::endl;
    return 0;
}
#else

#include <CGAL/Cartesian.h>
#include <CGAL/CORE_algebraic_number_traits.h>
#include <CGAL/Arr_conic_traits_2.h>

```

```

#include <CGAL/Env_sphere_traits_3.h>
#include <CGAL/envelope_3.h>
#include <CGAL/Timer.h>
#include <iostream>
#include <list>

typedef CGAL::CORE_algebraic_number_traits      Nt_traits;
typedef Nt_traits::Rational                    Rational;
typedef Nt_traits::Algebraic                   Algebraic;
typedef CGAL::Cartesian<Rational>              Rat_kernel;
typedef Rat_kernel::Point_3                    Rat_point_3;
typedef CGAL::Cartesian<Algebraic>             Alg_kernel;

typedef CGAL::Arr_conic_traits_2<Rat_kernel, Alg_kernel, Nt_traits>
                                                Conic_traits_2;

typedef CGAL::Env_sphere_traits_3<Conic_traits_2> Traits_3;
typedef Traits_3::Surface_3                     Sphere_3;
typedef CGAL::Envelope_diagram_2<Traits_3>       Envelope_diagram_2;

int main(int argc, char **argv)
{
    // Get the name of the input file from the command line, or use the default
    // fan_grids.dat file if no command-line parameters are given.
    const char * filename = (argc > 1) ? argv[1] : "spheres.dat";

    // Open the input file.
    std::ifstream      in_file(filename);

    if (! in_file.is_open())
    {
        std::cerr << "Failed to open " << filename << " ..." << std::endl;
        return 1;
    }

    // Read the spheres from the file.
    // The input file format should be (all coordinate values are integers):
    // <n>                                // number of spheres.
    // <x_1> <y_1> <x_1> <R_1>            // center and squared radius of sphere #1.
    // <x_2> <y_2> <x_2> <R_2>            // center and squared radius of sphere #2.
    //   :   :   :   :
    // <x_n> <y_n> <x_n> <R_n>            // center and squared radius of sphere #n.
    int      n;
    std::list<Sphere_3>  spheres;
    int      x, y, z, sqr_r;
    int      i;

    in_file >> n;
    for (i = 0; i < n; ++i)
    {
        in_file >> x >> y >> z >> sqr_r;
        spheres.push_back(Sphere_3(Rat_point_3(x, y, z), Rational(sqr_r)));
    }
    in_file.close();
}

```

```

// Compute the lower envelope.
Envelope_diagram_2    min_diag;
CGAL::Timer           timer;

std::cout << "Constructing the lower envelope of "
            << n << " spheres." << std::endl;

timer.start();
CGAL::lower_envelope_3(spheres.begin(), spheres.end(), min_diag);
timer.stop();

// Print the dimensions of the minimization diagram.
std::cout << "V = " << min_diag.number_of_vertices()
            << ", E = " << min_diag.number_of_edges()
            << ", F = " << min_diag.number_of_faces() << std::endl;

std::cout << "Construction took " << timer.time()
            << " seconds." << std::endl;

return 0;
}

#endif

```

File: examples/Envelope_3/ex_envelope_spheres.cpp

24.3.3 Example for Envelope of Planes

The next example demonstrates how to instantiate and use the envelope-traits class for planes, based on the *Arr_linear_traits_2* class that handles infinite linear objects such as lines and rays.

```

#include <CGAL/Gmpq.h>

Envelopes of Surfaces in 3D

Reference Manual

Michal Meyerovitch, Ron Wein and Baruch Zukerman

Introduction

This package consists of functions that compute the lower (or upper) envelope of a set of arbitrary surfaces in 3D. The output is represented as an 2D envelope diagram — a planar subdivision such that the identity of the surfaces that induce the envelope over each diagram cell is unique.

CGAL::lower_envelope_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>  
void lower_envelope_3( InputIterator begin,  
                      InputIterator end,  
                      Envelope_diagram_2<Traits>& diag)
```

Computes the lower envelope of a set of surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Surface_3*.

CGAL::upper_envelope_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>  
void          upper_envelope_3( InputIterator begin,  
                                InputIterator end,  
                                Envelope_diagram_2<Traits>& diag)
```

Computes the upper envelope of a set of surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The upper envelope is represented using the output maximization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Surface_3*.

CGAL::lower_envelope_xy_monotone_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>
```

```
void lower_envelope_xy_monotone_3( InputIterator begin,  
                                   InputIterator end,  
                                   Envelope_diagram_2<Traits>& diag)
```

Computes the lower envelope of a set of *xy*-monotone surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The lower envelope is represented using the output minimization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Xy_monotone_surface_3*.

CGAL::upper_envelope_xy_monotone_3

```
#include <CGAL/envelope_3.h>
```

```
template<class InputIterator, class Traits>
```

```
void          upper_envelope_xy_monotone_3( InputIterator begin,
                                             InputIterator end,
                                             Envelope_diagram_2<Traits>& diag)
```

Computes the upper envelope of a set of *xy*-monotone surfaces in \mathbb{R}^3 , as given by the range $[begin, end)$. The lower envelope is represented using the output maximization diagram *diag*.

Precondition: The value-type of *InputIterator* is *Traits::Xy_monotone_surface_3*.

EnvelopeTraits_3

Definition

This concept defines the minimal set of geometric predicates and operations needed to compute the envelope of a set of arbitrary surfaces in \mathbb{R}^3 . It refines the *ArrangementXMonotoneTraits_2* concept. In addition to the *Point_2* and *X_monotone_curve_2* types and the *Has_boundary_category* category tag listed in the base concept, it also lists the *Surface_3* and *Xy_monotone_surface_3* types, which represent arbitrary surfaces and *xy*-monotone surfaces, respectively, and some constructions and predicates on these types. Note however, that these operations usually involve the projection of 3D objects onto the *xy*-plane.

Refines

ArrangementXMonotoneTraits_2

Types

<i>EnvelopeTraits_3:: Surface_3</i>	represents an arbitrary surface in \mathbb{R}^3 .
<i>EnvelopeTraits_3:: Xy_monotone_surface_3</i>	represents a weakly <i>xy</i> -monotone surface in \mathbb{R}^3 .

Functor Types

EnvelopeTraits_3:: Make_xy_monotone_3

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator()* (*Surface_3 S*, *bool is_lower*, *OutputIterator oi*)
which subdivides the given surface *S* into *xy*-monotone parts and inserts them into the output iterator. The value of *is_lower* indicates whether we compute the lower or the upper envelope, so that *xy*-monotone surfaces that are irrelevant to the lower-envelope (resp. upper-envelope) computation may be discarded. The value-type of *OutputIterator* is *Xy_monotone_surface_3*. The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Construct_projected_boundary_2

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator()* (*Xy_monotone_surface_3 s*, *OutputIterator oi*)
which computes all planar *x*-monotone curves and possibly isolated planar points that form the projection of the boundary of the given *xy*-monotone surface *s* onto the *xy*-plane, and inserts them into the output iterator. The value-type of *OutputIterator* is *Object*, where *Object* wraps either a *Point_2*, or a *pair*<*X_monotone_curve_2*, *Oriented_side*>. In the former case, the object represents an isolated point of the projected boundary. In the latter, more general, case the object represents an *x*-monotone boundary curve along with an enumeration value which is either *ON_NEGATIVE_SIDE* or *ON_POSITIVE_SIDE*, indicating whether the projection of the surface onto the *xy*-plane lies below or above this *x*-monotone curve, respectively. In degenerate case, namely when the surface itself is vertical, and its projection onto the plane is 1-dimensional, the *Oriented_side* value is *ON_ORIENTED_BOUNDARY*. The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Construct_projected_intersections_2

provides the operator (templated by the *OutputIterator* type) :

- *OutputIterator operator()* (*Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*, *OutputIterator* *oi*)
which computes the projection of the intersections of the *xy*-monotone surfaces *s1* and *s2* onto the *xy*-plane, and inserts them into the output iterator. The value-type of *OutputIterator* is *Object*, where each *Object* either wraps a *pair<X_monotone_curve_2, Multiplicity>* instance, which represents a projected intersection curve with its multiplicity (in case the multiplicity is undefined or not known, it should be set to 0) or an *Point_2* instance, representing the projected image of a degenerate intersection (the projection of an isolated intersection point, or of a vertical intersection curve). The operator returns a past-the-end iterator for the output sequence.

EnvelopeTraits_3:: Compare_z_at_xy_3

provides the operators :

- *Comparison_result operator()* (*Point_2* *p*, *Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces at the *xy*-coordinates of the point *p*, with the precondition that both surfaces are defined over *p*. Namely, it returns the comparison result of $s_1(p)$ and $s_2(p)$.
- *Comparison_result operator()* (*X_monotone_curve_2* *c*, *Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces over the interior of a given *x*-monotone curve *c*, with the precondition that *c* is fully contained in the *xy*-definition range of both *s1* and *s2*, and that the surfaces do not intersect over *c*. The functor should therefore return the comparison result of $s_1(p')$ and $s_2(p')$ for some point p' in the interior of *c*.
- *Comparison_result operator()* (*Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given unbounded *xy*-monotone surfaces, which are defined over the entire *xy*-plane and have no boundary, with the precondition that the surfaces do not intersect at all. The functor should therefore return the comparison result of $s_1(p)$ and $s_2(p)$ for some planar point $p \in \mathbb{R}^2$. This operator is required iff the category tag *Has_boundary_category* is defined as *Tag_true*.

EnvelopeTraits_3:: Compare_z_at_xy_above_3

provides the operator :

- *Comparison_result operator()* (*X_monotone_curve_2* *c*, *Xy_monotone_surface_3* *s1*, *Xy_monotone_surface_3* *s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces immediately above their projected intersection curve *c* (a planar point *p* is *above* an *x*-monotone curve *c* if it is in the *x*-range of *c*, and lies to its left when the curve is traversed from its *xy*-lexicographically smaller endpoint to its larger endpoint). We have the precondition that both surfaces are defined “above” *c*, and their relative *z*-order is the same for some small enough neighborhood of points above *c*.

EnvelopeTraits_3:: Compare_z_at_xy_below_3

provides the operator :

- *Comparison_result operator()* (*X_monotone_curve_2 c*, *Xy_monotone_surface_3 s1*, *Xy_monotone_surface_3 s2*)
which determines the relative *z*-order of the two given *xy*-monotone surfaces immediately below their projected intersection curve *c* (a planar point *p* is *below* an *x*-monotone curve *c* if it is in the *x*-range of *c*, and lies to its right when the curve is traversed from its *xy*-lexicographically smaller endpoint to its larger endpoint). We have the precondition that both surfaces are defined “below” *c*, and their relative *z*-order is the same for some small enough neighborhood of points below *c*.

CGAL::Env_surface_data_traits_3<Traits,XyData,SData,Cnv>

CGAL::Env_triangle_traits_3<Kernel>

Definition

The traits class *Env_triangle_traits_3<Kernel>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of triangles in the space. It is parameterized by a CGAL-kernel, which is parameterized in turn by a number type. The number type should support exact rational arithmetic, to avoid numerical errors and robustness problems. In particular, the number type should support the arithmetic operations $+$, $-$, \times , and \div without loss of precision. For optimal performance, we recommend instantiating the traits class with the predefined *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Note that when we project the boundary of a triangle, or the intersection of two triangles, onto the *xy*-plane, we obtain line segments. Indeed, *Env_triangle_traits_3<Kernel>* inherits from the *Arr_segment_traits_2<Kernel>* traits class, and extends it by adding operations on 3D objects, namely spacial triangles. Note that the traits class does *not* define *Kernel::Triangle_3* as its surface (and *xy*-monotone surface) type, as one may expect. This is because the traits class needs to store extra data with the triangles in order to efficiently operate on them. Nevertheless, the nested *Xy_monotone_surface_3* and *Surface_3* types are however constructible from a *Kernel::Triangle_3* instance and are also convertible to a *Kernel::Triangle_3* object. Both types, *Xy_monotone_surface_3* and *Surface_3*, refer to the same class, as every triangle is (weakly) *xy*-monotone).

```
#include <CGAL/Env_triangle_traits_3.h>
```

EnvelopeTraits_3

Inherits From

Arr_segment_traits_2<Kernel>

CGAL::Env_sphere_traits_3<ConicTraits>

Definition

The traits class *Env_sphere_traits_3<ConicTraits>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of spheres. Note that when projecting the intersection curve of two spheres (a circle in 3D) onto the *xy*-plane, the resulting curve is an ellipse. The traits class is therefore parameterized by an arrangement-traits class that is capable of handling conic curves — namely an instantiation of the *Arr_conic_traits_2* class-template — and inherits from it.

The conic-traits class defines a nested type named *Rat_kernel*, which is a geometric kernel parameterized by an exact rational type. *Env_sphere_traits_3<ConicTraits>* defines its *Surface_3* type to be constructible from *Rat_kernel::Sphere_3*. Namely, it can handle spheres whose center points have rational coordinates (i.e., of the type *Rat_kernel::FT*), and whose squared radius is also rational. The *Surface_3* type is also convertible to a *Rat_kernel::Sphere_3* object.

The *Xy_monotone_surface_3* type is the same as the nested *Surface_3* type. The traits-class simply ignores the upper hemisphere when it computes lower envelopes, and ignores the lower hemisphere when it computes upper envelopes.

```
#include <CGAL/Env_sphere_traits_3.h>
```

CGAL::Env_surface_data_traits_3<Traits,XyData,SData,Cnv>

Definition

The class *Env_surface_data_traits_3*<*Traits*,*XyData*,*SData*,*Cnv*> is a model of the *EnvelopeTraits_3* concept and serves as a decorator class that allows the extension of the surfaces defined by the base traits-class (the *Traits* parameter), which serves as a geometric traits-class (a model of the *EnvelopeTraits_3* concept), with extraneous (non-geometric) data fields.

The traits-class decorator extends the *Surface_3* and the *Xy_monotone_surface_3* types as detailed below. Each *Surface_3* object is associated with a single data field of type *SData*, and each *Xy_monotone_surface_3* object is associated with a single data field of type *XyData*. When a surface is subdivided into *xy*-monotone surfaces, its data field is converted using the conversion functor, which is specified by the *Cnv* template-parameter, and the resulting objects is copied to all *Xy_monotone_surface_3* objects induced by this surface. The conversion functor should provide an operator with the following prototype:

XyData operator() (*const SData& d*) *const*;

By default, the two data types are the same, so the conversion operator is trivial and just copies the data object:

SData = *XyData*

Cnv = *_Default_convert_functor*<*SData*,*XyData*>

#include <*CGAL/Env_surface_data_traits_3.h*>

Is Model for the Concepts

Types

typedef Traits *Base_traits_3*; the base traits-class.

typedef typename Base_traits_3::Surface_3

Base_surface_3; the base surface.

typedef typename Base_traits_3::Xy_monotone_surface_3

Base_xy_monotone_surface_3;

the base *xy*-monotone surface surface.

typedef Cnv *Convert*; the conversion functor.

typedef SData *Surface_data*; the type of data associated with surfaces.

typedef XyData *Xy_monotone_surface_data*;

the type of data associated with *xy*-monotone surfaces.

Inherits From

Base_traits_3

Class **Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3**

The *Surface_3* class nested within the surface-data traits extends the *Base_traits_3::Surface_3* type with an extra data field.

Inherits From

Base_surface_3

Creation

Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3 s;

default constructor.

Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3 s(Base_surface_3 base);

constructs surface from the given *base* surface with uninitialized data field.

*Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Surface_3 s(Base_surface_3 base,
Surface_data data)*

constructs surface from the given *base* surface with an attached *data* field.

Access Functions

<i>Surface_data</i>	<i>s.data()</i>	returns the data field (a non-const version, which returns a reference to the data object, is also available).
---------------------	-----------------	--

<i>void</i>	<i>s.set_data(Surface_data data)</i>	sets the data field.
-------------	---------------------------------------	----------------------

Class **Env_surface_data_traits_3<Traits,XyData,SData,Cnv>::Xy_monotone_surface_3**

The *Xy_monotone_surface_3* class nested within the surface-data traits extends the *Base_traits_3::Xy_monotone_surface_3* type with an extra data field.

Inherits From

Base_xy_monotone_surface_3

Creation

Arr_surface_data_traits_3<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*>::*Xy_monotone_surface_3* *xys*;

default constructor.

Arr_surface_data_traits_3<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*>::*Xy_monotone_surface_3* *xys*(*Base_xy_monotone_surface_3* *base*)

constructs an *xy*-monotone surface from the given *base* surface with uninitialized data field.

Arr_surface_data_traits_3<*Tr*,*XData*,*Mrg*,*CData*,*Cnv*>::*Xy_monotone_surface_3* *xys*(*Base_xy_monotone_surface_3* *base*,
Xy_monotone_surface_data *data* *data*)

constructs an *x*-monotone surface from the given *base* *x*-monotone surface with an attached *data* field.

Access Functions

Xy_monotone_surface_data

xys.data()

returns the field (a non-const version, which returns a reference to the data object, is also available).

void

xys.set_data(*Xy_monotone_surface_data* *data*)

sets the data field.

CGAL::Env_plane_traits_3<Kernel>

Definition

The traits class *Env_plane_traits_3<Kernel>* models the *EnvelopeTraits_3* concept, and is used for the construction of lower and upper envelopes of planes and half planes in the space. It is parameterized by a CGAL-kernel model, which is parameterized in turn by a number type. The number type should support exact rational arithmetic, to avoid numerical errors and robustness problems. In particular, the number type should support the arithmetic operations $+$, $-$, \times , and \div without loss of precision. For optimal performance, we recommend instantiating the traits class with the predefined *Exact_predicates_exact_constructions_kernel* provided by CGAL. Using this kernel guarantees exactness and robustness, while it incurs only a minor overhead (in comparison to working with a fast, inexact number type) for most inputs.

Note that an entire plane has no boundaries, and the projection of a half-plane is an (unbounded) line. Naturally, rays and segments may occur as a result of overlaying projections of several half planes. Indeed, *Env_plane_traits_3<Kernel>* inherits from the *Arr_linear_traits_2<Kernel>* traits class, and extends it by adding operations on planes and half planes. The nested *Xy_monotone_surface_3* and *Surface_3* types refer to the same type. They are constructible from a *Kernel::Plane_3* in case of an entire plane, or from *Kernel::Plane_3* and *Kernel::Line_2* in case of a half-plane. The line orientation determines which half is considered.

```
#include <CGAL/Env_plane_traits_3.h>
```

Inherits From

Arr_linear_traits_2<Kernel>

CGAL::Envelope_diagram_2<EnvTraits>

Definition

The class-template *Envelope_diagram_2<EnvTraits>* represents the minimization diagram that corresponds to the lower envelope of a set of curves, or the maximization diagram that corresponds to their upper envelope. It is parameterized by a traits class that must be a model of the *EnvelopeTraits_3* concept, and is basically a planar arrangement of *x*-monotone curves, as defined by this traits class. These *x*-monotone curves are the projections of boundary curves of *xy*-monotone surfaces, or the intersection curves between such surfaces, onto the *xy*-plane. Thus, it is possible to traverse the envelope diagram using the methods inherited from the *Arrangement_2* class.

The envelope diagram extends the arrangement features (namely the vertices, halfedges, and faces), such that each feature stores a container of originators — namely, the *xy*-monotone surfaces (instances of the type *EnvTraits::Xy_monotone_surface_3*) that induce the lower envelope (or the upper envelope, in case of a maximization diagram) over this feature. The envelope diagram provides access methods to these originators.

```
#include <CGAL/envelope_3.h>
```

Inherits From

```
Arrangement_2<EnvTraits>
```

Types

```
typedef Envelope_diagram_2<EnvTraits>
```

```
    Self;
typedef Arrangement_2<EnvTraits>
```

```
    Base;
```

```
Envelope_diagram_2<EnvTraits>:: Surface_const_iterator
```

an iterator for the *xy*-monotone surfaces that induce a diagram feature. Its value-type is *EnvTraits::Xy_monotone_surface_3*.

Creation

```
Envelope_diagram_2<EnvTraits> diag;
```

constructs an empty diagram containing one unbounded face, which corresponds to the entire plane and has no originators.

```
Envelope_diagram_2<EnvTraits> diag( Self other);
```

copy constructor.

Envelope_diagram_2<EnvTraits> *diag*(*EnvTraits* **traits*);

constructs an empty diagram that uses the given *traits* instance for performing the geometric predicates.

Class *Envelope_diagram_2*<EnvTraits>::Vertex

Inherits From

Base::*Vertex*

Access Functions

size_t *v.number_of_surfaces()*

returns the number of *xy*-monotone surfaces that induce *v*.

Surface_const_iterator

v.surfaces_begin()

returns an iterator for the first *xy*-monotone surface that induces *v*.

Surface_const_iterator

v.surfaces_end()

returns a past-the-end iterator for the *xy*-monotone surfaces that induce *v*.

Xy_monotone_surface_3

v.surface()

returns the first *xy*-monotone surface that induce *v*.

Precondition: The number of surfaces is not 0.

Class *Envelope_diagram_2*<EnvTraits>::Halfedge

Inherits From

Base::*Halfedge*

Access Functions

This chapter describes the two dimensional triangulations of CGAL. Section 25.1 recalls the main definitions about triangulations. Sections 25.2 discusses the way two-dimensional triangulations are represented in CGAL. Section 25.3 presents the overall software design of the 2D triangulations package. The next sections present the different two dimensional triangulations classes available in CGAL: basic triangulations (section 25.4), Delaunay triangulations (Section 25.5), regular triangulations (Section 25.6), constrained triangulations (Section 25.7), and constrained Delaunay triangulations (Section 25.8). Section 25.9 describes a class which implements a constrained or constrained Delaunay triangulation with an additional data structure to describe how the constraints are refined by the edges of the triangulations. Section 25.10 describes a hierarchical data structure for fast point location queries. At last, Section 25.11 explains how the user can benefit from the flexibility of CGAL triangulations using customized classes for faces and vertices.

25.1 Definitions

A two dimensional triangulation can be roughly described as a set T of triangular facets such that :

- two facets either are disjoint or share a lower dimensional face (edge or vertex).
- the set of facets in T is connected for the adjacency relation.
- the domain U_T which is the union of facets in T has no singularity.

More precisely, a triangulation can be described as a simplicial complex. Let us first record a few definitions.

A simplicial complex is a set T of simplices such that

- any face of a simplex in T is a simplex in T
- two simplices in T either are disjoint or share a common sub-face.

The dimension d of a simplicial complex is the maximal dimension of its simplices.

A simplicial complex T is pure if any simplex of T is included in a simplex of T with maximal dimension.

Two simplices in T with maximal dimension d are said to be adjacent if they share a $(d - 1)$ dimensional sub-face. A simplicial complex is connected if the adjacency relation defines a connected graph over the set of simplices of T with maximal dimension.

The union U_T of all simplices in T is called the domain of T . A point p in the domain of T is said to singular if its surrounding in U_T is neither a topological ball nor a topological disc.

Then, a two dimensional triangulation can be described as a two dimensional simplicial complex that is pure, connected and without singularity.

Each facet of a triangulation can be given an orientation which in turn induces an orientation on the edges incident to that facet. The orientation of two adjacent facets are said to be consistent if they induce opposite orientations on their common incident edge. A triangulation is said to be orientable if the orientation of each facet can be chosen in such a way that all pairs of incident facets have consistent orientations.

The data structure underlying CGAL triangulations allows to represent the combinatorics of any orientable two dimensional triangulations without boundaries. On top of this data structure, the 2D triangulations classes take care of the geometric embedding of the triangulation and are designed to handle planar triangulations. The plane of the triangulation may be embedded in a higher dimensional space.

The triangulations of CGAL are complete triangulations which means that their domain is the convex hull of their vertices. Because any planar triangulation can be completed, this is not a real restriction. For instance, a triangulation of a polygonal region can be constructed and represented as a subset of a constrained triangulation in which the region boundary edges have been input as constrained edges (see Section 25.7, 25.8 and 25.9).

Strictly speaking, the term *face* should be used to design a face of any dimension, and the two-dimensional faces of a triangulation should be properly called *facets*. However, following a common usage, we hereafter often call *faces*, the facets of a two dimensional triangulation.

25.2 Representation

The set of faces

A 2D triangulation of CGAL can be viewed as a planar partition whose bounded faces are triangular and cover the convex hull of the set of vertices. The single unbounded face of this partition is the complementary of the convex hull. In many applications, such as Kirkpatrick's hierarchy or incremental Delaunay construction, it is convenient to deal with only triangular faces. Therefore, a fictitious vertex, called the *infinite vertex* is added to the triangulation as well as *infinite edges* and *infinite faces* incident to it.. Each infinite edge is incident to the infinite vertex and to a vertex of the convex hull. Each infinite face is incident to the infinite vertex and to a convex hull edge.

Therefore, each edge of the triangulation is incident to exactly two faces and the set of faces of a triangulation is topologically equivalent to a two-dimensional sphere. This extends to lower dimensional triangulations arising in degenerate cases or when the triangulations as less than three vertices. Including the infinite faces, a one dimensional triangulation is a ring of edges and vertices topologically equivalent to a 1-sphere. A zero dimensional triangulation, whose domain is reduced to a single point, is represented by two vertices that is topologically equivalent to a 0-sphere.

Note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it nor on an infinite face.

A representation based on faces and vertices

Because a triangulation is a set of triangular faces with constant-size complexity, triangulations are not implemented as a layer on top of a planar map. CGAL uses a proper internal representation of triangulations based on faces and vertices rather than on edges. Such a representation saves storage space and results in faster algorithms [BDTY00].

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

Figure 25.1: Infinite vertex and infinite faces

Figure 25.2: Vertices and neighbors.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 25.2, the functions $ccw(i)$ and $cw(i)$ shown on this figure compute respectively $i + 1$ and $i - 1$ modulo 3.

The edges are not explicitly represented, they are only implicitly represented through the adjacency relations of two faces. Each edge has two implicit representations: the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f .

25.3 Software Design

The triangulations classes of CGAL provide high-level geometric functionalities such as location of a point in the triangulation, insertion or removal of a point. They are build as a layer on top of a data structure called the triangulation data structure. The triangulation data structure can be thought of as a container for the faces and vertices of the triangulation. This data structure also takes care of all the combinatorial aspects of the triangulation.

This separation between the geometric aspect and the combinatorial part is reflected in the software design by the fact that the triangulation classes have two template parameters:

- the first parameter stands for a **geometric traits** class providing the geometric primitives (points, segments

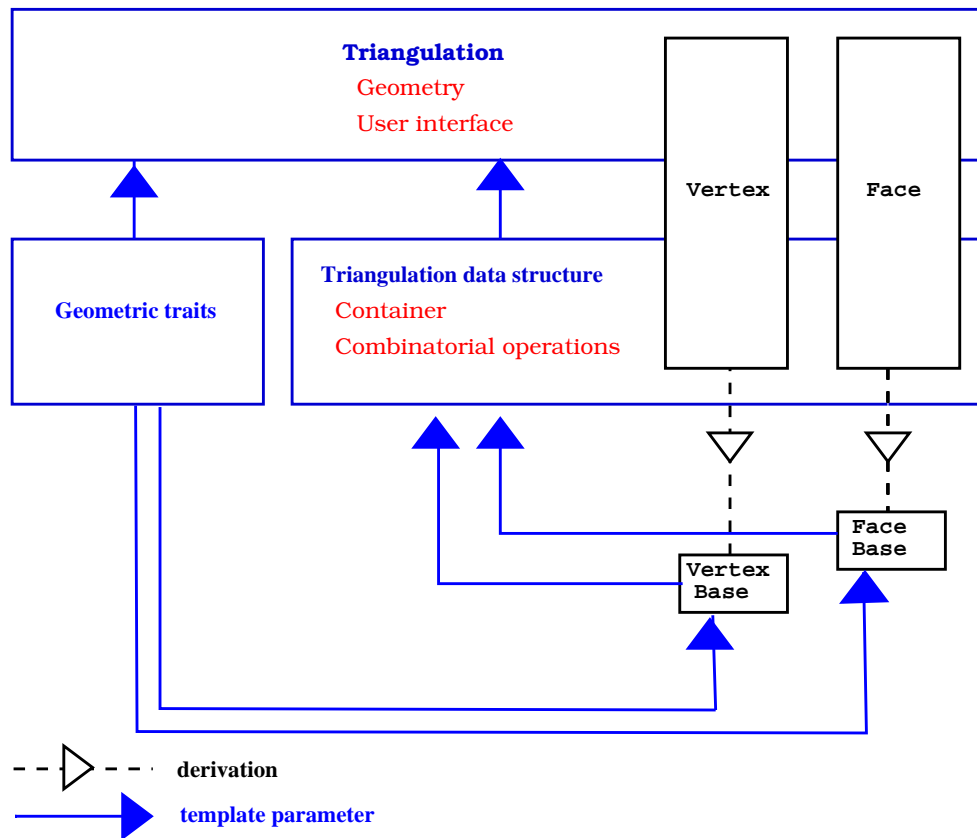

Figure 25.3: The triangulations software design.

and triangles) of the triangulation and the elementary operations (predicate or constructions) on those objects.

- the second parameter stands for a **triangulation data structure** class. The concept of triangulation data structure is described in Section 26.2 of Chapter 26. The triangulation data structure defines the types used to represent the faces and vertices of the triangulation, as well as additional types (handles, iterators and circulators) to access and visit the faces and vertices.

CGAL provides the class *Triangulation_data_structure_2*<*Vb*,*Fb*> as a default model of triangulation data structure. The class *Triangulation_data_structure_2*<*Vb*,*Fb*> has two template parameters standing for a vertex class and a face class. CGAL defines concepts for these template parameters and provide default models for these concepts. The vertex and base classes are templated by the geometric traits which allows them to have some knowledge of the geometric primitives of the triangulation. Those default vertex and face base classes can be replaced by user customized base classes in order, for example, to deal with additional properties attached to the vertices or faces of a triangulation. See section 25.11 for more details on the way to make use of this flexibility.

The Figure 25.3 summarizes the design of the triangulation package, showing the three layers (base classes, triangulation data structure and triangulation) forming this design.

The top triangulation level, responsible for the geometric embedding of the triangulation comes in different flavors according to the different kind of triangulations: basic, Delaunay, regular, constrained or constrained Delaunay. Each kind of triangulations correspond to a different class. Figure 25.4 summarizes the derivation dependencies of CGAL 2D triangulations classes. Any 2D triangulation class is parametrized by a geometric

Figure 25.4: The derivation tree of 2D triangulations.

traits and a triangulation data structure. While a unique concept *TriangulationDataStructure_2* describes the triangulation data structure requirements for any triangulation class, the concept of geometric traits actually depends on the triangulation class. In general, the requirements for the vertex and face base classes are described by the basic concepts *TriangulationVertexBase_2* and *TriangulationFaceBase_2*. However, some triangulation classes requires base classes implementing refinements of the basic concepts.

25.4 Basic Triangulations

25.4.1 Description

The class *Triangulation_2*<*Traits*,*Tds*> serves as a base class for the other 2D triangulations classes and implements the user interface to a triangulation.

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a model of the concept *Handle* which basically offers the two dereference operators * and -> . A circulator is a type devoted to visit circular sequences. Handles are used whenever the accessed element is not part of a sequence. Iterators and circulators are used to visit all or parts of the triangulation.

The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to the handles with the same value type, so that when calling a member function, any handle type argument can be replaced by an iterator or a circulator with the same value type.

The triangulation class allows to visit the vertices and neighbors of a face in clockwise or counterclockwise order.

There are circulators to visit the edges or faces incident to a given vertex or the vertices adjacent to it. Another circulator type allows to visit all the faces traversed by a given line. Circulators step through infinite features as well as through finite ones.

The triangulation class offers some iterators to visit all the faces, edges or vertices and also iterators to visit selectively the finite faces, edges or vertices.

Figure 25.5: Flip.

Figure 25.6: Flip.

The triangulation class provides methods to test the infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face) given its vertices.

The triangulation class provides a method to locate a given point with respect to a triangulation. In particular, this method reports whether the point coincides with a vertex of the triangulation, lies on an edge, in a face or outside of the convex hull. In case of a degenerate lower dimensional triangulation, the query point may also lie outside the triangulation affine hull.

The triangulation class also provides methods to locate a point with respect to a given finite face of the triangulation or with respect to its circumcircle. The faces of the triangulation and their circumcircles have the counterclockwise orientation.

The triangulation can be modified by several functions : insertion of a point, removal of a vertex, flipping of an edge. The flipping of an edge is possible when the union of the two incident faces forms a convex quadrilateral (see Figure 25.6).

Implementation

Locate is implemented by a line walk. The walk begins at a vertex of the face which is given as an optional argument or at an arbitrary vertex of the triangulation if no optional argument is given. It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random. The class *Triangulation_hierarchy_2*<Traits,Tds>, described in section 25.10, implements a data structure designed to offer an alternate more efficient point location algorithm.

Insertion of a point is done by locating a face that contains the point, and splitting this face into three new faces. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and re-triangulating the hole. Removal takes a time at most proportional to d^2 , where d is the degree of the removed vertex, which is $O(1)$ for a random vertex.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

Geometric Traits

The geometric traits of a triangulation is required to provide the geometric objects (points, segments and triangles) building up the triangulation together with the geometric predicates on those objects. The required predicates are:

- comparison of the x or y coordinates of two points.
- the orientation test which computes the order type of three given point.

The concept *TriangulationTraits_2* describes the requirements for the geometric traits class of a triangulation. The CGAL kernel classes are models for this concept. The CGAL library also provides dedicated models of *TriangulationTraits_2* using the kernel geometric objects and predicates. These classes are themselves templated with a CGAL kernel and extract the required types and predicates from the kernel. The traits class *Triangulation_euclidean_traits_2<R>* is designed to deal with ordinary two dimensional points. The class *Triangulation_euclidean_traits_xy_3<R>* is a geometric traits class to build the triangulation of a terrain. Such a triangulation is a two-dimensional triangulation embedded in three dimensional space. The data points are three-dimensional points. The triangulation is build according to the projections of those points on the xy plane and then lifted up to the original three-dimensional data points. This is especially useful to deal with GIS terrains. Instead of really projecting the three-dimensional points and maintaining a mapping between each point and its projection (which costs space and is error prone), the traits class supplies geometric predicates that ignore the z -coordinates of the points. See Section 25.5 for an example. CGAL provides also the geometric traits classes *Triangulation_euclidean_traits_yz_3<R>* and *Triangulation_euclidean_traits_zx_3<R>* to deal with projections on the xz plane and yz -plane, respectively.

25.4.2 Example of a Basic Triangulation

The following program creates a triangulation of 2D points using the default kernel *Exact_predicate_inexact_constructions_kernel* as geometric traits and the default triangulation data structure. The input points are read from a file and inserted in the triangulation. Finally points on the convex hull are written to `cout`.

```
#include <fstream>

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_2<K>          Triangulation;
typedef Triangulation::Vertex_circulator Vertex_circulator;
typedef Triangulation::Point              Point;

int main() {
    std::ifstream in("data/triangulation_progl.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;

    Triangulation t;
    t.insert(begin, end);

    Vertex_circulator vc = t.incident_vertices(t.infinite_vertex()),
        done(vc);
    if (vc != 0) {
        do { std::cout << vc->point() << std::endl;

```

```

        }while(++vc != done);
    }
    return 0;
}

```

25.5 Delaunay Triangulations

25.5.1 Description

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> is designed to represent the Delaunay triangulation of a set of data points in the plane. A Delaunay triangulation fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no data point in its interior. For a point set with no subset of four co-circular points the Delaunay triangulation is unique, it is dual to the Voronoi diagram of the set of points.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> derives from the class *Triangulation_2*<*Traits*,*Tds*>.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> inherits the types defined by the basic class *Triangulation_2*<*Traits*,*Tds*>. Additional types, provided by the traits class, are defined to represent the dual Voronoi diagram.

The class *Delaunay_triangulation_2*<*Traits*,*Tds*> overwrites the member functions that insert a new point in the triangulation or remove a vertex from it to maintain the Delaunay property. It also has a member function (*Vertex_handle nearest_vertex(const Point& p)*) to answer nearest neighbor queries and member functions to construct the elements (vertices and edges) of the dual Voronoi diagram.

Geometric traits

The geometric traits has to be a model of the concept *DelaunayTriangulationTraits_2* which refines the concept *TriangulationTraits_2*. In particular this concept provides the *side_of_oriented_circle* predicate which, given four points p, q, r, s decides the position of the point s with respect to the circle passing through p, q and r . The *side_of_oriented_circle* predicate actually defines the Delaunay triangulation. Changing this predicate allows to build variant of Delaunay triangulations for different metrics such that L_1 or L_∞ metric or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points.

The CGAL kernel classes and the class *Triangulation_euclidean_traits_2*<*R*> are models of the concept *DelaunayTriangulationTraits_2* for the euclidean metric. The traits class for terrains, *Triangulation_euclidean_traits_xy_3*<*R*>,

Triangulation_euclidean_traits_yz_3<*R*>, and

Triangulation_euclidean_traits_zx_3<*R*>

are also models of *DelaunayTriangulationTraits_2* except that they do not fulfill the requirements for the duality functions and nearest vertex queries.

Implementation

The insertion of a new point in the Delaunay triangulation is performed using first the insertion member function of the basic triangulation and second performing a sequence of flips to restore the Delaunay property. The

number of flips that have to be performed is $O(d)$ if the new vertex has degree d in the updated Delaunay triangulation. For points distributed uniformly at random, each insertion takes time $O(1)$ on average, once the point has been located in the triangulation.

Removal calls the removal in the triangulation and then re-triangulates the hole created in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation.

After having performed a point location, the nearest neighbor of a point is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

25.5.2 Example: a Delaunay Terrain

The following code creates a Delaunay triangulation with the usual Euclidean metric for the vertical projection of a terrain model. The points have elevation, that is they are 3D points, but the predicates used to build the Delaunay triangulation are computed using only the x and y coordinates of these points.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_euclidean_traits_xy_3.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_euclidean_traits_xy_3<K> Gt;
typedef CGAL::Delaunay_triangulation_2<Gt> Delaunay;

typedef K::Point_3 Point;

int main()
{
    std::ifstream in("data/terrain.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;

    Delaunay dt;
    dt.insert(begin, end);
    std::cout << dt.number_of_vertices() << std::endl;
    return 0;
}
```

File: examples/Triangulation_2/terrain.cpp

25.5.3 Example: Voronoi Diagram

The following code computes the edges of Voronoi diagram of a set of data points and counts the number of finite edges and the number of rays of this diagram

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
```

```

#include <CGAL/Delaunay_triangulation_2.h>

#include <fstream>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Delaunay_triangulation_2<K>   Triangulation;
typedef Triangulation::Edge_iterator         Edge_iterator;
typedef Triangulation::Point                 Point;

int main( )
{
    std::ifstream in("data/voronoi.cin");
    std::istream_iterator<Point> begin(in);
    std::istream_iterator<Point> end;
    Triangulation T;
    T.insert(begin, end);

    int ns = 0;
    int nr = 0;
    Edge_iterator eit =T.edges_begin();
    for ( ; eit !=T.edges_end(); ++eit) {
        CGAL::Object o = T.dual(eit);
        K::Segment_2 s;
        K::Ray_2      r;
        if (CGAL::assign(s,o)) {++ns;}
        if (CGAL::assign(r,o)) {++nr;}
    }
    std::cout << "The voronoi diagram as " << ns << "finite edges "
        << " and " << nr << " rays" << std::endl;
    return 0;
}

```

File: examples/Triangulation_2/voronoi.cpp

25.6 Regular Triangulations

25.6.1 Description

Let $PW = \{(p_i, w_i), i = 1, \dots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i . Alternatively, each weighted point (p_i, w_i) can be regarded as a sphere (or a circle, depending on the dimensionality of p_i) with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a space partition in which each cell corresponds to a sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere in PW . In the two-dimensional space, the dual of this diagram is a triangulation whose domain covers the convex hull of the set $P = \{p_i, i = 1, \dots, n\}$ of center points and whose vertices form a subset of P . Such a triangulation is called a regular triangulation. Three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane with equal powers with respect to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) and such that this power is less than the power of p with respect to any other sphere in PW .

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i) , and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) .

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ is a face of the regular triangulation of PW iff the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is positive or null. We call power test of (p_i, w_i) , (p_j, w_j) , (p_k, w_k) , and (p_l, w_l) , the predicates which amount to compute the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i) , (p_j, w_j) and (p_k, w_k) . This predicate amounts to computing the sign of the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_i, w_i) , (p_j, w_j) , (p_k, w_k) , and (p_l, w_l) is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW , is a regular triangulation of PW .

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i), i = 1, \dots, n\}$.

The class *Regular_triangulation_2*<Traits, Tds> is designed to maintain the regular triangulation of a set of 2d weighted points. It derives from the class *Triangulation_2*<Traits, Tds>. The functions *insert* and *remove* are overwritten to handle weighted points and maintain the regular property. The vertices of the regular triangulation of a set of weighted points PW correspond only to a subset of PW . Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Such a point is called a hidden point. Because hidden points can reappear later on as vertices when some other point is removed, they have to be stored somewhere. The regular triangulation store those points in special vertices, called hidden vertices. A hidden point can reappear as vertex of the triangulation only when the two dimensional face that hides it is removed from the triangulation. To deal with this feature, each face of a regular triangulation stores a list of hidden vertices. The points in those vertices are reinserted in the triangulation when the face is removed.

Regular triangulation have member functions to construct the vertices and edges of the dual power diagrams.

The geometric traits

The geometric traits of a regular triangulation must provide a weighted point type and a power test on these weighted points. The concept *RegularTriangulationTraits_2*, is a refinement of the concept *TriangulationTraits_2*. CGAL provides the class *Regular_triangulation_euclidean_traits_2*<Rep, Weight> which is a model for the traits concept *RegularTriangulationTraits_2*. The class *Regular_triangulation_euclidean_traits_2*<Rep, Weight> derives from the class *Triangulation_euclidean_traits_2*<Rep> and uses a *Weighted_point* type derived from the type *Point_2* of *Triangulation_euclidean_traits_2*<Rep>.

Note that, since the type *Weighted_point* is not defined in CGAL kernels, plugging a filtered kernel such as *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_2*<K, Weight> will

in fact not provide exact predicates on weighted points. To solve this, there is also another model of the traits concept, *Regular_triangulation_filtered_traits_2<FK>*, which is providing filtered predicates (exact and efficient). The argument *FK* must be a model of the *Kernel* concept, and it is also restricted to be a instance of the *Filtered_kernel* template.

The Vertex type and Face Type of a Regular Triangulation

The base vertex type of a regular triangulation includes a Boolean data member to mark the hidden state of the vertex. Therefore CGAL defines the concept *RegularTriangulationVertexBase_2* which refine the concept *TriangulationVertexBase_2* and provides a default model for this concept.

The base face type of a regular triangulation is required to provide a list of hidden vertices, designed to store the points hidden by the face. It has to be a model of the concept *RegularTriangulationFaceBase_2*. CGAL provides the templated class *Regular_triangulation_face_base_2<Traits>* as a default base class for faces of regular triangulations.

25.6.2 Example: a Regular Triangulation

The following code creates a regular triangulation of a set of weighted points and output the number of vertices and the number of hidden vertices.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
#include <CGAL/Regular_triangulation_filtered_traits_2.h>
#include <CGAL/Regular_triangulation_2.h>

#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Regular_triangulation_filtered_traits_2<K> Traits;
typedef CGAL::Regular_triangulation_2<Traits> Regular_triangulation;

int main()
{
    Regular_triangulation rt;
    std::ifstream in("data/regular.cin");

    Regular_triangulation::Weighted_point wp;
    int count = 0;
    while(in >> wp){
        count++;
        rt.insert(wp);
    }
    rt.is_valid();
    std::cout << "number of inserted points : " << count << std::endl;
    std::cout << "number of vertices : " ;
    std::cout << rt.number_of_vertices() << std::endl;
    std::cout << "number of hidden vertices : " ;
    std::cout << rt.number_of_hidden_vertices() << std::endl;
    return 0;
}
```

25.7 Constrained Triangulations

A constrained triangulation is a triangulation of a set of points that has to include among its edges a given set of segments joining the points. The corresponding edges are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include other vertices as well. There are three versions of constrained triangulations.

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges or constrained edges with null length are allowed.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduces additional vertices at each point that is the proper intersection points of two constraints. A single constraint intersecting other constraints will then appear as several edges in the triangulation. The two versions dealing with intersecting constraints differ in the way intersecting constraints are dealt with.
 - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximate.
 - The other one is designed to be used with exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure (which allows one to avoid the cascading of intersection computations) as provided in the class *Constrained_triangulation_plus_2*. See section 25.9.

A constrained triangulation is represented in the CGAL library as an object of the class *Constrained_triangulation_2*<*Traits*,*Tds*,*Itag*>. The third parameter *Itag* is the intersection tag which serves to choose how intersecting constraints are dealt with. This parameter has to be instantiated by one of the following classes :

CGAL::No_intersection_tag when input constraints do not intersect

CGAL::Exact_predicates_tag if the geometric traits provides exact predicates but approximate constructions

CGAL::Exact_intersections_tag when an exact predicates and exact constructions are provided.

The class *Constrained_triangulation_2*<*Traits*,*Tds*, *Itag*> inherits from *Triangulation_2*<*Traits*,*Tds*>. It defines an additional type *Constraint* to represent the constraints. A constraint is represented as a pair of points.

A constrained triangulation can be created from a list of constrained edges. The class *Constrained_triangulation_2*<*Traits*,*Tds*,*Itag*> overrides the insertion and removal of a point to take care of the information about constrained edges. The class also allows inline insertion of a new constraint, given by its two endpoints or the removal of a constraint.

Figure 25.7: Constrained and Constrained Delaunay triangulation: the constraining edges are the green edges, a constrained triangulation is shown on the left, the constrained Delaunay triangulation with two examples of circumcircles is shown on the right.

The Geometric Traits

The geometric traits of a constraint triangulation has to be a model of the concept *TriangulationTraits_2*. When intersections of input constraints are supported, the geometric traits class has to be a model of the concept *ConstrainedTriangulationTraits_2* which refines the concept *TriangulationTraits_2* providing additional function object types to compute the intersection of two segments.

The Base Face of a Constrained Triangulation

The information about constrained edges is stored in the faces of the triangulation. The base face of a Constrained Triangulation has to be a model for the concept *ConstrainedTriangulationFaceBase_2* which refines the concept *TriangulationFaceBase_2*. The concept *ConstrainedTriangulationFaceBase_2* requires member functions the get and set the constrained status of the edges.

CGAL provides a default base face class for constrained triangulations. This class, named *Constrained_triangulation_face_base_2<Traits>*, derives from the class *Triangulation_face_base_2<Traits>* and adds three Boolean data members to store the status of its edges.

25.8 Constrained Delaunay Triangulations

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. As constrained edges are not necessarily Delaunay edges, the triangles of a constrained Delaunay triangulation do not necessarily fulfill the empty circle property but they fulfill a weaker *constrained empty circle property*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay iff the circumscribing circle of any facet encloses no vertex visible from the interior of the facet. As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are provided. The first version handle set of constraints which do not intersect except possibly at the endpoints. The two other versions handle intersecting input constraints. One of them is designed to be designed to be robust when used in conjunction with a geometric traits providing exact predicates and approximate constructions (such as a *CGAL::Filtered_Kernel* or any kernel providing filtered exact predicates). The third version is designed to be used with an exact arithmetic number type.

The CGAL class *Constrained_Delaunay_triangulation_2*<*Traits,Tds,Itag*> is designed to represent constrained Delaunay triangulations.

As in the case of constraints triangulation, the third parameter *Itag* is the intersection tag and serves to choose how intersecting constraints are dealt with. It can be instantiated with one of the following class : *CGAL::No_intersection_tag*, *CGAL::Exact_predicates_tag*, *CGAL::Exact_intersections_tag* (see Section 25.7).

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class *Constrained_Delaunay_triangulation_2*<*Traits,Tds,Itag*> derives from the class *Constrained_triangulation_2*<*Traits,Tds,Itag*>.

The constrained Delaunay triangulation has member functions to override the insertion and removal of a point or of a constraint. Each of those member function takes care to restore the constrained empty circle property.

The Geometric Traits

The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* predicate as the geometric traits of a Delaunay triangulation and has to a model of the concept *DelaunayTriangulationTraits_2*. When intersecting input constraints are supported the geometric traits is further required to provide function objects to compute constraints intersections. Then the geometric traits has to be at the same time a model of the concept *ConstrainedTriangulationTraits_2*.

The face base class

Information about the status (constrained or not) of the edges of the triangulation has to be stored in the face class and the base face class of a constrained Delaunay triangulation has to be a model of *ConstrainedTriangulationFaceBase_2*.

25.8.1 Example: a Constrained Delaunay Triangulation

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> TDS;
typedef CGAL::Exact_predicates_tag Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, TDS, Itag> CDT;
typedef CDT::Point Point;

int
main( )
{
    CDT cdt;
```

```

std::cout << "Inserting a grid of 5x5 constraints " << std::endl;
for (int i = 1; i < 6; ++i)
    cdt.insert_constraint( Point(0,i), Point(6,i));
for (int j = 1; j < 6; ++j)
    cdt.insert_constraint( Point(j,0), Point(j,6));

assert(cdt.is_valid());
int count = 0;
for (CDT::Finite_edges_iterator eit = cdt.finite_edges_begin();
     eit != cdt.finite_edges_end();
     ++eit)
    if (cdt.is_constrained(*eit)) ++count;
std::cout << "The number of resulting constrained edges is ";
std::cout << count << std::endl;
return 0;
}

```

File: examples/Triangulation_2/constrained.cpp

25.9 Constrained Triangulations Plus

The class *Constrained_triangulation_plus_2*<Tr> provides a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation. The class *Constrained_triangulation_plus_2*<Tr> inherits from its template parameter Tr, which has to be instantiated by a constrained or constrained Delaunay triangulation. According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection points and refining the input constraints into sub-constraints which appear as edges (more precisely as constrained edges) of the triangulation. The data structure maintains for each input constraint the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

The class *Constrained_triangulation_plus_2*<Tr> is especially useful when the base constrained triangulation class handles intersections of constraints and uses an exact number type, i.e. when its intersection tag is *CGAL::Exact_intersections_tag*. Indeed in this case, the *Constrained_triangulation_plus_2*<Tr> is specially designed to avoid cascading in the computations of intersection points.

25.9.1 Example: Building a Triangulated Arrangement of Segments

The following code inserts a set of intersecting constraint segments into a triangulation and counts the number of constrained edges of the resulting triangulation.

```

#include <CGAL/Exact_predicates_exact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

struct K : CGAL::Exact_predicates_exact_constructions_kernel {};

```

```

typedef CGAL::Triangulation_vertex_base_2<K>          Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>   TDS;
typedef CGAL::Exact_intersections_tag                 Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Constrained_triangulation_plus_2<CDT>    CDTplus;
typedef CDTplus::Point                                 Point;

int
main( )
{
    CDTplus cdt;
    std::cout << "Inserting a grid 5 x 5 of constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    assert(cdt.is_valid());
    int count = 0;
    for (CDTplus::Subconstraint_iterator scit = cdt.subconstraints_begin();
         scit != cdt.subconstraints_end();
         ++scit) ++count;
    std::cout << "The number of resulting constrained edges is  "
              << count << std::endl;
    return 0;
}

```

File: examples/Triangulation_2/constrained_plus.cpp

25.10 The Triangulation Hierarchy

The class *Triangulation_hierarchy_2*<*Tr*> implements a triangulation augmented with a data structure to answer efficiently point location queries. The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation, the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behavior when it is built for Delaunay triangulations. However it can be used as well for other triangulations and the class *Triangulation_hierarchy_2*<*Tr*> is templated by a parameter which is to be instantiated by one of the CGAL triangulation classes.

The class *Triangulation_hierarchy_2*<*Tr*> inherits from the triangulation type passed as template parameter *Tr*. The insert and remove member functions are overwritten to update the data structure at each operation. The locate queries are also overwritten to take advantage of the data structure for a fast processing.

The Vertex of a Triangulation Hierarchy

The base vertex class of a triangulation hierarchy has to be a model of the concept *TriangulationHierarchyVertexBase_2* which extends the concept *TriangulationVertexBase_2*. This extension adds access and setting member functions for two pointers to the corresponding vertices in the triangulations of the next and preceding levels.

CGAL provides the class *Triangulation_hierarchy_vertex_base_2<Vb>* which is a model for the concept *TriangulationHierarchyVertexBase_2*. This class is templated by a parameter *Vb* which is to be instantiated by a model of the concept *TriangulationVertexBase_2*. The class *Triangulation_hierarchy_vertex_base_2<Vb>* inherits from its template parameter *Vb*. This design allows to use for *Vb* either the default vertex class or a user customized vertex class with additional functionalities.

25.10.1 Examples For the Use of a Triangulation Hierarchy

The following program is example for the standard use of a triangulation hierarchy to enhance the efficiency of a Delaunay triangulation. The program outputs the number of vertices at the different levels of the hierarchy.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/algorithm.h>
#include <cassert>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K> Vbb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Triangulation_hierarchy_2<Dt> Triangulation;
typedef Triangulation::Point Point;
typedef CGAL::Creator_uniform_2<double,Point> Creator;

int main( )
{
    std::cout << "insertion of 1000 random points" << std::endl;
    Triangulation t;
    CGAL::Random_points_in_square_2<Point,Creator> g(1.);
    CGAL::copy_n( g, 1000, std::back_inserter(t));

    //verbose mode of is_valid ; shows the number of vertices at each level
    std::cout << "The number of vertices at successive levels" << std::endl;
    assert(t.is_valid(true));

    return 0;
}
```

File: examples/Triangulation_2/hierarchy.cpp

The following program shows how to use a triangulation hierarchy in conjunction with a constrained triangulation plus.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_hierarchy_2.h>
#include <CGAL/Constrained_triangulation_plus_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K>          Vbb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Vbb> Vb;
typedef CGAL::Constrained_triangulation_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb>    TDS;
typedef CGAL::Exact_predicates_tag                    Itag;
typedef CGAL::Constrained_Delaunay_triangulation_2<K,TDS,Itag> CDT;
typedef CGAL::Triangulation_hierarchy_2<CDT>          CDTH;
typedef CGAL::Constrained_triangulation_plus_2<CDTH>   Triangulation;

typedef Triangulation::Point                          Point;

int
main( )
{
    Triangulation cdt;
    std::cout << "Inserting a grid 5 x 5 of constraints " << std::endl;
    for (int i = 1; i < 6; ++i)
        cdt.insert_constraint( Point(0,i), Point(6,i));
    for (int j = 1; j < 6; ++j)
        cdt.insert_constraint( Point(j,0), Point(j,6));

    int count = 0;
    for (Triangulation::Subconstraint_iterator scit = cdt.subconstraints_begin();
         scit != cdt.subconstraints_end();
         ++scit) ++count;
    std::cout << "The number of resulting constrained edges is ";
    std::cout << count << std::endl;

    //verbose mode of is_valid ; shows the number of vertices at each level
    std::cout << "The number of vertices at successive levels" << std::endl;
    assert(cdt.is_valid(true));

    return 0;
}
```

File: examples/Triangulation_2/constrained_hierarchy_plus.cpp

25.11 Flexibility: Using Customized Vertices and Faces

To be able to adapt to various needs, a highly flexible design has been selected for 2D triangulations. We have already seen that the triangulation classes have two parameters: a geometric traits class and a triangulation data structure class which the user can instantiate with his own customized classes.

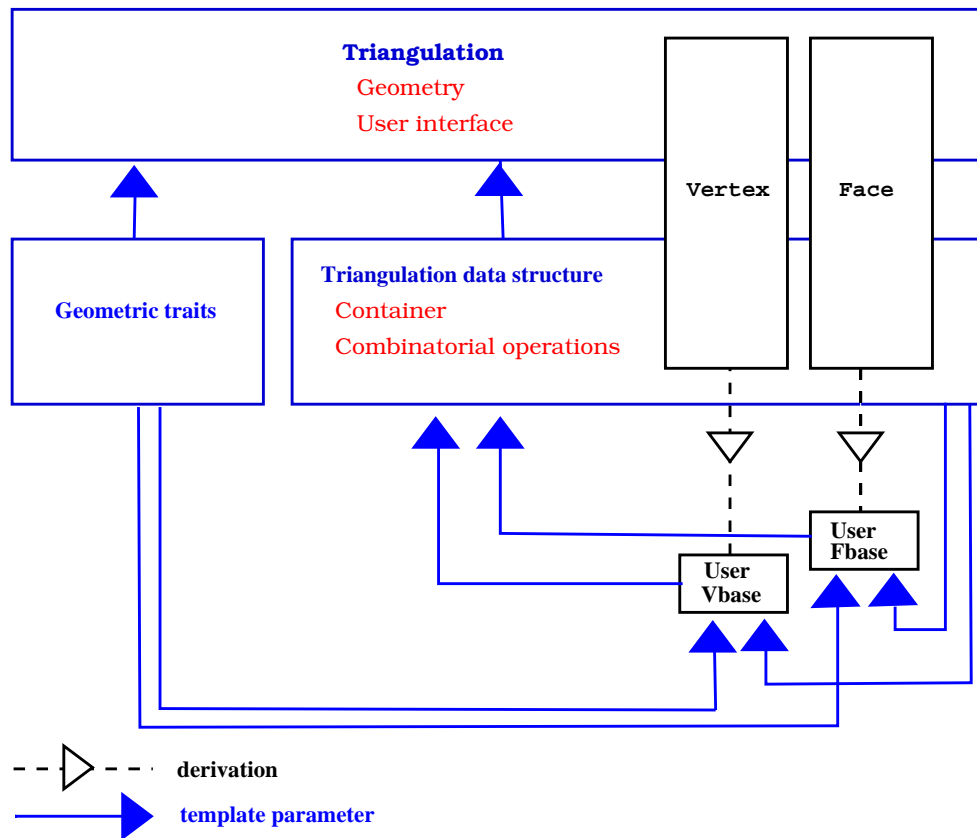

Figure 25.8: The cyclic dependency in triangulations software design.

The most useful flexibility however comes from the fact that the triangulation data structure itself has two template parameters to be instantiated by classes for the vertices and faces of the triangulation. Using his own customized classes to instantiate these parameters, the user can easily build up a triangulation with additional information or functionality in the vertices and faces.

A cyclic dependency

To insure flexibility, the triangulation data structure is templated by the vertex and face base classes. Also since incidence and adjacency relations are stored in vertices and faces, the base classes have to know the types of handles on vertices and faces provided by the triangulation data structure. Thus the vertex and base classes have to be themselves parameterized by the triangulation data structure, and there is a cyclic dependency on template parameter.

Previously, this cyclic dependency was avoided by using only *void** pointers in the interface of base classes. These *void** were converted to appropriate types at the triangulation data structure levels. This solution had some drawbacks : mainly the user could not add in the vertices or faces of the triangulation a functionality related to types defined by the triangulation data structure, for instance a handle to a vertex, and he was lead to use himself *void** pointers). The new solution to resolve the template dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class `std::allocator`. The rebind mechanism is described in Section 26.3 of Chapter 26. For now, we will just notice that the design requires the existence in the vertex and face base classes of a nested template class *Rebind_TDS* defining a type *Other* used by the rebinding mechanism.

The two following examples show how the user can put in use the flexibility offered by the base classes parameters.

Adding colors

The first example corresponds to a case where the user wishes to add in the vertices or faces of the triangulation an additional information that does not depend on types provided by the triangulation data structure. In that case, predefined classes *Triangulation_vertex_base_with_info_2*<Info,Traits,Vb> or *Triangulation_face_base_with_info_2*<Info,Traits,Vb> can be used. Those classes have a template parameter *Info* devoted to handle additional information. The following examples shows how to add a *CGAL::Color* in the triangulation faces.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/IO/Color.h>
#include <CGAL/Triangulation_2.h>
#include <CGAL/Triangulation_face_base_with_info_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Triangulation_face_base_with_info_2<CGAL::Color,K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Face_handle Face_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point Point;

int main() {
    Triangulation t;
    t.insert(Point(0,1));
    t.insert(Point(0,0));
    t.insert(Point(2,0));
    t.insert(Point(2,2));

    Finite_faces_iterator fc = t.finite_faces_begin();
    for( ; fc != t.finite_faces_end(); ++fc) fc->info() = CGAL::BLUE;

    Point p(0.5,0.5);
    Face_handle fh = t.locate(p);
    fh->info() = CGAL::RED;

    return 0;
}
```

File: examples/Triangulation_2/colored_face.cpp

Adding handles

The second example shows how the user can still derive and plug in his own vertex or face class when he would like to have additional functionalities depending on types provided by the triangulation data structure.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_2.h>
#include <cassert>

/* A facet with an additionnal handle */
template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt> >
class My_vertex_base
    : public Vb
{
    typedef Vb                                Base;
public:
    typedef typename Vb::Vertex_handle        Vertex_handle;
    typedef typename Vb::Face_handle          Face_handle;
    typedef typename Vb::Point                Point;

    template < typename TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_base<Gt,Vb2>                            Other;
    };

private:
    Vertex_handle va_;

public:
    My_vertex_base() : Base() {}
    My_vertex_base(const Point & p) : Base(p) {}
    My_vertex_base(const Point & p, Face_handle f) : Base(f,p) {}
    My_vertex_base(Face_handle f) : Base(f) {}

    void set_associated_vertex(Vertex_handle va) { va_ = va;}
    Vertex_handle get_associated_vertex() {return va_ ; }
};

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef My_vertex_base<K> Vb;
typedef CGAL::Triangulation_data_structure_2<Vb> Tds;
typedef CGAL::Triangulation_2<K,Tds> Triangulation;

typedef Triangulation::Vertex_handle Vertex_handle;
typedef Triangulation::Finite_faces_iterator Finite_faces_iterator;
typedef Triangulation::Point Point;

int main() {
    Triangulation t;
    Vertex_handle v0 = t.insert(Point(0,1));
    Vertex_handle v1 = t.insert(Point(0,0));
    Vertex_handle v2 = t.insert(Point(2,0));
    Vertex_handle v3 = t.insert(Point(2,2));

    // associate vertices as you like
    v0->set_associated_vertex(v1);
    v1->set_associated_vertex(v2);

```

```
v2->set_associated_vertex(v3);  
v3->set_associated_vertex(v0);  
assert( v0->get_associated_vertex() == v1);  
  
return 0;  
}
```

File: examples/Triangulation_2/adding_handles.cpp

25.12 Design and Implementation History

The code of this package is the result of a long development process. Here follows a tentative list of people who added their stone to this package : Jean-Daniel Boissonnat, Hervé Brönnimann, Olivier Devillers, Andreas Fabri, Frédéric Fichel, Julia Flötotto, Monique Teillaud and Mariette Yvinec.

2D Triangulations

Reference Manual

Mariette Yvinec

A triangulation is a 2-dimensional simplicial complex which is pure connected and without singularities. Thus a triangulation can be viewed as a collection of triangular faces, such that two faces either have an empty intersection or share an edge or a vertex.

The basic elements of the representation are vertices and faces. Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces. The edges are not explicitly represented, they are only represented through the adjacency relations of two faces.

The triangulation classes of CGAL depend on two template parameters. The first template parameter stands for a geometric traits class which is assumed to provide the geometric objects (points, segments and triangles) forming the triangulation and the geometric predicates on those objects. The second template parameter stands for a model of triangulation data structure acting as a container for faces and vertices while taking care of the combinatorial aspects of the triangulation. The concepts and models relative to the triangulation data structure are described in Chapter [26.3.4](#).

ConstrainedDelaunayTriangulationTraits_2

Definition

The concept `ConstrainedDelaunayTriangulationTraits_2` defines the requirements for the geometric traits class of a constrained Delaunay triangulation that supports intersections of input constraints. This is the case when the template parameter *Itag* of (*Constrained_Delaunay_triangulation_2*<*Traits*,*Tds*,*Itag*>) is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*. The concept `ConstrainedDelaunayTriangulationTraits_2` refines both the concept *DelaunayTriangulationTraits_2* and the concept *ConstrainedTriangulationTraits_2*.

ConstrainedTriangulationFaceBase_2

Definition

In a constrained triangulation, the information about constrained edges is stored in the faces of the triangulation. The base face of a constrained triangulation has to be a model of the concept `ConstrainedTriangulationFaceBase_2` which refines the concept `TriangulationFaceBase_2` providing functionalities to deal with constraints.

Refines

`TriangulationFaceBase_2`

Types

Defines the same types as the `TriangulationFaceBase_2` concept

Access Functions

`bool f.is_constrained(int i)`

returns true if the edge between f and its neighbor $f.\text{neighbor}(i)$ is constrained.
Precondition: $0 \leq i \leq 2$.

— advanced —

Modifiers

`void f.set_constraint(int i, bool b)`

sets the edge between f and its neighbor $f.\text{neighbor}(i)$ as a constrained or unconstrained edge according to b .

`void f.set_constraints(bool c0, bool c1, bool c2)`

sets the status (constrained or unconstrained) of the three edges of f .

`void f.reorient()`

Changes the orientation of f by exchanging $\text{vertex}(0)$ with $\text{vertex}(1)$ and $\text{neighbor}(0)$ with $\text{neighbor}(1)$ and the corresponding constrained status.

`void f.ccw_permute()`

performs a counterclockwise permutation of the vertices, neighbors and constrained status of f .

`void f.cw_permute()`

performs a clockwise permutation of the vertices and neighbors and constrained status of f .

Miscellaneous

bool *f.is_valid()* tests the validity of face *f* as a face of a plain triangulation and additionally checks if the edges of *f* are consistently marked as constrained or unconstrained edges in face *f* and its neighbors.

ConstrainedTriangulationTraits_2

Definition

The concept `ConstrainedTriangulationTraits_2` defines the requirements for the geometric traits class of a constrained triangulation (*Constrained_Triangulation_2*<*Traits*,*Tds*,*Itag*>) that supports intersections of input constraints (i. e. when the template parameter *Itag* is instantiated by one of the tag classes *Exact_intersections_tag* or *Exact_predicates_tag*). This concept refines the concept *TriangulationTraits_2*, adding requirements for function objects to compute the intersection points of two constraints. When *Exact_predicates_tag* is used, the traits class is also required to provide additional types to compute the squared distance between a point and a line

Refines

TriangulationTraits_2

Types

ConstrainedTriangulationTraits_2:: Intersect_2

A function object whose operator() computes the intersection of two segments :

Object_2 operator()(Segment_2 s1, Segment_2 s2); Returns the intersection of *s1* and *s2*.

When the constrained triangulation is instantiated with the intersection tag *Exact_predicates_tag*, the used algorithm needs to be able to compare some distances between points and lines and the following types are further required.

ConstrainedTriangulationTraits_2:: RT

A number type supporting the comparison operator <.

ConstrainedTriangulationTraits_2:: Line_2

The line type.

ConstrainedTriangulationTraits_2:: Construct_line_2

A function object whose operator() constructs a line from two points :

Line_2 operator()(Point_2 p1, Point_2 p2).

ConstrainedTriangulationTraits_2:: Compute_squared_distance_2

A function object with an operator() designed to compute the squared distance between a line and a point : *RT operator()(Point_2 p1, Line_2);* Return the squared distance between *p* and *l*.

Access to constructor object

Intersect_2

traits.intersect_2_object()

Construct_line_2 *traits.construct_line_2_object()*

required when the intersection tag is *Exact_predicates_tag*.

Compute_squared_distance_2

traits.compute_squared_distance_2_object()

required when the intersection tag is *Exact_predicates_tag*.

CGAL:Constrained_Triangulation_2<*Traits*,*Tds*,*Itag*>

CGAL::Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>

Definition

A constrained Delaunay triangulation is a triangulation with constrained edges which tries to be as much Delaunay as possible. Constrained edges are not necessarily Delaunay edges, therefore a constrained Delaunay triangulation is not a Delaunay triangulation. A constrained Delaunay is a triangulation whose faces do not necessarily fulfill the empty circle property but fulfill a weaker property called the *constrained empty circle*. To state this property, it is convenient to think of constrained edges as blocking the view. Then, a triangulation is constrained Delaunay if the circumscribing circle of any of its triangular faces includes in its interior no vertex that is visible from the interior of the triangle. The class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* is designed to represent constrained Delaunay triangulations.

As in the case of constrained triangulations, three different versions of Delaunay constrained triangulations are offered depending on whether the user wishes to handle intersecting input constraints or not. The desired version can be selected through the instantiation of the third template parameter *Itag* which can be one of the following :

CGAL::No_intersection_tag if intersections of input constraints are disallowed,

CGAL::Exact_predicates_tag allows intersections between input constraints and is to be used when the traits class provides exact predicates but approximate constructions of the intersection points. *CGAL::Exact_intersections_tag* allows intersections between input constraints and is to be used in conjunction with an exact arithmetic type.

The template parameters *Tds* has to be instantiate with a model of *TriangulationDataStructure_2*. The geometric traits of a constrained Delaunay triangulation is required to provide the *side_of_oriented_circle* test as the geometric traits of a Delaunay triangulation and the *Traits* parameter has to be instantiated with a model *DelaunayTriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. and has then to be also a model of the concept *ConstrainedTriangulationTraits_2*.

A constrained Delaunay triangulation is not a Delaunay triangulation but it is a constrained triangulation. Therefore the class *Constrained_Delaunay_triangulation_2<Traits,Tds,Itag>* derives from the class *Constrained_triangulation_2<Traits,Tds>*. Also, information about the status (constrained or not) of the edges of the triangulation is stored in the faces. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides a default for the template parameters. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2<CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt> >*. The default intersection tag is *CGAL::No_intersection_tag*.

```
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
```

Inherits From

Constrained_triangulation_2<Traits,Tds,Itag>

Types

All types used in this class are inherited from the base class *Constrained_triangulation_2<Traits,Tds,Itag>*.

Creation

```
Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt( Traits t = Traits());
```

Introduces an empty constrained Delaunay triangulation *cdt*.

```
Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt( Constrained_Delaunay_triangulation_2 cdt1);
```

Copy constructor, all faces and vertices are duplicated and the constrained status of edges is copied.

```
template<class InputIterator>  
Constrained_Delaunay_triangulation_2<Traits,Tds,Itag> cdt( InputIterator first,  
InputIterator last,  
Traits t=Traits())
```

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range $[first, last)$.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

Insertion and Removal

The following member functions overwrite the corresponding members of the base class to include a step restoring the Delaunay constrained property after modification of the triangulation.

```
Vertex_handle cdt.insert( Point p, Face_handle f = Face_handle());
```

Inserts point *p* in the triangulation. If present *f* is used as an hint for the location of *p*.

```
Vertex_handle cdt.insert( Point p, Locate_type& lt, Face_handle loc, int li)
```

Same as above except that the location of the point *p* to be inserted is assumed to be given by (lt, loc, i) .

```
Vertex_handle cdt.push_back( Point p)
```

Equivalent to *insert(p)*.

```
template < class InputIterator >  
int cdt.insert( InputIterator first, InputIterator last)
```

Inserts the points in the range $[first, last)$. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

<i>void</i>	<i>cdt.insert_constraint(Point a, Point b)</i>	Inserts segment <i>ab</i> as a constrained edge in the triangulation.
<i>void</i>	<i>cdt.push_back(Constraint c)</i>	Inserts constraints <i>c</i> as above.
<i>void</i>	<i>cdt.insert_constraint(Vertex_handle va, Vertex_handle vb)</i>	Inserts the line segment whose endpoints are the vertices <i>va</i> and <i>vb</i> as a constrained edge <i>e</i> in the triangulation.
<i>void</i>	<i>cdt.remove(Vertex_handle & v)</i>	Removes vertex <i>v</i> . <i>Precondition:</i> Vertex <i>v</i> is not incident to a constrained edge.
<i>void</i>	<i>cdt.remove_incident_constraints(Vertex_handle v)</i>	Make the edges incident to vertex <i>v</i> unconstrained edges.
<i>void</i>	<i>cdt.remove_constraint(Face_handle f, int i)</i>	Edge <i>(f,i)</i> is no longer constrained.

Queries

The following template member functions query the set of faces in conflict with a point *p*. The notion of conflict refers here to a constrained Delaunay setting which means the following. Constrained edges are considered as visibility obstacles and a point *p* is considered to be in conflict with a face *f* iff it is visible from the interior of *f* and included in the circumcircle of *f*.

```
template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces, OutputItBoundaryEdges>
```

```
    cdt.get_conflicts_and_boundary( Point p,
                                   OutputItFaces fit,
                                   OutputItBoundaryEdges eit,
                                   Face_handle start)
```

OutItFaces is an output iterator with *Face_handle* as value type. *OutItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a `std::pair` the resulting output iterators.

```
template <class OutputItFaces>
```

```
OutputItFaces      cdt.get_conflicts( Point p, OutputItFaces fit, Face_handle start)
```

Same as above except that only the faces in conflict with p are output. The function returns the resulting output iterator.

```
template <class OutputItBoundaryEdges>
```

```
OutputItBoundaryEdges
```

```
      cdt.get_boundary_of_conflicts( Point p,
                                   OutputItBoundaryEdges eit,
                                   Face_handle start)
```

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This functions outputs in the container pointed to by *eit*, the boundary of the zone in conflict with p . The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through the incident face which is not in conflict with p . The function returns the resulting output iterator.

Checking

```
bool              cdt.is_valid()
```

Checks if the triangulation is valid and if each constrained edge is consistently marked constrained in its two incident faces.

└────────── advanced ─────────┘

Flips

```
bool              cdt.is_flipable( Face_handle f, int i)
```

Determines if edge (f,i) can be flipped. Returns true if edge (f,i) is not constrained and the circle circumscribing f contains the vertex of $f->neighbor(i)$ opposite to edge (f,i) .

```
void              cdt.flip( Face_handle& f, int i)
```

Flip f and $f->neighbor(i)$.

```
void              cdt.propagating_flip( List_edges & edges)
```

Makes the triangulation constrained Delaunay by flipping edges. List edges contains an initial list of edges to be flipped. The returned triangulation is constrained Delaunay if the initial list contains at least all the edges of the input triangulation that failed to be constrained Delaunay. (An edge is said to be constrained Delaunay if it is either constrained or locally Delaunay.)

CGAL::Constrained_triangulation_2<Traits,Tds,Itag>

Definition

A constrained triangulation is a triangulation of a set of points which has to include among its edges a given set of segments joining the points. The given segments are called *constraints* and the corresponding edges in the triangulation are called *constrained edges*.

The endpoints of constrained edges are of course vertices of the triangulation. However the triangulation may include other vertices as well. There are three versions of constrained triangulations

- In the basic version, the constrained triangulation does not handle intersecting constraints, and the set of input constraints is required to be a set of segments that do not intersect except possibly at their endpoints. Any number of constrained edges are allowed to share the same endpoint. Vertical constrained edges are allowed as well as constrained edges with null length.
- The two other versions support intersecting input constraints. In those versions, input constraints are allowed to be intersecting, overlapping or partially overlapping segments. The triangulation introduces additional vertices at each point which is a proper intersection point of two constraints. A single constraint intersecting other constraints will then appear as the union of several constrained edges of the triangulation. The two versions dealing with intersecting constraints, slightly differ in the way intersecting constraints are dealt with.
 - One of them is designed to be robust when predicates are evaluated exactly but constructions (i. e. intersection computations) are approximate.
 - The other one is designed to be used with an exact arithmetic (meaning exact evaluation of predicates and exact computation of intersections.) This last version finds its full efficiency when used in conjunction with a constraint hierarchy data structure as provided in the class *Constrained_triangulation_plus_2*. See section 25.9.

The class *Constrained_triangulation_2<Traits,Tds,Itag>* of the CGAL library implements constrained triangulations. The template parameter *Traits* stands for a geometric traits class. It has to be a model of the concept *TriangulationTraits_2*. When intersection of input constraints are supported, the geometric traits class is required to provide additional function object types to compute the intersection of two segments. It has then to be a model of the concept *ConstrainedTriangulationTraits_2*. The template parameter *Tds* stands for a triangulation data structure class that has to be a model of the concept *TriangulationDataStructure_2*. The third parameter *Itag* is the intersection tag which serves to choose between the different strategies to deal with constraints intersections. CGAL provides three valid types for this parameter :

CGAL::No_intersection_tag disallows intersections of input constraints,

CGAL::Exact_predicates_tag is to be used when the traits class provides exact predicates but approximate constructions of the intersection points.

CGAL::Exact_intersections_tag is to be used in conjunction with an exact arithmetic type.

The information about constrained edges is stored in the faces of the triangulation. Thus the nested *Face* type of a constrained triangulation offers additional functionalities to deal with this information. These additional

functionalities induce additional requirements on the base face class plugged into the triangulation data structure of a constrained Delaunay triangulation. The base face of a constrained Delaunay triangulation has to be a model of the concept *ConstrainedTriangulationFaceBase_2*.

CGAL provides default instantiations for the template parameters *Tds* and *Itag*, and for the *ConstrainedTriangulationFaceBase_2*. If *Gt* is the geometric traits parameter, the default for *ConstrainedTriangulationFaceBase_2* is the class *CGAL::Constrained_triangulation_face_base_2<Gt>* and the default for the triangulation data structure parameter is the class *CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Constrained_triangulation_face_base_2<Gt> >*. The default intersection tag is *CGAL::No_intersection_tag*.

```
#include <CGAL/Constrained_triangulation_2.h>
```

Inherits From

Triangulation_2<Traits,Tds>

Types

```
typedef std::pair<Point,Point>
```

Constraint;

The type of input constraints

```
typedef Itag
```

Intersection_tag;

The intersection tag which decides how intersections between input constraints are dealt with.

Creation

```
Constrained_triangulation_2<Traits,Tds,Itag> ct;
```

default constructor.

```
Constrained_triangulation_2<Traits,Tds,Itag> ct( Constrained_triangulation_2 ct1);
```

Copy constructor, all faces and vertices are duplicated and the constrained status of edges is copied.

```
template<class InputIterator>
```

```
Constrained_triangulation_2<Traits,Tds,Itag> ct( InputIterator first, InputIterator last, Traits t=Traits());
```

A templated constructor which introduces and builds a constrained triangulation with constrained edges in the range *[first, last)*.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

Queries

bool *ct.is_constrained(Edge e)*

Returns true if edge *e* is a constrained edge.

bool *ct.are_there_incident_constraints(Vertex_handle v)*

Returns true if at least one of the edges incident to vertex *v* is constrained.

template<class OutputItEdges>

OutputItEdges *ct.incident_constraints(Vertex_handle v, OutputItEdges out)*

OutputItEdges is an output iterator with *Edge* as value type. Outputs the constrained edges incident to *v* in the sequence pointed to by *out* and returns the resulting output iterator.

Insertion and removal

Vertex_handle *ct.insert(Point p, Face_handle f = Face_handle())*

Inserts point *p* and restores the status (constrained or not) of all the touched edges. If present *f* is used as an hint for the location of *p*.

Vertex_handle *ct.insert(Point p, Locate_type& lt, Face_handle loc, int li)*

Same as above except that the location of the point *p* to be inserted is assumed to be given by *(lt,loc,i)*.

Vertex_handle *ct.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >

int *ct.insert(InputIterator first, InputIterator last)*

Inserts the points in the range *[first, last)*. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *ct.insert_constraint(Point a, Point b)*

Inserts points *a* and *b*, and inserts segment *ab* as a constraint. Removes the faces crossed by segment *ab* and creates new faces instead. If a vertex *c* lies on segment *ab*, constraint *ab* is replaced by the two constraints *ac* and *cb*. Apart from the insertion of *a* and *b*, the algorithm runs in time proportional to the number of removed triangles.

Precondition: The relative interior of segment *ab* does not intersect the relative interior of another constrained edge.

void *ct.push_back(Constraint c)*

Inserts constraints *c* as above.

void *ct.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts the line segment *s* whose endpoints are the vertices *va* and *vb* as a constrained edge *e*. The triangles intersected by *s* are removed and new ones are created.

void *ct.remove(Vertex_handle v)*

Removes a vertex *v*.

Precondition: Vertex *v* is not incident to a constrained edge.

void *ct.remove_incident_constraints(Vertex_handle v)*

Make the edges incident to vertex *v* unconstrained edges.

void *ct.remove_constrained_edge(Face_handle f, int i)*

Make edge *(f,i)* no longer constrained.

┌────────── *advanced* ───────────┐
|
bool *ct.is_valid(bool verbose = false, int level = 0)*

Checks the validity of the triangulation and the consistency of the constrained marks in edges.

└────────── *advanced* ───────────┘

I/O

ostream & *ostream& os << Constrained_triangulation_2<Traits,Tds> Ct*

Writes the triangulation and, for each face *f*, and integers *i=0,1,2*, write “C” or “N” depending whether edge *(f,i)* is constrained or not.

CGAL::Triangulation_face_base_2<Traits>

CGAL::Constrained_triangulation_plus_2<Tr>

The class *Constrained_triangulation_plus_2<Tr>* implements a constrained triangulation with an additional data structure called the constraint hierarchy that keeps track of the input constraints and of their refinement in the triangulation.

The class *Constrained_triangulation_plus_2<Tr>* inherits from its template parameter *Tr*, which has to be instantiated by a constrained or constrained Delaunay triangulation.

According to its intersection tag, the base class will support intersecting input constraints or not. When intersections of input constraints are supported, the base class constructs a triangulation of the arrangement of the constraints, introducing new vertices at each proper intersection point and refining the input constraints into sub-constraints which are edges (more precisely constrained edges) of the triangulation. In this context, the constraint hierarchy keeps track of the input constraints and of their refinement in the triangulation. This data structure maintains for each input constraints the sequence of intersection vertices added on this constraint. The constraint hierarchy also allows the user to retrieve the set of constrained edges of the triangulation, and for each constrained edge, the set of input constraints that overlap it.

Tr

Types

<i>typedef Tr</i>	<i>Triangulation;</i>	the triangulation base class.
<i>typedef Itag</i>	<i>Intersection_tag;</i>	the intersection tag.s

Constrained_triangulation_plus_2<Tr>:: Constraint_iterator

An iterator to visit all the input constraints. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the endpoints of the constraint.

Constrained_triangulation_plus_2<Tr>:: Subconstraint_iterator

An iterator to visit all the sub-constraints of the triangulation. The order of visit is arbitrary. The value type of this iterator is a pair *std::pair<Vertex_handle, Vertex_handle>* corresponding to the vertices of the sub-constraint.

Constrained_triangulation_plus_2<Tr>:: Vertices_in_constraint_iterator

An iterator on the vertices of the chain of triangulation edges representing a constraint. The value type of this iterator is *Vertex_handle*.

<i>typedef</i>	<i>Context</i> ;	This type is intended to describe a constraint enclosing a sub-constraint and the position of the sub-constraint in this constraint. It provides three member functions <i>vertices_begin()</i> , <i>vertices_end()</i> and <i>current()</i> returning iterators of the type <i>Vertices_in_constraint_iterator</i> on the sequence of vertices of the enclosing constraint. These iterators point respectively on the first vertex of the enclosing constraint, past the last vertex and on the first vertex of the sub-constraint.
<i>typedef</i>	<i>Context_iterator</i> ;	An iterator on constraints enclosing a given sub-constraint. The value type of this iterator is <i>Context</i> .

Creation

Constrained_triangulation_plus_2<Tr> *ctp*(*Geom_traits* gt=*Geom_traits*());

Introduces an empty triangulation.

Constrained_triangulation_plus_2<Tr> *ctp*(*Constrained_triangulation_plus_2* ct);

Copy constructor.

Constrained_triangulation_plus_2<Tr> *ctp*(*std::list*<*Constrained*>& lc, *Geom_traits* t = *Geom_traits*());

Introduces and builds a constrained triangulation from the list of constraints *lc*.

template<*class InputIterator*>

Constrained_triangulation_plus_2<Tr> *ctp*(*InputIterator* first,
InputIterator last,
Geom_traits gt= *Geom_traits*())

Introduces and builds a constrained triangulation from the constraints in the range *[first, last)*.

Precondition: The *value_type* of *first* and *last* is *Constraint*.

void *~ctp*()

Destructor. All vertices and faces are deleted. The constraint hierarchy is deleted.

Assignment

Constrained_triangulation_plus_2

ctp = *Constrained_triangulation_plus_2* tr

Assignment. All the vertices and faces are duplicated. The constraint hierarchy is also duplicated.

void *ctp.swap(Constrained_triangulation_plus_2 tr)*

The triangulations *tr* and *ctp* are swapped. This operation should be preferred to *ctp = tr* or to *t(tr)* if *tr* is deleted after that.

Insertion and Removal

The class *Constrained_triangulation_plus_2<Tr>* overwrites the following insertion and removal member functions for points and constraints.

Vertex_handle *ctp.insert(Point p, Face_handle start = Face_handle())*

Inserts point *p* as a vertex of the triangulation.

Vertex_handle *ctp.insert(Point p, Locate_type lt, Face_handle loc, int li)*

inserts a point *p* whose location is assumed to be given by *(lt,loc,li)*.

Vertex_handle *ctp.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >

int *ctp.insert(InputIterator first, InputIterator last)*

Inserts the points in the range *[first, last)*. Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void *ctp.insert_constraint(Point a, Point b)*

Inserts the constraint segment *ab* in the triangulation.

void *ctp.push_back(Constraint c)*

Inserts the constraint *c*.

void *ctp.insert_constraint(Vertex_handle va, Vertex_handle vb)*

Inserts a constraint whose endpoints are the vertices pointed by *va* and *vb* in the triangulation.

<i>void</i>	<i>ctp.remove_constraint(Vertex_handle va, Vertex_handle vb)</i>	<p>Removes the constraint joining the vertices pointed by <i>va</i> and <i>vb</i>.</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> have to refer to the endpoint vertices of an input constraint.</p>
Queries		
<i>Constraint_iterator</i>	<i>ctp.constraints_begin()</i>	Returns a <i>Constraint_iterator</i> pointing on the first constraint.
<i>Constraint_iterator</i>	<i>ctp.constraints_end()</i>	Returns a <i>Constraint_iterator</i> pointing past the last constraint.
<i>Subconstraint_iterator</i>	<i>ctp.subconstraints_begin()</i>	Returns a <i>Subconstraint_iterator</i> pointing on the first sub-constraint.
<i>Subconstraint_iterator</i>	<i>ctp.subconstraints_end()</i>	Returns a <i>Subconstraint_iterator</i> pointing past the last sub-constraint.
<i>int</i>	<i>ctp.number_of_enclosing_constraints(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns the number of constraints enclosing the sub-constraint (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context</i>	<i>ctp.context(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns the <i>Context</i> relative to one of the constraint enclosing the sub-constraint (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context_iterator</i>	<i>ctp.contexts_begin(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns an iterator pointing on the first <i>Context</i> of the sequence of <i>Contexts</i> corresponding to the constraints enclosing the sub-constraint(<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>
<i>Context_iterator</i>	<i>ctp.contexts_end(Vertex_handle va, Vertex_handle vb)</i>	<p>Returns an iterator past the last <i>Context</i> of the sequence of <i>Contexts</i> corresponding to the constraints enclosing the (<i>va,vb</i>).</p> <p><i>Precondition:</i> <i>va</i> and <i>vb</i> refer to the vertices of a constrained edge of the triangulation.</p>

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_begin(Vertex_handle va, Vertex_handle vb)

Returns an iterator on the first vertex on the constraint (*va,vb*)
Precondition: *va* and *vb* refer to the vertices of an input constraint.

Vertices_in_constraint_iterator

ctp.vertices_in_constraint_end(Vertex_handle va, Vertex_handle vb)

Returns an iterator past the last vertex on the constraint (*va,vb*)
Precondition: *va* and *vb* refer to the vertices of an input constraints.

DelaunayTriangulationTraits_2

Definition

In addition to the requirements of the concept *TriangulationTraits_2* described page 1756, the concept *DelaunayTriangulationTraits_2* provide a predicate to check the empty circle property. The corresponding predicate type is called type *Side_of_oriented_circle_2*.

The additional types *Line_2*, *Ray_2* and the constructor objects *Construct_ray_2* *Construct_circumcenter_2*, *Construct_bisector_2*, *Construct_midpoint* are used to build the dual Voronoi diagram and are required only if the dual functions are called. The additional predicate type *Compare_distance_2* is required if calls to *nearest_vertex(..)* are issued.

Refines

TriangulationTraits_2

Types

DelaunayTriangulationTraits_2:: Line_2 The line type. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Ray_2 The type for ray. This type is required only if some dual functions are called.

DelaunayTriangulationTraits_2:: Side_of_oriented_circle_2

Predicate type. Provides the operator :
Oriented_side operator()(Point p, Point q, Point r, Point s) which takes four points *p,q,r,s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or *ON_ORIENTED_BOUNDARY* according to the position of points *s* with respect to the oriented circle through *p,q* and *r*.

DelaunayTriangulationTraits_2:: Compare_distance_2

Predicate type. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q, Point_2 r) which returns *SMALLER*, *EQUAL* or *LARGER* according to the distance between *p* and *q* being smaller, equal or larger than the distance between *p* and *r*. This type is only require if *nearest_vertex* queries are issued.

DelaunayTriangulationTraits_2:: Construct_circumcenter_2

Constructor object. Provides the operator :
Point_2 operator()(Point_2 p, Point_2 q, Point_2 r) which returns the circumcenter of the three points *p, q* and *r*. This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_bisector_2

Constructor object. Provides the operator :
Line_2 operator()(Point_2 p, Point_2 q) which constructs the bisector line of points p and q . This type is required only if functions relative to the dual Voronoi diagram are called.

DelaunayTriangulationTraits_2:: Construct_ray_2

A constructor object to build a ray from a point and a line.
Provides :
Ray_2 operator() (Point_2 p, Line_2 l);

Creation

DelaunayTriangulationTraits_2 traits; default constructor.
DelaunayTriangulationTraits_2 traits(dtt); copy constructor
DelaunayTriangulationTraits_2 traits = traits2

Assignment operator.

Access to predicate and constructor objects

Side_of_oriented_circle_2 traits.side_of_oriented_circle_2_object()

The following functions are required only if member functions of the Delaunay triangulation relative to the dual Voronoi diagram are called. *Compare_distance_2 traits.compare_distance_2_object()*

Construct_circumcenter_2 traits.construct_circumcenter_2_object()

Construct_bisector_2 traits.construct_bisector_2_object()

Construct_direction_2 traits.construct_direction_2_object()

Construct_ray_2 traits.construct_ray_2_object()

TriangulationTraits_2

CGAL::Delaunay_triangulation_2<Traits,Tds>

Definition

The class *Delaunay_triangulation_2<Traits,Tds>* is designed to represent the Delaunay triangulation of a set of points in a plane. A Delaunay triangulation of a set of points is a triangulation of the sets of points that fulfills the following *empty circle property* (also called *Delaunay property*): the circumscribing circle of any facet of the triangulation contains no point of the set in its interior. For a point set with no case of co-circularity of more than three points, the Delaunay triangulation is unique, it is the dual of the Voronoi diagram of the points.

Inherits From

Triangulation_2<Traits,Tds>.

Parameters

The template parameter *Tds* is to be instantiated with a model of *TriangulationDataStructure_2*. CGAL provides a default instantiation for this parameter, which is the class *CGAL::Triangulation_data_structure_2 <CGAL::Triangulation_vertex_base_2<Traits>, CGAL::Triangulation_face_base_2<Traits>>*.

The geometric traits *Traits* is to be instantiated with a model of *DelaunayTriangulationTraits_2*. The concept *DelaunayTriangulationTraits_2* refines the concept *TriangulationTraits_2*, providing a predicate type to check the empty circle property.

Changing this predicate type allows to build Delaunay triangulations for different metrics such that L_1 or L_∞ or any metric defined by a convex object. However, the user of an exotic metric must be careful that the constructed triangulation has to be a triangulation of the convex hull which means that convex hull edges have to be Delaunay edges. This is granted for any smooth convex metric (like L_2) and can be ensured for other metrics (like L_∞) by the addition to the point set of well chosen sentinel points. The concept of *DelaunayTriangulationTraits_2* is described page [1731](#).

When dealing with a large triangulations, the user is advised to encapsulate the Delaunay triangulation class into a triangulation hierarchy, which means to use the class *Triangulation_hierarchy_2<Tr>* with the template parameter instantiated with *Delaunay_triangulation_2<Traits,Tds>*. The triangulation hierarchy will then offer the same functionalities but be much more efficient for locations and insertions.

```
#include <CGAL/Delaunay_triangulation_2.h>
```

Inherits From

Triangulation_2<Traits,Tds>

Types

Inherits all the types defined in *Triangulation_2<Traits,Tds>*.

Creation

Delaunay_triangulation_2<Traits,Tds> dt(Traits gt = Traits());

default constructor.

Delaunay_triangulation_2<Traits,Tds> dt(tr);

copy constructor. All the vertices and faces are duplicated.

Insertion and Removal

The following insertion and removal functions overwrite the functions inherited from the class *Triangulation_2*<Traits,Tds> to maintain the Delaunay property.

Vertex_handle dt.insert(Point p, Face_handle f=Face_handle())

inserts point *p*. If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation is not updated. Optional parameter *f* is used to initialize the location of *p*.

Vertex_handle dt.insert(Point p, Locate_type& lt, Face_handle loc, int li)

inserts a point *p*, the location of which is supposed to be given by (*lt,loc,li*), see the description of member function *locate* in class *Triangulation_2*<Traits,Tds>.

Vertex_handle dt.push_back(Point p)

equivalent to *insert(p)*.

template < class InputIterator >

int dt.insert(InputIterator first, InputIterator last)

inserts the points in the range [*first*, *last*). Returns the number of inserted points.

Precondition: The *value_type* of *first* and *last* is *Point*.

void dt.remove(Vertex_handle v)

removes the vertex from the triangulation.

Note that the other modifier functions of *Triangulation_2*<Traits,Tds> are not overwritten. Thus a call to *insert_in_face* *insert_in_edge*, *insert_outside_convex_hull*, *insert_outside_affine_hull* or *flip* on a valid Delaunay triangulation might lead to a triangulation which is no longer a Delaunay triangulation.

Queries

Vertex_handle *dt.nearest_vertex(Point p, Face_handle f=Face_handle())*

returns any nearest vertex of *p*. The implemented function begins with a location step and *f* may be used to initialize the location.

template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces, OutputItBoundaryEdges>

dt.get_conflicts_and_boundary(Point p,
 OutputItFaces fit,
 OutputItBoundaryEdges eit,
 Face_handle start)

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. This members function outputs in the container pointed to by *fit* the faces which are in conflict with point *p* i. e. the faces whose circumcircle contains *p*. It outputs in the container pointed to by *eit* the the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a *std::pair* the resulting output iterators.

template <class OutputItFaces>
OutputItFaces *dt.get_conflicts(Point p, OutputItFaces fit, Face_handle start)*

same as above except that only the faces in conflict with *p* are output. The function returns the resulting output iterator.

template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

dt.get_boundary_of_conflicts(Point p,
 OutputItBoundaryEdges eit,
 Face_handle start)

OutputItBoundaryEdges stands for an output iterator with *Edge* as value type. This function outputs in the container pointed to by *eit*, the boundary of the zone in conflict with *p*. The boundary edges of the conflict zone are output in counterclockwise order and each edge is described through the incident face which is not in conflict with *p*. The function returns the resulting output iterator.

Voronoi diagram

The following member functions provide the elements of the dual Voronoi diagram.

<i>Point</i>	<i>dt.dual(Face_handle f)</i>	Returns the center of the circle circumscribed to face <i>f</i> . <i>Precondition:</i> <i>f</i> is not infinite
<i>Object</i>	<i>dt.dual(Edge e)</i>	returns a segment, a ray or a line supported by the bisector of the endpoints of <i>e</i> . If faces incident to <i>e</i> are both finite, a segment whose endpoints are the duals of each incident face is returned. If only one incident face is finite, a ray whose endpoint is the dual of the finite incident face is returned. Otherwise both incident faces are infinite and the bisector line is returned.
<i>Object</i>	<i>dt.dual(Edge_circulator ec)</i>	Idem
<i>Object</i>	<i>dt.dual(Edge_iterator ei)</i>	Idem
<i>template < class Stream></i> <i>Stream&</i>		
	<i>dt.draw_dual(Stream & ps)</i>	output the dual Voronoi diagram to stream <i>ps</i> .

Predicates

<i>Oriented_side</i>	<i>dt.side_of_oriented_circle(Face_handle f, Point p)</i>	Returns the side of <i>p</i> with respect to the circle circumscribing the triangle associated with <i>f</i>
----------------------	--	--

└────────── *advanced* ─────────┘

Miscellaneous

The checking function *is_valid()* is also overwritten to additionally test the empty circle property.

<i>bool</i>	<i>dt.is_valid(bool verbose = false, int level = 0)</i>	tests the validity of the triangulation as a <i>Triangulation_2</i> and additionally tests the Delaunay property. This method is mainly useful for debugging Delaunay triangulation algorithms designed by the user.

CGAL::Triangulation_2<Traits,Tds>,
TriangulationDataStructure_2,
DelaunayTriangulationTraits_2,
Triangulation_hierarchy_2<Tr>.

Implementation

Insertion is implemented by inserting in the triangulation, then performing a sequence of Delaunay flips. The number of flips is $O(d)$ if the new vertex is of degree d in the new triangulation. For points distributed uniformly at random, insertion takes time $O(1)$ on average.

Removal calls the removal in the triangulation and then re-triangulates the hole in such a way that the Delaunay criterion is satisfied. Removal of a vertex of degree d takes time $O(d^2)$. The degree d is $O(1)$ for a random vertex in the triangulation.

After a point location step, the nearest neighbor is found in time $O(n)$ in the worst case, but in time $O(1)$ for vertices distributed uniformly at random and any query point.

CGAL::Triangulation_2<Traits,Tds>::Locate_type

Definition

The enum *Locate_type* is defined by the *Triangulation_2<Traits,Tds>* class to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0, EDGE, FACET, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL};
```

The locate type is :

VERTEX when the located point coincides with a vertex of the triangulation

EDGE when the point is in the relative interior of an edge

FACET when the point is in the interior of a facet

OUTSIDE_CONVEX_HULL when the point is outside the convex hull but in the affine hull of the current triangulation

OUTSIDE_AFFINE_HULL when the point is outside the affine hull of the current triangulation.

RegularTriangulationFaceBase_2

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted points are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal of some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation stores those hidden points in special vertices called *hidden* vertices.

A hidden point can appear as a vertex of the triangulation only when the two-dimensional face where its point component is located (the face which hides it) is removed. Therefore we decided to store in each face of a regular triangulation the list of hidden vertices whose points are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base face of a regular triangulation has to be a model of the concept `RegularTriangulationFaceBase_2`, which refines the concept `TriangulationFaceBase_2` by adding in the face a list to store hidden vertices.

Refines

`TriangulationFaceBase_2`

Types

`typedef std::list<Vertex_handle>`

`Vertex_list;` An std list of hidden vertices.

Access Functions

`Vertex_list&` `rfb.vertex_list()` Returns a reference to the list of vertices hidden by the face.

RegularTriangulationTraits_2

Definition

The concept `RegularTriangulationTraits_2` describe the requirements for the traits class of regular triangulations. It refines the concept `TriangulationTraits_2` providing the type `Weighted_point_2` and the *power-test* predicate on those weighted points. A weighted point is basically a point augmented with a scalar weight. It can be seen as a circle when the weight is interpreted as a square radius. The *power-test* on weighted points is the fundamental test to build regular triangulations as the *side_of_oriented_circle* test is the fundamental test of Delaunay triangulations.

Refines

`TriangulationTraits_2`

Types

`RegularTriangulationTraits_2::Bare_point` Another name for the point type.

`RegularTriangulationTraits_2::Weighted_point_2`

The weighted point type, it has to be a model of the concept `WeightedPoint`.

`RegularTriangulationTraits_2::Power_test_2`

A predicate object type. Must provide the operators:

— `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r, Weighted_point_2 s)` which is the power test for points p , q , r and s .

Precondition: the bare points corresponding to p , q , r are not collinear.

— `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r)` which is the degenerated power test for collinear points p , q , r .

Precondition: the bare points corresponding to p , q , r are collinear and $p \neq q$.

— `Oriented_side operator() (Weighted_point_2 p, Weighted_point_2 q)` which is the degenerated power test for weighted points p and q whose corresponding bare-points are identical.

Precondition: the bare points corresponding to p and q are identical.

The following type/predicate is required if a call to `nearest_power_vertex` is issued:

`RegularTriangulationTraits_2::Compare_power_distance_2`

A predicate object type. Must provide the operator:

`Comparison_result operator()(Bare_point p, Weighted_point_2 q, Weighted_point_2 r)`, which compares the power distance between p and q to the power distance between p and r .

A constructor object which constructs the weighted circum-center of three weighted points. Provides the operator *Bare_point operator()* (*Weighted_point_2 p, Weighted_point_2 q, Weighted_point_2 r*);

A constructor type which constructs the radical axis of two weighted points. Provides the operator :

Line_2 operator() (*Weighted_point_2 p*, *Weighted_point_2 q*);

<i>Power_test_2</i>	<i>traits.power_test_2_object()</i>
<i>Compare_power_distance_2</i>	<i>traits.compare_power_distance_2_object()</i>
<i>Construct_weighted_circumcenter_2</i>	<i>traits.construct_weighted_circumcenter_2_object()</i>
<i>Construct_radical_axis_2</i>	<i>traits.construct_radical_axis_2_object()</i>

RegularTriangulationVertexBase_2

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted point are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal on some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation store those hidden points in special vertices called *hidden* vertices.

A hidden point can appear as vertex of the triangulation only when the two dimensional face where its point component is located (the face which hides it) is removed. Therefore we decided to store in each face of a regular triangulation the list of hidden vertices whose points are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base vertex of a regular triangulation has to be a model of the concept `RegularTriangulationVertexBase_2`. The concept `RegularTriangulationVertexBase_2` refines the concept `TriangulationVertexBase_2`, just adding a Boolean to mark if the vertex is a vertex of the triangulation or a hidden vertex.

Refines

`TriangulationVertexBase_2`

Access Functions

bool *rvb.is_hidden()* returns *true*, iff the vertex is hidden.

void *rvb.set_hidden(bool b)*

Mark the vertex as hidden or as not hidden.

CGAL::Regular_triangulation_2<Traits,Tds>

Definition

The class *Regular_triangulation_2<Traits,Tds>* is designed to maintain the regular triangulation of a set of weighted points.

Let $PW = \{(p_i, w_i), i = 1, \dots, n\}$ be a set of weighted points where each p_i is a point and each w_i is a scalar called the weight of point p_i . Alternatively, each weighted point (p_i, w_i) can be regarded as a two dimensional sphere with center p_i and radius $r_i = \sqrt{w_i}$.

The power diagram of the set PW is a planar partition such that each cell corresponds to sphere (p_i, w_i) of PW and is the locus of points p whose power with respect to (p_i, w_i) is less than its power with respect to any other sphere (p_j, w_j) in PW . The dual of this diagram is a triangulation whose domain covers the convex hull of the set $P = \{p_i, i = 1, \dots, n\}$ of center points and whose vertices are a subset of P . Such a triangulation is called a regular triangulation. The three points p_i, p_j and p_k of P form a triangle in the regular triangulation of PW iff there is a point p of the plane whose powers with respect to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) are equal and less than the power of p with respect to any other sphere in PW .

Let us defined the power product of two weighted points (p_i, w_i) and (p_j, w_j) as:

$$\Pi(p_i, w_i, p_j, w_j) = p_i p_j^2 - w_i - w_j.$$

$\Pi(p_i, w_i, p_j, 0)$ is simply the power of point p_j with respect to the sphere (p_i, w_i) , and two weighted points are said to be orthogonal if their power product is null. The power circle of three weighted points (p_i, w_i) , (p_j, w_j) and (p_k, w_k) is defined as the unique circle (π, ω) orthogonal to (p_i, w_i) , (p_j, w_j) and (p_k, w_k) .

The regular triangulation of the sets PW satisfies the following *regular property* (which just reduces to the Delaunay property when all the weights are null): a triangle $p_i p_j p_k$ of the regular triangulation of PW is such that the power product of any weighted point (p_l, w_l) of PW with the power circle of (p_i, w_i) , (p_j, w_j) is (p_k, w_k) is positive or null. We call power test of the weighted point (p_l, w_l) with respect to the face $p_i p_j p_k$, the predicates testing the sign of the power product of (p_l, w_l) with respect to the power circle of (p_i, w_i) , (p_j, w_j) is (p_k, w_k) . This power product is given by the following determinant

$$\begin{vmatrix} 1 & x_i & y_i & x_i^2 + y_i^2 - w_i \\ 1 & x_j & y_j & x_j^2 + y_j^2 - w_j \\ 1 & x_k & y_k & x_k^2 + y_k^2 - w_k \\ 1 & x_l & y_l & x_l^2 + y_l^2 - w_l \end{vmatrix}$$

A pair of neighboring faces $p_i p_j p_k$ and $p_i p_j p_l$ is said to be locally regular (with respect to the weights in PW) if the power test of (p_l, w_l) with respect to $p_i p_j p_k$ is positive. A classical result of computational geometry establishes that a triangulation of the convex hull of P such that any pair of neighboring faces is regular with respect to PW , is a regular triangulation of PW .

Alternatively, the regular triangulation of the weighted points set PW can be obtained as the projection on the two dimensional plane of the convex hull of the set of three dimensional points $P' = \{(p_i, p_i^2 - w_i), i = 1, \dots, n\}$.

The vertices of the regular triangulation of a set of weighted points PW form only a subset of the set of center points of PW . Therefore the insertion of a weighted point in a regular triangulation does not necessarily imply the creation of a new vertex. If the new inserted point does not appear as a vertex in the regular triangulation, it is said to be hidden.

Hidden points are stored in special vertices called hidden vertices. A hidden point is considered as hidden by the facet of the triangulation where its point component is located : in fact, the hidden point can appear as vertex of the triangulation only if this facet is removed. Each face of a regular triangulation stores the list of hidden vertices whose points are located in the facet. When a facet is removed, points hidden by this facet are reinserted in the triangulation.

```
#include <CGAL/Regular_triangulation_2.h>
```

Parameters

The geometric traits parameter *Traits* has to be instantiated with a model of the concept *RegularTriangulationTraits_2*. The concept *RegularTriangulationTraits_2* refines the concept *TriangulationTraits_2* by adding the type *Weighted_point_2* to describe weighted points and the type *Power_test_2* to perform power tests on weighted points.

The *Tds* parameter has to be instantiated by a model of *TriangulationDataStructure_2*. The face base of a regular triangulation has to be a model of the concept *RegularTriangulationFaceBase_2*. while the vertex base class has to be a model of *RegularTriangulationVertexBase_2*. CGAL provides a default instantiation for the *Tds* parameter by the class *CGAL::Triangulation_data_structure_2 < CGAL::Regular_triangulation_vertex_base_2<Traits>, CGAL::Regular_Triangulation_face_base_2<Traits> >*.

Inherits From

Triangulation_2<Traits,Tds>

Types

```
typedef Traits::Distance      Distance;
```

```
typedef Traits::Line          Line;
```

```
typedef Traits::Ray           Ray;
```

```
typedef Traits::Bare_point    Bare_point;
```

```
typedef Traits::Weighted_point Weighted_point;
```

Regular_triangulation_2<Traits,Tds>:: All_vertices_iterator

An iterator that allows to enumerate the vertices that are not hidden.

Regular_triangulation_2<Traits,Tds>:: Finite_vertices_iterator

An iterator that allows to enumerate the finite vertices that are not hidden.

Regular_triangulation_2<Traits,Tds>:: Hidden_vertices_iterator

An iterator that allows to enumerate the hidden vertices.

Creation

```
Regular_triangulation_2<Traits,Tds> rt( Traits gt = Traits());
```

Introduces an empty regular triangulation *rt*.

```
Regular_triangulation_2<Traits,Tds> rt( Regular_triangulation_2 rt);
```

Copy constructor.

Insertion and Removal

```
Vertex_handle rt.insert( Weighted_point p, Face_handle f=Face_handle())
```

inserts weighted point *p* in the regular triangulation. If the point *p* does not appear as a vertex of the triangulation, the returned vertex is a hidden vertex. If given the parameter *f* is used as an hint for the place to start the location process of point *p*.

```
Vertex_handle rt.insert( Weighted_point p, Locate_type lt, Face_handle loc, int li)
```

insert a weighted point *p* whose bare-point is assumed to be located in *lt,loc,li*.

```
Vertex_handle rt.push_back( Point p)
```

 Equivalent to *insert(p)*.

```
template < class InputIterator >  
int rt.insert( InputIterator first, InputIterator last)
```

inserts the weighted points in the range [*first*, *last*). Returns the number of created vertices.

Precondition: The *value_type* of *first* and *last* is *Weighted_point*.

```
void rt.remove( Vertex_handle v)
```

 removes the vertex from the triangulation.

Queries

```
template <class OutputItFaces, class OutputItBoundaryEdges, class OutputItHiddenVertices>  
CGAL::Triple<OutputItFaces,OutputItBoundaryEdges,OutputItHiddenVertices>
```

```
rt.get_conflicts_and_boundary_and_hidden_vertices( Weighted_point p,  
                                                    OutputItFaces fit,  
                                                    OutputItBoundaryEdges eit,  
                                                    OutputItHiddenVertices vit,
```

Face_handle start)

OutputItFaces is an output iterator with *Face_handle* as value type. *OutputItBoundaryEdges* stands for an output iterator with *Edge* as value type. *OutputItHiddenVertices* is an output iterator with *Vertex_handle* as value type. This member function outputs in the container pointed to by *fit* the faces which are in conflict with point *p* i. e. the faces whose power circles have negative power wrt. *p*. It outputs in the container pointed to by *eit* the boundary of the zone in conflict with *p*. It inserts the vertices that would be hidden by *p* into the container pointed to by *vit*. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through its incident face which is not in conflict with *p*. The function returns in a *CGAL::Triple* the resulting output iterators.

```
template <class OutputItFaces, class OutputItBoundaryEdges>
std::pair<OutputItFaces,OutputItBoundaryEdges>
```

```
    rt.get_conflicts_and_boundary( Weighted_point p,
                                   OutputItFaces fit,
                                   OutputItBoundaryEdges eit,
                                   Face_handle start)
```

same as above except that only the faces in conflict with *p* and the boundary edges of the conflict zone are output via the corresponding output iterators. The function returns in a *std::pair* the resulting output iterators.

```
template <class OutputItFaces, class OutputItHiddenVertices>
std::pair<OutputItFaces,OutputItHiddenVertices>
```

```
    rt.get_conflicts_and_hidden_vertices( Weighted_point p,
                                           OutputItFaces fit,
                                           OutputItHiddenVertices vit,
                                           Face_handle start)
```

same as above except that only the faces in conflict with *p* and the vertices that would be hidden by *p* are output via the corresponding output iterators. The function returns in a *std::pair* the resulting output iterators.

```
template <class OutputItBoundaryEdges, class OutputItHiddenVertices>
std::pair<OutputItBoundaryEdges,OutputItHiddenVertices>
```

```
    rt.get_boundary_of_conflicts_and_hidden_vertices( Weighted_point p,
                                                       OutputItBoundaryEdges eit,
                                                       OutputItHiddenVertices vit,
```

Face_handle start)

same as above except that only the vertices that would be hidden by p and the boundary of the zone in conflict with p are output via the corresponding output iterators. The boundary edges of the conflict zone are output in counter-clockwise order and each edge is described through the incident face which is not in conflict with p . The function returns in a `std::pair` the resulting output iterators.

template <class OutputItFaces>
OutputItFaces

rt.get_conflicts(Point p, OutputItFaces fit, Face_handle start)

same as above except that only the faces in conflict with p are output. The function returns the resulting output iterator.

template <class OutputItBoundaryEdges>
OutputItBoundaryEdges

rt.get_boundary_of_conflicts(Point p, OutputItBoundaryEdges eit, Face_handle start)

same as above except that only the boundary edges of the conflict zone are output in counterclockwise order where each edge is described through the incident face which is not in conflict with p . The function returns the resulting output iterator.

template <class OutputItHiddenVertices>
OutputItHiddenVertices

rt.get_hidden_vertices(Point p, OutputItHiddenVertices vit, Face_handle start)

same as above except that only the vertices that would be hidden by p are output. The function returns the resulting output iterator.

Vertex_handle *rt.nearest_power_vertex(Bare_point p)*

Returns the vertex of the triangulation which is nearest to p with respect to the power distance. This means that the power of the query point p with respect to the weighted point in the nearest vertex is smaller than the power of p with respect to the weighted point in any other vertex. Ties are broken arbitrarily. The default constructed handle is returned if the triangulation is empty.

Access functions

<i>int</i>	<i>rt.number_of_vertices()</i>	returns the number of finite vertices that are not hidden.
<i>int</i>	<i>rt.number_of_hidden_vertices()</i>	
		returns the number of hidden vertices.
<i>Hidden_vertices_iterator</i>	<i>rt.hidden_vertices_begin()</i>	
		starts at an arbitrary hidden vertex.
<i>Hidden_vertices_iterator</i>	<i>rt.hidden_vertices_end()</i>	past the end iterator for the sequence of hidden vertices.
<i>Finite_vertices_iterator</i>	<i>rt.finite_vertices_begin()</i>	starts at an arbitrary unhidden finite vertex
<i>Finite_vertices_iterator</i>	<i>rt.finite_vertices_end()</i>	Past-the-end iterator
<i>All_vertices_iterator</i>	<i>rt.all_vertices_end()</i>	starts at an arbitrary unhidden vertex.
<i>All_vertices_iterator</i>	<i>rt.all_vertices_begin()</i>	past the end iterator.

Dual power diagram

The following member functions provide the elements of the dual power diagram.

<i>Point</i>	<i>rt.weighted_circumcenter(Face_handle f)</i>	
		returns the center of the circle orthogonal to the three weighted points corresponding to the vertices of face <i>f</i> . <i>Precondition:</i> <i>f</i> is not infinite
<i>Point</i>	<i>rt.dual(Face_handle f)</i>	same as <i>weighted_circumcenter</i>
<i>Object</i>	<i>rt.dual(Edge e)</i>	If both incident faces are finite, returns a segment whose endpoints are the duals of each incident face. If only one incident face is finite, returns a ray whose endpoint is the dual of the finite incident face and supported by the line which is the bisector of the edge's endpoints. If both incident faces are infinite, returns the line which is the bisector of the edge's endpoints otherwise.
<i>Object</i>	<i>rt.dual(Edge_circulator ec)</i>	
		Idem
<i>Object</i>	<i>rt.dual(Edge_iterator ei)</i>	
		Idem
<i>template < class Stream></i> <i>Stream&</i>	<i>rt.draw_dual(Stream & ps)</i>	
		output the dual power diagram to stream <i>ps</i> .

Predicates

Oriented_side *rt.power_test(Face_handle f, Weighted_point p)*

Returns the power test of *p* with respect to the power circle associated with *f*

————— *advanced* —————

Miscellaneous

bool *rt.is_valid(bool verbose = false, int level = 0)*

Tests the validity of the triangulation as a *Triangulation_2* and additionally test the regularity of the triangulation. This method is useful to debug regular triangulation algorithms implemented by the user.

CGAL::Regular_triangulation_euclidean_traits_2<K,Weight>

Definition

Regular_triangulation_euclidean_traits_2<K,Weight> is a model for the concept *RegularTriangulationTraits_2*. This traits class is templated by a kernel class *K* and a weight type *Weight*. This class inherits from *K* and uses a *Weighted_point* type derived from the type *K::Point_2*.

Note that this template class is specialized for *CGAL::Exact_predicates_inexact_constructions_kernel*, so that it is as if *Regular_triangulation_filtered_traits_2* was used, i.e. you get filtered predicates automatically.

```
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
```

TriangulationFaceBase_2

Definition

The concept `TriangulationFaceBase_2` describes the requirements for the base face class of a triangulation data structure that is itself plugged into a basic triangulation or a Delaunay triangulation.

This concept refines the concept *TriangulationDSFaceBase_2* and could add geometric information. In fact, currently the triangulations of CGAL do not store any geometric information in the faces and, thus this concept is just equal to *TriangulationDSFaceBase_2* and only provided for symmetry with the vertex case.

TriangulationTraits_2

Definition

The concept `TriangulationTraits_2` describes the set of requirements to be fulfilled by any class used to instantiate the first template parameter of the class `Triangulation_2<Traits,Tds>`. This concept provides the types of the geometric primitives used in the triangulation and some function object types for the required predicates on those primitives.

Types

<code>TriangulationTraits_2:: Point_2</code>	The point type.
<code>TriangulationTraits_2:: Segment_2</code>	The segment type.
<code>TriangulationTraits_2:: Triangle_2</code>	The triangle type.
<code>TriangulationTraits_2:: Construct_segment_2</code>	A constructor object for <code>Segment_2</code> . Provides : <code>Segment_2 operator()(Point_2 p,Point_2 q)</code> , which constructs a segment from two points.
<code>TriangulationTraits_2:: Construct_triangle_2</code>	A constructor object for <code>Triangle_2</code> . Provides : <code>Triangle_2 operator()(Point_2 p,Point_2 q,Point_2 r)</code> , which constructs a triangle from three points.
<code>TriangulationTraits_2:: Less_x_2</code>	Predicate object. Provides the operator : <code>bool operator()(Point p, Point q)</code> which returns <code>true</code> if <code>p</code> is before <code>q</code> according to the <code>x</code> -ordering of points.
<code>TriangulationTraits_2:: Less_y_2</code>	Predicate object. Provides the operator : <code>bool operator()(Point p, Point q)</code> which returns <code>true</code> if <code>p</code> is before <code>q</code> according to the <code>y</code> -ordering of points.
<code>TriangulationTraits_2:: Compare_x_2</code>	Predicate object. Provides the operator : <code>Comparison_result operator()(Point p, Point q)</code> which returns <code>SMALLER</code> , <code>EQUAL</code> or <code>LARGER</code> according to the <code>x</code> -ordering of points <code>p</code> and <code>q</code> .
<code>TriangulationTraits_2:: Compare_y_2</code>	Predicate object. Provides the operator : <code>Comparison_result operator()(Point p, Point q)</code> which returns (<code>SMALLER</code> , <code>EQUAL</code> or <code>LARGER</code>) according to the <code>y</code> -ordering of points <code>p</code> and <code>q</code> .
<code>TriangulationTraits_2:: Orientation_2</code>	Predicate object. Provides the operator : <code>Orientation operator()(Point p, Point q, Point r)</code> which returns <code>LEFT_TURN</code> , <code>RIGHT_TURN</code> or <code>COLLINEAR</code> depending on <code>r</code> being, with respect to the oriented line <code>pq</code> , on the left side , on the right side or on the line.

TriangulationTraits_2:: Side_of_oriented_circle_2

Predicate object. Must provide the operator *Oriented_side operator()(Point p, Point q, Point r, Point s)* which takes four points *p,q,r,s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or, *ON_ORIENTED_BOUNDARY* according to the position of points *s* with respect to the oriented circle through through *p,q* and *r*. This type is required only if the function *side_of_oriented_circle(Face_handle f, Point p)* is called.

TriangulationTraits_2:: Construct_circumcenter_2

Constructor object. Provides the operator :
Point operator()(Point p, Point q, Point r)
which returns the circumcenter of the three points *p, q* and *r*. This type is required only if the function *Point circumcenter(Face_handle f)* is called.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.
TriangulationTraits_2 traits; default constructor.
TriangulationTraits_2 traits(gtr); Copy constructor

TriangulationTraits_2 traits = gtr Assignment operator.

Predicate functions

The following functions give access to the predicate and constructor objects.

Construct_segment_2 traits.construct_segment_2_object()

Construct_triangle_2 traits.construct_triangle_2_object()

Comparison_x_2 traits.compare_x_2_object()

Comparison_y_2 traits.compare_y_2_object()

Orientation_2 traits.orientation_2_object()

Side_of_oriented_circle_2

traits.side_of_oriented_circle_2_object()

Required only if *side_of_oriented_circle* is called.

Construct_circumcenter_2

traits.construct_circumcenter_2_object()

Required only if *circumcenter* is called.

TriangulationVertexBase_2

Definition

The concept `TriangulationVertexBase_2` describes the requirements for the vertex base class of a triangulation data structure to be plugged in a basic, Delaunay or constrained triangulations.

The concept `TriangulationVertexBase_2` refines the concept `TriangulationDSVertexBase_2` adding geometric information : the vertex base of a triangulation stores a point.

Refines

`TriangulationDSVertexBase_2`

Types

`TriangulationVertexBase_2::Point`

Must be the same as the point type `TriangulationTraits_2::Point_2` defined by the geometric traits class of the triangulation.

Creation

`TriangulationVertexBase_2 v(Point p);` constructs a vertex embedded in point p .

`TriangulationVertexBase_2 v(Point p, Face_handle f);`
constructs a vertex embedded in point p and pointing on face f .

Access Functions

`Point v.point()` returns the point.

Setting

`void v.set_point(Point p)`
sets the point.

I/O

`istream& istream& is >> &v`

Inputs the non-combinatorial information given by the vertex: the point and other possible information.

ostream&

ostream& os << v

Outputs the non combinatorial operation given by the vertex: the point and other possible information.

Has Models

CGAL::TriangulationVertexBase_2<Traits>.

CGAL::Triangulation_vertex_base_2<Traits>

CGAL::Triangulation_2<Traits,Tds>

Definition

The class *Triangulation_2<Traits,Tds>* is the basic class designed to handle triangulations of set of points *A* in the plane.

Such a triangulation has vertices at the points of *A* and its domain covers the convex hull of *A*. It can be viewed as a planar partition of the plane whose bounded faces are triangular and cover the convex hull of *A*. The single unbounded face of this partition is the complementary of the convex hull of *A*.

In many applications, it is convenient to deal only with triangular faces. Therefore, we add to the triangulation a fictitious vertex, called the *infinite vertex* and we make each convex hull edge incident to an *infinite* face having as third vertex the *infinite vertex*. In that way, each edge is incident to exactly two faces and special cases at the boundary of the convex hull are simpler to deal with.

Figure 25.9: The infinite vertex.

The class *Triangulation_2<Traits,Tds>* implements this point of view and therefore considers the triangulation of the set of points as a set of triangular, finite and infinite faces. Although it is convenient to draw a triangulation as in figure 25.9, note that the *infinite vertex* has no significant coordinates and that no geometric predicate can be applied on it or on an infinite face.

A triangulation is a collection of vertices and faces that are linked together through incidence and adjacency relations. Each face give access to its three incident vertices and to its three adjacent faces. Each vertex give access to one of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2 in counterclockwise order. The neighbor of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by *i* is opposite to the vertex with the same index.

The triangulation class offer two functions *int cw(int i)* and *int ccw(int i)* which given the index of a vertex in a face compute the index of the next vertex of the same face in clockwise or counterclockwise order. Thus, for example the neighbor *neighbor(cw(i))* is the neighbor of *f* which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f* (see Figure 25.10).

```
#include <CGAL/Triangulation_2.h>
```

Parameters

The class *Triangulation_2<Traits,Tds>* has two template parameters. The first one *Traits* is the geometric traits, it is to be instantiated by a model of the concept *TriangulationTraits_2*.

Figure 25.10: Vertices and neighbors.

The second parameter is the triangulation data structure, it has to be instantiated by a model of the concept *TriangulationDataStructure_2*. By default, the triangulation data structure is instantiated by `CGAL::Triangulation_data_structure_2 < CGAL::Triangulation_vertex_base_2<Gt>, CGAL::Triangulation_face_base_2<Gt> >>`.

Inherits From

Triangulation_cw_ccw_2 This class provides the functions *cw(i)* and *ccw(i)*.

Types

<code>typedef Traits</code>	<code>Geom_traits;</code>	the traits class.
<code>typedef Tds</code>	<code>Triangulation_data_structure;</code>	the triangulation data structure type.
<code>typedef Traits::Point_2</code>	<code>Point;</code>	the point type
<code>typedef Traits::Segment_2</code>	<code>Segment;</code>	the segment type
<code>typedef Traits::Triangle_2</code>	<code>Triangle;</code>	the triangle type
<code>typedef Tds::Vertex</code>	<code>Vertex;</code>	the vertex type.
<code>typedef Tds::Face</code>	<code>Face;</code>	the face type.
<code>typedef Tds::Edge</code>	<code>Edge;</code>	the edge type.
<code>typedef Tds::size_type</code>	<code>size_type;</code>	Size type (an unsigned integral type)
<code>typedef Tds::difference_type</code>	<code>difference_type;</code>	Difference type (a signed integral type)

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. The handles are models of the concept *Handle* which basically offers the two dereference operators `*` and `->`. The iterators and circulators are all bidirectional and non mutable. The circulators and iterators are convertible to handles with the same value type, so that whenever a handle appear in the parameter list of a function, an appropriate iterator or circulator can be passed as well.

The edges of the triangulation can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non mutable.

In the following, we called *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the triangulation is said to be *finite*. Some iterators (the *All* iterators

) allows to visit finite or infinite feature while others (the *Finite* iterators) visit only finite features. Circulators visit infinite features as well as finite ones.

<code>typedef Tds::Vertex_handle</code>	<code>Vertex_handle;</code>	handle to a vertex
<code>typedef Tds::Face_handle</code>	<code>Face_handle;</code>	handle to a face
<code>typedef Tds::Face_iterator</code>	<code>All_faces_iterator;</code>	iterator over all faces.
<code>typedef Tds::Edge_iterator</code>	<code>All_edges_iterator;</code>	iterator over all edges
<code>typedef Tds::Vertex_iterator</code>	<code>All_vertices_iterator;</code>	iterator over all vertices
<code>Triangulation_2<Traits,Tds>:: Finite_faces_iterator</code>		iterator over finite faces.
<code>Triangulation_2<Traits,Tds>:: Finite_edges_iterator</code>		iterator over finite edges.
<code>Triangulation_2<Traits,Tds>:: Finite_vertices_iterator</code>		iterator over finite vertices.
<code>Triangulation_2<Traits,Tds>:: Point_iterator</code>		iterator over the points corresponding the finite vertices of the triangulation.
<code>Triangulation_2<Traits,Tds>:: Line_face_circulator</code>		circulator over all faces intersected by a line.
<code>Triangulation_2<Traits,Tds>:: Face_circulator</code>		circulator over all faces incident to a given vertex.
<code>Triangulation_2<Traits,Tds>:: Edge_circulator</code>		circulator over all edges incident to a given vertex.
<code>Triangulation_2<Traits,Tds>:: Vertex_circulator</code>		circulator over all vertices incident to a given vertex.

The triangulation class also defines the following enum type to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0, EDGE, FACE, OUTSIDE_CONVEX_HULL, OUTSIDE_AFFINE_HULL};
```

The locate type is *OUTSIDE_CONVEX_HULL* when the point is outside the convex hull but in the affine hull of the current triangulation.

The locate type is *OUTSIDE_AFFINE_HULL* when the point is outside the affine hull of the current triangulation.

Creation

```
Triangulation_2<Traits,Tds> t;           default constructor.
Triangulation_2<Traits,Tds> t( Traits gt = Traits());
```

Introduces an empty triangulation *t*.

Triangulation_2<*Traits*,*Tds*> *t*(*Triangulation_2 tr*);

Copy constructor. All the vertices and faces are duplicated. After the copy, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.

Triangulation_2 *t = tr*

Assignment. All the vertices and faces are duplicated. After the assignment, *t* and *tr* refer to different triangulations : if *tr* is modified, *t* is not.

void *t.swap(Triangulation_2& tr)*

The triangulations *tr* and *t* are swapped. *t.swap(tr)* should be preferred to *t = tr* or to *t(tr)* if *tr* is deleted after that.

void *t.clear()*

Deletes all faces and finite vertices resulting in an empty triangulation.

Access Functions

Geom_traits *t.geom_traits()*
TriangulationDataStructure_2

Returns a const reference to the triangulation traits object.

t.tds()

Returns a const reference to the triangulation data structure.

————— *advanced* —————

Non const access

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*.

TriangulationDataStructure_2&

t.tds()

Returns a reference to the triangulation data structure.

This method is mainly a help for users implementing their own triangulation algorithms.

————— *advanced* —————

int *t.dimension()*

Returns the dimension of the convex hull.

size_type *t.number_of_vertices()*

Returns the number of finite vertices.

size_type *t.number_of_faces()*

Returns the number of finite faces.

Face_handle *t.infinite_face()*

a face incident to the *infinite_vertex*.

Vertex_handle *t.infinite_vertex()*

the *infinite_vertex*.

Vertex_handle *t.finite_vertex()*

a vertex distinct from the *infinite_vertex*.

Predicates

The class *Triangulation_2*<*Traits*,*Tds*> provides methods to test the finite or infinite character of any feature, and also methods to test the presence in the triangulation of a particular feature (edge or face).

bool t.is_infinite(Vertex_handle v) *true* iff *v* is the *infinite_vertex*.
bool t.is_infinite(Face_handle f) *true* iff face *f* is infinite.
bool t.is_infinite(Face_handle f, int i) *true* iff edge (*f,i*) is infinite.
bool t.is_infinite(Edge e) *true* iff edge *e* is infinite.
bool t.is_infinite(Edge_circulator ec) *true* iff edge **ec* is infinite.
bool t.is_infinite(Edge_iterator ei) *true* iff edge **ei* is infinite.

bool t.is_edge(Vertex_handle va, Vertex_handle vb)
true if there is an edge having *va* and *vb* as vertices.

bool t.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle& fr, int & i)
as above. In addition, if *true* is returned, the edge with vertices *va* and *vb* is the edge *e=(fr,i)* where *fr* is a handle to the face incident to *e* and on the right side of *e* oriented from *va* to *vb*.

bool t.includes_edge(Vertex_handle va, Vertex_handle & vb, Face_handle& fr, int & i)
true if the line segment from *va* to *vb* includes an edge *e* incident to *va*. If *true*, *vb* becomes the other vertex of *e*, *e* is the edge (*fr,i*) where *fr* is a handle to the face incident to *e* and on the right side *e* oriented from *va* to *vb*.

bool t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)
true if there is a face having *v1*, *v2* and *v3* as vertices.

bool t.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr)
as above. In addition, if *true* is returned, *fr* is a handle to the face with *v1*, *v2* and *v3* as vertices.

Queries

The class *Triangulation_2<Traits,Tds>* provides methods to locate a given point with respect to a triangulation. It also provides methods to locate a point with respect to a given finite face of the triangulation.

Face_handle t.locate(Point query, Face_handle f = Face_handle())

If the point *query* lies inside the convex hull of the points, a face that contains the query in its interior or on its boundary is returned.

If the point *query* lies outside the convex hull of the triangulation but in the affine hull, the returned face is an infinite face which is a proof of the point's location :

- for a two dimensional triangulation, it is a face (∞, p, q) such that *query* lies to the left of the oriented line *pq* (the rest of the triangulation lying to the right of this line).

- for a degenerate one dimensional triangulation it is the (degenerate one dimensional) face $(\infty, p, NULL)$ such that *query* and the triangulation lie on either side of *p*.

If the point *query* lies outside the affine hull, the returned *Face_handle* is *NULL*.

The optional *Face_handle* argument, if provided, is used as a hint of where the locate process has to start its search.

Face_handle *t.locate(Point query, Locate_type& lt, int& li, Face_handle h = Face_handle())*

Same as above. Additionally, the parameters *lt* and *li* describe where the query point is located. The variable *lt* is set to the locate type of the query. If *lt*==*VERTEX* the variable *li* is set to the index of the vertex, and if *lt*==*EDGE* *li* is set to the index of the vertex opposite to the edge. Be careful that *li* has no meaning when the query type is *FACE*, *OUTSIDE_CONVEX_HULL*, or *OUTSIDE_AFFINE_HULL* or when the triangulation is 0-dimensional.

Oriented_side *t.oriented_side(Face_handle f, Point p)*

Returns on which side of the oriented boundary of *f* lies the point *p*.
Precondition: *f* is finite.

Oriented_side *t.side_of_oriented_circle(Face_handle f, Point p)*

Returns on which side of the circumcircle of face *f* lies the point *p*. The circle is assumed to be counterclockwise oriented, so its positive side correspond to its bounded side. This predicate is available only if the corresponding predicates on points is provided in the geometric traits class.

Modifiers

The following operations are guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

void *t.flip(Face_handle f, int i)*

Exchanges the edge incident to *f* and *f->neighbor(i)* with the other diagonal of the quadrilateral formed by *f* and *f->neighbor(i)*.
Precondition: The faces *f* and *f->neighbor(i)* are finite faces and their union form a convex quadrilateral.

Vertex_handle *t.insert(Point p, Face_handle f = Face_handle())*

Inserts point *p* in the triangulation and returns the corresponding vertex.
 If point *p* coincides with an already existing vertex, this vertex is returned and the triangulation remains unchanged.
 If point *p* is on an edge, the two incident faces are split in two.
 If point *p* is strictly inside a face of the triangulation, the face is split in three.
 If point *p* is strictly outside the convex hull, *p* is linked to all visible points on the convex hull to form the new triangulation.
 At last, if *p* is outside the affine hull (in case of degenerate 1-dimensional or 0-dimensional triangulations), *p* is linked all the other vertices to form a triangulation whose dimension is increased by one.
 The last argument *f* is an indication to the underlying locate algorithm of where to start.

Figure 25.11: Insertion of a point on an edge.

Figure 25.12: Insertion in a face.

Vertex_handle *t.insert(Point p, Locate_type lt, Face_handle loc, int li)*

Same as above except that the location of the point *p* to be inserted is assumed to be given by (lt, loc, i) (see the description of the *locate* method above.)

Vertex_handle *t.push_back(Point p)*

Equivalent to *insert(p)*.

template < class InputIterator >
int *t.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.

Precondition: The *value_type* of *InputIterator* is *Point*.

void *t.remove(Vertex_handle v)*

Removes the vertex from the triangulation. The created hole is re-triangulated.

Precondition: Vertex *v* must be finite.

— *advanced* —

The following member functions offer more specialized versions of the insertion or removal operations to be used when one knows to be in the corresponding case.

Figure 25.13: Insertion outside the convex hull.

Figure 25.14: Removal

Vertex_handle *t.insert_first(Point p)*

Inserts the first finite vertex .

Vertex_handle *t.insert_second(Point p)*

Inserts the second finite vertex .

Vertex_handle *t.insert_in_face(Point p, Face_handle f)*

Inserts vertex v in face f . Face f is modified, two new faces are created.

Precondition: The point in vertex v lies inside face f .

Vertex_handle *t.insert_in_edge(Point p, Face_handle f, int i)*

Inserts vertex v in edge i of f .

Precondition: The point in vertex v lies on the edge opposite to the vertex i of face f .

Vertex_handle *t.insert_outside_convex_hull(Point p, Face_handle f)*

Inserts a point which is outside the convex hull but in the affine hull.

Precondition: The handle f points to a face which is a proof of the location of p , see the description of the *locate* method above.

Vertex_handle *t.insert_outside_affine_hull(Point p)*

Inserts a point which is outside the affine hull.

void *t.remove_degree_3(Vertex_handle v)*

Removes a vertex of degree three. Two of the incident faces are destroyed, the third one is modified.

Precondition: Vertex v is a finite vertex with degree three.

void *t.remove_second(Vertex_handle v)*

Removes the before last finite vertex.

void *t.remove_first(Vertex_handle v)*

Removes the last finite vertex.

The following functions are mainly intended to be used in conjunction with the *find_conflicts()* member functions of Delaunay and constrained Delaunay triangulations to perform insertions.

```
template<class EdgeIt>
Vertex_handle t.star_hole( Point p, EdgeIt edge_begin, EdgeIt edge_end)
```

creates a new vertex v and use it to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end]$. Returns a handle to the new vertex.

```
template<class EdgeIt, class FaceIt>
Vertex_handle t.star_hole( Point p,
                          EdgeIt edge_begin,
                          EdgeIt edge_end,
                          FaceIt face_begin,
                          FaceIt face_end)
```

same as above, except that the algorithm first recycles faces in the sequence $[face_begin, face_end]$ and create new ones only when the sequence is exhausted.

_____ advanced _____

Traversal of the Triangulation

A triangulation can be seen as a container of faces and vertices. Therefore the triangulation provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex
<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_end()</i>	Past-the-end iterator
<i>Finite_edges_iterator</i>	<i>t.finite_edges_begin()</i>	Starts at an arbitrary finite edge
<i>Finite_edges_iterator</i>	<i>t.finite_edges_end()</i>	Past-the-end iterator
<i>Finite_faces_iterator</i>	<i>t.finite_faces_begin()</i>	Starts at an arbitrary finite face
<i>Finite_faces_iterator</i>	<i>t.finite_faces_end()</i>	Past-the-end iterator
<i>Point_iterator</i>	<i>t.points_begin()</i>	
<i>Point_iterator</i>	<i>t.points_end()</i>	Past-the-end iterator

The following iterators allow respectively to visit all (finite or infinite) faces, edges and vertices of the triangulation. These iterators are non mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>All_vertices_iterator</i>	<i>t.all_vertices_begin()</i>	Starts at an arbitrary vertex
<i>All_vertices_iterator</i>	<i>t.all_vertices_end()</i>	Past-the-end iterator
<i>All_edges_iterator</i>	<i>t.all_edges_begin()</i>	Starts at an arbitrary edge

<i>All_edges_iterator</i>	<i>t.all_edges_end()</i>	Past-the-end iterator
<i>All_faces_iterator</i>	<i>t.all_faces_begin()</i>	Starts at an arbitrary face
<i>All_faces_iterator</i>	<i>t.all_faces_end()</i>	Past-the-end iterator

Line Face Circulator

The triangulation defines a circulator that allows to visit all faces that are intersected by a line. A face f is considered as being intersected by the oriented line l if either:

- f is a finite face whose interior intersects l , or
- f is a finite face with an edge collinear with l and lies to the left of l , or
- f is an infinite face incident to a convex hull edge whose interior is intersected by l , or
- f is an infinite face incident to a convex hull vertex lying on l and the finite edge of f lies to the left of l .

The circulator has a singular value if the line l intersect no finite face of the triangulation. This circulator is non-mutable and bidirectional. Its value type is *Face*.

Line_face_circulator *t.line_walk(Point p, Point q, Face_handle f = Face_handle())*

This function returns a circulator that allows to visit the faces intersected by the line pq . If there is no such face the circulator has a singular value.

The starting point of the circulator is the face f , or the first finite face traversed by l , if f is omitted.

The circulator wraps around the *infinite_vertex* : after the last traversed finite face, it steps through the infinite face adjacent to this face then through the infinite face adjacent to the first traversed finite face then through the first finite traversed face again.

Precondition: Points p and q must be different points.

Precondition: If $f \neq \text{NULL}$, it must point to a finite face and the point p must be inside or on the boundary of f .

Figure 25.15 illustrates which finite faces are enumerated. Lines l_1 and l_2 have no face to their left. Lines l_3 and l_4 have faces to their left. Note that the finite faces that are only vertex incident to lines l_3 and l_4 are not enumerated.

A line face circulator is invalidated if the face the circulator refers to is changed.

Face, Edge and Vertex Circulators

The triangulation also provides circulators that allows to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge or a vertex circulator are invalidated by any modification of one of the two faces incident to the edge pointed to.

Face_circulator *t.incident_faces(Vertex_handle v)*

Starts at an arbitrary face incident to v .

Figure 25.15: The line face circulator.

<i>Face_circulator</i>	<i>t.incident_faces(Vertex_handle v, Face_handle f)</i>	Starts at face <i>f</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .
<i>Edge_circulator</i>	<i>t.incident_edges(Vertex_handle v)</i>	Starts at an arbitrary edge incident to <i>v</i> .
<i>Edge_circulator</i>	<i>t.incident_edges(Vertex_handle v, Face_handle f)</i>	Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .
<i>Vertex_circulator</i>	<i>t.incident_vertices(Vertex_handle v)</i>	Starts at an arbitrary vertex incident to <i>v</i> .
<i>Vertex_circulator</i>	<i>t.incident_vertices(Vertex_handle v, Face_handle f)</i>	Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above functions allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

<i>Face_circulator</i>	<i>t.incident_faces(t.infinite_vertex())</i>
<i>Face_circulator</i>	<i>t.incident_faces(t.infinite_vertex(), Face_handle f)</i>
<i>Edge_circulator</i>	<i>t.incident_edges(t.infinite_vertex())</i>
<i>Edge_circulator</i>	<i>t.incident_edges(t.infinite_vertex(), Face_handle f)</i>
<i>Vertex_circulator</i>	<i>t.incident_vertices(t.infinite_vertex() v)</i>
<i>Vertex_circulator</i>	<i>t.incident_vertices(t.infinite_vertex(), Face_handle f)</i>

Traversal between adjacent faces

Vertex_handle *t.mirror_vertex(Face_handle f, int i)*

returns the vertex of the i^{th} neighbor of f that is opposite to f .
Precondition: $0 \leq i \leq 2$.

int *t.mirror_index(Face_handle f, int i)*

returns the index of f in its i^{th} neighbor.
Precondition: $0 \leq i \leq 2$.

Miscellaneous

int *t.ccw(int i)*

Returns $i + 1$ modulo 3.

Precondition: $0 \leq i \leq 2$.

int *t.cw(int i)*

Returns $i + 2$ modulo 3.

Precondition: $0 \leq i \leq 2$.

Triangle

t.triangle(Face_handle f)

Returns the triangle formed by the three vertices of f .

Precondition: The face is finite.

Segment *t.segment(Face_handle f, int i)*

Returns the line segment formed by the vertices $ccw(i)$ and $cw(i)$ of face f .

Precondition: $0 \leq i \leq 2$. The vertices $ccw(i)$ and $cw(i)$ of f are finite.

Segment *t.segment(Edge e)*

Returns the line segment corresponding to edge e .

Precondition: e is a finite edge

Segment *t.segment(Edge_circulator ec)*

Returns the line segment corresponding to edge $*ec$.

Precondition: $*ec$ is a finite edge.

Segment *t.segment(Edge_iterator ei)*

Returns the line segment corresponding to edge $*ei$.

Precondition: $*ei$ is a finite edge.

Point *t.circumcenter(Face_handle f)*

Compute the circumcenter of the face pointed to by f . This function is available only if the corresponding function is provided in the geometric traits.

————— *advanced* —————

Setting

void *t.set_infinite_vertex(Vertex_handle v)*

Checking

The responsibility of keeping a valid triangulation belongs to the users if advanced operations are used. Obviously the advanced user, who implements higher levels operations may have to make a triangulation invalid at some times. The following method is provided to help the debugging.

bool *t.is_valid(bool verbose = false, int level = 0)*

Checks the combinatorial validity of the triangulation and also the validity of its geometric embedding. This method is mainly a debugging help for the users of advanced features.

I/O

The I/O operators are defined for *iostream*. The format for the *iostream* is an internal format.

ostream& *ostream*& *os* << *T*

Inserts the triangulation *t* into the stream *os*.

Precondition: The insert operator must be defined for *Point*.

istream& *istream*& *is* >> *T* Reads a triangulation from stream *is* and assigns it to *t*.

Precondition: The extract operator must be defined for *Point*.

The information output in the *iostream* is:

- the dimension, the number of vertices (including the infinite one), and the number of faces (including infinite ones).
- for each vertex (except the infinite vertex), the non combinatorial information stored in that vertex (point, etc.).
- for each faces, the indices of its vertices and the non combinatorial information (if any) in this face. - for each face again the indices of the neighboring faces.

The index of an item (vertex or face) is the rank of this item in the output order. When dimension < 2, the same information is output for faces of maximal dimension instead of faces.

CGAL also provides stream operators << to draw triangulations on *CGAL::Window_stream*, the LEDA based graphic package, and on *CGAL::Qt_widget*, the Qt based graphic package. These operators requires respectively the include statements :

#include CGAL/IO/Window_stream.h

#include CGAL/IO/Qt_widget_Triangulation_2.h

See the *Window_stream* and *Qt_widget* classes.

Implementation

Locate is implemented by a line walk from a vertex of the face given as optional parameter (or from a finite vertex of *infinite_face()* if no optional parameter is given). It takes time $O(n)$ in the worst case, but only $O(\sqrt{n})$ on average if the vertices are distributed uniformly at random.

Insertion of a point is done by locating a face that contains the point, and then splitting this face. If the point falls outside the convex hull, the triangulation is restored by flips. Apart from the location, insertion takes a time time $O(1)$. This bound is only an amortized bound for points located outside the convex hull.

Removal of a vertex is done by removing all adjacent triangles, and re-triangulating the hole. Removal takes time $O(d^2)$ in the worst case, if *d* is the degree of the removed vertex, which is $O(1)$ for a random vertex.

The face, edge, and vertex iterators on finite features are derived from their counterparts visiting all (finite and infinite) features which are themselves derived from the corresponding iterators of the triangulation data structure.

CGAL::Triangulation_face_base_2<Traits>

Definition

Many of the classes in the triangulation package inherit from *Triangulation_cw_ccw_2*. This is for instance the case for *CGAL::Triangulation_2<Traits,Tds>::Face*. Thus, for example the neighbor *neighbor(cw(i))* of a face *f* is the neighbor which is next to *neighbor(i)* turning clockwise around *f*. The face *neighbor(cw(i))* is also the first face encountered after *f* when turning clockwise around vertex *i* of *f*.

```
#include <CGAL/Triangulation_2.h>
```

Creation

Triangulation_cw_ccw_2 *a*; default constructor.

Operations

<i>int</i>	<i>a.ccw(const int i)</i>	returns the index of the neighbor or vertex that is next to the neighbor or vertex with index <i>i</i> in counterclockwise order around a face.
------------	-----------------------------	---

<i>int</i>	<i>a.cw(const int i)</i>	returns the index of the neighbor or vertex that is next to the neighbor or vertex with index <i>i</i> in counterclockwise order around a face.

CGAL::Delaunay_triangulation_2<*Traits*,*Tds*>

CGAL::Triangulation_euclidean_traits_xy_3<*K*>

CGAL::Triangulation_euclidean_traits_xy_3<K>

Definition

The class *Triangulation_euclidean_traits_xy_3<K>* is a geometric traits class which allows to triangulate a terrain. This traits class is designed to build a two dimensional triangulation embedded in 3D space, i.e. a triangulated surface, such that its on the *xy* plane is a Delaunay triangulation. This is a usual construction for GIS terrains. Instead of really projecting the 3D points and maintaining a mapping between each point and its projection (which costs space and is error prone) the class *Triangulation_euclidean_traits_xy_3<K>* supplies geometric predicates that ignore the *z*-coordinate of the points.

The class is a model of the concept *DelaunayTriangulationTraits_2* except that it does not provide the type and constructors required to build the dual Voronoi diagram.

Parameters

The template parameter *K* has to be instantiated by a model of the *Kernel* concept. *Triangulation_euclidean_traits_xy_3<K>* uses types and predicates defined in *K*.

```
#include <CGAL/Triangulation_euclidean_traits_xy_3.h>
```

Types

```
typedef Point_3<K>      Point_2;
typedef Segment_3<K>    Segment_2;

typedef Triangle_3<K>    Triangle_2;
```

The following predicates and constructor types are provided

Triangulation_euclidean_traits_xy_3<K>::Construct_segment_2

A constructor object for *Segment_2*. Provides :
Segment_2 operator()(Point_2 p, Point_2 q),
 which constructs a segment from two points.

Triangulation_euclidean_traits_xy_3<K>::Construct_triangle_2

A constructor object for *Triangle_2*. Provides :
Triangle_2 operator()(Point_2 p, Point_2 q, Point_2 r),
 which constructs a triangle from three points.

Triangulation_euclidean_traits_xy_3<K>::Compare_x_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
 which returns *SMALLER*, *EQUAL* or *LARGER* according to the *x*-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Compare_y_2

Predicate object. Provides the operator :
Comparison_result operator()(Point_2 p, Point_2 q)
which returns (*SMALLER*, *EQUAL* or *LARGER*) according to the y-ordering of points *p* and *q*.

Triangulation_euclidean_traits_xy_3<K>:: Orientation_2

Predicate object. Provides the operator :
Orientation operator()(Point_2 p, Point_2 q, Point_2 r)
which returns *LEFT_TURN*, *RIGHT_TURN* or *COLLINEAR* according to the position of the projection of *r* with respect to the projection of the oriented line *pq*.

Triangulation_euclidean_traits_xy_3<K>:: Side_of_oriented_circle_2

Predicate object. Provides the operator : *Oriented_side operator()(Point_2 p, Point_2 q, Point_2 r, Point_2 s)* which takes four points *p, q, r, s* as arguments and returns *ON_POSITIVE_SIDE*, *ON_NEGATIVE_SIDE* or, *ON_ORIENTED_BOUNDARY* according to the position of the projection of points with respect to the oriented circle through the projections of *p, q* and *r*.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.

Triangulation_euclidean_traits_xy_3<K> traits;

default constructor.

Triangulation_euclidean_traits_xy_3<K> traits(Triangulation_euclidean_traits_xy_3 tr);

Copy constructor.

Triangulation_euclidean_traits_xy_3 traits = Triangulation_euclidean_traits_xy_3 tr

Assignment operator.

Access to predicate objects

The following access functions are provided

<i>Construct_segment_2</i>	<i>traits.construct_segment_2_object()</i>
<i>Construct_triangle_2</i>	<i>traits.construct_triangle_2_object()</i>
<i>Comparison_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Comparison_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Orientation_2</i>	<i>traits.orientation_2_object()</i>
<i>Side_of_oriented_circle_2</i>	<i>traits.side_of_oriented_circle_2_object()</i>

CGAL::Triangulation_face_base_2<Traits,Fb>

Definition

The class *Triangulation_face_base_2<Traits,Fb>* is a model for the concept *TriangulationFaceBase_2*. It is the default face base class for basic and Delaunay triangulation.

These default base class can be used directly or can serve as a base to derive other base classes with some additional attribute (a color for example) tuned for specific applications.

Parameters

The first template parameter of *Triangulation_face_base_2<Traits,Fb>* is a geometric traits class. The geometric traits is actually not used by the class.

The second template parameter has to be a model of the concept *TriangulationDSFaceBase_2* and will serve as a base class for *Triangulation_face_base_2<Traits,Fb>*. CGAL provides a default instantiation for this parameter which is *Triangulation_ds_face_base_2<>*.

CGAL::Triangulation_face_base_with_info_2<Info,Traits,Fb>

Definition

The class *Triangulation_face_base_with_info_2<Info,Traits,Fb>* is a model of the concept *TriangulationFaceBase_2* to be plugged into the triangulation data structure of a triangulation class. It provides an easy way to add some user defined information in the faces of a triangulation.

```
#include <CGAL/Triangulation_face_base_with_info_2.h>
```

Parameters

The first template argument is the information the user would like to add to a face. It has to be *DefaultConstructible* and *Assignable*.

The second template argument is a geometric traits class and is actually not used in *Triangulation_face_base_with_info_2<Info,Traits,Fb>* .

The third parameter is a face base class from which *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives.

Inherits From

Fb

Is Model for the Concepts

Because *Triangulation_face_base_with_info_2<Info,Traits,Fb>* derives from the class instantiating its third parameter, it will be a model of the same face base concept as its parameter : *TriangulationFaceBase_2*, *ConstrainedTriangulationFaceBase_2* , or *RegularTriangulationFaceBase_2*

Types

```
typedef Info          Info;
```

Access Functions

<i>const Info&</i>	<i>f.info() const</i>	Returns a const reference to the object of type <i>Info</i> stored in the face.
<i>Info&</i>	<i>f.info()</i>	Returns a reference to the object of type <i>Info</i> stored in the face.

CGAL::Triangulation_hierarchy_2<Tr>

Definition

The class *Triangulation_hierarchy_2<Tr>* implements a triangulation augmented with a data structure which allows fast point location queries.

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level.

Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level.

Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data. As proved in [Dev98], this structure has an optimal behavior when it is built for Delaunay triangulations. However it can be used as well for other triangulations. The class *Triangulation_hierarchy_2<Tr>* is templated by a parameter which is to be instantiated by anyone of the CGAL triangulation classes.

```
#include <CGAL/Triangulation_hierarchy_2.h>
```

Inherits From

Tr

Types

The class *Triangulation_hierarchy_2<Tr>* inherits the types from its base triangulation class *Tr*.

The class *Triangulation_hierarchy_2<Tr>* offers exactly the same functionalities as the triangulation *Tr* does. Location queries are overloaded to benefit from the data structure. Modifiers (insertion, removal) are overloaded to take care of updating the data structure.

Be careful that I/O operations are not overloaded. Writing a *Triangulation_hierarchy_2<Tr>* into a file writes only the lowest level triangulation and drop the hierarchy and reading it from a file results in a triangulation whose efficiency will be that of an ordinary triangulation.

CGAL::Triangulation_vertex_base_2<Traits,Vb>

Definition

The class *Triangulation_vertex_base_2<Traits,Vb>* is the default model for the concept *TriangulationVertexBase_2*.

Triangulation_vertex_base_2<Traits,Vb> can be simply plugged in the triangulation data structure of a triangulation, or used as a base class to derive other base vertex classes tuned for specific applications.

```
#include <CGAL/Triangulation_vertex_base_2.h>
```

Parameters

Triangulation_vertex_base_2<Traits,Vb> is templated by a geometric traits class which provide the type *Point*. It is strongly recommended to instantiate this traits class with the model used for the triangulation traits class. This ensures that the point type defined by *Triangulation_vertex_base_2<Traits,Vb>* is the same as the point type defined by the triangulation.

The second template parameter of *Triangulation_vertex_base_2<Traits,Vb>* has to be a model of the concept *TriangulationDSVertexBase_2*. By default this parameter is instantiated by *CGAL::Triangulation_ds_vertex_base_2<>*.

26.1 Definition

A triangulation data structure is a data structure designed to handle the representation of a two dimensional triangulation. The concept of triangulation data structure was primarily designed to serve as a data structure for CGAL 2D triangulation classes which are triangulations embedded in a plane. However it appears that the concept is more general and can be used for any orientable triangulated surface without boundary, whatever may be the dimensionality of the space the triangulation is embedded in.

26.1.1 A Data Structure Based on Faces and Vertices

The representation of CGAL 2D triangulations is based on faces and vertices, Edges are only implicitly represented through the adjacency relations between two faces.

The triangulation data structure can be seen as a container for faces and vertices maintaining incidence and adjacency relations among them.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

Figure 26.1: Vertices and neighbors.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 26.1, the functions $ccw(i)$ and $cw(i)$ shown on this figure compute respectively $i + 1$ and $i - 1$ modulo 3

Each edge has two implicit representations: the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f .

This kind of representation of simplicial complexes extends in any dimension. More precisely, in dimension d , the data structure will explicitly represents cells (i. e. faces of maximal dimension) and vertices (i. e. faces of dimension 0). All faces of dimension between 1 and $d - 1$ will have an implicit representation. The 2D triangulation data structure can represent simplicial complexes of dimension 2, 1 or 0.

26.1.2 The Set of Faces and Vertices

The set of faces maintained by a 2D triangulation data structure is such that each edge is incident to two faces. In other words, the set of maintained faces is topologically equivalent to a two-dimensional triangulated sphere.

This rule extends to lower dimensional triangulation data structure arising in degenerate cases or when the triangulations have less than three vertices. A one dimensional triangulation structure maintains a set of vertices and edges which forms a ring topologically equivalent to a 1-sphere.

A zero dimensional triangulation data structure only includes two adjacent vertices that is topologically equivalent to a 0-sphere.

26.2 The Concept of Triangulation Data Structure

A model of *TriangulationDataStructure_2* can be seen has a container for the faces and vertices of the triangulation. This class is also responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure maintains proper incidence and adjacency relations among the vertices and faces of a triangulation while combinatorial modifications of the triangulation are performed. The term combinatorial modification refers to operations which do not involve any knowledge about the geometric embedding of the triangulation. For example, the insertion of a new vertex in a given face, or in a given edge, the suppression of a vertex of degree three, the flip of two edge are examples of combinatorial operation performed at the data structure level.

The triangulation data structure is required to provide:

Figure 26.2: Insertion of a new vertex, splitting a face

- the types *Vertex* and *Face* for the vertices and faces of the triangulations
- the type *Vertex_handle* and *Face_handle* which are models of the concept *Handle* and through which the vertices and faces are accessed.
- iterators to visit all the vertices, edges and faces of the triangulation,
- circulators to visit all the vertices, edges and faces incident to a given vertex

The triangulation data structure is responsible for the creation and removal of faces and vertices (memory management). It provides function that gives the number of faces, edges and vertices of the triangulation.

The triangulation data structure provides member functions to perform the following combinatorial transformation of the triangulation:

- flip of two adjacent faces,
- addition of a new vertex splitting a given face see Figure 26.2,
- addition of a new vertex splitting a given edge,
- addition of a new vertex raising by one the dimension of a degenerate – lower dimensional triangulation,
- removal of a vertex incident to three faces,
- removal of a vertex lowering the dimension of the triangulation

26.3 The Default Triangulation Data Structure

CGAL provides the class *CGAL::Triangulation_data_structure_2<Vb,Fb>* as a default triangulation data structure.

26.3.1 Flexibility

In order to provide flexibility, the default triangulation data structure is templated by two parameters which stands respectively for a vertex base class and a face base class. The concept *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2* describe the requirements for the vertex and face classes of a triangulation data structure.

This design allows the user to plug in the triangulation data structure his own vertex or face classes tuned for his application.

Figure 26.3: The cyclic dependency in triangulations software design.

26.3.2 The Cyclic Dependency of Template Parameters

Since adjacency and incidence relation are stored in vertices and faces, the vertex and face classes have to know the types of handles on faces and vertices provided by the triangulation data structure. Therefore, vertex and face classes need to be templated by the triangulation data structure. Because the triangulation data structure is itself templated by the vertex and face classes this induces a cyclic dependency. See figure 26.3.

26.3.3 The Rebind Mechanism

The solution proposed by CGAL to resolve this cyclic dependency is based on a rebind mechanism similar to the mechanism used in the standard allocator class `std::allocator`. The vertex and face classes plugged in the instantiation of a triangulation data structure are themselves instantiated with a fake data structure. The triangulation data structure will then rebind these classes, plugging itself at the place of the fake data structure, before using them to derive the vertex and face classes. The rebinding is performed through a nested template class *Rebind.TDS* in the vertex and face class, which provide the rebound class as a type called *Other*.

Here is how it works schematically. First, here is the rebinding taking place in the triangulation data structure.

```
template < class Vb, class Fb >
class Triangulation_data_structure
{
```

```

typedef Triangulation_data_structure<Vb,Fb>    Self;

// Rebind the vertex and face base to the actual TDS (Self).
typedef typename Vb::template Rebind_TDS<Self>::Other  VertexBase;
typedef typename Fb::template Rebind_TDS<Self>::Other  FaceBase;

// ... further internal machinery leads to the final public types:
public:
    typedef ...  Vertex;
    typedef ...  Face;
    typedef ...  Vertex_handle;
    typedef ...  Face_handle;
};

```

Then, here is the vertex class with its nested *Rebind_TDS* template class and its template parameter set by default to an internal type faking a triangulation data structure.

```

template < class TDS = an internal type faking a triangulation data
structure >
class Vertex_base
{
public:
    template < class TDS2 >
    struct Rebind_TDS {
        typedef Vertex_base<TDS2>    Other;
    };
    ...
};

```

Imagine an analog *Face_base* class. The triangulation data structure is then instantiated as follows :

```

typedef Triangulation_data_structure< Vertex_base<>, Face_base<> > TDS;

```

26.3.4 Making Use of the Flexibility

There are several possibilities to make use of the flexibility offered by the triangulation data structure.

- First, when the user needs to have, in vertices and faces, additional information which do not depend on types defined by the triangulated data structure, predefined classes *Triangulation_vertex_base_with_info* and *Triangulation_face_base_with_info* can be plugged in. Those classes have a template parameter *Info* to be instantiated by a user defined type. They store a data member of this type and gives access to it.
- Second, the user can derive his own base classes from the default base classes: *Triangulation_ds_vertex_base_2*, and *Triangulation_ds_face_base_2* are the default base classes to be plugged in a triangulation data structure used alone. Triangulation classes requires a data structure in which other base classes have been plugged in. The default base classes for most of the triangulation classes are *Triangulation_vertex_base_2*, and *Triangulation_face_base_2* are the default base classes to be used when the triangulation data structure is plugged in a triangulation class.

When derivation is used, the rebinding mechanism is slightly more involved, because it is necessary to rebind the base class itself. However the user will be able to use in his classes references to types provided by the triangulation data structure. For example,

```

template < class Gt, class Vb = CGAL::Triangulation_vertex_base_2<Gt> >
class My_vertex_base
    : public Vb
{
public :
    template < typename TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_base<Gt,Vb2>                          Other;
    };

    typedef typename Vb::Triangulation_data_structure    Tds;
    typedef typename Tds::Vertex_handle                  Vertex_handle;
    .....
};

```

- At last the user can write his own base classes. If the triangulation data structure is used alone, the requirements for the base classes are described by the concepts *TriangulationDSVertexBase_2* and *TriangulationDSFaceBase_2*, documented page [1810](#) and page [1805](#). If the triangulation data structure is plugged into a triangulation class, the concepts for the vertex and base classes depends on the triangulation class. The most basic concepts, valid for basic and Delaunay triangulations are *TriangulationVertexBase_2* and *TriangulationFaceBase_2*, documented page [1759](#) and page [1754](#).

See section [25.11](#) for examples of using the triangulation data structure flexibility.

2D Triangulation Data Structure Reference Manual

Sylvain Pion and Mariette Yvinec

The triangulation data structure can be seen as a container for the faces and vertices of a triangulation. This class also takes care of all the combinatorial operations performed on the triangulation.

The class `CGAL::Triangulation_data_structure_2<Vb,Fb>` is a model of the concept `TriangulationDataStructure_2`, which includes the sub-concepts `TriangulationDataStructure_2::Face` and `TriangulationDataStructure_2::Vertex`.

To ensure all the **flexibility** of the triangulation classes, described and in Section 25.11 of Chapter 25, the model `CGAL::Triangulation_data_structure_2<Vb,Fb>` has two templates parameters. The class `CGAL::Triangulation_data_structure_2<Vb,Fb>` derives its `Vertex` and `Face` types from the two template parameters `Vb` and `Fb` respectively.

If the triangulation data structure is used alone, these parameters have to be instantiated by models of the concepts `TriangulationDSFaceBase_2` and `TriangulationDSVertexBase_2`. These concepts are described in this chapter together with their default models `CGAL::Triangulation_ds_face_base_2<Tds>` and `CGAL::Triangulation_ds_vertex_base_2<Tds>`.

If the triangulation data structure is plugged into a triangulation class, the parameters have to be instantiated by models of different refining concepts according to the actual type of the triangulation. These refining concepts and their models are described in Chapter 25.12

TriangulationDataStructure_2

Definition

The concept `TriangulationDataStructure_2` describes the requirements for the second template parameter of the basic triangulation class `Triangulation_2<Traits,Tds>` and of all other 2D triangulation classes.

The concept can be seen as a container for the faces and vertices of the triangulation. The concept `TriangulationDataStructure_2` includes two sub-concepts `TriangulationDataStructure_2::Vertex` and `TriangulationDataStructure_2::Face`, described respectively page [1812](#) and page [1808](#).

The `TriangulationDataStructure_2` maintains incidence and adjacency relations among vertices and faces.

Each triangular face gives access to its three incident vertices and to its three adjacent faces. Each vertex gives access to one of its incident faces and through that face to the circular list of its incident faces.

The three vertices of a face are indexed with 0, 1 and 2. The neighbors of a face are also indexed with 0,1,2 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

Each edge has two implicit representations : the edge of a face f which is opposed to the vertex indexed i , can be represented as well as an edge of the $neighbor(i)$ of f . See Figure [25.2](#)

The triangulation data structure is responsible for the combinatorial integrity of the triangulation. This means that the triangulation data structure allows to perform some combinatorial operations on the triangulation and guarantees the maintenance on proper incidence and adjacency relations among the vertices and faces. The term combinatorial operations means that those operations are purely topological and do not depend on the geometric embedding. Insertion of a new vertex in a given face, or in a given edge, suppression of a vertex of degree three, flip of two edges are examples of combinatorial operations.

Types

<code>TriangulationDataStructure_2::size_type</code>	Size type (unsigned integral type)
<code>TriangulationDataStructure_2::difference_type</code>	Difference type (signed integral type)
<code>TriangulationDataStructure_2::Vertex</code>	The vertex type. Requirements for this type are described in concept <code>TriangulationDataStructure_2::Vertex</code> page 1812 .
<code>TriangulationDataStructure_2::Face</code>	The face type. Requirements for this type are described in concept <code>TriangulationDataStructure_2::Face</code> page 1808 .

Vertices and faces are accessed via `Vertex_handle` and `Face_handle`. These types are models of the concept `Handles` which basically supports the two dereference operators `*` and `->`.

<code>TriangulationDataStructure_2::Vertex_handle</code>	Handle to a vertex
<code>TriangulationDataStructure_2::Face_handle</code>	Handle to a face.
<code>typedef std::pair<Face_handle,int> Edge;</code>	The edge type. The <code>Edge(f,i)</code> is edge common to faces f and $f.neighbor(i)$. It is also the edge joining the vertices $vertex(cw(i))$ and $vertex(ccw(i))$ of f .

The following iterators allow one to visit all the vertices, edges and faces of a triangulation data structure. They are all bidirectional, non-mutable iterators.

TriangulationDataStructure_2:: Face_iterator
TriangulationDataStructure_2:: Edge_iterator
TriangulationDataStructure_2:: Vertex_iterator

The following circulators allow to visit all the edges or faces incident to a given vertex and all the vertices adjacent to a given vertex. They are all bidirectional and non mutable.

TriangulationDataStructure_2:: Face_circulator
TriangulationDataStructure_2:: Edge_circulator
TriangulationDataStructure_2:: Vertex_circulator

Iterators and circulators are convertible to the corresponding handles, thus they can be passed directly as argument to the functions expecting a handle.

Creation

TriangulationDataStructure_2 tds; default constructor.

TriangulationDataStructure_2 tds(tds1); Copy constructor. All the vertices and faces are duplicated.

TriangulationDataStructure_2& tds = tds1

Assignment. All the vertices and faces of *tds1* are duplicated in *tds* . Former faces and vertices of *tds* , if any, are deleted

Vertex_handle tds.copy_tds(tds1, Vertex_handle v = Vertex_handle())

tds1 is copied into *tds*. If *v* != *NULL*, the vertex of *tds* corresponding to *v* is returned, otherwise *Vertex_handle()* is returned.

Precondition: The optional argument *v* is a vertex of *tds1*.

void tds.swap(& tds1) Swaps *tds* and *tds1*. Should be preferred to *tds=tds1* or *tds(tds1)* when *tds1* is deleted after that.

void tds.clear() Deletes all faces and all finite vertices.

Access Functions

int tds.dimension() returns the dimension of the triangulation.
size_type

size_type tds.number_of_vertices() returns the number of vertices in the data structure.

tds.number_of_faces() returns the number of two dimensional faces in the data structure.

size_type

tds.number_of_edges()

returns the number of edges in the triangulation data structure.

size_type

tds.number_of_full_dim_faces()

returns the number of full dimensional faces, i.e. faces of dimension equal to the dimension of the triangulation. This is the actual number of faces stored in the triangulation data structure.

— *advanced* —

Setting

void tds.set_dimension(int n)

sets the dimension.

— *advanced* —

Queries

bool tds.is_vertex(Vertex_handle v)

returns true if *v* is a vertex of *tds*.

bool tds.is_edge(Face_handle fh, int i)

tests whether (fh, i) is an edge of *tds*. Answers *false* when *dimension()* < 1 .

bool tds.is_edge(Vertex_handle va, Vertex_handle vb)

returns true if *va vb* is an edge of *tds*.

bool tds.is_edge(Vertex_handle va, Vertex_handle vb, Face_handle &fr, int &i)

as previous. In addition, if true is returned *fr* and *i* are set such that the pair (fr, i) is the description of the ordered edge *va vb*.

bool tds.is_face(Face_handle fh)

tests whether *fh* is a face of *tds*. Answers *false* when *dimension()* < 2 .

bool tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)

true if there is a face having *v1*, *v2* and *v3* as vertices.

bool tds.is_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle &fr)

as above. In addition, if *true* is returned, *fr* is a pointer to the face with *v1*, *v2* and *v3* as vertices.

Traversing the triangulation

Face_iterator tds.faces_begin()

visits all faces

Face_iterator tds.faces_end()

Vertex_iterator tds.vertices_begin()

visits all vertices

Vertex_iterator tds.vertices_end()

<i>Edge_iterator</i>	<i>tds.edges_begin()</i>	visits all edges
<i>Edge_iterator</i>	<i>tds.edges_end()</i>	

Three circulator classes allow to traverse the edges or faces incident to a vertex or the vertices adjacent to this vertex.. A face circulator is invalidated by any modification of the face it points to. An edge circulator is invalidated by any modification of anyone of the two faces incident to the edge pointed to. A vertex circulator that turns around vertex v and that has as value a pointer to vertex w , is invalidated by any modification of anyone of the two faces incident to v and w .

<i>Vertex_circulator</i>	<i>tds.incident_vertices(Vertex_handle v, Face_handle f=NULL)</i>
--------------------------	--

Precondition: If the face f is given, it has to be incident to be a face of tds incident to v and the circulator begins with the vertex $f->vertex(ccw(i))$ if i is the index of v in f .

<i>Edge_circulator</i>	<i>tds.incident_edges(Vertex_handle v, Face_handle f=NULL)</i>
------------------------	---

Precondition: If the face f is given, it has to be a face of tds incident to v and the circulator begins with the edge $(f,cw(i))$ of f if i is the index of v in f .

<i>Face_circulator</i>	<i>tds.incident_faces(Vertex_handle v, Face_handle f=NULL)</i>
------------------------	---

Precondition: If the face f is given, it has to be a face of tds incident to v and the circulator begins with the face f .

<i>Vertex_handle</i>	<i>tds.mirror_vertex(Face_handle f, int i)</i>
----------------------	---

returns vertex of $f->neighbor(i)$.

<i>int</i>	<i>tds.mirror_index(Face_handle f, int i)</i>
------------	--

returns the index of f as a neighbor of $f->neighbor(i)$.

Modifiers

The following modifier member functions guarantee the combinatorial validity of the resulting triangulation.

<i>void</i>	<i>tds.flip(Face_handle f, int i)</i>	exchanges the edge incident to f and $f->neighbor(i)$ with the other diagonal of the quadrilateral formed by f and $f->neighbor(i)$.
-------------	--	---

<i>Vertex_handle</i>	<i>tds.insert_first()</i>	creates the first vertex and returns a pointer to it.
<i>Vertex_handle</i>	<i>tds.insert_second()</i>	creates the second vertex and returns a pointer to it.

<i>Vertex_handle</i>	<i>tds.insert_in_edge(Face_handle f, int i)</i>	adds a vertex v splitting edge i of face f . Return a pointer to v .
----------------------	--	--

<i>Vertex_handle</i>	<i>tds.insert_in_face(Face_handle f)</i>	adds a vertex v splitting face f in three. Face f is modified, two new faces are created. Return a pointer to v
----------------------	---	---

Figure 26.4: Flip.

Figure 26.5: Insertion

Vertex_handle *tds.insert_dim_up(Vertex_handle w, bool orient=true)*

adds a vertex v , increasing by one the dimension of the triangulation. Vertex v and the existing vertex w are linked to all the vertices of the triangulation. The Boolean *orient* decides the final orientation of all faces. A pointer to vertex v is returned.

void *tds.remove_degree_3(Vertex_handle v, Face *f=NULL)*

removes a vertex of degree 3. Two of the incident faces are destroyed, the third one is modified. If parameter f is specified, it has to be a face incident to v and will be the modified face.

Precondition: Vertex v is a finite vertex with degree 3 and, if specified, face f is incident to v .

void *tds.remove_second(Vertex_handle v)*

removes the before last vertex.

void *tds.remove_first(Vertex_handle v)*

removes the last vertex.

void *tds.remove_dim_down(Vertex_handle v)*

removes vertex v incident to all other vertices and decreases by one the dimension of the triangulation.

Precondition: if the dimension is 2, the number of vertices is more than 3, if the dimension is 1, the number of vertices is 2.

————— *advanced* —————

The following modifiers are required for convenience of the advanced user. They do not guarantee the combinatorial validity of the resulting triangulation.

```
template< class EdgeIt>
Vertex_handle    tds.star_hole( EdgeIt edge_begin, EdgeIt edge_end)
```

creates a new vertex v and use it to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end[$. Returns a pointer to the vertex.

```
template< class EdgeIt, class FaceIt>
Vertex_handle    tds.star_hole( EdgeIt edge_begin, EdgeIt edge_end, FaceIt face_begin, FaceIt face_end)
```

same as above, except that, to build the new faces, the algorithm first recycles faces in the sequence $[face_begin, face_end[$ and create new ones when the sequence is exhausted.

```
template< class EdgeIt>
void             tds.star_hole( Vertex_handle v, EdgeIt edge_begin, EdgeIt edge_end)
```

uses vertex v to star the hole whose boundary is described by the sequence of edges $[edge_begin, edge_end[$.

```
template< class EdgeIt, class FaceIt>
void             tds.star_hole( Vertex_handle v,
                               EdgeIt edge_begin,
                               EdgeIt edge_end,
                               FaceIt face_begin,
                               FaceIt face_end)
```

same as above, recycling faces in the sequence $[face_begin, face_end[$.

```
void             tds.make_hole( Vertex_handle v, List_edges& hole)
```

removes the vertex v , and store in $hole$ the list of edges on the boundary of the hole.

```
Vertex_handle    tds.create_vertex()           adds a new vertex.
Face_handle      tds.create_face( Face_handle f1, int i1, Face_handle f2, int i2, Face_handle f3, int i3)
```

adds a face which is the neighbor $i1$ of $f1$, $i2$ of $f2$ and $i3$ of $f3$.

```
Face_handle      tds.create_face( Face_handle f1, int i1, Face_handle f2, int i2)
```

adds a face which is the neighbor $i1$ of $f1$, and the neighbor $i2$ of $f2$.

```
Face_handle      tds.create_face( Face_handle f1, int i1, Vertex_handle v)
```

adds a face which is the neighbor $i1$ of $f1$, and has v as vertex.

```
Face_handle      tds.create_face( Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)
```

adds a face with vertices $v1$, $v2$ and $v3$.

<i>Face_handle</i>	<i>tds.create_face(Vertex_handle v1, Vertex_handle v2, Vertex_handle v3, Face_handle f1, Face_handle f2, Face_handle f3)</i>	adds a face with vertices <i>v1</i> , <i>v2</i> and <i>v3</i> , and neighbors <i>f1</i> , <i>f2</i> , <i>f3</i> .
<i>Face_handle</i>	<i>tds.create_face()</i>	adds a face whose vertices and neighbors are set to NULL.
<i>void</i>	<i>tds.delete_face(Face_handle)</i>	deletes a face.
<i>void</i>	<i>tds.delete_vertex(Vertex_handle)</i>	deletes a vertex.

└────────── advanced ─────────┘

Miscellaneous

<i>int</i>	<i>tds.ccw(int i)</i>	returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>tds.cw(int i)</i>	returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>bool</i>	<i>tds.is_valid()</i>	checks the combinatorial validity of the triangulation: call the <i>is_valid()</i> member function for each vertex and each face, checks the number of vertices and the Euler relation between numbers of vertices, faces and edges.
<i>size_type</i>	<i>tds.degree(Vertex_handle v)</i>	Returns the degree of <i>v</i> in the triangulation.

I/O

The information output in the *iostream* is: the dimension, the number of (finite) vertices, the number of (finite) faces. Then comes for each vertex, the non combinatorial information stored in that vertex if any. Then comes for each faces, the indices of its vertices and the non combinatorial information (if any) stored in this face. Then comes for each face again the indices of the neighboring faces. The index of an item (vertex of face) the rank of this item in the output order. When dimension < 2, the same information is output for faces of maximal dimension instead of faces.

<i>void</i>	<i>tds.file_output(ostream& os, Vertex_handle v = Vertex_handle(), bool skip_first=false)</i>	writes <i>tds</i> into the stream <i>os</i> . If <i>v</i> is not a null handle, vertex <i>v</i> is output first or skipped if <i>skip_first</i> is true.
-------------	--	--

<i>Vertex_handle</i>	<i>tds.file_input(istream& is, bool skip_first=false)</i>	inputs <i>tds</i> from file and returns a pointer to the first input vertex. If <i>skip_first</i> is true, it is assumed that the first vertex has been omitted when output.
----------------------	--	--

istream& *istream*& *is* >> *TriangulationDataStructure_3* & *tds*

reads a combinatorial triangulation from *is* and assigns it to
tds

ostream& *ostream*& *os* << *TriangulationDataStructure_3* *tds*

writes *tds* into the stream *os*

Access Functions

<i>int</i>	<i>f.dimension()</i>	returns the dimension.
<i>Vertex_handle</i>	<i>f.vertex(int i)</i>	returns the vertex <i>i</i> of <i>f</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>bool</i>	<i>f.has_vertex(Vertex_handle v)</i>	returns true if <i>v</i> is a vertex of <i>f</i> .
<i>bool</i>	<i>f.has_vertex(Vertex_handle v, int& i)</i>	as above, and sets <i>i</i> to the index of <i>v</i> in <i>f</i> .
<i>int</i>	<i>f.index(Vertex_handle v)</i>	returns the index of <i>v</i> in <i>f</i> .
<i>Face_handle</i>	<i>f.neighbor(int i)</i>	returns the neighbor <i>i</i> of <i>f</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>bool</i>	<i>f.has_neighbor(Face_handle n)</i>	returns true if <i>n</i> is a neighbor of <i>f</i> .
<i>bool</i>	<i>f.has_neighbor(Face_handle n, int& i)</i>	as above, and sets <i>i</i> to the index of <i>n</i> in <i>f</i> .
<i>int</i>	<i>f.index(const Face_handle n)</i>	returns the index of neighbor <i>n</i> in <i>f</i> .

Setting

<i>void</i>	<i>f.set_vertex(int i, Vertex_handle v)</i>	sets vertex <i>i</i> to <i>v</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_vertices()</i>	sets the vertices to <i>Vertex_handle()</i> .
<i>void</i>	<i>f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)</i>	sets the vertices.
<i>void</i>	<i>f.set_neighbor(int i, Face_handle n)</i>	sets neighbors <i>i</i> to <i>n</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_neighbors()</i>	sets the neighbors to <i>Face_handle()</i> .
<i>void</i>	<i>f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)</i>	sets the neighbors.

Orientation

<i>void</i>	<i>f.reorient()</i>	Changes the orientation of <i>f</i> by exchanging <i>vertex(0)</i> with <i>vertex(1)</i> and <i>neighbor(0)</i> with <i>neighbor(1)</i> .
<i>void</i>	<i>f.ccw_permute()</i>	performs a counterclockwise permutation of the vertices and neighbors of <i>f</i> .
<i>void</i>	<i>f.cw_permute()</i>	performs a clockwise permutation of the ver- tices and neighbors of <i>f</i> .

Checking

bool *f.is_valid(bool verbose = false)*

performs any required test on a face.
If *verbose* is set to *true*, messages are printed to give a precise indication of the kind of invalidity encountered.

Various

*void** *f.for_compact_container()*
void&* *f.for_compact_container()*

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

TriangulationDataStructure_2::Face

Definition

The concept `TriangulationDataStructure_2::Face` describes the types used to store the faces face class of a *TriangulationDataStructure_2*, see page 1797. A `TriangulationDataStructure_2::Face` stores three pointers to its three vertices and three pointers to its three neighbors. The vertices are indexed 0,1, and 2 in counterclockwise order. The neighbor indexed i lies opposite to vertex i .

In degenerate cases, when the triangulation data structure stores a simplicial complex of dimension 0 and 1, the type `TriangulationDataStructure_2::Face` is used to store the faces of maximal dimension of the complex : i.e. a vertex in dimension 0, an edge in dimension 1. Only vertices and neighbors with index 0 are set in the first case, only vertices and neighbors with index 0 or 1 are set in the second case.

Types

The class `TriangulationDataStructure_2::Face` defines the same types as the triangulation data structure except the iterators and the circulators.

Creation

The methods *create_face* and *delete_face()* have to be used to define new faces and to delete non longer used faces.

Vertex Access Functions

<i>Vertex_handle</i>	<i>f.vertex(int i)</i>	returns the vertex i of f . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.index(Vertex_handle v)</i>	returns the index of vertex v in f . <i>Precondition:</i> v is a vertex of f
<i>bool</i>	<i>f.has_vertex(Vertex_handle v)</i>	returns <i>true</i> if v is a vertex of f .
<i>bool</i>	<i>f.has_vertex(Vertex_handle v, int& i)</i>	returns <i>true</i> if v is a vertex of f , and computes the index i of v in f .

Neighbor Access Functions

The neighbor with index i is the neighbor which is opposite to the vertex with index i .

<i>Face_handle</i>	<i>f.neighbor(int i)</i>	returns the neighbor i of f . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.index(Face_handle n)</i>	returns the index of face n . <i>Precondition:</i> n is a neighbor of f .
<i>bool</i>	<i>f.has_neighbor(Face_handle n)</i>	returns <i>true</i> if n is a neighbor of f .
<i>bool</i>	<i>f.has_neighbor(Face_handle n, int& i)</i>	returns <i>true</i> if n is a neighbor of f , and compute the index i of n .

Setting

<i>void</i>	<i>f.set_vertex(int i, Vertex_handle v)</i>	sets vertex <i>i</i> to be <i>v</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_neighbor(int i, Face_handle n)</i>	sets neighbor <i>i</i> to be <i>n</i> . <i>Precondition:</i> $0 \leq i \leq 2$.
<i>void</i>	<i>f.set_vertices()</i>	sets the vertices pointers to <i>NULL</i> .
<i>void</i>	<i>f.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2)</i>	sets the vertices pointers.
<i>void</i>	<i>f.set_neighbors()</i>	sets the neighbors pointers to <i>NULL</i> .
<i>void</i>	<i>f.set_neighbors(Face_handle n0, Face_handle n1, Face_handle n2)</i>	sets the neighbors pointers.

Checking

<i>bool</i>	<i>f.is_valid()</i>	returns <i>true</i> if the function <i>is_valid()</i> of the base class returns <i>true</i> and if, for each index <i>i</i> , $0 \leq i < 3$, face <i>f</i> is a neighbor of its neighboring face <i>neighbor(i)</i> and shares with this neighbor the vertices <i>cw(i)</i> and <i>ccw(i)</i> in correct reverse order.
-------------	---------------------	---

Miscellaneous

<i>int</i>	<i>f.ccw(int i)</i>	Returns $i + 1$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.
<i>int</i>	<i>f.cw(int i)</i>	Returns $i + 2$ modulo 3. <i>Precondition:</i> $0 \leq i \leq 2$.

I/O

<i>istream&</i>	<i>istream& is >> &f</i>	Inputs any non combinatorial information possibly stored in the face.
<i>ostream&</i>	<i>ostream& os << f</i>	Outputs any non combinatorial information possibly stored in the face.

TriangulationDSVertexBase_2

Definition

The concept `TriangulationDSVertexBase_2` describes the requirements for the vertex base class of a `Triangulation_data_structure_2<Vb,Fb>`.

Note that if the `Triangulation_data_structure_2` is plugged into a triangulation class, the vertex base class has additional geometric requirements depending on the triangulation class.

At the base level, provides access to one of its incident face through a *Face_handle*.

Since the `Triangulation_data_structure_2` is the class which defines the handle types, the vertex base class has to be somehow parameterized by the triangulation data structure. But since the `Triangulation_data_structure_2` itself is parameterized by the face and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for faces and vertices which are plugged in to instantiate a `Triangulation_data_structure_2` use a *void* as triangulation data structure parameter. Then, the `Triangulation_data_structure_2` uses a *rebind* mechanism (similar to the one specified in `std::allocator`) in order to plug itself as parameter in the face and vertex base classes. This mechanism requires that the base class provides a templated nested class *Rebind_TDS* that itself provides the subtype *Rebind_TDS<TDS2>::Other* which is the *rebound* version of the base class. This *rebound* base class is the class that the `Triangulation_data_structure_2` actually uses as a base class for the class of `Triangulation_data_structure_2::Vertex`.

Refines

`TriangulationDataStructure_2::Vertex`

Types

The concept `TriangulationDSVertexBase_2` has to provide the following types.

`TriangulationDSVertexBase_2::template <typename TDS2> struct Rebind_TDS`

This nested template class has to define a type *Other* which is the *rebound* vertex base , where the actual `Triangulation_data_structure_2` is plugged in. This type *Other* will be the actual base of the class `Triangulation_data_structure_2::Vertex`.

<code>typedef TriangulationDataStructure_2</code>	<code>Triangulation_data_structure;</code>
<code>typedef TriangulationDataStructure_2::Vertex_handle</code>	<code>Vertex_handle;</code>
<code>typedef TriangulationDataStructure_2::Face_handle</code>	<code>Face_handle;</code>

Creation

<code>TriangulationDSVertexBase_2 v;</code>	default constructor.
<code>TriangulationDSVertexBase_2 v(Face_handle f);</code>	Constructs a vertex pointing to face <i>f</i> .

Various

```
void*          v.for_compact_container()
void*&          v.for_compact_container()
```

These member functions are required by *Triangulation_data_structure_2* because it uses *Compact_container* to store its faces. See the documentation of *Compact_container* for the exact requirements.

TriangulationDataStructure_2::Vertex

Definition

The concept `TriangulationDataStructure_2::Vertex` describes the type used by a *TriangulationDataStructure_2* to store the vertices, see page [1797](#).

Some of the requirements listed below are of geometric nature and are *optional* when using the triangulation data structure class alone. They became required when the triangulation data structure is plugged into a triangulation.

Types

The class `TriangulationDataStructure_2::Vertex` defines the same types as the triangulation data structure except the iterators.

TriangulationDataStructure_2::Vertex::Point *Optional for the triangulation data structure used alone.*

Creation

In order to obtain new vertices or destruct unused vertices, the user must call the *create_vertex()* and *delete_vertex()* methods of the triangulation data structure.

Access Functions

<i>Point</i>	<i>v.point()</i>	returns the geometric information of <i>v</i> .
<i>Face_handle</i>	<i>v.face()</i>	returns a face of the triangulation having <i>v</i> as vertex.

— *advanced* —

Setting

<i>void</i>	<i>v.set_point(Point p)</i>	sets the geometric information to <i>p</i> .
<i>void</i>	<i>v.set_face(Face_handle f)</i>	sets the incident face to <i>f</i> .

— *advanced* —

Checking

<i>bool</i>	<i>v.is_valid(bool verbose = false)</i>
-------------	--

Checks the validity of the vertex. Must check that its incident face has this vertex. The validity of the base vertex is also checked. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

I/O

istream& *istream*& *is* >> & *v* Inputs the non-combinatorial information possibly stored in the vertex.

ostream& *ostream*& *os* << *v* Outputs the non combinatorial operation possibly stored in the vertex.

The class *Triangulation_data_structure_2<Vb,Fb>* is a model for the *TriangulationDataStructure_2* concept. It can be used to represent an orientable 2D triangulation embedded in a space of any dimension.

```
#include <CGAL/Triangulation_data_structure_2.h>
```

Is Model for the Concepts

TriangulationDataStructure_2

Modifiers

In addition to the modifiers required by the *TriangulationDataStructure_2* concept, the *Triangulation_data_structure_2<Vb,Fb>* class supports also the modifiers below. Note also that the modifiers below guarantee the combinatorial validity of the resulting data structure.

<i>Vertex_handle</i>	<i>tds.join_vertices(Face_handle f, int i)</i>	Joins the vertices that are endpoints of the edge (f,i) . It returns a vertex handle to common vertex (see Fig. 26.6). <i>Precondition:</i> f must be different from <i>Face_handle()</i> and i must be 0, 1 or 2.
<i>Vertex_handle</i>	<i>tds.join_vertices(Edge e)</i>	Joins the vertices that are endpoints of the edge e . It returns a vertex handle to common vertex.
<i>Vertex_handle</i>	<i>tds.join_vertices(Edge_iterator eit)</i>	Joins the vertices that are endpoints of the edge $*eit$. It returns a vertex handle to common vertex.
<i>Vertex_handle</i>	<i>tds.join_vertices(Edges_circulator ec)</i>	Joins the vertices that are endpoints of the edge $*ec$. It returns a vertex handle to common vertex.

```
boost::tuples::tuple<Vertex_handle, Vertex_handle, Face_handle, Face_handle>
```

```
tds.split_vertex( Vertex_handle v, Face_handle f1, Face_handle f2 )
```

Splits the vertex v into two vertices $v1$ and $v2$. The common faces f and g of $v1$ and $v2$ are created after (in the counter-clockwise sense) the faces $f1$ and $f2$. The 4-tuple $(v1,v2,f,g)$ is returned (see Fig. 26.6).
Precondition: *dimension()* must be equal to 2, $f1$ and $f2$ must be different from *Face_handle()* and v must be a vertex of both $f1$ and $f2$.

<i>Vertex_handle</i>	<i>tds.insert_degree_2(Face_handle f, int i)</i>	Inserts a degree two vertex and two faces adjacent to it that have two common edges. The edge defined by the face handle f and the integer i is duplicated. It returns a handle to the vertex created (see Fig. 26.7).
----------------------	--	--

void

tds.remove_degree_2(Vertex_handle v)

Removes a degree 2 vertex and the two faces adjacent to it. The two edges of the star of v that are not incident to it are collapsed (see Fig. 26.7).

Precondition: The degree of v must be equal to 2.

Figure 26.6: The join and split operations.

Figure 26.7: Insertion and removal of degree 2 vertices.

CGAL::Triangulation_ds_face_base_2<Tds>

The basic 3D-triangulation class of CGAL is primarily designed to represent the triangulations of a set of points A in \mathbb{R}^3 . It is a partition of the convex hull of A into tetrahedra whose vertices are the points of A . Together with the unbounded cell having the convex hull boundary as its frontier, the triangulation forms a partition of \mathbb{R}^3 . Its cells (3-faces) are such that two cells either do not intersect or share a common facet (2-face), edge (1-face) or vertex (0-face).

27.1 Representation

In order to deal only with tetrahedra, which is convenient for many applications, the unbounded cell can be subdivided into tetrahedra by considering that each convex hull facet is incident to an *infinite cell* having as fourth vertex an auxiliary vertex called the *infinite vertex*. In that way, each facet is incident to exactly two cells and special cases at the boundary of the convex hull are simple to deal with.

The class `Triangulation_3<TriangulationTraits_3, TriangulationDataStructure_3>` of CGAL implements this point of view and therefore considers the triangulation of the set of points as a set of finite and infinite tetrahedra. Notice that the infinite vertex has no significant coordinates and that no geometric predicate can be applied on it.

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying Euclidean space \mathbb{R}^3 (see Figure 27.1). The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index.

Figure 27.1: Orientation of a cell (3-dimensional case).

As in the underlying combinatorial triangulation (see Chapter 28), edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex with index i) and an edge is given by a cell and two indices (the edge (i,j) of a cell c is the edge whose endpoints are the vertices of c with indices i and j). See Figure 28.1.

Degenerate Dimensions The class `Triangulation_3` can also deal with triangulations whose dimension d is less than 3. A triangulation of a set of points in \mathbb{R}^d covers the whole space \mathbb{R}^d and consists of cells having $d + 1$ vertices: some of them are infinite, they are obtained by linking the additional infinite vertex to each facet of the convex hull of the points.

- *dimension 2*: when a triangulation only contains coplanar points (which is the case when there are only three points), it consists of triangular faces.
- *dimension 1*: the triangulation contains only collinear points (which is the case when there are only two points), it consists of edges.
- *dimension 0*: the triangulation contains only one finite point.
- *dimension -1*: this is a convention to handle the case when the only vertex of the triangulation is the infinite one.

The same cell class is used in all cases: triangular faces in 2D can be considered as degenerate cells, having only three vertices (resp. neighbors) numbered (0, 1, 2); edges in 1D have only two vertices (resp. neighbors) numbered 0 and 1.

The implicit representation of facets (resp. edges) still holds for degenerate dimensions (*i.e.* dimensions < 3): in dimension 2, each cell has only one facet of index 3, and 3 edges (0, 1), (1, 2) and (2, 0); in dimension 1, each cell has one edge (0, 1).

Validity A triangulation of \mathbb{R}^3 is said to be *locally valid* iff

- (a)-(b) Its underlying combinatorial graph, the triangulation data structure, is *locally valid* (see Section 28.1 of Chapter 28)
- (c) Any cell has its vertices ordered according to positive orientation. See Figure 27.1.

When the triangulation is degenerated into a triangulation of dimension 2, the geometric validity reduces to:

(c-2D) For any two adjacent triangles (u, v, w_1) and (u, v, w_2) with common edge (u, v) , w_1 and w_2 lie on opposite sides of (u, v) in the plane.

When all the points are collinear, this condition becomes:

(c-1D) For any two adjacent edges (u, v) and (v, w) , u and w lie on opposite sides of the common vertex v on the line.

The *is_valid()* method provided in *Triangulation_3* checks the local validity of a given triangulation. This does not always ensure global validity [MNS⁺96, DLPT98] but it is sufficient for practical cases.

27.2 Delaunay Triangulation

The class *Delaunay_triangulation_3* represents a three-dimensional Delaunay triangulation.

Delaunay triangulations have the specific *empty sphere property*, that is, the circumscribing sphere of each cell of such a triangulation does not contain any other vertex of the triangulation in its interior. These triangulations are uniquely defined except in degenerate cases where five points are co-spherical. Note however that the CGAL implementation computes a unique triangulation even in these cases.

This implementation is fully dynamic: it supports both insertions of points and vertex removal. The user is advised to use the class *Triangulation_hierarchy_3* in order to benefit from an increased efficiency for large data sets.

27.3 Regular Triangulation

The class *Regular_triangulation_3* implements incremental regular triangulations, also known as weighted Delaunay triangulations.

Let $S^{(w)}$ be a set of weighted points in \mathbb{R}^3 . Let $p^{(w)} = (p, w_p)$, $p \in \mathbb{R}^3$, $w_p \in \mathbb{R}$ and $z^{(w)} = (z, w_z)$, $z \in \mathbb{R}^3$, $w_z \in \mathbb{R}$ be two weighted points. A weighted point $p^{(w)} = (p, w_p)$ can also be seen as a sphere of center p and radius $\sqrt{w_p}$. The *power product* between $p^{(w)}$ and $z^{(w)}$ is defined as

$$\Pi(p^{(w)}, z^{(w)}) = \|p - z\|^2 - w_p - w_z$$

where $\|p - z\|$ is the Euclidean distance between p and z . $p^{(w)}$ and $z^{(w)}$ are said to be *orthogonal* iff $\Pi(p^{(w)}, z^{(w)}) = 0$ (see Figure 27.2).

Figure 27.2: Orthogonal weighted points (picture in 2D).

Four weighted points have a unique common orthogonal weighted point called the *power sphere*. The weighted point orthogonal to three weighted points in the plane defined by these three points is called the *power circle*. The *power segment* will denote the weighted point orthogonal to two weighted points on the line defined by these two points.

A sphere $z^{(w)}$ is said to be *regular* if $\forall p^{(w)} \in S^{(w)}, \Pi(p^{(w)}, z^{(w)}) \geq 0$.

A triangulation of $S^{(w)}$ is *regular* if the power spheres of all simplices are regular.

The regular triangulation of $S^{(w)}$ is in fact the projection onto \mathbb{R}^3 of the convex hull of the four-dimensional points $(p, \|p - O\|^2 - w_p)$, for $p^{(w)} = (p, w_p) \in S^{(w)}$. Note that all points of $S^{(w)}$ do not necessarily appear as vertices of the regular triangulation. To know more about regular triangulations, see for example [ES96].

When all weights are 0, power spheres are nothing more than circumscribing spheres, and the regular triangulation is exactly the Delaunay triangulation.

27.4 Triangulation Hierarchy

The class *Triangulation_hierarchy_3* implements a triangulation augmented with a data structure that allows fast point location queries. Thus, it allows fast construction of the triangulation. As proved in [Dev02], this structure has an optimal behavior when it is built for Delaunay triangulations.

Note that, since the algorithms that are provided are randomized, the running time of constructing a triangulation with a hierarchy may be improved when shuffling the data points.

27.5 Software Design

The main classes *Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3* are connected to each other by the derivation diagram shown in Figure 27.3. This diagram also shows two other classes: *Triangulation_utils_3* (page 1937), which provides a set of tools operating on the indices of vertices in cells, and *Triangulation_hierarchy_3*, which implements a hierarchy of triangulations suitable for speeding up point location.

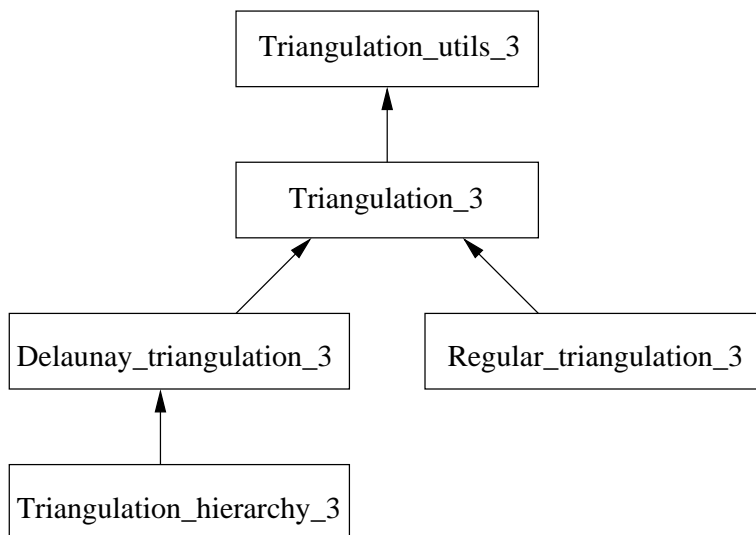

Figure 27.3: Derivation diagram of the 3D triangulation classes.

The three main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) provide high-level geometric functionality such as location of a point in the triangulation [DPT02], insertion and possibly removal of a point [DT03], and are responsible for the geometric validity. They are built as layers on top of a triangulation data structure, which stores their combinatorial structure. This separation between the geometry and the combinatorics is reflected in the software design by the fact that these three triangulation classes take two template parameters :

- the **geometric traits** class, which provides the type of points to use as well as the elementary operations on them (predicates and constructions). The concepts for these parameters are described in more details in Section 27.5.1 and in page 1872.
- the **triangulation data structure** class, which stores their combinatorial structure, described in Section 28.2 of Chapter 28.

The class *Triangulation_hierarchy_3* is parameterized by a class, which at the moment can only be *Delaunay_triangulation_3*. It fetches its geometric traits from this parameter directly.

27.5.1 The Geometric Traits Parameter

The first template parameter of the triangulation class *Triangulation_3*<*TriangulationTraits_3*, *TriangulationDataStructure_3*> is the geometric traits class, described by the concept *TriangulationTraits_3*. It must define the types of the geometric objects (points, segments, triangles and tetrahedra) forming the

triangulation together with a few geometric predicates on these objects: orientation in space, orientation in case of coplanar points, order of collinear points.

In addition to the requirements described before, the geometric traits class of *Delaunay_triangulation_3* must define predicates to test for the *empty sphere property*. It is described by the concept *DelaunayTriangulationTraits_3*, which refines *TriangulationTraits_3*.

The kernels provided by CGAL: *Cartesian*, *Homogeneous*, *Simple_cartesian*, *Simple_homogeneous* and *Filtered_kernel* can all be used as models for the geometric traits parameter. They supply the user with all the functionalities described for the concepts *TriangulationTraits_3* (page 1872) and *DelaunayTriangulationTraits_3* (page 1874). In addition, the predefined kernels *Exact_predicates_inexact_constructions_kernel* (page ??) and *Exact_predicates_exact_constructions_kernel* (page ??) can also be used, the later being recommended when the dual construction is used.

In order to be used as the traits class for *Regular_triangulation_3*, a class must provide functions to compute the *power tests* (see Section 27.3). *Regular_triangulation_euclidean_traits_3<K,Weight>* is a traits class designed to be used by the class *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*. It provides *Weighted_point*, a class for weighted points needed by the regular triangulation, which derives from the three dimensional point class *K::Point_3*. It supplies the user with all the functionalities described for the concept *RegularTriangulationTraits_3* (page 1877). It can be used as a traits class for *Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>*.

Note that for regular triangulations, plugging a filtered kernel such as *Exact_predicates_inexact_constructions_kernel* or *Exact_predicates_exact_constructions_kernel* in *Regular_triangulation_euclidean_traits_3<K,Weight>* will in fact not provide exact predicates since the weighted points and the predicates on them are not defined in the CGAL kernels. To solve this, there is also another model of the traits concept, *Regular_triangulation_filtered_traits_3<FK>*, which is providing filtered predicates (exact and efficient). The template parameter *FK* must be a model of the *Kernel* concept, and it is also restricted to be a instance of the *Filtered_kernel* template.

27.5.2 The Triangulation Data Structure Parameter

The second template parameter of the main classes (*Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*) is a triangulation data structure class. This class can be seen as a container for the cells and vertices maintaining incidence and adjacency relations (see Chapter 28). A model of this triangulation data structure is *Triangulation_data_structure_3* (page 1934), and it is described by the *TriangulationDataStructure_3* concept (page 1913). This model is itself parameterized by a vertex base and a cell base classes, which gives the possibility to customize the vertices and cells used by the triangulation data structure, and hence by the geometric triangulation using it. Depending on the kind of triangulation used, the requirements on the vertex and cell base classes vary, and are expressed by various concepts, following the refinement diagram shown in Figure 27.4.

A default value for the triangulation data structure parameter is provided in all the triangulation classes, so it need not be specified by the user unless he wants to use a different triangulation data structure or a different vertex or cell base class.

27.5.3 Flexibility of the Design

In order to satisfy as many uses as possible, a design has been selected that allows to exchange different parts to meet the users' needs, while still re-using a maximum of the provided functionalities. We have already seen that the main triangulation classes are parameterized by a geometric traits class and a triangulation data structure (TDS), so that each of them can be interchanged with alternate implementations.

Figure 27.4: Concepts refinement hierarchy for the vertex and cell base classes parameters.

The most useful flexibility is the ability given to the user to add his own data in the vertices and cells by providing his own vertex and cell base classes to *Triangulation_data_structure_3*. The Figure 27.5 shows in more detail the flexibility that is provided, and the place where the user can insert his own vertex and/or cell base classes.

27.5.4 Backward Compatibility

Starting with CGAL release 3.0, the design of the triangulation data structure has been changed in order to give the possibility to store handles (an entity akin to pointers) directly in the vertex and cell base classes. Previously, `void*` pointers were stored there instead, and later converted internally to handles, but this happened to be too restrictive for some uses.

The difference is visible to the user when he provides his own vertex or cell base class. Previously, something like the following had to be written:

```

...
template < class GT >
class My_vertex
  : public Triangulation_vertex_base<GT>
{
  typedef Triangulation_vertex_base<GT> Vb;
public:
  typedef typename Vb::Point          Point;

  My_vertex() {}
  My_vertex(const Point&p)              : Vb(p) {}
  My_vertex(const Point&p, void *c)    : Vb(p, c) {}
  ...
};

typedef Cartesian<double>                               GT;
typedef Triangulation_data_structure_3<My_vertex<GT>,
                                     Triangulation_cell_base_3<GT> > My_TDS;
typedef Triangulation_3<GT, My_TDS>                               Tr;
...

```

While now, there are three possibilities. The simplest one is to use the class *Triangulation_vertex_base_with_*

Figure 27.5: Triangulation software design.

info_3, and this approach is illustrated in a following subsection 27.6.2. The most complicated one, and probably useless for almost all cases, is to write a vertex base class from scratch, following the documented requirements. This is mostly useless because most of the time it is enough to derive from the models that CGAL provides, and add the desired features. In this case, when the user needs to access some type that depends on the triangulation data structure (typically handles), then he should write something like:

```
...
template < class GT, class Vb = Triangulation_vertex_base<GT> >
class My_vertex
: public Vb
{
public:
    typedef typename Vb::Point          Point;
    typedef typename Vb::Cell_handle    Cell_handle;

    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other Vb2;
        typedef My_vertex<GT, Vb2>                               Other;
    };

    My_vertex() {}
    My_vertex(const Point&p) : Vb(p) {}
    My_vertex(const Point&p, Cell_handle c) : Vb(p, c) {}
...
};
```

```
... // The rest has not changed
```

The changes that need to be made are the following:

- *My_vertex* is now parameterized by the vertex base class it derives from.
- a nested template class *Rebind_TDS* must be defined.
- `void*` must be changed to *Cell_handle*, and you need to extract the *Cell_handle* type from the vertex base class that *My_vertex* derives from.

The situation is exactly similar for cell base classes. Section [28.2](#) provides more detailed information.

27.6 Examples

27.6.1 Basic Example

This example shows the incremental construction of a 3D triangulation, the location of a point and how to perform elementary operations on indices in a cell. It uses the default parameter of the *Triangulation_3* class.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_3.h>

#include <iostream>
#include <fstream>
#include <cassert>
#include <list>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_3<K>      Triangulation;

typedef Triangulation::Cell_handle    Cell_handle;
typedef Triangulation::Vertex_handle Vertex_handle;
typedef Triangulation::Locate_type    Locate_type;
typedef Triangulation::Point          Point;

int main()
{
    // construction from a list of points :
    std::list<Point> L;
    L.push_front(Point(0,0,0));
    L.push_front(Point(1,0,0));
    L.push_front(Point(0,1,0));

    Triangulation T(L.begin(), L.end());

    int n = T.number_of_vertices();
```

```

// insertion from a vector :
std::vector<Point> V(3);
V[0] = Point(0,0,1);
V[1] = Point(1,1,1);
V[2] = Point(2,2,2);

n = n + T.insert(V.begin(), V.end());

assert( n == 6 );           // 6 points have been inserted
assert( T.is_valid() );    // checking validity of T

Locate_type lt;
int li, lj;
Point p(0,0,0);
Cell_handle c = T.locate(p, lt, li, lj);
// p is the vertex of c of index li :
assert( lt == Triangulation::VERTEX );
assert( c->vertex(li)->point() == p );

Vertex_handle v = c->vertex( (li+1)&3 );
// v is another vertex of c
Cell_handle nc = c->neighbor(li);
// nc = neighbor of c opposite to the vertex associated with p
// nc must have vertex v :
int nli;
assert( nc->has_vertex( v, nli ) );
// nli is the index of v in nc

std::ofstream outFileT("output",std::ios::out);
// writing file output;
outFileT << T;

Triangulation Tl;
std::ifstream inFileT("output",std::ios::in);
// reading file output;
inFileT >> Tl;
assert( Tl.is_valid() );
assert( Tl.number_of_vertices() == T.number_of_vertices() );
assert( Tl.number_of_cells() == T.number_of_cells() );

return 0;
}

```

File: examples/Triangulation_3/simple.cpp

27.6.2 Changing the Vertex Base

The following two examples show how the user can plug his own vertex base in a triangulation. Changing the cell base is similar.

Adding a Color

When the user doesn't need to add a type in a vertex which depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he can use the *Triangulation_vertex_base_with_info_3* class to add his own information easily in the vertices. The example below shows how to add a *CGAL::Color* this way.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_with_info_3.h>
#include <CGAL/IO/Color.h>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_with_info_3<CGAL::Color, K> Vb;
typedef CGAL::Triangulation_data_structure_3<Vb> Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds> Delaunay;

typedef Delaunay::Point Point;

int main()
{
    Delaunay T;

    T.insert(Point(0,0,0));
    T.insert(Point(1,0,0));
    T.insert(Point(0,1,0));
    T.insert(Point(0,0,1));
    T.insert(Point(2,2,2));
    T.insert(Point(-1,0,1));

    // Set the color of finite vertices of degree 6 to red.
    Delaunay::Finite_vertices_iterator vit;
    for (vit = T.finite_vertices_begin(); vit != T.finite_vertices_end(); ++vit)
        if (T.degree(vit) == 6)
            vit->info() = CGAL::RED;

    return 0;
}
```

File: examples/Triangulation_3/color.cpp

Adding Handles

When the user needs to add a type in a vertex which depends on the *TriangulationDataStructure_3* (e.g. a *Vertex_handle* or *Cell_handle*), then he has to derive his own vertex base class, as the following example shows.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_vertex_base_3.h>
```

```

template < class GT, class Vb = CGAL::Triangulation_vertex_base_3<GT> >
class My_vertex_base
    : public Vb
{
public:
    typedef typename Vb::Vertex_handle    Vertex_handle;
    typedef typename Vb::Cell_handle      Cell_handle;
    typedef typename Vb::Point            Point;

    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_base<GT, Vb2>                          Other;
    };

    My_vertex_base() {}

    My_vertex_base(const Point& p)
        : Vb(p) {}

    My_vertex_base(const Point& p, Cell_handle c)
        : Vb(p, c) {}

    Vertex_handle    vh;
    Cell_handle      ch;
};

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_data_structure_3<My_vertex_base<K> >    Tds;
typedef CGAL::Delaunay_triangulation_3<K, Tds>                      Delaunay;

typedef Delaunay::Vertex_handle    Vertex_handle;
typedef Delaunay::Point            Point;

int main()
{
    Delaunay T;

    Vertex_handle v0 = T.insert(Point(0,0,0));
    Vertex_handle v1 = T.insert(Point(1,0,0));
    Vertex_handle v2 = T.insert(Point(0,1,0));
    Vertex_handle v3 = T.insert(Point(0,0,1));
    Vertex_handle v4 = T.insert(Point(2,2,2));
    Vertex_handle v5 = T.insert(Point(-1,0,1));

    // Now we can link the vertices as we like.
    v0->vh = v1;
    v1->vh = v2;
    v2->vh = v3;
    v3->vh = v4;
    v4->vh = v5;
    v5->vh = v0;

```

```

    return 0;
}

```

File: examples/Triangulation_3/adding_handles.cpp

27.6.3 The Simplex Class

The triangulation defines a *Simplex* class that represents a simplex (vertex, edge, facet or cell). This example demonstrates how simplices can be stored in a set.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Triangulation_3.h>

#include <iostream>
#include <fstream>
#include <cassert>
#include <list>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_3<K>      Triangulation;

typedef Triangulation::Finite_vertices_iterator Finite_vertices_iterator;
typedef Triangulation::Finite_edges_iterator Finite_edges_iterator;
typedef Triangulation::Finite_facets_iterator Finite_facets_iterator;
typedef Triangulation::Finite_cells_iterator Finite_cells_iterator;
typedef Triangulation::Simplex          Simplex;
typedef Triangulation::Locate_type       Locate_type;
typedef Triangulation::Point             Point;

int main()
{
    // construction from a list of points :
    std::list<Point> L;
    L.push_front(Point(0,0,0));
    L.push_front(Point(1,0,0));
    L.push_front(Point(0,1,0));
    L.push_front(Point(0,1,1));

    Triangulation T(L.begin(), L.end());

    std::set<Simplex> simplices;

    Finite_vertices_iterator vit = T.finite_vertices_begin();
    simplices.insert(Simplex(vit));

    Finite_cells_iterator cit = T.finite_cells_begin();
    simplices.insert(Simplex(cit));
}

```

```

Finite_edges_iterator eit = T.finite_edges_begin();
simplices.insert(Simplex(*eit));

Finite_facets_iterator fit = T.finite_facets_begin();
simplices.insert(Simplex(*fit));

for (std::set<Simplex>::iterator it = simplices.begin();
     it != simplices.end(); it++) {
    std::cout << it->dimension() << std::endl;
}

return 0;
}

```

File: examples/Triangulation_3/simplex.cpp

27.6.4 Use of the Delaunay Hierarchy

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_hierarchy_3.h>

#include <cassert>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Triangulation_vertex_base_3<K> Vb;
typedef CGAL::Triangulation_hierarchy_vertex_base_3<Vb> Vbh;
typedef CGAL::Triangulation_data_structure_3<Vbh> Tds;
typedef CGAL::Delaunay_triangulation_3<K,Tds> Dt;
typedef CGAL::Triangulation_hierarchy_3<Dt> Dh;

typedef Dh::Finite_vertices_iterator Finite_vertices_iterator;
typedef Dh::Vertex_handle Vertex_handle;
typedef Dh::Point Point;

int main()
{
    // generating points on a grid.
    std::vector<Point> P;

    for (int z=0 ; z<5 ; z++)
        for (int y=0 ; y<5 ; y++)
            for (int x=0 ; x<5 ; x++)
                P.push_back(Point(x,y,z));

    Dh T;

    // using the range insert (it is faster than inserting points one by one)
    T.insert (P.begin(), P.end());
}

```

```

assert( T.is_valid() );
assert( T.number_of_vertices() == 125 );
assert( T.dimension() == 3 );

// get the vertices.
std::vector<Vertex_handle> V;
for (Finite_vertices_iterator v = T.finite_vertices_begin();
     v != T.finite_vertices_end(); ++v)
    V.push_back (v);

// removal of the vertices in random order
std::random_shuffle(V.begin(), V.end());

for (int i=0; i<125; ++i)
    T.remove(V[i]);

assert( T.is_valid() );
assert( T.number_of_vertices() == 0 );

return 0;
}

```

File: examples/Triangulation_3/hierarchy.cpp

27.6.5 Finding the Cells in Conflict with a Point in a Delaunay Triangulation

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/point_generators_3.h>

#include <vector>
#include <cassert>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Delaunay_triangulation_3<K> Delaunay;
typedef Delaunay::Point Point;
typedef Delaunay::Cell_handle Cell_handle;
typedef Delaunay::Facet Facet;

int main()
{
    Delaunay T;
    CGAL::Random_points_in_sphere_3<Point> rnd;

    // First, make sure the triangulation is 3D.
    T.insert(Point(0,0,0));
    T.insert(Point(1,0,0));
    T.insert(Point(0,1,0));
    T.insert(Point(0,0,1));
}

```

```

assert(T.dimension() == 3);

// Inserts 100 random points if and only if their insertion
// in the Delaunay tetrahedralization conflicts with
// an even number of cells.
for (int i = 0; i != 100; ++i) {
    Point p = *rnd++;

    // Locate the point
    Delaunay::Locate_type lt;
    int li, lj;
    Cell_handle c = T.locate(p, lt, li, lj);
    if (lt == Delaunay::VERTEX)
        continue; // Point already exists

    // Get the cells that conflict with p in a vector V,
    // and a facet on the boundary of this hole in f.
    std::vector<Cell_handle> V;
    Facet f;

    T.find_conflicts(p, c,
                    CGAL::Oneset_iterator<Facet>(f), // Get one boundary facet
                    std::back_inserter(V));          // Conflict cells in V

    if ((V.size() & 1) == 0) // Even number of conflict cells ?
        T.insert_in_hole(p, V.begin(), V.end(), f.first, f.second);
}

std::cout << "Final triangulation has " << T.number_of_vertices()
           << " vertices." << std::endl;

return 0;
}

```

File: examples/Triangulation_3/find_conflicts.cpp

27.6.6 Regular Triangulation

This example shows the building of a regular triangulation. In this triangulation, points have an associated weight, and some points can be hidden and do not result in vertices in the triangulation. Another difference is that a specific traits class has to be used (at least at the moment).

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_3.h>
#include <CGAL/Regular_triangulation_euclidean_traits_3.h>
#include <CGAL/Regular_triangulation_filtered_traits_3.h>
#include <cassert>
#include <vector>

```

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

```

```

typedef CGAL::Regular_triangulation_filtered_traits_3<K> Traits;

typedef Traits::RT Weight;
typedef Traits::Bare_point Point;
typedef Traits::Weighted_point Weighted_point;

typedef CGAL::Regular_triangulation_3<Traits> Rt;

typedef Rt::Vertex_iterator Vertex_iterator;
typedef Rt::Vertex_handle Vertex_handle;

int main()
{
    // generate points on a 3D grid
    std::vector<Weighted_point> P;

    int number_of_points = 0;

    for (int z=0 ; z<5 ; z++)
        for (int y=0 ; y<5 ; y++)
            for (int x=0 ; x<5 ; x++) {
                Point p(x, y, z);
                Weight w = (x+y-z*y*x)*2.0; // let's say this is the weight.
                P.push_back(Weighted_point(p, w));
                ++number_of_points;
            }

    Rt T;

    // insert all points in a row (this is faster than one insert() at a time).
    T.insert (P.begin(), P.end());

    assert( T.is_valid() );
    assert( T.dimension() == 3 );

    std::cout << "Number of vertices : " << T.number_of_vertices() << std::endl;

    // removal of all vertices
    int count = 0;
    while (T.number_of_vertices() > 0) {
        T.remove (T.finite_vertices_begin());
        ++count;
    }

    assert( count == number_of_points );

    return 0;
}

```

File: examples/Triangulation_3/regular.cpp

27.7 Design and Implementation History

Monique Teillaud started to work on the 3D triangulation packages in 1997, following the design of the 2D triangulation packages. The notions of degenerate dimensions and infinite vertex were formalized [Tei99] and induced changes in the 2D triangulation packages. The packages were first released in CGAL 2.1. They contained basic functionalities on triangulations, Delaunay triangulations, regular triangulations.

A first version of removal of a vertex from a Delaunay triangulation was released in CGAL 2.2. However, this removal became really robust only in CGAL 2.3, after some research that allowed to deal with degenerate cases quite easily [DT03]. Andreas Fabri implemented this revised version of the removal, and a faster removal algorithm for CGAL 3.0.

The latter algorithm was proposed by Mariette Yvinec, who contributed in several ways to the package, first since she was maintaining the close 2D triangulation package and participated in many discussions, she also wrote the traits classes for regular triangulations.

In 2000, Sylvain Pion started working on these packages. He improved the efficiency of triangulations in CGAL 2.3 and 2.4 in several ways [BDP⁺02]: he implemented the Delaunay hierarchy [Dev02] in 2.3, he improved the memory footprint in 2.4 and 3.0, he also performed work on arithmetic filters [DP03] (see *Filtered_kernel*) to improve the speed of triangulations. He changed the design in CGAL 3.0, allowing users to add handles in their own vertices and cells.

Olivier Devillers, co-author of preliminary versions of the CGAL 2d triangulations, participated in many discussions, in particular about the perturbations, and more concretely in the implementation of the Delaunay hierarchy.

In 2005, Christophe Delage implemented the vertex removal function for regular triangulations, which allowed to release this functionality in CGAL 3.2.

In 2006, Nico Kruithof wrote the *Triangulations_simplex_3* class that can store simplices of any dimension and improved the internal organization of the code.

As of March 2007, Christophe Delage made the iterator range insert methods and constructors use *spatial_sort* to improve efficiency.

The authors also wish to thank Jean-Daniel Boissonnat for helpful discussions [BDTY00].

3D Triangulations

Reference Manual

Sylvain Pion and Monique Teillaud

A three-dimensional triangulation is a three-dimensional simplicial complex, pure connected and without singularities [BY98]. Its cells (3-faces) are such that two cells either do not intersect or share a common facet (2-face), edge (1-face) or vertex (0-face).

The basic 3D-triangulation class of CGAL is primarily designed to represent the triangulations of a set of points A in \mathbb{R}^3 . It can be viewed as a partition of the convex hull of A into tetrahedra whose vertices are the points of A . Together with the unbounded cell having the convex hull boundary as its frontier, the triangulation forms a partition of \mathbb{R}^3 .

In order to deal only with tetrahedra, which is convenient for many applications, the unbounded cell can be subdivided into tetrahedra by considering that each convex hull facet is incident to an *infinite cell* having as fourth vertex an auxiliary vertex called the *infinite vertex*. In that way, each facet is incident to exactly two cells and special cases at the boundary of the convex hull are simple to deal with.

A triangulation is a collection of vertices and cells that are linked together through incidence and adjacency relations. Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives access to one of its incident cells.

The four vertices of a cell are indexed with 0, 1, 2 and 3 in positive orientation, the positive orientation being defined by the orientation of the underlying Euclidean space \mathbb{R}^3 . The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index. See Figure 27.1.

CGAL::Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>

Definition

The class *Triangulation_3* represents a 3-dimensional tetrahedralization of points.

```
#include <CGAL/Triangulation_3.h>
```

Parameters

The first template argument must be a model of the *TriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3<Triangulation_vertex_base_3<TriangulationTraits_3>,Triangulation_cell_base_3<TriangulationTraits_3>>*.

Inherits From

Triangulation_utils_3

Types

The class *Triangulation_3* defines the following types:

<code>typedef TriangulationDataStructure_3</code>	<code>Triangulation_data_structure;</code>
<code>typedef TriangulationTraits_3</code>	<code>Geom_traits;</code>
<code>typedef TriangulationTraits_3::Point_3</code>	<code>Point;</code>
<code>typedef TriangulationTraits_3::Segment_3</code>	<code>Segment;</code>
<code>typedef TriangulationTraits_3::Triangle_3</code>	<code>Triangle;</code>
<code>typedef TriangulationTraits_3::Tetrahedron_3</code>	<code>Tetrahedron;</code>

Only vertices (0-faces) and cells (3-faces) are stored. Edges (1-faces) and facets (2-faces) are not explicitly represented and thus there are no corresponding classes (see Section [27.1](#)).

<code>typedef TriangulationDataStructure_3::Vertex</code>	<code>Vertex;</code>
<code>typedef TriangulationDataStructure_3::Cell</code>	<code>Cell;</code>
<code>typedef TriangulationDataStructure_3::Facet</code>	<code>Facet;</code>
<code>typedef TriangulationDataStructure_3::Edge</code>	<code>Edge;</code>

The vertices and faces of the triangulations are accessed through *handles*, *iterators* and *circulators*. A handle is a type which supports the two dereference operators *operator** and *operator->*. The Handle concept is documented in the support library. Iterators and circulators are bidirectional and non-mutable. The edges and facets of the triangulation can also be visited through iterators and circulators which are bidirectional and non-mutable.

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

<i>typedef TriangulationDataStructure_3::Vertex_handle</i>	<i>Vertex_handle;</i>	handle to a vertex
<i>typedef TriangulationDataStructure_3::Cell_handle</i>	<i>Cell_handle;</i>	handle to a cell
<i>typedef Triangulation_simplex_3<Self></i>	<i>Simplex;</i>	Reference to a simplex (vertex, edge, facet or cell) of the triangulation
<i>typedef TriangulationDataStructure_3::size_type</i>	<i>size_type;</i>	Size type (an unsigned integral type)
<i>typedef TriangulationDataStructure_3::difference_type</i>	<i>difference_type;</i>	Difference type (a signed integral type)
<i>typedef TriangulationDataStructure_3::Cell_iterator</i>	<i>All_cells_iterator;</i>	iterator over cells
<i>typedef TriangulationDataStructure_3::Facet_iterator</i>	<i>All_facets_iterator;</i>	iterator over facets
<i>typedef TriangulationDataStructure_3::Edge_iterator</i>	<i>All_edges_iterator;</i>	iterator over edges
<i>typedef TriangulationDataStructure_3::Vertex_iterator</i>	<i>All_vertices_iterator;</i>	iterator over vertices
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_cells_iterator</i>		iterator over finite cells
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_facets_iterator</i>		iterator over finite facets
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_edges_iterator</i>		iterator over finite edges
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Finite_vertices_iterator</i>		iterator over finite vertices
<i>Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3>:: Point_iterator</i>		iterator over the points corresponding to the finite vertices of the triangulation.
<i>typedef TriangulationDataStructure_3::Cell_circulator</i>	<i>Cell_circulator;</i>	circulator over all cells incident to a given edge
<i>typedef TriangulationDataStructure_3::Facet_circulator</i>	<i>Facet_circulator;</i>	circulator over all facets incident to a given edge

The triangulation class also defines the following enum type to specify which case occurs when locating a point in the triangulation.

```
enum Locate_type { VERTEX=0,
                  EDGE,
                  FACET,
                  CELL,
                  OUTSIDE_CONVEX_HULL,
                  OUTSIDE_AFFINE_HULL }
```

Creation

```
Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t( TriangulationTraits_3 traits =
TriangulationTraits_3())
```

Introduces a triangulation t having only one vertex which is the infinite vertex.

```
Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t( Triangulation_3 tr);
```

Copy constructor. All vertices and faces are duplicated.

```
template < class InputIterator>
Triangulation_3<TriangulationTraits_3,TriangulationDataStructure_3> t( InputIterator first,
                                                                    InputIterator last,
                                                                    TriangulationTraits_3 traits =
TriangulationTraits_3())
```

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Assignment

```
Triangulation_3 & t = Triangulation_3 tr
```

The triangulation tr is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by t is deleted.

```
void t.swap( Triangulation_3 & tr)
```

The triangulations tr and t are swapped. *t.swap(tr)* should be preferred to $t = tr$ or to $t(tr)$ if tr is deleted after that. Indeed, there is no copy of cells and vertices, thus this method runs in constant time.

```
void t.clear() Deletes all finite vertices and all cells of t.
```

```
template < class GT, class Tds >
```

bool *Triangulation_3<GT, Tds> t1 == Triangulation_3<GT, Tds> t2*

Equality operator. Returns true iff there exist a bijection between the vertices of *t1* and those of *t2* and a bijection between the cells of *t1* and those of *t2*, which preserve the geometry of the triangulation, that is, the points of each corresponding pair of vertices are equal, and the tetrahedra corresponding to each pair of cells are equal (up to a permutation of their vertices).

template < class GT, class Tds >

bool *Triangulation_3<GT, Tds> t1 != Triangulation_3<GT, Tds> t2*

The opposite of *operator==*.

Access Functions

TriangulationTraits_3 *t.geom_traits()* Returns a const reference to the geometric traits object.

TriangulationDataStructure_3 *t.tds()* Returns a const reference to the triangulation data structure.

————— *advanced* —————

Non const access

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of the *tds*.

TriangulationDataStructure_3& *t.tds()* Returns a reference to the triangulation data structure.

This method is mainly a help for users implementing their own triangulation algorithms.

————— *advanced* —————

int *t.dimension()* Returns the dimension of the affine hull.
size_type *t.number_of_vertices()* Returns the number of finite vertices.
size_type *t.number_of_cells()* Returns the number of cells or 0 if *t.dimension()* < 3.

Vertex_handle *t.infinite_vertex()* Returns the infinite vertex.
Cell_handle *t.infinite_cell()* Returns a cell incident to the infinite vertex.

Non-constant-time access functions

As previously said, the triangulation is a collection of cells that are either infinite or represent a finite tetrahedra, where an infinite cell is a cell incident to the infinite vertex. Similarly we call an edge (resp. facet) *infinite* if it is incident to the infinite vertex.

size_type *t.number_of_facets()* The number of facets. Returns 0 if *t.dimension()* < 2.
size_type *t.number_of_edges()* The number of edges. Returns 0 if *t.dimension()* < 1.

size_type *t.number_of_finite_cells()* The number of finite cells. Returns 0 if *t.dimension()* < 3.
size_type *t.number_of_finite_facets()* The number of finite facets. Returns 0 if *t.dimension()* < 2.

size_type *t.number_of_finite_edges()* The number of finite edges. Returns 0 if *t.dimension()* < 1.

Geometric access functions

Tetrahedron *t.tetrahedron(const Cell_handle c)*

Returns the tetrahedron formed by the four vertices of *c*.

Precondition: *t.dimension()* = 3 and the cell is finite.

Triangle *t.triangle(const Cell_handle c, int i)*

Returns the triangle formed by the three vertices of facet (c, i) . The triangle is oriented so that its normal points to the inside of cell *c*.

Precondition: *t.dimension()* ≥ 2 and $i \in \{0, 1, 2, 3\}$ in dimension 3, $i = 3$ in dimension 2, and the facet is finite.

Triangle *t.triangle(Facet f)*

Same as the previous method for facet *f*.

Precondition: *t.dimension()* ≥ 2 and the facet is finite.

Segment *t.segment(Edge e)*

Returns the line segment formed by the vertices of *e*.

Precondition: *t.dimension()* ≥ 1 and *e* is finite.

Segment *t.segment(const Cell_handle c, int i, int j)*

Same as the previous method for edge (c, i, j) .

Precondition: As above and $i \neq j$. Moreover $i, j \in \{0, 1, 2, 3\}$ in dimension 3, $i, j \in \{0, 1, 2\}$ in dimension 2, $i, j \in \{0, 1\}$ in dimension 1.

Tests for Finite and Infinite Vertices and Faces

bool *t.is_infinite(const Vertex_handle v)*

true, iff vertex *v* is the infinite vertex.

bool *t.is_infinite(const Cell_handle c)*

true, iff *c* is incident to the infinite vertex.

Precondition: *t.dimension()* = 3.

bool *t.is_infinite(const Cell_handle c, int i)*

true, iff the facet *i* of cell *c* is incident to the infinite vertex.

Precondition: *t.dimension()* ≥ 2 and $i \in \{0, 1, 2, 3\}$ in dimension 3, $i = 3$ in dimension 2.

bool *t.is_infinite(Facet f)*

true iff facet *f* is incident to the infinite vertex.

Precondition: *t.dimension()* ≥ 2.

bool *t.is_infinite(const Cell_handle c, int i, int j)*

true, iff the edge (i, j) of cell *c* is incident to the infinite vertex.

Precondition: *t.dimension()* ≥ 1 and $i \neq j$. Moreover $i, j \in \{0, 1, 2, 3\}$ in dimension 3, $i, j \in \{0, 1, 2\}$ in dimension 2, $i, j \in \{0, 1\}$ in dimension 1.

bool *t.is_infinite(Edge e)*

true iff edge *e* is incident to the infinite vertex.
Precondition: t.dimension() ≥ 1.

Queries

bool *t.is_vertex(Point p, Vertex_handle & v)*

Tests whether *p* is a vertex of *t* by locating *p* in the triangulation. If *p* is found, the associated vertex *v* is given.

bool *t.is_vertex(Vertex_handle v)*

Tests whether *v* is a vertex of *t*.

bool *t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j)*

Tests whether (u,v) is an edge of *t*. If the edge is found, it gives a cell *c* having this edge and the indices *i* and *j* of the vertices *u* and *v* in *c*, in this order.
Precondition: u and v are vertices of t.

bool *t.is_facet(Vertex_handle u,*
 Vertex_handle v,
 Vertex_handle w,
 Cell_handle & c,
 int & i,
 int & j,
 int & k)

Tests whether (u,v,w) is a facet of *t*. If the facet is found, it computes a cell *c* having this facet and the indices *i, j* and *k* of the vertices *u, v* and *w* in *c*, in this order.
Precondition: u, v and w are vertices of t.

bool *t.is_cell(Cell_handle c)*

Tests whether *c* is a cell of *t*.

bool *t.is_cell(Vertex_handle u,*
 Vertex_handle v,
 Vertex_handle w,
 Vertex_handle x,
 Cell_handle & c,
 int & i,
 int & j,
 int & k,
 int & l)

Tests whether (u,v,w,x) is a cell of *t*. If the cell *c* is found, the method computes the indices *i, j, k* and *l* of the vertices *u, v, w* and *x* in *c*, in this order.
Precondition: u, v, w and x are vertices of t.

```

bool      t.is_cell( Vertex_handle u,
                    Vertex_handle v,
                    Vertex_handle w,
                    Vertex_handle x,
                    Cell_handle & c)

```

Tests whether (u,v,w,x) is a cell of t and computes this cell c .
Precondition: u, v, w and x are vertices of t .

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

```

bool      t.has_vertex( Facet f, Vertex_handle v, int & j)

```

If v is a vertex of f , then j is the index of v in the cell $f.first$, and the method returns *true*.
Precondition: $t.dimension()=3$

```

bool      t.has_vertex( Cell_handle c, int i, Vertex_handle v, int & j)

```

Same for facet (c,i) . Computes the index j of v in c .

```

bool      t.has_vertex( Facet f, Vertex_handle v)

```

```

bool      t.has_vertex( Cell_handle c, int i, Vertex_handle v)

```

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

```

bool      t.are_equal( Cell_handle c, int i, Cell_handle n, int j)

```

```

bool      t.are_equal( Facet f, Facet g)

```

```

bool      t.are_equal( Facet f, Cell_handle n, int j)

```

For these three methods:
Precondition: $t.dimension()=3$.

Point location

The class *Triangulation_3*<*TriangulationTraits_3*,*TriangulationDataStructure_3*> provides two functions to locate a given point with respect to a triangulation. It provides also functions to test if a given point is inside a finite face or not. Note that the class *Delaunay-triangulation_3* also provides a *nearest_vertex()* function.

```

Cell_handle  t.locate( Point query, Cell_handle start = Cell_handle())

```

If the point *query* lies inside the convex hull of the points, the cell that contains the query in its interior is returned. If *query* lies on a facet, an edge or on a vertex, one of the cells having *query* on its boundary is returned.

If the point *query* lies outside the convex hull of the points, an infinite cell with vertices $\{p,q,r,\infty\}$ is returned such that the tetrahedron $(p,q,r,query)$ is positively oriented (the rest of the triangulation lies on the other side of facet (p,q,r)).

Note that *locate* works even in degenerate dimensions: in dimension 2 (resp. 1, 0) the *Cell_handle* returned is the one that represents the facet (resp. edge, vertex) containing the query point.

The optional argument *start* is used as a starting place for the search.

Cell_handle *t.locate(Point query, Locate_type & lt, int & li, int & lj, Cell_handle start = Cell_handle())*

If *query* lies inside the affine hull of the points, the *k*-face (finite or infinite) that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX*, *EDGE*, *FACET*, *CELL*, or *OUTSIDE_CONVEX_HULL* if the cell is infinite and *query* lies strictly in it) and two indices *li* and *lj* that specify the *k*-face of the cell containing *query*.

If the *k*-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is an edge, *li* and *lj* give the indices of its vertices.

If the point *query* lies outside the affine hull of the points, which can happen in case of degenerate dimensions, *lt* is set to *OUTSIDE_AFFINE_HULL*, and the cell returned has no meaning. As a particular case, if there is no finite vertex yet in the triangulation, *lt* is set to *OUTSIDE_AFFINE_HULL* and *locate* returns the default constructed handle.

The optional argument *start* is used as a starting place for the search.

Bounded_side *t.side_of_cell(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj)*

Returns a value indicating on which side of the oriented boundary of *c* the point *p* lies. More precisely, it returns:

- *ON_BOUNDED_SIDE* if *p* is inside the cell. For an infinite cell this means that *p* lies strictly in the half space limited by its finite facet and not containing any other point of the triangulation.

- *ON_BOUNDARY* if *p* on the boundary of the cell. For an infinite cell this means that *p* lies on the *finite* facet. Then *lt* together with *li* and *lj* give the precise location on the boundary. (See the descriptions of the *locate* methods.)

- *ON_UNBOUNDED_SIDE* if *p* lies outside the cell. For an infinite cell this means that *p* does not satisfy either of the two previous conditions.

Precondition: t.dimension() = 3

Bounded_side *t.side_of_facet(Point p, Facet f, Locate_type & lt, int & li, int & lj)*

Returns a value indicating on which side of the oriented boundary of *f* the point *p* lies:

- *ON_BOUNDED_SIDE* if *p* is inside the facet. For an infinite facet this means that *p* lies strictly in the half plane limited by its finite edge and not containing any other point of the triangulation .

- *ON_BOUNDARY* if *p* is on the boundary of the facet. For an infinite facet this means that *p* lies on the finite edge. *lt*, *li* and *lj* give the precise location of *p* on the boundary of the facet. *li* and *lj* refer to indices in the degenerate cell *c* representing *f*.

- *ON_UNBOUNDED_SIDE* if *p* lies outside the facet. For an infinite facet this means that *p* does not satisfy either of the two previous conditions.

Precondition: t.dimension() = 2 and p lies in the plane containing the triangulation. f.second = 3 (in dimension 2 there is only one facet per cell).

Bounded_side *t.side_of_facet(Point p, Cell_handle c, Locate_type & lt, int & li, int & lj)*

Same as the previous method for the facet (*c*,3).

Figure 27.6: Flips.

Bounded_side $t.side_of_edge(Point\ p, Edge\ e, Locate_type\ \&\ lt, int\ \&\ li)$

Returns a value indicating on which side of the oriented boundary of e the point p lies:

- *ON_BOUNDED_SIDE* if p is inside the edge. For an infinite edge this means that p lies in the half line defined by the vertex and not containing any other point of the triangulation.
- *ON_BOUNDARY* if p equals one of the vertices, li give the index of the vertex in the cell storing e
- *ON_UNBOUNDED_SIDE* if p lies outside the edge. For an infinite edge this means that p lies on the other half line, which contains the other points of the triangulation.

Precondition: $t.dimension() = 1$ and p is collinear with the points of the triangulation. $e.second = 0$ and $e.third = 1$ (in dimension 1 there is only one edge per cell).

Bounded_side $t.side_of_edge(Point\ p, Cell_handle\ c, Locate_type\ \&\ lt, int\ \&\ li)$

Same as the previous method for edge $(c, 0, 1)$.

Flips

Two kinds of flips exist for a three-dimensional triangulation. They are reciprocal. To be flipped, an edge must be incident to three tetrahedra. During the flip, these three tetrahedra disappear and two tetrahedra appear. Figure 27.6(left) shows the edge that is flipped as bold dashed, and one of its three incident facets is shaded. On the right, the facet shared by the two new tetrahedra is shaded.

Flips are possible only under the following conditions:

- the edge or facet to be flipped is not on the boundary of the convex hull of the triangulation
- the five points involved are in convex position.

The following methods guarantee the validity of the resulting 3D triangulation.

Flips for a 2d triangulation are not implemented yet

```
bool      t.flip( Edge e)
bool      t.flip( Cell_handle c, int i, int j)
```

Before flipping, these methods check that edge $e=(c,i,j)$ is flippable (which is quite expensive). They return *false* or *true* according to this test.

```
void      t.flip_flippable( Edge e)
void      t.flip_flippable( Cell_handle c, int i, int j)
```

Should be preferred to the previous methods when the edge is known to be flippable.

Precondition: The edge is flippable.

```
bool      t.flip( Facet f)
bool      t.flip( Cell_handle c, int i)
```

Before flipping, these methods check that facet $f=(c,i)$ is flippable (which is quite expensive). They return *false* or *true* according to this test.

```
void      t.flip_flippable( Facet f)
void      t.flip_flippable( Cell_handle c, int i)
```

Should be preferred to the previous methods when the facet is known to be flippable.

Precondition: The facet is flippable.

Insertions

The following operations are guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

```
Vertex_handle  t.insert( Point p, Cell_handle start = Cell_handle())
```

Inserts point p in the triangulation and returns the corresponding vertex.

If point p coincides with an already existing vertex, this vertex is returned and the triangulation remains unchanged.

If point p lies in the convex hull of the points, it is added naturally: if it lies inside a cell, the cell is split into four cells, if it lies on a facet, the two incident cells are split into three cells, if it lies on an edge, all the cells incident to this edge are split into two cells.

If point p is strictly outside the convex hull but in the affine hull, p is linked to all visible points on the convex hull to form the new triangulation. See Figure 27.7.

If point p is outside the affine hull of the points, p is linked to all the points, and the dimension of the triangulation is incremented. All the points now belong to the boundary of the convex hull, so, the infinite vertex is linked to all the points to triangulate the new infinite face. See Figure 27.8. The optional argument *start* is used as a starting place for the search.

Vertex_handle *t.insert(Point p, Locate_type lt, Cell_handle loc, int li, int lj)*

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *locate()* above.

template < class InputIterator >

int *t.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *InputIterator*.

Precondition: The *value_type* of *first* and *last* is *Point*.

The previous methods are sufficient to build a whole triangulation. We also provide some other methods that can be used instead of *insert(p)* when the place where the new point *p* must be inserted is already known. They are also guaranteed to lead to a valid triangulation when they are applied on a valid triangulation.

Vertex_handle *t.insert_in_cell(Point p, Cell_handle c)*

Inserts point *p* in cell *c*. Cell *c* is split into 4 tetrahedra.

Precondition: *t.dimension()* = 3 and *p* lies strictly inside cell *c*.

Vertex_handle *t.insert_in_facet(Point p, Facet f)*

Inserts point *p* in facet *f*. In dimension 3, the 2 neighboring cells are split into 3 tetrahedra; in dimension 2, the facet is split into 3 triangles.

Precondition: *t.dimension()* ≥ 2 and *p* lies strictly inside face *f*.

Vertex_handle *t.insert_in_facet(Point p, Cell_handle c, int i)*

As above, insertion in facet (c,i) .

Precondition: As above and $i \in \{0, 1, 2, 3\}$ in dimension 3, $i = 3$ in dimension 2.

Vertex_handle *t.insert_in_edge(Point p, Edge e)*

Inserts *p* in edge *e*. In dimension 3, all the cells having this edge are split into 2 tetrahedra; in dimension 2, the 2 neighboring facets are split into 2 triangles; in dimension 1, the edge is split into 2 edges.

Precondition: *t.dimension()* ≥ 1 and *p* lies on edge *e*.

Vertex_handle *t.insert_in_edge(Point p, Cell_handle c, int i, int j)*

As above, inserts *p* in edge (i,j) of *c*.

Precondition: As above and $i \neq j$. Moreover $i, j \in \{0, 1, 2, 3\}$ in dimension 3, $i, j \in \{0, 1, 2\}$ in dimension 2, $i, j \in \{0, 1\}$ in dimension 1.

Vertex_handle *t.insert_outside_convex_hull(Point p, Cell_handle c)*

The cell *c* must be an infinite cell containing *p*.

Links *p* to all points in the triangulation that are visible from *p*. Updates consequently the infinite faces. See Figure 27.7.

Precondition: *t.dimension()* > 0 , *c*, and the *k*-face represented by *c* is infinite and contains *t*.

Figure 27.7: *insert_outside_convex_hull* (2-dimensional case).

Vertex_handle *t.insert_outside_affine_hull(Point p)*

p is linked to all the points, and the infinite vertex is linked to all the points (including *p*) to triangulate the new infinite face, so that all the points now belong to the boundary of the convex hull. See Figure 27.8.

This method can be used to insert the first point in an empty triangulation.

Precondition: *t.dimension()* < 3 and *p* lies outside the affine hull of the points.

Figure 27.8: *insert_outside_affine_hull* (2-dimensional case).

Vertex_handle *t.insert_in_hole(Point p, CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)*

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*] of *Cell_handles* which specifies a hole: a set of connected cells (resp. facets in dimension 2) which is star-shaped wrt *p*. (*begin*, *i*) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin->neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex *v*, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with *v* as vertex. Then *v->set_point(p)* is called and *v* is returned.

This operation is equivalent to calling *tds().insert_in_hole(cell_begin, cell_end, begin, i); v->set_point(p)*.

Precondition: *t.dimension()* ≥ 2 , the set of cells (resp. facets in dimension 2) is connected, its boundary is connected, and *p* lies inside the hole, which is star-shaped wrt *p*.

Traversal of the Triangulation

The triangulation class provides several iterators and circulators that allow one to traverse it (completely or partially).

Cell, Face, Edge and Vertex Iterators

The following iterators allow the user to visit cells, facets, edges and vertices of the triangulation. These iterators are non-mutable, bidirectional and their value types are respectively *Cell*, *Facet*, *Edge* and *Vertex*. They are all invalidated by any change in the triangulation.

<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex. Then ++ and -- will iterate over finite vertices. Returns <i>finite_vertices_end()</i> when <i>t.number_of_vertices()</i> = 0.
<i>Finite_vertices_iterator</i>	<i>t.finite_vertices_end()</i>	Past-the-end iterator
<i>Finite_edges_iterator</i>	<i>t.finite_edges_begin()</i>	Starts at an arbitrary finite edge. Then ++ and -- will iterate over finite edges. Returns <i>finite_edges_end()</i> when <i>t.dimension()</i> < 1.
<i>Finite_edges_iterator</i>	<i>t.finite_edges_end()</i>	Past-the-end iterator
<i>Finite_facets_iterator</i>	<i>t.finite_facets_begin()</i>	Starts at an arbitrary finite facet. Then ++ and -- will iterate over finite facets. Returns <i>finite_facets_end()</i> when <i>t.dimension()</i> < 2.
<i>Finite_facets_iterator</i>	<i>t.finite_facets_end()</i>	Past-the-end iterator
<i>Finite_cells_iterator</i>	<i>t.finite_cells_begin()</i>	Starts at an arbitrary finite cell. Then ++ and -- will iterate over finite cells. Returns <i>finite_cells_end()</i> when <i>t.dimension()</i> < 3.
<i>Finite_cells_iterator</i>	<i>t.finite_cells_end()</i>	Past-the-end iterator
<i>All_vertices_iterator</i>	<i>t.all_vertices_begin()</i>	Starts at an arbitrary vertex. Iterates over all vertices (even the infinite one). Returns <i>vertices_end()</i> when <i>t.number_of_vertices()</i> = 0.
<i>All_vertices_iterator</i>	<i>t.all_vertices_end()</i>	Past-the-end iterator

<i>All_edges_iterator</i>	<i>t.all_edges_begin()</i>	Starts at an arbitrary edge. Iterates over all edges (even infinite ones). Returns <i>edges_end()</i> when <i>t.dimension()</i> < 1.
<i>All_edges_iterator</i>	<i>t.all_edges_end()</i>	Past-the-end iterator
<i>All_facets_iterator</i>	<i>t.all_facets_begin()</i>	Starts at an arbitrary facet. Iterates over all facets (even infinite ones). Returns <i>facets_end()</i> when <i>t.dimension()</i> < 2.
<i>All_facets_iterator</i>	<i>t.all_facets_end()</i>	Past-the-end iterator
<i>All_cells_iterator</i>	<i>t.all_cells_begin()</i>	Starts at an arbitrary cell. Iterates over all cells (even infinite ones). Returns <i>cells_end()</i> when <i>t.dimension()</i> < 3.
<i>All_cells_iterator</i>	<i>t.all_cells_end()</i>	Past-the-end iterator
<i>Point_iterator</i>	<i>t.points_begin()</i>	Iterates over the points of the triangulation.
<i>Point_iterator</i>	<i>t.points_end()</i>	Past-the-end iterator

Cell and Facet Circulators

The following circulators respectively visit all cells or all facets incident to a given edge. They are non-mutable and bidirectional. They are invalidated by any modification of one of the cells traversed.

<i>Cell_circulator</i>	<i>t.incident_cells(Edge e)</i>	Starts at an arbitrary cell incident to <i>e</i> . <i>Precondition: t.dimension() = 3.</i>
<i>Cell_circulator</i>	<i>t.incident_cells(Cell_handle c, int i, int j)</i>	As above for edge (i,j) of <i>c</i> .
<i>Cell_circulator</i>	<i>t.incident_cells(Edge e, Cell_handle start)</i>	Starts at cell <i>start</i> . <i>Precondition: t.dimension() = 3 and start is incident to e.</i>
<i>Cell_circulator</i>	<i>t.incident_cells(Cell_handle c, int i, int j, Cell_handle start)</i>	As above for edge (i,j) of <i>c</i> .

The following circulators on facets are defined only in dimension 3, though facets are defined also in dimension 2: there are only two facets sharing an edge in dimension 2.

<i>Facet_circulator</i>	<i>t.incident_facets(Edge e)</i>	Starts at an arbitrary facet incident to <i>e</i> . <i>Precondition: t.dimension() = 3</i>
<i>Facet_circulator</i>	<i>t.incident_facets(Cell_handle c, int i, int j)</i>	As above for edge (i,j) of <i>c</i> .
<i>Facet_circulator</i>	<i>t.incident_facets(Edge e, Facet start)</i>	Starts at facet <i>start</i> . <i>Precondition: start is incident to e.</i>
<i>Facet_circulator</i>	<i>t.incident_facets(Edge e, Cell_handle start, int f)</i>	Starts at facet of index <i>f</i> in <i>start</i> .

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Facet start)*

As above for edge (i,j) of c .

Facet_circulator *t.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f)*

As above for edge (i,j) of c and facet $(start,f)$.

Traversal of the incident cells and facets, and the adjacent vertices of a given vertex

template <class OutputIterator>

OutputIterator *t.incident_cells(Vertex_handle v, OutputIterator cells)*

Copies the *Cell_handles* of all cells incident to v to the output iterator *cells*. If $t.dimension() < 3$, then do nothing. Returns the resulting output iterator.

Precondition: $v \neq \text{Vertex_handle}()$, $t.is_vertex(v)$.

template <class OutputIterator>

OutputIterator *t.incident_facets(Vertex_handle v, OutputIterator facets)*

Copies the *Facets* incident to v to the output iterator *facets*. Returns the resulting output iterator.

Precondition: $t.dimension() = 3$, $v \neq \text{Vertex_handle}()$, $t.is_vertex(v)$.

template <class OutputIterator>

OutputIterator *t.incident_vertices(Vertex_handle v, OutputIterator vertices)*

Copies the *Vertex_handles* of all vertices incident to v to the output iterator *vertices*. If $t.dimension() < 2$, then do nothing. Returns the resulting output iterator.

Precondition: $v \neq \text{Vertex_handle}()$, $t.is_vertex(v)$.

size_type *t.degree(Vertex_handle v)*

Returns the degree of a vertex, that is, the number of incident vertices. The infinite vertex is counted.

Precondition: $v \neq \text{Vertex_handle}()$, $t.is_vertex(v)$.

Traversal between adjacent cells

int *t.mirror_index(Cell_handle c, int i)*

Returns the index of c in its i^{th} neighbor.

Precondition: $i \in \{0, 1, 2, 3\}$.

Vertex_handle *t.mirror_vertex(Cell_handle c, int i)*

Returns the vertex of the i^{th} neighbor of c that is opposite to c .

Precondition: $i \in \{0, 1, 2, 3\}$.

<i>Facet</i>	<i>t.mirror_facet(Facet f)</i>	Returns the same facet viewed from the other adjacent cell.
--------------	---------------------------------	---

— *advanced* —

Checking

The responsibility of keeping a valid triangulation belongs to the user when using advanced operations allowing a direct manipulation of cells and vertices. We provide the user with the following methods to help debugging.

<i>bool</i>	<i>t.is_valid(bool verbose = false)</i>	Checks the combinatorial validity of the triangulation. Checks also the validity of its geometric embedding (see Section 27.1). When <i>verbose</i> is set to true, messages describing the first invalidity encountered are printed.
-------------	--	--

<i>bool</i>	<i>t.is_valid(Cell_handle c, bool verbose = false)</i>	Checks the combinatorial validity of the cell by calling the <i>is_valid</i> method of the <i>TriangulationDataStructure_3</i> cell class. Also checks the geometric validity of <i>c</i> , if <i>c</i> is finite. (See Section 1820.) When <i>verbose</i> is set to <i>true</i> , messages are printed to give a precise indication of the kind of invalidity encountered.
-------------	---	--

— *advanced* —

I/O

CGAL provides an interface to Geomview for a 3D-triangulation, see Chapter 64 on *Geomview_stream*. `#include <CGAL/IO/Triangulation_geomview_ostream_3.h>`

<i>istream&</i>	<i>istream& is >> Triangulation_3 &t</i>	Reads the underlying combinatorial triangulation from <i>is</i> by calling the corresponding input operator of the triangulation data structure class, and the non-combinatorial information by calling the corresponding input operators of the vertex and the cell classes (such as point coordinates), which are provided by overloading the stream operators of the vertex and cell types. Assigns the resulting triangulation to <i>t</i> .
---------------------	--	--

<i>ostream&</i>	<i>ostream& os << Triangulation_3 t</i>	Writes the triangulation <i>t</i> into <i>os</i> .
---------------------	---	--

The information in the *iostream* is: the dimension, the number of finite vertices, the non-combinatorial information about vertices (point, etc), the number of cells, the indices of the vertices of each cell, plus the non-combinatorial information about each cell, then the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells. When dimension < 3, the same information is stored for faces of maximal dimension instead of cells.

TriangulationDataStructure_3::Vertex

TriangulationDataStructure_3::Cell

CGAL::Delaunay_triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3>

Definition

The class *Delaunay_triangulation_3* represents a three-dimensional Delaunay triangulation.

The user is advised to use the class *Triangulation_hierarchy_3* rather than this basic Delaunay triangulation class: it offers the same functionalities but is much more efficient for large data sets.

```
#include <CGAL/Delaunay_triangulation_3.h>
```

Parameters

The first template argument must be a model of the *DelaunayTriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3<Triangulation_vertex_base_3<DelaunayTriangulationTraits_3>, Triangulation_cell_base_3<DelaunayTriangulationTraits_3> >*.

Inherits From

Triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3>

Types

In addition to those inherited, the following types are defined, for use by the construction of the Voronoi diagram:

```
typedef DelaunayTriangulationTraits_3::Line_3      Line;
typedef DelaunayTriangulationTraits_3::Ray_3       Ray;
typedef DelaunayTriangulationTraits_3::Plane_3     Plane;
typedef DelaunayTriangulationTraits_3::Object_3    Object;
```

Creation

```
Delaunay_triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3> dt(
DelaunayTriangulationTraits_3 traits = DelaunayTriangulationTraits_3())
```

Creates an empty Delaunay triangulation, possibly specifying a traits class *traits*.

```
Delaunay_triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3> dt( Delaunay_
triangulation_3 dt1)
```

Copy constructor.

```

template < class InputIterator >
Delaunay_triangulation_3<DelaunayTriangulationTraits_3, TriangulationDataStructure_3> dt( InputIterator
first,
                                                    InputIterator
last,
                                                    DelaunayTriangulationTraits_
3 traits = DelaunayTriangulationTraits_3())

```

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Operations

Insertion

The following methods overload the corresponding methods of triangulations to ensure the empty sphere property of Delaunay triangulations.

In the degenerate case when there are co-spherical points, the Delaunay triangulation is known not to be uniquely defined. In this case, CGAL chooses a particular Delaunay triangulation using a symbolic perturbation scheme [DT03].

```
Vertex_handle dt.insert( Point p, Cell_handle start = Cell_handle())
```

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the insertion in a triangulation, but ensures in addition the empty sphere property of all the created faces. The optional argument *start* is used as a starting place for the search.

```
Vertex_handle dt.insert( Point p, Locate_type lt, Cell_handle loc, int li, int lj)
```

Inserts point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Triangulation_3::locate()*.

The following method allows one to insert several points. It returns the number of inserted points.

```

template < class InputIterator >
int dt.insert( InputIterator first, InputIterator last)

```

Inserts the points in the iterator range $[first, last)$. Returns the number of inserted points. Note that this function is not guaranteed to insert the points following the order of *InputIterator*.

Precondition: The *value_type* of *first* and *last* is *Point*.

Point moving

Vertex_handle *dt.move_point(Vertex_handle v, Point p)*

Moves the point stored in *v* to *p*, while preserving the Delaunay property. This performs an action semantically equivalent to *remove(v)* followed by *insert(p)*, but is supposedly faster when the point has not moved much. Returns the handle to the new vertex.

Precondition: *v* is a finite vertex of the triangulation.

Removal

When a vertex *v* is removed from a triangulation, all the cells incident to *v* must be removed, and the polyhedral region consisting of all the tetrahedra that are incident to *v* must be re-triangulated. So, the problem reduces to triangulating a polyhedral region, while preserving its boundary, or to compute a *constrained* triangulation. This is known to be sometimes impossible: the Schönhardt polyhedron cannot be triangulated [She98].

However, when dealing with Delaunay triangulations, the case of such polyhedra that cannot be re-triangulated cannot happen, so CGAL proposes a vertex removal.

void *dt.remove(Vertex_handle v)*

Removes the vertex *v* from the triangulation.

Note that in CGAL 3.0 we have implemented a new algorithm for re-triangulating the hole after the removal. In case that you experience problems when removing a vertex, the old code can be enabled with a *#define CGAL_DELAUNAY_3_OLD_REMOVE 1*.

Precondition: *v* is a finite vertex of the triangulation.

template < typename InputIterator >

int *dt.remove(InputIterator first, InputIterator beyond)*

Removes the vertices specified by the iterator range [*first*, *beyond*) of value type *Vertex_handle*. *remove()* is called over each element of the range. The number of vertices removed is returned.

Precondition: All vertices of the range are finite vertices of the triangulation.

Queries

Bounded_side *dt.side_of_sphere(Cell_handle c, Point p)*

Returns a value indicating on which side of the circumscribed sphere of *c* the point *p* lies. More precisely, it returns:

- *ON_BOUNDED_SIDE* if *p* is inside the sphere. For an infinite cell this means that *p* lies strictly either in the half space limited by its finite facet and not containing any other point of the triangulation, or in the interior of the disk circumscribing the *finite* facet.

- *ON_BOUNDARY* if *p* on the boundary of the sphere. For an infinite cell this means that *p* lies on the circle circumscribing the *finite* facet.

- *ON_UNBOUNDED_SIDE* if *p* lies outside the sphere. For an infinite cell this means that *p* does not satisfy either of the two previous conditions.

Precondition: *dt.dimension() = 3*.

Bounded_side *dt.side_of_circle(Facet f, Point p)*

Returns a value indicating on which side of the circumscribed circle of *f* the point *p* lies. More precisely, it returns:

- in dimension 3:

– For a finite facet, *ON_BOUNDARY* if *p* lies on the circle, *ON_UNBOUNDED_SIDE* when it lies in the exterior of the disk, *ON_BOUNDED_SIDE* when it lies in its interior.

– For an infinite facet, it considers the plane defined by the finite facet of the same cell, and does the same as in dimension 2 in this plane.

- in dimension 2:

– For a finite facet, *ON_BOUNDARY* if *p* lies on the circle, *ON_UNBOUNDED_SIDE* when it lies in the exterior of the disk, *ON_BOUNDED_SIDE* when it lies in its interior.

– For an infinite facet, *ON_BOUNDARY* if the point lies on the finite edge of *f* (endpoints included), *ON_BOUNDED_SIDE* for a point in the open half plane defined by *f* and not containing any other point of the triangulation, *ON_UNBOUNDED_SIDE* elsewhere.

Precondition: *dt.dimension()* ≥ 2 and in dimension 3, *p* is coplanar with *f*.

Bounded_side *dt.side_of_circle(Cell_handle c, int i, Point p)*

Same as the previous method for facet *i* of cell *c*.

Vertex_handle *dt.nearest_vertex(Point p, Cell_handle c = Cell_handle())*

Returns any nearest vertex to the point *p*, or the default constructed handle if the triangulation is empty. The optional argument *c* is a hint specifying where to start the search.

Precondition: *c* is a cell of *dt*.

Vertex_handle *dt.nearest_vertex_in_cell(Point p, Cell_handle c)*

Returns the vertex of the cell *c* that is nearest to *p*.

A point *p* is said to be in conflict with a cell *c* in dimension 3 (resp. a facet *f* in dimension 2) iff *dt.side_of_sphere(c, p)* (resp. *dt.side_of_circle(f, p)*) returns *ON_BOUNDED_SIDE*. The set of cells (resp. facets in dimension 2) which are in conflict with *p* is connected, and it forms a hole.

```
template <class OutputIteratorBoundaryFacets, class OutputIteratorCells>
std::pair<OutputIteratorBoundaryFacets, OutputIteratorCells>
```

```
    dt.find_conflicts( Point p,
                      Cell_handle c,
                      OutputIteratorBoundaryFacets bfit,
```

OutputIteratorCells cit)

Computes the conflict hole induced by p . The starting cell (resp. facet) c must be in conflict. Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict.
- *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) (t, i) where the cell (resp. facet) t is in conflict, but $t \rightarrow neighbor(i)$ is not.

This function can be used in conjunction with *insert_in_hole()* in order to decide the insertion of a point after seeing which elements of the triangulation are affected. Returns the pair composed of the resulting output iterators.

Precondition: $dt.dimension() \geq 2$, and c is in conflict with p .

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>

Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>

dt.find_conflicts(Point p,
Cell_handle c,
OutputIteratorBoundaryFacets bfit,
OutputIteratorCells cit,
OutputIteratorInternalFacets ifit)

Same as the other *find_conflicts()* function, except that it also computes the internal facets, i.e. the facets common to two cells which are in conflict with p . Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict.
- *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) (t, i) where the cell (resp. facet) t is in conflict, but $t \rightarrow neighbor(i)$ is not.
- *ifit*: the facets (resp. edges) inside the hole, that is, delimiting two cells (resp. facets) in conflict.

Returns the *Triple* composed of the resulting output iterators.

Precondition: $dt.dimension() \geq 2$, and c is in conflict with p .

template <class OutputIterator>
OutputIterator

dt.vertices_in_conflict(Point p, Cell_handle c, OutputIterator res)

Similar to *find_conflicts()*, but reports the vertices which are on the boundary of the conflict hole of p , in the output iterator *res*. Returns the resulting output iterator.

Precondition: $dt.dimension() \geq 2$, and c is in conflict with p .

A face (cell, facet or edge) is said to be a Gabriel face iff its smallest circumscribing sphere do not enclose any vertex of the triangulation. Any Gabriel face belongs to the Delaunay triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of Delaunay faces.

bool dt.is_Gabriel(Cell_handle c, int i)
bool dt.is_Gabriel(Cell_handle c, int i, int j)
bool dt.is_Gabriel(Facet f)
bool dt.is_Gabriel(Edge e)

Voronoi diagram

CGAL offers several functionalities to display the Voronoi diagram of a set of points in 3D.

Note that the user should use a kernel with exact constructions in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

Point *dt.dual(Cell_handle c)*

Returns the circumcenter of the four vertices of *c*.
Precondition: *dt.dimension()* = 3 and *c* is not infinite.

Object *dt.dual(Facet f)*

Returns the dual of facet *f*, which is
in dimension 3: either a segment, if the two cells incident to *f* are finite, or a ray, if one of them is infinite;
in dimension 2: a point.
Precondition: *dt.dimension()* ≥ 2 and *f* is not infinite.

Object *dt.dual(Cell_handle c, int i)*

same as the previous method for facet *(c,i)*.

Line *dt.dual_support(Cell_handle c, int i)*

returns the line supporting the dual of the facet.
Precondition: *dt.dimension()* ≥ 2 and *f* is not infinite.

template <class Stream>
Stream& *dt.draw_dual(Stream & os)*

Sends the set of duals to all the facets of *dt* into *os*.

— advanced —

Checking

bool *dt.is_valid(bool verbose = false)*

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section 27.1). Also checks that all the circumscribing spheres (resp. circles in dimension 2) of cells (resp. facets in dimension 2) are empty.
When *verbose* is set to true, messages describing the first invalidity encountered are printed.

bool *dt.is_valid(Cell_handle c, bool verbose = false)*

Checks the combinatorial and geometric validity of the cell (see Section 27.1). Also checks that the circumscribing sphere (resp. circle in dimension 2) of cells (resp. facet in dimension 2) is empty. When *verbose* is set to true, messages are printed to give a precise indication of the kind of invalidity encountered.

These methods are mainly a debugging help for the users of advanced features.

CGAL::Triangulation_hierarchy_3.

CGAL::Triangulation_hierarchy_3<Tr>

Definition

The class *Triangulation_hierarchy_3* implements a triangulation augmented with a data structure which allows fast point location queries. As proved in [Dev02], this structure has an optimal behavior when it is built for Delaunay triangulations. It can however be used for other triangulations.

```
#include <CGAL/Triangulation_hierarchy_3.h>
```

Parameters

It is templated by a parameter which must be instantiated by one of the CGAL triangulation classes. *In the current implementation, only Delaunay_triangulation_3 is supported for Tr.*

Tr::Vertex has to be a model of the concept *TriangulationHierarchyVertexBase_3*.

Tr::Geom_traits has to be a model of the concept *DelaunayTriangulationTraits_3*.

Inherits From

Tr

Triangulation_hierarchy_3<Tr> offers exactly the same functionalities as *Tr*. Most of them (point location, insertion, removal...) are overloaded to improve their efficiency by using the hierarchic structure.

Note that, since the algorithms that are provided are randomized, the running time of constructing a triangulation with a hierarchy may be improved when shuffling the data points.

However, the I/O operations are not overloaded. So, writing a hierarchy into a file will lose the hierarchic structure and reading it from the file will result in an ordinary triangulation whose efficiency will be the same as *Tr*.

Implementation

The data structure is a hierarchy of triangulations. The triangulation at the lowest level is the original triangulation where operations and point location are to be performed. Then at each succeeding level, the data structure stores a triangulation of a small random sample of the vertices of the triangulation at the preceding level. Point location is done through a top-down nearest neighbor query. The nearest neighbor query is first performed naively in the top level triangulation. Then, at each following level, the nearest neighbor at that level is found through a linear walk performed from the nearest neighbor found at the preceding level. Because the number of vertices in each triangulation is only a small fraction of the number of vertices of the preceding triangulation the data structure remains small and achieves fast point location queries on real data.

See Also

CGAL::Triangulation_hierarchy_vertex_base_3

CGAL::Delaunay_triangulation_3

CGAL::Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>

Definition

Let $S^{(w)}$ be a set of weighted points in \mathbb{R}^3 . Let $p^{(w)} = (p, w_p)$, $p \in \mathbb{R}^3$, $w_p \in \mathbb{R}$ and $z^{(w)} = (z, w_z)$, $z \in \mathbb{R}^3$, $w_z \in \mathbb{R}$ be two weighted points. A weighted point $p^{(w)} = (p, w_p)$ can also be seen as a sphere of center p and radius $\sqrt{w_p}$. The *power product* (or *power distance*) between $p^{(w)}$ and $z^{(w)}$ is defined as

$$\Pi(p^{(w)}, z^{(w)}) = \|p - z\|^2 - w_p - w_z$$

where $\|p - z\|$ is the Euclidean distance between p and z . $p^{(w)}$ and $z^{(w)}$ are said to be *orthogonal* if $\Pi(p^{(w)} - z^{(w)}) = 0$ (see Figure 27.2).

Four weighted points have a unique common orthogonal weighted point called the *power sphere*. A sphere $z^{(w)}$ is said to be *regular* if $\forall p^{(w)} \in S^{(w)}, \Pi(p^{(w)} - z^{(w)}) \geq 0$.

A triangulation of $S^{(w)}$ is *regular* if the power spheres of all simplices are regular.

```
#include <CGAL/Regular_triangulation_3.h>
```

Parameters

The first template argument must be a model of the *RegularTriangulationTraits_3* concept.

The second template argument must be a model of the *TriangulationDataStructure_3* concept. It has the default value *Triangulation_data_structure_3<Triangulation_vertex_base_3<RegularTriangulationTraits_3>, Regular_triangulation_cell_base_3<RegularTriangulationTraits_3>>*.

Inherits From

Triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>

Types

```
typedef RegularTriangulationTraits_3::Bare_point      Bare_point;      The type for points  $p$  of
                                                                    weighted points  $p^{(w)} = (p, w_p)$ 
typedef RegularTriangulationTraits_3::Weighted_point_3 Weighted_point;
```

Creation

```
Regular_triangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3>      rt(
RegularTriangulationTraits_3 traits = RegularTriangulationTraits_3())
```

Creates an empty regular triangulation, possibly specifying a traits class *traits*.

RegularTriangulation_3<*RegularTriangulationTraits_3*,*TriangulationDataStructure_3*> *rt*(*RegularTriangulation_3* *rt1*)

Copy constructor.

```
template < class InputIterator >
RegularTriangulation_3<RegularTriangulationTraits_3, TriangulationDataStructure_3> rt( InputIterator first,
                                                                                      InputIterator last,
                                                                                      RegularTriangulationTraits_
3 traits = RegularTriangulationTraits_3())
```

Equivalent to constructing an empty triangulation with the optional traits class argument and calling *insert(first,last)*.

Operations

Insertion

The following methods, which already exist in triangulations, are overloaded to ensure the property that all power spheres are regular.

Vertex_handle *rt.insert(Weighted_point p, Cell_handle start = Cell_handle())*

Inserts weighted point *p* in the triangulation. The optional argument *start* is used as a starting place for the search.
 If this insertion creates a vertex, this vertex is returned.
 If *p* coincides with an existing vertex and has a greater weight, then the existing weighted point becomes hidden (see *RegularTriangulationCellBase_3*) and *p* replaces it as vertex of the triangulation.
 If *p* coincides with an already existing vertex (both point and weights being equal), then this vertex is returned and the triangulation remains unchanged.
 Otherwise if *p* does not appear as a vertex of the triangulation, then it is stored as a hidden point and this method returns the default constructed handle.

Vertex_handle *rt.insert(Weighted_point p, Locate_type lt, Cell_handle loc, int li, int lj)*

Inserts weighted point *p* in the triangulation and returns the corresponding vertex. Similar to the above *insert()* function, but takes as additional parameter the return values of a previous location query. See description of *Triangulation_3::locate()*.

The following method allows one to insert several points.

```
template < class InputIterator >
int rt.insert( InputIterator first, InputIterator last)
```

Inserts the weighted points in the range *[first, last)*. Note that this function is not guaranteed to insert the points following the order of *InputIterator*. It returns the difference of the number of vertices between after and before the insertions (it may be negative due to hidden points).
Precondition: The *value_type* of *first* and *last* is *Point*.

Removal

```
void      rt.remove( Vertex_handle v)
```

Removes the vertex v from the triangulation.

Queries

Let us remark that

$$\Pi(p^{(w)} - z^{(w)}) > 0$$

is equivalent to

p lies outside the sphere with center z and radius $\sqrt{w_p^2 + w_z^2}$.

This remark helps provide an intuition about the following predicates.

Figure 27.9: side_of_power_circle.

```
Bounded_side  rt.side_of_power_sphere( Cell_handle c, Weighted_point p)
```

Returns the position of the weighted point p with respect to the power sphere of c . More precisely, it returns:

- *ON_BOUNDED_SIDE* if $\Pi(p^{(w)} - z(c)^{(w)}) < 0$ where $z(c)^{(w)}$ is the power sphere of c . For an infinite cell this means either that p lies strictly in the half space limited by its finite facet and not containing any other point of the triangulation, or that the angle between p and the power circle of the *finite* facet of c is greater than $\pi/2$.
- *ON_BOUNDARY* if p is orthogonal to the power sphere of c i.e. $\Pi(p^{(w)} - z(c)^{(w)}) = 0$. For an infinite cell this means that p is orthogonal to the power circle of its *finite* facet.
- *ON_UNBOUNDED_SIDE* if $\Pi(p^{(w)} - z(c)^{(w)}) > 0$ i.e. the angle between the weighted point p and the power sphere of c is less than $\pi/2$ or if these two spheres do not intersect. For an infinite cell this means that p does not satisfy either of the two previous conditions.

Precondition: $rt.dimension() = 3$.

Bounded_side *rt.side_of_power_circle(Facet f, Weighted_point p)*

Returns the position of the point p with respect to the power circle of f .
 More precisely, it returns:
 — in dimension 3:
 – For a finite facet,
ON_BOUNDARY if p is orthogonal to the power circle in the plane of the facet,
ON_UNBOUNDED_SIDE when their angle is less than $\pi/2$,
ON_BOUNDED_SIDE when it is greater than $\pi/2$ (see Figure 27.9).
 – For an infinite facet, it considers the plane defined by the finite facet of the cell $f.first$, and does the same as in dimension 2 in this plane.
 — in dimension 2:
 – For a finite facet,
ON_BOUNDARY if p is orthogonal to the circle,
ON_UNBOUNDED_SIDE when the angle between p and the power circle of f is less than $\pi/2$, *ON_BOUNDED_SIDE* when it is greater than $\pi/2$.
 – For an infinite facet,
ON_BOUNDED_SIDE for a point in the open half plane defined by f and not containing any other point of the triangulation,
ON_UNBOUNDED_SIDE in the other open half plane.
 If the point p is collinear with the finite edge e of f , it returns:
ON_BOUNDED_SIDE if $\Pi(p^{(w)} - z(e)^{(w)}) < 0$, where $z(e)^{(w)}$ is the power segment of e in the line supporting e ,
ON_BOUNDARY if $\Pi(p^{(w)} - z(e)^{(w)}) = 0$,
ON_UNBOUNDED_SIDE if $\Pi(p^{(w)} - z(e)^{(w)}) > 0$.
Precondition: rt.dimension() \geq 2.

Bounded_side *rt.side_of_power_circle(Cell_handle c, int i, Weighted_point p)*

Same as the previous method for facet i of cell c .

Bounded_side *rt.side_of_power_segment(Cell_handle c, Weighted_point p)*

In dimension 1, returns
ON_BOUNDED_SIDE if $\Pi(p^{(w)} - z(c)^{(w)}) < 0$, where $z(c)^{(w)}$ is the power segment of the edge represented by c ,
ON_BOUNDARY if $\Pi(p^{(w)} - z(c)^{(w)}) = 0$,
ON_UNBOUNDED_SIDE if $\Pi(p^{(w)} - z(c)^{(w)}) > 0$.
Precondition: rt.dimension() = 1.

Vertex_handle

rt.nearest_power_vertex(Point p, Cell_handle c = Cell_handle())

Returns the vertex of the triangulation which is nearest to p with respect to the power distance. This means that the power of the query point p with respect to the weighted point in the returned vertex is smaller than the power of p with respect to the weighted point in any other vertex. Ties are broken arbitrarily. The default constructed handle is returned if the triangulation is empty. The optional argument c is a hint specifying where to start the search.

Precondition: c is a cell of rt .

Vertex_handle

rt.nearest_power_vertex_in_cell(Point p, Cell_handle c)

Returns the vertex of the cell c that is nearest to p with respect to the power distance.

A weighted point p is said to be in conflict with a cell c in dimension 3 (resp. with a facet f in dimension 2) if it has a negative power distance to the power sphere of c (resp. to the power circle of f). The set of cells (resp. facets in dimension 2) which are in conflict with p is connected.

template <class OutputIteratorBoundaryFacets, class OutputIteratorCells, class OutputIteratorInternalFacets>

Triple<OutputIteratorBoundaryFacets, OutputIteratorCells, OutputIteratorInternalFacets>

*rt.find_conflicts(const Weighted_point p,
Cell_handle c,
OutputIteratorBoundaryFacets bfit,
OutputIteratorCells cit,
OutputIteratorInternalFacets ifit)*

Compute the conflicts with p . The starting cell (resp. facet) c must be in conflict with p . Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict with p .
- *bfit*: the facets (resp. edges) on the boundary of the conflict zone, that is, the facets (resp. edges) (t, i) where the cell (resp. facet) t is in conflict, but $t \rightarrow neighbor(i)$ is not.
- *ifit*: the facets (resp. edges) inside the conflict zone, that facets incident to two cells (resp. facets) in conflict.

Returns the *Triple* composed of the resulting output iterators.

Precondition: $rt.dimension() \geq 2$, and c is in conflict with p .

*template <class OutputIterator>
OutputIterator*

rt.vertices_in_conflict(Point p, Cell_handle c, OutputIterator res)

Similar to *find_conflicts()*, but reports the vertices which are on the boundary of the conflict hole of p , in the output iterator *res*. Returns the resulting output iterator.

Precondition: $rt.dimension() \geq 2$, and c is a cell containing p .

In the weighted setting, a face (cell, facet, edge or vertex) is said to be a Gabriel face iff the smallest sphere orthogonal to the weighted points associated to its vertices, has a positive power product with the weighted point of any other vertex of the triangulation. Any weighted Gabriel face belongs to the regular triangulation, but the reciprocal is not true. The following member functions test the Gabriel property of the faces of the regular triangulation.

```
bool          rt.is_Gabriel( Cell_handle c, int i)
bool          rt.is_Gabriel( Cell_handle c, int i, int j)
bool          rt.is_Gabriel( Facet f)
bool          rt.is_Gabriel( Edge e)
bool          rt.is_Gabriel( Vertex_handle v)
```

Power diagram

CGAL offers several functionalities to display the Power diagram of a set of points in 3D.

Note that the user should use a kernel with exact constructions in order to guarantee the computation of the Voronoi diagram (as opposed to computing the triangulation only, which requires only exact predicates).

```
Point          rt.dual( Cell_handle c)
```

Returns the weighted circumcenter of the four vertices of c .

Precondition: $rt.dimension() = 3$ and c is not infinite.

```
Object          rt.dual( Facet f)
```

Returns the dual of facet f , which is
in dimension 3: either a segment, if the two cells incident to f are finite,
or a ray, if one of them is infinite;
in dimension 2: a point.

Precondition: $rt.dimension() \geq 2$ and f is not infinite.

```
Object          rt.dual( Cell_handle c, int i)
```

same as the previous method for facet (c,i) .

```
template <class Stream>
```

```
Stream&          rt.draw_dual( Stream & os)
```

Sends the set of duals to all the facets of rt into os .

— advanced —

Checking

```
bool          rt.is_valid( bool verbose = false)
```

Checks the combinatorial validity of the triangulation and the validity of its geometric embedding (see Section 27.1). Also checks that all the power spheres (resp. power circles in dimension 2, power segments in dimension 1) of cells (resp. facets in dimension 2, edges in dimension 1) are regular. When *verbose* is set to true, messages describing the first invalidity encountered are printed.

This method is mainly a debugging help for the users of advanced features.

_____ *advanced* _____

TriangulationTraits_3

Definition

The concept `TriangulationTraits_3` is the first template parameter of the class `Triangulation_3`. It defines the geometric objects (points, segments, triangles and tetrahedra) forming the triangulation together with a few geometric predicates and constructions on these objects : lexicographical comparison, orientation in case of coplanar points and orientation in space.

Types

`TriangulationTraits_3::Point_3` The point type. It must be *DefaultConstructible*, *CopyConstructible* and *Assignable*.

`TriangulationTraits_3::Segment_3` The segment type.

`TriangulationTraits_3::Tetrahedron_3` The tetrahedron type.

`TriangulationTraits_3::Triangle_3` The triangle type.

`TriangulationTraits_3::Construct_segment_3`

A constructor object that must provide the function operator
Segment_3 operator()(Point_3 p, Point_3 q),
which constructs a segment from two points.

`TriangulationTraits_3::Construct_triangle_3`

A constructor object that must provide the function operator
Triangle_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs a triangle from three points.

`TriangulationTraits_3::Construct_tetrahedron_3`

A constructor object that must provide the function operator
Tetrahedron_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs a tetrahedron from four points.

`TriangulationTraits_3::Compare_xyz_3`

A predicate object that must provide the function operator
Comparison_result operator()(Point p, Point q),
which returns *EQUAL* if the two points are equal. Otherwise it must return a consistent order for any two points chosen in a same line.

`TriangulationTraits_3::Coplanar_orientation_3`

A predicate object that must provide the function operator
Orientation operator()(Point p, Point q, Point r),
which returns *COLLINEAR* if the points are collinear. Otherwise it must return a consistent orientation for any three points chosen in a same plane.

TriangulationTraits_3:: Orientation_3

A predicate object that must provide the function operator
Orientation operator()(Point p, Point q, Point r, Point s),
which returns POSITIVE, if *s* lies on the positive side of the oriented plane *h* defined
by *p*, *q*, and *r*, returns NEGATIVE if *s* lies on the negative side of *h*, and returns
COPLANAR if *s* lies on *h*.

Creation

<i>TriangulationTraits_3 traits;</i>	Default constructor.
<i>TriangulationTraits_3 traits(Triangulation_traits_3 tr);</i>	Copy constructor.

Operations

The following functions give access to the predicate and construction objects:

<i>Construct_tetrahedron_3</i>	<i>traits.construct_tetrahedron_3_object()</i>
<i>Construct_triangle_3</i>	<i>traits.construct_triangle_3_object()</i>
<i>Construct_segment_3</i>	<i>traits.construct_segment_3_object()</i>
<i>Compare_xyz_3</i>	<i>traits.compare_xyz_3_object()</i>
<i>Coplanar_orientation_3</i>	<i>traits.coplanar_orientation_3_object()</i>
<i>Orientation_3</i>	<i>traits.orientation_3_object()</i>

Has Models

CGAL::Exact_predicates_inexact_constructions_kernel (recommended)
CGAL::Exact_predicates_exact_constructions_kernel
CGAL::Filtered_kernel
CGAL::Cartesian
CGAL::Simple_cartesian
CGAL::Homogeneous
CGAL::Simple_homogeneous

DelaunayTriangulationTraits_3

Definition

The concept `DelaunayTriangulationTraits_3` is the first template parameter of the class `Delaunay_triangulation_3`. It defines the geometric objects (points, segments...) forming the triangulation together with a few geometric predicates and constructions on these objects.

Refines

TriangulationTraits_3

In addition to the requirements described for the traits class of *Triangulation_3*, the geometric traits class of a Delaunay triangulation must fulfill the following requirements:

Types

<code>DelaunayTriangulationTraits_3:: Line_3</code>	The line type.
<code>DelaunayTriangulationTraits_3:: Object_3</code>	The object type.
<code>DelaunayTriangulationTraits_3:: Ray_3</code>	The ray type.

`DelaunayTriangulationTraits_3:: Coplanar_side_of_bounded_circle_3`

A predicate object that must provide the function operator `Bounded_side operator()(Point p, Point q, Point r, Point s)`, which determines the bounded side of the circle defined by p , q , and r on which s lies.

Precondition: p , q , r , and s are coplanar and p , q , and r are not collinear.

`DelaunayTriangulationTraits_3:: Side_of_oriented_sphere_3`

A predicate object that must provide the function operator `Oriented_side operator()(Point p, Point q, Point r, Point s, Point t)`, which determines on which side of the oriented sphere circumscribing p , q , r , s the point t lies.

The following additional predicate is required only when the *Triangulation_hierarchy_3* is used on top of *Delaunay_triangulation_3*:

`DelaunayTriangulationTraits_3:: Compare_distance_3`

A predicate object that must provide the function operator `Comparison_result operator()(Point p, Point q, Point r)`, which compares the distance between p and q to the distance between p and r .

In addition, only when the dual operations are used, the traits class must provide the following constructor objects:

DelaunayTriangulationTraits_3:: Construct_circumcenter_3

A constructor object that must provide the function operator
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r, Point_3 s),
which constructs the circumcenter of four points.

Precondition: *p, q, r* and *s* must be non coplanar.

It must also provide the function operator
Point_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs the circumcenter of three points.

Precondition: *p, q* and *r* must be non collinear.

DelaunayTriangulationTraits_3:: Construct_object_3

A constructor object that must provide the function operators

Object_3 operator()(Point_3 p),

Object_3 operator()(Segment_3 s) and

Object_3 operator()(Ray_3 r)

that construct an object respectively from a point, a segment and a ray.

DelaunayTriangulationTraits_3:: Construct_equidistant_line_3

A constructor object that must provide the function operator

Line_3 operator()(Point_3 p1, Point_3 p2, Point_3 p3),

which constructs the line which is at the same distance from the three points.

Precondition: *p1, p2* and *p3* must be non collinear.

DelaunayTriangulationTraits_3:: Construct_ray_3

A constructor object that must provide the function operator

Ray_3 operator()(Point_3 p, Line_3 l),

which constructs the ray starting at *p* with direction given by *l*.

Operations

The following functions give access to the predicate and construction objects:

Coplanar_side_of_bounded_circle_3 *traits.coplanar_side_of_bounded_circle_3_object()*

Side_of_oriented_sphere_3 *traits.side_of_oriented_sphere_3_object()*

When using the triangulation hierarchy, the traits must provide:

Compare_distance_3 *traits.compare_distance_3_object()*

The following functions must be provided only if the methods of *DelaunayTriangulation_3* returning elements of the Voronoi diagram are instantiated:

Construct_circumcenter_3 *traits.construct_circumcenter_3_object()*

Construct_object_3 *traits.construct_object_3_object()*

Construct_perpendicular_line_3 *traits.construct_perpendicular_line_object()*

Construct_plane_3 *traits.construct_plane_3_object()*

Construct_ray_3 *traits.construct_ray_3_object()*

RegularTriangulationTraits_3

Definition

The concept `RegularTriangulationTraits_3` is the first template parameter of the class *Regular_triangulation_3*. It defines the geometric objects (points, segments...) forming the triangulation together with a few geometric predicates and constructions on these objects.

Refines

TriangulationTraits_3

In addition to the requirements described for the traits class of *Triangulation_3*, the geometric traits class of *Regular_triangulation_3* must fulfill the following requirements.

Types

<i>RegularTriangulationTraits_3:: Line_3</i>	The line type.
<i>RegularTriangulationTraits_3:: Object_3</i>	The object type.
<i>RegularTriangulationTraits_3:: Plane_3</i>	The plane type.
<i>RegularTriangulationTraits_3:: Ray_3</i>	The ray type.

We use here the same notation as in Section 27.3. To simplify notation, p will often denote in the sequel either the point $p \in \mathbb{R}^3$ or the weighted point $p^{(w)} = (p, w_p)$.

<i>RegularTriangulationTraits_3:: Weighted_point_3</i>	The weighted point type.
--	--------------------------

RegularTriangulationTraits_3:: Power_test_3

A predicate object which must provide the following function operators:

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*, *Weighted_point_3* *s*, *Weighted_point_3* *t*),

which performs the following:

Let $z(p, q, r, s)^{(w)}$ be the power sphere of the weighted points (p, q, r, s) . Returns

ON_ORIENTED_BOUNDARY if *t* is orthogonal to $z(p, q, r, s)^{(w)}$,

ON_NEGATIVE_SIDE if *t* lies outside the oriented sphere of center $z(p, q, r, s)$ and radius $\sqrt{w_{z(p,q,r,s)}^2 + w_t^2}$ (which is equivalent to $\Pi(t^{(w)}, z(p, q, r, s)^{(w)}) > 0$),

ON_POSITIVE_SIDE if *t* lies inside this oriented sphere.

Precondition: *p*, *q*, *r*, *s* are not coplanar. Note that with this definition, if all the points have a weight equal to 0, then $power_test_3(p, q, r, s, t) = side_of_oriented_sphere(p, q, r, s, t)$.

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*, *Weighted_point_3* *t*),

which has an definition analogous to the previous method, for coplanar points, with the power circle $z(p, q, r)^{(w)}$.

Precondition: *p*, *q*, *r* are not collinear and *p*, *q*, *r*, *t* are coplanar. If all the points have a weight equal to 0, then $power_test_3(p, q, r, s, t) = side_of_oriented_circle(p, q, r, s, t)$.

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *t*),

which is the same for collinear points, where $z(p, q)^{(w)}$ is the power segment of *p* and *q*.

Precondition: *p* and *q* have different Bare_points, and *p*, *q*, *t* are collinear. If all points have a weight equal to 0, then $power_test_3(p, q, t)$ gives the same answer as the kernel predicate $s(p, q).has_on(t)$ would give, where $s(p, q)$ denotes the segment with endpoints *p* and *q*.

Oriented_side operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*),

which is the same for equal points, that is when *p* and *q* have equal coordinates, then it returns the comparison of the weights (*ON_POSITIVE_SIDE* when *q* is heavier than *p*).

Precondition: *p* and *q* have equal Bare_points.

The following predicate is required if a call to *nearest_power_vertex* or *nearest_power_vertex_in_cell* is issued:

RegularTriangulationTraits_3:: Compare_power_distance_3

A predicate object that must provide the function operator

Comparison_result operator()(*Point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*),

which compares the power distance between *p* and *q* to the power distance between *p* and *r*.

In addition, only when the dual operations are used, the traits class must provide the following constructor objects:

RegularTriangulationTraits_3:: Construct_weighted_circumcenter_3

A constructor type. The operator() constructs the bare point which is the center of the smallest orthogonal sphere to the input weighted points.

Bare_point operator()(*Weighted_point_3* *p*, *Weighted_point_3* *q*, *Weighted_point_3* *r*, *Weighted_point_3* *s*);

RegularTriangulationTraits_3:: Construct_object_3

A constructor object that must provide the function operators
Object_3 operator()(Point_3 p),
Object_3 operator()(Segment_3 s) and
Object_3 operator()(Ray_3 r)
that construct an object respectively from a point, a segment and a ray.

RegularTriangulationTraits_3:: Construct_perpendicular_line_3

A constructor object that must provide the function operator
Line_3 operator()(Plane_3 pl, Point_3 p),
which constructs the line perpendicular to *pl* passing through *p*.

RegularTriangulationTraits_3:: Construct_plane_3

A constructor object that must provide the function operator
Plane_3 operator()(Point_3 p, Point_3 q, Point_3 r),
which constructs the plane passing through *p*, *q* and *r*.
Precondition: *p*, *q* and *r* are non collinear.

RegularTriangulationTraits_3:: Construct_ray_3

A constructor object that must provide the function operator
Ray_3 operator()(Point_3 p, Line_3 l),
which constructs the ray starting at *p* with direction given by *l*.

Operations

The following function gives access to the predicate object:

Power_test_3 *traits.power_test_3_object()*

The following functions must be provided only if the member functions of *Regular_triangulation_3* returning elements of the dual diagram are called:

Construct_weighted_circumcenter_3

traits.construct_weighted_circumcenter_3_object()

Construct_object_3 *traits.construct_object_3_object()*

Construct_perpendicular_line_3

traits.construct_perpendicular_line_object()

Construct_plane_3 *traits.construct_plane_3_object()*

Construct_ray_3 *traits.construct_ray_3_object()*

Has Models

CGAL::Regular_triangulation_euclidean_traits_3

CGAL::Regular_triangulation_filtered_traits_3.

CGAL::Regular_triangulation_euclidean_traits_3<K,Weight>

Definition

The class *Regular_triangulation_euclidean_traits_3*<*K*,*Weight*> is designed as a default traits class for the class *Regular_triangulation_3*<*RegularTriangulationTraits_3*,*TriangulationDataStructure_3*>. It provides *Weighted_point_3*, a class for weighted points, which derives from the three dimensional point class *K::Point_3*.

The first argument *K* must be a model of the *Kernel* concept.

The second argument *Weight* of the class *Regular_triangulation_euclidean_traits_3*<*K*,*Weight*> is in fact optional: if it is not provided, *K::RT* will be used.

The class is a model of the concept *RegularTriangulationTraits_3* but it also contains predicates and constructors on weighted points that are not required in the concept *RegularTriangulationTraits_3*.

Note that this template class is specialized for *CGAL::Exact_predicates_inexact_constructions_kernel*, so that it is as if *Regular_triangulation_filtered_traits_3* was used, i.e. you get filtered predicates automatically.

```
#include <CGAL/Regular_triangulation_euclidean_traits_3.h>
```

Is Model for the Concepts

RegularTriangulationTraits_3

Inherits From

K

Types

<code>typedef K::Point_3</code>	<code>Bare_point;</code>	The type for point p of a weighted point $p^{(w)} = (p, w_p)$.
<code>typedef Weighted_point <Bare_point, Weight></code>	<code>Weighted_point_3;</code>	The type for weighted points.

Types for predicate functors

Regular_triangulation_euclidean_traits_3<*K*,*Weight*>:: *Power_test_3*

A predicate type for power test. Belongs to the *RegularTriangulationTraits_3* concept.

Regular_triangulation_euclidean_traits_3<*K*,*Weight*>:: *Compare_power_distance_3*

A predicate type to compare power distance. Belongs to the *RegularTriangulationTraits_3* concept.

Regular_triangulation_euclidean_traits_3<K,Weight>:: In_smallest_orthogonal_sphere_3

A predicate type. The operator() takes weighted points as arguments and returns the sign of the power distance of the last one with respect to the smallest sphere orthogonal to the others.

Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t);

Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s);

Sign operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r);

Sign operator()(Weighted_point_3 p, Weighted_point_3 q);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Side_of_bounded_orthogonal_sphere_3

A predicate type. The operator() is similar to the operator() of *In_smallest_orthogonal_sphere_3* except that the returned type is not a *Sign* but belongs to the enum *Bounded_side* (A *NEGATIVE*, *ZERO* and *POSITIVE*) corresponding respectively to *ON_BOUNDED_SIDE*, *ON_BOUNDARY* and *ON_UNBOUNDED_SIDE*)).

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s, Weighted_point_3 t);

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s);

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Does_simplex_intersect_dual_support_3

A predicate type. The operator() takes weighted points as arguments, considers the subspace of points with equal power distance with respect to its arguments and the intersection of this subspace with the affine hull of the bare points associated to the arguments. The operator() returns *ON_BOUNDED_SIDE*, *ON_BOUNDARY* or *ON_UNBOUNDED_SIDE* according to the position of this intersection with respect to the simplex formed by the bare points. This predicate is useful for flow computations.

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s);

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r);

Bounded_side operator()(Weighted_point_3 p, Weighted_point_3 q);

Types for constructor functors

Regular_triangulation_euclidean_traits_3<K,Weight>:: Construct_weighted_circumcenter_3

A constructor type. The operator() constructs the bare point which is the center of the smallest orthogonal sphere to the input weighted points.

Bare_point operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r, Weighted_point_3 s);

Bare_point operator()(Weighted_point_3 p, Weighted_point_3 q, Weighted_point_3 r);

Bare_point operator()(Weighted_point_3 p, Weighted_point_3 q);

Regular_triangulation_euclidean_traits_3<K,Weight>:: Compute_power_product_3

A functor type. The operator() computes the power distance between its arguments.

FT operator()(Weighted_point_3 p, Weighted_point_3 q);

Regular_triangulation_euclidean_traits_3<K,Weight>:: *Compute_squared_radius_smallest_orthogonal_sphere_3*

A functor type. The operator() computes the squared radius of the smallest sphere orthogonal to the arguments.

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*, *Weighted_point_3 s*);

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*);

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*);

Regular_triangulation_euclidean_traits_3<K,Weight>:: *Compute_critical_squared_radius_3*

A functor type. The operator() takes weighted points as arguments and computes the squared radius of the sphere centered in the last point and orthogonal to the other weighted points. The last argument is a weighted point but its weight does not matter. This construction is ad hoc for pumping slivers. For robustness issue, a predicate to compare critical squared radii for a given last point should be needed.

FT operator() (*Weighted_point_3 p*, *Weighted_point_3 q*, *Weighted_point_3 r*, *Weighted_point_3 s*, *Weighted_point_3 t*);

Operations

The following functions give access to the predicate and constructor functors.

<i>Power_test_3</i>	<i>traits.power_test_3_object()</i>
<i>Compare_power_distance_3</i>	<i>traits.compare_power_distance_3_object()</i>
<i>In_smallest_orthogonal_sphere_3</i>	<i>traits.in_smallest_orthogonal_sphere_3_object()</i>
<i>Side_of_bounded_orthogonal_sphere_3</i>	<i>traits.side_of_bounded_orthogonal_sphere_3_object()</i>
<i>Does_simplex_intersect_dual_support_3</i>	<i>traits.does_simplex_intersect_dual_support_3_object()</i>
<i>Construct_weighted_circumcenter_3</i>	<i>traits.construct_weighted_circumcenter_3_object()</i>
<i>Compute_power_product_3</i>	<i>traits.compute_power_product_3_object()</i>
<i>Compute_squared_radius_smallest_orthogonal_sphere_3</i>	
	<i>traits.compute_squared_radius_smallest_orthogonal_sphere_3_object()</i>
<i>Compute_critical_squared_radius_3</i>	<i>traits.compute_critical_squared_radius_3_object()</i>

CGAL::Regular_triangulation_euclidean_traits_3.

TriangulationCellBase_3

Definition

The cell base required by the basic triangulation does not need to store any geometric information, so only the requirements of the triangulation data structure apply.

However, for the Delaunay triangulation, the ability to store the circumcenter is provided (for optimization reasons), hence an additional requirement only in this case, and only when the dual functions are called.

Refines

TriangulationDSCellBase_3

DelaunayTriangulationTraits_3::Point_3

```
3() c.circumcenter( DelaunayTriangulationTraits_3 gt = DelaunayTriangulationTraits_3())
```

Returns the circumcenter.

TriangulationVertexBase_3

TriangulationVertexBase_3

Definition

The vertex base used by the geometric triangulation must store a point. So we list here the additional requirements compared to a vertex base usable for the triangulation data structure.

Refines

TriangulationDSVertexBase_3

Types

TriangulationVertexBase_3::Point

Must be the same as the point type *TriangulationTraits_3::Point_3* defined by the geometric traits class of the triangulation.

Creation

TriangulationVertexBase_3 v(Point p);

Constructs a vertex whose geometric embedding is point *p*.

TriangulationVertexBase_3 v(Point p, Cell_handle c);

Constructs a vertex embedding the point *p* and pointing to cell *c*.

Access Functions

Point v.point()

Returns the point.

Setting

void v.set_point(Point p)

Sets the point.

I/O

istream& istream& is >> & v

Inputs the non-combinatorial information given by the vertex: the point and other possible information.

ostream& ostream& os << v

Outputs the non-combinatorial information given by the vertex: the point and other possible information.

CGAL::Triangulation_simplex_3<Triangulation_3>

Definition

The class *Triangulation_simplex_3<Triangulation_3>* stores a simplex of any dimension defined by the *Triangulation_3* class. It also defines the operator less such that simplices can be stored in a *map* or a *set* of simplices. The simplex is invalidated by any change in the triangulation.

```
#include <CGAL/Triangulation_simplex_3.h>
```

Parameters

It is parameterized by the triangulation it derives the simplices from.

Types

```
typedef Triangulation_simplex_3<Triangulation_3>   Simplex;           The simplex class itself.
```

```
typedef Triangulation_3::Vertex_handle             Vertex_handle;
typedef Triangulation_3::Edge                     Edge;
typedef Triangulation_3::Facet                    Facet;
typedef Triangulation_3::Cell_handle              Cell_handle;
```

```
typedef Triangulation_3::Cell_circulator           Cell_circulator;
typedef Triangulation_3::Facet_circulator          Facet_circulator;
```

```
typedef Triangulation_3::Edge_iterator             Edge_iterator;
typedef Triangulation_3::Facet_iterator            Facet_iterator;
```

```
typedef Triangulation_3::Finite_vertices_iterator Finite_vertices_iterator;
typedef Triangulation_3::Finite_edges_iterator    Finite_edges_iterator;
typedef Triangulation_3::Finite_facets_iterator   Finite_facets_iterator;
typedef Triangulation_3::Finite_cells_iterator    Finite_cells_iterator;
```

Creation

```
Triangulation_simplex_3<Triangulation_3> simplex;    Initializes the simplex to an invalid simplex.
```

```
Triangulation_simplex_3<Triangulation_3> simplex( Vertex_handle vh);
Triangulation_simplex_3<Triangulation_3> simplex( Edge e);
Triangulation_simplex_3<Triangulation_3> simplex( Facet f);
Triangulation_simplex_3<Triangulation_3> simplex( Cell_handle ch);
```

```
Triangulation_simplex_3<Triangulation_3> simplex( Cell_circulator ccir);
Triangulation_simplex_3<Triangulation_3> simplex( Facet_circulator fcir);
```

```

Triangulation_simplex_3<Triangulation_3> simplex( Edge_iterator eit);
Triangulation_simplex_3<Triangulation_3> simplex( Facet_iterator fit);

```

Operations

<i>int</i>	<i>simplex.dimension()</i>	returns the dimension of the simplex.
<i>Vertex_handle</i>	<i>Vertex_handle (simplex)</i>	Returns the <i>Vertex_handle</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 0</i>
<i>Edge</i>	<i>Edge (simplex)</i>	Returns the <i>Edge</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 1</i>
<i>Facet</i>	<i>Facet (simplex)</i>	Returns the <i>Facet</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 2</i>
<i>Cell_handle</i>	<i>Cell_handle (simplex)</i>	Returns the <i>Cell_handle</i> stored in the simplex. <i>Precondition:</i> <i>dimension() == 3</i>
<i>Cell_handle</i>	<i>simplex.incident_cell()</i>	Returns a cell incident to the simplex.
<i>bool</i>	<i>simplex == s1</i>	Test whether two simplices are equal.
<i>bool</i>	<i>simplex < s1</i>	Defines a ordering on the simplices. This ordering depends on the memory layout and is independent of the geometry. Therefore, the ordering is not intrinsic

TriangulationHierarchyVertexBase_3

Definition

The vertex base used by *Triangulation_hierarchy_3* must provide access to two vertex handles for linking between the levels of the hierarchy.

Refines

TriangulationVertexBase_3

Access Functions

<i>Vertex_handle</i>	<i>v.up()</i> <i>const</i>	Returns the <i>Vertex_handle</i> pointing to the level above.
<i>Vertex_handle</i>	<i>v.down()</i> <i>const</i>	Returns the <i>Vertex_handle</i> pointing to the level below.

Setting

<i>void</i>	<i>v.set_up(Vertex_handle v)</i>	Sets the <i>Vertex_handle</i> pointing to the level above to <i>v</i> .
<i>void</i>	<i>v.set_down(Vertex_handle v)</i>	Sets the <i>Vertex_handle</i> pointing to the level below to <i>v</i> .

Has Models

CGAL::Triangulation_hierarchy_vertex_base_3

RegularTriangulationCellBase_3

Definition

The regular triangulation of a set of weighted points does not necessarily have one vertex for each of the input points. Some of the input weighted points have no cell in the dual power diagrams and therefore do not correspond to a vertex of the regular triangulation. Those weighted points are said to be *hidden* points. A point which is hidden at a given time may appear later as a vertex of the regular triangulation upon removal of some other weighted point. Therefore, hidden points have to be stored somewhere. The regular triangulation stores those hidden points in its cells.

A hidden point can appear as vertex of the triangulation only when the three dimensional cell where its point component is located (the cell which hides it) is removed. Therefore we decided to store in each cell of a regular triangulation the list of hidden points that are located in the face. Thus points hidden by a face are easily reinserted in the triangulation when the face is removed.

The base cell of a regular triangulation has to be a model of the concept `RegularTriangulationCellBase_3`, which refines the concept *TriangulationCellBase_3* by adding in the cell a container to store hidden points.

Refines

TriangulationCellBase_3

Types

<i>RegularTriangulationCellBase_3:: Point</i>	Must be the same as the point type <i>TriangulationTraits_3::Point_3</i> defined by the geometric traits class of the triangulation.
---	--

Types

<i>RegularTriangulationCellBase_3:: Point_iterator</i>	Iterator of value type <code>Point</code>
--	---

Access Functions

<i>Point_iterator</i>	<i>rcb.hidden_points_begin()</i>	Returns an iterator pointing to the first hidden point.
<i>Point_iterator</i>	<i>rcb.hidden_points_end()</i>	Returns a past-the-end iterator.

Setting

void *rcb.hide_point(Point p)*

Adds p to the set of hidden points of the cell.

CGAL::Triangulation_cell_base_3<TriangulationTraits_3, TriangulationDSCellBase_3>

Definition

The class *Triangulation_cell_base_3* is a model of the concept *TriangulationCellBase_3*, the base cell of a 3D-triangulation.

This class can be used directly or can serve as a base to derive other classes with some additional attributes (a color for example) tuned for a specific application.

```
#include <CGAL/Triangulation_cell_base_3.h>
```

Parameters

The first template argument is the geometric traits class *TriangulationTraits_3*. It is actually not used by this class.

The second template argument is a combinatorial cell base class from which *Triangulation_cell_base_3* derives. It has the default value *Triangulation_ds_cell_base_3*<>.

Note that this model does not store the circumcenter, but computes it every time the circumcenter function is called. See *CGAL::Triangulation_cell_base_with_circumcenter_3* for a way to cache the circumcenter computation.

CGAL::Triangulation_cell_base_3

CGAL::Triangulation_cell_base_with_info_3

CGAL::Triangulation_vertex_base_3<TriangulationTraits_3, TriangulationDSVertexBase_3>

Definition

The class *Triangulation_vertex_base_3* is a model of the concept *TriangulationVertexBase_3*, the base vertex of a 3D-triangulation. This class stores a point.

This class can be used directly or can serve as a base to derive other classes with some additional attributes (a color for example) tuned for a specific application.

```
#include <CGAL/Triangulation_vertex_base_3.h>
```

Parameters

The first template argument is the geometric traits class *TriangulationTraits_3* which provides the point type, *Point_3*. Users of the geometric triangulations (Section 28.2 and Chapter 27) are strongly advised to use the same geometric traits class *TriangulationTraits_3* as the one used for *Triangulation_3*. This way, the point type defined by the base vertex is the same as the point type defined by the geometric traits class.

The second template argument is a combinatorial vertex base class from which *Triangulation_vertex_base_3* derives. It has the default value *Triangulation_ds_vertex_base_3*<>.

CGAL::Triangulation_vertex_base_with_info_3<Info, TriangulationTraits_3, TriangulationVertexBase_3>

Definition

The class *Triangulation_vertex_base_with_info_3* is a model of the concept *TriangulationVertexBase_3*, the base vertex of a 3D-triangulation. It provides an easy way to add some user defined information in vertices. Note that input/output operators discard this additional information.

```
#include <CGAL/Triangulation_vertex_base_with_info_3.h>
```

Parameters

The first template argument is the information the user would like to add to a vertex. It has to be *DefaultConstructible* and *Assignable*.

The second template argument is the geometric traits class *TriangulationTraits_3* which provides the *Point_3*.

The third template argument is a vertex base class from which *Triangulation_vertex_base_with_info_3* derives. It has the default value *Triangulation_vertex_base_3<TriangulationTraits_3>*.

CGAL::Triangulation_hierarchy_vertex_base_3<TriangulationVertexBase_3>

Definition

This class is designed to be used as the vertex base class for *Triangulation_hierarchy_3*.

It inherits from its parameter *TriangulationVertexBase_3*, and adds the requirements in order to match the concept *TriangulationHierarchyVertexBase_3*, it does so by storing two *Vertex_handles*. This design allows to use either a vertex base class provided by CGAL, or a user customized vertex base with additional functionalities.

```
#include <CGAL/Triangulation_hierarchy_vertex_base_3.h>
```

Parameters

It is parameterized by a model of the concept *TriangulationVertexBase_3*.

A geometric triangulation has two aspects: the combinatorial structure, which gives the incidence and adjacency relations between faces, and the geometric information related to the position of vertices.

CGAL provides 3D geometric triangulations in which these two aspects are clearly separated. As described in Chapter 27, a geometric triangulation of a set of points in \mathbb{R}^d , $d \leq 3$ is a partition of the whole space \mathbb{R}^d into cells having $d + 1$ vertices. Some of them are infinite, they are obtained by linking an additional vertex at infinity to each facet of the convex hull of the points (see Section 27.1). The underlying combinatorial graph of such a triangulation without boundary of \mathbb{R}^d can be seen as a triangulation of the topological sphere S^d in \mathbb{R}^{d+1} .

This chapter deals with 3D-triangulation data structures, meant to maintain the combinatorial information for 3D-geometric triangulations. The reader interested in geometric triangulations of \mathbb{R}^3 is advised to read Chapter 27.

28.1 Representation

In CGAL, a 3D triangulation data structure is a container of cells (3-faces) and vertices (0-faces). Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives direct access to one of its incident cells, which is sufficient to retrieve all the incident cells when needed.

The four vertices of a cell are indexed with 0, 1, 2 and 3. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index (see Figure 28.1).

Figure 28.1: Representation.

Edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex of index i) and an edge is given by a cell and two indices (the edge (i,j) of a cell c is the edge whose endpoints are the vertices of indices i and j of c).

Degenerate Dimensions As CGAL explicitly deals with all degenerate cases, a 3D-triangulation data structure in CGAL can handle the cases when the dimension of the triangulation is lower than 3.

Thus, a 3D-triangulation data structure can store a triangulation of a topological sphere S^d of \mathbb{R}^{d+1} , for any $d \in \{-1, 0, 1, 2, 3\}$.

Let us give, for each dimension, the example corresponding to the triangulation data structure having a minimal number of vertices, i.e. a simplex. These examples are illustrated by presenting their usual geometric embedding.

- *dimension 3*. The triangulation data structure consists of the boundary of a 4-dimensional simplex, which has 5 vertices. A geometric embedding consists in choosing one of these vertices to be infinite, thus four of the five 3-cells become infinite: the geometric triangulation has one finite tetrahedron remaining, each of its facets being incident to an infinite cell. See Figure 28.2.
- *dimension 2*. We have 4 vertices forming one 3-dimensional simplex, i.e. the boundary of a tetrahedron. The geometric embedding in the plane results from choosing one of these vertices to be infinite, then the geometric triangulation has one finite triangle whose edges are incident to the infinite triangles. See Figure 28.3.
- *dimension 1*. A 2-dimensional simplex (a triangle) has 3 vertices. The geometric embedding is an edge whose vertices are linked to an infinite point. See Figure 28.4.

The last three cases are defined uniquely:

- *dimension 0*. A 0-dimensional triangulation is combinatorially equivalent to the boundary of a 1-dimensional simplex (an edge), which consists of 2 vertices. One of them becomes infinite in the geometric embedding, and there is only one finite vertex remaining. The two vertices are adjacent.
- *dimension -1*. This dimension is a convention to represent a 0-dimensional simplex, that is a sole vertex, which will be geometrically embedded as an “empty” triangulation, having only one infinite vertex.
- *dimension -2*. This is also a convention. The triangulation data structure has no vertex. There is no associated geometric triangulation.

Figure 28.2: 4D simplex and a 3D geometric embedding.

Figure 28.3: 3D simplex and a 2D geometric embedding.

Figure 28.4: 2D simplex and a 1D geometric embedding.

Note that the notion of infinite vertex has no meaning for the triangulation data structure. The infinite vertex of the geometric embedding is a vertex that cannot be distinguished from the other vertices in the combinatorial triangulation.

The same cell class is used in all cases: triangular faces in 2D can be considered as degenerate cells, having only three vertices (resp. neighbors) numbered $(0, 1, 2)$; edges in 1D have only two vertices (resp. neighbors) numbered 0 and 1.

The implicit representation of facets (resp. edges) still holds for degenerate (< 3) dimensions : in dimension 2, each cell has only one facet of index 3, and 3 edges $(0, 1)$, $(1, 2)$ and $(2, 0)$; in dimension 1, each cell has one edge $(0, 1)$.

Validity A 3D combinatorial triangulation is said to be *locally valid* iff the following is true:

(a) When a cell c has a neighbor pointer to another cell c' , then reciprocally this cell c' has a neighbor pointer to c , and c and c' have three vertices in common. These cells are called adjacent.

(b) The cells have a coherent orientation: if two cells c_1 and c_2 are adjacent and share a facet with vertices u, v, w , then the vertices of c_1 are numbered $(v_0^1 = u, v_1^1 = v, v_2^1 = w, v_3^1)$, and the vertices of c_2 are numbered $(v_0^2 = v, v_1^2 = u, v_2^2 = w, v_3^2)$, up to positive permutations of $(0, 1, 2, 3)$. In other words, if we embed the triangulation in \mathbb{R}^3 , then the fourth vertices v_3^1 and v_3^2 of c_1 and c_2 see the common facet in opposite orientations. See Figure 28.5.

The set \mathfrak{S}_4 of permutations of $(0, 1, 2, 3)$ has cardinality 24, and the set of positive permutations A_4 has cardinality 12. Thus, for a given orientation, there are up to 12 different orderings of the four vertices of a cell. Note that cyclic permutations are negative and so do not preserve the orientation of a cell.

Figure 28.5: Coherent orientations of two cells (3-dimensional case).

The *is_valid()* method provided by *Triangulation_data_structure_3* checks the local validity of a given triangulation data structure.

28.2 Software Design

The 3D-triangulation data structure class of CGAL, *Triangulation_data_structure_3*, is designed to be used as a combinatorial layer upon which a geometric layer can be built [Ket98]. This geometric layer is typically one of

the 3D-triangulation classes of CGAL: *Triangulation_3*, *Delaunay_triangulation_3* and *Regular_triangulation_3*. This relation is described in more details in Chapter 27, where the Section 27.5 explains other important parts of the design related to the geometry.

We focus here on the design of the triangulation data structure (TDS) itself, which the Figure 28.6 illustrates.

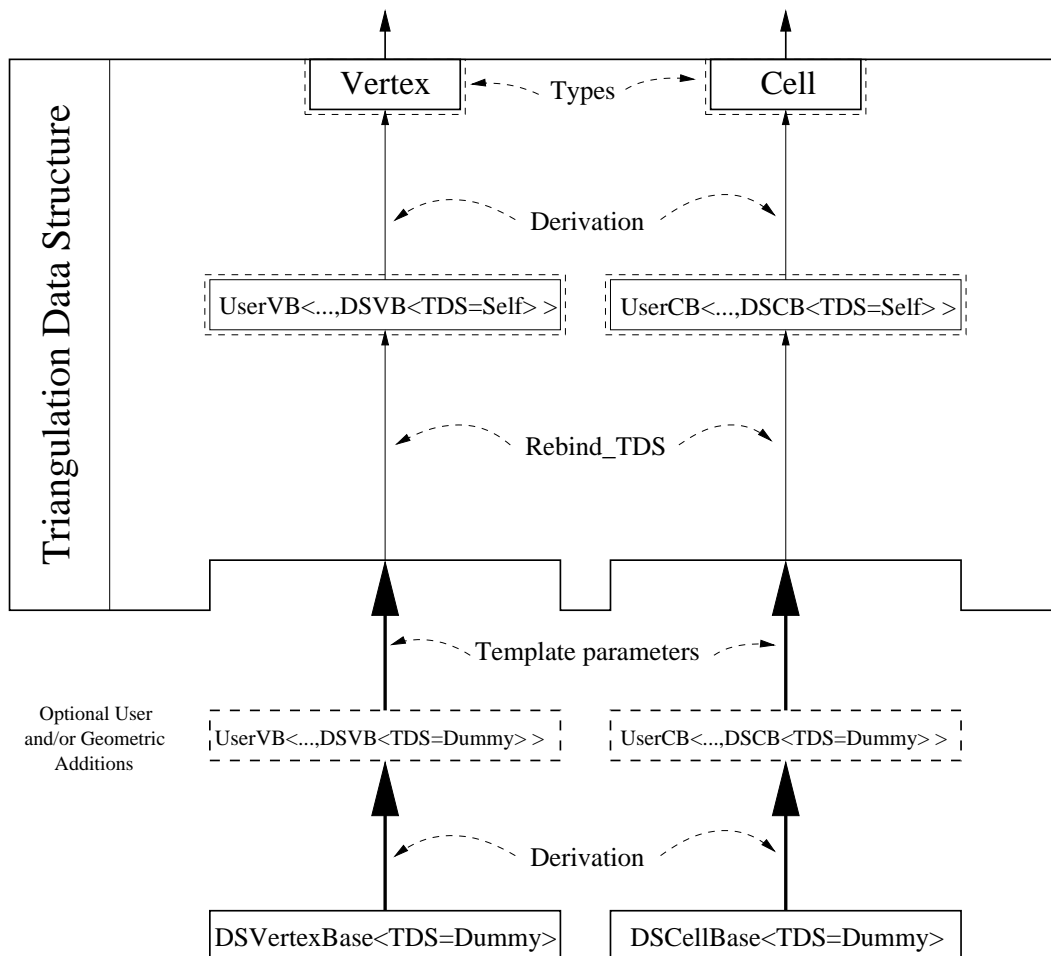

Figure 28.6: Triangulation Data Structure software design.

28.2.1 Flexibility of the Design

In order for the user to be able to add his own data in the vertices and cells, the design of the TDS is split into two layers:

- In the bottom layer, the (vertex and cell) base classes store elementary incidence and adjacency (and possibly geometric or other) information. These classes are parameterized by the TDS which provides the handle types. (They can also be parameterized by a geometric traits class or anything else.) A vertex stores a *Cell_handle*, and a cell stores four *Vertex_handles* and four *Cell_handles*.
- The middle layer is the TDS, which is purely combinatorial. It provides operations such as insertion of a new vertex in a given cell, on a 1 or 2-face. It also allows one, if the dimension of the triangulation is smaller than 3, to insert a vertex so that the dimension of the triangulation is increased by one. The TDS

is responsible for the combinatorial integrity of the eventual geometric triangulation built on top of it (the upper layer, see Chapter 27).

The user has several ways to add his own data in the vertex and cell base classes used by the TDS. He can either:

- use the classes *Triangulation_vertex_base_with_info* and *Triangulation_cell_base_with_info*, which allow to add one data member of a user provided type, and give access to it.
- derive his own classes from the default base classes *Triangulation_ds_vertex_base*, and *Triangulation_ds_cell_base* (or the geometric versions typically used by the geometric layer, *Triangulation_vertex_base*, and *Triangulation_cell_base*).
- write his own base classes following the requirements given by the concepts *TriangulationCellBase_3* and *TriangulationVertexBase_3* (described in page 1884 and page 1885).

28.2.2 Cyclic Dependency

Since adjacency relations are stored in the vertices and cells, it means that the vertex and cell base classes have to be able to store handles (an entity akin to pointers) to their neighbors in the TDS. This in turns means that the vertex and cell base classes have to know the types of these handles, which are provided by the TDS. So in a sense, the base classes are parameterized by the TDS, and the TDS is parameterized by the vertex and cell base classes ! This is a cycle which cannot be resolved easily.

The solution that we have chosen is similar to the mechanism used by the standard class *std::allocator*: the vertex and cell base classes are initially given a fake or dummy TDS template parameter, whose unique purpose is to provide the types that can be used by the vertex and cell base classes (such as handles). Then, inside the TDS itself, these base classes are *rebound* to the real TDS type, that is we obtain the same vertex and cell base classes, but parameterized with the real TDS instead of the dummy one. Rebinding is performed by a nested template class of the vertex and cell base classes (see code below), which provides a type which is the rebound vertex or cell base class¹.

Here is how it works, schematically:

```
template < class Vb, class Cb >
class TDS
{
    typedef TDS<Vb, Cb>    Self;

    // Rebind the vertex and cell base to the actual TDS (Self).
    typedef typename Vb::template Rebind_TDS<Self>::Other  VertexBase;
    typedef typename Cb::template Rebind_TDS<Self>::Other  CellBase;

    // ... further internal machinery leads to the final public types:
public:
    typedef ...  Vertex;
    typedef ...  Cell;
    typedef ...  Vertex_handle;
    typedef ...  Cell_handle;
};
```

¹It is logically equivalent to a mechanism that does not exist yet in the C++ language: *template typedef* or *template aliasing*

```

template < class TDS = ... > // The default is some internal type faking a TDS
class Triangulation_ds_vertex_base_3
{
public:
    template < class TDS2 >
    struct Rebind_TDS {
        typedef Triangulation_ds_vertex_base_3<TDS2>    Other;
    };
    ...
};

```

When derivation is used for the vertex or cell base classes, which is the case at the geometric level with *Triangulation_vertex_base_3*, then it gets slightly more involved because its base class has to be rebound as well:

```

template < class GT, class Vb = Triangulation_ds_vertex_base_3<> >
class Triangulation_vertex_base_3 : public Vb
{
public:
    template < class TDS2 >
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef Triangulation_vertex_base_3<GT, Vb2>            Other;
    };
    ...
};

```

28.2.3 Backward Compatibility

The rebinding scheme has been introduced in CGAL version 3.0. It is incompatible with the previous versions, for the cases where the user provides his own vertex or cell base class. In these cases, the user needs to add the rebind nested template class appropriately. More information is given in [27.5.4](#).

28.3 Examples

28.3.1 Incremental Construction

The following example shows how to construct a 3D triangulation data structure by inserting vertices.

```

#include <CGAL/Triangulation_data_structure_3.h>
#include <iostream>
#include <fstream>
#include <cassert>
#include <vector>

typedef CGAL::Triangulation_data_structure_3<>    Tds;

typedef Tds::size_type                            size_type;

```

```

typedef Tds::Cell_handle          Cell_handle;
typedef Tds::Vertex_handle       Vertex_handle;

int main()
{
    Tds T;

    assert( T.number_of_vertices() == 0 );
    assert( T.dimension() == -2 );
    assert( T.is_valid() );

    std::vector<Vertex_handle> PV(7);

    PV[0] = T.insert_increase_dimension();
    assert( T.number_of_vertices() == 1 );
    assert( T.dimension() == -1 );
    assert( T.is_valid() );

    // each of the following insertions of vertices increases the dimension
    for ( int i=1; i<5; i++ ) {
        PV[i] = T.insert_increase_dimension(PV[0]);
        assert( T.number_of_vertices() == (size_type) i+1 );
        assert( T.dimension() == i-1 );
        assert( T.is_valid() );
    }
    assert( T.number_of_cells() == 5 );

    // we now have a simplex in dimension 4

    // cell incident to PV[0]
    Cell_handle c = PV[0]->cell();
    int ind;
    bool check = c->has_vertex( PV[0], ind );
    assert( check );
    // PV[0] is the vertex of index ind in c

    // insertion of a new vertex in the facet opposite to PV[0]
    PV[5] = T.insert_in_facet(c, ind);

    assert( T.number_of_vertices() == 6 );
    assert( T.dimension() == 3 );
    assert( T.is_valid() );

    // insertion of a new vertex in c
    PV[6] = T.insert_in_cell(c);

    assert( T.number_of_vertices() == 7 );
    assert( T.dimension() == 3 );
    assert( T.is_valid() );

    std::ofstream oFileT("output_tds",std::ios::out);
    // writing file output_tds;
    oFileT << T;

```

```

    return 0;
}

```

File: examples/Triangulation_3/tds.cpp

28.3.2 Cross-Linking Between a 2D and a 3D Data Structures

This example program illustrates how to setup a 2D and a 3D triangulation data structures whose vertices respectively store vertex handles of the other one.

```

#include <CGAL/Triangulation_data_structure_2.h>
#include <CGAL/Triangulation_data_structure_3.h>
#include <cassert>

// declare the 2D vertex base type, parametrized by some 3D TDS.
template < typename T3, typename Vb = CGAL::Triangulation_ds_vertex_base_2<> >
class My_vertex_2;

// declare the 3D vertex base type, parametrized by some 2D TDS.
template < typename T2, typename Vb = CGAL::Triangulation_ds_vertex_base_3<> >
class My_vertex_3;

// Then, we have to break the dependency cycle.

// we need to refer to a dummy 3D TDS.
typedef CGAL::Triangulation_ds_vertex_base_3<>::Triangulation_data_structure
    Dummy_tds_3;
// the 2D TDS, initially plugging a dummy 3D TDS in the vertex type
// (to break the dependency cycle).
typedef CGAL::Triangulation_data_structure_2<My_vertex_2<Dummy_tds_3> > TDS_2;
// the 3D TDS, here we can plug the 2D TDS directly.
typedef CGAL::Triangulation_data_structure_3<My_vertex_3<TDS_2> > TDS_3;

template < typename T3, typename Vb >
class My_vertex_2
    : public Vb
{
public:
    typedef typename Vb::Face_handle Face_handle;

    template <typename TDS2>
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other Vb2;
        // we also have to break the cycle here by hardcoding TDS_3 instead of T3.
        typedef My_vertex_2<TDS_3, Vb2> Other;
    };

    My_vertex_2() {}

    My_vertex_2(Face_handle f) : Vb(f) {}

```

```

    // we store a vertex handle of the 3D TDS.
    typename T3::Vertex_handle v3;
};

template < typename T2, typename Vb >
class My_vertex_3
    : public Vb
{
public:
    typedef typename Vb::Cell_handle    Cell_handle;

    template <typename TDS2>
    struct Rebind_TDS {
        typedef typename Vb::template Rebind_TDS<TDS2>::Other    Vb2;
        typedef My_vertex_3<T2, Vb2>                             Other;
    };

    My_vertex_3() {}

    My_vertex_3(Cell_handle c) : Vb(c) {}

    // we store a vertex handle of the 2D TDS.
    typename T2::Vertex_handle v2;
};

int main() {
    TDS_2 t2;
    TDS_3 t3;

    TDS_2::Vertex_handle v2 = t2.insert_dim_up();
    TDS_3::Vertex_handle v3 = t3.insert_increase_dimension();

    v2->v3 = v3;
    v3->v2 = v2;

    assert(t2.is_valid());
    assert(t3.is_valid());
    return 0;
}

```

File: examples/Triangulation_3/linking_2d_and_3d.cpp

28.4 Design and Implementation History

Monique Teillaud introduced the triangulation of the topological sphere S^d in \mathbb{R}^{d+1} to manage the underlying graph of geometric triangulations and handle degenerate dimensions [Tei99].

Sylvain Pion improved the software in several ways, in particular regarding the memory management.

3D Triangulation Data Structure Reference Manual

Sylvain Pion and Monique Teillaud

The triangulation data structure is able to represent a triangulation of a topological sphere S^d of \mathbb{R}^{d+1} , for $d \in \{-1, 0, 1, 2, 3\}$. (See [28.1.](#))

The vertex class of a 3D-triangulation data structure must define a number of types and operations. The requirements that are of geometric nature are required only when the triangulation data structure is used as a layer for the geometric triangulation classes. (See [Section 28.2.](#))

The cell class of a triangulation data structure stores four handles to its four vertices and four handles to its four neighbors. The vertices are indexed 0, 1, 2, and 3 in a consistent order. The neighbor indexed i lies opposite to vertex i .

In degenerate dimensions, cells are used to store faces of maximal dimension: in dimension 2, each cell represents only one facet of index 3, and 3 edges (0,1), (1,2) and (2,0); in dimension 1, each cell represents one edge (0,1). (See [Section 28.1.](#))

TriangulationDataStructure_3

Definition

3D-triangulation data structures are meant to maintain the combinatorial information for 3D-geometric triangulations.

In CGAL, a triangulation data structure is a container of cells (3-faces) and vertices (0-faces). Each cell gives access to its four incident vertices and to its four adjacent cells. Each vertex gives direct access to one of its incident cells, which is sufficient to retrieve all the incident cells when needed.

The four vertices of a cell are indexed with 0, 1, 2 and 3. The neighbors of a cell are also indexed with 0, 1, 2, 3 in such a way that the neighbor indexed by i is opposite to the vertex with the same index (see Figure 28.1).

Edges (1-faces) and facets (2-faces) are not explicitly represented: a facet is given by a cell and an index (the facet i of a cell c is the facet of c that is opposite to the vertex of index i) and an edge is given by a cell and two indices (the edge (i,j) of a cell c is the edge whose endpoints are the vertices of indices i and j of c).

As CGAL explicitly deals with all degenerate cases, a 3D-triangulation data structure in CGAL can handle the cases when the dimension of the triangulation is lower than 3 (see Section 28.1).

Thus, a 3D-triangulation data structure can store a triangulation of a topological sphere S^d of \mathbb{R}^{d+1} , for any $d \in \{-1, 0, 1, 2, 3\}$.

The second template parameter of the basic triangulation class (see Chapter 27, page 1840) *Triangulation_3* is a triangulation data structure class. (See Chapter 28.)

To ensure all the **flexibility** of the class *Triangulation_3*, a model of a triangulation data structure must be templated by the base vertex and the base cell classes (see 28.1): *TriangulationDataStructure_3* < *TriangulationVertexBase_3*, *TriangulationCellBase_3* >. The optional functionalities related to geometry are compulsory for this use as a template parameter of *Triangulation_3*.

A class that satisfies the requirements for a triangulation data structure class must provide the following types and operations.

Types

<i>TriangulationDataStructure_3:: Vertex</i>	Vertex type
<i>TriangulationDataStructure_3:: Cell</i>	Cell type
<i>TriangulationDataStructure_3:: size_type</i>	Size type (unsigned integral type)
<i>TriangulationDataStructure_3:: difference_type</i>	Difference type (signed integral type)

Vertices and cells are usually manipulated via *handles*, which support the two dereference operators *operator** and *operator->*.

TriangulationDataStructure_3::Vertex_handle
TriangulationDataStructure_3::Cell_handle

Requirements for *Vertex* and *Cell* are described in *TriangulationDataStructure_3::Vertex* and *TriangulationDataStructure_3::Cell* (page 1927 and page 1925).

typedef Triple<Cell_handle, int, int> Edge; (c,i,j) is the edge of cell c whose vertices indices are i and j .
 (See Section 28.1.)
typedef std::pair<Cell_handle, int> Facet; (c,i) is the facet of c opposite to the vertex of index i . (See
 Section 28.1.)

The following iterators allow one to visit all the vertices, edges, facets and cells of the triangulation data structure. They are all bidirectional, non-mutable iterators.

TriangulationDataStructure_3::Cell_iterator
TriangulationDataStructure_3::Facet_iterator
TriangulationDataStructure_3::Edge_iterator
TriangulationDataStructure_3::Vertex_iterator

The following circulators allow us to visit all the cells and facets incident to a given edge. They are bidirectional and non-mutable.

TriangulationDataStructure_3::Facet_circulator
TriangulationDataStructure_3::Cell_circulator

Iterators and circulators are convertible to the corresponding handles, thus the user can pass them directly as arguments to the functions.

Creation

<i>TriangulationDataStructure_3 tds;</i>	Default constructor.
<i>TriangulationDataStructure_3 tds(tds1);</i>	Copy constructor. All vertices and cells are duplicated.
<i>TriangulationDataStructure_3& tds = tds1</i>	Assignment operator. All vertices and cells are duplicated, and the former data structure of <i>tds</i> is deleted.

Vertex_handle tds.copy_tds(tds1, Vertex_handle v = Vertex_handle())

tds1 is copied into *tds*. If $v \neq \text{Vertex_handle}()$, the vertex of *tds* corresponding to v is returned, otherwise *Vertex_handle()* is returned.
Precondition: The optional argument v is a vertex of *tds1*.

<i>void tds.swap(& tds1)</i>	Swaps <i>tds</i> and <i>tds1</i> . There is no copy of cells and vertices, thus this method runs in constant time. This method should be preferred to <i>tds=tds1</i> or <i>tds(tds1)</i> when <i>tds1</i> is deleted after that.
<i>void tds.clear()</i>	Deletes all cells and vertices. <i>tds</i> is reset as a triangulation data structure constructed by the default constructor.

Operations

Access Functions

<i>int</i>	<i>tds.dimension()</i>	The dimension of the triangulated topological sphere.
<i>size_type</i>	<i>tds.number_of_vertices()</i>	The number of vertices. Note that the triangulation data structure has one more vertex than an associated geometric triangulation, if there is one, since the infinite vertex is a standard vertex and is thus also counted.
<i>size_type</i>	<i>tds.number_of_cells()</i>	The number of cells. Returns 0 if <i>tds.dimension()</i> < 3.

Non constant-time access functions

<i>size_type</i>	<i>tds.number_of_facets()</i>	The number of facets. Returns 0 if <i>tds.dimension()</i> < 2.
<i>size_type</i>	<i>tds.number_of_edges()</i>	The number of edges. Returns 0 if <i>tds.dimension()</i> < 1.

advanced

Setting

<i>void</i>	<i>tds.set_dimension(int n)</i>	Sets the dimension to <i>n</i> .
-------------	----------------------------------	----------------------------------

advanced

Queries

<i>bool</i>	<i>tds.is_vertex(Vertex_handle v)</i>	Tests whether <i>v</i> is a vertex of <i>tds</i> .
<i>bool</i>	<i>tds.is_edge(Cell_handle c, int i, int j)</i>	Tests whether <i>(c,i,j)</i> is an edge of <i>tds</i> . Answers <i>false</i> when <i>dimension()</i> < 1 . Precondition: <i>i, j</i> ∈ {0, 1, 2, 3}
<i>bool</i>	<i>tds.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j)</i>	Tests whether <i>(u,v)</i> is an edge of <i>tds</i> . If the edge is found, it computes a cell <i>c</i> having this edge and the indices <i>i</i> and <i>j</i> of the vertices <i>u</i> and <i>v</i> , in this order.
<i>bool</i>	<i>tds.is_edge(Vertex_handle u, Vertex_handle v)</i>	Tests whether <i>(u,v)</i> is an edge of <i>tds</i> .
<i>bool</i>	<i>tds.is_facet(Cell_handle c, int i)</i>	Tests whether <i>(c,i)</i> is a facet of <i>tds</i> . Answers <i>false</i> when <i>dimension()</i> < 2 . Precondition: <i>i</i> ∈ {0, 1, 2, 3}

bool *tds.is_facet*(*Vertex_handle* *u*,
 Vertex_handle *v*,
 Vertex_handle *w*,
 Cell_handle & *c*,
 int & *i*,
 int & *j*,
 int & *k*)

Tests whether (u,v,w) is a facet of *tds*. If the facet is found, it computes a cell *c* having this facet and the indices *i*, *j* and *k* of the vertices *u*, *v* and *w*, in this order.

bool *tds.is_cell*(*Cell_handle* *c*)

Tests whether *c* is a cell of *tds*. Answers *false* when *dimension()* < 3 .

bool *tds.is_cell*(*Vertex_handle* *u*,
 Vertex_handle *v*,
 Vertex_handle *w*,
 Vertex_handle *t*,
 Cell_handle & *c*,
 int & *i*,
 int & *j*,
 int & *k*,
 int & *l*)

Tests whether (u,v,w,t) is a cell of *tds*. If the cell *c* is found, it computes the indices *i*, *j*, *k* and *l* of the vertices *u*, *v*, *w* and *t* in *c*, in this order.

There is a method *has_vertex* in the cell class. The analogous methods for facets are defined here.

bool *tds.has_vertex*(*Facet* *f*, *Vertex_handle* *v*, *int* & *j*)

If *v* is a vertex of *f*, then *j* is the index of *v* in the cell *f.first*, and the method returns *true*.

Precondition: *tds.dimension()*=3

bool *tds.has_vertex*(*Cell_handle* *c*, *int* *i*, *Vertex_handle* *v*, *int* & *j*)

Same for facet (c,i) . Computes the index *j* of *v* in *c*.

bool *tds.has_vertex*(*Facet* *f*, *Vertex_handle* *v*)

bool *tds.has_vertex*(*Cell_handle* *c*, *int* *i*, *Vertex_handle* *v*)

Same as the first two methods, but these two methods do not return the index of the vertex.

The following three methods test whether two facets have the same vertices.

bool *tds.are_equal*(*Facet* *f*, *Facet* *g*)

bool *tds.are_equal*(*Cell_handle* *c*, *int* *i*, *Cell_handle* *n*, *int* *j*)

bool *tds.are_equal*(*Facet* *f*, *Cell_handle* *n*, *int* *j*)

For these three methods:

Precondition: *tds.dimension()*=3.

Figure 28.7: Flips.

Flips

Two kinds of flips exist for a three-dimensional triangulation. They are reciprocal. To be flipped, an edge must be incident to three tetrahedra. During the flip, these three tetrahedra disappear and two tetrahedra appear. Figure 28.7(left) shows the edge that is flipped as bold dashed, and one of its three incident facets is shaded. On the right, the facet shared by the two new tetrahedra is shaded.

The following methods guarantee the validity of the resulting 3D combinatorial triangulation. Moreover the flip operations do not invalidate the vertex handles, and only invalidate the cell handles of the affected cells.

Flips for a 2d triangulation are not implemented yet

```
bool    tds.flip( Edge e)
bool    tds.flip( Cell_handle c, int i, int j)
```

Before flipping, these methods check that edge $e=(c,i,j)$ is flip-pable (which is quite expensive). They return *false* or *true* according to this test.

```
void    tds.flip_flippable( Edge e)
void    tds.flip_flippable( Cell_handle c, int i, int j)
```

Should be preferred to the previous methods when the edge is known to be flippable.

Precondition: The edge is flippable.

```
bool    tds.flip( Facet f)
bool    tds.flip( Cell_handle c, int i)
```

Before flipping, these methods check that facet $f=(c,i)$ is flip-pable (which is quite expensive). They return *false* or *true* according to this test.

```
void    tds.flip_flippable( Facet f)
```

void tds.flip_flippable(Cell_handle c, int i)

Should be preferred to the previous methods when the facet is known to be flippable.

Precondition: The facet is flippable.

Insertions

The following modifier member functions guarantee the combinatorial validity of the resulting triangulation.

Vertex_handle tds.insert_in_cell(Cell_handle c)

Creates a new vertex, inserts it in cell c and returns its handle. The cell c is split into four new cells, each of these cells being formed by the new vertex and a facet of c .

Precondition: $tds.dimension() = 3$ and c is a cell of tds .

Vertex_handle tds.insert_in_facet(Facet f)

Creates a new vertex, inserts it in facet f and returns its handle. In dimension 3, the two incident cells are split into 3 new cells; in dimension 2, the facet is split into 3 facets.

Precondition: $tds.dimension() \geq 2$ and f is a facet of tds .

Vertex_handle tds.insert_in_facet(Cell_handle c, int i)

Creates a new vertex, inserts it in facet i of c and returns its handle.

Precondition: $tds.dimension() \geq 2$, $i \in \{0, 1, 2, 3\}$ in dimension 3, $i = 3$ in dimension 2 and (c, i) is a facet of tds .

Vertex_handle tds.insert_in_edge(Edge e)

Creates a new vertex, inserts it in edge e and returns its handle. In dimension 3, all the incident cells are split into 2 new cells; in dimension 2, the 2 incident facets are split into 2 new facets; in dimension 1, the edge is split into 2 new edges.

Precondition: $tds.dimension() \geq 1$ and e is an edge of tds .

Vertex_handle tds.insert_in_edge(Cell_handle c, int i, int j)

Creates a new vertex, inserts it in edge (i, j) of c and returns its handle.

Precondition: $tds.dimension() \geq 1$. $i \neq j$, $i, j \in \{0, 1, 2, 3\}$ in dimension 3, $i, j \in \{0, 1, 2\}$ in dimension 2, $i, j \in \{0, 1\}$ in dimension 1 and (c, i, j) is an edge of tds .

Vertex_handle *tds.insert_increase_dimension(Vertex_handle star = Vertex_handle())*

Transforms a triangulation of the sphere S^d of \mathbb{R}^{d+1} into the triangulation of the sphere S^{d+1} of \mathbb{R}^{d+2} by adding a new vertex v : v is linked to all the vertices to triangulate one of the two half-spheres of dimension $(d+1)$. Vertex *star* is used to triangulate the second half-sphere (when there is an associated geometric triangulation, *star* is in fact the vertex associated with its infinite vertex). See Figure 28.8.

The numbering of the cells is such that, if f was a face of maximal dimension in the initial triangulation, then (f,v) (in this order) is the corresponding face in the new triangulation. This method can be used to insert the first two vertices in an empty triangulation.

A handle to v is returned.

Precondition: *tds.dimension()* = $d < 3$. When *tds.number_of_vertices()* > 0, *star* \neq *Vertex_handle()* and *star* is a vertex of *tds*.

Figure 28.8: *insert_increase_dimension* (1-dimensional case).

Vertex_handle *tds.insert_in_hole(CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)*

Creates a new vertex by starring a hole. It takes an iterator range $[cell_begin; cell_end]$ of *Cell_handles* which specifies a set of connected cells (resp. facets in dimension 2) describing a hole. $(begin, i)$ is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin*->*neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex *v*, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with *v* as vertex. *v* is returned.

Precondition: *tds.dimension()* ≥ 2 , the set of cells (resp. facets) is connected, and its boundary is connected.

Removal

void *tds.remove_decrease_dimension(Vertex_handle v, Vertex_handle w = v)*

This operation is the reciprocal of *insert_increase_dimension()*. It transforms a triangulation of the sphere S^d of \mathbb{R}^{d+1} into the triangulation of the sphere S^{d-1} of \mathbb{R}^d by removing the vertex *v*. Delete the cells incident to *w*, keep the others.

Precondition: *tds.dimension()* $= d \geq -1$. *tds.degree(v)* $= \text{degree}(w) = \text{tds.number_of_vertices()} - 1$.

Cell_handle *tds.remove_from_maximal_dimension_simplex(Vertex_handle v)*

Removes *v*. The incident simplices of maximal dimension incident to *v* are replaced by a single simplex of the same dimension. This operation is exactly the reciprocal to *tds.insert_in_cell(v)* in dimension 3, *tds.insert_in_facet(v)* in dimension 2, and *tds.insert_in_edge(v)* in dimension 1.

Precondition: *tds.degree(v)* $= \text{tds.dimension()} + 1$.

— advanced —

Other modifiers

The following modifiers can affect the validity of the triangulation data structure.

void *tds.reorient()* Changes the orientation of all cells of the triangulation data structure.

Precondition: *tds.dimension()* ≥ 1 .

Vertex_handle *tds.create_vertex(Vertex v = Vertex())*

Adds a copy of the vertex *v* to the triangulation data structure.

```
Vertex_handle    tds.create_vertex( Vertex_handle v)
```

Creates a vertex which is a copy of the one pointed to by v and adds it to the triangulation data structure.

<i>Cell_handle</i>	<i>tds.create_cell(Cell c = Cell())</i>
--------------------	--

Adds a copy of the cell c to the triangulation data structure.

```
Cell_handle    tds.create_cell( Cell_handle c)
```

Creates a cell which is a copy of the one pointed to by c and adds it to the triangulation data structure.

<i>Cell_handle</i>	<i>tds.create_cell(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)</i>
--------------------	---

Creates a cell and adds it into the triangulation data structure. Initializes the vertices of the cell, its neighbor handles being initialized with the default constructed handle.

```
Cell_handle      tds.create_cell( Vertex_handle v0,
                                   Vertex_handle v1,
                                   Vertex_handle v2,
                                   Vertex_handle v3,
                                   Cell_handle n0,
                                   Cell_handle n1,
                                   Cell_handle n2,
                                   Cell_handle n3)
```

Creates a cell, initializes its vertices and neighbors, and adds it into the triangulation data structure.

```
void          tds.delete_vertex( Vertex_handle v)
```

Removes the vertex from the triangulation data structure.
Precondition: The vertex is a vertex of *tds*.

```
void          tds.delete_cell( Cell_handle c)
```

Removes the cell from the triangulation data structure.
Precondition: The cell is a cell of *tds*.

```
template <class VertexIt>
void          tds.delete_vertices( VertexIt first, VertexIt last)
```

Calls *delete_vertex* over an iterator range of value type *Vertex_handle*.

```
template <class CellIt>
```

void *tds.delete_cells(CellIt first, CellIt last)*

Calls *delete_cell* over an iterator range of value type *Cell_handle*.

└────────── *advanced* ─────────┘

Traversing the triangulation

<i>Cell_iterator</i>	<i>tds.cells_begin()</i>	Returns <i>cells_end()</i> when <i>tds.dimension()</i> < 3.
<i>Cell_iterator</i>	<i>tds.cells_end()</i>	
<i>Cell_iterator</i>	<i>tds.raw_cells_begin()</i>	
		Low-level access to the cells, does not return <i>cells_end()</i> when <i>tds.dimension()</i> < 3.
<i>Cell_iterator</i>	<i>tds.raw_cells_end()</i>	
<i>Facet_iterator</i>	<i>tds.facets_begin()</i>	Returns <i>facets_end()</i> when <i>tds.dimension()</i> < 2.
<i>Facet_iterator</i>	<i>tds.facets_end()</i>	
<i>Edge_iterator</i>	<i>tds.edges_begin()</i>	Returns <i>edges_end()</i> when <i>tds.dimension()</i> < 1.
<i>Edge_iterator</i>	<i>tds.edges_end()</i>	
<i>Vertex_iterator</i>	<i>tds.vertices_begin()</i>	
<i>Vertex_iterator</i>	<i>tds.vertices_end()</i>	

Cell and facet circulators

<i>Cell_circulator</i>	<i>tds.incident_cells(Edge e)</i>	Starts at an arbitrary cell incident to <i>e</i> . <i>Precondition: tds.dimension() = 3</i>
<i>Cell_circulator</i>	<i>tds.incident_cells(Cell_handle c, int i, int j)</i>	As above for edge (i,j) of <i>c</i> .
<i>Cell_circulator</i>	<i>tds.incident_cells(Edge e, Cell_handle start)</i>	Starts at cell <i>start</i> . <i>Precondition: tds.dimension() = 3 and start is incident to e.</i>
<i>Cell_circulator</i>	<i>tds.incident_cells(Cell_handle c, int i, int j, Cell_handle start)</i>	

As above for edge (i,j) of *c*.

The following circulators on facets are defined only in dimension 3, though facets are defined also in dimension 2: there are only two facets sharing an edge in dimension 2.

<i>Facet_circulator</i>	<i>tds.incident_facets(Edge e)</i>	Starts at an arbitrary facet incident to <i>e</i> . <i>Precondition: tds.dimension() = 3</i>
<i>Facet_circulator</i>	<i>tds.incident_facets(Cell_handle c, int i, int j)</i>	As above for edge (i,j) of <i>c</i> .
<i>Facet_circulator</i>	<i>tds.incident_facets(Edge e, Facet start)</i>	Starts at facet <i>start</i> . <i>Precondition: start is incident to e.</i>
<i>Facet_circulator</i>	<i>tds.incident_facets(Edge e, Cell_handle start, int f)</i>	

Starts at facet of index *f* in *start*.

<i>Facet_circulator</i>	<i>tds.incident_facets(Cell_handle c, int i, int j, Facet start)</i>
-------------------------	---

As above for edge (i,j) of *c*.

<i>Facet_circulator</i>	<i>tds.incident_facets(Cell_handle c, int i, int j, Cell_handle start, int f)</i>
-------------------------	--

As above for edge (i,j) of *c* and facet (start,f).

Traversal of the incident cells and facets, and the adjacent vertices of a given vertex

template <class *OutputIterator*>

OutputIterator *tds.incident_cells*(*Vertex_handle* *v*, *OutputIterator* *cells*)

Copies the *Cell_handles* of all cells (resp. facets in dimension 2) incident to *v* to the output iterator *cells*. If *tds.dimension()* < 2, then do nothing. Returns the resulting output iterator.

Precondition: $v \neq \text{Vertex_handle}()$, *tds.is_vertex*(*v*).

template <class *OutputIterator*>

OutputIterator *tds.incident_facets*(*Vertex_handle* *v*, *OutputIterator* *facets*)

Copies the *Facets* incident to *v* to the output iterator *facets*. Returns the resulting output iterator.

Precondition: *tds.dimension()* = 3, $v \neq \text{Vertex_handle}()$, *tds.is_vertex*(*v*).

template <class *OutputIterator*>

OutputIterator *tds.incident_vertices*(*Vertex_handle* *v*, *OutputIterator* *vertices*)

Copies the *Vertex_handles* of all vertices incident to *v* to the output iterator *vertices*. If *tds.dimension()* < 2, then do nothing. Returns the resulting output iterator.

Precondition: $v \neq \text{Vertex_handle}()$, *tds.is_vertex*(*v*).

size_type *tds.degree*(*Vertex_handle* *v*)

Returns the degree of a vertex, that is, the number of incident vertices.

Precondition: $v \neq \text{Vertex_handle}()$, *tds.is_vertex*(*v*).

Traversal between adjacent cells

int *tds.mirror_index*(*Cell_handle* *c*, *int* *i*)

Returns the index of *c* in its i^{th} neighbor.

Precondition: $i \in \{0, 1, 2, 3\}$.

Vertex_handle *tds.mirror_vertex*(*Cell_handle* *c*, *int* *i*)

Returns the vertex of the i^{th} neighbor of *c* that is opposite to *c*.

Precondition: $i \in \{0, 1, 2, 3\}$.

Facet *tds.mirror_facet*(*Facet* *f*)

Returns the same facet viewed from the other adjacent cell.

————— *advanced* —————

Checking

bool *tds.is_valid(bool verbose = false)* Checks the combinatorial validity of the triangulation by checking the local validity of all its cells and vertices (see functions below). (See Section [28.1](#).) Moreover, the Euler relation is tested.
When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

bool *tds.is_valid(Vertex_handle v, bool verbose = false)*

Checks the local validity of the adjacency relations of the triangulation. It also calls the *is_valid* member function of the vertex. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

bool *tds.is_valid(Cell_handle c, bool verbose = false)*

Checks the local validity of the adjacency relations of the triangulation. It also calls the *is_valid* member function of the cell. When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

└────────── *advanced* ─────────┘

I/O

istream& *istream& is >> & tds* Reads a combinatorial triangulation from *is* and assigns it to *tds*

ostream& *ostream& os << tds* Writes *tds* into the stream *os*

The information stored in the *iostream* is: the dimension, the number of vertices, the number of cells, the indices of the vertices of each cell, then the indices of the neighbors of each cell, where the index corresponds to the preceding list of cells. When $\text{dimension} < 3$, the same information is stored for faces of maximal dimension instead of cells.

Has Models

CGAL::Triangulation_data_structure_3

See Also

TriangulationDataStructure_3::Vertex
TriangulationDataStructure_3::Cell

TriangulationDataStructure_3::Cell

Definition

The concept `Cell` stores four *Vertex_handles* to its four vertices and four *Cell_handles* to its four neighbors. The vertices are indexed 0, 1, 2, and 3 in consistent order. The neighbor indexed i lies opposite to vertex i .

In degenerate dimensions, cells are used to store faces of maximal dimension: in dimension 2, each cell represents only one facet of index 3, and 3 edges (0,1), (1,2) and (2,0); in dimension 1, each cell represents one edge (0,1). (See also Section [28.1](#).)

Types

The class `Cell` defines the following types.

```
typedef TriangulationDataStructure_3      Triangulation_data_structure;
typedef TriangulationDataStructure_3::Vertex_handle Vertex_handle;
typedef TriangulationDataStructure_3::Cell_handle   Cell_handle;
```

Creation

In order to obtain new cells or destruct unused cells, the user must call the *create_cell()* and *delete_cell()* methods of the triangulation data structure.

Operations

Access Functions

<i>Vertex_handle</i>	<i>c.vertex(int i)</i>	Returns the vertex i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Vertex_handle v)</i>	Returns the index of vertex v in c . <i>Precondition:</i> v is a vertex of c .
<i>bool</i>	<i>c.has_vertex(Vertex_handle v)</i>	Returns <i>true</i> if v is a vertex of c .
<i>bool</i>	<i>c.has_vertex(Vertex_handle v, int & i)</i>	Returns <i>true</i> if v is a vertex of c , and computes its index i in c .
<i>Cell_handle</i>	<i>c.neighbor(int i)</i>	Returns the neighbor i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Cell_handle n)</i>	Returns the index corresponding to neighboring cell n . <i>Precondition:</i> n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n)</i>	Returns <i>true</i> if n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n, int & i)</i>	Returns <i>true</i> if n is a neighbor of c , and computes its index i in c .

Setting

<i>void</i>	<i>c.set_vertex(int i, Vertex_handle v)</i>	Sets vertex <i>i</i> to <i>v</i> . <i>Precondition: $i \in \{0, 1, 2, 3\}$.</i>
<i>void</i>	<i>c.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)</i>	Sets the vertex pointers.
<i>void</i>	<i>c.set_neighbor(int i, Cell_handle n)</i>	Sets neighbor <i>i</i> to <i>n</i> . <i>Precondition: $i \in \{0, 1, 2, 3\}$.</i>
<i>void</i>	<i>c.set_neighbors(Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)</i>	Sets the neighbors pointers.

Checking

<i>bool</i>	<i>c.is_valid(bool verbose = false, int level = 0)</i>	User defined local validity checking function.
-------------	---	--

See Also

TriangulationDataStructure_3::Vertex.

TriangulationDataStructure_3::Vertex

Definition

The concept Vertex represents the vertex class of a 3D-triangulation data structure. It must define the types and operations listed in this section. Some of these requirements are of geometric nature, they are *optional* when using the triangulation data structure class alone. They become compulsory when the triangulation data structure is used as a layer for the geometric triangulation class. (See Section 28.2.)

Types

Vertex:: Point *Optional for the triangulation data structure alone.*

The class Vertex defines types that are the same as some of the types defined by the triangulation data structure class *TriangulationDataStructure_3*.

```
typedef TriangulationDataStructure_3      Triangulation_data_structure;
typedef TriangulationDataStructure_3::Vertex_handle  Vertex_handle;
typedef TriangulationDataStructure_3::Cell_handle    Cell_handle;
```

Creation

In order to obtain new vertices or destruct unused vertices, the user must call the *create_vertex()* and *delete_vertex()* methods of the triangulation data structure.

Operations

Access Functions

<i>Cell_handle</i>	<i>v.cell()</i>	Returns a cell of the triangulation having <i>v</i> as vertex.
<i>Point</i>	<i>v.point()</i>	Returns the point stored in the vertex. <i>Optional for the triangulation data structure alone.</i>

Setting

<i>void</i>	<i>v.set_cell(Cell_handle c)</i>	Sets the incident cell to <i>c</i> .
<i>void</i>	<i>v.set_point(Point p)</i>	Sets the point to <i>p</i> . <i>Optional for the triangulation data structure alone.</i>

Checking

bool *v.is_valid(bool verbose = false)*

Checks the validity of the vertex. Must check that its incident cell has this vertex. The validity of the base vertex is also checked.

When *verbose* is set to *true*, messages are printed to give a precise indication on the kind of invalidity encountered.

See Also

TriangulationDataStructure_3::Cell.

TriangulationDSCellBase_3

Definition

At the base level (see Sections 27.5 and 28.2), a cell stores handles to its four vertices and to its four neighbor cells. The vertices and neighbors are indexed 0, 1, 2 and 3. Neighbor i lies opposite to vertex i .

Since the Triangulation data structure is the class which defines the handle types, the cell base class has to be somehow parameterized by the Triangulation data structure. But since it is itself parameterized by the cell and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for vertex and cell which are given as arguments for the Triangulation data structure use *void* as Triangulation data structure parameter, and the Triangulation data structure then uses a *rebind*-like mechanism (similar to the one specified in *std::allocator*) in order to put itself as parameter to the vertex and cell classes. The *rebound* base classes so obtained are the classes which are used as base classes for the final vertex and cell classes. More information can be found in Section 28.2.

Types

The concept TriangulationDSCellBase_3 has to provide the following types.

TriangulationDSCellBase_3::template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* cell, that is, the one whose *Triangulation_data_structure* will be the actually used one. The *Other* type will be the real base class of *Triangulation_data_structure_3::Cell*.

<i>typedef TriangulationDataStructure_3</i>	<i>Triangulation_data_structure;</i>
<i>typedef TriangulationDataStructure_3::Vertex_handle</i>	<i>Vertex_handle;</i>
<i>typedef TriangulationDataStructure_3::Cell_handle</i>	<i>Cell_handle;</i>

Creation

<i>TriangulationDSCellBase_3 c;</i>	Default constructor
<i>TriangulationDSCellBase_3 c(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3);</i>	

Initializes the vertices with $v0$, $v1$, $v2$, $v3$. Neighbors are initialized to the default constructed handle.

*TriangulationDSCellBase_3 c(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Vertex_handle v3,
Cell_handle n0,
Cell_handle n1,
Cell_handle n2,*

Cell_handle n3)

Initializes the vertices with $v0$, $v1$, $v2$, $v3$ and the neighbors with $n0$, $n1$, $n2$, $n3$.

Access Functions

<i>Vertex_handle</i>	<i>c.vertex(int i)</i>	Returns the vertex i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Vertex_handle v)</i>	Returns the index of v . <i>Precondition:</i> v is a vertex of c
<i>bool</i>	<i>c.has_vertex(Vertex_handle v)</i>	True iff v is a vertex of c .
<i>bool</i>	<i>c.has_vertex(Vertex_handle v, int & i)</i>	Returns <i>true</i> if v is a vertex of c , and computes its index i in c .
<i>Cell_handle</i>	<i>c.neighbor(int i)</i>	Returns the neighbor i of c . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>int</i>	<i>c.index(Cell_handle n)</i>	Returns the index of cell n in c . <i>Precondition:</i> n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n)</i>	Returns <i>true</i> if n is a neighbor of c .
<i>bool</i>	<i>c.has_neighbor(Cell_handle n, int & i)</i>	Returns <i>true</i> if n is a neighbor of c , and computes its index i in c .

Setting

<i>void</i>	<i>c.set_vertex(int i, Vertex_handle v)</i>	Sets vertex i to v . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>void</i>	<i>c.set_vertices()</i>	Sets the vertices to the default constructed handle.
<i>void</i>	<i>c.set_vertices(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3)</i>	Sets the vertices.
<i>void</i>	<i>c.set_neighbor(int i, Cell_handle n)</i>	Sets neighbor i to n . <i>Precondition:</i> $i \in \{0, 1, 2, 3\}$.
<i>void</i>	<i>c.set_neighbors()</i>	Sets the neighbors to the default constructed handle.
<i>void</i>	<i>c.set_neighbors(Cell_handle n0, Cell_handle n1, Cell_handle n2, Cell_handle n3)</i>	Sets the neighbors.

Checking

<i>bool</i>	<i>c.is_valid(bool verbose = false, int level = 0)</i>	Performs any desired geometric test on a cell. When <i>verbose</i> is set to <i>true</i> , messages are printed to give a precise indication of the kind of invalidity encountered. <i>level</i> increases the level of testing.
-------------	---	---

Various

```
void*          c.for_compact_container()
void*&          c.for_compact_container()
```

These member functions are required by *Triangulation_data_structure_3* because it uses *Compact_container* to store its cells. See the documentation of *Compact_container* for the exact requirements.

```
void          c.set_in_conflict_flag( unsigned char f)
unsigned char c.get_in_conflict_flag()
```

These functions are used internally to mark cells with a flag. The user is not encouraged to use them directly as they may change in the future.

I/O

<i>istream&</i>	<i>istream& is >> & c</i>	Inputs the possible non combinatorial information given by the cell.
<i>ostream&</i>	<i>ostream& os << c</i>	Outputs the possible non combinatorial information given by the cell.

Has Models

TriangulationDSVertexBase_3

Definition

At the bottom level of 3D-triangulations (see Sections [27.5](#) and [28.2](#)), a vertex provides access to one of its incident cells through a handle.

Note that when you use the triangulation data structure as parameter of a geometric triangulation, the vertex base class has additional geometric requirements : it has to match the *TriangulationVertexBase_3* concept.

Since the Triangulation data structure is the class which defines the handle types, the vertex base class has to be somehow parameterized by the Triangulation data structure. But since it is itself parameterized by the cell and vertex base classes, there is a cycle in the definition of these classes. In order to break the cycle, the base classes for vertex and cell which are given as arguments for the Triangulation data structure use *void* as Triangulation data structure parameter, and the Triangulation data structure then uses a *rebind*-like mechanism (similar to the one specified in *std::allocator*) in order to put itself as parameter to the vertex and cell classes. The *rebound* base classes so obtained are the classes which are used as base classes for the final vertex and cell classes. More information can be found in Section [28.2](#).

Types

The class *TriangulationDSVertexBase_3* has to define the following types.

TriangulationDSVertexBase_3::template <typename TDS2> struct Rebind_TDS

This nested template class has to define a type *Other* which is the *rebound* vertex, that is, the one whose *Triangulation_data_structure* will be the actually used one. The *Other* type will be the real base class of *Triangulation_data_structure_3::Vertex*.

```
typedef TriangulationDataStructure_3      Triangulation_data_structure;
typedef TriangulationDataStructure_3::Vertex_handle Vertex_handle;
typedef TriangulationDataStructure_3::Cell_handle  Cell_handle;
```

Creation

<i>TriangulationDSVertexBase_3</i> v;	Default constructor.
<i>TriangulationDSVertexBase_3</i> v(<i>Cell_handle</i> c);	Constructs a vertex pointing to cell <i>c</i> .

Operations

Access Functions

<i>Cell_handle</i> v.cell()	Returns the pointer to an incident cell
-----------------------------	---

Setting

void *v.set_cell(Cell_handle c)* Sets the incident cell.

Checking

bool *v.is_valid(bool verbose=false, int level=0)*

Performs any desired test on a vertex. Checks that the pointer to an incident cell is not the default constructed handle.

Various

*void** *v.for_compact_container()*
void&* *v.for_compact_container()*

These member functions are required by *Triangulation_data_structure_3* because it uses *Compact_container* to store its cells. See the documentation of *Compact_container* for the exact requirements.

I/O

istream& *istream& is >> & v* Inputs the non-combinatorial information given by the vertex.

ostream& *ostream& os << v* Outputs the non-combinatorial information given by the vertex.

CGAL::Triangulation_data_structure_3<TriangulationDSVertexBase_3, TriangulationDSCellBase_3>

Definition

The class *Triangulation_data_structure_3* stores a 3D-triangulation data structure and provides the optional geometric functionalities to be used as a parameter for a 3D-geometric triangulation (see Chapter 27).

```
#include <CGAL/Triangulation_data_structure_3.h>
```

Parameters

It is parameterized by base classes for vertices and cells which have to match the requirements for the concepts *TriangulationDSCellBase_3* and *TriangulationDSVertexBase_3* respectively (see page 1929 and page 1932).

They have the default values *Triangulation_ds_vertex_base_3*<> and *Triangulation_ds_cell_base_3*<> respectively.

Definition

The class *Triangulation_utils_3* defines operations on the indices of vertices and neighbors within a cell.

```
#include <CGAL/Triangulation_utils_3.h>
```

Operations

unsigned int *next_around_edge(unsigned int i, unsigned int j)*

In dimension 3, index of the neighbor *n* that is next to the current cell, when turning positively around an oriented edge whose endpoints are indexed *i* and *j*. According to the usual numbering of vertices and neighbors in a given cell, it is also the index of the vertex opposite to this neighbor *n*. (see Figure 28.9).

Precondition: $(i < 4) \ \&\& \ (j < 4) \ \&\& \ (i \neq j)$.

unsigned int *ccw(unsigned int i)*

Has a meaning only in dimension 2.

Computes the index of the vertex that is next to the vertex numbered *i* in counterclockwise direction. (see Figure 28.9).

Precondition: $i < 3$.

unsigned int *cw(unsigned int i)*

Same for clockwise.

Assume we are given a set S of points in 2D or 3D and we'd like to have something like “the shape formed by these points.” This is quite a vague notion and there are probably many possible interpretations, the α -shape being one of them. Alpha shapes can be used for shape reconstruction from a dense unorganized set of data points. Indeed, an α -shape is demarcated by a frontier, which is a linear approximation of the original shape [BB97].

As mentioned in Edelsbrunner’s and Mücke’s paper [EM94], one can intuitively think of an α -shape as the following. Imagine a huge mass of ice-cream making up the space \mathbb{R}^3 and containing the points as “hard” chocolate pieces. Using one of these sphere-formed ice-cream spoons we carve out all parts of the ice-cream block we can reach without bumping into chocolate pieces, thereby even carving out holes in the inside (e.g. parts not reachable by simply moving the spoon from the outside). We will eventually end up with a (not necessarily convex) object bounded by caps, arcs and points. If we now straighten all “round” faces to triangles and line segments, we have an intuitive description of what is called the α -shape of S . Here’s an example for this process in 2D (where our ice-cream spoon is simply a circle):

And what is α in the game? α is the squared radius of the carving spoon. A very small value will allow us to eat up all of the ice-cream except the chocolate points themselves. Thus we already see that the α -shape degenerates to the point-set S for $\alpha \rightarrow 0$. On the other hand, a huge value of α will prevent us even from moving the spoon between two points since it’s way too large. So we will never spoon up ice-cream lying in the inside of the convex hull of S , and hence the α -shape for $\alpha \rightarrow \infty$ is the convex hull of S .¹

29.1 Definitions

We distinguish two versions of alpha shapes. *Basic alpha shapes* are based on the Delaunay triangulation. *Weighted alpha shapes* are based on its generalization, the regular triangulation, replacing the euclidean distance by the power to weighted points.

There is a close connection between alpha shapes and the underlying triangulations. More precisely, the α -complex of S is a subcomplex of this triangulation of S , containing the α -exposed k -simplices, $0 \leq k \leq d$. A simplex is α -exposed, if there is an open disk (resp. ball) of radius $\sqrt{\alpha}$ through the vertices of the simplex that does not contain any other point of S , for the metric used in the computation of the underlying triangulation. The corresponding α -shape is defined as the underlying interior space of the α -complex (see [EM94]).

In general, an α -complex is a non-connected and non-pure polytope, it means, that one k -simplex, $0 \leq k \leq d - 1$ is not necessary adjacent to a $(k + 1)$ -simplex.

The α -shapes of S form a discrete family, even though they are defined for all real numbers α with $0 \leq \alpha \leq \infty$. Thus, we can represent the entire family of α -shapes of S by the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the α -shape. Relying on this fact, the family of α -shapes can be computed efficiently and relatively easily. Furthermore, we can select an appropriate α -shape from a finite number of different α -shapes and corresponding α -values.

29.2 Functionality

The class `CGAL::Alpha_shape_2<Dt>` represents the family of α -shapes of points in a plane for *all* positive α . It maintains the underlying triangulation Dt which represents connectivity and order among squared radius of its faces. Each k -dimensional face of the Dt is associated with an interval that specifies for which values of α the face belongs to the α -shape. There are links between the intervals and the k -dimensional faces of the triangulation.

The class `CGAL::Alpha_shape_2<Dt>` provides functions to set and get the current α -value, as well as an iterator that enumerates the α -values where the α -shape changes.

¹ice cream, ice cream!!! The wording of this introductory paragraphs is borrowed from Kaspar Fischer’s “Introduction to Alpha Shapes” which can be found at <http://n.ethz.ch/student/fischerk/alphashapes/as/index.html>. The picture has been taken from Walter Luh’s homepage at <http://www.stanford.edu/~wluh/cs448b/alphashapes.html>.

It provides iterators to enumerate the vertices and edges that are in the α -shape, and functions that allow to classify vertices, edges and faces with respect to the α -shape. They can be in the interior of a face that belongs or does not belong to the α -shape. They can be singular/regular, that is be on the boundary of the α -shape, but not incident/incident to a triangle of the α -complex.

Finally, it provides a function to determine the α -value such that the α -shape satisfies the following two properties, or at least the second one if there is no such α that both are satisfied:

- (i) The number of components equals a number of your choice and
- (ii) all data points are either on the boundary or in the interior of the regularized version of the α -shape (no singular edges).

The current implementation is static, that is after its construction points cannot be inserted or removed.

29.3 Concepts and Models

We currently do not specify concepts for the underlying triangulation type. Models that work for a basic alpha-shape are the classes *CGAL::Delaunay_triangulation_2* and *CGAL::Triangulation_hierarchy_2* templated with a Delaunay triangulation. A model that works for a weighted alpha-shape is the class *CGAL::Regular_triangulation_2*.

The triangulation needs a geometric traits class as argument. The requirements of this class are described in the concept *CGAL::AlphaShapeTraits_2* for which the CGAL kernels and *CGAL::Weighted_alpha_shape_euclidean_traits_2* are models.

There are no requirements on the triangulation data structure. However it must be parameterized with vertex and face classes, which are model of the concepts *AlphaShapeVertex_2* and *AlphaShapeFace_2*, by default the classes *CGAL::Alpha_shape_vertex_base_2<Gt>* and *CGAL::Alpha_shape_face_base_2<Tf>*.

29.4 Examples

29.4.1 Example for Basic Alpha-Shapes

The basic alpha shape needs a Delaunay triangulation as underlying triangulation *Dt*. The Delaunay triangulation class is parameterized with a geometric and a triangulation data structure traits.

For the geometric traits class we can use a CGAL kernel.

For the triangulation data structure traits, we have to choose the vertex and face classes needed for alpha shapes, namely *CGAL::Alpha_shape_vertex_base_2<Gt, Dv>* and *CGAL::Alpha_shape_face_base_2<Gt, Df>*. As default vertex and face type they use *CGAL::Triangulation_vertex_base_2<Gt>* and *CGAL::Triangulation_face_base_2<Gt>* respectively.

The following code snippet shows how to obtain a basic alpha shape type.

```
typedef CGAL::Cartesian<double> K;

typedef CGAL::Alpha_shape_vertex_base_2<K> Av;
```

```

typedef CGAL::Triangulation_face_base_2<K> Tf;
typedef CGAL::Alpha_shape_face_base_2<K,Tf> Af;

typedef CGAL::Triangulation_default_data_structure_2<K,Av,Af> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Alpha_shape_2<Dt> Alpha_shape_2;

```

29.4.2 Example for Basic Alpha-Shapes with Many Points

When the input data set is huge, say more than 10.000 points, it pays off to use a triangulation hierarchy. It has the same API as the Delaunay triangulation and differs only in the types of the vertices and faces. Therefore, the only part that changes are the typedefs in the beginning.

```

typedef CGAL::Cartesian<double> K;

typedef CGAL::Alpha_shape_vertex_base_2<K> Avb;
typedef CGAL::Triangulation_hierarchy_vertex_base_2<Avb> Av;

typedef CGAL::Triangulation_face_base_2<K> Tf;
typedef CGAL::Alpha_shape_face_base_2<K,Tf> Af;

typedef CGAL::Triangulation_default_data_structure_2<K,Av,Af> Tds;
typedef CGAL::Delaunay_triangulation_2<K,Tds> Dt;
typedef CGAL::Triangulation_hierarchy_2<Dt> Ht;
typedef CGAL::Alpha_shape_2<Ht> Alpha_shape_2;

```

29.4.3 Example for Weighted Alpha-Shapes

A weighted alpha shape, needs a regular triangulation as underlying triangulation *Dt*, and it needs a particular face class, namely *CGAL::Regular_triangulation_face_base_2<Gt>*. Note that there is no special weighted alpha shape class.

```

typedef CGAL::Cartesian<double> K;
typedef CGAL::Weighted_alpha_shape_euclidean_traits_2<K> Gt;

typedef CGAL::Alpha_shape_vertex_base_2<Gt> Av;

typedef CGAL::Regular_triangulation_face_base_2<Gt> Rf;
typedef CGAL::Alpha_shape_face_base_2<Gt,Rf> Af;

typedef CGAL::Triangulation_default_data_structure_2<Gt,Av,Af> Tds;
typedef CGAL::Regular_triangulation_2<Gt,Tds> Rt;
typedef CGAL::Alpha_shape_2<Rt> Alpha_shape_2;

```

2D Alpha Shapes

Reference Manual

Tran Kai Frank Da

This chapter presents a framework for alpha shapes. The description is based on the articles [EM94, Ede92]. Alpha shapes are the generalization of the convex hull of a point set. Let S be a finite set of points in \mathbb{R}^d , $d = 2, 3$ and α a parameter with $0 \leq \alpha \leq \infty$. For $\alpha = \infty$, the α -shape is the convex hull of S . As α decreases, the α -shape shrinks and develops cavities, as soon as a sphere of radius $\sqrt{\alpha}$ can be put inside. Finally, for $\alpha = 0$, the α -shape is the set S itself.

We distinguish two versions of alpha shapes, one is based on the Delaunay triangulation and the other on its generalization, the regular triangulation, replacing the natural distance by the power to weighted points. The metric used determines an underlying triangulation of the alpha shape and thus, the version computed. The *basic alpha shape* (cf. 29.4.1) is associated with the Delaunay triangulation (cf. 25.5). The *weighted alpha shape* (cf. 29.4.3) is associated with the regular triangulation (cf. 25.6).

There is a close connection between alpha shapes and the underlying triangulations. More precisely, the α -complex of S is a subcomplex of this triangulation of S , containing the α -exposed k -simplices, $0 \leq k \leq d$. A simplex is α -exposed, if there is an open disk (resp. ball) of radius $\sqrt{\alpha}$ through the vertices of the simplex that does not contain any other point of S , for the metric used in the computation of the underlying triangulation. The corresponding α -shape is defined as the underlying interior space of the α -complex.

In general, an α -complex is a non-connected and non-pure polytope, it means, that one k -simplex, $0 \leq k \leq d - 1$ is not necessary adjacent to a $(k + 1)$ -simplex.

The α -shapes of S form a discrete family, even though they are defined for all real numbers α with $0 \leq \alpha \leq \infty$. Thus, we can represent the entire family of α -shapes of S by the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the α -shape. Relying on this result, the family of α -shapes can be computed efficiently and relatively easily. Furthermore, we can select an appropriate α -shape from a finite number of different α -shapes and corresponding α -values.

CGAL::Alpha_shape_2<Dt>

Definition

The class *Alpha_shape_2<Dt>* represents the family of α -shapes of points in a plane for *all* positive α . It maintains the underlying triangulation *Dt* which represents connectivity and order among its faces. Each *k*-dimensional face of the *Dt* is associated with an interval that specifies for which values of α the face belongs to the α -shape. There are links between the intervals and the *k*-dimensional faces of the triangulation.

Note that this class is at the same time used for *basic* and for *weighted* Alpha Shapes.

Inherits From

Dt

This class is the underlying triangulation class.

The modifying functions *insert* and *remove* will overwrite the inherited functions. At the moment, only the static version is implemented.

Types

Alpha_shape_2<Dt>:: Gt the alpha shape traits type.

it has to derive from a triangulation traits class. For example *Dt::Point* is a Point class.

typedef Gt::FT

FT; the number type for computation.

Alpha_shape_2<Dt>:: Alpha_iterator

A bidirectional and non-mutable iterator that allow to traverse the increasing sequence of different α -values.

Precondition: Its *value_type* is *FT*

Alpha_shape_2<Dt>:: Alpha_shape_vertices_iterator

A bidirectional and non-mutable iterator that allow to traverse the vertices which belongs to the α -shape for the current α .

Precondition: Its *value_type* is *Dt::Vertex_handle*

Alpha_shape_2<Dt>:: Alpha_shape_edges_iterator

A bidirectional and non-mutable iterator that allow to traverse the edges which belongs to the α -shape for the current α .

Precondition: Its *value_type* is *Dt::Edge*.

enum Classification_type { EXTERIOR, SINGULAR, REGULAR, INTERIOR};

Distinguishes the different cases for classifying a k -dimensional face of the underlying triangulation of the α -shape.

EXTERIOR if the face does not belong to the α -complex.

SINGULAR if the face belongs to the boundary of the α -shape, but is not incident to any 2-dimensional face of the α -complex

REGULAR if the face belongs to the boundary of the α -shape and is incident to a 2-dimensional face of the α -complex

INTERIOR if the face belongs to the α -complex, but does not belong to the boundary of the α -shape.

enum Mode { GENERAL, REGULARIZED};

In general, an alpha shape can be disconnected and contain many singular edges or vertices. Its regularized version is formed by the set of regular edges and their vertices.

Creation

Alpha_shape_2<Dt> A(FT alpha = 0, Mode m = GENERAL);

Introduces an empty α -shape A for a positive α -value $alpha$.

Precondition: $alpha \geq 0$.

template < class InputIterator >

Alpha_shape_2<Dt> A(InputIterator first, InputIterator last, FT alpha = 0, Mode m = GENERAL);

Initializes the family of alpha-shapes with the points in the range $[first, last)$ and introduces an α -shape A for a positive α -value $alpha$.

Precondition: The *value_type* of *first* and *last* is *Point*.
 $alpha \geq 0$.

Operations

template < class InputIterator >

int A.make_alpha_shape(InputIterator first, InputIterator last)

Initialize the family of alpha-shapes with the points in the range $[first, last)$. Returns the number of inserted points.

If the function is applied to a non-empty family of alpha-shape, it is cleared before initialization.

Precondition: The *value_type* of *first* and *last* is *Point*.

void A.clear() Clears the structure.

<i>FT</i>	<i>A.set_alpha(FT alpha)</i>	Sets the α -value to <i>alpha</i> . Returns the previous α -value. <i>Precondition: alpha \geq 0.</i>
<i>FT</i>	<i>A.get_alpha(void)</i>	Returns the current α -value.
<i>FT</i>	<i>A.get_nth_alpha(int n)</i>	Returns the <i>n</i> -th alpha-value, sorted in an increasing order. <i>Precondition: n < number of alphas.</i>
<i>int</i>	<i>A.number_of_alphas()</i>	Returns the number of different alpha-values.
<i>Mode</i>	<i>A.set_mode(Mode m = GENERAL)</i>	Sets <i>A</i> to its general or regularized version. Returns the previous mode.
<i>Mode</i>	<i>A.get_mode(void)</i>	Returns whether <i>A</i> is general or regularized.
<i>Alpha_shape_vertices_iterator</i>		
	<i>A.alpha_shape_vertices_begin()</i>	Starts at an arbitrary finite vertex which belongs to the α -shape for the current α .
<i>Alpha_shape_vertices_iterator</i>		
	<i>A.alpha_shape_vertices_end()</i>	Past-the-end iterator.
<i>Alpha_shape_edges_iterator</i>		
	<i>A.alpha_shape_edges_begin()</i>	Starts at an arbitrary finite edge which belongs to the α -shape for the current α . In regularized mode, edges are represented as a pair (f,i), where f is an interior face of the α -shape.
<i>Alpha_shape_edges_iterator</i>		
	<i>A.alpha_shape_edges_end()</i>	Past-the-end iterator.

Predicates

Classification_type

A.classify(Point p, FT alpha = get_alpha())

Locates a point p in the underlying triangulation and Classifies the associated k -face with respect to A .

Classification_type

A.classify(Face_handle f, FT alpha = get_alpha())

Classifies the face f of the underlying triangulation with respect to A .

Classification_type

A.classify(Edge e, FT alpha = get_alpha())

Classifies the edge e of the underlying triangulation with respect to A .

Classification_type

A.classify(Face_handle f, int i, FT alpha = get_alpha())

Classifies the edge of the face f opposite to the vertex with index i of the underlying triangulation with respect to A .

Classification_type

A.classify(Vertex_handle v, FT alpha = get_alpha())

Classifies the vertex v of the underlying triangulation with respect to A .

Traversal of the α -Values

Alpha_iterator

A.alpha_begin() Returns an iterator that allows to traverse the sorted sequence of α -values of the family of alpha shapes.

Alpha_iterator

A.alpha_end() Returns the corresponding past-the-end iterator.

Alpha_iterator

A.alpha_find(FT alpha)

Returns an iterator pointing to an element with α -value $alpha$, or the corresponding past-the-end iterator if such an element is not found.

Alpha_iterator

A.alpha_lower_bound(FT alpha)

Returns an iterator pointing to the first element with α -value not less than *alpha*.

Alpha_iterator

A.alpha_upper_bound(FT alpha)

Returns an iterator pointing to the first element with α -value greater than *alpha*.

Operations

int

A.number_of_solid_components(FT alpha = get_alpha())

Returns the number of solid components of *A*, that is, the number of components of its regularized version.

Alpha_iterator

A.find_optimal_alpha(int nb_components)

Returns an iterator pointing to the first element with α -value such that *A* satisfies the following two properties:

nb_components equals the number of solid components and all data points are either on the boundary or in the interior of the regularized version of *A*.

If no such value is found, the iterator points to the first element with α -value such that *A* satisfies the second property.

I/O

The I/O operators are defined for *iostream*. The format for the *iostream* is an internal format.

#include <CGAL/IO/io.h>

ostream&

ostream& os << A

Inserts the alpha shape *A* for the current α -value into the stream *os*.

Precondition: The insert operator must be defined for *Point*.

Implementation

The set of intervals associated with the *k*-dimensional faces of the underlying triangulation are stored in *multimaps*.

The cross links between the intervals and the *k*-dimensional faces of the triangulation are realized using methods in the *k*-dimensional faces themselves.

A.alpha find uses linear search, while *A.alpha lower bound* and *A.alpha upper bound* use binary search. *A.number of solid components* performs a graph traversal and takes time linear in the number of faces of the underlying triangulation. *A.find optimal alpha* uses binary search and takes time $O(n \log n)$, where n is the number of points.

AlphaShapeFace_2

Definition

Refines

TriangulationFaceBase_2.

Types

AlphaShapeFace_2:: Interval_3

A container type to get (and put) the three special values $(\alpha_1, \alpha_2, \alpha_3)$ associated with an alpha shape edge.

AlphaShapeFace_2:: FT

A type to hold a coordinate type class. The type must provide a copy constructor, assignment, comparison operators, negation, multiplication, division and allow the declaration and initialization with a small integer constant (cf. requirements for number types). An obvious choice would be coordinate type of the point class

Creation

advanced

AlphaShapeFace_2 f;

default constructor.

AlphaShapeFace_2 f(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2);

constructor setting the incident vertices.

*AlphaShapeFace_2 f(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Face_handle n0,
Face_handle n1,
Face_handle n2)*

constructor setting the incident vertices and the neighboring faces.

advanced

Access Functions

Interval_3 f.get_ranges(int i)

returns the interval associated with the edge indexed with i , which contains three alpha values $\alpha_1 \leq \alpha_2 \leq \alpha_3$, such as for α between α_1 and α_2 , the edge indexed with i is attached but singular, for α between α_2 and α_3 , the edge is regular, and for α greater than α_3 , the edge is interior.

<i>FT</i>	<i>f.get_alpha()</i>	return the alpha value, under which the alpha shape contains the face.

AlphaShapeTraits_2

Definition

A model of the concept AlphaShapeTraits_2 must provide the following predicate and operations in addition to the requirements for the underlying triangulation traits class. It means, the metric has to be euclidean for Delaunay triangulation or the power metric for regular triangulation.

Refines

TriangulationTraits_2

Types

AlphaShapeTraits_2::FT

A type to hold a coordinate type class. The type must provide a copy constructor, assignment, comparison operators, negation, multiplication, division and allow the declaration and initialization with a small integer constant (cf. requirements for number types).

Precondition: An obvious choice would be coordinate type of the point class.

Creation

Only a default constructor is required. Note that further constructors can be provided.

AlphaShapeTraits_2 t;

A default constructor.

Constructions by function objects

Compute_squared_radius_2

t.compute_squared_radius_2_object()

Returns an object, which has to be able to compute the squared radius of the circle of the points p_0 , p_1 , p_2 or the squared radius of smallest circle of the points p_0 , p_1 , as *FT* associated with *the metric used by Dt*.

Predicate by function object

Side_of_bounded_circle_2

t.side_of_bounded_circle_2_object()

Returns an object, which has to be able to compute the relative position of point *test* to the smallest circle of the points p_0 , p_1 , using *the same metric as Dt*.

CGAL::Weighted_alpha_shape_euclidean_traits_2<K>

Definition

The class *Weighted_alpha_shape_euclidean_traits_2<K>* is the default model for the concept *AlphaShapeTraits_2* for the regular version of Alpha Shapes. *K* must be a kernel.

Assume we are given a set S of points in 2D or 3D and we'd like to have something like “the shape formed by these points.” This is quite a vague notion and there are probably many possible interpretations, the alpha shape being one of them. Alpha shapes can be used for shape reconstruction from a dense unorganized set of data points. Indeed, an alpha shape is demarcated by a frontier, which is a linear approximation of the original shape [BB97].

As mentioned in Edelsbrunner's and Mücke's paper [EM94], one can intuitively think of an alpha shape as the following. Imagine a huge mass of ice-cream making up the space \mathbb{R}^3 and containing the points as “hard” chocolate pieces. Using one of those sphere-formed ice-cream spoons we carve out all parts of the ice-cream block we can reach without bumping into chocolate pieces, thereby even carving out holes in the inside (e.g. parts not reachable by simply moving the spoon from the outside). We will eventually end up with a (not necessarily convex) object bounded by caps, arcs and points. If we now straighten all “round” faces to triangles and line segments, we have an intuitive description of what is called the alpha shape of S . Here's an example for this process in 2D (where our ice-cream spoon is simply a circle):

Alpha shapes depend on a parameter α from which they are named. What is α in the ice-cream game? α is the squared radius of the carving spoon. A very small value will allow us to eat up all of the ice-cream except the chocolate points themselves. Thus we already see that the alpha shape degenerates to the point-set S for $\alpha \rightarrow 0$. On the other hand, a huge value of α will prevent us even from moving the spoon between two points since it's way too large. So we will never spoon up ice-cream lying in the inside of the convex hull of S , and hence the alpha shape for $\alpha \rightarrow \infty$ is the convex hull of S .¹

30.1 Definitions

More precisely, the definition of alpha shapes is based on an underlying triangulation that may be a Delaunay triangulation in case of basic alpha shapes or a regular triangulation (cf. 27.3) in case of weighted alpha shapes.

Let us consider the basic case with a Delaunay triangulation. We first define the alpha complex of the set of points S . The alpha complex is a subcomplex of the Delaunay triangulation. For a given value of α , the alpha complex includes all the simplices in the Delaunay triangulation which have an empty circumsphere with squared radius equal or smaller than α . Here “empty” means that the open sphere does not include any points of S . The alpha shape is then simply the domain covered by the simplices of the alpha complex (see [EM94]).

In general, an alpha complex is a non-connected and non-pure complex. This means in particular that the alpha complex may have singular faces. For $0 \leq k \leq d - 1$, a k -simplex of the alpha complex is said to be singular if it is not a facet of a $(k + 1)$ -simplex of the complex. CGAL provides two versions of the alpha shapes. In the general mode, the alpha shapes correspond strictly to the above definition. The regularized mode provides a regularized version of the alpha shapes corresponding to the domain covered by a regularized version of the alpha complex where singular faces are removed.

The alpha shapes of a set of points S form a discrete family, even though they are defined for all real numbers α . The entire family of alpha shapes can be represented through the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the alpha complex. Relying on this fact, the family of alpha shapes can be computed efficiently and relatively easily. Furthermore, we can select the optimal value of α to get an alpha shape including all data points and having less than a given number of connected components. Also, the alpha-values allow to define a filtration on the faces of the triangulation of a set of points. In this filtration, the faces of the triangulation are output in increasing order of the alpha value for which they appear in the alpha complex. In case of equal alpha value lower dimensional faces are output first.

¹ice cream, ice cream!!! The wording of this introductory paragraph is borrowed from Kaspar Fischer's “Introduction to Alpha Shapes” which can be found at <http://n.ethz.ch/student/fischerk/alphashapes/as/index.html>. The picture has been taken from Walter Luh's homepage at <http://www.stanford.edu/~luh/cs448b/alphashapes.html>.

The definition is analog in the case of weighted alpha shapes. The input set is now a set of weighted points (which can be regarded as spheres) and the underlying triangulation is the regular triangulation of this set. Two spheres, or two weighted points, with centers C_1, C_2 and radii r_1, r_2 are said to be orthogonal iff $C_1 C_2^2 = r_1^2 + r_2^2$ and suborthogonal iff $C_1 C_2^2 < r_1^2 + r_2^2$. For a given value of α the weighted alpha complex is formed with the simplices of the regular triangulation such that there is a sphere orthogonal to the weighted points associated with the vertices of the simplex and suborthogonal to all the other input weighted points. Once again the alpha shape is then defined as the domain covered by the alpha complex and arise in two versions general or regularized.

30.2 Functionality

The class `CGAL::Alpha_shape_3<Dt>` represents the whole family of alpha shapes for a given set of points. The class includes the underlying triangulation Dt of the set, and associates to each k -face of this triangulation an interval specifying for which values of α the face belongs to the alpha complex.

The class `CGAL::Alpha_shape_3<Dt>` provides functions to set and get the current α -value, as well as an iterator that enumerates the α values where the alpha shape changes.

The class provides member functions to classify for a given value of *alpha* the different faces of the triangulation as *EXTERIOR*, *SINGULAR*, *REGULAR* or *INTERIOR* with respect to the alpha shape. A k face on the boundary of the alpha complex is said to be *REGULAR* if it is a subface of the alpha complex which is a subface of some $k + 1$ face of the alpha complex and *SINGULAR* otherwise.

The class provides also output iterators to get for a given *alpha* value the vertices, edges, facets and cells of the different types (*EXTERIOR*, *SINGULAR*, *REGULAR* or *INTERIOR*).

Also the class has a filtration member function that, given an output iterator with `CGAL::object` as value type, outputs the faces of the triangulation according to the order of apparition in the alpha complex when alpha increases.

Finally, it provides a function to determine the smallest value α such that the alpha shape satisfies the following two properties

- (ii) all data points are either on the boundary or in the interior of the regularized version of the alpha shape (no singular faces).
- (i) The number of components is equal or less than a given number .

The current implementation is static, that is after its construction points cannot be inserted or removed.

30.3 Concepts and Models

We currently do not specify concepts for the underlying triangulation type. Models that work for a basic alpha-shape are the classes `CGAL::Delaunay_triangulation_3` and `CGAL::Triangulation_hierarchy_3` templated with a Delaunay triangulation. A model that works for a weighted alpha-shape is the class `CGAL::Regular_triangulation_3`.

The triangulation needs a geometric traits class as argument. The requirements of this class are described in the concept `CGAL::AlphaShapeTraits_3` for which the CGAL kernels are models in the non-weighted case, and for which the class `CGAL::Weighted_alpha_shape_euclidean_traits_3` is model in the weighted case.

The triangulation data structure of the triangulation with any has to be a model of the concept `CGAL::TriangulationDataStructure_3`. However it must be parameterized with vertex and cell classes, which

are model of the concepts *AlphaShapeVertex_3* and *AlphaShapeCell_3*. The package provides by default the classes *CGAL::Alpha_shape_vertex_base_3<Gt>* and *CGAL::Alpha_shape_cell_base_3<Gt>*.

30.4 Examples

30.4.1 Example for Basic Alpha-Shapes

This example builds a basic alpha shape using a Delaunay triangulation as underlying triangulation.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <fstream>
#include <list>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Alpha_shape_vertex_base_3<K>          Vb;
typedef CGAL::Alpha_shape_cell_base_3<K>           Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb> Tds;
typedef CGAL::Delaunay_triangulation_3<K,Tds>      Triangulation_3;
typedef CGAL::Alpha_shape_3<Triangulation_3>       Alpha_shape_3;

typedef K::Point_3 Point;
typedef Alpha_shape_3::Alpha_iterator Alpha_iterator;

int main()
{
    std::list<Point> lp;

    //read input
    std::ifstream is("./data/bunny_1000");
    int n;
    is >> n;
    std::cout << "Reading " << n << " points " << std::endl;
    Point p;
    for( ; n>0 ; n--) {
        is >> p;
        lp.push_back(p);
    }

    // compute alpha shape
    Alpha_shape_3 as(lp.begin(),lp.end());
    std::cout << "Alpha shape computed in REGULARIZED mode by default"
        << std::endl;

    // find optimal alpha value
    Alpha_iterator opt = as.find_optimal_alpha(1);
    std::cout << "Optimal alpha value to get one connected component is "
        << *opt << std::endl;
}
```

```

as.set_alpha(*opt);
assert(as.number_of_solid_components() == 1);
return 0;
}

```

File: examples/Alpha_shapes_3/alpha_shapes_3.cpp

30.4.2 Building Basic Alpha Shapes for Many Points

When many points are input in the alpha shape, say more than 10 000, it pays off to use a triangulation hierarchy as underlying triangulation (cf. [27.4](#)).

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_3.h>
#include <CGAL/Triangulation_hierarchy_3.h>
#include <CGAL/Alpha_shape_3.h>

#include <fstream>
#include <list>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Alpha_shape_vertex_base_3<K>          Vb;
typedef CGAL::Triangulation_hierarchy_vertex_base_3<Vb> Vbh;
typedef CGAL::Alpha_shape_cell_base_3<K>           Fb;
typedef CGAL::Triangulation_data_structure_3<Vbh,Fb> Tds;
typedef CGAL::Delaunay_triangulation_3<K,Tds>      Delaunay;
typedef CGAL::Triangulation_hierarchy_3<Delaunay>   Delaunay_hierarchy;
typedef CGAL::Alpha_shape_3<Delaunay_hierarchy>     Alpha_shape_3;

typedef K::Point_3 Point;
typedef Alpha_shape_3::Alpha_iterator Alpha_iterator;
typedef Alpha_shape_3::NT NT;

int main()
{
    Delaunay_hierarchy dt;
    std::ifstream is("../data/bunny_1000");
    int n;
    is >> n;
    Point p;
    std::cout << n << " points read" << std::endl;
    for( ; n>0 ; n--) {
        is >> p;
        dt.insert(p);
    }
    std::cout << "Delaunay computed." << std::endl;

    // compute alpha shape
    Alpha_shape_3 as(dt);
    std::cout << "Alpha shape computed in REGULARIZED mode by default."

```

```

    << std::endl;

    // find optimal alpha values
    Alpha_shape_3::NT alpha_solid = as.find_alpha_solid();
    Alpha_iterator opt = as.find_optimal_alpha(1);
    std::cout << "Smallest alpha value to get a solid through data points is "
    << alpha_solid << std::endl;
    std::cout << "Optimal alpha value to get one connected component is "
    << *opt << std::endl;
    as.set_alpha(*opt);
    assert(as.number_of_solid_components() == 1);
    return 0;
}

```

File: examples/Alpha_shapes_3/alpha_shapes_with_hierarchy_3.cpp

30.4.3 Example for Weighted Alpha-Shapes

The following examples build a weighted alpha shape requiring a regular triangulation as underlying triangulation. The alpha shape is build in *GENERAL* mode.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Weighted_alpha_shape_euclidean_traits_3.h>
#include <CGAL/Regular_triangulation_3.h>
#include <CGAL/Alpha_shape_3.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Weighted_alpha_shape_euclidean_traits_3<K> Gt;

typedef CGAL::Alpha_shape_vertex_base_3<Gt> Vb;
typedef CGAL::Alpha_shape_cell_base_3<Gt> Fb;
typedef CGAL::Triangulation_data_structure_3<Vb,Fb> Tds;
typedef CGAL::Regular_triangulation_3<Gt,Tds> Triangulation_3;
typedef CGAL::Alpha_shape_3<Triangulation_3> Alpha_shape_3;

typedef Alpha_shape_3::Cell_handle Cell_handle;
typedef Alpha_shape_3::Vertex_handle Vertex_handle;
typedef Alpha_shape_3::Facet Facet;
typedef Alpha_shape_3::Edge Edge;
typedef Gt::Weighted_point Weighted_point;
typedef Gt::Bare_point Bare_point;

int main()
{
    std::list<Weighted_point> lwp;

    //input : a small molecule
    lwp.push_back(Weighted_point(Bare_point( 1, -1, -1), 4));
    lwp.push_back(Weighted_point(Bare_point(-1, 1, -1), 4));

```

```

lwp.push_back(Weighted_point(Bare_point(-1, -1, 1), 4));
lwp.push_back(Weighted_point(Bare_point( 1, 1, 1), 4));
lwp.push_back(Weighted_point(Bare_point( 2, 2, 2), 1));

//build alpha_shape in GENERAL mode and set alpha=0
Alpha_shape_3 as(lwp.begin(), lwp.end(), 0, Alpha_shape_3::GENERAL);

//explore the 0-shape - It is dual to the boundary of the union.
std::list<Cell_handle> cells;
std::list<Facet> facets;
std::list<Edge> edges;
as.get_alpha_shape_cells(std::back_inserter(cells),
    Alpha_shape_3::INTERIOR);
as.get_alpha_shape_facets(std::back_inserter(facets),
    Alpha_shape_3::REGULAR);
as.get_alpha_shape_facets(std::back_inserter(facets),
    Alpha_shape_3::SINGULAR);
as.get_alpha_shape_edges(std::back_inserter(edges),
    Alpha_shape_3::SINGULAR);
std::cout << " The 0-shape has : " << std::endl;
std::cout << cells.size() << " interior tetrahedra" << std::endl;
std::cout << facets.size() << " boundary facets" << std::endl;
std::cout << edges.size() << " singular edges" << std::endl;
return 0;
}

```

3D Alpha Shapes

Reference Manual

Tran Kai Frank Da and Mariette Yvinec

Alpha shapes definition is based on an underlying triangulation that may be a Delaunay triangulation in case of basic alpha shapes or a regular triangulation (cf. [27.3](#)) in case of weighted alpha shapes.

Let us consider the basic case with a Delaunay triangulation. We first define the alpha complex of the set of points S . The alpha complex is a subcomplex of the Delaunay triangulation. For a given value of α , the alpha complex includes all the simplices in the Delaunay triangulation which have an empty circumsphere with squared radius equal or smaller than α . Here “empty” means that the open sphere do not include any points of S . The alpha shape is then simply the domain covered by the simplices of the alpha complex (see [\[EM94\]](#)).

In general, an alpha complex is a non-connected and non-pure complex. This means in particular that the alpha complex may have singular faces. For $0 \leq k \leq d - 1$, a k -simplex of the alpha complex is said to be singular if it is not a facet of a $(k + 1)$ -simplex of the complex. CGAL provides two versions of the alpha shapes. In the general mode, the alpha shapes correspond strictly to the above definition. The regularized mode provides a regularized version of the alpha shapes corresponding to the domain covered by a regularized version of the alpha complex where singular faces are removed.

The alpha shapes of a set of points S form a discrete family, even though they are defined for all real numbers α . The entire family of alpha shapes can be represented through the underlying triangulation of S . In this representation each k -simplex of the underlying triangulation is associated with an interval that specifies for which values of α the k -simplex belongs to the alpha complex. Relying on this fact, the family of alpha shapes can be computed efficiently and relatively easily. Furthermore, we can select the optimal value of α to get an alpha shape including all data points and having less than a given number of connected components.

The definition is analog in the case of weighted alpha shapes. The input set is now a set of weighted points (which can be regarded as spheres) and the underlying triangulation is the regular triangulation of this set. Two spheres, or two weighted points, with centers C_1, C_2 and radii r_1, r_2 are said to be orthogonal iff $C_1 C_2^2 = r_1^2 + r_2^2$ and suborthogonal iff $C_1 C_2^2 < r_1^2 + r_2^2$. For a given value of α the weighted alpha complex is formed with the simplices of the regular triangulation such that there is a sphere orthogonal to the weighted points associated with the vertices of the simplex and suborthogonal to all the other input weighted points. Once again the alpha shape is then defined as the domain covered by the alpha complex and arise in two versions general or regularized.

AlphaShapeCell_3

Definition

This concept describes the requirements for the base cell of an alpha shape.

Refines

TriangulationCellBase_3.

AlphaShapeCell_3:: NT A number type. Must be the same as the number type used in the traits class of the triangulation underlying the alpha shape.

AlphaShapeCell_3:: Alpha_status_iterator An iterator with value type *CGAL::Alpha_status<NT>*.

Creation

AlphaShapeCell_3 f; default constructor.

AlphaShapeCell_3 f(Vertex_handle v0, Vertex_handle v1, Vertex_handle v2, Vertex_handle v3);

constructor setting the incident vertices.

*AlphaShapeCell_3 f(Vertex_handle v0,
Vertex_handle v1,
Vertex_handle v2,
Vertex_handle v3,
Cell_handle n0,
Cell_handle n1,
Cell_handle n2,
Cell_handle n3)*

constructor setting the incident vertices and the neighboring cells.

Access Functions

NT *f.get_alpha()* Returns the alpha value of the cell.

Alpha_status_iterator

f.get_facet_status(int i)

Returns an iterator on the *CGAL::Alpha_status<NT>* of the facet *i* of the cell.

Modifiers

void *f.set_alpha(NT alpha)*

Sets the critical value of the cell.

void *f.set_facet_status(int i, Alpha_status_iterator as)*

Sets the iterator pointing to the *CGAL::Alpha_status<NT>* of the facet *i* of the cell.

AlphaShapeTraits_3

Definition

The concept AlphaShapeTraits_3 describes the requirements for the geometric traits class of the underlying Delaunay triangulation of a basic alpha shape.

Generalizes

DelaunayTriangulationTraits_3

In addition to the requirements described in the concept *DelaunayTriangulationTraits_3*, the geometric traits class of a Delaunay triangulation plugged in a basic alpha shapes provides the following.

Types

AlphaShapeTraits_3::NT A number type compatible with the type used for the points coordinate.

AlphaShapeTraits_3::Compute_squared_radius_3

An object constructor able to compute the squared radius of the smallest circumsphere of 4 points p_0, p_1, p_2, p_3 , the squared radius of the smallest circumsphere of 3 points p_0, p_1, p_2 , and the squared radius of smallest circumsphere of the points p_0, p_1 .

Creation

AlphaShapeTraits_3 traits; Default constructor.

Access Functions

Compute_squared_radius_3 *traits.compute_squared_radius_3_object()*

Has Models

All CGAL kernels.

CGAL::Exact_predicates_inexact_constructions_kernel (recommended)

CGAL::Exact_predicates_exact_constructions_kernel

CGAL::Filtered_kernel

CGAL::Cartesian

CGAL::Simple_cartesian

CGAL::Homogeneous

AlphaShapeVertex_3

Definition

This concept describe the requirements for the base vertex of an alpha shape.

Refines

TriangulationVertexBase_3.

Types

AlphaShapeVertex_3:: Point

Must be the same as the point type provided by the geometric traits class of the triangulation.

AlphaShapeVertex_3:: Alpha_status

Must be *CGAL::Alpha_status<NT>* where *NT* is the number type used in the geometric traits class of the triangulation.

Creation

AlphaShapeVertex_3 v;

default constructor.

AlphaShapeVertex_3 v(Point p);

constructor setting the point associated to.

AlphaShapeVertex_3 v(Point p, Cell_handle c);

constructor setting the point associated to and an incident cell.

Modifiers

*Alpha_status**

v.get_alpha_status()

Returns a pointer the alpha status of the vertex.

CGAL::Alpha_status

CGAL::Alpha_shape_3<Dt>

Definition

The class *Alpha_shape_3<Dt>* represents the family of alpha shapes of points in the 3D space for *all* positive α . It maintains an underlying triangulation of the class *Dt* which represents connectivity and order among its faces. Each *k*-dimensional face of the *Dt* is associated with an interval that specifies for which values of α the face belongs to the alpha shape.

Note that this class is at the same time used for *basic* and for *weighted* Alpha Shapes.

Inherits From

Dt

This class is the underlying triangulation class.

The modifying functions *insert* and *remove* will overwrite the inherited functions. At the moment, only the static version is implemented.

Types

Alpha_shape_3<Dt>:: Gt the alpha shape traits type.

it has to derive from a triangulation traits class. For example *Dt::Point* is a Point class.

typedef Gt::FT

NT; the number type of alpha values.

Alpha_shape_3<Dt>:: Alpha_iterator

A bidirectional and non-mutable iterator that allow to traverse the increasing sequence of different alpha values.

Precondition: Its *value_type* is *NT*

enum Mode { GENERAL, REGULARIZED};

In GENERAL mode, the alpha complex can have singular faces, i. e. faces of dimension *k*, for $k = (0, 1, 2)$ that are not subfaces of a $k + 1$ face of the complex. In REGULARIZED mode, the complex is regularized, that is singular faces are dropped and the alpha complex includes only a subset of the tetrahedral cells of the triangulation and the subfaces of those cells.

enum Classification_type { EXTERIOR, SINGULAR, REGULAR, INTERIOR};

Enum to classify the faces of the underlying triangulation with respect to the alpha shape.

In GENERAL mode, for $k = (0, 1, 2)$, each k -dimensional simplex of the triangulation can be classified as EXTERIOR, SINGULAR, REGULAR or INTERIOR. In GENERAL mode a k simplex is REGULAR if it is on the boundary of the alpha complex and belongs to a $k + 1$ simplex in this complex and it is SINGULAR if it is a boundary simplex that is not included in a $k + 1$ simplex of the complex.

In REGULARIZED mode, for $k = (0, 1, 2)$ each k -dimensional simplex of the triangulation can be classified as EXTERIOR, REGULAR or INTERIOR, i.e. there is no singular faces. A k simplex is REGULAR if it is on the boundary of alpha complex and belongs to a tetrahedral cell of the complex.

Creation

Alpha_shape_3<Dt> A(FT alpha = 0, Mode m = REGULARIZED);

Introduces an empty alpha shape data structure A for and set the current alpha value to $alpha$ and the mode to m .

Alpha_shape_3<Dt> A(Dt& dt, NT alpha = 0, Mode m = REGULARIZED);

Build an alpha shape of mode m from the triangulation dt . Be careful that this operation destroy the triangulation.

template < class InputIterator >

Alpha_shape_3<Dt> A(InputIterator first, InputIterator last, FT alpha = 0, Mode m = REGULARIZED);

Build an alpha shape data structure in mode m for the points in the range $[first, last)$ and set the current alpha value to $alpha$.

Precondition: The *value_type* of *first* and *last* is *Point* (the type point of the underlying triangulation.)

Modifiers

template < class InputIterator >

int A.make_alpha_shape(InputIterator first, InputIterator last)

Initialize the alpha shape data structure for points in the range $[first, last)$. Returns the number of data points inserted in the underlying triangulation.

If the function is applied to a non-empty alpha shape data structure, it is cleared before initialization.

Precondition: The *value_type* of *first* and *last* is *Point*.

void A.clear() Clears the structure.

<i>FT</i>	<i>A.set_alpha(Coord_type alpha)</i>	Sets the α -value to <i>alpha</i> . Returns the previous α -value. <i>Precondition: alpha</i> ≥ 0 .
<i>Mode</i>	<i>A.set_mode(Mode m = REGULARIZED)</i>	Sets <i>A</i> in GENERAL or REGULARIZED. Returns the previous mode. Changing the mode of an alpha shape data structure entails a partial re-computation of the data structure.

Query Functions

<i>Mode</i>	<i>A.get_mode(void)</i>	Returns whether <i>A</i> is general or regularized.
<i>FT</i>	<i>A.get_alpha(void)</i>	Returns the current α -value.
<i>FT</i>	<i>A.get_nth_alpha(int n)</i>	Returns the <i>n</i> -th alpha-value, sorted in an increasing order. <i>Precondition: n</i> \leq number of alphas.
<i>int</i>	<i>A.number_of_alphas()</i>	Returns the number of different alpha-values.
<i>Classification_type</i>	<i>A.classify(Point p, FT alpha = get_alpha())</i>	Locates a point <i>p</i> in the underlying triangulation and Classifies the associated k-face with respect to <i>alpha</i> .
<i>Classification_type</i>	<i>A.classify(Cell_handle f, FT alpha = get_alpha())</i>	Classifies the cell <i>f</i> of the underlying triangulation with respect to <i>alpha</i> .
<i>Classification_type</i>	<i>A.classify(Facet f, FT alpha = get_alpha())</i>	Classifies the facet <i>e</i> of the underlying triangulation with respect to <i>alpha</i> .

Classification_type

A.classify(Cell_handle f, int i, FT alpha = get_alpha())

Classifies the facet of the cell *f* opposite to the vertex with index *i* of the underlying triangulation with respect to *alpha*.

Classification_type

A.classify(Edge e, FT alpha = get_alpha())

Classifies the edge *e* with respect to *alpha* .

Classification_type

A.classify(Vertex_handle v, FT alpha = get_alpha())

Classifies the vertex *v* of the underlying triangulation with respect to *alpha*.

template<class OutputIterator>

OutputIterator

A.get_alpha_shape_cells(OutputIterator it,
Classification_type type,
NT alpha = get_alpha())

Write the cells which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

template<class OutputIterator>

OutputIterator

A.get_alpha_shape_facets(OutputIterator it,
Classification_type type,
NT alpha= get_alpha())

Write the facets which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

template<class OutputIterator>

OutputIterator

A.get_alpha_shape_edges(OutputIterator it,
Classification_type type,
NT alpha = get_alpha())

Write the edges which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

```
template<class OutputIterator>
OutputIterator
```

```
A.get_alpha_shape_vertices( OutputIterator it,
                             Classification_type type,
                             NT alpha get_alpha())
```

Write the vertices which are of type *type* for the alpha value *alpha* to the sequence pointed to by the output iterator *it*. Return past the end of the output sequence.

```
template<class OutputIterator>
OutputIterator
```

```
A.filtration( OutputIterator it)
```

Output all the faces of the triangulation in increasing order of the alpha value for which they appear in the alpha complex. In case of equal alpha value lower dimensional faces are output first. The value type of the OutputIterator has to be a CGAL::Object

Traversal of the α -Values

Alpha_iterator

```
A.alpha_begin()
```

Returns an iterator that allows to traverse the sorted sequence of α -values of the family of alpha shapes.

Alpha_iterator

```
A.alpha_end()
```

Returns the corresponding past-the-end iterator.

Alpha_iterator

```
A.alpha_find( FT alpha)
```

Returns an iterator pointing to an element with α -value *alpha*, or the corresponding past-the-end iterator if such an element is not found.

Alpha_iterator

```
A.alpha_lower_bound( FT alpha)
```

Returns an iterator pointing to the first element with α -value not less than *alpha*.

Alpha_iterator

```
A.alpha_upper_bound( FT alpha)
```

Returns an iterator pointing to the first element with α -value greater than *alpha*.

Operations

int *A.number_of_solid_components(FT alpha = get_alpha())*

Returns the number of solid components of *A*, that is, the number of components of its regularized version.

Alpha_iterator

A.find_optimal_alpha(int nb_components)

Returns an iterator pointing to smallest α value such that *A* satisfies the following two properties:

all data points are either on the boundary or in the interior of the regularized version of *A*.

The number of solid component of *A* is equal to or smaller than *nb_components*.

I/O

The I/O operators are defined for *iostream*, and for the window stream provided by CGAL. The format for the *iostream* is an internal format.

#include <CGAL/IO/io.h>

ostream& *ostream& os << A* Inserts the alpha shape *A* for the current alpha value into the stream *os*.
Precondition: The insert operator must be defined for *Point*.

#include <CGAL/IO/Geomview_stream.h>

#include <CGAL/IO/alpha_shape_geomview_ostream_3.h>

Geomview_stream&

Geomview_stream& W << A

Inserts the alpha shape *A* for the current alpha value into the Geomview stream *W*.

Precondition: The insert operator must be defined for *Point* and *Triangle*.

Implementation

In GENERAL mode, the alpha intervals of each triangulation face is computed and stored at initialization time. In REGULARIZED mode, the alpha shape intervals of edges are not stored nor computed at initialization. Edges are simply classified on the fly upon request. This allows to have much faster building of alpha shapes in REGULARIZED mode.

A.alpha find uses linear search, while *A.alpha lower bound* and *A.alpha upper bound* use binary search. *A.number of solid components* performs a graph traversal and takes time linear in the number of cells of the underlying triangulation. *A.find of optimal alpha* uses binary search and takes time $O(n \log n)$, where *n* is the number of points.

CGAL::Alpha_shape_cell_base_3<Traits,Fb>

Definition

The class *Alpha_shape_cell_base_3<Traits,Fb>* is the default model for the concept *AlphaShapeCell_3*.

The class has two parameters. The traits class *Traits* provides the number type for alpha values. The second parameter *Fb* is a base class instantiated by default with *CGAL::Triangulation_cell_base_3<Traits>*.

This chapter describes the two-dimensional segment Delaunay graph package of CGAL. We start with a few definitions in Section 31.1. The software design of the 2D segment Delaunay graph package is described in Section 31.2. In Section 31.3 we discuss the geometric traits of the 2D segment Delaunay graph package and in Section 31.4 the segment Delaunay graph hierarchy, a data structure suitable for fast nearest neighbor queries, is briefly described.

31.1 Definitions

The 2D segment Delaunay graph package of CGAL is designed to compute the Delaunay graph of a set of possibly intersecting segments on the plane. Although we compute the Delaunay graph, we will often refer to its dual, the segment Voronoi diagram, since it is easier to explain and understand. The algorithm that has been implemented is incremental. The corresponding CGAL class is called *SegmentDelaunay_graph_2* <*SegmentDelaunayGraphTraits_2*, *SegmentDelaunayGraphStructure_2*> and will be discussed in more detail in the sequel. The interested reader may want to refer to the paper by Karavelas [Kar04] for the general idea as well as the details of the algorithm implemented.

Definitions. Before describing the details of the implementation we make a brief introduction to the theory of segment Delaunay graphs and segment Voronoi diagrams. The segment Voronoi diagram is defined over a set of non-intersecting sites, which can either be points or linear segments, which we assume that are given through their endpoints. The segment Voronoi diagram a subdivision of the plane into connected regions, called *cells*, associated with the sites. The dual graph of the segment Voronoi diagram is called the segment Delaunay graph.

Figure 31.1: The segment Voronoi diagram for a set of weakly (left) and strongly (right) intersecting sites.

The cell of a site t_i is the locus of points on the plane that are closer to t_i than any other site t_j , $j \neq i$. The distance $\delta(x, t_i)$ of a point x in the plane to a site t_i is defined as the minimum of the Euclidean distances of x from the points in t_i . Hence, if t_i is a point p_i , then

$$\delta(x, t_i) = \|x - t_i\|,$$

whereas if t_i is a segment, then

$$\delta(x, t_i) = \min_{y \in t_i} \|x - y\|,$$

where $\|\cdot\|$ denotes the Euclidean norm. It can easily be seen that it is a generalization of the Voronoi diagram for points.

In many applications the restriction that sites are non-intersecting is too strict. Often we want to allow segments that touch at their endpoints, or even segments that overlap or intersect properly at their interior (for example, see Fig. 31.1). Allowing such configurations poses certain problems. More specifically, when we allow segments to touch at their endpoints we may end up with pairs of segments whose bisector is two-dimensional. If we allow pairs of segments that intersect properly at their interior, the interiors of their Voronoi cells are no longer simply connected. In both cases above the resulting Voronoi diagrams are no longer instances of abstract Voronoi diagrams (cf. [Kle89]), which has a direct consequence on the efficient computation of the corresponding Voronoi diagram. The remedy to these problems is to consider linear segments not as one object, but rather as three, namely the two endpoints and the interior. This choice guarantees that all bisectors in the Voronoi diagram are one-dimensional and that all Voronoi cells are simply connected. Moreover, we further distinguish between two cases, according to the type of intersecting pair that our input data set contains. A pair of sites is called *weakly intersecting* if they share a single common point and this common point does not lie in the interior of any of the two sites. A pair of sites is called *strongly intersecting* if they intersect and they either have more than one common point or their common point lies in the interior of at least one of the two sites. As it will be seen later the two cases have different representation (and thus storage) requirements, as well as they require a somehow different treatment on how the predicates are evaluated. Having made the distinction between weakly and strongly intersecting sites, and having said that segment sites are treated as three objects, we are now ready to precisely define the Delaunay graph we compute. Given a set \mathcal{S} of input sites, let $\mathcal{S}_{\mathcal{A}}$ be the set of points and (open) segments in the arrangement $\mathcal{A}(\mathcal{S})$ of \mathcal{S} . The 2D segment Delaunay graph package of CGAL computes the (triangulated) Delaunay graph that is dual to the Euclidean Voronoi diagram of the sites in the set $\mathcal{S}_{\mathcal{A}}$.

The segment Delaunay graph is uniquely defined once we have the segment Voronoi diagram. If all sites are in *general position*, then the Delaunay graph is a graph with triangular faces away from the convex hull of the set of sites. To unify our approach and handling of the Delaunay graph we add to the set of (finite) sites a fictitious site

at infinity, which we call the *site at infinity*. We can then connect all vertices of the outer face of the Delaunay graph to the site at infinity which gives us a graph with the property that all of its faces are now triangular. However, the Delaunay graph is not a triangulation for two main reasons: we cannot always embed it on the plane with straight line segments that yield a triangulation and, moreover, we may have two faces of the graph that have two edges in common, which is not allowed in a triangulation.

We would like to finish our brief introduction to the theory of segment Delaunay graphs and segment Voronoi diagrams by discussing the concept of general position. We say that a set of sites is in general position if no two triplets of sites have the same tritangent Voronoi circle. This statement is rather technical and it is best understood in the context of points. The equivalent statement for points is that we have no two triplets of points that define the same circumcircle, or equivalently that no four points are co-circular. The statement about general position made above is a direct generalization of the (much simpler to understand) statement about points. On the contrary, when we have sites in degenerate position, the Delaunay graph has faces with more than three edges on their boundary. We can get a triangulated version of the Delaunay graph by simply *triangulating* the corresponding faces in an arbitrary way. In fact the algorithm that has been implemented in CGAL has the property that it always returns a valid *triangulated* version of the segment Delaunay graph. By valid we mean that it contains the actual (non-triangulated) Delaunay graph, and whenever there are faces with more than three edges then they are triangulated. The way that they are triangulated depends on the order of insertion of the sites in the diagram.

One final remark has to be made with respect to the difference between the set of *input sites* and the set of *output sites*. The set of input sites consists of the closed sites that the user inserts in the diagram. Since segment sites are treated as three objects, internally our algorithm sees only points and open segments. As a result, from the point of view of the algorithm, the input sites have no real meaning. What has real meaning is the set of sites that correspond to cells of the Voronoi diagram and this is the set of output sites.

Degenerate Dimensions. The dimension of the segment Delaunay graph is in general 2. The exceptions to this rule are as follows:

- The dimension is -1 if the segment Delaunay graph contains no sites.
- The dimension is 0 if the segment Delaunay graph contains exactly one (output) site.
- The dimension is 1 if the segment Delaunay graph contains exactly two (output) sites.

31.2 Software Design

The 2D segment Delaunay graph class `SegmentDelaunay_graph_2<SegmentDelaunayGraphTraits_2, SegmentDelaunayGraphDataStructure_2>` follows the design of the triangulation package of CGAL. It is parametrized by two arguments:

- the **geometric traits** class. It provides the basic geometric objects involved in the algorithm, such as sites, points etc. It also provides the geometric predicates for the computation of the segment Delaunay graph, as well as some basic constructions that can be used, for example, to visualize the diagram. The geometric traits for the segment Delaunay graph will be discussed in more detail in the next section.
- the **segment Delaunay graph data structure**. This is essentially the same as the Apollonius graph data structure (discussed in Chapter 32.2), augmented with some additional operations that are specific to segment Voronoi diagrams. The corresponding concept is that of `SegmentDelaunayGraphDataStructure_2`, which in fact is a refinement of the `ApolloniusGraphDataStructure_2` concept. The class `Triangulation_data_structure_2<Vb, Fb>` is a model of the concept `SegmentDelaunayGraphDataStructure_2`. A default value for the corresponding template parameter is provided, so the user does not need to specify it.

Strongly Intersecting Sites and their Representation. As we have mentioned above, the segment Delaunay graph package of CGAL is designed to support the computation of the segment Voronoi diagram even when the input segment sites are intersecting. This choice poses certain issues for the design of the software package. The major concern is the representation of the subsegments that appear in the arrangement of these sites, because the sites in the arrangement are the ones over which the diagram is actually defined. A direct consequence of the choice of representation is the algebraic degree of the predicates involved in the computation of the segment Delaunay graph, as well as the storage requirements for the subsegments and points on intersection in the arrangement.

The case of weakly intersecting sites does not require any special treatment. We can simply represent points by their coordinates and segments by their endpoints. In the case of strongly intersecting sites, the obvious choice to use the afore-mentioned representation has severe disadvantages. Consider two strongly intersecting segments t_i and t_j , whose endpoints have homogeneous coordinates of size b . Their intersection point will have homogeneous coordinates of bit size $6b + O(1)$. This effect can be cascaded, which implies that after inserting k (input) segments we can arrive at having points of intersection whose bit sizes are exponential with respect to k , i.e., their homogeneous coordinates will have bit size $\Omega(2^k b)$. Not only the points of intersection, but also the adjacent subsegments will be represented by quantities of arbitrarily high bit size, and as a result we would not be able to give a bound on the bit sizes of the coordinates of the points of intersection. As a result, we would not be able to give a bound on the memory needed to store these coordinates. An equally important consequence is that we would also not be able to give a bound on the algebraic degree of the algebraic expressions involved in the evaluation of the predicates.

Such a behavior is obviously undesirable. For robustness, efficiency, and scalability purposes, it is critical that the bit size of the algebraic expressions in the predicates does not depend on the input size. For this reason, as well as for others to be discussed below, we decided to represent sites in an implicit manner, which somehow encodes the history of their construction. In particular, we exploit the fact that points of intersection always lie on two input segments, and that segments that are not part of the input are always supported by input segments.

For example, let us consider the configuration in Fig. 31.2. We assume that the segments $t_i = p_i q_i$, $i = 1, 2, 3$, are inserted in that order. Upon the insertion of t_2 , our algorithm will split the segment t_1 into the subsegments $p_1 s_1$ and $s_1 q_1$, then add s_1 , and finally insert the subsegments $p_2 s_1$ and $s_1 q_2$. How do we represent the five new sites? s_1 will be represented by its two defining segments t_1 and t_2 . The segment $p_1 s_1$ will be represented by two segments, a point, and a boolean. The first segment is t_1 , which is always the segment with the same support as the newly created segment. The second segment is t_2 and the point is p_1 . The boolean indicates whether the first endpoint of $p_1 s_1$ is an input point; in this case the boolean is equal to *true*. The segment $s_1 q_1$ will also be represented by two segments, a point, and a boolean, namely, t_1 (the supporting segment of $s_1 q_1$), t_2 and *false* (it is the second endpoint of $s_1 q_1$ that is an input point). Subsegments $p_2 s_2$ and $s_2 q_2$ are represented analogously. Consider now what happens when we insert t_3 . The point s_2 will again be represented by two segments, but not $s_1 q_1$ and t_3 . In fact, it will be represented by t_1 (the supporting segment of $s_1 q_1$) and t_3 . $s_2 q_1$ will be represented by two segments, a point, and a boolean (t_1 , t_3 and *false*), and similarly for $p_3 s_2$ and $s_2 q_3$. On the other hand, both endpoints of $s_1 s_2$ are non-input points. In such a case we represent the segment by three input segments. More precisely, $s_1 s_2$ is represented by the segments t_1 (the supporting segment of $s_1 q_1$), t_2 (it defines s_1 along with t_1) and t_3 (it defines s_2 along with t_1).

The five different presentations, two for points (coordinates; two input segments) and three for segments (two input points; two input segments, an input point and a boolean; three input segments), form a closed set of representations and thus represent any point of intersection or subsegment regardless of the number of input segments. Moreover, every point (input or intersection) has homogeneous coordinates of bit size at most $3b + O(1)$. The supporting lines of the segments (they are needed in some of the predicates) have coefficients which are always of bit size $2b + O(1)$. As a result, the bit size of the expressions involved in our predicates will always be $O(b)$, independently of the size of the input. The *SegmentDelaunayGraphSite_2* concept encapsulates the ideas presented above. A site is represented in this concept by up to four points and a boolean, or up to six points, depending on its type. The class *Segment_Delaunay_graph_site_2<K>* implements this concept.

Even this representation, however, has some degree of redundancy. The endpoint of a segment appears in both

Figure 31.2: Site representation. The point s_1 is represented by the four points p_1 , q_1 , p_2 and q_2 . The segment p_1s_1 is represented by the points p_1 , q_1 , p_2 , q_2 and a boolean which is set to *true* to indicate that the first endpoint is not a point of intersection. The segment s_1s_2 is represented by the six points: p_1 , q_1 , p_2 , q_2 , p_3 and q_3 . The remaining (non-input) points and segments in the figure are represented similarly.

the representation of the (open) segment site as well as the representation of the point site itself. The situation becomes even worse in the presence of strongly intersecting sites: a point may appear in the representation of multiple subsegments and/or points of intersection. To avoid this redundancy, input points are stored in a container, and the various types of sites (input points and segments, points of intersection, subsegments with one or two points of intersection as endpoints) only store handles to the points in the container. This is achieved by the *Segment_Delaunay_graph_storage_site_2<Gt>* class which is a model of the corresponding concept: *SegmentDelaunayGraphStorageSite_2*. This concept enforces a site to be represented by up to 6 handles (which are very lightweight objects) instead of 6 points, which are, compared to handles of course, very heavy objects.

Optimizing Memory Allocation. There are applications where we know beforehand that the input consists of only weakly intersecting sites. In these cases the site representation described above poses a significant overhead in the memory requirements of our implementation: instead of representing sites with up to two points (or ultimately with up to two handles), we require sites to store six points (respectively, six handles). To avoid this overhead we have introduced two series of traits classes:

- One that supports the full-fledged sites, and is suitable when the input consists of strongly intersecting sites. This series consists of the *Segment_Delaunay_graph_traits_2<K,MTag>* and *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* classes.
- One that is customized for input that contain only weakly intersecting sites. This series consists of the *Segment_Delaunay_graph_traits_without_intersections_2<K,MTag>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes.

The advantages of having different traits classes are as follows:

- When the user chooses to use one of the traits classes in the second series we only store two handles per site. This implies a reduction by a factor of three in the memory allocated per site with respect to the first series of traits classes.
- In the case of the first series of traits classes, we can better exploit the knowledge that have strongly intersecting sites, in order to further apply geometric filters (see below) during the evaluation of the

predicates. On the contrary, if the second series of traits classes is used, we can avoid geometric filtering tests that have meaning only in the case of strongly intersecting sites.

31.3 The Geometric Traits

The predicates required for the computation of the segment Voronoi diagram are rather complicated. It is not the purpose of this document to discuss them in detail. The interested reader may refer to Burnikel's thesis [Bur96], where it is shown that in the case of weakly intersecting sites represented in homogeneous coordinates of bit size b , the maximum bit size of the algebraic expressions involved in the predicates is $40b + O(1)$. Given our site representation given above we can guarantee that even in the case of strongly intersecting sites, the algebraic degree of the predicates remains $O(b)$, independently of the size of the input. What we want to focus in the remainder of this section are the different kinds of filtering techniques that we have employed in our implementation.

Geometric Filtering. Our representation of sites is coupled very naturally, with what we call *geometric filtering*. The technique amounts to performing simple geometric tests exploiting the representation of our data, as well as the geometric structure inherent in our problem, in order to evaluate predicates in seemingly degenerate configurations. Geometric filtering can be seen as a preprocessing step before performing arithmetic filtering. Roughly speaking, by arithmetic filtering we mean that we first try to evaluate the predicates using a fixed-precision floating-point number type (such as `double`), and at the same time keep error bounds on the numerical errors of the computations we perform. If the numerical errors are too big and do not permit us to evaluate the predicate, we switch to an exact number type, and repeat the evaluation of the predicate. Geometric filtering can help by eliminating situations in which the arithmetic filter will fail, thus decreasing the number of times we need to evaluate a predicate using exact arithmetic.

To illustrate the application and effectiveness of this approach, let us consider a very simple example usage. Suppose we want to determine if two non-input points are identical (we assume here that the input sites are represented by *doubles*). In order to do that we need to compute their coordinates and compare them. If the two points are identical, the answer to our question using *double* arithmetic may be wrong (due to numerical errors), in which case we will have to reside to the more expensive exact computation. Instead, before testing the coordinates for equality, we can use the representation of the points to potentially answer the question. More specifically, and this is the geometric filtering part of the computation, we can first test if the defining segments of the two points are the same. If they are not, then we proceed to comparing their coordinates as usual. Testing the defining segments for equality does not involve any arithmetic operations on the input, but rather only comparisons on *doubles*. By performing this very simple test we avoid a numerically difficult computation, which could be performed thousands of times during the computation of a Delaunay graph.

Geometric filtering has been implemented in all our models of the *SegmentDelaunayGraphTraits_2* concept. These models are the classes: *Segment_Delaunay_graph_traits_2*< $K, MTag$ >, *Segment_Delaunay_graph_traits_without_intersections_2*< $K, MTag$ >, *Segment_Delaunay_graph_filtered_traits_2*< CK, CM, EK, EM, FK, FM > and *Segment_Delaunay_graph_filtered_traits_without_intersections_2*< CK, CM, EK, EM, FK, FM >.

Arithmetic Filtering. As mentioned above, performing computations with exact arithmetic can be very costly. For this reason we have devoted considerable effort in implementing different kinds of arithmetic filtering mechanisms. Presently, there two ways of performing arithmetic filtering for the predicates involved in the computation of segment Delaunay graphs:

1. The user can define his/her kernel using as number type, a number type of the form *CGAL::Filtered_exact*< CT, ET >. Then this kernel can be entered as the first template parameter in the *Segment_Delaunay_graph_2*< $K, MTag$ > or *Segment_Delaunay_graph_without_intersections_2*< $K, MTag$ > class.

2. The user can define up to three different kernels *CK*, *FK* and *EK* (default values are provided for most parameters). The first kernel *CK* is used only for constructions. The second kernel *FK* is the filtering kernel: the traits class will attempt to compute the predicates using this kernel. If the filtering kernel fails to successfully compute a predicate, the exact kernel *EK* will be used. These three kernels are then used in the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes, which have been implemented using the *Filtered_predicate<EP,FP>* mechanism.

Our experience so far has shown that for all reasonable and valid values of the template parameters, the second method for arithmetic filtering is more efficient among the two.

Let's consider once more the classes *Segment_Delaunay_graph_2<K,MTag>* and *Segment_Delaunay_graph_without_intersections_2<K,MTag>*. The template parameter *MTag* provides another degree of freedom to the user, who can indicate the type of arithmetic operations to be used in the evaluation of the predicates. More specifically, in both classes, *MTag* can be *CGAL::Sqrt_field_tag*, in which case the predicates will be evaluated using all four basic arithmetic operations plus square roots; this requires, of course, that the number type used in the kernel *K* supports these operations exactly. The second choices are *CGAL::Field_tag* for the *Segment_Delaunay_graph_2<K,MTag>* class, and *CGAL::Ring_tag* for the *Segment_Delaunay_graph_without_intersections_2<K,MTag>* class. In the first case we indicate that we want the predicates to be computed using only the four basic arithmetic operations, whereas in the second case we evaluate the predicates using only ring operations. Again, for the predicates to be evaluated correctly, the number type used in the kernel *K* must support the corresponding operations exactly.

The semantics for the template parameters *CM*, *FM* and *EM* in the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* and *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* classes are analogous. With each of these template parameters we can control the type of arithmetic operations that are going to be used in calculations involving each of the corresponding kernels *CK*, *FK* and *EK*. When the *Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>* is used the possible values for *CM*, *FM* and *EM* are *CGAL::Sqrt_field_tag* and *CGAL::Field_tag*, whereas if the *Segment_Delaunay_graph_filtered_traits_without_intersections_2<CK,CM,EK,EM,FK,FM>* class is used, the possible values are *CGAL::Sqrt_field_tag* and *CGAL::Ring_tag*. The semantics are the same as in the case of the *Segment_Delaunay_graph_2<K,MTag>* and *Segment_Delaunay_graph_without_intersections_2<K,MTag>* classes.

31.4 The Segment Delaunay Graph Hierarchy

The *Segment_Delaunay_graph_hierarchy_2<SegmentDelaunayGraphTraits_2, SSTag, SegmentDelaunayGraphDataStructure_2>* class is the analogue of the *Triangulation_hierarchy_2* or the *Apollonius_graph_hierarchy_2* classes, applied to the segment Delaunay graph. It consists of a hierarchy of segment Delaunay graphs constructed in a manner analogous to the Delaunay hierarchy by Devillers [Dev02]. Unlike the triangulation hierarchy or the Apollonius graph hierarchy, the situation here is more complicated because of two factors: firstly, segments are treated as three objects instead of one (the two endpoints and the interior of the segments), and secondly, the presence of strongly intersecting sites complicates significantly the way the hierarchy is constructed. The interested reader may refer to the paper by Karavelas [Kar04] for the details of the construction of the hierarchy. Another alternative is to have a hybrid hierarchy that consists of the segment Delaunay graph at the bottom-most level and point Voronoi diagrams at all other levels. This choice seems to work very well in practice, primarily because it avoids the overhead of maintaining a Delaunay graph for segments at the upper levels of the hierarchy. However, it seems much less likely to be possible to give any theoretical guarantees for its performance, in contrast to the hierarchy with segment Delaunay graphs at all levels (cf. [Kar04]). The user can choose between the two types of hierarchies by means of the template parameter *SSTag*. If *SSTag* is set to *false* (which is also the default value), the upper levels of the hierarchy

consist of point Delaunay graphs. If *SSTag* is set to *true*, we have segment Delaunay graphs at all levels of the hierarchy.

The class *Segment_Delaunay_graph_hierarchy_2*<*SegmentDelaunayGraphTraits_2*, *SSTag*, *SegmentDelaunayGraphDataStructure_2*> has exactly the same interface and functionality as the *Segment_Delaunay_graph_2*<*SegmentDelaunayGraphTraits_2*, *SegmentDelaunayGraphDataStructure_2*> class. Using the segment Delaunay graph hierarchy involves an additional cost in space and time for maintaining the hierarchy. Our experiments have shown that it usually pays off to use the hierarchy for inputs consisting of more than about 1,000 sites.

31.5 Examples

31.5.1 First Example

The following example shows to use the segment Delaunay graph traits in conjunction with the *Filtered_exact*<*CT,ET*> mechanism. In addition it shows how to use a few of the iterators provided by the *Segment_Delaunay_graph_2* class in order to count a few site-related quantities.

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// define the exact number type
# include <CGAL/Quotient.h>
# include <CGAL/MP_Float.h>
typedef CGAL::Quotient<CGAL::MP_Float> ENT;

// define the kernels
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<double> CK;
typedef CGAL::Simple_cartesian<ENT> EK;

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_filtered_traits_2.h>
#include <CGAL/Segment_Delaunay_graph_2.h>

typedef CGAL::Segment_Delaunay_graph_filtered_traits_2<CK,
/* The construction kernel allows for / and sqrt */ CGAL::Field_with_sqrt_tag,
    EK,
/* The exact kernel supports field ops exactly */ CGAL::Field_tag> Gt;

typedef CGAL::Segment_Delaunay_graph_2<Gt> SDG2;

using namespace std;

int main() {
    ifstream ifs("data/sitesx.cin");
```

```

assert( ifs );

SDG2          sdg;
SDG2::Site_2  site;

while ( ifs >> site ) { sdg.insert( site ); }

ifs.close();

assert( sdg.is_valid(true, 1) );
cout << endl << endl;

// print the number of input and output sites
cout << "# of input sites : " << sdg.number_of_input_sites() << endl;
cout << "# of output sites: " << sdg.number_of_output_sites() << endl;

unsigned int n_ipt(0), n_iseg(0), n_opt(0), n_oseg(0), n_ptx(0);

// count the number of input points and input segments
SDG2::Input_sites_iterator iit;
for (iit = sdg.input_sites_begin(); iit != sdg.input_sites_end(); ++iit)
{
    if ( iit->is_point() ) { n_ipt++; } else { n_iseg++; }
}

// count the number of output points and output segments, as well
// as the number of points that are points of intersection of pairs
// of strongly intersecting sites
SDG2::Output_sites_iterator oit;
for (oit = sdg.output_sites_begin(); oit != sdg.output_sites_end(); ++oit)
{
    if ( oit->is_segment() ) { n_oseg++; } else {
        n_opt++;
        if ( !oit->is_input() ) { n_ptx++; }
    }
}

cout << endl << "# of input segments: " << n_iseg << endl;
cout << "# of input points:      " << n_ipt << endl << endl;
cout << "# of output segments: " << n_oseg << endl;
cout << "# of output points:    " << n_opt << endl << endl;
cout << "# of intersection points: " << n_ptx << endl;

return 0;
}

```

31.5.2 Second Example

The following example shows how to use the segment Delaunay graph hierarchy along with the filtered traits class that supports intersecting sites.

```

#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// example that uses the filtered traits and
// the segment Delaunay graph hierarchy

// choose the kernel
#include <CGAL/Simple_cartesian.h>

struct Rep : public CGAL::Simple_cartesian<double> {};

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_hierarchy_2.h>
#include <CGAL/Segment_Delaunay_graph_filtered_traits_2.h>

struct Gt
    : public CGAL::Segment_Delaunay_graph_filtered_traits_2<Rep> {};

typedef CGAL::Segment_Delaunay_graph_hierarchy_2<Gt>   SDG2;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    SDG2          sdg;
    SDG2::Site_2  site;

    // read the sites and insert them in the segment Delaunay graph
    while ( ifs >> site ) {
        sdg.insert(site);
    }

    // validate the segment Delaunay graph
    assert( sdg.is_valid(true, 1) );

    return 0;
}

```

File: examples/Segment_Delaunay_graph_2/sdg-filtered-traits.cpp

31.5.3 Third Example

The following example demonstrates how to recover the defining sites for the edges of the Voronoi diagram (which are the duals of the edges of the segment Delaunay graph computed).

```

#include <CGAL/basic.h>

```

```

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>
#include <string>

// define the kernel
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Filtered_kernel.h>

typedef CGAL::Simple_cartesian<double>    CK;
typedef CGAL::Filtered_kernel<CK>        Kernel;

// typedefs for the traits and the algorithm
#include <CGAL/Segment_Delaunay_graph_traits_2.h>
#include <CGAL/Segment_Delaunay_graph_2.h>

typedef CGAL::Segment_Delaunay_graph_traits_2<Kernel>  Gt;
typedef CGAL::Segment_Delaunay_graph_2<Gt>            SDG2;

using namespace std;

int main()
{
    ifstream ifs("data/sites2.cin");
    assert( ifs );

    SDG2      sdg;
    SDG2::Site_2  site;

    // read the sites from the stream and insert them in the diagram
    while ( ifs >> site ) { sdg.insert( site ); }

    ifs.close();

    // validate the diagram
    assert( sdg.is_valid(true, 1) );
    cout << endl << endl;

    /*
    // now walk through the non-infinite edges of the segment Delaunay
    // graphs (which are dual to the edges in the Voronoi diagram) and
    // print the sites defining each Voronoi edge.
    //
    // Each oriented Voronoi edge (horizontal segment in the figure
    // below) is defined by four sites A, B, C and D.
    //
    //      \           /
    //      \         B /
    //      \       /   /
    //      C ----- D
    //      /       \   \
    //      /         A \
    */

```

```

//      /      \
//
// The sites A and B define the (oriented) bisector on which the
// edge lies whereas the sites C and D, along with A and B define
// the two endpoints of the edge. These endpoints are the Voronoi
// vertices of the triples A, B, C and B, A, D.
// If one of these vertices is the vertex at infinity the string
// "infinite vertex" is printed; the corresponding Voronoi edge is
// actually a straight-line or parabolic ray.
// The sites below are printed in the order A, B, C, D.
*/

string inf_vertex("infinite vertex");
char vid[] = {'A', 'B', 'C', 'D'};

SDG2::Finite_edges_iterator eit = sdg.finite_edges_begin();
for (int k = 1; eit != sdg.finite_edges_end(); ++eit, ++k) {
    SDG2::Edge e = *eit;
    // get the vertices defining the Voronoi edge
    SDG2::Vertex_handle v[] = { e.first->vertex( sdg.ccw(e.second) ),
                                e.first->vertex( sdg.cw(e.second) ),
                                e.first->vertex( e.second ),
                                sdg.tds().mirror_vertex(e.first, e.second) };

    cout << "--- Edge " << k << " ---" << endl;
    for (int i = 0; i < 4; i++) {
        // check if the vertex is the vertex at infinity; if yes, print
        // the corresponding string, otherwise print the site
        if ( sdg.is_infinite(v[i]) ) {
            cout << vid[i] << ": " << inf_vertex << endl;
        } else {
            cout << vid[i] << ": " << v[i]->site() << endl;
        }
    }
    cout << endl;
}

return 0;
}

```

2D Segment Delaunay Graphs

Reference Manual

Menelaos Karavelas

CGAL provides the class `CGAL::Segment_Delaunay_graph_2<Gt,DS>` for computing the 2D Delaunay graph of segments and points. The two template parameters must be models of the `SegmentDelaunayGraphTraits_2` and `SegmentDelaunayGraphDataStructure_2` concepts. The first concept is related to the geometric objects and predicates associated with segment Delaunay graphs, whereas the second concept refers to the data structure used to represent the segment Delaunay graph, which is dual to the 2D Voronoi diagram of segments and points. The classes `Segment_Delaunay_graph_traits_2<K,MTag>`, `Segment_Delaunay_graph_traits_without_intersections_2<K,MTag>`, `Segment_Delaunay_graph_filtered_traits_2<K,MTag>`, `Segment_Delaunay_graph_filtered_traits_without_intersections_2<K,MTag>` are models of the `SegmentDelaunayGraphTraits_2` concept, whereas the class `Triangulation_data_structure_2<Vb,Fb>` is a model of the `SegmentDelaunayGraphDataStructure_2` concept.

CGAL::Segment_Delaunay_graph_2<Gt,DS>

Definition

The class *Segment_Delaunay_graph_2<Gt,DS>* represents the segment Delaunay graph (which is the dual graph of the 2D segment Voronoi diagram). Currently it supports only insertions of sites. It is templated by two template arguments *Gt*, which must be a model of *SegmentDelaunayGraphTraits_2* and *DS*, which must be a model of *SegmentDelaunayGraphDataStructure_2*. The second template argument defaults to *CGAL::Triangulation_data_structure_2< CGAL::Segment_Delaunay_graph_vertex_base_2<Gt>, CGAL::Triangulation_face_base_2<Gt> >*.

```
#include <CGAL/Segment_Delaunay_graph_2.h>
```

Is Model for the Concepts

DelaunayGraph_2

Types

<code>typedef Gt</code>	<code>Geom_traits;</code>	A type for the geometric traits.
<code>typedef DS</code>	<code>Data_structure;</code>	A type for the underlying data structure.
<code>typedef Data_structure</code>	<code>Triangulation_data_structure;</code>	
		This type has been added so that the <i>Segment_Delaunay_graph_2<Gt,DS></i> class is a model of the <i>DelaunayGraph_2</i> concept.
<code>typedef typename DS::size_type</code>	<code>size_type;</code>	Size type (an unsigned integral type)
<code>typedef typename Gt::Point_2</code>	<code>Point_2;</code>	A type for the point defined in the geometric traits.
<code>typedef typename Gt::Site_2</code>	<code>Site_2;</code>	A type for the segment Delaunay graph site, defined in the geometric traits.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Point_container</code>		A type for the container of points.
<code>typedef typename Point_container::iterator</code>	<code>Point_handle;</code>	A handle for points in the point container.

The vertices and faces of the segment Delaunay graph are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles. The edges of the segment Delaunay graph can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non-mutable. In the following, we call *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the segment Delaunay graph is said to be *finite*. Some iterators (the *All* iterators) allow to visit finite or infinite features while the others (the *Finite* iterators) visit only finite features. Circulators visit both infinite and finite features.

<code>typedef typename DS::Edge</code>	<code>Edge;</code>	The edge type. The <i>Edge(f,i)</i> is the edge common to faces <i>f</i> and <i>f.neighbor(i)</i> . It is also the edge joining the vertices <i>vertex(cw(i))</i> and <i>vertex(ccw(i))</i> of <i>f</i> . <i>Precondition:</i> <i>i</i> must be 0, 1 or 2.
--	--------------------	---

<code>typedef typename DS::Vertex</code>	<code>Vertex;</code>	A type for a vertex.
<code>typedef typename DS::Face</code>	<code>Face;</code>	A type for a face.
<code>typedef typename DS::Vertex_handle</code>	<code>Vertex_handle;</code>	A type for a handle to a vertex.
<code>typedef typename DS::Face_handle</code>	<code>Face_handle;</code>	A type for a handle to a face.
<code>typedef typename DS::Vertex_circulator</code>	<code>Vertex_circulator;</code>	A type for a circulator over vertices incident to a given vertex.
<code>typedef typename DS::Face_circulator</code>	<code>Face_circulator;</code>	A type for a circulator over faces incident to a given vertex.
<code>typedef typename DS::Edge_circulator</code>	<code>Edge_circulator;</code>	A type for a circulator over edges incident to a given vertex.
<code>typedef typename DS::Vertex_iterator</code>	<code>All_vertices_iterator;</code>	A type for an iterator over all vertices.
<code>typedef typename DS::Face_iterator</code>	<code>All_faces_iterator;</code>	A type for an iterator over all faces.
<code>typedef typename DS::Edge_iterator</code>	<code>All_edges_iterator;</code>	A type for an iterator over all edges.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Finite_vertices_iterator</code>		A type for an iterator over finite vertices.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Finite_faces_iterator</code>		A type for an iterator over finite faces.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Finite_edges_iterator</code>		A type for an iterator over finite edges.

In addition to iterators and circulators for vertices and faces, iterators for sites are provided. In particular there are iterators for the set of input sites and the set of output sites. The set of input sites is the set of sites inserted by the user using the *insert* methods of this class. If a site is inserted multiple times, every instance of this site will be reported. The set of output sites is the set of sites in the segment Delaunay graph. The value type of these iterators is *Site_2*.

<code>Segment_Delaunay_graph_2<Gt,DS>:: Input_sites_iterator</code>	A type for a bidirectional iterator over all input sites.
<code>Segment_Delaunay_graph_2<Gt,DS>:: Output_sites_iterator</code>	A type for a bidirectional iterator over all output sites (the sites in the Delaunay graph).

Creation

In addition to the default and copy constructors the following constructors are defined:

<code>Segment_Delaunay_graph_2<Gt,DS> sdg(Gt gt=Gt());</code>	Creates the segment Delaunay graph using <i>gt</i> as geometric traits.
--	---

`template< class Input_iterator >`

`Segment_Delaunay_graph_2<Gt,DS> sdg(Input_iterator first, Input_iterator beyond, Gt gt=Gt());`

Creates the segment Delaunay graph using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).

Precondition: *Input_iterator* must be a model of *InputIterator*. The value type of *Input_iterator* must be either *Point_2* or *Site_2*.

Access Functions

<code>Geom_traits</code>	<code>sdg.geom_traits()</code>	Returns a reference to the segment Delaunay graph traits object.
--------------------------	--------------------------------	--

<i>int</i>	<i>sdg.dimension()</i>	Returns the dimension of the segment Delaunay graph. The dimension is -1 if the graph contains no sites, 0 if the graph contains one site, 1 if it contains two sites and 2 if it contains three or more sites.
<i>size_type</i>	<i>sdg.number_of_vertices()</i>	Returns the number of finite vertices of the segment Delaunay graph.
<i>size_type</i>	<i>sdg.number_of_faces()</i>	Returns the number of faces (both finite and infinite) of the segment Delaunay graph.
<i>size_type</i>	<i>sdg.number_of_input_sites()</i>	Return the number of input sites.
<i>size_type</i>	<i>sdg.number_of_output_sites()</i>	Return the number of output sites. This is equal to the number of vertices in the segment Delaunay graph.
<i>Face_handle</i>	<i>sdg.infinite_face()</i>	Returns a face incident to the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>sdg.infinite_vertex()</i>	Returns the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>sdg.finite_vertex()</i>	Returns a vertex distinct from the <i>infinite_vertex</i> . <i>Precondition:</i> The number of sites in the segment Delaunay graph must be at least one.
<i>Data_structure</i>	<i>sdg.data_structure()</i>	Returns a reference to the segment Delaunay graph data structure object.
<i>Data_structure</i>	<i>sdg.tds()</i>	Same as <i>data_structure()</i> . It has been added for compliance to the <i>DelaunayGraph_2</i> concept.
<i>Point_container</i>	<i>sdg.point_container()</i>	Returns a reference to the point container object.

Traversal of the segment Delaunay graph

A segment Delaunay graph can be seen as a container of faces and vertices. Therefore the *Segment_Delaunay_graph_2*<Gt,DS> class provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the segment Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the segment Delaunay graph.

<i>Finite_vertices_iterator</i>	<i>sdg.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex.
<i>Finite_vertices_iterator</i>	<i>sdg.finite_vertices_end()</i>	Past-the-end iterator.
<i>Finite_edges_iterator</i>	<i>sdg.finite_edges_begin()</i>	Starts at an arbitrary finite edge.
<i>Finite_edges_iterator</i>	<i>sdg.finite_edges_end()</i>	Past-the-end iterator.
<i>Finite_faces_iterator</i>	<i>sdg.finite_faces_begin()</i>	Starts at an arbitrary finite face.
<i>Finite_faces_iterator</i>	<i>sdg.finite_faces_end()</i>	Past-the-end iterator.

The following iterators allow respectively to visit all (both finite and infinite) faces, edges and vertices of the segment Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the segment Delaunay graph.

<i>All_vertices_iterator</i>	<i>sdg.all_vertices_begin()</i>	Starts at an arbitrary vertex.
<i>All_vertices_iterator</i>	<i>sdg.all_vertices_end()</i>	Past-the-end iterator.
<i>All_edges_iterator</i>	<i>sdg.all_edges_begin()</i>	Starts at an arbitrary edge.

<i>All_edges_iterator</i>	<i>sdg.all_edges_end()</i>	Past-the-end iterator.
---------------------------	----------------------------	------------------------

<i>All_faces_iterator</i>	<i>sdg.all_faces_begin()</i>	Starts at an arbitrary face.
<i>All_faces_iterator</i>	<i>sdg.all_faces_end()</i>	Past-the-end iterator.

Site iterators

The following iterators allow respectively to visit all sites. These iterators are non-mutable, bidirectional and their value type is *Site_2*. They are all invalidated by any change in the segment Delaunay graph.

<i>Input_sites_iterator</i>	<i>sdg.input_sites_begin()</i>	Starts at an arbitrary input site.
<i>Input_sites_iterator</i>	<i>sdg.input_sites_end()</i>	Past-the-end iterator.
<i>Output_sites_iterator</i>	<i>sdg.output_sites_begin()</i>	Starts at an arbitrary output site.
<i>Output_sites_iterator</i>	<i>sdg.output_sites_end()</i>	Past-the-end iterator.

Face, Edge and Vertex Circulators

The *Segment_Delaunay_graph_2*<*Gt,DS*> class also provides circulators that allow to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge circulator is invalidated by any modification in one of the two faces incident to the edge pointed to. A vertex circulator is invalidated by any modification in any of the faces adjacent to the vertex pointed to.

<i>Face_circulator</i>	<i>sdg.incident_faces(Vertex_handle v)</i>	Starts at an arbitrary face incident to <i>v</i> .
<i>Face_circulator</i>	<i>sdg.incident_faces(Vertex_handle v, Face_handle f)</i>	Starts at face <i>f</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

<i>Edge_circulator</i>	<i>sdg.incident_edges(Vertex_handle v)</i>	Starts at an arbitrary edge incident to <i>v</i> .
<i>Edge_circulator</i>	<i>sdg.incident_edges(Vertex_handle v, Face_handle f)</i>	Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

<i>Vertex_circulator</i>	<i>sdg.incident_vertices(Vertex_handle v)</i>	Starts at an arbitrary vertex incident to <i>v</i> .
<i>Vertex_circulator</i>	<i>sdg.incident_vertices(Vertex_handle v, Face_handle f)</i>	Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above methods allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

```
Vertex_circulator    sdg.incident_vertices( sdg.infinite_vertex())
Vertex_circulator    sdg.incident_vertices( sdg.infinite_vertex(), Face_handle f)
Face_circulator      sdg.incident_faces( sdg.infinite_vertex())
Face_circulator      sdg.incident_faces( sdg.infinite_vertex(), Face_handle f)
Edge_circulator      sdg.incident_edges( sdg.infinite_vertex())
Edge_circulator      sdg.incident_edges( sdg.infinite_vertex(), Face_handle f)
```

Predicates

The class *Segment_Delaunay_graph_2*<*Gt,DS*> provides methods to test the finite or infinite character of any feature.

```
bool    sdg.is_infinite( Vertex_handle v)      true, iff v is the infinite_vertex.
bool    sdg.is_infinite( Face_handle f)        true, iff face f is infinite.
bool    sdg.is_infinite( Face_handle f, int i) true, iff edge (f,i) is infinite.
bool    sdg.is_infinite( Edge e)               true, iff edge e is infinite.
bool    sdg.is_infinite( Edge_circulator ec)    true, iff edge *ec is infinite.
```

Insertion

```
template< class Input_iterator >
size_type    sdg.insert( Input_iterator first, Input_iterator beyond)
```

Inserts the sites in the range [*first,beyond*). The number of additional sites inserted in the Delaunay graph is returned. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

```
template< class Input_iterator >
size_type    sdg.insert( Input_iterator first, Input_iterator beyond, Tag_false)
```

Same as the previous method. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

```
template< class Input_iterator >
size_type    sdg.insert( Input_iterator first, Input_iterator beyond, Tag_true)
```

Inserts the sites in the range [*first,beyond*) after performing a random shuffle on them. The number of additional sites inserted in the Delaunay graph is returned. *Input_iterator* must be a model of *InputIterator* and its value type must be either *Point_2* or *Site_2*.

```
Vertex_handle    sdg.insert( Point_2 p)
```

Inserts the point *p* in the segment Delaunay graph. If *p* has already been inserted, then the vertex handle of its already inserted copy is returned. If *p* has not been inserted yet, the vertex handle of *p* is returned.

Vertex_handle *sdg.insert(Point_2 p, Vertex_handle vnear)*

Inserts p in the segment Delaunay graph using the site associated with $vnear$ as an estimate for the nearest neighbor of p . The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Point_2 p)*.

Vertex_handle *sdg.insert(Point_2 p1, Point_2 p2)*

Inserts the closed segment with endpoints $p1$ and $p2$ in the segment Delaunay graph. If the segment has already been inserted in the Delaunay graph then the vertex handle of its already inserted copy is returned. If the segment does not intersect any segment in the existing diagram, the vertex handle corresponding to its corresponding open segment is returned. Finally, if the segment intersects other segments in the existing Delaunay graph, the vertex handle to one of its open subsegments is returned.

Vertex_handle *sdg.insert(Point_2 p1, Point_2 p2, Vertex_handle vnear)*

Inserts the segment whose endpoints are $p1$ and $p2$ in the segment Delaunay graph using the site associated with $vnear$ as an estimate for the nearest neighbor of $p1$. The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Point_2 p1, Point_2 p2)*.

Vertex_handle *sdg.insert(Site_2 s)*

Inserts the site s in the segment Delaunay graph. The vertex handle returned has the same semantics as the vertex handle returned by the methods *Vertex_handle insert(Point_2 p)* and *Vertex_handle insert(Point_2 p1, Point_2 p2)*, depending on whether s represents a point or a segment respectively.

Precondition: s.is_input() must be true.

Vertex_handle *sdg.insert(Site_2 s, Vertex_handle vnear)*

Inserts s in the segment Delaunay graph using the site associated with $vnear$ as an estimate for the nearest neighbor of s , if s is a point, or the first endpoint of s , if s is a segment. The vertex handle returned has the same semantics as the vertex handle returned by the method *Vertex_handle insert(Site_2 s)*.

Precondition: s.is_input() must be true.

Nearest neighbor location

Vertex_handle *sdg.nearest_neighbor(Point_2 p)*

Finds the nearest neighbor of the point p . In other words it finds the site whose segment Voronoi diagram cell contains p . Ties are broken arbitrarily and one of the nearest neighbors of p is returned. If there are no sites in the segment Delaunay graph *Vertex_handle()* is returned.

Vertex_handle *sdg.nearest_neighbor(Point_2 p, Vertex_handle vnear)*

Finds the nearest neighbor of the point p using the site associated with $vnear$ as an estimate for the nearest neighbor of p . Ties are broken arbitrarily and one of the nearest neighbors of p is returned. If there are no sites in the segment Delaunay graph *Vertex_handle()* is returned.

I/O

template < class Stream >
Stream& sdg.draw_dual(Stream& str) Draws the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

template < class Stream >
Stream& sdg.draw_skeleton(Stream& str)

Draws the segment Voronoi diagram to the stream *str*, except the edges of the diagram corresponding to a segment and its endpoints.

The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

template< class Stream >
Stream& sdg.draw_dual_edge(Edge e, Stream& str)

Draws the edge *e* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

Precondition: e must be a finite edge.

template< class Stream >
Stream& sdg.draw_dual_edge(Edge_circulator ec, Stream& str)

Draws the edge **ec* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

*Precondition: *ec must be a finite edge.*

template< class Stream >
Stream& sdg.draw_dual_edge(All_edges_iterator eit, Stream& str)

Draws the edge **eit* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

*Precondition: *eit must be a finite edge.*

template< class Stream >
Stream& sdg.draw_dual_edge(Finite_edges_iterator eit, Stream& str)

Draws the edge **eit* of the segment Voronoi diagram to the stream *str*. The following operators must be defined:

Stream& operator<<(Stream&, Gt::Segment_2)

Stream& operator<<(Stream&, Gt::Ray_2)

Stream& operator<<(Stream&, Gt::Line_2)

<code>void</code>	<code>sdg.file_output(std::ostream& os)</code>	Writes the current state of the segment Delaunay graph to an output stream. In particular, all sites in the diagram are written to the stream (represented through appropriate input sites), as well as the underlying combinatorial data structure.
<code>void</code>	<code>sdg.file_input(std::istream& is)</code>	Reads the state of the segment Delaunay graph from an input stream.
<code>std::ostream&</code>	<code>std::ostream& os << sdg</code>	Writes the current state of the segment Delaunay graph to an output stream.
<code>std::istream&</code>	<code>std::istream& is >> sdg</code>	Reads the state of the segment Delaunay graph from an input stream.

Validity check

<code>bool</code>	<code>sdg.is_valid(bool verbose = false, int level = 1)</code>	Checks the validity of the segment Delaunay graph. If <i>verbose</i> is <i>true</i> a short message is sent to <code>std::cerr</code> . If <i>level</i> is 0, only the data structure is validated. If <i>level</i> is 1, then both the data structure and the segment Delaunay graph are validated. Negative values of <i>level</i> always return true, and values greater than 1 are equivalent to <i>level</i> being 1.
-------------------	---	--

Miscellaneous

<code>void</code>	<code>sdg.clear()</code>	Clears all contents of the segment Delaunay graph.
<code>void</code>	<code>sdg.swap(other)</code>	The segment Delaunay graphs <i>other</i> and <i>sdg</i> are swapped. <code>sdg.swap(other)</code> should be preferred to <code>sdg= other</code> or to <code>sdg(other)</code> if <i>other</i> is deleted afterwards.

SegmentDelaunayGraphSite_2

Definition

The concept *SegmentDelaunayGraphSite_2* provides the requirements for the sites of a segment Delaunay graph.

Refines

DefaultConstructible

CopyConstructible

Assignable

Types

<i>SegmentDelaunayGraphSite_2:: Point_2</i>	The point type.
<i>SegmentDelaunayGraphSite_2:: Segment_2</i>	The segment type.
<i>SegmentDelaunayGraphSite_2:: FT</i>	The field number type.
<i>SegmentDelaunayGraphSite_2:: RT</i>	The ring number type.

Creation

In addition to the default and copy constructors the following static methods are available for constructing sites:

<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p)</i>	Constructs a site from a point: the site represents the point p .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2)</i>	Constructs a site from two points: the site represents the (open) segment $(p1,p2)$.
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2)</i>	Constructs a site from four points: the site represents the point of intersection of the segments $(p1,p2)$ and $(q1,q2)$.
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2, bool b)</i>	Constructs a site from four points and a boolean: the site represents a segment. If b is <i>true</i> the endpoints are $p1$ and p_{\times} , otherwise p_{\times} and $p2$. p_{\times} is the point of intersection of the segments $(p1,p2),(q1,q2)$.
<i>SegmentDelaunayGraphSite_2</i>	<i>s.construct_site_2(Point_2 p1, Point_2 p2, Point_2 q1, Point_2 q2, Point_2 r1,</i>	

Point_2 r2)

Constructs a site from six points: the site represents the segment with endpoints the points of intersection of the pairs of segments $(p1,p2),(q1,q2)$ and $(p1,p2),(r1,r2)$.

Predicates

<i>bool</i>	<i>s.is_defined()</i>	Returns <i>true</i> if the site represents a valid point or segment.
<i>bool</i>	<i>s.is_point()</i>	Returns <i>true</i> if the site represents a point.
<i>bool</i>	<i>s.is_segment()</i>	Returns <i>true</i> if the site represents a segment.
<i>bool</i>	<i>s.is_input()</i>	Returns <i>true</i> if the site represents an input point or a segment defined by two input points. Returns <i>false</i> if it represents a point of intersection of two segments, or if it represents a segment, at least one endpoint of which is a point of intersection of two segments.
<i>bool</i>	<i>s.is_input(unsigned int i)</i>	Returns <i>true</i> if the <i>i</i> -th endpoint of the site is an input point. Returns <i>false</i> if the <i>i</i> -th endpoint of the site is the intersection of two segments. <i>Precondition:</i> <i>i</i> must be at most 1, and <i>s.is_segment()</i> must be <i>true</i> .

Access Functions

<i>Point_2</i>	<i>s.point()</i>	Returns the point represented by the site <i>s</i> . <i>Precondition:</i> <i>s.is_point()</i> must be <i>true</i> .
<i>Segment_2</i>	<i>s.segment()</i>	Returns the segment represented by the site <i>s</i> . <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>Point_2</i>	<i>s.source()</i>	Returns the source endpoint of the segment. Note that this method can construct an inexact point if the number type used is inexact. <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>Point_2</i>	<i>s.target()</i>	Returns the target endpoint of the segment. Note that this method can construct an inexact point if the number type used is inexact. <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.supporting_site()</i>	Returns a segment site object representing the segment that supports the segment represented by the site. Both endpoints of the returned site are input points. <i>Precondition:</i> <i>s.is_segment()</i> must be <i>true</i> .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.supporting_site(unsigned int i)</i>	Returns a segment site object representing the <i>i</i> -th segment that supports the point of intersection represented by the site. Both endpoints of the returned site are input points. <i>Precondition:</i> <i>i</i> must be at most 1, <i>s.is_point()</i> must be <i>true</i> and <i>s.is_input()</i> must be <i>false</i> .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.crossing_site(unsigned int i)</i>	Returns a segment site object representing the <i>i</i> -th segment that supports the <i>i</i> -th endpoint of the site which is not the supporting segment of the site. Both endpoints of the returned site are input points. <i>Precondition:</i> <i>i</i> must be at most 1, <i>s.is_segment()</i> must be <i>true</i> and <i>s.is_input(i)</i> must be <i>false</i> .

<i>SegmentDelaunayGraphSite_2</i>	<i>s.source_site()</i>	Returns a point site object representing the source point of the site. <i>Precondition: s.is_segment()</i> must be <i>true</i> .
<i>SegmentDelaunayGraphSite_2</i>	<i>s.target_site()</i>	Returns a point site object representing the target point of the site. <i>Precondition: s.is_segment()</i> must be <i>true</i> .
<i>Point_2</i>	<i>s.source_of_supporting_site()</i>	Returns the source point of the supporting site of the this site. <i>Precondition: is_segment()</i> must be <i>true</i> .
<i>Point_2</i>	<i>s.target_of_supporting_site()</i>	Returns the target point of the supporting site of the this site. <i>Precondition: is_segment()</i> must be <i>true</i> .
<i>Point_2</i>	<i>s.source_of_supporting_site(unsigned int i)</i>	Returns the source point of the <i>i</i> -th supporting site of the this site. <i>Precondition: is_point()</i> must be <i>true</i> , <i>is_input()</i> must be <i>false</i> and <i>i</i> must either be 0 or 1.
<i>Point_2</i>	<i>s.target_of_supporting_site(unsigned int i)</i>	Returns the target point of the <i>i</i> -th supporting site of the this site. <i>Precondition: is_point()</i> must be <i>true</i> , <i>is_input()</i> must be <i>false</i> and <i>i</i> must either be 0 or 1.
<i>Point_2</i>	<i>s.source_of_crossing_site(unsigned int i)</i>	Returns the source point of the <i>i</i> -th crossing site of the this site. <i>Precondition: is_segment()</i> must be <i>true</i> , <i>is_input(i)</i> must be <i>false</i> and <i>i</i> must either be 0 or 1.
<i>Point_2</i>	<i>s.target_of_crossing_site(unsigned int i)</i>	Returns the target point of the <i>i</i> -th supporting site of the this site. <i>Precondition: is_segment()</i> must be <i>true</i> , <i>is_input(i)</i> must be <i>false</i> and <i>i</i> must either be 0 or 1.

SegmentDelaunayGraphStorageSite_2

Definition

The concept *SegmentDelaunayGraphStorageSite_2* provides the requirements for the storage sites of a segment Delaunay graph. The storage sites are sites that are used to store the information of a site in a more compact form (that uses less storage). This is achieved by storing handles to points instead of points.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

<i>SegmentDelaunayGraphStorageSite_2:: Site_2</i>		The site type.
<i>typedef typename std::set<typename Site_2::Point_2>::iterator</i>	<i>Point_handle;</i>	The type for a handle to a point.

Creation

In addition to the default and copy constructors, the following static methods should be available for constructing sites:

<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.construct_storage_site_2(Point_handle hp)</i>	Constructs a storage site from a point handle. The storage site represents the point associated with the point handle <i>hp</i> .
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2)</i>	Constructs a storage site from two point handles. The storage site represents the segment the endpoints of which are the points associated with the point handles <i>hp1</i> and <i>hp2</i> .
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.construct_storage_site_2(Point_handle hp1, Point_handle hp2, Point_handle hq1, Point_handle hq2)</i>	Constructs a storage site from four point handles. The storage site represents the point of intersection of the segments the endpoints of which are the points associated with the point handles <i>hp1</i> , <i>hp2</i> and <i>hq1</i> and <i>hq2</i> , respectively.

SegmentDelaunayGraphStorageSite_2 *ss.construct_storage_site_2(Point_handle hp1,
Point_handle hp2,
Point_handle hq1,
Point_handle hq2,
bool b)*

Constructs a site from four point handles and a boolean. The storage site represents a segment. If *b* is *true*, the first endpoint of the segment is the point associated with the handle *hp1* and the second endpoint is the point of intersection of the segments the endpoints of which are the point associated with the point handles *hp1*, *hp2* and *hq1*, *hq2*, respectively. If *b* is *false*, the first endpoint of the represented segment is the one mentioned above, whereas the second endpoint if the point associated with the point handle *hp2*.

SegmentDelaunayGraphStorageSite_2 *ss.construct_storage_site_2(Point_handle hp1,
Point_handle hp2,
Point_handle hq1,
Point_handle hq2,
Point_handle hr1,
Point_handle hr2)*

Constructs a storage site from six point handles. The storage site represents of segment the endpoints of which are points of intersection of two pairs of segments, the endpoints of which are *hp1*, *hp2/hq1*, *hq2* and *hp1*, *hp2/hr1*, *hr2*, respectively.

Predicates

<i>bool</i> <i>ss.is_defined()</i>	Returns <i>true</i> if the storage site represents a valid point or segment.
<i>bool</i> <i>ss.is_point()</i>	Returns <i>true</i> if the storage site represents a point.
<i>bool</i> <i>ss.is_segment()</i>	Returns <i>true</i> if the storage site represents a segment.
<i>bool</i> <i>ss.is_input()</i>	Returns <i>true</i> if the storage site represents an input point or a segment defined by two input points. Returns <i>false</i> if it represents a point of intersection of two segments, or if it represents a segment, at least one endpoint of which is a point of intersection of two segments.
<i>bool</i> <i>ss.is_input(unsigned int i)</i>	Returns <i>true</i> if the <i>i</i> -th endpoint of the corresponding site is an input point. Returns <i>false</i> if the <i>i</i> -th endpoint of the corresponding site is the intersection of two segments. <i>Precondition:</i> <i>i</i> must be at most 1, and <i>ss.is_segment()</i> must be <i>true</i> .

Access Functions

SegmentDelaunayGraphStorageSite_2 *ss.supporting_site()*

Returns a storage site object representing the segment that supports the segment represented by the storage site. The returned storage site represents a site, both endpoints of which are input points.
Precondition: *ss.is_segment()* must be *true*.

<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.source_site()</i>	Returns a storage site that represents the first endpoint of the represented segment. <i>Precondition: ss.is_segment() must be true.</i>
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.target_site()</i>	Returns a storage site that represents the second endpoint of the represented segment. <i>Precondition: ss.is_segment() must be true.</i>
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.supporting_site(unsigned int i)</i>	Returns a storage site object representing the <i>i</i> -th segment that supports the point of intersection represented by the storage site. The returned storage site represents a site, both endpoints of which are input points. <i>Precondition: i must be at most 1, ss.is_point() must be true and ss.is_input() must be false.</i>
<i>SegmentDelaunayGraphStorageSite_2</i>	<i>ss.crossing_site(unsigned int i)</i>	Returns a storage site object representing the <i>i</i> -th segment that supports the <i>i</i> -th endpoint of the site which is not the supporting segment of the site. The returned storage site represents a site, both endpoints of which are input points. <i>Precondition: i must be at most 1, ss.is_segment() must be true and ss.is_input(i) must be false.</i>
<i>Site_2</i>	<i>ss.site()</i>	Returns the site represented by the storage site.
<i>Point_handle</i>	<i>ss.point()</i>	Returns a handle associated with the represented point. <i>Precondition: is_point() and is_input() must both be true.</i>
<i>Point_handle</i>	<i>ss.source_of_supporting_site()</i>	Returns a handle to the source point of the supporting site of the this site. <i>Precondition: is_segment() must be true.</i>
<i>Point_handle</i>	<i>ss.target_of_supporting_site()</i>	Returns a handle to the target point of the supporting site of the this site. <i>Precondition: is_segment() must be true.</i>
<i>Point_handle</i>	<i>ss.source_of_supporting_site(unsigned int i)</i>	Returns a handle to the source point of the <i>i</i> -th supporting site of the this site. <i>Precondition: is_point() must be true, is_input() must be false and i must either be 0 or 1.</i>
<i>Point_handle</i>	<i>ss.target_of_supporting_site(unsigned int i)</i>	Returns a handle to the target point of the <i>i</i> -th supporting site of the this site. <i>Precondition: is_point() must be true, is_input() must be false and i must either be 0 or 1.</i>

Point_handle

ss.source_of_crossing_site(unsigned int i)

Returns a handle to the source point of the *i*-th crossing site of the this site.

Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be 0 or 1.

Point_handle

ss.target_of_crossing_site(unsigned int i)

Returns a handle to the target point of the *i*-th supporting site of the this site.

Precondition: *is_segment()* must be *true*, *is_input(i)* must be *false* and *i* must either be 0 or 1.

SegmentDelaunayGraphDataStructure_2

Definition

The concept *SegmentDelaunayGraphDataStructure_2* refines the concept *ApolloniusGraphDataStructure_2*. In addition it provides two methods for the merging of two vertices joined by an edge of the data structure, and the splitting of a vertex into two. The method that merges two vertices, called *join_vertices* identifies the two vertices and deletes their common two faces. The method that splits a vertex, called *split_vertex* introduces a new vertex that shares an edge and two faces with the old vertex (see figure below). Notice that the *join_vertices* and *split_vertex* operations are complementary, in the sense that one reverses the action of the other.

Figure 31.3: The join and split operations. Left to right: The vertex v is split into v_1 and v_2 . The faces f and g are inserted after f_1 and f_2 , respectively, in the counter-clockwise sense. The vertices v_1 , v_2 and the faces f and g are returned as a *boost tuple* in that order. Right to left: The edge (f, i) is collapsed, and thus the vertices v_1 and v_2 are joined. The vertex v is returned.

We only describe the additional requirements with respect to the *ApolloniusGraphDataStructure_2* concept.

Refines

ApolloniusGraphDataStructure_2

Modification

Vertex_handle `sdgds.join_vertices(Face_handle f, int i)`

Joins the vertices that are endpoints of the edge (f, i) . It returns a vertex handle to common vertex.

boost::tuples::tuple<Vertex_handle, Vertex_handle, Face_handle, Face_handle>

sdgds.split_vertex(Vertex_handle v, Face_handle f1, Face_handle f2)

Splits the vertex v into two vertices $v1$ and $v2$. The common faces f and g of $v1$ and $v2$ are created after (in the counter-clockwise sense) the faces $f1$ and $f2$. The 4-tuple $(v1, v2, f, g)$ is returned (see Fig. 31.6).

TriangulationFaceBase_2

SegmentDelaunayGraphVertexBase_2

Definition

The concept *SegmentDelaunayGraphVertexBase_2* describes the requirements for the vertex base class of the *SegmentDelaunayGraphDataStructure_2* concept. A vertex stores a site of the segment Delaunay graph and provides access to one of its incident faces through a *Face_handle*.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

<i>SegmentDelaunayGraphVertexBase_2::Geom_traits</i>	A type for the geometric traits that defines the site. <i>Precondition:</i> The type <i>Geom_traits</i> must define the type <i>Site_2</i> .
<i>SegmentDelaunayGraphVertexBase_2::Site_2</i>	A type for the site. This type must coincide with the type <i>Geom_traits::Site_2</i> .
<i>SegmentDelaunayGraphVertexBase_2::Storage_site_tag</i>	A type that indicates what kind of storage type to use. <i>Storage_site_tag</i> must either be <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>SegmentDelaunayGraphVertexBase_2::Storage_site_2</i>	A type for the internal representation of sites. This type must satisfy the requirements of the concept <i>SegmentDelaunayGraphStorageSite_2</i> .
<i>SegmentDelaunayGraphVertexBase_2::Data_structure</i>	A type for the underlying data structure, to which the vertex belongs to.
<i>SegmentDelaunayGraphVertexBase_2::Vertex_handle</i>	A type for the vertex handle of the segment Delaunay graph data structure.
<i>SegmentDelaunayGraphVertexBase_2::Face_handle</i>	A type for the face handle of the segment Delaunay graph data structure.

Creation

In addition to the default and copy constructors and following constructors are required:

<i>SegmentDelaunayGraphVertexBase_2</i> <i>v</i> (<i>Storage_site_2</i> <i>ss</i>);	Constructs a vertex associated with the site represented by the storage site <i>ss</i> .
<i>SegmentDelaunayGraphVertexBase_2</i> <i>v</i> (<i>Storage_site_2</i> <i>ss</i> , <i>Face_handle</i> <i>f</i>);	Constructs a vertex associated with the site represented by the storage site <i>ss</i> , and pointing to the face associated with the face handle <i>f</i> .

Access Functions

<i>Storage_site_2</i>	<i>v.storage_site()</i>	Returns the storage site representing the site.
<i>Site_2</i>	<i>v.site()</i>	Returns the site.
<i>Face_handle</i>	<i>v.face()</i>	Returns a handle to an incident face.

Setting

<i>void</i>	<i>v.set_site(Storage_site_2 ss)</i>	Sets the storage site.
<i>void</i>	<i>v.set_face(Face_handle f)</i>	Sets the incident face.

Checking

<i>bool</i>	<i>v.is_valid(bool verbose, int level)</i>	Performs any required tests on a vertex.

CGAL::Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>

Definition

The class *Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>* provides a model for the *SegmentDelaunayGraphVertexBase_2* concept which is the vertex base required by the *SegmentDelaunayGraphDataStructure_2* concept. The class *Segment_Delaunay_graph_vertex_base_2<Gt,SSTag>* has two template arguments, the first being the geometric traits of the segment Delaunay graph and should be a model of the concept *SegmentDelaunayGraphTraits_2*. The second template argument indicates whether or not to use the simple storage site that does not support intersecting segments, or the full storage site, that supports intersecting segments. The possible values are *CGAL::Tag_true* and *CGAL::Tag_false*. *CGAL::Tag_true* indicates that the full storage site is to be used, whereas *CGAL::Tag_false* indicates that the simple storage site is to be used.

SegmentDelaunayGraphTraits_2

Definition

The concept *SegmentDelaunayGraphTraits_2* provides the traits requirements for the *SegmentDelaunay_graph_2*<Gt,DS> and *SegmentDelaunay_graph_hierarchy_2*<Gt,STag,DS> classes. In particular, it provides a type *Site_2*, which must be a model of the concept *SegmentDelaunayGraphSite_2*. It also provides constructions for sites and several function object types for the predicates.

Refines

DefaultConstructible
CopyConstructible
Assignable

Types

<i>SegmentDelaunayGraphTraits_2:: Intersections_tag</i>	Indicates or not whether the intersecting segments are to be supported. The tag must either be <i>CGAL::Tag_true</i> or <i>CGAL::Tag_false</i> .
<i>SegmentDelaunayGraphTraits_2:: Site_2</i>	A type for a site of the segment Delaunay graph. Must be a model of the concept <i>SegmentDelaunayGraphSite_2</i> .
<i>SegmentDelaunayGraphTraits_2:: Point_2</i>	A type for a point.
<i>SegmentDelaunayGraphTraits_2:: Line_2</i>	A type for a line. Only required if the segment Delaunay graph is inserted in a stream.
<i>SegmentDelaunayGraphTraits_2:: Ray_2</i>	A type for a ray. Only required if the segment Delaunay graph is inserted in a stream.
<i>SegmentDelaunayGraphTraits_2:: Segment_2</i>	A type for a segment. Only required if if the segment Delaunay graph is inserted in a stream.
<i>SegmentDelaunayGraphTraits_2:: FT</i>	A type for the field number type of sites, points, etc..
<i>SegmentDelaunayGraphTraits_2:: RT</i>	A type for the ring number type of sites, points, etc.
<i>SegmentDelaunayGraphTraits_2:: Arrangement_type</i>	An enumeration type that indicates the type of the arrangement of two sites. The possible values are <i>DISJOINT</i> , <i>IDENTICAL</i> , <i>CROSSING</i> , <i>TOUCHING_1</i> , <i>TOUCHING_2</i> , <i>TOUCHING_11</i> , <i>TOUCHING_12</i> , <i>TOUCHING_21</i> , <i>TOUCHING_22</i> , <i>OVERLAPPING_11</i> , <i>OVERLAPPING_12</i> , <i>OVERLAPPING_21</i> , <i>OVERLAPPING_22</i> , <i>INTERIOR</i> , <i>INTERIOR_1</i> , <i>INTERIOR_2</i> , <i>TOUCHING_11_INTERIOR_1</i> , <i>TOUCHING_11_INTERIOR_2</i> , <i>TOUCHING_12_INTERIOR_1</i> , <i>TOUCHING_12_INTERIOR_2</i> , <i>TOUCHING_21_INTERIOR_1</i> , <i>TOUCHING_21_INTERIOR_2</i> , <i>TOUCHING_22_INTERIOR_1</i> , <i>TOUCHING_22_INTERIOR_2</i> . A detailed description of the meaning of these values is shown the end of the reference manual for this concept. (to be done)

<i>SegmentDelaunayGraphTraits_2:: Object_2</i>	A type representing different types of objects in two dimensions, namely: <i>Point_2</i> , <i>Site_2</i> , <i>Line_2</i> , <i>Ray_2</i> and <i>Segment_2</i> .
<i>SegmentDelaunayGraphTraits_2:: Assign_2</i>	Must provide <i>template <class T> bool operator() (T& t, Object_2 o)</i> which assigns <i>o</i> to <i>t</i> if <i>o</i> was constructed from an object of type <i>T</i> . Returns <i>true</i> , if the assignment was possible.
<i>SegmentDelaunayGraphTraits_2:: Construct_object_2</i>	Must provide <i>template <class T> Object_2 operator()(T t)</i> that constructs an object of type <i>Object_2</i> that contains <i>t</i> and returns it.
<i>SegmentDelaunayGraphTraits_2:: Construct_svd_vertex_2</i>	A constructor for a point of the segment Voronoi diagram equidistant from three sites. Must provide <i>Point_2 operator()(Site_2 s1, Site_2 s2, Site_2 s3)</i> , which constructs a point equidistant from the sites <i>s1</i> , <i>s2</i> and <i>s3</i> .
<i>SegmentDelaunayGraphTraits_2:: Compare_x_2</i>	A predicate object type. Must provide <i>Comparison_result operator()(Site_2 s1, Site_2 s2)</i> , which compares the x-coordinates of the points represented by the sites <i>s1</i> and <i>s2</i> . <i>Precondition: s1 and s2 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Compare_y_2</i>	A predicate object type. Must provide <i>Comparison_result operator()(Site_2 s1, Site_2 s2)</i> , which compares the y-coordinates of the points represented by the sites <i>s1</i> and <i>s2</i> . <i>Precondition: s1 and s2 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Orientation_2</i>	A predicate object type. Must provide <i>Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3)</i> , which performs the usual orientation test for three points. <i>s1</i> , <i>s2</i> and <i>s3</i> . <i>Precondition: the sites s1, s2 and s3 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Equal_2</i>	A predicate object type. Must provide <i>bool operator()(Site_2 s1, Site_2 s2)</i> , which determines if the points represented by the sites <i>s1</i> and <i>s2</i> are identical. <i>Precondition: s1 and s2 must be points.</i>
<i>SegmentDelaunayGraphTraits_2:: Are_parallel_2</i>	A predicate object type. Must provide <i>bool operator()(Site_2 s1, Site_2 s2)</i> , which determines if the segments represented by the sites <i>s1</i> and <i>s2</i> are parallel. <i>Precondition: s1 and s2 must be segments.</i>
<i>SegmentDelaunayGraphTraits_2:: Oriented_side_of_bisector_2</i>	A predicate object type. Must provide <i>Oriented_side operator()(Site_2 s1, Site_2 s2, Point_2 p)</i> , which returns the oriented side of the bisector of <i>s1</i> and <i>s2</i> that contains <i>p</i> . Returns <i>ON_POSITIVE_SIDE</i> if <i>p</i> lies in the half-space of <i>s1</i> (i.e., <i>p</i> is closer to <i>s1</i> than <i>s2</i>); returns <i>ON_NEGATIVE_SIDE</i> if <i>p</i> lies in the half-space of <i>s2</i> ; returns <i>ON_ORIENTED_BOUNDARY</i> if <i>p</i> lies on the bisector of <i>s1</i> and <i>s2</i> .

SegmentDelaunayGraphTraits_2:: Vertex_conflict_2

A predicate object type. Must provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q)*, which returns the sign of the distance of q from the Voronoi circle of $s1, s2, s3$ (the Voronoi circle of three sites $s1, s2, s3$ is a circle co-tangent to all three sites, that touches them in that order as we walk on its circumference in the counter-clockwise sense).

Precondition: the Voronoi circle of $s1, s2, s3$ must exist.

Must also provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 q)*, which returns the sign of the distance of q from the bitangent line of $s1, s2$ (a degenerate Voronoi circle, with its center at infinity).

SegmentDelaunayGraphTraits_2:: Finite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4, Site_2 q, Sign sgn)*. The sites $s1, s2, s3$ and $s4$ define a Voronoi edge that lies on the bisector of $s1$ and $s2$ and has as endpoints the Voronoi vertices defined by the triplets $s1, s2, s3$ and $s1, s4$ and $s2$. The sign sgn is the common sign of the distance of the site q from the Voronoi circle of the triplets $s1, s2, s3$ and $s1, s4$ and $s2$. In case that sgn is equal to *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If sgn is equal to *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

Precondition: the Voronoi vertices of $s1, s2, s3$, and $s1, s4, s2$ must exist.

Must also provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, Sign sgn)*. The sites $s1, s2, s3$ and the site at infinity s_∞ define a Voronoi edge that lies on the bisector of $s1$ and $s2$ and has as endpoints the Voronoi vertices v_{123} and $v_{1\infty 2}$ defined by the triplets $s1, s2, s3$ and $s1, s_\infty$ and $s2$ (the second vertex is actually at infinity). The sign sgn is the common sign of the distance of the site q from the two Voronoi circles centered at the Voronoi vertices v_{123} and $v_{1\infty 2}$. In case that sgn is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If sgn is *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

Precondition: the Voronoi vertex v_{123} of $s1, s2, s3$ must exist.

Must finally provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 q, Sign sgn)*. The sites $s1, s2$ and the site at infinity s_∞ define a Voronoi edge that lies on the bisector of $v_{12\infty}$ and $v_{1\infty 2}$ $s1$ and $s2$ and has as endpoints the Voronoi vertices defined by the triplets $s1, s2, s_\infty$ and $s1, s_\infty$ and $s2$ (both vertices are actually at infinity). The sign sgn denotes the common sign of the distance of the site q from the Voronoi circles centered at $v_{12\infty}$ and $v_{1\infty 2}$. If sgn is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If *POSITIVE* or *ZERO* is *false*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

SegmentDelaunayGraphTraits_2:: Infinite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, Sign sgn)*. The sites $s_\infty, s1, s2$ and $s3$ define a Voronoi edge that lies on the bisector of s_∞ and $s1$ and has as endpoints the Voronoi vertices $v_{\infty 12}$ and $v_{\infty 31}$ defined by the triplets $s_\infty, s1, s2$ and $s_\infty, s3$ and $s1$. The sign sgn is the common sign of the distances of q from the Voronoi circles centered at the vertices $v_{\infty 12}$ and $v_{\infty 31}$. If sgn is *NEGATIVE*, the predicate returns *true* if and only if the entire Voronoi edge is in conflict with q . If sgn is *POSITIVE* or *ZERO*, the predicate returns *false* if and only if q is not in conflict with the Voronoi edge.

SegmentDelaunayGraphTraits_2:: Oriented_side_2

A predicate object type. Must provide *Oriented_side operator()*(*Site_1 s1*, *Site_2 s2*, *Site_2 s3*, *Site_2 s*, *Site_2 p*). Determines the oriented side of the line ℓ that contains the point site p , where ℓ is the line that passes through the Voronoi vertex of the sites $s1$, $s2$, $s3$ and is perpendicular to the segment site s .

Precondition: s must be a segment and p must be a point.

SegmentDelaunayGraphTraits_2:: Arrangement_type_2

A predicate object type. Must provide *Arrangement_type operator()*(*Site_2 s1*, *Site_2 s2*) that returns the type of the arrangement of the two sites $s1$ and $s2$.

CGAL::Segment_Delaunay_graph_traits_2<K,MTag>

Definition

The class *Segment_Delaunay_graph_traits_2<K,MTag>* provides a model for the *SegmentDelaunayGraphTraits_2* concept. This class has two template parameters. The first template parameter must be a model of the *Kernel* concept. The second template parameter corresponds to how predicates are evaluated. There are two possible values for *MTag*, namely *CGAL::Sqrt_field_tag* and *CGAL::Field_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of field-type expressions, i.e., expressions involving additions, subtractions, multiplications and divisions. The default value for *MTag* is *CGAL::Field_tag*. The way the predicates are evaluated is discussed in [Bur96] and [Kar04] (the geometric filtering part).

```
#include <CGAL/Segment_Delaunay_graph_traits_2.h>

CGAL::Segment_Delaunay_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>

Definition

The class *Segment_Delaunay_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> provides a model for the *SegmentDelaunayGraphTraits_2* concept.

The class *Segment_Delaunay_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> uses the filtering technique [BBP01] to achieve traits for the *Segment_Delaunay_graph_2*<Gt,DS> class with efficient and exact predicates given an exact kernel *EK* and a filtering kernel *FK*. The geometric constructions associated provided by this class are equivalent to those provided by the traits class *Segment_Delaunay_graph_traits_2*<CK,CM>, which means that they may be inexact depending on the choice of the *CK* kernel.

This class has six template parameters. The first, third and fifth template parameters must be a models of the *Kernel* concept. The parameter *CK* is the construction kernel and it is the kernel that will be used for constructions. The parameter *FK* is the filtering kernel; this kernel will be used for performing the arithmetic filtering for the predicates involved in the computation of the segment Delaunay graph. Finally, the parameter *EK* is the exact kernel; this kernel will be used for computing the predicates if the filtering kernel fails to produce an answer.

The second, fourth and sixth template parameters correspond to how predicates are evaluated. There are two predefined possible values for these parameters, namely *CGAL::Sqrt_field_tag* and *CGAL::Field_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires that only field operations are exact. Finally, in order to get exact constructions *CM* must be set to *CGAL::Sqrt_field_tag* and the number type in *CK* must support operations involving divisions and square roots (as well as the other three basic operations of course). The way the predicates are evaluated is discussed in [Bur96] and [Kar04] (the geometric filtering part).

The default values for the template parameters are as follows: *CM* = *CGAL::Sqrt_field_tag* (it is assumed that *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<double>* will be the entry for the template parameter *CK*), *EM* = *CGAL::Field_tag*, *FK* = *CGAL::Simple_cartesian<CGAL::Interval_nt<false> >*, *FM* = *CGAL::Sqrt_field_tag*. If the GMP package is installed with CGAL, the template parameter *EK* has the default value: *EK* = *CGAL::Simple_cartesian<CGAL::Gmpq>*, otherwise its default value is *EK* = *CGAL::Simple_cartesian<CGAL::Quotient<CGAL::MP_Float> >*.

CGAL::Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>

Definition

We provide an alternative to the class *Segment_Delaunay_graph_2<Gt,DS>* for the incremental construction of the segment Delaunay graph. The *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class maintains a hierarchy of Delaunay graphs. There are two possibilities as to how this hierarchy is constructed.

In the first case the bottom-most level of the hierarchy contains the full segment Delaunay graph. The upper levels of the hierarchy contain only points that are either point sites or endpoints of segment sites in the bottom-most Delaunay graph. A point that is in level i (either as an individual point or as the endpoint of a segment), is inserted in level $i + 1$ with probability $1/\alpha$ where $\alpha > 1$ is some constant. In the second case the upper levels of the hierarchy contains not only points but also segments. A site that is in level i , is in level $i + 1$ with probability $1/\beta$ where $\beta > 1$ is some constant.

The difference between the *Segment_Delaunay_graph_2<Gt,DS>* class and the *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class (both versions of it) is on how the nearest neighbor location is done. Given a point p the location is done as follows: at the top most level we find the nearest neighbor of p as in the *Segment_Delaunay_graph_2<Gt,DS>* class. At every subsequent level i we use the nearest neighbor found at level $i + 1$ to find the nearest neighbor at level i . This is a variant of the corresponding hierarchy for points found in [Dev02]. The details are described in [Kar04].

The class has three template parameters. The first and third have essentially the same semantics as in the *Segment_Delaunay_graph_2<Gt,DS>* class. The first template parameter must be a model of the *SegmentDelaunayGraphTraits_2* concept. The third template parameter must be a model of the *SegmentDelaunayGraphDataStructure_2* concept. However, the vertex base class that is to be used in the segment Delaunay graph data structure must be a model of the *SegmentDelaunayGraphHierarchyVertexBase_2* concept. The third template parameter defaults to *Triangulation_data_structure_2<Segment_Delaunay_graph_hierarchy_vertex_base_2<Segment_Delaunay_graph_vertex_base_2<Gt>>, Triangulation_face_base_2<Gt>>*. The second template parameter controls whether or not segments are added in the upper levels of the hierarchy. It's possible values are *CGAL::Tag_true* and *CGAL::Tag_false*. If it is set to *CGAL::Tag_true*, segments are also inserted in the upper levels of the hierarchy. The value *CGAL::Tag_false* indicates that only points are to be inserted in the upper levels of the hierarchy. The default value for the second template parameter is *CGAL::Tag_false*.

The *Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS>* class derives publicly from the *Segment_Delaunay_graph_2<Gt,DS>* class. The interface is the same with its base class. In the sequel only additional types and methods defined are documented.

Types

Segment_Delaunay_graph_hierarchy_2<*Gt*,*S**Tag*,*DS*> introduces the following types in addition to those introduced by its base class *Segment_Delaunay_graph_2*<*Gt*,*DS*>.

```
typedef STag                               Segments_in_hierarchy_tag;
                                           A type for the STag template parameter.

typedef CGAL::Segment_Delaunay_graph_2<Gt,DS> Base;    A type for the base class.
```

Creation

In addition to the default and copy constructors, the following constructors are defined:

```
Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS> sdgh( Gt gt=Gt() );

                                           Creates a hierarchy of segment Delaunay graphs using gt as geometric
                                           traits.

template< class Input_iterator >
Segment_Delaunay_graph_hierarchy_2<Gt,STag,DS> sdgh( Input_iterator first,
                                           Input_iterator beyond,
                                           Gt gt=Gt() )

                                           Creates a segment Delaunay graph hierarchy using gt as geometric
                                           traits and inserts all sites in the range [first, beyond). Input_iterator
                                           must be a model of InputIterator. The value type of Input_iterator
                                           must be either Point_2 or Site_2.
```

I/O

```
std::ostream&    std::ostream& os << svdh    Writes the current state of the segment Delaunay graph hierar-
                                                    chy to an output stream. In particular, all sites in the diagram
                                                    are written to the stream (represented through appropriate in-
                                                    put sites), as well as the underlying combinatorial hierarchical
                                                    data structure.

std::istream&    std::istream& is >> svdh    Reads the state of the segment Delaunay graph hierarchy from
                                                    an input stream.

SegmentDelaunayGraphHierarchyVertexBase_2

Definition

The vertex of a segment Delaunay graph included in a segment Delaunay graph hierarchy has to provide some pointers to the corresponding vertices in the graphs of the next and preceeding levels. Therefore, the concept *SegmentDelaunayGraphHierarchyVertexBase_2* refines the concept *SegmentDelaunayGraphVertexBase_2*, by adding two vertex handles to the corresponding vertices for the next and previous level graphs.

Refines

SegmentDelaunayGraphVertexBase_2

Types

SegmentDelaunayGraphHierarchyVertexBase_2 does not introduce any types in addition to those of *SegmentDelaunayGraphVertexBase_2*.

Creation

The *SegmentDelaunayGraphHierarchyVertexBase_2* concept does not introduce any constructors in addition to those of the *SegmentDelaunayGraphVertexBase_2* concept.

Operations

<i>Vertex_handle</i>	<i>v.up()</i>	Returns a handle to the corresponding vertex of the next level segment Delaunay graph. If such a vertex does not exist <i>Vertex_handle()</i> is returned.
<i>Vertex_handle</i>	<i>v.down()</i>	Returns a handle to the corresponding vertex of the previous level segment Delaunay graph. If such a vertex does not exist <i>Vertex_handle()</i> is returned.
<i>void</i>	<i>v.set_up(Vertex_handle u)</i>	Sets the handle for the vertex of the next level segment Delaunay graph.
<i>void</i>	<i>v.set_down(Vertex_handle d)</i>	Sets the handle for the vertex of the previous level segment Delaunay graph.

This chapter describes the two-dimensional Apollonius graph of CGAL. We start with a few definitions in Section [32.1](#). The software design of the 2D Apollonius graph package is described in Section [32.2](#). In Section [32.3](#) we discuss the geometric traits of the 2D Apollonius graph package and in Section [32.4](#) the Apollonius graph hierarchy, a data structure suitable for fast nearest neighbor queries, is briefly described.

32.1 Definitions

The 2D Apollonius graph class of CGAL is designed to compute the dual of the *Apollonius diagram* or, as it is also known, the *Additively weighted Voronoi diagram*. The algorithm that has been implemented is dynamic, which means that we can perform insertions and deletions on line. The corresponding CGAL class is called `Apollonius_graph_2<ApolloniusGraphTraits_2, ApolloniusGraphDataStructure_2>` and will be discussed in more detail in the sequel. The interested reader may want to refer to the paper by Karavelas and Yvinec [[KY02](#)] for the general idea as well as the details of the algorithm implemented.

Before describing the details of the implementation we make a brief introduction to the theory of Apollonius diagrams. The Apollonius diagram is defined over a set of sites $P_i = (c_i, w_i)$, $i = 1, \dots, n$, where c_i is the point and w_i the weight of P_i . It is a subdivision of the plane into connected regions, called *cells*, associated with the

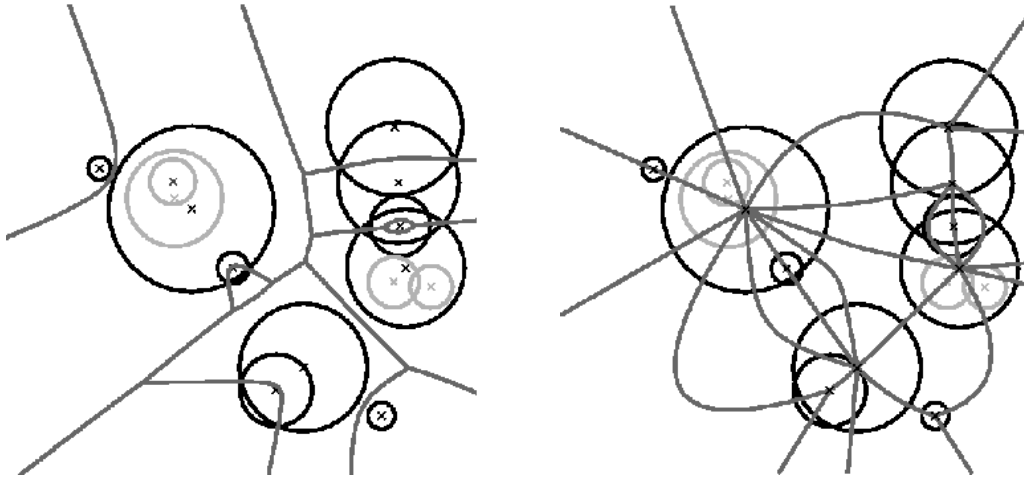

Figure 32.1: The Apollonius diagram (left) and its dual the Apollonius graph (right).

sites (see Fig. 32.1(left)). The cell of a site P_i is the locus of points on the plane that are closer to P_i than any other site P_j , $j \neq i$. The distance $\delta(x, P_i)$ of a point x in the plane to a site P_i is defined as:

$$\delta(x, P_i) = \|x - c_i\| - w_i,$$

where $\|\cdot\|$ denotes the Euclidean norm. It can easily be seen that it is a generalization of the Voronoi diagram for points, which can actually be obtained if all the weights w_i are equal. Unlike the case of points, however, it is possible that a site P_i might have an empty cell. This can also happen in the case of the power diagram, whose dual is the regular triangulation (see Section 25.6). If this is the case we call the site *hidden* (these are the black circles in Fig. 32.1). A site which is not hidden will be referred to as *visible*.

If all weights w_i are non-negative, the Apollonius diagram can be viewed as the Voronoi diagram of the set of circles $\{P_1, \dots, P_n\}$, where c_i is the center of the circle P_i and w_i its radius. If the weights are allowed to be negative, we need to go to 3D in order to explain what the Apollonius diagram means geometrically. We identify the 2D Euclidean plane with the xy -plane in 3D. Then the Voronoi diagram of a set of points can be seen as the vertical projection on the xy -plane of the lower envelope of a set of 3D cones defined as follows: for each point p in the set of 2D points we have a cone C_p whose apex is the point p . The axis of C_p is a line parallel to the z -axis passing through p , the angle of C_p is 45° and, finally C_p is facing in the positive z -direction (that is, C_p is contained in the positive z -halfspace). The Apollonius diagram corresponds to shifting the apexes of these cones in the z -direction by a quantity equal to the weight. Sites with negative weight will give rise to cones whose apex is in the negative z -halfspace and sites with positive weight will give rise to cones whose apex is in the positive z -halfspace. In a manner analogous to the case of points, the Apollonius diagram can then be defined as the vertical projection on the xy -plane of the lower envelope of the set of shifted cones. Notice that when all apexes are translated along the z -direction by the same amount, the projection of the lower envelope of the set of cones does not change. In particular, we can translate all cones by a large enough amount so that all apexes are in the positive z -halfspace. Algebraically, this means that the Apollonius diagram does not change if we add to all weights the same quantity, which in particular, implies that we can assume without loss of generality that all weights are positive. Given the observations above and in order to simplify our discussion of Apollonius diagrams, we will, from now on, assume that all weights are positive, and we will refer to the sites as circles.

The Apollonius diagram is a planar graph, and so is its dual, the Apollonius graph. There are many ways to embed it on the plane and one such way is shown in Fig. 32.1(right). The Apollonius graph is uniquely defined once we have the Apollonius diagram. If the circles are in *general position* (see precise definition below), then the Apollonius graph is a graph with triangular faces away from the convex hull of the set of circles (by

triangular we mean that every face has exactly three edges). Near the convex hull we may have some spikes (i.e., vertices of degree 1). To unify our approach and handling of the Apollonius graph we add to the set of (finite) circles a fictitious circle at infinity, which we call the *site at infinity*. We can then connect all vertices of the outer face of the Apollonius graph to the site at infinity which gives us a graph with the property that all of its faces are now triangular. However, the Apollonius graph is not a triangulation for two main reasons: we cannot always embed it on the plane with straight line segments that yield a triangulation and, moreover, we may have two faces of the graph that have two edges in common, which is not allowed in a triangulation. Both of these particularities appear when we consider the Apollonius graph of the set of circles in Fig. 32.1(right).

We would like to finish our brief introduction to the theory of Apollonius graphs by discussing the concept of general position. We say that a set of circles is in general position if no two triplets of circles have the same tritangent circle. This statement is rather technical and it is best understood in the context of points. The equivalent statement for points is that we have no two triplets of points that define the same circumcircle, or equivalently that no four points are co-circular. The statement about general position made above is a direct generalization of the (much simpler to understand) statement about points. On the contrary, when we have circles in degenerate position, the Apollonius graph has faces with more than three edges on their boundary. We can get a triangulated version of the graph by simply *triangulating* the corresponding faces in an arbitrary way. In fact the algorithm that has been implemented in CGAL has the property that it always returns a valid *triangulated* version of the Apollonius graph. By valid we mean that it contains the actual Apollonius graph (i.e., the actual dual of the Apollonius diagram) and whenever there are faces with more than three faces then they are triangulated. The way that they are triangulated depends on the order of insertion and deletion of the circles in the diagram.

One final point has to be made about hidden circles. First of all we would like to be more precise about our definition of hidden circles: we say that a circle is hidden if its cell has empty interior. This definition allows us to guarantee that all visible circles have cells that are two-dimensional regions. Geometrically the fact that a circle is hidden means that it is contained in the closure of the disk of another circle (see again Fig. 32.1). Note that a circle contained in the union of several disks, but not in the closure of any one of them, is not hidden.

Hidden circles pose an additional difficulty to our algorithm and software design. Since we allow circles to be inserted and deleted at wish, it is possible that a circle that was hidden at some point in time, may become visible at a later point in time; for example this can happen if we delete the circle that hides it. For this purpose we store hidden circles and have them reappear when they become visible. We will discuss this issue in detail below. For the time being it suffices to say that the user has the ability to control this behavior. More specifically it is possible to discard the circles that become hidden. This choice is totally natural when for example we expect to do only insertions, since in this case a circle that becomes hidden will never reappear. On the other hand if deletions are expected as well, then we lose the ability to have the hidden circles reappear.

Degenerate Dimensions. The dimension of the Apollonius graph is in general 2. The exceptions to this rule are as follows:

- The dimension is -1 if the Apollonius graph contains no circles.
- The dimension is 0 if the Apollonius graph contains exactly one visible circle.
- The dimension is 1 if the Apollonius graph contains exactly two visible circles.

32.2 Software Design

The 2D Apollonius graph class `Apollonius_graph_2<ApolloniusGraphTraits_2, ApolloniusGraphDataStructure_2>` follows the design of the triangulation package of CGAL. It is parametrized by two arguments:

- the **geometric traits** class. It provides the basic geometric objects involved in the algorithm, such as sites, points etc. It also provides the geometric predicates for the computation of the Apollonius graph, as well as some basic constructions that can be used, for example, to visualize the Apollonius graph or the Apollonius diagram. The geometric traits for the Apollonius graph will be discussed in more detail in the next section.
- the **Apollonius graph data structure**. This is essentially the same as the triangulation data structure (discussed in Chapter 26), augmented with some additional operations that are specific to Apollonius graphs. The corresponding concept is that of *ApolloniusGraphDataStructure_2*, which in fact is a refinement of the *TriangulationDataStructure_2* concept. The class *Triangulation_data_structure_2<Vb,Fb>* is a model of the concept *ApolloniusGraphDataStructure_2*. A default value for the corresponding template parameter is provided, so the user does not need to specify it.

Storing Hidden Sites. As we have already mentioned a circle is hidden if it is contained inside some visible circle. This creates a parent-child relationship between visible and hidden circles: the parent of a hidden circle is the visible circle that contains it. If more than one visible circles contain a hidden circle then the hidden circle can be assigned to any of the visible circles arbitrarily.

To store hidden circles we assign to every visible circle a list. This list comprises the hidden circles that are contained in the visible circle. The user can access the hidden circles associated with a visible circle through an iterator called *Hidden_sites_iterator*. This iterator is defined in the *ApolloniusGraphVertexBase_2* concept and is implemented by its model, the *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* class. It is also possible to iterate through the entire set of hidden sites using an homonymous iterator defined by the *Apollonius_graph_2<Gt,Agds>* class.

Since storing hidden sites may not be of interest in some cases (e.g., for example this is the case if we only perform insertions in the Apollonius graph), the user has the possibility of controlling this behavior. More precisely, the class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* has two template parameters, the second of which is a Boolean value. This value is by default *true* and it indicates that hidden sites should be stored. The user can indicate that hidden sites may be discarded by setting this value to *false*.

32.3 The Geometric Traits

The predicates required for the computation of the Apollonius graph are rather complicated. It is not the purpose of this document to discuss them in detail. The interested reader may refer to the papers by Karavelas and Emiris for the details [KE02, KE03]. However, we would like to give a brief overview of what they compute. There are several predicates needed by this algorithm. We will discuss the most important/complicated ones. It turns out that it is much easier to describe them in terms of the Apollonius diagram, rather than the Apollonius graph. Whenever it is applicable we will also describe their meaning in terms of the Apollonius graph.

The first two geometric predicates are called *Is_hidden_2* and *Oriented_side_of_bisector_2*. The first one involves two circles, say P_1 and P_2 . It determines if P_1 is hidden with respect to P_2 ; more precisely it checks whether the circle P_1 is contained in the closure of the disk defined by the circle P_2 . As its name indicates, it determines if a circle is hidden or not. The second predicate involves two circles P_1 and P_2 and a point q . It answers the question whether q is closer to P_1 or P_2 . Its name stems from the fact that answering the aforementioned question is equivalent to determining the oriented side of the bisector of P_1 and P_2 that contains the query point q . This predicate is used by the algorithm for closest neighbor queries for points.

The next geometric predicate is called *Vertex_conflict_2* and it involves four circles P_1 , P_2 , P_3 , and P_4 (see Fig. 32.3). The first three (red circles in Fig. 32.3) define a tritangent circle (yellow circle in Fig. 32.3). What we want to determine is the sign of the distance of the green circle from the yellow circle. The distance between

two circles $K_1 = (c_1, r_1)$ and $K_2 = (c_2, r_2)$ is defined as the distance of their centers minus their radii:

$$\delta(K_1, K_2) = \|c_1 - c_2\| - r_1 - r_2.$$

This predicate determines if a vertex in the Apollonius diagram (the center of the yellow circle) is destroyed when a new circle is inserted in the diagram (the green circle). In the Apollonius graph it tells us if a triangular face of the diagram is to be destroyed or not.

Figure 32.2: The *Vertex_conflict_2* predicate. The left-most, bottom-most and top-most circles define the tritangent circle in the middle. We want to determine the sign of the distance of the left-most circle from the one in the middle. The almost horizontal curve is the bisector of the top-most and bottom-most circles. Left: the predicate returns *CGAL::NEGATIVE*. Right: the predicate returns *CGAL::POSITIVE*.

What we essentially want to compute when we construct incrementally a Voronoi diagram, is whether the object to be inserted destroys an edge of the Voronoi diagram or not. In the case of points this is really easy and it amounts to the well known *incircle* test. In the case of circles the situation is more complicated. We can have six possible outcomes as to what portion of an edge of the Apollonius diagram the new circle destroys (see Fig. 32.3). The first two can be answered directly by the *Vertex_conflict_2* predicate evaluated for the two endpoints of the Apollonius diagram edge. This is due to the fact that the value of the *Vertex_conflict_2* predicate is different for the two endpoints. If the two values are the same then we need an additional test which determines if the interior of the Apollonius diagram edge is destroyed by the new circle. This is what the *Finite_edge_interior_conflict_2* and *Infinite_edge_interior_conflict_2* predicates do. In essence, it is the same predicate (same idea) applied to two different types of edges in the Apollonius diagram: a finite or an infinite edge. An edge is infinite if its dual edge in the Apollonius graph connects the site at infinity with the vertex corresponding to a (finite) circle; otherwise it is a finite edge.

The last predicate that we want to discuss is called *Is_degenerate_edge_2*. It tells us whether an edge in the Apollonius diagram is degenerate, that is if its two endpoints coincide. In the Apollonius graph such an edge corresponds to one of the additional edges that we use to triangulate the non-triangular faces.

The aforementioned predicates are part of the *ApolloniusGraphTraits_2* concept of CGAL. CGAL also provides a model for this concept, the *Apollonius_graph_traits_2<K,Method_tag>* class. The first template parameter of this class must be a model of the *Kernel* concept. The second template parameter is a tag that indicates what operations are allowed in the computations that take place within the traits class. The two possible values of the *Method_tag* parameter are *CGAL::Ring_tag* and *CGAL::Sqrt_field_tag*. When *CGAL::Ring_tag* is used, only ring operations are used during the evaluation of the predicates, whereas if *CGAL::Sqrt_field_tag* is chosen, all four field operations, as well as square roots, are used during the predicate evaluation.

The *Apollonius_graph_traits_2<K,Method_tag>* class provides exact predicates if the number type in the kernel

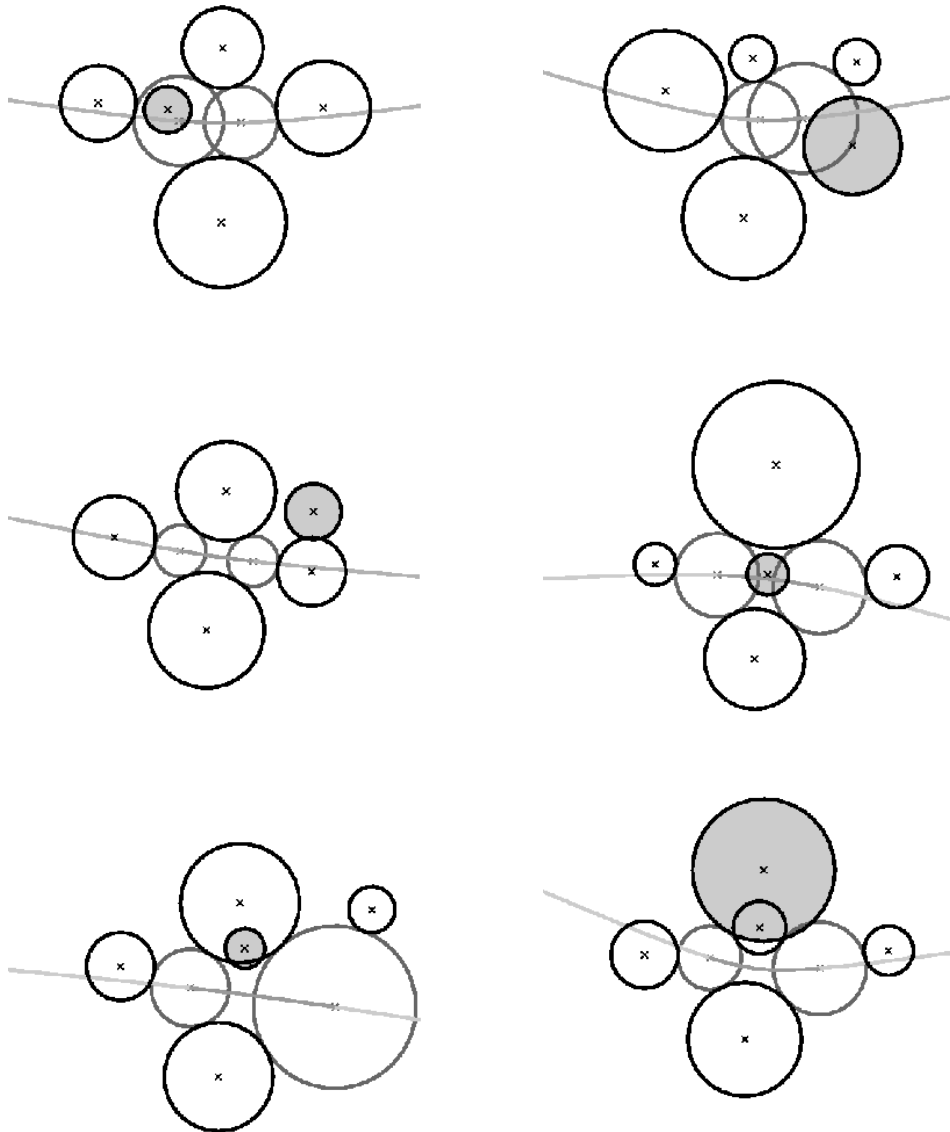

Figure 32.3: The 6 possible outcomes of the *Finite_edge_interior_conflict_2* predicate. Top left: only a neighborhood around the left-most endpoint of the edge will be destroyed. Top right: only a neighborhood around the right-most endpoint of the edge will be destroyed. Middle left: no portion of the edge is destroyed. Middle right: the entire edge will be destroyed. Bottom left: a neighborhood in the interior of the edge will be destroyed; the regions near the endpoints remain unaffected. Bottom right: The neighborhood around the two endpoints will be destroyed, but an interval in the interior of the edge will remain in the new diagram.

K is an exact number type. This is to be associated with the type of operations allowed for the predicate evaluation. For example `CGAL::MP_Float` as number type, with `CGAL::Ring_tag` as tag will give exact predicates, whereas `CGAL::MP_Float` with `CGAL::Sqrt_field_tag` will give inexact predicates.

Since using an exact number type may be too slow, the `Apollonius_graph_traits_2<K,Method_tag>` class is designed to support the dynamic filtering of CGAL through the `CGAL::Filtered_exact<CT,ET>` mechanism. In

particular if CT is an inexact number type that supports the operations denoted by the tag *Method_tag* and ET is an exact number type for these operations, then kernel with number type `CGAL::Filtered_exact<CT,ET>` will yield exact predicates for the Apollonius graph traits. To give a concrete example, `CGAL::Filtered_exact<double,CGAL::MP_Float>` with `CGAL::Ring_tag` will produce exact predicates.

Another possibility for fast and exact predicate evaluation is to use the `Apollonius_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>` class. This class is the analog of a filtered kernel. It takes a constructions kernel CK , a filtering kernel FK and an exact kernel EK , as well as the corresponding tags (CM , FM and EM , respectively). It evaluates the predicates by first using the filtering kernel, and if this fails the evaluation is performed using the exact kernel. The constructions are done using the kernel CK , which means that they are not necessarily exact. All template parameters except CK have default values, which are explained in the reference manual.

32.4 The Apollonius Graph Hierarchy

The `Apollonius_graph_hierarchy_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>` class is nothing but the equivalent of the `Triangulation_hierarchy_2` class, applied to the Apollonius graph. It consists of a series of Apollonius graphs constructed in a manner analogous to the Delaunay hierarchy by Devillers [Dev98]. The class `Apollonius_graph_hierarchy_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>` has exactly the same interface and functionality as the `Apollonius_graph_2<ApolloniusGraphTraits_2,ApolloniusGraphDataStructure_2>` class. Using the Apollonius graph hierarchy involves an additional cost in space and time for maintaining the hierarchy. Our experiments have shown that it usually pays off to use the hierarchy for inputs consisting of more than 1,000 circles. This threshold holds for both the construction of the Apollonius diagram itself, as well as for nearest neighbor queries.

32.5 Examples

32.5.1 First Example

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// the number type
#include <CGAL/MP_Float.h>

// example that uses an exact number type

typedef CGAL::MP_Float NT;

// choose the kernel
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<NT> Kernel;

// typedefs for the traits and the algorithm
```

```

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Apollonius_graph_traits_2.h>

typedef CGAL::Apollonius_graph_traits_2<Kernel> Traits;
typedef CGAL::Apollonius_graph_2<Traits> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }

    // validate the Apollonius graph
    assert( ag.is_valid(true, 1) );
    std::cout << std::endl;

    return 0;
}

```

File: examples/Apollonius_graph_2/ag2_exact_traits.cpp

32.5.2 Second Example

```

#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

#if defined CGAL_USE_LEDA
#   include <CGAL/leda_real.h>
#elif defined CGAL_USE_CORE
#   include <CGAL/CORE_Expr.h>
#endif

#if defined CGAL_USE_LEDA
// If LEDA is present use leda_real as the exact number type
typedef leda_real NT;

```

```

#elif defined CGAL_USE_CORE
// Otherwise if CORE is present use CORE's Expr as the exact number type
typedef CORE::Expr NT;

#else

// Otherwise just use double. This may cause numerical errors but it
// is still worth doing it to show how to define correctly the traits
// class
typedef double NT;

#endif

#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<NT> Kernel;

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Apollonius_graph_traits_2.h>

// the traits class is now going to assume that the operations
// +,-,*,/ and sqrt are supported exactly
typedef
CGAL::Apollonius_graph_traits_2<Kernel,CGAL::Field_with_sqrt_tag> Traits;

typedef CGAL::Apollonius_graph_2<Traits> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }

    // validate the Apollonius graph
    assert( ag.is_valid(true, 1) );
    std::cout << std::endl;

    return 0;
}

```

File: examples/Apollonius_graph_2/ag2_exact_traits_sqrt.cpp

32.5.3 Third Example

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

#include <CGAL/basic.h>

// example that uses the filtered traits

// choose the representation
#include <CGAL/Simple_cartesian.h>

typedef CGAL::Simple_cartesian<double> Rep;

#include <CGAL/Apollonius_graph_2.h>
#include <CGAL/Triangulation_data_structure_2.h>
#include <CGAL/Apollonius_graph_vertex_base_2.h>
#include <CGAL/Triangulation_face_base_2.h>
#include <CGAL/Apollonius_graph_filtered_traits_2.h>

// typedef for the traits; the filtered traits class is used
typedef CGAL::Apollonius_graph_filtered_traits_2<Rep> Traits;

// typedefs for the algorithm

// With the second template argument in the vertex base class being
// false, we indicate that there is no need to store the hidden sites.
// One case where this is indeed not needed is when we only do
// insertions, like in the main program below.
typedef CGAL::Apollonius_graph_vertex_base_2<Traits,false> Vb;
typedef CGAL::Triangulation_face_base_2<Traits> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb,Fb> Agds;
typedef CGAL::Apollonius_graph_2<Traits,Agds> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/sites.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }

    // validate the Apollonius graph
    assert( ag.is_valid(true, 1) );
}
```

```

std::cout << std::endl;

// now remove all sites
std::cout << "Removing all sites... " << std::flush;
while ( ag.number_of_vertices() > 0 ) {
    ag.remove( ag.finite_vertex() );
}
std::cout << "done!" << std::endl << std::endl;

return 0;
}

```

File: examples/Apollonius_graph_2/ag2_filtered_traits_no_hidden.cpp

32.5.4 Fourth Example

```

#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// example that uses the filtered traits

#include <CGAL/MP_Float.h>
#include <CGAL/Simple_cartesian.h>

// constructions kernel (inexact)
typedef CGAL::Simple_cartesian<double> CK;

// exact kernel
typedef CGAL::Simple_cartesian<CGAL::MP_Float> EK;

// typedefs for the traits and the algorithm

#include <CGAL/Apollonius_graph_hierarchy_2.h>
#include <CGAL/Apollonius_graph_filtered_traits_2.h>

// Type definition for the traits class.
// In this example we explicitly define the exact kernel. We also
// explicitly define what operations to use for the evaluation of the
// predicates and constructions, when the filtering and the exact
// kernels are used respectively.
// Note that the operations allowed for the filtering and the
// constructions (field operations plus square roots) are different
// from the operations allowed when the exact kernel is used (ring
// operations).
typedef CGAL::Field_with_sqrt_tag CM;
typedef CGAL::Integral_domain_without_division_tag EM;

```

```

typedef CGAL::Apollonius_graph_filtered_traits_2<CK,CM,EK,EM> Traits;

// Now we use the Apollonius graph hierarchy.
// The hierarchy is faster for inputs consisting of about more than
// 1,000 sites
typedef CGAL::Apollonius_graph_hierarchy_2<Traits> Apollonius_graph;

int main()
{
    std::ifstream ifs("data/hierarchy.cin");
    assert( ifs );

    Apollonius_graph ag;
    Apollonius_graph::Site_2 site;

    // read the sites and insert them in the Apollonius graph
    while ( ifs >> site ) {
        ag.insert(site);
    }

    // validate the Apollonius graph
    assert( ag.is_valid(true, 1) );

    return 0;
}

```

File: examples/Apollonius_graph_2/ag2_hierarchy.cpp

2D Apollonius Graphs (Delaunay Graphs of Disks)

Reference Manual

Menelaos Karavelas and Mariette Yvinec

An Apollonius graph is the dual of the Apollonius diagram, also known as the *additively weighted Voronoi diagram*. It is essentially the Voronoi diagram of a set of disks, where the distance of a point of the plane from a disk is defined as the Euclidean distance of the point and the center of the circle, minus the radius of the disk.

CGAL provides the class `CGAL::Apollonius_graph_2<Gt,Agds>` for computing the 2D Apollonius graph. The two template parameters must be models of the `ApolloniusGraphTraits_2` and `ApolloniusGraphDataStructure_2` concepts. The first concept is related to the geometric objects and predicates associated with Apollonius graphs, whereas the second concept refers to the data structure used to represent the Apollonius graph. The classes `Apollonius_graph_traits_2<K,Method_tag>` and `Triangulation_data_structure_2<Vb,Fb>` are models of the aforementioned concepts.

CGAL::Apollonius_graph_2<Gt,Agds>

Definition

The class *Apollonius_graph_2*<*Gt*,*Agds*> represents the Apollonius graph. It supports insertions and deletions of sites. It is templated by two template arguments *Gt*, which must be a model of *ApolloniusGraphTraits_2*, and *Agds*, which must be a model of *ApolloniusGraphDataStructure_2*. The second template argument defaults to *CGAL::Triangulation_data_structure_2*< *CGAL::Apollonius_graph_vertex_base_2*<*Gt*,*true*>, *CGAL::Triangulation_face_base_2*<*Gt*> >.

```
#include <CGAL/Apollonius_graph_2.h>
```

Is Model for the Concepts

DelaunayGraph_2

Types

<i>typedef Agds</i>	<i>Data_structure;</i>	A type for the underlying data structure.
<i>typedef Data_structure</i>	<i>Triangulation_data_structure;</i>	Same as the <i>Data_structure</i> type. This type has been introduced in order for the <i>Apollonius_graph_2</i> < <i>Gt</i> , <i>Agds</i> > class to be a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Gt</i>	<i>Geom_traits;</i>	A type for the geometric traits.
<i>typedef Gt::Point_2</i>	<i>Point_2;</i>	A type for the point defined in the geometric traits.
<i>typedef Gt::Site_2</i>	<i>Site_2;</i>	A type for the Apollonius site, defined in the geometric traits.

The vertices and faces of the Apollonius graph are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles. The edges of the Apollonius graph can also be visited through iterators and circulators, the edge circulators and iterators are also bidirectional and non-mutable. In the following, we call *infinite* any face or edge incident to the infinite vertex and the infinite vertex itself. Any other feature (face, edge or vertex) of the Apollonius graph is said to be *finite*. Some iterators (the *All* iterators) allow to visit finite or infinite features while the others (the *Finite* iterators) visit only finite features. Circulators visit both infinite and finite features.

<i>typedef Data_structure::Edge</i>	<i>Edge;</i>	the edge type. The <i>Edge(f,i)</i> is the edge common to faces <i>f</i> and <i>f.neighbor(i)</i> . It is also the edge joining the vertices <i>vertex(cw(i))</i> and <i>vertex(ccw(i))</i> of <i>f</i> . <i>Precondition:</i> <i>i</i> must be 0, 1 or 2.
<i>typedef Data_structure::Vertex</i>	<i>Vertex;</i>	A type for a vertex.
<i>typedef Data_structure::Face</i>	<i>Face;</i>	A type for a face.
<i>typedef Data_structure::Vertex_handle</i>	<i>Vertex_handle;</i>	A type for a handle to a vertex.
<i>typedef Data_structure::Face_handle</i>	<i>Face_handle;</i>	A type for a handle to a face.
<i>typedef Data_structure::Vertex_circulator</i>	<i>Vertex_circulator;</i>	A type for a circulator over vertices incident to a given vertex.

<i>typedef Data_structure::Face_circulator</i>	<i>Face_circulator;</i>	A type for a circulator over faces incident to a given vertex.
<i>typedef Data_structure::Edge_circulator</i>	<i>Edge_circulator;</i>	A type for a circulator over edges incident to a given vertex.
<i>typedef Data_structure::Vertex_iterator</i>	<i>All_vertices_iterator;</i>	A type for an iterator over all vertices.
<i>typedef Data_structure::Face_iterator</i>	<i>All_faces_iterator;</i>	A type for an iterator over all faces.
<i>typedef Data_structure::Edge_iterator</i>	<i>All_edges_iterator;</i>	A type for an iterator over all edges.
<i>typedef Data_structure::size_type</i>	<i>size_type;</i>	An unsigned integral type.
<i>Apollonius_graph_2<Gt,Agds>:: Finite_vertices_iterator</i>		A type for an iterator over finite vertices.
<i>Apollonius_graph_2<Gt,Agds>:: Finite_faces_iterator</i>		A type for an iterator over finite faces.
<i>Apollonius_graph_2<Gt,Agds>:: Finite_edges_iterator</i>		A type for an iterator over finite edges.

In addition to iterators and circulators for vertices and faces, iterators for sites are provided. In particular there are iterators for the entire set of sites, the hidden sites and the visible sites of the Apollonius graph.

<i>Apollonius_graph_2<Gt,Agds>:: Sites_iterator</i>	A type for an iterator over all sites.
<i>Apollonius_graph_2<Gt,Agds>:: Visible_sites_iterator</i>	A type for an iterator over all visible sites.
<i>Apollonius_graph_2<Gt,Agds>:: Hidden_sites_iterator</i>	A type for an iterator over all hidden sites.

Creation

Apollonius_graph_2<Gt,Agds> ag(Gt gt=Gt()); Creates an Apollonius graph using *gt* as geometric traits.

template< class Input_iterator >

Apollonius_graph_2<Gt,Agds> ag(Input_iterator first, Input_iterator beyond, Gt gt=Gt());

Creates an Apollonius graph using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).

Precondition: *Input_iterator* must be a model of *InputIterator*. The value type of *Input_iterator* must be *Site_2*.

Apollonius_graph_2<Gt,Agds> ag(other); Copy constructor. All faces and vertices are duplicated. After the construction, *ag* and *other* refer to two different Apollonius graphs : if *other* is modified, *ag* is not.

Apollonius_graph_2<Gt,Agds> ag = other Assignment. If *ag* and *other* are the same object nothing is done. Otherwise, all the vertices and faces are duplicated. After the assignment, *ag* and *other* refer to different Apollonius graphs : if *other* is modified, *ag* is not.

Access Functions

<i>Geom_traits</i>	<i>ag.geom_traits()</i>	Returns a reference to the Apollonius graph traits object.
<i>Data_structure</i>	<i>ag.data_structure()</i>	Returns a reference to the underlying data structure.
<i>Data_structure</i>	<i>ag.tds()</i>	Same as <i>data_structure()</i> . This method has been added in compliance with the <i>DelaunayGraph_2</i> concept.
<i>int</i>	<i>ag.dimension()</i>	Returns the dimension of the Apollonius graph.
<i>size_type</i>	<i>ag.number_of_vertices()</i>	Returns the number of finite vertices.
<i>size_type</i>	<i>ag.number_of_visible_sites()</i>	Returns the number of visible sites.

<i>size_type</i>	<i>ag.number_of_hidden_sites()</i>	Returns the number of hidden sites.
<i>size_type</i>	<i>ag.number_of_faces()</i>	Returns the number of faces (both finite and infinite) of the Apollonius graph.
<i>Face_handle</i>	<i>ag.infinite_face()</i>	Returns a face incident to the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>ag.infinite_vertex()</i>	Returns the <i>infinite_vertex</i> .
<i>Vertex_handle</i>	<i>ag.finite_vertex()</i>	Returns a vertex distinct from the <i>infinite_vertex</i> . <i>Precondition:</i> The number of (visible) vertices in the Apollonius graph must be at least one.

Traversal of the Apollonius graph

An Apollonius graph can be seen as a container of faces and vertices. Therefore the Apollonius graph provides several iterators and circulators that allow to traverse it (completely or partially).

Face, Edge and Vertex Iterators

The following iterators allow respectively to visit finite faces, finite edges and finite vertices of the Apollonius graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the Apollonius graph.

<i>Finite_vertices_iterator</i>	<i>ag.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex.
<i>Finite_vertices_iterator</i>	<i>ag.finite_vertices_end()</i>	Past-the-end iterator.
<i>Finite_edges_iterator</i>	<i>ag.finite_edges_begin()</i>	Starts at an arbitrary finite edge.
<i>Finite_edges_iterator</i>	<i>ag.finite_edges_end()</i>	Past-the-end iterator.
<i>Finite_faces_iterator</i>	<i>ag.finite_faces_begin()</i>	Starts at an arbitrary finite face.
<i>Finite_faces_iterator</i>	<i>ag.finite_faces_end()</i>	Past-the-end iterator.

The following iterators allow respectively to visit all (both finite and infinite) faces, edges and vertices of the Apollonius graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*. They are all invalidated by any change in the Apollonius graph.

<i>All_vertices_iterator</i>	<i>ag.all_vertices_begin()</i>	Starts at an arbitrary vertex.
<i>All_vertices_iterator</i>	<i>ag.all_vertices_end()</i>	Past-the-end iterator.
<i>All_edges_iterator</i>	<i>ag.all_edges_begin()</i>	Starts at an arbitrary edge.
<i>All_edges_iterator</i>	<i>ag.all_edges_end()</i>	Past-the-end iterator.
<i>All_faces_iterator</i>	<i>ag.all_faces_begin()</i>	Starts at an arbitrary face.
<i>All_faces_iterator</i>	<i>ag.all_faces_end()</i>	Past-the-end iterator.

Site iterators

The following iterators allow respectively to visit all sites, the visible sites and the hidden sites. These iterators are non-mutable, bidirectional and their value type is *Site_2*. They are all invalidated by any change in the Apollonius graph.

<i>Sites_iterator</i>	<i>ag.sites_begin()</i>	Starts at an arbitrary site.
-----------------------	-------------------------	------------------------------

<i>Sites_iterator</i>	<i>ag.sites_end()</i>	Past-the-end iterator.
<i>Visible_sites_iterator</i>	<i>ag.visible_sites_begin()</i>	Starts at an arbitrary visible site.
<i>Visible_sites_iterator</i>	<i>ag.visible_sites_end()</i>	Past-the-end iterator.
<i>Hidden_sites_iterator</i>	<i>ag.hidden_sites_begin()</i>	Starts at an arbitrary hidden site.
<i>Hidden_sites_iterator</i>	<i>ag.hidden_sites_end()</i>	Past-the-end iterator.

Face, Edge and Vertex Circulators

The Apollonius graph also provides circulators that allow to visit respectively all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* moves the circulator counterclockwise around the vertex while the *operator--* moves clockwise. A face circulator is invalidated by any modification of the face pointed to. An edge circulator is invalidated by any modification in one of the two faces incident to the edge pointed to. A vertex circulator is invalidated by any modification in any of the faces adjacent to the vertex pointed to.

<i>Face_circulator</i>	<i>ag.incident_faces(Vertex_handle v)</i>	Starts at an arbitrary face incident to <i>v</i> .
<i>Face_circulator</i>	<i>ag.incident_faces(Vertex_handle v, Face_handle f)</i>	Starts at face <i>f</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .
<i>Edge_circulator</i>	<i>ag.incident_edges(Vertex_handle v)</i>	Starts at an arbitrary edge incident to <i>v</i> .
<i>Edge_circulator</i>	<i>ag.incident_edges(Vertex_handle v, Face_handle f)</i>	Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .
<i>Vertex_circulator</i>	<i>ag.incident_vertices(Vertex_handle v)</i>	Starts at an arbitrary vertex incident to <i>v</i> .
<i>Vertex_circulator</i>	<i>ag.incident_vertices(Vertex_handle v, Face_handle f)</i>	Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> is incident to vertex <i>v</i> .

Traversal of the Convex Hull

Applied on the *infinite_vertex* the above functions allow to visit the vertices on the convex hull and the infinite edges and faces. Note that a counterclockwise traversal of the vertices adjacent to the *infinite_vertex* is a clockwise traversal of the convex hull.

<i>Vertex_circulator</i>	<i>ag.incident_vertices(ag.infinite_vertex())</i>
<i>Vertex_circulator</i>	<i>ag.incident_vertices(ag.infinite_vertex(), Face_handle f)</i>
<i>Face_circulator</i>	<i>ag.incident_faces(ag.infinite_vertex())</i>

<i>Face_circulator</i>	<i>ag.incident_faces(ag.infinite_vertex(), Face_handle f)</i>
<i>Edge_circulator</i>	<i>ag.incident_edges(ag.infinite_vertex())</i>
<i>Edge_circulator</i>	<i>ag.incident_edges(ag.infinite_vertex(), Face_handle f)</i>

Predicates

The class *Apollonius_graph_2<Gt,Agds>* provides methods to test the finite or infinite character of any feature.

<i>bool</i>	<i>ag.is_infinite(Vertex_handle v)</i>	<i>true</i> , iff <i>v</i> is the <i>infinite_vertex</i> .
<i>bool</i>	<i>ag.is_infinite(Face_handle f)</i>	<i>true</i> , iff face <i>f</i> is infinite.
<i>bool</i>	<i>ag.is_infinite(Face_handle f, int i)</i>	<i>true</i> , iff edge (<i>f</i> , <i>i</i>) is infinite.
<i>bool</i>	<i>ag.is_infinite(Edge e)</i>	<i>true</i> , iff edge <i>e</i> is infinite.
<i>bool</i>	<i>ag.is_infinite(Edge_circulator ec)</i>	<i>true</i> , iff edge <i>*ec</i> is infinite.

Insertion

```
template< class Input_iterator >
unsigned int    ag.insert( Input_iterator first, Input_iterator beyond)
```

Inserts the sites in the range [*first*,*beyond*). The number of sites in the range [*first*, *beyond*) is returned.

Precondition: *Input_iterator* must be a model of *InputIterator* and its value type must be *Site_2*.

<i>Vertex_handle</i>	<i>ag.insert(Site_2 s)</i>	Inserts the site <i>s</i> in the Apollonius graph. If <i>s</i> is visible then the vertex handle of <i>s</i> is returned, otherwise <i>Vertex_handle(NULL)</i> is returned.
----------------------	-----------------------------	---

<i>Vertex_handle</i>	<i>ag.insert(Site_2 s, Vertex_handle vnear)</i>
----------------------	--

Inserts *s* in the Apollonius graph using the site associated with *vnear* as an estimate for the nearest neighbor of the center of *s*. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned.

Removal

<i>void</i>	<i>ag.remove(Vertex_handle v)</i>	Removes the site associated to the vertex handle <i>v</i> from the Apollonius graph. <i>Precondition:</i> <i>v</i> must correspond to a valid finite vertex of the Apollonius graph.
-------------	------------------------------------	---

Nearest neighbor location

<i>Vertex_handle</i>	<i>ag.nearest_neighbor(Point_2 p)</i>	Finds the nearest neighbor of the point <i>p</i> . In other words it finds the site whose Apollonius cell contains <i>p</i> . Ties are broken arbitrarily and one of the nearest neighbors of <i>p</i> is returned. If there are no visible sites in the Apollonius diagram <i>Vertex_handle(NULL)</i> is returned.
----------------------	--	---

Vertex_handle *ag.nearest_neighbor(Point_2 p, Vertex_handle vnear)*

Finds the nearest neighbor of the point p using the site associated with $vnear$ as an estimate for the nearest neighbor of p . Ties are broken arbitrarily and one of the nearest neighbors of p is returned. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned.

Access to the dual

The *Apollonius_graph_2* class provides access to the duals of the faces of the graph. The dual of a face of the Apollonius graph is a site. If the originating face is infinite, its dual is a site with center at infinity (or equivalently with infinite weight), which means that it can be represented geometrically as a line. If the originating face is finite, its dual is a site with finite center and weight. In the following three methods the returned object is assignable to either *Site_2* or *Gt::Line_2*, depending on whether the corresponding face of the Apollonius graph is finite or infinite, respectively.

<i>Gt::Object_2</i> <i>ag.dual(Face_handle f)</i>	Returns the dual corresponding to the face handle f . The returned object can be assignable to one of the following: <i>Site_2</i> , <i>Gt::Line_2</i> .
<i>Gt::Object_2</i> <i>ag.dual(All_faces_iterator it)</i>	Returns the dual of the face to which it points to. The returned object can be assignable to one of the following: <i>Site_2</i> , <i>Gt::Line_2</i> .
<i>Gt::Object_2</i> <i>ag.dual(Finite_faces_iterator it)</i>	Returns the dual of the face to which it points to. The returned object can be assignable to one of the following: <i>Site_2</i> , <i>Gt::Line_2</i> .

I/O

<pre>template< class Stream > Stream& ag.draw_primal(Stream& str)</pre>	<p>Draws the Apollonius graph to the stream str. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2).</i></p>
<pre>template < class Stream > Stream& ag.draw_dual(Stream& str)</pre>	<p>Draws the dual of the Apollonius graph, i.e., the Apollonius diagram, to the stream str. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2),</i> <i>Stream& operator<<(Stream&, Gt::Line_2).</i></p>
<pre>template< class Stream > Stream& ag.draw_primal_edge(Edge e, Stream& str)</pre>	<p>Draws the edge e of the Apollonius graph to the stream str. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2).</i></p>
<pre>template< class Stream ></pre>	

<i>Stream&</i>	<i>ag.draw_dual_edge(Edge e, Stream& str)</i>	Draws the dual of the edge <i>e</i> to the stream <i>str</i> . The dual of <i>e</i> is an edge of the Apollonius diagram. <i>Precondition:</i> The following operators must be defined: <i>Stream& operator<<(Stream&, Gt::Segment_2),</i> <i>Stream& operator<<(Stream&, Gt::Ray_2),</i> <i>Stream& operator<<(Stream&, Gt::Line_2).</i>
<i>void</i>	<i>ag.file_output(std::ostream& os)</i>	Writes the current state of the Apollonius graph to an output stream. In particular, all visible and hidden sites are written as well as the underlying combinatorial data structure.
<i>void</i>	<i>ag.file_input(std::istream& is)</i>	Reads the state of the Apollonius graph from an input stream.
<i>std::ostream&</i>	<i>std::ostream& os << ag</i>	Writes the current state of the Apollonius graph to an output stream.
<i>std::istream&</i>	<i>std::istream& is >> ag</i>	Reads the state of the Apollonius graph from an input stream.

Validity check

<i>bool</i>	<i>ag.is_valid(bool verbose = false, int level = 1)</i>	Checks the validity of the Apollonius graph. If <i>verbose</i> is <i>true</i> a short message is sent to <i>std::cerr</i> . If <i>level</i> is 0, only the data structure is validated. If <i>level</i> is 1, then both the data structure and the Apollonius graph are validated. Negative values of <i>level</i> always return true, and values greater than 1 are equivalent to <i>level</i> being 1.
-------------	--	--

Miscellaneous

<i>void</i>	<i>ag.clear()</i>	Clears all contents of the Apollonius graph.
<i>void</i>	<i>ag.swap(other)</i>	The Apollonius graphs <i>other</i> and <i>ag</i> are swapped. <i>ag.swap(other)</i> should be preferred to <i>ag= other</i> or to <i>ag(other)</i> if <i>other</i> is deleted afterwards.

ApolloniusSite_2

Definition

The concept *ApolloniusSite_2* provides the requirements for an Apollonius site class.

Types

<i>ApolloniusSite_2:: Point_2</i>	The point type.
<i>ApolloniusSite_2:: FT</i>	The field number type.
<i>ApolloniusSite_2:: RT</i>	The ring number type.
<i>ApolloniusSite_2:: Weight</i>	The weight type.
<i>Precondition:</i> It must be the same as <i>FT</i> .	

Creation

<i>ApolloniusSite_2</i> <i>s</i> (<i>Point_2</i> <i>p</i> = <i>Point_2</i> (), <i>Weight</i> <i>w</i> = <i>Weight</i> (0));	
<i>ApolloniusSite_2</i> <i>s</i> (<i>other</i>);	Copy constructor.

Access Functions

<i>Point_2</i>	<i>s.point()</i>	Returns the center of the Apollonius site.
<i>Weight</i>	<i>s.weight()</i>	Returns the weight of the Apollonius site.

CGAL::Apollonius_site_2<K>

Definition

The class *Apollonius_site_2*<*K*> is a model for the concept *ApolloniusSite_2*. It is parametrized by a template parameter *K* which must be a model of the *Kernel* concept.

```
#include <CGAL/Apollonius_site_2.h>
```

Is Model for the Concepts

ApolloniusSite_2

Types

The class *Apollonius_site_2*<*K*> does not introduce any types in addition to the concept *ApolloniusSite_2*.

Creation

```
Apollonius_site_2<K> s( Point_2 p=Point_2(), Weight w= Weight(0));  
Apollonius_site_2<K> s( other);           Copy constructor.
```

I/O

The I/O operators are defined for *iostream*.

```
std::ostream&      std::ostream& os << s      Inserts the Apollonius site s into the stream os.  
Precondition: The insert operator must be defined for Point_2 and  
Weight.
```

```
std::istream&      std::istream& is >> s      Reads an Apollonius site from the stream is and assigns it to s.  
Precondition: The extract operator must be defined for Point_2 and  
Weight.
```

The information output in the *iostream* is: the point of the Apollonius site and its weight.

```
#include <CGAL/IO/Qt_widget_Apollonius_site_2.h>
```

```
Qt_widget&         Qt_widget& w << s           Inserts the Apollonius site s into the Qt_widget stream w.  
Precondition: The insert operator must be defined for K::Circle_2.
```

ApolloniusGraphDataStructure_2

Definition

The concept *ApolloniusGraphDataStructure_2* refines the concept *TriangulationDataStructure_2*. In addition it provides two methods for the insertion and removal of a degree 2 vertex in the data structure. The insertion method adds a new vertex to the specified edge, thus creating two new edges. Moreover, it creates two new faces that have the two newly created edges in common (see figure below). The removal method performs the reverse operation.

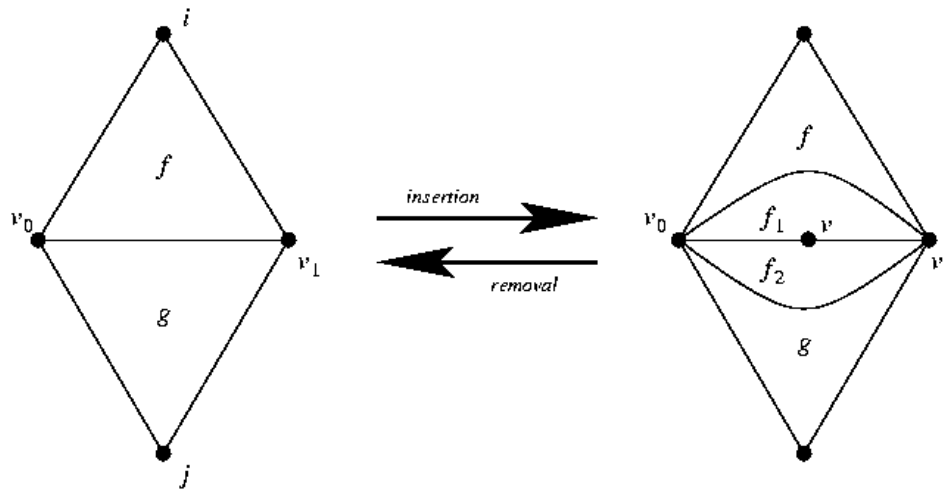

Figure 32.4: Insertion and removal of degree 2 vertices. Left to right: The edge (f,i) is replaced by two edges by means of inserting a vertex v on the edge. The faces f_1 and f_2 are created. Right to left: the faces f_1 and f_2 are destroyed. The vertex v is deleted and its two adjacent edges are merged.

We only describe the additional requirements with respect to the *TriangulationDataStructure_2* concept.

Refines

TriangulationDataStructure_2

Insertion

Vertex_handle `agds.insert_degree_2(Face_handle f, int i)`

Inserts a degree two vertex and two faces adjacent to it that have two common edges. The edge defined by the face handle f and the integer i is duplicated. It returns a handle to the vertex created.

Removal

void *agds.remove_degree_2(Vertex_handle v)* Removes a degree 2 vertex and the two faces adjacent to it. The two edges of the star of v that are not incident to it are collapsed.
Precondition: The degree of v must be equal to 2.

ApolloniusGraphVertexBase_2

Definition

The concept *ApolloniusGraphVertexBase_2* describes the requirements for the vertex base class of the *ApolloniusGraphDataStructure_2* concept. A vertex stores an Apollonius site and provides access to one of its incident faces through a *Face_handle*. In addition, it maintains a container of sites. The container stores the hidden sites related to the vertex.

Types

<i>ApolloniusGraphVertexBase_2:: Geom_traits</i>	A type for the geometric traits that defines the site stored. <i>Precondition:</i> The type <i>Geom_traits</i> must define the type <i>Site_2</i> .
<i>ApolloniusGraphVertexBase_2:: Store_hidden</i>	A Boolean that indicates if hidden sites are actually stored or not. Its value is <i>true</i> if hidden sites are stored, <i>false</i> otherwise.
<i>ApolloniusGraphVertexBase_2:: Site_2</i>	A type for the site stored. <i>Precondition:</i> This type must coincide with the type <i>Geom_traits::Site_2</i> .
<i>ApolloniusGraphVertexBase_2:: Apollonius_graph_data_structure_2</i>	A type for the Apollonius graph data structure, to which the vertex belongs to.
<i>ApolloniusGraphVertexBase_2:: Vertex_handle</i>	A type for the vertex handle of the Apollonius graph data structure.
<i>ApolloniusGraphVertexBase_2:: Face_handle</i>	A type for the face handle of the Apollonius graph data structure.
<i>ApolloniusGraphVertexBase_2:: Hidden_sites_iterator</i>	An iterator that iterates over the hidden sites in the hidden sites container of the vertex. <i>Precondition:</i> Must be a model of <i>Iterator</i> .

Creation

<i>ApolloniusGraphVertexBase_2 v;</i>	Default constructor.
<i>ApolloniusGraphVertexBase_2 v(Site_2 s);</i>	Constructs a vertex associated with the Apollonius site <i>s</i> and embedded at the center of <i>s</i> .
<i>ApolloniusGraphVertexBase_2 v(Site_2 s, Face_handle f);</i>	Constructs a vertex associated with the site <i>s</i> , embedded at the center of <i>s</i> , and pointing to the face associated with the face handle <i>f</i> .

Access Functions

<i>Site_2</i>	<i>v.site()</i>	Returns the Apollonius site.
<i>Face_handle</i>	<i>v.face()</i>	Returns a handle to an incident face.
<i>unsigned int</i>	<i>v.number_of_hidden_sites()</i>	Returns the number of hidden sites in the hidden sites container.

<i>Hidden_sites_iterator</i>	<i>v.hidden_sites_begin()</i>	Starts at an arbitrary hidden site.
<i>Hidden_sites_iterator</i>	<i>v.hidden_sites_end()</i>	Past-the-end iterator.

Setting and unsetting

<i>void</i>	<i>v.set_site(Site_2 s)</i>	Sets the Apollonius site.
<i>void</i>	<i>v.set_face(Face_handle f)</i>	Sets the incident face.
<i>void</i>	<i>v.add_hidden_site(Site_2 s)</i>	Adds a hidden site to the container of hidden sites.
<i>void</i>	<i>v.clear_hidden_sites_container()</i>	Clears the container of hidden sites.

Checking

bool

<i>v.is_valid(bool verbose, int level)</i>	Performs any required tests on a vertex.

ApolloniusGraphTraits_2

CGAL::Apollonius_graph_vertex_base_2<Gt,StoreHidden>

CGAL::Apollonius_graph_vertex_base_2<Gt,StoreHidden>

Definition

The class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* provides a model for the *ApolloniusGraphVertexBase_2* concept which is the vertex base required by the *ApolloniusGraphDataStructure_2* concept. The class *Apollonius_graph_vertex_base_2<Gt,StoreHidden>* has two template arguments, the first being the geometric traits of the Apollonius graph and should be a model of the concept *ApolloniusGraphTraits_2*. The second is a Boolean which controls whether hidden sites are actually stored. Such a control is important if the user is not interested in hidden sites and/or if only insertions are made, in which case no hidden site can become visible. If *StoreHidden* is set to *true*, hidden sites are stored, otherwise they are discarded. By default *StoreHidden* is set to *true*.

```
#include <CGAL/Apollonius_graph_vertex_base_2.h>
```

Is Model for the Concepts

ApolloniusGraphVertexBase_2

Creation

<i>Apollonius_graph_vertex_base_2<Gt,StoreHidden></i> vb;	Default constructor.
<i>Apollonius_graph_vertex_base_2<Gt,StoreHidden></i> vb(<i>Site_2</i> s);	Constructs a vertex associated with the site <i>s</i> and embedded at the center of <i>s</i> .
<i>Apollonius_graph_vertex_base_2<Gt,StoreHidden></i> vb(<i>Site_2</i> s, <i>Face_handle</i> f);	Constructs a vertex associated with the site <i>s</i> , embedded at the center of <i>s</i> , and pointing to the face associated with the face handle <i>f</i> .

ApolloniusGraphTraits_2

Definition

The concept *ApolloniusGraphTraits_2* provides the traits requirements for the *Apollonius_graph_2* class. In particular, it provides a type *Site_2*, which must be a model of the concept *ApolloniusSite_2*. It also provides constructions for sites and several function object types for the predicates.

Types

<i>ApolloniusGraphTraits_2:: Point_2</i>	A type for a point.
<i>ApolloniusGraphTraits_2:: Site_2</i>	A type for an Apollonius site. Must be a model of the concept <i>ApolloniusSite_2</i> .
<i>ApolloniusGraphTraits_2:: Line_2</i>	A type for a line. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
<i>ApolloniusGraphTraits_2:: Ray_2</i>	A type for a ray. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
<i>ApolloniusGraphTraits_2:: Segment_2</i>	A type for a segment. Only required if access to the dual of the Apollonius graph is required or if the primal or dual diagram are inserted in a stream.
<i>ApolloniusGraphTraits_2:: Object_2</i>	A type representing different types of objects in two dimensions, namely: <i>Point_2</i> , <i>Site_2</i> , <i>Line_2</i> , <i>Ray_2</i> and <i>Segment_2</i> .
<i>ApolloniusGraphTraits_2:: FT</i>	A type for the field number type of sites.
<i>ApolloniusGraphTraits_2:: RT</i>	A type for the ring number type of sites.
<i>ApolloniusGraphTraits_2:: Assign_2</i>	Must provide <i>template <class T> bool operator() (T& t, Object_2 o)</i> which assigns <i>o</i> to <i>t</i> if <i>o</i> was constructed from an object of type <i>T</i> . Returns <i>true</i> , if the assignment was possible.
<i>ApolloniusGraphTraits_2:: Construct_object_2</i>	Must provide <i>template <class T> Object_2 operator() (T t)</i> that constructs an object of type <i>Object_2</i> that contains <i>t</i> and returns it.
<i>ApolloniusGraphTraits_2:: Construct_Apollonius_vertex_2</i>	A constructor for a point of the Apollonius diagram equidistant from three sites. Must provide <i>Point_2 operator() (Site_2 s1, Site_2 s2, Site_2 s3)</i> , which constructs a point equidistant from the sites <i>s1</i> , <i>s2</i> and <i>s3</i> .
<i>ApolloniusGraphTraits_2:: Construct_Apollonius_site_2</i>	A constructor for a dual Apollonius site (a site whose center is a vertex of the Apollonius diagram and its weight is the common distance of its center from the three defining sites). Must provide <i>Site_2 operator() (Site_2 s1, Site_2 s2, Site_2 s3)</i> , which constructs a dual site whose center <i>c</i> is equidistant from <i>s1</i> , <i>s2</i> and <i>s3</i> , and its weight is equal to the (signed) distance of <i>c</i> from <i>s1</i> (or <i>s2</i> or <i>s3</i>). Must also provide <i>Line_2 operator() (Site_2 s1, Site_2 s2)</i> , which constructs a line bitangent to <i>s1</i> and <i>s2</i> . This line is the dual site of <i>s1</i> , <i>s2</i> and the site at infinity; it can be viewed as a dual Apollonius site whose center is at infinity and its weight is infinite.

ApolloniusGraphTraits_2:: Compare_x_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the x-coordinates of the centers of *s1* and *s2*.

ApolloniusGraphTraits_2:: Compare_y_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the y-coordinates of the centers of *s1* and *s2*.

ApolloniusGraphTraits_2:: Compare_weight_2

A predicate object type. Must provide *Comparison_result operator()(Site_2 s1, Site_2 s2)*, which compares the weights of *s1* and *s2*.

ApolloniusGraphTraits_2:: Orientation_2

A predicate object type. Must provide *Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3)*, which performs the usual orientation test for the centers of the three sites *s1*, *s2* and *s3*.

Must also provide *Orientation operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 p1, Site_2 p2)*, which performs the usual orientation test for the Apollonius vertex of *s1*, *s2*, *s3* and the centers of *p1* and *p2*.

Precondition: the Apollonius vertex of *s1*, *s2* and *s3* must exist.

ApolloniusGraphTraits_2:: Is_hidden_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2)*, which returns *true* if the circle corresponding to *s2* is contained in the closure of the disk corresponding to *s1*, *false* otherwise.

ApolloniusGraphTraits_2:: Oriented_side_of_bisector_2

A predicate object type. Must provide *Oriented_side operator()(Site_2 s1, Site_2 s2, Point_2 p)*, which returns the oriented side of the bisector of *s1* and *s2* that contains *p*. Returns *ON_POSITIVE_SIDE* if *p* lies in the half-space of *s1* (i.e., *p* is closer to *s1* than *s2*); returns *ON_NEGATIVE_SIDE* if *p* lies in the half-space of *s2*; returns *ON_ORIENTED_BOUNDARY* if *p* lies on the bisector of *s1* and *s2*.

ApolloniusGraphTraits_2:: Vertex_conflict_2

A predicate object type. Must provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q)*, which returns the sign of the distance of *q* from the dual Apollonius site of *s1*, *s2*, *s3*.

Precondition: the dual Apollonius site of *s1*, *s2*, *s3* must exist.

Must also provide *Sign operator()(Site_2 s1, Site_2 s2, Site_2 q)*, which returns the sign of the distance of *q* from the bitangent line of *s1*, *s2* (a degenerate dual Apollonius site, with its center at infinity).

ApolloniusGraphTraits_2:: Finite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4, Site_2 q, bool b)*. The sites *s1*, *s2*, *s3* and *s4* define an Apollonius edge that lies on the bisector of *s1* and *s2* and has as endpoints the Apollonius vertices defined by the triplets *s1*, *s2*, *s3* and *s1*, *s4* and *s2*. The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*). In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.

Precondition: the Apollonius vertices of *s1*, *s2*, *s3*, and *s1*, *s4*, *s2* must exist.

Must also provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, bool b)*. The sites *s1*, *s2*, *s3* and the site at infinity s_∞ define an Apollonius edge that lies on the bisector of *s1* and *s2* and has as endpoints the Apollonius vertices defined by the triplets *s1*, *s2*, *s3* and *s1*, s_∞ and *s2* (the second Apollonius vertex is actually at infinity). The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*). In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.

Precondition: the Apollonius vertex of *s1*, *s2*, *s3* must exist.

Must finally provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 q, bool b)*. The sites *s1*, *s2* and the site at infinity s_∞ define an Apollonius edge that lies on the bisector of *s1* and *s2* and has as endpoints the Apollonius vertices defined by the triplets *s1*, *s2*, s_∞ and *s1*, s_∞ and *s2* (both Apollonius vertices are actually at infinity). The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*). In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.

ApolloniusGraphTraits_2:: Infinite_edge_interior_conflict_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 q, bool b)*. The sites s_∞ , *s1*, *s2* and *s3* define an Apollonius edge that lies on the bisector of s_∞ and *s1* and has as endpoints the Apollonius vertices defined by the triplets s_∞ , *s1*, *s2* and s_∞ , *s3* and *s1*. The Boolean *b* denotes if the two Apollonius vertices are in conflict with the site *q* (in which case *b* should be *true*, otherwise *false*). In case that *b* is *true*, the predicate returns *true* if and only if the entire Apollonius edge is in conflict with *q*. If *b* is *false*, the predicate returns *false* if and only if *q* is not in conflict with the Apollonius edge.

ApolloniusGraphTraits_2:: Is_degenerate_edge_2

A predicate object type. Must provide *bool operator()(Site_2 s1, Site_2 s2, Site_2 s3, Site_2 s4)*. It returns *true* if the Apollonius edge defined by *s1*, *s2*, *s3* and *s4* is degenerate, *false* otherwise. An Apollonius edge is called degenerate if its two endpoints coincide.

Precondition: the Apollonius vertices of *s1*, *s2*, *s3*, and *s1*, *s4*, *s2* must exist.

CGAL::Apollonius_graph_traits_2<K,Method_tag>

Definition

The class *Apollonius_graph_traits_2*<*K*,*Method_tag*> provides a model for the *ApolloniusGraphTraits_2* concept. This class has two template parameters. The first template parameter must be a model of the *Kernel* concept. The second template parameter corresponds to how predicates are evaluated. There are two predefined possible values for *Method_tag*, namely *CGAL::Sqrt_field_tag* and *CGAL::Ring_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of ring-type expressions, i.e., expressions involving only additions, subtractions and multiplications. The default value for *Method_tag* is *CGAL::Ring_tag*. The way the predicates are evaluated is discussed in [KE02, KE03].

CGAL::Apollonius_graph_filtered_traits_2<CK,CM,EK,EM,FK,FM>

Definition

The class *Apollonius_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> provides a model for the *ApolloniusGraphTraits_2* concept.

The class *Apollonius_graph_filtered_traits_2*<CK,CM,EK,EM,FK,FM> uses the filtering technique [BBP01] to achieve traits for the *Apollonius_graph_2*<Gt,Agds> class with efficient and exact predicates given an exact kernel *EK* and a filtering kernel *FK*. The geometric constructions associated provided by this class are equivalent to those provided by the traits class *Apollonius_graph_traits_2*<CK,CM>, which means that they may be inexact.

This class has six template parameters. The first, third and fifth template parameters must be a models of the *Kernel* concept. The second, fourth and sixth template parameters correspond to how predicates are evaluated. There are two predefined possible values for *Method_tag*, namely *CGAL::Sqrt_field_tag* and *CGAL::Ring_tag*. The first one must be used when the number type used in the representation supports the exact evaluation of signs of expressions involving all four basic operations and square roots, whereas the second one requires the exact evaluation of signs of ring-type expressions, i.e., expressions involving only additions, subtractions and multiplications. The way the predicates are evaluated is discussed in [KE02, KE03].

The default values for the template parameters are as follows: *CM* = *CGAL::Ring_tag*, *EK* = *CGAL::Simple_cartesian*<*CGAL::MP_Float*>, *EM* = *CM*, *FK* = *CGAL::Simple_cartesian*<*CGAL::Interval_nt*<false> >, *FM* = *CM*.

CGAL::Apollonius_graph_hierarchy_2<Gt,Agds>

Definition

We provide an alternative to the class *Apollonius_graph_2<Gt,Agds>* for the dynamic construction of the Apollonius graph. The *Apollonius_graph_hierarchy_2<Gt,Agds>* class maintains a hierarchy of Apollonius graphs. The bottom-most level of the hierarchy contains the full Apollonius diagram. A site that is in level i , is in level $i + 1$ with probability $1/\alpha$ where $\alpha > 1$ is some constant. The difference between the *Apollonius_graph_2<Gt,Agds>* class and the *Apollonius_graph_hierarchy_2<Gt,Agds>* is on how the nearest neighbor location is done. Given a point p the location is done as follows: at the top most level we find the nearest neighbor of p as in the *Apollonius_graph_2<Gt,Agds>* class. At every subsequent level i we use the nearest neighbor found at level $i + 1$ to find the nearest neighbor at level i . This is a variant of the corresponding hierarchy for points found in [Dev98]. The class has two template parameters which have essentially the same meaning as in the *Apollonius_graph_2<Gt,Agds>* class. The first template parameter must be a model of the *ApolloniusGraphTraits_2* concept. The second template parameter must be a model of the *ApolloniusGraphDataStructure_2* concept. However, the vertex base class that is to be used in the Apollonius graph data structure must be a model of the *ApolloniusGraphHierarchyVertexBase_2* concept. The second template parameter defaults to *Triangulation_data_structure_2< Apollonius_graph_hierarchy_vertex_base_2< Apollonius_graph_vertex_base_2<Gt,true> >, Triangulation_face_base_2<Gt> >*.

The *Apollonius_graph_hierarchy_2<Gt,Agds>* class derives publicly from the *Apollonius_graph_2<Gt,Agds>* class. The interface is the same with its base class. In the sequel only the methods overridden are documented.

```
#include <CGAL/Apollonius_graph_hierarchy_2.h>
```

Inherits From

CGAL::Apollonius_graph_2<Gt,Agds>

Types

Apollonius_graph_hierarchy_2<Gt,Agds> does not introduce other types than those introduced by its base class *Apollonius_graph_2<Gt,Agds>*.

Creation

Apollonius_graph_hierarchy_2<Gt,Agds> *agh*(*Gt* *gt*=*Gt*()); Creates an hierarchy of Apollonius graphs using *gt* as geometric traits.

template< class Input_iterator >
Apollonius_graph_hierarchy_2<Gt,Agds> *agh*(*Input_iterator* *first*, *Input_iterator* *beyond*, *Gt* *gt*=*Gt*());

Creates an Apollonius graph hierarchy using *gt* as geometric traits and inserts all sites in the range [*first*, *beyond*).

Apollonius_graph_hierarchy_2<Gt,Agds> *agh*(*other*); Copy constructor. All faces, vertices and inter-level pointers are duplicated. After the construction, *agh* and *other* refer to two different Apollonius graph hierarchies: if *other* is modified, *agh* is not.

<i>Apollonius_graph_hierarchy_2</i> < <i>Gt,Agds</i> >	<i>agh</i> = <i>other</i>	Assignment. All faces, vertices and inter-level pointers are duplicated. After the construction, <i>agh</i> and <i>other</i> refer to two different Apollonius graph hierarchies: if <i>other</i> is modified, <i>agh</i> is not.
--	---------------------------	---

Insertion

template< *class Input_iterator* >

unsigned int *agh.insert(Input_iterator first, Input_iterator beyond)*

Inserts the sites in the range [*first*,*beyond*). The number of sites in the range [*first*, *beyond*) is returned.

Precondition: *Input_iterator* must be a model of *InputIterator* and its value type must be *Site_2*.

<i>Vertex_handle</i>	<i>agh.insert(Site_2 s)</i>	Inserts the site <i>s</i> in the Apollonius graph hierarchy. If <i>s</i> is visible then the vertex handle of <i>s</i> is returned, otherwise <i>Vertex_handle(NULL)</i> is returned.
----------------------	------------------------------	---

<i>Vertex_handle</i>	<i>agh.insert(Site_2 s, Vertex_handle vnear)</i>
----------------------	---

Inserts *s* in the Apollonius graph hierarchy using the site associated with *vnear* as an estimate for the nearest neighbor of the center of *s*. If *s* is visible then the vertex handle of *s* is returned, otherwise *Vertex_handle(NULL)* is returned. A call to this method is equivalent to *agh.insert(s)*; and it has been added for the sake of conformity with the interface of the *Apollonius_graph_2*<*Gt,Agds*> class.

Removal

<i>void</i>	<i>agh.remove(Vertex_handle v)</i>	Removes the site associated to the vertex handle <i>v</i> from the Apollonius graph hierarchy. <i>Precondition:</i> <i>v</i> must correspond to a valid finite vertex of the Apollonius graph hierarchy.
-------------	-------------------------------------	---

Nearest neighbor location

<i>Vertex_handle</i>	<i>agh.nearest_neighbor(Point p)</i>	Finds the nearest neighbor of the point <i>p</i> . In other words it finds the site whose Apollonius cell contains <i>p</i> . Ties are broken arbitrarily and one of the nearest neighbors of <i>p</i> is returned. If there are no visible sites in the Apollonius diagram <i>Vertex_handle(NULL)</i> is returned.
----------------------	---------------------------------------	---

<i>Vertex_handle</i>	<i>agh.nearest_neighbor(Point p, Vertex_handle vnear)</i>
----------------------	--

Finds the nearest neighbor of the point *p*. If there are no visible sites in the Apollonius diagram *Vertex_handle(NULL)* is returned. A call to this method is equivalent to *agh.nearest_neighbor(p)*; and it has been added for the sake of conformity with the interface of the *Apollonius_graph_2*<*Gt,Agds*> class.

I/O

<code>void</code>	<code>agh.file_output(std::ostream& os)</code>	Writes the current state of the Apollonius graph hierarchy to an output stream. In particular, all visible and hidden sites are written as well as the underlying combinatorial hierarchical data structure.
<code>void</code>	<code>agh.file_input(std::istream& is)</code>	Reads the state of the Apollonius graph hierarchy from an input stream.
<code>std::ostream&</code>	<code>std::ostream& os << agh</code>	Writes the current state of the Apollonius graph hierarchy to an output stream.
<code>std::istream&</code>	<code>std::istream& is >> agh</code>	Reads the state of the Apollonius graph hierarchy from an input stream.

Validity check

<code>bool</code>	<code>agh.is_valid(bool verbose = false, int level = 1)</code>	Checks the validity of the Apollonius graph hierarchy. If <i>verbose</i> is <i>true</i> a short message is sent to <code>std::cerr</code> . If <i>level</i> is 0, the data structure at all levels is validated, as well as the inter-level pointers. If <i>level</i> is 1, then the data structure at all levels is validated, the inter-level pointers are validated and all levels of the Apollonius graph hierarchy are also validated. Negative values of <i>level</i> always return <i>true</i> , and values greater than 1 are equivalent to <i>level</i> being 1.
-------------------	---	---

Miscellaneous

<code>void</code>	<code>agh.clear()</code>	Clears all contents of the Apollonius graph hierarchy.
<code>void</code>	<code>agh.swap(other)</code>	The Apollonius graph hierarchies <i>other</i> and <i>agh</i> are swapped. <code>agh.swap(other)</code> should be preferred to <code>agh= other</code> or to <code>agh(other)</code> if <i>other</i> is deleted afterwards.

ApolloniusGraphHierarchyVertexBase_2

Definition

The vertex of an Apollonius graph included in an Apollonius graph hierarchy has to provide some pointers to the corresponding vertices in the graphs of the next and preceding levels. Therefore, the concept *ApolloniusGraphHierarchyVertexBase_2* refines the concept *ApolloniusGraphVertexBase_2*, by adding two vertex handles to the corresponding vertices for the next and previous level graphs.

Refines

ApolloniusGraphVertexBase_2

Types

ApolloniusGraphHierarchyVertexBase_2 does not introduce any types in addition to those of *ApolloniusGraphVertexBase_2*.

Creation

ApolloniusGraphHierarchyVertexBase_2 *v*;
ApolloniusGraphHierarchyVertexBase_2 *v*(*Site_2* *s*);

Default constructor.
 Constructs a vertex associated with the site *s* and embedded at the center of *s*.

ApolloniusGraphHierarchyVertexBase_2 *v*(*Site_2* *s*, *Face_handle* *f*);

Constructs a vertex associated with the site *s*, embedded at the center of *s*, and pointing to face *f*.

Operations

Vertex_handle *v.up*()

Returns a handle to the corresponding vertex of the next level Apollonius graph. If such a vertex does not exist *Vertex_handle(NULL)* is returned.

Vertex_handle *v.down*()

Returns a handle to the corresponding vertex of the previous level Apollonius graph.

void *v.set_up*(*Vertex_handle* *u*)

Sets the handle for the vertex of the next level Apollonius graph.

void *v.set_down*(*Vertex_handle* *d*)

Sets the handle for the vertex of the previous level Apollonius graph;

Chapter 33

2D Voronoi Diagram Adaptor

Menelaos Karavelas

Contents

33.1 Introduction	2079
33.2 Software Design	2081
33.3 The Adaptation Traits	2082
33.4 The Adaptation Policy	2083
33.5 Examples	2085

This chapter describes an adaptor that adapts two-dimensional triangulated Delaunay graphs to the corresponding Voronoi diagrams. We start with a few definitions and a description of the issues that this adaptor addresses in Section [33.1](#). The software design of the Voronoi diagram adaptor package is described in Section [33.2](#). In Section [33.3](#) we discuss the traits required for performing the adaptation, and finally in Section [33.5](#) we present a few examples using this adaptor.

33.1 Introduction

A Voronoi diagram is typically defined for a set of objects, also called sites in the sequel, that lie in some space Σ and a distance function that measures the distance of a point x in Σ from an object in the object set. In this package we are interested in planar Voronoi diagrams, so in the sequel the space Σ will be the space \mathbb{R}^2 . Let $\mathcal{S} = \{S_1, S_2, \dots, S_n\}$ be our set of sites and let $\delta(x, S_i)$ denote the distance of a point $x \in \mathbb{R}^2$ from the site S_i . Given two sites S_i and S_j , the set V_{ij} of points that are closer to S_i than to S_j with respect to the distance function $\delta(x, \cdot)$ is simply the set:

$$V_{ij} = \{x \in \mathbb{R}^2 : \delta(x, S_i) < \delta(x, S_j)\}.$$

We can then define the set V_i of points on the plane that are closer to S_i than to any other object in \mathcal{S} as:

$$V_i = \bigcap_{i \neq j} V_{ij}.$$

The set V_i is said to be the *Voronoi cell* or *Voronoi face* of the site S_i . The locus of points on the plane that are equidistant from exactly two sites S_i and S_j is called a *Voronoi bisector*. A point that is equidistant to three or more objects in \mathcal{S} is called a *Voronoi vertex*. A simply connected subset of a Voronoi bisector is called a *Voronoi edge*. The collection of Voronoi faces, edges and vertices is called the *Voronoi diagram* of the set \mathcal{S} with respect to the distance function $\delta(x, \cdot)$, and it turns out that it is a subdivision of the plane, i.e., it is a planar graph.

We typically think of faces as 2-dimensional objects, edges as 1-dimensional objects and vertices as 0-dimensional objects. However, this may not be the case for several combinations of sites and distance functions (for example points in \mathbb{R}^2 under the L_1 or the L_∞ distance can produce 2-dimensional Voronoi edges). We call a Voronoi diagram *nice* if no such artifacts exist, i.e., if all vertices edges and faces are 0-, 1- and 2-dimensional, respectively.

Even nice Voronoi diagrams can end up being not so nice. The cell of a site can in general consist of several disconnected components. Such a case can happen, for example, when we consider weighted points $Q_i = (p_i, \lambda_i)$, where $p_i \in \mathbb{R}^2$, $\lambda_i \in \mathbb{R}$, and the distance function is the Euclidean distance multiplied by the weight of each site, i.e., $\delta_M(x, Q_i) = \lambda_i \|x - p_i\|$, where $\|\cdot\|$ denotes the Euclidean norm. In this package we are going to restrict ourselves to nice Voronoi diagrams that have the property that the Voronoi cell of each site is a simply connected region of the plane. We are going to call such Voronoi diagrams *simple Voronoi diagrams*. Examples of simple Voronoi diagrams include the usual Euclidean Voronoi diagram of points, the Euclidean Voronoi diagram of a set of disks on the plane (i.e., the Apollonius diagram), the Euclidean Voronoi diagram of a set of disjoint convex objects on the plane, or the power or (Laguerre) diagram for a set of circles on the plane. In fact every instance of an *abstract Voronoi diagram* in the sense of Klein [Kle89] is a simple Voronoi diagram in our setting. In the sequel when we refer to Voronoi diagrams we will refer to simple Voronoi diagrams.

In many cases we are not really interested in computing the Voronoi diagram itself, but rather its dual graph, called the *Delaunay graph*. In general the Delaunay graph is a planar graph, each face of which consists of at least three edges. Under the non-degeneracy assumption that no point on the plane is equidistant, under the distance function, to more than three sites, the Delaunay graph is a planar graph with triangular faces. In certain cases this graph can actually be embedded with straight line segments in which case we talk about a triangulation. This is the case, for example, for the Euclidean Voronoi diagram of points, or the power diagram of a set of circles. The dual graphs are, respectively, the Delaunay triangulation and the regular triangulation of the corresponding site sets. Graphs of non-constant non-uniform face complexity can be undesirable in many applications, so typically we end up triangulating the non-triangular faces of the Delaunay graph. Intuitively this amounts to imposing an implicit or explicit perturbation scheme during the construction of the Delaunay graph, that perturbs the input sites in such a way so as not to have degenerate configurations.

Choosing between computing the Voronoi diagram or the (triangulated) Delaunay graph is a major decision while implementing an algorithm. It heavily affects the design and choice of the different data structures involved. Although in theory the two approaches are entirely equivalent, it is not so straightforward to go from one representation to the other. The objective of this package is to provide a generic way of going from triangulated Delaunay graphs to planar subdivisions represented through a DCEL data structure. The goal is to provide an adaptor that gives the look and feel of a DCEL data structure, although internally it keeps a graph data structure representing triangular graphs.

The adaptation might seem straightforward at a first glance, and more or less this is case; after all one graph is the dual of the other. The situation becomes complicated whenever we want to treat artifacts of the representation used. Suppose for example that we have a set of sites that contains subsets of sites in degenerate positions. The computed triangulated Delaunay graph has triangular faces that may be the result of an implicit or explicit perturbation scheme. The dual of such a triangulated Delaunay graph is a Voronoi diagram that has all its vertices of degree 3, and for that purpose we are going to call it a *degree-3 Voronoi diagram* in order to distinguish it from the true Voronoi diagram of the input sites. A degree-3 Voronoi diagram can have degenerate features, namely Voronoi edges of zero length, and/or Voronoi faces of zero area. Although we can potentially treat such artifacts, they are nonetheless artifacts of the algorithm we used and do not correspond to the true geometry of the Voronoi diagram.

The manner that we treat such issues in this package in a generic way is by defining an *adaptation policy*. The adaptation policy is responsible for determining which features in the degree-3 Voronoi diagram are to be rejected and which not. The policy to be used can vary depending on the application or the intended usage of the resulting Voronoi diagram. What we care about is that firstly the policy itself is consistent and, secondly, that the adaptation is also done in a consistent manner. The latter is the responsibility of the adaptor provided by this package, whereas the former is the responsibility of the implementor of a policy.

In this package we currently provide two types of adaptation policies. The first one is the simplest: we reject no feature of the degree-3 Voronoi diagram; we call such a policy an *identity policy* since the Voronoi diagram produced is identical to the degree-3 Voronoi diagram. The second type of policy eliminates the degenerate features from the degree-3 Voronoi diagram yielding the true geometry of the Voronoi diagram of the input sites; we call such policies *degeneracy removal policies*.

Delaunay graphs can be mutable or non-mutable. By mutable we mean that sites can be inserted or removed at any time, in an entirely on-line fashion. By non-mutable we mean that once the Delaunay graph has been created, no changes, with respect to the set of sites defining it, are allowed. If the Delaunay graph is a non-mutable one, then the Voronoi diagram adaptor is a non-mutable adaptor as well.

If the Delaunay graph is mutable then the question of whether the Voronoi diagram adaptor is also mutable is slightly more complex to answer. As long as the adaptation policy used does not maintain a state, the Voronoi diagram adaptor is a mutable one; this is the case, for example, with our identity policy or the degeneracy removal policies. If, however, the adaptor maintains a state, then whether it is mutable or non-mutable really depends on whether its state can be updated after every change in the Delaunay graph. Such policies are our caching degeneracy removal policies: some of them result in mutable adaptors others result in non-mutable ones. In Section 33.4 we discuss the issue in more detail.

33.2 Software Design

The *Voronoi_diagram_2*<*DG,AT,AP*> class is parameterized by three template parameters. The first one must be a model of the *DelaunayGraph_2* concept. It corresponds to the API required by an object representing a Delaunay graph. All classes of CGAL that represent Delaunay diagrams are models of this concept, namely, Delaunay triangulations, regular triangulations, Apollonius graphs and segment Delaunay graphs. The second template parameter must be a model of the *AdaptationTraits_2* concept. We discuss this concept in detail in Section 33.3. The third template parameter must be model of the *AdaptationPolicy_2* concept, which we discuss in detail in Section 33.4.

The *Voronoi_diagram_2*<*DG,AT,AP*> class has been intentionally designed to provide an API similar to the arrangements class in CGAL: Voronoi diagrams are special cases of arrangements after all. The API of the two classes, however, could not be identical. The reason is that arrangements in CGAL do not yet support more than one unbounded faces, or equivalently, cannot handle unbounded curves. On the contrary, a Voronoi diagram defined over at least two generating sites, has at least two unbounded faces.

On a more technical level, the *Voronoi_diagram_2*<*DG,AT,AP*> class imitates the representation of the Voronoi diagram (seen as a planar subdivision) by a DCEL (Doubly Connected Edge List) data structure. We have vertices (the Voronoi vertices), halfedges (oriented versions of the Voronoi edges) and faces (the Voronoi cells). In particular, we can basically perform every operation we can perform in a standard DCEL data structure:

- go from a halfedge to its next and previous in the face;
- go from one face to an adjacent one through a halfedge and its twin (opposite) halfedge;
- walk around the boundary of a face;
- enumerate/traverse the halfedges incident to a vertex
- from a halfedge, access the adjacent face;
- from a face, access an adjacent halfedges;
- from a halfedges, access its source and target vertices;

- from a vertex, access an incident halfedge.

In addition to the above possibilities for traversal, we can also traverse the following features through iterators:

- the vertices of the Voronoi diagram;
- the edges or halfedges of the Voronoi diagram;
- the faces of the Voronoi diagram;
- the bounded faces of the Voronoi diagram;
- the bounded halfedges of the Voronoi diagram;
- the unbounded faces of the Voronoi diagram;
- the unbounded halfedges of the Voronoi diagram;
- the sites defining the Voronoi diagram.

Finally, depending on the adaptation traits passed to the Voronoi diagram adaptor, we can perform point location queries, namely given a point p we can determine the feature of the Voronoi diagram (vertex, edge, face) on which p lies.

33.3 The Adaptation Traits

The *AdaptationTraits_2* concept defines the types and functor required by the adaptor in order to access geometric information in the Delaunay graph that is needed by the *Voronoi_diagram_2<DG,AT,AP>* class. In particular, it provides functors for accessing sites in the Delaunay graph and constructing Voronoi vertices from their dual faces in the Delaunay graph. Finally, it defines a tag that indicates whether nearest site queries are to be supported by the Voronoi diagram adaptor. If such queries are to be supported, a functor is required.

Given a query point, the nearest site functor should return information related to how many and which sites of the Voronoi diagram are at equal and minimal distance from the query point. In particular, if the query point is closest to a single site, the vertex handle of the Delaunay graph corresponding to this site is returned. If the query point is closest to exactly two site, the edge of the Delaunay graph that is dual to the Voronoi edges on which the query point lies is returned. If three (or more) sites are closest to the query point, then the query point coincides with a vertex in the Voronoi diagram, and the face handle of the face in the Delaunay graph that is dual to the Voronoi vertex is returned. This way of abstracting the point location mechanism allows for multiple different point location strategies, which are passed to the Voronoi diagram adaptor through different models of the *AdaptationTraits_2* concept. The point location and nearest sites queries of the *Voronoi_diagram_2<DG,AT,AP>* class use internally this nearest site query functor.

In this package we provide four adaptation traits classes, all of which support nearest site queries:

- The *Apollonius_graph_adaptation_traits_2<AG2>* class: it provides the adaptation traits for Apollonius graphs.
- The *Delaunay_triangulation_adaptation_traits_2<DT2>* class: it provides the adaptation traits for Delaunay triangulations.
- The *Regular_triangulation_adaptation_traits_2<RT2>* class: it provides the adaptation traits for regular triangulations.
- The *Segment_Delaunay_graph_adaptation_traits_2<SDG2>* class: it provides the adaptation traits for segment Delaunay graphs.

33.4 The Adaptation Policy

As mentioned above, when we perform the adaptation of a triangulated Delaunay graph to a Voronoi diagram, a question that arises is whether we want to eliminate certain features of the Delaunay graph when we construct its Voronoi diagram representation (such features could be the Voronoi edges of zero length or, for the Voronoi diagram of a set of segments forming a polygon, all edges outside the polygon). The manner that we treat such issues in this package in a generic way is by defining an adaptation policy. The adaptation policy is responsible for determining which features in the degree-3 Voronoi diagram are to be rejected and which not. The policy to be used can vary depending on the application or the intended usage of the resulting Voronoi diagram.

The concept *AdaptationPolicy_2* defines the requirements on the predicate functors that determine whether a feature of the triangulated Delaunay graph should be rejected or not. More specifically it defines an *Edge_rejector* and a *Face_rejector* functor that answer the question: “should this edge (face) of the Voronoi diagram be rejected?”. In addition to the edge and face rejectors the adaptation policy defines a tag, the *Has_inserter* tag. This tag is either set to *CGAL::Tag_true* or to *CGAL::Tag_false*. Semantically it determines if the adaptor is allowed to insert sites in an on-line fashion (on-line removals are not yet supported). In the former case, i.e., when on-line site insertions are allowed, an additional functor is required, the *Site_inserter* functor. This functor takes a reference to a Delaunay graph and a site, and inserts the site in the Delaunay graph. Upon successful insertion, a handle to the vertex representing the site in the Delaunay graph is returned.

We have implemented two types of policies that provide two different ways for answering the question of which features of the Voronoi diagram to keep and which to discard. The first one is called the *identity policy* and corresponds to the *Identity_policy_2<DG,VT>* class. This policy is in some sense the simplest possible one, since it does not reject any feature of the Delaunay graph. The Voronoi diagram provided by the adaptor is the true dual (from the graph-theoretical point of view) of the triangulated Delaunay graph adapted. This policy assumes that the Delaunay graph adapted allows for on-line insertions, and the *Has_inserter* tag is set to *CGAL::Tag_true*. A default site inserter functor is also provided.

The second type of policy we provide is called *degeneracy removal policy*. If the set of sites defining the triangulated Delaunay graph contains subsets of sites in degenerate configurations, the graph-theoretical dual of the triangulated Delaunay graph has edges and potentially faces that are geometrically degenerate. By that we mean that the dual of the triangulated Delaunay graph can have Voronoi edges of zero length or Voronoi faces/cells of zero area. Such features may not be desirable and ideally we would like to eliminate them. The degeneracy removal policies eliminate exactly these features and provide a Voronoi diagram where all edges have non-zero length and all cells have non-zero area. More specifically, in these policies the *Edge_rejector* and *Face_rejector* functors reject the edges and vertices of the Delaunay graph that correspond to dual edges and faces that have zero length and area, respectively. In this package we provide four degeneracy removal policies, namely:

- The *Apollonius_graph_degeneracy_removal_policy_2<AG2>* class: it provides an adaptation policy for removing degeneracies when adapting an Apollonius graph to an Apollonius diagram.
- The *Delaunay_triangulation_degeneracy_removal_policy_2<DT2>* class: it provides an adaptation policy for removing degeneracies when adapting a Delaunay triangulation to a point Voronoi diagram.
- The *Regular_triangulation_degeneracy_removal_policy_2<RT2>* class: it provides an adaptation policy for removing degeneracies when adapting a regular triangulation to a power diagram
- The *Segment_Delaunay_graph_degeneracy_removal_policy_2<SDG2>* class: it provides an adaptation policy for removing degeneracies when adapting a segment Delaunay graph to a segment Voronoi diagram.

A variation of the degeneracy removal policies are the *caching degeneracy removal policies*. In these policies we cache the results of the edge and face rejectors. In particular, every time we want to determine, for example,

if an edge of the Delaunay graph has, as dual edge in the Voronoi diagram, an edge of zero length, we check if the result has already been computed. If yes, we simply return the outcome. If not, we perform the necessary geometric tests, compute the answer, cache it and return it. Such a policy really pays off when we have a lot of degenerate data in our input set of sites. Verifying whether a Voronoi edge is degenerate or not implies computing the outcome of a predicate in a possibly degenerate or near degenerate configuration, which is typically very costly (compared to computing the same predicate in a generic configuration). To avoid this cost every single time we want to check if a Voronoi edge is degenerate or not, we compute the result of the geometric predicate the first time the adaptor asks for it, and simply lookup the answer in the future. In this package we provide four caching degeneracy removal policies, one per degeneracy removal policy mentioned above. Intentionally, we have not indicated the value of the *Has_inserter* tag for the degeneracy removal and caching degeneracy removal policies. The issue is discussed in detail in the sequel.

We raised the question above, as to whether the adaptor is a mutable or non-mutable one, in the sense of whether we can add/remove sites in an on-line fashion. The answer to this question depends on: (1) whether the Delaunay graph adapted allows for on-line insertions/removals and (2) whether the adaptation policies maintains a state and whether this state is easily maintainable when we want to allow for on-line modifications.

The way we indicate if we allow on-line insertions of sites is via the *Has_inserter* tag (as mentioned, on-line removals are currently not supported). The *Has_inserter* tag has two possible values, namely, *CGAL::Tag_true* and *CGAL::Tag_false*. The value *CGAL::Tag_true* indicates that the Delaunay graph allows for on-line insertions, whereas the value *CGAL::Tag_false* indicates the opposite. Note that these values *do not* indicate if the Delaunay graph supports on-line insertions, but rather whether the Voronoi diagram adaptor should be able to perform on-line insertions or not. This delicate point will become clearer below.

Let us consider the various scenarios. If the Delaunay graph is non-mutable, the Voronoi diagram adaptor cannot perform on-line insertions of sites. In this case not only degeneracy removal policies, but rather every single adaptation policy for adapting the Delaunay graph in question should have the *Has_inserter* tag set to *CGAL::Tag_false*.

If the Delaunay graph is mutable, i.e., on-line site insertions as are allowed, we can choose between two types of adaptation policies, those that allow these on-line insertions and those that do not. In the former case the *Has_inserter* tag should be set to *CGAL::Tag_true*, whereas in the latter to *CGAL::Tag_false*. In other words, even if the Delaunay graph is mutable, we can choose (by properly determining the value of the *Has_inserter* tag) if the adaptor should be mutable as well. At a first glance it may seem excessive to restrict existing functionality. There are situations, however, where such a choice is necessary.

Consider a caching degeneracy removal policy. If we do not allow for on-line insertions then the cached quantities are always valid since the Voronoi diagram never changes. If we allow for on-line insertions the Voronoi diagram can change, which implies that the results of the edge and faces degeneracy testers that we have cached are no longer valid or relevant. In these cases, we need to somehow update these cached results, and ideally we would like to do this in an efficient manner. The inherent dilemma in the above discussion is whether the Voronoi diagram adaptor should be able to perform on-line insertions of sites. The answer to this question in this framework is given by the *Has_inserter* tag. If the tag is set to *CGAL::Tag_false* the adaptor cannot insert sites on-line, whereas if the tag is set to *CGAL::Tag_true* the adaptor can add sites on-line. In other words, the *Has_inserter* tag determines how the Voronoi diagram adaptor should behave, and this is enough from the adaptor's point of view.

From the point of view of a policy writer the dilemma is still there: should the policy allow for on-line insertions or not? The answer really depends on what are the consequences of such a choice. For a policy that has no state, such as our degeneracy removal policies, it is natural to set the *Has_inserter* tag to *CGAL::Tag_true*. For our caching degeneracy removal policies, our choice was made on the grounds of whether we can update the cached results efficiently when insertions are performed. For CGAL's Apollonius graphs, Delaunay triangulation and regular triangulations it is possible to ask what are the edges and faces of the Delaunay graph that are to be destroyed when a query site is inserted. This is done via the *get_conflicts* method provided by these classes. Using the outcome of the *get_conflicts* method the site inserter can first update the cached results

(i.e., indicate which are invalidated) and then perform the actual insertion. Such a method does not yet exist for segment Delaunay graphs. We have thus chosen to support on-line insertions for all non-caching degeneracy removal policies. The caching degeneracy removal policy for segment Delaunay graphs does not support on-line insertions, whereas the remaining three caching degeneracy removal policies support on-line insertions.

Efficiency Considerations

One last item that merits some discussion are the different choices from the point of view of time- and space-efficiency.

As far as the Voronoi diagram adaptor is concerned, only a copy of the adaptation traits and a copy of the adaptation policy are stored in it. The various adaptation traits classes we provide are empty classes (i.e., they do not store anything). The major time and space efficiency issues arise from the various implementations of the adaptation policies. Clearly, the identity policy has no dominant effect on neither the time or space efficiency. The costs when choosing this policy are due to the underlying Delaunay graph.

The non-caching degeneracy removal policies create a significant time overhead since every time we want to access a feature of the Voronoi diagram, we need to perform geometric tests in order to see if this feature or one of its neighboring ones has been rejected. Such a policy is acceptable if we know we are away from degeneracies or for small input sizes. In the case of the segment Delaunay graph, it is also the only policy we provide that at the same time removes degeneracies and allows for on-line insertion of sites. Caching policies seem to be the best choice for moderate to large input sizes (1000 sites and more). They do not suffer from the problem of dealing with degenerate configurations, but since they cache the results, they increase the space requirements by linear additive factor. To conclude, if the user is interested in getting a Voronoi diagram without degenerate features and knows all sites in advance, the best course of action is to insert all sites at construction time and use a caching degeneracy removal policy. This strategy avoids the updates of the cached results after each individual insertion, due to the features of the Voronoi diagram destroyed because of the site inserted.

33.5 Examples

In this section we present an example that shows how to perform point location queries.

```
#include <CGAL/basic.h>

// standard includes
#include <iostream>
#include <fstream>
#include <cassert>

// includes for defining the Voronoi diagram adaptor
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Voronoi_diagram_2.h>
#include <CGAL/Delaunay_triangulation_adaptation_traits_2.h>
#include <CGAL/Delaunay_triangulation_adaptation_policies_2.h>

// typedefs for defining the adaptor
typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Delaunay_triangulation_2<K> DT;
typedef CGAL::Delaunay_triangulation_adaptation_traits_2<DT> AT;
```

```

typedef CGAL::Delaunay_triangulation_caching_degeneracy_removal_policy_2<DT> AP;
typedef CGAL::Voronoi_diagram_2<DT,AT,AP> VD;

// typedef for the result type of the point location
typedef AT::Site_2 Site_2;
typedef AT::Point_2 Point_2;

typedef VD::Locate_result Locate_result;
typedef VD::Vertex_handle Vertex_handle;
typedef VD::Face_handle Face_handle;
typedef VD::Halfedge_handle Halfedge_handle;
typedef VD::Ccb_halfedge_circulator Ccb_halfedge_circulator;

void print_endpoint(Halfedge_handle e, bool is_src) {
    std::cout << "\t";
    if ( is_src ) {
        if ( e->has_source() ) std::cout << e->source()->point() << std::endl;
        else std::cout << "point at infinity" << std::endl;
    } else {
        if ( e->has_target() ) std::cout << e->target()->point() << std::endl;
        else std::cout << "point at infinity" << std::endl;
    }
}

int main()
{
    std::ifstream ifs("data/data1.dt.cin");
    assert( ifs );

    VD vd;

    Site_2 t;
    while ( ifs >> t ) { vd.insert(t); }
    ifs.close();

    assert( vd.is_valid() );

    std::ifstream ifq("data/queries1.dt.cin");
    assert( ifq );

    Point_2 p;
    while ( ifq >> p ) {
        std::cout << "Query point (" << p.x() << ", " << p.y()
            << ") lies on a Voronoi " << std::flush;

        Locate_result lr = vd.locate(p);
        if ( Vertex_handle* v = boost::get<Vertex_handle>(&lr) ) {
            std::cout << "vertex." << std::endl;
            std::cout << "The Voronoi vertex is:" << std::endl;
            std::cout << "\t" << (*v)->point() << std::endl;
        } else if ( Halfedge_handle* e = boost::get<Halfedge_handle>(&lr) ) {
            std::cout << "edge." << std::endl;
            std::cout << "The source and target vertices "
                << "of the Voronoi edge are:" << std::endl;

```

```

    print_endpoint(*e, true);
    print_endpoint(*e, false);
} else if ( Face_handle* f = boost::get<Face_handle>(&lr) ) {
    std::cout << "face." << std::endl;
    std::cout << "The vertices of the Voronoi face are"
                << " (in counterclockwise order):" << std::endl;
    Ccb_halfedge_circulator ec_start = (*f)->outer_ccb();
    Ccb_halfedge_circulator ec = ec_start;
    do {
        print_endpoint(ec, false);
    } while ( ++ec != ec_start );
}
std::cout << std::endl;
}
ifq.close();

return 0;
}

```

2D Voronoi Diagram Adaptor Reference Manual

Menelaos Karavelas

CGAL provides the class `CGAL::Voronoi_diagram_2<DG,AT,AP>` for adapting the various (triangulated) Delaunay graphs to Voronoi diagrams according to some adaptation policy. In particular, the class `CGAL::Voronoi_diagram_2<DG,AT,AP>` provides an API for the duals of (triangulated) Delaunay graphs, that makes them look like planar subdivisions. The adaptation policy is responsible for deciding which edges and faces of these duals should be eliminated. This is especially important when, for instance, we want to eliminate degenerate features in the Voronoi diagram that are the result of the fact that Delaunay graphs are always triangulated and are due to degenerate configurations in the generating data.

The three template parameters must be models of the *DelaunayGraph_2*, *AdaptationTraits_2* and *AdaptationPolicy_2* concepts, respectively. The first concept is related to the Delaunay graphs that are to be adapted, whereas the second one is responsible for manipulating/accessing in a unified way the geometry of a specific Voronoi diagram as well as for performing nearest site queries. The third template parameter corresponds to the chosen adaptation policy and provides the necessary types and functors needed for performing this adaptation.

CGAL::Voronoi_diagram_2<DG,AT,AP>

Definition

The class *Voronoi_diagram_2<DG,AT,AP>* provides an adaptor that enables us to view a triangulated Delaunay graph as their dual subdivision, the Voronoi diagram. The class *Voronoi_diagram_2<DG,AT,AP>* is designed to provide an API that is similar to that of CGAL's arrangements.

The first template parameter of the *Voronoi_diagram_2<DG,AT,AP>* class corresponds to the triangulated Delaunay graph and must be a model of the *DelaunayGraph_2* concept. The second template parameter must be a model of the *AdaptationTraits_2* concept. The third template parameter must be a model of the *AdaptationPolicy_2* concept. The third template parameter defaults to *CGAL::Identity_policy_2<DG,AT>*.

```
#include <CGAL/Voronoi_diagram_2.h>
```

Types

<i>typedef DG</i>	<i>Delaunay_graph;</i>	A type for the dual Delaunay graph.
<i>typedef AT</i>	<i>Adaptation_traits;</i>	A type for the adaptation traits needed by the Voronoi diagram adaptor.
<i>typedef AP</i>	<i>Adaptation_policy;</i>	A type for the adaptation policy used.
<i>typedef Adaptation_traits::Point_2</i>	<i>Point_2;</i>	A type a point.
<i>typedef Adaptation_traits::Site_2</i>	<i>Site_2;</i>	A type for the sites of the Voronoi diagram.
<i>typedef Delaunay_graph::size_type</i>	<i>size_type;</i>	A type for sizes.
<i>typedef Delaunay_graph::Geom_traits</i>	<i>Delaunay_geom_traits;</i>	A type for the geometric traits of the Delaunay graph.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>	A type for the vertex handles of the Delaunay graph.
<i>typedef Delaunay_graph::Face_handle</i>	<i>Delaunay_face_handle;</i>	A type for the face handles of the Delaunay graph.
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>	A type for the edges of the Delaunay graph.
<i>Voronoi_diagram_2<DG,AT,AP>:: Halfedge</i>	A type for the halfedges of the Voronoi diagram.	
<i>Voronoi_diagram_2<DG,AT,AP>:: Vertex</i>	A type for the vertices of the Voronoi diagram.	
<i>Voronoi_diagram_2<DG,AT,AP>:: Face</i>	A type for the faces of the Voronoi diagram.	

The vertices, edges and faces of the Voronoi diagram are accessed through *handles*, *iterators* and *circulators*. The iterators and circulators are all bidirectional and non-mutable. The circulators and iterators are assignable to the corresponding handle types, and they are also convertible to the corresponding handles.

Voronoi_diagram_2<DG,AT,AP>:: Halfedge_handle Handle for halfedges.

<i>Voronoi_diagram_2<DG,AT,AP>:: Vertex_handle</i>	Handle for vertices.
<i>Voronoi_diagram_2<DG,AT,AP>:: Face_handle</i>	Handle for faces.
<i>Voronoi_diagram_2<DG,AT,AP>:: Edge_iterator</i>	A type for an iterator over Voronoi edges. Edges are considered non-oriented. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Halfedge_iterator</i>	A type for an iterator over Voronoi halfedges. Halfedges are oriented and come in pairs. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Face_iterator</i>	A type for an iterator over Voronoi faces. Its value type is <i>Face</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Vertex_iterator</i>	A type for an iterator over Voronoi vertices. Its value type is <i>Vertex</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Halfedge_around_vertex_circulator</i>	A type for a circulator over the halfedges that have a common vertex as their target. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Ccb_halfedge_circulator</i>	A type for a circulator over the halfedges on the boundary of a Voronoi face. Its value type of is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Unbounded_faces_iterator</i>	A type for an iterator over the unbounded faces of the Voronoi diagram. Its value type is <i>Face</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Bounded_faces_iterator</i>	A type for an iterator over the bounded faces of the Voronoi diagram. Its value type is <i>Face</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Unbounded_halfedges_iterator</i>	A type for an iterator over the unbounded halfedges of the Voronoi diagram. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Bounded_halfedges_iterator</i>	A type for an iterator over the bounded halfedges of the Voronoi diagram. Its value type is <i>Halfedge</i> .
<i>Voronoi_diagram_2<DG,AT,AP>:: Site_iterator</i>	A type for an iterator over the sites of the Voronoi diagram. Its value type is <i>Site_2</i> .
<i>typedef boost::variant<Face_handle,Halfedge_handle,Vertex_handle></i>	<i>Locate_result;</i> The result type of the point location queries.

Creation

```
Voronoi_diagram_2<DG,AT,AP> vd( Adaptation_traits at = Adaptation_traits(),
                                Adaptation_policy ap = Adaptation_policy(),
                                Delaunay_geom_traits gt = Delaunay_geom_traits())
```

Creates a Voronoi diagram using *at* as adaptation traits and *ap* as adaptation policy; the underlying Delaunay graph is created using *gt* as geometric traits.

```
Voronoi_diagram_2<DG,AT,AP> vd( Delaunay_graph dg,
                                bool swap_dg = false,
                                Adaptation_traits at = Adaptation_traits(),
                                Adaptation_policy ap = Adaptation_policy())
```

Creates a Voronoi diagram from the Delaunay graph *dg* and using *at* as adaptation traits and *ap* as adaptation policy. The Delaunay graph *dg* is fully copied if *swap_dg* is set to *false*, or swapped with the one stored internally if *swap_dg* is set to *true*.

```
template<class Iterator>
Voronoi_diagram_2<DG,AT,AP> vd( Iterator first,
                                Iterator beyond,
                                Adaptation_traits at = Adaptation_traits(),
                                Adaptation_policy ap = Adaptation_policy(),
                                Delaunay_geom_traits gt = Delaunay_geom_traits())
```

Creates a Voronoi diagram using as sites the sites in the iterator range [*first*, *beyond*), *at* as adaptation traits and *ap* as adaptation policy; the underlying Delaunay graph is created using *gt* as geometric traits. *Iterator* must be a model of the *InputIterator* concept and its value type must be *Site_2*.

Access Methods

<i>Delaunay_graph</i>	<i>vd.dual()</i>	Returns a const reference to the dual graph, i.e., the Delaunay graph.
<i>Halfedge_handle</i>	<i>vd.dual(Delaunay_edge e)</i>	Returns a handle to the halfedge in the Voronoi diagram that is dual to the edge <i>e</i> in the Delaunay graph.
<i>Face_handle</i>	<i>vd.dual(Delaunay_vertex_handle v)</i>	Returns a handle to the face in the Voronoi diagram that is dual to the vertex corresponding to the vertex handle <i>v</i> in the Delaunay graph.
<i>Vertex_handle</i>	<i>vd.dual(Delaunay_face_handle f)</i>	Returns a handle to the vertex in the Voronoi diagram that is dual to the face corresponding to the face handle <i>f</i> in the Delaunay graph.
<i>Adaptation_traits</i>	<i>vd.adaptation_traits()</i>	Returns a reference to the Voronoi traits.
<i>Adaptation_policy</i>	<i>vd.adaptation_policy()</i>	Returns a reference to the adaptation policy.
<i>size_type</i>	<i>vd.number_of_vertices()</i>	Returns the number of Voronoi vertices.
<i>size_type</i>	<i>vd.number_of_faces()</i>	Returns the number of Voronoi faces (bounded and unbounded).
<i>size_type</i>	<i>vd.number_of_halfedges()</i>	Returns the number of halfedges (bounded and unbounded) in the Voronoi diagram. This is always an even number.
<i>size_type</i>	<i>vd.number_of_connected_components()</i>	Returns the number of connected components of the Voronoi skeleton.
<i>Face_handle</i>	<i>vd.unbounded_face()</i>	Returns one of the unbounded faces of the Voronoi diagram. If no unbounded faces exist (this can happen if the number of sites is zero) the default constructed face handle is returned.

<i>Face_handle</i>	<i>vd.bounded_face()</i>	Returns one of the bounded faces of the Voronoi diagram. If no bounded faces exist the default constructed face handle is returned.
<i>Halfedge_handle</i>	<i>vd.unbounded_halfedge()</i>	Returns one of the unbounded halfedges of the Voronoi diagram. If no unbounded halfedges exist the default constructed halfedge handle is returned.
<i>Halfedge_handle</i>	<i>vd.bounded_halfedge()</i>	Returns one of the bounded halfedges of the Voronoi diagram. If no bounded halfedges exist the default constructed halfedge handle is returned.

Traversal of the Voronoi diagram

A Voronoi diagram can be seen as a container of faces, vertices and halfedges. Therefore the Voronoi diagram provides several iterators and circulators that allow to traverse it.

Iterators

The following iterators allow respectively to visit the faces (all or only the unbounded/bounded ones), edges, halfedges (all or only the unbounded/bounded ones) and vertices of the Voronoi diagram. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Halfedge*, *Halfedge* and *Vertex*. All iterators are convertible to the corresponding handles and are invalidated by any change in the Voronoi diagram.

<i>Face_iterator</i>	<i>vd.faces_begin()</i>	Starts at an arbitrary Voronoi face.
<i>Face_iterator</i>	<i>vd.faces_end()</i>	Past-the-end iterator.
<i>Unbounded_faces_iterator</i>	<i>vd.unbounded_faces_begin()</i>	Starts at an arbitrary unbounded Voronoi face.
<i>Unbounded_faces_iterator</i>	<i>vd.unbounded_faces_end()</i>	Past-the-end iterator.
<i>Bounded_faces_iterator</i>	<i>vd.bounded_faces_begin()</i>	Starts at an arbitrary bounded Voronoi face.
<i>Bounded_faces_iterator</i>	<i>vd.bounded_faces_end()</i>	Past-the-end iterator.
<i>Edge_iterator</i>	<i>vd.edges_begin()</i>	Starts at an arbitrary Voronoi edge.
<i>Edge_iterator</i>	<i>vd.edges_end()</i>	Past-the-end iterator.
<i>Halfedge_iterator</i>	<i>vd.halfedges_begin()</i>	Starts at an arbitrary Voronoi halfedge.
<i>Halfedge_iterator</i>	<i>vd.halfedges_end()</i>	Past-the-end iterator.
<i>Unbounded_halfedges_iterator</i>	<i>vd.unbounded_halfedges_begin()</i>	Starts at an arbitrary unbounded Voronoi edge.
<i>Unbounded_halfedges_iterator</i>	<i>vd.unbounded_halfedges_end()</i>	Past-the-end iterator.
<i>Bounded_halfedges_iterator</i>	<i>vd.bounded_halfedges_begin()</i>	Starts at an arbitrary bounded Voronoi edge.
<i>Bounded_halfedges_iterator</i>	<i>vd.bounded_halfedges_end()</i>	Past-the-end iterator.

<i>Vertex_iterator</i>	<i>vd.vertices_begin()</i>	Starts at an arbitrary Voronoi vertex.
<i>Vertex_iterator</i>	<i>vd.vertices_end()</i>	Past-the-end iterator.

The following iterator provides access to the sites that define the Voronoi diagram. Its value type is *Site_2*. It is invalidated by any change in the Voronoi diagram.

<i>Site_iterator</i>	<i>vd.sites_begin()</i>	Starts at an arbitrary site.
<i>Site_iterator</i>	<i>vd.sites_end()</i>	Past-the-end iterator.

Circulators

The Voronoi diagram adaptor also provides circulators that allow to visit all halfedges whose target is a given vertex – this is the *Halfedge_around_vertex_circulator*, as well as all halfedges on the boundary of a Voronoi face – this is the *Ccb_halfedge_circulator*. These circulators are non-mutable and bidirectional. The operator *operator++* moves the former circulator counterclockwise around the vertex while the *operator--* moves clockwise. The latter circulator is moved by the operator *operator++* to the next halfedge on the boundary in the counterclockwise sense, while *operator--* moves clockwise. When the *Ccb_halfedge_circulator* is defined over an infinite Voronoi face *f*, then applying *operator++* to a circulator corresponding to a halfedge whose target is not finite moves to the next infinite (or semi-infinite) halfedge of *f* in the counterclockwise sense. Similarly, applying *operator++* to a circulator corresponding to a halfedge whose source is not finite, moves to the previous infinite (or semi-infinite) halfedge of *f* in the clockwise sense. The *Halfedge_around_vertex_circulator* circulator is invalidated by any modification in the faces adjacent to the vertex over which it is defined. The *Ccb_halfedge_circulator* is invalidated by any modification in the face over which it is defined.

<i>Ccb_halfedge_circulator</i>	<i>vd.ccb_halfedges(Face_handle f)</i>	Returns a circulator over the halfedges on the boundary of <i>f</i> . The circulator is initialized to an arbitrary halfedge on the boundary of the Voronoi face <i>f</i> .
--------------------------------	---	---

<i>Ccb_halfedge_circulator</i>	<i>vd.ccb_halfedges(Face_handle f, Halfedge_handle h)</i>	Returns a circulator over the halfedges on the boundary of <i>f</i> . The circulator is initialized with the halfedge <i>h</i> . <i>Precondition:</i> The halfedge <i>h</i> must lie on the boundary of <i>f</i> .
--------------------------------	--	---

<i>Halfedge_around_vertex_circulator</i>	<i>vd.incident_halfedges(Vertex_handle v)</i>	Returns a circulator over the halfedges whose target is the Voronoi vertex <i>v</i> . The circulator is initialized to an arbitrary halfedge incident to <i>v</i> .
--	--	---

<i>Halfedge_around_vertex_circulator</i>	<i>vd.incident_halfedges(Vertex_handle v, Halfedge_handle h)</i>	Returns a circulator over the halfedges whose target is the Voronoi vertex <i>v</i> . The circulator is initialized with the halfedge <i>h</i> . <i>Precondition:</i> The vertex <i>v</i> must be the target vertex of the halfedge <i>h</i> .
--	---	---

Insertion

Face_handle *vd.insert(Site_2 t)* Inserts the site *t* in the Voronoi diagram. A handle to the face corresponding to the Voronoi face of *t* in the Voronoi diagram is returned. If *t* has an empty Voronoi cell, the default constructed face handle is returned. This method is supported only if *Voronoi_traits::Has_inserter* is set to *CGAL::Tag_true*.

template<class Iterator>
size_type *vd.insert(Iterator first, Iterator beyond)*

Inserts, in the Voronoi diagram, the sites in the iterator range [*first*, *beyond*). The value type of *Iterator* must be *Site_2*. The number of sites in the iterator range is returned. This method is supported only if *Voronoi_traits::Has_inserter* is set to *CGAL::Tag_true*.

Queries

Locate_result *vd.locate(Point_2 p)* Performs point location for the query point *p*. In other words, the face, halfedge or vertex of the Voronoi diagram is found on which the point *p* lies. This method is supported only if *Voronoi_traits::Has_nearest_site_2* is set to *CGAL::Tag_true*.
Precondition: The Voronoi diagram must contain at least one face.

I/O

void *vd.file_output(std::ostream& os)* Writes the current state of the Voronoi diagram to the output stream *os*.
The following operator must be defined:
std::ostream& operator<<(std::ostream&, Delaunay_graph)

void *vd.file_input(std::istream& is)* Reads the current state of the Voronoi diagram from the input stream *is*.
The following operator must be defined:
std::istream& operator>>(std::istream&, Delaunay_graph)

std::ostream& *std::ostream& os << vd* Writes the current state of the Voronoi diagram to the output stream *os*.
The following operator must be defined:
std::ostream& operator<<(std::ostream&, Delaunay_graph)

std::istream& *std::istream& is >> vd* Reads the current state of the Voronoi diagram from the input stream *is*.
The following operator must be defined:
std::istream& operator>>(std::istream&, Delaunay_graph)

Validity check

bool *vd.is_valid()* Checks the validity of the dual Delaunay graph and the Voronoi diagram adaptor.

Miscellaneous

`void vd.clear()` Clears all contents of the Voronoi diagram.
`void vd.swap(other)` The Voronoi diagrams *other* and *vd* are swapped. *vd.swap(other)* should be preferred to *vd= other* or to *vd(other)* if *other* is deleted afterwards.

CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge

Definition

The class *Halfedge* is the class provided by the *Voronoi_diagram_2<DG,AT,AP>* class for Voronoi halfedges. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

<i>Halfedge::Vertex</i>		A type for the vertices of the Voronoi diagram.
<i>Halfedge::Face</i>		A type for the faces of the Voronoi diagram.
<i>Halfedge::Vertex_handle</i>		Handle for the vertices of the Voronoi diagram.
<i>Halfedge::Face_handle</i>		Handle for the faces of the Voronoi diagram.
<i>Halfedge::Halfedge_handle</i>		Handle for the halfedges of the Voronoi diagram.
<i>Halfedge::Ccb_halfedge_circulator</i>		A type for a bidirectional circulator over the halfedges of the boundary of a Voronoi face. The value type of the circulator is <i>CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge</i> and is convertible to <i>Halfedge_handle</i> .
<i>Halfedge::Delaunay_graph</i>		A type for the Delaunay graph. It is a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>	A type for the dual edge in the Delaunay graph.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>	A type for vertex handles in the Delaunay graph.

Access Methods

<i>Halfedge_handle</i>	<i>e.twin()</i>	Returns the twin halfedge.
<i>Halfedge_handle</i>	<i>e.opposite()</i>	Same as <i>e.twin()</i> .
<i>Halfedge_handle</i>	<i>e.next()</i>	Returns the next halfedge in the counterclockwise sense around the boundary of the face that <i>e</i> is incident to.
<i>Halfedge_handle</i>	<i>e.previous()</i>	Returns the previous halfedge in the counterclockwise sense around the boundary of the adjacent face.

<i>Face_handle</i>	<i>e.face()</i>	Returns the face that <i>e</i> is incident to.
<i>Vertex_handle</i>	<i>e.source()</i>	Returns the source vertex of <i>e</i> . <i>Precondition:</i> The source vertex must exist, i.e., <i>has_source()</i> must return <i>true</i> .
<i>Vertex_handle</i>	<i>e.target()</i>	Returns the target vertex of <i>e</i> . <i>Precondition:</i> The target vertex must exist, i.e., <i>has_target()</i> must return <i>true</i> .
<i>Ccb_halfedge_circulator</i>	<i>e.ccb()</i>	Returns a bidirectional circulator to traverse the halfedges on the boundary of the Voronoi face containing <i>e</i> . The circulator is initialized to <i>e</i> . Applying <i>operator++</i> (resp. <i>operator--</i>) to this circulator returns the next halfedge on the boundary of the face containing <i>e</i> in the counterclockwise (resp. clockwise) sense.
<i>Delaunay_edge</i>	<i>e.dual()</i>	Returns the corresponding dual edge in the Delaunay graph.

In the four methods below we consider Voronoi halfedges to be “parallel” to the *x*-axis, oriented from left to right.

<i>Delaunay_vertex_handle</i>	<i>e.up()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site above the Voronoi edge.
<i>Delaunay_vertex_handle</i>	<i>e.down()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site below the Voronoi edge.
<i>Delaunay_vertex_handle</i>	<i>e.left()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site to the left of the Voronoi edge. <i>Precondition:</i> <i>has_source()</i> must be <i>true</i> .
<i>Delaunay_vertex_handle</i>	<i>e.right()</i>	Returns a handle to the vertex in the Delaunay graph corresponding to the defining site to the right of the Voronoi edge. <i>Precondition:</i> <i>has_target()</i> must be <i>true</i> .

Predicate Methods

<i>bool e.has_source()</i>	Returns <i>true</i> iff the halfedge corresponds to a bisecting segment or a bisecting ray oriented appropriately so that its apex is its source.
<i>bool e.has_target()</i>	Returns <i>true</i> iff the halfedge corresponds to a bisecting segment or a bisecting ray oriented appropriately so that its apex is its target.
<i>bool e.is_unbounded()</i>	Returns <i>true</i> iff the source or the target of the halfedge does not exist, i.e., if either of <i>has_source()</i> or <i>has_target()</i> return <i>false</i> .
<i>bool e.is_bisector()</i>	Returns <i>true</i> iff the Voronoi edge is an entire bisector.
<i>bool e.is_segment()</i>	Returns <i>true</i> iff the Voronoi edge has both a source and a target Voronoi vertex.
<i>bool e.is_ray()</i>	Returns <i>true</i> iff the Voronoi edge has either a source or a target Voronoi vertex, but not both; in other words it is a bisecting ray.
<i>bool e.is_valid()</i>	Returns <i>true</i> if the following conditions are met: the halfedge is not a rejected edge with respect to the chosen adaptation policy; the twin edge of its twin edge is itself; its adjacent face is not a rejected face with respect to the chosen adaptation policy; its source and target vertices are valid (provided they exist, of course); the previous of its next halfedge is itself and the next of its previous halfedge is itself.

CGAL::Voronoi_diagram_2<DG,AT,AP>::Vertex

Definition

The class *Vertex* is the Voronoi vertex class provided by the class *Voronoi_diagram_2<DG,AT,AP>* class. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

<i>Vertex:: Halfedge</i>		A type for the halfedges of the Voronoi diagram.
<i>Vertex:: Face</i>		A type for the faces of the Voronoi diagram.
<i>Vertex:: Vertex_handle</i>		Handle for the vertices of the Voronoi diagram.
<i>Vertex:: Face_handle</i>		Handle for the faces of the Voronoi diagram.
<i>Vertex:: Halfedge_handle</i>		Handle for the halfedges of the Voronoi diagram.
<i>Vertex:: Point_2</i>		A type for the point represented by the vertex.
<i>Vertex:: size_type</i>		A type for sizes.
<i>Vertex:: Halfedge_around_vertex_circulator</i>		A type for a bidirectional circulator that allows to traverse all incident halfedges, i.e., all halfedges that have the vertex as their target. The value type of the circulator is <i>CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge</i> and is convertible to <i>Halfedge_handle</i> .
<i>Vertex:: Delaunay_graph</i>		A type for the Delaunay graph. It is a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Face_handle</i>	<i>Delaunay_face_handle;</i>	A type for the handle of the dual face.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>	A type for the vertex handles in the Delaunay graph.

Access Methods

<i>Halfedge_handle</i>	<i>v.halfedge()</i>	Returns an incident halfedge that has <i>v</i> as its target.
<i>size_type</i>	<i>v.degree()</i>	Returns the in-degree of the vertex, i.e. the number of halfedges that have <i>v</i> as their target.
<i>Point_2</i>	<i>v.point()</i>	Returns the point represented by the vertex.
<i>Delaunay_face_handle</i>	<i>v.dual()</i>	Returns a handle to the corresponding dual face in the Delaunay graph.

Delaunay_vertex_handle *v.site(unsigned int i)* Returns a handle to the vertex in the Delaunay graph corresponding to the $(i + 1)$ -th generating site of the Voronoi vertex.

Precondition: *i* must be smaller or equal to 2.

Halfedge_around_vertex_circulator *v.incident_halfedges()* Returns a bidirectional circulator that allows the traversal of the halfedges that have *v* as their target. Applying *operator++* (resp. *operator--*) to this circulator returns the next incident halfedge in the counterclockwise (resp. clockwise) sense.

Predicate Methods

bool v.is_incident_edge(Halfedge_handle e) Returns *true* if the halfedge *e* is incident to *v*.
bool v.is_incident_face(Face_handle e) Returns *true* if the face *f* is incident to *v*.
bool v.is_valid() Returns *true* if the following conditions are met: the dual face is not an infinite face; all incident halfedges have the vertex as their target.

CGAL::Voronoi_diagram_2<DG,AT,AP>::Face

Definition

The class *Face* is the class provided by the *Voronoi_diagram_2<DG,AT,AP>* class for Voronoi faces. Below we present its interface.

Is Model for the Concepts

DefaultConstructible, *CopyConstructible*, *Assignable*, *EqualityComparable*, *LessThanComparable*

Types

<i>Face:: Vertex</i>	A type for the vertices of the Voronoi diagram.
<i>Face:: Halfedge</i>	A type for the halfedges of the Voronoi diagram.
<i>Face:: Vertex_handle</i>	Handle for the vertices of the Voronoi diagram.
<i>Face:: Face_handle</i>	Handle for the faces of the Voronoi diagram.
<i>Face:: Halfedge_handle</i>	Handle for the halfedges of the Voronoi diagram.
<i>Face:: Ccb_halfedge_circulator</i>	A type for a bidirectional circulator over the halfedges on the boundary of the face. The value type of the circulator is <i>CGAL::Voronoi_diagram_2<DG,AT,AP>::Halfedge</i> , and is convertible to <i>Halfedge_handle</i> .
<i>Face:: Delaunay_graph</i>	A type for the Delaunay graph. It is a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle</i> ; A type for the handle of the dual vertex.

Access Methods

<i>Halfedge_handle</i>	<i>f.halfedge()</i>	Returns an incident halfedge on the boundary of <i>f</i> .
<i>Ccb_halfedge_circulator</i>	<i>f.ccb()</i>	Returns a bidirectional circulator for traversing the halfedges on the boundary of <i>f</i> . The halfedges are traversed in counterclockwise order.
<i>Delaunay_vertex_handle</i>	<i>f.dual()</i>	Returns a handle to the corresponding dual vertex in the Delaunay graph.

Predicate Methods

<i>bool</i>	<i>f.is_unbounded()</i>	Returns <i>true</i> iff the face is an unbounded face in the Voronoi diagram.
<i>bool</i>	<i>f.is_halfedge_on_ccb(Halfedge e)</i>	Returns <i>true</i> iff <i>e</i> is a halfedge of the boundary of <i>f</i> .

bool *f.is_valid()*

Returns *true* iff the following conditions are met: the face is not rejected by the chosen adaptation policy; all its adjacent halfedges do not have zero length; all its adjacent halfedges return the face as their adjacent face.

DelaunayGraph_2

DelaunayGraph_2

Definition

The concept *DelaunayGraph_2* defines the requirements for the first template parameter of the *Voronoi_diagram_2*<DG,AT,AP> class. The *DelaunayGraph_2* concept essentially defines the requirements that a class representing a Delaunay graph must obey so that the Voronoi diagram adaptor can adapt it.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

<i>DelaunayGraph_2:: size_type</i>	A type for sizes.
<i>DelaunayGraph_2:: Geom_traits</i>	A type for the geometric traits associated with the Delaunay graph.
<i>DelaunayGraph_2:: Triangulation_data_structure</i>	A type for the underlying triangulation data structure. It must be a model of the concept <i>TriangulationDataStructure_2</i> .
<i>DelaunayGraph_2:: Vertex</i>	A type for the vertices of the Delaunay graph.
<i>DelaunayGraph_2:: Face</i>	A type for the faces of the Delaunay graph.
<i>typedef std::pair<Face_handle,int> Edge;</i>	The type of the edges of the Delaunay graph.
<i>DelaunayGraph_2:: Vertex_handle</i>	Handle to the vertices of the Delaunay graph.
<i>DelaunayGraph_2:: Face_handle</i>	Handle to the faces of the Delaunay graph.

The following iterators and circulators must be defined. All iterators and circulators must be assignable and convertible to their corresponding handles.

<i>DelaunayGraph_2:: All_edges_iterator</i>	A type for an iterator over all edges of the Delaunay graph. Its value type must be <i>Edge</i> .
<i>DelaunayGraph_2:: Finite_edges_iterator</i>	A type for an iterator over the finite edges of the Delaunay graph. Its value type must be <i>Edge</i> .
<i>DelaunayGraph_2:: All_faces_iterator</i>	A type for an iterator over all faces of the Delaunay graph. Its value type must be <i>Face</i> .
<i>DelaunayGraph_2:: Finite_faces_iterator</i>	A type for an iterator over the finite faces of the Delaunay graph. Its value type must be <i>Face</i> .
<i>DelaunayGraph_2:: All_vertices_iterator</i>	A type for an iterator over all vertices of the Delaunay graph. Its value type must be <i>Vertex</i> .
<i>DelaunayGraph_2:: Finite_vertices_iterator</i>	A type for an iterator over the finite vertices of the Delaunay graph. Its value type must be <i>Vertex</i> .
<i>DelaunayGraph_2:: Face_circulator</i>	A type for a circulator over the adjacent faces of a vertex of the Delaunay graph. Its value type must be <i>Face</i> .
<i>DelaunayGraph_2:: Vertex_circulator</i>	A type for a circulator over the adjacent vertices of a vertex of the Delaunay graph. Its value type must be <i>Vertex</i> .
<i>DelaunayGraph_2:: Edge_circulator</i>	A type for a circulator over the adjacent edges of a vertex of the Delaunay graph. Its value type must be <i>Edge</i> .

Creation

In addition to the default and copy constructors, as well as the assignment operator, the following constructors are required.

<i>DelaunayGraph_2</i> <i>dg</i> (<i>Geom_traits</i> <i>gt</i>);	Constructor that takes an instance of the geometric traits.
<i>template<class It></i> <i>DelaunayGraph_2</i> <i>dg</i> (<i>It</i> <i>first</i> , <i>It</i> <i>beyond</i>);	Constructor that takes an iterator range. The value type of the iterator must be the type of the sites of the Delaunay graph.
<i>template<class It></i> <i>DelaunayGraph_2</i> <i>dg</i> (<i>It</i> <i>first</i> , <i>It</i> <i>beyond</i> , <i>Geom_traits</i> <i>gt</i>);	Constructor that takes an iterator range and an instance of the geometric traits. The value type of the iterator must be the type of the sites of the Delaunay graph.

Access methods

<i>Triangulation_data_structure</i>	<i>dg.tds()</i>	Returns a reference to the underlying triangulation data structure.
<i>Geom_traits</i>	<i>dg.geom_traits()</i>	Returns a reference to the geometric traits object.
<i>Vertex_handle</i>	<i>dg.infinite_vertex()</i>	Returns a handle to the infinite vertex.
<i>Vertex_handle</i>	<i>dg.finite_vertex()</i>	Returns a handle to a finite vertex, provided there exists one.
<i>Face_handle</i>	<i>dg.infinite_face()</i>	Returns a handle to a face incident to the infinite vertex.
<i>int</i>	<i>dg.dimension()</i>	Returns the dimension of the Delaunay graph.
<i>size_type</i>	<i>dg.number_of_vertices()</i>	Returns the number of finite vertices.
<i>size_type</i>	<i>dg.number_of_faces()</i>	Returns the number of faces (both finite and infinite).

Traversal of the Delaunay graph

A model of the *DelaunayGraph_2* concept must provide several iterators and circulators that allow to traverse it (completely or partially). All iterators and circulators must be convertible to the corresponding handles.

Face, Edge and Vertex Iterators

The following iterators must allow, respectively, to visit finite faces, finite edges and finite vertices of the Delaunay graph. These iterators must be non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*.

<i>Finite_vertices_iterator</i>	<i>dg.finite_vertices_begin()</i>	Starts at an arbitrary finite vertex.
<i>Finite_vertices_iterator</i>	<i>dg.finite_vertices_end()</i>	Past-the-end iterator.
<i>Finite_edges_iterator</i>	<i>dg.finite_edges_begin()</i>	Starts at an arbitrary finite edge.
<i>Finite_edges_iterator</i>	<i>dg.finite_edges_end()</i>	Past-the-end iterator.
<i>Finite_faces_iterator</i>	<i>dg.finite_faces_begin()</i>	Starts at an arbitrary finite face.

<i>Finite_faces_iterator</i>	<i>dg.finite_faces_end()</i>	Past-the-end iterator.
------------------------------	------------------------------	------------------------

The following iterators must allow, respectively, to visit all (both finite and infinite) faces, edges and vertices of the Delaunay graph. These iterators are non-mutable, bidirectional and their value types are respectively *Face*, *Edge* and *Vertex*.

<i>All_vertices_iterator</i>	<i>dg.all_vertices_begin()</i>	Starts at an arbitrary vertex.
<i>All_vertices_iterator</i>	<i>dg.all_vertices_end()</i>	Past-the-end iterator.
<i>All_edges_iterator</i>	<i>dg.all_edges_begin()</i>	Starts at an arbitrary edge.
<i>All_edges_iterator</i>	<i>dg.all_edges_end()</i>	Past-the-end iterator.
<i>All_faces_iterator</i>	<i>dg.all_faces_begin()</i>	Starts at an arbitrary face.
<i>All_faces_iterator</i>	<i>dg.all_faces_end()</i>	Past-the-end iterator.

Face, Edge and Vertex Circulators

A model of the *DelaunayGraph_2* concept must also provide circulators that allow to visit, respectively, all faces or edges incident to a given vertex or all vertices adjacent to a given vertex. These circulators are non-mutable and bidirectional. The operator *operator++* must move the circulator counterclockwise around the vertex while the *operator--* must move the circulator clockwise.

<i>Face_circulator</i>	<i>dg.incident_faces(Vertex_handle v)</i>	Starts at an arbitrary face incident to <i>v</i> .
<i>Face_circulator</i>	<i>dg.incident_faces(Vertex_handle v, Face_handle f)</i>	Starts at face <i>f</i> . <i>Precondition:</i> Face <i>f</i> must be incident to vertex <i>v</i> .
<i>Edge_circulator</i>	<i>dg.incident_edges(Vertex_handle v)</i>	Starts at an arbitrary edge incident to <i>v</i> .
<i>Edge_circulator</i>	<i>dg.incident_edges(Vertex_handle v, Face_handle f)</i>	Starts at the first edge of <i>f</i> incident to <i>v</i> , in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> must be incident to vertex <i>v</i> .
<i>Vertex_circulator</i>	<i>dg.incident_vertices(Vertex_handle v)</i>	Starts at an arbitrary vertex incident to <i>v</i> .
<i>Vertex_circulator</i>	<i>dg.incident_vertices(Vertex_handle v, Face_handle f)</i>	Starts at the first vertex of <i>f</i> adjacent to <i>v</i> in counterclockwise order around <i>v</i> . <i>Precondition:</i> Face <i>f</i> must be incident to vertex <i>v</i> .

Predicates

A model of the *DelaunayGraph_2* concept must provide methods to test the finite or infinite character of any feature.

<i>bool</i>	<i>dg.is_infinite(Vertex_handle v)</i>	<i>true</i> , iff <i>v</i> is the <i>infinite_vertex</i> .
<i>bool</i>	<i>dg.is_infinite(Face_handle f)</i>	<i>true</i> , iff face <i>f</i> is infinite.
<i>bool</i>	<i>dg.is_infinite(Face_handle f, int i)</i>	<i>true</i> , iff edge (<i>f</i> , <i>i</i>) is infinite.
<i>bool</i>	<i>dg.is_infinite(Edge e)</i>	<i>true</i> , iff edge <i>e</i> is infinite.
<i>bool</i>	<i>dg.is_infinite(Edge_circulator ec)</i>	<i>true</i> , iff edge <i>*ec</i> is infinite.

Validity check

<i>bool</i>	<i>dg.is_valid(bool verbose = false)</i>	Checks the validity of the Delaunay graph. If <i>verbose</i> is <i>true</i> a short message is sent to <i>std::cerr</i> .
-------------	---	---

Miscellaneous

<i>void</i>	<i>dg.clear()</i>	Clears all contents of the Delaunay graph.
<i>void</i>	<i>dg.swap(other)</i>	The Delaunay graphs <i>other</i> and <i>dg</i> are swapped. <i>dg.swap(other)</i> should be preferred to <i>dg= other</i> or to <i>dg(other)</i> if <i>other</i> is deleted afterwards.

AdaptationTraits_2

Definition

The concept *AdaptationTraits_2* defines the functors required for accessing geometric information in the Delaunay graph that is needed by the *Voronoi_diagram_2<DG,AT,AP>* class. It optionally defines a functor for performing nearest site queries. A tag is provided for determining whether this functor is defined or not.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

<i>AdaptationTraits_2:: Point_2</i>	A type for a point.	
<i>AdaptationTraits_2:: Site_2</i>	A type for the sites of the Voronoi diagram.	
<i>AdaptationTraits_2:: Delaunay_graph</i>	A type for the triangulated Delaunay graph. The type <i>Delaunay_graph</i> must be a model of the <i>DelaunayGraph_2</i> concept.	
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>	The type of the edges of the Delaunay graph
<i>typedef Delaunay_graph::Face_handle</i>	<i>Delaunay_face_handle;</i>	The type of the face handles of the Delaunay graph
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>	The type of the vertex handles of the Delaunay graph.
<i>AdaptationTraits_2:: Access_site_2</i>	<p>A type for a functor that accesses the site associated with a vertex. The functor should be a model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i> and <i>AdaptableFunctor</i> (with one argument). The functor must provide the following operator:</p> <p style="text-align: center;"><i>result_type operator()(Delaunay_vertex_handle v)</i></p> <p>where the result type <i>result_type</i> must be either <i>Site_2</i> or <i>const Site_2&</i>.</p>	
<i>AdaptationTraits_2:: Construct_Voronoi_point_2</i>	<p>A type for a functor that constructs the dual point of a (triangular) face in the Delaunay graph. This point is the Voronoi vertex of the three sites defining the face in the Delaunay graph. The functor must be a model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i>, <i>AdaptableFunctor</i> (with one argument). It must provide the following operator:</p> <p style="text-align: center;"><i>Point_2 operator()(Delaunay_face_handle f)</i></p> <p>The face handle <i>f</i> must not correspond to an infinite face.</p>	
<i>AdaptationTraits_2:: Has_nearest_site_2</i>	<p>A tag for determining if the adaptation traits class provides a functor for performing nearest site queries. This tag is equal to either <i>CGAL::Tag_true</i> (a nearest site query functor is available) or <i>CGAL::Tag_false</i> (a nearest site query functor is not available).</p>	

AdaptationTraits_2::Nearest_site_2

A type for a functor that performs nearest site queries. Semantically, the result of the query is either a face, edge or vertex of the Delaunay graph. It is a face if the query point has at least three closest sites; the returned face has closest sites as vertices. It is an edge if the query point is equidistant to exactly two vertices of the Delaunay graph, which are the source and target vertices of the edge. In all other cases, the search result is a vertex, namely, the unique vertex of the Delaunay graph closest to the query point. The functor must be a model of the concepts *DefaultConstructible*, *CopyConstructible*, *Assignable*, *AdaptableFunctor* (with two arguments). It must provide the following operator:

```
result_type operator()(Delaunay_graph dg, Point_2 p)
where the result type result_type is boost::variant<
Delaunay_vertex_handle,Delaunay_edge,Delaunay_
face_handle>.
```

This type is required only if *Has_nearest_site_2* is equal to *CGAL::Tag_true*.

Access to objects

<i>Access_site_2</i>	<i>at.access_site_2_object()</i>
<i>Construct_Voronoi_point_2</i>	<i>at.construct_Voronoi_point_2_object()</i>
<i>Nearest_site_2</i>	<i>at.nearest_site_2_object()</i>

This method is required only if *Has_nearest_site_2* is equal to *CGAL::Tag_true*.

Has Models

AdaptationPolicy_2

Definition

The concept *AdaptationPolicy_2* defines the requirements on the predicate functors that determine whether a feature of the triangulated Delaunay graph should be rejected or not. It also provides a functor for inserting sites in the Delaunay graph. The last functor is optional and a tag determines whether it is provided or not. Note that while the first two functors do not modify the Delaunay graph they take as an argument, the last ones does.

Refines

DefaultConstructible, *CopyConstructible*, *Assignable*

Types

<i>AdaptationPolicy_2:: Site_2</i>	A type for the sites of the Voronoi diagram.
<i>AdaptationPolicy_2:: Delaunay_graph</i>	A type for the triangulated Delaunay graph. The type <i>Delaunay_graph</i> must be a model of the <i>DelaunayGraph_2</i> concept.
<i>typedef Delaunay_graph::Vertex_handle</i>	<i>Delaunay_vertex_handle;</i>
<i>typedef Delaunay_graph::Face_handle</i>	<i>Delaunay_face_handle;</i>
<i>typedef Delaunay_graph::Edge</i>	<i>Delaunay_edge;</i>
<i>typedef Delaunay_graph::All_edges_iterator</i>	<i>All_Delaunay_edges_iterator;</i>
<i>typedef Delaunay_graph::Finite_edges_iterator</i>	<i>Finite_Delaunay_edges_iterator;</i>
<i>typedef Delaunay_graph::Edge_circulator</i>	<i>Delaunay_edge_circulator;</i>
<i>AdaptationPolicy_2:: Edge_rejector</i>	<p>A type for the predicate functor that is responsible for rejecting an edge of the Delaunay graph (or equivalently rejecting its dual edge in the Voronoi diagram). It must be model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i>, and <i>AdaptableFunctor</i> (with two arguments). It must provide the following operators:</p> <pre> bool operator()(Delaunay_graph dg, Delaunay_edge e) bool operator()(Delaunay_graph dg, Delaunay_face_handle f, int i) bool operator()(Delaunay_graph dg, Delaunay_edge_circulator ec) bool operator()(Delaunay_graph dg, All_Delaunay_edges_iterator eit) bool operator()(Delaunay_graph dg, Finite_Delaunay_edges_iterator eit) </pre> <p>The functor returns <i>true</i> iff the edge is rejected.</p>
<i>AdaptationPolicy_2:: Face_rejector</i>	<p>A type for the predicate functor that is responsible for rejecting a vertex of the Delaunay graph (or equivalently its dual face in the Voronoi diagram – hence the name of the functor). It must be model of the concepts <i>DefaultConstructible</i>, <i>CopyConstructible</i>, <i>Assignable</i>, <i>AdaptableFunctor</i> (with two arguments). It must provide the following operator:</p> <pre> bool operator()(Delaunay_graph dg, Delaunay_vertex_handle v) </pre> <p>The functor returns <i>true</i> iff the face is rejected.</p>
<i>AdaptationPolicy_2:: Has_inserter</i>	A tag for determining if the adaptation policy class provides a functor for inserting sites in the Delaunay graph. This tag is equal to either <i>CGAL::Tag_true</i> (a site inserter functor is available) or <i>CGAL::Tag_false</i> (a site inserter functor is not available).

CGAL::Apollonius_graph_adaptation_traits_2<AG2>

Definition

The class *Apollonius_graph_adaptation_traits_2*<AG2> provides a model for the *AdaptationTraits_2* concept. The template parameter of the *Apollonius_graph_adaptation_traits_2*<AG2> class must be a model of the *DelaunayGraph_2* concept, and in particular it has the semantics of a (triangulated) 2D Apollonius graph.

CGAL::Identity_policy_2<DG,AT>

Definition

The class *Identity_policy_2<DG,AT>* provides a model for the *AdaptationPolicy_2* concept. The first template parameter of the *Identity_policy_2<DG,AT>* class must be a model of the *DelaunayGraph_2* concept, whereas as the second template parameter must be a model of the *AdaptationTraits_2* concept. This policy rejects no edge and no face of the Delaunay graph, thus giving a Voronoi diagram which is the true dual of the triangulation Delaunay graph. The Voronoi diagram created with this adaptation policy may have degenerate features, such as Voronoi edges of zero length, or Voronoi faces of zero area. This policy assumes that the Delaunay graph, that is adapted, allows for site insertions through an *insert* method that takes as argument an object of type *AT::Site_2*. The site inserter functor provided by this policy uses the aforementioned *insert* method.

```
#include <CGAL/Identity_policy_2.h>

This package implements Shewchuk’s algorithm [She00] to construct conforming triangulations and 2D meshes. Conforming triangulations will be described in Section 34.1 and meshes in Section 34.2.

34.1 Conforming Triangulations

34.1.1 Definitions

A triangulation is a *Delaunay triangulation* if the circumscribing circle of any facet of the triangulation contains no vertex in its interior. A *constrained Delaunay triangulation* is a constrained triangulation which is as much Delaunay as possible. The circumscribing circle of any facet of a constrained Delaunay triangulation contains in its interior no data point *visible* from the facet.

An edge is said to be a *Delaunay edge* if it is inscribed in an empty circle (containing no data point in its interior). This edge is said to be a *Gabriel edge* if its diametrical circle is empty.

A constrained Delaunay triangulation is said to be a *conforming Delaunay triangulation* if every constrained edge is a Delaunay edge. Because any edge in a constrained Delaunay triangulation is either a Delaunay edge or a constrained edge, a conforming Delaunay triangulation is in fact a Delaunay triangulation. The only difference is that some of the edges are marked as constrained edges.

A constrained Delaunay triangulation is said to be a *conforming Gabriel triangulation* if every constrained edge is a Gabriel edge. The Gabriel property is stronger than the Delaunay property and each Gabriel edge is a Delaunay edge. Conforming Gabriel triangulations are thus also conforming Delaunay triangulations.

Any constrained Delaunay triangulation can be refined into a conforming Delaunay triangulation or into a conforming Gabriel triangulation by adding vertices, called *Steiner vertices*, on constrained edges until they are decomposed into subconstraints small enough to be Delaunay or Gabriel edges.

34.1.2 Building Conforming Triangulations

Constrained Delaunay triangulations can be refined into conforming triangulations by the two following global functions:

```
template<class CDT> void make_conforming_Delaunay_2 (CDT& t) and
template<class CDT> void make_conforming_Gabriel_2 (CDT& t).
```

In both cases, the template parameter *CDT* must be instantiated by a constrained Delaunay triangulation class. Such a class must be a model of the concept *ConstrainedDelaunayTriangulation_2*.

The geometric traits of the constrained Delaunay triangulation used to instantiate the parameter *CDT* has to be a model of the concept *ConformingDelaunayTriangulationTraits_2*.

The constrained Delaunay triangulation *t* is passed by reference and is refined into a conforming Delaunay triangulation or into a conforming Gabriel triangulation by adding vertices. The user is advised to make a copy of the input triangulation in the case where the original triangulation has to be preserved for other computations

The algorithm used by *make_conforming_Delaunay_2* and *make_conforming_Gabriel_2* builds internal data structures that would be computed twice if the two functions are called consecutively on the same triangulation. In order to avoid these data to be constructed twice, the advanced user can use the class *Triangulation_conformer_2<CDT>* to refine a constrained Delaunay triangulation into a conforming Delaunay triangulation and then into a conforming Gabriel triangulation. For additional control of the refinement algorithm, this class also provides separate functions to insert one Steiner point at a time.

34.1.3 Example: Making a Triangulation Conforming Delaunay and Then Conforming Gabriel

This example inserts several segments into a constrained Delaunay triangulation, makes it conforming Delaunay, and then conforming Gabriel. At each step, the number of vertices of the triangulation is printed.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_conformer_2.h>

#include <iostream>

struct K : public CGAL::Exact_predicates_inexact_constructions_kernel {};
typedef CGAL::Constrained_Delaunay_triangulation_2<K> CDT;
```

```

typedef CDT::Point Point;
typedef CDT::Vertex_handle Vertex_handle;

int main()
{
    CDT cdt;

    // construct a constrained triangulation
    Vertex_handle
        va = cdt.insert(Point( 5., 5.)),
        vb = cdt.insert(Point(-5., 5.)),
        vc = cdt.insert(Point( 4., 3.)),
        vd = cdt.insert(Point( 5.,-5.)),
        ve = cdt.insert(Point( 6., 6.)),
        vf = cdt.insert(Point(-6., 6.)),
        vg = cdt.insert(Point(-6.,-6.)),
        vh = cdt.insert(Point( 6.,-6.));

    cdt.insert_constraint(va,vb);
    cdt.insert_constraint(vb,vc);
    cdt.insert_constraint(vc,vd);
    cdt.insert_constraint(vd,va);
    cdt.insert_constraint(ve,vf);
    cdt.insert_constraint(vf,vg);
    cdt.insert_constraint(vg,vh);
    cdt.insert_constraint(vh,ve);

    std::cout << "Number of vertices before: "
                << cdt.number_of_vertices() << std::endl;

    // make it conforming Delaunay
    CGAL::make_conforming_Delaunay_2(cdt);

    std::cout << "Number of vertices after make_conforming_Delaunay_2: "
                << cdt.number_of_vertices() << std::endl;

    // then make it conforming Gabriel
    CGAL::make_conforming_Gabriel_2(cdt);

    std::cout << "Number of vertices after make_conforming_Gabriel_2: "
                << cdt.number_of_vertices() << std::endl;
}

```

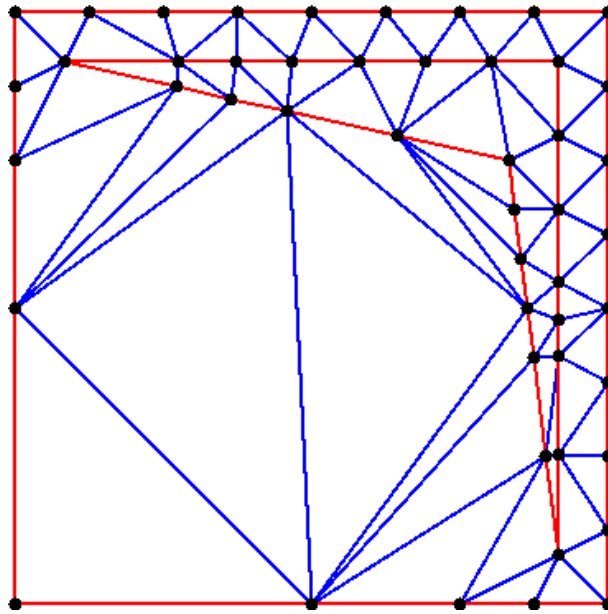

Figure 34.3: The corresponding conforming Gabriel triangulation.

34.2 Meshes

34.2.1 Definitions

A mesh is a partition of a given region into simplices whose shapes and sizes satisfy several criteria.

The domain is the region that the user wants to mesh. It has to be a bounded region of the plane. The domain is defined by a *planar straight line graph*, PSLG for short, which is a set of segments such that two segments in the set are either disjoint or share an endpoint. The segments of the PSLG are constraints that will be represented by a union of edges in the mesh. The PSLG can also contain isolated points that will appear as vertices of the mesh.

The segments of the PSLG are either segments of the boundary or internal constraints. The segments of the PSLG have to cover the boundary of the domain.

The PSLG divides the plane into several connected components. By default, the domain is the union of the bounded connected components. The user can override this default by providing a set of seed points. Either seed points mark components to be meshed or they mark components not to be meshed (holes).

See figures 34.4 and 34.5 for an example of a domain defined without using seed points, and a possible mesh of it. See figure 34.6 for another domain defined with the same PSLG and two seed points used to define holes. In the corresponding mesh (figure 34.7), these two holes are triangulated but not meshed.

34.2.2 Shape and Size Criteria

The shape criterion for triangles is a lower bound B on the ratio between the circumradius and the shortest edge length. Such a bound implies a lower bound of $\arcsin \frac{1}{2B}$ on the minimum angle of the triangle and an upper

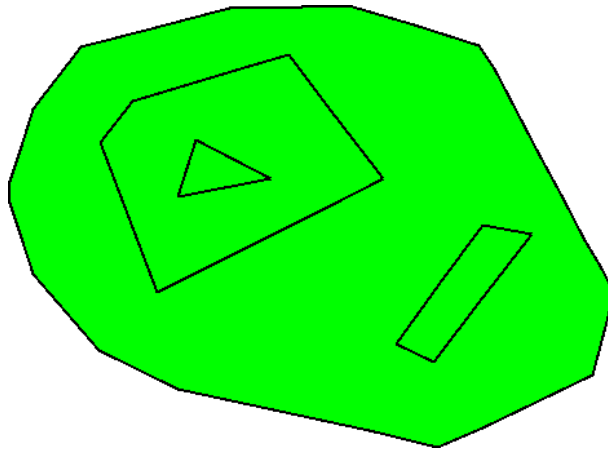

Figure 34.4: A domain defined without seed points.

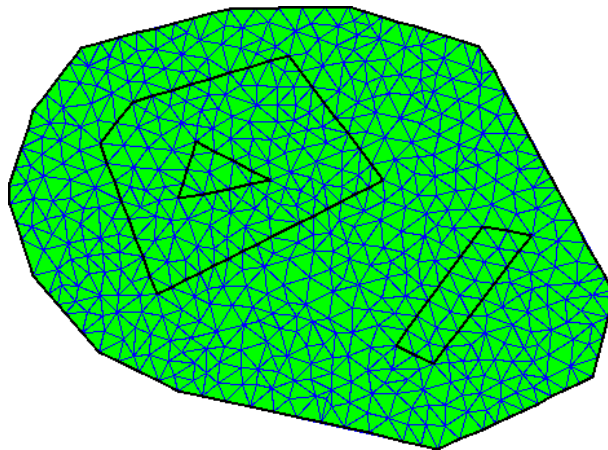

Figure 34.5: A mesh of the domain defined without seed points.

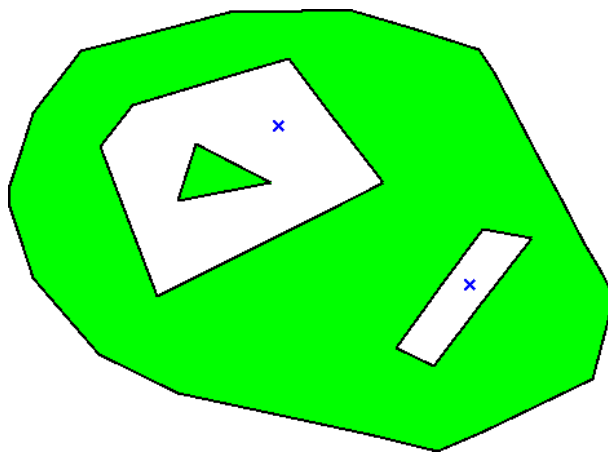

Figure 34.6: A domain with two seeds points defining holes.

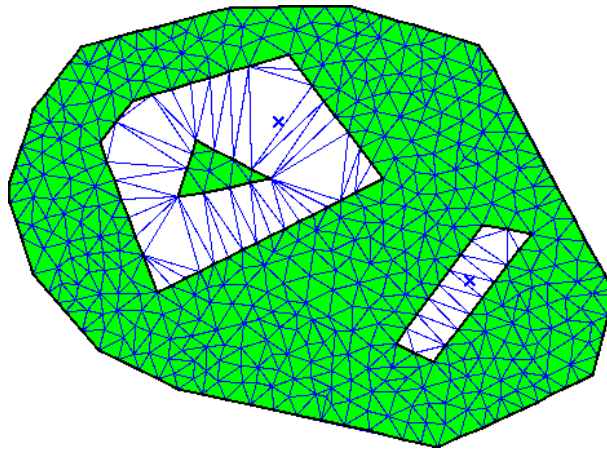

Figure 34.7: A mesh of the domain with two seeds defining holes.

bound of $\pi - 2 * \arcsin \frac{1}{2B}$ on the maximum angle. Unfortunately, the termination of the algorithm is guaranteed only if $B \geq \sqrt{2}$, which corresponds to a lower bound of 20.7 degrees over the angles.

The size criterion can be any criterion that tends to prefer small triangles. For example, the size criterion can be an upper bound on the length of longest edge of triangles, or an upper bound on the radius of the circumcircle. The size bound can vary over the domain. For example, the size criterion could impose a small size for the triangles intersecting a given line.

Both types of criteria are defined in an object *criteria* passed as parameter of the meshing functions.

34.2.3 The Meshing Algorithm

The input to a meshing problem is a PSLG and a set of seeds describing the domain to be meshed, and a set of size and shape criteria. The algorithm implemented in this package starts with a constrained Delaunay triangulation of the input PSLG and produces a mesh using the Delaunay refinement method. This method inserts new vertices to the triangulation, as far as possible from other vertices, and stops when the criteria are satisfied.

If all angles between incident segments of the input PSLG are greater than 60 degrees and if the bound on the circumradius/edge ratio is greater than $\sqrt{2}$, the algorithm is guaranteed to terminate with a mesh satisfying the size and shape criteria.

If some input angles are smaller than 60 degrees, the algorithm will end up with a mesh in which some triangles violate the criteria near small input angles. This is unavoidable since small angles formed by input segments cannot be suppressed. Furthermore, it has been shown ([She00]), that some domains with small input angles cannot be meshed with angles even smaller than the small input angles. Note that if the domain is a polygonal region, the resulting mesh will satisfy size and shape criteria except for the small input angles. In addition, the algorithm may succeed in producing meshes with a lower angle bound greater than 20.7 degrees, but there is no such guarantee.

34.2.4 Building Meshes

Meshes are obtained from constrained Delaunay triangulations by calling the global function `template<class CDT, class Criteria> void refine_Delaunay_mesh_2 (CDT &t, typename CDT::Geom_traits gt)`. The template parameter `CDT` must be instantiated by a constrained Delaunay triangulation class, which is a model of the concept `ConstrainedDelaunayTriangulation_2`. In order to override the domain, a version of this function has two more arguments that define a sequence of seed points.

The geometric traits class of `CDT` has to be a model of the concept `DelaunayMeshTraits_2`. This concept refines the concept `ConformingDelaunayTriangulationTraits_2` adding the geometric predicates and constructors. The template parameter `Criteria` must be a model of `MeshingCriteria_2`. This concept defines criteria that the triangles have to satisfy. CGAL provides two models for this concept:

- `Delaunay_mesh_criteria_2<CDT>`, that defines a shape criterion that bounds the minimum angle of triangles,
- `Delaunay_mesh_size_criteria_2<CDT>`, that adds to the previous criterion a bound on the maximum edge length.

If the function `refine_Delaunay_mesh_2` is called several times on the same triangulation with different criteria, the algorithm rebuilds the internal data structure used for meshing at every call. In order to avoid rebuild the data structure at every call, the advanced user can use the class `Delaunay_mesher_2<CDT>`. This class provides also step by step functions. Those functions insert one vertex at a time.

Any object of type `Delaunay_mesher_2<CDT>` is constructed from a reference to a `CDT`, and has several member functions to define the domain to be meshed and to mesh the `CDT`. See the example given below and the reference manual for details. Note that the `CDT` should not be externally modified during the life time of the `Delaunay_mesher_2<CDT>` object.

34.2.5 Example Using the Global Function

The following example inserts several segments into a constrained triangulation and then meshes it using the global function `refine_Delaunay_mesh_2`. The size and shape criteria are the default ones provided by the criteria class `Delaunay_mesh_criteria_2<K>`. No seeds are given, meaning that the mesh domain covers the whole plane except the unbounded component.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

struct K : public CGAL::Exact_predicates_inexact_constructions_kernel {};
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;
```

```

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
    CDT cdt;

    Vertex_handle va = cdt.insert(Point(-4,0));
    Vertex_handle vb = cdt.insert(Point(0,-1));
    Vertex_handle vc = cdt.insert(Point(4,0));
    Vertex_handle vd = cdt.insert(Point(0,1));
    cdt.insert(Point(2, 0.6));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    std::cout << "Number of vertices: " << cdt.number_of_vertices() << std::endl;

    std::cout << "Meshing the triangulation..." << std::endl;
    CGAL::refine_Delaunay_mesh_2(cdt, Criteria(0.125, 0.5));

    std::cout << "Number of vertices: " << cdt.number_of_vertices() << std::endl;
}

```

File: examples/Mesh_2/mesh_global.cpp

34.2.6 Example Using the Class `Delaunay_mesher_2<CDT>`

This example uses the class `Delaunay_mesher_2<CDT>` and calls the `refine_mesh()` member function twice, changing the size and shape criteria in between. In such a case, using twice the global function `refine_Delaunay_mesh_2` would be less efficient, because some internal structures needed by the algorithm would be built twice.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

struct K : public CGAL::Exact_predicates_inexact_constructions_kernel {};
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;
typedef CGAL::Delaunay_mesher_2<CDT, Criteria> Mesher;

typedef CDT::Vertex_handle Vertex_handle;

```

```

typedef CDT::Point Point;

int main()
{
    CDT cdt;

    Vertex_handle va = cdt.insert(Point(-4,0));
    Vertex_handle vb = cdt.insert(Point(0,-1));
    Vertex_handle vc = cdt.insert(Point(4,0));
    Vertex_handle vd = cdt.insert(Point(0,1));
    cdt.insert(Point(2, 0.6));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    std::cout << "Number of vertices: " << cdt.number_of_vertices() << std::endl;

    std::cout << "Meshing the triangulation with default criterias..."
                << std::endl;

    Mesher mesher(cdt);
    mesher.refine_mesh();

    std::cout << "Number of vertices: " << cdt.number_of_vertices() << std::endl;

    std::cout << "Meshing with new criterias..." << std::endl;
    // 0.125 is the default shape bound. It corresponds to about 20.6 degree.
    // 0.5 is the upper bound on the length of the longest edge.
    // See reference manual for Delaunay_mesh_size_traits_2<K>.
    mesher.set_criteria(Criteria(0.125, 0.5));
    mesher.refine_mesh();

    std::cout << "Number of vertices: " << cdt.number_of_vertices() << std::endl;
}

```

File: examples/Mesh_2/mesh_class.cpp

34.2.7 Example Using Seeds

This example uses the global function *refine_Delaunay_mesh_2* but defines a domain by using one seed. The size and shape criteria are the default ones provided by the criteria class *Delaunay_mesh_criteria_2<K>*.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Constrained_Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_mesher_2.h>
#include <CGAL/Delaunay_mesh_face_base_2.h>
#include <CGAL/Delaunay_mesh_size_criteria_2.h>

#include <iostream>

```

```

struct K : public CGAL::Exact_predicates_inexact_constructions_kernel {};
typedef CGAL::Triangulation_vertex_base_2<K> Vb;
typedef CGAL::Delaunay_mesh_face_base_2<K> Fb;
typedef CGAL::Triangulation_data_structure_2<Vb, Fb> Tds;
typedef CGAL::Constrained_Delaunay_triangulation_2<K, Tds> CDT;
typedef CGAL::Delaunay_mesh_size_criteria_2<CDT> Criteria;

typedef CDT::Vertex_handle Vertex_handle;
typedef CDT::Point Point;

int main()
{
    CDT cdt;
    Vertex_handle va = cdt.insert(Point(2,0));
    Vertex_handle vb = cdt.insert(Point(0,2));
    Vertex_handle vc = cdt.insert(Point(-2,0));
    Vertex_handle vd = cdt.insert(Point(0,-2));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    va = cdt.insert(Point(3,3));
    vb = cdt.insert(Point(-3,3));
    vc = cdt.insert(Point(-3,-3));
    vd = cdt.insert(Point(3,0-3));

    cdt.insert_constraint(va, vb);
    cdt.insert_constraint(vb, vc);
    cdt.insert_constraint(vc, vd);
    cdt.insert_constraint(vd, va);

    std::list<Point> list_of_seeds;

    list_of_seeds.push_back(Point(0, 0));

    std::cout << "Number of vertices: " << cdt.number_of_vertices() << std::endl;

    std::cout << "Meshing the domain..." << std::endl;
    CGAL::refine_Delaunay_mesh_2(cdt, list_of_seeds.begin(), list_of_seeds.end(),
                                Criteria());

    std::cout << "Number of vertices: " << cdt.number_of_vertices() << std::endl;
}

```

ConformingDelaunayTriangulationTraits_2

Definition

The concept `ConformingDelaunayTriangulationTraits_2` refines the concept `ConstrainedDelaunayTriangulationTraits_2` by providing a numeric field type *FT*, a type *Vector_2* and several constructors on *Vector_2*, *Point_2*, and a predicate on angles. The field type has to be a model of the concept *SqrtFieldType*. This field type and the constructors are used by the conforming algorithm to compute Steiner points on constrained edges.

Refines

DelaunayTriangulationTraits_2

Types

ConformingDelaunayTriangulationTraits_2:: FT

The field type. It must be a model of *SqrtFieldType*, that is must be a number type supporting the operations $+$, $-$, $*$, $/$, and $\sqrt{\cdot}$.

ConformingDelaunayTriangulationTraits_2:: Vector_2

The vector type.

ConformingDelaunayTriangulationTraits_2:: Construct_vector_2

Constructor object. Must provide the operator *Vector_2 operator()(Point a, Point b)* that computes the vector $b - a$.

ConformingDelaunayTriangulationTraits_2:: Construct_scaled_vector_2

Constructor object. Must provide the operator *Vector_2 operator()(Vector_2 v, FT scale)* that computes the vector $scale \cdot \mathbf{v}$.

ConformingDelaunayTriangulationTraits_2:: Construct_translated_point_2

Constructor object. Must provide the operator *Point_2 operator()(Point_2 p, Vector_2 v)* that computes the point $p + \mathbf{v}$.

ConformingDelaunayTriangulationTraits_2:: Construct_midpoint_2

Constructor object. Must provide the operator *Point_2 operator()(Point_2 a, Point_2 b)* that computes the midpoint of the segment ab .

ConformingDelaunayTriangulationTraits_2:: Compute_squared_distance_2

Constructor object. Must provide the operator *FT operator()(Point_2 a, Point_2 b)* that computes the squared distance between *a* and *b*.

ConformingDelaunayTriangulationTraits_2:: Angle_2

Predicate object. Must provide the operator *CGAL::Angle operator()(Point_2 p, Point_2 q, Point_2 r)* that returns OB-TUSE, RIGHT or ACUTE depending on the angle formed by the three points *p*, *q*, *r* (*q* being the vertex of the angle).

Access to predicate and constructor objects

<i>Construct_vector_2</i>	<i>traits.construct_vector_2_object()</i>
<i>Construct_scaled_vector_2</i>	<i>traits.construct_scaled_vector_2_object()</i>
<i>Construct_translated_point_2</i>	<i>traits.construct_translated_point_2_object()</i>
<i>Constructor_midpoint_2</i>	<i>traits.construct_midpoint_2_object()</i>
<i>Compute_squared_distance_2</i>	<i>traits.compute_squared_distance_2_object()</i>
<i>Angle_2</i>	<i>traits.angle_2_object()</i>

Has Models

Any model of *Kernel* concept. In particular, all CGAL kernels.

DelaunayMeshTraits_2

Definition

The concept `DelaunayMeshTraits_2` refines the concept `ConformingDelaunayTriangulationTraits_2`. It provides a construction object `Construct_circumcenter_2`.

Refines

`ConformingDelaunayTriangulationTraits_2`

Types

`DelaunayMeshTraits_2::Construct_circumcenter_2`

Constructor object. Must provide an operator `Point_2 operator()(Point_2 p, Point_2 q, Point_2 r)`; that computes the center of the circle passing through the points p , q and r .
Precondition: p , q and r are not collinear.

Access to predicate and constructor objects

`Construct_circumcenter_2` `traits.construct_circumcenter_2_object()`

Has Models

Any model of the *Kernel* concept. In particular, all CGAL kernels.

CGAL::Delaunay_mesher_2<CDT, Criteria>

This class implements a 2D mesh generator.

Parameters

The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*, and type *CDT::Face* should be a model of the concept *MeshFaceBase_2*.

The geometric traits class of the instance of *CDT* has to be a model of the concept *DelaunayMeshTraits_2*.

The template parameter *Criteria* should be a model of the concept *MeshingCriteria_2*. This traits class defines the shape and size criteria for the triangles of the mesh. *Criteria::Face_handle* has to be the same as *CDT::Face_handle*.

Using this class

The constructor of the class *Delaunay_mesher_2<CDT, Criteria>* takes a reference to a *CDT* as an argument. A call to the refinement method *refine_mesh()* will refine the constrained Delaunay triangulation into a mesh satisfying the size and shape criteria specified in the traits class. Note that if, during the life time of the *Delaunay_mesher_2<CDT, Criteria>* object, the triangulation is externally modified, any further call to its member methods may crash. Consider constructing a new *Delaunay_mesher_2<CDT, Criteria>* object if the triangulation has been modified.

Meshing domain

The domain to be mesh is defined by the constrained edges and a set of seed points. The constrained edges divides the plane into several connected components. The mesh domain is either the union of the bounded connected components including at least one seed, or the union of the bounded connected components that do not contain any seed. Note that the unbounded component of the plane is never meshed.

```
#include <CGAL/Delaunay_mesher_2.h>
```

Types

```
typedef CDT::Geom_traits
```

Geom_traits; the geometric traits class.

```
Delaunay_mesher_2<CDT, Criteria>:: Seeds_iterator
```

const iterator over defined seeds. Its value type is *Geom_traits::Point_2*.

Creation

```
Delaunay_mesher_2<CDT, Criteria> mesher( CDT& t, Criteria criteria = Criteria());
```

Create a new mesher, working on *t*, with meshing criteria *criteria*.

Seeds functions

The following functions are used to define seeds.

<i>void</i>	<i>mesher.clear_seeds()</i>	Sets seeds to the empty set. All finite connected components of the constrained triangulation will be refined.
-------------	-----------------------------	--

<i>template<class InputIterator></i>		
<i>void</i>	<i>mesher.set_seeds(InputIterator begin, InputIterator end, const bool mark=false)</i>	Sets seeds to the sequence <i>[begin, end]</i> . If <i>mark=true</i> , the mesh domain is the union of the bounded connected components including at least one seed. If <i>mark=false</i> , the domain is the union of the bounded components including no seed. Note that the unbounded component of the plane is never meshed. <i>Requirement:</i> The <i>value_type</i> of <i>begin</i> and <i>end</i> is <i>Geom_traits::Point_2</i> .

<i>Seeds_const_iterator</i>	<i>mesher.seeds_begin()</i>	Start of the seeds sequence.
<i>Seeds_const_iterator</i>	<i>mesher.seeds_end()</i>	Past the end of the seeds sequence.

Meshing methods

<i>void</i>	<i>mesher.refine_mesh()</i>	Refines the constrained Delaunay triangulation into a mesh satisfying the criteria defined by the traits.
-------------	-----------------------------	---

<i>Criteria</i>	<i>mesher.get_criteria()</i>	Returns a const reference to the criteria traits object.
-----------------	------------------------------	--

<i>void</i>	<i>mesher.set_criteria(Criteria criteria)</i>	
		Assigns <i>criteria</i> to the criteria traits object.

— *advanced* —

The function *set_criteria* scans all faces to recalculate the list of *bad faces*, that are faces not conforming to the meshing criteria. This function actually has an optional argument that permits to prevent this recalculation. The filling of the list of bad faces can then be done by a call to *set_bad_faces*.

<i>void</i>	<i>mesher.set_criteria(Criteria criteria, bool recalculate_bad_faces)</i>	
		Assigns <i>criteria</i> to the criteria traits object. If <i>recalculate_bad_faces</i> is <i>false</i> , the list of bad faces is let empty and the function <i>set_bad_faces</i> should be called before <i>refine_mesh</i> .

template <class InputIterator>

void *mesher.set_bad_faces(InputIterator begin, InputIterator end)*

This method permits to set the list of bad triangles directly, from the sequence [begin, end], so that the algorithm will not scan the whole set of triangles to find bad ones. To use if there is a non-naive way to find bad triangles.

Requirement: The *value_type* of *begin* and *end* is *Face_handle*.

_____ *advanced* _____

_____ *advanced* _____

Step by step operations

The *Delaunay_mesher_2*<*CDT*, *Criteria*> class allows, for debugging or demos, to play the meshing algorithm step by step, using the following methods.

void *mesher.init()*

This method must be called just before the first call to the following step by step refinement method, that is when all vertices and constrained edges have been inserted into the constrained Delaunay triangulation. It must be called again before any subsequent calls to the step by step refinement method if new vertices or constrained edges have been inserted since the last call.

bool *mesher.is_refinement_done()*

Tests if the step by step refinement algorithm is done. If it returns *true*, the following calls to *step_by_step_refine_mesh* will not insert any points, until some new constrained segments or points are inserted in the triangulation and *init* is called again.

bool *mesher.step_by_step_refine_mesh()*

Applies one step of the algorithm, by inserting one point, if the algorithm is not done. Returns *false* iff no point has been inserted because the algorithm is done.

_____ *advanced* _____

CGAL::Delaunay_mesh_criteria_2<CDT>

Definition

The class *Delaunay_mesh_criteria_2<CDT>* is a model for the *MeshingCriteria_2* concept. The shape criterion on triangles is given by a bound B such that for good triangles $\frac{r}{l} \leq B$ where l is the shortest edge length and r is the circumradius of the triangle. By default, $B = \sqrt{2}$, which is the best bound one can use with the guarantee that the refinement algorithm will terminate. The upper bound B is related to a lower bound α_{min} on the minimum angle in the triangle:

$$\sin \alpha_{min} = \frac{1}{2B}$$

so $B = \sqrt{2}$ corresponds to $\alpha_{min} \geq 20.7$ degrees.

```
#include <CGAL/Delaunay_mesh_criteria_2.h>
```

Is Model for the Concepts

MeshingCriteria_2

Creation

Delaunay_mesh_criteria_2<CDT> traits; Default constructor. $B = \sqrt{2}$.

Delaunay_mesh_criteria_2<CDT> traits(double $b = 0.125$);

Construct a traits class with bound $B = \sqrt{\frac{1}{4b}}$.

CGAL::Delaunay_mesh_face_base_2<Traits, Fb>

Definition

The class *Delaunay_mesh_face_base_2<Traits, Fb>* is a model for the concept *DelaunayMeshFaceBase_2*.

This class can be used directly or it can serve as a base to derive other classes with some additional attributes (a color for example) tuned to a specific application.

```
#include <CGAL/Delaunay_mesh_face_base_2.h>
```

Parameters

- The first parameter *Traits* is the geometric traits class. It must be the same as the one used for the Delaunay mesh.
- The second parameter *Fb* is the base class from which *Delaunay_mesh_face_base_2<Traits, Fb>* derives. It must be a model of the *TriangulationFaceBase_2* concept.

DelaunayMeshFaceBase_2

CGAL::Delaunay_mesh_size_criteria_2<CDT>

Definition

The class *Delaunay_mesh_size_criteria_2<CDT>* is a model for the *MeshingCriteria_2* concept. The shape criterion on triangles is given by a bound B such that for good triangles $\frac{l}{r} \leq B$ where l is the shortest edge length and r is the circumradius of the triangle. By default, $B = \sqrt{2}$, which is the best bound one can use with the guarantee that the refinement algorithm will terminate. The upper bound B is related to a lower bound α_{min} on the minimum angle in the triangle:

$$\sin \alpha_{min} = \frac{1}{2B}$$

so $B = \sqrt{2}$ corresponds to $\alpha_{min} \geq 20.7$ degrees.

This traits class defines also a size criteria: all segments of all triangles must be shorter than a bound S .

```
#include <CGAL/Delaunay_mesh_size_criteria_2.h>
```

Is Model for the Concepts

MeshingCriteria_2

Creation

Delaunay_mesh_size_criteria_2<CDT> traits; Default constructor. $B = \sqrt{2}$. No bound on size

Delaunay_mesh_size_criteria_2<CDT> traits(double $b = 0.125$, double $S = 0$);

Construct a traits class with bound $B = \sqrt{\frac{1}{4b}}$. If $S \neq 0$, the size bound is S . If $S = 0$, there is no bound on size.

CGAL::Mesh_2::Face_badness

```
#include <CGAL/Mesh_2/Face_badness.h>
```

```
enum Mesh_2::Face_badness { NOT_BAD, BAD, IMPERATIVELY_BAD};
```

CGAL::make_conforming_Delaunay_2

```
#include <CGAL/Triangulation_conformer_2.h>
```

```
template<class CDT>  
void make_conforming_Delaunay_2( CDT &t)
```

Refines the constrained Delaunay triangulation t into a conforming Delaunay triangulation. After a call to this function, all edges of t are Delaunay edges.

Requirement: The template parameter CDT should be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of into the constrained Delaunay triangulation must be a model of *ConformingDelaunayTriangulationTraits_2*.

CGAL::make_conforming_Gabriel_2

```
#include <CGAL/Triangulation_conformer_2.h>
```

```
template<class CDT>  
void make_conforming_Gabriel_2( CDT &t)
```

Refines the constrained Delaunay triangulation t into a conforming Gabriel triangulation. After a call to this function, all constrained edges of t have the *Gabriel property*: the circle that has e as diameter does not contain any vertex from the triangulation.

Requirement: The template parameter CDT should be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of the constrained Delaunay triangulation must be a model of *ConformingDelaunayTriangulationTraits_2*.

MeshingCriteria_2

Definition

The concept `MeshingCriteria_2` defines the meshing criteria to be used in the algorithm. It provides a predicate *Is_bad* that tests a triangle according to criteria. The return type of *Is_bad* is an enum *Mesh_2::Face_badness*.

The possible values of *Mesh_2::Face_badness* are *NOT_BAD*, *BAD* and *IMPERATIVELY_BAD*. If the predicate returns *BAD*, the triangle is marked as bad and the algorithm will try to destroy it. If the predicate returns *IMPERATIVELY_BAD*, the algorithm will destroy the triangle unconditionally during its execution.

The termination of the algorithm is guaranteed when criteria are shape criteria corresponding to a bound on smallest angles not less than 20.7 degrees (this corresponds to a radius-edge ratio bound not less than $\sqrt{2}$). Any size criteria that are satisfied by small enough tetrahedra can be added to the set of criteria without compromising the termination.

Note that, in the presence of input angles smaller than 60 degrees, some bad shaped triangles can appear in the finale mesh in the neighboring of small angles. To achieve termination and the respect of size criteria everywhere, the *Is_bad* predicate has to return *IMPERATIVELY_BAD* when size criteria are not satisfied, and *BAD* when shape criteria are not satisfied.

`MeshingCriteria_2` also provides a type *Quality* designed to code a quality measure for triangles. The type *Quality* must be *less-than comparable* as the meshing algorithm will order bad triangles by quality, to split those with smallest quality first. The predicate *Is_bad* computes the quality of the triangle as a by-product.

Types

<i>MeshingCriteria_2:: Face_handle</i>	Handle to a face of the triangulation.
<i>MeshingCriteria_2:: Quality</i>	Default constructible, copy constructible, assignable, and less-than comparable type.
<i>MeshingCriteria_2:: Is_bad</i>	Predicate object. Must provide two operators. The first operator <i>Mesh_2::Face_badness operator()(Face_handle fh, Quality& q)</i> returns <i>NOT_BAD</i> if it satisfies the desired criteria for mesh triangles, <i>BAD</i> if it does not, and <i>IMPERATIVELY_BAD</i> if it does not and should be refined unconditionally. In addition, this operator assigns to <i>q</i> a value measuring the quality of the triangle pointed by <i>fh</i> . The second operator <i>Mesh_2::Face_badness operator()(Quality q)</i> returns <i>NOT_BAD</i> if <i>q</i> is the quality of a good triangle, <i>BAD</i> if the <i>q</i> represents a poor quality, and <i>IMPERATIVELY_BAD</i> if <i>q</i> represents the quality of a bad triangle that should be refined unconditionally.

Access to predicate and constructor objects

Is_bad *traits.is_bad_object()*

Has Models

Delaunay_mesh_criteria_2<CDT>

Delaunay_mesh_size_criteria_2<CDT>

CGAL::refine_Delaunay_mesh_2

```
template<class CDT, class Criteria>
void refine_Delaunay_mesh_2( CDT &t, Criteria criteria = Criteria())
```

Refines the default domain defined by a constrained Delaunay triangulation without seeds into a mesh satisfying the criteria defined by the traits *criteria*. The domain of the mesh covers all the connected components of the plane defined by the constrained edges of *t*, except for the unbounded component.

Precondition: The template parameter *CDT* must be a model of the concept *ConstrainedDelaunayTriangulation_2*. The geometric traits class of the constrained Delaunay triangulation must be a model of *DelaunayMeshTraits_2*.

Requirement: The face of the constrained Delaunay triangulation must be a model of the concept *DelaunayMeshFaceBase_2*. *Criteria* must be a model of the concept *MeshingCriteria_2* and *CDT::Face_handle* must be the same as *Criteria::Face_handle*.

```
template <class CDT, class Criteria, class InputIterator>
void refine_Delaunay_mesh_2( CDT& t,
                             InputIterator begin,
                             InputIterator end,
                             Criteria criteria = Criteria(),
                             bool mark = false)
```

Refines the default domain defined by a constrained Delaunay triangulation into a mesh satisfying the criteria defined by the traits *criteria*. The sequence [*begin*, *end*] gives a set of seeds points, that defines the domain to be meshed as follows. The constrained edges of *t* partition the plane into connected components. If *mark=true*, the mesh domain is the union of the bounded connected components including at least one seed. If *mark=false*, the domain is the union of the bounded components including no seed. Note that the unbounded component of the plane is never meshed.

Requirement: The *value_type* of *begin* and *end* is *CDT::Geom_traits::Point_2*.

CGAL::Triangulation_conformer_2<CDT>

The class *Triangulation_conformer_2<CDT>* is an auxiliary class of *Delaunay_mesher_2<CDT>*. It permits to refine a constrained Delaunay triangulation into a conforming Delaunay or conforming Gabriel triangulation. For standard needs, consider using the global functions *make_conforming_Gabriel_2* and *make_conforming_Delaunay_2*.

Parameters

The template parameter *CDT* should be a model of the concept *ConstrainedDelaunayTriangulation_2*.

The geometric traits class of the instance of *CDT* has to be a model of the concept *ConformingDelaunayTriangulationTraits_2*.

Using this class

The constructor of the class *Triangulation_conformer_2<CDT>* takes a reference to a *CDT* as an argument. A call to the method *make_conforming_Delaunay()* or *make_conforming_Gabriel()* will refine this constrained Delaunay triangulation into a conforming Delaunay or conforming Gabriel triangulation. Note that if, during the life time of the *Triangulation_conformer_2<CDT>* object, the triangulation is externally modified, any further call to its member methods may lead to undefined behavior. Consider reconstructing a new *Triangulation_conformer_2<CDT>* object if the triangulation has been modified.

The conforming methods insert points into constrained edges, thereby splitting them into several sub-constraints. You have access to the initial inserted constraints if you instantiate the template parameter by a *CGAL::Constrained_triangulation_plus_2<CDT>*.

```
#include <CGAL/Triangulation_conformer_2.h>
```

Creation

```
Triangulation_conformer_2<CDT> m( CDT& t);
```

Create a new conforming maker, working on *t*.

Operations

Conforming methods

```
void m.make_conforming_Delaunay()
```

Refines the triangulation into a conforming Delaunay triangulation. After a call to this method, all triangles fulfill the Delaunay property, that is the empty circle property.

void *m.make_conforming_Gabriel()*

Refines the triangulation into a conforming Gabriel triangulation. After a call to this method, all constrained edges *e* have the *Gabriel property*: the circle with diameter *e* does not contain any vertex of the triangulation.

Checking

The following methods verify that the constrained triangulation is conforming Delaunay or conforming Gabriel. These methods scan the whole triangulation and their complexity is proportional to the number of edges.

bool *m.is_conforming_Delaunay()*

Returns *true* iff all triangles fulfill the Delaunay property.

bool *m.is_conforming_Gabriel()*

Returns *true* iff all constrained edges have the Gabriel property: their circumsphere is empty.

— *advanced* —

Step by step operations

The *Triangulation_conformer_2<CDT>* class allows, for debugging or demos, to play the conforming algorithm step by step, using the following methods. They exist in two versions, depending on whether you want the triangulation to be conforming Delaunay or conforming Gabriel, respectively. Any call to a *step_by_step_conforming_XX* function requires a previous call to the corresponding function *init_XX* and Gabriel and Delaunay methods can not be mixed between two calls of *init_XX*.

void *m.init_Delaunay()*

The method must be called after all points and constrained segments are inserted and before any call to the following methods. If some points or segments are then inserted in the triangulation, this method must be called again.

bool *m.step_by_step_conforming_Delaunay()*

Applies one step of the algorithm, by inserting one point, if the algorithm is not done. Returns *false* iff no point has been inserted because the algorithm is done.

void *m.init_Gabriel()*

Analog to *init_Delaunay* for Gabriel conforming.

bool *m.step_by_step_conforming_Gabriel()*

Analog to *step_by_step_conforming_Delaunay()* for Gabriel conforming.

bool

m.is_conforming_done()

Tests if the step by step conforming algorithm is done. If it returns *true*, the following calls to *step_by_step_conforming_XX* will not insert any points, until some new constrained segments or points are inserted in the triangulation and *init_XX* is called again.

35.1 Introduction

This package provides a function template to compute a triangular mesh approximating a surface.

The meshing algorithm requires to know the surface to be meshed only through an oracle able to tell whether a given segment, line or ray intersects the surface or not and to compute an intersection point if any. This feature makes the package generic enough to be applied in a wide variety of situations. For instance, it can be used to mesh implicit surfaces described as the zero level set of some function. It may also be used in the field of medical imaging to mesh surfaces described as a gray level set in a three dimensional image.

The meshing algorithm is based on the notion of the restricted Delaunay triangulation. Basically the algorithm computes a set of sample points on the surface, and extract an interpolating surface mesh from the three dimensional triangulation of these sample points. Points are iteratively added to the sample, as in a Delaunay refinement process, until some size and shape criteria on mesh elements are satisfied.

The size and shape criteria guide the behavior of the refinement process and control its termination. They also condition the size and shape of the elements in the final mesh. Naturally, those criteria can be customized to satisfy the user needs. The *Surface mesh generation* package offers a set of standard criteria that can be scaled through three numerical values. Also the user can also plug in its own set of refinement criteria.

There is no restriction on the topology and number of components of the surface provided that the oracle (or the user) is able to provide one initial sample point on each connected component. If the surface is smooth enough, and if the size criteria are small enough, the algorithm guarantees that the output mesh is homeomorphic to the surface, and is within a small bounded distance (Hausdorff or even Frechet distance) from the surface. The algorithm can also be used for non smooth surfaces but then there is no guarantee.

35.2 The Surface Mesh Generator Interface

The meshing process is launched through a call to a function template. There are two overloaded versions of the meshing function whose signatures are the following:

```
template <class SurfaceMeshC2T3, class Surface, class Criteria, class Tag >
void      make_surface_mesh( SurfaceMeshC2T3& c2t3,
                           Surface surface,
                           Criteria criteria,
                           Tag)
```

```
template <class SurfaceMeshC2T3, class SurfaceMeshTraits, class Criteria, class Tag >
void      make_surface_mesh( SurfaceMeshC2T3& c2t3,
                           SurfaceMeshTraits::Surface_3 surface,
                           SurfaceMeshTraits traits,
                           Criteria criteria,
                           Tag)
```

The template parameter *SurfaceMeshC2T3* stands for a data structure type that is used to store the surface mesh. This type is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*. Such a data structure has a pointer to a three dimensional triangulation and encodes the surface mesh as a subset of facets in this triangulation. An argument of type *SurfaceMeshC2T3* is passed by reference to the meshing function. This argument holds the output mesh at the end of the process.

The template parameter *Surface* stands for the surface type. This type has to be a model of the concept *Surface_3*.

The knowledge on the surface, required by the surface mesh generator is encapsulated in a traits class. Actually, the mesh generator accesses the surface to be meshed through this traits class only. The traits class is required to be a model of the concept *SurfaceMeshTraits_3*. The difference between the two overloaded versions of *make_surface_mesh* can be explained as follows

- In the first overloaded version of *make_surface_mesh*, the surface type is given as template parameter (*Surface*) and the *surface* to be meshed is passed as parameter to the mesh generator. In that case the surface mesh generator traits type is automatically generated from the surface type by an auxiliary class called the *Surface_mesh_traits_generator_3*.
- In the second overloaded version of *make_surface_mesh*, the surface mesh generator traits type is provided by the template parameter *SurfaceMeshTraits_3* and the surface type is obtained from this traits type. Both a surface and a traits are passed to the mesh generator as arguments.

The first overloaded version can be used whenever the surface type either provides a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3* or is a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3<Surface>* is provided. Currently, the library provides partial specializations of *Surface_mesher_traits_generator_3<Surface>* for implicit surfaces (*Implicit_surface_3<Traits, Function>*) and gray level images (*Gray_level_image_3<FT, Point>*).

The parameter *criteria* handles the description of the size and shape criteria driving the meshing process. The template parameter *Criteria* has to be instantiated by a model of the concept *MeshCriteria*.

The parameter *Tag* is a tag whose type influences the behavior of the meshing algorithm. For instance, this parameter can be used to enforce the manifold property of the output mesh while avoiding an over-refinement of the mesh. Further details on this subject are given in Section 35.4.

A call to *make_surface_mesh(c2t3, surface, criteria, tag)* launches the meshing process with an initial set of points which is the union of two subsets: the set of vertices in the initial triangulation pointed to by *c2t3*, and a set of points provided by the *Compute_initial_points()* functor of the traits class. This initial set of points is required to include at least one point on each connected component of the surface to be meshed.

35.3 Examples

35.3.1 Meshing an Implicit Surface

The first code example meshes a sphere given as the zero level set of a function $\mathbb{R}^3 \longrightarrow \mathbb{R}$. More precisely, the surface to be meshed is created by the constructor of the class *Implicit_surface_3<Kernel, Function>* from a pointer to the function (*sphere_function*) and a bounding sphere.

The default meshing criteria are determined by three numerical values:

- *angular_bound* is a lower bound in degrees for the angles of mesh facets.
- *radius_bound* is an upper bound on the radii of surface Delaunay balls. A surface Delaunay ball is a ball circumscribing a mesh facet and centered on the surface.
- *distance_bound* is an upper bound for the distance between the circumcenter of a mesh facet and the center of a surface Delaunay ball of this facet.

Given this surface type, the surface mesh generator will use an automatically generated traits class.

The resulting mesh is shown in Figure 35.1.

Figure 35.1: Surface mesh of a sphere

```
#include <CGAL/Surface_mesh_default_triangulation_3.h>
#include <CGAL/Complex_2_in_triangulation_3.h>
#include <CGAL/make_surface_mesh.h>
#include <CGAL/Implicit_surface_3.h>

// default triangulation for Surface_mesher
typedef CGAL::Surface_mesh_default_triangulation_3 Tr;

// c2t3

    const FT x2=p.x()*p.x(), y2=p.y()*p.y(), z2=p.z()*p.z();
```

```

    return x2+y2+z2-1;
}

int main() {
    Tr tr;                // 3D-Delaunay triangulation
    C2t3 c2t3 (tr);       // 2D-complex in 3D-Delaunay triangulation

    // defining the surface
    Surface_3 surface(sphere_function,           // pointer to function
                     Sphere_3(CGAL::ORIGIN, 2.)); // bounding sphere

    // defining meshing criteria
    CGAL::Surface_mesh_default_criteria_3<Tr> criteria(30., // angular bound
                                                       0.1, // radius bound
                                                       0.1); // distance bound

    // meshing surface
    CGAL::make_surface_mesh(c2t3, surface, criteria, CGAL::Non_manifold_tag());

    std::cout << "Final number of points: " << tr.number_of_vertices() << "\n";
}

```

File: examples/Surface_mesher/mesh_an_implicit_function.cpp

35.3.2 Meshing a Surface Defined as a Gray Level in a 3D Image

In this example the surface to be meshed is defined as the locus of points with a given gray level in a 3D image. The code is quite similar to the previous example.

The main difference with the previous code is that the function used to define the surface is an object of type *CGAL::Gray_level_image_3* created from an image file and a numerical value that is the gray value of the level one wishes to mesh.

Note that surface, which is still an object of type *Implicit_surface_3* is now, defined by three parameters that are the function, the bounding sphere and a numerical value called *the precision*. This precision, whose value is relative to the bounding sphere radius, is used in the intersection computation. This parameter has a default which was used in the previous example. Also note that the center of the bounding sphere is required to be internal a point where the function has a negative value.

The chosen iso-value of this 3D image corresponds to a head skull. The resulting mesh is the introducing picture of this chapter.

```

#include <CGAL/Surface_mesh_default_triangulation_3.h>
#include <CGAL/Complex_2_in_triangulation_3.h>
#include <CGAL/make_surface_mesh.h>
#include <CGAL/Gray_level_image_3.h>
#include <CGAL/Implicit_surface_3.h>

// default triangulation for Surface_mesher
typedef CGAL::Surface_mesh_default_triangulation_3 Tr;

// c2t3
typedef CGAL::Complex_2_in_triangulation_3<Tr> C2t3;

```

```

typedef Tr::Geom_traits GT;
typedef CGAL::Gray_level_image_3<GT::FT, GT::Point_3> Gray_level_image;
typedef CGAL::Implicit_surface_3<GT, Gray_level_image> Surface_3;

int main() {
    Tr tr;                // 3D-Delaunay triangulation
    C2t3 c2t3 (tr);       // 2D-complex in 3D-Delaunay triangulation

    // the 'function' is a 3D gray level image
    Gray_level_image image("data/skull_2.9.inr", 2.9);

    // Carefully choosen bounding sphere: the center must be inside the
    // surface defined by 'image' and the radius must be high enough so that
    // the sphere actually bounds the whole image.
    GT::Point_3 bounding_sphere_center(122., 102., 117.);
    GT::FT bounding_sphere_squared_radius = 200.*200.*2.;
    GT::Sphere_3 bounding_sphere(bounding_sphere_center,
                                bounding_sphere_squared_radius);

    // definition of the surface, with 10^-2 as relative precision
    Surface_3 surface(image, bounding_sphere, 1e-2);

    // defining meshing criteria
    CGAL::Surface_mesh_default_criteria_3<Tr> criteria(30.,
                                                       5.,
                                                       5.);

    // meshing surface, with the "manifold without boundary" algorithm
    CGAL::make_surface_mesh(c2t3, surface, criteria, CGAL::Manifold_tag());

    std::cout << "Final number of points: " << tr.number_of_vertices() << "\n";
}

```

File: examples/Surface_mesher/mesh_a_3d_gray_image.cpp

35.4 Meshing Criteria, Guarantees and Variations

The guarantees on the output mesh depend on the mesh criteria. Theoretical guarantees are given in [B005]. First, the meshing algorithm is proved to terminate if the angular bound is not smaller than 30 degrees. Furthermore, the output mesh is guaranteed to be homeomorphic to the surface, and there is a guaranteed bound on the distance (Hausdorff and even Frechet distance) between the mesh and the surface if the radius bound is everywhere smaller than the ϵ times the local feature size. Here ϵ is a constant that has to be less than 0.16, and the local feature size $lfs(x)$ is defined on each point x of the surface as the distance from x to the medial axis. Note that the radius bound need not be uniform, although it is a uniform bound in the default criteria.

Naturally, such a theoretical guarantee can be only achieved for smooth surfaces that have a finite, non zero reach value. (The reach of a surface is the minimum value of local feature size on this surface).

The value of the local feature size on any point of the surface or its minimum on the surface it usually unknown although it can sometimes be guessed. Also it happens frequently that setting the meshing criteria so as to fulfill the theoretical conditions yields an over refined mesh. On the other hand, when the size criteria are relaxed,

no homeomorphism with the input surface is guaranteed, and the output mesh is not even guaranteed to be manifold. To remedy this problem and give a more flexible meshing algorithm, the function template *make_surface_mesh* has a tag template parameter allowing to slightly change the behavior of the refinement process. This feature allows, for instance, to run the meshing algorithm with a relaxed size criteria, more coherent with the size of the mesh expected by the user, and still have a guarantee that the output mesh forms a manifold surface. The function *make_surface_mesh* has specialized versions for the following tag types:

Manifold_tag: the output mesh is guaranteed to be a manifold surface without boundary.

Manifold_with_boundary_tag: the output mesh is guaranteed to be manifold but may have boundaries.

Non_manifold_tag: the algorithm relies on the given criteria and guarantees nothing else.

35.5 Design and Implementation History

The algorithm implemented in this package is mainly based on the work of Boissonnat and Oudot [BO05]

The meshing algorithm is implemented using the design of mesher levels described in [RY06].

David Rey, Steve Oudot and Andreas Fabri have participated in the development of this package.

3D Surface Mesh Generation

Reference Manual

Laurent Rineau and Mariette Yvinec

The surface mesh generation package offers a function template which builds a triangular mesh approximating a surface.

The meshing algorithms requires to know the surface to be meshed through an oracle that mainly can tell whether a given segment, ray or line intersects the surface or not and can compute the intersections point if any. The oracle is represented by a traits class which can be passed to the meshing function or automatically generated for certain types of surfaces. The current implementation provides traits classes to mesh implicit surfaces as well as surfaces described as a gray level in a three dimensional image.

The output mesh conforms to some size and shape criteria which are customizable. The criteria are passed to the mesher through a parameter whose type is a model of the concept *SurfaceMeshCriteria_3*.

The meshing algorithm is a Delaunay refinement process which is mainly guided by the criteria. The output mesh may offer some guarantees, as being manifold, homeomorphic to the surface or within a given Hausdorff distance. However, these guarantees depend on the quality of the input surface (smoothness, with or without boundary, manifold or not), the type and values of the given criteria. The behavior of the refinement process can also be influenced through a tag, which allows for instance to enforce the manifold property of the output mesh while avoiding an over-refinement of the mesh.

CGAL::Gray_level_image_3<FT, Point>

Definition

A 3D gray image is a tri-dimensional array that associates a scalar value to each triple of integer (x, y, z) in the range of the image. A trilinear interpolation algorithm provides a map $f : \mathbb{R}^3 \rightarrow \mathbb{R}$.

The class *Gray_level_image_3<FT, Point>* is a 3D gray image loader and a model of the concept *ImplicitFunction*. An object of the class *Gray_level_image_3<FT, Point>* is created with a parameter *iso* and then its *operator()* implements the function *sign of (f(p) - iso)*, for $p \in \mathbb{R}^3$. Plugging such a function in the creation of the *Implicit_surface_3* object given as parameter to *make_surface_mesh* yields a mesh approximating the level with value *iso* in the input 3D gray image.

Gray_level_image_3<FT, Point> provides an interface with an auxiliary library called *CGALImageIO*. An executable that uses *Gray_level_image_3<FT, Point>* must be linked with the *CGALImageIO* library. This library is shipped with CGAL and will be linked automatically by any makefile created by the script *cgal_create_makefile*.

The library *CGALImageIO* and therefore *Gray_level_image_3<FT, Point>* support several types of 3D images: INRIMAGE (extension *.inr[.gz]*), GIS (extension *.dim*, of *.ima[.gz]*), and ANALYZE (extension *.hdr*, or *.img[.gz]*).

```
#include <CGAL/Gray_level_image_3.h>
```

Is Model for the Concepts

ImplicitFunction

Types

Gray_level_image_3<FT, Point>:: FT the numerical type *FT*

Gray_level_image_3<FT, Point>:: Point the point type *Point*

Creation

```
Gray_level_image_3<FT, Point> image( const char* filename, FT iso_value);
```

filename is the path to a file of a type supported by *ImageIO*.
iso_value is an isovalue of *f*.

CGAL::Implicit_surface_3<Traits, Function>

Definition

The class *Implicit_surface_3*<*Traits*, *Function*> implements a surface described as the zero level set of a function $f : \mathbb{R}^3 \longrightarrow \mathbb{R}$.

For this type of surface, the library provides a partial specialization of the surface mesher traits generator: *Surface_mesh_traits_generator_3*<*Implicit_surface_3*<*Traits*, *Function*> >, that provides a traits class, model of the concept *SurfaceMeshTraits_3*, to be used by the surface mesher.

The parameter *Traits* is a traits class that has to be implemented with a model of *ImplicitSurfaceTraits_3*. Actually, this traits class implements the oracle needed by the surface mesher: the types, predicates and constructors provided in *Traits* are passed by the surface mesher traits generator to the generated the traits class used by the surface mesher.

The template parameter *Function* stands for a model of the concept *ImplicitFunction*. The number type *Function::FT* has to match the type *Traits::FT*.

```
#include <CGAL/Implicit_surface_3.h>
```

Creation

```
Implicit_surface_3<Traits, Function> surface( Function f,
                                             Sphere_3 bounding_sphere,
                                             FT error_bound = FT(1e-3))
```

f is the object of type *Function* that represents the implicit surface.

bounding_sphere is a bounding sphere of the implicit surface. The evaluation of *f* at the center *c* of this sphere must be negative: $f(c) < 0$.

error_bound is a relative error bound used to compute intersection points between the implicit surface and query segments. This bound is used in the default generated traits class. In this traits class, the intersection points between the surface and segments/rays/line are constructed by dichotomy. The dichotomy is stopped when the size of the intersected segment is less than the product of *error_bound* by the radius of *bounding_sphere*.

ImplicitSurfaceTraits_3

Definition

The concept `ImplicitSurfaceTraits_3` describes the requirements of the traits class to be plugged as *Traits* in `Implicit_surface_3<Traits, Function>`.

When `make_surface_mesh` is called with a surface of type `Implicit_surface_3<Traits,Function>`, the surface mesher traits generator generates automatically a traits class that is a model of `SurfaceMeshTraits_3`. Actually, the concept `ImplicitSurfaceTraits_3` provides the types, predicates and constructors that are passed to the generated model of `SurfaceMeshTraits_3`.

Types

<code>ImplicitSurfaceTraits_3:: FT</code>	The numerical type. It must be model of <i>SqrtFieldNumber-Type</i> and constructible from a <i>double</i> .
<code>ImplicitSurfaceTraits_3:: Point_3</code>	The point type. This point type must have a constructor <code>Point_3(FT, FT, FT)</code> .
<code>ImplicitSurfaceTraits_3:: Line_3</code>	The line type.
<code>ImplicitSurfaceTraits_3:: Ray_3</code>	The ray type.
<code>ImplicitSurfaceTraits_3:: Segment_3</code>	The segment type.
<code>ImplicitSurfaceTraits_3:: Vector_3</code>	The vector type.
<code>ImplicitSurfaceTraits_3:: Sphere_3</code>	The sphere type.

`ImplicitSurfaceTraits_3:: Compute_scalar_product_3`

A function object that provides the operator
`FT operator()(Vector_3 v, Vector_3 w)` which returns the scalar (inner) product of the two vectors *v* and *w*.

`ImplicitSurfaceTraits_3:: Compute_squared_distance_3`

A function object that provides the operator
`FT operator()(Point_3, Point_3)` which returns the squared distance between two points.

`ImplicitSurfaceTraits_3:: Compute_squared_radius_3`

A function object providing the operator
`FT operator()(const Sphere_3& s)` which returns the squared radius of *s*.

`ImplicitSurfaceTraits_3:: Construct_center_3`

A function object providing the operator
`Point_3 operator()(const Sphere_3& s)` which computes the center of the sphere *s*.

ImplicitSurfaceTraits_3:: Construct_midpoint_3

A function object providing the operator

Point_3 operator()(const Point_3& p, const Point_3& q) which computes the midpoint of the segment pq .

ImplicitSurfaceTraits_3:: Construct_point_on_3

A function object providing the following operators:

Point_3 operator()(const Line_3& l, int i); which returns an arbitrary point on l . It holds $point(i) == point(j)$, iff $i=j$. Furthermore, is directed from $point(i)$ to $point(j)$, for all $i < j$.

Point_3 operator()(const Ray_3& r, int i); which returns a point on r . $point(0)$ is the source, $point(i)$, with $i > 0$, is different from the source.

Precondition: $i \geq 0$.

Point_3 operator()(const Segment_3& s, int i); which returns source or target of s : $point(0)$ returns the source of s , $point(1)$ returns the target of s . The parameter i is taken modulo 2, which gives easy access to the other end point.

ImplicitSurfaceTraits_3:: Construct_segment_3

A function object providing the operators

Segment_3 operator()(const Point_3 &p, const Point_3 &q); which returns a segment with source p and target q . It is directed from the source towards the target.

ImplicitSurfaceTraits_3:: Construct_scaled_vector_3

A function object providing the operator

Vector_3 operator()(const Vector_3 &v, const FT& scale) which returns the vector v scaled by a factor $scale$.

ImplicitSurfaceTraits_3:: Construct_translated_point_3

A function object providing the operator

Point_3 operator()(const Point_3& p, const Vector_3& v) which returns the point obtained by translating p by the vector v .

ImplicitSurfaceTraits_3:: Construct_vector_3

A function object providing the operator

Vector_3 operator()(const Point_3 &a, const Point_3 &b) which returns the vector $b-a$.

ImplicitSurfaceTraits_3:: Has_on_bounded_side_3

A function object providing the operator

bool operator()(const Sphere_3& s, const Point_3& p); which returns true iff p lies on the bounded side of s .

Operations

The following functions give access to the predicate and construction objects:

<i>Compute_scalar_product_3</i>	<i>traits.compute_scalar_product_3_object()</i>
<i>Compute_squared_distance_3</i>	<i>traits.compute_squared_distance_3_object()</i>
<i>Compute_squared_radius_3</i>	<i>traits.compute_squared_radius_3_object()</i>
<i>Construct_center_3</i>	<i>traits.construct_center_3_object()</i>
<i>Construct_midpoint_3</i>	<i>traits.construct_midpoint_3_object()</i>
<i>Construct_point_on_3</i>	<i>traits.construct_point_on_3_object()</i>
<i>Construct_scaled_vector_3</i>	<i>traits.construct_scaled_vector_3_object()</i>
<i>Construct_segment_3</i>	<i>traits.construct_segment_3_object()</i>
<i>Construct_translated_point_3</i>	<i>traits.construct_translated_point_3_object()</i>
<i>Construct_vector_3</i>	<i>traits.construct_vector_3_object()</i>
<i>Has_on_bounded_side_3</i>	<i>traits.has_on_bounded_side_3_object()</i>

make_surface_mesh

CGAL::make_surface_mesh

```
#include <CGAL/make_surface_mesh.h>
```

Definition

The function *make_surface_mesh* is a surface mesh generator, that is a function to build a two dimensional mesh approximating a surface.

The library provides two overloaded version of this function:

```
template <class SurfaceMeshC2T3, class Surface, class Criteria, class Tag >
void      make_surface_mesh( SurfaceMeshC2T3& c2t3,
                           Surface surface,
                           Criteria criteria,
                           Tag,
                           int initial_number_of_points = 20)
```

```
template <class SurfaceMeshC2T3, class SurfaceMeshTraits, class Criteria, class Tag >
void      make_surface_mesh( SurfaceMeshC2T3& c2t3,
                           SurfaceMeshTraits::Surface_3 surface,
                           SurfaceMeshTraits traits,
                           Criteria criteria,
                           Tag,
                           int initial_number_of_points = 20)
```

Parameters

The template parameter *SurfaceMeshC2T3* is required to be a model of the concept *SurfaceMeshComplex_2InTriangulation_3*, a data structure able to represent a two dimensional complex embedded in a three dimensional triangulation. The argument *c2t3* of type *SurfaceMeshC2T3*, passed by reference to the surface mesh generator, is used to maintain the current approximating mesh and it stores the final mesh at the end of the procedure. The type *SurfaceMeshC2T3* is in particular required to provide a type *SurfaceMeshC2T3::Triangulation_3* for the three dimensional triangulation embedding the surface mesh. The vertex and cell base classes of the triangulation *SurfaceMeshC2T3::Triangulation_3* are required to be models of the concepts *SurfaceMeshVertexBase_3* and *SurfaceMeshCellBase_3* respectively.

The template parameter *Surface* stands for the surface type. This type has to be a model of the concept *Surface_3*.

The knowledge on the surface, required by the surface mesh generator is encapsulated in a traits class. Actually, the mesh generator accesses the surface to be meshed through this traits class only. The traits class is required to be a model of the concept *SurfaceMeshTraits_3*.

In the first version of *make_surface_mesh* the surface type is a template parameter *Surface* and the surface mesh generator traits type is automatically generated from the surface type through the class *Surface_mesh_traits_generator_3<Surface>*.

The difference between the two overloaded versions of *make_surface_mesh* can be explained as follows

- In the first overloaded version of *make_surface_mesh*, the surface type is given as template parameter (*Surface*) and the *surface* to be meshed is passed as parameter to the mesh generator. In that case the surface mesh generator traits type is automatically generated from the surface type by an auxiliary class called the *Surface_mesh_traits_generator_3*.
- In the second overloaded version of *make_surface_mesh*, the surface mesh generator traits type is provided by the template parameter *SurfaceMeshTraits_3* and the surface type is obtained from this traits type. Both the surface and the traits are passed to the mesh generator as arguments.

The first overloaded version can be used whenever the surface type either provides a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3* or is a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3*<*Surface*> is provided. Currently, the library provides partial specializations of *Surface_mesher_traits_generator_3*<*Surface*> for implicit surfaces (*Implicit_surface_3*<*Traits*, *Function*>) and gray level images (*Gray_level_image_3*<*FT*, *Point*>).

The template parameter *Criteria* has to be a model of the concept *SurfaceMeshCriteria_3*. The argument of type *Criteria* passed to the surface mesh generator specifies the size and shape requirements on the output surface mesh.

The template parameter *Tag* is a tag whose type affects the behavior of the meshing algorithm. The function *make_surface_mesh* has specialized versions for the following tag types:

- *Manifold_tag*: the output mesh is guaranteed to be a manifold surface without boundary.
- *Manifold_with_boundary_tag*: the output mesh is guaranteed to be manifold but may have boundaries.
- *Non_manifold_tag*: the algorithm relies on the given criteria and guarantees nothing else.

The Delaunay refinement process is started with an initial set of points which is the union of two sets: the set of vertices in the initial triangulation pointed to by the *c2t3* argument and a set of points provided by the traits class. The optional parameter *initial_number_of_points* allows to monitor the number of points in this second set. (This parameter is passed to the *operator()* of the constructor object *Construct_initial_points* in the traits class.) The meshing algorithm requires that the initial set of points includes at least one point on each connected components of the surface to be meshed. one.

SurfaceMeshCellBase_3

Definition

The concept `SurfaceMeshCellBase_3` describes the cell base type of the three dimensional triangulation used to embed the surface mesh.

More precisely, the first template parameter `SurfaceMeshC2T3` of the surface mesher `make_surface_mesh` is a model of the concept `SurfaceMeshComplex_2InTriangulation_3` which describes a data structure to store a pure two dimensional complex embedded in a three dimensional triangulation. In particular, the type `SurfaceMeshC2T3` is required to provide a three dimensional triangulation type `SurfaceMeshC2T3::Triangulation_3`. The concept `SurfaceMeshCellBase_3` describes the cell base type required in this triangulation type.

Generalizes

TriangulationCellBase_3

The concept `SurfaceMeshCellBase_3` adds four markers to mark the facets of the triangulation that belong to the two dimensional complex, and four markers that are helpers used in some operations to mark for instance the facets that have been visited.

This concept also provides storage for the center of a Delaunay surface ball. Given a surface and a 3D Delaunay triangulation, a Delaunay surface ball is a ball circumscribed to a facet of the triangulation and centered on the surface and empty of triangulation vertices. Such a ball does exist when the facet is part of the restriction to the surface of a three dimensional triangulation. In the following we call *surface center* of a facet, the center of its biggest Delaunay surface ball.

Types

SurfaceMeshCellBase_3::Point

The point type, required to match the point type of the three dimensional triangulation in which the surface mesh is embedded.

Creation

Operations

bool *cell.is_facet_on_surface(int i)*

returns *true*, if *facet(i)* is in the 2D complex.

void *cell.set_facet_on_surface(int i, bool b)*

Sets *facet(i)* as part of the 2D complex, if *b* is *true*, and *NOT_IN_COMPLEX*, otherwise.

bool *cell.is_facet_visited(int i)*

Returns *true*, if *facet(i)* has been visited, *false* otherwise.

void *cell.set_facet_visited(int i, bool b)*

Marks *facet(i)* as visited, if *b* is *true*, and non visited otherwise.

Point *cell.get_facet_surface_center(int i)*

Returns a const reference to the surface center of *facet(i)*.

void *cell.set_facet_surface_center(int i, Point p)*

Sets point *p* as the surface center of *facet(i)*.

SurfaceMeshTriangulation_3

SurfaceMeshComplex_2InTriangulation_3

Definition

The concept `SurfaceMeshComplex_2InTriangulation_3` describes a data structure designed to represent a two dimensional pure complex embedded in a three dimensional triangulation.

A *complex* is a set C of faces such that:

- any subface of a face in C is a face of C
- two faces of C are disjoint or share a common subface

The complex is *two dimensional*, if its faces have dimension at most two. It is *pure* if any face in the complex is a subface of some face of maximal dimension. Thus, a two dimensional pure complex is a set of facets together with their edges and vertices. A two dimensional pure complex embedded in a three dimensional triangulation is a subset of the facets of this triangulation, together with their edges and vertices.

The concept `SurfaceMeshComplex_2InTriangulation_3` is particularly suited to handle surface meshes obtained as the restriction to a surface of a three dimensional Delaunay triangulation. A model of this concept is a type to be plugged as first template parameter in the function template `make_surface_mesh`.

Types

`SurfaceMeshComplex_2InTriangulation_3` provides the following types.

SurfaceMeshComplex_2InTriangulation_3::Triangulation

The type of the embedding 3D triangulation. Must be a model of *SurfaceMeshTriangulation_3*.

typedef Triangulation::Vertex_handle

Vertex_handle;
typedef Triangulation::Cell_handle

The type of the embedding triangulation vertex handles.

Cell_handle;
typedef Triangulation::Facet

The type of the embedding triangulation cell handles.

Facet;
typedef Triangulation::Edge

The type of the embedding triangulation facets.

Edge;
typedef Triangulation::size_type

The type of the embedding triangulation edges.

size_type;

Size type (an unsigned integral type)

enum Face_status { NOT_IN_COMPLEX, BOUNDARY, REGULAR, SINGULAR};

A type to describe the status of a face (facet, edge, or vertex) with respect to the 2D pure complex. A *NOT_IN_COMPLEX* face does not belong to the 2D complex. Facets can only be *NOT_IN_COMPLEX* or *REGULAR* depending on whether they belong to the 2D complex or not. Edges and vertices can be *NOT_IN_COMPLEX*, *BOUNDARY*, *REGULAR* or *SINGULAR*. An edge in the complex is *BOUNDARY*, *REGULAR*, or *SINGULAR*, if it is incident to respectively 1, 2, or 3 or more facets in the complex. The status of a vertex is determined by the adjacency graph of the facets of the 2D complex incident to that vertex. The vertex of the 2D complex is *BOUNDARY*, if this adjacency graph is a simple path, it is *REGULAR*, if the adjacency graph is cyclic, and *SINGULAR* in any other case.

SurfaceMeshComplex_2InTriangulation_3:: Facet_iterator

An iterator type to visit the facets of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Edge_iterator

An iterator type to visit the edges of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Vertex_iterator

An iterator type to visit vertices of the 2D complex.

SurfaceMeshComplex_2InTriangulation_3:: Boundary_edges_iterator

An iterator type to visit the boundary edges of the 2D complex.

Creation

SurfaceMeshComplex_2InTriangulation_3 c2t3(Triangulation& t3);

Builds an empty 2D complex embedded in the triangulation *t3*

template < class FacetSelector>

SurfaceMeshComplex_2InTriangulation_3 c2t3(Triangulation& t3, FacetSelector select);

Builds a 2D complex embedded in the triangulation *t3*, including in the 2D complex the facets of *t3* for which the predicate *select* returns *true*.

The type *FacetSelector* must be a function object with an operator to select facets: *bool operator()(Facet f);*

Member access

Triangulation & *c2t3.triangulation()* Returns the reference to the triangulation.

Modifications

void *c2t3.add_to_complex(Facet f)*
Adds facet *f* to the 2D complex.

void *c2t3.add_to_complex(Cell_handle c, int i)*
Adds facet *(c,i)* to the 2D complex.

void *c2t3.remove_from_complex(Facet f)*
Removes facet *f* from the 2D complex.

void *c2t3.remove_from_complex(Cell_handle c, int i)*
Removes facet *(c,i)* from the 2D complex.

Queries

Queries on the status of individual face with respect to the 2D complex.

size_type *c2t3.number_of_facets()*
Returns the number of facets that belong to the 2D complex.

Face_status *c2t3.face_status(Facet f)*
Returns the status of the facet *f* with respect to the 2D complex.

Face_status *c2t3.face_status(Cell_handle c, int i)*
Returns the status of the facet *(c,i)* with respect to the 2D complex.

Face_status *c2t3.face_status(Edge e)*
Returns the status of edge *e* in the 2D complex.

Face_status *c2t3.face_status(Cell_handle c, int i, int j)*
Returns the status of edge *(c,i,j)* in the 2D complex.

Face_status *c2t3.face_status(Vertex_handle v)*
Returns the status of vertex *v* in the 2D complex.

bool *c2t3.is_in_complex(Facet f)*
Returns *true*, if the facet *f* belongs to the 2D complex.

<i>bool</i>	<i>c2t3.is_in_complex(Cell_handle c, int i)</i>	Returns <i>true</i> , if the facet (c,i) belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_in_complex(Edge e)</i>	Returns <i>true</i> , if the edge e belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_in_complex(Cell_handle c, int i, int j)</i>	Returns <i>true</i> , if the edge (c,i,j) belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_in_complex(Vertex_handle v)</i>	Returns <i>true</i> , if the vertex v belongs to the 2D complex.
<i>bool</i>	<i>c2t3.is_regular_or_boundary_for_vertices(Vertex_handle v)</i>	Returns <i>true</i> if the status of vertex v is <i>REGULAR</i> or <i>BOUNDARY</i> . <i>Precondition:</i> All the edges of the complex incident to v are <i>REGULAR</i> or <i>BOUNDARY</i> .

Traversal of the complex

The data structure provides iterators to visit the facets, edges and vertices of the complex. All those iterators are bidirectional and non mutable.

<i>Facet_iterator</i>	<i>c2t3.facets_begin()</i>	Returns an iterator with value type <i>Facet</i> to visit the facets of the 2D complex.
<i>Facet_iterator</i>	<i>c2t3.facets_end()</i>	Returns the past the end iterator for the above iterator.
<i>Edge_iterator</i>	<i>c2t3.edges_begin()</i>	Returns an iterator with value type <i>Edge</i> to visit the edges of the 2D complex which are not isolated.
<i>Edge_iterator</i>	<i>c2t3.edges_end()</i>	Returns the past the end iterator for the above iterator.
<i>Boundary_edges_iterator</i>	<i>c2t3.boundary_edges_begin()</i>	Returns an iterator with value type <i>Edge</i> to visit the boundary edges of the complex.
<i>Boundary_edges_iterator</i>	<i>c2t3.boundary_edges_end()</i>	Returns the past the end iterator for the above iterator.
<i>Vertex_iterator</i>	<i>c2t3.vertices_begin()</i>	Returns an iterator with value type <i>Vertex_handle</i> to visit the vertices of the 2D complex.
<i>Vertex_iterator</i>	<i>c2t3.vertices_end()</i>	Returns the past the end iterator for the above iterator.

template <class OutputIterator>

OutputIterator *c2t3.incident_facets(Vertex_handle v, OutputIterator facets)*

Copies the *Facets* of the complex incident to *v* to the output iterator *facets*. Returns the resulting output iterator.

Precondition: *c2t3.triangulation().dimension() = 3*, *v* \neq *Vertex_handle()*, *c2t3.triangulation().is_vertex(v)*.

SurfaceMeshCriteria_3

Definition

The Delaunay refinement process involved in the function template *make_surface_mesh* is guided by a set of refinement criteria. The concept *SurfaceMeshCriteria_3* describes the type which handles those criteria. It corresponds to the requirements for the template parameter *Criteria* of the surface mesher function *make_surface_mesh*<*SurfaceMeshC2T3*,*Surface*,*Criteria*,*Tag*>.

Typically the meshing criteria are a set of elementary criteria, each of which has to be met by the facets of the final mesh. The meshing algorithm eliminates in turn *bad* facets, i.e., facets that do not meet all the criteria.

The size and quality of the final mesh depends on the order according to which bad facets are handled. Therefore, the meshing algorithm needs to be able to quantify the facet qualities and to compare the qualities of different faces. The concept *SurfaceMeshCriteria_3* defines a type *Quality* designed to measure the quality of a mesh facet. Typically this quality is a multi-component variable. Each component corresponds to one criterion and measures how much the facet deviates from meeting this criterion. Then, the comparison operator on qualities is just a lexicographical comparison. The meshing algorithm handles facets with lowest quality first. The qualities are computed by a function *is_bad*(*Facet* *f*, *Quality*& *q*).

Types

SurfaceMeshCriteria_3::Facet

The type of facets. This type has to match the *Facet* type in the triangulation type used by the mesher function. (This triangulation type is the type *SurfaceMeshC2T3::Triangulation* provided by the the model of *SurfaceMeshComplex_2InTriangulation_3* plugged as first template parameter of *make_surface_mesh*).

SurfaceMeshCriteria_3::Quality

Default constructible, copy constructible, assignable, and less-than comparable type.

Operations

bool *criteria.is_bad*(*Facet* *f*, *Quality*& *q*)

Assigns the quality of the facet *f* to *q*, and returns *true* if *f* does not meet the criteria.

CGAL::Surface_mesh_default_criteria_3<Tr>

Definition

The class *Surface_mesh_default_criteria_3<Tr>* implements the most commonly used combination of meshing criteria. It involves mainly three criteria which are in order:

- a lower bound on the minimum angle in degrees of the surface mesh facets.
- an upper bound on the radius of surface Delaunay balls. A surface Delaunay ball is a ball circumscribing a facet, centered on the surface and empty of vertices. Such a ball exists for each facet of the current surface mesh. Indeed the current surface mesh is the Delaunay triangulation of the current sampling restricted to the surface which is just the set of facets in the three dimensional Delaunay triangulation of the sampling that have a Delaunay surface ball.
- an upper bound on the center-center distances of the surface mesh facets. The center-center distance of a surface mesh facet is the distance between the facet circumcenter and the center of its surface Delaunay ball.

```
#include <CGAL/Surface_mesh_default_criteria_3.h>
```

Is Model for the Concepts

SurfaceMeshCriteria_3

Types

```
typedef Tr::FT          FT;          The numerical type.
```

Creation

```
Surface_mesh_default_criteria_3<Tr> criteria( FT angle_bound, FT radius_bound, FT distance_bound);
```

Returns a *Surface_mesh_default_criteria_3<Tr>* with *angle_bound*, *radius_bound*, *distance_bound* as bounds for the minimum facet angle in degrees, the radius of the surface Delaunay balls and the center-center distances respectively.

SurfaceMeshTraits_3

Definition

The concept `SurfaceMeshTraits_3` describes the knowledge that is required on the surface to be meshed. A model of this concept implements an oracle that is able to tell whether a segment (or a ray, or a line) intersects the surface or not and to compute some intersection points if any. The concept `SurfaceMeshTraits_3` also includes a constructor able to provide a small set of initial points on the surface.

Types

<code>SurfaceMeshTraits_3:: Point_3</code>	The type of points. This type is required to match the point type of the three dimensional embedding triangulation <code>C2T3::Triangulation_3</code> .
<code>SurfaceMeshTraits_3:: Segment_3</code>	The type of segments.
<code>SurfaceMeshTraits_3:: Ray_3</code>	The type of rays.
<code>SurfaceMeshTraits_3:: Line_3</code>	The type of lines.
<code>SurfaceMeshTraits_3:: Surface_3</code>	The surface type.
<code>SurfaceMeshTraits_3:: Intersect_3</code>	A model of this type provides the operator <code>CGAL::object operator()(Surface_3 surface, Type1 type1)</code> to compute the intersection of the surface with an object of type <code>Type1</code> which may be <code>Segment_3</code> , <code>Ray_3</code> or <code>Line_3</code> .
<code>SurfaceMeshTraits_3:: Construct_initial_points</code>	A model of this type provides the following operators to construct initial points on the surface: <pre>template <class OutputIteratorPoints> OutputIteratorPoints operator()(OutputIteratorPoints pts) which outputs a set of points on the surface, template <class OutputIteratorPoints> OutputIteratorPoints operator() (OutputIteratorPoints pts, int n) which outputs a set of n points on the surface.</pre>

Operations

The following functions give access to the construction objects:

```
Intersect_3          traits.intersect_3_object()
Construct_initial_points
                    traits.construct_initial_points_object()
```

CGAL::Surface_mesh_traits_generator_3<Surface>

Definition

The class *Surface_mesh_traits_generator_3<Surface>* provides a type *Type*, that is a model of the concept *SurfaceMeshTraits_3* for the surface type *Surface*.

The type *Surface* is required to be a model of the concept *Surface_3*, which means that it is copy constructible and assignable. In addition, a *Surface* type is required

- either to provide a nested type *Surface::Surface_mesher_traits_3* that is a model of *SurfaceMeshTraits_3*
- or to be a surface type for which a specialization of the traits generator *Surface_mesh_traits_generator_3<Surface>* exists.

Currently, the library provides partial specializations of the traits generator for implicit surfaces (*Implicit_surface_3<Traits, Function>*) and gray level images (*Gray_level_image_3<FT, Point>*).

```
#include <CGAL/Surface_mesh_traits_generator_3.h>
```

```
Surface_mesh_traits_generator_3<Surface>:: Type
```

A model of the concept *SurfaceMeshTraits_3*.

SurfaceMeshTriangulation_3

Definition

The concept `SurfaceMeshTriangulation_3` describes the triangulation type used by the surface mesher `make_surface_mesh` to represent the three dimensional triangulation embedding the surface mesh. Thus, this concept describes the requirements for the triangulation type `SurfaceMeshC2T3::Triangulation` nested in the model of `SurfaceMeshComplex2InTriangulation3` plugged as the template parameter `SurfaceMeshC2T3` of `make_surface_mesh`. It also describes the requirements for the triangulation type plugged in the class `Surface_mesh_complex_2_in_triangulation_3<Tr>`.

Types

<i>SurfaceMeshTriangulation_3::Point</i>	The point type. It must be DefaultConstructible, CopyConstructible and Assignable.
--	--

Vertices and cells of the triangulation are manipulated via handles, which support the two dereference operators *operator** and *operator->*.

<i>SurfaceMeshTriangulation_3::Vertex_handle</i>	Handle to a data representing a <i>vertex</i> . <i>Vertex_handle</i> must be a model of <i>Handle</i> and its <i>value type</i> must be model of <i>TriangulationDataStructure_3::Vertex</i> .
--	--

<i>SurfaceMeshTriangulation_3::Cell_handle</i>	Handle to a data representing a <i>cell</i> . <i>Cell_handle</i> must be a model of <i>Handle</i> and its <i>value</i> type must be model of <i>TriangulationDataStructure_3::Cell</i> .
--	--

```
typedef CGAL::Triple<Cell_handle, int, int>
```

```
Edge;                                The edge type.
typedef std::pair<Cell_handle, int>
```

Facet; The facet type.

The following iterators allow one to visit all finite vertices, edges and facets of the triangulation.

SurfaceMeshTriangulation_3::Finite_vertices_iterator

Iterator over finite vertices

SurfaceMeshTriangulation_3::Finite_edges_iterator

Iterator over finite edges

SurfaceMeshTriangulation_3::Finite_facets_iterator

Iterator over finite facets

<i>SurfaceMeshTriangulation_3::Geom_traits</i>	The geometric traits class.	Must be a model of
	<i>DelaunayTriangulationTraits_3</i> .	

Creation

<i>SurfaceMeshTriangulation_3</i> <i>t</i> ;	default constructor.
<i>SurfaceMeshTriangulation_3</i> <i>t</i> (<i>tr</i>);	Copy constructor. All vertices and faces are duplicated.

Assignment

<i>SurfaceMeshTriangulation_3</i> &		
<i>t</i> = <i>tr</i>		The triangulation <i>tr</i> is duplicated, and modifying the copy after the duplication does not modify the original. The previous triangulation held by <i>t</i> is deleted.
<i>void</i>	<i>t.clear()</i>	Deletes all finite vertices and all cells of <i>t</i> .

Access Functions

<i>int</i>	<i>t.dimension()</i>	Returns the dimension of the affine hull.
<i>DelaunayTriangulationTraits_3</i>		
	<i>t.geom_traits()</i>	Returns a const reference to a model of <i>DelaunayTriangulationTraits_3</i> .

Voronoi diagram

<i>Object</i>	<i>t.dual</i> (<i>Facet</i> <i>f</i>)	Returns the dual of facet <i>f</i> , which is in dimension 3: either a segment, if the two cells incident to <i>f</i> are finite, or a ray, if one of them is infinite; in dimension 2: a point.
---------------	---	--

Queries

A point *p* is said to be in conflict with a cell *c* in dimension 3 (resp. a facet *f* in dimension 2) iff *t.side_of_sphere*(*c*, *p*) (resp. *t.side_of_circle*(*f*, *p*)) returns *ON_BOUNDED_SIDE*. The set of cells (resp. facets in dimension 2) which are in conflict with *p* is connected, and it forms a hole.

template <*class* *OutputIteratorBoundaryFacets*, *class* *OutputIteratorCells*, *class* *OutputIteratorInternalFacets*>

Triple<*OutputIteratorBoundaryFacets*, *OutputIteratorCells*, *OutputIteratorInternalFacets*>

t.find_conflicts(*Point* *p*,
 Cell_handle *c*,
 OutputIteratorBoundaryFacets *bfit*,
 OutputIteratorCells *cit*,

OutputIteratorInternalFacets ifit)

Computes the conflict hole induced by p . The starting cell (resp. facet) c must be in conflict. Then this function returns respectively in the output iterators:

- *cit*: the cells (resp. facets) in conflict.
- *bfit*: the facets (resp. edges) on the boundary, that is, the facets (resp. edges) (t, i) where the cell (resp. facet) t is in conflict, but $t \rightarrow neighbor(i)$ is not.
- *ifit*: the facets (resp. edges) inside the hole, that is, delimiting two cells (resp facets) in conflict.

Returns the *Triple* composed of the resulting output iterators.

The following iterators allow the user to visit facets, edges and vertices of the triangulation.

Finite_vertices_iterator

t.finite_vertices_begin()

Starts at an arbitrary finite vertex. Then ++ and -- will iterate over finite vertices. Returns *finite_vertices_end()* when *t.number_of_vertices()* = 0.

Finite_vertices_iterator

t.finite_vertices_end()

Past-the-end iterator

Finite_edges_iterator

t.finite_edges_begin()

Starts at an arbitrary finite edge. Then ++ and -- will iterate over finite edges. Returns *finite_edges_end()* when *t.dimension()* < 1.

Finite_edges_iterator

t.finite_edges_end()

Past-the-end iterator

Finite_facets_iterator

t.finite_facets_begin()

Starts at an arbitrary finite facet. Then ++ and -- will iterate over finite facets. Returns *finite_facets_end()* when *t.dimension()* < 2.

Finite_facets_iterator

t.finite_facets_end()

Past-the-end iterator

template <class OutputIterator>

OutputIterator *t*.incident_cells(Vertex_handle v, OutputIterator cells)

Copies the *Cell_handles* of all cells incident to v to the output iterator *cells*. If *t.dimension()* < 3, then do nothing. Returns the resulting output iterator.

Precondition: $v \neq \text{Vertex_handle}()$, $t.is_vertex(v)$.

template <class OutputIterator>

OutputIterator *t*.incident_cells(Vertex_handle v, OutputIterator cells)

Copies the *Cell_handles* of all cells incident to v to the output iterator *cells*. If *t.dimension()* < 3, then do nothing. Returns the resulting output iterator.

<i>bool</i>	<i>t.is_vertex(Point p, Vertex_handle & v)</i>	Tests whether <i>p</i> is a vertex of <i>t</i> by locating <i>p</i> in the triangulation. If <i>p</i> is found, the associated vertex <i>v</i> is given.
<i>bool</i>	<i>t.is_edge(Vertex_handle u, Vertex_handle v, Cell_handle & c, int & i, int & j)</i>	Tests whether <i>(u,v)</i> is an edge of <i>t</i> . If the edge is found, it gives a cell <i>c</i> having this edge and the indices <i>i</i> and <i>j</i> of the vertices <i>u</i> and <i>v</i> in <i>c</i> , in this order. <i>Precondition: u and v are vertices of t.</i>
<i>bool</i>	<i>t.is_infinite(const Vertex_handle v)</i>	<i>true</i> , iff vertex <i>v</i> is the infinite vertex.
<i>bool</i>	<i>t.is_infinite(const Cell_handle c)</i>	<i>true</i> , iff <i>c</i> is incident to the infinite vertex. <i>Precondition: t.dimension() = 3.</i>
<i>Facet</i>	<i>t.mirror_facet(Facet f)</i>	Returns the same facet viewed from the other adjacent cell.
<i>int</i>	<i>t.vertex_triple_index(const int i, const int j)</i>	Return the indexes of the <i>j</i> th vertex of the facet of a cell opposite to vertex <i>i</i> .

Point location

<i>Cell_handle</i>	<i>t.locate(Point query, Cell_handle start = Cell_handle())</i>	<p>If the point <i>query</i> lies inside the convex hull of the points, the cell that contains the query in its interior is returned. If <i>query</i> lies on a facet, an edge or on a vertex, one of the cells having <i>query</i> on its boundary is returned.</p> <p>If the point <i>query</i> lies outside the convex hull of the points, an infinite cell with vertices $\{p, q, r, \infty\}$ is returned such that the tetrahedron $(p, q, r, query)$ is positively oriented (the rest of the triangulation lies on the other side of facet (p, q, r)).</p> <p>Note that <i>locate</i> works even in degenerate dimensions: in dimension 2 (resp. 1, 0) the <i>Cell_handle</i> returned is the one that represents the facet (resp. edge, vertex) containing the query point.</p> <p>The optional argument <i>start</i> is used as a starting place for the search.</p>
--------------------	--	--

Cell_handle

```
t.locate( Point query,  
         Locate_type & lt,  
         int & li,  
         int & lj,  
         Cell_handle start = Cell_handle())
```

If *query* lies inside the affine hull of the points, the *k*-face (finite or infinite) that contains *query* in its interior is returned, by means of the cell returned together with *lt*, which is set to the locate type of the query (*VERTEX*, *EDGE*, *FACET*, *CELL*, or *OUTSIDE_CONVEX_HULL* if the cell is infinite and *query* lies strictly in it) and two indices *li* and *lj* that specify the *k*-face of the cell containing *query*.

If the *k*-face is a cell, *li* and *lj* have no meaning; if it is a facet (resp. vertex), *li* gives the index of the facet (resp. vertex) and *lj* has no meaning; if it is an edge, *li* and *lj* give the indices of its vertices.

If the point *query* lies outside the affine hull of the points, which can happen in case of degenerate dimensions, *lt* is set to *OUTSIDE_AFFINE_HULL*, and the cell returned has no meaning. As a particular case, if there is no finite vertex yet in the triangulation, *lt* is set to *OUTSIDE_AFFINE_HULL* and *locate* returns the default constructed handle.

The optional argument *start* is used as a starting place for the search.

template <class CellIt>

Vertex_handle

```
t.insert_in_hole( Point p, CellIt cell_begin, CellIt cell_end, Cell_handle begin, int i)
```

Creates a new vertex by starring a hole. It takes an iterator range [*cell_begin*; *cell_end*] of *Cell_handles* which specifies a hole: a set of connected cells (resp. facets in dimension 2) which is star-shaped wrt *p*. (*begin*, *i*) is a facet (resp. an edge) on the boundary of the hole, that is, *begin* belongs to the set of cells (resp. facets) previously described, and *begin*->*neighbor(i)* does not. Then this function deletes all the cells (resp. facets) describing the hole, creates a new vertex *v*, and for each facet (resp. edge) on the boundary of the hole, creates a new cell (resp. facet) with *v* as vertex. Then *v*->*set_point(p)* is called and *v* is returned.

Precondition: *t.dimension()* ≥ 2 , the set of cells (resp. facets in dimension 2) is connected, its boundary is connected, and *p* lies inside the hole, which is star-shaped wrt *p*.

SurfaceMeshVertexBase_3

Definition

The concept `SurfaceMeshVertexBase_3` describes the vertex base type of the three dimensional triangulation used to embed the surface mesh.

More precisely, the first template parameter `SurfaceMeshC2T3` of the surface mesher `make_surface_mesh` is a model of the concept `SurfaceMeshComplex_2InTriangulation_3` which describes a data structure to store a pure two dimensional complex embedded in a three dimensional triangulation. In particular, the type `SurfaceMeshC2T3` is required to provide a three dimensional triangulation type `SurfaceMeshC2T3::Triangulation_3`. The concept `SurfaceMeshVertexBase_3` describes the vertex base type required in this triangulation type.

Generalizes

`TriangulationVertexBase_3`

The surface mesher algorithm issues frequent queries about the status of the vertices with respect to the two dimensional complex that represents the current surface approximation. The class `SurfaceMeshVertexBase_3` offers a caching mechanism to answer more efficiently these queries. The caching mechanism includes two cached integers, which, when they are valid, store respectively the number of complex facets incident to the vertex and the number of connected components of the adjacency graph of those facets.

Creation

Operations

<code>bool</code>	<code>vb.is_c2t3_cache_valid()</code>	Returns <code>true</code> if the cache is valid.
<code>void</code>	<code>vb.invalidate_c2t3_cache()</code>	Invalidates the cash.
<code>int</code>	<code>vb.cached_number_of_incident_facets()</code>	Returns the cached number of facets of the complex incident to the vertex.
<code>int</code>	<code>vb.cached_number_of_components()</code>	This method concerns the adjacency graph of the facets of the complex incident to the vertex and returns a cached value for the number of connected components this graph.

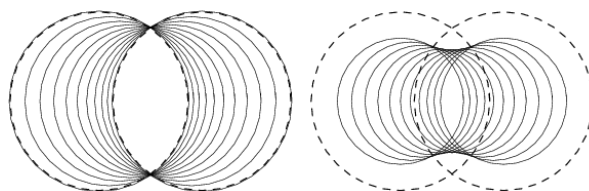

Figure 36.1: Left: Convex combinations of two weighted points (the two dashed circles). Right: The skin curve of the weighted points. The smaller circles form a subset of the weighted points whose boundary is the skin curve.

36.1 Introduction

Skin surfaces, introduced by Edelsbrunner in [Ede99], have a rich and simple combinatorial and geometric structure that makes them suitable for modeling large molecules in biological computing. Meshing such surfaces is often required for further processing of their geometry, like in numerical simulation and visualization.

A skin surface is defined by a set of weighted points (input balls) and a scalar called the shrink factor. If the shrink factor is equal to one, the surface is just the boundary of the union of the input balls. For a shrink factor smaller than one, the skin surface becomes tangent continuous, due to the appearance of patches of spheres and hyperboloids connecting the balls.

This package constructs a mesh isotopic to the skin surface defined by a set of balls and a shrink factor using the algorithm described in [KV05].

An optimized algorithm is implemented for meshing the union of a set of balls.

36.2 Definition of a Skin Surface

This section first briefly reviews skin surfaces. For a more thorough introduction to skin surfaces, we refer to [Ede99] where they were originally introduced.

A skin surface is defined in terms of a finite set of weighted points \mathbf{P} and a shrink factor s , with $0 \leq s \leq 1$. A weighted point $\mathbf{p} = (p, w_p) \in \mathbb{R}^3 \times \mathbb{R}$ corresponds to a ball with center p and radius $\sqrt{w_p}$. A weighted point with zero weight is called an unweighted point.

A pseudo distance between a weighted point $\mathbf{p} = (p, w_p)$ and an unweighted point x is defined as

$$\pi(\mathbf{p}, x) = \|p - x\|^2 - w_p,$$

where $\|p - x\|$ is the Euclidean distance between p and x . The ball corresponding to a weighted point \mathbf{p} is the zero set of $\pi(\mathbf{p}, \cdot)$. Note that if $w_p < 0$ the radius of the ball is imaginary and the zero-set is empty.

We can take convex combinations of weighted points by taking convex combinations of their distance functions. Figure 36.1 (left) shows weighted points that are obtained as convex combinations of the dashed circles. For further reading on the space of circles and spheres we refer to [Ped70].

Starting from a weighted point $\mathbf{p} = (p, w_p)$, the shrunk weighted point \mathbf{p}^s is obtained by taking a convex combination with the unweighted point centered at p , formally $\mathbf{p}^s = s\mathbf{p} + (1 - s)\mathbf{p}'$, with $\mathbf{p}' = (p, 0)$. A simple calculation shows that, $\mathbf{p}^s = (p, s \cdot w_p)$. The set \mathbf{P}^s is the set obtained by shrinking every weighted point of \mathbf{P} by a factor s : $\mathbf{P}^s = \{\mathbf{p}^s \mid \mathbf{p} \in \mathbf{P}\}$. The shrunk weighted points of Figure 36.1 (left) are shown in Figure 36.1 (right).

We now define the skin surface $\text{skn}^s(\mathbf{P})$ associated with a set of weighted points \mathbf{P} . Consider the set of weighted points obtained by taking the convex hull of the input weighted points. A calculation shows that every weighted point lies within the union of the input balls. Next, we shrink each weighted point in the convex hull with the shrink factor s . Hence, we multiply the radius of the corresponding (real) input circles with a factor \sqrt{s} . The skin surface is the boundary of the union of this set of weighted points:

$$\text{skn}^s(\mathbf{P}) = \partial \bigcup \{\mathbf{p}^s \mid \mathbf{p} \in \text{conv}(\mathbf{P})\}. \quad (36.1)$$

Here $\text{conv}(\mathbf{P}) \subset \mathbb{R}^3 \times \mathbb{R}$ is the convex hull of a set of weighted points \mathbf{P} , whereas ∂ denotes the boundary – in \mathbb{R}^3 – of the union of the corresponding set of balls.

Recall that each weighted point in the convex hull of the input weighted points is contained in the union of the input weighted points. Hence, for a shrink factor equal to one, the skin surface is the boundary of the union of the input weighted points.

By definition of a skin surface, the weights of the input balls (their radius-squared) are shrunk with a factor of s and the skin surface wraps around the shrunk input balls. In order to make the skin surface wrap around the (unshrunk) input balls, we can first increase the weights of the input balls by multiplying them with a factor $1/s$ and then compute the skin surface.

36.3 The Interface

The interface to the skin surface package consists of one main function, taking a set of weighted points and a shrink factor and outputting the meshed surface. Further, it defines classes and functions and classed used to perform the main steps of the algorithm. There are two global classes *Skin_surface_3* and *Union_of_balls_3* both of which are models of the concept *SkinSurface_3* and there are two functions to extract a mesh of the skin surface (union of balls) from the objects of the aforementioned classes. A final function takes a mesh and the *Skin_surface_3* (*Union_of_balls_3*) object it is constructed from and refines the mesh. This section describes these classes and functions in more detail.

The main function of the skin surface package takes an iterator range of weighted points, a shrink factor and the number of subdivision steps and outputs a mesh in a *CGAL::Polyhedron_3*:

```
template <class WP_iterator, class Polyhedron_3>
void    make_skin_surface_mesh_3( Polyhedron_3 &p,
                                WP_iterator begin,
                                WP_iterator end,
                                FT shrink_factor=.5,
                                int nSubdiv=0,
                                bool grow_balls = true)
```

Where, *FT* is the number type used by the *Weighted_points*.

To obtain more control over the algorithm, the different steps can also be performed separately. First, a *Skin_surface_3* object is created from an iterator range of weighted points and a shrink factor. Optional arguments are a boolean telling whether the input weighted points should be grown in such a way that the skin surface wraps around the input balls instead of the shrunk input balls.

```
template <class SkinSurfaceTraits_3>
Skin_surface_3( WP_iterator begin, WP_iterator end, FT shrink_factor, bool grow_balls = true)
```

The template parameter should implement the *SkinSurfaceTraits_3* concept. The type *WP_iterator*, is an iterator over weighted points as defined by *SkinSurfaceTraits_3* and *FT* is the number type used by the weighted points.

For a shrink factor equal to one the skin surface is the boundary of the union of the input balls. In this case the algorithm used for meshing the skin surface greatly simplifies. These optimizations are implemented in the class *Union_of_balls_3*. The constructor for the union of balls class is similar, except for the missing shrink factor:

```
template <class SkinSurfaceTraits_3>
    Union_of_balls_3( WP_iterator begin, WP_iterator end, bool grow_balls = true)
```

With a model of the concept *SkinSurface_3* it is possible to generate a coarse mesh isotopic to the skin surface. Using the function *mesh_skin_surface_3* with signature:

```
template <class SkinSurface_3, class Polyhedron>
void    mesh_skin_surface_3( SkinSurface_3 skin_surface, Polyhedron &p)
```

The last function takes the (coarse) mesh and subdivides it in-situ by applying a given number of 1-4 split operations (each triangle is split into four sub-triangles) and moving the new vertices towards the skin surface. If the number of iterations is not specified, one subdivision step is done. The object of the *SkinSurface_3* concept used to construct the coarse mesh is needed to move new points on the skin surface.

```
template <class SkinSurface_3, class Polyhedron >
void    subdivide_skin_surface_mesh_3( SkinSurface_3 skinsurface, Polyhedron &p, int iterations=1)
```

36.4 Timings

The timings of the construction of the coarse mesh and the first subdivision are given in seconds and were done on a Pentium 4, 3.5 GHz, with 1 Gb of memory.

Data set	Number of weighted points	Coarse mesh	first subdivision step
Caffeine	23	0.2 sec.	0.05 sec.
Gramicidin A	318	5 sec.	2 sec.

36.5 Example Programs

36.5.1 Meshing a Skin Surface

The following example shows the construction of a coarse mesh of the skin surface using the function *make_skin_surface_mesh_3*. The output is a *CGAL::Polyhedron*.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/make_skin_surface_mesh_3.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_3 Bare_point;
```

```

typedef CGAL::Weighted_point<Bare_point,K::RT>           Weighted_point;
typedef CGAL::Polyhedron_3<K>                             Polyhedron;

int main() {
    std::list<Weighted_point> l;
    double shrinkfactor = 0.5;

    l.push_front(Weighted_point(Bare_point( 1,-1,-1), 1.25));
    l.push_front(Weighted_point(Bare_point( 1, 1, 1), 1.25));
    l.push_front(Weighted_point(Bare_point(-1, 1,-1), 1.25));
    l.push_front(Weighted_point(Bare_point(-1,-1, 1), 1.25));

    Polyhedron p;

    CGAL::make_skin_surface_mesh_3(p, l.begin(), l.end(), shrinkfactor);

    return 0;
}

```

File: examples/Skin_surface_3/skin_surface_simple.cpp

36.5.2 Meshing and Subdividing a Skin Surface

The following example shows the construction of mesh of the skin surface by explicitly performing different steps of the algorithm. It first constructs a *Skin_surface_3* object from an iterator range of weighted points and a shrink factor. From this object, the coarse mesh isotopic to the skin surface is extracted using the function *CGAL::mesh_skin_surface_3*

Next, the coarse mesh is refined to obtain a better approximation. The use of *CGAL::Skin_surface_polyhedral_items_3<Skin_surface_3>* in the *CGAL::Polyhedron* is not necessary, but gives the subdivision a significant speedup.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Skin_surface_3.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/mesh_skin_surface_3.h>
#include <CGAL/subdivide_skin_surface_mesh_3.h>
#include "skin_surface_writer.h"
#include <list>
#include <fstream>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef CGAL::Skin_surface_traits_3<K> Traits;
typedef CGAL::Skin_surface_3<Traits> Skin_surface_3;
typedef Skin_surface_3::FT FT;
typedef Skin_surface_3::Weighted_point Weighted_point;
typedef Weighted_point::Point Bare_point;
typedef CGAL::Polyhedron_3<K,
    CGAL::Skin_surface_polyhedral_items_3<Skin_surface_3> > Polyhedron;

int main() {
    std::list<Weighted_point> l;

```

```

FT                                shrinkfactor = 0.5;

l.push_front(Weighted_point(Bare_point( 1,-1,-1), 1.25));
l.push_front(Weighted_point(Bare_point( 1, 1, 1), 1.25));
l.push_front(Weighted_point(Bare_point(-1, 1,-1), 1.25));
l.push_front(Weighted_point(Bare_point(-1,-1, 1), 1.25));

Polyhedron p;

Skin_surface_3 skin_surface(l.begin(), l.end(), shrinkfactor);
CGAL::mesh_skin_surface_3(skin_surface, p);

CGAL::subdivide_skin_surface_mesh_3(skin_surface, p);

std::ofstream out("mesh.off");
out << p;

return 0;
}

```

3D Skin Surface Meshing

Reference Manual

Nico Kruithof

Skin surfaces form a class of tangent continuous surfaces defined by a set of balls and a scalar called the shrink factor. The skin surface package constructs an triangular mesh isotopic to the skin surface, using the algorithm described in [KV05]. The mesh is stored in a *CGAL::Polyhedron_3*.

SkinSurface_3

Definition

The concept `SkinSurface_3` defines a skin surface and provides an interface for the dedicated skin surface mesher. The concept requires a constructor from an iterator range of weighted points and a shrink factor. By default the input balls are grown in such that the skin surface wraps around the input balls.

Has Models

`CGAL::Skin_surface_3<SkinSurfaceTraits_3>`
`CGAL::Union_of_balls_3<SkinSurfaceTraits_3>`

Types

<code>SkinSurface_3:: Geometric_traits</code>	The geometric traits used for the construction of the regular triangulation.
<code>SkinSurface_3:: Weighted_point</code>	The <code>Weighted_point</code> type defined by the <code>Geometric_traits</code> .
<code>SkinSurface_3:: Bare_point</code>	The <code>Bare_point</code> type defined by the <code>Geometric_traits</code> .
<code>SkinSurface_3:: FT</code>	The <code>FT</code> type defined by the <code>Geometric_traits</code> . This is the number type used by the weighted points.

Creation

`SkinSurface_3 skin(WP_iterator begin, WP_iterator end, RT shrink_factor);`

The mandatory arguments to the constructor are an iterator range `[begin,end)` of weighted points and a shrink factor between 0 and 1.

Operations

`template <class Polyhedron_3>`
`void skin.mesh_skin_surface_3(Polyhedron_3 &p)`

Constructs a coarse mesh in `p`.
Precondition: `Polyhedron_3::HDS` can be used as the template argument of the `Polyhedron_incremental_builder_3<HDS>`.

`template <class Polyhedron_3>`
`void skin.subdivide_skin_surface_mesh_3(Polyhedron_3 &p, int nSubdiv = 1)`

Subdivides the skin surface using `nSubdiv` 1-4 split operations (each triangle is split into four sub-triangles) and the new vertices are moved towards the skin surface.

SkinSurfaceTraits_3

Required types and member functions for the `SkinSurfaceTraits_3` concept. This geometric traits concept is used for the construction of a polyhedral mesh approximating a skin surface `CGAL::skin_surface_3<Traits>`.

Refines

RegularTriangulationTraits_3

Types

<i>SkinSurfaceTraits_3:: RT</i>	The number type.
---------------------------------	------------------

SkinSurfaceTraits_3::Construct_anchor_point_3

A constructor object which provides the following function operator:
Point operator()(const Point ¢er_del, const Point ¢er_vor);
Constructs the anchor point in between the Delaunay and Voronoi centers, i.e., the point $(1 - s) \cdot \text{center_del} + s \cdot \text{center_vor}$, where s is the shrink factor.

Creation

SkinSurfaceTraits_3 traits(RT s=.5);

constructor that takes the shrink factor as argument. For meshing the boundary of the union of a set of balls, the shrink factor is discarded.

Has Models

CGAL::Skin_surface_traits_3<K> page 2219

Operations

The following functions give access to the constructor objects:

<i>Regular_RT</i>	<i>traits.shrink_factor()</i>	Returns the shrink factor.
-------------------	-------------------------------	----------------------------

Construct_anchor_point_3 traits.construct_anchor_point_3_object()

returns a *Construct_anchor_point_3* object.

CGAL::Skin_surface_3<SkinSurfaceTraits_3>

Definition

The *Skin_surface_3<SkinSurfaceTraits_3>* is the main class in the *Skin_surface_3* package. It is a model of the concept *SkinSurface_3*.

The template argument is required to be a model of the concept *SkinSurfaceTraits_3*, which means that it provides predicates to construct a regular triangulation of the weighted points and for point location in the mixed complex.

```
#include <CGAL/Skin_surface_3.h>
```

Is Model for the Concepts

SkinSurface_3

CGAL::Union_of_balls_3<SkinSurfaceTraits_3>

Definition

The *Union_of_balls_3<SkinSurfaceTraits_3>* is used to represent a skin surface with shrink factor equal to one, which is the boundary of the union of the input balls. This case is handled separately since the mixed complex is equal to the power diagram, which has a much simpler structure.

The template argument must be a model of the concept *SkinSurfaceTraits_3*, which means that it provides the predicates to construct a regular triangulation of the weighted points.

```
#include <CGAL/Union_of_balls_3.h>
```

Is Model for the Concepts

SkinSurface_3

CGAL::Skin_surface_traits_3<K>

Definition

The class *Skin_surface_traits_3*<*K*> is designed as a default traits class for the class *Skin_surface_3*<*SkinSurfaceTraits_3*>. It is a model of the *SkinSurfaceTraits_3*.

The template argument *K* must be a model of the *Kernel* concept.

```
#include <CGAL/Skin_surface_traits_3.h>
```

Is Model for the Concepts

SkinSurfaceTraits_3

CGAL::make_skin_surface_mesh_3<Polyhedron_3>

Definition

The function *make_skin_surface_mesh_3<Polyhedron_3>* constructs a mesh isotopic to the skin surface based on the algorithm in [KV05]. It takes as input a range of weighted points and a shrink factor and outputs the mesh in a *Polyhedron_3* object. A number of subdivision steps might be applied to refine the mesh.

```
#include <CGAL/make_skin_surface_mesh_3.h>
```

```
void    mesh_skin_surface_3<Polyhedron_3>( Polyhedron_3 &p,
                                           WP_iterator begin,
                                           WP_iterator end,
                                           double shrink_factor=.5,
                                           int nSubdivisions=0,
                                           bool grow_balls=true)
```

Constructs a mesh of the skin surface defined by the weighted points and the shrink factor.

Precondition: *Polyhedron_3::HDS* can be used as the template argument of the *Polyhedron_incremental_builder_3<HDS>*.

CGAL::mesh_skin_surface_3<SkinSurface_3, Polyhedron_3>

Definition

The function *mesh_skin_surface_3*<*SkinSurface_3*, *Polyhedron_3*> constructs a mesh isotopic to the skin surface based on the algorithm in [KV05]. It takes as input a *SkinSurface_3* object, which is a model of the *SkinSurface_3* concept and outputs the mesh in a *Polyhedron_3* object.

```
#include <CGAL/mesh_skin_surface_3.h>
```

```
void    make_skin_surface_mesh_3<SkinSurface_3, Polyhedron_3>( SkinSurface_3 skin_surface,
                                                                Polyhedron_3 &p)
```

Constructs a mesh of the *skin_surface* in *p*.

Precondition: *SkinSurface_3* is a model of the concept *SkinSurface_3* and *Polyhedron_3::HDS* can be used as the template argument of the *Polyhedron_incremental_builder_3*<*HDS*>.

CGAL::subdivide_skin_surface_mesh_3<SkinSurface_3, Polyhedron_3>

Definition

The function *subdivide_skin_surface_mesh_3*<*SkinSurface_3*, *Polyhedron_3*> subdivides a skin surface mesh constructed by the function *mesh_skin_surface_3*<*SkinSurface_3*, *Polyhedron_3*>.

```
#include <CGAL/subdivide_skin_surface_mesh_3.h>
```

```
void    subdivide_skin_surface_mesh_3<SkinSurface_3,Polyhedron_3>( SkinSurface_3 skin_surface,
                                                                    Polyhedron_3 &p,
                                                                    int nSubdiv = 1)
```

Subdivides the skin surface using *nSubdiv* 1-4 split operations (each triangle is split into four sub-triangles) and the new vertices are moved towards the skin surface.

37.7 The Four Subdivision Methods	2234
37.8 Other Subdivision Methods	2235

37.1 Introduction

Subdivision methods are simple yet powerful ways to generate smooth surfaces from arbitrary polyhedral meshes. Unlike spline-based surfaces (e.g NURBS) or other numeric-based modeling techniques, users of subdivision methods do not need the mathematical knowledge of the subdivision methods. The natural intuition of the geometry suffices to control the subdivision methods.

Subdivision_method_3, designed to work on the class *Polyhedron_3*, aims to be easy to use and to extend. *Subdivision_method_3* is not a class, but a namespace which contains four popular subdivision methods and their refinement functions. These include Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivisions. Variations of these methods can be easily extended by substituting the geometry computation of the refinement host.

37.2 Subdivision Method

In this chapter, we explain some fundamentals of subdivision methods. We focus only on the topics that help you to understand the design of the package. [WW02] has details on subdivision methods. Some terminology introduced in this section will be used again in later sections. If you are only interested in using a specific subdivision method, Section 37.3 gives a quick tutorial on Catmull-Clark subdivision.

A subdivision method recursively refines a coarse mesh and generates an ever closer approximation to a smooth surface. The coarse mesh can have arbitrary shape, but it has to be a 2-manifold. In a 2-manifold, every interior point has a neighborhood homeomorphic to a 2D disk. Subdivision methods on non-manifolds have been developed, but are not considered in *Subdivision_method_3*. The chapter teaser shows the steps of Catmull-Clark subdivision on a CAD model. The coarse mesh is repeatedly refined by a quadrissection pattern, and new points are generated to approximate a smooth surface.

Many refinement patterns are used in practice. *Subdivision_method_3* supports the four most popular patterns, and each of them is used by Catmull-Clark[CC78], Loop, Doo-Sabin and $\sqrt{3}$ subdivision (left to right in the figure). We name these patterns by their topological characteristics instead of the associated subdivision methods. PQQ indicates the *Primal Quadrateral Quadrissection*. PTQ indicates the *Primal Triangle Quadrissection*. DQQ indicates the *Dual Quadrateral Quadrissection*. $\sqrt{3}$ indicates the converging speed of the triangulation toward the subdivision surface.

The figure demonstrates these four refinement patterns on the 1-disk of a valence-5 vertex/facet. Refined meshes are shown below the source meshes. Points on the refined mesh are generated by averaging neighbor points on the source mesh. A graph, called *stencil*, determines the source neighborhood whose points contribute to the position of a refined point. A refinement pattern usually defines more than one stencil. For example, the PQQ refinement has a vertex-node stencil, which defines the 1-ring of an input vertex; an edge-node stencil, which defines the 1-ring of an input edge; and a facet-node stencil, which defines an input facet. The stencils of the PQQ refinement are shown in the following figure. The blue neighborhoods in the top row indicate the corresponding stencils of the refined nodes in red.

Stencils with weights are called *geometry masks*. A subdivision method defines a geometry mask for each stencil, and generates new points by averaging source points weighted by the mask. Geometry masks are carefully chosen to meet requirements of certain surface smoothness and shape quality. The geometry masks of Catmull-Clark subdivision are shown below.

The weights shown here are unnormalized, and n is the valence of the vertex. The generated point, in red, is computed by a summation of the weighted points. For example, a Catmull-Clark facet-node is computed by the summation of $1/4$ of each point on its stencil.

A stencil can have an unlimited number of geometry masks. For example, a facet-node of PQQ refinement may be computed by the summation of $1/5$ of each stencil node instead of $1/4$. Although it is legal in *Subdivision_method_3* to have any kind of geometry mask, the result surfaces may be odd, not smooth, or not even exist. [WW02] explains the details on designing masks for a quality subdivision surface.

37.3 A Quick Example: Catmull-Clark Subdivision

Assuming you are familiar with *Polyhedron_3*, you can integrate *Subdivision_method_3* into your program without much effort.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Subdivision_method_3.h>
#include <iostream>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;

using namespace std;
using namespace CGAL;
```

```

int main(int argc, char** argv) {
    if (argc != 2) {
        cout << "Usage: CatmullClark_subdivision d < filename" << endl;
        cout << "          d: the depth of the subdivision (0 < d < 10)" << endl;
        cout << "          filename: the input mesh (.off)" << endl;
        return 0;
    }

    int d = argv[1][0] - '0';

    Polyhedron P;
    cin >> P; // read the .off

    Subdivision_method_3::CatmullClark_subdivision(P,d);

    cout << P; // write the .off

    return 0;
}

```

File: examples/Subdivision_method_3/CatmullClark_subdivision.cpp

This example demonstrates the use of the Catmull-Clark subdivision method on a *Polyhedron_3*. The polyhedron is restricted in the Cartesian space, where most subdivision applications are designed to work. There is only one line deserving a detailed explanation:

```
Subdivision_method_3::CatmullClark_subdivision(P,d);
```

Subdivision_method_3 specifies the namespace of our subdivision functions. *CatmullClark_subdivision(P,d)* computes the Catmull-Clark subdivision surface of the polyhedron *P* after *d* iterations of the refinements. The polyhedron *P* is passed by reference, and is modified (i.e. subdivided) by the subdivision function.

This example shows how to subdivide a simple *Polyhedron_3* with *Subdivision_method_3*. An application-defined polyhedron might use a specialized kernel and/or a specialized internal container. There are two major restrictions on the application-defined polyhedron to work with *Subdivision_method_3*.

- *Point_3* is type-defined by the kernel. Without *Point_3* and the associated operations being defined, *Subdivision_method_3* can not know how to compute and store the new vertex points.
- The primitives (such as vertices, halfedges and facets) in the internal container are sequentially ordered (e.g. *std::vector* and *std::list*). This implies that the iterators traverse the primitives in the order of their creations/insertions.

Section 37.5 gives detailed explanations on those two restrictions.

37.4 Catmull-Clark Subdivision

Subdivision_method_3 is designed to allow customization of the subdivision methods. This section explains the implementation of the Catmull-Clark subdivision function in *Subdivision_method_3*. The implementation demonstrates the customization of the PQQ refinement to Catmull-Clark subdivision.

When a subdivision method is developed, a refinement pattern is chosen, and then a set of geometry masks are developed to position the new points. There are three key components to implement a subdivision method:

- a mesh data structure that can represent arbitrary 2-manifolds,
- a process that refines the mesh data structure,
- and the geometry masks that compute the new points.

E. Catmull and J. Clark picked the PQQ refinement for their subdivision method, and developed a set of geometry masks to generate (or more precisely, to approximate) the B-spline surface from the control mesh. *Subdivision_method_3* provides a function that glues all three components of the Catmull-Clark subdivision method.

```
template <class Polyhedron_3, template <typename> class Mask>
void PQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int depth)
```

Polyhedron_3 is a generic mesh data structure for arbitrary 2-manifolds. *PQQ()*, which refines the control mesh *p*, is a *refinement host* that uses a policy class *Mask<Polyhedron_3>* as part of its geometry computation. During the refinement, *PQQ()* computes and assigns new points by cooperating with the *mask*. To implement Catmull-Clark subdivision, *Mask*, the *geometry policy*, has to realize the geometry masks of Catmull-Clark subdivision. *depth* specifies the iterations of the refinement on the control mesh.

To implement the geometry masks, we need to know how a refinement host communicates with its geometry masks. The PQQ refinement defines three stencils, and hence three geometry masks are required for Catmull-Clark subdivision. The following class defines the interfaces of the stencils for the PQQ refinement.

```
template <class Polyhedron_3>
class PQQ_stencil_3 {
    void facet_node(Facet_handle facet, Point_3& pt);
    void edge_node(Halfedge_handle edge, Point_3& pt);
    void vertex_node(Vertex_handle vertex, Point_3& pt);
};
```

Each class function in *PQQ_stencil_3* computes a new point based on the neighborhood of the primitive handle, and assigns the new point to *Point_3& pt*.

We realize each class function with the geometry masks of Catmull-Clark subdivision.

```
template <class Polyhedron_3>
class CatmullClark_mask_3 {
    void facet_node(Facet_handle facet, Point_3& pt) {
        Halfedge_around_facet_circulator hcir = facet->facet_begin();
        int n = 0;
        Point_3 p(0,0,0);
        do {
            p = p + (hcir->vertex()->point() - ORIGIN);
            ++n;
        } while (++hcir != facet->facet_begin());
        pt = ORIGIN + (p - ORIGIN)/FT(n);
    }
};
```

```

void edge_node(Halfedge_handle edge, Point_3& pt) {
    Point_3 p1 = edge->vertex()->point();
    Point_3 p2 = edge->opposite()->vertex()->point();
    Point_3 f1, f2;
    facet_node(edge->facet(), f1);
    facet_node(edge->opposite()->facet(), f2);
    pt = Point_3((p1[0]+p2[0]+f1[0]+f2[0])/4,
                 (p1[1]+p2[1]+f1[1]+f2[1])/4,
                 (p1[2]+p2[2]+f1[2]+f2[2])/4 );
}

void vertex_node(Vertex_handle vertex, Point_3& pt) {
    Halfedge_around_vertex_circulator vcir = vertex->vertex_begin();
    int n = circulator_size(vcir);

    FT Q[] = {0.0, 0.0, 0.0}, R[] = {0.0, 0.0, 0.0};
    Point_3& S = vertex->point();

    Point_3 q;
    for (int i = 0; i < n; i++, ++vcir) {
        Point_3& p2 = vcir->opposite()->vertex()->point();
        R[0] += (S[0]+p2[0])/2;
        R[1] += (S[1]+p2[1])/2;
        R[2] += (S[2]+p2[2])/2;
        facet_node(vcir->facet(), q);
        Q[0] += q[0];
        Q[1] += q[1];
        Q[2] += q[2];
    }
    R[0] /= n;    R[1] /= n;    R[2] /= n;
    Q[0] /= n;    Q[1] /= n;    Q[2] /= n;

    pt = Point_3((Q[0] + 2*R[0] + S[0]*(n-3))/n,
                 (Q[1] + 2*R[1] + S[1]*(n-3))/n,
                 (Q[2] + 2*R[2] + S[2]*(n-3))/n );
}
};

```

This example shows the default implementation of Catmull-Clark masks in *Subdivision_method_3*. This default implementation assumes the *types* (such as *Point_3* and *Facet_handle*) are defined within *Polyhedron_3*. *CatmullClark_mask_3* is designed to work on a *Polyhedron_3* with the *Cartesian* kernel. You may need to rewrite the geometry computation to match the kernel geometry of your application.

To invoke the Catmull-Clark subdivision method, we call *PQQ()* with the Catmull-Clark masks we just defined.

```
PQQ(p, CatmullClark_mask_3<Polyhedron_3>(), depth);
```

Loop, Doo-Sabin and $\sqrt{3}$ subdivisions are implemented in the similar process: pick a refinement host and implement the geometry policy. The key of developing your own subdivision method is implementing the right combination of the refinement host and the geometry policy. It is explained in the next two sections.

37.5 Refinement Host

A refinement host is a template function of a polyhedron class and a geometry mask class. It refines the input polyhedron, and computes new points through the geometry masks. *Subdivision_method_3* supports four refinement hosts: primal quadrilateral quadrisection (PQQ), primal triangle quadrisection (PTQ), dual quadrilateral quadrisection (DQQ) and $\sqrt{3}$ triangulation. Respectively, they are used by Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivision.

```
namespace Subdivision_method_3 {
    template <class Polyhedron_3, template <typename> class Mask>
    void PQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step);

    template <class Polyhedron_3, template <typename> class Mask>
    void PTQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step);

    template <class Polyhedron_3, template <typename> class Mask>
    void DQQ(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step);

    template <class Polyhedron_3, template <typename> class Mask>
    void Sqrt3(Polyhedron_3& p, Mask<Polyhedron_3> mask, int step)
}
```

The polyhedron class is a specialization of *Polyhedron_3*, and the mask is a policy class realizing the geometry masks of the subdivision method.

A refinement host refines the input polyhedron, maintains the stencils (i.e., the mapping between the control mesh and the refined mesh), and calls the geometry masks to compute the new points. In *Subdivision_method_3*, refinements are implemented as a sequence of connectivity operations (mainly Euler operations). The order of the connectivity operations plays a key role when maintaining stencils. By matching the order of the source submeshes to the refined vertices, no flag in the primitives is required to register the stencils. It avoids the data dependency of the refinement host on the polyhedron class. To make the ordering trick work, the polyhedron class must have a sequential container, such as a vector or a linked-list, as the internal storage. A sequential container guarantees that the iterators of the polyhedron always traverse the primitives in the order of their insertions. Non-sequential structures such as trees or maps do not provide the required ordering, and hence can not be used with *Subdivision_method_3*.

Although *Subdivision_method_3* does not require flags to support the refinements and the stencils, it still needs to know how to compute and store the geometry data (i.e. the points). *Subdivision_method_3* expects that the typename *Point_3* is defined in the geometry kernel of the polyhedron (i.e. the *Polyhedron_3::Traits::Kernel*).

A point of the type *Point_3* is returned by the geometry policy and is then assigned to the new vertex. The geometry policy is explained in next section.

Refinement hosts *PQQ* and *DQQ* work on a general polyhedron, and *PTQ* and *Sqrt3* work on a triangulated polyhedron. The result of *PTQ* and *Sqrt3* on a non-triangulated polyhedron is undefined. *Subdivision_method_3* does not verify the precondition of the mesh characteristics before the refinement.

For details of the refinement implementation, interested users should refer to [SP05].

37.6 Geometry Policy

A geometry policy defines a set of geometry masks. Each geometry mask is realized as a member function that computes new points of the subdivision surface.

Each geometry mask receives a primitive handle (e.g. *Halfedge_handle*) of the control mesh, and returns a *Point_3* to the subdivided vertex. The function collects the vertex neighbors of the primitive handle (i.e. nodes on the stencil), and computes the new point based on the neighbors and the mask (i.e. the stencil weights).

This figure shows the geometry masks of Catmull-Clark subdivision. The weights shown here are unnormalized, and n is the valence of the vertex. The new points are computed by the summation of the weighted points on their stencils. Following codes show an implementation of the geometry mask of the facet-node. The complete listing of a Catmull-Clark geometry policy is in the Section 37.4.

```
template <class Polyhedron_3>
class CatmullClark_mask_3 {
    void facet_node(Facet_handle facet, Point_3& pt) {
        Halfedge_around_facet_circulator hcir = facet->facet_begin();
        int n = 0;
        Point_3 p(0,0,0);
        do {
            p = p + (hcir->vertex()->point() - ORIGIN);
            ++n;
        } while (++hcir != facet->facet_begin());
        pt = ORIGIN + (p - ORIGIN)/FT(n);
    }
}
```

In this example, the computation is based on the assumption that the *Point_3* is the *CGAL::Point_3*. It is an assumption, but not a restriction. You are allowed to use any point class as long as it is defined as the *Point_3* in your polyhedron. You may need to modify the geometry policy to support the computation and the assignment of the specialized point. This extension is not unusual in graphics applications. For example, you might want to subdivide the texture coordinates for your subdivision surface.

The refinement host of Catmull-Clark subdivision requires three geometry masks for polyhedrons without open boundaries: a vertex-node mask, an edge-node mask, and a facet-node mask. To support polyhedrons with boundaries, a border-node mask is also required. The border-node mask for Catmull-Clark subdivision is listed below, where *ept* returns the new point splitting *edge* and *vpt* returns the new point on the vertex pointed by *edge*.

```
void border_node(Halfedge_handle edge, Point_3& ept, Point_3& vpt) {
    Point_3& ep1 = edge->vertex()->point();
    Point_3& ep2 = edge->opposite()->vertex()->point();
    ept = Point_3((ep1[0]+ep2[0])/2, (ep1[1]+ep2[1])/2, (ep1[2]+ep2[2])/2);

    Halfedge_around_vertex_circulator vcir = edge->vertex_begin();
    Point_3& vp1 = vcir->opposite()->vertex()->point();
    Point_3& vp0 = vcir->vertex()->point();
    Point_3& vp_1 = (--vcir)->opposite()->vertex()->point();
    vpt = Point_3((vp_1[0] + 6*vp0[0] + vp1[0])/8,
                  (vp_1[1] + 6*vp0[1] + vp1[1])/8,
                  (vp_1[2] + 6*vp0[2] + vp1[2])/8 );
}
```

The mask interfaces of all four refinement hosts are listed below. *DQQ_stencil_3* and *Sqrt3_stencil_3* do not have the border-node stencil because the refinement hosts of DQQ and $\sqrt{3}$ refinements do not support global boundaries in the current release. This might be changed in the future releases.

```
template <class Polyhedron_3>
class PQQ_stencil_3 {
    void facet_node(Facet_handle, Point_3&);
    void edge_node(Halfedge_handle, Point_3&);
    void vertex_node(Vertex_handle, Point_3&);

    void border_node(Halfedge_handle, Point_3&, Point_3&);
};
```

```
template <class Polyhedron_3>
class PTQ_stencil_3 {
    void edge_node(Halfedge_handle, Point_3&);
    void vertex_node(Vertex_handle, Point_3&);

    void border_node(Halfedge_handle, Point_3&, Point_3&);
};
```

```
template <class Polyhedron_3>
class DQQ_stencil_3 {
public:
    void corner_node(Halfedge_handle edge, Point_3& pt);
};
```

```
template <class Polyhedron_3>
class Sqrt3_stencil_3 {
public:
    void vertex_node(Vertex_handle vertex, Point_3& pt);
};
```

The source codes of *CatmullClark_mask_3*, *Loop_mask_3*, *DooSabin_mask_3*, and *Sqrt3_mask_3* are the best sources of learning these stencil interfaces.

37.7 The Four Subdivision Methods

Subdivision_method_3 supports Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivisions by specializing their respective refinement hosts. They are designed to work on a *Polyhedron_3*. If your application uses a polyhedron with a specialized geometry kernel, you need to specialize the refinement host with a geometry policy based on that kernel.

```
namespace Subdivision_method_3 {
    template <class Polyhedron_3>
    void CatmullClark_subdivision(Polyhedron_3& p, int step = 1) {
        PQQ(p, CatmullClark_mask_3<Polyhedron_3>(), step);
    }

    template <class Polyhedron_3>
    void Loop_subdivision(Polyhedron_3& p, int step = 1) {
        PTQ(p, Loop_mask_3<Polyhedron_3>(), step);
    }

    template <class Polyhedron_3>
    void DooSabin_subdivision(Polyhedron_3& p, int step = 1) {
        DQQ(p, DooSabin_mask_3<Polyhedron_3>(), step);
    }

    template <class Polyhedron_3>
    void Sqrt3_subdivision(Polyhedron_3& p, int step = 1) {
        Sqrt3(p, Sqrt3_mask_3<Polyhedron_3>(), step);
    }
}
```

The following example demonstrates the use of Doo-Sabin subdivision on a polyhedral mesh.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Subdivision_method_3.h>

#include <iostream>

#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel>      Polyhedron;

using namespace std;
using namespace CGAL;

int main(int argc, char **argv) {
    if (argc != 2) {
```

```

    cout << "Usage: DooSabin_subdivision d < filename" << endl;
    cout << "          d: the depth of the subdivision (0 < d < 10)" << endl;
    cout << "          filename: the input mesh (.off)" << endl;
    return 0;
}

int d = argv[1][0] - '0';

Polyhedron P;
cin >> P; // read the .off

Subdivision_method_3::DooSabin_subdivision(P,d);

cout << P; // write the .off

return 0;
}

```

File: examples/Subdivision_method_3/DooSabin_subdivision.cpp

37.8 Other Subdivision Methods

Subdivision_method_3 supports four practical subdivision methods on a Cartesian *Polyhedron_3*. More subdivision methods can be supported through the specialization of refinement hosts with custom geometry masks. The following example develops a subdivision method generating an improved Loop subdivision surface.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Subdivision_method_3.h>

#include <cstdio>
#include <iostream>

#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel>      Polyhedron;

using namespace std;
using namespace CGAL;

// =====
template <class Poly>
class WLoop_mask_3 {
    typedef Poly                                Polyhedron;

    typedef typename Polyhedron::Vertex_iterator    Vertex_iterator;
    typedef typename Polyhedron::Halfedge_iterator  Halfedge_iterator;
    typedef typename Polyhedron::Facet_iterator     Facet_iterator;

    typedef typename Polyhedron::Halfedge_around_facet_circulator

```

```

Halfedge_around_facet_circulator;
typedef typename Polyhedron::Halfedge_around_vertex_circulator
Halfedge_around_vertex_circulator;

typedef typename Polyhedron::Traits Traits;
typedef typename Traits::Kernel Kernel;

typedef typename Kernel::FT FT;
typedef typename Kernel::Point_3 Point;
typedef typename Kernel::Vector_3 Vector;

public:
void edge_node(Halfedge_iterator eitr, Point& pt) {
    Point& p1 = eitr->vertex()->point();
    Point& p2 = eitr->opposite()->vertex()->point();
    Point& f1 = eitr->next()->vertex()->point();
    Point& f2 = eitr->opposite()->next()->vertex()->point();

    pt = Point((3*(p1[0]+p2[0])+f1[0]+f2[0])/8,
               (3*(p1[1]+p2[1])+f1[1]+f2[1])/8,
               (3*(p1[2]+p2[2])+f1[2]+f2[2])/8 ));
}
void vertex_node(Vertex_iterator vitr, Point& pt) {
    float R[] = {0.0, 0.0, 0.0};
    Point& S = vitr->point();

    Halfedge_around_vertex_circulator vcir = vitr->vertex_begin();
    int n = circulator_size(vcir);
    for (int i = 0; i < n; i++, ++vcir) {
        Point& p = vcir->opposite()->vertex()->point();
        R[0] += p[0]; R[1] += p[1]; R[2] += p[2];
    }
    if (n == 6) {
        pt = Point((10*S[0]+R[0])/16, (10*S[1]+R[1])/16, (10*S[2]+R[2])/16);
    } else if (n == 3) {
        double B = (5.0/8.0 - std::sqrt(3+2*std::cos(6.283/n)))/64.0/n;
        double A = 1-n*B;
        pt = Point((A*S[0]+B*R[0]), (A*S[1]+B*R[1]), (A*S[2]+B*R[2]));
    } else {
        double B = 3.0/8.0/n;
        double A = 1-n*B;
        pt = Point((A*S[0]+B*R[0]), (A*S[1]+B*R[1]), (A*S[2]+B*R[2]));
    }
}
void border_node(Halfedge_iterator eitr, Point& ept, Point& vpt) {
    Point& ep1 = eitr->vertex()->point();
    Point& ep2 = eitr->opposite()->vertex()->point();
    ept = Point((ep1[0]+ep2[0])/2, (ep1[1]+ep2[1])/2, (ep1[2]+ep2[2])/2);

    Halfedge_around_vertex_circulator vcir = eitr->vertex_begin();
    Point& vp1 = vcir->opposite()->vertex()->point();
    Point& vp0 = vcir->vertex()->point();
    Point& vp_1 = (--vcir)->opposite()->vertex()->point();
    vpt = Point((vp_1[0] + 6*vp0[0] + vp1[0])/8,

```

```

        (vp_1[1] + 6*vp0[1] + vp1[1])/8,
        (vp_1[2] + 6*vp0[2] + vp1[2])/8 );
    }
};

int main(int argc, char **argv) {
    if (argc != 2) {
        cout << "Usage: Customized_subdivision d < filename" << endl;
        cout << "        d: the depth of the subdivision (0 < d < 10)" << endl;
        cout << "        filename: the input mesh (.off)" << endl;
        return 0;
    }

    int d = argv[1][0] - '0';

    Polyhedron P;
    cin >> P; // read the .off

    Subdivision_method_3::PTQ(P, WLoop_mask_3<Polyhedron>(), d);

    cout << P; // write the .off

    return 0;
}

```

File: examples/Subdivision_method_3/Customized_subdivision.cpp

The points generated by the geometry mask are semantically required to converge to a smooth surface. This is the requirement imposed by the theory of the subdivision surface. *Subdivision_method_3* does not enforce this requirement, nor will it verify the smoothness of the subdivided mesh. *Subdivision_method_3* guarantees the topological properties of the subdivided mesh. A genus- n 2-manifold is assured to be subdivided into a genus- n 2-manifold. But when specialized with ill-designed geometry masks, *Subdivision_method_3* may generate a surface that is odd, not smooth, or not even exist.

3D Surface Subdivision Methods

Reference Manual

Le-Jeng Andy Shiue

Subdivision methods recursively refine the control mesh (i.e. the input mesh) and generate points approximating the limit surface. Designed to work on the class *Polyhedron_3*, *Subdivision_method_3* aims to be easy to use and to extend. *Subdivision_method_3* is not a class, but a namespace which consists of four popular subdivision methods and their refinement hosts. Supported subdivision methods include Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivisions. Their respective refinement hosts are PQQ, PTQ, DQQ and $\sqrt{3}$ refinements. Variations of those methods can be easily extended by substituting the geometry computation of the refinement host.

CGAL::Subdivision_method_3

Definition

A subdivision method recursively refines a coarse mesh and generates an ever closer approximation to a smooth surface. *Subdivision_method_3* consists of four subdivision methods and their refinement hosts. Each refinement host is a template function of a polyhedron class and a geometry policy class. It refines the connectivity of the control mesh and computes the geometry of the refined mesh. The geometry computation is dedicated to the custom geometry policy. A geometry policy consists of functions that compute the new point based on the subdivision stencil. A stencil defines the footprint (a submesh of the control mesh) of a new point.

The four supported refinement hosts are the primal quadrilateral quadrissection (PQQ), the primal triangle quadri-section (PTQ), the dual quadrilateral quadrissection (DQQ), and the $\sqrt{3}$ triangulation. These refinements are respectively used in Catmull-Clark, Loop, Doo-Sabin and $\sqrt{3}$ subdivision.

```
#include <CGAL/Subdivision_method_3.h>
```

Refinement Host

A refinement host is a template function of a polyhedron class and a geometry mask class. It refines the input polyhedron, and computes new points through the geometry masks. *Subdivision_method_3* supports four refinement hosts: *PQQ*, *PTQ*, *DQQ* and *Sqrt3*.

```
template <class Polyhedron_3, template <typename> class Mask>
void PQQ( Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)
```

applies the PQQ refinement on the control mesh *p* *step* times. The geometry of the refined mesh is computed by the geometry policy *mask*. This function overwrites the control mesh *p* with the refined mesh.

```
template <class Polyhedron_3, template <typename> class Mask>
void PTQ( Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)
```

applies the PTQ refinement on the control mesh *p* *step* times, where *p* contains only triangle facets. The geometry of the refined mesh is computed by the geometry policy *mask*. This function overwrites the control mesh *p* with the refined mesh. The result of a non-triangle mesh *p* is undefined.

```
template <class Polyhedron_3, template <typename> class Mask>
void DQQ( Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)
```

applies the DQQ refinement on the control mesh p $step$ times. The geometry of the refined mesh is computed by the geometry policy $mask$. This function overwrites the control mesh p with the refined mesh.

```
template <class Polyhedron_3, template <typename> class Mask>
void Sqrt3( Polyhedron_3& p, Mask<Polyhedron_3> mask, int step = 1)
```

applies the $\sqrt{3}$ triangulation on the control mesh p $step$ times, where p contains only triangle facets. The geometry of the refined mesh is computed by the geometry policy $mask$. This function overwrites the control mesh p with the refined mesh. The result of a non-triangle mesh p is undefined.

Subdivision Method

```
template <class Polyhedron_3>
void CatmullClark_subdivision( Polyhedron_3& p, int step = 1)
```

applies Catmull-Clark subdivision $step$ times on the control mesh p . This function overwrites the control mesh p with the subdivided mesh.

```
template <class Polyhedron_3>
void Loop_subdivision( Polyhedron_3& p, int step = 1)
```

applies Loop subdivision $step$ times on the control mesh p . This function overwrites the control mesh p with the subdivided mesh.

```
template <class Polyhedron_3>
void DooSabin_subdivision( Polyhedron_3& p, int step = 1)
```

applies Doo-Sabin subdivision $step$ times on the control mesh p . This function overwrites the control mesh p with the subdivided mesh.

```
template <class Polyhedron_3>
void Sqrt3_subdivision( Polyhedron_3& p, int step = 1)
```

applies $\sqrt{3}$ subdivision $step$ times on the control mesh p . This function overwrites the control mesh p with the subdivided mesh.

Example

This example program subdivides a polyhedral mesh with Catmull-Clark subdivision.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Subdivision_method_3.h>
#include <iostream>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

typedef CGAL::Cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel>      Polyhedron;

using namespace std;
using namespace CGAL;

int main(int argc, char** argv) {
    if (argc != 2) {
        cout << "Usage: CatmullClark_subdivision d < filename" << endl;
        cout << "          d: the depth of the subdivision (0 < d < 10)" << endl;
        cout << "          filename: the input mesh (.off)" << endl;
        return 0;
    }

    int d = argv[1][0] - '0';

    Polyhedron P;
    cin >> P; // read the .off

    Subdivision_method_3::CatmullClark_subdivision(P,d);

    cout << P; // write the .off

    return 0;
}
```

PQQMask_3

Required member functions for the PQQMask_3 concept. This policy concept of geometric computations is used in `CGAL::Subdivision_method_3::PQQ<Polyhedron_3, Mask>`.

Operations

`void mask.facet_node(Facet_handle facet, Point_3& pt)`

computes the facet-point pt based on the neighborhood of the facet f .

`void mask.edge_node(Edge_handle e, Point_3& pt)`

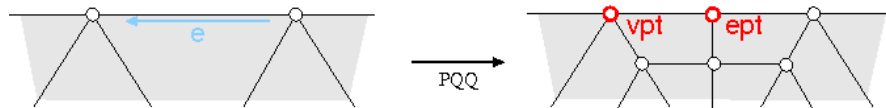

computes the edge-point pt based on the neighborhood of the edge e .

`void mask.vertex_node(Vertex_handle v, Point_3& pt)`

computes the vertex-point pt based on the neighborhood of the vertex v .

`void mask.border_node(Halfedge_handle e, Point_3& ept, Point_3& vpt)`

computes the edge-point ept and the vertex-point vpt based on the neighborhood of the border edge e .

Has Models

`CGAL::CatmullClark_mask_3<Polyhedron_3>` page [2248](#)

CGAL::CatmullClark_mask_3<Polyhedron_3>

Definition

A stencil determines a source neighborhood whose points contribute to the position of a refined point. The geometry mask of a stencil specifies the computation on the nodes of the stencil. *CatmullClark_mask_3<Polyhedron_3>* implements the geometry masks of Catmull-Clark subdivision on a *Polyhedron_3<Cartesian>*.

```
#include <CGAL/Subdivision_mask_3.h>
```

Parameters

The full template declaration of *CatmullClark_mask_3<Polyhedron_3>* states one template parameter:

```
template < class Polyhedron_3> class CatmullClark_mask_3;
```

The only parameter requires a *Polyhedron_3* as the argument. The *Polyhedron_3* should be specialized with the *Cartesian* kernel, which defines the *Point_3* for the vertices.

Creation

```
CatmullClark_mask_3<Polyhedron_3> CC;      default constructor.
```

Stencil functions

```
void CC.facet_node( Facet_handle f, Point_3& pt)
```

computes the Catmull-Clark facet-point *pt* of the facet *f*.

```
void CC.edge_node( Edge_handle e, Point_3& pt)
```

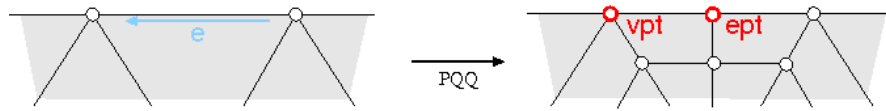

computes the Catmull-Clark edge-point *pt* of the edge *e*.

```
void CC.vertex_node( Vertex_handle v, Point_3& pt)
```

computes the Catmull-Clark vertex-point *pt* of the vertex *v*.

```
void CC.border_node( Halfedge_handle e, Point_3& ept, Point_3& vpt)
```

computes the Catmull-Clark edge-point *ept* and the Catmull-Clark vertex-point *vpt* of the border edge *e*.

CGAL::Loop_mask_3<Polyhedron_3>

Definition

A stencil determines a source neighborhood whose points contribute to the position of a refined point. The geometry mask of a stencil specifies the computation on the nodes of the stencil. *Loop_mask_3<Polyhedron_3>* implements the geometry masks of Loop subdivision on a triangulated *Polyhedron_3<Cartesian>*.

```
#include <CGAL/Subdivision_mask_3.h>
```

Parameters

The full template declaration of *Loop_mask_3<Polyhedron_3>* states one template parameter:

```
template < class Polyhedron_3> class Loop_mask_3;
```

The only parameter requires a *Polyhedron_3* as the argument. The *Polyhedron_3* should be specialized with the *Cartesian* kernel, which defines the *Point_3* for the vertices.

Creation

```
Loop_mask_3<Polyhedron_3> L;           default constructor.
```

Stencil functions

```
void L.edge_node( Edge_handle e, Point_3& pt)
```

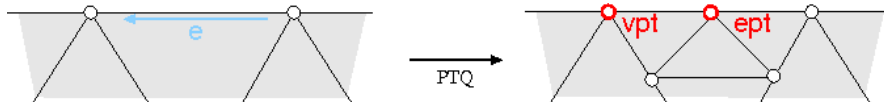

computes the Loop edge-point *pt* of the edge *e*.

```
void L.vertex_node( Vertex_handle v, Point_3& pt)
```

computes the Loop vertex-point *pt* of the vertex *v*.

```
void L.border_node( Halfedge_handle e, Point_3& ept, Point_3& vpt)
```

computes the Loop edge-point *ept* and the Loop vertex-point *vpt* of the border edge *e*.

38.1 Introduction

Surface mesh simplification is the process of reducing the number of faces used in the surface while keeping the overall shape, volume and boundaries preserved as much as possible. It is the opposite of subdivision.

The algorithm presented here can simplify any *oriented 2-manifold surface*, with any number of connected components, with or without boundaries (border or holes) and handles (arbitrary genus), using a method known as *edge collapse*. Roughly speaking, the method consists of iteratively replacing an edge with a single vertex, removing 2 triangles per collapse.

Edges are collapsed according to a priority given by a user-supplied *cost* function, and the coordinates of the replacing vertex are determined by another user-supplied *placement* function. The algorithm terminates when a user-supplied *stop predicate* is met, such as reaching the desired number of edges.

The algorithm implemented here is generic in the sense that it does not require the surface to be of a particular type. Instead, it defines the concept of a *EdgeCollapsibleMesh*, which presents the surface as being a halfedge data structure, and any surface that is a model of that concept can be simplified. The concept is defined not in terms of a monolithic class, but in terms of a set of functions and traits, making it easy to adapt any concrete surface type, even if it is not a halfedge data structure at all. In particular, the concept definition follows the design of the [Boost Graph Library \(BGL\)](#) [SLL02].

The design is *policy-based* (http://en.wikipedia.org/wiki/Policy-based_design), meaning that you can customize some aspects of the process by passing a set of *policy objects*. Each policy object specifies a particular aspect of the algorithm, such as how edges are selected and where the replacement vertex is placed. All policies have a sensible default. Furthermore, the API uses the so-called *named-parameters* technique which allows you to pass only the relevant parameters, in any order, omitting those parameters whose default is appropriate.

38.2 Overview of the Simplification Process

The free function that implements the simplification algorithm takes not only the surface and the desired stop predicate but a number of additional parameters which control and monitor the simplification process. This section briefly describes the process in order to set the background for the discussion of the parameters to the algorithm.

There are two slightly different "edge" collapse operations. One is known as *edge-collapse* while the other is known as *halfedge-collapse*. Given an edge 'e' joining vertices 'w' and 'v', the edge-collapse operation replaces 'e', 'w' and 'v' for a new vertex 'r', while the halfedge-collapse operation pulls 'v' into 'w', disappearing 'e' and leaving 'w' in place. In both cases the operation removes the edge 'e' along with the 2 triangles adjacent to it.

This package uses the halfedge-collapse operation, which is implemented by removing, additionally, 1 vertex ('v') and 2 edges, one per adjacent triangle. It optionally moves the remaining vertex ('w') into a new position, called *placement*, in which case the net effect is the same as in the edge-collapse operation.

Naturally, the surface that results from an edge collapse deviates from the initial surface by some amount, and since the goal of simplification is to reduce the number of triangles while retaining the overall look of the surface as much as possible, it is necessary to measure such a deviation. Some methods attempt to measure the total deviation from the initial surface to the completely simplified surface, for example, by tracking an accumulated error while keeping a history of the simplification changes. Other methods, like the one implemented in this package, attempt to measure only the *cost* of each individual edge collapse (the local deviation introduced by a single simplification step) and plan the entire process as a sequence of steps of increasing cost.

Global error tracking methods produce highly accurate simplifications but take up a lot of additional space. Cost-driven methods, like the one in this package, produce slightly less accurate simplifications but take up much less additional space, even none in some cases.

The cost-driven method implemented in this package is mainly based on [LT98, LT99], with contributions from [HDD⁺93], [GH97] and [DEGN99].

The algorithm proceeds in two stages. In the first stage, called *collection stage*, an initial *collapse cost* is assigned to each and every edge in the surface. Then in the second stage, called *collapsing stage*, edges are processed in order of increasing cost. Some processed edges are collapsed while some are just discarded. Collapsed edges are replaced by a vertex and the collapse cost of all the edges now incident on the replacement vertex is recalculated, affecting the order of the remaining unprocessed edges.

Not all edges selected for processing are collapsed. A processed edge can be discarded right away, without being collapsed, if it doesn't satisfy certain topological and geometric conditions.

The algorithm presented in [GH97] contracts (collapses) arbitrary vertex pairs and not only edges by considering certain vertex pairs as forming a pseudo-edge and proceeding to collapse both edges and pseudo-edges in the same way as in [LT98, LT99] (which is the algorithm implemented here). However, contracting an arbitrary vertex-pair may result in a non-manifold surface, but the current state of this package can only deal with manifold surfaces, thus, it can only collapse edges. That is, this package cannot be used as a framework for vertex contraction.

38.3 Cost Strategy

The specific way in which the collapse cost and vertex placement is calculated is called the *cost strategy*. The user can choose different strategies in the form of policies and related parameters, passed to the algorithm.

The current version of the package provides a set of policies implementing two strategies: the Lindstrom-Turk strategy, which is the default, and a strategy consisting of an edge-length cost with an optional midpoint placement (much faster but less accurate).

38.3.1 Lindstrom-Turk Cost and Placement Strategy

The main characteristic of the strategy presented in [LT98, LT99] is that the simplified surface is not compared at each step with the original surface (or the surface at a previous step) so there is no need to keep extra information, such as the original surface or a history of the local changes. Hence the name *memoryless* simplification.

At each step, all remaining edges are potential candidates for collapsing and the one with the lowest cost is selected.

The cost of collapsing an edge is given by the position chosen for the vertex that replaces it.

The replacement vertex position is computed as the solution to a system of 3 linearly-independent linear equality constraints. Each constraint is obtained by minimizing a quadratic objective function subject to the previously computed constraints.

There are several possible candidate constraints and each is considered in order of importance. A candidate constraint might be *incompatible* with the previously accepted constraints, in which case it is rejected and the next constraint is considered.

Once 3 constraints have been accepted, the system is solved for the vertex position.

The first constraints considered preserves the shape of the surface boundaries (in case the edge profile has boundary edges). The next constraints preserve the total volume of the surface. The next constraints, if needed, optimize the local changes in volume and boundary shape. Lastly, if a constraint is still needed (because the ones previously computed were incompatible), a third (and last) constraint is added to favor equilateral triangles over elongated triangles.

The cost is then a weighted sum of the shape, volume and boundary optimization terms, where the user specifies the unit *weighting unit factor* for each term.

The local changes are computed independently for each edge using only the triangles currently adjacent to it at the time when the edge is about to be collapsed, that is, after all previous collapses. Thus, the transitive path of minimal local changes yields at the end a global change reasonably close to the absolute minimum.

38.3.2 Cost Strategy Policies

The cost strategy used by the algorithm is selected by means of two policies: *GetPlacement* and *GetCost*.

The *GetPlacement* policy is called to compute the new position for the remaining vertex after the halfedge-collapse. It returns an optional value, which can be absent, in which case the remaining vertex is kept in its place.

The *GetCost* policy is called to compute the cost of collapsing an edge. This policy uses the placement to compute the cost (which is an error measure) and determines the ordering of the edges.

The algorithm maintains an internal data structure (a mutable priority queue) which allows each edge to be processed in increasing cost order. Such a data structure requires some per-edge additional information, such as the edge's cost. If the record of per-edge additional information occupies N bytes of storage, simplifying a surface of 1 million edges (a normal size) requires 1 million times N bytes of additional storage. Thus, to minimize the amount of additional memory required to simplify a surface only the cost is attached to each edge and nothing else.

But this is a tradeoff: the cost of a collapse is a function of the placement (the new position chosen for the remaining vertex) so before *GetCost* is called for each and every edge, *GetPlacement* must also be called to obtain the placement parameter to the cost function. But that placement, which is a 3D Point, is not attached to each and every edge since that would easily *triple* the additional storage requirement.

On the one hand, this dramatically saves on memory but on the other hand is a processing waste because when an edge is effectively collapsed, *GetPlacement* must be called *again* to know where to move the remaining vertex.

Earlier prototypes shown that attaching the placement to the edge, thus avoiding one redundant call to the placement function after the edge collapsed, has little impact on the total running time. This is because the cost of an each edge is not just computed once but changes several times during the process so the placement function must be called several times just as well. Caching the placement can only avoid the very last call, when the edge is collapsed, but not all the previous calls which are needed because the placement (and cost) changes.

38.4 API

38.4.1 API Overview

Since the algorithm is free from robustness issues there is no need for exact predicates nor constructions and *Simple_cartesian<double>* can be used safely.¹

The simplification algorithm is implemented as the free template function *CGAL::Surface_mesh_simplification::edge_collapse*. The function has two mandatory and several optional parameters.

Mandatory Parameters

There are two main parameters to the algorithm: the surface to be simplified (in-place) and the stop predicate.

The surface to simplify must be a model of the *EdgeCollapsibleMesh* concept. Many concrete surface types, such as *CGAL::Polyhedron_3* with only triangular faces, become models of that concept via a technique known as *external adaptation*, which is described in [SLL02] and this BGL web page: http://www.boost.org/libs/graph/doc/leda_conversion.html

External adaptation is a way to add an interface to an object without coercing the type of the object (which happens when you adapt it by means of a wrapper). That is, the formal parameter to the *edge_collapse* function that implements the simplification is the concrete surface object itself, not an adaptor which delegates the functionality to the concrete type.

The stop predicate is called after each edge is selected for processing, *before* it is classified as collapsible or not (thus before it is collapsed). If the stop predicate returns *true* the algorithm terminates.

Optional Named Parameters

The notion of *named parameters* was also introduced in the BGL. You can read about it in [SLL02] or the following site: http://www.boost.org/libs/graph/doc/bgl_named_params.html. Named parameters allow the user to specify only those parameters which are really needed, by name, making the parameter ordering unimportant.

Say there is a function *f()* that takes 3 parameters called *name*, *age* and *gender*, and you have variables *n*, *a* and *g* to pass as parameters to that function. Without named parameters, you would call it like this: *f(n,a,g)*, but with named parameters, you call it like this: *f(name(n).age(a).gender(g))*.

That is, you give each parameter a name by wrapping it into a function whose name matches that of the parameter. The entire list of named parameters is really a composition of function calls separated by a dot (.). Thus, if the function takes a mix of mandatory and named parameters, you use a comma to separate the last non-named parameter from the first named parameters, like this:

f(non_named_par0, non_named_par1, name(n).age(a).gender(g))

When you use named parameters, the ordering is irrelevant, so this: *f(name(n).age(a).gender(g))* is equivalent to this: *f(age(a).gender(g).name(n))*, and you can just omit any named parameter that has a default value.

¹In the current version, 3.3, the LindstromTurk policies are not implemented for homogeneous coordinates, so a cartesian kernel must be used.

Sample Call

```
/*
surface           : the surface to simplify
stop_predicate    : policy indicating when the simplification must finish
vertex_index_map(vimap) : property-map giving each vertex a unique integer index
edge_index_map(eimap)  : property-map giving each edge a unique integer index
edge_is_border_map(ebmap): property-map specifying whether an edge is a border edge or not
get_cost(cf)         : function object computing the cost of a collapse
get_placement(pf)     : function object computing the placement for the remaining vertex
visitor(vis)         : function object tracking the simplification process
*/
int r = edge_collapse(surface
                      ,stop_predicate
                      ,vertex_index_map(vimap)
                      .edge_index_map(eimap)
                      .edge_is_border_map(ebmap)
                      .get_cost(cf)
                      .get_placement(pf)
                      .visitor(vis)
                      );
```

38.4.2 Examples

Example Using a Default Polyhedron

The following example illustrates the simplest of the cases. It uses an ordinary polyhedron and only one of the optional parameters. The unspecified cost strategy defaults to Lindstrom-Turk.

```
#include <iostream>
#include <fstream>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

// Adaptor for Polyhedron_3
#include <CGAL/Surface_mesh_simplification/HalfedgeGraph_Polyhedron_3.h>

// Simplification function
#include <CGAL/Surface_mesh_simplification/edge_collapse.h>

// Stop-condition policy
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Count_stop_predicate.h>

typedef CGAL::Simple_cartesian<double> Kernel;
typedef CGAL::Polyhedron_3<Kernel> Surface;

namespace SMS = CGAL::Surface_mesh_simplification ;

int main( int argc, char** argv )
```

```

{
    Surface surface;

    std::ifstream is(argv[1]) ; is >> surface ;

    // This is a stop predicate (defines when the algorithm terminates).
    // In this example, the simplification stops when the number of undirected edges
    // left in the surface drops below the specified number (1000)
    SMS::Count_stop_predicate<Surface> stop(1000);

    // This the actual call to the simplification algorithm.
    // The surface and stop conditions are mandatory arguments.
    // The index maps are needed because the vertices and edges
    // of this surface lack an "id()" field.
    int r = SMS::edge_collapse
        (surface
        ,stop
        ,CGAL::vertex_index_map(boost::get(CGAL::vertex_external_index,surface))
        .edge_index_map (boost::get(CGAL::edge_external_index ,surface))
        );

    std::cout << "\nFinished...\n" << r << " edges removed.\n"
        << (surface.size_of_halfedges()/2) << " final edges.\n" ;

    std::ofstream os( argc > 2 ? argv[2] : "out.off" ) ; os << surface ;

    return 0 ;
}

// EOF //

```

File: examples/Surface_mesh_simplification/edge_collapse_polyhedron.cpp

Example Using an Enriched Polyhedron

The following example is equivalent to the previous example but using an enriched polyhedron whose halfedges support an *id* field to store the edge index needed by the algorithm. It also shows how to explicitly specify a cost strategy (other than the default) and how to use a visitor policy to track the simplification process.

```

#include <iostream>
#include <fstream>

#include <CGAL/Simple_cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

// Adaptor for Polyhedron_3
#include <CGAL/Surface_mesh_simplification/HalfedgeGraph_Polyhedron_3.h>

// Simplification function
#include <CGAL/Surface_mesh_simplification/edge_collapse.h>

```

```

// Extended polyhedron items which include an id() field
#include <CGAL/Polyhedron_items_with_id_3.h>

// Stop-condition policy
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Count_ratio_stop_predicate.h>

// Non-default cost and placement policies
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Midpoint_and_length.h>

typedef CGAL::Simple_cartesian<double> Kernel;

typedef Kernel::Point_3 Point ;

//
// Setup an enriched polyhedron type which stores an id() field in the items
//
typedef CGAL::Polyhedron_3<Kernel,CGAL::Polyhedron_items_with_id_3> Surface;

typedef Surface::Halfedge_handle Halfedge_handle ;

namespace SMS = CGAL::Surface_mesh_simplification ;

typedef SMS::Edge_profile<Surface> Profile ;

// The following is a Visitor that keeps track of the simplification process.
// In this example the progress is printed real-time and a few statistics are
// recorded (and printed in the end).
//
struct Visitor
{
    Visitor()
        : collected(0)
        , processed(0)
        , collapsed(0)
        , non_collapsable(0)
        , cost_uncomputable(0)
        , placement_uncomputable(0)
    {}

    // Called on algorithm entry
    void OnStarted( Surface& ) {}

    // Called on algorithm exit
    void OnFinished ( Surface& ) { std::cerr << "\n" << std::flush ; }

    // Called when the stop condition returned true
    void OnStopConditionReached( Profile const& ) {}

    // Called during the collecting phase for each edge collected.
    void OnCollected( Profile const&, boost::optional<double> const& )
    {
        ++ collected ;
        std::cerr << "\rEdges collected: " << collected << std::flush ;
    }
}

```

```

}

// Called during the processing phase for each edge selected.
// If cost is absent the edge won't be collapsed.
void OnSelected(Profile const&
                ,boost::optional<double> cost

Triangulated Surface Mesh Simplification

Reference Manual

This chapter introduces the concepts and classes of the triangulated surface mesh simplification package. The packages provides a policy-based algorithm for the simplification of triangulated surface meshes by iterative edge-collapsing.

EdgeCollapsibleMesh

Definition

The concept `EdgeCollapsibleMesh` describes the requirements for the type of triangulated surface mesh that can be passed to the simplification algorithm.

The surface must be structurally equivalent to a polyhedral surface having only triangular faces. It can have any number of connected components, boundaries (borders and holes) and handles (arbitrary genus).

Refines

HalfedgeGraph

Valid Expressions

The mesh simplification algorithm requires the free function *collapse_triangulation_edge*.

```
template<class EdgeCollapsibleMesh>
typename boost::graph_traits<EdgeCollapsibleMesh>::vertex_descriptor
```

```
halfedge_collapse( typename boost::graph_traits<EdgeCollapsibleMesh>::edge_descriptor const& ue,
                  EdgeCollapsibleMesh& mesh)
```

Collapses the undirected edge $(v0v1, v1v0)$ replacing it with $v0$ or $v1$, as described in the following paragraph.

Precondition: This function requires *mesh* to be an oriented 2-manifold with or without boundaries. Furthermore, the undirected edge $(v0v1, v1v0)$ must satisfy the *link condition* [DEGN99], which guarantees that the surface is also 2-manifold after the edge collapse.

Let $v0$ be the source and $v1$ be the target vertices of $v0v1$.

For $e \in \{v0v1, v1v0\}$, let en and ep be the next and previous edges, that is $en = next_edge(e, mesh)$, $ep = prev_edge(e, mesh)$, and let eno and epo be their opposite edges, that is $eno = opposite_edge(en, mesh)$ and $epo = opposite_edge(ep, mesh)$.

Then, after the collapse of $(v0v1, v1v0)$ the following holds:

- The edge e is no longer in *mesh*.
- One of $\{v0, v1\}$ is no longer in *mesh* while the other remains. ² Let *vgone* be the removed vertex and *vkept* be the remaining vertex.
- If e was a border edge, that is $get(is_border, e, mesh) == true$, then $next_edge(ep) == en$, and $prev_edge(en) == ep$.
- If e was not a border edge, that is $get(is_border, e, mesh) == false$, then ep and epo are no longer in *mesh* while en and eno are kept in *mesh*.

²Even though it would appear that $v0$ can always be the vertex being removed, there is a case when removing the edge e requires $v1$ to be removed as well. See figure 38.5.

- For all edges ie in $in_edges(vgone, mesh)$, $target(ie, mesh) == vkept$ and $source(opposite_edge(ie), mesh) == vkept$.
- No other incidence information has changed in $mesh$.

The function returns vertex $vkept$ (which can be either $v0$ or $v1$).

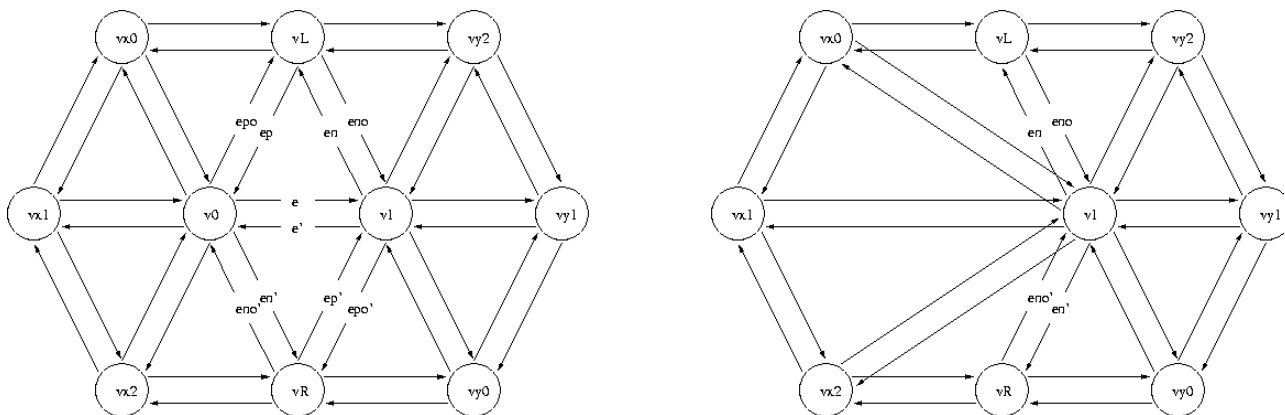

Figure 38.1: General case. The following mesh elements are removed: triangles $(v0, v1, vL)$ and $(v1, v0, vR)$, edges (e, e') , (ep, epo) and (ep', epo') , and vertex $v0$.

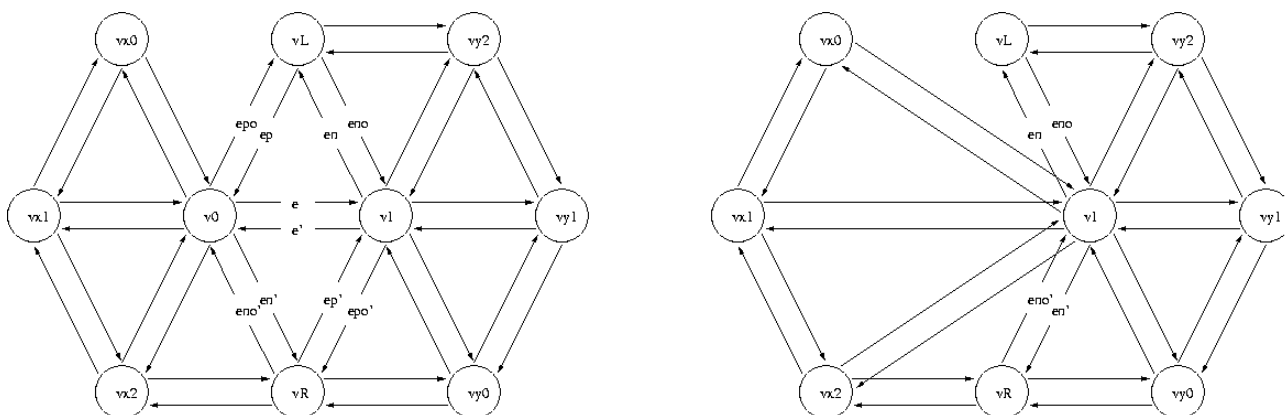

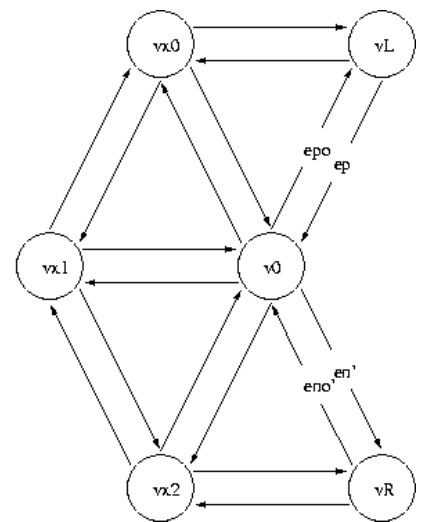

Figure 38.2: When the collapsing edge is not itself a border, but is incident upon a border edge that is removed, the operation is the same as in the general case.

Has Models

`CGAL::Polyhedron_3<Traits>` page 979
 (If it has only triangular faces, and via *External Adaptation*, which is described in [SLL02] and this BGL web page: http://www.boost.org/libs/graph/doc/leda_conversion.html).

EdgeProfile

Definition

The concept EdgeProfile describes the requirements for a data structure that caches the local topology and geometry in the surroundings of an undirected edge.

This profile is used by the stop, cost and placement policies.

Types

EdgeProfile::ECM The type of the surface to simplify. Must be a model of the *EdgeCollapsableMesh* concept.

typename boost::graph_traits<ECM>::vertex_descriptor

vertex_descriptor; A BGL vertex descriptor representing a vertex of the surface.

typename boost::graph_traits<ECM>::edge_descriptor

edge_descriptor; A BGL edge descriptor representing an edge of the surface.

typename CGAL::halfedge_graph_traits<ECM>::Point

Point; The point type for the surface vertex. Must be a model of *Point_3*.

Access Functions

<i>vertex_descriptor</i>	<i>ep.v0()</i>	One of vertices of the edge to be collapsed.
<i>vertex_descriptor</i>	<i>ep.v1()</i>	The other vertex of the edge to be collapsed.
<i>edge_descriptor</i>	<i>ep.v0v1()</i>	One of the directed edges corresponding to the undirected edge being collapsed.
<i>edge_descriptor</i>	<i>ep.v1v0()</i>	The other directed edge corresponding to the undirected edge being collapsed.
<i>Point</i>	<i>ep.p0()</i>	The point of vertex <i>v0</i> .
<i>Point</i>	<i>ep.p1()</i>	The point of vertex <i>v1</i> .
<i>vertex_descriptor</i>	<i>ep.vL()</i>	If <i>v0v1</i> belongs to a finite face (is not a border edge) the third vertex of that triangular face, a <i>null descriptor</i> otherwise.
<i>edge_descriptor</i>	<i>ep.v1vL()</i>	If <i>v0v1</i> belongs to a finite face (is not a border edge) the directed edge from <i>v1</i> to <i>vL</i> , a <i>null descriptor</i> otherwise.
<i>edge_descriptor</i>	<i>ep.vLv0()</i>	If <i>v0v1</i> belongs to a finite face (is not a border edge) the directed edge from <i>vL</i> to <i>v0</i> , a <i>null descriptor</i> otherwise.
<i>vertex_descriptor</i>	<i>ep.vR()</i>	If <i>v1v0</i> belongs to a finite face (is not a border edge) the third vertex of that triangular face, a <i>null descriptor</i> otherwise.
<i>edge_descriptor</i>	<i>ep.v0vR()</i>	If <i>v1v0</i> belongs to a finite face (is not a border edge) the directed edge from <i>v0</i> to <i>vR</i> , a <i>null descriptor</i> otherwise.
<i>edge_descriptor</i>	<i>ep.vRv1()</i>	If <i>v1v0</i> belongs to a finite face (is not a border edge) the directed edge from <i>vR</i> to <i>v1</i> , a <i>null descriptor</i> otherwise.

std::vector<vertex_descriptor>

ep.link()

The unique sequence of the vertices around v_0v_1 in topological order (*ccw* or *ccw* depending on the relative ordering of v_0 and v_1 in the profile).

std::vector<edge_descriptor>

ep.border_edges()

The unique collection of the border directed edges incident upon v_0 and v_1 .

bool

ep.left_face_exits()

Indicates if v_0v_1 belongs to a finite face of the mesh (i.e, v_0v_1 is not a border edge).

bool

ep.right_face_exits()

Indicates if v_0v_1 belongs to a finite face of the mesh (i.e, v_1v_0 is not a border edge).

Has Models

CGAL::Surface_mesh_simplification::Edge_profile<ECM> page [2281](#)

StopPredicate

Definition

The concept StopPredicate describes the requirements for the predicate which indicates if the simplification process must finish.

Types

<i>StopPredicate:: ECM</i>	The type of the surface to simplify. Must be a model of the <i>EdgeCollapsableMesh</i> concept.
<i>StopPredicate:: FT</i>	A field type representing the collapse cost
<i>StopPredicate:: size_type</i>	An integer type representing the number of edges
<i>StopPredicate:: Profile</i>	The type of the edge profile cache. Must be a model of the <i>EdgeProfile</i> concept.

Operations

<i>bool</i>	<i>sp.operator()(FT const& current_cost,</i> <i>Profile const& profile,</i> <i>size_type initial_count,</i> <i>size_type current_count) const</i>	<p>This predicate is called each time an edge is selected for processing, before it is collapsed. <i>current_cost</i> is the cost of the selected edge. <i>initial_count</i> and <i>current_count</i> are the number of initial and current edges.</p> <p>If the return value is <i>true</i> the simplification terminates before processing the edge, otherwise it continues normally.</p>
-------------	---	---

Has Models

<i>CGAL::Surface_mesh_simplification::Count_stop_predicate<ECM></i>	page 2282
<i>CGAL::Surface_mesh_simplification::Count_ratio_stop_predicate<ECM></i>	page 2283

The concept `GetCost` describes the requirements for the *policy function object* which gets the *collapse cost* of an edge.

The cost returned is a *boost::optional* value (i.e. it can be absent). An *absent* cost indicates that the edge should not be collapsed. This could be the result of a computational limitation (such as overflow), or can be intentionally returned to prevent the edge from being collapsed.

```
DefaultConstructible
CopyConstructible
```

Types

<i>GetCost:: Profile</i>	The type of the edge profile cache. Must be a model of the <i>EdgeProfile</i> concept.
--------------------------	--

<i>GetCost:: FT</i>	A field type representing the collapse cost
<i>typename CGAL::halfedge_graph_traits<ECM>::Point</i>	

Point; The point type for the surface vertex. Must be a model of *Point_3*.

<code>boost::optional<FT></code>	<code>result_type;</code>	The type of the result (an optional cost value).
--	---------------------------	--

Operations

```
result_type gc.operator()( Profile const& edge_profile,
                           boost::optional<Point> const& placement) const
```

Computes and returns the cost of collapsing the edge (represented by its profile), using the calculated placement.

Has Models

<i>CGAL::Surface_mesh_simplification::Edge_length_cost</i> < <i>ECM</i> >	page 2284
<i>CGAL::Surface_mesh_simplification::LindstromTurk_cost</i> < <i>ECM</i> >	page 2286

Definition

The placement returned is a *boost::optional* value (i.e., it can be absent). An absent result indicates that the remaining vertex must be kept in place, not moved to a new position.

DefaultConstructible
CopyConstructible

<i>GetPlacement:: Profile</i>	The type of the edge profile cache. Must be a model of the <i>EdgeProfile</i> concept.
<i>typename CGAL::halfedge_graph_traits<ECM>::Point</i>	
<i>Point;</i>	The point type for the surface vertex. Must be a model of <i>Point_3</i> .
<i>boost::optional<Point></i>	
<i>result_type;</i>	The type of the result (an optional point).

<i>result_type</i>	<i>gp.operator()(Profile const& edge_profile) const</i>	Computes and returns the placement, that is, the position of the vertex which replaces the collapsing edge (represented by its profile).
--------------------	--	--

<i>CGAL::Surface_mesh_simplification::Midpoint_placement<ECM></i>	page 2285
<i>CGAL::Surface_mesh_simplification::LindstromTurk_placement<ECM></i>	page 2287

EdgeCollapseSimplificationVisitor

Definition

The concept `EdgeCollapseSimplificationVisitor` describes the requirements for the *visitor object* which is used to track the edge collapse simplification algorithm.

The several callbacks given as member functions in the visitor are called from certain places in the algorithm implementation.

Types

`EdgeCollapseSimplificationVisitor::ECM` The type of the surface to simplify. Must be a model of the *EdgeCollapsableMesh* concept.

`EdgeCollapseSimplificationVisitor::FT` A field type representing the collapse cost
`typename boost::graph_traits<ECM>::edge_descriptor`

`edge_descriptor;` A BGL edge descriptor representing an undirected edge of the surface.

`typename CGAL::halfedge_graph_traits<ECM>::Point`

`Point;` The point type of the vertex. Must be a model of *Point_3*.

`EdgeCollapseSimplificationVisitor::size_type` An integer type representing the number of edges

Operations

`void` `v.OnStarted(ECM& surface)`
 Called before the algorithm starts.

`void` `v.OnFinished(ECM& surface)`
 Called after the algorithm finishes.

`void` `v.OnStopConditionReached(ECM& surface)`
 Called when the *StopPredicate* returned *true* (but not if the algorithm terminates because the surface could not be simplified any further).

`void` `v.OnCollected(edge_descriptor edge, ECM& surface)`
 Called during the *collecting phase* (when a cost is assigned to the edges), for each *edge* collected.

<i>void</i>	<p><i>v.OnSelected(edge_descriptor edge,</i> <i>ECM& surface,</i> <i>boost::optional<double> cost,</i> <i>size_type initial_count,</i> <i>size_type current_count)</i></p> <p>Called during the <i>processing phase</i> (when edges are collapsed), for each <i>edge</i> that is selected. This method is called before the algorithm checks if the edge is collapsable. <i>cost</i> indicates the current collapse cost for the <i>edge</i>. If absent (meaning that it could not be computed) the edge will not be collapsed. <i>initial_count</i> and <i>current_count</i> refer to the number of edges.</p>
<i>void</i>	<p><i>v.OnCollapsing(edge_descriptor edge,</i> <i>ECM& surface,</i> <i>boost::optional<Point> placement)</i></p> <p>Called when <i>edge</i> is about to be collapsed and replaced by a vertex whose position is <i>*placement</i>. If <i>placement</i> is absent (meaning that it could not be computed) the edge will not be collapsed.</p>
<i>void</i>	<p><i>v.OnNonCollapsible(edge_descriptor edge, ECM& surface)</i></p> <p>Called for each selected <i>edge</i> which cannot be collapsed because doing so would change the topological type of the surface (turn it into a non-manifold for instance).</p>

CGAL::Surface_mesh_simplification::edge_collapse

Definition

The function *Surface_mesh_simplification::edge_collapse* simplifies in-place a triangulated surface mesh by iteratively collapsing edges.

```
#include <CGAL/Surface_mesh_simplification/edge_collapse.h>
```

```
template<class EdgeCollapsibleMesh, class StopPredicate, class P, class T, class R>
int      edge_collapse( EdgeCollapsibleMesh& surface,
                       StopPredicate should_stop,
                       sms_named_params<P,T,R> named_parameters)
```

Simplifies *surface* in-place by collapsing edges, and returns the number of edges effectively removed.

Non-named parameters

surface is the surface to simplify. It must be a model of the *EdgeCollapsibleMesh* concept.

should_stop is the stop-condition policy. It must be a model of the *StopPredicate* concept.

Named parameters

named_parameters holds the list of all the additional parameters used by the *edge_collapse* function (including default parameters).

The named parameters list is a composition of function calls separated by a dot (.) where the name of each function matches the name of an argument and wraps the actual parameter.

This is an example with 2 arguments:

```
vertex_index_map(the_actual_vertex_index_map).edge_index_map(the_actual_edge_index_map)
```

the_actual_vertex_index_map and *the_actual_edge_index_map* are the actual parameters, while *vertex_index_map()* and *edge_index_map()* are wrapper functions used to designate each formal argument.

All named parameters have default values so you only need to compose those for which the default is inappropriate. Furthermore, since each actual parameter is wrapped in a function whose name designates the formal argument, the order of named parameters in the list is totally irrelevant.

In the following subsections, each named parameter is documented as a helper function. The argument to each helper function is the actual parameter to *edge_collapse()*, while the name of the helper function designates which formal argument it is.

vertex_index_map(VertexIndexMap vpm)

Maps each vertex in the surface into an unsigned integer number in the range $[0, \text{num_vertices}(\text{surface}))$.

VertexIndexMap must be a **ReadablePropertyMap** whose *key_type* is *boost::graph_traits<EdgeCollapsibleMesh const>::vertex_descriptor* and whose *value_type* is *boost::graph_traits<EdgeCollapsibleMesh>::size_type*,

Default: the property map obtained by calling *get(vertex_index,surface)*, which requires the surface vertices to have an *id()* member properly initialized to the required value.

If the vertices don't have such an *id()*, you must pass some property map explicitly. An external property map can be easily obtained by calling *get(vertex_external_index,surface)*. This constructs on the fly, and returns, a property map which non-intrusively associates a proper id with each vertex.

edge_index_map(EdgeIndexMap eim)

Maps each *directed* edge in the surface into an unsigned integer number in the range $[0, \text{num_edges}(\text{surface}))$.

EdgeIndexMap must be a **ReadablePropertyMap** whose *key_type* is *boost::graph_traits<EdgeCollapsibleMesh const>::edge_descriptor* and whose *value_type* is *boost::graph_traits<EdgeCollapsibleMesh>::size_type*

Default: the property map obtained by calling *get(edge_index,surface)*, which requires the surface edges to have an *id()* member properly initialized to the required value.

If the edges don't have such an *id()*, you must pass some property map explicitly. An external property map can be easily obtained by calling *get(edge_external_index,surface)*. This constructs on the fly, and returns, a property map which non-intrusively associates a proper id with each edge.

edge_is_border_map(EdgeIsBorderMap ebm)

Maps each *directed* edge in the surface into a Boolean value which indicates if the edge belongs to the boundary of the surface (facing the outside). *EdgeIsBorderMap* must be a **ReadablePropertyMap** whose *key_type* is *boost::graph_traits<EdgeCollapsibleMesh const>::edge_descriptor* and whose *value_type* is *bool*.

Default: the property map obtained by calling *get(edge_is_border,surface)*.

get_cost(GetCost gc)

The policy which returns the collapse cost for an edge.

The type of *gc* must be a model of the *GetCost* concept.

Default: *CGAL::Surface_mesh_simplification::LindstromTurk_cost<EdgeCollapsibleMesh>*.

get_placement(GetPlacement gp)

The policy which returns the placement (position of the replacement vertex) for an edge.

The type of *gp* must be a model of the *GetPlacement* concept.

Default: *CGAL::Surface_mesh_simplification::LindstromTurk_placement<EdgeCollapsibleMesh>*

visitor(EdgeCollapseSimplificationVisitor const* v)

The visitor that is called by the *edge_collapse* function in certain points to allow the user to track the simplification process.

The type of object pointed to by *v* must be a model of the *EdgeCollapseSimplificationVisitor* concept.

Default: *NULL*.

All these functions naming parameters are defined in *namespace CGAL*. Being non-member functions, they could clash with equally named functions in some other namespace. If that happens, simply qualify the *first* ³ named parameter with *CGAL::*, as shown in the examples in the user manual.

Semantics

The simplification process continues until the *should_stop* policy returns *true* or the surface cannot be simplified any further due to topological constraints.

get_cost and *get_placement* are the policies which control the *cost-strategy*, that is, the order in which edges are collapsed and the remaining vertex is re-positioned.

visitor is an optional object (can be null) which can be used to keep track of the simplification process. It has several member functions which are called at certain points in the simplification code.

³The second and subsequent named parameters shall not be qualified as they are member functions

CGAL::Surface_mesh_simplification::Edge_profile<ECM>

Definition

The class *Surface_mesh_simplification::Edge_profile<ECM>* provides a model for the *EdgeProfile* concept. It has one template argument: the type of surface being simplified, which must be a model of the *EdgeCollapsibleMesh* concept.

```
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Edge_profile.h>
```

Is Model for the Concepts

EdgeProfile

CGAL::Surface_mesh_simplification::Count_stop_predicate<ECM>

Definition

The class *Surface_mesh_simplification::Count_stop_predicate<ECM>* provides a model for the *StopPredicate* concept. It has one template argument: the type of surface being simplified, which must be a model of the *EdgeCollapsibleMesh* concept. It returns *true* when the number of current edges drops below a certain threshold.

```
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Count_stop_predicate.h>
```

Is Model for the Concepts

StopPredicate

Creation

```
Surface_mesh_simplification::Count_stop_predicate<ECM> sp( size_type threshold);
```

Initializes the predicate establishing the *threshold* value.

Operations

```
bool sp.operator()( FT const& current_cost,
                   Profile const& edge_profile,
                   size_type initial_count,
                   size_type current_count) const
```

Returns (*current_{count}* < *threshold*). All other parameters are ignored (but exist since this is a generic policy).

CGAL::Surface_mesh_simplification::Count_ratio_stop_predicate<ECM>

CGAL::Surface_mesh_simplification::Count_ratio_stop_predicate<ECM>

Definition

The class *Surface_mesh_simplification::Count_ratio_stop_predicate<ECM>* provides a model for the *StopPredicate* concept. It has one template argument: the type of surface being simplified, which must be a model of the *EdgeCollapsibleMesh* concept. It returns *true* when the relation between the initial and current number of edges drops below a certain ratio.

```
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Count_ratio_stop_predicate.h>
```

Is Model for the Concepts

StopPredicate

Creation

```
Surface_mesh_simplification::Count_ratio_stop_predicate<ECM> sp( double ratio);
```

Initializes the predicate establishing the *ratio*.

Operations

```
bool sp.operator()( FT const& current_cost,
                  Profile const& edge_profile,
                  size_type initial_count,
                  size_type current_count) const
```

Returns $((double)current_count / (double)initial_count) < ratio$. All other parameters are ignored (but exist since this is a generic policy).

result_type gc.operator()( Profile const& profile, boost::optional<Point> const& placement) const
```

Returns the *collapse cost* as the squared distance between the points of the source and target vertices (that is, *profile.p0()* and *profile.p1()*).

The *placement* argument is ignored.

CGAL::Surface_mesh_simplification::Midpoint_placement<ECM>

Definition

The class *Surface_mesh_simplification::Midpoint_placement<ECM>* provides a model for the *GetPlacement* concept. It computes the placement as the midpoint position along the edge.

The class *Surface_mesh_simplification::Midpoint_placement<ECM>* has one template arguments: the type of surface being simplified. It be a model of the *EdgeCollapsableMesh* concept.

```
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/Midpoint_placement.h>
```

Is Model for the Concepts

GetPlacement

Creation

```
Surface_mesh_simplification::Midpoint_placement<ECM> gp;
```

Default constructor

Operations

```
result_type gp.operator()( Profile const& edge_profile) const
```

Returns the *placement* (vertex position) as the midpoint between the points of the source and target vertices (*profile.p0()* and *profile.p1()*)

CGAL::Surface_mesh_simplification::LindstromTurk_cost<ECM>

Definition

The class `Surface_mesh_simplification::LindstromTurk_cost<ECM>` provides a model for the *GetCost* concept. It computes the collapse cost following the Lindstrom-Turk strategy (Section [38.3.1](#))

The class `Surface_mesh_simplification::LindstromTurk_cost<ECM>` has one template argument: the type of surface being simplified. It must be a model of the *EdgeCollapsibleMesh* concept.

```
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/LindstromTurk_cost.h>
```

Is Model for the Concepts

GetCost

Creation

```
Surface_mesh_simplification::LindstromTurk_cost<ECM> gc( FT factor = FT(0.5));
```

Initializes the policy with the given *weighting unit factor*.
See [38.3.1](#) for details on the meaning of this factor.

Operations

```
result_type gc.operator()( Profile const& profile, boost::optional<Point> const& placement) const
```

Returns the cost of collapsing the edge (represented by its profile) considering the new *placement* computed for it.

`CGAL::Surface_mesh_simplification::LindstromTurk_placement<ECM>`

CGAL::Surface_mesh_simplification::LindstromTurk_placement<ECM>

Definition

The class *Surface_mesh_simplification::LindstromTurk_placement<ECM>* provides a model for the *GetPlacement* concept. It computes the placement, that is, the new position for the remaining vertex after a halfedge-collapse, following the Lindstrom-Turk strategy (Section 38.3.1).

The class *Surface_mesh_simplification::LindstromTurk_placement<ECM>* has one template argument: the type of surface being simplified. It must be a model of the *EdgeCollapsableMesh* concept.

```
#include <CGAL/Surface_mesh_simplification/Policies/Edge_collapse/LindstromTurk_placement.h>
```

Is Model for the Concepts

GetPlacement

Creation

```
Surface_mesh_simplification::LindstromTurk_placement<ECM> gp( FT factor = FT(0.5));
```

Initializes the policy with the given *weighting unit factor*. See 38.3.1 for details on the meaning of this factor.

Operations

```
result_type gp.operator()( Profile const& edge_profile) const
```

Returns the new position for the remaining vertex after collapsing the edge (represented by its profile).

39.1 Introduction

Parameterizing a surface amounts to finding a one-to-one mapping from a suitable domain to the surface. A good mapping is the one which minimizes either angle distortions (conformal parameterization) or area distortions (equiareal parameterization) in some sense. In this package, we focus on parameterizing triangulated surfaces which are homeomorphic to a disk, and on piecewise linear mappings onto a planar domain.

Although the main motivation behind the first parameterization methods was the application to texture mapping, it is now frequently used for mapping more sophisticated modulation signals (such as normal, transparency, reflection or light modulation maps), fitting scattered data, re-parameterizing spline surfaces, repairing CAD models, approximating surfaces and remeshing.

This CGAL package implements some of the state-of-the-art surface parameterization methods, such as least squares conformal maps, discrete conformal map, discrete authalic parameterization, Floater mean value coordinates or Tutte barycentric mapping. These methods mainly distinguish by the distortion they minimize (angles vs. areas), by the constrained border onto the planar domain (convex polygon vs. free border) and by the guarantees provided in terms of bijective mapping.

The package proposes currently an interface with `CGAL::Polyhedron_3<Traits>` data structure.

Since parameterizing meshes require efficient representation of sparse matrices and efficient iterative or direct linear solvers, we provide a unified interface to state-of-the-art linear solver libraries (TAUCS), and propose a separate package devoted to OpenNL sparse linear solver.

Note that linear solvers commonly use double precision floating point numbers. Therefore, this package is intended to be used with a CGAL Cartesian kernel with doubles.

The intended audience of this package is researchers, developers or students developing algorithms around parameterization of triangle meshes for geometry processing as well as for signal mapping on triangulated surfaces.

Figure 39.1: Texture mapping via Least Squares Conformal Maps parameterization. Top: original mesh and texture. Bottom: parameterized mesh (left: parameter space, right: textured mesh).

39.2 Basics

39.2.1 Default Surface Parameterization

From the user point of view, the simplest entry point to this package is the following function:

Parameterizer_traits_3<ParameterizationMesh_3>::Error_code

parameterize(ParameterizationMesh_3 & mesh)

Compute a one-to-one mapping from a 3D triangle surface mesh to a 2D circle, using Floater Mean Value Coordinates algorithm. A one-to-one piecewise linear mapping is guaranteed. The result is a pair of (u,v) parameter coordinates for each vertex of the input mesh.

Preconditions: mesh must be a triangle mesh surface with one connected component.

The function *CGAL::parameterize()* applies a default surface parameterization method: Floater Mean Value Coordinates [Flo03a], with an arc-length circular border parameterization, and using OpenNL sparse linear solver [Lev05]. The *ParameterizationMesh_3* concept defines the input meshes handled by *CGAL::parameterize()*. See Section 39.2.2. The result is stored into the (u,v) fields of the mesh halfedges.

Note: *CGAL::Parameterizer_traits_3<ParameterizationMesh_3>* is the (pure virtual) superclass of all surface parameterizations and defines the error codes.

39.2.2 Input Mesh for parameterize()

The input meshes handled *directly* by *CGAL::parameterize()* must be models of *ParameterizationMesh_3*, triangulated, 2-manifold, oriented, and homeomorphic to discs (possibly with holes).

Note: *ParameterizationMesh_3* is a general concept to access a polyhedral mesh. It is optimized for the *Surface_mesh_parameterization* package only in the sense that it defines the accessors to fields specific to the parameterization domain (*index*, *u*, *v*, *is_parameterized*). The extra constraints needed by the surface parameterization methods (triangulated, 2-manifold, homeomorphic to a disc) are not part of the concept and are checked at runtime.

This package provides a model of the *ParameterizationMesh_3* concept to access *CGAL::Polyhedron_3<Traits>* :

CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>

We will see later that *CGAL::parameterize()* can support *indirectly* meshes that are not topological disks.

39.2.3 Default Parameterization Example

Simple_parameterization.cpp applies the default parameterization to a *CGAL::Polyhedron_3<Traits>* mesh (must be a topological disk). Eventually, it extracts the result from halfedges and prints it.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Parameterization_polyhedron_adaptor_3.h>
#include <CGAL/parameterize.h>

#include <iostream>
#include <fstream>
```

```

// -----
// Private types
// -----

typedef CGAL::Cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel>      Polyhedron;

// -----
// main()
// -----

int main(int argc, char * argv[])
{
    std::cerr << "PARAMETERIZATION" << std::endl;
    std::cerr << "  Floater parameterization" << std::endl;
    std::cerr << "  Circle border" << std::endl;
    std::cerr << "  OpenNL solver" << std::endl;

    //*****
    // decode parameters
    //*****

    if (argc-1 != 1)
    {
        std::cerr << "Usage: " << argv[0] << " input_file.off" << std::endl;
        return(EXIT_FAILURE);
    }

    // File name is:
    const char* input_filename = argv[1];

    //*****
    // Read the mesh
    //*****

    // Read the mesh
    std::ifstream stream(input_filename);
    Polyhedron mesh;
    stream >> mesh;
    if(!stream || !mesh.is_valid() || mesh.empty())
    {
        std::cerr << "FATAL ERROR: cannot read OFF file " << input_filename << std::endl;
        return EXIT_FAILURE;
    }

    //*****
    // Create Polyhedron adaptor
    // Note: no cutting => we support only
    // meshes that are topological disks
    //*****

```

```

typedef CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron>
                                   Parameterization_polyhedron_adaptor;
Parameterization_polyhedron_adaptor mesh_adaptor(mesh);

//*****
// Floater Mean Value Coordinates parameterization
// (defaults are circular border and OpenNL solver)
//*****

// Type that defines the error codes
typedef CGAL::Parameterizer_traits_3<Parameterization_polyhedron_adaptor>
                                   Parameterizer;

Parameterizer::Error_code err = CGAL::parameterize(mesh_adaptor);
if (err != Parameterizer::OK)
    std::cerr << "FATAL ERROR: " << Parameterizer::get_error_message(err) << std::endl;

//*****
// Output
//*****

if (err == Parameterizer::OK)
{
    // Raw output: dump (u,v) pairs
    Polyhedron::Vertex_const_iterator pVertex;
    for (pVertex = mesh.vertices_begin();
         pVertex != mesh.vertices_end();
         pVertex++)
    {
        // (u,v) pair is stored in any halfedge
        double u = mesh_adaptor.info(pVertex->halfedge())->uv().x();
        double v = mesh_adaptor.info(pVertex->halfedge())->uv().y();
        std::cout << "(u,v) = (" << u << ", " << v << ")" << std::endl;
    }
}

return (err == Parameterizer::OK) ? EXIT_SUCCESS : EXIT_FAILURE;
}

```

File: examples/Surface_mesh_parameterization/Simple_parameterization.cpp

39.2.4 Enhanced parameterize() function

This package provides a second *CGAL::parameterize()* entry point where the user can specify a parameterization method:

Parameterizer_traits_3<ParameterizationMesh_3>::Error_code

parameterize(ParameterizationMesh_3 & mesh,

ParameterizerTraits_3 parameterizer)

Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a simple 2D domain. The mapping is piecewise linear on the triangle mesh. The result is a pair (u,v) of parameter coordinates for each vertex of the input mesh. One-to-one mapping may be guaranteed or not, depending on the chosen *ParameterizerTraits_3* algorithm.

Preconditions: 'mesh' must be a triangle surface mesh with one connected component, and the mesh border must be mapped onto a convex polygon (for fixed border parameterizations).

39.2.5 Introduction to the Package Concepts

The *ParameterizerTraits_3* concept

This CGAL package implements some of the state-of-the-art surface parameterization methods, such as Least Squares Conformal Maps, Discrete Conformal Map, Discrete Authalic Parameterization, Floater Mean Value Coordinates or Tutte Barycentric Mapping. These methods are provided as models of the *ParameterizerTraits_3* concept. See Section 39.3.

Each of these surface parameterization methods is templated by the input mesh type, a border parameterization and a solver:

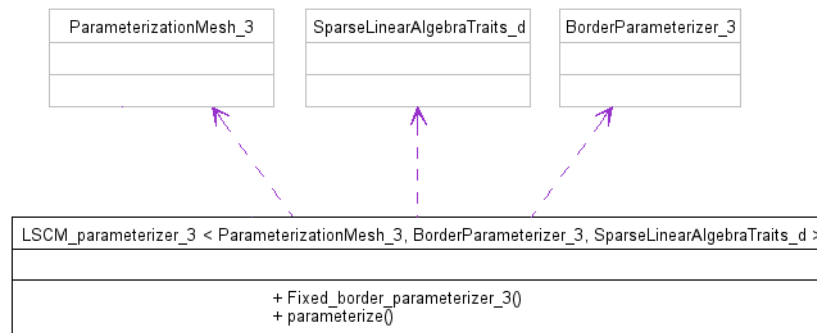

Figure 39.2: A parameterizer UML class diagram (simplified).

The *BorderParameterizer_3* concept

Parameterization methods for borders are used as traits classes modifying the behavior of *ParameterizerTraits_3* models. They are provided as models of the *BorderParameterizer_3* concept. See Sections 39.3.1 and 39.3.2.

The *SparseLinearAlgebraTraits_d* concept

This package solves sparse linear systems using solvers which are models of *SparseLinearAlgebraTraits_d*. See Section 39.4.

The `ParameterizationMesh_3` and `ParameterizationPatchableMesh_3` Concepts

As described in Section 39.2.2 the input meshes handled by `CGAL::parameterize()` must be models of the `ParameterizationMesh_3` concept. The surface parameterization methods provided by this package only support surfaces which are homeomorphic to disks, possibly with holes. Nevertheless meshed with arbitrary topology and number of connected components can be parameterized, provided that the user specifies a *cut graph* (an oriented list of vertices) which is the border of a topological disc. If no cut graph is specified as input, the longest border of the input mesh is taken by default, the others being considered as holes.

For this purpose, the `CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>` class is responsible for *virtually* cutting a patch into a `ParameterizationPatchableMesh_3` mesh. The resulting patch is a topological disk (if the input cutting path is correct) and provides a `ParameterizationMesh_3` interface. It can be used as parameter for the function `CGAL::parameterize()`.

`ParameterizationPatchableMesh_3` inherits from `ParameterizationMesh_3`, thus is a concept for a 3D surface mesh. `ParameterizationPatchableMesh_3` adds the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* behave as if the surface was cut along a cut graph. More information is provided in Section 39.5.

39.3 Surface Parameterization Methods

This CGAL package implements some of the state-of-the-art surface parameterization methods, such as Least Squares Conformal Maps, Discrete Conformal Map, Discrete Authalic Parameterization, Floater Mean Value Coordinates or Tutte Barycentric Mapping. These methods are provided as models of the `ParameterizerTraits_3` concept.

39.3.1 Fixed Border Surface Parameterizations

Fixed Border Surface Parameterizations need a set of constraints: two (u,v) coordinates for each vertex along the border. Such border parameterizations are described in Section 39.3.1.

Tutte Barycentric Mapping

`CGAL::Barycentric_mapping_parameterizer_3<ParameterizationMesh_3, SparseLinearAlgebraTraits_d>`, `BorderParameterizer_3`,

The Barycentric Mapping parameterization method has been introduced by Tutte [Tut63]. In parameter space, each vertex is placed at the barycenter of its neighbors to achieve the so-called convex combination condition. This algorithm amounts to solve one sparse linear solver for each set of parameter coordinates, with a $\#vertices \times \#vertices$ sparse and symmetric positive definite matrix (if the border vertices are eliminated from the linear system). A coefficient (i, j) of the matrix is set to 1 for an edge linking the vertex v_i to the vertex v_j , to minus the degree of the vertex v_i for a diagonal element, and to 0 for any other matrix entry. Although a bijective mapping is guaranteed when the border is convex, this method does not minimize angles nor areas distortion.

Figure 39.3: Left: Tutte barycentric mapping parameterization (the red line depicts the cut graph). Right: parameter space.

Discrete Conformal Map

CGAL::Discrete_conformal_map_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*, *SparseLinearAlgebraTraits_d*>

Discrete conformal map parameterization has been introduced by Eck et al. to the graphics community [EDD⁺95]. It attempts to lower angle deformation by minimizing a discrete version of the Dirichlet energy as derived by Pinkall and Polthier [PP93]. A one-to-one mapping is guaranteed only when the two following conditions are fulfilled: the barycentric mapping condition (each vertex in parameter space is a convex combination of its neighboring vertices), and the border is convex. This method solves two $\#vertices \times \#vertices$ sparse linear systems. The matrix (the same for both systems) is sparse and symmetric definite positive (if the border vertices are eliminated from the linear system and if the mesh contains no hole), thus can be efficiently solved using dedicated linear solvers.

Figure 39.4: Left: discrete conformal map. Right: parameter space.

Floater Mean Value Coordinates

CGAL::Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3, SparseLinearAlgebraTraits_d> *BorderParameterizer_3,*

The mean value coordinates parameterization method has been introduced by Floater [Flo03a]. Each vertex in parameter space is optimized so as to be a convex combination of its neighboring vertices. The barycentric coordinates are this time unconditionally positive, by deriving an application of the mean theorem for harmonic functions. This method is in essence an approximation of the discrete conformal maps, with a guaranteed one-to-one mapping when the border is convex. This method solves two $\#vertices \times \#vertices$ sparse linear systems. The matrix (the same for both systems) is asymmetric.

Figure 39.5: Floater Mean Value Coordinates

Discrete Authalic parameterization

CGAL::Discrete_authalic_parameterizer_3<ParameterizationMesh_3, SparseLinearAlgebraTraits_d> *BorderParameterizer_3,*

The discrete authalic parameterization method has been introduced by Desbrun et al. [DMA02]. It corresponds to a weak formulation of an area-preserving method, and in essence locally minimizes the area distortion. A one-to-one mapping is guaranteed only if the convex combination condition is fulfilled and the border is convex. This method solves two $\#vertices \times \#vertices$ sparse linear systems. The matrix (the same for both systems) is asymmetric.

Figure 39.6: Discrete Authalic Parameterization

Border Parameterizations for Fixed Methods

Parameterization methods for borders are used as traits classes modifying the behavior of *ParameterizerTraits_3* models. They are provided as models of the *BorderParameterizer_3* concept. Border parameterizations for fixed border surface parameterizations are a family of methods to define a set of constraints, namely two u, v coordinates for each vertex along the border.

- The user can select a border parameterization among two commonly used methods: uniform or arc-length parameterization.

Usage:

Uniform border parameterization is more stable, although it gives poor visual results. The arc-length border parameterization is used by default.

- One convex shape specified by one shape among two standard ones: a circle or a square.

Usage:

The circular border parameterization is used by default as it corresponds to the simplest convex shape. The square border parameterization is commonly used for texture mapping.

```
CGAL::Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>
CGAL::Circular_border_uniform_parameterizer_3<ParameterizationMesh_3>
CGAL::Square_border_arc_length_parameterizer_3<ParameterizationMesh_3>
CGAL::Square_border_uniform_parameterizer_3<ParameterizationMesh_3>
```

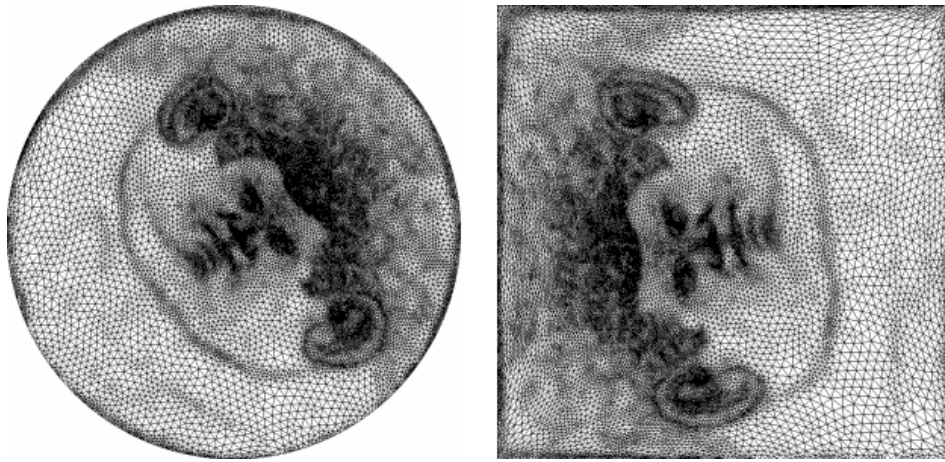

Figure 39.7: Left: Julius Cesar mask parameterization with Authalic/circular border. Right: Julius Cesar mask's image with Floater/square border.

39.3.2 Free Border Surface Parameterizations

Least Squares Conformal Maps

CGAL::LSCM_parameterizer_3<*ParameterizationMesh_3*,
SparseLinearAlgebraTraits_d>

BorderParameterizer_3,

The Least Squares Conformal Maps (LSCM) parameterization method has been introduced by Lévy et al. [LPRM02]. It corresponds to a conformal method with a free border (at least two vertices have to be constrained to obtain a unique solution), which allows further lowering of the angle distortion. A one-to-one mapping is not guaranteed by this method. It solves a $(2 \times \text{\#triangles}) \times \text{\#vertices}$ sparse linear system in the least squares sense, which implies solving a symmetric matrix.

Figure 39.8: Least squares conformal maps.

Border Parameterizations for Free Methods

Parameterization methods for borders are used as traits classes modifying the behavior of *ParameterizerTraits_3* models. They are provided as models of the *BorderParameterizer_3* concept. The border parameterizations associated to free border surface parameterization methods define only two constraints: the pinned vertices.

- *CGAL::Two_vertices_parameterizer_3<ParameterizationMesh_3>*

Usage:

CGAL::Two_vertices_parameterizer_3<ParameterizationMesh_3> is the default free border parameterization, and is the only one available in the current version of this package.

39.3.3 Discrete Authalic Parameterization Example

Authalic_parameterization.cpp computes a Discrete Authalic parameterization over a *CGAL::Polyhedron_3<Traits>* mesh. Specifying a specific surface parameterization instead of the default one means using the second parameter of *CGAL::parameterize()*. The differences with the first example *Simple_parameterization.cpp* are:

```
#include <CGAL/Discrete_authalic_parameterizer_3.h>

...

//*****
// Discrete Authalic Parameterization
//*****

typedef CGAL::Discrete_authalic_parameterizer_3<Parameterization_polyhedron_adaptor>
        Parameterizer;

Parameterizer::Error_code err = CGAL::parameterize(mesh_adaptor, Parameterizer());

...
```

39.3.4 Square Border Arc Length Parameterization Example

Square_border_parameterization.cpp computes a Floater mean value coordinates parameterization with a square border arc length parameterization. Specifying a specific border parameterization instead of the default one means using the second parameter of *CGAL::Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>*. The differences with the first example *Simple_parameterization.cpp* are:

```
#include <CGAL/Square_border_parameterizer_3.h>
```

```

...

//*****
// Floater Mean Value Coordinates parameterization
// with square border
//*****

// Square border parameterizer
typedef CGAL::Square_border_arc_length_parameterizer_3<Parameterization_polyhedron_adaptor>
        Border_parameterizer;

// Floater Mean Value Coordinates parameterizer with square border
typedef CGAL::Mean_value_coordinates_parameterizer_3<Parameterization_polyhedron_adaptor,
        Border_parameterizer>
        Parameterizer;

Parameterizer::Error_code err = CGAL::parameterize(mesh_adaptor, Parameterizer());

...

```

39.4 Sparse Linear Algebra

Parameterizing triangle meshes requires both efficient representation of sparse matrices and efficient iterative or direct linear solvers. We provide links to standard libraries (TAUCS) and include a separate package devoted to OpenNL sparse linear solver.

39.4.1 List of Solvers

We provide an interface to several sparse linear solvers, as models of the *SparseLinearAlgebraTraits_d* concept:

- OpenNL [\[Lev05\]](#) is shipped with CGAL. This is the default solver.

OpenNL::DefaultLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER> in OpenNL package
OpenNL::SymmetricLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER> in OpenNL package

Usage:

OpenNL (in the version shipped with CGAL) is a lightweight sparse linear solver. It does not support large systems, but it is highly portable and supports exact number types.

- **TAUCS** is a state-of-the-art direct solver for sparse symmetric matrices. It also includes an out-of-core general sparse solver.

CGAL::Taucs_solver_traits<T>
CGAL::Taucs_symmetric_solver_traits<T>

Usage:

TAUCS is very robust and supports large systems. On the other hand, it is not available on all platforms supported by CGAL and does not support exact number types.

Install:

TAUCS can be downloaded from http://www.tau.ac.il/~stoledo/taucs/2.2/taucs_full.zip.

39.4.2 TAUCS Solver Example

examples/Surface_mesh_parameterization/Taucs_parameterization.cpp computes the default parameterization method (Floater mean value coordinates with a circular border), but specifically instantiates the TAUCS solver. Specifying a specific solver instead of the default one (OpenNL) means using the third parameter of *CGAL::Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>*. The differences with the first example *examples/Surface_mesh_parameterization/Simple_parameterization.cpp* are:

```
#include <CGAL/Taucs_solver_traits.h>

...

//*****
// Floater Mean Value Coordinates parameterization
// (circular border) with TAUCS solver
//*****

// Circular border parameterizer (the default)
typedef CGAL::Circular_border_arc_length_parameterizer_3<Parameterization_polyhedron_adaptor>
                                                    Border_parameterizer;

// TAUCS solver
typedef CGAL::Taucs_solver_traits<double> Solver;

// Floater Mean Value Coordinates parameterization
// (circular border) with TAUCS solver
typedef CGAL::Mean_value_coordinates_parameterizer_3<Parameterization_polyhedron_adaptor,
                                                    Border_parameterizer,
                                                    Solver>
                                                    Parameterizer;

Parameterizer::Error_code err = CGAL::parameterize(mesh_adaptor, Parameterizer());

...
```

39.5 Cutting a Mesh

39.5.1 Computing a Cut Graph

All surface parameterization methods proposed in this package only deal with meshes which are homeomorphic (topologically equivalent) to discs. Nevertheless meshes with arbitrary topology and number of connected

components can be parameterized, provided that the user specifies a cut graph (an oriented list of vertices), which is the border of a topological disc. If no cut graph is provided as input, the longest border already in the input mesh is taken as default border, all other borders being considered as holes. Note that only the inside part (i.e., one connected component) of the given border is parameterized.

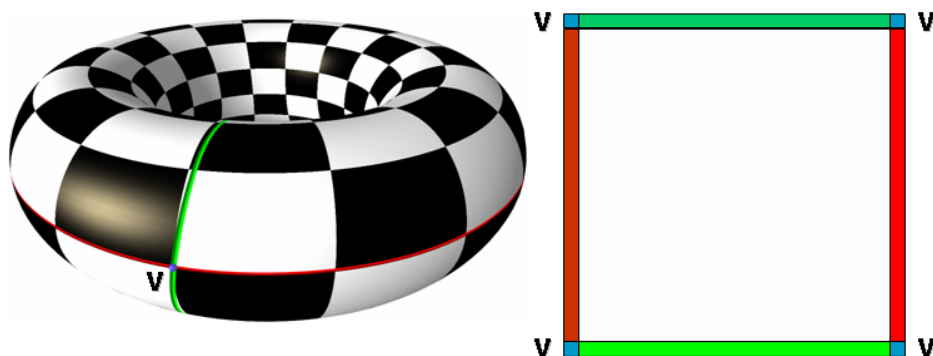

Figure 39.9: Cut Graph

This package does not provide any algorithm to transform an arbitrary mesh into a topological disk, the user being responsible for generating such a cut graph. Nevertheless, we provide in *polyhedron_ex_parameterization.cpp* a simple cutting algorithm for the sake of completeness.

39.5.2 Applying a Cut

The surface parameterization classes in this package only *directly* support surfaces which are homeomorphic to disks (models of *ParameterizationMesh_3*). This software design simplifies the implementation of all new parameterization methods.

The *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>* class is responsible for *virtually* cutting a patch in a *ParameterizationPatchableMesh_3* mesh. The resulting patch is a topological disk (if the cut graph is correct) and provides a *ParameterizationMesh_3* interface. It can be used as parameter of *CGAL::parameterize()*.

ParameterizationPatchableMesh_3 inherits from concept *ParameterizationMesh_3*, thus is a concept for a 3D surface mesh. *ParameterizationPatchableMesh_3* adds the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* behave exactly as if the surface was cut along a certain graph.

The *ParameterizationMesh_3* interface with the Polyhedron is both a model of *ParameterizationMesh_3* and *ParameterizationPatchableMesh_3*:

```
CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>
```

Note that this class is a decorator which adds *on the fly* the necessary fields to unmodified CGAL data structures (using STL maps). For better performances, it is recommended to use CGAL data structures enriched with the proper fields. See *Polyhedron_ex* class in *polyhedron_ex_parameterization.cpp* example.

39.5.3 Cutting a Mesh Example

Mesh_cutting_parameterization.cpp virtually cuts a *CGAL::Polyhedron_3<Traits>* mesh to make it a topologi-

cal disk, then applies the default parameterization:

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/Parameterization_polyhedron_adaptor_3.h>
#include <CGAL/parameterize.h>
#include <CGAL/Parameterization_mesh_patch_3.h>

#include <iostream>
#include <fstream>

// -----
// Private types
// -----

typedef CGAL::Cartesian<double>          Kernel;
typedef CGAL::Polyhedron_3<Kernel>      Polyhedron;

// Polyhedron adaptor
typedef CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron>
    Parameterization_polyhedron_adaptor;

// Type describing a border or seam as a vertex list
typedef std::list<Parameterization_polyhedron_adaptor::Vertex_handle>
    Seam;

// -----
// Private functions
// -----

// If the mesh is a topological disk, extract its longest border,
// else compute a very simple cut to make it homeomorphic to a disk.
// Return the border of this region (empty on error)
//
// CAUTION: this cutting algorithm is very naive. Write your own!
static Seam cut_mesh(Parameterization_polyhedron_adaptor& mesh_adaptor)
{
    // Helper class to compute genus or extract borders
    typedef CGAL::Parameterization_mesh_feature_extractor<Parameterization_polyhedron_adaptor>
        Mesh_feature_extractor;

    Seam seam;          // returned list

    // Get reference to Polyhedron_3 mesh
    Polyhedron& mesh = mesh_adaptor.get_adapted_mesh();

    // Extract mesh borders and compute genus
    Mesh_feature_extractor feature_extractor(mesh_adaptor);
    int nb_borders = feature_extractor.get_nb_borders();
    int genus = feature_extractor.get_genus();
}
```

```

// If mesh is a topological disk
if (genus == 0 && nb_borders > 0)
{
    // Pick the longest border
    seam = feature_extractor.get_longest_border();
}

}

```

File: examples/Surface_mesh_parameterization/Mesh_cutting_parameterization.cpp

39.6 Output

Parameterization methods compute (u, v) fields for each vertex of the input mesh, with the seam vertices being virtually duplicated (thanks to *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>*). To support this duplication, *CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3>* stores the result in the (u, v) fields of the input mesh halfedges. A (u, v) pair is computed for each inner vertex (i.e. its halfedges share the same (u, v) pair), while a (u, v) pair is computed for each border halfedge. The user has to iterate over the mesh halfedges to get the result. Note that (u, v) fields do not exist in *CGAL::Polyhedron_3<Traits>*, thus the output traversal is specific to the way the (u, v) fields are implemented by the adaptor.

39.6.1 EPS Output Example

Complete_parameterization_example.cpp is a complete parameterization example which outputs the resulting parameterization to a EPS file. It gets the (u, v) fields computed by a parameterization method over a *CGAL::Polyhedron_3<Traits>* mesh with a *CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3>* adaptor:

```
#include <CGAL/basic.h> // include basic.h before testing #defines
```

```

#ifdef CGAL_USE_TAUCS

#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>

39.7 Complexity and Guarantees

39.7.1 Parameterization Methods and Guarantees

- Fixed boundaries
 - One-to-one mapping

Tutte's theorem guarantees a one-to-one mapping provided that the weights are all positive and the border convex. It is the case for Tutte barycentric mapping and Floater mean value coordinates. It is not always the case for discrete conformal map (cotangents) and discrete authalic parameterization.
 - Non-singularity of the matrix

Geshorgin's theorem guarantees the convergence of the solver if the matrix is diagonal dominant. This is the case with positive weights (Tutte barycentric mapping and Floater mean value coordinates).
- Free boundaries

- One-to-one mapping
No guarantee is provided by LSCM (both global overlaps and triangle flips can occur).
- Non-singularity of the matrix
For LSCM, the matrix of the system is the Gram matrix of a matrix with maximal rank, and is therefore non-singular (Gram theorem).

39.7.2 Precision

Two algorithms of this package construct the sparse linear system(s) using trigonometric functions, and are this incompatible with exact arithmetic:

- Floater mean value coordinates
- Circular border parameterization

On the other hand, linear solvers commonly use double precision floating point numbers.

OpenNL's BICGSTAB solver (accessible through the *OpenNL::DefaultLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER>* interface) is the only solver supported by this package which computes exact results, when used with an exact arithmetic. This package is intended to be used mainly with a CGAL Cartesian kernel with doubles.

OpenNL's BICGSTAB Solver with an Exact Arithmetic

The BICGSTAB conjugate gradient is in disguise a direct solver. In a nutshell, it computes a vector basis orthogonal with respect to the matrix, and the coordinates of the solution in this vector basis. Each iteration computes one component of the basis and one coordinate, therefore the algorithm converges to the solution in n iterations, where n is the dimension of the matrix. More precisely, it is shown to converge in k iteration, where k is the number of distinct eigenvalues of the matrix.

Solvers with a Floating Point Arithmetic

OpenNL's BICGSTAB example:

When inexact numerical types are used (e.g. doubles), accumulated errors slow down convergence (in practice, it requires approximately $5k$ iterations to converge). The required number of iterations depends on the eigenvalues of the matrix, and these eigenvalues depend on the shape of the triangles. The optimum is when the triangles are equilateral (then the solver converges in less than 10 iterations). The worst case is obtained when the mesh has a large number of skinny triangles (near-singular Jacobian matrix of the triangle). In this case, the spectrum of the matrix is wide (many different eigenvalues), and the solver requires nearly $5n$ iterations to converge.

39.7.3 Algorithmic Complexity

In this package, we focus on piecewise linear mappings onto a planar domain. All surface parameterization methods are based on solving one (or two) sparse linear system(s). The algorithmic complexity is dominated by the resolution of the sparse linear system(s).

OpenNL's BICGSTAB example:

At each iteration, the operation of highest complexity is the product between the sparse-matrix and a vector. The sparse matrix has a fixed number of non-zero coefficients per row, therefore the matrix / vector product has $O(n)$ complexity. Since convergence is reached after k iterations, the complexity is $O(k.n)$ (where k is the number of distinct eigenvalues of the matrix). Therefore, best case complexity is $O(n)$ (equilateral triangles), and worst case complexity is $O(n^2)$ (skinny triangles).

39.8 Software Design

39.8.1 Global Function `parameterize()`

This package's entry point is:

```
// Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a
// 2D circle, using Floater Mean Value Coordinates algorithm.
// A one-to-one mapping is guaranteed.
template <class ParameterizationMesh_3>
typename Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
parameterize(ParameterizationMesh_3& mesh) // 3D mesh, model of ParameterizationMesh_3 concept
{
    Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3> parameterizer;
    return parameterizer.parameterize(mesh);
}

// Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a
// simple 2D domain.
// One-to-one mapping may be guaranteed or not,
// depending on the chosen ParameterizerTraits_3 algorithm.
template <class ParameterizationMesh_3, class ParameterizerTraits_3>
typename Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
parameterize(ParameterizationMesh_3& mesh, // 3D mesh, model of ParameterizationMesh_3
             ParameterizerTraits_3 parameterizer) // Parameterization method for 'mesh'
{
    return parameterizer.parameterize(mesh);
}
```

You may notice that these global functions simply call the `parameterize()` method of a *ParameterizerTraits_3* object. The purpose of these global functions is:

- to be consistent with other CGAL algorithms that are also provided as global functions, e.g. *CGAL::convex_hull_2()*,
- to provide a default parameterization method (Floater Mean Value Coordinates), which wouldn't be possible with a direct call to an object's method.

You may also wonder why there is not just one *CGAL::parameterize()* function with a default *ParameterizerTraits_3* argument equal to *CGAL::Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3>*. The reason is simply that this is not allowed by the C++ standard (see [C++98], paragraph 14.1/9).

39.8.2 No Common Parameterization Algorithm

ParameterizerTraits_3 models modify the behavior of the global function *CGAL::parameterize()* - hence the *Traits* in the name. On the other hand, *ParameterizerTraits_3* models do not modify the behavior of a common parameterization algorithm - as you might expect.

In this package, we focus on triangulated surfaces that are homeomorphic to a disk and on piecewise linear mappings onto planar domains. A consequence is that the skeleton of all parameterization methods of this package is the same:

- Allocate a sparse linear system $A.X = B$
- Parameterize the mesh border and initialize B
- Parameterize the inner points of the mesh and set A coefficients
- Solve the system

It is tempting to make the parameterization method a traits class that modifies the behavior of a common parameterization algorithm. On the other hand, there are several differences among methods:

- Fixed border methods need to parameterize all border vertices, while free border methods parameterize only two vertices.
- Some methods create symmetric definite positive systems, which may be solved more efficiently than general systems.
- Most parameterization methods use two $\#vertices \times \#vertices$ systems, where Least Squares Conformal Maps uses one $(2 * \#triangles) \times \#vertices$ system.
- Most parameterization methods invert the A matrix, when Least Squares Conformal Maps solves the system in the least squares sense.

Therefore, the software design chosen is:

- Each *ParameterizerTraits_3* model implements its own version of the parameterization algorithm as a *parameterize()* method.
- Each *ParameterizerTraits_3* model has template arguments defining the border parameterization and sparse linear solver to use, with default values adapted to the method.
- Code factorization is achieved using a class hierarchy and (few) virtual methods.

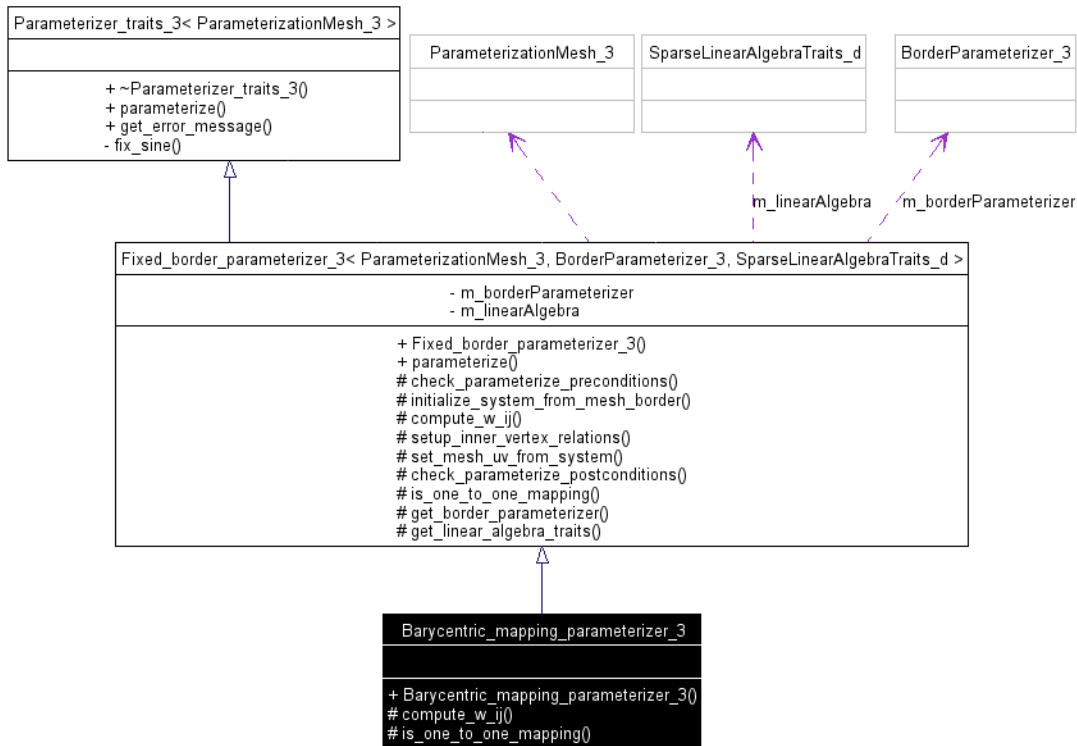

Figure 39.10: A parameterizer UML class diagram (main types and methods only)

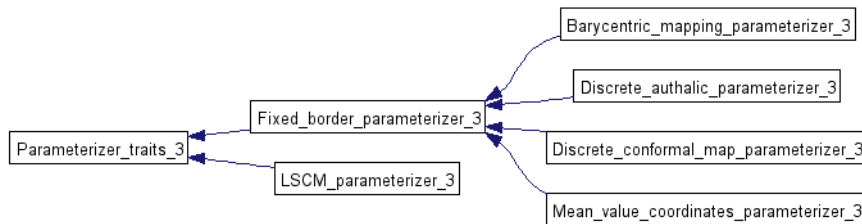

Figure 39.11: Surface parameterizer classes hierarchy

Note: *CGAL::Parameterizer_traits_3<ParameterizationMesh_3>* is the (pure virtual) superclass of all surface parameterization classes.

39.8.3 Fixed_border_parameterizer_3 Class

Linear fixed border parameterization algorithms are very close. They mainly differ by the energy that they try to minimize, i.e. by the value of the w_{ij} coefficient of the A matrix, for v_i and v_j neighbor vertices of the mesh [FH05]. One consequence is that most of the code of the fixed border methods is factorized in the *CGAL::Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>* class.

Subclasses:

- must provide *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* default template parameters that make sense,
- must implement *compute_w_ij()* to compute $w_{ij} = (i, j)$ coefficient of matrix A for v_j neighbor vertex of v_i ,
- may implement an optimized version of *is_one_to_one_mapping()*.

See `CGAL::Barycentric_mapping_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>` class as an example.

39.8.4 Border Parameterizations

Border Parameterizations are models of the *BorderParameterizer_3* concept. To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* mesh class. They do not know the parameterization algorithm or the sparse linear solver used.

39.8.5 ParameterizationMesh_3 and ParameterizationPatchableMesh_3 Concepts

All parameterization methods are templated by the kind of mesh they are applied on. The mesh type must be a model of *ParameterizationMesh_3*.

The purpose of such a model is to:

1. Support several kind of meshes.
2. Hide the implementation of extra fields specific to the parameterization domain (*index*, *u*, *v*, *is_parameterized*).
3. Handle in the mesh type the complexity of *virtually* cutting a mesh to make it homeomorphic to a disk (instead of duplicating this code in each parameterization method).

Two options are possible for 1) and 2):

- Pass to all classes and methods a mesh pointer, a traits class to manipulate it, and accessors to the extra field arrays. This is the choice of the Boost Graph Library with *boost::graph_traits<>* and the property maps.
- Pass to all classes and methods an object that points to the actual mesh and knows how to access to its fields. This is the Adaptor concept [GHJV95].

The current design of this package uses the second option, which is simpler. Of course, we may decide at some point to switch to the first one to reach a deeper integration of CGAL with Boost.

Point 3) is solved by class `CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>`, which takes care of *virtually* cutting a patch in a *ParameterizationPatchableMesh_3* mesh, to make it appear as a topological disk with a *ParameterizationMesh_3* interface. *ParameterizationPatchableMesh_3* inherits from concept *ParameterizationMesh_3* and adds the ability to support patches and virtual seams.

This mainly means that:

- vertices can be tagged as inside or outside the patch to parameterize,
- the fields specific to parameterizations (*index*, *u*, *v*, *is_parameterized*) can be set *per corner* (which is a more general way of saying *per half-edge*).

39.8.6 SparseLinearAlgebraTraits_d Concept

This package solves sparse linear systems using solvers which are models of *SparseLinearAlgebraTraits_d*.

SparseLinearAlgebraTraits_d is a sub-concept of the *LinearAlgebraTraits_d* concept in *Kernel_d*. The goal is to adapt easily code written for dense matrices to sparse ones, and vice-versa.

39.8.7 Cutting a Mesh

In this package, we focus on triangulated surfaces that are homeomorphic to a disk.

Computing a cutting path that transforms a closed mesh of arbitrary genus into a topological disk is a research topic on its own. This package does not intend to cover this topic at the moment.

39.9 Extending the Package and Reusing Code

39.9.1 Reusing Mesh Adaptors

ParameterizationMesh_3 defines a concept to access to a general polyhedral mesh. It is optimized for the *Surface_mesh_parameterization* package only in the sense that it defines the accessors to fields specific to the parameterization domain (*index*, *u*, *v*, *is_parameterized*).

It may be easily generalized.

39.9.2 Reusing Sparse Linear Algebra

The *SparseLinearAlgebraTraits_d* concept and the traits classes for OpenNL and TAUCS are independent of the rest of the *Surface_mesh_parameterization* package, and may be reused by CGAL developers for other purposes.

39.9.3 Adding New Parameterization Methods

Implementing a new fixed border linear parameterization is easy. Most of the code of the fixed border methods is factorized in the *CGAL::Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>* class. Subclasses must mainly implement a *compute_w_ij()* method which computes each $w_{ij} = (i, j)$ coefficient of the matrix *A* for v_j neighboring vertices of v_i .

Although implementing a new free border linear parameterization method is more challenging, the Least Squares Conformal Maps parameterization method provides a good starting point.

Implementing *non* linear parameterizations is a natural extension to this package, although only the mesh adaptors can be reused.

39.9.4 Adding New Border Parameterization Methods

Implementing a new border parameterization method is easy. Square, circular and two-points border parameterizations are good starting points.

39.9.5 Mesh Cutting

Obviously, this package would benefit of having robust algorithms which transform arbitrary meshes into topological disks.

Planar Parameterization of Triangulated Surface Meshes

Reference Manual

Laurent Saboret, Pierre Alliez and Bruno Lévy

Parameterizing a surface amounts to finding a one-to-one mapping from a suitable domain to the surface. A good mapping is the one which minimizes either angle or area distortions in some sense. In this package, we focus on triangulated surfaces that are homeomorphic to a disk and on piecewise linear mappings into a planar domain.

Surface Parameterization Methods

This CGAL package implements some of the state-of-the-art parameterization methods:

- Fixed border:
 - Tutte Barycentric Mapping [[Tut63](#)]. One-to-one mapping is guaranteed for convex border.
 - Floater Mean Value Coordinates [[Flo03a](#)]. One-to-one mapping is guaranteed for convex border.

- Discrete Conformal Map [EDD⁺95]. Conditionally guaranteed if all weights are positive and border is convex.
- Discrete Authalic parameterization [DMA02]. Conditionally guaranteed if all weights are positive and border is convex.
- Free border:
 - Least Squares Conformal Maps [LPRM02].

Border Parameterization Methods

Border parameterization methods define a set of constraints (a constraint specifies two (u,v) coordinates for each instance of a vertex along the border).

This package implements all common border parameterization methods:

- For fixed border methods:
 - the user can select a border parameterization among two common methods: uniform or arc-length parameterizations.
 - one convex shape specified by:
 - * one shape among a set of standard ones (circle, square).
- For free border methods: at least two constraints (the pinned vertices).

<i>CGAL::Two_vertices_parameterizer_3<ParameterizationMesh_3></i>	page 2395

Mesh

The general definition of input meshes handled *directly* by *CGAL::parameterize()* is:

- Model of *ParameterizationMesh_3*.
- Triangulated.
- 2-manifold.
- Oriented.
- Homeomorphic to a disc (may have holes).

This package provides a model of the *ParameterizationMesh_3* concept to access *CGAL::Polyhedron_3<Traits>* :
CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>

Fortunately, the meshes supported *indirectly* by the package can be of any genus and have any number of connected components. If it is not a topological disc, the input mesh has to come with a description of a cutting path (an oriented list of vertices) which is the border of a topological disc. If no cutting path is given as input, we assume that the surface border is the longest border already in the input mesh (the other borders will be considered as holes).

The *CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>* class is responsible for *virtually* cutting a patch in a *ParameterizationPatchableMesh_3* mesh. The resulting patch is a topological disk (if the input cutting path is correct) and provides a *ParameterizationMesh_3* interface. It can be used as parameter of *CGAL::parameterize()*.

Note that this way the user is responsible for cutting a closed mesh of arbitrary genus (even a topological disc with an intricate seam cut), as long as this condition is fulfilled.

The package provides an interface with *CGAL::Polyhedron_3<Traits>*:
CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_> page [2366](#)

Output

A (u, v) pair is computed for each inner vertex (i.e. its halfedges share the same (u, v) pair), while a (u, v) pair is computed for each border halfedge. The user has to iterate over the mesh halfedges to get the result.

Sparse Linear Algebra

Since parameterizing meshes requires efficient representation of sparse matrices and efficient iterative or direct linear solvers, we provide an interface to several sparse linear solvers:

- OpenNL (Bruno Lévy) is shipped with CGAL. This is the default solver.
- TAUCS is a state-of-the-art direct solver for sparse symmetric matrices. It also includes an out-of-core general solver.

CGAL::Taucs_symmetric_solver_traits<T> page [2392](#)

Helper Classes

CGAL::Parameterization_mesh_feature_extractor<ParameterizationMesh_3> page [2356](#)

Assertions

The assertion flags for the package use *SURFACE_MESH_PARAMETERIZATION* in their names (e.g., *CGAL_SURFACE_MESH_PARAMETERIZATION_NO_ASSERTIONS*).

For *fixed* border parameterizations:

- Preconditions:
 - check that the border is mapped onto a convex polygon.
 - check that the input mesh is triangular (expensive check).
 - check that the input mesh is a surface with one connected component (expensive check).
- Postconditions:
 - check one-to-one mapping.

For *free* border parameterizations:

- Preconditions:
 - check that the input mesh is triangular (expensive check).
 - check that the input mesh is a surface with one connected component (expensive check).
- Postconditions:
 - check one-to-one mapping.

Expensive checking is off by default. It can be enabled by defining *CGAL_SURFACE_MESH_PARAMETERIZATION_CHECK_EXPENSIVE*.

CGAL::Barycentric_mapping_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Barycentric_mapping_parameterizer_3* implements Tutte Barycentric Mapping algorithm [Tut63]. This algorithm is also called *Tutte Uniform Weights* by other authors.

One-to-one mapping is guaranteed if the surface's border is mapped to a convex polygon.

This class is a Strategy [GHJV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize()*. *Barycentric_mapping_parameterizer_3*:

- provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense.
- implements *compute_w_ij()* to compute $w_{ij} = (i,j)$ coefficient of matrix A for j neighbor vertex of i based on Tutte Barycentric Mapping method.
- implements an optimized version of *is_one_to_one_mapping()*.

```
#include <CGAL/Barycentric_mapping_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept.

Design Pattern

Barycentric_mapping_parameterizer_3<*ParameterizationMesh_3*, ...> class is a Strategy [GHJV95]: it implements a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3,
class BorderParameterizer_3 = Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>,
class SparseLinearAlgebraTraits_d = OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>>
class Barycentric_mapping_parameterizer_3;
```

Parameters: *ParameterizationMesh_3* 3D surface mesh.

BorderParameterizer_3 Strategy to parameterize the surface border.

SparseLinearAlgebraTraits_d Traits class to solve a sparse linear system. Note: the system is NOT symmetric because *Fixed_border_parameterizer_3* does not remove (yet) border vertices from the system.

Creation

Barycentric_mapping_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*,
SparseLinearAlgebraTraits_d> *param*(*Border_param* *border_param* = *Border_param*()),

LA sparse_la = *Sparse_LA*()

Constructor.

Parameters: *border_param* Object that maps the surface's border to 2D space.

sparse_la Traits object to access a sparse linear system.

Operations

virtual NT *param.compute_w_ij*(*Adaptor mesh*,
Vertex_const_handle main_vertex_v_i,
Vertex_around_vertex_const_circulator neighbor_vertex_v_j)

Compute $w_{ij} = (i,j)$ coefficient of matrix A for j neighbor vertex of i. Tutte Barycentric Mapping algorithm is the most simple one: $w_{ij} = 1$ for j neighbor vertex of i.

virtual bool *param.is_one_to_one_mapping*(*Adaptor mesh*, *Matrix A*, *Vector Bu*, *Vector Bv*)

Check if 3D \rightarrow 2D mapping is one-to-one. Theorem: one-to-one mapping is guaranteed if all w_{ij} coefficients are > 0 (for j vertex neighbor of i) and if the surface border is mapped onto a 2D convex polygon. All w_{ij} coefficients = 1 (for j vertex neighbor of i), thus mapping is guaranteed if the surface border is mapped onto a 2D convex polygon.

BorderParameterizer_3

Definition

BorderParameterizer_3 is a concept of class that parameterizes a given type of mesh, 'Adaptor', which is a model of the *ParameterizationMesh_3* concept.

Implementation note: To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* class. They do not know the parameterization algorithm requirements or the kind of sparse linear system used.

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Types

BorderParameterizer_3::Adaptor Export *ParameterizationMesh_3* template parameter.
BorderParameterizer_3::Error_code The various errors detected by this package.

Creation

Construction and destruction are undefined.

Operations

<i>Error_code</i>	<i>bp.parameterize_border(Adaptor& mesh)</i>	Assign to mesh's border vertices a 2D position (i.e. a (u,v) pair) on border's shape. Mark them as <i>parameterized</i> . Return false on error.
<i>bool</i>	<i>bp.is_border_convex()</i>	Indicate if border's shape is convex.

Has Models

CGAL::Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>

Definition

Circular_border_arc_length_parameterizer_3 is the default border parameterizer for fixed border parameterization methods.

This class parameterizes the border of a 3D surface onto a circle, with an arc-length parameterization: (u,v) values are proportional to the length of border edges. *Circular_border_parameterizer_3* implements most of the border parameterization algorithm. This class implements only *compute_edge_length()* to compute a segment's length.

```
#include <CGAL/Circular_border_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept.

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Circular_border_arc_length_parameterizer_3;
```

Types

Creation

```
Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3> bp;
```

default constructor.

Operations

```
virtual double bp.compute_edge_length( Adaptor mesh,
                                       Vertex_const_handle source,
                                       Vertex_const_handle target)
```

Compute the length of an edge. Arc-length border parameterization: (u,v) values are proportional to the length of border edges.

CGAL::Circular_border_parameterizer_3<ParameterizationMesh_3>

Definition

This is the base class of strategies that parameterize the border of a 3D surface onto a circle. *Circular_border_parameterizer_3* is a pure virtual class, thus cannot be instantiated. It implements most of the algorithm. Sub-classes just have to implement *compute_edge_length()* to compute a segment's length.

Implementation note: To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* class. They do not know the parameterization algorithm requirements or the kind of sparse linear system used.

```
#include <CGAL/Circular_border_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept (although you cannot instantiate this class).

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Circular_border_parameterizer_3;
```

Types

Circular_border_parameterizer_3<ParameterizationMesh_3>::Adaptor

Export *ParameterizationMesh_3* template parameter.

Creation

Circular_border_parameterizer_3<ParameterizationMesh_3> bp;

default constructor.

Operations

Parameterizer_traits_3<Adaptor>::Error_code

bp.parameterize_border(Adaptor& mesh)

Assign to mesh's border vertices a 2D position (i.e. a (u,v) pair) on border's shape. Mark them as *parameterized*.

bool

bp.is_border_convex()

Indicate if border's shape is convex.

virtual double

*bp.compute_edge_length(Adaptor mesh,
Vertex_const_handle source,
Vertex_const_handle target)*

Compute the length of an edge.

CGAL::Circular_border_uniform_parameterizer_3<ParameterizationMesh_3>

Definition

This class parameterizes the border of a 3D surface onto a circle in a uniform manner: points are equally spaced. *Circular_border_parameterizer_3* implements most of the border parameterization algorithm. This class implements only *compute_edge_length()* to compute a segment's length.

```
#include <CGAL/Circular_border_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept.

Design Pattern

BorderParameterizer_3 models are Strategies [\[GHJV95\]](#): they implement a strategy of border parameterization for models of *ParameterizationMesh_3*

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Circular_border_uniform_parameterizer_3;
```

Types

Creation

```
Circular_border_uniform_parameterizer_3<ParameterizationMesh_3> bp;
```

default constructor.

Operations

```
virtual double bp.compute_edge_length( Adaptor mesh,
                                       Vertex_const_handle source,
                                       Vertex_const_handle target)
```

Compute the length of an edge. Uniform border parameterization: points are equally spaced.

CGAL::Discrete_authalic_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Discrete_authalic_parameterizer_3* implements the Discrete Authalic Parameterization algorithm [DMA02]. This method is sometimes called *DAP* or just *Authalic parameterization*.

DAP is a weak area-preserving parameterization. It is a compromise between area-preserving and angle-preserving.

One-to-one mapping is guaranteed if surface's border is mapped onto a convex polygon.

This class is a Strategy [GHV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize()*. *Discrete_authalic_parameterizer_3*:

- provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense.
- implements *compute_w_ij()* to compute $w_{ij} = (i, j)$ coefficient of matrix A for j neighbor vertex of i based on Discrete Authalic Parameterization algorithm.

```
#include <CGAL/Discrete_authalic_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept.

Design Pattern

Discrete_authalic_parameterizer_3<ParameterizationMesh_3, ...> class is a Strategy [GHV95]: it implements a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3,
class BorderParameterizer_3 = Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>,
class SparseLinearAlgebraTraits_d = OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>>
class Discrete_authalic_parameterizer_3;
```

Types

Creation

Discrete_authalic_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*,
SparseLinearAlgebraTraits_d> param(*Border_param* *border_param* = *Border_param*()),

LA sparse_la = *Sparse_LA*()

Constructor.

Parameters: *border_param* Object that maps the surface's border to 2D space.

sparse_la Traits object to access a sparse linear system.

Operations

virtual NT *param.compute_w_ij*(*Adaptor mesh*,
Vertex_const_handle *main_vertex_v_i*,
Vertex_around_vertex_const_circulator *neighbor_vertex_v_j*)

Compute $w_{ij} = (i, j)$ coefficient of matrix A for j neighbor vertex of i.

CGAL::Discrete_conformal_map_parameterizer_3< ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Discrete_conformal_map_parameterizer_3* implements the Discrete Conformal Map (DCM) parameterization [EDD⁺95]. This algorithm is also called *Discrete Conformal Parameterization (DCP)*, *Discrete Harmonic Map* or *Fixed Conformal Parameterization* by other authors.

This is a conformal parameterization, i.e. it attempts to preserve angles.

One-to-one mapping is guaranteed if surface's border is mapped onto a convex polygon.

This class is a Strategy [GHJV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize()*. *Discrete_conformal_map_parameterizer_3*:

- provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense.
- implements *compute_w_ij()* to compute $w_{ij} = (i, j)$ coefficient of matrix A for j neighbor vertex of i based on Discrete Conformal Map method.

```
#include <CGAL/Discrete_conformal_map_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept.

Design Pattern

Discrete_conformal_map_parameterizer_3<*ParameterizationMesh_3*, ...> class is a Strategy [GHJV95]: it implements a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3,
class BorderParameterizer_3 = Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>,
class SparseLinearAlgebraTraits_d = OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>>
class Discrete_conformal_map_parameterizer_3;
```

Parameters: *ParameterizationMesh_3* 3D surface mesh.

BorderParameterizer_3 Strategy to parameterize the surface border.

SparseLinearAlgebraTraits_d Traits class to solve a sparse linear system. Note: the system is NOT symmetric because *Fixed_border_parameterizer_3* does not remove (yet) border vertices from the system.

Types

Creation

Discrete_conformal_map_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*,
SparseLinearAlgebraTraits_d> *param*(*Border_param* *border_param* = *Border_param*() ,

LA sparse_la = *Sparse_LA*())

Constructor.

Parameters: *border_param* Object that maps the surface's border to 2D space.

sparse_la Traits object to access a sparse linear system.

Operations

virtual NT *param.compute_w_ij*(*Adaptor mesh*,
Vertex_const_handle main_vertex_v_i,
Vertex_around_vertex_const_circulator neighbor_vertex_v_j)

Compute $w_{ij} = (i,j)$ coefficient of matrix A for j neighbor vertex of i.

CGAL::Fixed_border_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Fixed_border_parameterizer_3* is the base class of fixed border parameterization methods (Tutte, Floater, ...).

One-to-one mapping is guaranteed if surface's border is mapped onto a convex polygon.

This class is a pure virtual class, thus cannot be instantiated. Anyway, it implements most of the parameterization algorithm *parameterize()*. Subclasses are Strategies [GHJV95] that modify the behavior of this algorithm:

- They provide *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense.
- They implement *compute_w_ij()* to compute $w_{ij} = (i, j)$ coefficient of matrix A for j neighbor vertex of i.
- They may implement an optimized version of *is_one_to_one_mapping()*.

Todo *Fixed_border_parameterizer_3* should remove border vertices from the linear systems in order to have a symmetric positive definite matrix for Tutte Barycentric Mapping and Discrete Conformal Map algorithms.

```
#include <CGAL/Fixed_border_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept (although you cannot instantiate this class).

Design Pattern

Fixed_border_parameterizer_3<*ParameterizationMesh_3*, ...> class is a Strategy [GHJV95]: it implements (part of) a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3,
class BorderParameterizer_3 = Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>,
class SparseLinearAlgebraTraits_d = OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>>
class Fixed_border_parameterizer_3;
```

Types

Fixed_border_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*,
SparseLinearAlgebraTraits_d>::*Border_param*

Export *BorderParameterizer_3* template parameter.

Fixed_border_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*,
SparseLinearAlgebraTraits_d>::*Sparse_LA*

Export *SparseLinearAlgebraTraits_d* template parameter.

Creation

Fixed_border_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*,
SparseLinearAlgebraTraits_d> param(*Border_param* *border_param* = *Border_param*() ,

LA *sparse_la* = *Sparse_LA*())

Sparse_

Constructor.

Parameters: *border_param* Object that maps the surface's border to 2D space
sparse_la Traits object to access a sparse linear system

Operations

Parameterizer_traits_3<*Adaptor*>::*Error_code*

param.parameterize(*Adaptor*& *mesh*)

Compute a one-to-one mapping from a triangular 3D surface 'mesh' to a piece of the 2D space. The mapping is linear by pieces (linear in each triangle). The result is the (u,v) pair image of each vertex of the 3D surface. Preconditions:

- 'mesh' must be a surface with one connected component.
- 'mesh' must be a triangular mesh.
- the mesh border must be mapped onto a convex polygon.

Parameterizer_traits_3<*Adaptor*>::*Error_code*

param.check_parameterize_preconditions(*Adaptor*& *mesh*)

Check *parameterize*() preconditions:

- 'mesh' must be a surface with one connected component.
- 'mesh' must be a triangular mesh.
- the mesh border must be mapped onto a convex polygon.

void *param.initialize_system_from_mesh_border(Matrix& A,
Vector& Bu,
Vector& Bv,
Adaptor mesh)*

Initialize A, Bu and Bv after border parameterization. Fill the border vertices' lines in both linear systems: $u = \text{constant}$ and $v = \text{constant}$. Preconditions:

- vertices must be indexed.
- A, Bu and Bv must be allocated.
- border vertices must be parameterized.

virtual NT *param.compute_w_ij(Adaptor mesh,
Vertex_const_handle main_vertex_v_i,
Vertex_around_vertex_const_circulator neighbor_vertex_v_j)*

Compute $w_{ij} = (i, j)$ coefficient of matrix A for j neighbor vertex of i. Implementation note: Subclasses must at least implement *compute_w_ij()*.

Parameterizer_traits_3<Adaptor>::Error_code

*param.setup_inner_vertex_relations(Matrix& A,
Vector& Bu,
Vector& Bv,
Adaptor mesh,
Vertex_const_handle vertex)*

Compute the line i of matrix A for i inner vertex:

- call *compute_w_ij()* to compute the A coefficient w_{ij} for each neighbor v_j .
- compute $w_{ii} = - \text{sum of } w_{ijs}$.

Preconditions:

- vertices must be indexed.
- vertex i mustn't be already parameterized.
- line i of A must contain only zeros.

void *param.set_mesh_uv_from_system(Adaptor& mesh, Vector Xu, Vector Xv)*

Copy Xu and Xv coordinates into the (u,v) pair of each surface vertex.

Parameterizer_traits_3<Adaptor>::Error_code

*param.check_parameterize_postconditions(Adaptor mesh,
Matrix A,
Vector Bu,*

Vector Bv)

Check parameterize() postconditions:

- 3D -> 2D mapping is one-to-one.

bool *param.is_one_to_one_mapping(Adaptor mesh, Matrix A, Vector Bu, Vector Bv)*

Check if 3D -> 2D mapping is one-to-one. The default implementation checks each normal.

Border_param& *param.get_border_parameterizer()*

Get the object that maps the surface's border onto a 2D space.

Sparse_LA& *param.get_linear_algebra_traits()*

Get the sparse linear algebra (traits object to access the linear system).

CGAL::LSCM_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *LSCM_parameterizer_3* implements the Least Squares Conformal Maps (LSCM) parameterization [LPRM02].

This is a conformal parameterization, i.e. it attempts to preserve angles.

This is a free border parameterization. No need to map the surface's border onto a convex polygon (only two pinned vertices are needed to ensure a unique solution), but one-to-one mapping is NOT guaranteed.

```
#include <CGAL/LSCM_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept.

Design Pattern

LSCM_parameterizer_3<*ParameterizationMesh_3*, ...> class is a Strategy [GHJV95]: it implements a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3,
class BorderParameterizer_3 = Two_vertices_parameterizer_3<ParameterizationMesh_3>,
class SparseLinearAlgebraTraits_d = OpenNL::SymmetricLinearSolverTraits<typename
ParameterizationMesh_3::NT>>
class LSCM_parameterizer_3;
```

Types

LSCM_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*, *SparseLinearAlgebraTraits_d*>::*Border_param*

Export *BorderParameterizer_3* template parameter.

LSCM_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*, *SparseLinearAlgebraTraits_d*>::*Sparse_LA*

Export *SparseLinearAlgebraTraits_d* template parameter.

Creation

LSCM_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*, *SparseLinearAlgebraTraits_d*>
param(*Border_param* *border_param* = *Border_param*() ,

Sparse_

LA sparse_la = *Sparse_LA*()

Constructor.

Parameters: *border_param* Object that maps the surface's border to 2D space
sparse_la Traits object to access a sparse linear system

Operations

Parameterizer_traits_3<*Adaptor*>::*Error_code*

param.parameterize(*Adaptor*& *mesh*)

Compute a one-to-one mapping from a triangular 3D surface 'mesh' to a piece of the 2D space. The mapping is linear by pieces (linear in each triangle). The result is the (u,v) pair image of each vertex of the 3D surface. Preconditions:

- 'mesh' must be a surface with one connected component.
- 'mesh' must be a triangular mesh.

Parameterizer_traits_3<*Adaptor*>::*Error_code*

param.check_parameterize_preconditions(*Adaptor*& *mesh*)

Check parameterize() preconditions:

- 'mesh' must be a surface with one connected component.
- 'mesh' must be a triangular mesh.

void

param.initialize_system_from_mesh_border(*LeastSquaresSolver*& *solver*,
Adaptor *mesh*)

Initialize $A * X = B$ linear system after (at least two) border vertices are parameterized. Preconditions:

- vertices must be indexed.
- X and B must be allocated and empty.
- (at least two) border vertices must be parameterized.

void

param.project_triangle(*Point_3* *p0*,
Point_3 *p1*,
Point_3 *p2*,
Point_2& *z0*,
Point_2& *z1*,

Point_2& z2)

Utility for *setup_triangle_relations()*: Computes the coordinates of the vertices of a triangle in a local 2D orthonormal basis of the triangle's plane.

Parameterizer_traits_3<Adaptor>::Error_code

```
param.setup_triangle_relations( LeastSquaresSolver& solver,  
                               Adaptor mesh,  
                               Facet_const_handle facet)
```

Create two lines in the linear system per triangle (one for u, one for v). Preconditions:

- vertices must be indexed.

void *param.set_mesh_uv_from_system(Adaptor& mesh, LeastSquaresSolver solver)*

Copy X coordinates into the (u,v) pair of each vertex.

Parameterizer_traits_3<Adaptor>::Error_code

```
param.check_parameterize_postconditions( Adaptor mesh,  
                                          LeastSquaresSolver solver)
```

Check *parameterize()* postconditions:

- 3D -> 2D mapping is one-to-one.

bool *param.is_one_to_one_mapping(Adaptor mesh, LeastSquaresSolver solver)*

Check if 3D -> 2D mapping is one-to-one.

Border_param& *param.get_border_parameterizer()*

Get the object that maps the surface's border onto a 2D space.

Sparse_LA& *param.get_linear_algebra_traits()*

Get the sparse linear algebra (traits object to access the linear system).

SparseLinearAlgebra_d::Matrix

Definition

SparseLinearAlgebraTraits_d::Matrix is a concept of a sparse matrix class.

Refines

This is a sub-concept of *LinearAlgebraTraits_d::Matrix*.

Types

Matrix::NT

Creation

Matrix M(int dimension);

Create a square matrix initialized with zeros.

Matrix M(int rows, int columns);

Create a rectangular matrix initialized with zeros.

Operations

int

M.row_dimension()

Return the matrix number of rows.

int

M.column_dimension()

Return the matrix number of columns.

NT

M.get_coef(int row, int column)

Read access to a matrix coefficient. Preconditions:

- $0 \leq \text{row} < \text{row_dimension}()$.
- $0 \leq \text{column} < \text{column_dimension}()$.

void

M.add_coef(int row, int column, NT value)

Write access to a matrix coefficient: $a_{ij} \leftarrow a_{ij} + \text{val}$. Preconditions:

- $0 \leq \text{row} < \text{row_dimension}()$.
- $0 \leq \text{column} < \text{column_dimension}()$.

void

M.set_coef(int row, int column, NT value)

Write access to a matrix coefficient. Preconditions:

- $0 \leq \text{row} < \text{row_dimension}()$.
- $0 \leq \text{column} < \text{column_dimension}()$.

CGAL::Mean_value_coordinates_parameterizer_3<ParameterizationMesh_3, BorderParameterizer_3, SparseLinearAlgebraTraits_d>

Definition

The class *Mean_value_coordinates_parameterizer_3* implements Floater Mean Value Coordinates parameterization [Flo03a]. This method is sometimes called simply *Floater parameterization*.

This is a conformal parameterization, i.e. it attempts to preserve angles.

One-to-one mapping is guaranteed if the surface's border is mapped to a convex polygon.

This class is a Strategy [GHJV95] called by the main parameterization algorithm *Fixed_border_parameterizer_3::parameterize()*. *Mean_value_coordinates_parameterizer_3*:

- provides default *BorderParameterizer_3* and *SparseLinearAlgebraTraits_d* template parameters that make sense.
- implements *compute_w_ij()* to compute $w_{ij} = (i, j)$ coefficient of matrix A for j neighbor vertex of i based on Floater Mean Value Coordinates parameterization.
- implements an optimized version of *is_one_to_one_mapping()*.

```
#include <CGAL/Mean_value_coordinates_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept.

Design Pattern

Mean_value_coordinates_parameterizer_3<*ParameterizationMesh_3*, ...>class is a Strategy [GHJV95]: it implements a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3,
class BorderParameterizer_3 = Circular_border_arc_length_parameterizer_3<ParameterizationMesh_3>,
class SparseLinearAlgebraTraits_d = OpenNL::DefaultLinearSolverTraits<typename ParameterizationMesh_3::NT>>
class Mean_value_coordinates_parameterizer_3;
```

Types

Creation

Mean_value_coordinates_parameterizer_3<*ParameterizationMesh_3*, *BorderParameterizer_3*,
SparseLinearAlgebraTraits_d> *param*(*Border_param* *border_param* = *Border_param*() ,

LA sparse_la = *Sparse_LA*())

Constructor.

Parameters: *border_param* Object that maps the surface's border to 2D space.

sparse_la Traits object to access a sparse linear system.

Operations

virtual NT *param.compute_w_ij*(*Adaptor mesh*,
Vertex_const_handle main_vertex_v_i,
Vertex_around_vertex_const_circulator neighbor_vertex_v_j)

Compute $w_{ij} = (i, j)$ coefficient of matrix A for j neighbor vertex of i.

virtual bool *param.is_one_to_one_mapping*(*Adaptor mesh*, *Matrix A*, *Vector Bu*, *Vector Bv*)

Check if 3D \rightarrow 2D mapping is one-to-one. Theorem: one-to-one mapping is guaranteed if all w_{ij} coefficients are > 0 (for j vertex neighbor of i) and if the surface border is mapped onto a 2D convex polygon. Floater formula above implies that $w_{ij} > 0$ (for j vertex neighbor of i), thus mapping is guaranteed if the surface border is mapped onto a 2D convex polygon.

ParameterizationMesh_3

Definition

ParameterizationMesh_3 is a concept for a 3D surface mesh. Its main purpose is to allow the parameterization methods to access meshes in a uniform manner.

A *ParameterizationMesh_3* surface consists of vertices, facets and an incidence relation on them. No notion of edge is requested. Vertices represent points in 3d-space. Facets are planar polygons without holes defined by the circular sequence of vertices along their border. The surface itself can have holes. The vertices along the border of a hole are called *border vertices*. A surface is *closed* if it contains no border vertices.

The surface must be an oriented 2-manifold with border vertices, i.e. the neighborhood of each point on the surface is either homeomorphic to a disc or to a half disc, except for vertices where many holes and surfaces with border can join.

ParameterizationMesh_3 defines the types, data and methods that a mesh must implement to allow surface parameterization. Among other things, this concept defines accessors to fields specific to parameterizations methods: `index`, `u`, `v`, `is_parameterized`.

ParameterizationMesh_3 meshes can have any genus, arity or number of components. On the other hand, as parameterization methods deal only with topological disks, *ParameterizationMesh_3* defines an interface oriented towards topological disks.

Design Pattern

ParameterizationMesh_3 is an Adaptor [GHJV95]: it changes the interface of a 3D mesh to match the interface expected by the parameterization methods.

Types

The following mutable handles, iterators, and circulators have appropriate non-mutable counterparts, i.e. *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Vertex_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well.

<i>ParameterizationMesh_3:: NT</i>	Number type to represent coordinates.
<i>ParameterizationMesh_3:: Point_2</i>	2D point that represents (u,v) coordinates computed by parameterization methods. Must provide X() and Y() methods.
<i>ParameterizationMesh_3:: Point_3</i>	3D point that represents vertices coordinates. Must provide X() and Y() methods.
<i>ParameterizationMesh_3:: Vector_2</i>	2D vector. Must provide X() and Y() methods.
<i>ParameterizationMesh_3:: Vector_3</i>	3D vector. Must provide X() and Y() methods.
<i>ParameterizationMesh_3:: Facet</i>	Opaque type representing a facet of the 3D mesh. No methods are expected.
<i>ParameterizationMesh_3:: Facet_handle</i>	Handle to a facet. Model of the Handle concept.
<i>ParameterizationMesh_3:: Facet_const_handle</i>	
<i>ParameterizationMesh_3:: Facet_iterator</i>	Iterator over all mesh facets. Model of the ForwardIterator concept.

<i>ParameterizationMesh_3:: Facet_const_iterator</i>	
<i>ParameterizationMesh_3:: Vertex</i>	Opaque type representing a vertex of the 3D mesh. No methods are expected.
<i>ParameterizationMesh_3:: Vertex_handle</i>	Handle to a vertex. Model of the Handle concept.
<i>ParameterizationMesh_3:: Vertex_const_handle</i>	
<i>ParameterizationMesh_3:: Vertex_iterator</i>	Iterator over all vertices of a mesh. Model of the ForwardIterator concept.
<i>ParameterizationMesh_3:: Vertex_const_iterator</i>	
<i>ParameterizationMesh_3:: Border_vertex_iterator</i>	Iterator over vertices of the mesh <i>main border</i> . Model of the ForwardIterator concept.
<i>ParameterizationMesh_3:: Border_vertex_const_iterator</i>	
<i>ParameterizationMesh_3:: Vertex_around_facet_circulator</i>	Counter-clockwise circulator over a facet's vertices. Model of the BidirectionalCirculator concept.
<i>ParameterizationMesh_3:: Vertex_around_facet_const_circulator</i>	
<i>ParameterizationMesh_3:: Vertex_around_vertex_circulator</i>	Clockwise circulator over the vertices incident to a vertex. Model of the BidirectionalCirculator concept.
<i>ParameterizationMesh_3:: Vertex_around_vertex_const_circulator</i>	

Creation

Construction and destruction are undefined.

Operations

The following mutable methods returning a handle, iterator, or circulator have appropriate non-mutable counterpart methods, i.e. *const*, returning a *const_handle*, *const_iterator*, or *const_circulator*.

<i>bool</i>	<i>mesh.is_valid()</i>	Indicate if the mesh matches the <i>ParameterizationMesh_3</i> concept.
<i>Vertex_iterator</i>	<i>mesh.mesh_vertices_begin()</i>	Get iterator over first vertex of mesh.
<i>Vertex_const_iterator</i>		
	<i>mesh.mesh_vertices_begin()</i>	
<i>Vertex_iterator</i>	<i>mesh.mesh_vertices_end()</i>	Get iterator over past-the-end vertex of mesh.
<i>Vertex_const_iterator</i>		
	<i>mesh.mesh_vertices_end()</i>	
<i>int</i>	<i>mesh.count_mesh_vertices()</i>	Count the number of vertices of the mesh.

<i>void</i>	<i>mesh.index_mesh_vertices()</i>	Index vertices of the mesh from 0 to <i>count_mesh_vertices()</i> -1.
<i>Border_vertex_iterator</i>	<i>mesh.mesh_main_border_vertices_begin()</i>	Get iterator over first vertex of mesh's <i>main border</i> .
<i>Border_vertex_const_iterator</i>	<i>mesh.mesh_main_border_vertices_end()</i>	
<i>Border_vertex_iterator</i>	<i>mesh.mesh_main_border_vertices_end()</i>	Get iterator over past-the-end vertex of mesh's <i>main border</i> .
<i>std::list<Vertex_handle></i>	<i>mesh.get_border(Vertex_handle seed_vertex)</i>	Return the border containing <i>seed_vertex</i> . Return an empty list if not found.
<i>Facet_iterator</i>	<i>mesh.mesh_facets_begin()</i>	Get iterator over first facet of mesh.
<i>Facet_const_iterator</i>	<i>mesh.mesh_facets_end()</i>	
<i>Facet_iterator</i>	<i>mesh.mesh_facets_end()</i>	Get iterator over past-the-end facet of mesh.
<i>Facet_const_iterator</i>	<i>mesh.mesh_facets_end()</i>	
<i>int</i>	<i>mesh.count_mesh_facets()</i>	Count the number of facets of the mesh.
<i>bool</i>	<i>mesh.is_mesh_triangular()</i>	Return true if all mesh's facets are triangles.
<i>int</i>	<i>mesh.count_mesh_halfedges()</i>	Count the number of halfedges of the mesh.
<i>Vertex_around_facet_circulator</i>	<i>mesh.facet_vertices_begin(Facet_handle facet)</i>	Get circulator over facet's vertices.
<i>Vertex_around_facet_const_circulator</i>	<i>mesh.facet_vertices_end(Facet_const_handle facet)</i>	

<i>int</i>	<i>mesh.count_facet_vertices(Facet_const_handle facet)</i>	Count the number of vertices of a facet.
<i>Point_3</i>	<i>mesh.get_vertex_position(Vertex_const_handle vertex)</i>	Get the 3D position of a vertex.
<i>Point_2</i>	<i>mesh.get_vertex_uv(Vertex_const_handle vertex)</i>	Get/set the 2D position (u/v pair) of a vertex. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_uv(Vertex_handle vertex, Point_2 uv)</i>	
<i>bool</i>	<i>mesh.is_vertex_parameterized(Vertex_const_handle vertex)</i>	Get/set <i>is parameterized</i> field of vertex. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_parameterized(Vertex_handle vertex, bool parameterized)</i>	
<i>int</i>	<i>mesh.get_vertex_index(Vertex_const_handle vertex)</i>	Get/set vertex index. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_index(Vertex_handle vertex, int index)</i>	
<i>int</i>	<i>mesh.get_vertex_tag(Vertex_const_handle vertex)</i>	Get/set vertex' all purpose tag. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_tag(Vertex_handle vertex, int tag)</i>	
<i>bool</i>	<i>mesh.is_vertex_on_border(Vertex_const_handle vertex)</i>	Return true if a vertex belongs to ANY mesh's border.
<i>bool</i>	<i>mesh.is_vertex_on_main_border(Vertex_const_handle vertex)</i>	Return true if a vertex belongs to the UNIQUE mesh's main border.
<i>Vertex_around_vertex_circulator</i>	<i>mesh.vertices_around_vertex_begin(Vertex_handle vertex, Vertex_handle start_position = Vertex_handle())</i>	Get circulator over the vertices incident to 'vertex'. 'start_position' defines the optional initial position of the circulator.
<i>Vertex_around_vertex_const_circulator</i>	<i>mesh.vertices_around_vertex_begin(Vertex_const_handle vertex, Vertex_const_handle start_position = Vertex_const_handle())</i>

CGAL::Parameterization_mesh_feature_extractor<ParameterizationMesh_3>

Definition

The class *Parameterization_mesh_feature_extractor* computes features (genus, borders, ...) of a 3D surface, model of the *ParameterizationMesh_3* concept.

```
#include <CGAL/Parameterization_mesh_feature_extractor.h>
```

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Parameterization_mesh_feature_extractor;
```

Types

Parameterization_mesh_feature_extractor<ParameterizationMesh_3>::Adaptor

Export *ParameterizationMesh_3* template parameter.

Parameterization_mesh_feature_extractor<ParameterizationMesh_3>::Border

Type representing a border = STL container of vertex handles.

Parameterization_mesh_feature_extractor<ParameterizationMesh_3>::Skeleton

Type representing the list of all borders of the mesh = STL container of Border elements.

Creation

```
Parameterization_mesh_feature_extractor<ParameterizationMesh_3> extractor( Adaptor& mesh);
```

Constructor. CAUTION: This class caches the result of feature extractions => The caller must NOT modify 'mesh' during the *Parameterization_mesh_feature_extractor* life cycle.

Operations

```
int extractor.get_nb_borders()
```

Get number of borders.

```
Skeleton extractor.get_borders()
```

Get extracted borders. The longest border is the first one.

<i>Border</i>	<i>extractor.get_longest_border()</i>	Get longest border.
<i>int</i>	<i>extractor.get_nb_connex_components()</i>	Get # of connected components.
<i>int</i>	<i>extractor.get_genus()</i>	Get the genus.

CGAL::Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>

Definition

Parameterization_mesh_patch_3 is a Decorator class to *virtually* cut a patch in a *ParameterizationPatchableMesh_3* 3D surface. Only the patch is exported, making the 3D surface look like a topological disk.

The input mesh can be of any genus, but it has to come with a *seam* that describes the border of a topological disc. This border may be an actual border of the mesh or a virtual border.

```
#include <CGAL/Parameterization_mesh_patch_3.h>
```

Is Model for the Concepts

Model of *ParameterizationMesh_3* concept, whose purpose is to allow the *Surface_mesh_parameterization* package to access meshes in a uniform manner.

Design Pattern

Parameterization_mesh_patch_3 is a Decorator [GHJV95]: it changes the behavior of a *ParameterizationPatchableMesh_3* 3D surface while keeping its *ParameterizationMesh_3* interface.

Parameters

The full template declaration is:

```
template<
class ParameterizationPatchableMesh_3>
class Parameterization_mesh_patch_3;
```

Types

The following mutable handles, iterators, and circulators have appropriate non-mutable counterparts, i.e. *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Vertex_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>::Adaptor

Export template parameter.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>::NT

Number type to represent coordinates.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>::Point_2

2D point that represents (u,v) coordinates computed by parameterization methods. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Point_3

3D point that represents vertices coordinates. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vector_2

2D vector. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vector_3

3D vector. Must provide X() and Y() methods.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet

Opaque type representing a facet of the 3D mesh. No methods are expected.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_handle

Handle to a facet. Model of the Handle concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_const_handle

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_iterator

Iterator over all mesh facets. Model of the ForwardIterator concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Facet_const_iterator

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex

Opaque type representing a vertex of the 3D mesh. No methods are expected.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_handle

Handle to a vertex. Model of the Handle concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_const_handle

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_iterator

Iterator over all vertices of a mesh. Model of the ForwardIterator concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_const_iterator

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Border_vertex_iterator

Iterator over vertices of the mesh *main border*. Model of the ForwardIterator concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Border_vertex_const_iterator

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_facet_circulator

Counter-clockwise circulator over a facet's vertices. Model of the BidirectionalCirculator concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_facet_const_circulator

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_vertex_circulator

Clockwise circulator over the vertices incident to a vertex. Model of the BidirectionalCirculator concept.

Parameterization_mesh_patch_3<ParameterizationPatchableMesh_3>:: Vertex_around_vertex_const_circulator

Creation

Parameterization_mesh_patch_3<*ParameterizationPatchableMesh_3*> *mesh*(*Adaptor*& *mesh*,
InputIterator *first_seam_vertex*,
InputIterator *end_seam_vertex*)

Create a Decorator for an existing *ParameterizationPatchableMesh_3* mesh. The input mesh can be of any genus, but it has to come with a *seam* that describes the border of a topological disc. This border may be an actual border of the mesh or a virtual border. Preconditions:

- *first_seam_vertex* -> *end_seam_vertex* defines the outer seam, i.e. *Parameterization_mesh_patch_3* will export the *right* of the seam.
- The *seam* is given as a container of *Adaptor::Vertex_handle* elements.
- The *seam* is implicitly a loop. The first vertex should **not** be duplicated at the end.

Operations

The following methods returning a mutable handle, iterator, or circulator have appropriate non-mutable counterpart methods, i.e. *const*, returning a *const_handle*, *const_iterator*, or *const_circulator*.

Adaptor& *mesh.get_decorated_mesh()*

Get the decorated mesh.

Adaptor *mesh.get_decorated_mesh()*

bool *mesh.is_valid()* Indicate if the mesh matches the *ParameterizationMesh_3* concept.

Vertex_iterator *mesh.mesh_vertices_begin()*

Get iterator over first vertex of mesh.

Vertex_const_iterator

Vertex_iterator *mesh.mesh_vertices_begin()*
 mesh.mesh_vertices_end()

Get iterator over past-the-end vertex of mesh.

Vertex_const_iterator

int *mesh.mesh_vertices_end()*
 mesh.count_mesh_vertices()

Count the number of vertices of the mesh.

void *mesh.index_mesh_vertices()*

Index vertices of the mesh from 0 to *count_mesh_vertices()*-1.

Border_vertex_iterator

mesh.mesh_main_border_vertices_begin()

Get iterator over first vertex of mesh's main border (aka *seam*).

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_begin()

Border_vertex_iterator

mesh.mesh_main_border_vertices_end()

Get iterator over past-the-end vertex of mesh's main border (aka *seam*).

Border_vertex_const_iterator

mesh.mesh_main_border_vertices_end()

std::list<Vertex_handle>

mesh.get_border(Vertex_handle seed_vertex)

Return the border containing *seed_vertex*. Return an empty list if not found.

Facet_iterator

mesh.mesh_facets_begin()

Get iterator over first facet of mesh.

Facet_const_iterator

mesh.mesh_facets_begin()

Facet_iterator

mesh.mesh_facets_end()

Get iterator over past-the-end facet of mesh.

Facet_const_iterator

mesh.mesh_facets_end()

int

mesh.count_mesh_facets()

Count the number of facets of the mesh.

bool

mesh.is_mesh_triangular()

Return true if all mesh's facets are triangles.

int

mesh.count_mesh_halfedges()

Count the number of halfedges of the mesh.

Vertex_around_facet_circulator

mesh.facet_vertices_begin(Facet_handle facet)

Get circulator over facet's vertices.

Vertex_around_facet_const_circulator

mesh.facet_vertices_begin(Facet_const_handle facet)

int

mesh.count_facet_vertices(Facet_const_handle facet)

Count the number of vertices of a facet.

<i>Point_3</i>	<i>mesh.get_vertex_position(Vertex_const_handle vertex)</i>	
		Get the 3D position of a vertex.
<i>Point_2</i>	<i>mesh.get_vertex_uv(Vertex_const_handle vertex)</i>	
		Get/set the 2D position (u/v pair) of a vertex. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_uv(Vertex_handle vertex, Point_2 uv)</i>	
<i>bool</i>	<i>mesh.is_vertex_parameterized(Vertex_const_handle vertex)</i>	
		Get/set <i>is parameterized</i> field of vertex. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_parameterized(Vertex_handle vertex, bool parameterized)</i>	
<i>int</i>	<i>mesh.get_vertex_index(Vertex_const_handle vertex)</i>	
		Get/set vertex index. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_index(Vertex_handle vertex, int index)</i>	
<i>int</i>	<i>mesh.get_vertex_tag(Vertex_const_handle vertex)</i>	
		Get/set vertex' all purpose tag. Default value is undefined.
<i>void</i>	<i>mesh.set_vertex_tag(Vertex_handle vertex, int tag)</i>	
<i>bool</i>	<i>mesh.is_vertex_on_border(Vertex_const_handle vertex)</i>	
		Return true if a vertex belongs to ANY mesh's border.
<i>bool</i>	<i>mesh.is_vertex_on_main_border(Vertex_const_handle vertex)</i>	
		Return true if a vertex belongs to the UNIQUE mesh's main border set by the constructor.
<i>Vertex_around_vertex_circulator</i>		
	<i>mesh.vertices_around_vertex_begin(Vertex_handle vertex,</i> <i>Vertex_handle start_position = Vertex_handle())</i>	
		Get circulator over the vertices incident to 'vertex'. 'start_position' defines the optional initial position of the circulator.
<i>Vertex_around_vertex_const_circulator</i>		
	<i>mesh.vertices_around_vertex_begin(Vertex_const_handle vertex,</i> <i>Vertex_const_handle start_position = Vertex_</i> <i>const_handle())</i>

Example

See *Mesh_cutting_parameterization.cpp* example.

ParameterizationPatchableMesh_3

Definition

ParameterizationPatchableMesh_3 inherits from concept *ParameterizationMesh_3*, thus is a concept of a 3D surface mesh.

ParameterizationPatchableMesh_3 adds the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* are the ability to behave exactly as if the surface was cut following a certain path.

This mainly means that:

- vertices can be tagged as inside or outside the patch to parameterize.
- the fields specific to parameterizations (index, u, v, *is_parameterized*) can be set per *corner* (aka half-edge).

The main purpose of this feature is to allow the *Surface_mesh_parameterization* package to parameterize any 3D surface by decomposing it as a list of topological disks.

Design Pattern

ParameterizationPatchableMesh_3 is an Adaptor [GHJV95]: it changes the interface of a 3D mesh to match the interface expected by class *Parameterization_mesh_patch_3*.

Refines

ParameterizationPatchableMesh_3 inherits from concept *ParameterizationMesh_3*.

In addition to the requirements described in the concept *ParameterizationMesh_3*, *ParameterizationPatchableMesh_3* provides the following:

Types

Creation

Construction and destruction are undefined.

Operations

int *mesh.get_vertex_seaming(Vertex_const_handle vertex)*

Get/set vertex seaming flag. Default value is undefined.

void *mesh.set_vertex_seaming(Vertex_handle vertex, int seaming)*

<i>int</i>	<i>mesh.get_halfedge_seaming(Vertex_const_handle source,</i> <i>Vertex_const_handle target)</i>	Get/set oriented edge's seaming flag, i.e. position of the oriented edge w.r.t. to the UNIQUE main border.
<i>void</i>	<i>mesh.set_halfedge_seaming(Vertex_handle source,</i> <i>Vertex_handle target,</i> <i>int seaming)</i>	
<i>Point_2</i>	<i>mesh.get_corners_uv(Vertex_const_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex)</i>	Get/set the 2D position (= (u,v) pair) of corners at the <i>right</i> of the <i>prev_vertex</i> -> <i>vertex</i> -> <i>next_vertex</i> line. Default value is undefined.
<i>void</i>	<i>mesh.set_corners_uv(Vertex_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex,</i> <i>Point_2 uv)</i>	
<i>bool</i>	<i>mesh.are_corners_parameterized(Vertex_const_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex)</i>	Get/set <i>is parameterized</i> field of corners at the <i>right</i> of the <i>prev_vertex</i> -> <i>vertex</i> -> <i>next_vertex</i> line. Default value is undefined.
<i>void</i>	<i>mesh.set_corners_parameterized(Vertex_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex,</i> <i>bool parameterized)</i>	
<i>int</i>	<i>mesh.get_corners_index(Vertex_const_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex)</i>	Get/set index of corners at the <i>right</i> of the <i>prev_vertex</i> -> <i>vertex</i> -> <i>next_vertex</i> line. Default value is undefined.
<i>void</i>	<i>mesh.set_corners_index(Vertex_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex,</i> <i>int index)</i>	
<i>int</i>	<i>mesh.get_corners_tag(Vertex_const_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex)</i>	Get/set all purpose tag of corners at the <i>right</i> of the <i>prev_vertex</i> -> <i>vertex</i> -> <i>next_vertex</i> line. Default value is undefined.
<i>void</i>	<i>mesh.set_corners_tag(Vertex_handle vertex,</i> <i>Vertex_const_handle prev_vertex,</i> <i>Vertex_const_handle next_vertex,</i> <i>int tag)</i>	

Has Models

Adaptator for *Polyhedron_3* is provided.

CGAL::Parameterization_polyhedron_adaptor_3<Polyhedron_3_>

Definition

Parameterization_polyhedron_adaptor_3 is an adaptor class to access to a Polyhedron 3D mesh using the *ParameterizationPatchableMesh_3* interface. Among other things, this concept defines the accessor to the (u,v) values computed by parameterizations methods.

Note that these interfaces are decorators that add *on the fly* the necessary fields to unmodified CGAL data structures (using STL maps). For performance reasons, it is recommended to use CGAL data structures enriched with the proper fields.

A *ParameterizationMesh_3* surface consists of vertices, facets and an incidence relation on them. No notion of edge is requested.

ParameterizationMesh_3 meshes can have any genus, arity or number of components.

It can have any number of borders. Its *main border* will be the mesh's longest border (if there is at least one border).

It has also the ability to support patches and virtual seams. *Patches* are a subset of a 3D mesh. *Virtual seams* are the ability to behave exactly as if the surface was cut following a certain path.

```
#include <CGAL/Parameterization_polyhedron_adaptor_3.h>
```

Is Model for the Concepts

Model of *ParameterizationPatchableMesh_3* concept, whose purpose is to allow the *Surface_mesh_parameterization* package to access meshes in a uniform manner.

Design Pattern

Parameterization_polyhedron_adaptor_3 is an Adaptor [GHJV95]: it changes the Polyhedron interface to match the *ParameterizationPatchableMesh_3* concept.

Parameters

The full template declaration is:

```
template<
class Polyhedron_3_>
class Parameterization_polyhedron_adaptor_3;
```

Types

The following mutable handles, iterators, and circulators have appropriate non-mutable counterparts, i.e. *const_handle*, *const_iterator*, and *const_circulator*. The mutable types are assignable to their non-mutable counterparts. Both circulators are assignable to the *Vertex_iterator*. The iterators are assignable to the respective handle types. Wherever the handles appear in function parameter lists, the corresponding iterators can be used as well.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Polyhedron

Export template parameter.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: NT

Number type to represent coordinates.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Point_2

2D point that represents (u,v) coordinates computed by parameterization methods. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Point_3

3D point that represents vertices coordinates. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vector_2

2D vector. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vector_3

3D vector. Must provide X() and Y() methods.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet

Opaque type representing a facet of the 3D mesh. No methods are expected.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_handle

Handle to a facet. Model of the Handle concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_const_handle

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_iterator

Iterator over all mesh facets. Model of the ForwardIterator concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Facet_const_iterator

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex

Opaque type representing a vertex of the 3D mesh. No methods are expected.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_handle

Handle to a vertex. Model of the Handle concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_const_handle

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_iterator

Iterator over all vertices of a mesh. Model of the ForwardIterator concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Vertex_const_iterator

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Border_vertex_iterator

Iterator over vertices of the mesh *main border*. Model of the ForwardIterator concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3_>:: Border_vertex_const_iterator

Parameterization_polyhedron_adaptor_3<Polyhedron_3>::Vertex_around_facet_circulator

Counter-clockwise circulator over a facet's vertices. Model of the BidirectionalCirculator concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3>::Vertex_around_facet_const_circulator

Parameterization_polyhedron_adaptor_3<Polyhedron_3>::Vertex_around_vertex_circulator

Clockwise circulator over the vertices incident to a vertex. Model of the BidirectionalCirculator concept.

Parameterization_polyhedron_adaptor_3<Polyhedron_3>::Vertex_around_vertex_const_circulator

Creation

Parameterization_polyhedron_adaptor_3<Polyhedron_3> mesh(Polyhedron& mesh);

Create an adaptor for an existing *Polyhedron_3* mesh. The input mesh can be of any genus. It can have any number of borders. Its *main border* will be the mesh's longest border (if there is at least one border).

Operations

The following methods returning a mutable handle, iterator, or circulator have appropriate non-mutable counterpart methods, i.e. *const*, returning a *const_handle*, *const_iterator*, or *const_circulator*.

Polyhedron& mesh.get_adapted_mesh()

Get the adapted mesh.

Polyhedron mesh.get_adapted_mesh()

Polyhedron::Halfedge_const_handle

mesh.get_halfedge(Vertex_const_handle source, Vertex_const_handle target)

Get halfedge from source and target vertices. Will assert if such an halfedge doesn't exist.

Polyhedron::Halfedge_handle

mesh.get_halfedge(Vertex_handle source, Vertex_handle target)

const Halfedge_info mesh.info(Halfedge_const_handle halfedge)*

Access to additional info attached to halfedges.

Halfedge_info mesh.info(Halfedge_handle halfedge)*

const Vertex_info mesh.info(Vertex_const_handle vertex)*

Access to additional info attached to vertices.

Vertex_info mesh.info(Vertex_handle vertex)*

bool mesh.is_valid() Indicate if the mesh matches the *ParameterizationMesh_3* concept.

Vertex_iterator mesh.mesh_vertices_begin()

Get iterator over first vertex of mesh.

Vertex_const_iterator

mesh.mesh_vertices_begin()

<i>Vertex_iterator</i>	<i>mesh.mesh_vertices_end()</i>	
		Get iterator over past-the-end vertex of mesh.
<i>Vertex_const_iterator</i>		
	<i>mesh.mesh_vertices_end()</i>	
<i>int</i>	<i>mesh.count_mesh_vertices()</i>	
		Count the number of vertices of the mesh.
<i>void</i>	<i>mesh.index_mesh_vertices()</i>	
<i>Border_vertex_iterator</i>		
	<i>mesh.mesh_main_border_vertices_begin()</i>	
		Get iterator over first vertex of mesh's <i>main border</i> .
<i>Border_vertex_const_iterator</i>		
	<i>mesh.mesh_main_border_vertices_begin()</i>	
<i>Border_vertex_iterator</i>		
	<i>mesh.mesh_main_border_vertices_end()</i>	
		Get iterator over past-the-end vertex of mesh's <i>main border</i> .
<i>Border_vertex_const_iterator</i>		
	<i>mesh.mesh_main_border_vertices_end()</i>	
<i>std::list<Vertex_handle></i>		
	<i>mesh.get_border(Vertex_handle seed_vertex)</i>	
		Return the border containing <i>seed_vertex</i> . Return an empty list if not found.
<i>Facet_iterator</i>	<i>mesh.mesh_facets_begin()</i>	
		Get iterator over first facet of mesh.
<i>Facet_const_iterator</i>	<i>mesh.mesh_facets_begin()</i>	
<i>Facet_iterator</i>	<i>mesh.mesh_facets_end()</i>	
		Get iterator over past-the-end facet of mesh.
<i>Facet_const_iterator</i>	<i>mesh.mesh_facets_end()</i>	
<i>int</i>	<i>mesh.count_mesh_facets()</i>	
		Count the number of facets of the mesh.
<i>bool</i>	<i>mesh.is_mesh_triangular()</i>	
		Return true if all mesh's facets are triangles.
<i>int</i>	<i>mesh.count_mesh_halfedges()</i>	
		Count the number of halfedges of the mesh.
<i>Vertex_around_facet_circulator</i>		
	<i>mesh.facet_vertices_begin(Facet_handle facet)</i>	
		Get circulator over facet's vertices.

Vertex_around_facet_const_circulator

int *mesh.facet_vertices_begin(Facet_const_handle facet)*
mesh.count_facet_vertices(Facet_const_handle facet)

Count the number of vertices of a facet.

Point_3 *mesh.get_vertex_position(Vertex_const_handle vertex)*

Get the 3D position of a vertex.

Point_2 *mesh.get_vertex_uv(Vertex_const_handle vertex)*

Get/set the 2D position (u/v pair) of a vertex. Default value is undefined. (stored in halfedges sharing the same vertex).

void *mesh.set_vertex_uv(Vertex_handle vertex, Point_2 uv)*
bool *mesh.is_vertex_parameterized(Vertex_const_handle vertex)*

Get/set *is parameterized* field of vertex. Default value is undefined. (stored in halfedges sharing the same vertex).

void *mesh.set_vertex_parameterized(Vertex_handle vertex, bool parameterized)*
int *mesh.get_vertex_index(Vertex_const_handle vertex)*

Get/set vertex index. Default value is undefined. (stored in Polyhedron vertex for debugging purpose).

void *mesh.set_vertex_index(Vertex_handle vertex, int index)*
int *mesh.get_vertex_tag(Vertex_const_handle vertex)*

Get/set vertex' all purpose tag. Default value is undefined. (stored in halfedges sharing the same vertex).

void *mesh.set_vertex_tag(Vertex_handle vertex, int tag)*
bool *mesh.is_vertex_on_border(Vertex_const_handle vertex)*

Return true if a vertex belongs to ANY mesh's border.

bool *mesh.is_vertex_on_main_border(Vertex_const_handle vertex)*

Return true if a vertex belongs to the UNIQUE mesh's main border, i.e. the mesh's LONGEST border.

Vertex_around_vertex_circulator

mesh.vertices_around_vertex_begin(Vertex_handle vertex,
Vertex_handle start_position = Vertex_handle())

Get circulator over the vertices incident to 'vertex'. 'start_position' defines the optional initial position of the circulator.

Vertex_around_vertex_const_circulator

mesh.vertices_around_vertex_begin(Vertex_const_handle vertex,
Vertex_const_handle start_position = Vertex_
const_handle())

int *mesh.get_vertex_seaming(Vertex_const_handle vertex)*

Get/set vertex seaming flag. Default value is undefined.

void *mesh.set_vertex_seaming(Vertex_handle vertex, int seaming)*

<i>int</i>	<i>mesh.get_halfedge_seaming(Vertex_const_handle source, Vertex_const_handle target)</i>	
		Get/set oriented edge's seaming flag, i.e. position of the oriented edge w.r.t. to the UNIQUE main border.
<i>void</i>	<i>mesh.set_halfedge_seaming(Vertex_handle source, Vertex_handle target, int seaming)</i>	
<i>Point_2</i>	<i>mesh.get_corners_uv(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex)</i>	
		Get/set the 2D position (= (u,v) pair) of corners at the <i>right</i> of the <i>prev_vertex -> vertex -> next_vertex</i> line. Default value is undefined. (stored in incident halfedges).
<i>void</i>	<i>mesh.set_corners_uv(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, Point_2 uv)</i>	
<i>bool</i>	<i>mesh.are_corners_parameterized(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex)</i>	
		Get/set <i>is parameterized</i> field of corners at the <i>right</i> of the <i>prev_vertex -> vertex -> next_vertex</i> line. Default value is undefined. (stored in incident halfedges).
<i>void</i>	<i>mesh.set_corners_parameterized(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, bool parameterized)</i>	
<i>int</i>	<i>mesh.get_corners_index(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex)</i>	
		Get/set index of corners at the <i>right</i> of the <i>prev_vertex -> vertex -> next_vertex</i> line. Default value is undefined. (stored in incident halfedges).
<i>void</i>	<i>mesh.set_corners_index(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, int index)</i>	
<i>int</i>	<i>mesh.get_corners_tag(Vertex_const_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex)</i>	
		Get/set all purpose tag of corners at the <i>right</i> of the <i>prev_vertex -> vertex -> next_vertex</i> line. Default value is undefined. (stored in incident halfedges).
<i>void</i>	<i>mesh.set_corners_tag(Vertex_handle vertex, Vertex_const_handle prev_vertex, Vertex_const_handle next_vertex, int tag)</i>

CGAL::Parameterizer_traits_3<ParameterizationMesh_3>

Definition

The class *Parameterizer_traits_3* is the base class of all parameterization methods. This class is a pure virtual class, thus cannot be instantiated.

This class doesn't do much. Its main goal is to ensure that subclasses will be proper models of the *ParameterizerTraits_3* concept:

- *Parameterizer_traits_3* defines the *Error_code* list of errors detected by this package
- *Parameterizer_traits_3* declares a pure virtual method *parameterize()*

```
#include <CGAL/Parameterizer_traits_3.h>
```

Is Model for the Concepts

Model of the *ParameterizerTraits_3* concept (although you cannot instantiate this class).

Design Pattern

ParameterizerTraits_3 models are Strategies [GHJV95]: they implement a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Parameterizer_traits_3;
```

Types

Parameterizer_traits_3<ParameterizationMesh_3>::Adaptor

Export *ParameterizationMesh_3* template parameter.

Constants

```
enum Error_code { OK,
                  ERROR_EMPTY_MESH,
                  ERROR_NON_TRIANGULAR_MESH,
                  ERROR_NO_SURFACE_MESH,
                  ERROR_INVALID_BORDER,
                  ERROR_CANNOT_SOLVE_LINEAR_SYSTEM,
                  ERROR_NO_1_TO_1_MAPPING,
                  ERROR_OUT_OF_MEMORY,
```

ERROR_WRONG_PARAMETER}

List of errors detected by this package.

Enumeration values: **OK** Success.

ERROR_EMPTY_MESH input mesh is empty

ERROR_NON_TRIANGULAR_MESH input mesh is not triangular

ERROR_NO_SURFACE_MESH input mesh is not a surface

ERROR_INVALID_BORDER parameterization requires a convex border

ERROR_CANNOT_SOLVE_LINEAR_SYSTEM cannot solve linear system

ERROR_NO_1_TO_1_MAPPING parameterization does not ensure a one-to-one mapping

ERROR_OUT_OF_MEMORY not enough memory

ERROR_WRONG_PARAMETER a method received an unexpected parameter

Creation

Parameterizer_traits_3<ParameterizationMesh_3> *param*;

default constructor.

Operations

virtual Error_code *param.parameterize(Adaptor& mesh)*

Compute a one-to-one mapping from a 3D surface 'mesh' to a piece of the 2D space. The mapping is linear by pieces (linear in each triangle). The result is the (u,v) pair image of each vertex of the 3D surface. Preconditions:

- 'mesh' must be a surface with one connected component.
- 'mesh' must be a triangular mesh.

*static const char** *param.get_error_message(int error_code)*

Get message (in English) corresponding to an error code

Parameters: *error_code* The code returned by *parameterize()*

Returns: The string describing the error code

ParameterizerTraits_3

Definition

ParameterizerTraits_3 is a concept of parameterization object for a given type of mesh, 'Adaptor', which is a model of the *ParameterizationMesh_3* concept.

Design Pattern

ParameterizerTraits_3 models are Strategies [GHJV95]: they implement a strategy of surface parameterization for models of *ParameterizationMesh_3*.

Types

ParameterizerTraits_3::Adaptor Export the type of mesh to parameterize.

Constants

```
enum Error_code { OK,
                  ERROR_EMPTY_MESH,
                  ERROR_NON_TRIANGULAR_MESH,
                  ERROR_NO_SURFACE_MESH,
                  ERROR_INVALID_BORDER,
                  ERROR_CANNOT_SOLVE_LINEAR_SYSTEM,
                  ERROR_NO_1_TO_1_MAPPING,
                  ERROR_OUT_OF_MEMORY,
                  ERROR_WRONG_PARAMETER}
```

List of errors detected by this package.

Enumeration values: **OK** Success.

ERROR_EMPTY_MESH Error: input mesh is empty.

ERROR_NON_TRIANGULAR_MESH Error: input mesh is not triangular.

ERROR_NO_SURFACE_MESH Error: input mesh is not a surface.

ERROR_INVALID_BORDER Error: parameterization requires a convex border.

ERROR_CANNOT_SOLVE_LINEAR_SYSTEM Error: cannot solve linear system.

ERROR_NO_1_TO_1_MAPPING Error: parameterization does not ensure a one-to-one mapping.

ERROR_OUT_OF_MEMORY Error: not enough memory.

ERROR_WRONG_PARAMETER Error: a method received an unexpected parameter.

Creation

Construction and destruction are undefined.

Operations

Error_code *param.parameterize(Adaptor& mesh)*

Compute a one-to-one mapping from a triangular 3D surface 'mesh' to a piece of the 2D space. The mapping is linear by pieces (linear in each triangle). The result is the (u,v) pair image of each vertex of the 3D surface. Preconditions:

- 'mesh' must be a surface with one connected component and no hole.
- 'mesh' must be a triangular mesh.

CGAL::parameterize

Definition

CGAL::parameterize() is the main entry-point of the *Surface_mesh_parameterization* package.

It computes a one-to-one mapping from a 3D triangle surface 'mesh' to a simple 2D domain. The mapping is piecewise linear on the triangle mesh. The result is a pair (u,v) of parameter coordinates for each vertex of the input mesh. One-to-one mapping may be guaranteed or not, depending on the chosen *ParameterizerTraits* algorithm.

The *CGAL::parameterize()* function exists in two flavors, to provide a default parameterization algorithm of Floater Mean Value Coordinates.

```
#include <CGAL/parameterize.h>
```

```
Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
```

```
parameterize( ParameterizationMesh_3& mesh)
```

Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a 2D circle, using Floater Mean Value Coordinates algorithm. A one-to-one mapping is guaranteed. The mapping is piecewise linear on the input mesh triangles. The result is a (u,v) pair of parameter coordinates for each vertex of the input mesh. Preconditions:

- 'mesh' must be a surface with one connected component.
- 'mesh' must be a triangular mesh.

Parameters: **mesh** 3D mesh, model of *ParameterizationMesh_3* concept

```
Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
```

```
parameterize( ParameterizationMesh_3& mesh,
              ParameterizerTraits_3 parameterizer)
```

Compute a one-to-one mapping from a 3D triangle surface 'mesh' to a simple 2D domain. The mapping is piecewise linear on the triangle mesh. The result is a pair (u,v) of parameter coordinates for each vertex of the input mesh. One-to-one mapping may be guaranteed or not, depending on the chosen *ParameterizerTraits_3* algorithm. Preconditions:

- 'mesh' must be a surface with one connected component.
- 'mesh' must be a triangular mesh.
- the mesh border must be mapped onto a convex polygon (for fixed border parameterizations).

Parameters: **mesh** 3D mesh, model of *ParameterizationMesh_3*
parameterizer Parameterization method for 'mesh'

Parameters

The full template declarations are:

```
template<
class ParameterizationMesh_3>
Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
parameterize (ParameterizationMesh_3 &mesh);
```

```
template<
class ParameterizationMesh_3,
class ParameterizerTraits_3>
Parameterizer_traits_3<ParameterizationMesh_3>::Error_code
parameterize (ParameterizationMesh_3 &mesh, ParameterizerTraits_3 parameterizer);
```

Example

See *Simple_parameterization.cpp* example.

Implementation

This function simply calls the `parameterize()` method of the parameterization algorithm chosen.

SparseLinearAlgebraTraits_d

Definition

The concept *SparseLinearAlgebraTraits_d* is used to solve sparse linear systems $A * X = B$.

Refines

This is a sub-concept of *LinearAlgebraTraits_d*.

Types

SparseLinearAlgebraTraits_d::Matrix

SparseLinearAlgebraTraits_d::Vector

SparseLinearAlgebraTraits_d::NT

Creation

SparseLinearAlgebraTraits_d *sparse_LA*; Default constructor.

Operations

bool *sparse_LA.linear_solver(Matrix A, Vector B, Vector& X, NT& D)*

Solve the sparse linear system $A * X = B$. Return true on success. The solution is then $(1/D) * X$. Preconditions:

- *A.row_dimension() == B.dimension()*.
- *A.column_dimension() == X.dimension()*.

CGAL::Square_border_arc_length_parameterizer_3<ParameterizationMesh_3>

Definition

This class parameterizes the border of a 3D surface onto a square, with an arc-length parameterization: (u,v) values are proportional to the length of border edges.

Square_border_parameterizer_3 implements most of the border parameterization algorithm. This class implements only *compute_edge_length()* to compute a segment's length.

```
#include <CGAL/Square_border_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept.

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Square_border_arc_length_parameterizer_3;
```

Types

Creation

```
Square_border_arc_length_parameterizer_3<ParameterizationMesh_3> bp;
```

default constructor.

Operations

```
virtual double bp.compute_edge_length( Adaptor mesh,
                                       Vertex_const_handle source,
                                       Vertex_const_handle target)
```

Compute the length of an edge. Arc-length border parameterization: (u,v) values are proportional to the length of border edges.

CGAL::Square_border_parameterizer_3<ParameterizationMesh_3>

Definition

This is the base class of strategies that parameterize the border of a 3D surface onto a square. *Square_border_parameterizer_3* is a pure virtual class, thus cannot be instantiated.

It implements most of the algorithm. Subclasses just have to implement *compute_edge_length()* to compute a segment's length.

Implementation note: To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* class. They do not know the parameterization algorithm requirements or the kind of sparse linear system used.

```
#include <CGAL/Square_border_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept (although you cannot instantiate this class).

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Square_border_parameterizer_3;
```

Types

Square_border_parameterizer_3<ParameterizationMesh_3>::Adaptor

Export *ParameterizationMesh_3* template parameter.

Creation

Square_border_parameterizer_3<ParameterizationMesh_3> bp;

default constructor.

Operations

Parameterizer_traits_3<Adaptor>::Error_code

bp.parameterize_border(Adaptor& mesh)

Assign to mesh's border vertices a 2D position (i.e. a (u,v) pair) on border's shape. Mark them as *parameterized*.

bool

bp.is_border_convex()

Indicate if border's shape is convex.

virtual double

*bp.compute_edge_length(Adaptor mesh,
Vertex_const_handle source,
Vertex_const_handle target)*

Compute the length of an edge.

CGAL::Square_border_uniform_parameterizer_3<ParameterizationMesh_3>

Definition

This class parameterizes the border of a 3D surface onto a square in a uniform manner: points are equally spaced.

Square_border_parameterizer_3 implements most of the border parameterization algorithm. This class implements only *compute_edge_length()* to compute a segment's length.

```
#include <CGAL/Square_border_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept.

Design Pattern

BorderParameterizer_3 models are Strategies [GHJV95]: they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Square_border_uniform_parameterizer_3;
```

Types

Creation

```
Square_border_uniform_parameterizer_3<ParameterizationMesh_3> bp;
```

default constructor.

Operations

```
virtual double      bp.compute_edge_length( Adaptor mesh,
                                           Vertex_const_handle source,
                                           Vertex_const_handle target)
```

Compute the length of an edge. Uniform border parameterization: points are equally spaced.

CGAL::Taucs_matrix<T>

Definition

The class *Taucs_matrix* is a C++ wrapper around TAUCS' matrix type *taucs_ccs_matrix*.

This kind of matrix can be either symmetric or not. Symmetric matrices store only the lower triangle.

```
#include <CGAL/Taucs_matrix.h>
```

Is Model for the Concepts

Model of the *SparseLinearAlgebraTraits_d::Matrix* concept.

Parameters

The full template declaration is:

```
template<
class T>
struct Taucs_matrix;
```

Types

Taucs_matrix<T>::NT

Creation

```
Taucs_matrix<T> M( int dim, bool is_symmetric = false);
```

Create a square matrix initialized with zeros.

Parameters: **dim** Matrix dimension.

is_symmetric Symmetric/hermitian?

```
Taucs_matrix<T> M( int rows, int columns, bool is_symmetric = false);
```

Create a rectangular matrix initialized with zeros.

Parameters: **rows** Matrix dimensions.

is_symmetric Symmetric/hermitian?

Operations

<i>int</i>	<i>M.row_dimension()</i>	Return the matrix number of rows.
<i>int</i>	<i>M.column_dimension()</i>	

Return the matrix number of columns.

<i>T</i>	<i>M.get_coef(int i, int j)</i>	<p>Read access to a matrix coefficient. Preconditions:</p> <ul style="list-style-type: none"> • $0 \leq i < \text{row_dimension}()$. • $0 \leq j < \text{column_dimension}()$.
<i>void</i>	<i>M.set_coef(int i, int j, T val)</i>	<p>Write access to a matrix coefficient: $a_{ij} \leftarrow \text{val}$. Optimization: For symmetric matrices, <i>Taucs_matrix</i> stores only the lower triangle <i>set_coef()</i> does nothing if (i, j) belongs to the upper triangle. Preconditions:</p> <ul style="list-style-type: none"> • $0 \leq i < \text{row_dimension}()$. • $0 \leq j < \text{column_dimension}()$.
<i>void</i>	<i>M.add_coef(int i, int j, T val)</i>	<p>Write access to a matrix coefficient: $a_{ij} \leftarrow a_{ij} + \text{val}$. Optimization: For symmetric matrices, <i>Taucs_matrix</i> stores only the lower triangle <i>add_coef()</i> does nothing if (i, j) belongs to the upper triangle. Preconditions:</p> <ul style="list-style-type: none"> • $0 \leq i < \text{row_dimension}()$. • $0 \leq j < \text{column_dimension}()$.
<i>const taucs_ccs_matrix*</i>	<i>M.get_taucs_matrix()</i>	<p>Construct and return the TAUCS matrix wrapped by this object. Note: the TAUCS matrix returned by this method is valid only until the next call to <i>set_coef()</i>, <i>add_coef()</i> or <i>get_taucs_matrix()</i>.</p>

CGAL::Taucs_solver_traits<T>

Definition

The class *Taucs_solver_traits* is a traits class for solving GENERAL (aka unsymmetric) sparse linear systems using TAUCS out-of-core LU factorization.

```
#include <CGAL/Taucs_solver_traits.h>
```

Is Model for the Concepts

Model of the *SparseLinearAlgebraTraits_d* concept.

Parameters

The full template declaration is:

```
template<
class T>
class Taucs_solver_traits;
```

Types

```
Taucs_solver_traits<T>:: Matrix
Taucs_solver_traits<T>:: Vector
Taucs_solver_traits<T>:: NT
```

Creation

```
Taucs_solver_traits<T> solver;           default constructor.
```

```
Taucs_solver_traits<T> solver;           Create a TAUCS sparse linear solver for GENERAL (aka un-
                                           symmetric) matrices.
```

Operations

```
bool solver.linear_solver( Matrix A, Vector B, Vector& X, NT& D)
```

Solve the sparse linear system $A * X = B$. Return true on success. The solution is then $(1/D) * X$. Preconditions:

- $A.\text{row_dimension}() == B.\text{dimension}()$.
- $A.\text{column_dimension}() == X.\text{dimension}()$.

CGAL::Taucs_symmetric_matrix<T>

Definition

The class *Taucs_symmetric_matrix* is a C++ wrapper around a TAUCS *symmetric* matrix (type *taucs_ccs_matrix*).

Symmetric matrices store only the lower triangle.

```
#include <CGAL/Taucs_matrix.h>
```

Is Model for the Concepts

Model of the *SparseLinearAlgebraTraits_d::Matrix* concept.

Parameters

The full template declaration is:

```
template<
class T>
struct Taucs_symmetric_matrix;
```

Types

Taucs_symmetric_matrix<T>::NT

Creation

Taucs_symmetric_matrix<T> M(int dim); Create a square SYMMETRIC matrix initialized with zeros. The max number of non 0 elements in the matrix is automatically computed.

Parameters: **dim** Matrix dimension.

Taucs_symmetric_matrix<T> M(int rows, int columns, int nb_max_elements = 0);

Create a square SYMMETRIC matrix initialized with zeros.

Parameters: **rows** Matrix dimensions.

nb_max_elements Max number of non 0 elements in the matrix (automatically computed if 0).

Operations

OpenNL::SymmetricLinearSolverTraits<COEFFTYPE, MATRIX, VECTOR, SOLVER> in OpenNL package

CGAL::Taucs_symmetric_solver_traits<T>

Definition

The class *Taucs_symmetric_solver_traits* is a traits class for solving symmetric positive definite sparse linear systems using TAUCS solvers family. The default solver is the Multifrontal Supernodal Cholesky Factorization.

```
#include <CGAL/Taucs_solver_traits.h>
```

Is Model for the Concepts

Model of the *SparseLinearAlgebraTraits_d* concept.

Parameters

The full template declaration is:

```
template<
class T>
class Taucs_symmetric_solver_traits;
```

Types

```
Taucs_symmetric_solver_traits<T>:: Matrix
Taucs_symmetric_solver_traits<T>:: Vector
Taucs_symmetric_solver_traits<T>:: NT
```

Creation

```
Taucs_symmetric_solver_traits<T> solver( const char * options[] = NULL,
                                         const void * arguments[] = NULL)
```

Create a TAUCS sparse linear solver for symmetric positive definite matrices. The default solver is the Multifrontal Supernodal Cholesky Factorization. See *taucs_linsolve()* documentation for the meaning of the 'options' and 'arguments' parameters.

Parameters: **options** must be persistent
arguments must be persistent

Operations

```
bool solver.linear_solver( Matrix A, Vector B, Vector& X, NT& D)
```

Solve the sparse linear system $A * X = B$. Return true on success. The solution is then $(1/D) * X$. Preconditions:

- *A.row_dimension()* == *B.dimension()*.
- *A.column_dimension()* == *X.dimension()*.

CGAL::Taucs_vector<T>

Definition

The class *Taucs_vector* is a C++ wrapper around TAUCS' vector type, which is a simple array.

```
#include <CGAL/Taucs_vector.h>
```

Is Model for the Concepts

Model of the *SparseLinearAlgebraTraits_d::Vector* concept.

Parameters

The full template declaration is:

```
template<
class T>
class Taucs_vector;
```

Types

Taucs_vector<T>::NT

Creation

<i>Taucs_vector<T></i> <i>v</i> (<i>int dimension</i>);	Create a vector initialized with zeros.
<i>Taucs_vector<T></i> <i>v</i> (<i>toCopy</i>);	Copy constructor.

Operations

<i>Taucs_vector&</i>	<i>v = toCopy</i>	operator =()
<i>int</i>	<i>v.dimension()</i>	Return the vector's number of coefficients.
<i>T</i>	<i>v[int i]</i>	Read/write access to a vector coefficient. Preconditions: 0 <= i < dimension().
<i>T&</i>	<i>v[int i]</i>	
<i>const T*</i>	<i>v.get_taucs_vector()</i>	Get TAUCS vector wrapped by this object.
<i>T*</i>	<i>v.get_taucs_vector()</i>

CGAL::Two_vertices_parameterizer_3<ParameterizationMesh_3>

Definition

Two_vertices_parameterizer_3 is the default border parameterizer for Least Squares Conformal Maps parameterization.

The class *Two_vertices_parameterizer_3* parameterizes two extreme vertices of a 3D surface. This kind of border parameterization is used by free border parameterizations.

Implementation note: To simplify the implementation, *BorderParameterizer_3* models know only the *ParameterizationMesh_3* class. They do not know the parameterization algorithm requirements or the kind of sparse linear system used.

```
#include <CGAL/Two_vertices_parameterizer_3.h>
```

Is Model for the Concepts

Model of the *BorderParameterizer_3* concept.

Design Pattern

BorderParameterizer_3 models are Strategies [\[GHJV95\]](#): they implement a strategy of border parameterization for models of *ParameterizationMesh_3*.

Parameters

The full template declaration is:

```
template<
class ParameterizationMesh_3>
class Two_vertices_parameterizer_3;
```

Types

Two_vertices_parameterizer_3<ParameterizationMesh_3>::Adaptor

Export *ParameterizationMesh_3* template parameter.

Creation

Two_vertices_parameterizer_3<ParameterizationMesh_3> bp;

default constructor.

Operations

Parameterizer_traits_3<Adaptor>::Error_code

bp.parameterize_border(Adaptor& mesh)

Map two extreme vertices of the 3D mesh and mark them as *parameterized*. Map two extreme vertices of the 3D mesh and mark them as *parameterized*. Return false on error.

bool

bp.is_border_convex()

Indicate if border's shape is convex. Meaningless for free border parameterization algorithms.

SparseLinearAlgebra_d::Vector

Definition

SparseLinearAlgebraTraits_d::Vector is a concept of a vector that can be multiplied by a sparse matrix.

Refines

This is a sub-concept of *LinearAlgebraTraits_d::Vector*.

Types

Vector::NT

Creation

<i>Vector</i> <i>v</i> (<i>int</i> <i>rows</i>);	Create a vector initialized with zeros.
<i>Vector</i> <i>v</i> (<i>Vector toCopy</i>);	Copy constructor.

Operations

<i>Vector</i> &	<i>v</i> = <i>Vector toCopy</i>	operator =()
<i>int</i>	<i>v.dimension()</i>	Return the vector's number of coefficients.
<i>NT</i>	<i>v</i> [<i>int</i> <i>row</i>]	Read/write access to a vector coefficient. Precondition: 0 <= <i>row</i> < <i>dimension()</i> .
<i>NT</i> &	<i>v</i> [<i>int</i> <i>row</i>]	

Has Models

CGAL::Taucs_vector<*T*>
OpenNL::FullVector<*T*> in OpenNL package

40.5 Examples	2402

This chapter describes the CGAL 2D streamline placement package. Basic definitions and notions are given in Section 40.1. Section 40.2 gives a description of the integration process. Section 40.3 provides a brief description of the algorithm. Section 40.4 presents the implementation of the package, and Section 40.5 details two example placements.

Figure 40.1: The core idea of the algorithm is to integrate the streamlines from the center of the biggest empty cavities in the domain (left). A Delaunay triangulation of all the sample points is used to model the streamlines and the spaces within the domain (middle). A final result is shown (right).

40.1 Definitions

In physics, a *field* is an assignment of a quantity to every point in space. For example, a gravitational field assigns a gravitational potential to each point in space.

Vector and direction fields are commonly used for modeling physical phenomena, where a direction and magnitude, namely a vector is assigned to each point inside a domain (such as the magnitude and direction of the force at each point in a magnetic field).

Streamlines are important tools for visualizing flow fields. A *streamline* is a curve everywhere tangent to the field. In practice, a streamline is often represented as a polyline (series of points) iteratively elongated by bidirectional numerical integration started from a *seed point*, until it comes close to another streamline (according to a specified distance called *the separating distance*), hits the domain boundary, reaches a critical point or generates a closed path.

A *valid* placement of streamlines consists of saturating the domain with a set of tangential streamlines in accordance with a specified *density*, determined by the *separating distance* between the streamlines.

40.2 Fundamental Notions

A streamline can be considered as the path traced by an imaginary massless particle dropped into a steady fluid flow described by the field. The construction of this path consists in the solving an ordinary differential equation for successive time intervals. In this way, we obtain a series of points $p_k, 0 < k < n$ which allow visualizing the streamline. The differential equation is defined as follows :

$$\frac{dp}{dt} = v(p(t)), \quad p(0) = p_0$$

where $p(t)$ is the position of the particle at time t , v is a function which assigns a vector value at each point in the domain (possibly by interpolation), and p_0 is the initial position. The position after a given interval Δt is given by :

$$p(t + \Delta t) = p(t) + \int_t^{t+\Delta t} v(p(t))dt$$

. Several numeric methods have been proposed to solve this equation. In this package, the Euler, and the Second Order Runge-Kutta algorithm are implemented.

40.2.1 Euler Integrator

This algorithm approximates the point computation by this formula

$$p_{k+1} = p_k + hv(p_k)$$

where h specifies the *integration step* (see Figure 40.2). The integration can be done forward (resp. backward) by specifying a positive (resp. negative) integration step h . The streamline is then constructed by successive integration from a seed point both forward and backward.

Figure 40.2: Euler integrator.

Figure 40.3: Runge-Kutta second order integrator (The empty circle represents the intermediate point, and the gray disk represents the Euler integrated point).

40.2.2 Second Order Runge-Kutta Integrator

This method introduces an intermediate point p'_k between p_k and p_{k+1} to increase the precision of the computation (see Figure 40.3), where:

$$\begin{aligned} p'_k &= p_k + \frac{1}{2}hv(p_k) \\ p_{k+1} &= p_k + hv(p'_k) \end{aligned}$$

See [PTVF02] for further details about numerical integration.

40.3 Farthest Point Seeding Strategy

The algorithm implemented in this package [MAD05] consists of placing one streamline at a time by numerical integration starting farthest away from all previously placed streamlines.

The input of our algorithm is given by (i) a flow field, (ii) a *density* specified either globally, by the inverse of the ideal spacing distance, or locally by a density field, and (iii) a *saturation* ratio over the desired spacing required to trigger the seeding of a new streamline.

The input flow field is given by a discrete set of vectors or directions sampled within a domain, associated with an interpolation scheme (*e.g.* bilinear interpolation over a regular grid, or natural neighbor interpolation over an irregular point set to allow for an evaluation at each point coordinate within the domain).

The *output* is a streamline placement, represented as a list of streamlines. The core idea of our algorithm consists of placing one streamline at a time by numerical integration seeded at the farthest point from all previously placed streamlines.

The streamlines are approximated by polylines, whose points are inserted to a 2D Delaunay triangulation (see figure 40). The empty circumscribed circles of the Delaunay triangles provide us with a good approximation of the cavities in the domain.

After each streamline integration, all incident triangles whose circumcircle diameter is larger (within the saturation ratio) than the desired spacing distance are pushed to a priority queue sorted by the triangle circumcircle diameter. To start each new streamline integration, the triangle with largest circumcircle diameter (and hence the biggest cavity) is popped out of the queue. We first test if it is still a valid triangle of the triangulation, since it could have been destroyed by a streamline previously added to the triangulation. If it is not, we pop another triangle out of the queue. If it is, we use the center of its circumcircle as seed point to integrate a new streamline.

Our algorithm terminates when the priority queue is empty. The size of the biggest cavity being monotonically decreasing, our algorithm guarantees the domain saturation.

40.4 Implementation

Streamlines are represented as polylines, and are obtained by iterative integration from the seed point. A polyline is represented as a range of points. The computation is processed via a list of Delaunay triangulation vertices.

To implement the triangular grid, the `CGAL Delaunay_triangulation_2` class is used. The priority queue used to store candidate seed points is taken from the Standard Template Library [Sil97].

40.5 Examples

The first example illustrates the generation of a 2D streamline placement from a vector field defined on a regular grid.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Filtered_kernel.h>
#include <CGAL/Stream_lines_2.h>
#include <CGAL/Runge_kutta_integrator_2.h>
#include <CGAL/Regular_grid_2.h>
#include <CGAL/Triangular_field_2.h>

#include <iostream>
#include <fstream>

typedef double coord_type;
typedef CGAL::Cartesian<coord_type> K1;
typedef CGAL::Filtered_kernel<K1> K;
```

```

typedef CGAL::Regular_grid_2<K> Field;
typedef CGAL::Runge_kutta_integrator_2<Field> Runge_kutta_integrator;
typedef CGAL::Stream_lines_2<Field, Runge_kutta_integrator> Strl;
typedef Strl::Point_iterator_2 Point_iterator;
typedef Strl::Stream_line_iterator_2 Strl_iterator;
typedef Strl::Point_2 Point_2;
typedef Strl::Vector_2 Vector_2;

int main()
{
    Runge_kutta_integrator runge_kutta_integrator;

    /*data.vec.cin is an ASCII file containing the vector field values*/
    std::ifstream infile("data/vnoise.vec.cin", std::ios::in);
    double iXSize, iYSize;
    unsigned int x_samples, y_samples;
    iXSize = iYSize = 512;
    infile >> x_samples;
    infile >> y_samples;
    Field regular_grid_2(x_samples, y_samples, iXSize, iYSize);
    /*fill the grid with the appropriate values*/
    for (unsigned int i=0; i<x_samples; i++)
        for (unsigned int j=0; j<y_samples; j++)
        {
            double xval, yval;
            infile >> xval;
            infile >> yval;
            regular_grid_2.set_field(i, j, Vector_2(xval, yval));
        }
    infile.close();

    /* the placement of streamlines */
    std::cout << "processing...\n";
    double dSep = 3.5;
    double dRat = 1.6;
    Strl Stream_lines(regular_grid_2, runge_kutta_integrator, dSep, dRat);
    std::cout << "placement generated\n";

    /*writing streamlines to streamlines_on_regular_grid_1.stl */
    std::ofstream fw("streamlines_on_regular_grid_1.stl", std::ios::out);
    fw << Stream_lines.number_of_lines() << "\n";
    for(Strl_iterator sit = Stream_lines.begin(); sit != Stream_lines.end(); sit++)
    {
        fw << "\n";
        for(Point_iterator pit = sit->first; pit != sit->second; pit++){
            Point_2 p = *pit;
            fw << p.x() << " " << p.y() << "\n";
        }
    }

    fw.close();
}

```

File: examples/Stream_lines_2/stl_regular_field.cpp

The second example depicts the generation of a streamline placement from a vector field defined on a triangular grid.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Filtered_kernel.h>
#include <CGAL/Stream_lines_2.h>
#include <CGAL/Runge_kutta_integrator_2.h>
#include <CGAL/Triangular_field_2.h>

#include <iostream>
#include <fstream>

typedef double coord_type;
typedef CGAL::Cartesian<coord_type> K1;
typedef CGAL::Filtered_kernel<K1> K;
typedef K::Point_2 Point;
typedef K::Vector_2 Vector;
typedef CGAL::Triangular_field_2<K> Field;
typedef CGAL::Runge_kutta_integrator_2<Field> Runge_kutta_integrator;
typedef CGAL::Stream_lines_2<Field, Runge_kutta_integrator> Strl;
typedef Strl::Stream_line_iterator_2 stl_iterator;

int main()
{
    Runge_kutta_integrator runge_kutta_integrator(1);

    /*datap.tri.cin and datav.tri.cin are ascii files where are stored the vector values*/
    std::ifstream inp("data/datap.tri.cin");
    std::ifstream inv("data/datav.tri.cin");
    std::istream_iterator<Point> beginp(inp);
    std::istream_iterator<Vector> beginv(inv);
    std::istream_iterator<Point> endp;

    Field triangular_field(beginp, endp, beginv);

    /* the placement of streamlines */
    std::cout << "processing...\n";
    double dSep = 30.0;
    double dRat = 1.6;
    Strl Stream_lines(triangular_field, runge_kutta_integrator, dSep, dRat);
    std::cout << "placement generated\n";

    /*writing streamlines to streamlines.stl */
    std::cout << "streamlines.stl\n";
    std::ofstream fw("streamlines.stl", std::ios::out);
    Stream_lines.print_stream_lines(fw);
}
```

2D Placement of Streamlines

Reference Manual

Abdelkrim Mebarki

Vector and direction fields are commonly used for modeling physical phenomena, where a direction and magnitude, namely a vector is assigned to each point inside a domain.

A streamline is a curve everywhere tangent to the field. It can be considered as the path traced by an imaginary massless particle dropped into a steady fluid flow described by the field.

A streamline is represented as a polyline iteratively elongated by bidirectional numerical integration started from a seed point, until it comes close to another streamline, hits the domain boundary, or reaches a critical point.

The *Stream_lines_2* class consists of saturating the domain with a set of tangential streamlines in accordance with a specified density.

Streamlines are represented as containers of points, manipulated by an iterator range of points, and the whole placement is accessible via an iterator range of streamlines.

The main class in this package, the *Stream_lines_2* class of CGAL depends on two template parameters. The first template parameter stands for a class which represents both the vector field and the visualization domain with operations on them, and should be instantiated by a model of the concept *VectorField_2*. The second template parameter stands for a function object that ensures the numerical integration used to construct the streamlines, and should be instantiated by a model of the concept *Integrator_2*.

CGAL::Euler_integrator_2<VectorField_2>

Definition

This class implements the first order Euler integrator. The template parameter *VectorField_2* has to be instantiated by a model of the concept *VectorField_2*.

Creation

```
Euler_integrator_2<VectorField_2> einteg( FT integration_step);
```

Creates an Euler integrator class *einteg* with *integration_step* as integration step.

Is Model for the Concepts

Integrator_2

Runge_kutta_integrator_2<*VectorField_2*>

CGAL::Regular_grid_2<StreamLinesTraits_2>

Definition

The template parameter *StreamLinesTraits_2* has to be instantiated by a model of the concept *StreamLinesTraits_2*.

This class provides a 2D vector field specified by a set of sample points defined on a regular grid, with a bilinear interpolation scheme over its cells (i.e. for each point p in a cell c , the vector value is interpolated from the vertices of c).

Types

<code>typedef StreamLinesTraits_2::FT</code>	<code>FT;</code>	the scalar type.
<code>typedef StreamLinesTraits_2::Point_2</code>	<code>Point_2;</code>	the point type.
<code>typedef StreamLinesTraits_2::Vector_2</code>	<code>Vector_2;</code>	the vector type.

Creation

`Regular_grid_2<StreamLinesTraits_2> rgrid(int x_samples, int y_samples, FT x_size, FT y_size);`

Generate a regular grid *rgrid* whose size is *x_size* by *y_size*, while *x_samples* and *y_samples* specify the number of samples on *x* and *y*.

Modifiers

In addition to the minimum interface required by the concept definition, the class *Regular_grid_2<StreamLinesTraits_2>* provides the following function to fill the vector field with the user data.

`void rgrid.set_xy(int i, int j, Vector_2 v)`

Attribute the vector *v* to the position (*i,j*) on the regular grid.

Access Functions

<code>std::pair<int, int></code>	<code>rgrid.get_dimension()</code>	returns the dimension of the grid.
--	------------------------------------	------------------------------------

<code>std::pair<FT, FT></code>	<code>rgrid.get_size()</code>	returns the size of the grid.
--------------------------------------	-------------------------------	-------------------------------

StreamLinesTraits_2

Definition

The concept `StreamLinesTraits_2` describes the set of requirements to be fulfilled by any class used to instantiate the template parameter of the class `Regular_grid_2<StreamLinesTraits_2>`. This concept provides the types handled by the `Stream_lines_2<VectorField_2, Integrator_2>` class.

Types

<code>StreamLinesTraits_2:: FT</code>	The scalar type.
<code>StreamLinesTraits_2:: Point_2</code>	The point type.
<code>StreamLinesTraits_2:: Vector_2</code>	The vector type.

Has Models

The kernels of CGAL are models for this traits class.

CGAL::Stream_lines_2<VectorField_2,Integrator_2>

Definition

The class *Stream_lines_2<VectorField_2,Integrator_2>* is designed to handle a placement of streamlines in a 2D domain according to a bidimensional vector field.

The class *Stream_lines_2<VectorField_2,Integrator_2>* creates a placement of streamlines according to a specified density and gives access to those streamlines via two iterators over a container of iterators that provide access to the streamline points.

Parameters

The class *Stream_lines_2<VectorField_2,Integrator_2>* has two template parameters. The first parameter *VectorField_2* has to be instantiated by a model of the concept *VectorField_2*. The second parameter is the function object *Integrator_2*, and has to be instantiated by a model of the concept *Integrator_2*.

Types

<i>typedef VectorField_2::Geom_traits</i>	<i>Geom_traits;</i>	the traits class.
<i>typedef VectorField_2::FT</i>	<i>FT;</i>	the scalar type.
<i>typedef VectorField_2::Point_2</i>	<i>Point_2;</i>	the point type.
<i>typedef VectorField_2::Vector_2</i>	<i>Vector_2;</i>	the vector type.

The class *Stream_lines_2<VectorField_2,Integrator_2>* provides also two types for handling streamlines:

Stream_lines_2<VectorField_2,Integrator_2>:: Point_iterator_2

iterator of points with value type *Point_2*.

Stream_lines_2<VectorField_2,Integrator_2>:: Stream_line_iterator_2

an iterator to visit the streamlines with value type *std::pair< Point_iterator_2, Point_iterator_2>*.

Creation

```
Stream_lines_2<VectorField_2,Integrator_2> stl( VectorField_2 vector_field_2,
                                              Integrator_2 integrator_2,
                                              FT separating_distance,
                                              FT saturation_ratio)
```

Generates a streamline placement *stl*.

Modifiers

```
void stl.set_separating_distance( FT new_value)
```

Modify the separating distance.

void *stl.set_saturation_ratio(FT new_value)*

Modify the saturation ratio.

void *stl.update()*

Update the placement after changing the separating distance or the saturation ratio.

Access Functions

void *stl.get_separating_distance()*

returns the separating distance.

void *stl.get_saturation_ratio()*

returns the saturation ratio.

void *stl.print_stream_lines(std::ofstream & fw)*

prints the streamlines to an ASCII file : line by line, and point by point.

Streamline iterators

The following iterators allow to visit all the streamlines generated by the constructor or the update function.

Stream_line_iterator *stl.begin()*

Starts at the first streamline

Stream_line_iterator *stl.end()*

Past-the-end iterator

CGAL::Triangular_field_2<StreamLinesTraits_2>

Definition

The template parameter *StreamLinesTraits_2* has to be instantiated by a model of the concept *StreamLinesTraits_2*.

This class provides a vector field specified by a set of sample points defined on a triangulated domain. All sample points are inserted to a *Delaunay triangulation*, and for each point p in the domain located in a face f , its vector value is interpolated from the vertices of the face f .

Types

<code>typedef StreamLinesTraits_2::FT</code>	<code>FT;</code>	the scalar type.
<code>typedef StreamLinesTraits_2::Point_2</code>	<code>Point_2;</code>	the point type.
<code>typedef StreamLinesTraits_2::Vector_2</code>	<code>Vector_2;</code>	the vector type.

Creation

```
Triangular_field_2<StreamLinesTraits_2> tfield_2( InputIterator1 first_point,
                                                    InputIterator1 last_point,
                                                    InputIterator2 first_vector)
```

Defines the points in the range $[first_point, last_point)$ as the sample points of the grid, with the corresponding number of vectors started at *first_vector*.
Precondition: The *value_type* of *InputIterator1* is *Point*.
Precondition: The *value_type* of *InputIterator2* is *Vector*.

VectorField_2

Definition

The concept `VectorField_2` describes the set of requirements to be fulfilled by any class used to instantiate the first template parameter of the class `Stream_lines_2<VectorField_2,Integrator_2>`. This concept provides the types of the geometric primitives used in the placement of streamlines and some functions for answering different queries.

Types

<code>VectorField_2::Geom_traits</code>	The traits class.
<code>VectorField_2::FT</code>	The scalar type.
<code>VectorField_2::Point_2</code>	The point type.
<code>VectorField_2::Vector_2</code>	The vector type.

Creation

<code>VectorField_2 vfield;</code>	Any constructor has to allow the user to fill the vector values (i.e. assign a vector to each position within the domain).
------------------------------------	--

Query Functions

<code>Geom_traits::Iso_rectangle_2</code>	
<code>std::pair<Vector_2,FT> vfield.bbox()</code>	returns the bounding box of the whole domain.
<code>bool vfield.get_field(Point_2 p)</code>	returns the vector field value and the local density. <i>Precondition: is_in_domain(p) must be true.</i>
<code>bool vfield.is_in_domain(Point_2 p)</code>	returns true if the point p is inside the domain boundaries, false otherwise.
<code>FT vfield.get_integration_step(Point_2 p)</code>	returns the integration step at the point p (i.e. the distance between p and the next point in the polyline.). <i>Precondition: is_in_domain(p) must be true.</i>

This chapter describes the CGAL package for the approximating the ridges and umbilics of a smooth surface discretized by a triangle mesh. Given a smooth surface, a ridge is a curve along which one of the principal curvatures has an extremum along its curvature line. An umbilic is a point at which both principal curvatures are equal. Ridges define a singular curve —i.e. a self-intersecting curve, and umbilics are special points on this curve. Ridges are curves of *extremal* curvature and therefore encode important informations used in segmentation, registration, matching and surface analysis. Based on the results of the article [CP05c], we propose algorithms to identify and extract different parts of this singular ridge curve as well as umbilics on a surface given as a triangulated surface mesh. Differential quantities associated to the mesh vertices are assumed to be given for these algorithms; such quantities may be computed by the package *Estimation of Local Differential Properties of Sampled Surfaces via Polynomial Fitting*.

Note that this package needs the third party libraries Lapack (Page 5) and Blas (Page 5) for linear algebra operations.

41.0.1 Overview

Section 41.1 presents the basics of the theory of ridges and umbilics on smooth surfaces. Sections 41.2 and 41.3 present algorithms for approximating the ridges and umbilics (of a smooth surface) from a triangle mesh. Section 41.4 gives the package specifications, while example calls to functions of the package are provided in Section 41.5.

Figure 41.1: Crest ridges on the David.

41.1 Ridges and Umbilics of a Smooth Surface

For a detailed introduction to ridges and related topics, the reader may consult [HGY⁺99, Por01], as well as the following survey article [CP05b]. In the sequel, we just introduce the basic notions so as to explain our algorithms. Consider a smooth embedded surface, and denote k_1 and k_2 the principal curvatures, with $k_1 \geq k_2$. Umbilics are the points where $k_1 = k_2$. For any non umbilical point, the corresponding principal directions of curvature are well defined, and we denote them d_1 and d_2 . In local coordinates, we denote $\langle \cdot, \cdot \rangle$ the inner product induced by the ambient Euclidean space, and dk_1, dk_2 the gradients of the principal curvatures. Ridges, illustrated on figure 41.2 for the standard ellipsoid, are defined by:

Definition. 1 *A non umbilical point is called*

- *a max ridge point if the extremality coefficient $b_0 = \langle dk_1, d_1 \rangle$ vanishes, i.e. $b_0 = 0$.*
- *a min ridge point if the extremality coefficient $b_3 = \langle dk_2, d_2 \rangle$ vanishes, i.e. $b_3 = 0$ ¹.*

The previous characterization of ridges involves third-order differential properties. Using fourth-order differential quantities, a ridge point can further be qualified as *elliptic* if it corresponds to a maximum of k_1 or a minimum of k_2 , or *hyperbolic* otherwise. Hence we end with four types of ridges, namely : *MAX_ELLIPTIC_RIDGE*, *MAX_HYPERBOLIC_RIDGE*, *MIN_ELLIPTIC_RIDGE*, *MIN_HYPERBOLIC_RIDGE*, see figure 41.2. Also of interest are the *crest lines*, a crest line being an elliptic ridge which is a maximum of $\max(|k_1|, |k_2|)$. Crest lines form a subset of elliptic ridges, and can be seen as the visually most salient curves on a surface. Hence we provide two additional ridge types : *MAX_CREST_RIDGE* and *MIN_CREST_RIDGE*, see figure 41.

At any point of the surface which is not an umbilic, principal directions d_1, d_2 are well defined, and these (non oriented) directions together with the normal vector n define two direct orthonormal frames. If v_1 is a unit vector of direction d_1 then there exists a unique unit vector v_2 so that (v_1, v_2, n) is direct, that is has the same orientation

¹Notations b_0, b_3 comes from equation 42.2

Figure 41.2: Ridges on the ellipsoid, normals pointing outward. Color coding : *MAX_ELLIPTIC_RIDGE* are blue, *MAX_HYPERBOLIC_RIDGE* are green, *MIN_ELLIPTIC_RIDGE* are red and *MIN_HYPERBOLIC_RIDGE* are yellow. The red line is also the *MIN_CREST_RIDGE* and this is the only crest ridge of the ellipsoid.

as the canonical basis of the ambient $3d$ space (and the other possible frame is $(-v_1, -v_2, n)$). In the coordinate systems (v_1, v_2, n) , the surface has the following canonical form, known as the Monge form :

$$z(x, y) = \frac{1}{2}(k_1 x^2 + k_2 y^2) + \frac{1}{6}(b_0 x^3 + 3b_1 x^2 y + 3b_2 x y^2 + b_3 y^3) \quad (41.1)$$

$$+ \frac{1}{24}(c_0 x^4 + 4c_1 x^3 y + 6c_2 x^2 y^2 + 4c_3 x y^3 + c_4 y^4) + h.o.t \quad (41.2)$$

The Taylor expansion of k_1 (resp. k_2) along the max (resp. min) curvature line going through the origin and parameterized by x (resp. y) are:

$$k_1(x) = k_1 + b_0 x + \frac{P_1}{2(k_1 - k_2)} x^2 + h.o.t, \quad P_1 = 3b_1^2 + (k_1 - k_2)(c_0 - 3k_1^3). \quad (41.3)$$

$$k_2(y) = k_2 + b_3 y + \frac{P_2}{2(k_2 - k_1)} y^2 + h.o.t, \quad P_2 = 3b_2^2 + (k_2 - k_1)(c_4 - 3k_2^3). \quad (41.4)$$

Notice also that switching from one to the other of the two afore-mentioned coordinate systems reverts the sign of all the odd coefficients on the Monge form of the surface.

Hence ridge types are characterized by

- max ridge if $b_0 = 0$
- *MAX_ELLIPTIC_RIDGE* if $b_0 = 0$ and $P_1 < 0$
- *MAX_HYPERBOLIC_RIDGE* if $b_0 = 0$ and $P_1 > 0$
- min ridge if $b_3 = 0$
- *MIN_ELLIPTIC_RIDGE* if $b_3 = 0$ and $P_2 < 0$
- *MIN_HYPERBOLIC_RIDGE* if $b_3 = 0$ and $P_2 > 0$
- *MAX_CREST_RIDGE* if $b_0 = 0$ and $P_1 < 0$ and $|k_1| > |k_2|$
- *MIN_CREST_RIDGE* if $b_3 = 0$ and $P_2 < 0$ and $|k_2| > |k_1|$

As illustrated on Fig. 41.3 and 41.4, the patterns made by curvature lines around an umbilic can be characterized using the notion of *index* associated to the principal directions —see also [CP05b]. As depicted on Fig. 41.3, consider a small circuit C around the umbilic, and a point $p \in C$. Starting from an initial orientation u of a tangent vector to the curvature line through point p , propagate *by continuity* this orientation around the circuit. The index is defined by the angle swept by u around this revolution, normalized by 2π . On our example, the index is thus $1/2$.

If the index of the principal direction field is $1/2$ then it is called a *ELLIPTIC_UMBILIC*, if it is $-1/2$ it is called a *HYPERBOLIC_UMBILIC*. Otherwise the umbilic is qualified *NON_GENERIC_UMBILIC*.

Figure 41.4: Elliptic and hyperbolic umbilics.

41.2 Approximating Ridges on Triangulated Surface Meshes

Our method aims at reporting ridges as polygonal lines living on the mesh. It assumes differential quantities are available for each vertex of the mesh (principal curvatures and directions together with third order quantities b_0, b_3 and optionally fourth order quantities P_1, P_2). These differential quantities may be computed for the smooth surface the mesh is inscribed in (analytically or using approximation methods), or may be estimated for a mesh given without reference to a underlying smooth surface. Although the ridge approximation algorithm is the same in both cases, one cannot ambition to ask for the same certificates. This distinction calls for the notion of *compliant* mesh.

Compliant meshes. Ridges of a smooth surface are points with prescribed differential properties, and reporting them from a mesh inscribed in the surface requires delicate hypothesis on the geometry of that mesh so as to get a certified result. In this paragraph, we assume the mesh provided complies with a number of hypothesis, which guarantee the topology of the ridges reported matches that of the ridges on the smooth surface. To summarize things, a compliant mesh is a mesh dense enough so that (i) umbilics are properly isolated (ii) ridges running next to one another are also properly separated. See [CP05c] for a detailed discussion of *compliant* meshes.

As 0-level set of the extremality coefficients b_0 and b_3 , ridges are extracted by a marching triangles algorithm ²

As the signs of these extremality coefficients depend on the orientation of the principal directions, we expect both extremalities and vectors orienting the principal direction to be given at each point vertex of the mesh. Except in the neighborhood of umbilics, if the mesh is dense enough, a coherent orientation of principal directions at both endpoints of an edge is chosen such than the angle between the two vectors is acute. This rule, the *acute rule*, is precisely analyzed in [CP05c]. Moreover, we only seek ridges in triangles such than one can find an orientation of its three vertices such that the three edges are coherently oriented by the acute rule. Such triangles are termed *regular*. This said, two remarks are in order.

—*Regular triangles and ridge segments.* A regular triangle has 0 or 2 edges crossed by a max (resp. min) ridge, which is tantamount to a sign change of b_0 (resp. b_3) along the corresponding edges. In the later case, we say that the triangle contains a ridge segment. Two methods are provided to compute its type, be it elliptic or hyperbolic. First, if fourth order differential quantities are provided, one can use the P_1 (P_2) values of Eq. (41.3) ((41.4)) for a max (min) ridge. The value of P_i for a ridge segment is defined as the mean value of the P_i values of the two crossing points on edges (while the value at a crossing point on an edge is the b_i -weighted mean value of the values at endpoints). Alternatively, if third order differential quantities only are available, one may use the geometric method developed in [CP05c].

Using the notion of ridge segment, a *Ridge_line* is defined as a maximal connected sequence of ridge segments of the same type and connected together. Notice that the topology of a *Ridge_line* is either that of an interval or a circle.

—*Non-regular triangles.* In the neighborhood of umbilics, triangle are less likely to be regular and the detection of ridges cannot be relevant by this method. This is why we propose another method to detect umbilics independently.

Non compliant meshes : filtering ridges on *strength* and *sharpness*. For real world applications dealing with coarse meshes, or meshes featuring degenerate regions or sharp features, or meshes conveying some amount of noise, the *compliance* hypothesis [CP05c] cannot be met. In that case, it still makes sense to seek loci of points featuring extremality of estimated principal curvatures, but the ridges reported may require filtering. For

²A marching triangles algorithm is similar to a 2d marching cubes algorithm (or marching rectangles algorithm), excepted that a one-manifold is reported on a two-manifold tessellated by triangles.

example, if the principal curvatures are constant—which is the case on a plane or a cylinder, then all points are ridge points. In this context, an appealing notion is that of *sharp* ridge or *prominent* ridge. Since ridges are witnessed by zero crossings of b_0 and b_3 , one can expect erroneous detections as long as these coefficients remain small. In order to select the most prominent ridge points, we focus on points where the variation of the curvature is fast along the curvature line. One can observe that, at a ridge point, according to equation 41.3, the second derivative of k_1 along its curvature line satisfies $k_1''(0) = P_1/(k_1 - k_2)$. Using this observation, one can define the *sharpness of a ridge* as the integral of the absolute value of $P_1/(k_1 - k_2)$ along the ridge. As the second derivative of the curvature is homogeneous to the inverse of the cube of a length, the sharpness is homogeneous to the inverse of the square of a length. Multiplying the sharpness by the square of the model size gives a threshold and an associated sharpness-filter which are scale independent. Another filtering is also available with the *strength* which is the integral of the curvature along the ridge line [OBS04].

41.3 Approximating Umbilics on Triangulated Surface Meshes

The method aims at identifying some vertices of a mesh as umbilics. It assumes principal curvatures and directions are given at each vertex on the mesh.

Algorithm. Assume each vertex v of the mesh comes with a patch (a topological disk) around it. Checking whether vertex v is an umbilic is a two stages process, which are respectively concerned with the variation of the function $k_1 - k_2$ over the patch, and the index of the vertex computed from the boundary of the patch. More precisely, vertex v is declared to be an umbilic if the following two conditions are met:

- the function $k_1 - k_2$ has its minimum at v amongst all the vertices of the patch;
- the deviation δ of any principal direction along the patch boundary, traversed counter-clock-wise (CCW), has prescribed properties:
 - $\delta \in]\pi/2, 3\pi/2[$, then the umbilic is called elliptic,
 - $\delta \in]-3\pi/2, -\pi/2[$, then the umbilic is called a hyperbolic,
 - otherwise the umbilic is called non-generic.

Finding patches around vertices. Given a vertex v and a parameter t , we aim at defining a collection of triangles around v so that (i) this collection defines a topological disk on the triangulation T and (ii) its size depends on t . First we collect the 1-ring triangles. We define the size s of this 1-ring patch as the (Euclidean) distance from v to its farthest 1-ring vertex neighbor. We then collect recursively adjacent triangles so that the patch remains a topological disk and such that these triangles are at distance less than $s \times t$. Parameter t is the only parameter of the algorithm.

Umbilical patches versus ridges. On a generic surface, generic umbilics are traversed by one or three ridges. For compliant meshes, an umbilic can thus be connected to the ridge points located on the boundary of its patch. This functionality is not provided, and the interested reader is referred to [CP05c] for more details.

41.4 Software Design

All classes of this package are templated by the parameter *TriangulatedSurfaceMesh*, which defines the type of the mesh to which the approximation algorithms operate.

The differential quantities are provided at vertices of this mesh via property maps, a concept commonly used in the Boost library. Scalar data (curvatures and their derivatives) are provided via *Vertex2FTPPropertyMap* concepts, while 3d vector data (principal directions of curvatures) are provided via *Vertex2VectorPropertyMap* concepts. The rationale for introducing these concepts is that properties are used independently from the way they are stored. This enables the user to store them *internally* in extended vertices or *externally* with maps. We provide a class *Vertex2Data_Property_Map_with_std_map* to adapt *std::map* with a *boost::associative_property_map* to model these concepts.

Output of ridges or umbilics are provided via output iterator.

Approximation of ridges and umbilics are performed by two independent classes, which we now further describe.

41.4.1 Ridge Approximation

The main class is *Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPPropertyMap,Vertex2VectorPropertyMap>*. Its construction requires the mesh and the property maps defining the differential quantities for principal curvatures k_1 and k_2 , the third order extremalities b_0 and b_3 , the principal directions of curvature d_1 and d_2 , and the fourth order quantities P_1 and P_2 if the tagging of ridges as elliptic or hyperbolic is to be done using the polynomials P_1 and P_2 .

Three functions (provided as members and also as global functions) enable the computation of different types of ridges :

- *compute_max_ridges* (resp. *compute_min_ridges*) outputs ridges of types *MAX_ELLIPTIC_RIDGE* and *MAX_HYPERBOLIC_RIDGE* (resp. *MIN_ELLIPTIC_RIDGE* and *MIN_HYPERBOLIC_RIDGE*).
- *compute_crest_ridges* outputs ridges of types *MAX_CREST_RIDGE* and *MIN_CREST_RIDGE*.

These functions allows the user to specify how the elliptic/hyperbolic tagging is carried out. Notice the rationale for the choice of these three functions is simple: each computation needs a single pass over the triangles of the mesh. This should be clear for the min and max ridges. For crests, just notice max and min crests cannot intersect over a triangle.

The ridge lines are stored in *Ridge_line* objects and output through an iterator. Each ridge line is represented as a list of halfedges of the mesh it crosses with a scalar defining the barycentric coordinate of the crossing point with respect to the half-edge endpoints. Each ridge line comes with its type *Ridge_type*, its strength and sharpness.

If one chooses to use only third order quantities, the quantities P_i do not have to be defined. Then the sharpness will not be defined.

41.4.2 Umbilic Approximation

The main class is *Umbilic_approximation<TriangulatedSurfaceMesh,Vertex2FTPPropertyMap,Vertex2VectorPropertyMap>*. Its construction requires the mesh and the property maps defining the differential quantities for principal curvatures k_1 and k_2 , and the principal directions of curvature d_1 and d_2 . The member function *compute* (or the global function *compute_umbilics*) has a parameter to define the size of the neighborhood of the umbilic.

Umbilics are stored in *Umbilic* objects, they come with their type : *ELLIPTIC_UMBILIC*, *HYPERBOLIC_UMBILIC* or *NON_GENERIC_UMBILIC*; the vertex of the mesh they are associated to and the list of half-edges representing the contour of the neighborhood.

41.4.3 Models for the Property Map Concepts

The class `Vertex2Data_Property_Map_with_std_map<TriangulatedSurfaceMesh>` enables the definition of models for the concepts `Vertex2FTPPropertyMap` and `Vertex2VectorPropertyMap` using `std::maps` and `boost::associative_property_map`.

41.5 Illustrations - Examples

Example program. ³ The following program computes ridges and umbilics from an off file. It uses the Jet fitting package to estimate the differential quantities. The default output file gives rough data for visualization purpose, a verbose output file may also be asked for. Parameters are

- d , the degree of the jet for the *Monge_via_jet_fitting* class, d must be greater or equal to 3 which is the default value;
- m , the degree of the Monge representation for the *Monge_via_jet_fitting* class, m must be 3 (the default value) or 4 and smaller than d ;
- a , the number of rings of neighbors collected for the *Monge_via_jet_fitting* class, in addition the number of vertices collected must be greater than $Nd := (d + 1)(d + 2)/2$ to make the approximation possible. a may be an integer greater than 1, the value 0 (which is the default) means that the minimum number of rings is collected to make the approximation possible. (Alternatively option p allows the specification of a constant number of neighbors);
- t , the *CGAL::Ridge_order* for the distinction between elliptic and hyperbolic ridges, t is 3 (default) or 4;
- u , the parameter for umbilic patch size, $u \geq 1$ (default is 1).

```
#include <CGAL/Ridges.h>

```

Example: Fig. 41.5. For that figure, the data have been computed as follows

```
./Compute_Ridges_Umbilics -f data/ellipsoid_u_0.02.off -d 4 -m 4 -a 3 -t 3
```

In addition, the four elliptic umbilics are detected, the standard output being

```
nb of umbilics 4
Umbilic at location (-0.80899 0.00426003 0.293896) of type elliptic
Umbilic at location (-0.811197 0.0122098 -0.292259) of type elliptic
Umbilic at location (0.808372 -0.00551307 -0.29431) of type elliptic
Umbilic at location (0.81413 0.0018689 0.290339) of type elliptic
```

Figure 41.5: Ridges on the ellipsoid, normals pointing outward. Color coding : *MAX_ELLIPTIC_RIDGE* are blue, *MAX_HYPERBOLIC_RIDGE* are green, *MIN_ELLIPTIC_RIDGE* are red and *MIN_HYPERBOLIC_RIDGE* are yellow.

Example: Fig. 41.6. This Fig. illustrates the filtering of crest ridges on a mechanical model, and has been computed as follows:

```
./Compute_Ridges_Umbilics -f data/mecanic.off -d 4 -m 4 -a 4 -t 4
```

Figure 41.6: Mechanical part (37k pts): (a) All crest lines, (b) crests filtered with the strength threshold 1 and (c) crests filtered with the sharpness threshold 100 000. Notice that any point on a flat or cylindrical part lies on two ridges, so that the noise observed on the top two Figs. is unavoidable. It is however easily filtered out with the sharpness on the bottom figure.

CGAL::Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPPropertyMap,Vertex2VectorPropertyMap>

Definition

The class *Ridge_approximation*<*TriangulatedSurfaceMesh*,*Vertex2FTPPropertyMap*,*Vertex2VectorPropertyMap*> computes the approximation of ridges of a triangular polyhedral surface.

```
#include <CGAL/Ridges.h>
```

Parameters

The class *Ridge_approximation*<*TriangulatedSurfaceMesh*,*Vertex2FTPPropertyMap*,*Vertex2VectorPropertyMap*> has three template parameters. *TriangulatedSurfaceMesh* provides the surface. Parameters *Vertex2FTPPropertyMap* and *Vertex2VectorPropertyMap* provide the differential properties of the surface associated to its vertices.

Requirements (checked at compile time) : the types *TriangulatedSurfaceMesh::Traits::FT* and *Vertex2FTPPropertyMap::value_type* must coincide; the types *TriangulatedSurfaceMesh::Traits::Vector_3* and *Vertex2VectorPropertyMap::value_type* must coincide; the types *TriangulatedSurfaceMesh::Vertex_handle*, *Vertex2FTPPropertyMap::key_type* and *Vertex2VectorPropertyMap::key_type* must coincide;

Types

```
enum Tag_order { Tag_3, Tag_4};
```

Order of differential quantities used to distinguish elliptic and hyperbolic ridges. Third (*Tag_3*) or fourth (*Tag_4*) order quantities may be used as explained in section 41.2 of the user manual.

Creation

```
Ridge_approximation<TriangulatedSurfaceMesh,Vertex2FTPPropertyMap,Vertex2VectorPropertyMap> ridge_
approximation( TriangulatedSurfaceMesh P,
```

```
Vertex2FTPPropertyMap vertex2k1_pm,
```

```
Vertex2FTPPropertyMap vertex2k2_pm,
```

```
Vertex2FTPPropertyMap vertex2b0_pm,
```

```
Vertex2FTPPropertyMap vertex2b3_pm,
```

```
Vertex2VectorPropertyMap vertex2d1_pm,
```

```
Vertex2VectorPropertyMap vertex2d2_pm,
```

```

tex2FTPPropertyMap vertex2P1_pm,
tex2FTPPropertyMap vertex2P2_pm)

```

The two last property maps may not be used if computations are performed with the parameter *Tag_3*, in which case these property maps shall be initialized with their default constructors.

```

template <class OutputIterator>
OutputIterator      ridge_approximation.compute_max_ridges( OutputIterator it,
                                                             Tag_order ord = Tag_3)

```

Outputs ridges of types *MAX_ELLIPTIC_RIDGE* and *MAX_HYPERBOLIC_RIDGE*. Parameter *it* is a STL output iterator whose *value_type* is *Ridge_line**.

```

template <class OutputIterator>
OutputIterator      ridge_approximation.compute_min_ridges( OutputIterator it,
                                                             Tag_order ord = Tag_3)

```

Outputs ridges of types *MIN_ELLIPTIC_RIDGE* and *MIN_HYPERBOLIC_RIDGE*. Parameter *it* is a STL output iterator whose *value_type* is *Ridge_line**.

```

template <class OutputIterator>
OutputIterator      ridge_approximation.compute_crest_ridges( OutputIterator it,
                                                                Tag_order ord = Tag_3)

```

Outputs ridges of types *MAX_CRESC_RIDGE* and *MIN_CRESC_RIDGE*. Parameter *it* is a STL output iterator whose *value_type* is *Ridge_line**.

Ridge_line

CGAL::Ridge_line<TriangulatedSurfaceMesh>

Definition

The class *Ridge_line*<*TriangulatedSurfaceMesh*> stores the description of a ridge line. The list of halfedges defines a connected sequence of edges (but not as oriented halfedges). The scalar b paired with a halfedge pq is the barycentric coordinate of the crossing point r with the ridge : $r = b \times p + (1 - b) \times q$.

```
#include <CGAL/Ridges.h>
```

Types

```
typedef typename TriangulatedSurfaceMesh::Traits::FT
```

```
FT;
```

```
typedef typename TriangulatedSurfaceMesh::Halfedge_handle
```

```
Halfedge_handle;
```

```
typedef std::pair< Halfedge_handle, FT>
```

```
Ridge_halfedge;
```

A halfedge crossed by a ridge is paired with the barycentric coordinate of the crossing point.

Creation

```
Ridge_line<TriangulatedSurfaceMesh> ridge_line;
```

default constructor.

Access Functions

```
const Ridge_type    ridge_line.line_type()
```

```
const FT            ridge_line.strength()
```

```
const FT            ridge_line.sharpness()
```

```
const std::list<Ridge_halfedge>*
```

```
ridge_line.line()
```

The opertor << is overloaded for this class and returns the line type, strength, sharpness and coordinates of the points of the polyline.

TriangulatedSurfaceMesh

Definition

The concept `TriangulatedSurfaceMesh` describes an oriented surface (possibly with boundary) embedded in the 3 space. It is combinatorially based on a halfedge data structure with triangular faces, geometrically 3d points associated to the vertices define the embedding.

Types

<i>TriangulatedSurfaceMesh:: Traits</i>	geometric Traits, this is a <code>CGAL::Kernel</code> concept.
<i>TriangulatedSurfaceMesh:: Facet</i>	Opaque type representing a facet of the <code>TriangulatedSurfaceMesh</code> .
<i>TriangulatedSurfaceMesh:: Facet_handle</i>	Handle to a facet. Model of the Handle concept.
<i>TriangulatedSurfaceMesh:: Facet_const_handle</i>	
<i>TriangulatedSurfaceMesh:: Facet_iterator</i>	Iterator over all mesh facets. Model of the <code>ForwardIterator</code> concept.
<i>TriangulatedSurfaceMesh:: Facet_const_iterator</i>	
<i>TriangulatedSurfaceMesh:: Vertex</i>	Opaque type representing a vertex of the <code>TriangulatedSurfaceMesh</code> .
<i>TriangulatedSurfaceMesh:: Vertex_handle</i>	Handle to a vertex. Model of the Handle concept.
<i>TriangulatedSurfaceMesh:: Vertex_const_handle</i>	
<i>TriangulatedSurfaceMesh:: Vertex_iterator</i>	Iterator over all vertices of a mesh. Model of the <code>ForwardIterator</code> concept.
<i>TriangulatedSurfaceMesh:: Vertex_const_iterator</i>	
<i>TriangulatedSurfaceMesh:: Halfedge</i>	Opaque type representing a halfedge of the <code>TriangulatedSurfaceMesh</code> .
<i>TriangulatedSurfaceMesh:: Halfedge_handle</i>	Handle to a halfedge. Model of the Handle concept.
<i>TriangulatedSurfaceMesh:: Halfedge_const_handle</i>	
<i>TriangulatedSurfaceMesh:: Halfedge_iterator</i>	Iterator over all halfedges of a <code>TriangulatedSurfaceMesh</code> . Model of the <code>ForwardIterator</code> concept.
<i>TriangulatedSurfaceMesh:: Halfedge_const_iterator</i>	
<i>TriangulatedSurfaceMesh:: Point_iterator</i>	Iterator over all points of a <code>TriangulatedSurfaceMesh</code> , its value type is <code>Traits::Point_3</code> . Model of the <code>ForwardIterator</code> concept.
<i>TriangulatedSurfaceMesh:: Point_const_iterator</i>	

Creation

Construction and destruction are undefined.

Operations

<i>Facet_const_iterator</i>	<i>mesh.facets_begin()</i>	iterator over all facets (excluding holes).
<i>Facet_const_iterator</i>	<i>mesh.facets_end()</i>	past-the-end iterator.
<i>Point_iterator</i>	<i>mesh.points_begin()</i>	iterator over all points.

Point_iterator *mesh.points_end()* past-the-end iterator.

Methods for the Vertex :

Traits::Point_3 & *vertex.point()* The point associated to the vertex

Methods for the Halfedge :

Halfedge_const_handle

halfedge.opposite() the opposite halfedge.

Halfedge_const_handle

halfedge.next() the next halfedge around the facet.

Halfedge_const_handle

bool *halfedge.prev()* the previous halfedge around the facet.
 halfedge.is_border_edge()

is true if *halfedge* or *halfedge.opposite()* is a border halfedge.

Vertex_const_handle *halfedge.vertex()* the incident vertex of *halfedge*.

Facet_const_handle *halfedge.facet()* the incident facet of *halfedge*. If *halfedge* is a border halfedge the result is default construction of the handle.

Methods for the Facet :

Halfedge_const_handle

facet.halfedge() an incident halfedge that points to *facet*.

Has Models

CGAL::Polyhedron_3 with the restriction that faces are triangular.

CGAL::Umbilic<TriangulatedSurfaceMesh>

Definition

The class *Umbilic<TriangulatedSurfaceMesh>* stores the description of an umbilic.

```
#include <CGAL/Umbilics.h>
```

Types

```
typedef typename TriangulatedSurfaceMesh::Vertex_handle
                                Vertex_handle;
typedef typename TriangulatedSurfaceMesh::Halfedge_handle
                                Halfedge_handle;
```

Creation

Access Functions

```
const Vertex_handle    umbilic.vertex()

const Umbilic_type     umbilic.umbilic_type()

std::list<Halfedge_handle>
                        umbilic.contour_list()
```

Operations

The usual insert operator (<<) is overloaded for *Umbilic*, it gives the location (3d coordinates of the vertex) and the type.

Umbilic_approximation

CGAL::Umbilic_approximation<TriangulatedSurfaceMesh,Vertex2FTPPropertyMap,Vertex2VectorPropertyMap>

Definition

The class *Umbilic_approximation*<*TriangulatedSurfaceMesh*,*Vertex2FTPPropertyMap*,*Vertex2VectorPropertyMap*> computes the approximation of umbilics on a triangular polyhedral surface.

```
#include <CGAL/Umbilics.h>
```

Parameters

The class *Umbilic_approximation*<*TriangulatedSurfaceMesh*,*Vertex2FTPPropertyMap*,*Vertex2VectorPropertyMap*> has three template parameters. *TriangulatedSurfaceMesh* provides the surface. Parameters *Vertex2FTPPropertyMap* and *Vertex2VectorPropertyMap* provide the differential properties of the surface associated to its vertices.

Requirements (checked at compile time) : the types *TriangulatedSurfaceMesh::Traits::FT* and *Vertex2FTPPropertyMap::value_type* must coincide; the types *TriangulatedSurfaceMesh::Traits::Vector_3* and *Vertex2VectorPropertyMap::value_type* must coincide; the types *TriangulatedSurfaceMesh::Vertex_handle*, *Vertex2FTPPropertyMap::key_type* and *Vertex2VectorPropertyMap::key_type* must coincide;

Types

```
typedef typename TriangulatedSurfaceMesh::Traits::FT
                    FT;
```

Creation

```
Umbilic_approximation<TriangulatedSurfaceMesh,Vertex2FTPPropertyMap,Vertex2VectorPropertyMap>
umbilic_approximation( TriangulatedSurfaceMesh P,
```

```
tex2FTPPropertyMap vertex2k1_pm,
```

```
tex2FTPPropertyMap vertex2k2_pm,
```

```
tex2VectorPropertyMap vertex2d1_pm,
```

```
tex2VectorPropertyMap vertex2d2_pm)
```

default constructor.

Operations

```
template <class OutputIterator>
```

OutputIterator *umbilic_approximation.compute(OutputIterator it, FT size)*

Performs the approximation, *size* determines the size of the patches around vertices, taken as *size* times the size of the 1-ring. Umbilics are output through the *OutputIterator* which is a concept of output iterator of the STL with value type *Umbilic**.

This package allows the estimation of local differential quantities of a surface from a point sample, given either as a mesh or as point cloud.

Note that this package needs the third party libraries Lapack (Page 5) and Blas (Page 5) to be installed to compile the example code.

Figure 42.1: Principal directions associated with k_{max} scaled by k_{min} .

42.1 Introduction

42.1.1 Overview

Consider a sampled smooth surface, and assume we are given a collection of points P about a given sample p . We aim at estimating the differential properties up to any fixed order of the surface at point p from the point set $P^+ = P \cup \{p\}$ — we denote $N = |P^+|$. More precisely, first order properties correspond to the normal or the tangent plane; second order properties provide the principal curvatures and directions, third order properties provide the directional derivatives of the principal curvatures along the curvature lines, etc. Most of the time, estimating first and second order differential quantities is sufficient. However, some applications involving shape analysis require estimating third and fourth order differential quantities. Many different estimators have been proposed in the vast literature of applied geometry [Pet01] (section 3, page 7), and all of them need to define a neighborhood around the point at which the estimation is computed. Our method relies on smooth differential geometry calculations, carried out on smooth objects *fitted* from the sample points. Datasets amenable to such a processing are naturally unstructured point clouds, as well as meshes —whose topological information may be discarded.

Estimating differential properties from discrete data always raises a philosophical issue. On one hand, estimating differential quantities subsumes a smooth surface does exist. In this spirit one wishes to recover its differential properties, so that any estimation method must come with an asymptotic convergence analysis of the results returned. For the method developed in this CGAL package, the interested will find such an analysis in [CP05a], (Theorem 3)— it should be stressed the error bounds proved therein are optimal.

On the other hand, any estimation method may be applied to arbitrarily data —surface unknown, surface piecewise smooth etc. In such a case, no analysis can be carried out, and it is up to the users to check the results match their needs.

Unlike most of the CGAL packages, this package uses approximation methods and is not intended to provide an exact canonical result in any sense. This is why internal computations are performed with a number type

possibly different from that of the input data, even if for convenience the results are returned with this original number type. A reasonable choice for this internal number type is for example the *double* type.

42.1.2 Smooth Surfaces, d -Jets and the Monge Form

To present the method, we shall need the following notions. Consider a smooth surface. About one of its points, consider a coordinate system whose z -axis does not belong to the tangent space. In such a frame, the surface can locally be written as the graph of a bivariate function. Letting *h.o.t.* stand for *higher order terms*, one has :

$$z(x,y) = J_{B,d}(x,y) + h.o.t. ; \quad J_{B,d}(x,y) = \sum_{k=0}^{k=d} \left(\sum_{i=0}^{i=k} \frac{B_{k-i,i} x^{k-i} y^i}{i!(k-i)!} \right). \quad (42.1)$$

The degree d polynomial $J_{B,d}$ is the Taylor expansion of the function z , and is called its d -jet. Notice that a d -jet contains $N_d = (d+1)(d+2)/2$ coefficients.

Recall that an umbilical point of a surface — or umbilic for short, is a point where both principal curvatures are identical. At any point of the surface which is not an umbilic, principal directions d_1, d_2 are well defined, and these (non oriented) directions together with the normal vector n define two direct orthonormal frames. If v_1 is a unit vector of direction d_1 , there exists a unique unit vector v_2 so that (v_1, v_2, n) is direct; and the other possible frame is $(-v_1, -v_2, n)$. Both these coordinate systems are known as the *Monge coordinate systems*. In both these systems, the surface is said to be given in the Monge form and its jet has the following canonical form :

$$z(x,y) = \frac{1}{2}(k_1 x^2 + k_2 y^2) + \frac{1}{6}(b_0 x^3 + 3b_1 x^2 y + 3b_2 x y^2 + b_3 y^3) \quad (42.2)$$

$$+ \frac{1}{24}(c_0 x^4 + 4c_1 x^3 y + 6c_2 x^2 y^2 + 4c_3 x y^3 + c_4 y^4) + h.o.t. \quad (42.3)$$

The coefficients k_1, k_2 are the principal curvatures, b_0, b_3 are the directional derivatives of k_1, k_2 along their respective curvature line, while b_1, b_2 are the directional derivatives of k_1, k_2 along the other curvature lines.

The Monge coordinate system can be computed from any d -jet ($d \geq 2$), and so are the Monge coefficients. These informations characterize the local geometry of the surface in a canonical way, and are the quantities returned by our algorithm.

42.1.3 Algorithm

Based on the above concepts, the algorithm consists of 4 steps.

1. We perform a Principal Component Analysis (PCA) on P^+ . This analysis outputs three orthonormal eigenvectors and the associated eigenvalues. The fitting basis consists of these three vectors so that the vector associated to the smallest eigenvalue is the last vector of the basis. (Indeed, if the surface is well sampled, one expects the PCA to provide one small and two large eigenvalues, the eigenvector associated to the small one approximating the normal vector.)
2. We perform a change of coordinates to move the samples into the coordinate system of the fitting basis and with origin the point p at which the estimation is sought. We then resort to polynomial fitting, so as to either interpolate or approximate the d -jet of the surface in this coordinate system. This bivariate polynomial approximation reduces to linear algebra operations.
3. From the fitted d -jet, we compute the Monge basis (d_1, d_2, n) .

4. Finally, we compute the Monge coefficients : k_i, b_i, c_i .

Further details can be found in section 42.4 and in [CP05a] (section 6).

42.1.4 Degenerate Cases

As usual, the fitting procedure may run into (almost) degenerate cases:

- Due to poor sampling, the PCA used to determine a rough normal vector may not be good. The nearer this direction to the tangent plane the worse the estimation.
- As observed in [CP05a] (section 3.1), the interpolating problem is not *poised* if the points project, into the fitting frame, onto an algebraic curve of degree d . More generally, the problem is ill poised if the condition number is too large.

In these cases, even if a result is provided, the estimation may not be relevant. To inform the user of these issues, we provide the PCA results and the condition number of the fitting. In any case, it is up to the user to judge if the result meets its need.

42.2 Software Design

42.2.1 Options and Interface Specifications

The fitting strategy performed by the class *Monge_via_jet_fitting* requires the following parameters:

- the degree d of the fitted polynomial ($d \geq 1$),
- the degree d' of the Monge coefficients sought, with $1 \leq d' \leq \min(d, 4)$,
- a range of N input points on the surface, with the precondition that $N \geq N_d = (d+1)(d+2)/2$. Note that if $N = N_d$, interpolation is performed; and if $N > N_d$, approximation is used.

42.2.2 Output

As explained in Section 42.1, the output consists of a coordinate system, the Monge basis, together with the Monge coefficients which are stored in the *Monge_form* class. In addition, more information on the computational issues are stored in the *Monge_via_jet_fitting* class.

The *Monge_form* class provides the following information.

- Origin. This is the point on the fitted polynomial surface where the differential quantities have been computed. In the approximation case, it differs from the input point p : it is the projection of p onto the fitted surface following the z -direction of the fitting basis.

- **Monge Basis.** The Monge basis (d_1, d_2, n) is orthonormal direct, and the maximal, minimal curvatures are defined wrt this basis. If the user has a predefined normal n_0 (e.g. the sample points come from an oriented mesh) then if $n_0 \cdot n > 0$ then max-min is correct; if not, i.e. $n_0 \cdot n < 0$, the user should switch to the orthonormal direct basis $(d'_1, d'_2, n') = (d_2, d_1, -n)$ with the maximal curvature $k'_1 = -k_2$ and the minimal curvature $k'_2 = -k_1$. If $n_0 \cdot n = 0$ or is small, the orientation of the surface is clearly ill-defined, and the user may proof-check the samples used to comply with its predefined normal.
- **Monge Coefficients.** The coefficient of the Monge form is $(k_1, k_2 (\leq k_1), b_0, b_1, b_2, b_3, c_0, c_1, c_2, c_3, c_4)$ for $d' = 4$.

In addition, the class *Monge_via_jet_fitting* stores

- the condition number of the fitting system,
- the coordinate system of the PCA (in which the fitting is performed).

42.2.3 Template Parameters

Template parameter **DataKernel**

This concept provides the types for the input sample points, together with $3d$ vectors and a number type. It is used as template for the classe *Monge_via_jet_fitting* \langle *DataKernel*, *LocalKernel* = *Cartesian* \langle *double* \rangle , *SvdTraits* = *lapack_svd* \rangle . Typically, one can use *CGAL::Cartesian* \langle *double* \rangle .

Template parameter **LocalKernel**

This is a parameter of the class *Monge_via_jet_fitting* \langle *DataKernel*, *LocalKernel* = *Cartesian* \langle *double* \rangle , *SvdTraits* = *lapack_svd* \rangle . This concept defines the vector and number types used for local computations and to store the PCA basis data.

Input points of type *DataKernel::Point_3* are converted to *LocalKernel::Point_3*. For output of the *Monge_form* class, these types are converted back to *DataKernel* ones. Typically, one can use *CGAL::Cartesian* \langle *double* \rangle which is the default.

Template parameter **SvdTraits**

This concept provides the number, vector and matrix types for algebra operations required by the fitting method in *Monge_via_jet_fitting* \langle *DataKernel*, *LocalKernel* = *Cartesian* \langle *double* \rangle , *SvdTraits* = *lapack_svd* \rangle . The main method is a linear solver using a singular value decomposition.

Compatibility requirements

To solve the fitting problem, the sample points are first converted from the *DataKernel* to the *LocalKernel* (this is done using the *CGAL::Cartesian_converter*). Then change of coordinate systems and linear algebra operations are performed with this kernel. This implies that the number types *LocalKernel::FT* and *SvdTraits::FT* must be identical. Second the Monge basis and coefficients, computed with the *LocalKernel*, are converted back to the *DataKernel* (this is done using the *CGAL::Cartesian_converter* and the *CGAL::NT_converter*).

42.3 Examples

42.3.1 Single Estimation about a Point of a Point Cloud

The first example illustrates the computation of the local differential quantities from a set of points given in a text file as input. The first point of the list is the one at which the computation is performed. The user has to specify a file for the input points and the degrees d and d' .

```
#include <CGAL/Cartesian.h>

#ifndef CGAL_USE_LAPACK
int main()
{
    std::cerr << "Skip since LAPACK is not installed" << std::endl;
    std::cerr << std::endl;
    return 0;
}
#else

#include <fstream>
#include <vector>

#include <CGAL/Monge_via_jet_fitting.h>
typedef double          DFT;
typedef CGAL::Cartesian<DFT>    Data_Kernel;
typedef Data_Kernel::Point_3    DPoint;
typedef CGAL::Monge_via_jet_fitting<Data_Kernel> My_Monge_via_jet_fitting;
typedef My_Monge_via_jet_fitting::Monge_form    My_Monge_form;

int main(int argc, char *argv[])
{
    //check command line
    if (argc<4)
    {
        std::cout << " Usage : " << argv[0]
                  << " <inputPoints.txt> <d_fitting> <d_monge>" << std::endl;
        return 0;
    }
    //open the input file
    std::ifstream inFile( argv[1]);
    if ( !inFile )
    {
        std::cerr << "cannot open file for input\n";
        exit(-1);
    }
    //italize the in_points container
    double x, y, z;
    std::vector<DPoint> in_points;
    while (inFile >> x) {
        inFile >> y >> z;
        DPoint p(x,y,z);
        in_points.push_back(p);
    }
}
```

```

inFile.close();
// fct parameters
size_t d_fitting = std::atoi(argv[2]);
size_t d_monge = std::atoi(argv[3]);

My_Monge_form monge_form;
My_Monge_via_jet_fitting monge_fit;
monge_form = monge_fit(in_points.begin(), in_points.end(), d_fitting, d_monge);

//OUTPUT on std::cout
CGAL::set_pretty_mode(std::cout);
std::cout << "vertex : " << in_points[0] << std::endl
    << "number of points used : " << in_points.size() << std::endl
    << monge_form;
std::cout << "condition_number : " << monge_fit.condition_number() << std::endl
    << "pca_eigen_vals and associated pca_eigen_vecs : " << std::endl;
for (int i=0; i<3; i++)
    std::cout << monge_fit.pca_basis(i).first << std::endl
        << monge_fit.pca_basis(i).second << std::endl;
return 0;
}
#endif //CGAL_USE_LAPACK

```

File: examples/Jet_fitting_3/Single_estimation.cpp

42.3.2 On a Mesh

The second example (cf `Mesh_estimation.cpp` in the example directory) illustrates the computation of local differential quantities for all vertices of a given mesh. The neighborhood of a given vertex is computed using rings on the triangulation. Results are twofold:

- a human readable text file featuring the *Monge_form* and numerical informations on the computation : condition number and the PCA basis;
- another text file which may be visualised with the demo program `introspect-qt` (experimental CGAL package) displaying the Monge basis at each vertex of the mesh.

Figs. 42.1 and 42.2 provide illustrations of principal directions of curvature.

—advanced—

42.4 Mathematical and Algorithmic Details

In this Section, we detail the mathematics involved, in order to justify the design choices made. To begin with, observe the fitting problem involves three relevant direct orthonormal basis: the world-basis (w_x, w_y, w_z) , the fitting-basis (f_x, f_y, f_z) , the Monge basis (d_1, d_2, n) .

Figure 42.2: Principal directions of curvature and normals at vertices of a mesh of the graph of the function $f(x,y) = 2x^2 + y^2$.

Figure 42.3: The three bases involved in the estimation.

42.4.1 Computing a Basis for the Fitting

Input : samples

Output : fitting-basis

Performing a PCA requires diagonalizing a symmetric matrix. This analysis gives an orthonormal basis whose z -axis is provided by the eigenvector associated to the smallest eigenvalue.¹ Note one may have to swap the orientation of a vector to get a direct basis.

Let us denote $P_{W \rightarrow F}$ the matrix that changes coordinates from the world-basis (w_x, w_y, w_z) to the fitting-basis (f_x, f_y, f_z) . The rows of $P_{W \rightarrow F}$ are the coordinates of the vectors (f_x, f_y, f_z) in the world-basis. This matrix represents a orthogonal transformation hence its inverse is its transpose. To obtain the coordinates of a point in the fitting-basis from the coordinates in the world-basis, one has to multiply by $P_{W \rightarrow F}$.

As mentioned above, the eigenvalues are returned, from which the sampling quality can be assessed. For a good sampling, the eigenvector associated to the smallest eigenvalue should roughly give the normal direction.

¹Another possibility is to choose as z -axis the axis of the world-basis with the least angle with the axis determined with the PCA. Then the change of basis reduces to a permutation of axis.

42.4.2 Solving the Interpolation / Approximation Problem

Input : samples, fitting-basis

Output : coefficients $A_{i,j}$ of the bivariate fitted polynomial in the fitting-basis

Computations are done in the fitting-basis and the origin is the point p . First, one has to transform coordinates of sample points with a translation $(-p)$ and multiplication by $P_{W \rightarrow F}$.

The fitting process consists of finding the coefficients $A_{i,j}$ of the degree d polynomial

$$J_{A,d} = \sum_{k=0}^d \left(\sum_{i=0}^k \frac{A_{k-i,i} x^{k-i} y^i}{i!(k-i)!} \right). \quad (42.4)$$

Denote $p_i = (x_i, y_i, z_i)$, $i = 1, \dots, N$ the coordinates of the sample points of P^+ . For interpolation the linear equations to solve are $A(x_i, y_i) = z_i$, $i = 1, \dots, N$, and for approximation one has to minimize $\sum_{i=1}^N (A(x_i, y_i) - z_i)^2$. The linear algebra formulation of the problem is given by

$$A = (A_{0,0}, A_{1,0}, A_{0,1}, \dots, A_{0,d})^T \quad (42.5)$$

$$Z = (z_1, z_2, \dots, z_N)^T \quad (42.6)$$

$$M = (1, x_i, y_i, \frac{x_i^2}{2}, \dots, \frac{x_i y_i^{d-1}}{(d-1)!}, \frac{y_i^d}{d!})_{i=1, \dots, N} \quad (42.7)$$

$$(42.8)$$

The equations for interpolation become $MA = Z$. For approximation, the system $MA = Z$ is solved in the least square sense, i.e. one seeks the vector A such that $A = \arg \min_A \|MA - Z\|_2$.

In any case, there is a preconditioning of the matrix M so as to improve the condition number. Assuming the $\{x_i\}$, $\{y_i\}$ are of order h , the pre-conditioning consists of performing a column scaling by dividing each monomial $x_i^k y_i^l$ by h^{k+l} — refer to Eq. (42.5). Practically, the parameter h is chosen as the mean value of the $\{x_i\}$ and $\{y_i\}$. In other words, the new system is $M'Y = (MD^{-1})(DA) = Z$ with D the diagonal matrix $D = (1, h, h, h^2, \dots, h^d, h^d)$, so that the solution A of the original system is $A = D^{-1}Y$.

There is always a single solution since for under constrained systems we also minimize $\|A\|_2$. The method uses a singular value decomposition of the $N \times N_d$ matrix $M = USV^T$, where U is a $N \times N$ orthogonal matrix, V is a $N_d \times N_d$ orthogonal matrix and S is a $N \times N_d$ matrix with the singular values on its diagonal. Denote r the rank of M , we can decompose $S = \begin{pmatrix} D_r & 0_{r, N_d-r} \\ 0_{N-r, r} & 0_{N-r, N_d-r} \end{pmatrix}$. The number r , which is the number of non zero singular values, is strictly lower than N_d if the system is under constrained. In any case, the unique solution which minimize $\|A\|_2$ is given by :

$$A = V \begin{pmatrix} D_r^{-1} & 0_{N_d-r, r} \\ 0_{r, N-r} & 0_{N_d-r, N-r} \end{pmatrix} U^T Z. \quad (42.9)$$

One can provide the condition number of the matrix M (after preconditioning) which is the ratio of the maximal and the minimal singular values. It is infinite if the system is under constrained, that is the smallest singular value is zero.

Implementation details. We assume a *solve* function is provided by the traits *SvdTraits*. This function solves the system $MX=B$ (in the least square sense if M is not square) using a Singular Value Decomposition and gives the condition number of M .

Remark: as an alternative, other methods may be used to solve the system. A *QR* decomposition can be substituted to the *SVD*. One can also use the normal equation $M^T M X = M^T B$ and apply methods for square

systems such as LU , QR or Cholesky since $M^T M$ is symmetric definite positive when M has full rank. The advantages of the SVD is that it works directly on the rectangular system and gives the condition number of the system. For more on these alternatives, see [GvL83] (Chap. 5).

42.4.3 Principal Curvature / Directions

Input : coefficients of the fit $A_{i,j}$, fitting-basis

Output : Monge basis wrt fitting-basis and world-basis

In the fitting basis, we have determined a height function expressed by Eq. (42.4). Computations are done in the fitting-basis. The partial derivatives, evaluated at $(x,y) = (0,0)$, of the fitted polynomial $J_{A,d}(x,y)$ are

$A_{i,j} = \frac{\partial^{i+j} J_{A,d}}{\partial^i x \partial^j y}$ Expanding Eq. (42.4) yields:

$$J_{A,d}(x,y) = A_{0,0} + A_{1,0}x + A_{0,1}y + \frac{1}{2}(A_{2,0}x^2 + 2A_{1,1}xy + A_{0,2}y^2) + \frac{1}{6}(A_{3,0}x^3 + 3A_{2,1}x^2y + \dots) + \dots (42.10)$$

- The origin, that is the point of the fitted surface where the estimation is performed, is $(0,0,A_{0,0})$.
- The normal is $n = (-A_{1,0}, -A_{0,1}, 1) / \sqrt{A_{1,0}^2 + A_{0,1}^2 + 1}$.
- Curvature related properties are retrieved resorting to standard differential calculus [dC76] (Chap. 3). More precisely, the Weingarten operator $W = -I^{-1}II$ is first computed in the basis of the tangent plane $\{(1,0,A_{1,0}), (0,1,A_{0,1})\}$. We compute an orthonormal basis of the tangent plane using the Gram-Schmidt algorithm, and then we compute Weingarten in this basis (applying a change of basis with the matrix $W' = P^{-1}WP$). In this orthonormal basis, the matrix of the Weingarten map is symmetric and we diagonalize it. One finally gets the principal curvatures which are the eigenvalues of W , and the associated principal directions. This gives an orthonormal direct basis (d_1, d_2, n) . Let us denote $P_{F \rightarrow M}$ the matrix to change coordinates from the fitting-basis to the Monge basis. Its rows are the coordinates of the vectors (d_1, d_2, n) in the fitting-basis. It is an orthogonal matrix $P_{F \rightarrow M}^{-1} = P_{F \rightarrow M}^T$. The Monge basis expressed in the world-basis is obtained by multiplying the coordinates of (d_1, d_2, n) in the fitting-basis by $P_{W \rightarrow F}^{-1}$, (the same holds for the origin point which has in addition to be translated by p , i.e. the coordinates of the origin point are $P_{W \rightarrow F}^{-1}(0,0,A_{0,0}) + p$).

42.4.4 Computing Higher Order Monge Coefficients

Input : coefficients of the fit, Monge basis wrt fitting-basis ($P_{F \rightarrow M}$)

Output : third and fourth order coefficients of Monge

We use explicit formula. The implicit equation of the fitted polynomial surface in the fitting-basis with origin the point $(0,0,A_{0,0})$ is $Q = 0$ with

$$Q = -w - A_{0,0} + \sum_{i,j} \frac{A_{i,j} u^i v^j}{i!j!}. \quad (42.11)$$

The equation in the Monge basis is obtained by substituting (u,v,w) by $P_{F \rightarrow M}^T(x,y,z)$. Denote $f(x,y,z) = 0$ this implicit equation. By definition of the Monge basis, we have locally (at $(0,0,0)$)

$$f(x,y,z) = 0 \Leftrightarrow z = g(x,y) \quad (42.12)$$

and the Taylor expansion of g at $(0,0)$ are the Monge coefficients sought. Let us denote the partial derivatives evaluated at the origin of f and g by $f_{i,j,k} = \frac{\partial^{i+j+k} f}{\partial^i x \partial^j y \partial^k z}$ and $g_{i,j} = \frac{\partial^{i+j} g}{\partial^i x \partial^j y}$. One has $f_{1,0,0} = f_{0,1,0} = f_{1,1,0} = 0$, $g_{0,0} = g_{1,0} = g_{0,1} = g_{1,1} = 0$ and $g_{2,0} = k_1$, $g_{0,2} = k_2$. The partial derivative of order n of f depends on the

matrix $P_{F \rightarrow M}$ and the partial derivatives of order at most n of $J_{A,d}$. The third and fourth order coefficients of are computed with the implicit function theorem. For instance :

$$\begin{aligned} b_0 &= g_{3,0} = -\frac{f_{3,0,0}f_{0,0,1}-3f_{1,0,1}f_{2,0,0}}{f_{0,0,1}^2} \\ b_1 &= g_{2,1} = -\frac{-f_{0,1,1}f_{2,0,0}+f_{2,1,0}f_{0,0,1}}{f_{0,0,1}^2} \\ &\dots \end{aligned}$$

DataKernel

Definition

The concept `DataKernel` describes the set of requirements to be fulfilled by any class used to instantiate first template parameter of the class `Monge_via_jet_fitting<DataKernel,LocalKernel,SvdTraits>`.

Types

<code>DataKernel:: FT</code>	The scalar type.
<code>DataKernel:: Point_3</code>	The point type.
<code>DataKernel:: Vector_3</code>	The vector type.

Operations

Only constructors (from 3 scalars and copy constructors) and access methods to coordinates $x()$, $y()$, $z()$ are needed.

Has Models

`CGAL::Cartesian<FieldNumberType>`

See Also

The `LocalKernel` concept.

CGAL::Lapack_svd

Definition

The class *Lapack_svd* provides an algorithm to solve in the least square sense a linear system with a singular value decomposition. The field type is *double*.

```
#include <CGAL/Lapack/Linear_algebra_lapack.h>
```

Is Model for the Concepts

SvdTraits

LocalKernel

Definition

The concept `LocalKernel` describes the set of requirements to be fulfilled by any class used to instantiate the second template parameter of the class `Monge_via_jet_fitting<DataKernel,LocalKernel,SvdTraits>`.

This concept provides the geometric primitives used for the computations in the class `Monge_via_jet_fitting`.

Requirements

In the class `Monge_via_jet_fitting` the scalar type, `LocalKernel::FT`, must be the same as that of the `SvdTraits` concept : `SvdTraits::FT`.

The type `LocalKernel::FT` is a model of the `FieldWithSqrt` concept.

Types

<code>LocalKernel:: FT</code>	The scalar type.
<code>LocalKernel:: Point_3</code>	The point type.
<code>LocalKernel:: Vector_3</code>	The vector type.

Operations

The scalar type `LocalKernel::FT` must be a field type with a square root.

Only constructors (from 3 scalars and copy constructors) and access methods to coordinates $x()$, $y()$, $z()$ are needed for the point and vector types.

Has Models

`CGAL::Cartesian<FieldNumberType>`

See Also

The `DataKernel` and `SvdTraits` concepts.

CGAL::Monge_via_jet_fitting< DataKernel, LocalKernel, SvdTraits> ::Monge_form

Definition

The class *Monge_form* stores the Monge representation, i.e., the Monge coordinate system and the coefficients of the Monge form in this system.

```
#include <CGAL/Monge_via_jet_fitting.h>
```

Types

```
typedef typename DataKernel::FT
```

```
FT;
```

```
typedef typename DataKernel::Point_3
```

```
Point_3;
```

```
typedef typename DataKernel::Vector_3
```

```
Vector_3;
```

Creation

```
Monge_form monge_form;          default constructor.
```

Access Functions

```
Point_3          monge_form.origin()  Point on the fitted surface where differential quantities are
                                         computed.
```

The Monge basis is given by:

```
Vector_3          monge_form.maximal_principal_direction()
```

```
Vector_3          monge_form.minimal_principal_direction()
```

```
Vector_3          monge_form.normal_direction()
```

The Monge coefficients are given by:

```
FT          monge_form.principal_curvatures( size_t i)
```

$i = 0$ for the maximum and $i = 1$ for the minimum.

```
FT          monge_form.third_order_coefficients( size_t i)
```

$0 \leq i \leq 3$

```
FT          monge_form.fourth_order_coefficients( size_t i)
```

$0 \leq i \leq 4$

Operations

void *monge_form.comply_wrt_given_normal(const Vector_3 given_normal)*

change principal basis and Monge coefficients so that the *given_normal* and the Monge normal make an acute angle.
If *given_normal.monge_normal* < 0 then change the orientation: if $z = g(x,y)$ in the basis (d1,d2,n) then in the basis (d2,d1,-n) $z = h(x,y) = -g(y,x)$.

The usual insert operator (*operator<<*) is overloaded for *Monge_form*, it gives the Monge coordinate system (the origin and an orthonormal basis) and the coefficients of the Monge form in this system.

Monge_via_jet_fitting

CGAL::Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>

Definition

The class *Monge_via_jet_fitting*<*DataKernel*, *LocalKernel*, *SvdTraits*> is designed to perform the estimation of the local differential quantities at a given point. The point range is given by a pair of input iterators, and it is assumed that the point where the calculation is carried out is the point that the begin iterator refers to. The results are stored in an instance of the nested class *Monge_form*, the particular information returned depending on the degrees specified for the polynomial fitting and for the Monge form.

The default for the template *LocalKernel* is *Cartesian*<*double*> and the default for *SvdTraits* is *Lapack_svd*.

```
#include <CGAL/Monge_via_jet_fitting.h>
```

Parameters

The class *Monge_via_jet_fitting*<*DataKernel*, *LocalKernel*, *SvdTraits*> has three template parameters. Parameter *DataKernel* provides the geometric classes and tools corresponding to the input points, and also members of the *Monge_form* class. Parameter *LocalKernel* provides the geometric classes and tools required by local computations. Parameter *SvdTraits* features the linear algebra algorithm required by the fitting method.

Types

```
typedef DataKernel      Data_kernel;
typedef LocalKernel     Local_kernel;
typedef typename Local_kernel::FT
                        FT;
typedef typename Local_kernel::Vector_3
                        Vector_3;
```

```
Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits>:: Monge_form
```

see the section below.

Creation

```
Monge_via_jet_fitting<DataKernel, LocalKernel, SvdTraits> monge_fitting;
```

default constructor

Operations

```
template <class InputIterator>
```

Monge_form

monge_fitting(InputIterator begin, InputIterator end, size_t d, size_t d')

This operator performs all the computations. The N input points are given by the *InputIterator* parameters which value-type are *Data_kernel::Point_3*, d is the degree of the fitted polynomial, d' is the degree of the expected Monge coefficients.

Precondition: $N \geq N_d := (d + 1)(d + 2)/2$, $1 \leq d' \leq \min(d, 4)$.

FT

monge_fitting.condition_number()

condition number of the linear fitting system.

std::pair<FT, Vector_3>

monge_fitting.pca_basis(size_t i)

pca eigenvalues and eigenvectors, the *pca_basis* has always 3 such pairs. *Precondition* : i ranges from 0 to 2.

Lapack_svd, Monge_form

SvdTraits

Definition

The concept `SvdTraits` describes the set of requirements to be fulfilled by any class used to instantiate the third template parameter of the class `Monge_via_jet_fitting<DataKernel,LocalKernel,SvdTraits>`.

It describes the linear algebra types and algorithms needed by the class `Monge_via_jet_fitting`.

Requirements

The scalar type, `SvdTraits::FT`, must be the same as that of the `LocalKernel` concept : `LocalKernel::FT`.

Types

<code>SvdTraits:: FT</code>	The scalar type.
<code>SvdTraits:: Vector</code>	The vector type.
<code>SvdTraits:: Matrix</code>	The matrix type.

Operations

`SvdTraits vector(size_t n);` initialize all the elements of the vector to zero.

The type `Vector` has the access methods

<code>size_t</code>	<code>vector.size()</code>	
<code>FT</code>	<code>vector(size_t i)</code>	return the i^{th} entry, i from 0 to <code>size()</code> - 1.
<code>void</code>	<code>vector.set(size_t i, const FT value)</code>	set the i^{th} entry to <code>value</code> .

The type `Matrix` has the access methods

`SvdTraits matrix(size_t n1, size_t n2);` initialize all the entries of the matrix to zero.

<code>size_t</code>	<code>matrix.number_of_rows()</code>	
<code>size_t</code>	<code>matrix.number_of_columns()</code>	
<code>FT</code>	<code>matrix(size_t i, size_t j)</code>	return the entry at row i and column j , i from 0 to <code>number_of_rows</code> - 1, j from 0 to <code>number_of_columns</code> - 1.
<code>void</code>	<code>matrix.set(size_t i, size_t j, const FT value)</code>	set the entry at row i and column j to <code>value</code> .

The concept `SvdTraits` has a linear solver using a singular value decomposition algorithm.

FT

traits.solve(Matrix& M, Vector& B)

Solves the system $MX = B$ (in the least square sense if M is not square) using a singular value decomposition and returns the condition number of M . The solution is stored in B .

Has Models

Lapack_svd.

43.1 Introduction	2475
43.2 Example: Range Search	2476

43.1 Introduction

Geometric queries are fundamental to many applications in computational geometry. The task is to maintain a dynamic set of geometric objects in such a way that certain queries can be performed efficiently. Typical examples of queries are: find out whether a given object is contained in the set, find all objects of the set lying in a given area (e.g. rectangle), find the object closest to a given point or find the pair of objects in the set lying closest to each other. Furthermore, the set should be dynamic in the sense that deletions and insertions of objects can be performed efficiently.

In computational geometry literature one can find many different data structures for maintaining sets of geometric objects. Most of them are data structures that have been developed to support a single very special kind of query operation. Examples are Voronoi diagrams for answering nearest neighbor searches, range trees for orthogonal range queries, partition trees for more general range queries, hierarchical triangulations for point location and segment trees for intersection queries

In many applications, different types of queries have to be performed on the same set of objects. A naive approach to this problem would use a collection of the above mentioned data structures to represent the set of objects and delegate every query operation to the corresponding structure. However, this is completely impractical since it uses too much memory and requires the maintenance of all these data structures in the presence of update operations.

Data structures that are non-optimal in theory seem to perform quite well in practice for many of these queries. For example, the Delaunay diagram turns out to be a very powerful data structure for storing dynamic sets of points under range and nearest neighbor queries. A first implementation and computational study of using Delaunay diagrams for geometric queries is described by Mehlhorn and Näher in [\[MN00\]](#).

In this section we present a generic variant of a two dimensional point set data type supporting various geometric queries.

The `CGAL::Point_set_2` class in this section is inherited from the two-dimensional *CGAL Delaunay Triangulation* data type.

The `CGAL::Point_set_2` class depends on two template parameters *T1* and *T2*. They are used as template parameters for the `CGAL::Delaunay_triangulation_2` class `CGAL::Point_set_2` is inherited from. *T1* is a model for the geometric traits and *T2* is a model for the triangulation data structure that the Delaunay triangulation expects.

The `CGAL::Point_set_2` class supports the following kinds of queries:

- circular range search
- triangular range search
- isorectangular range search
- (k) nearest neighbor(s)

For details about the running times see [\[MN00\]](#).

43.2 Example: Range Search

The following example program demonstrates the various range search operations of the two dimensional point set. First we construct a two dimensional point set *PSet* and initialize it with a few points. Then we perform circular, triangular and isorectangular range search operations on the point set.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Point_set_2.h>
#include <list>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;

typedef CGAL::Point_set_2<K>::Vertex_handle Vertex_handle;
typedef K::Point_2 Point_2;

int main()
{
    CGAL::Point_set_2<K> PSet;
    std::list<Point_2> Lr;

    Point_2 p1(12,14);
    Point_2 p2(-12,14);
    Point_2 p3(2,11);
    Point_2 p4(5,6);
    Point_2 p5(6.7,3.8);
    Point_2 p6(11,20);
    Point_2 p7(-5,6);
    Point_2 p8(12,0);
    Point_2 p9(4,31);
    Point_2 p10(-10,-10);
```

```

Lr.push_back(p1); Lr.push_back(p2); Lr.push_back(p3);
Lr.push_back(p4); Lr.push_back(p5); Lr.push_back(p6);
Lr.push_back(p7); Lr.push_back(p8); Lr.push_back(p9);
Lr.push_back(p10);

PSet.insert(Lr.begin(),Lr.end());

std::cout << "circular range search !\n";
CGAL::Circle_2<K> rc(p5,p6);

std::list<Vertex_handle> LV;
PSet.range_search(rc, std::back_inserter(LV));

std::list<Vertex_handle>::const_iterator it;
for (it=LV.begin();it != LV.end(); it++)
    std::cout << (*it)->point() << "\n";

std::cout << "triangular range search !\n";

LV.clear();
PSet.range_search(p1,p2,p3, std::back_inserter(LV));
for (it=LV.begin();it != LV.end(); it++)
    std::cout << (*it)->point() << "\n";
LV.clear();

std::cout << "isorectangular range search !\n";
Point_2 pt1=p10;
Point_2 pt3=p3;
Point_2 pt2 = Point_2(pt3.x(),pt1.y());
Point_2 pt4 = Point_2(pt1.x(),pt3.y());

PSet.range_search(pt1,pt2,pt3,pt4, std::back_inserter(LV));
for (it=LV.begin();it != LV.end(); it++)
    std::cout << (*it)->point() << "\n";
return 0;
}

```

2D Range and Neighbor Search

Reference Manual

Matthias Bäcken

The two dimensional point set is a class for geometric queries. It supports circular, triangular and iso rectangular range searches and nearest neighbor searches. The point set is inherited from the CGAL Delaunay triangulation data type. That means that it is a dynamic data structure supporting the insertion and deletion of points.

This package also provides function template versions of the range search and nearest neighbor query operations. They all have to be templated by the type of a CGAL Delaunay triangulation and provide functionality similar to the corresponding member functions of the point set class.

CGAL::Point_set_2<Gt,Tds>

Definition

```
#include <CGAL/Point_set_2.h>
```

An instance *PS* of the data type *Point_set_2<Gt,Tds>* is a *Delaunay Triangulation* of its vertex set. The class *Point_set_2<Gt,Tds>* is inherited from the CGAL Delaunay triangulation, and provides additional nearest neighbor query operations and range searching operations.

The *Point_set_2<Gt,Tds>* class of CGAL depends on template parameters standing for the geometric traits classes used by the point set and by the Delaunay triangulation (*Gt*) and for the triangulation data structure (*Tds*).

Types

<code>typedef Gt::Point_2</code>	<code>Point;</code>	the point type
<code>typedef Gt::Segment_2</code>	<code>Segment;</code>	the segment type
<code>typedef Gt::Circle_2</code>	<code>Circle;</code>	the circle type
<code>typedef Gt::FT</code>	<code>Numb_type;</code>	the representation field number type.
 <i>Point_set_2<Gt,Tds>::Triangulation::Vertex</i>		
		the vertex type of the underlying triangulation.
 <i>Point_set_2<Gt,Tds>::Triangulation::Edge</i>		
		the edge type of the underlying triangulation.
 <i>Point_set_2<Gt,Tds>::Triangulation::Vertex_handle</i>		
		handles to vertices.

Creation

<code>Point_set_2<Gt,Tds> PS;</code>	creates an empty <i>Point_set_2<Gt,Tds></i> .
 <code>template<class InputIterator></code>	
<code>Point_set_2<Gt,Tds> PS(InputIterator first, InputIterator last);</code>	creates a <i>Point_set_2<Gt,Tds></i> <i>PS</i> of the points in the range <i>[first,last)</i> .

Operations

Vertex_handle

PS.lookup(Point p)

if *PS* contains a Vertex v with $|pos(v)| = p$ the result is a handle to v otherwise the result is *NULL*.

Vertex_handle

PS.nearest_neighbor(Point p)

computes a handle to a vertex v of *PS* that is closest to p . If *PS* is empty, *NULL* is returned.

Vertex_handle

PS.nearest_neighbor(Vertex_handle v)

computes a handle to a vertex w of *PS* that is closest to v . If v is the only vertex in *PS*, *NULL* is returned.

template<class OutputIterator>

OutputIterator

PS.nearest_neighbors(Point p, int k, OutputIterator res)

computes the k nearest neighbors of p in *PS*, and places the handles to the corresponding vertices as a sequence of objects of type *Vertex_handle* in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>

OutputIterator

PS.nearest_neighbors(Vertex_handle v, int k, OutputIterator res)

computes the k nearest neighbors of v , and places them as a sequence of objects of type *Vertex_handle* in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>

OutputIterator

PS.range_search(Circle C, OutputIterator res)

computes handles to all vertices contained in the closure of disk C . The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>

OutputIterator

PS.range_search(Point a, Point b, Point c, OutputIterator res)

computes handles to all vertices contained in the closure of the triangle (a,b,c) .

Precondition: a , b , and c must not be collinear. The computed vertex handles will be placed as a sequence of objects in a container of value type of res which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

template<class OutputIterator>

OutputIterator

PS.range_search(Point a1, Point b1, Point c1, Point d1, OutputIterator res)

computes handles to all vertices contained in the closure of the iso-rectangle $(a1,b1,c1,d1)$.

Precondition: $a1$ is the upper left point, $b1$ the lower left, $c1$ the lower right and $d1$ the upper right point of the iso rectangle. The computed vertex handles will be placed as a sequence of objects in a container of value type of res which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

PointSetTraits

A point set traits class has to provide some primitives that are used by the point set class. The following catalog lists the involved primitives. For details about these types see the Kernel traits documentation.

Types

PointSetTraits:: Point_2

PointSetTraits:: Circle_2

PointSetTraits:: Segment_2

PointSetTraits:: FT

PointSetTraits:: Orientation_2

PointSetTraits:: Side_of_oriented_circle_2

PointSetTraits:: Construct_circle_2

PointSetTraits:: Compute_squared_distance_2

PointSetTraits:: Bounded_side_2

PointSetTraits:: Compare_distance_2

PointSetTraits:: Construct_center_2

CGAL::nearest_neighbor

Definition

The function *nearest_neighbor* is the function template version of the nearest neighbor search on Delaunay triangulations.

```
#include <CGAL/nearest_neighbor_delaunay_2.h>
```

```
template<class Dt>
Dt::Vertex_handle nearest_neighbor( Dt delau, Dt::Vertex_handle v)
```

computes a handle to a vertex *w* of *delau* that is closest to *v*.
If *v* is the only vertex in *delau*, *NULL* is returned.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Point*
- *Dt::Vertex_circulator*
- *Dt::Vertex_handle*
- *Dt::Geom_traits::Compare_distance_2*

CGAL::nearest_neighbors

Definition

The function *nearest_neighbors* is the function template version of the *k* nearest neighbors search on Delaunay triangulations. There are two versions of this function, one taking a point of the Delaunay triangulation and the other taking a vertex handle.

```
#include <CGAL/nearest_neighbor_delaunay_2.h>
```

```
template<class Dt, class OutputIterator>
OutputIterator      nearest_neighbors( Dt& delau, Dt::Point p, int k, OutputIterator res)
```

computes the *k* nearest neighbors of *p* in *delau*, and places the handles to the corresponding vertices as a sequence of objects of type *Vertex_handle* in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Vertex_handle*
- *Dt::Vertex_iterator*
- *Dt::Vertex_circulator*
- *Dt::Vertex*
- *Dt::Face*
- *Dt::Face_handle*
- *Dt::Locate_type*
- *Dt::Point*
- *Dt::Geom_traits::FT*
- *Dt::Geom_traits::Compute_squared_distance_2*

```
template<class Dt, class OutputIterator>
```

OutputIterator *nearest_neighbors(Dt& delau, Dt::Vertex_handle v, int k, OutputIterator res)*

computes the k nearest neighbors of v (including v) in *delau*, and places them as a sequence of objects of type *Vertex_handle* in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Vertex_handle*
- *Dt::Vertex_iterator*
- *Dt::Vertex_circulator*
- *Dt::Vertex*
- *Dt::Point*
- *Dt::Geom_traits::FT*
- *Dt::Geom_traits::Compute_squared_distance_2*

CGAL::range_search

Definition

There are six versions of the function template *range_search* that perform range searches on Delaunay triangulations. The first performs circular range searches, the second triangular range searches and the third performs iso-rectangular range searches. The other three range search function templates perform enhanced variants of the three aforementioned operations.

They get a user-defined object that has to control the range search operation. This way one can for instance stop the search, when n points were found.

```
#include <CGAL/range_search_delaunay_2.h>
```

```
template<class Dt, class Circle, class OutputIterator>
OutputIterator      range_search( Dt& delau, Circle C, OutputIterator res)
```

computes handles to all vertices contained in the closure of disk C . The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. *delau* is the CGAL Delaunay triangulation on which we perform the range search operation.

Requirements

- *Dt* is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:
 - *Dt::Geom_traits*
 - *Dt::Vertex_handle*
 - *Dt::Vertex*
 - *Dt::Vertex_circulator*
 - *Dt::Vertex_iterator*
 - *Dt::Point*
 - *Dt::Geom_traits::Bounded_side_2*
 - *Dt::Geom_traits::Construct_center_2*
- the template parameter *Circle* corresponds to *Dt::Geom_traits::Circle_2*

```
template<class Dt, class OutputIterator>
```

OutputIterator *range_search(Dt& delau, Dt::Point a, Dt::Point b, Dt::Point c, OutputIterator res)*

computes handles to all vertices contained in the closure of the triangle (a, b, c) .

Precondition: a , b , and c must not be collinear. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. *delau* is the CGAL Delaunay triangulation on which we perform the range search operation.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- *Dt::Geom_traits*
- *Dt::Vertex_handle*
- *Dt::Vertex*
- *Dt::Vertex_circulator*
- *Dt::Vertex_iterator*
- *Dt::Point*
- *Dt::Geom_traits::Circle_2*
- *Dt::Geom_traits::Bounded_side_2*
- *Dt::Geom_traits::Construct_center_2*
- *Dt::Geom_traits::Orientation_2*
- *Dt::Geom_traits::Construct_circle_2*

```
template<class Dt, class OutputIterator>
OutputIterator      range_search( Dt& delau,
                                Dt::Point a,
                                Dt::Point b,
                                Dt::Point c,
                                Dt::Point d,
```

OutputIterator res)

computes handles to all vertices contained in the closure of the iso-rectangle (a,b,c,d) .

Precondition: a is the upper left point, b the lower left, c the lower right and d the upper right point of the iso rectangle. The computed vertex handles will be placed as a sequence of objects in a container of value type of res which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. $delau$ is the CGAL Delaunay triangulation on which we perform the range search operation.

Requirements

Dt is a CGAL Delaunay triangulation and contains the following subset of types from the concept *PointSetTraits* and from the Delaunay triangulation data type:

- $Dt::Geom_traits$
- $Dt::Vertex_handle$
- $Dt::Vertex$
- $Dt::Vertex_circulator$
- $Dt::Vertex_iterator$
- $Dt::Point$
- $Dt::Geom_traits::Circle_2$
- $Dt::Geom_traits::Bounded_side_2$
- $Dt::Geom_traits::Construct_center_2$
- $Dt::Geom_traits::Orientation_2$
- $Dt::Geom_traits::Construct_circle_2$

```
template<class Dt, class Circle, class OutputIterator, class Pred>
OutputIterator      range_search( Dt& delau,
                                Circle C,
                                OutputIterator res,
                                Pred& pred,
                                bool return_if_succeeded)
```

computes handles to all vertices contained in the closure of disk C . The computed vertex handles will be placed as a sequence of objects in a container of value type of res which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. $delau$ is the CGAL Delaunay triangulation on that we perform the range search operation. $pred$ controls the search operation. If $return_if_succeeded$ is *true*, we will end the search after the first success of the predicate, otherwise we will continue till the search is finished.

Requirements

For the requirements of *Dt* see the description for the non-predicate version.

Requirements of *Pred*:

- *void set_result(bool);*
- *bool operator()(const Point&);*

The *operator()* is used for testing the current point in the search operation. If this operator returns *true* and *return_if_succeeded* is *true*, the range search will stop. Otherwise the range search operation will continue. Member function *set_result* can be used to store the result of the range search in the function object. The result will be *true* if the last call to the *operator()* of the predicate returned *true*, *false* otherwise.

```
template<class Dt, class OutputIterator, class Pred>
OutputIterator      range_search( Dt& delau,
                                Dt::Point a,
                                Dt::Point b,
                                Dt::Point c,
                                OutputIterator res,
                                Pred& pred,
                                bool return_if_succeeded)
```

computes handles to all vertices contained in the closure of the triangle (a, b, c) .

Precondition: *a*, *b*, and *c* must not be collinear. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. *delau* is the CGAL Delaunay triangulation on which we perform the range search operation. *pred* controls the search operation. If *return_if_succeeded* is *true*, we will end the search after the first success of the predicate, otherwise we will continue till the search is finished.

Requirements

For the requirements of *Dt* see the description for the non-predicate version.

For the requirements of *Pred* see the description above.

```
template<class Dt, class OutputIterator, class Pred>
OutputIterator      range_search( Dt& delau,
                                Dt::Point a,
                                Dt::Point b,
                                Dt::Point c,
                                Dt::Point d,
                                OutputIterator res,
                                Pred& pred,
```

bool return_if_succeeded)

computes handles to all vertices contained in the closure of the iso-rectangle (a, b, c, d) .

Precondition: a is the upper left point, b the lower left, c the lower right and d the upper right point of the iso rectangle. The computed vertex handles will be placed as a sequence of objects in a container of value type of *res* which points to the first object in the sequence. The function returns an output iterator pointing to the position beyond the end of the sequence. *delau* is the CGAL Delaunay triangulation on which we perform the range search operation. *pred* controls the search operation. If *return_if_succeeded* is *true*, we will end the search after the first success of the predicate, otherwise we will continue till the search is finished.

Requirements

For the requirements of *Dt* see the description for the non-predicate version.

For the requirements of *Pred* see the description above.

Chapter 44

Interval Skip List

Andreas Fabri

Contents

44.1 Definition	2493
44.2 Example Programs	2493
44.2.1 First Example with Simple Interval	2493
44.2.2 Example with Faces of a Triangulated Terrain	2495

44.1 Definition

An interval skip list is a data structure for finding all intervals that contain a point, and for stabbing queries, that is for answering the question whether a given point is contained in an interval or not. The implementation we provide is dynamic, that is the user can freely mix calls to the methods *insert(..)*, *remove(..)*, *find_intervals(..)*, and *is_contained(..)*

The interval skip list class is parameterized with an interval class.

The data structure was introduced by Hanson [[Han91](#)], and it is called interval skip list, because it is an extension of the randomized list structure known as skip list [[Pug90](#)].

44.2 Example Programs

We give two examples. The first one uses a basic interval class. In the second example we create an interval skip list for the *z*-ranges of the faces of a terrain, allowing to answer level queries.

44.2.1 First Example with Simple Interval

The first example reads two numbers *n* and *d* from *std::cin*. It creates *n* intervals of length *d* with the left endpoint at *n*. It then reads out the intervals for the 1-dimensional points with coordinates $0 \dots n + d$.

The interval skip list class has as template argument an interval class. In this example we use the class *Interval_skip_list_interval*.

```

#include <CGAL/Interval_skip_list.h>
#include <CGAL/Interval_skip_list_interval.h>
#include <vector>
#include <list>
#include <iostream>

typedef CGAL::Interval_skip_list_interval<double> Interval;
typedef CGAL::Interval_skip_list<Interval> Interval_skip_list;

int main()
{
    Interval_skip_list isl;
    int i, n, d;

    n = 10;
    d = 3;
    //std::cin >> n >> d;
    std::vector<Interval> intervals(n);
    for(i = 0; i < n; i++) {
        intervals[i] = Interval(i, i+d);
    }
    std::random_shuffle(intervals.begin(), intervals.end());

    isl.insert(intervals.begin(), intervals.end());

    for(i = 0; i < n+d; i++) {
        std::list<Interval> L;
        isl.find_intervals(i, std::back_inserter(L));
        for(std::list<Interval>::iterator it = L.begin(); it != L.end(); it++){
            std::cout << *it;
        }
        std::cout << std::endl;
    }

    for(i = 0; i < n; i++) {
        isl.remove(intervals[i]);
    }
    return 0;
}

```

File: examples/Interval_skip_list/intervals.cpp

44.2.2 Example with Faces of a Triangulated Terrain

The second example creates an interval skip list that allows to find all the faces of a terrain intersected by an horizontal plane at a given height. The data points for the terrain are read from a file.

As model for the interval concept, we use a class that is a wrapper around a face handle of a triangulated terrain. Lower and upper bound of the interval are smallest and largest z -coordinate of the face.

```

#include <CGAL/Simple_cartesian.h>

```

```

#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_euclidean_traits_xy_3.h>
#include <CGAL/Interval_skip_list.h>

Interval Skip List Reference Manual

Andreas Fabri

This chapter presents the interval skip list introduced by Hanson [[Han91](#)], and derived from the skip list data structure [[Pug90](#)].

The data structure stores intervals and allows to perform stabbing queries, that is to test whether a point is covered by any of the intervals. It further allows to find all intervals that contain a point.

The interval skip list is, as far as its functionality is concerned, related to the *Segment_tree*. Both allow to do stabbing queries and both allow to find all intervals that contain a given point. The implementation of segment trees in CGAL works in higher dimensions, whereas the interval skip list is limited to the 1D case. However, this interval skip list implementation is fully dynamic, whereas the segment tree implementation in CGAL is static, that is all intervals must be known in advance.

This package has one concept, namely for the interval with which the interval skip list class is parameterized.

CGAL::Interval_skip_list<Interval>

Definition

The class *Interval_skip_list<Interval>* is a dynamic data structure that allows to find all members of a set of intervals that overlap a point.

```
#include <CGAL/Interval_skip_list.h>
```

Types

```
typedef Interval::Value    Value;    the type of inf and sup of the interval.
```

```
Interval_skip_list<Interval>:: const_iterator
```

An iterator over all intervals.

Creation

```
Interval_skip_list<Interval> isl;    Default constructor.
```

```
template < class InputIterator >
```

```
Interval_skip_list<Interval> isl( InputIterator first, InputIterator last);
```

Constructor that inserts the iterator range $[first, last)$ in the interval skip list.

Precondition: The *value_type* of *first* and *last* is *Interval*.

Operations

```
template < class InputIterator >
```

```
int isl.insert( InputIterator first, InputIterator last)
```

Inserts the iterator range $[first, last)$ in the interval skip list, and returns the number of inserted intervals.

Precondition: The *value_type* of *first* and *last* is *Interval*.

```
void isl.insert( Interval i)
```

inserts interval *i* in the interval skip list.

```
bool isl.remove( Interval i)
```

removes interval *i* from the interval skip list. Returns *true* iff removal was successful.

bool *isl.is_contained(Value v)*

Returns *true* iff there is an interval that contains *v*.

template < class OutputIterator >
OutputIterator *isl.find_intervals(Value v, OutputIterator out)*

Writes the intervals *i* with $i.inf() \leq v \leq i.sup$ to the output iterator *out*.
Precondition: The *value_type* of *out* is *Interval*.

void *isl.clear()*

Removes all intervals from the interval skip list.

const_iterator *isl.begin()*

Returns an iterator over all intervals.

const_iterator *isl.end()* Returns the past the end iterator.

I/O

ostream& *ostream& os << isl*

Inserts the interval skip list *isl* into the stream *os*.
Precondition: The output operator must be defined for *Interval*.

Implementation

The insertion and deletion of a segment in the interval skip list takes expected time $O(\log^2 n)$, if the segment endpoints are chosen from a continuous distribution. A stabbing query takes expected time $O(\log n)$, and finding all intervals that contain a point takes expected time $O(\log n + k)$, where *k* is the number of intervals.

The implementation is based on the code developed by Eric N. Hansen, which can be found at <http://www-pub.cise.ufl.edu/~hanson/IS-lists/>. Attention, this code has memory leaks.

CGAL::Interval_skip_list_interval<Value>

Definition

The class *Interval_skip_list_interval*<Value> represents intervals with lower and upper bound of type *Value*. These intervals can be opened or closed at each endpoint.

```
#include <CGAL/Interval_skip_list_interval.h>
```

Creation

```
Interval_skip_list_interval<Value> i;
```

Default constructor.

```
Interval_skip_list_interval<Value> i( Value i, Value s, bool ic = true, bool uc = true);
```

Constructs the interval with infimum *i* and supremum *s*. The arguments *ic* and *uc* have value *true*, iff the interval is closed at the lower and upper bound, respectively.

Operations

```
bool          i.inf_closed()    returns true, iff the interval is closed at the lower bound.
```

```
bool          i.sup_closed()    returns true, iff the interval is closed at the upper bound.
```

I/O

The output operator is defined for *std::ostream*.

```
ostream&      ostream& os << Interval_skip_list_interval<V> i
```

Inserts the interval *i* into the stream *os*.

Precondition: The output operator for *Value* is defined.

Interval

CGAL::Level_interval<FaceHandle>

Definition

The class *Level_interval*<*FaceHandle*> represents intervals for the minimum and maximum value of the *z*-coordinate of a face of a triangulation.

```
#include <CGAL/Level_interval.h>
```

Requirements

The *value_type* of *FaceHandle* must be *Face*, which must have a nested type *Vertex*, which must have a nested type *Point*, whose *Kernel_traits*<*Point*>*Kernel* must have a nested type *FT*. These requirements are fulfilled, if one uses a CGAL triangulation and a CGAL kernel.

Types

```
typedef FT      Value;           The type of the z-coordinate of points stored in vertices of faces.
```

Creation

```
Level_interval<FaceHandle> i;      Default constructor.
```

```
Level_interval<FaceHandle> i( FaceHandle fh);
```

Constructs the interval with smallest and largest *z* coordinate of the points stored in the vertices of the face *fh* points to.

Operations

```
FaceHandle      i.face_handle()    returns the face handle.
```

I/O

```
ostream&        ostream& os << i    Inserts the interval i into the stream os.  
Precondition: The output operator for *Face_handle is defined.
```

45.1 Introduction

The spatial searching package implements exact and approximate distance browsing by providing implementations of algorithms supporting

- both nearest and furthest neighbor searching
- both exact and approximate searching
- (approximate) range searching
- (approximate) k -nearest and k -furthest neighbor searching
- (approximate) incremental nearest and incremental furthest neighbor searching
- query items representing points and spatial objects.

In these searching problems a set P of data points in d -dimensional space is given. The points can be represented by Cartesian coordinates or homogeneous coordinates. These points are preprocessed into a tree data structure, so that given any query item q the points of P can be browsed efficiently. The approximate spatial searching package is designed for data sets that are small enough to store the search structure in main memory (in contrast to approaches from databases that assume that the data reside in secondary storage).

45.1.1 Neighbor Searching

Spatial searching supports browsing through a collection of d -dimensional spatial objects stored in a spatial data structure on the basis of their distances to a query object. The query object may be a point or an arbitrary spatial object, e.g., a d -dimensional sphere. The objects in the spatial data structure are d -dimensional points.

Often the number of the neighbors to be computed is not known beforehand, e.g., because the number may depend on some properties of the neighbors (for example when querying for the nearest city to Paris with population greater than a million) or the distance to the query point. The conventional approach is *k-nearest neighbor searching* that makes use of a k -nearest neighbor algorithm, where k is known prior to the invocation of the algorithm. Hence, the number of nearest neighbors has to be guessed. If the guess is too large redundant computations are performed. If the number is too small the computation has to be re-invoked for a larger number of neighbors, thereby performing redundant computations. Therefore, Hjalason and Samet [HS95] introduced *incremental nearest neighbor searching* in the sense that having obtained the k nearest neighbors, the $k + 1^{st}$ neighbor can be obtained without having to calculate the $k + 1$ nearest neighbor from scratch.

Spatial searching typically consists of a preprocessing phase and a searching phase. In the preprocessing phase one builds a search structure and in the searching phase one makes the queries. In the preprocessing phase the user builds a tree data structure storing the spatial data. In the searching phase the user invokes a searching method to browse the spatial data.

With relatively minor modifications, nearest neighbor searching algorithms can be used to find the furthest object from the query object. Therefore, *furthest neighbor searching* is also supported by the spatial searching package.

The execution time for exact neighbor searching can be reduced by relaxing the requirement that the neighbors should be computed exactly. If the distances of two objects to the query object are approximately the same, instead of computing the nearest/furthest neighbor exactly, one of these objects may be returned as the approximate nearest/furthest neighbor. I.e., given some non-negative constant ϵ the distance of an object returned as an approximate k -nearest neighbor must not be larger than $(1 + \epsilon)r$, where r denotes the distance to the real k^{th} nearest neighbor. Similar the distance of an approximate k -furthest neighbor must not be smaller than $r/(1 + \epsilon)$. Obviously, for $\epsilon = 0$ we get the exact result, and the larger ϵ is, the less exact the result.

Neighbor searching is implemented by the following four classes.

The class `CGAL::Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>` implements the standard search strategy for orthogonal distances like the weighted Minkowski distance. It requires the use of extended nodes in the spatial tree and supports only k neighbor searching for point queries.

The class `CGAL::K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>` implements the standard search strategy for general distances like the Manhattan distance for iso-rectangles. It does not require the use of extended nodes in the spatial tree and supports only k neighbor searching for queries defined by points or spatial objects.

The class `Orthogonal_incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>` implements the incremental search strategy for general distances like the weighted Minkowski distance. It requires the use of extended nodes in the spatial tree and supports incremental neighbor searching and distance browsing for point queries.

The class `CGAL::Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>` implements the incremental search strategy for general distances like the Manhattan distance for iso-rectangles. It does not require the use of extended nodes in the spatial tree and supports incremental neighbor searching and distance browsing for queries defined by points or spatial objects.

45.1.2 Range Searching

Exact range searching and *approximate range searching* is supported using exact or fuzzy d -dimensional objects enclosing a region. The fuzziness of the query object is specified by a parameter ϵ denoting a maximal allowed distance to the boundary of a query object. If the distance to the boundary is at least ϵ , points inside the object are always reported and points outside the object are never reported. Points within distance ϵ to the boundary may be or may be not reported. For exact range searching the fuzziness parameter ϵ is set to zero.

The class `Kd_tree` implements range searching in the method `search`, which is a template method with an output iterator and a model of the concept `FuzzyQueryItem` as `CGAL::Fuzzy_iso_box_d` or `CGAL::Fuzzy_sphere_d`. For range searching of large data sets the user may set the parameter `bucket_size` used in building the k - d tree to a large value (e.g. 100), because in general the query time will be less then using the default value.

45.2 Splitting Rules

Instead of using the default splitting rule *Sliding_midpoint* described below, a user may, depending upon the data, select one from the following splitting rules, which determine how a separating hyperplane is computed:

Midpoint_of_rectangle This splitting rule cuts a rectangle through its midpoint orthogonal to the longest side.

Midpoint_of_max_spread This splitting rule cuts a rectangle through $(Mind + Maxd)/2$ orthogonal to the dimension with the maximum point spread $[Mind, Maxd]$.

Sliding_midpoint This is a modification of the midpoint of rectangle splitting rule. It first attempts to perform a midpoint of rectangle split as described above. If data points lie on both sides of the separating plane the sliding midpoint rule computes the same separator as the midpoint of rectangle rule. If the data points lie only on one side it avoids this by sliding the separator, computed by the midpoint of rectangle rule, to the nearest data point.

Median_of_rectangle The splitting dimension is the dimension of the longest side of the rectangle. The splitting value is defined by the median of the coordinates of the data points along this dimension.

Median_of_max_spread The splitting dimension is the dimension of the longest side of the rectangle. The splitting value is defined by the median of the coordinates of the data points along this dimension.

Fair This splitting rule is a compromise between the median of rectangle splitting rule and the midpoint of rectangle splitting rule. This splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among the splits that satisfy this bound, it selects the one in which the points have the largest spread. It then splits the points in the most even manner possible, subject to maintaining the bound on the ratio of the resulting rectangles.

Sliding_fair This splitting rule is a compromise between the fair splitting rule and the sliding midpoint rule. Sliding fair-split is based on the theory that there are two types of splits that are good: balanced splits that produce fat rectangles, and unbalanced splits provided the rectangle with fewer points is fat.

Also, this splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among

the splits that satisfy this bound, it selects the one one in which the points have the largest spread. It then considers the most extreme cuts that would be allowed by the aspect ratio bound. This is done by dividing the longest side of the rectangle by the aspect ratio bound. If the median cut lies between these extreme cuts, then we use the median cut. If not, then consider the extreme cut that is closer to the median. If all the points lie to one side of this cut, then we slide the cut until it hits the first point. This may violate the aspect ratio bound, but will never generate empty cells.

45.3 Example Programs

We give six examples. The first example illustrates k nearest neighbor searching, and the second example incremental neighbor searching. The third is an example of approximate furthest neighbor searching using a d -dimensional iso-rectangle as an query object. Approximate range searching is illustrated by the fourth example. The fifth example illustrates k neighbor searching for a user defined point class. The last example shows how to choose another splitting rule in the k - d tree that is used as search tree.

45.3.1 Example for K Neighbor Searching

The first example illustrates k neighbor searching with an Euclidean distance and 2-dimensional points. The generated random data points are inserted in a search tree. We then initialize the k neighbor search object with the origin as query. Finally, we obtain the result of the computation in the form of an iterator range. The value of the iterator is a pair of a point and its square distance to the query point. We use square distances, or *transformed distances* for other distance classes, as they are computationally cheaper.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include <CGAL/Search_traits_2.h>
#include <list>
#include <cmath>

typedef CGAL::Simple_cartesian<double> K;
typedef K::Point_2 Point_d;
typedef CGAL::Search_traits_2<K> TreeTraits;
typedef CGAL::Orthogonal_k_neighbor_search<TreeTraits> Neighbor_search;
typedef Neighbor_search::Tree Tree;

int main() {
    const int N = 1;

    std::list<Point_d> points;
    points.push_back(Point_d(0,0));

    Tree tree(points.begin(), points.end());

    Point_d query(0,0);

    // Initialize the search structure, and search all N points

    Neighbor_search search(tree, query, N);

    // report the N nearest neighbors and their distance
    // This should sort all N points by increasing distance from origin
    for(Neighbor_search::iterator it = search.begin(); it != search.end(); ++it){
        std::cout << it->first << " " << std::sqrt(it->second) << std::endl;
    }

    return 0;
}
```

File: examples/Spatial_searching/nearest_neighbor_searching.cpp

45.3.2 Example for Incremental Searching

This example program illustrates incremental searching for the closest point with a positive first coordinate. We can use the orthogonal incremental neighbor search class, as the query is also a point and as the distance is the Euclidean distance.

As for the k neighbor search, we first initialize the search tree with the data. We then create the search object, and finally obtain the iterator with the *begin()* method. Note that the iterator is of the input iterator category, that is one can make only one pass over the data.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/Orthogonal_incremental_neighbor_search.h>
#include <CGAL/Search_traits_2.h>

typedef CGAL::Simple_cartesian<double> K;
typedef K::Point_2 Point_d;
typedef CGAL::Search_traits_2<K> TreeTraits;
typedef CGAL::Orthogonal_incremental_neighbor_search<TreeTraits> NN_incremental_search;
typedef NN_incremental_search::iterator NN_iterator;
typedef NN_incremental_search::Tree Tree;

// A functor that returns true, iff the x-coordinate of a dD point is not positive
struct X_not_positive {
    bool operator()(const NN_iterator& it) { return ((*it).first)[0]<0; }
};

// An iterator that only enumerates dD points with positive x-coordinate
typedef CGAL::Filter_iterator<NN_iterator, X_not_positive> NN_positive_x_iterator;

int main() {

    Tree tree;
    tree.insert(Point_d(0,0));
    tree.insert(Point_d(1,1));
    tree.insert(Point_d(0,1));
    tree.insert(Point_d(10,110));
    tree.insert(Point_d(45,0));
    tree.insert(Point_d(0,2340));
    tree.insert(Point_d(0,30));

    Point_d query(0,0);

    NN_incremental_search NN(tree, query);
    NN_positive_x_iterator it(NN.end(), X_not_positive(), NN.begin(), end(NN.end(), X_not_positive()));

    std::cout << "The first 5 nearest neighbours with positive x-coord are: " << std::endl;
    for (int j=0; (j < 5)&&(it!=end); ++j,++it)
        std::cout << (*it).first << " at squared distance = " << (*it).second << std::endl;

    return 0;
}
```

File: examples/Spatial_searching/distance_browsing.cpp

45.3.3 Example for General Neighbor Searching

This example program illustrates approximate nearest and furthest neighbor searching using 4-dimensional Cartesian coordinates. Five approximate nearest neighbors of the query rectangle $[0.1, 0.2]^4$ are computed. Because the query object is a rectangle we cannot use the Orthogonal neighbor search. As in the previous examples we first initialize a search tree, create the search object with the query, and obtain the result of the search as iterator range.

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/Manhattan_distance_iso_box_point.h>
#include <CGAL/K_neighbor_search.h>
#include <CGAL/Search_traits_2.h>

typedef CGAL::Cartesian_d<double> K;
typedef K::Point_d Point_d;
typedef CGAL::Random_points_in_square_2<Point_d> Random_points_iterator;
typedef K::Iso_box_d Iso_box_d;
typedef K TreeTraits;
typedef CGAL::Manhattan_distance_iso_box_point<TreeTraits> Distance;
typedef CGAL::K_neighbor_search<TreeTraits, Distance> Neighbor_search;
typedef Neighbor_search::Tree Tree;

int main() {
    const int N = 1000;
    const int K = 10;

    Tree tree;
    Random_points_iterator rpg;
    for(int i = 0; i < N; i++){
        tree.insert(*rpg++);
    }
    Point_d pp(0.1,0.1);
    Point_d qq(0.2,0.2);
    Iso_box_d query(pp,qq);

    Distance tr_dist;
    Neighbor_search N1(tree, query, K, 0.0, false); // eps=10.0, nearest=false

    std::cout << "For query rectangle = [0.1,0.2]^2 " << std::endl
        << "The " << K << " approximate furthest neighbors are: " << std::endl;
    for (Neighbor_search::iterator it = N1.begin(); it != N1.end(); it++) {
        std::cout << " Point " << it->first << " at distance = " << tr_dist.inverse_of_transformed_distance(it)
    }
    return 0;
}
```

File: examples/Spatial_searching/general_neighbor_searching.cpp

45.3.4 Example for a Range Query

This example program illustrates approximate range querying for 4-dimensional fuzzy iso-rectangles and spheres using homogeneous coordinates. The range queries are member functions of the k - d tree class.

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/point_generators_d.h>
#include <CGAL/Kd_tree.h>
#include <CGAL/Fuzzy_sphere.h>
#include <CGAL/Fuzzy_iso_box.h>
#include <CGAL/Search_traits_d.h>

typedef CGAL::Cartesian_d<double> K;
typedef K::Point_d Point_d;
typedef CGAL::Search_traits_d<K> Traits;
typedef CGAL::Random_points_in_iso_box_d<Point_d> Random_points_iterator;
typedef CGAL::Counting_iterator<Random_points_iterator> N_Random_points_iterator;
typedef CGAL::Kd_tree<Traits> Tree;
typedef CGAL::Fuzzy_sphere<Traits> Fuzzy_sphere;
typedef CGAL::Fuzzy_iso_box<Traits> Fuzzy_iso_box;

int main() {
    const int D = 4;
    const int N = 1000;
    // generator for random data points in the square ( (-1000,-1000), (1000,1000) )
    Random_points_iterator rpit(4, 1000.0);

    // Insert N points in the tree
    Tree tree(N_Random_points_iterator(rpit,0),
             N_Random_points_iterator(N));

    // define range query objects
    double pcoord[D] = { 300, 300, 300, 300 };
    double qcoord[D] = { 900.0, 900.0, 900.0, 900.0 };
    Point_d p(D, pcoord, pcoord+D);
    Point_d q(D, qcoord, qcoord+D);
    Fuzzy_sphere fs(p, 700.0, 100.0);
    Fuzzy_iso_box fib(p, q, 100.0);

    std::cout << "points approximately in fuzzy range query" << std::endl;
    std::cout << "with center (300.0, 300.0, 300.0, 300.0)" << std::endl;
    std::cout << "and fuzzy radius <200.0,400.0> are:" << std::endl;
    tree.search(std::ostream_iterator<Point_d>(std::cout, "\n"), fs);

    std::cout << "points approximately in fuzzy range query ";
    std::cout << "[<200,4000>,<800,1000>]]^4 are:" << std::endl;

    tree.search(std::ostream_iterator<Point_d>(std::cout, "\n"), fib);
    return 0;
}
```

File: examples/Spatial_searching/fuzzy_range_query.cpp

45.3.5 Example for User Defined Point and Distance Class

The neighbor searching works with all CGAL kernels, as well as with user defined points and distance classes. In this example we assume that the user provides the following 3-dimensional points class.

```
struct Point {
    double vec[3];

    Point() { vec[0]= vec[1] = vec[2] = 0; }
    Point (double x, double y, double z) { vec[0]=x; vec[1]=y; vec[2]=z; }

    double x() const { return vec[ 0 ]; }
    double y() const { return vec[ 1 ]; }
    double z() const { return vec[ 2 ]; }

    double& x() { return vec[ 0 ]; }
    double& y() { return vec[ 1 ]; }
    double& z() { return vec[ 2 ]; }

    bool operator==(const Point& p) const
    {
        return (x() == p.x()) && (y() == p.y()) && (z() == p.z()) ;
    }

    bool operator!=(const Point& p) const { return ! (*this == p); }
}; //end of class

namespace CGAL {

    template <>
    struct Kernel_traits<Point> {
        struct Kernel {
            typedef double FT;
            typedef double RT;
        };
    };

}

struct Construct_coord_iterator {
    const double* operator()(const Point& p) const
    { return static_cast<const double*>(p.vec); }

    const double* operator()(const Point& p, int) const
    { return static_cast<const double*>(p.vec+3); }
};
```

File: examples/Spatial_searching/Point.h

We have put the glue layer in this file as well, that is a class that allows to iterate over the Cartesian coordinates of the point, and a class to construct such an iterator for a point. We next need a distance class

```

struct Distance {
    typedef Point Query_item;

    double transformed_distance(const Point& p1, const Point& p2) const {
        double distx= p1.x()-p2.x();
        double disty= p1.y()-p2.y();
        double distz= p1.z()-p2.z();
        return distx*distx+disty*disty+distz*distz;
    }

45.3.6 Example for Selecting a Splitting Rule and Setting the Bucket Size

This example program illustrates selecting a splitting rule and setting the maximal allowed bucket size. The only differences with the first example are the declaration of the *Fair* splitting rule, needed to set the maximal allowed bucket size.

```
#include <CGAL/Simple_cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/Search_traits_2.h>
#include <CGAL/Orthogonal_k_neighbor_search.h>
#include <cmath>

typedef CGAL::Simple_cartesian<double> R;
typedef R::Point_2 Point_d;
typedef CGAL::Random_points_in_square_2<Point_d> Random_points_iterator;
typedef CGAL::Counting_iterator<Random_points_iterator> N_Random_points_iterator;
typedef CGAL::Search_traits_2<R> Traits;
typedef CGAL::Euclidean_distance<Traits> Distance;
typedef CGAL::Fair<Traits> Fair;
typedef CGAL::Orthogonal_k_neighbor_search<Traits,Distance,Fair> Neighbor_search;
typedef Neighbor_search::Tree Tree;

int main() {
    const int N = 1000;
    // generator for random data points in the square ( (-1,-1), (1,1) )
    Random_points_iterator rpit( 1.0);

    Fair fair(5); // bucket size=5
    // Insert number_of_data_points in the tree
    Tree tree(N_Random_points_iterator(rpit,0),
        N_Random_points_iterator(N),
        fair);

    Point_d query(0,0);

    // Initialize the search structure, and search all N points
    Neighbor_search search(tree, query, N);

    // report the N nearest neighbors and their distance
    // This should sort all N points by increasing distance from origin
    for(Neighbor_search::iterator it = search.begin(); it != search.end(); ++it){
        std::cout << it->first << " " << std::sqrt(it->second) << std::endl;
    }
    return 0;
}
```

45.4 Software Design

45.4.1 The k - d tree

Bentley [Ben75] introduced the k - d tree as a generalization of the binary search tree in higher dimensions. k - d trees hierarchically decompose space into a relatively small number of rectangles such that no rectangle contains too many input objects. For our purposes, a *rectangle* in real d dimensional space, \mathbb{R}^d , is the product of d closed intervals on the coordinate axes. k - d trees are obtained by partitioning point sets in \mathbb{R}^d using $(d-1)$ -dimensional hyperplanes. Each node in the tree is split into two children by one such separating hyperplane. Several splitting rules (see Section 45.2) can be used to compute a separating $(d-1)$ -dimensional hyperplane.

Each internal node of the k - d tree is associated with a rectangle and a hyperplane orthogonal to one of the coordinate axis, which splits the rectangle into two parts. Therefore, such a hyperplane, defined by a splitting dimension and a splitting value, is called a separator. These two parts are then associated with the two child nodes in the tree. The process of partitioning space continues until the number of data points in the rectangle falls below some given threshold. The rectangles associated with the leaf nodes are called *buckets*, and they define a subdivision of the space into rectangles. Data points are only stored in the leaf nodes of the tree, not in the internal nodes.

Friedmann, Bentley and Finkel [FBF77] described the standard search algorithm to find the k th nearest neighbor by searching a k - d tree recursively.

When encountering a node of the tree, the algorithm first visits the child that is closest to the query point. On return, if the rectangle containing the other child lies within $1/(1+\epsilon)$ times the distance to the k th nearest neighbors so far, then the other child is visited recursively. Priority search [AM93b] visits the nodes in increasing order of distance from the queue with help of a priority queue. The search stops when the distance of the query point to the nearest nodes exceeds the distance to the nearest point found with a factor $1/(1+\epsilon)$. Priority search supports next neighbor search, standard search does not.

In order to speed-up the internal distance computations in nearest neighbor searching in high dimensional space, the approximate searching package supports orthogonal distance computation. Orthogonal distance computation implements the efficient incremental distance computation technique introduced by Arya and Mount [AM93a]. This technique works only for neighbor queries with query items represented as points and with a quadratic form distance, defined by $d_A(x, y) = (x - y)A(x - y)^T$, where the matrix A is positive definite, i.e. $d_A(x, y) \geq 0$. An important class of quadratic form distances are weighted Minkowski distances. Given a parameter $p > 0$ and parameters $w_i \geq 0, 0 < i \leq d$, the weighted Minkowski distance is defined by $l_p(w)(r, q) = (\sum_{i=1}^d w_i(r_i - q_i)^p)^{1/p}$ for $0 < p < \infty$ and defined by $l_\infty(w)(r, q) = \max\{w_i|r_i - q_i| \mid 1 \leq i \leq d\}$. The Manhattan distance ($p = 1, w_i = 1$) and the Euclidean distance ($p = 2, w_i = 1$) are examples of a weighted Minkowski metric.

To speed up distance computations also transformed distances are used instead of the distance itself. For instance for the Euclidean distance, to avoid the expensive computation of square roots, squared distances are used instead of the Euclidean distance itself.

dD Spatial Searching Reference Manual

Hans Tangelder and Andreas Fabri

This package provides data structures and algorithms for exact and approximate distance browsing, supporting

- both nearest and furthest neighbor searching,
- both exact and approximate searching,
- (approximate) range searching,
- (approximate) k -nearest and k -furthest neighbor searching,
- (approximate) incremental nearest and incremental furthest neighbor searching,
- query items representing points and spatial objects.

The spatial searching package consists of the following concepts and classes that are described in the reference pages.

CGAL::Euclidean_distance<Traits>

Definition

The class *Euclidean_distance<Traits>* provides an implementation of the concept *OrthogonalDistance*, with the Euclidean distance (l_2 metric). To optimize distance computations squared distances are used.

```
#include <CGAL/Euclidean_distance.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Cartesian<double>>*.

Is Model for the Concepts

OrthogonalDistance

Types

<i>Traits::FT</i>	<i>FT</i> ;	Number type.
<i>Traits::Point_d</i>	<i>Point_d</i> ;	Point type.
<i>Point_d</i>	<i>Query_item</i> ;	Query item type.

Creation

Euclidean_distance<Traits> ed;

Default constructor.

Operations

FT *ed.transformed_distance(Query_item q, Point_d p)*

Returns the squared Euclidean distance between *q* and *p*.

FT *ed.min_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r)*

Returns the squared Euclidean distance between *q* and the point on the boundary of *r* closest to *q*.

FT *ed.max_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r;)*

Returns the squared Euclidean distance, where *d* denotes the distance between *q* and the point on the boundary of *r* farthest to *q*.

FT *ed.new_distance(FT dist, FT old_off, FT new_off, int cutting_dimension)*

Updates the squared *dist* incrementally and returns the updated squared distance.

FT *ed.transformed_distance(FT d)*

Returns d^2 .

FT *ed.inverse_of_transformed_distance(FT d)*

Returns $d^{1/2}$.

See Also

OrthogonalDistance

CGAL::Weighted_Minkowski_distance<Traits>.

CGAL::Euclidean_distance_sphere_point<Traits>

Definition

The class *Euclidean_distance_sphere_point*<Traits> provides an implementation of the *GeneralDistance* concept for the Euclidean distance (l_2 metric) between a d -dimensional sphere and a point, and the Euclidean distance between a d -dimensional sphere and a d -dimensional iso-rectangle defined as a k - d tree rectangle.

```
#include <CGAL/Euclidean_distance_sphere_point.h>
```

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d<double>*.

Is Model for the Concepts

GeneralDistance

Types

<i>Traits::FT</i>	<i>FT</i> ;	Number type.
<i>Traits::Point_d</i>	<i>Point_d</i> ;	Point type.
<i>Traits::Sphere_d</i>	<i>Sphere_d</i> ;	Query item type.

Creation

Euclidean_distance_sphere_point<Traits> *ed*; Default constructor.

Operations

NT *ed.transformed_distance(Query_item s, Point_d p)*
Returns the distance between s and p .

NT *ed.min_distance_to_rectangle(Query_item s, Kd_tree_rectangle<Traits> r)*
Returns the minimal distance between a point from the sphere s and a point from r .

NT *ed.max_distance_to_rectangle(Query_item s, Kd_tree_rectangle<Traits> r)*

Returns the maximal distance between the sphere s and a point from r furthest to s .

NT *ed.transformed_distance(NT d)*

Returns d^2 .

NT *ed.inverse_of_transformed_distance(NT d)*

Returns $d^{1/2}$.

GeneralDistance

FuzzyQueryItem

Definition

The concept FuzzyQueryItem describes the requirements for fuzzy d -dimensional spatial objects.

Has Models

CGAL::Fuzzy_sphere<Traits>,
CGAL::Fuzzy_iso_box<Traits>

Types

FuzzyQueryItem:: Point_d represents a d -dimensional point.

FuzzyQueryItem:: FT Number type.

Operations

bool *q.contains(Point_d p)*
 test whether q contains p .

bool *q.inner_range_intersects(Kd_tree_rectangle<Traits> rectangle)*
 test whether the inner approximation of the spatial object intersects a rectangle associated with a node of a tree.

bool *q.outer_range_contains(Kd_tree_rectangle<Traits> rectangle)*
 test whether the outer approximation of the spatial object encloses the rectangle associated with a node of a tree.

CGAL::Fuzzy_iso_box<Traits>

Definition

The class *Fuzzy_iso_box<Traits>* implements fuzzy d -dimensional iso boxes. A fuzzy iso box with fuzziness value ϵ has as outer approximation a box dilated, and as inner approximation a box eroded by a d -dim square with side length ϵ .

```
#include <CGAL/Fuzzy_iso_box.h>
```

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Simple_cartesian<double>>*.

Is Model for the Concepts

FuzzyQueryItem

Types

<i>Traits::Point_d</i>	<i>Point_d</i> ;	Point type.
<i>Traits::FT</i>	<i>FT</i> ;	Number type.

Creation

```
Fuzzy_iso_box<Traits> b( Point_d p, Point_d q, FT epsilon=FT(0));
```

Constructs a fuzzy iso box specified by the minimal iso box containing p and q and fuzziness value *epsilon*.

Precondition: p must be lexicographically smaller than q .

Operations

<i>bool</i>	<i>b.contains(Point_d p)</i>	test whether b contains p .
-------------	-------------------------------	---------------------------------

<i>bool</i>	<i>b.inner_range_intersects(Kd_tree_rectangle<FT> rectangle)</i>	test whether the inner box intersects the rectangle associated with a node of a tree.
-------------	---	---

bool

b.outer_range_contains(Kd_tree_rectangle<FT> rectangle)

test whether the outer box encloses the rectangle associated with a node of a tree.

See Also

FuzzyQueryItem

CGAL::Fuzzy_sphere<Traits>

Definition

The class *Fuzzy_sphere<Traits>* implements fuzzy d -dimensional spheres. A fuzzy sphere with radius r and fuzziness value ϵ has as outer approximation a sphere with radius $r + \epsilon$ and as inner approximation a sphere with radius $r - \epsilon$.

#include <CGAL/Fuzzy_sphere.h>

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d<double>*.

Is Model for the Concepts

FuzzyQueryItem

Types

<i>Traits::Point_d</i>	<i>Point_d</i> ;	Point type.
<i>Traits::FT</i>	<i>FT</i> ;	Number type.

Creation

Fuzzy_sphere<Traits> s(Point_d center, FT radius, FT epsilon=FT(0));

Constructs a fuzzy sphere centered at *center* with radius *radius* and fuzziness value *epsilon*.

Operations

bool s.contains(Point_d p) test whether *s* contains *p*.

bool s.inner_range_intersects(Kd_tree_rectangle<FT> rectangle)

test whether the inner sphere intersects the rectangle associated with a node of a tree.

bool s.outer_range_contains(Kd_tree_rectangle<FT> rectangle)

test whether the outer sphere encloses the rectangle associated with a node of a tree.

FuzzyQueryItem

GeneralDistance

Definition

Requirements of a distance class defining a distance between a query item denoting a spatial object and a point. To optimize distance computations transformed distances are used, e.g., for a Euclidean distance the transformed distance is the squared Euclidean distance.

Has Models

CGAL::Manhattan_distance_rectangle_point<Traits, IsoBox>
CGAL::Euclidean_distance_sphere_point<Traits, Sphere>.

Types

<i>GeneralDistance:: FT</i>	Number type.
<i>GeneralDistance:: Point_d</i>	Point type.
<i>GeneralDistance:: Query_item</i>	Query item type.

Operations

<i>FT</i>	<i>gd.transformed_distance(Query_item q, Point_d r)</i>	Returns the transformed distance between <i>q</i> and <i>r</i> .
<i>FT</i>	<i>gd.min_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r)</i>	Returns the transformed distance between <i>q</i> and the point on the boundary of <i>r</i> closest to <i>q</i> .
<i>FT</i>	<i>gd.max_distance_to_rectangle(Query_item q, Kd_tree_rectangle<FT> r)</i>	Returns the transformed distance between <i>q</i> and the point on the boundary of <i>r</i> furthest to <i>q</i> .
<i>FT</i>	<i>gd.transformed_distance(FT d)</i>	Returns the transformed distance.
<i>FT</i>	<i>gd.inverse_of_transformed_distance(FT d)</i>	Returns the inverse of the transformed distance.

CGAL::Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>

Definition

The class *Incremental_neighbor_search*<Traits, GeneralDistance, Splitter, SpatialTree> implements incremental nearest and furthest neighbor searching on a tree. The tree may have extended or unextended nodes.

```
#include <CGAL/Incremental_neighbor_search.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2*<*CGAL::Cartesian*<*double*>>.

Expects for the second template argument a model of the concept *GeneralDistance*. The default type is *CGAL::Euclidean_distance*<Traits>.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding_midpoint*<Traits>.

Expects for fourth template argument a model of the concept *SpatialTree*. The default type is *CGAL::Kd_tree*<Traits, Splitter, CGAL::Tag_false>. The template argument *CGAL::Tag_false* makes that the tree is built with unextended nodes.

Types

Traits::Point_d *Point_d*; Point type.

Traits::NT *NT*; Number type.

std::pair<*Point_d*, *NT*>

Point_with_transformed_distance;

Pair of point and transformed distance.

Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>:: *iterator*

Input iterator with value type *Point_with_transformed_distance* for enumerating approximate neighbors.

GeneralDistance::Query_item

Query_item; Query item type.

SpatialTree *Tree*; The tree type.

Creation

```
Incremental_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree> s(  
    Tree& tree,  
    QueryItem q,  
    NT eps=NT(0.0),  
    bool search_nearest=true,  
    GeneralDistance d=GeneralDistance())
```

Constructor for incremental neighbor searching of the query item q in the points stored $tree$ using a distance d and approximation factor eps .

Operations

<i>iterator</i>	<i>s.begin()</i>	Returns an iterator to the approximate nearest or furthest neighbor.
-----------------	------------------	--

<i>iterator</i>	<i>s.end()</i>	Past-the-end iterator.
-----------------	----------------	------------------------

_____ <i>advanced</i> _____		
<i>std::ostream&</i>	<i>s.statistics(std::ostream& s)</i>	Inserts statistics of the search process into the output stream s .

_____ <i>advanced</i> _____

See Also

CGAL::Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>.

CGAL::K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>

Definition

The class *K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>* implements approximate *k*-nearest and *k*-furthest neighbor searching using standard search on a tree using a general distance class. The tree may be built with extended or unextended nodes.

```
#include <CGAL/K_neighbor_search.h>
```

Parameters

Expects for the first template argument an implementation of the concept *SearchTraits*, for example *CGAL::Cartesian_d<double>*.

Expects for the second template argument a model of the concept *GeneralDistance*. The default type is *CGAL::Euclidean_distance<Traits>*.

Expects for fourth template argument an implementation of the concept *SpatialTree*. The default type is *CGAL::Kd_tree<Traits, Splitter, CGAL::Tag_false>*. The template argument *CGAL::Tag_false* makes that the tree is built with unextended nodes.

Types

Traits::Point_d *Point_d*; Point type.

Traits::FT *FT*; Number type.

std::pair<Point_d,FT>

Point_with_transformed_distance;

Pair of point and transformed distance.

K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>:: iterator

Bidirectional iterator with value type *Point_with_distance* for enumerating approximate neighbors.

GeneralDistance::Query_item

Query_item; Query item type.

SpatialTree *Tree*; The tree type.

Creation

```
K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree> s(  
    Tree& tree,  
    Query_item q,  
    int k=1,  
    FT eps=FT(0.0),  
    bool search_nearest=true,  
    GeneralDistance d=GeneralDistance())
```

Constructor for searching approximately k neighbors of the query item q in the points stored in $tree$ using distance class d and approximation factor eps .

Operations

<i>iterator</i>	<i>s.begin()</i>	Returns an iterator to the approximate neighbors.
-----------------	------------------	---

<i>iterator</i>	<i>s.end()</i>	Past-the-end iterator.
-----------------	----------------	------------------------

_____ *advanced* _____
|

<i>std::ostream</i> &	<i>s.statistics(std::ostream& s)</i>
-----------------------	--

Inserts statistics of the search process into the output stream s .

| _____ *advanced* _____

CGAL::Kd_tree<Traits, Splitter, UseExtendedNode>

Definition

The class *Kd_tree<Traits, Splitter, UseExtendedNode>* defines a *k-d* tree.

```
#include <CGAL/Kd_tree.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<CGAL::Cartesian<double>>*.

Excepts for the second template argument a model for the concept *Splitter*. It defaults to *Sliding_midpoint<Traits>*.

Expects for the third template argument *CGAL::Tag_true*, if the tree shall be built with extended nodes, and *CGAL::Tag_false* otherwise.

Types

<i>Traits::Point_d</i>	<i>Point_d</i> ;	Point class.
------------------------	------------------	--------------

<i>Traits::FT</i>	<i>FT</i> ;	Number type.
-------------------	-------------	--------------

Kd_tree<*Traits*, *Splitter*, *UseExtendedNode*>:: *Splitter*

Splitter type.

Kd_tree<Traits, Splitter, UseExtendedNode>::iterator

Bidirectional iterator with value type *Point_d* that allows to enumerate all points in the tree.

_____ *advanced* _____

Kd_tree<Traits, Splitter, UseExtendedNode>:: Node_handle

A handle with value type *Kd_tree_node<Traits, Splitter>*.

Kd_tree<Traits, Splitter, UseExtendedNode>:: Point_d_iterator

Random access iterator with value type *Point_d**.

_____ *advanced* _____

Creation

```
Kd_tree<Traits, Splitter, UseExtendedNode> tree( Splitter s=Splitter());
```

Constructs an empty k - d tree.

```
template <class InputIterator>
```

[illegible]

Constructs a k - d tree on the elements from the sequence $[first, beyond)$ using the splitting rule implemented by s . The value type of the *InputIterator* must be *Point_d*.

Operations

```
void tree.insert( Point_d p)
```

Inserts the point p in the k - d tree.

```
template <class InputIterator>
```

```
void tree.insert( InputIterator first, InputIterator beyond)
```

Inserts the elements from the sequence $[first, beyond)$ in the k -d tree. The value type of the *InputIterator* must be *Point_d*.

```
template <class OutputIterator, class FuzzyQueryItem>
```

```
OutputIterator tree.search( OutputIterator it, FuzzyQueryItem q)
```

Reports the points that are approximately contained by q . The types *FuzzyQueryItem::Point_d* and *Point_d* must be equivalent.

<i>iterator</i>	<i>tree.begin()</i>
-----------------	---------------------

Returns an iterator to the first point in the tree.

<i>iterator</i>	<i>tree.end()</i>
-----------------	-------------------

Returns the corresponding past-the-end iterator.

```
void tree.clear()
```

Removes all points from the k - d tree.

```
unsigned int      tree.size()
```

Returns the number of points that are stored in the tree.

_____ *advanced* _____

<i>Node_handle</i>	<i>tree.root()</i>
--------------------	--------------------

Returns a handle to the root node of the tree.

Kd_tree_rectangle<Traits>

tree.bounding_box() returns a const reference to the bounding box of the root node of the tree.

std::ostream& *tree.statistics(std::ostream& s)*

Inserts statistics of the tree into the output stream *s*.

└────────── *advanced* ─────────┘

CGAL::Kd_tree_node<Traits, Splitter, UseExtendedNode>

advanced

Definition

The class *Kd_tree_node*<*Traits*, *Splitter*, *UseExtendedNode*> implements a node class for a *k-d* tree. A node is either a leaf node, an internal node or an extended internal node. A leaf node contains one or more points. An internal node contains a pointer to its lower child, a pointer to its upper child, and a pointer to its separator. An extended internal node is an internal node containing the lower and upper limit of an extended node's rectangle along the node's cutting dimension.

```
#include <CGAL/Kd_tree_node.h>
```

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2*<*CGAL::Cartesian*<*double*> >, or *CGAL::Cartesian_d*<*double*>.

Types

```
enum Node_type { LEAF, INTERNAL, EXTENDED_INTERNAL};
```

Denotes type of node.

```
Traits::FT          FT;          Number type.
```

```
Traits::Point_d     Point_d;     Point type.
```

```
Splitter::Separator Separator;   Separator type.
```

```
Kd_tree<Traits,Splitter,UseExtendedNode>::Point_d_iterator
```

```
Point_d_iterator;    Iterator over points.
```

```
Kd_tree<Traits,Splitter,UseExtendedNode>::Node_handle
```

```
Node_handle;         Node handle.
```

Creation

Operations

```
template <class OutputIterator, class FuzzyQueryItem>
```

<i>OutputIterator</i>	<i>n.search(OutputIterator it, FuzzyQueryItem q)</i>	Reports the points from the subtree of the node, that are approximately contained by q.
<i>template <class OutputIterator></i>		
<i>OutputIterator</i>	<i>n.tree_points(OutputIterator it)</i>	Reports all the points contained by the subtree of the node.
<i>bool</i>	<i>n.is_leaf()</i>	Indicates whether a node is a leaf node.
<i>int</i>	<i>n.size()</i>	Returns the number of items stored in a leaf node.
<i>Point_d_iterator</i>	<i>n.begin()</i>	Returns the iterator to the first item in a leaf node.
<i>Point_d_iterator</i>	<i>n.end()</i>	Returns the past-the-end iterator in a leaf node.
<i>Node_handle</i>	<i>n.lower()</i>	Returns a handle to the lower child of an internal node.
<i>Node_handle</i>	<i>n.upper()</i>	Returns a handle to the upper child of an internal node.
<i>Separator&</i>	<i>n.separator()</i>	Returns a reference to the separator.
<i>FT</i>	<i>n.low_val()</i>	Returns the lower limit of an extended node's rectangle along the node's cutting dimension.
<i>FT</i>	<i>n.high_val()</i>	Returns the upper limit of an extended node's rectangle along the node's cutting dimension.

└────────── advanced ─────────┘

CGAL::Kd_tree_rectangle<Traits>

advanced

Definition

The class *Kd_tree_rectangle<Traits>* implements *d*-dimensional iso-rectangles and related operations, e.g., methods to compute bounding boxes of point sets.

```
#include <CGAL/Kd_tree_rectangle.h>
```

Types

Traits::FT *FT*; Number type.

Creation

Kd_tree_rectangle<Traits> *r*(*int d*); Constructs a *d*-dimensional rectangle *r* with lower bound and upper bound set to zero in each dimension.

```
template <class PointIter>
Kd_tree_rectangle<Traits> r( int d, PointIter begin, PointIter end);
```

Constructs the bounding box of the points in the range [*begin*,*end*), where the value type of *PointIter* must be *Traits::Point_d*.

Operations

FT *r.min_coord(int i)* Returns the lower bound of the rectangle in dimension *i*.

FT *r.max_coord(int i)* Returns the upper bound of the rectangle in dimension *i*.

void *r.set_upper_bound(int i, FT x)*
Sets upper bound in dimension *i* to *x*.

void *r.set_lower_bound(int i, FT x)*
Sets lower bound in dimension *i* to *x*.

FT *r.max_span()* Returns the maximal span of the rectangle.

FT *r.max_span_coord()* Returns the smallest coordinate for which the rectangle has its maximal span.

int *r.dimension()* Returns the dimension of the rectangle.

void *r.split(& r, int d, FT value)*

Splits rectangle in dimension *d* at coordinate-value *value* by modifying itself to lower half and by modifying *r* to upper half.

Output Routines

template<class FT>
std::ostream& *std::ostream& s << & r*

Inserts rectangle *r* in the output stream *s* and returns *s*.

└────────── *advanced* ─────────┘

CGAL::Manhattan_distance_iso_box_point<Traits>

Definition

The class *Manhattan_distance_iso_box_point*<Traits> provides an implementation of the *GeneralDistance* concept for the Manhattan distance (l_1 metric) between a d -dimensional iso-box and a d -dimensional point and the Manhattan distance between a d -dimensional iso-box and a d -dimensional iso-box defined as a k - d tree rectangle.

```
#include <CGAL/Manhattan_distance_iso_box_point.h>
```

Parameters

Expects for the template argument a model for the concept *SearchTraits*, for example *CGAL::Search_traits_3*<*CGAL::Cartesian*<*double*> >.

Is Model for the Concepts

GeneralDistance

Types

<i>Traits::FT</i>	<i>FT</i> ;	Number type.
<i>Traits::Point_d</i>	<i>Point_d</i> ;	Point type.
<i>Traits::Iso_box_d</i>	<i>Query_item</i> ;	Query item type.

Creation

```
Manhattan_distance_iso_box_point<Traits> md;
```

Default constructor.

Operations

<i>FT</i>	<i>md.transformed_distance(Query_item b, Point_d p)</i>	Returns the transformed distance between b and p .
<i>FT</i>	<i>md.transformed_distance(FT d)</i>	Returns the transformed value of d .

FT *md.inverse_of_transformed_distance(FT d)*

Returns the value of the inverse of the transform function applied to *d*.

FT *md.min_distance_to_rectangle(Query_item b, Kd_tree_rectangle<Traits> r)*

Returns the minimal distance between a point from *b* and a point from *r*.

FT *md.max_distance_to_rectangle(Query_item b, Kd_tree_rectangle<Traits> r)*

Returns the maximal distance between the iso-box *b* and a point from *r* furthest to *b*.

See Also

GeneralDistance.

CGAL::Median_of_max_spread<Traits, SpatialSeparator>

Definition

Implements the *median of max spread* splitting rule. The splitting dimension is the dimension of the longest side of the rectangle. The splitting value is defined by the median of the coordinates of the data points along this dimension.

```
#include <CGAL/Splitters.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example the type `CGAL::Search_traits_3<Cartesian<double>>`.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, `CGAL::Plane_separator<Traits::FT>`.

Is Model for the Concepts

Splitter

Creation

```
Median_of_max_spread<Traits, SpatialSeparator> s;
```

Default constructor.

```
Median_of_max_spread<Traits, SpatialSeparator> s( unsigned int bucket_size);
```

Constructor.

Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.
---------------------	------------------------	--

Splitter,
SpatialSeparator

CGAL::Median_of_rectangle<Traits, SpatialSeparator>

Definition

Implements the *median of rectangle* splitting rule. The splitting dimension is the dimension of the longest side of the rectangle. The splitting value is defined by the median of the coordinates of the data points along this dimension.

#include <CGAL/Splitters.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example the type *CGAL::Search_traits_3<Cartesian<double>>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane_separator<Traits::FT>*.

Is Model for the Concepts

Splitter

Creation

Median_of_rectangle<Traits, SpatialSeparator> s;

Default constructor.

Median_of_rectangle<Traits, SpatialSeparator> s(unsigned int bucket_size);

Constructor.

Operations

unsigned int *s.bucket_size()* Returns the bucket size of the leaf nodes.

See Also

Splitter,
SpatialSeparator

CGAL::Midpoint_of_max_spread<Traits, SpatialSeparator>

Definition

Implements the *midpoint of max spread* splitting rule. A rectangle is cut through $(Mind + Maxd)/2$ orthogonal to the dimension with the maximum point spread $[Mind, Maxd]$.

```
#include <CGAL/Splitters.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example the type `CGAL::Search_traits_3< Cartesian<double> >`.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, `CGAL::Plane_separator<Traits::FT>`

Is Model for the Concepts

Splitter

Creation

```
Midpoint_of_max_spread<Traits, SpatialSeparator> s;
```

Default constructor.

```
Midpoint_of_max_spread<Traits, SpatialSeparator> s( unsigned int bucket_size);
```

Constructor.

Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.
---------------------	------------------------	--

See Also

Splitter,
SpatialSeparator

CGAL::Midpoint_of_rectangle<Traits, SpatialSeparator>

Definition

Implements the *midpoint of rectangle* splitting rule. A rectangles is cut through its midpoint orthogonal to the longest side.

#include <CGAL/Splitters.h>

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example the type *CGAL::Search_traits_3< Cartesian<double> >*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane_separator<Traits::FT>*

Is Model for the Concepts

Splitter

Creation

Midpoint_of_rectangle<Traits, SpatialSeparator> s;

Default constructor.

Midpoint_of_rectangle<Traits, SpatialSeparator> s(unsigned int bucket_size);

Constructor.

Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.
---------------------	------------------------	--

See Also

Splitter,
SpatialSeparator

OrthogonalDistance

Definition

Requirements of an orthogonal distance class supporting incremental distance updates. To optimize distance computations transformed distances are used. E.g., for an Euclidean distance the transformed distance is the squared Euclidean distance.

Refines

GeneralDistance

Has Models

CGAL::Euclidean_distance<Traits>,
CGAL::Weighted_Minkowski_distance<Traits>

Types

<i>OrthogonalDistance:: FT</i>	Number type.
<i>OrthogonalDistance:: Point_d</i>	Point type.
<i>OrthogonalDistance:: Query_item</i>	Query item type.

Creation

<i>OrthogonalDistance od(int d);</i>	Constructor implementing distance for d -dimensional points.
---------------------------------------	--

Operations

<i>FT</i>	<i>od.transformed_distance(Query_item q, Point_d r)</i>	Returns the transformed distance between q and r .
<i>FT</i>	<i>od.min_distance_to_rectangle(Query_item q, Kd_tree_rectangle<Traits> r)</i>	Returns the transformed distance between q and the point on the boundary of r closest to q .
<i>FT</i>	<i>od.max_distance_to_rectangle(Query_item q, Kd_tree_rectangle<Traits> r)</i>	Returns the transformed distance between q and the point on the boundary of r farthest to q .

<i>FT</i>	<i>od.transformed_distance(FT d)</i>	Returns the transformed distance.
<i>FT</i>	<i>od.inverse_of_transformed_distance(FT d)</i>	Returns the inverse of the transformed distance.
<i>FT</i>	<i>od.new_distance(FT dist, FT old_off, FT new_off, int cutting_dimension)</i>	Updates <i>dist</i> incrementally and returns the updated distance.

CGAL::Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>

Definition

The class *Orthogonal_incremental_neighbor_search*<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*> implements incremental nearest and furthest neighbor searching on a tree.

```
#include <CGAL/Orthogonal_incremental_neighbor_search.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2*<*CGAL::Cartesian*<*double*>>.

Expects for the second template argument a model of the concept *GeneralDistance*. The default type is *CGAL::Euclidean_distance*<Traits>.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding_midpoint*<Traits>.

Expects for fourth template argument a model of the concept *SpatialTree*. The default type is *CGAL::Kd_tree*<Traits, *Splitter*, *CGAL::Tag_true*>. The template argument must be *CGAL::Tag_true* because orthogonal search needs extended kd tree nodes.

Types

Traits::Point_d *Point_d*; Point type.

Traits::FT *FT*; Number type.

OrthogonalDistance::Query_item
 Query_item; Query item.

std::pair<*Point_d*,*FT*>
 Point_with_transformed_distance;
 Pair of point and transformed distance.

Orthogonal_incremental_neighbor_search<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*>:: *iterator*
 Input iterator with value type *Point_with_transformed_distance* for enumerating approximate neighbors.

SpatialTree *Tree*; The tree type.

Creation

```
Orthogonal_incremental_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree> s(  
    SpatialTree& tree,  
    Query_item query,  
    FT eps=FT(0.0),  
    bool search_nearest=true,  
    OrthogonalDistance d=OrthogonalDistance())
```

Constructor for incremental neighbor searching of the query item *query* in the points stored *tree* using a distance *d* and approximation factor *eps*.

Operations

<i>iterator</i>	<i>s.begin()</i>	Returns an iterator to the approximate neighbors.
<i>iterator</i>	<i>s.end()</i>	Returns the corresponding past-the-end iterator.

```
┌────────── advanced ───────────┐  
|  
std::ostream&          s.statistics( std::ostream& s)
```

Inserts statistics of the search process into the output stream *s*.

See Also

CGAL::Incremental_neighbor_search<Traits, GeneralDistance, SpatialTree>.

CGAL::Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree>

Definition

The class *Orthogonal_k_neighbor_search*<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*> implements approximate *k*-nearest and *k*-furthest neighbor searching on a tree using an orthogonal distance class.

```
#include <CGAL/Orthogonal_k_neighbor_search.h>
```

Parameters

Expects for the first template argument an implementation of the concept *SearchTraits*, for example *CGAL::Search_traits_2*<*CGAL::Cartesian*<*double*>>.

Expects for the second template argument a model of the concept *GeneralDistance*. The default type is *CGAL::Euclidean_distance*<Traits>.

Expects for third template argument a model of the concept *Splitter*. The default type is *CGAL::Sliding_midpoint*<Traits>.

Expects for fourth template argument an implementation of the concept *SpatialTree*. The default type is *CGAL::Kd_tree*<Traits, *Splitter*, *CGAL::Tag_true*>. The template argument must be *CGAL::Tag_true* because orthogonal search needs extended kd tree nodes.

Types

Traits::Point_d *Point_d*; Point type.

Traits::FT *FT*; Number type.

GeneralDistance::Query_item
 Query_item; Query item.

std::pair<*Point_d*,*FT*>
 Point_with_transformed_distance;
 Pair of point and transformed distance.

Orthogonal_k_neighbor_search<Traits, *OrthogonalDistance*, *Splitter*, *SpatialTree*>:: *iterator*
 Bidirectional iterator with value type *Point_with_transformed_distance* for enumerating approximate neighbors.

SpatialTree *Tree*; The tree type.

Operations

```
Orthogonal_k_neighbor_search<Traits, OrthogonalDistance, Splitter, SpatialTree> s(  
    SpatialTree tree,  
    Query_item query,  
    int k=1,  
    FT eps=FT(0.0),  
    bool search_nearest=true,  
    OrthogonalDistance d=OrthogonalDistance())
```

Constructor for searching approximately k neighbors of the query item $query$ in the points stored in $tree$ using distance d and approximation factor eps .

<i>iterator</i>	<i>s.begin()</i>	Returns an iterator to the approximate neighbors.
-----------------	------------------	---

<i>iterator</i>	<i>s.end()</i>	Past-the-end iterator.
-----------------	----------------	------------------------

_____ *advanced* _____
|

<i>std::ostream&</i>	<i>s.statistics(std::ostream& s)</i>
--------------------------	--

Inserts statistics of the search process into the output stream s .

_____ *advanced* _____
|

See Also

CGAL::K_neighbor_search<Traits, GeneralDistance, Splitter, SpatialTree>.

CGAL::Plane_separator<FT>

— advanced —

Definition

The class *Plane_separator*<FT> implements a plane separator, i.e., a hyperplane that is used to separate two half spaces. This hyperplane is defined by a cutting dimension d and a cutting value v as $x_d = v$, where v denotes the d^{th} coordinate value.

```
#include <CGAL/Plane_separator.h>
```

Is Model for the Concepts

SpatialSeparator

Creation

```
Plane_separator<FT> s( int d, FT v);
```

Constructs a separator that separates two half spaces by a hyperplane defined by $x_d = v$, where v denotes the d^{th} coordinate value.

```
Plane_separator<FT> s( p);
```

Copy constructor.

Operations

```
void s.set_cutting_dimension( int d)
```

Sets the cutting dimension to d .

```
void s.set_cutting_value( FT v)
```

Sets the cutting value to v .

```
int s.cutting_dimension()
```

Returns the number of the cutting dimension.

```
FT s.cutting_value()
```

Returns the cutting value.

```
template <class SpatialPoint>
```

```
bool s.has_on_negative_side( SpatialPoint p)
```

Returns true if and only if the coordinate of p in the cutting dimension is smaller than the cutting value.

```
Plane_separator<FT>
```

```
s = s2
```

Assignment operator.

Output Operators

```
template<class FT>  
std::ostream&      std::ostream& os << s
```

Inserts the plane separator *s* in the output stream *os* and returns *os*.

└────────── *advanced* ─────────┘

SearchTraits

Definition

The concept *SearchTraits* defines the requirements for the template parameter of the search classes.

Types

<i>SearchTraits:: Point_d</i>	Point type. <i>CGAL::Kernel_traits</i> has to be specialized for this type.
<i>SearchTraits:: Iso_box_d</i>	Iso box type. It is only needed for range search queries.
<i>SearchTraits:: Sphere_d</i>	Sphere type. It is only needed for range search queries.
<i>SearchTraits:: FT</i>	The number type of the Cartesian coordinates of types <i>Point_d</i>
<i>SearchTraits:: Cartesian_const_iterator</i>	An random access iterator type to enumerate the Cartesian coordinates of a point.
<i>SearchTraits:: Construct_cartesian_const_iterator</i>	Functor with operators to construct iterators on the first and the past-the-end iterator for the Cartesian coordinates of a point.
<i>SearchTraits:: Construct_center_d</i>	Functor with operator to construct the center of an object of type <i>Sphere_d</i> .
<i>SearchTraits:: Construct_squared_radius_d</i>	Functor with operator to compute the squared radius of a an object of type <i>Sphere_d</i> .
<i>SearchTraits:: Construct_min_vertex_d</i>	Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type <i>Iso_box_d</i> .
<i>SearchTraits:: Construct_max_vertex_d</i>	Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type <i>Iso_box_d</i> .

Has Models

CGAL::Cartesian_d<FT>
CGAL::Homogeneous_d<RT>
CGAL::Search_traits_2<Kernel>
CGAL::Search_traits_3<Kernel>,
CGAL::Search_traits<NT,Point, CartesianCoordinateIterator,ConstructCartesianCoordinateIterator,ConstructMinVertex,ConstructM
 .

CGAL::Search_traits_2<Kernel>

Definition

The class *Search_traits_2<Kernel>* can be used as a template parameter of the kd tree and the search classes.

```
#include <CGAL/Search_traits_2.h>
```

Parameters

Expects for the template argument a model of the concept *Kernel*, for example *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<CGAL::Gmp_q>*.

Is Model for the Concepts

SearchTraits.

Types

Kernel::FT *FT*; Number type.

Kernel::Point_2 *Point_d*; Point type.

Kernel::Iso_rectangle_2
 Iso_box_d; Iso box type.

Kernel::Sphere_2 *Sphere_d*; Sphere type.

Kernel::Cartesian_const_iterator_2
 Cartesian_const_iterator_d;
 An iterator over the Cartesian coordinates.

Kernel::Construct_cartesian_const_iterator_2
 Construct_cartesian_const_iterator_d;
 A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point_d*. The functor for the past the end iterator, has as argument a *Point_d* and an *int*.

Kernel::Construct_iso_rectangle_2

Construct_iso_box_d; Functor with operator to construct the iso box from two points.

Kernel::Construct_center_2

Construct_center_d; Functor with operator to construct the center of an object of type *Sphere_d*.

Kernel::Compute_squared_radius_2

Construct_squared_radius_d;

Functor with operator to compute the squared radius of a an object of type *Sphere_d*.

Kernel::Construct_min_vertex_2

Construct_min_vertex_d;

Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso_box_d*.

Kernel::Construct_max_vertex_2

Construct_max_vertex_d;

Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso_box_d*.

See Also

Search_traits_3<Kernel>

Search_traits<NT_,Point, CartesianConstIterator, ConstructCartesianConstIterator

CGAL::Search_traits_3<Kernel>

Definition

The class *Search_traits_3<Kernel>* can be used as a template parameter of the kd tree and the search classes. *Kernel* must be a CGAL kernel.

```
#include <CGAL/Search_traits_3.h>
```

Parameters

Expects for the template argument a model of the concept *Kernel*, for example *CGAL::Cartesian<double>* or *CGAL::Simple_cartesian<CGAL::Gmp_q>*.

Is Model for the Concepts

SearchTraits.

Types

Kernel::FT *FT*; Number type.

Kernel::Point_3 *Point_d*; Point type.

Kernel::Iso_cuboid_3
 Iso_box_d; Iso box type.

Kernel::Sphere_3 *Sphere_d*; Sphere type.

Kernel::Cartesian_const_iterator_3
 Cartesian_const_iterator_d;
 An iterator over the Cartesian coordinates.

Kernel::Construct_cartesian_const_iterator_3
 Construct_cartesian_const_iterator_d;
 A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point_d*. The functor for the past the end iterator, has as argument a *Point_d* and an *int*.

Kernel::Construct_center_3

Construct_center_d; Functor with operator to construct the center of an object of type *Sphere_d*.

Kernel::Compute_squared_radius_3

Construct_squared_radius_d;

Functor with operator to compute the squared radius of a an object of type *Sphere_d*.

Kernel::Construct_min_vertex_3

Construct_min_vertex_d;

Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso_box_d*.

Kernel::Construct_max_vertex_3

Construct_max_vertex_d;

Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso_box_d*.

CGAL::Search_traits_d<Kernel>

Definition

The class *Search_traits_d<Kernel>* can be used as a template parameter of the kd tree and the search classes. *Kernel* must be a CGAL kernel.

Kernel must be a d-dimensional CGAL kernel.

```
#include <CGAL/Search_traits_d.h>
```

Parameters

Expects for the template argument a model of the concept *Kernel_d*, for example *CGAL::Cartesian_d<double>* or *CGAL::Homogeneous_d<CGAL::Gmp_z>*.

Is Model for the Concepts

SearchTraits.

Types

Kernel::FT *NT*; Number type.

Kernel::Point_d *Point_d*; Point type.

Kernel::Iso_cuboid_d
 Iso_box_d; Iso box type.

Kernel::Sphere_d *Sphere_d*; Sphere type.

Kernel::Cartesian_const_iterator_d
 Cartesian_const_iterator;
 An iterator over the Cartesian coordinates.

Kernel::Construct_cartesian_const_iterator_d
 Construct_cartesian_const_iterator;
 A functor with two function operators, which return the begin and past the end iterator for the Cartesian coordinates. The functor for begin has as argument a *Point_d*. The functor for the past the end iterator, has as argument a *Point_d* and an *int*.

Kernel::Construct_min_vertex_d

Construct_min_vertex_d;

Functor with operator to construct the vertex with lexicographically smallest coordinates of an object of type *Iso_box_d*.

Kernel::Construct_max_vertex_d

Construct_max_vertex_d;

Functor with operator to construct the vertex with lexicographically largest coordinates of an object of type *Iso_box_d*.

CGAL::Sliding_fair<Traits, SpatialSeparator>

Definition

Implements the *sliding fair* splitting rule. This splitting rule is a compromise between the *Fair* splitting rule and the *Sliding_midpoint* rule. Sliding fair-split is based on the theory that there are two types of splits that are good: balanced splits that produce fat rectangles, and unbalanced splits provided the rectangle with fewer points is fat.

Also, this splitting rule maintains an upper bound on the maximal allowed ratio of the longest and shortest side of a rectangle (the value of this upper bound is set in the constructor of the fair splitting rule). Among the splits that satisfy this bound, it selects the one one in which the points have the largest spread. It then considers the most extreme cuts that would be allowed by the aspect ratio bound. This is done by dividing the longest side of the rectangle by the aspect ratio bound. If the median cut lies between these extreme cuts, then we use the median cut. If not, then consider the extreme cut that is closer to the median. If all the points lie to one side of this cut, then we slide the cut until it hits the first point. This may violate the aspect ratio bound, but will never generate empty cells.

```
#include <CGAL/Splitters.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d<double>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane_separator<Traits::FT>*

Is Model for the Concepts

Splitter

Types

Traits::FT *FT*; Number type.

Creation

```
Sliding_fair<Traits, SpatialSeparator> s( unsigned int bucket_size, FT aspect_ratio=FT(3));
```

Constructor.

Operations

FT *s.aspect_ratio()* Returns the maximal ratio between the largest and smallest side of a cell allowed for fair splitting.

unsigned int *s.bucket_size()* Returns the bucket size of the leaf nodes.

Splitter,
SpatialSeparator

CGAL::Sliding_midpoint<Traits, SpatialSeparator>

Definition

Implements the *sliding midpoint* splitting rule. This is a modification of the *Midpoint_of_rectangle* splitting rule. It first attempts to perform a midpoint of rectangle split as described above. If data points lie on both sides of the separating plane the sliding midpoint rule computes the same separator as the midpoint of rectangle rule. If the data points lie only on one side it avoids this by sliding the separator, computed by the midpoint of rectangle rule, to the nearest data point.

```
#include <CGAL/Splitters.h>
```

Parameters

Expects for the first template argument a model of the concept *SearchTraits*, for example *CGAL::Cartesian_d<double>*.

Expects for the second template argument a model of the concept *Separator*. It has as default value the type, *CGAL::Plane_separator<Traits::FT>*.

Is Model for the Concepts

Splitter

Creation

```
Sliding_midpoint<Traits, SpatialSeparator> s( unsigned int bucket_size);
```

Constructor.

Operations

<i>unsigned int</i>	<i>s.bucket_size()</i>	Returns the bucket size of the leaf nodes.

SpatialSeparator

SpatialSeparator

advanced

Definition

The concept `SpatialSeparator` defines the requirements for a separator. A separator is a $(d-1)$ -dimensional subspace that separates a d -dimensional space into two parts. One part of space is said to be on the negative side of the separator and the other part of space is said to be on the positive side of the separator.

Has Models

`CGAL::Plane_separator<FT>`.

Types

`SpatialSeparator::FT` Number type.

Creation

`SpatialSeparator s;` Default constructor.

Operations

`void` `s.set_cutting_dimension(int d)` Sets the cutting dimension to d .

`void` `s.set_cutting_value(FT v)` Sets the cutting value to v .

`int` `s.cutting_dimension()` Returns the number of the cutting dimension.

`FT` `s.cutting_value()` Returns the cutting value.

`template <class Point_d>`
`bool` `s.has_on_negative_side(Point_d p)` Returns true if and only if the point p is on the negative side of the separator.

SpatialTree

Definition

The concept `SpatialTree` defines the requirements for a tree supporting both neighbor searching and approximate range searching.

Types

<code>SpatialTree:: SearchTraits</code>	Search traits.
<code>SpatialTree:: Point_d</code>	Point type.
<code>SpatialTree:: iterator</code>	Bidirectional iterator with value type <code>Point_d</code> that allows to enumerate all points in the tree.
<code>SpatialTree:: Node_handle</code>	Node handle.
<code>SpatialTree:: Point_d_iterator</code>	Iterator with value type <code>Point_d*</code> .
<code>SpatialTree:: Splitter</code>	Splitter.
<code>SpatialTree:: Distance</code>	Distance.

Creation

```
template <class InputIterator>
SpatialTree tree( InputIterator first, InputIterator beyond, SearchTraits t);
```

Constructs a tree on the elements from the sequence `[first,beyond)`.

Operations

```
template <class OutputIterator, class FuzzyQueryItem>
OutputIterator tree.search( OutputIterator it, FuzzyQueryItem q)
```

Reports the points that are approximately contained by `q`. The value type of `OutputIterator` must be `Point_d`.

<code>iterator</code>	<code>tree.begin()</code>	Returns an iterator to the first point in the tree.
<code>iterator</code>	<code>tree.end()</code>	Returns the corresponding past-the-end iterator.

<i>Node_handle</i>	<i>tree.root()</i>	Returns a handle to the root node of the tree.
<i>Kd_tree_rectangle<SearchTraits></i>		
	<i>tree.bounding_box()</i>	returns a const reference to the bounding box of the root node of the tree.
<i>unsigned int</i>	<i>tree.size()</i>	Returns the number of items that are stored in the tree.

Has Models

CGAL::Kd_tree<Traits,Splitter,UseExtendedNode>.

CGAL::Weighted_Minkowski_distance<Traits>

Definition

The class *Weighted_Minkowski_distance<Traits>* provides an implementation of the concept *OrthogonalDistance*, with a weighted Minkowski metric on d -dimensional points defined by $l_p(w)(r, q) = (\sum_{i=1}^d w_i(r_i - q_i)^p)^{1/p}$ for $0 < p < \infty$ and defined by $l_\infty(w)(r, q) = \max\{w_i|r_i - q_i| \mid 1 \leq i \leq d\}$. For the purpose of the distance computations it is more efficient to compute the transformed distance $\sigma_{i=1}^d w_i(r_i - q_i)^p$ instead of the actual distance.

```
#include <CGAL/Weighted_Minkowski_distance.h>
```

Parameters

Expects for the template argument a model of the concept *SearchTraits*, for example *CGAL::Search_traits_2<Kernel>*.

Is Model for the Concepts

OrthogonalDistance

Types

Traits::FT *FT*; Number type.

Traits::Point_d *Point_d*; Point type.

Creation

```
Weighted_Minkowski_distance<Traits> wd( int d);
```

Constructor implementing l_2 metric for d -dimensional points.

```
template <class InputIterator>
```

```
Weighted_Minkowski_distance<Traits> wd( FT power, int dim, InputIterator wb, InputIterator we);
```

Constructor implementing the $l_{power}(weights)$ metric. $power \leq 0$ denotes the $l_\infty(weights)$ metric. The values in the iterator range $[wb, we)$ are the weight.

Operations

```
FT                                      wd.transformed_distance( Point_d q, Point_d r)
```

Returns d^{power} , where d denotes the distance between q and r .

<i>FT</i>	<i>wd.min_distance_to_rectangle(Point_d q, Kd_tree_rectangle<Traits> r;)</i>	Returns d^{power} , where d denotes the distance between the query item q and the point on the boundary of r closest to q .
<i>FT</i>	<i>wd.max_distance_to_rectangle(Point_d q, Kd_tree_rectangle<Traits> r;)</i>	Returns d^{power} , where d denotes the distance between the query item q and the point on the boundary of r farthest to q .
<i>FT</i>	<i>wd.new_distance(FT dist, FT old_off, FT new_off, int cutting_dimension)</i>	Updates <i>dist</i> incrementally and returns the updated distance.
<i>FT</i>	<i>wd.transformed_distance(FT d)</i>	Returns d^p for $0 < p < \infty$. Returns d for $p = \infty$.
<i>FT</i>	<i>wd.inverse_of_transformed_distance(FT d)</i>	Returns $d^{1/p}$ for $0 < p < \infty$. Returns d for $p = \infty$.

46.1 Introduction

This chapter presents the CGAL range tree and segment tree data structures.

46.2 Definitions

This section presents d -dimensional range and segment trees. A one-dimensional range tree is a binary search tree on *one-dimensional point data*. Here we call all one-dimensional data types having a strict ordering (like integer and double) *point data*. d -dimensional *point data* are d -tuples of one-dimensional point data.

A one-dimensional segment tree is a binary search tree as well, but with *one-dimensional interval data* as input data. One-dimensional interval data is a pair (i.e., 2-tuple) (a, b) , where a and b are one-dimensional point data of the same type and $a < b$. The pair (a, b) represents a half open interval $[a, b)$. Analogously, a d -dimensional interval is represented by a d -tuple of one-dimensional intervals.

The *input data type* for a d -dimensional tree is a container class consisting of a d -dimensional point data type, interval data type or a mixture of both, and optionally a *value type*, which can be used to store arbitrary data. E.g.,

the d -dimensional bounding box of a d -dimensional polygon may define the interval data of a d -dimensional segment tree and the polygon itself can be stored as its value. An *input data item* is an instance of an input data type.

The range and segment tree classes are fully generic in the sense that they can be used to define *multilayer trees*. A multilayer tree of dimension (number of layers) d is a simple tree in the d -th layer, whereas the k -th layer, $1 \leq k \leq d - 1$, of the tree defines a tree where each (inner) vertex contains a multilayer tree of dimension $d - k + 1$. The $k - 1$ -dimensional tree which is nested in the k -dimensional tree (T) is called the *sublayer tree* (of T). For example, a d -dim tree can be a range tree on the first layer, constructed with respect to the first dimension of d -dimensional data items. On all the data items in each subtree, a $(d - 1)$ -dimensional tree is built, either a range or a segment tree, with respect to the second dimension of the data items. And so on. Figures 46.2, 46.3 and 46.5 illustrate the meaning of a sublayer tree graphically.

After creation of the tree, further insertions or deletions of data items are disallowed. The tree class does neither depend on the type of data nor on the concrete physical representation of the data items. E.g., let a multilayer tree be a segment tree for which each vertex defines a range tree. We can choose the data items to consist of intervals of type *double* and the point data of type *integer*. As value type we can choose *string*.

For this generality we have to define what the tree of each dimension looks like and how the input data is organized. For dimension k , $1 \leq k \leq 4$, CGAL provides ready-to-use range and segment trees that can store k -dimensional keys (intervals resp.). Examples illustrating the use of these classes are given in Sections 46.5.1 and 46.6.1. The description of the functionality of these classes as well as the definition of higher dimensional trees and mixed multilayer trees is given in the reference manual.

In the following two sections we give short definitions of the version of the range tree and segment tree implemented here together with some examples. The presentation closely follows [dBvKOS97].

46.3 Software Design

In order to be able to define a multilayer tree we first designed the range and segment tree to have a template argument defining the type of the sublayer tree. With this sublayer tree type information the sublayers could be created. This approach lead to nested template arguments, since the sublayer tree can again have a template argument defining the sublayer. Therefore, the internal class and function identifiers got longer than a compiler-dependent limit. This happened already for $d = 2$.

Therefore, we chose another, object oriented, design. We defined a pure virtual base class called *Tree_base* from which we derived the classes *Range_tree_d* and *Segment_tree_d*. The constructor of these classes expects an argument called *sublayer_prototype* of type *Tree_base*. Since class *Range_tree_d* and class *Segment_tree_d* are derived from class *Tree_base*, one can use an instantiation of class *Range_tree_d* or class *Segment_tree_d* as constructor argument. This argument defines the sublayer tree of the tree. E.g., you can construct a *Range_tree_d* with an instantiation of class *Segment_tree_d* as constructor argument. You then have defined a range tree with a segment tree as sublayer tree. Since both classes *Range_tree_d* and *Segment_tree_d* expect a sublayer tree in their constructor we had to derive a third class called *Tree_anchor* from class *Tree_base* which does not expect a constructor argument. An instantiation of this class is used as constructor argument of class *Range_tree_d* or *Segment_tree_d* in order to stop the recursion.

All classes provide a *clone()* function which returns an instance (a copy) of the same tree type. The *clone()* function of the *sublayer_prototype* is called in the construction of the tree. In case that the sublayer tree again has a sublayer, it also has a *sublayer_prototype* which is also cloned and so on. Thus, a call to the *clone()* function generates a sublayer tree which has the complete knowledge about its sublayer tree.

The trees allow to perform window queries, enclosing queries, and inverse range queries on the keys. Clearly, an inverse range query makes only sense in the segment tree. In order to perform an inverse range query, a range

query of ϵ width has to be performed. We preferred not to offer an extra function for this sort of query, since the inverse range query is a special case of the range query. Furthermore, offering an inverse range query in the segment tree class implies offering this function also in the range tree class and having an extra item in the traits class that accesses the inverse range query point.

The trees are templated with three arguments: *Data*, *Window* and *Traits*. Type *Data* defines the input data type and type *Window* defines the query window type. The tree uses a well defined set of functions in order to access data. These functions have to be provided by class *Traits*.

The design partly follows the *prototype design pattern* in [GHJV95]. In comparison to our first approach using templates we want to note the following: In this approach the sublayer type is defined in use of object oriented programming at run time, while in the approach using templates, the sublayer type is defined at compile time.

The runtime overhead caused in use of virtual member functions in this object oriented design is negligible since all virtual functions are non trivial. The design concept is illustrated in Figure 46.1.

E.g. in order to define a two dimensional multilayer tree, which consists of a range tree in the first dimension and a segment tree in the second dimension we proceed as follows: We construct an object of type *Tree_anchor* which stops the recursion. Then we construct an object of type *Segment_tree_d*, which gets as prototype argument our object of type *Tree_anchor*. After that, we define an object of type *Range_tree_d* which is constructed with the object of type *Segment_tree_d* as prototype argument. The following piece of code illustrates the construction of the two-dimensional multilayer tree.

```
int main() {
    Tree_Anchor *anchor=new Tree_Anchor;
    Segment_Tree_d *segment_tree = new Segment_Tree_d(*anchor);
    Range_Tree_d *range_segment_tree = new Range_Tree_d(*segment_tree);
    /* let data_items be a list of Data items */
    range_segment_tree->make_tree(data_items.begin(),data_items.end());
}
```

Here, class *Tree_Anchor*, *Segment_Tree_d*, and *Range_Tree_d* are defined by *typedefs*:

```
typedef Tree_anchor<Data,Window> Tree_Anchor;
typedef Segment_tree_d<Data,Window,Interval_traits> Segment_Tree_d;
typedef Range_tree_d<Data,Window,Point_traits> Range_Tree_d;
```

Class *Tree_base* and class *Tree_anchor* get two template arguments: a class *Data* which defines the type of data that is stored in the tree, and a class *Window* which defines the type of a query range. The derived classes *Range_tree_d* and *Segment_tree_d* additionally get an argument called *Tree_traits* which defines the interface between the *Data* and the tree. Let the *Data* type be a *d*-dimensional tuple, which is either a point data or an interval data in each dimension. Then, the class *Tree_traits* provides accessors to the point (resp. interval) data of that tree layer and a compare function. Remind our example of the two-dimensional tree which is a range tree in the first dimension and a segment tree in the second dimension. Then, the *Tree_traits* class template argument of class *Segment_tree_d* defines an accessor to the interval data of the *Data*, and the *Tree_traits* class template argument of class *Range_tree_d* defines an accessor to the point data of *Data*. An example implementation for these classes is listed below.

```
struct Data{
    int min,max; /* interval data */
    double point; /* point data */
}
```

Figure 46.1: Design of the range and segment tree data structure. The symbol triangle means that the lower class is derived from the upper class.

```

};

struct Window{
    int min,max;
    double min_point, max_point;
};

class Point_traits{
public:
    typedef double Key;
    Key get_key(Data& d){return d.point;} /*key accessor */
    Key get_left(Window& w){return w.min_point;}
    Key get_right(Window& w){return w.max_point;}
    bool comp(Key& key1, Key& key2){return (key1 < key2);}
}

class Interval_traits{
public:
    typedef int Key;
    Key get_left(Data& d){return d.min;}
    Key get_right(Data& d){return d.max;}
    Key get_left_win(Window& w){return w.min;}
    Key get_right_win(Window& w){return w.max;}
    bool comp(Key& key1, Key& key2){return (key1 < key2);}
}

```

46.4 Creating an Arbitrary Multilayer Tree

Now let us have a closer look on how a multilayer tree is built. In case of creating a d -dimensional tree, we handle a sequence of arbitrary data items, where each item defines a d -dimensional interval, point or other object. The tree is constructed with an iterator over this structure. In the i -th layer, the tree is built with respect to the data slot that defines the i -th dimension. Therefore, we need to define which data slot corresponds to which dimension. In addition we want our tree to work with arbitrary data items. This requires an adaptor between the algorithm and the data item. This is resolved by the use of traits classes, implemented in form of a traits class using function objects. These classes provide access functions to a specified data slot of a data item. A d -dimensional tree is then defined separately for each layer by defining a traits class for each layer.

46.5 Range Trees

A one-dimensional range tree is a binary search tree on one-dimensional point data. The point data of the tree is stored in the leaves. Each inner vertex stores the highest entry of its left subtree. The version of a range tree implemented here is static, which means that after construction of the tree, no elements be inserted or deleted. A d -dimensional range tree is a binary leaf search tree according to the first dimension of the d -dimensional point data, where each vertex contains a $(d - 1)$ -dimensional search tree of the points in the subtree (sublayer tree) with respect to the second dimension. See [dBvKOS97] and [Sam90] for more detailed information.

A d -dimensional range tree can be used to determine all d -dimensional points that lie inside a given d -dimensional interval (*window_query*). Figure 46.2 shows a two-dimensional range tree, Figure 46.3 a d -dimensional one.

Figure 46.2: A two-dimensional range tree. The tree is a binary search tree on the first dimension. Each sublayer tree of a vertex v is a binary search tree on the second dimension. The data items in a sublayer tree of v are all data items of the subtree of v .

Figure 46.3: A d -dimensional range tree. For each layer of the tree, one sublayer tree is illustrated.

The tree can be built in $O(n \log^{d-1} n)$ time and needs $O(n \log^{d-1} n)$ space. The d -dimensional points that lie in the d -dimensional query interval can be reported in $O(\log^d n + k)$ time, where n is the total number of points and k is the number of reported points.

46.5.1 Example for Range Tree on Map-like Data

The following example program uses the predefined *Range_tree_2* data structure together with the predefined traits class *Range_tree_map_traits_2* which has two template arguments specifying the type of the point data in each dimension (*CGAL::Cartesian<double>*) and the value type of the 2-dimensional point data (*char*). Therefore the *Range_tree_2* is defined on 2-dimensional point data each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_tree_map_traits_2<K, char> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
    typedef Traits::Key Key;
    typedef Traits::Interval Interval;

    std::vector<Key> InputList, OutputList;
```

```

InputList.push_back(Key(K::Point_2(8,5.1), 'a'));
InputList.push_back(Key(K::Point_2(1,1.1), 'b'));
InputList.push_back(Key(K::Point_2(3,2.1), 'c'));

Range_tree_2_type Range_tree_2(InputList.begin(),InputList.end());
Interval win(Interval(K::Point_2(4,8.1),K::Point_2(5,8.2)));
std::cout << "\n Window Query:\n ";
Range_tree_2.window_query(win, std::back_inserter(OutputList));
std::vector<Key>::iterator current=OutputList.begin();
while(current!=OutputList.end()){
    std::cout << (*current).first.x() << "," << (*current).first.y()
        << ":" << (*current++).second << std::endl;
}
}

```

46.5.2 Example for Range Tree on Set-like Data

This example illustrates the use of the range tree on 2-dimensional point data (no value is associated to a data item). After the definition of the tree, some input data items are created and the tree is constructed according to the input data items. After that, a window query is performed and the query elements are given to standard out.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_segment_tree_set_traits_2<K> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
    typedef Traits::Key Key;
    typedef Traits::Interval Interval;
    std::vector<Key> InputList, OutputList;
    std::vector<Key>::iterator first, last, current;

    InputList.push_back(Key(8,5.1));
    InputList.push_back(Key(1,1.1));
    InputList.push_back(Key(3,2.1));

    Range_tree_2_type Range_tree_2(InputList.begin(),InputList.end());

    Interval win=Interval(Key(4,8.1),Key(5,8.2));
    std::cout << std::endl << "Window Query: lower left point: (4.0,5.0),";
    std::cout << "upper right point: (8.1,8.2)" << std::endl;
    Range_tree_2.window_query(win, std::back_inserter(OutputList));
    current=OutputList.begin();
    while(current!=OutputList.end()){
        std::cout << (*current).x()<< "-" << (*current).y() << std::endl;
        current++;
    }
}

```

46.6 Segment Trees

A segment tree is a static binary search tree for a given set of coordinates. The set of coordinates is defined by the endpoints of the input data intervals. Any two adjacent coordinates build an elementary interval. Every leaf corresponds to an elementary interval. Inner vertices correspond to the union of the subtree intervals of the vertex. Each vertex or leaf v contains a sublayer type (or a list, if it is one-dimensional) that will contain all intervals I , such that I contains the interval of vertex v but not the interval of the parent vertex of v .

A d -dimensional segment tree can be used to solve the following problems:

- Determine all d -dimensional intervals that contain a d -dimensional point. This query type is called “inverse range query”.
- Determine all d -dimensional intervals that enclose a given d -dimensional interval (*enclosing_query*).
- Determine all d -dimensional intervals that partially overlap or are contained in a given d -dimensional interval (*window_query*).

In Figure 46.4 an example of a one-dimensional segment tree is given. Figure 46.5 shows a two-dimensional segment tree.

The tree can be built in $O(n \log^d n)$ time and needs $O(n \log^d n)$ space. The processing time for inverse range queries in an d -dimensional segment tree is $O(\log^d n + k)$ time, where n is the total number of intervals and k is the number of reported intervals.

One possible application of a two-dimensional segment tree is the following. Given a set of convex polygons in two-dimensional space (`CGAL::Polygon_2`), we want to determine all polygons that intersect a given rectangular query window. Therefore, we define a two-dimensional segment tree, where the two-dimensional interval of a data item corresponds to the bounding box of a polygon and the value type corresponds to the polygon itself. The segment tree is created with a sequence of all data items, and a window query is performed. The polygons of the resulting data items are finally tested independently for intersections.

46.6.1 Example for Segment Tree on Map-like Data

The following example program uses the predefined `Segment_tree_2` data structure together with the predefined traits class `Segment_tree_map_traits_2` which has two template arguments specifying the type of the point data in each dimension (`CGAL::Cartesian<double>`) and the value type of the 2-dimensional point data (`char`). Therefore the `Segment_tree_2` is defined on 2-dimensional point data (`CGAL::Point_2<Cartesian<double>>`) each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Segment_tree_map_traits_2<K, char> Traits;
typedef CGAL::Segment_tree_2<Traits > Segment_tree_2_type;

int main()
{
```

Figure 46.4: A one-dimensional segment tree. The segments and the corresponding elementary intervals are shown below the tree. The arcs from the nodes point to their subsets.

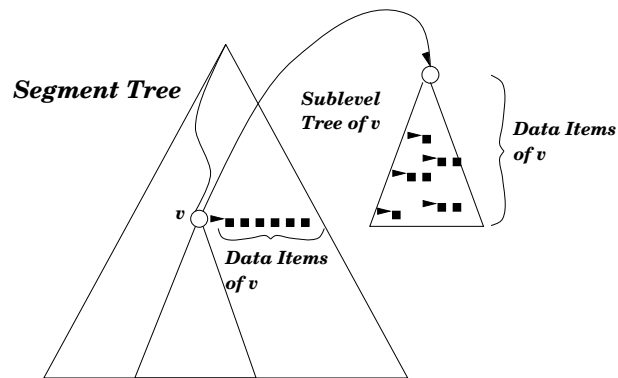

Figure 46.5: A two-dimensional segment tree. The first layer of the tree is built according to the elementary intervals of the first dimension. Each sublayer tree of a vertex v is a segment tree according to the second dimension of all data items of v .

```

typedef Traits::Interval Interval;
typedef Traits::Pure_interval Pure_interval;
typedef Traits::Key Key;
std::list<Interval> InputList, OutputList1, OutputList2;

InputList.push_back(Interval(Pure_interval(Key(1,5), Key(2,7)), 'a'));
InputList.push_back(Interval(Pure_interval(Key(2,7), Key(3,8)), 'b'));
InputList.push_back(Interval(Pure_interval(Key(6,9), Key(9,13)), 'c'));
InputList.push_back(Interval(Pure_interval(Key(1,3), Key(3,9)), 'd'));

Segment_tree_2_type Segment_tree_2(InputList.begin(), InputList.end());

Interval a=Interval(Pure_interval(Key(3,6), Key(7,12)), 'e');
Segment_tree_2.window_query(a, std::back_inserter(OutputList1));

std::list<Interval>::iterator j = OutputList1.begin();
std::cout << "\n window_query (3,6), (7,12)\n";
while(j!=OutputList1.end()){
    std::cout << (*j).first.first.x() << "-" << (*j).first.second.x() << " "
        << (*j).first.first.y() << "-" << (*j).first.second.y() << std::endl;
    j++;
}

Interval b=Interval(Pure_interval(Key(6,10), Key(7,11)), 'f');
Segment_tree_2.enclosing_query(b, std::back_inserter(OutputList2));
j = OutputList2.begin();
std::cout << "\n enclosing_query (6,10), (7,11)\n";
while(j!=OutputList2.end()){
    std::cout << (*j).first.first.x() << "-" << (*j).first.second.x() << " "
        << (*j).first.first.y() << "-" << (*j).first.second.y() << std::endl;
    j++;
}
return 0;
}

```

46.6.2 Example for Segment Tree on Set-like Data

This example illustrates the use of the predefined segment tree on 3-dimensional interval data (with no value associated). After the definition of the traits type and tree type, some intervals are constructed and the tree is build according to the intervals. Then, a window query is performed and the query elements are given out.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<int> K;
typedef CGAL::Range_segment_tree_set_traits_3<K> Traits;
typedef CGAL::Segment_tree_3<Traits > Segment_tree_3_type;

int main()
{

```

```

typedef Traits::Interval Interval;
typedef Traits::Key Key;
std::list<Interval> InputList, OutputList;

InputList.push_back(Interval(Key(1,5,7), Key(2,7,9)));
InputList.push_back(Interval(Key(2,7,6), Key(3,8,9)));
InputList.push_back(Interval(Key(6,9,5), Key(9,13,8)));
InputList.push_back(Interval(Key(1,3,4), Key(3,9,8)));

Segment_tree_3_type Segment_tree_3(InputList.begin(),InputList.end());

Interval a(Key(3,6,5), Key(7,12,8));
Segment_tree_3.window_query(a,std::back_inserter(OutputList));
std::list<Interval>::iterator j = OutputList1.begin();
std::cout << "\n window_query (3,6,5), (7,12,8) \n";
while(j!=OutputList.end()){
    std::cout << (*j).first.x() << "," << (*j).first.y() << ",";
    std::cout << (*j).first.z() <<"," << (*j).second.x() << ",";
    std::cout << (*j).second.y() << "," << (*j).second.z() << std::endl;
    j++;
}
}

```

dD Range and Segment Trees

Reference Manual

Gabriele Neyer

This chapter presents the CGAL range tree and segment tree data structures.

The range tree is theoretically superior to the *Kd*-tree, but the latter often seems to perform better. However, the range tree as implemented in CGAL is more flexible than the *Kd*-tree implementation, in that it enables to layer together range trees and segment trees in the same data structure.

RangeSegmentTreeTraits_k

Definition

A tree traits class gives the range tree and segment tree class the necessary type information of the keys and intervals. Further more, they define function objects that allow to access the keys and intervals, and provide comparison functions that are needed for window queries.

Types

<i>RangeSegmentTreeTraits_k:: Key</i>	The k-dimensional key type.
<i>RangeSegmentTreeTraits_k:: Interval</i>	The k-dimensional interval type.
<i>RangeSegmentTreeTraits_k:: Key_i</i>	The type in dimension i , with $1 \leq i \leq k$.
<i>RangeSegmentTreeTraits_k:: key_i</i>	function object providing an <i>operator()</i> that takes an argument of type <i>Key</i> and returns a component of type <i>Key_i</i> .
<i>RangeSegmentTreeTraits_k:: low_i</i>	function object providing an <i>operator()</i> that takes an argument of type <i>Interval</i> and returns a component of type <i>Key_i</i> .
<i>RangeSegmentTreeTraits_k:: high_i</i>	function object providing an <i>operator()</i> that takes an argument of type <i>Interval</i> and returns a component of type <i>Key_i</i> .
<i>RangeSegmentTreeTraits_k:: compare_i</i>	function object providing an <i>operator()</i> that takes two arguments argument a, b of type <i>Key_i</i> and returns true if $a < b$, false otherwise.

Example

The following piece of code gives an example of how a traits class might look like, if you have keys that are of the type *int* in the first and that are of the type *double* in the second dimension.

```
class Int_double_tree_traits_2{
public:
    typedef std::pair<int, double> Key;
    typedef int Key_1;
    typedef double Key_2;
    typedef std::pair<Key,Key> Interval;

    class C_Key_1{
    public:
        Key_1 operator()(const Key& k)
        { return k.first;}
    };
    class C_Key_2{
```

```

public:
    Key_2 operator() (const Key& k)
    { return k.second;}
};
class C_Low_1{
public:
    Key_1 operator() (const Interval& i)
    { return i.first.first;}
};
class C_High_1{
public:
    Key_1 operator() (const Interval& i)
    { return i.second.first;}
};
class C_Low_2{
public:
    Key_2 operator() (const Interval& i)
    { return i.first.second;}
};
class C_High_2{
public:
    Key_2 operator() (const Interval& i)
    { return i.second.second;}
};
class C_Compare_1{
public:
    bool operator() (Key_1 k1, Key_1 k2)
    { return less<int>() (k1,k2);}
};
class C_Compare_2{
public:
    bool operator() (Key_2 k1, Key_2 k2)
    { return less<double>() (k1,k2);}
};
typedef C_Compare_1 compare_1;
typedef C_Compare_2 compare_2;
typedef C_Low_1 low_1;
typedef C_High_1 high_1;
typedef C_Key_1 key_1;
typedef C_Low_2 low_2;
typedef C_High_2 high_2;
typedef C_Key_2 key_2;
};

```

CGAL::Range_segment_tree_traits_set_2<R>

Definition

The class is a range and segment tree traits class for the 2-dimensional point class from the CGAL kernel. The class is parameterized with a representation class R .

```
#include <CGAL/Range_segment_tree_traits.h>
```

Types

```
Point_2<R>                      Key;
```

```
std::pair<Key, Key>              Interval;
```

CGAL::Range_segment_tree_traits_set_3<R>

Definition

The class is a range and segment tree traits class for the 3-dimensional point class from the CGAL kernel. The class is parameterized with a representation class R .

```
#include <CGAL/Range_segment_tree_traits.h>
```

Types

```
Point_3<R>                    Key;
```

```
std::pair<Key, Key>          Interval;
```

CGAL::Range_tree_d<Data, Window, Traits>

Types

Range_tree_d<Data, Window, Traits>::Data container *Data*.

Range_tree_d<Data, Window, Traits>::Window
container *Window*.

Range_tree_d<Data, Window, Traits>::Traits container *Traits*.

Creation

```
#include <CGAL/Range_tree_d.h>
Range_tree_d<Data, Window, Traits> r( Tree_base<Data, Window> sublayer_tree);
```

A range tree is constructed, such that the subtree of each vertex is of the same type prototype *sublayer_tree* is.

We assume that the dimension of the tree is d . This means, that *sublayer_tree* is a prototype of a $d - 1$ -dimensional tree. All data items of the d -dimensional range tree have container type *Data*. The query window of the tree has container type *Window*. *Traits* provides access to the corresponding data slots of container *Data* and *Window* for the d -th dimension. The traits class *Traits* must at least provide all functions and type definitions as described in, for example, the reference page for *tree_point_traits*. The template class described there is fully generic and should fulfill the most requirements one can have. In order to generate a one-dimensional range tree instantiate *Tree_anchor<Data, Window> sublayer_tree* with the same template parameters (*Data* and *Window*) *Range_tree_d* is defined. In order to construct a two-dimensional range tree, create *Range_tree_d* with a one-dimensional *Range_tree_d* with the corresponding *Traits* class of the first dimension.

Precondition: *Traits::Data==Data* and *Traits::Window==Window*.

Operations

```
template<class ForwardIterator>
bool r.make_tree( ForwardIterator first, ForwardIterator last)
```

The tree is constructed according to the data items in the sequence between the element pointed by iterator *first* and iterator *last*. The data items of the iterator must have type *Data*.

Precondition: This function can only be called once. If it is the first call the tree is build and *true* is returned. Otherwise, nothing is done but a *CGAL warning* is given and *false* returned.

```
template<class OutputIterator>
OutputIterator r.window_query( Window win, OutputIterator result)
```

All elements that lay inside the d -dimensional interval defined through *win* are placed in the sequence container of *OutputIterator*; the output iterator that points to the last location the function wrote to is returned.

```
bool r.is_valid()
```

The tree structure is checked. For each vertex the subtree is checked on being valid and it is checked whether the value of the *Key_type* of a vertex corresponds to the highest *Key_type* value of the left subtree.

Protected Operations

bool *r.is_inside(Window win, Data object)*

returns true, if the data of *object* lies between the start and endpoint of interval *win*. False otherwise.

bool *r.is_anchor()* returns false.

Implementation

The construction of a d -dimensional range tree takes $O(n \log n^{d-1})$ time. The points in the query window are reported in time $O(k + \log^d n)$, where k is the number of reported points. The tree uses $O(n \log n^{d-1})$ storage.

CGAL::Range_tree_k<Traits>

Definition

An object of the class is a k -dimensional range tree that can store k -dimensional keys of type *Key*. The class allows to perform window queries on the keys. The class is parameterized with a range tree traits class *Traits* that defines, among other things, the type of the *Key*.

CGAL provides traits class implementations that allow to use the range tree with point classes from the CGAL kernel as keys. These classes are *CGAL::Range_segment_tree_traits_set_2<R>*, *CGAL::Range_segment_tree_traits_set_3<R>*, *CGAL::Range_tree_traits_map_2<R>* and *CGAL::Range_tree_traits_map_3<R>*. The concept *RangeSegmentTreeTraits_d* defines the requirements that range tree traits classes must fulfill. This allows the advanced user to develop further range tree traits classes.

```
#include <CGAL/Range_tree_k.h>
```

Types

Range_tree_k<Traits>::Traits the type of the range tree traits class.

```
typedef Traits::Key Key;
```

```
typedef Traits::Interval  
Interval;
```

Creation

Range_tree_k<Traits> R; Introduces an empty range tree *R*.

```
template < class ForwardIterator >  
Range_tree_k<Traits> R( ForwardIterator first, ForwardIterator last);
```

Introduces a range tree *R* and initializes it with the data in the range *[first, last)*.
Precondition: *value_type(first) == Traits::Key*.

Operations

```
template < class ForwardIterator >  
void R.make_tree( ForwardIterator first, ForwardIterator last)
```

Introduces a range tree *R* and initializes it with the data in the range *[first, last)*. This function can only be applied once on an empty range tree.
Precondition: *value_type(first) == Traits::Key*.

```
template < class OutputIterator >
OutputIterator      R.window_query( Interval window, OutputIterator out)
```

writes all data that are in the interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.

Precondition: `value_type(out) == Traits::Key`.

Example

The following example program uses the predefined *Range_tree_2* data structure together with the predefined traits class *Range_tree_map_traits_2* which has two template arguments specifying the type of the point data in each dimension (*CGAL::Cartesian<double>*) and the value type of the 2-dimensional point data (*char*). Therefore the *Range_tree_2* is defined on 2-dimensional point data (*CGAL::Point_2<Cartesian<double> >*) each of which is associated with a character. Then, a few data items are created and put into a list. After that the tree is constructed according to that list, a window query is performed, and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Range_segment_tree_traits.h>
#include <CGAL/Range_tree_k.h>

typedef CGAL::Cartesian<double> K;
typedef CGAL::Range_tree_map_traits_2<K, char> Traits;
typedef CGAL::Range_tree_2<Traits> Range_tree_2_type;

int main()
{
    typedef Traits::Key Key;
    typedef Traits::Interval Interval;

    std::vector<Key> InputList, OutputList;
    InputList.push_back(Key(K::Point_2(8,5.1), 'a'));
    InputList.push_back(Key(K::Point_2(1,1.1), 'b'));
    InputList.push_back(Key(K::Point_2(3,2.1), 'c'));

    Range_tree_2_type Range_tree_2(InputList.begin(), InputList.end());
    Interval win(Interval(K::Point_2(4,8.1), K::Point_2(5,8.2)));
    std::cout << "\n Window Query:\n ";
    Range_tree_2.window_query(win, std::back_inserter(OutputList));
    std::vector<Key>::iterator current=OutputList.begin();
    while(current!=OutputList.end()) {
        std::cout << (*current).first.x() << "," << (*current).first.y()
            << ":" << (*current++).second << std::endl;
    }
}
```

CGAL::Range_tree_traits_map_2<R,T>

Definition

The class is a range tree traits class for the 2-dimensional point class from the CGAL kernel, where data of type T is associated to each key. The class is parameterized with a representation class R and the type of the associated data T .

```
#include <CGAL/Range_segment_tree_traits.h>
```

Types

```
std::pair<R::Point_2,T>
```

```
Key;
```

```
std::pair<R::Point_2, R::Point_2 >
```

```
Interval;
```

CGAL::Range_tree_traits_map_3<R,T>

Definition

The class is a range and segment tree traits class for the 3-dimensional point class from the CGAL kernel, where data of type T is associated to each key. The class is parameterized with a representation class R and the type of the associated data T .

```
#include <CGAL/Range_segment_tree_traits.h>
```

Types

```
std::pair<R::Point_3,T>
```

```
Key;
```

```
std::pair<R::Point_3, R::Point_3>
```

```
Interval;
```

CGAL::Segment_tree_d<Data, Window, Traits>

Types

Segment_tree_d<*Data*, *Window*, *Traits*>::*Data*

container *Data*.

Segment_tree_d<*Data*, *Window*, *Traits*>::*Window*

container *Window*.

Segment_tree_d<*Data*, *Window*, *Traits*>::*Traits*

class *Traits*.

Creation

```
#include <CGAL/Segment_tree_d.h>
```

```
Segment_tree_d<Data, Window, Traits> s( Tree_base<Data, Window> sublayer_tree);
```

A segment tree is defined, such that the subtree of each vertex is of the same type prototype *sublayer_tree* is.

We assume that the dimension of the tree is d . This means, that *sublayer_tree* is a prototype of a $d - 1$ -dimensional tree. All data items of the d -dimensional segment tree have container type *Data*. The query window of the tree has container type *Window*. *Traits* provides access to the corresponding data slots of container *Data* and *Window* for the d -th dimension. The traits class *Traits* must at least provide all functions and type definitions described, for example, in the reference page for *tree_point_traits*. The template class described there is fully generic and should fulfill the most requirements one can have. In order to generate a one-dimensional segment tree instantiate *Tree_anchor*<*Data*, *Window*> *sublayer_tree* with the same template parameters *Data* and *Window* *Segment_tree_d* is defined. In order to construct a two-dimensional segment tree, create *Segment_tree_d* with a one-dimensional *Segment_tree_d* with the corresponding *Traits* of the first dimension.

Precondition: *Traits*::*Data*==*Data* and *Traits*::*Window*==*Window*.

Operations

bool *s.make_tree(In_it first, In_it last)*

The tree is constructed according to the data items in the sequence between the element pointed by iterator *first* and iterator *last*.

Precondition: This function can only be called once. If it is the first call the tree is build and *true* is returned. Otherwise, nothing is done but a *CGAL warning* is given and *false* returned.

OutputIterator *s.window_query(Window win, OutputIterator result)*

$win = [a_1, b_1), \dots, [a_d, b_d), a_i, b_i \in T_i, 1 \leq i \leq d$. All elements that intersect the associated d -dimensional interval of *win* are placed in the associated sequence container of *OutputIterator* and returns an output iterator that points to the last location the function wrote to. In order to perform an inverse range query, a range query of ϵ width has to be performed.

OutputIterator *s.enclosing_query(Window win, OutputIterator result)*

All elements that enclose the associated d -dimensional interval of *win* are placed in the associated sequence container of *OutputIterator* and returns an output iterator that points to the last location the function wrote to.

bool *s.is_valid()*

The tree structure is checked. For each vertex either the sublayer tree is a tree anchor, or it stores a (possibly empty) list of data items. In the first case, the sublayer tree of the vertex is checked on being valid. In the second case, each data item is checked weather it contains the associated interval of the vertex and does not contain the associated interval of the parent vertex or not. True is returned if the tree structure is valid, false otherwise.

Protected Operations

bool *s.is_inside(Window win, Data object)*

returns true, if the interval of *object* is contained in the interval of *win*. False otherwise.

bool *s.is_anchor()* returns false.

Implementation

A d -dimensional segment tree is constructed in $O(n \log n^d)$ time. An inverse range query is performed in time $O(k + \log^d n)$, where k is the number of reported intervals. The tree uses $O(n \log n^d)$ storage.

CGAL::Segment_tree_k<Traits>

Definition

An object of the class is a k -dimensional segment tree that can store k -dimensional intervals of type *Interval*. The class allows to perform window queries, enclosing queries, and inverse range queries on the keys. The class is parameterized with a segment tree traits class *Traits* that defines, among other things, the type of the *Interval*. In order to perform an inverse range query, a range query of ε width has to be performed. We preferred not to offer an extra function for this sort of query, since the inverse range query is a special case of the range query. Furthermore, offering an inverse range query in the segment tree class implies offering this function also in the range tree class and having an extra item in the traits class that accesses the inverse range query point.

CGAL provides traits class implementations that allow to use the segment tree with point classes from the CGAL kernel as keys. These classes are *CGAL::Range_segment_tree_traits_set_2<R>*, *CGAL::Range_segment_tree_traits_set_3<R>*, *CGAL::Segment_tree_traits_map_2<R>* and *CGAL::Segment_tree_traits_map_3<R>*. The concept *RangeSegmentTreeTraits_d* defines the requirements that segment tree traits classes must fulfill. This allows the advanced user to develop further segment tree traits classes.

```
#include <CGAL/Segment_tree_k.h>
```

Types

Segment_tree_k<Traits>::Traits the type of the segment tree traits class.

```
typedef Traits::Key      Key;
```

```
typedef Traits::Interval  
                        Interval;
```

Creation

Segment_tree_k<Traits> S; Introduces an empty segment tree S .

```
template < class ForwardIterator >  
Segment_tree_k<Traits> S( ForwardIterator first, ForwardIterator last);
```

Introduces a segment tree S and initializes it with the data in the range $[first, last)$.
Precondition: $value_type(first) == Traits::Interval$.

Operations

```
template < class ForwardIterator >  
void S.make_tree( ForwardIterator first, ForwardIterator last)
```

Introduces a segment tree S and initializes it with the data in the range $[first, last)$. This function can only be applied once on an empty segment tree.
Precondition: $value_type(first) == Traits::Interval$.

```
template < class OutputIterator >
OutputIterator      S.window_query( Interval window, OutputIterator out)
```

writes all intervals that have non empty intersection with interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.

Precondition: `value_type(out) == Traits::Interval`.

```
template < class OutputIterator >
OutputIterator      S.enclosing_query( Interval window, OutputIterator out)
```

writes all intervals that enclose in the interval *window* to the container where *out* points to, and returns an output iterator that points to the last location the function wrote to.

Precondition: `value_type(out) == Traits::Interval`.

Example

This example illustrates the use of the predefined segment tree on 3-dimensional interval data (with no value associated). After the definition of the traits type and tree type, some intervals are constructed and the tree is build according to the intervals. Then, a window query is performed and the query elements are given out.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Segment_tree_k.h>
#include <CGAL/Range_segment_tree_traits.h>

typedef CGAL::Cartesian<int> K;
typedef CGAL::Range_segment_tree_set_traits_3<K> Traits;
typedef CGAL::Segment_tree_3<Traits> Segment_tree_3_type;

int main()
{
    typedef Traits::Interval Interval;
    typedef Traits::Key Key;
    std::list<Interval> InputList, OutputList;

    InputList.push_back(Interval(Key(1,5,7), Key(2,7,9)));
    InputList.push_back(Interval(Key(2,7,6), Key(3,8,9)));
    InputList.push_back(Interval(Key(6,9,5), Key(9,13,8)));
    InputList.push_back(Interval(Key(1,3,4), Key(3,9,8)));

    Segment_tree_3_type Segment_tree_3(InputList.begin(),InputList.end());

    Interval a(Key(3,6,5), Key(7,12,8));
    Segment_tree_3.window_query(a,std::back_inserter(OutputList));
    std::list<Interval>::iterator j = OutputList1.begin();
    std::cout << "\n window_query (3,6,5), (7,12,8) \n";
    while(j!=OutputList.end()){
        std::cout << (*j).first.x() << "," << (*j).first.y() << ",";
        std::cout << (*j).first.z() <<"," << (*j).second.x() << ",";
        std::cout << (*j).second.y() << "," << (*j).second.z() << std::endl;
    }
```

```
        j++;  
    }  
}
```

CGAL::Segment_tree_traits_map_2<R,T>

Definition

The class is a segment tree traits class for the 2-dimensional point class from the CGAL kernel, where data of type T is associated to each interval. The class is parameterized with a representation class R and the type of the associated data T .

```
#include <CGAL/Range_segment_tree_traits.h>
```

Types

```
R::Point_2          Key;
```

```
std::pair<std::pair<Key,Key>,T>
```

```
Interval;
```

CGAL::Segment_tree_traits_map_3<R,T>

Definition

The class is a segment tree traits class for the 3-dimensional point class from the CGAL kernel, where data of type T is associated to each interval. The class is parameterized with a representation class R and the type of the associated data T .

```
#include <CGAL/Range_segment_tree_traits.h>
```

Types

```
std::pair<R::Point_3 >
```

```
Key;
```

```
std::pair<std::pair<Key, Key>, T>
```

```
Interval;
```

Sublayer

Definition

Defines the requirements that a *Sublayer_type* of class *Range_tree_d* or *Segment_tree_d* has to fulfill.

First of all, the class has to be derived from the abstract base class *Tree_base* and therefore has to provide methods *make_tree*, *window_query*, *enclosing_query* and *is_inside* with the same parameter types as the instantiated class *Range_tree_d* or *Segment_tree_d*, respectively. Furthermore a method *bool is_anchor()* has to be provided. If the *Sublayer_type* class builds a recursion anchor for class *Segment_tree_d*, this function is expected to return *true*, *false* otherwise.

Such a recursion anchor class is provided by the class class. *Tree_anchor<Data, Window>*.

CGAL::tree_interval_traits

Definition

tree_interval_traits is a template class that provides an interface to data items. It is similar to *tree_point_traits*, except that it provides access to two data slots of the same type of each container class (*Data*, *Window*) instead of providing access to one data slot of container class *Data* and two data slots of class *Window*.

```
#include <CGAL/Tree_traits.h>
```

Types

```
typedef
tree_interval_traits<Data, Window, Key, Data_left_func, Data_right_func, Window_left_func, Window_right_func, Compare> Interval_traits;
```

tree_interval_traits::Data the container *Data* — the data type. It may consist of several data slots. Two of these data slots have to be of type *Key*.

tree_interval_traits::Window the container *Window* — the query window type. It may consist of several data slots. Two of these data slots have to be of type *Key*.

tree_interval_traits::Key the type *Key* of the data slot this traits class provides access to.

tree_interval_traits::Data_left_func *Data_left_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a (the left) component of type *Key*.

tree_interval_traits::Data_right_func *Data_right_func* is a function object providing an *operator()* that takes an argument of type *Data* and returns a (the right) component of type *Key*.

tree_interval_traits::Window_left_func *Window_left_func* is a function objects that allow to access the left data slot of container *Window* which has type *Key*

tree_interval_traits::Window_right_func *Window_right_func* is a function objects that allow to access the right data slot of container *Window* which has type *Key*

tree_interval_traits::Compare defines a comparison relation which must define a strict ordering of the objects of type *Key*. If defined, *less<Key>* is sufficient.

Creation

```
tree_interval_traits<Data, Window, Key, Data_left_func, Data_right_func, Window_left_func, Window_right_func, Compare> d();
```

Generation of a *tree_point_traits* instance. It is a template class that provides an interface to data items.

Operations

<i>Key</i>	<i>d.get_left(Data d)</i>	The data slot of the data item of <i>d</i> of type <i>Key</i> is accessed by function object <i>Data_left_func</i> .
<i>Key</i>	<i>d.get_right(Data d)</i>	The data slot of the data item of <i>d</i> of type <i>Key</i> is accessed by function object <i>Data_right_func</i> .
<i>Key</i>	<i>d.get_left_win(Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_left_func</i> .
<i>Key</i>	<i>d.get_right_win(Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_right_func</i> .
<i>bool</i>	<i>d.comp(Key& key1, Key& key2)</i>	returns Compare(key1, key2).

CGAL::tree_point_traits

Definition

tree_point_traits is a template class that provides an interface to data items.

```
#include <CGAL/Tree_traits.h>
```

Types

typedef

```
tree_point_traits<Data, Window, Key, Data_func, Window_left_func, Window_right_func, Compare> Point_traits;
```

tree_point_traits::Data

the container *Data* — defines the *Data* type. It may consist of several data slots. One of these data slots has to be of type *Key*.

tree_point_traits::Window

the container *Window* — defines the type of the query rectangle. It may consist of several data slots. Two of these data slots has to be of type *Key*

tree_point_traits::Key

the type *Key* of the data slot this traits class provides access to.

tree_point_traits::Data_func

Data_func is a function object providing an *operator()* that takes an argument of type *Data* and returns a component of type *Key*.

tree_point_traits::Window_left_func

Window_left_func is a function objects that allow to access the left data slot of container *Window* which has type *Key*

tree_point_traits::Window_right_func

Window_right_func is a function objects that allow to access the right data slot of container *Window* which has type *Key*

tree_point_traits::Compare

defines a comparison relation which must define a strict ordering of the objects of type *Key*. If defined, *less*<*Key*> is sufficient.

Creation

```
tree_point_traits<Data, Window, Key, Data_func, Window_left_func, Window_right_func, Compare> d();
```

Generation of a *tree_point_traits* instance. It is a template class that provides an interface to data items.

Operations

<i>Key</i>	<i>d.get_key(Data d)</i>	The data slot of the data item of <i>d</i> of type <i>Key</i> is accessed by function object <i>Data_func</i> .
<i>Key</i>	<i>d.get_left(Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_left_func</i> .
<i>Key</i>	<i>d.get_right(Window w)</i>	The data slot of the data item of <i>w</i> of type <i>Key</i> is accessed by function object <i>Window_right_func</i> .
<i>bool</i>	<i>d.comp(Key& key1, Key& key2)</i>	returns <i>Compare(key1, key2)</i> .
<i>bool</i>	<i>d.key_comp(Data& data1, Data& data2)</i>	returns <i>Compare(get_key(data1), get_key(data2))</i> .

Definition

Tree_anchor is also derived from *Tree_base*. Therefore, it provides the same methods as *Range_tree_d* and *Segment_tree_d*, but does nothing; it can be used as a recursion anchor for those classes. Therefore, instantiate *Sublayer_type* of *Range_tree_d* (*Segment_tree_d* respectively) with *Tree_anchor* and the container classes for the data items (*Data* and *Window*).

Definition

Tree_anchor<Data, Window>::Data container *Data*.

Tree_anchor<*Data*, *Window*>:: *Window* container *Window*.

Creation

```
#include <CGAL/Tree_base.h>
```

```
Tree_anchor<Data, Window> a;
```

Operations

```
template<class OutputIterator>
OutputIterator      a.window_query( Window win, OutputIterator result)
```

```
template<class OutputIterator>
OutputIterator      a.enclosing_query( Window win, OutputIterator result)
```

<i>bool</i>	<i>a.is_valid()</i>	returns true;
-------------	---------------------	---------------

Protected Operations

bool *a.is_inside(Window win, Data object)*

returns true.

bool *a.is_anchor()* returns true.

Example

The following figures show a number of rectangles and a 2-dimensional segment tree built on them.

Figure 46.6: Two dimensional interval data.

47.1 Introduction

Simple questions on geometric primitives, such as intersection and distance computations, can themselves become quite expensive if the primitives are not so simple anymore, for example, three-dimensional triangles and facets of polyhedral surfaces. Thus algorithms operating on these primitives tend to be slow in practice. A common (heuristic) optimization approximates the geometric primitives with their axis-aligned bounding boxes, runs a suitable modification of the algorithm on the boxes, and whenever a pair of boxes has an interesting interaction¹, only then the exact answer is computed on the complicated geometric primitives contained in the boxes.

We provide an efficient algorithm [ZE02] for finding all intersecting pairs for large numbers of iso-oriented boxes, i.e., typically these will be such bounding boxes of more complicated geometries. One immediate application of this algorithm is the detection of all intersections (and self-intersections) for polyhedral surfaces,

¹Boxes represent volumes or point-sets. So, *intersection* means intersection of the point-set enclosed by the box and not only intersection of the boundary, of course.

i.e., applying the algorithm on a large set of triangles in space, we give an example program later in this chapter. Not so obvious applications are proximity queries and distance computations among such surfaces, see Section 47.10 for an example and [ZE02] for more details.

47.2 Definition

A d -dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \mid 0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \mid 0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed and half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the two possible values for the *topology* parameter:

- `CGAL::Box_intersection_d::HALF_OPEN` and
- `CGAL::Box_intersection_d::CLOSED`.

The number type of the interval boundaries must be one of the built-in types `int`, `unsigned int`, `double` or `float`.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. Note that boxes with equal *id*-number are not reported since they obviously intersect trivially.

The box intersection algorithm comes in two flavors: One algorithm works on a single sequence of boxes and computes all pairwise intersections, which is called the *complete* case, and used, for example, in the self-intersection test. The other algorithm works on two sequences of boxes and computes the pairwise intersections between boxes from the first sequence with boxes from the second sequence, which is called the *bipartite* case. For each pairwise intersection found a callback function is called with two arguments; the first argument is a box from the first sequence and the second argument a box from the second sequence. In the complete case, the second argument is a box from an internal copy of the first sequence.

47.3 Software Design

The box intersection algorithm is implemented as a family of generic functions; the functions for the complete case accept one iterator range, and the functions for the bipartite case accept two iterator ranges. The callback function for reporting the intersecting pairs is provided as a template parameter of the *BinaryFunction* concept. The two principle function calls utilizing all default arguments look as follows:

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator, class Callback >
void    box_intersection_d( RandomAccessIterator begin, RandomAccessIterator end, Callback callback)
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
```

```
void    box_intersection_d( RandomAccessIterator1 begin1,
                          RandomAccessIterator1 end1,
                          RandomAccessIterator2 begin2,
                          RandomAccessIterator2 end2,
                          Callback callback)
```

Additional parameters to the functions calls are a *cutoff* value to adjust performance trade-offs, and a *topology* parameter selecting between topologically closed boxes (the default) and topologically half-open boxes.

The algorithm reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value_type* of the iterator ranges *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type; these choices represent both options from above.

In general, the algorithms treat the box type as opaque type and just assume that they are models of the *Assignable* concept, so that the algorithms can modify the input sequences and reorder the boxes. The access to the box dimension and box coordinates is mediated with a traits class of the *BoxIntersectionTraits_d* concept. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type (see the previous paragraph for the value versus pointer nature of the box handle).

Two implementations of iso-oriented boxes are provided; *CGAL::Box_intersection_d::Box_d* as a plain box, and *CGAL::Box_intersection_d::Box_with_handle_d* as a box plus a handle that can be used to point to the full geometry that is approximated by the box. Both implementations have template parameters for the number type used for the interval bounds, for the fixed dimension of the box, and for a policy class [Ale01] selecting among several solutions for providing the *id*-number.

The function signatures for the bipartite case look as follows. The signatures for the complete case with the *box_self_intersection_d* function look the same except for the single iterator range.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void    box_intersection_d( RandomAccessIterator1 begin1,
                          RandomAccessIterator1 end1,
                          RandomAccessIterator2 begin2,
                          RandomAccessIterator2 end2,
                          Callback callback,
                          std::ptrdiff_t cutoff = 10,
                          Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
                          Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback, class BoxTraits >
void    box_intersection_d( RandomAccessIterator1 begin1,
                          RandomAccessIterator1 end1,
                          RandomAccessIterator2 begin2,
                          RandomAccessIterator2 end2,
                          Callback callback,
                          BoxTraits box_traits,
                          std::ptrdiff_t cutoff = 10,
                          Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
                          Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)
```

47.4 Minimal Example for Intersecting Boxes

The box implementation provided with `CGAL::Box_intersection_d::Box_d<double,2>` has a dedicated constructor for the CGAL bounding box type `CGAL::Bbox_2` (similar for dimension 3). We use this in our minimal example to create easily nine two-dimensional *boxes* in a grid layout of 3×3 boxes. Additionally we pick the center box and the box in the upper-right corner as our second box sequence *query*.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works, but it costs space that could potentially be avoided, see the example in the next section. We use the *id*-number in our callback function to report the result of the intersection algorithm. The result will be that the first *query* box intersects all nine *boxes* and the second *query* box intersects the four boxes in the upper-right quadrant. See Section 47.7 for the change of the *topology* parameter and its effect.

```
#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2 Bbox;

// 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), // middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)}; // upper
// 2 selected boxes as query; center and upper right
Box query[2] = { Bbox( 1,1,2,2), Bbox( 2,2,3,3)};

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() << std::endl;
}

int main() {
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2, callback);
    return 0;
}
```

File: examples/Box_intersection_d/minimal.cpp

47.5 Example for Finding Intersecting 3D Triangles

The conventional application of the axis-aligned box intersection algorithm will start from complex geometry, here 3D triangles, approximate them with their bounding box, compute the intersecting pairs of boxes, and check only for those if the original triangles intersect as well.

We start in the *main* function and create ten triangles with endpoints chosen randomly in a cube $[-1, +1]^3$. We store the triangles in a vector called *triangles*.

Next we create a vector for the bounding boxes of the triangles called *boxes*. For the boxes we choose the type `Box_with_handle_d<double,3,Iterator>` that works nicely together with the CGAL bounding boxes of type `CGAL::Bbox_3`. In addition, each box stores the iterator to the corresponding triangle.

The default policy of this box type uses for the *id*-number the address of the value of the iterator, i.e., the address of the triangle. This is a good choice that works correctly iff the boxes have unique iterators, i.e., there is a one-

to-one mapping between boxes and approximated geometry, which is the case here. It saves us the extra space that was needed for the explicit *id*-number in the previous example.

We run the self intersection algorithm with the *report_inters* function as callback. This callback reports the intersecting boxes. It uses the *handle* and the global *triangles* vector to calculate the triangle numbers. Then it checks the triangles themselves for intersection and reports if not only the boxes but also the triangles intersect. We take some precautions before the intersection test in order to avoid problems, although unlikely, with degenerate triangles that we might have created with the random process.

This example can be easily extended to test polyhedral surfaces of the *Polyhedron_3* class for (self-) intersections. The main difference are the numerous cases of incidences between triangles in the polyhedral surface that should not be reported as intersections, see the examples/Polyhedron/polyhedron_self_intersection.cpp example program in the CGAL distribution.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Bbox_3.h>
#include <CGAL/box_intersection_d.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/copy_n.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel    Kernel;
typedef Kernel::Point_3                                         Point_3;
typedef Kernel::Triangle_3                                       Triangle_3;
typedef std::vector<Triangle_3>                                  Triangles;
typedef Triangles::iterator                                       Iterator;
typedef CGAL::Box_intersection_d::Box_with_handle_d<double,3,Iterator> Box;

Triangles triangles; // global vector of all triangles

// callback function that reports all truly intersecting triangles
void report_inters( const Box& a, const Box& b) {
    std::cout << "Box " << (a.handle() - triangles.begin()) << " and "
                << (b.handle() - triangles.begin()) << " intersect";
    if ( ! a.handle()->is_degenerate() && ! b.handle()->is_degenerate()
        && CGAL::do_intersect( *(a.handle()), *(b.handle()) ) ) {
        std::cout << ", and the triangles intersect also";
    }
    std::cout << ' ' << std::endl;
}

int main() {
    // Create 10 random triangles
    typedef CGAL::Random_points_in_cube_3<Point_3>              Pts;
    typedef CGAL::Creator_uniform_3< Point_3, Triangle_3>       Creator;
    typedef CGAL::Join_input_iterator_3<Pts,Pts,Pts,Creator>    Triangle_gen;
    Pts    points( 1); // in centered cube [-1,1]^3
    Triangle_gen triangle_gen( points, points, points);
    CGAL::copy_n( triangle_gen, 10, std::back_inserter(triangles));
```

```

// Create the corresponding vector of bounding boxes
std::vector<Box> boxes;
for ( Iterator i = triangles.begin(); i != triangles.end(); ++i)
    boxes.push_back( Box( i->bbox(), i));

// Run the self intersection algorithm with all defaults
CGAL::box_self_intersection_d( boxes.begin(), boxes.end(), report_inters);
return 0;
}

```

File: examples/Box_intersection_d/triangle_self_intersect.cpp

47.6 Example for Using Pointers to Boxes

We modify the previous example, finding intersecting 3D triangles, and add an additional vector *ptr* that stores pointers to the bounding boxes, so that the intersection algorithm will work on a sequence of pointers and not on a sequence of boxes. The change just affects the preparation of the additional vector and the call of the box intersection function. The box intersection function (actually its default traits class) detects automatically that the value type of the iterators is a pointer type and not a class type.

```

// Create the corresponding vector of pointers to bounding boxes
std::vector<Box *> ptr;
for ( std::vector<Box>::iterator i = boxes.begin(); i != boxes.end(); ++i)
    ptr.push_back( &*i);

// Run the self intersection algorithm with all defaults on the
// indirect pointers to bounding boxes. Avoids copying the boxes.
CGAL::box_self_intersection_d( ptr.begin(), ptr.end(), report_inters);

```

In addition, the callback function *report_inters* needs to be changed to work with pointers to boxes. The full example program looks as follows:

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/intersections.h>
#include <CGAL/point_generators_3.h>
#include <CGAL/Bbox_3.h>
#include <CGAL/box_intersection_d.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/copy_n.h>
#include <vector>

typedef CGAL::Exact_predicates_inexact_constructions_kernel    Kernel;
typedef Kernel::Point_3                                         Point_3;
typedef Kernel::Triangle_3                                       Triangle_3;
typedef std::vector<Triangle_3>                                   Triangles;
typedef Triangles::iterator                                     Iterator;
typedef CGAL::Box_intersection_d::Box_with_handle_d<double,3,Iterator> Box;

```

```

Triangles triangles; // global vector of all triangles

// callback function that reports all truly intersecting triangles
void report_inters( const Box* a, const Box* b) {
    std::cout << "Box " << (a->handle() - triangles.begin()) << " and "
        << (b->handle() - triangles.begin()) << " intersect";
    if ( ! a->handle()->is_degenerate() && ! b->handle()->is_degenerate()
        && CGAL::do_intersect( *(a->handle()), *(b->handle())) ) {
        std::cout << ", and the triangles intersect also";
    }
    std::cout << ' ' << std::endl;
}

int main() {
    // Create 10 random triangles
    typedef CGAL::Random_points_in_cube_3<Point_3>          Pts;
    typedef CGAL::Creator_uniform_3< Point_3, Triangle_3>    Creator;
    typedef CGAL::Join_input_iterator_3<Pts,Pts,Pts,Creator> Triangle_gen;
    Pts    points( 1); // in centered cube [-1,1]^3
    Triangle_gen triangle_gen( points, points, points);
    CGAL::copy_n( triangle_gen, 10, std::back_inserter(triangles));

    // Create the corresponding vector of bounding boxes
    std::vector<Box> boxes;
    for ( Iterator i = triangles.begin(); i != triangles.end(); ++i)
        boxes.push_back( Box( i->bbox(), i));

    // Create the corresponding vector of pointers to bounding boxes
    std::vector<Box *> ptr;
    for ( std::vector<Box>::iterator i = boxes.begin(); i != boxes.end(); ++i)
        ptr.push_back( &*i);

    // Run the self intersection algorithm with all defaults on the
    // indirect pointers to bounding boxes. Avoids copying the boxes.
    CGAL::box_self_intersection_d( ptr.begin(), ptr.end(), report_inters);
    return 0;
}

```

File: examples/Box_intersection_d/triangle_self_intersect_pointers.cpp

A note on performance: The algorithm sorts and partitions the input sequences. It is clearly costly to copy a large box compared to a simple pointer. However, the algorithm benefits from memory locality in the later stages when it copies the boxes, while the pointers would refer to boxes that become wildly scattered in memory. These two effects, copying costs and memory locality, counteract each other. For small box sizes, i.e., small dimension, memory locality wins and one should work with boxes, while for larger box sizes one should work with pointers. The exact threshold depends on the memory hierarchy (caching) of the hardware platform and the size of the boxes, most notably the type used to represent the box coordinates. A concrete example; on a laptop with an Intel Mobile Pentium4 running at 1.80GHz with 512KB cache and 254MB main memory under Linux this version with pointers was 20% faster than the version above that copies the boxes for 10000 boxes, but the picture reversed for 100000 boxes, where the version above that copies the boxes becomes 300% faster.

Note that switching to the built-in type *float* is supported by the box intersection algorithm, but the interfacing with the CGAL bounding box *CGAL::Bbox_3* would not be that easy. In particular, just converting from the

double to the *float* representation incurs rounding that needs to be controlled properly, otherwise the box might shrink and one might miss intersections.

47.7 Example Using the *topology* and the *cutoff* Parameters

Boxes can be interpreted by the box intersection algorithm as closed or as half-open boxes, see also Section 47.2. Closed boxes support zero-width boxes and they can intersect at their boundaries, while half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The choice between closed or half-open boxes is selected with the *topology* parameter and its two values:

- `CGAL::Box_intersection_d::HALF_OPEN` and
- `CGAL::Box_intersection_d::CLOSED`.

The example program uses a two-dimensional box with *int* coordinates and *id*-numbers that are by default explicitly stored. We create the same boxes as in the minimal example in Section 47.4. We create a 3×3 grid of *boxes*, and two boxes for the *query* sequence, namely the box at the center and the box from the upper-right corner of the grid.

We write a more involved callback function object *Report* that stores an output iterator and writes the *id*-number of the box in the first argument to the output iterator. We also provide a small helper function *report* that simplifies the use of the function object.

We call the box intersection algorithm twice; once for the default *topology*, which is the closed box topology, and once for the half-open box topology. We sort the resulting output for better readability and verify its correctness with the *check1* and *check2* data. For the closed box topology, the center box in *query* intersects all *boxes*, and the upper-right box in *query* intersects the four boxes of the upper-right quadrant in *boxes*. Almost all intersections are with the box boundaries, thus, for the half-open topology only one intersection remains per *query* box, namely its corresponding box in *boxes*. So, the output of the algorithm will be:

```
0 1 2 3 4 4 5 5 6 7 7 8 8
4 8
```

For the second box intersection function call we have to specify the *cutoff* parameter explicitly. See the Section 47.8 below for a detailed discussion.

```
#include <CGAL/box_intersection_d.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <assert.h>

typedef CGAL::Box_intersection_d::Box_d<int,2> Box;

// coordinates for 9 boxes of a grid
int p[9*4] = { 0,0,1,1, 1,0,2,1, 2,0,3,1, // lower
               0,1,1,2, 1,1,2,2, 2,1,3,2, // middle
               0,2,1,3, 1,2,2,3, 2,2,3,3}; // upper

// 9 boxes
```

```

Box boxes[9] = { Box( p,    p+ 2),  Box( p+ 4, p+ 6),  Box( p+ 8, p+10),
                Box( p+12, p+14),  Box( p+16, p+18),  Box( p+20, p+22),
                Box( p+24, p+26),  Box( p+28, p+30),  Box( p+32, p+34)};
// 2 selected boxes as query; center and upper right
Box query[2] = { Box( p+16, p+18),  Box( p+32, p+34)};

// callback function object writing results to an output iterator
template <class OutputIterator>
struct Report {
    OutputIterator it;
    Report( OutputIterator i) : it(i) {} // store iterator in object
    // We write the id-number of box a to the output iterator assuming
    // that box b (the query box) is not interesting in the result.
    void operator()( const Box& a, const Box&) { *it++ = a.id(); }
};

template <class Iter> // helper function to create the function object
Report<Iter> report( Iter it) { return Report<Iter>(it); }

int main() {
    // run the intersection algorithm and store results in a vector
    std::vector<std::size_t> result;
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2,
                             report( std::back_inserter( result)));
    // sort, check, and show result
    std::sort( result.begin(), result.end());
    std::size_t check1[13] = {0,1,2,3,4,4,5,5,6,7,7,8,8};
    assert(result.size() == 13 && std::equal(check1,check1+13,result.begin()));
    std::copy( result.begin(), result.end(),
               std::ostream_iterator<std::size_t>( std::cout, " "));
    std::cout << std::endl;

    // run it again but for different cutoff value and half-open boxes
    result.clear();
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2,
                             report( std::back_inserter( result)),
                             std::ptrdiff_t(1),
                             CGAL::Box_intersection_d::HALF_OPEN);
    // sort, check, and show result
    std::sort( result.begin(), result.end());
    std::size_t check2[2] = {4,8};
    assert(result.size() == 2 && std::equal(check2, check2+2, result.begin()));
    std::copy( result.begin(), result.end(),
               std::ostream_iterator<std::size_t>( std::cout, " "));
    std::cout << std::endl;
    return 0;
}

```

File: examples/Box_intersection_d/box_grid.cpp

47.8 Runtime Performance

The implemented algorithm is described in [ZE02] as version two. Its performance depends on a *cutoff* parameter. When the size of both iterator ranges drops below the *cutoff* parameter the function switches from the streamed segment-tree algorithm to the two-way-scan algorithm, see [ZE02] for the details.

The streamed segment-tree algorithm needs $O(n \log^d(n) + k)$ worst-case running time and $O(n)$ space, where n is the number of boxes in both input sequences, d the (constant) dimension of the boxes, and k the output complexity, i.e., the number of pairwise intersections of the boxes. The two-way-scan algorithm needs $O(n \log(n) + l)$ worst-case running time and $O(n)$ space, where l is the number of pairwise overlapping intervals in one dimensions (the dimension where the algorithm is used instead of the segment tree). Note that l is not necessarily related to k and using the two-way-scan algorithm is a heuristic.

Unfortunately, we have no general method to automatically determine an optimal cutoff parameter, since it depends on the used hardware, the runtime ratio between callback runtime and segment-tree runtime, and of course the number of boxes to be checked and their distribution. In cases where the callback runtime is dominant, it may be best to make the threshold parameter small. Otherwise a *cutoff* = \sqrt{n} can lead to acceptable results. For well distributed boxes the original paper [ZE02] gives optimal cutoffs in the thousands. Anyway, for optimal runtime some experiments to compare different cutoff parameters are recommended.

To demonstrate that box intersection can be done quite fast, different box sequences are intersected in the range between 4 and 800000 boxes total. We use three-dimensional default boxes of closed topology with *float* coordinates and without additional data fields. The algorithm works directly on the boxes, not on pointer to boxes. Each box intersection is reported to an empty dummy callback.

For each box set, a near-optimal cutoff parameter is determined using an adaptive approximation. The runtime required for streaming is compared against usual scanning. Results on a Xeon 2.4GHz with 4GB main memory can be seen in Figure 47.1. For a small number of boxes, pure scanning is still faster than streaming with optimal cutoff, which would just delegate the box sets to the scanning algorithm. As there are more and more boxes, the overhead becomes less important.

Figure 47.1: Runtime comparison between the scanning and the streaming algorithm.

47.9 Example Using a Custom Box Implementation

The example in the previous Section 47.7 uses an array to provide the coordinates and then creates another array for the boxes. In the following example we write our own box class *Box* that we can initialize directly with the four coordinates and create the array of boxes directly. We also omit the explicitly stored *id*-number and use the address of the box itself as *id*-number. This works only if the boxes do not change their position, i.e., we work with pointers to the boxes in the intersection algorithm.

We follow with our own box class *Box* the *BoxIntersectionBox_d* concept, which allows us to reuse the default traits implementation, i.e., we can use the same default function call to compute all intersections. See the example in the next section for a self-written traits class. So, in principle, the remainder of the example stays the same and we omit the part from the previous example for brevity that illustrates the half-open box topology.

The requirements for the box implementation are best studied on page 2643 in the Reference Manual. In a nutshell, we have to define the type *NT* for the box coordinates and the type *ID* for the *id*-number. Member functions give access to the coordinates and the *id*-number. A static member function returns the dimension.

```
#include <CGAL/box_intersection_d.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <assert.h>

struct Box {
    typedef int NT;
    typedef std::ptrdiff_t ID;
    int x[2], y[2];
    Box( int x0, int x1, int y0, int y1) { x[0]=x0; x[1]=x1; y[0]=y0; y[1]=y1; }
    static int dimension() { return 2; }
    int min_coord(int dim) const { return x[dim]; }
    int max_coord(int dim) const { return y[dim]; }
    // id-function using address of current box,
    // requires to work with pointers to boxes later
    std::ptrdiff_t id() const { return (std::ptrdiff_t)(this); }
};

// 9 boxes of a grid
Box boxes[9] = { Box( 0,0,1,1), Box( 1,0,2,1), Box( 2,0,3,1), // low
                 Box( 0,1,1,2), Box( 1,1,2,2), Box( 2,1,3,2), // middle
                 Box( 0,2,1,3), Box( 1,2,2,3), Box( 2,2,3,3)}; // upper

// 2 selected boxes as query; center and upper right
Box query[2] = { Box( 1,1,2,2), Box( 2,2,3,3)};

// With the special id-function we need to work on box pointers
Box* b_ptr[9] = { boxes, boxes+1, boxes+2, boxes+3, boxes+4, boxes+5,
                 boxes+6, boxes+7, boxes+8};
Box* q_ptr[2] = { query, query+1};

// callback function object writing results to an output iterator
template <class OutputIterator>
struct Report {
    OutputIterator it;
    Report( OutputIterator i) : it(i) {} // store iterator in object
```

```

// We write the position with respect to 'boxes' to the output iterator
// assuming that box b (the query box) is not interesting in the result.
void operator()( const Box* a, const Box*) {
    *it++ = ( reinterpret_cast<Box*>(a->id()) - boxes);
}
};
template <class Iter> // helper function to create the function object
Report<Iter> report( Iter it) { return Report<Iter>(it); }

int main() {
    // run the intersection algorithm and store results in a vector
    std::vector<std::size_t> result;
    CGAL::box_intersection_d( b_ptr, b_ptr+9, q_ptr, q_ptr+2,
                            report( std::back_inserter( result)),
                            std::ptrdiff_t(0));
    // sort and check result
    std::sort( result.begin(), result.end());
    std::size_t chk[13] = {0,1,2,3,4,4,5,5,6,7,7,8,8};
    assert( result.size()==13 && std::equal(chk,chk+13,result.begin()));
    return 0;
}

```

47.10 Example for Point Proximity Search with a Custom Traits Class

Given a set of 3D points, we want to find all pairs of points that are less than a certain distance apart. We use the box intersection algorithm to find good candidates, namely those that are less than this specified distance apart in the L_∞ norm, which is a good approximation of the Euclidean norm.

We use an unusual representation for the box, namely pointers to the 3D points themselves. We implement a special box traits class that interprets the point as a box of the dimensions $[-eps, +eps]^3$ centered at this point. The value for eps is half the specified distance from above, i.e., points are reported if their distance is smaller than $2*eps$.

The requirements for the box traits class are best studied on page 2644 in the Reference Manual. In a nutshell, we have to define the type *NT* for the box coordinates, the type *ID* for the *id*-number, and the type *Box_parameter* similar to the box handle, here *Point_3** since we work with the pointers. All member functions in the traits class are static. Two functions give access to the max and min coordinates that we compute from the point coordinates plus or minus the eps value, respectively. For the *id*-number function the address of the point itself is sufficient, since the points stay stable. Another function returns the dimension.

The *report* callback function computes than the Euclidean distance and prints a message for points that are close enough.

Note that we need to reserve sufficient space in the *points* vector to avoid reallocations while we create the *points* vector and the *boxes* vector in parallel, since otherwise the *points* vector might reallocate and invalidate all pointers stored in the *boxes* so far.

```

#include <CGAL/Simple_cartesian.h>
#include <CGAL/box_intersection_d.h>

```

```

#include <CGAL/point_generators_3.h>
#include <CGAL/copy_n.h>
#include <vector>
#include <algorithm>
#include <iterator>
#include <cmath>

typedef CGAL::Simple_cartesian<float>          Kernel;
typedef Kernel::Point_3                        Point_3;
typedef CGAL::Random_points_on_sphere_3<Point_3> Points_on_sphere;

std::vector<Point_3> points;
std::vector<Point_3*> boxes;    // boxes are just pointers to points
const float          eps = 0.1; // finds point pairs of distance < 2*eps

// Boxes are just pointers to 3d points. The traits class adds the
// +- eps size to each interval around the point, effectively building
// on the fly a box of size 2*eps centered at the point.
struct Traits {
    typedef float          NT;
    typedef Point_3*       Box_parameter;
    typedef std::ptrdiff_t ID;

    static int    dimension() { return 3; }
    static float coord( Box_parameter b, int d) {
        return (d == 0) ? b->x() : ((d == 1) ? b->y() : b->z());
    }
    static float min_coord( Box_parameter b, int d) { return coord(b,d)-eps; }
    static float max_coord( Box_parameter b, int d) { return coord(b,d)+eps; }
    // id-function using address of current box,
    // requires to work with pointers to boxes later
    static std::ptrdiff_t id(Box_parameter b) { return (std::ptrdiff_t)(b); }
};

// callback function reports pairs in close proximity
void report( const Point_3* a, const Point_3* b) {
    float dist = std::sqrt( CGAL::squared_distance( *a, *b));
    if ( dist < 2*eps) {
        std::cout << "Point " << (a - &(points.front())) << " and Point "
                   << (b - &(points.front())) << " have distance " << dist
                   << "." << std::endl;
    }
}

int main() {
    // create some random points on the sphere of radius 1.0
    Points_on_sphere generator( 1.0);
    points.reserve( 50);
    for ( int i = 0; i != 50; ++i) {
        points.push_back( *generator++);
        boxes.push_back( & points.back());
    }

    // run the intersection algorithm and report proximity pairs

```

```
    CGAL::box_self_intersection_d( boxes.begin(), boxes.end(),  
                                  report, Traits());  
    return 0;  
}
```

47.11 Design and Implementation History

Lutz Kettner and Andreas Meyer implemented the algorithms starting from the publication [ZE02]. We had access to the original C implementation of Afra Zomorodian, which helped clarifying some questions, and we are grateful to the help of Afra Zomorodian in answering our questions during his visit. We thank Steve Robbins for an excellent review for this package. Steve Robbins provided an independent and earlier implementation of this algorithm, however, we learned too late about this implementation.

Intersecting Sequences of dD Iso-oriented Boxes

Reference Manual

Lutz Kettner, Andreas Meyer, and Afra Zomorodian

We provide an efficient algorithm [ZE02] for finding all intersecting² pairs for large numbers of iso-oriented boxes, i.e., typically these will be bounding boxes of more complicated geometries. For comparison and as a base case for other methods, we also offer the simple all-pairs test as a generic function.

CGAL::box_intersection_d

Definition

The function `box_intersection_d` computes the pairwise intersecting boxes between two sequences of iso-oriented boxes in arbitrary dimension. The sequences of boxes are given with two random-access iterator ranges and will be reordered in the course of the algorithm. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the first sequence, the second argument a box from the second sequence. The performance of the algorithm can be tuned with a *cutoff* parameter, see the implementation section below for more details.

The algorithm reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value_type* of the iterators *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type.

A d -dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \mid 0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \mid 0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect if their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, `CGAL::Box_intersection_d::HALF_OPEN` and `CGAL::Box_intersection_d::CLOSED`.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. Boxes with equal *id*-number are not reported since they obviously intersect trivially.

The algorithm uses a traits class of the `BoxIntersectionTraits_d` concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the `BoxIntersectionBox_d` concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

An important special application of this algorithm is the test for self-intersections where the second box sequence is an identical copy of the first sequence including the preserved *id*-number. Note that this implies that the address of the box is not sufficient for the *id*-number if boxes are copied by value. To ease the use of this special case we offer a simplified version of this function with one iterator range only, which then creates internally the second copy of the boxes, under the name `CGAL::box_self_intersection_d`.

In the general case, we distinguish between the bipartite case (the boxes are from different sequences) and the complete case (the boxes are from the same sequence, i.e., the self intersection case). The default is the bipartite case, since the complete case is typically handled with the simplified function call mentioned above. However, the general function call offers the *setting* parameter with the values `CGAL::Box_intersection_d::COMPLETE` and `CGAL::Box_intersection_d::BIPARTITE`.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback >
void    box_intersection_d( RandomAccessIterator1 begin1,
```

```

RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

```

Invocation of box intersection with default box traits *CGAL::Box_intersection_d::Box_traits_d<Box_handle>*, where *Box_handle* corresponds to the iterator value type of *RandomAccessIterator1*.

```

template< class RandomAccessIterator1, class RandomAccessIterator2, class Callback, class BoxTraits >
void box_intersection_d( RandomAccessIterator1 begin1,
RandomAccessIterator1 end1,
RandomAccessIterator2 begin2,
RandomAccessIterator2 end2,
Callback callback,
BoxTraits box_traits,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED,
Box_intersection_d::Setting setting = Box_intersection_d::BIPARTITE)

```

Invocation with custom box traits.

Requirements

- *RandomAccessIterator1*, and ...2, must be mutable random-access iterators and both value types must be the same. We call this value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

Implementation

The implemented algorithm is described in [ZE02] as version two. Its performance depends on a *cutoff* parameter. When the size of both iterator ranges drops below the *cutoff* parameter the function switches from the streamed segment-tree algorithm to the two-way-scan algorithm, see [ZE02] for the details.

The streamed segment-tree algorithm needs $O(n \log^d(n) + k)$ worst-case running time and $O(n)$ space, where n is the number of boxes in both input sequences, d the (constant) dimension of the boxes, and k the output complexity, i.e., the number of pairwise intersections of the boxes. The two-way-scan algorithm needs $O(n \log(n) + l)$ worst-case running time and $O(n)$ space, where l is the number of pairwise overlapping intervals in one dimensions (the dimension where the algorithm is used instead of the segment tree). Note that l is not necessarily related to k and using the two-way-scan algorithm is a heuristic.

Unfortunately, we have no general method to automatically determine an optimal cutoff parameter, since it depends on the used hardware, the runtime ratio between callback runtime and segment-tree runtime, and of course the number of boxes to be checked and their distribution. In cases where the callback runtime is dominant, it may be best to make the threshold parameter small. Otherwise a *cutoff* = \sqrt{n} can lead to acceptable results. For well distributed boxes the original paper [ZE02] gives optimal cutoffs in the thousands. Anyway, for optimal runtime some experiments to compare different cutoff parameters are recommended. See also Section 47.8.

Example

The box implementation provided with `CGAL::Box_intersection_d::Box_d<double,2>` has a special constructor for the CGAL bounding box type `CGAL::Bbox_2` (and similar for dimension 3). We use this in the example to create 3×3 boxes in a grid layout. Additionally we pick the center box and the box in the upper-right corner as our second box sequence *query*.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works. We use the *id*-number in our callback function to report the result of the intersection algorithm call. The result will be that the first *query* box intersects all nine boxes and the second *query* box intersects the four boxes in the upper-right quadrant.

```
#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2 Bbox;
// 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), // middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)}; // upper
// 2 selected boxes as query; center and upper right
Box query[2] = { Bbox( 1,1,2,2), Bbox( 2,2,3,3)};

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() << std::endl;
}

int main() {
    CGAL::box_intersection_d( boxes, boxes+9, query, query+2, callback);
    return 0;
}
```

CGAL::box_intersection_all_pairs_d

Definition

The function `box_intersection_all_pairs_d` computes the pairwise intersecting boxes between two sequences of iso-oriented boxes in arbitrary dimension. It does so by comparing all possible pairs of boxes and is thus inferior to the fast `CGAL::box_intersection_d` algorithm on page 2633.

The sequences of boxes are given with two forward iterator ranges. The sequences are not modified. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the first sequence, the second argument a box from the second sequence.

The algorithm is interface compatible with the `CGAL::box_intersection_d` function. Similarly, we call the *value_type* of the iterators the *box handle*, which is either our box type or a pointer type to our box type.

A d -dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \mid 0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \mid 0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, `CGAL::Box_intersection_d::HALF_OPEN` and `CGAL::Box_intersection_d::CLOSED`.

In addition, a box has an unique *id*-number. Boxes with equal *id*-number are not reported since they obviously intersect trivially.

The algorithm uses a traits class of the `BoxIntersectionTraits_d` concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the `BoxIntersectionBox_d` concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

An important special application of this algorithm is the test for self-intersections where the second box sequence is an identical copy of the first sequence including the preserved *id*-number. We offer a specialized implementation `CGAL::box_self_intersection_all_pairs` for this application.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class ForwardIterator1, class ForwardIterator2, class Callback >
void    box_intersection_all_pairs_d( ForwardIterator1 begin1,
                                     ForwardIterator1 end1,
                                     ForwardIterator2 begin2,
                                     ForwardIterator2 end2,
                                     Callback callback,
                                     Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits `CGAL::Box_intersection_d::Box_traits_d<Box_handle>`, where *Box_handle* corresponds to the iterator value type of *ForwardIterator1*.

```
template< class ForwardIterator1, class ForwardIterator2, class Callback, class BoxTraits >
void    box_intersection_all_pairs_d( ForwardIterator1 begin1,
```

```

ForwardIterator1 end1,
ForwardIterator2 begin2,
ForwardIterator2 end2,
Callback callback,
BoxTraits box_traits,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)

```

Invocation with custom box traits.

Requirements

- *ForwardIterator1*, and ...2, must be forward iterators and both value types must be the same. We call this value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

Implementation

The algorithm is trivially testing all pairs and runs therefore in time $O(nm)$ where n is the size of the first sequence and m is the size of the second sequence.

CGAL::box_self_intersection_d

Definition

The function *box_self_intersection_d* computes the pairwise intersecting boxes in a sequence of iso-oriented boxes in arbitrary dimension. The sequence of boxes is given with as a random-access iterator range and will be reordered in the course of the algorithm. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument; the first argument is a box from the sequence, the second argument is a copy of a box from the sequence. The performance of the algorithm can be tuned with a *cutoff* parameter, see the implementation section of the *CGAL::box_intersection_d* function on page 2633.

The algorithm creates a second copy of the boxes and reorders the boxes in the course of the algorithm. Now, depending on the size of a box it can be faster to copy the boxes, or to work with pointers to boxes and copy only pointers. We offer automatic support for both options. To simplify the description, let us call the *value_type* of the iterators *box handle*. The *box handle* can either be our box type itself or a pointer (or const pointer) to the box type.

A d -dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \mid 0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \mid 0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, *CGAL::Box_intersection_d::HALF_OPEN* and *CGAL::Box_intersection_d::CLOSED*.

In addition, a box has an unique *id*-number. It is used to order boxes consistently in each dimension even if boxes have identical coordinates. In consequence, the algorithm guarantees that a pair of intersecting boxes is reported only once. This self-intersection function creates internally a second copy of the box sequence. The copying has to preserve the *id*-number of boxes. Note that this implies that the address of the box is not sufficient for the *id*-number if boxes are copied by value. Boxes of equal *id*-number are not reported as intersecting pairs since they are always intersecting trivially.

The algorithm uses a traits class of the *BoxIntersectionTraits_d* concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the *BoxIntersectionBox_d* concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class RandomAccessIterator, class Callback >
void    box_self_intersection_d( RandomAccessIterator begin,
                                RandomAccessIterator end,
                                Callback callback,
                                std::ptrdiff_t cutoff = 10,
                                Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits *CGAL::Box_intersection_d::Box_traits_d<Box_handle>*, where *Box_handle* corresponds to the iterator value type of *RandomAccessIterator*.

```
template< class RandomAccessIterator, class Callback, class BoxTraits >
void    box_self_intersection_d( RandomAccessIterator begin,
```

```

RandomAccessIterator end,
Callback callback,
BoxTraits box_traits,
std::ptrdiff_t cutoff = 10,
Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)

```

Invocation with custom box traits.

Requirements

- *RandomAccessIterator* must be a mutable random-access iterator. We call its value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

[BoxIntersectionBox_d](#) page 2643
[BoxIntersectionTraits_d](#) page 2644

Implementation

See the implementation section of the [CGAL::box_intersection_d](#) function on page 2633.

Example

The box implementation provided with [CGAL::Box_intersection_d::Box_d<double,2>](#) has a special constructor for the CGAL bounding box type [CGAL::Bbox_2](#) (and similar for dimension 3). We use this in the example to create 3×3 boxes in a grid layout.

The default policy of the box type implements the *id*-number with an explicit counter in the boxes, which is the default choice since it always works. We use the *id*-number in our callback function to report the result of the intersection algorithm call. The result will be 20 pairwise intersections, but the order in which they are reported is non-intuitive.

```

#include <CGAL/box_intersection_d.h>
#include <CGAL/Bbox_2.h>
#include <iostream>

typedef CGAL::Box_intersection_d::Box_d<double,2> Box;
typedef CGAL::Bbox_2 Bbox;

// 9 boxes of a grid
Box boxes[9] = { Bbox( 0,0,1,1), Bbox( 1,0,2,1), Bbox( 2,0,3,1), // low
                 Bbox( 0,1,1,2), Bbox( 1,1,2,2), Bbox( 2,1,3,2), // middle
                 Bbox( 0,2,1,3), Bbox( 1,2,2,3), Bbox( 2,2,3,3)}; // upper

void callback( const Box& a, const Box& b ) {
    std::cout << "box " << a.id() << " intersects box " << b.id() << std::endl;
}

int main() {
    CGAL::box_self_intersection_d( boxes, boxes+9, callback);
    return 0;
}

```

CGAL::box_self_intersection_all_pairs_d

Definition

The function `box_self_intersection_all_pairs_d` computes the pairwise intersecting boxes in a sequence of iso-oriented boxes in arbitrary dimension. It does so by comparing all possible pairs of boxes and is thus inferior to the fast `CGAL::box_self_intersection_d` algorithm on page 2638.

The sequence of boxes is given with a forward iterator range. The sequences are not modified. For each intersecting pair of boxes a *callback* function object is called with the two intersecting boxes as argument.

The algorithm is interface compatible with the `CGAL::box_self_intersection_d` function. Similarly, we call the *value_type* of the iterators the *box handle*, which is either our box type or a pointer type to our box type.

A d -dimensional iso-oriented box is defined as the Cartesian product of d intervals. We call the box *half-open* if the d intervals $\{[lo_i, hi_i) \mid 0 \leq i < d\}$ are half-open intervals, and we call the box *closed* if the d intervals $\{[lo_i, hi_i] \mid 0 \leq i < d\}$ are closed intervals. Note that closed boxes support zero-width boxes and they can intersect at their boundaries, while non-empty half-open boxes always have a positive volume and they only intersect iff their interiors overlap. The distinction between closed or half-open boxes does not require a different representation of boxes, just a different interpretation when comparing boxes, which is selected with the *topology* parameter and its two values, `CGAL::Box_intersection_d::HALF_OPEN` and `CGAL::Box_intersection_d::CLOSED`.

The algorithm uses a traits class of the `BoxIntersectionTraits_d` concept to access the boxes. A default traits class is provided that assumes that the box type is a model of the `BoxIntersectionBox_d` concept and that the box handle, i.e., the iterators value type, is identical to the box type or a pointer to the box type.

```
#include <CGAL/box_intersection_d.h>
```

```
template< class ForwardIterator, class Callback >
void    box_self_intersection_all_pairs_d(
        ForwardIterator begin,
        ForwardIterator end,
        Callback callback,
        Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation of box intersection with default box traits `CGAL::Box_intersection_d::Box_traits_d<Box_handle>`, where *Box_handle* corresponds to the iterator value type of *ForwardIterator*.

```
template< class ForwardIterator, class Callback, class BoxTraits >
void    box_self_intersection_all_pairs_d(
        ForwardIterator begin,
        ForwardIterator end,
        Callback callback,
        BoxTraits box_traits,
        Box_intersection_d::Topology topology = Box_intersection_d::CLOSED)
```

Invocation with custom box traits.

Requirements

- *ForwardIterator* must be a forward iterator. We call its value type *Box_handle* in the following.
- *Callback* must be of the *BinaryFunction* concept. The *Box_handle* must be convertible to both argument types. The return type is not used and can be *void*.
- The *Box_handle* must be a model of the *Assignable* concept.
- In addition, if the default box traits is used the *Box_handle* must be a class type *T* or a pointer to a class type *T*, where *T* must be a model of the *BoxIntersectionBox_d* concept. In both cases, the default box traits specializes to a suitable implementation.
- *BoxTraits* must be of the *BoxIntersectionTraits_d* concept.

Implementation

The algorithm is trivially testing all pairs and runs therefore in time $O(n^2)$ where n is the size of the input sequence. This algorithm does not use the id-number of the boxes.

BoxIntersectionBox_d

Definition

The `BoxIntersectionBox_d` concept is used in the context of the intersection algorithms for sequences of iso-oriented boxes. These algorithms come with a default traits class that assumes that the boxes are a model of this `BoxIntersectionBox_d` concept. This concept defines the access functions to the dimension, the *id*-number, and the boundaries of the box.

Refines

Assignable.

Has Models

`CGAL::Box_intersection_d::Box_with_handle_d<NT, int D, Handle, IdPolicy>` page 2650

Types

`BoxIntersectionBox_d::NT` number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

`BoxIntersectionBox_d::ID` type for the box *id*-number, must be a model of the *LessThanComparable* concept.

Access Functions

<i>int</i>	<code>BoxIntersectionBox_d::dimension()</code>	returns the dimension of the box.
<i>ID</i>	<code>box.id()</code>	returns the unique <i>id</i> -number for the <i>box</i> .
<i>NT</i>	<code>box.min_coord(int d)</code>	returns the lower boundary in dimension <i>d</i> , $0 \leq d < \text{dimension}()$.
<i>NT</i>	<code>box.max_coord(int d)</code>	returns the upper boundary in dimension <i>d</i> , $0 \leq d < \text{dimension}()$.

BoxIntersectionTraits_d

Definition

The `BoxIntersectionTraits_d` concept is used for the intersection algorithms for sequences of iso-oriented boxes. This concept defines the access functions to the dimension, the *id*-number, and the boundaries of the boxes manipulated in these algorithms.

Refines

Assignable.

Has Models

`CGAL::Box_intersection_d::Box_traits_d<BoxHandle>` page [2649](#)

Types

`BoxIntersectionTraits_d::Box_parameter`

type used for passing box parameters in the functions below. Since we support in our algorithms passing the boxes by value as well as passing them as pointers, this type can be either *const B&*, *B**, or *const B** respectively, where *B* is the actual box type. The difference to the box handle type lies in the first case where the box handle would be *B* where this type is *const B&*.

`BoxIntersectionTraits_d::NT` number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

`BoxIntersectionTraits_d::ID` type for the *id*-number, model of the *LessThanComparable* concept.

Access Functions

int `BoxIntersectionTraits_d::dimension()` returns the dimension of the box.

ID `BoxIntersectionTraits_d::id(Box_parameter box)` returns the unique *id*-number for the *box*.

NT `BoxIntersectionTraits_d::min_coord(Box_parameter box, int d)`
returns the lower boundary of the *box* in dimension *d*, $0 \leq d < \text{dimension}()$.

NT `BoxIntersectionTraits_d::max_coord(Box_parameter box, int d)`
returns the upper boundary of the *box* in dimension *d*, $0 \leq d < \text{dimension}()$.

CGAL::Box_intersection_d::Box_d<NT,int D,IdPolicy>

Definition

Box_d<*NT*,*int D*,*IdPolicy*> is a generic iso-oriented bounding box in dimension *D*. It provides in each dimension an interval with lower and upper endpoints represented with the number type *NT*. This class is designed to work smoothly with the algorithms for intersecting sequences of iso-oriented boxes. For degeneracy handling, the boxes need to provide a unique *id*-number. The policy parameter *IdPolicy* offers several choices. The template parameters have to comply with the following requirements:

- *NT*: number type for the box boundaries, needs to be a model of the *Assignable* and the *LessThanComparable* concept.
- *int D*: the dimension of the box.
- *IdPolicy*: specifies how the *id*-number will be provided. Can be one of the following types, where *ID_EXPLICIT* is the default for this parameter:
 - *ID_NONE*: no *id*-number is provided. Can be useful if *Box_d* is used as a base class for a different implementation of *id*-numbers than the ones provided here.
 - *ID_EXPLICIT*: the *id*-number is stored explicitly in the box and automatically created and assigned at construction time of the box. Note that copying a box (copy-constructor and assignment) does not create a new *id*-number but keeps the old one, which is the behavior needed by the *CGAL::box_self_intersection* algorithm. This is therefore the safe default implementation.
 - *ID_FROM_BOX_ADDRESS*: casts the address of the box into a *std::ptrdiff_t* to create the *id*-number. Works fine if the intersection algorithms work effectively with pointers to boxes, but not in the case where the algorithms work with box values, because the algorithms modify the order of the boxes, and the *CGAL::box_self_intersection* algorithm creates copies of the boxes that would not have identical *id*-numbers.

```
#include <CGAL/Box_intersection_d/Box_d.h>
and also automatically with
#include <CGAL/box_intersection_d.h>
```

Is Model for the Concepts

BoxIntersectionBox_d.....page [2643](#)

Types

Box_d<*NT*,*int D*,*IdPolicy*>::*NT* number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

typedef std::size_t *ID*; type for the box *id*-number.

Creation

<code>Box_d<NT,int D,IdPolicy> box;</code>	Default constructor. No particular initialization.
<code>Box_d<NT,int D,IdPolicy> box(bool complete);</code>	initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.
<code>Box_d<NT,int D,IdPolicy> box(NT lo[D], NT hi[D]);</code>	initializes the box intervals to $[lo[i],hi[i]]$, $0 \leq i < D$. <i>Precondition:</i> $lo[i] < hi[i]$ for $0 \leq i < D$.
<code>Box_d<NT,int D,IdPolicy> box(Bbox_2 bbox);</code>	constructs from bbox <i>Requirement:</i> $D = 2$ and $NT \equiv double$.
<code>Box_d<NT,int D,IdPolicy> box(Bbox_3 bbox);</code>	constructs from bbox <i>Requirement:</i> $D = 3$ and $NT \equiv double$.

Modifiers

<code>void box.init(bool complete = false)</code>	initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.
<code>void box.extend(NT point[D])</code>	extend <i>box</i> to contain the old <i>box</i> and <i>point</i> .

Access Functions

<code>int Box_d::dimension()</code>	returns D , the dimension of the box.
<code>std::size_t box.id()</code>	returns a unique box id, see the <i>IdPolicy</i> template parameter above for the different choices. <i>Requirement:</i> $IdPolicy \neq ID_NONE$
<code>NT box.min_coord(int d)</code>	returns the lower boundary in dimension d <i>Precondition:</i> $0 \leq d < D$
<code>NT box.max_coord(int d)</code>	returns the upper boundary in dimension d <i>Precondition:</i> $0 \leq d < D$
<code>Bbox_2 box.bbox()</code>	returns the bounding box <i>Requirement:</i> $D = 2$ and $NT \equiv double$
<code>Bbox_3 box.bbox()</code>	returns the bounding box <i>Requirement:</i> $D = 3$ and $NT \equiv double$
<code>void box.extend(NT p[N])</code>	extends <i>box</i> to the smallest box that additionally contains the point represented by coordinates in p .

void *box.extend(std::pair<NT,NT> p[N])*

extends *box* to the smallest box that additionally contains
the point represented by coordinate intervals in *p*.

CGAL::Box_intersection_d::Box_traits_d<BoxHandle>

Definition

This is the default traits class for the intersection algorithms for iso-oriented boxes. There are actually three versions depending on the type of *BoxHandle*; there is one if *BoxHandle* is a class type and there are two if *BoxHandle* is a pointer type, one for a mutable and one for a const pointer, respectively.

This class implements the mapping from its *BoxHandle* argument to the *Box_parameter* type required in the *BoxIntersectionTraits_d* concept. In particular in the case where *BoxHandle* is a class type *B*, it defines *Box_parameter* to be of type *const B&*, while for the other cases it just uses the pointer type.

- *BoxHandle*: either a class type *B*, a pointer *B**, or a const-pointer *const B**, where *B* is a model of the *BoxIntersectionBox_d* concept.

`#include <CGAL/Box_intersection_d/Box_traits_d.h>` and also automatically with
`#include <CGAL/box_intersection_d.h>`

CGAL::Box_intersection_d::Box_with_handle_d<NT, int D, Handle, IdPolicy>

Definition

Box_with_handle_d<*NT*, *int D*, *Handle*, *IdPolicy*> is a generic iso-oriented bounding box in dimension *D* that stores additionally a handle to some underlying geometric object. It provides in each dimension an interval with lower and upper endpoints represented with the number type *NT*. This class is designed to work smoothly with the algorithms for intersecting sequences of iso-oriented boxes. For degeneracy handling, the boxes need to provide a unique *id*-number. The policy parameter *IdPolicy* offers several choices. The template parameters have to comply with the following requirements:

- *NT*: number type for the box boundaries, needs to be a model of the *Assignable* and the *LessThanComparable* concept.
- *int D*: the dimension of the box.
- *Handle* concept, e.g., a pointer, an iterator, or a circulator.
- *IdPolicy*: specifies how the *id*-number will be provided. Can be one of the following types, where *ID_EXPLICIT* is the default for this parameter:
 - *ID_NONE*: no *id*-number is provided. Can be useful to have this class as a base class for different implementations of *id*-numbers than the ones provided here.
 - *ID_EXPLICIT*: the *id*-number is stored explicitly in the box and automatically created and assigned at construction time of the box. Note that copying a box (copy-constructor and assignment) does not create a new *id*-number but keeps the old one, which is the behavior needed by the *CGAL::box_self_intersection* algorithm. This is therefore the safe default implementation.
 - *ID_FROM_BOX_ADDRESS*: casts the address of the box into a *std::ptrdiff_t* to create the *id*-number. Works fine if the intersection algorithms work effectively with pointers to boxes, but not in the case where the algorithms work with box values, because the algorithms modify the order of the boxes, and the *CGAL::box_self_intersection* algorithm creates copies of the boxes that would not have identical *id*-numbers.
 - *ID_FROM_HANDLE*: casts the address of the value of the handle into a *std::ptrdiff_t* to create the *id*-number. Works in many conceivable settings, e.g., it works with boxes copied by value or by pointer, and the self intersection test. It will not work if there is no one-to-one mapping between boxes and the geometry that is referred to with the handles, i.e., this *id*-number scheme fails if a geometric object creates several boxes with the same handle value. Note that this option is not available for the *CGAL::Box_intersection_d::Box_d* type that does not store a handle.

```
#include <CGAL/Box_intersection_d/Box_with_handle_d.h>
and also automatically with
#include <CGAL/box_intersection_d.h>
```

Is Model for the Concepts

BoxIntersectionBox_d.....page [2643](#)

Types

Box_with_handle_d<*NT*, *int D*, *Handle*, *IdPolicy*>::*NT*

number type to represent the box boundaries. Allowed are the built-in types *int*, *unsigned int*, *float*, and *double*.

typedef std::size_t ID;

type for the box *id*-number.

Creation

Box_with_handle_d<*NT*, *int D*, *Handle*, *IdPolicy*> *box*;

Default constructor. No particular initialization.

Box_with_handle_d<*NT*, *int D*, *Handle*, *IdPolicy*> *box*(*bool complete*, *Handle h*);

initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity, sets handle to *h*.

Box_with_handle_d<*NT*, *int D*, *Handle*, *IdPolicy*> *box*(*NT lo*[*D*], *NT hi*[*D*], *Handle h*);

initializes the box intervals to [*lo*[*i*],*hi*[*i*]], $0 \leq i < D$ and sets the handle to *h*.

Precondition: *lo*[*i*] < *hi*[*i*] for $0 \leq i < D$.

Box_with_handle_d<*NT*, *int D*, *Handle*, *IdPolicy*> *box*(*Bbox_2 bbox*, *Handle h*);

constructs from *bbox* and sets the handle to *h*, exists iff $D = 2$ and $NT \equiv double$.

Box_with_handle_d<*NT*, *int D*, *Handle*, *IdPolicy*> *box*(*Bbox_3 bbox*, *Handle h*);

constructs from *bbox* and sets the handle to *h*, exists iff $D = 3$ and $NT \equiv double$.

Modifiers

void box.init(*bool complete = false*)

initializes to the complete or the empty space. If empty, all interval starting(end) points will be set to positive(negative) infinity.

void box.extend(*NT point*[*D*])

extend *box* to contain the old *box* and *point*.

Access Functions

<i>Handle</i>	<i>box.handle()</i>	returns the handle stored in <i>box</i> .
<i>int</i>	<i>Box_with_handle_d::dimension()</i>	returns <i>D</i> , the dimension of the box.
<i>std::size_t</i>	<i>box.id()</i>	returns a unique box id, see the <i>IdPolicy</i> template parameter above for the different choices. Does not exist if <i>ID_NONE</i> has been chosen for the <i>IdPolicy</i> .
<i>NT</i>	<i>box.min_coord(int d)</i>	returns the lower boundary in dimension <i>d</i> , $0 \leq d < D$.
<i>NT</i>	<i>box.max_coord(int d)</i>	returns the upper boundary in dimension <i>d</i> , $0 \leq d < D$.
<i>Bbox_2</i>	<i>box.bbox()</i>	returns the bounding box iff $D = 2$ and $NT \equiv \text{double}$.
<i>Bbox_3</i>	<i>box.bbox()</i>	returns the bounding box iff $D = 3$ and $NT \equiv \text{double}$.

Part XIII

Shape Analysis, Fitting, and Distances

Chapter 48

Bounding Volumes

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr

This chapter describes algorithms which for a given point set compute the “best” circumscribing object from a specific class. If the class consists of all spheres in d -dimensional Euclidean space and “best” is defined as having smallest radius, then we obtain the smallest enclosing sphere problem already mentioned above.

In the following example a smallest enclosing circle (*CGAL::Min_circle_2<Traits>*) is constructed from points on a line and written to standard output. The example shows that it is advisable to switch on random shuffling in order to deal with a ‘bad’ order of the input points.

```
#include <CGAL/Homogeneous.h>
#include <CGAL/Min_circle_2.h>
#include <CGAL/Min_circle_2_traits_2.h>
#include <CGAL/Gmpz.h>
#include <iostream>

// typedefs
typedef CGAL::Gmpz NT;
typedef CGAL::Homogeneous<NT> K;
typedef CGAL::Min_circle_2_traits_2<K> Traits;
typedef CGAL::Min_circle_2<Traits> Min_circle;

typedef K::Point_2 Point;

int
main( int, char**)
```

```

{
    const int n = 100;
    Point P[n];

    for ( int i = 0; i < n; ++i)
P[ i] = Point( (i%2 == 0 ? i : -i), 0);
    // (0,0), (-1,0), (2,0), (-3,0), ...

    Min_circle mc1( P, P+n, false);    // very slow
    Min_circle mc2( P, P+n, true);     // fast

    CGAL::set_pretty_mode( std::cout);
    std::cout << mc2;

    return 0;
}

```

File: examples/Min_circle_2/min_circle_2.cpp

Other classes for which we provide solutions are ellipses (*CGAL::Min_ellipse_2<Traits>*), rectangles (*CGAL::min_rectangle_2*), parallelograms (*CGAL::min_parallelogram_2*) and strips (*CGAL::min_strip_2*) in the plane, with appropriate optimality criteria. For arbitrary dimensions we provide smallest enclosing spheres for points (*CGAL::Min_sphere_d<Traits>*) and spheres for spheres (*CGAL::Min_sphere_of_spheres_d<Traits>*), smallest enclosing annuli (*CGAL::Min_annulus_d<Traits>*), and approximate minimum-volume enclosing ellipsoid with user-specified approximation ratio (*CGAL::Approximate_min_ellipsoid_d<Traits>*).

Bounding volumes can be used to obtain simple approximations of complicated objects. For example, consider the problem of deciding whether two moving polygons currently intersect. An obvious solution is to discretize time and perform a full intersection test for any time step. If the polygons are far apart most of the time, this is unnecessary. Instead, simple bounding volumes (for examples, circles) are computed for both polygons at their initial positions. At subsequent time steps, an intersection test between the moving bounding circles replaces the actual intersection test; only if the circles do intersect, the expensive intersection test between the polygons is performed. In practice, bounding volume hierarchies are often used on top of simple bounding volumes to approximate complicated objects more accurately.

Bounding volumes are also frequently applied to extract geometric properties of objects. For example, the smallest enclosing annulus of a point set can be used to test whether a set of points is approximately cospherical. Here, the width of the annulus (or its area, or still another criterion that we use) is a good measure for this property. The largest area triangle is for example used in heuristics for matching archaeological aerial photographs. Largest perimeter triangles are used in scoring cross country soaring flights, where the goal is basically to fly as far as possible, but still return to the departure airfield. To score simply based on the total distance flown is not a good measure, since circling in thermals allows to increase it easily.

Bounding volumes also define geometric “center points” of objects. For example, if two objects are to be matched (approximately), one approach is to first apply the translation that maps the centers of their smallest enclosing spheres onto each other. Simpler centers are possible, of course (center of gravity, center of bounding box), but more advanced bounding volumes might give better results in some cases. It can also make sense to consider several center points instead of just one. For example, we provide algorithms to cover a planar point set with between two and four minimal boxes (*CGAL::rectangular_p_center_2*). Below is an example covering with three boxes; the center points are shown in red.

Bounded Volumes

Reference Manual

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr

This chapter describes concepts, classes, and functions for bounding areas and volumes.

These are Smallest enclosing circle and ellipse (2D), smallest enclosing rectangle, parallelogram, and strip (2D), rectangular p -center (2D), smallest enclosing sphere and annulus (dD), approximate minimum-volume enclosing ellipsoid with user-specified approximation ratio (dD).

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section ??.

CGAL::Min_circle_2<Traits>

Definition

An object of the class *Min_circle_2<Traits>* is the unique circle of smallest area enclosing a finite (multi)set of points in two-dimensional Euclidean space \mathbb{E}_2 . For a point set P we denote by $mc(P)$ the smallest circle that contains all points of P . Note that $mc(P)$ can be degenerate, i.e. $mc(P) = \emptyset$ if $P = \emptyset$ and $mc(P) = \{p\}$ if $P = \{p\}$.

An inclusion-minimal subset S of P with $mc(S) = mc(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most three, and all its points lie on the boundary of $mc(P)$. In general, neither the support set nor its size are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P may be empty or points may occur more than once. The algorithm computes a support set S which remains fixed until the next insert or clear operation.

Please note: This class is (almost) obsolete. The class *CGAL::Min_sphere_of_spheres_d<Traits>* solves a more general problem and is faster than *Min_circle_2<Traits>* even if used only for points in two dimensions as input. Most importantly, *CGAL::Min_sphere_of_spheres_d<Traits>* has a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). In contrast, *Min_circle_2<Traits>* is not tuned for floating-point computations. The only advantage of *Min_circle_2<Traits>* over *CGAL::Min_sphere_of_spheres_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *Min_circle_2<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

```
#include <CGAL/Min_circle_2.h>
```

Requirements

The template parameter *Traits* is a model for *MinCircle2Traits*.

We provide the model *CGAL::Min_circle_2_traits_2* using the two-dimensional CGAL kernel.

Types

Min_circle_2<Traits>::Point typedef to *Traits::Point*.

Min_circle_2<Traits>::Circle typedef to *Traits::Circle*.

Min_circle_2<Traits>::Point_iterator

non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points of the smallest enclosing circle.

Min_circle_2<Traits>::Support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing circle.

Creation

A *Min_circle_2*<*Traits*> object can be created from an arbitrary point set P and by specialized construction methods expecting no, one, two or three points as arguments. The latter methods can be useful for reconstructing $mc(P)$ from a given support set S of P .

```
template < class InputIterator >
Min_circle_2<Traits> min_circle( InputIterator first,
                                InputIterator last,
                                bool randomize,
                                Random& random = CGAL::default_random,
                                Traits traits = Traits())
```

initializes *min_circle* to $mc(P)$ with P being the set of points in the range $[first, last)$. If *randomize* is *true*, a random permutation of P is computed in advance, using the random numbers generator *random*. Usually, this will not be necessary, however, the algorithm's efficiency depends on the order in which the points are processed, and a bad order might lead to extremely poor performance (see example below).

Requirement: The value type of *first* and *last* is *Point*.

```
Min_circle_2<Traits> min_circle( Traits traits = Traits());
```

initializes *min_circle* to $mc(\emptyset)$, the empty set.
Postcondition: *min_circle.is_empty()* = *true*.

```
Min_circle_2<Traits> min_circle( Point p, Traits traits = Traits());
```

initializes *min_circle* to $mc(\{p\})$, the set $\{p\}$.
Postcondition: *min_circle.is_degenerate()* = *true*.

```
Min_circle_2<Traits> min_circle( Point p1, Point p2, Traits traits = Traits());
```

initializes *min_circle* to $mc(\{p1, p2\})$, the circle with diameter equal to the segment connecting $p1$ and $p2$.

```
Min_circle_2<Traits> min_circle( Point p1, Point p2, Point p3, Traits traits = Traits());
```

initializes *min_circle* to $mc(\{p1, p2, p3\})$.

Access Functions

int *min_circle.number_of_points()* returns the number of points of *min_circle*, i.e. $|P|$.

int *min_circle.number_of_support_points()*

returns the number of support points of *min_circle*, i.e. $|S|$.

Point_iterator *min_circle.points_begin()* returns an iterator referring to the first point of *min_circle*.

Point_iterator *min_circle.points_end()* returns the corresponding past-the-end iterator.

Support_point_iterator *min_circle.support_points_begin()* returns an iterator referring to the first support point of *min_circle*.

Support_point_iterator *min_circle.support_points_end()* returns the corresponding past-the-end iterator.

Point *min_circle.support_point(int i)*

returns the *i*-th support point of *min_circle*. Between two modifying operations (see below) any call to *min_circle.support_point(i)* with the same *i* returns the same point.
Precondition: $0 \leq i < \text{min_circle.number_of_support_points}()$.

Circle *min_circle.circle()* returns the current circle of *min_circle*.

Predicates

By definition, an empty *Min_circle_2<Traits>* has no boundary and no bounded side, i.e. its unbounded side equals the whole space \mathbb{E}_2 .

CGAL::Bounded_side

min_circle.bounded_side(Point p)

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary of, or properly outside of *min_circle*, resp.

bool *min_circle.has_on_bounded_side(Point p)*

returns *true*, iff *p* lies properly inside *min_circle*.

bool *min_circle.has_on_boundary(Point p)*

returns *true*, iff *p* lies on the boundary of *min_circle*.

bool *min_circle.has_on_unbounded_side(Point p)*

returns *true*, iff *p* lies properly outside of *min_circle*.

bool *min_circle.is_empty()*

returns *true*, iff *min_circle* is empty (this implies degeneracy).

bool min_circle.is_degenerate() returns *true*, iff *min_circle* is degenerate, i.e. if *min_circle* is empty or equal to a single point, equivalently if the number of support points is less than 2.

Modifiers

New points can be added to an existing *min_circle*, allowing to build $mc(P)$ incrementally, e.g. if P is not known in advance. Compared to the direct creation of $mc(P)$, this is not much slower, because the construction method is incremental itself.

void min_circle.insert(Point p) inserts p into *min_circle* and recomputes the smallest enclosing circle.

template < class InputIterator >

void min_circle.insert(InputIterator first, InputIterator last)

inserts the points in the range $[first, last)$ into *min_circle* and recomputes the smallest enclosing circle by calling *insert(p)* for each point p in $[first, last)$.

Requirement: The value type of *first* and *last* is *Point*.

void min_circle.clear() deletes all points in *min_circle* and sets *min_circle* to the empty set.
Postcondition: *min_circle.is_empty() = true*.

Validity Check

An object *min_circle* is valid, iff

- *min_circle* contains all points of its defining set P ,
- *min_circle* is the smallest circle spanned by its support set S , and
- S is minimal, i.e. no support point is redundant.

bool min_circle.is_valid(bool verbose = false, int level = 0)

returns *true*, iff *min_circle* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits&

min_circle.traits() returns a const reference to the traits class object.

I/O

std::ostream&

std::ostream& os << min_circle

writes *min_circle* to output stream *os*.

Requirement: The output operator is defined for *Point* (and for *Circle*, if pretty printing is used).

std::istream&

std::istream& is >> min_circle&

reads *min_circle* from input stream *is*.

Requirement: The input operator is defined for *Point*.

#include <CGAL/IO/Window_stream.h>

CGAL::Window_stream&

CGAL::Window_stream& ws << min_circle

writes *min_circle* to window stream *ws*.

Requirement: The window stream output operator is defined for *Point* and *Circle*.

Implementation

We implement the incremental algorithm of Welzl, with move-to-front heuristic [[Wel91](#)]. The whole implementation is described in [[GS98a](#)].

If randomization is chosen, the creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing circle from scratch. The clear operation and the check for validity each takes linear time.

Example

To illustrate the creation of *Min_circle_2<Traits>* and to show that randomization can be useful in certain cases, we give an example.

```

#include <CGAL/Homogeneous.h>
#include <CGAL/Min_circle_2.h>
#include <CGAL/Min_circle_2_traits_2.h>
#include <CGAL/Gmpz.h>
#include <iostream>

// typedefs
typedef CGAL::Gmpz NT;
typedef CGAL::Homogeneous<NT> K;
typedef CGAL::Min_circle_2_traits_2<K> Traits;
typedef CGAL::Min_circle_2<Traits> Min_circle;

typedef K::Point_2 Point;

int
main( int, char**)
{
    const int n = 100;
    Point P[n];

    for ( int i = 0; i < n; ++i)
P[ i] = Point( (i%2 == 0 ? i : -i), 0);
    // (0,0), (-1,0), (2,0), (-3,0), ...

    Min_circle mc1( P, P+n, false);    // very slow
    Min_circle mc2( P, P+n, true);     // fast

    CGAL::set_pretty_mode( std::cout);
    std::cout << mc2;

    return 0;
}

```

File: examples/Min_circle_2/min_circle_2.cpp

Definition

The class `Min_circle_2_traits_2<K>` is a traits class for `Min_circle_2<Traits>` using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_circle_2_traits_2.h>
```

Requirements

The template parameter K is a model for *Kernel*.

Is Model for the Concepts

MinCircle2Traits page 2669

Types

Min_circle_2_traits_2 $\langle K \rangle :: Point$ typedef to $K :: Point_2$.

Min_circle_2_traits_2<K>::Circle internal type.

Creation

Min_circle_2_traits_2<*K*> *traits*; default constructor.

`Min_circle_2_traits_2<K> traits(Min_circle_2_traits_2<K>);`
copy constructor.

Operations

[illegible]

MinCircle2Traits

Definition

This concept defines the requirements for traits classes of *CGAL::Min_circle_2<Traits>*.

Types

<i>MinCircle2Traits:: Point</i>	The point type must provide default and copy constructor, assignment and equality test.
<i>MinCircle2Traits:: Circle</i>	The circle type must fulfill the requirements listed below in the next section.

Variables

<i>Circle</i>	<i>circle;</i>	The current circle. This variable is maintained by the algorithm, the user should neither access nor modify it directly.
---------------	----------------	--

Creation

Only default and copy constructor are required.

```
MinCircle2Traits traits;

MinCircle2Traits traits( MinCircle2Traits);
```

Operations

The following predicate is only needed, if the member function *is_valid* of *Min_circle_2* is used.

```
CGAL::Orientation    traits.orientation( Point p, Point q, Point r)

returns constants    CGAL::LEFT_TURN,
CGAL::COLLINEAR, or CGAL::RIGHT_TURN iff r
lies properly to the left of, on, or properly to the right of the
oriented line through p and q, resp.
```

CGAL::Min_circle_2<Traits> page [2662](#)

Circle Type (*Circle*)

Definition

An object of the class *Circle* is a circle in two-dimensional Euclidean plane \mathbb{E}_2 . Its boundary splits the plane into a bounded and an unbounded side. By definition, an empty *Circle* has no boundary and no bounded side, i.e. its unbounded side equals the whole plane \mathbb{E}_2 . A *Circle* containing exactly one point p has no bounded side, its boundary is $\{p\}$, and its unbounded side equals $\mathbb{E}_2 \setminus \{p\}$.

Types

Circle::Point Point type.

The following type is only needed, if the member function *is_valid* of *Min_circle_2* is used.

<i>Circle::Distance</i>	Distance type. The function <i>squared_radius</i> (see below) returns an object of this type.
-------------------------	---

Creation

<code>void</code>	<code>circle.set()</code>	sets <i>circle</i> to the empty circle.
-------------------	---------------------------	---

<i>void</i>	<i>circle.set(Point p)</i>	sets <i>circle</i> to the circle containing exactly $\{p\}$.
-------------	-----------------------------	---

<i>void</i>	<i>circle.set(Point p, Point q)</i>	sets <i>circle</i> to the circle with diameter equal to the segment connecting <i>p</i> and <i>q</i> . The algorithm guarantees that <i>set</i> is never called with two equal points.
-------------	--------------------------------------	--

void circle.set(Point p, Point q, Point r)

sets *circle* to the circle through *p,q,r*. The algorithm guarantees that *set* is never called with three collinear points.

Predicates

bool *circle.has_on_unbounded_side(Point p)*

returns *true*, iff *p* lies properly outside of *circle*.

Each of the following predicates is only needed, if the corresponding predicate of *Min_circle_2* is used.

CGAL::Bounded_side

circle.bounded_side(*Point p*)

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*,
or *CGAL::ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on
the boundary, or properly outside of *circle*, resp.

bool *circle.has_on_bounded_side(Point p)*

returns *true*, iff *p* lies properly inside *circle*.

bool *circle.has_on_boundary(Point p)*

returns *true*, iff *p* lies on the boundary of *circle*.

bool *circle.is_empty()*

returns *true*, iff *circle* is empty (this implies degeneracy).

bool *circle.is_degenerate()*

returns *true*, iff *circle* is degenerate, i.e. if *circle* is empty or equal to a single point.

Additional Operations for Checking

The following operations are only needed, if the member function *is_valid* of *Min_circle_2* is used.

bool *circle == circle2*

returns *true*, iff *circle* and *circle2* are equal.

Point *circle.center()*

returns the center of *circle*.

Distance *circle.squared_radius()*

returns the squared radius of *circle*.

I/O

The following I/O operators are only needed, if the corresponding I/O operators of *Min_circle_2* are used.

std::ostream&

std::ostream& os << circle writes *circle* to output stream *os*.

CGAL::Window_stream&

CGAL::Window_stream& ws << circle

writes *circle* to window stream *ws*.

CGAL::Min_ellipse_2<Traits>

Definition

An object of the class *Min_ellipse_2<Traits>* is the unique ellipse of smallest area enclosing a finite (multi)set of points in two-dimensional euclidean space \mathbb{E}_2 . For a point set P we denote by $me(P)$ the smallest ellipse that contains all points of P . Note that $me(P)$ can be degenerate, i.e. $me(P) = \emptyset$ if $P = \emptyset$, $me(P) = \{p\}$ if $P = \{p\}$, and $me(P) = \{(1-\lambda)p + \lambda q \mid 0 \leq \lambda \leq 1\}$ if $P = \{p, q\}$.

An inclusion-minimal subset S of P with $me(S) = me(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most five, and all its points lie on the boundary of $me(P)$. In general, neither the support set nor its size are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P may be empty or points may occur more than once. The algorithm computes a support set S which remains fixed until the next insert or clear operation.

```
#include <CGAL/Min_ellipse_2.h>
```

Requirements

The template parameter *Traits* is a model for *MinEllipse2Traits*.

We provide the model *CGAL::Min_ellipse_2_traits_2<K>* using the two-dimensional CGAL kernel.

Types

Min_ellipse_2<Traits>::Point Typedef to *Traits::Point*.

Min_ellipse_2<Traits>::Ellipse Typedef to *Traits::Ellipse*. If you are using the predefined traits class *CGAL::Min_ellipse_2_traits_2<K>*, you can access the coefficients of the ellipse, see the documentation of *CGAL::Min_ellipse_2_traits_2<K>* and the example below.

Min_ellipse_2<Traits>::Point_iterator

Non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points of the smallest enclosing ellipse.

Min_ellipse_2<Traits>::Support_point_iterator

Non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing ellipse.

Creation

A *Min_ellipse_2*<*Traits*> object can be created from an arbitrary point set P and by specialized construction methods expecting no, one, two, three, four or five points as arguments. The latter methods can be useful for reconstructing $me(P)$ from a given support set S of P .

template < class InputIterator >

Min_ellipse_2<*Traits*> *min_ellipse*(*InputIterator* *first*,
InputIterator *last*,
bool *randomize*,
Random& *random* = *default_random*,
Traits *traits* = *Traits*())

initializes *min_ellipse* to $me(P)$ with P being the set of points in the range $[first, last)$. If *randomize* is *true*, a random permutation of P is computed in advance, using the random numbers generator *random*. Usually, this will not be necessary, however, the algorithm's efficiency depends on the order in which the points are processed, and a bad order might lead to extremely poor performance (see example below).

Requirement: The value type of *first* and *last* is *Point*.

Min_ellipse_2<*Traits*> *min_ellipse*(*Traits* *traits* = *Traits*());

creates a variable *min_ellipse* of type *Min_ellipse_2*<*Traits*>. It is initialized to $me(\emptyset)$, the empty set.

Postcondition: *min_ellipse.is_empty()* = *true*.

Min_ellipse_2<*Traits*> *min_ellipse*(*Point* *p*, *Traits* *traits* = *Traits*());

initializes *min_ellipse* to $me(\{p\})$, the set $\{p\}$.

Postcondition: *min_ellipse.is_degenerate()* = *true*.

Min_ellipse_2<*Traits*> *min_ellipse*(*Point* *p*, *Point* *q*, *Traits* *traits* = *Traits*());

initializes *min_ellipse* to $me(\{p, q\})$,

the set $\{(1 - \lambda)p + \lambda q \mid 0 \leq \lambda \leq 1\}$.

Postcondition: *min_ellipse.is_degenerate()* = *true*.

Min_ellipse_2<*Traits*> *min_ellipse*(*Point* *p1*, *Point* *p2*, *Point* *p3*, *Traits* *traits* = *Traits*());

initializes *min_ellipse* to $me(\{p1, p2, p3\})$.

Min_ellipse_2<*Traits*> *min_ellipse*(*Point* *p1*, *Point* *p2*, *Point* *p3*, *Point* *p4*, *Traits* *traits* = *Traits*());

initializes *min_ellipse* to $me(\{p1, p2, p3, p4\})$.

Min_ellipse_2<*Traits*> *min_ellipse*(*Point* *p1*, *Point* *p2*, *Point* *p3*, *Point* *p4*, *Point* *p5*, *Traits* *traits* = *Traits*());

initializes *min_ellipse* to $me(\{p1, p2, p3, p4, p5\})$.

Access Functions

int *min_ellipse.number_of_points()*

returns the number of points of *min_ellipse*, i.e. $|P|$.

int *min_ellipse.number_of_support_points()*

returns the number of support points of *min_ellipse*, i.e. $|S|$.

Point_iterator

min_ellipse.points_begin()

returns an iterator referring to the first point of *min_ellipse*.

Point_iterator

min_ellipse.points_end()

returns the corresponding past-the-end iterator.

Support_point_iterator

min_ellipse.support_points_begin()

returns an iterator referring to the first support point of *min_ellipse*.

Support_point_iterator

min_ellipse.support_points_end()

returns the corresponding past-the-end iterator.

Point *min_ellipse.support_point(int i)*

returns the *i*-th support point of *min_ellipse*. Between two modifying operations (see below) any call to *min_ellipse.support_point(i)* with the same *i* returns the same point.

Precondition: $0 \leq i < \text{min_ellipse.number_of_support_points}()$.

Ellipse *min_ellipse.ellipse()*

returns the current ellipse of *min_ellipse*.

Predicates

By definition, an empty *Min_ellipse_2<Traits>* has no boundary and no bounded side, i.e. its unbounded side equals the whole space \mathbb{E}_2 .

CGAL::Bounded_side

min_ellipse.bounded_side(Point p)

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary of, or properly outside of *min_ellipse*, resp.

bool *min_ellipse.has_on_bounded_side(Point p)*

returns *true*, iff *p* lies properly inside *min_ellipse*.

bool *min_ellipse.has_on_boundary(Point p)*

returns *true*, iff *p* lies on the boundary of *min_ellipse*.

bool *min_ellipse.has_on_unbounded_side(Point p)*

returns *true*, iff *p* lies properly outside of *min_ellipse*.

bool *min_ellipse.is_empty()*

returns *true*, iff *min_ellipse* is empty (this implies degeneracy).

bool *min_ellipse.is_degenerate()*

returns *true*, iff *min_ellipse* is degenerate, i.e. if *min_ellipse* is empty, equal to a single point or equal to a segment, equivalently if the number of support points is less than 3.

Modifiers

New points can be added to an existing *min_ellipse*, allowing to build $me(P)$ incrementally, e.g. if P is not known in advance. Compared to the direct creation of $me(P)$, this is not much slower, because the construction method is incremental itself.

void *min_ellipse.insert(Point p)*

inserts *p* into *min_ellipse* and recomputes the smallest enclosing ellipse.

template < *class InputIterator* >

void *min_ellipse.insert(InputIterator first, InputIterator last)*

inserts the points in the range $[first, last)$ into *min_ellipse* and recomputes the smallest enclosing ellipse by calling *insert(p)* for each point *p* in $[first, last)$.

Requirement: The value type of *first* and *last* is *Point*.

void *min_ellipse.clear()*

deletes all points in *min_ellipse* and sets *min_ellipse* to the empty set.

Postcondition: *min_ellipse.is_empty() = true*.

Validity Check

An object *min_ellipse* is valid, iff

- *min_ellipse* contains all points of its defining set P ,
- *min_ellipse* is the smallest ellipse spanned by its support set S , and
- S is minimal, i.e. no support point is redundant.

Note: In this release only the first item is considered by the validity check.

bool min_ellipse.is_valid(bool verbose = false, int level = 0)

returns *true*, iff *min_ellipse* contains all points of its defining set *P*. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits&

min_ellipse.traits() returns a const reference to the traits class object.

I/O

std::ostream&

std::ostream& os << min_ellipse

writes *min_ellipse* to output stream *os*.
Requirement: The output operator is defined for *Point* (and for *Ellipse*, if pretty printing is used).

std::istream&

std::istream& is >> min_ellipse&

reads *min_ellipse* from input stream *is*.
Requirement: The input operator is defined for *Point*.

#include <CGAL/IO/Window_stream.h>

CGAL::Window_stream&

CGAL::Window_stream& ws << min_ellipse

writes *min_ellipse* to window stream *ws*.
Requirement: The window stream output operator is defined for *Point* and *Ellipse*.

Implementation

We implement the incremental algorithm of Welzl, with move-to-front heuristic [Wel91], using the primitives as described in [GS97a, GS97b]. The whole implementation is described in [GS98b].

If randomization is chosen, the creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing ellipse from scratch. The clear operation and the check for validity each takes linear time.

Example

To illustrate the usage of *Min_ellipse_2*<Traits> and to show that randomization can be useful in certain cases, we give an example. The example also shows how the coefficients of the constructed ellipse can be accessed.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Min_ellipse_2.h>
#include <CGAL/Min_ellipse_2_traits_2.h>
#include <CGAL/Gmpq.h>

#include <cassert>

typedef CGAL::Gmpq NT;
typedef CGAL::Cartesian<NT> K;
typedef CGAL::Point_2<K> Point;
typedef CGAL::Min_ellipse_2_traits_2<K> Traits;
typedef CGAL::Min_ellipse_2<Traits> Min_ellipse;

int
main( int, char**)
{
    const int n = 200;
    Point P[n];

    for ( int i = 0; i < n; ++i)
        P[ i] = Point( i % 2 ? i : -i , 0);
    // (0,0), (-1,0), (2,0), (-3,0)

    std::cout << "Computing ellipse (without randomization)...\n";
    std::cout.flush();
    Min_ellipse me1( P, P+n, false);    // very slow
    std::cout << "done." << std::endl;

    std::cout << "Computing ellipse (with randomization)...\n";
    std::cout.flush();
    Min_ellipse me2( P, P+n, true);     // fast
    std::cout << "done." << std::endl;

    // because all input points are collinear, the ellipse is
    // degenerate and equals a line segment; the ellipse has
    // two support points
    assert(me2.is_degenerate());
}
```

```

assert(me2.number_of_support_points()==2);

// prettyprinting
CGAL::set_pretty_mode( std::cout);
std::cout << me2;

// in general, the ellipse is not explicitly representable
// over the input number type NT; when you use the default
// traits class CGAL::Min_ellipse_2_traits_2<K>, you can
// get double approximations for the coefficients of the
// underlying conic curve. NOTE: this curve only exists
// in the nondegenerate case!

me2.insert(Point(0,1)); // resolves the degeneracy
assert(!me2.is_degenerate());

// get the coefficients
double r,s,t,u,v,w;
me2.ellipse().double_coefficients( r, s, t, u, v, w);
std::cout << "ellipse has the equation " <<
  r << " x^2 + " <<
  s << " y^2 + " <<
  t << " xy + " <<
  u << " x + " <<
  v << " y + " <<
  w << " = 0." << std::endl;

return 0;
}

```

File: examples/Min_ellipse_2/min_ellipse_2.cpp

CGAL::Min_ellipse_2_traits_2<K>

Definition

The class `Min_ellipse_2_traits_2<K>` is a traits class for `CGAL::Min_ellipse_2<Traits>` using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_ellipse_2_traits_2.h>
```

Requirements

The template parameter K is a model for *Kernel*.

Is Model for the Concepts

MinEllipse2Traits page 2681

Types

$$Min_ellipse_2_traits_2<K>:: Point \quad \text{typedef to } K::Point_2.$$

Min_ellipse_2_traits_2<K>:: Ellipse internal type.

The `Ellipse` type provides the following access methods not required by the concept `MinEllipse2Traits`.

<i>bool</i>	<i>ellipse.is_circle()</i>	tests whether the ellipse is a circle.
-------------	----------------------------	--

```
void ellipse.double_coefficients( double &r,
                                double &s,
                                double &t,
                                double &u,
                                double &v,
                                double &w)
```

gives a double approximation of the ellipse's conic equation. If K is a Cartesian kernel, the ellipse is the set of all points (x, y) satisfying $rx^2 + sy^2 + txy + ux + vy + w = 0$. In the Homogeneous case, the ellipse is the set of points (hx, hy, hw) satisfying $r(hx)^2 + s(hy)^2 + t(hx)(hy) + u(hx)(hw) + v(hy)(hw) + w(hw)^2 = 0$.

Creation

Min_ellipse_2_traits_2 $\langle K \rangle$ *traits*; default constructor.

Min_ellipse_2_traits_2<*K*> traits(*Min_ellipse_2_traits_2*<*K*>);

copy constructor.

MinEllipse2Traits

Definition

This concept defines the requirements for traits classes of *CGAL::Min_ellipse_2<Traits>*.

Types

<i>MinEllipse2Traits:: Point</i>	The point type must provide default and copy constructor, assignment and equality test.
<i>MinEllipse2Traits:: Ellipse</i>	The ellipse type must fulfill the requirements listed below in the next section.

Variables

<i>Ellipse</i>	<i>ellipse;</i>	The current ellipse. This variable is maintained by the algorithm, the user should neither access nor modify it directly.
----------------	-----------------	---

Creation

Only default and copy constructor are required.

```
MinEllipse2Traits traits;

MinEllipse2Traits traits( Traits);
```

Has Models

CGAL::Min_ellipse_2_traits_2<K> page [2679](#)

See Also

CGAL::Min_ellipse_2<Traits> page [2672](#)

Ellipse Type (*Ellipse*)

Definition

An object of the class *Ellipse* is an ellipse in two-dimensional Euclidean plane \mathbb{E}_2 . Its boundary splits the plane into a bounded and an unbounded side. By definition, an empty *Ellipse* has no boundary and no bounded side, i.e. its unbounded side equals the whole plane \mathbb{E}_2 .

Types

Ellipse::Point Point type.

Creation

<i>void</i>	<i>ellipse.set()</i>	sets <i>ellipse</i> to the empty ellipse.
-------------	----------------------	---

<i>void</i>	<i>ellipse.set(Point p)</i>	sets <i>ellipse</i> to the ellipse containing exactly $\{p\}$.
-------------	------------------------------	---

void ellipse.set(Point p, Point q)

sets *ellipse* to the ellipse containing exactly the segment connecting *p* and *q*. The algorithm guarantees that *set* is never called with two equal points.

void ellipse.set(Point p, Point q, Point r)

sets *ellipse* to the smallest ellipse through *p,q,r*. The algorithm guarantees that *set* is never called with three collinear points.

void *ellipse.set(Point p, Point q, Point r, Point s)*

sets *ellipse* to the smallest ellipse through p, q, r, s . The algorithm guarantees that this ellipse exists.

void ellipse.set(Point p, Point q, Point r, Point s, Point t)

sets *ellipse* to the unique conic through p, q, r, s, t . The algorithm guarantees that this conic is an ellipse.

Predicates

bool ellipse.has_on_unbounded_side(Point p)
returns *true*, iff *p* lies properly outside of *ellipse*.

Each of the following predicates is only needed, if the corresponding predicate of *Min_ellipse_2* is used.

CGAL::Bounded_side

ellipse.bounded_side(Point p)

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *ellipse*, resp.

bool ellipse.has_on_bounded_side(Point p)

returns *true*, iff *p* lies properly inside *ellipse*.

bool ellipse.has_on_boundary(Point p)

returns *true*, iff *p* lies on the boundary of *ellipse*.

bool ellipse.is_empty() returns *true*, iff *ellipse* is empty (this implies degeneracy).

bool ellipse.is_degenerate()

returns *true*, iff *ellipse* is degenerate, i.e. if *ellipse* is empty or equal to a single point.

I/O

The following I/O operators are only needed, if the corresponding I/O operators of *Min_ellipse_2* are used.

ostream& ostream& os << ellipse

writes *ellipse* to output stream *os*.

Window_stream& Window_stream& ws << ellipse

writes *ellipse* to window stream *ws*.

CGAL::min_rectangle_2

Definition

The function computes a minimum area enclosing rectangle $R(P)$ of a given convex point set P . Note that $R(P)$ is not necessarily axis-parallel, and it is in general not unique. The focus on convex sets is no restriction, since any rectangle enclosing P – as a convex set – contains the convex hull of P . For general point sets one has to compute the convex hull as a preprocessing step.

```
#include <CGAL/min_quadrilateral_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator      min_rectangle_2(
                    ForwardIterator points_begin,
                    ForwardIterator points_end,
                    OutputIterator o,
                    Traits& t = Default_traits)
```

computes a minimum area enclosing rectangle of the point set described by $[points_begin, points_end)$, writes its vertices (counterclockwise) to o , and returns the past-the-end iterator of this sequence.

If the input range is empty, o remains unchanged.

If the input range consists of one element only, this point is written to o four times.

Precondition: The points denoted by the range $[points_begin, points_end)$ form the boundary of a simple convex polygon P in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter t . The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one of the CGAL kernels. In this case, a default traits class (*Min_quadrilateral_default_traits_2<K>*) is used.

Requirement:

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits_2* and the value type *VT* of *ForwardIterator* is *Traits::Point_2*. Otherwise *VT* is *CGAL::Point_2<K>* for some kernel K .
2. *OutputIterator* accepts *VT* as value type.

CGAL::min_strip_2 page [2688](#)
MinQuadrilateralTraits_2 page [2694](#)
CGAL::Min_quadrilateral_default_traits_2<K> page [2690](#)

Implementation

We use a rotating caliper algorithm [[Tou83](#)] with worst case running time linear in the number of input points.

Example

The following code generates a random convex polygon P with 20 vertices and computes the minimum enclosing rectangle of P .

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/min_quadrilateral_2.h>
#include <iostream>

struct Kernel : public CGAL::Cartesian<double> {};

typedef Kernel::Point_2          Point_2;
typedef Kernel::Line_2           Line_2;
typedef CGAL::Polygon_2<Kernel>  Polygon_2;
typedef CGAL::Random_points_in_square_2<Point_2> Generator;

int main()
{
    // build a random convex 20-gon p
    Polygon_2 p;
    CGAL::random_convex_set_2(20, std::back_inserter(p), Generator(1.0));
    std::cout << p << std::endl;

    // compute the minimal enclosing rectangle p_m of p
    Polygon_2 p_m;
    CGAL::min_rectangle_2(
        p.vertices_begin(), p.vertices_end(), std::back_inserter(p_m));
    std::cout << p_m << std::endl;

    return 0;
}
```

File: examples/Min_quadrilateral_2/minimum_enclosing_rectangle_2.cpp

CGAL::min_parallelgram_2

Definition

The function computes a minimum area enclosing parallelogram $A(P)$ of a given convex point set P . Note that $R(P)$ is not necessarily axis-parallel, and it is in general not unique. The focus on convex sets is no restriction, since any parallelogram enclosing P – as a convex set – contains the convex hull of P . For general point sets one has to compute the convex hull as a preprocessing step.

```
#include <CGAL/min_quadrilateral_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator      min_parallelgram_2(
                    ForwardIterator points_begin,
                    ForwardIterator points_end,
                    OutputIterator o,
                    Traits& t = Default_traits)
```

computes a minimum area enclosing parallelogram of the point set described by $[points_begin, points_end)$, writes its vertices (counterclockwise) to o and returns the past-the-end iterator of this sequence. If the input range is empty, o remains unchanged.

If the input range consists of one element only, this point is written to o four times.

Precondition: The points denoted by the range $[points_begin, points_end)$ form the boundary of a simple convex polygon P in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter t . The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one the CGAL kernels. In this case, a default traits class (*Min_quadrilateral_default_traits_2<K>*) is used.

Requirement:

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits_2* and the value type *VT* of *ForwardIterator* is *Traits::Point_2*. Otherwise *VT* is *CGAL::Point_2<K>* for some kernel *K*.
2. *OutputIterator* accepts *VT* as value type.

Implementation

We use a rotating caliper algorithm [[STV⁺95](#), [Vai90](#)] with worst case running time linear in the number of input points.

Example

The following code generates a random convex polygon P with 20 vertices and computes the minimum enclosing parallelogram of P .

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/min_quadrilateral_2.h>
#include <iostream>

struct Kernel : public CGAL::Cartesian<double> {};

typedef Kernel::Point_2          Point_2;
typedef Kernel::Line_2           Line_2;
typedef CGAL::Polygon_2<Kernel>  Polygon_2;
typedef CGAL::Random_points_in_square_2<Point_2> Generator;

int main()
{
    // build a random convex 20-gon p
    Polygon_2 p;
    CGAL::random_convex_set_2(20, std::back_inserter(p), Generator(1.0));
    std::cout << p << std::endl;

    // compute the minimal enclosing parallelogram p_m of p
    Polygon_2 p_m;
    CGAL::min_parallelogram_2(
        p.vertices_begin(), p.vertices_end(), std::back_inserter(p_m));
    std::cout << p_m << std::endl;

    return 0;
}
```

File: examples/Min_quadrilateral_2/minimum_enclosing_parallelogram_2.cpp

CGAL::min_strip_2

Definition

The function computes a minimum width enclosing strip $S(P)$ of a given convex point set P . A strip is the closed region bounded by two parallel lines in the plane. Note that $S(P)$ is not unique in general. The focus on convex sets is no restriction, since any parallelogram enclosing P – as a convex set – contains the convex hull of P . For general point sets one has to compute the convex hull as a preprocessing step.

```
#include <CGAL/min_quadrilateral_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class Traits >
OutputIterator      min_strip_2(
                    ForwardIterator points_begin,
                    ForwardIterator points_end,
                    OutputIterator o,
                    Traits& t = Default_traits)
```

computes a minimum enclosing strip of the point set described by $[points_begin, points_end)$, writes its two bounding lines to o and returns the past-the-end iterator of this sequence.

If the input range is empty or consists of one element only, o remains unchanged.

Precondition: The points denoted by the range $[points_begin, points_end)$ form the boundary of a simple convex polygon P in counterclockwise orientation.

The geometric types and operations to be used for the computation are specified by the traits class parameter t . The parameter can be omitted, if *ForwardIterator* refers to a two-dimensional point type from one the CGAL kernels. In this case, a default traits class (*Min_quadrilateral_default_traits_2*< K >) is used.

Requirement:

1. If *Traits* is specified, it is a model for *MinQuadrilateralTraits_2* and the value type *VT* of *ForwardIterator* is *Traits::Point_2*. Otherwise *VT* is *CGAL::Point_2*< K > for some kernel K .
2. *OutputIterator* accepts *Traits::Line_2* as value type.

Implementation

We use a rotating caliper algorithm [[Tou83](#)] with worst case running time linear in the number of input points.

Example

The following code generates a random convex polygon P with 20 vertices and computes the minimum enclosing strip of P .

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/min_quadrilateral_2.h>
#include <iostream>

struct Kernel : public CGAL::Cartesian<double> {};

typedef Kernel::Point_2          Point_2;
typedef Kernel::Line_2           Line_2;
typedef CGAL::Polygon_2<Kernel>  Polygon_2;
typedef CGAL::Random_points_in_square_2<Point_2> Generator;

int main()
{
    // build a random convex 20-gon p
    Polygon_2 p;
    CGAL::random_convex_set_2(20, std::back_inserter(p), Generator(1.0));
    std::cout << p << std::endl;

    // compute the minimal enclosing strip p_m of p
    Line_2 p_m[2];
    CGAL::min_strip_2(p.vertices_begin(), p.vertices_end(), p_m);
    std::cout << p_m[0] << "\n" << p_m[1] << std::endl;

    return 0;
}
```

Min_quadrilateral_default_traits_2<K>:: Construct_rectangle_2

Function class

op: Point_2 \times Direction_2 \times Point_2 \times Point_2 \times Point_2 \rightarrow Rectangle_2.

If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op*($p1, d, p2, p3, p4$) returns the rectangle with one of the points on each side and one sides parallel to d .

Min_quadrilateral_default_traits_2<K>:: Construct_parallelogram_2

Function class

op: Point_2 \times Direction_2 \times Point_2 \times Direction_2 \times Point_2 \times Point_2 \rightarrow Rectangle_2.

If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op*($p1, d1, p2, d2, p3, p4$) returns the parallelogram with one of the points on each side and one side parallel to each of $d1$ and $d2$.

Min_quadrilateral_default_traits_2<K>:: Construct_strip_2

Function class

op: Point_2 \times Direction_2 \times Point_2 \rightarrow Strip_2.

op($p1, d, p2$) returns the strip bounded by the lines through $p1$ resp. $p2$ with direction d .

Operations

template < class OutputIterator >

OutputIterator *t.copy_rectangle_vertices_2(const Rectangle_2& r, OutputIterator o) const*

copies the four vertices of *r* in counterclockwise order to *o*.

template < class OutputIterator >

OutputIterator *t.copy_parallelogram_vertices_2(const Parallelogram_2& p, OutputIterator o) const*

copies the four vertices of *p* in counterclockwise order to *o*.

template < class OutputIterator >

OutputIterator *t.copy_strip_lines_2(const Strip_2& s, OutputIterator o) const*

copies the two lines bounding *s* to *o*.

Additionally, for each of the predicate and construction functor types listed above, there is a member function that requires no arguments and returns an instance of that functor type. The name of the member function is the uncapitalized name of the type returned with the suffix *_object* appended. For example, for the functor type *Construct_vector_2* the following member function exists:

Construct_vector_2

t.construct_vector_2_object() const

MinQuadrilateralTraits_2

Definition

The concept `MinQuadrilateralTraits_2` defines types and operations needed to compute minimum enclosing quadrilaterals of a planar point set using the functions `min_rectangle_2`, `min_parallelogram_2` and `min_strip_2`.

Types

<code>MinQuadrilateralTraits_2:: Point_2</code>	type for representing points.
<code>MinQuadrilateralTraits_2:: Vector_2</code>	type for representing vectors.
<code>MinQuadrilateralTraits_2:: Direction_2</code>	type for representing directions.
<code>MinQuadrilateralTraits_2:: Line_2</code>	type for representing lines.
<code>MinQuadrilateralTraits_2:: Rectangle_2</code>	type for representing (not necessarily axis-parallel) rectangles.
<code>MinQuadrilateralTraits_2:: Parallelogram_2</code>	type for representing parallelograms.
<code>MinQuadrilateralTraits_2:: Strip_2</code>	type for representing strips, that is the closed region bounded by two parallel lines.

Predicates

<code>MinQuadrilateralTraits_2:: Equal_2</code>	a model for <code>Kernel::Equal_2</code> page 388.
<code>MinQuadrilateralTraits_2:: Less_xy_2</code>	a model for <code>Kernel::Less_xy_2</code> page ??.
<code>MinQuadrilateralTraits_2:: Less_yx_2</code>	a model for <code>Kernel::Less_yx_2</code> page ??.
<code>MinQuadrilateralTraits_2:: Has_on_negative_side_2</code>	a model for <code>Kernel::Has_on_negative_side_2</code> page ??.
<code>MinQuadrilateralTraits_2:: Compare_angle_with_x_axis_2</code>	a model for <code>Kernel::Compare_angle_with_x_axis_2</code> page ??.
<code>MinQuadrilateralTraits_2:: Area_less_rectangle_2</code>	<p>AdaptableFunctor</p> <p>$op: Rectangle_2 \times Rectangle_2 \rightarrow bool.$</p> <p>$op(r1,r2)$ returns true, iff the area of $r1$ is strictly less than the area of $r2$.</p>

MinQuadrilateralTraits_2:: Area_less_parallelogram_2

AdaptableFunctor

op: Parallelogram_2 \times Parallelogram_2 \rightarrow bool.

op(p1,p2) returns true, iff the area of *p1* is strictly less than the area of *p2*.

MinQuadrilateralTraits_2:: Width_less_strip_2

AdaptableFunctor

op: Strip_2 \times Strip_2 \rightarrow bool.

op(s1,s2) returns true, iff the width of *s1* is strictly less than the width of *s2*.

The following type is used for expensive precondition checking only.

MinQuadrilateralTraits_2:: Orientation_2

a model for Kernel::Orientation_2 page 430.

Constructions

MinQuadrilateralTraits_2:: Construct_vector_2

a model for Kernel::Construct_vector_2 page ??.

MinQuadrilateralTraits_2:: Construct_vector_from_direction_2

AdaptableFunctor

op: Direction_2 \rightarrow Vector_2.

op(d) returns a vector in direction *d*.

MinQuadrilateralTraits_2:: Construct_perpendicular_vector_2

a model for Kernel::Construct_perpendicular_vector_2
page ??.

MinQuadrilateralTraits_2:: Construct_direction_2

a model for Kernel::Construct_direction_2 page ??.

MinQuadrilateralTraits_2:: Construct_opposite_direction_2

a model for Kernel::Construct_opposite_direction_2
page ??.

MinQuadrilateralTraits_2:: Construct_line_2

a model for Kernel::Construct_line_2 page ??.

MinQuadrilateralTraits_2:: Construct_rectangle_2

Function class

op: $Point_2 \times Direction_2 \times Point_2 \times Point_2 \times Point_2 \rightarrow Rectangle_2$.

If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op*($p1, d, p2, p3, p4$) returns the rectangle with one of the points on each side and one sides parallel to d .

MinQuadrilateralTraits_2:: Construct_parallelogram_2

Function class

op: $Point_2 \times Direction_2 \times Point_2 \times Direction_2 \times Point_2 \times Point_2 \rightarrow Rectangle_2$.

If the points $p1, p2, p3, p4$ form the boundary of a convex polygon (oriented counterclockwise), *op*($p1, d1, p2, d2, p3, p4$) returns the parallelogram with one of the points on each side and one side parallel to each of $d1$ and $d2$.

MinQuadrilateralTraits_2:: Construct_strip_2

Function class

op: $Point_2 \times Direction_2 \times Point_2 \rightarrow Strip_2$.

op($p1, d, p2$) returns the strip bounded by the lines through $p1$ resp. $p2$ with direction d .

Operations

```
template < class OutputIterator >
```

```
OutputIterator t.copy_rectangle_vertices_2( const Rectangle_2& r, OutputIterator o) const
```

copies the four vertices of r in counterclockwise order to o .

```
template < class OutputIterator >
```

```
OutputIterator t.copy_parallelogram_vertices_2( const Parallelogram_2& p, OutputIterator o) const
```

copies the four vertices of p in counterclockwise order to o .

```
template < class OutputIterator >
```

```
OutputIterator t.copy_strip_lines_2( const Strip_2& s, OutputIterator o) const
```

copies the two lines bounding s to o .

Additionally, for each of the predicate and construction functor types listed above, there must exist a member function that requires no arguments and returns an instance of that functor type. The name of the member function is the uncapsalized name of the type returned with the suffix *_object* appended. For example, for the functor type *Construct_vector_2* the following member function must exist:

Construct_vector_2

```
t.construct_vector_2_object() const
```

CGAL::rectangular_p_center_2

Definition

The function *rectangular_p_center_2* computes rectilinear p -centers of a planar point set, i.e. a set of p points such that the maximum minimal L_∞ -distance between both sets is minimized.

More formally the problem can be defined as follows.

Given a finite set \mathcal{P} of points, compute a point set \mathcal{C} with $|\mathcal{C}| \leq p$ such that the p -radius of \mathcal{P} ,

$$\text{rad}_p(\mathcal{P}) := \max_{P \in \mathcal{P}} \min_{Q \in \mathcal{C}} \|P - Q\|_\infty$$

is minimized. We can interpret \mathcal{C} as the best approximation (with respect to the given metric) for \mathcal{P} with at most p points.

```
#include <CGAL/rectangular_p_center_2.h>
```

```
template < class ForwardIterator, class OutputIterator, class FT, class Traits >
OutputIterator rectangular_p_center_2(
    ForwardIterator f,
    ForwardIterator l,
    OutputIterator o,
    FT& r,
    int p,
    Traits t = Default_traits)
```

computes rectilinear p -centers for the point set described by the range $[f, l)$, sets r to the corresponding p -radius, writes the at most p center points to o and returns the past-the-end iterator of this sequence.

Precondition:

1. The range $[f, l)$ is not empty.
2. $2 \leq p \leq 4$.

The geometric types and operations to be used for the computation are specified by the traits class parameter t . This parameter can be omitted if *ForwardIterator* refers to a point type from the 2D-Kernel. In this case, a default traits class (*Rectangular_p_center_default_traits_2*< K >) is used.

Requirement:

1. *Either:* (if no traits parameter is given) Value type of *ForwardIterator* is *CGAL::Point_2*< K > for some representation class K and FT is equivalent to $K::FT$,
2. *Or:* (if a traits parameter is specified) *Traits* is a model for *RectangularPCenterTraits_2*.
3. *OutputIterator* accepts the value type of *ForwardIterator* as value type.

RectangularPCenterTraits_2 page [2704](#)
CGAL::Rectangular_p_center_default_traits_2<K> page [2701](#)
CGAL::sorted_matrix_search page [3229](#)

Implementation

The runtime is linear for $p \in \{2, 3\}$ and $O(n \cdot \log n)$ for $p = 4$ where n is the number of input points. These runtimes are worst case optimal. The 3-center algorithm uses a prune-and-search technique described in [[Hof99](#)]. The 4-center implementation uses sorted matrix search [[FJ83](#), [FJ84](#)] and fast algorithms for piercing rectangles [[SW96](#)].

Example

The following code generates a random set of ten points and computes its two-centers.

```
#include <CGAL/Cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/rectangular_p_center_2.h>
#include <CGAL/IO/Ostream_iterator.h>
#include <CGAL/algorithm.h>
#include <iostream>
#include <algorithm>
#include <vector>

typedef double FT;

struct Kernel : public CGAL::Cartesian<FT> {};

typedef Kernel::Point_2 Point;
typedef std::vector<Point> Cont;
typedef CGAL::Random_points_in_square_2<Point> Generator;
typedef CGAL::Ostream_iterator<Point, std::ostream> OIterator;

int main()
{
    int n = 10;
    int p = 2;
    OIterator cout_ip(std::cout);
    CGAL::set_pretty_mode(std::cout);

    Cont points;
    CGAL::copy_n(Generator(1), n, std::back_inserter(points));
    std::cout << "Generated Point Set:\n";
    std::copy(points.begin(), points.end(), cout_ip);

    FT p_radius;
    std::cout << "\n\n" << p << "-centers:\n";
    CGAL::rectangular_p_center_2(
        points.begin(), points.end(), cout_ip, p_radius, 3);
    std::cout << "\n\n" << p << "-radius = " << p_radius << std::endl;
```

```
    return 0;
}
// -----
// ** EOF
// -----
```

CGAL::Min_sphere_d<Traits>

Definition

An object of the class *Min_sphere_d<Traits>* is the unique sphere of smallest volume enclosing a finite (multi)set of points in d -dimensional Euclidean space \mathbb{E}_d . For a set P we denote by $ms(P)$ the smallest sphere that contains all points of P . $ms(P)$ can be degenerate, i.e. $ms(P) = \emptyset$ if $P = \emptyset$ and $ms(P) = \{p\}$ if $P = \{p\}$.

An inclusion-minimal subset S of P with $ms(S) = ms(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most $d + 1$, and all its points lie on the boundary of $ms(P)$. In general, neither the support set nor its size are unique.

The algorithm computes a support set S which remains fixed until the next insert or clear operation.

Please note: This class is (almost) obsolete. The class *CGAL::Min_sphere_of_spheres_d<Traits>* solves a more general problem and is faster than *Min_sphere_d<Traits>* even if used only for points as input. Most importantly, *CGAL::Min_sphere_of_spheres_d<Traits>* has a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). In contrast, *Min_sphere_d<Traits>* is not reliable under floating-point computations. The only advantage of *Min_sphere_d<Traits>* over *CGAL::Min_sphere_of_spheres_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *Min_sphere_d<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

```
#include <CGAL/Min_sphere_d.h>
```

Requirements

The class *Min_sphere_d<Traits>* expects a model of the concept *OptimisationDTraits* as its template argument. We provide the models *CGAL::Optimisation_d_traits_2*, *CGAL::Optimisation_d_traits_3* and *CGAL::Optimisation_d_traits_d* for two-, three-, and d -dimensional points respectively.

Types

Min_sphere_d<Traits>:: Traits

Min_sphere_d<Traits>:: FT typedef to *Traits::FT*.

Min_sphere_d<Traits>:: Point typedef to *Traits::Point*.

Min_sphere_d<Traits>:: Point_iterator non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the points used to build the smallest enclosing sphere.

Min_sphere_d<Traits>:: Support_point_iterator non-mutable model of the STL concept *BidirectionalIterator* with value type *Point*. Used to access the support points defining the smallest enclosing sphere.

Creation

Min_sphere_d<Traits> *min_sphere*(Traits traits = Traits());

creates a variable of type *Min_sphere_d*<Traits> and initializes it to *ms*(\emptyset). If the traits parameter is not supplied, the class *Traits* must provide a default constructor.

template < class InputIterator >

Min_sphere_d<Traits> *min_sphere*(InputIterator first, InputIterator last, Traits traits = Traits());

creates a variable *min_sphere* of type *Min_sphere_d*<Traits>. It is initialized to *ms*(*P*) with *P* being the set of points in the range [*first*,*last*).

Requirement: The value type of *first* and *last* is *Point*. If the traits parameter is not supplied, the class *Traits* must provide a default constructor.

Precondition: All points have the same dimension.

int *min_sphere.number_of_points*()

returns the number of points of *min_sphere*, i.e. $|P|$.

int *min_sphere.number_of_support_points*()

returns the number of support points of *min_sphere*, i.e. $|S|$.

Point_iterator *min_sphere.points_begin*()

returns an iterator referring to the first point of *min_sphere*.

Point_iterator *min_sphere.points_end*()

returns the corresponding past-the-end iterator.

Support_point_iterator *min_sphere.support_points_begin*()

returns an iterator referring to the first support point of *min_sphere*.

Support_point_iterator *min_sphere.support_points_end*()

returns the corresponding past-the-end iterator.

int *min_sphere.ambient_dimension*()

returns the dimension of the points in *P*. If *min_sphere* is empty, the ambient dimension is -1 .

Point *min_sphere.center*()

returns the center of *min_sphere*.

Precondition: *min_sphere* is not empty.

FT *min_sphere.squared_radius*()

returns the squared radius of *min_sphere*.

Precondition: *min_sphere* is not empty.

Predicates

By definition, an empty *Min_sphere.d*<Traits> has no boundary and no bounded side, i.e. its unbounded side equals the whole space \mathbb{E}_d .

Bounded_side *min_sphere.bounded_side(Point p)*

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff *p* lies properly inside, on the boundary, or properly outside of *min_sphere*, resp.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.has_on_bounded_side(Point p)*

returns *true*, iff *p* lies properly inside *min_sphere*.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.has_on_boundary(Point p)*

returns *true*, iff *p* lies on the boundary of *min_sphere*.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.has_on_unbounded_side(Point p)*

returns *true*, iff *p* lies properly outside of *min_sphere*.
Precondition: if *min_sphere* is not empty, the dimension of *p* equals *ambient_dimension()*.

bool *min_sphere.is_empty()*

returns *true*, iff *min_sphere* is empty (this implies degeneracy).

bool *min_sphere.is_degenerate()*

returns *true*, iff *min_sphere* is degenerate, i.e. if *min_sphere* is empty or equal to a single point, equivalently if the number of support points is less than 2.

Modifiers

void *min_sphere.clear()*

resets *min_sphere* to *ms(0)*.

template < class InputIterator >

void *min_sphere.set(InputIterator first, InputIterator last)*

sets *min_sphere* to the $ms(P)$, where P is the set of points in the range $[first, last)$.
Requirement: The value type of *first* and *last* is *Point*.
Precondition: All points have the same dimension.

void *min_sphere.insert(Point p)*

inserts p into *min_sphere*. If p lies inside the current sphere, this is a constant-time operation, otherwise it might take longer, but usually substantially less than recomputing the smallest enclosing sphere from scratch.
Precondition: The dimension of p equals *ambient_dimension()* if *min_sphere* is not empty.

template < class InputIterator >
void *min_sphere.insert(InputIterator first, InputIterator last)*

inserts the points in the range $[first, last)$ into *min_sphere* and recomputes the smallest enclosing sphere, by calling *insert* for all points in the range.
Requirement: The value type of *first* and *last* is *Point*.
Precondition: All points have the same dimension. If *min_sphere* is not empty, this dimension must be equal to *ambient_dimension()*.

Validity Check

An object *min_sphere* is valid, iff

- *min_sphere* contains all points of its defining set P ,
- *min_sphere* is the smallest sphere containing its support set S , and
- S is minimal, i.e. no support point is redundant.

Note: Under inexact arithmetic, the result of the validation is not reliable, because the checker itself can suffer from numerical problems.

bool *min_sphere.is_valid(bool verbose = false, int level = 0)*

returns *true*, iff *min_sphere* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

`const Traits& min_sphere.traits()`

returns a const reference to the traits class object.

I/O

`std::ostream& os << min_sphere`

writes *min_sphere* to output stream *os*.

Requirement: The output operator is defined for *Point*.

`std::istream& is >> min_sphere&`

reads *min_sphere* from input stream *is*.

Requirement: The input operator is defined for *Point*.

Implementation

We implement the algorithm of Welzl with move-to-front heuristic [\[Wel91\]](#) for small point sets, combined with a new efficient method for large sets, which is particularly tuned for moderately large dimension ($d \leq 20$) [\[Gär99\]](#). The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time, but substantially less than computing the new smallest enclosing sphere from scratch. The clear operation and the check for validity each take linear time.

Example

```
#include <CGAL/Cartesian_d.h>
#include <iostream>
#include <cstdlib>
#include <CGAL/Random.h>
#include <CGAL/Min_sphere_annulus_d_traits_d.h>
#include <CGAL/Min_sphere_d.h>

typedef CGAL::Cartesian_d<double>          K;
typedef CGAL::Min_sphere_annulus_d_traits_d<K> Traits;
typedef CGAL::Min_sphere_d<Traits>         Min_sphere;
typedef K::Point_d                          Point;
```

```

const int n = 10;                // number of points
const int d = 5;                // dimension of points

int main ()
{
    Point      P[n];             // n points
    double     coord[d];         // d coordinates
    CGAL::Random r;              // random number generator

    for (int i=0; i<n; ++i) {
        for (int j=0; j<d; ++j)
            coord[j] = r.get_double();
        P[i] = Point(d, coord, coord+d); // random point
    }

    Min_sphere ms (P, P+n);      // smallest enclosing sphere

    CGAL::set_pretty_mode (std::cout);
    std::cout << ms;            // output the sphere

    return 0;
}

```

MinSphereAnnulusDTraits

Definition

This concept defines the requirements for traits classes of d -dimensional min sphere and min annulus algorithms.

Types

<i>MinSphereAnnulusDTraits:: Point_d</i>	point type used to represent the input points.
<i>MinSphereAnnulusDTraits:: Rep_tag</i>	compile time tag to distinguish between Cartesian and homogeneous representation of the input points. <i>Rep_tag</i> has to be either <i>CGAL::Cartesian_tag</i> or <i>CGAL::Homogeneous_tag</i> .
<i>MinSphereAnnulusDTraits:: RT</i>	number type used to represent the coordinates of the input points. It has to be a model for <i>RingNumberType</i> .
<i>MinSphereAnnulusDTraits:: FT</i>	number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. <i>FT</i> has to be either <i>RT</i> or <i>CGAL::Quotient<RT></i> if the input points have Cartesian or homogeneous representation, respectively (cf. <i>Rep_tag</i>).
<i>MinSphereAnnulusDTraits:: Access_dimension_d</i>	data accessor object used to access the dimension of the input points.
<i>MinSphereAnnulusDTraits:: Access_coordinates_begin_d</i>	data accessor object used to access the coordinates of the input points.
<i>MinSphereAnnulusDTraits:: Construct_point_d</i>	constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.
The following two number types are only needed for <i>CGAL::Min_annulus_d<Traits></i> and <i>CGAL::Polytope_distance_d<Traits></i> .	
<i>MinSphereAnnulusDTraits:: ET</i>	exact number type used to do the exact computations in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be an implicit conversion from <i>RT</i> to <i>ET</i> available.
<i>MinSphereAnnulusDTraits:: NT</i>	fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be implicit conversions from <i>RT</i> to <i>NT</i> and from <i>NT</i> to <i>ET</i> available.

Creation

Only default and copy constructor are required.

```
MinSphereAnnulusDTraits traits;
```

```
MinSphereAnnulusDTraits traits( MinSphereAnnulusDTraits);
```

Operations

The following functions just return the corresponding function class object.

```
Access_dimension_d traits.access_dimension_d_object()
```

```
Access_coordinates_begin_d traits.access_coordinates_begin_d_object()
```

```
Construct_point_d traits.construct_point_d_object()
```

CGAL::Min_sphere_annulus_d_traits_2<K,ET,NT>

Definition

The class `Min_sphere_annulus_d_traits_2<K,ET,NT>` is a traits class for the d -dimensional optimisation algorithms using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_sphere_annulus_d_traits_2.h>
```

Requirements

The template parameter K is a model for *Kernel*. Template parameters ET and NT are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

Is Model for the Concepts

MinSphereAnnulusDTraits page 2761

Types

$$Min_sphere_annulus_d_traits_2<K,ET,NT>::Point_d \quad \text{typedef to } K::Point_2.$$
$$Min_sphere_annulus_d_traits_2<K,ET,NT>::Rep_tag \quad \text{typedef to } K::Rep_tag.$$
$$Min_sphere_annulus_d_traits_2\langle K, ET, NT \rangle :: RT \quad \text{typedef to } K :: RT.$$
$$Min_sphere_annulus_d_traits_2<K,ET,NT>::FT \quad \text{typedef to } K::FT.$$

```
Min_sphere_annulus_d_traits_2<K,ET,NT>:: Access_dimension_d
```

typedef to *K*::*Access_dimension_2*.

```
Min_sphere_annulus_d_traits_2<K,ET,NT>::Access_coordinates_begin_d  
                                     typedef to K::Access_coordinates_begin_2.
```

$$\text{Min_sphere_annulus_d_traits_2} \langle K, ET, NT \rangle :: \text{Construct_point_d}$$

$$\text{typedef to } K :: \text{Construct_point_2.}$$

Min_sphere_annulus_d_traits_2 $\langle K, ET, NT \rangle:: ET$ second template parameter (default is $K::RT$).

Min_sphere_annulus_d_traits_2<*K*,*ET*,*NT*>::*NT* third template parameter (default is *K*::*RT*).

Creation

Min_sphere_annulus_d_traits_2<*K,ET,NT*> *traits*; default constructor.

Min_sphere_annulus_d_traits_2<*K,ET,NT*> *traits*(*Min_sphere_annulus_d_traits_2*<*K,ET,NT*>);
copy constructor.

Operations

The following functions just return the corresponding function class object.

Access_dimension_d *traits.access_dimension_d_object()*

Access_coordinates_begin_d *traits.access_coordinates_begin_d_object()*

Construct_point_d *traits.construct_point_d_object()*

CGAL::Min_sphere_annulus_d_traits_3<K,ET,NT>

Definition

The class *Min_sphere_annulus_d_traits_3<K,ET,NT>* is a traits class for the d -dimensional optimisation algorithms using the three-dimensional CGAL kernel.

```
#include <CGAL/Min_sphere_annulus_d_traits_3.h>
```

Requirements

The template parameter K is a model for *Kernel*. Template parameters ET and NT are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

Is Model for the Concepts

MinSphereAnnulusDTraits page 2761

Types

CGAL::Min_annulus_d<Traits>

Definition

An object of the class *Min_annulus_d<Traits>* is the unique annulus (region between two concentric spheres with radii r and R , $r \leq R$) enclosing a finite set of points in d -dimensional Euclidean space \mathbb{E}_d , where the difference $R^2 - r^2$ is minimal. For a point set P we denote by $ma(P)$ the smallest annulus that contains all points of P . Note that $ma(P)$ can be degenerate, i.e. $ma(P) = \emptyset$ if $P = \emptyset$ and $ma(P) = \{p\}$ if $P = \{p\}$.

An inclusion-minimal subset S of P with $ma(S) = ma(P)$ is called a *support set*, the points in S are the *support points*. A support set has size at most $d + 2$, and all its points lie on the boundary of $ma(P)$. In general, the support set is not necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P may be empty or points may occur more than once. The algorithm computes a support set S which remains fixed until the next set, insert, or clear operation.

```
#include <CGAL/Min_annulus_d.h>
```

Requirements

The template parameter *Traits* is a model for *OptimisationDTraits*.

We provide the models *Optimisation_d_traits_2*, *Optimisation_d_traits_3*, and *Optimisation_d_traits_d* using the two-, three-, and d -dimensional CGAL kernel, respectively.

Types

Min_annulus_d<Traits>::Point typedef to *Traits::Point_d*. Point type used to represent the input points.

Min_annulus_d<Traits>::FT typedef to *Traits::FT*. Number type used to return the squared radii of the smallest enclosing annulus.

Min_annulus_d<Traits>::ET typedef to *Traits::ET*. Number type used to do the exact computations in the underlying solver for quadratic programs (cf. **Implementation**).

Min_annulus_d<Traits>::Point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the points of the smallest enclosing annulus.

Min_annulus_d<Traits>::Support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points of the smallest enclosing annulus.

Min_annulus_d<Traits>::Inner_support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the inner support points of the smallest enclosing annulus.

Min_annulus_d<Traits>:: Outer_support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the outer support points of the smallest enclosing annulus.

Min_annulus_d<Traits>:: Coordinate_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *ET*. Used to access the coordinates of the center of the smallest enclosing annulus.

Creation

```
Min_annulus_d<Traits> min_annulus( Traits traits = Traits(),  
    int verbose = 0,  
    std::ostream& stream = std::cout)  
  
    initializes min_annulus to ma( $\emptyset$ ).
```

```
template < class InputIterator >  
Min_annulus_d<Traits> min_annulus( InputIterator first,  
    InputIterator last,  
    Traits traits = Traits(),  
    int verbose = 0,  
    std::ostream& stream = std::cout)  
  
    initializes min_annulus to ma(P) with P being the set of points in  
    the range [first,last).  
Requirement: The value type of InputIterator is Point.  
Precondition: All points have the same dimension.
```

Access Functions

```
int min_annulus.ambient_dimension()  
  
    returns the dimension of the points in P. If min_annulus is empty,  
    the ambient dimension is  $-1$ .
```

```
int min_annulus.number_of_points()  
  
    returns the number of points of min_annulus, i.e.  $|P|$ .
```

```
int min_annulus.number_of_support_points()  
  
    returns the number of support points of min_annulus, i.e.  $|S|$ .
```

<i>int</i>	<i>min_annulus.number_of_inner_support_points()</i>	returns the number of support points of <i>min_annulus</i> which lie on the inner sphere.
<i>int</i>	<i>min_annulus.number_of_outer_support_points()</i>	returns the number of support points of <i>min_annulus</i> which lie on the outer sphere.
<i>Point_iterator</i>	<i>min_annulus.points_begin()</i>	returns an iterator referring to the first point of <i>min_annulus</i> .
<i>Point_iterator</i>	<i>min_annulus.points_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_iterator</i>	<i>min_annulus.support_points_begin()</i>	returns an iterator referring to the first support point of <i>min_annulus</i> . <i>Precondition:</i> $ma(P)$ is not degenerate, i.e., <i>number_of_support_points()</i> is at least one.
<i>Support_point_iterator</i>	<i>min_annulus.support_points_end()</i>	returns the corresponding past-the-end iterator. <i>Precondition:</i> $ma(P)$ is not degenerate, i.e., <i>number_of_support_points()</i> is at least one.
<i>Inner_support_point_iterator</i>	<i>min_annulus.inner_support_points_begin()</i>	returns an iterator referring to the first inner support point of <i>min_annulus</i> .
<i>Inner_support_point_iterator</i>	<i>min_annulus.inner_support_points_end()</i>	returns the corresponding past-the-end iterator.
<i>Outer_support_point_iterator</i>	<i>min_annulus.outer_support_points_begin()</i>	returns an iterator referring to the first outer support point of <i>min_annulus</i> .
<i>Outer_support_point_iterator</i>	<i>min_annulus.outer_support_points_end()</i>	returns the corresponding past-the-end iterator.
<i>Point</i>	<i>min_annulus.center()</i>	returns the center of <i>min_annulus</i> . <i>Requirement:</i> An implicit conversion from <i>ET</i> to <i>RT</i> is available. <i>Precondition:</i> <i>min_annulus</i> is not empty.
<i>FT</i>	<i>min_annulus.squared_inner_radius()</i>	returns the squared inner radius of <i>min_annulus</i> . <i>Requirement:</i> An implicit conversion from <i>ET</i> to <i>RT</i> is available. <i>Precondition:</i> <i>min_annulus</i> is not empty.

FT *min_annulus.squared_outer_radius()*

returns the squared outer radius of *min_annulus*.
Requirement: An implicit conversion from *ET* to *RT* is available.
Precondition: *min_annulus* is not empty.

Coordinate_iterator
min_annulus.center_coordinates_begin()

returns an iterator referring to the first coordinate of the center of *min_annulus*.
Note: The coordinates have a rational representation, i.e. the first d elements of the iterator range are the numerators and the $(d+1)$ -st element is the common denominator.

Coordinate_iterator
min_annulus.center_coordinates_end()

returns the corresponding past-the-end iterator.

ET *min_annulus.squared_inner_radius_numerator()*

returns the numerator of the squared inner radius of *min_annulus*.

ET *min_annulus.squared_outer_radius_numerator()*

returns the numerator of the squared outer radius of *min_annulus*.

ET *min_annulus.squared_radii_denominator()*

returns the denominator of the squared radii of *min_annulus*.

Predicates

The bounded area of the smallest enclosing annulus lies between the inner and the outer sphere. The boundary is the union of both spheres. By definition, an empty annulus has no boundary and no bounded side, i.e. its unbounded side equals the whole space \mathbb{E}_d .

CGAL::Bounded_side

min_annulus.bounded_side(Point p)

returns *CGAL::ON_BOUNDED_SIDE*, *CGAL::ON_BOUNDARY*, or *CGAL::ON_UNBOUNDED_SIDE* iff p lies properly inside, on the boundary, or properly outside of *min_annulus*, resp.
Precondition: The dimension of p equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.has_on_bounded_side(Point p)*

returns *true*, iff p lies properly inside *min_annulus*.
Precondition: The dimension of p equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.has_on_boundary(Point p)*

returns *true*, iff *p* lies on the boundary of *min_annulus*.
Precondition: The dimension of *p* equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.has_on_unbounded_side(Point p)*

returns *true*, iff *p* lies properly outside of *min_annulus*.
Precondition: The dimension of *p* equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

bool *min_annulus.is_empty()* returns *true*, iff *min_annulus* is empty (this implies degeneracy).

bool *min_annulus.is_degenerate()*

returns *true*, iff *min_annulus* is degenerate, i.e. if *min_annulus* is empty or equal to a single point.

Modifiers

void *min_annulus.clear()* resets *min_annulus* to *ma(∅)*.

template < class InputIterator >
void *min_annulus.set(InputIterator first, InputIterator last)*

sets *min_annulus* to *ma(P)*, where *P* is the set of points in the range *[first,last)*.
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points have the same dimension.

void *min_annulus.insert(Point p)*

inserts *p* into *min_annulus*.
Precondition: The dimension of *p* equals *min_annulus.ambient_dimension()* if *min_annulus* is not empty.

template < class InputIterator >
void *min_annulus.insert(InputIterator first, InputIterator last)*

inserts the points in the range *[first,last)* into *min_annulus* and re-computes the smallest enclosing annulus.
Requirement: The value type of *InputIterator* is *Point*.
Precondition: All points have the same dimension. If *min_annulus* is not empty, this dimension must be equal to *min_annulus.ambient_dimension()*.

Validity Check

An object *min_annulus* is valid, iff

- *min_annulus* contains all points of its defining set *P*,
- *min_annulus* is the smallest annulus containing its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

Note: In this release only the first item is considered by the validity check.

bool min_annulus.is_valid(bool verbose = false, int level = 0)

returns *true*, iff *min_annulus* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits&

min_annulus.traits() returns a const reference to the traits class object.

I/O

std::ostream&

std::ostream& os << min_annulus

writes *min_annulus* to output stream *os*.
Requirement: The output operator is defined for *Point*.

std::istream&

std::istream& is >> min_annulus&

reads *min_annulus* from input stream *is*.
Requirement: The input operator is defined for *Point*.

Implementation

The problem of finding the smallest enclosing annulus of a finite point set can be formulated as an optimization problem with linear constraints and a linear objective function. The solution is obtained using our exact solver for linear and quadratic programs [GS00].

The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point takes almost always linear time. The clear operation and the check for validity each take linear time.

CGAL::Min_sphere_of_spheres_d<Traits>

Definition

An object of the class *Min_sphere_of_spheres_d<Traits>* is a data structure that represents the unique sphere of smallest volume enclosing a finite set of spheres in d -dimensional Euclidean space \mathbb{E}_d . For a set S of spheres we denote by $ms(S)$ the smallest sphere that contains all spheres of S ; we call $ms(S)$ the *minsphere* of S . $ms(S)$ can be degenerate, i.e., $ms(S) = \emptyset$, if $S = \emptyset$ and $ms(S) = \{s\}$, if $S = \{s\}$. Any sphere in S may be degenerate, too, i.e., any sphere from S may be a point. Also, S may contain several copies of the same sphere.

An inclusion-minimal subset R of S with $ms(R) = ms(S)$ is called a *support set* for $ms(S)$; the spheres in R are the *support spheres*. A support set has size at most $d + 1$, and all its spheres lie on the boundary of $ms(S)$. (A sphere s' is said to *lie on the boundary* of a sphere s , if s' is contained in s and if their boundaries intersect.) In general, the support set is not unique.

The algorithm computes the center and the radius of $ms(S)$, and finds a support set R (which remains fixed until the next *insert()*, *clear()* or *set()* operation). We also provide a specialization of the algorithm for the case when the center coordinates and radii of the input spheres are floating-point numbers. This specialized algorithm uses floating-point arithmetic only, is very fast and especially tuned for stability and robustness. Still, its output may be incorrect in some (rare) cases; termination is guaranteed.

When default constructed, an instance of type *Min_sphere_of_spheres_d<Traits>* represents the set $S = \emptyset$, together with its minsphere $ms(S) = \emptyset$. You can add spheres to the set S by calling *insert()*. Querying the minsphere is done by calling the routines *is_empty()*, *radius()* and *center_cartesian_begin()*, among others.

In general, the radius and the Euclidean center coordinates of $ms(S)$ need not be rational. Consequently, the algorithm computing the exact minsphere will have to deal with algebraic numbers. Fortunately, both the radius and the coordinates of the minsphere are numbers of the form $a_i + b_i\sqrt{t}$, where $a_i, b_i, t \in \mathbb{Q}$ and where $t \geq 0$ is the same for all coordinates and the radius. Thus, the exact minsphere can be described by the number t , which is called the sphere's *discriminant*, and by $d + 1$ pairs $(a_i, b_i) \in \mathbb{Q}^2$ (one for the radius and d for the center coordinates).

```
#include <CGAL/Min_sphere_of_spheres_d.h>
```

Note: This class (almost) replaces *CGAL::Min_sphere_d<Traits>*, which solves the less general problem of finding the smallest enclosing ball of a set of *points*. *Min_sphere_of_spheres_d<Traits>* is faster than *CGAL::Min_sphere_d<Traits>*, and in contrast to the latter provides a specialized implementation for floating-point arithmetic which ensures correct results in a large number of cases (including highly degenerate ones). The only advantage of *CGAL::Min_sphere_d<Traits>* over *Min_sphere_of_spheres_d<Traits>* is that the former can deal with points in homogeneous coordinates, in which case the algorithm is division-free. Thus, *CGAL::Min_sphere_d<Traits>* might still be an option in case your input number type cannot (efficiently) divide.

Requirements

The class *Min_sphere_of_spheres_d<Traits>* expects a model of the concept *MinSphereOfSpheresTraits* as its template argument.

Types

Min_sphere_of_spheres_d<Traits>::Sphere is a typedef to *Traits::Sphere*.

<i>Min_sphere_of_spheres_d<Traits>:: FT</i>	is a typedef to <i>Traits::FT</i> .
<i>Min_sphere_of_spheres_d<Traits>:: Result</i>	is the type of the radius and of the center coordinates of the computed minsphere: When <i>FT</i> is an inexact number type (<i>double</i> , for instance), then <i>Result</i> is simply <i>FT</i> . However, when <i>FT</i> is an exact number type, then <i>Result</i> is a typedef to a derived class of <i>std::pair<FT,FT></i> ; an instance of this type represents the number $a + b\sqrt{t}$, where <i>a</i> is the first and <i>b</i> the second element of the pair and where the number <i>t</i> is accessed using the member function <i>discriminant()</i> of class <i>Min_sphere_of_spheres_d<Traits></i> .
<i>Min_sphere_of_spheres_d<Traits>:: Algorithm</i>	is either <i>CGAL::LP_algorithm</i> or <i>CGAL::Farthest_first_heuristic</i> . As is described in the documentation of concept <i>MinSphereOfSpheresTraits</i> , the type <i>Algorithm</i> reflects the method which is used to compute the minsphere. (Normally, <i>Algorithm</i> coincides with <i>Traits::Algorithm</i> . However, if the method <i>Traits::Algorithm</i> should not be supported anymore in a future release, then <i>Algorithm</i> will have another type.)
<i>Min_sphere_of_spheres_d<Traits>:: Support_iterator</i>	non-mutable model of the STL concept <i>BidirectionalIterator</i> with value type <i>Sphere</i> . Used to access the support spheres defining the smallest enclosing sphere.
<i>Min_sphere_of_spheres_d<Traits>:: Cartesian_const_iterator</i>	non-mutable model of the STL concept <i>BidirectionalIterator</i> to access the center coordinates of the minsphere.

Creation

<i>Min_sphere_of_spheres_d<Traits> minsphere(Traits traits = Traits());</i>	creates a variable of type <i>Min_sphere_of_spheres_d<Traits></i> and initializes it to <i>ms(0)</i> . If the traits parameter is not supplied, the class <i>Traits</i> must provide a default constructor.
<i>template < typename InputIterator ></i> <i>Min_sphere_of_spheres_d<Traits> minsphere(InputIterator first, InputIterator last, Traits traits = Traits());</i>	creates a variable <i>minsphere</i> of type <i>Min_sphere_of_spheres_d<Traits></i> and inserts (cf. <i>insert()</i>) the spheres from the range <i>[first,last)</i> . <i>Requirement:</i> The value type of <i>first</i> and <i>last</i> is <i>Sphere</i> . If the traits parameter is not supplied, the class <i>Traits</i> must provide a default constructor.

Access Functions

<i>Support_iterator</i>	<i>minsphere.support_begin()</i>	returns an iterator referring to the first support sphere of <i>minsphere</i> .
<i>Support_iterator</i>	<i>minsphere.support_end()</i>	returns the corresponding past-the-end iterator.
<i>FT</i>	<i>minsphere.discriminant()</i>	<p>returns the discriminant of <i>minsphere</i>. This number is undefined when <i>FT</i> is an inexact number type. When <i>FT</i> is exact, the center coordinates and the radius of the minsphere are numbers of the form $a + b\sqrt{t}$, where t is the discriminant of the minsphere as returned by this function.</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty, and <i>FT</i> is an exact number type.</p>
<i>Result</i>	<i>minsphere.radius()</i>	<p>returns the radius of <i>minsphere</i>. If <i>FT</i> is an exact number type then the radius of the minsphere is the real number $a + b\sqrt{t}$, where t is the minsphere's discriminant, a is the first and b the second component of the pair returned by <i>radius()</i>.</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty.</p>
<i>Cartesian_const_iterator</i>	<i>minsphere.center_cartesian_begin()</i>	<p>returns a const-iterator to the first of the <i>Traits::D</i> center coordinates of <i>minsphere</i>. The iterator returns objects of type <i>Result</i>. If <i>FT</i> is an exact number type, then a center coordinate is represented by a pair (a, b) describing the real number $a + b\sqrt{t}$, where t is the minsphere's discriminant (cf. <i>discriminant()</i>).</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty.</p>
<i>Cartesian_const_iterator</i>	<i>minsphere.center_cartesian_end()</i>	<p>returns the corresponding past-the-end iterator, i.e. <i>center_cartesian_begin()+Traits::D</i>.</p> <p><i>Precondition:</i> <i>minsphere</i> is not empty.</p>

Predicates

<i>bool</i>	<i>minsphere.is_empty()</i>	returns <i>true</i> , iff <i>minsphere</i> is empty, i.e. iff $ms(S) = \emptyset$.
-------------	-----------------------------	---

Modifiers

void *minsphere.clear()* resets *minsphere* to $ms(\emptyset)$, with $S := \emptyset$.

template < *class InputIterator* >

void *minsphere.set(InputIterator first, InputIterator last)*

sets *minsphere* to the $ms(S)$, where S is the set of spheres in the range $[first, last)$.

Requirement: The value type of *first* and *last* is *Sphere*.

void *minsphere.insert(Sphere s)*

inserts the sphere s into the set S of instance *minsphere*.

template < *class InputIterator* >

void *minsphere.insert(InputIterator first, InputIterator last)*

inserts the spheres in the range $[first, last)$ into the set S of instance *minsphere*.

Requirement: The value type of *first* and *last* is *Sphere*.

Validity Check

An object *minsphere* is valid, iff

- *minsphere* contains all spheres of its defining set S ,
- *minsphere* is the smallest sphere containing its support set R , and
- R is minimal, i.e., no support sphere is redundant.

bool *minsphere.is_valid()* returns *true*, iff *minsphere* is valid. When *FT* is inexact, this routine always returns *true*.

Miscellaneous

const Traits& *minsphere.traits()* returns a const reference to the traits class object.

Implementation

We implement two algorithms, the LP-algorithm and a heuristic [MSW92]. As described in the documentation of concept *MinSphereOfSpheresTraits*, each has its advantages and disadvantages: Our implementation of the LP-algorithm has maximal expected running time $O(2^d n)$, while the heuristic comes without any complexity guarantee. In particular, the LP-algorithm runs in linear time for fixed dimension d . (These running times hold for the arithmetic model, so they count the number of operations on the number type FT .)

On the other hand, the LP-algorithm is, for inexact number types FT , much worse at handling degeneracies and should therefore not be used in such a case. (For exact number types FT , both methods handle all kinds of degeneracies.)

Currently, we require *Traits::FT* to be either an exact number type or *double* or *float*; other inexact number types are not supported at this time. Also, the current implementation only handles spheres with Cartesian coordinates; homogenous representation is not supported yet.

Example

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/Random.h>
#include <CGAL/Gmpq.h>
#include <CGAL/Min_sphere_of_spheres_d.h>
#include <vector>

const int N = 1000;           // number of spheres
const int D = 3;             // dimension of points
const int LOW = 0, HIGH = 10000; // range of coordinates and radii

typedef CGAL::Gmpq            FT;
//typedef double              FT;
typedef CGAL::Cartesian_d<FT> K;
typedef CGAL::Min_sphere_of_spheres_d_traits_d<K,FT,D> Traits;
typedef CGAL::Min_sphere_of_spheres_d<Traits> Min_sphere;
typedef K::Point_d            Point;
typedef Traits::Sphere         Sphere;

int main () {
    std::vector<Sphere> S;      // n spheres
    FT coord[D];              // d coordinates
    CGAL::Random r;           // random number generator

    for (int i=0; i<N; ++i) {
        for (int j=0; j<D; ++j)
            coord[j] = r.get_int(LOW,HIGH);
        Point p(D,coord,coord+D); // random center...
        S.push_back(Sphere(p,r.get_int(LOW,HIGH))); // ...and random radius
    }

    Min_sphere ms(S.begin(),S.end()); // check in the spheres
    CGAL_assertion(ms.is_valid());
}
```

MinSphereOfSpheresTraits

Definition

A model of concept *MinSphereOfSpheresTraits* must provide the following constants, types, predicates and operations.

Has Models

```
CGAL::Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>
CGAL::Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>
CGAL::Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>
```

Constants

MinSphereOfSpheresTraits:: D specifies the dimension of the spheres you want to compute the minsphere of.

Types

MinSphereOfSpheresTraits:: Sphere is a typedef to to some class representing a sphere. (The package will compute the minsphere of spheres of type *Sphere*.) The type *Sphere* must provide a copy constructor.

MinSphereOfSpheresTraits:: FT is a (exact or inexact) field number type.
Requirement: Currently, *FT* must either be *double* or *float*, or an exact field number type. (An *exact* number type is one which evaluates arithmetic expressions involving the four basic operations and comparisons with infinite precision, that is, like in \mathbb{R} .)

MinSphereOfSpheresTraits:: Cartesian_const_iterator non-mutable model of the STL concept *ForwardIterator* with value type *FT*. Used to access the center coordinates of a sphere.

MinSphereOfSpheresTraits:: Use_square_roots

must typedef to either *CGAL::Tag_true* or *CGAL::Tag_false*. The algorithm uses (depending on the type *MinSphereOfSpheresTraits::Algorithm*) floating-point arithmetic internally for some intermediate computations. The type *Use_square_roots* affects how these calculations are done: When *Use_square_roots* is *Tag_true*, the algorithm computing the minsphere will perform square-root operations on *doubles* and *floats* where appropriate. On the other hand, if *Use_square_roots* is *CGAL::Tag_false*, the algorithm will work without doing square-roots.

Note: On some platforms the algorithm is much faster when square-roots are disabled (due to lacking hardware support).

MinSphereOfSpheresTraits:: Algorithm

selects the method to compute the minsphere with. It must typedef to either *CGAL::Default_algorithm*, *CGAL::LP_algorithm* or *CGAL::Farthest_first_heuristic*. The recommended choice is the first, which is a synonym to the one of the other two methods which we consider “the best in practice.” In case of *CGAL::LP_algorithm*, the minsphere will be computed using the LP-algorithm [MSW92], which in our implementation has maximal expected running time $O(2^d n)$ (in the number of operations on the number type *FT*). In case of *CGAL::Farthest_first_heuristic*, a simple heuristic will be used instead which seems to work fine in practice, but comes without a guarantee on the running time. For an inexact number type *FT* we strongly recommend *CGAL::Default_algorithm*, or, if you want, *CGAL::Farthest_first_heuristic*, since these handle most degeneracies in a satisfying manner. Notice that this compile-time flag is taken as a hint only. Should one of the methods not be available anymore in a future release, then the default algorithm will be chosen.

Access Functions

FT *traits.radius(Sphere s)*

returns the radius of sphere *s*.

Postcondition: The returned number is greater or equal to 0.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

returns an iterator referring to the first of the *D* Cartesian coordinates of the center of *s*.

CGAL::Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>

Definition

The class *Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point_2* to represent circles.

Is Model for the Concepts

MinSphereOfSpheresTraits

Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag_false* and *CGAL::Default_algorithm*, respectively.

The template parameters of class *Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: K

is a model for *Kernel*.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: FT

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: UseSqrt

fulfills the requirements of type *Use_square_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag_true* or *Tag_false*.

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: Algorithm

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default_algorithm*, *LP_algorithm* or *Farthest_first_heuristic*.

Constants

Min_sphere_of_spheres_d_traits_2<K,FT,UseSqrt,Algorithm>:: D

is the constant 2, i.e. the dimension of \mathbb{R}^2 .

Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

Min_sphere_of_spheres_d_traits_2<*K*,*FT*,*UseSqrt*,*Algorithm*>::*FT*

Min_sphere_of_spheres_d_traits_2<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Use_square_roots*

Min_sphere_of_spheres_d_traits_2<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Algorithm*

Min_sphere_of_spheres_d_traits_2<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Radius*

is a typedef to the template parameter *FT*

Min_sphere_of_spheres_d_traits_2<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Point*

is a typedef to *K::Point_2*.

Min_sphere_of_spheres_d_traits_2<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Sphere*

is a typedef to *std::pair<Point,Radius>*.

Min_sphere_of_spheres_d_traits_2<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Cartesian_const_iterator*

is a typedef to *K::Cartesian_const_iterator_2*.

Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point_2*:

FT *traits.radius(Sphere s)*

maps to *s.second*.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

maps to *s.first.cartesian_begin()*.

CGAL::Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>

Definition

The class *Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>* is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point_3* to represent circles.

Is Model for the Concepts

MinSphereOfSpheresTraits

Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag_false* and *CGAL::Default_algorithm*, respectively.

The template parameters of class *Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>* must fulfill the following requirements:

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: K

is a model for *Kernel*.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: FT

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: UseSqrt

fulfills the requirements of type *Use_square_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag_true* or *Tag_false*.

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: Algorithm

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default_algorithm*, *LP_algorithm* or *Farthest_first_heuristic*.

Constants

Min_sphere_of_spheres_d_traits_3<K,FT,UseSqrt,Algorithm>:: D

is the constant 3, i.e. the dimension of \mathbb{R}^3 .

Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

Min_sphere_of_spheres_d_traits_3<*K*,*FT*,*UseSqrt*,*Algorithm*>::*FT*

Min_sphere_of_spheres_d_traits_3<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Use_square_roots*

Min_sphere_of_spheres_d_traits_3<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Algorithm*

Min_sphere_of_spheres_d_traits_3<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Radius*

is a typedef to the template parameter *FT*

Min_sphere_of_spheres_d_traits_3<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Point*

is a typedef to *K::Point_3*.

Min_sphere_of_spheres_d_traits_3<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Sphere*

is a typedef to *std::pair<Point,Radius>*.

Min_sphere_of_spheres_d_traits_3<*K*,*FT*,*UseSqrt*,*Algorithm*>::*Cartesian_const_iterator*

is a typedef to *K::Cartesian_const_iterator_2*.

Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point_3*:

FT *traits.radius(Sphere s)*

maps to *s.second*.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

maps to *s.first.cartesian_begin()*.

CGAL::Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>

Definition

The class *Min_sphere_of_spheres_d_traits_d*<K,FT,Dim,UseSqrt,Algorithm> is a model for concept *MinSphereOfSpheresTraits*. It uses the CGAL type *Point_d* to represent circles.

Is Model for the Concepts

MinSphereOfSpheresTraits

Parameters

The last two template parameters, *UseSqrt* and *Algorithm*, have default arguments, namely *CGAL::Tag_false* and *CGAL::Default_algorithm*, respectively.

The template parameters of class *Min_sphere_of_spheres_d_traits_d*<K,FT,UseSqrt,Algorithm> must fulfill the following requirements:

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: *K*

is a model for *Kernel*.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: *FT*

is a number type, which fulfills the requirements of type *FT* of concept *MinSphereOfSpheresTraits*: It must be either *double* or *float*, or an exact number type.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: *UseSqrt*

fulfills the requirements of type *Use_square_roots* of concept *MinSphereOfSpheresTraits*: It must be either *Tag_true* or *Tag_false*.

Min_sphere_of_spheres_d_traits_d<K,FT,Dim,UseSqrt,Algorithm>:: *Algorithm*

fulfills the requirements of type *Algorithm* of concept *MinSphereOfSpheresTraits*: It must be either *Default_algorithm*, *LP_algorithm* or *Farthest_first_heuristic*.

Constants

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*D*

is the constant *Dim*.

Types

In addition to the types required by the concept *MinSphereOfSpheresTraits*, this model also defines the types *Radius* and *Point*. Here's the complete list of defined types:

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*FT*

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Use_square_roots*

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Algorithm*

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Radius*

is a typedef to the template parameter *FT*

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Point*

is a typedef to *K::Point_d*.

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Sphere*

is a typedef to *std::pair<Point,Radius>*.

Min_sphere_of_spheres_d_traits_d<*K*,*FT*,*Dim*,*UseSqrt*,*Algorithm*>::*Cartesian_const_iterator*

is a typedef to *K::Cartesian_const_iterator_d*.

Access Functions

The class provides the access functions required by the concept *MinSphereOfSpheresTraits*; they simply map to the corresponding routines of class *K::Point_d*:

FT *traits.radius(Sphere s)*

maps to *s.second*.

Cartesian_const_iterator

traits.center_cartesian_begin(Sphere s)

maps to *s.first.cartesian_begin()*.

CGAL::Approximate_min_ellipsoid_d<Traits>

Definition

An object of class *Approximate_min_ellipsoid_d<Traits>* is an approximation to the ellipsoid of smallest volume enclosing a finite multiset of points in d -dimensional Euclidean space \mathbb{E}^d , $d \geq 2$.

An *ellipsoid* in \mathbb{E}^d is a Cartesian pointset of the form $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$, where E is some positive definite matrix from the set $\mathbb{R}^{d \times d}$, e is some real d -vector, and $\eta \in \mathbb{R}$. A pointset $P \subseteq \mathbb{E}^d$ is called *full-dimensional* if its affine hull has dimension d . For a finite, full-dimensional pointset P we denote by $\text{MEL}(P)$ the smallest ellipsoid that contains all points of P ; this ellipsoid exists and is unique.

For a given finite and full-dimensional pointset $P \subset \mathbb{E}^d$ and a real number $\varepsilon \geq 0$, we say that an ellipsoid $\mathcal{E} \subset \mathbb{E}^d$ is an $(1 + \varepsilon)$ -approximation to $\text{MEL}(P)$ if $P \subset \mathcal{E}$ and $\text{VOL}(\mathcal{E}) \leq (1 + \varepsilon) \text{VOL}(\text{MEL}(P))$. In other words, an $(1 + \varepsilon)$ -approximation to $\text{MEL}(P)$ is an enclosing ellipsoid whose volume is by at most a factor of $1 + \varepsilon$ larger than the volume of the smallest enclosing ellipsoid of P .

Given this notation, an object of class *Approximate_min_ellipsoid_d<Traits>* represents an $(1 + \varepsilon)$ -approximation to $\text{MEL}(P)$ for a given finite and full-dimensional multiset of points $P \subset \mathbb{E}^d$ and a real constant $\varepsilon > 0$.¹ When an *Approximate_min_ellipsoid_d<Traits>* object is constructed, an iterator over the points P and the number ε have to be specified; the number ε defines the *desired approximation ratio* $1 + \varepsilon$. The underlying algorithm will then try to compute an $(1 + \varepsilon)$ -approximation to $\text{MEL}(P)$, and one of the following two cases takes place.

- The algorithm determines that P is not full-dimensional (see *is_full_dimensional()* below).

Important note: due to rounding errors, the algorithm cannot in all cases decide correctly whether P is full-dimensional or not. If *is_full_dimensional()* returns *false*, the points lie in such a “thin” subspace of \mathbb{E}^d that the algorithm is incapable of computing an approximation to $\text{MEL}(P)$. More precisely, if *is_full_dimensional()* returns *false*, there exist two parallel hyperplanes in \mathbb{E}^d with the points P in between so that the distance δ between the hyperplanes is very small, possibly zero. (If $\delta = 0$ then P is not full-dimensional.)

If P is not full-dimensional, linear algebra techniques should be used to determine an affine subspace S of \mathbb{E}^d that contains the points P as a (w.r.t. S) full-dimensional pointset; once S is determined, the algorithm can be invoked again to compute an approximation to (the lower-dimensional) $\text{MEL}(P)$ in S . Since *is_full_dimensional()* might (due to rounding errors, see above) return *false* even though P is full-dimensional, the lower-dimensional subspace S containing P need not exist. Therefore, it might be more advisable to fit a hyperplane H through the pointset P , project P onto this affine subspace H , and compute an approximation to the minimum-volume enclosing ellipsoid of the projected points within H ; the fitting can be done for instance using the *linear_least_squares_fitting()* function from the CGAL package *Principal_component_analysis*.

- The algorithm determines that P is full-dimensional. In this case, it provides an approximation \mathcal{E} to $\text{MEL}(P)$, but depending on the input problem (i.e., on the pair (P, ε)), it may not have achieved the desired approximation ratio but merely some *worse* approximation ratio $1 + \varepsilon' > 1 + \varepsilon$. The achieved approximation ratio $1 + \varepsilon'$ can be queried using *achieved_epsilon()*, which returns ε' . The ellipsoid \mathcal{E} itself can be queried via the methods *defining_matrix()*, *defining_vector()*, and *defining_scalar()*.

The ellipsoid \mathcal{E} computed by the algorithm satisfies the inclusions

$$\frac{1}{(1 + \varepsilon')^d} \mathcal{E} \subseteq \text{conv}(P) \subseteq \mathcal{E} \quad (48.1)$$

¹A *multiset* is a set where elements may have multiplicity greater than 1.

where $f\mathcal{E}$ denotes the ellipsoid \mathcal{E} scaled by the factor $f \in \mathbb{R}^+$ with respect to its center, and where $\text{conv}(A)$ denotes the *convex hull* of a pointset $A \subset \mathbb{E}^d$.

The underlying algorithm can cope with all kinds of inputs (multisets P , $\varepsilon \in [0, \infty)$) and terminates in all cases. There is, however, no guarantee that any desired approximation ratio is actually achieved; the performance of the algorithm in this respect highly depends on the input pointset. Values of at least 0.01 for ε are usually handled without problems.

Internally, the algorithm represents the input points' Cartesian coordinates as *double*'s. For this conversion to work, the input point coordinates must be convertible to *double*. Also, in order to compute the achieved epsilon ε' mentioned above, the algorithm requires a number type *ET* that provides *exact* arithmetic. (Both these aspects are discussed in the documentation of the concept *ApproximateMinEllipsoid_d_Traits_d*.)

```
#include <CGAL/Approximate_min_ellipsoid_d.h>
```

Requirements

The template parameter *Traits* is a model for *ApproximateMinEllipsoid_d_Traits_d*.

We provide the model *CGAL::Approximate_min_ellipsoid_d_traits_d<K>* using the d -dimensional CGAL kernel; the models *CGAL::Approximate_min_ellipsoid_d_traits_2<K>* and *CGAL::Approximate_min_ellipsoid_d_traits_3<K>* are for use with the 2- and 3-dimensional CGAL kernel, respectively.

Types

Approximate_min_ellipsoid_d<Traits>:: FT

typedef Traits::FT FT (which is always a typedef to *double*).

Approximate_min_ellipsoid_d<Traits>:: ET

typedef Traits::ET ET (which is an exact number type used for exact computation like for example in *achieved_epsilon()*).

Approximate_min_ellipsoid_d<Traits>:: Point

typedef Traits::Point Point

Approximate_min_ellipsoid_d<Traits>:: Cartesian_const_iterator

typedef Traits::Cartesian_const_iterator Cartesian_const_iterator

Approximate_min_ellipsoid_d<Traits>:: Center_coordinate_iterator

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the Cartesian center coordinates of the computed ellipsoid, see *center_cartesian_begin()*.

Approximate_min_ellipsoid_d<Traits>::Axes_lengths_iterator

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the lengths of the semiaxes of the computed ellipsoid, see *axes_lengths_begin()*.

Approximate_min_ellipsoid_d<Traits>::Axis_direction_iterator

A model of STL concept *RandomAccessIterator* with value type *double* that is used to iterate over the Cartesian coordinates of the direction of a fixed axis of the computed ellipsoid, see *axis_direction_cartesian_begin()*.

Creation

An object of type *Approximate_min_ellipsoid_d<Traits>* can be created from an arbitrary point set P and some nonnegative *double* value *eps*.

template < class Iterator >

Approximate_min_ellipsoid_d<Traits> ame(double eps, Iterator first, Iterator last, Traits traits = Traits());

initializes *ame* to an $(1 + \epsilon)$ -approximation of $\text{MEL}(P)$ with P being the set of points in the range $[first, last)$. The number ϵ in this will be at most *eps*, if possible. However, due to the limited precision in the algorithm's underlying arithmetic, it can happen that the computed approximation ellipsoid has a worse approximation ratio (and ϵ can thus be larger than *eps* in general). In any case, the number ϵ (and with this, the achieved approximation $1 + \epsilon$) can be queried by calling the routine *achieved_epsilon()* discussed below.

Requirement: *Iterator* must be a model for concept *InputIterator* with value type *Point*.

Precondition: The dimension d of the input points must be at least 2, and $\epsilon > 0$.

Access Functions

The following methods can be used to query the achieved approximation ratio $1 + \epsilon'$ and the computed ellipsoid $\mathcal{E} = \{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$. The methods *defining_matrix()*, *defining_vector()*, and *defining_scalar()* do not return E , e , and η directly but yield multiples of these quantities that are exactly representable using the *double* type. (This is necessary because the parameters E , e , and η of the computed approximation ellipsoid \mathcal{E} might not be exactly representable as *double* numbers.)

unsigned int ame.number_of_points()

returns the number of points of *ame*, i.e., $|P|$.

<i>double</i>	<i>ame.achieved_epsilon()</i>	<p>returns a number ϵ' such that the computed approximation is (under exact arithmetic) guaranteed to be an $(1 + \epsilon')$-approximation to $\text{MEL}(P)$.</p> <p><i>Precondition:</i> <i>ame.is_full_dimensional()</i> == <i>true</i>.</p> <p><i>Postcondition:</i> $\epsilon' > 0$.</p>
<i>double</i>	<i>ame.defining_matrix(int i, int j)</i>	<p>gives access to the (i, j)th entry of the matrix E in the representation $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ of the computed approximation ellipsoid \mathcal{E}. The number returned by this routine is $(1 + \epsilon')(d + 1) E_{ij}$, where ϵ' is the number returned by <i>achieved_epsilon()</i>.</p> <p><i>Precondition:</i> $0 \leq i, j \leq d$, where d is the dimension of the points P, and <i>ame.is_full_dimensional()</i> == <i>true</i>.</p>
<i>double</i>	<i>ame.defining_vector(int i)</i>	<p>gives access to the ith entry of the vector e in the representation $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ of the computed approximation ellipsoid \mathcal{E}. The number returned by this routine is $(1 + \epsilon')(d + 1) e_i$, where ϵ' is the number returned by <i>achieved_epsilon()</i>.</p> <p><i>Precondition:</i> $0 \leq i \leq d$, where d is the dimension of the points P, and <i>ame.is_full_dimensional()</i> == <i>true</i>.</p>
<i>double</i>	<i>ame.defining_scalar()</i>	<p>gives access to the scalar η from the representation $\{x \in \mathbb{E}^d \mid x^T E x + x^T e + \eta \leq 0\}$ of the computed approximation ellipsoid \mathcal{E}. The number returned by this routine is $(1 + \epsilon')(d + 1)(\eta + 1)$, where ϵ' is the number returned by <i>achieved_epsilon()</i>.</p> <p><i>Precondition:</i> <i>ame.is_full_dimensional()</i> == <i>true</i>.</p>
<i>Traits</i>	<i>ame.traits()</i>	returns a const reference to the traits class object.
<i>int</i>	<i>ame.dimension()</i>	returns the dimension of the ambient space, i.e., the dimension of the points P .

In order to access the center and semiaxes of the computed approximation ellipsoid, the functions *center_cartesian_begin()*, *axes_lengths_begin()*, and *axis_direction_cartesian_begin()* can be used. In contrast to the above access functions *achieved_epsilon()*, *defining_matrix()*, *defining_vector()*, and *defining_scalar()*, which return the described quantities exactly, the routines below return *numerical approximations* to the real center and real semiaxes of the computed ellipsoid; the comprised relative error may be larger than zero, and there are no guarantees for the returned quantities.

Center_coordinate_iterator

ame.center_cartesian_begin()

returns an iterator pointing to the first of the d Cartesian coordinates of the computed ellipsoid's center.

The returned point is a floating-point approximation to the ellipsoid's exact center; no guarantee is given w.r.t. the involved relative error.

Precondition: *ame.is_full_dimensional()* == *true*.

Center_coordinate_iterator

ame.center_cartesian_end()

returns the past-the-end iterator corresponding to *center_cartesian_begin()*.

Precondition: *ame.is_full_dimensional()* == *true*.

Axes_lengths_iterator

ame.axes_lengths_begin()

returns an iterator pointing to the first of the d descendantly sorted lengths of the computed ellipsoid's axes. The d returned numbers are floating-point approximations to the exact axes-lengths of the computed ellipsoid; no guarantee is given w.r.t. the involved relative error. (See also method *axes_direction_cartesian_begin()*.)

Precondition: *ame.is_full_dimensional()* == *true*, and $d \in \{2, 3\}$.

Axes_lengths_iterator

ame.axes_lengths_end()

returns the past-the-end iterator corresponding to *axes_lengths_begin()*.

Precondition: *ame.is_full_dimensional()* == *true*, and $d \in \{2, 3\}$.

Axes_direction_coordinate_iterator

ame.axis_direction_cartesian_begin(int i)

returns an iterator pointing to the first of the d Cartesian coordinates of the computed ellipsoid's i th axis direction (i.e., unit vector in direction of the ellipsoid's i th axis). The direction described by this iterator is a floating-point approximation to the exact axis direction of the computed ellipsoid; no guarantee is given w.r.t. the involved relative error. An approximation to the length of axis i is given by the i th entry of *axes_lengths_begin()*.

Precondition: *ame.is_full_dimensional()* == *true*, and $d \in \{2, 3\}$, and $0 \leq i < d$.

Axes_direction_coordinate_iterator

ame.axis_direction_cartesian_end(int i)

returns the past-the-end iterator corresponding to *axis_direction_cartesian_begin()*.

Precondition: *ame.is_full_dimensional()* == *true*, and $d \in \{2, 3\}$, and $0 \leq i < d$.

Predicates

bool

ame.is_full_dimensional()

returns whether P is full-dimensional or not, i.e., returns *true* if and only if P is full-dimensional.

Note: due to the limited precision in the algorithm's underlying arithmetic, the result of this method is not always correct. Rather, a return value of *false* means that the points P are contained in a “very thin” linear subspace of \mathbb{E}^d , and as a consequence, the algorithm cannot compute an approximation. More precisely, a return value of *false* means that the points P are contained between two parallel hyperplanes in \mathbb{E}^d that are very close to each other (possibly at distance zero) — so close, that the algorithm could not compute an approximation ellipsoid. Similarly, a return value of *true* does not guarantee P to be full-dimensional; but there exists an input pointset P' such that the points P' and P have almost identical coordinates and P' is full-dimensional.

Validity Check

An object *ame* is valid iff

- *ame* contains all points of its defining set P ,
- *ame* is an $(1 + \varepsilon')$ -approximation to the smallest ellipsoid $\text{MEL}(P)$ of P ,
- The ellipsoid represented by *ame* fulfills the inclusion (48.1).

bool *ame.is_valid(bool verbose = false)*

returns *true* iff *ame* is valid according to the above definition.
If *verbose* is *true*, some messages concerning the performed checks are written to the standard error stream.

Miscellaneous

void *ame.write_eps(const std::string& name)*

Writes the points P and the computed approximation to $\text{MEL}(P)$ as an EPS-file under pathname *name*.
Precondition: The dimension of points P must be 2.
Note: this routine is provided as a debugging routine; future version of CGAL might not provide it anymore.
Precondition: *ame.is_full_dimensional() == true*.

Implementation

We implement Khachyan's algorithm for rounding polytopes [Kha96]. Internally, we use *double*-arithmetic and (initially a single) Cholesky-decomposition. The algorithm's running time is $O(nd^2(\varepsilon^{-1} + \ln d + \ln \ln(n)))$, where $n = |P|$ and $1 + \varepsilon$ is the desired approximation ratio.

Example

To illustrate the usage of *Approximate_min_ellipsoid_d<Traits>* we give two examples in 2D. The first program generates a random set $P \subset \mathbb{E}^2$ and outputs the points and a 1.01-approximation of $\text{MEL}(P)$ as an EPS-file, which you can view using *gv*, for instance. (In both examples you can change the variables n and d to experiment with the code.)

```
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include <CGAL/point_generators_d.h>
```

```

#include <CGAL/Approximate_min_ellipsoid_d.h>
#include <CGAL/Approximate_min_ellipsoid_d_traits_d.h>

#include <vector>
#include <iostream>

typedef CGAL::Cartesian_d<double> Kernel;
typedef CGAL::MP_Float ET;
typedef CGAL::Approximate_min_ellipsoid_d_traits_d<Kernel, ET> Traits;

typedef std::vector<Point> Point_list;
typedef CGAL::Approximate_min_ellipsoid_d<Traits> AME;

int main()
{
    const int      n = 1000;          // number of points
    const int      d = 2;             // dimension
    const double eps = 0.01;          // approximation ratio is (1+eps)

    // create a set of random points:
    Point_list P;
    CGAL::Random_points_in_iso_box_d<Point> rpg(d,100.0);
    for (int i = 0; i < n; ++i) {
        P.push_back(*rpg);
        ++rpg;
    }

    // compute approximation:
    Traits traits;
    AME ame(eps, P.begin(), P.end(), traits);

    // write EPS file:
    if (ame.is_full_dimensional() && d == 2)
        ame.write_eps("example.eps");

    // output center coordinates:
    std::cout << "Cartesian center coordinates: ";
    for (AME::Center_coordinate_iterator c_it = ame.center_cartesian_begin();
        c_it != ame.center_cartesian_end();
        ++c_it)
        std::cout << *c_it << ' ';
    std::cout << ".\n";

    if (d == 2 || d == 3) {
        // output axes:
        AME::Axes_lengths_iterator axes = ame.axes_lengths_begin();
        for (int i = 0; i < d; ++i) {
            std::cout << "Semiaxis " << i << " has length " << *axes++ << "\n"
                << "and Cartesian coordinates ";
            for (AME::Axes_direction_coordinate_iterator
                d_it = ame.axis_direction_cartesian_begin(i);
                d_it != ame.axis_direction_cartesian_end(i); ++d_it)
                std::cout << *d_it << ' ';
            std::cout << ".\n";
        }
    }
}

```

```

    }
}
}

```

ApproximateMinEllipsoid_d_Traits_d

Definition

This concept defines the requirements for traits classes of *CGAL::Approximate_min_ellipsoid_d<Traits>*.

Refines

DefaultConstructible

CopyConstructible

Assignable

Types

ApproximateMinEllipsoid_d_Traits_d:: FT *typedef double FT*

ApproximateMinEllipsoid_d_Traits_d:: ET Some model of concept *RingNumberType* that provides exact arithmetic, meaning that *CGAL::Number_type_traits<ET>::Has_exact_ring_operations* must be *CGAL::Tag_true*. In addition, *ET* must be able to exactly represent any finite *double* value. (An example for such a type is *CGAL::MP_Float*.)
The type *ET* is to be used by the *Approximate_min_ellipsoid_d<Traits>* class for internal, exact computations.

ApproximateMinEllipsoid_d_Traits_d:: Point Type of the input points. *Point* must provide the default and copy constructor, and must be a model of *DefaultConstructible*, *CopyConstructible*, and *Assignable*.

ApproximateMinEllipsoid_d_Traits_d:: Cartesian_const_iterator Model for the STL concept *RandomAccessIterator* whose value type must be convertible to *double*. This type is used to iterate over the Cartesian coordinates of an instance of type *Point*, see *cartesian_begin()* below.

Access Functions

int *traits.dimension(Point p)*
returns the dimension of a point *p*.

Cartesian_const_iterator *traits.cartesian_begin(Point p)*
returns an input iterator over the Euclidean coordinates of the point *p*. The range of the iterator must have size *dimension(p)*.

CGAL::Approximate_min_ellipsoid_d_traits_2<K,ET>

Definition

The class *Approximate_min_ellipsoid_d_traits_2<K,ET>* is a traits class for *CGAL::Approximate_min_ellipsoid_d<Traits>* using the 2-dimensional CGAL kernel. In order to use this class, an exact number-type *ET* has to be provided which *Approximate_min_ellipsoid_d<Traits>* will use for its internal exact computations.

```
#include <CGAL/Approximate_min_ellipsoid_d_traits_2.h>
```

Requirements

The template parameter *K* must be a model for concept *Kernel*. The template parameter *ET* must be a model for concept *RingNumberType* with exact arithmetic operations, i.e., the type *CGAL::Number_type_traits<ET>::Has_exact_ring_operations* must be *CGAL::Tag_true*. In addition, *ET* must be able to exactly represent any finite *double* value. (Examples of such a number-type are *CGAL::MP_Float*, *CORE::Expr*, and *CGAL::Gmpq*.)

Is Model for the Concepts

ApproximateMinEllipsoid_d_Traits_d

Types

Approximate_min_ellipsoid_d_traits_2<K,ET>::FT *typedef double FT*. The kernel's number type *K::RT* must be convertible to *double*.

Approximate_min_ellipsoid_d_traits_2<K,ET>::ET *typedef* to the second template argument, *ET*.

Approximate_min_ellipsoid_d_traits_2<K,ET>::Point
typedef K::Point_2 Point

CGAL::Approximate_min_ellipsoid_d_traits_3<K,ET>

Definition

The class *Approximate_min_ellipsoid_d_traits_3<K,ET>* is a traits class for *CGAL::Approximate_min_ellipsoid_d<Traits>* using the 3-dimensional CGAL kernel. In order to use this class, an exact number-type *ET* has to be provided which *Approximate_min_ellipsoid_d<Traits>* will use for its internal exact computations.

```
#include <CGAL/Approximate_min_ellipsoid_d_traits_3.h>
```

Requirements

The template parameter *K* must be a model for concept *Kernel*. The template parameter *ET* must be a model for concept *RingNumberType* with exact arithmetic operations, i.e., the type *CGAL::Number_type_traits<ET>::Has_exact_ring_operations* must be *CGAL::Tag_true*. In addition, *ET* must be able to exactly represent any finite *double* value. (Examples of such a number-type are *CGAL::MP_Float*, *CORE::Expr*, and *CGAL::Gmpq*.)

Is Model for the Concepts

ApproximateMinEllipsoid_d_Traits_d

Types

Approximate_min_ellipsoid_d_traits_3<K,ET>::FT

typedef double FT. The kernel's number type *K::RT* must be convertible to *double*.

Approximate_min_ellipsoid_d_traits_3<K,ET>::ET

typedef to the second template argument, *ET*.

Approximate_min_ellipsoid_d_traits_3<K,ET>::Point

typedef K::Point_3 Point

Approximate_min_ellipsoid_d_traits_3<K,ET>::Cartesian_const_iterator

typedef K::Cartesian_const_iterator_3 Cartesian_const_iterator

CGAL::Min_sphere_annulus_d_traits_2<K,ET,NT>

Definition

The class `Min_sphere_annulus_d_traits_2<K,ET,NT>` is a traits class for the d -dimensional optimisation algorithms using the two-dimensional CGAL kernel.

```
#include <CGAL/Min_sphere_annulus_d_traits_2.h>
```

Requirements

The template parameter K is a model for *Kernel*. Template parameters ET and NT are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

Is Model for the Concepts

MinSphereAnnulusDTraits page 2761

Types

```
Min_sphere_annulus_d_traits_2<K,ET,NT>::Point_d typedef to K::Point_2.
```

$$Min_sphere_annulus_d_traits_2<K,ET,NT>::Rep_tag \quad \text{typedef to } K::Rep_tag.$$
$$Min_sphere_annulus_d_traits_2\langle K, ET, NT \rangle :: RT \quad \text{typedef to } K :: RT.$$
$$Min_sphere_annulus_d_traits_2<K,ET,NT>::FT \quad \text{typedef to } K::FT.$$

```

MinSphereAnnulusDTraits

Definition

This concept defines the requirements for traits classes of d -dimensional min sphere and min annulus algorithms.

Types

<i>MinSphereAnnulusDTraits:: Point_d</i>	point type used to represent the input points.
<i>MinSphereAnnulusDTraits:: Rep_tag</i>	compile time tag to distinguish between Cartesian and homogeneous representation of the input points. <i>Rep_tag</i> has to be either <i>CGAL::Cartesian_tag</i> or <i>CGAL::Homogeneous_tag</i> .
<i>MinSphereAnnulusDTraits:: RT</i>	number type used to represent the coordinates of the input points. It has to be a model for <i>RingNumberType</i> .
<i>MinSphereAnnulusDTraits:: FT</i>	number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. <i>FT</i> has to be either <i>RT</i> or <i>CGAL::Quotient<RT></i> if the input points have Cartesian or homogeneous representation, respectively (cf. <i>Rep_tag</i>).
<i>MinSphereAnnulusDTraits:: Access_dimension_d</i>	data accessor object used to access the dimension of the input points.
<i>MinSphereAnnulusDTraits:: Access_coordinates_begin_d</i>	data accessor object used to access the coordinates of the input points.
<i>MinSphereAnnulusDTraits:: Construct_point_d</i>	constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.

The following two number types are only needed for *CGAL::Min_annulus_d<Traits>* and *CGAL::Polytope_distance_d<Traits>*.

<i>MinSphereAnnulusDTraits:: ET</i>	exact number type used to do the exact computations in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be an implicit conversion from <i>RT</i> to <i>ET</i> available.
<i>MinSphereAnnulusDTraits:: NT</i>	fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be implicit conversions from <i>RT</i> to <i>NT</i> and from <i>NT</i> to <i>ET</i> available.

Creation

Only default and copy constructor are required.

```
MinSphereAnnulusDTraits traits;
```

```
MinSphereAnnulusDTraits traits( MinSphereAnnulusDTraits);
```

Operations

The following functions just return the corresponding function class object.

```
Access_dimension_d traits.access_dimension_d_object()
```

```
Access_coordinates_begin_d traits.access_coordinates_begin_d_object()
```

```
Construct_point_d traits.construct_point_d_object()
```

Chapter 49

Inscribed Areas

Michael Hoffmann and Eli Packer

This chapter describes algorithms which for a given point set compute the “best” inscribed object from a specific class. We provide algorithms for computing maximal inscribed k -gons (triangles, quadrilaterals, ...) of a planar point set P . Maximal k -gons are convex, and it is known that their vertices can be chosen to be vertices of the convex hull of P . Hence, the functions `CGAL::maximum_area_inscribed_k_gon_2` and `CGAL::maximum_perimeter_inscribed_k_gon_2` operate on convex polygons only. The example below shows that the largest area triangle (green) and the largest perimeter triangle (orange, containing the top point) of a point set are different in general.

We further provide an algorithm for computing the maximal area inscribed axis parallel rectangle

Given a set of points in the plane, the class `CGAL::Largest_empty_iso_rectangle_2<T>` is a data structure that maintains an iso-rectangle with the largest area among all iso-rectangles that are inside a given iso-rectangles, and that do not contain any point of the point set.

Inscribed volumes are also frequently applied to extract geometric properties of objects. The largest area triangle is for example used in heuristics for matching archaeological aerial photographs. Largest perimeter triangles are used in scoring cross country soaring flights, where the goal is basically to fly as far as possible, but still return to the departure airfield. To score simply based on the total distance flown is not a good measure, since circling in thermals allows to increase it easily.

Inscribed Areas

Reference Manual

Michael Hoffmann and Eli Packer

This chapter describes concepts, classes, and functions for maximum area and perimeter inscribed k -gon (2D), extremal inscribed k -gon (2D), largest empty isorectangle (2D).

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section ??.

CGAL::maximum_area_inscribed_k_gon_2

Definition

The function *maximum_area_inscribed_k_gon_2* computes a maximum area k -gon P_k that can be inscribed into a given convex polygon P . Note that

- P_k is not unique in general, but it can be chosen in such a way that its vertices form a subset of the vertex set of P and
- the vertices of a maximum area k -gon, where the k vertices are to be drawn from a planar point set S , lie on the convex hull of S i.e. a convex polygon.

```
#include <CGAL/extremal_polygon_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      maximum_area_inscribed_k_gon_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    int k,
                    OutputIterator o)
```

computes a maximum area inscribed k -gon of the convex polygon described by $[points_begin, points_end)$, writes its vertices to o and returns the past-the-end iterator of this sequence.

Precondition:

1. the – at least three – points denoted by the range $[points_begin, points_end)$ form the boundary of a convex polygon (oriented clock- or counterclockwise).
2. $k \geq 3$.

Requirement:

1. Value type of *RandomAccessIterator* is $K::Point_2$ where K is a model for *Kernel*.
2. *OutputIterator* accepts the value type of *RandomAccessIterator* as value type.

Implementation

The implementation uses monotone matrix search [AKM⁺87] and has a worst case running time of $O(k \cdot n + n \cdot \log n)$, where n is the number of vertices in P .

Example

The following code generates a random convex polygon p with ten vertices and computes the maximum area inscribed five-gon of p .

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/extremal_polygon_2.h>
#include <iostream>
#include <vector>

typedef double FT;

struct Kernel : public CGAL::Cartesian<FT> {};

typedef Kernel::Point_2 Point;
typedef std::vector<int> Index_cont;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Random_points_in_square_2<Point> Generator;

int main() {

    int n = 10;
    int k = 5;

    // generate random convex polygon:
    Polygon_2 p;
    CGAL::random_convex_set_2(n, std::back_inserter(p), Generator(1));
    std::cout << "Generated Polygon:\n" << p << std::endl;

    // compute maximum area inscribed k-gon of p:
    Polygon_2 k_gon;
    CGAL::maximum_area_inscribed_k_gon_2(
        p.vertices_begin(), p.vertices_end(), k, std::back_inserter(k_gon));
    std::cout << "Maximum area " << k << "-gon:\n"
        << k_gon << std::endl;

    return 0;
}
```

CGAL::maximum_perimeter_inscribed_k_gon_2

Definition

The function *maximum_perimeter_inscribed_k_gon_2* computes a maximum perimeter k -gon P_k that can be inscribed into a given convex polygon P . Note that

- P_k is not unique in general, but it can be chosen in such a way that its vertices form a subset of the vertex set of P and
- the vertices of a maximum perimeter k -gon, where the k vertices are to be drawn from a planar point set S , lie on the convex hull of S i.e. a convex polygon.

```
#include <CGAL/extremal_polygon_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      maximum_perimeter_inscribed_k_gon_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    int k,
                    OutputIterator o)
```

computes a maximum perimeter inscribed k -gon of the convex polygon described by $[points_begin, points_end)$, writes its vertices to o and returns the past-the-end iterator of this sequence.

Precondition:

1. the – at least three – points denoted by the range $[points_begin, points_end)$ form the boundary of a convex polygon (oriented clock- or counterclockwise).
2. $k \geq 2$.

Requirement:

1. Value type of *RandomAccessIterator* is $K::Point_2$ where K is a model for *Kernel*.
2. There is a global function $K::FT$ $CGAL::sqrt(K::FT)$ defined that computes the squareroot of a number.
3. *OutputIterator* accepts the value type of *RandomAccessIterator* as value type.

    Polygon_2 k_gon;
    CGAL::maximum_perimeter_inscribed_k_gon_2(
        p.vertices_begin(), p.vertices_end(), k, std::back_inserter(k_gon));
    std::cout << "Maximum perimeter " << k << "-gon:\n"
        << k_gon << std::endl;

    return 0;
}
```

File: examples/Matrix_search/extremal_polygon_2_perimeter.cpp

CGAL::extremal_polygon_2

— advanced —

Definition

The function *extremal_polygon_2* computes a maximal k -gon that can be inscribed into a given convex polygon. The criterion for maximality and some basic operations have to be specified in an appropriate traits class parameter.

```
#include <CGAL/extremal_polygon_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator, class Traits >
OutputIterator      extremal_polygon_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    int k,
                    OutputIterator o,
                    Traits t)
```

computes a maximal (as specified by t) inscribed k -gon of the convex polygon described by $[points_begin, points_end)$, writes its vertices to o and returns the past-the-end iterator of this sequence.

Precondition:

1. the – at least three – points denoted by the range $[points_begin, points_end)$ form the boundary of a convex polygon (oriented clock- or counterclockwise).
2. $k \geq t.min_k()$.

Requirement:

1. *Traits* is a model for *ExtremalPolygonTraits_2*.
2. Value type of *RandomAccessIterator* is *Traits::Point_2*.
3. *OutputIterator* accepts *Traits::Point_2* as value type.

 CGAL::monotone_matrix_search page [3222](#)

Implementation

The implementation uses monotone matrix search [[AKM⁺87](#)] and has a worst case running time of $O(k \cdot n + n \cdot \log n)$, where n is the number of vertices in P .

— advanced —

Definition

Requirements

Is Model for the Concepts

Types

Extremal_polygon_area_traits_2<K>:: Operation

AdaptableBinaryFunction class *op*: $Point_2 \times Point_2 \rightarrow FT$. For a fixed *Point_2* *root*, *op*(*p*, *q*) returns twice the area of the triangle (*root*, *q*, *p*).

2771

Operation *t.operation(const Point_2& p) const*

returns *Operation* where *p* is the fixed *root* point.

```
template < class RandomAccessIterator, class OutputIterator >
OutputIterator      t.compute_min_k_gon( RandomAccessIterator points_begin,
                                         RandomAccessIterator points_end,
                                         FT& max_area,
                                         OutputIterator o) const
```

writes the vertices of [*points_begin*, *points_end*) forming a maximum area triangle rooted at *points_begin*[0] to *o* and returns the past-the-end iterator for that sequence ($== o + 3$).

Less_xy_2 *t.less_xy_2_object()*
Orientation_2 *t.orientation_2_object()*

CGAL::Extremal_polygon_perimeter_traits_2<K>

— *advanced* —

Definition

The class provides the types and operations needed to compute a maximum perimeter k -gon P_k that can be inscribed into a given convex polygon P using the function *extremal_polygon_2*.

Requirements

The template parameter K is a model for *Kernel*.

Is Model for the Concepts

ExtremalPolygonTraits_2.....page [2775](#)

Types

Extremal_polygon_perimeter_traits_2<K>:: FT

typedef to $K::FT$.

Extremal_polygon_perimeter_traits_2<K>:: Point_2

typedef to $K::Point_2$.

Extremal_polygon_perimeter_traits_2<K>:: Less_xy_2

typedef to $K::Less_{xy_2}$.

Extremal_polygon_perimeter_traits_2<K>:: Orientation_2

typedef to $K::Orientation_2$.

Extremal_polygon_perimeter_traits_2<K>:: Operation

AdaptableBinaryFunction class *op*: $Point_2 \times Point_2 \rightarrow FT$. For a fixed *Point_2* *root*, *op*(*p*, *q*) returns $d(r, p) + d(p, q) - d(r, q)$ where d denotes the Euclidean distance.

Operations

int *t.min_k()* *const* returns 2.

FT *t.init(const Point_2& p, const Point_2& q) const*
returns twice the Euclidean distance between *p* and *q*.

Operation *t.operation(const Point_2& p) const*
returns *Operation* where *p* is the fixed *root* point.

template < class RandomAccessIterator, class OutputIterator >
OutputIterator *t.compute_min_k_gon(RandomAccessIterator points_begin,*
 RandomAccessIterator points_end,
 FT& max_area,
 OutputIterator o) const
writes the pair (*points_begin*[0], *p*) where *p* is drawn from
[*points_begin*, *points_end*) such that the Euclidean distance
between both points is maximized (maximum perimeter 2-
gon rooted at *points_begin*[0]) to *o* and returns the past-the-
end iterator for that sequence (*== o + 2*).

Less_xy_2 *t.less_xy_2_object()*
Orientation_2 *t.orientation_2_object()*

ExtremalPolygonTraits_2

advanced

Definition

The concept `ExtremalPolygonTraits_2` provides the types and operations needed to compute a maximal k -gon that can be inscribed into a given convex polygon.

Types

<code>ExtremalPolygonTraits_2:: FT</code>	model for <code>FieldNumberType</code> page 726 .
<code>ExtremalPolygonTraits_2:: Point_2</code>	model for <code>Kernel::Point_2</code> page 435 .
<code>ExtremalPolygonTraits_2:: Less_xy_2</code>	model for <code>Kernel::Less_xy_2</code> page ?? .
<code>ExtremalPolygonTraits_2:: Orientation_2</code>	model for <code>Kernel::Orientation_2</code> page 430 .
<code>ExtremalPolygonTraits_2:: Operation</code>	AdaptableBinaryFunction class <code>op: Point_2 × Point_2 → FT</code> . Together with <code>init</code> this operation recursively defines the objective function to maximize. Let p and q be two vertices of a polygon P such that q precedes p in the oriented vertex chain of P starting with vertex <code>root</code> . Then <code>op(p,q)</code> returns the value by which an arbitrary sub-polygon of P with vertices from $[root, q]$ increases when p is added to it. E.g. in the maximum area case this is the area of the triangle $(root, q, p)$.

Operations

<code>int</code>	<code>t.min_k() const</code>	returns the minimal k for which a maximal k -gon can be computed. (e.g. in the maximum area case this is three.)
<code>FT</code>	<code>t.init(const Point_2& p, const Point_2& q) const</code>	returns the value of the objective function for a polygon consisting of the two points p and q . (e.g. in the maximum area case this is <code>FT(0)</code> .)
<code>Operation</code>	<code>t.operation(const Point_2& p) const</code>	return <code>Operation</code> where p is the fixed <code>root</code> point.

`template < class RandomAccessIterator, class OutputIterator >`

OutputIterator *t.compute_min_k_gon(RandomAccessIterator points_begin,*
 RandomAccessIterator points_end,
 FT& max_area,
 OutputIterator o) const

writes the points of [*points_begin*, *points_end*) forming a *min_k*()-gon rooted at *points_begin*[0] of maximal value to *o* and returns the past-the-end iterator for that sequence (*== o + min_k()*).

Less_xy_2 *t.less_xy_2_object()*
Orientation_2 *t.orientation_2_object()*

Notes

- *::Less_xy_2* and *::Orientation_2* are used for (expensive) precondition checking only. Therefore, they need not to be specified, in case that precondition checking is disabled.

CGAL::Largest_empty_iso_rectangle_2<T>

Definition

Given a set of points in the plane, the class *Largest_empty_iso_rectangle_2<T>* is a data structure that maintains an iso-rectangle with the largest area among all iso-rectangles that are inside a given bounding box(iso-rectangle), and that do not contain any point of the point set.

The class *Largest_empty_iso_rectangle_2<T>* expects a model of the concept *LargestEmptyIsoRectangleTraits_2* as its template argument.

```
#include <CGAL/Largest_empty_iso_rectangle_2.h>
```

Types

The class *Largest_empty_iso_rectangle_2<T>* defines the following types:

```
typedef T Traits;
```

```
typedef Traits::Point_2
```

```
Point_2;
```

```
typedef Traits::Iso_rectangle_2
```

```
Iso_rectangle_2;
```

The following iterator allows to enumerate the points. It is non mutable, bidirectional and its value type is *Point_2*. It is invalidated by any insertion or removal of a point.

```
Largest_empty_iso_rectangle_2<T>::const_iterator
```

Iterator over the points.

Creation

```
Largest_empty_iso_rectangle_2<T> l( Iso_rectangle_2 b);
```

Constructor. The iso-rectangle *b* is the bounding rectangle.

```
Largest_empty_iso_rectangle_2<T> l( const Point_2 p, const Point_2 q);
```

Constructor. The iso-rectangle whose lower left and upper right points are *p* and *q* respectively is the bounding rectangle.

```
Largest_empty_iso_rectangle_2<T> l;
```

Constructor. The iso-rectangle whose lower left point and upper right points are (0,0) and (1,1) respectively is the bounding rectangle.

Largest_empty_iso_rectangle_2<*T*> *l*(*const Largest_empty_iso_rectangle_2*<*Traits*> *tr*);

Copy constructor.

Operations

Assignment

Largest_empty_iso_rectangle_2<*T*>

l = *tr*

Access Functions

<i>Traits</i>	<i>l.traits()</i>	Returns a const reference to the traits object.
<i>const_iterator</i>	<i>l.begin()</i>	Returns an iterator to the beginning of the point set.
<i>const_iterator</i>	<i>l.end()</i>	Returns a past-the-end iterator for the point set.

Queries

Quadruple<*Point_2*, *Point_2*, *Point_2*, *Point_2*>

l.get_left_bottom_right_top()

Returns the four points that define the largest empty iso-rectangle. (Note that these points are not necessarily on a corner of an iso-rectangle.)

Iso_rectangle_2

l.get_largest_empty_iso_rectangle()

Returns the largest empty iso-rectangle. (Note that the two points defining the iso-rectangle are not necessarily part of the point set.)

Iso_rectangle_2

l.get_bounding_box() Returns the iso-rectangle passed in the constructor.

Insertion

void *l.insert(Point_2 p)* Inserts point *p* in the point set, if it is not already in the set.

void *l.push_back(Point_2 p)* Inserts point *p* in the point set, if it is not already in the set.

template < class InputIterator >

int *l.insert(InputIterator first, InputIterator last)*

Inserts the points in the range $[first, last)$. Returns the number of inserted points.

Requirements

The *value_type* of *first* and *last* is *Point*.

Removal

bool *l.remove(Point_2 p)* Removes point *p*. Returns false iff *p* is not in the point set.

void *l.clear()* Removes all points of *l*.

Implementation

The algorithm is an implementation of [Ori90]. The runtime of an insertion or a removal is $O(\log n)$. A query takes $O(n^2)$ worst case time and $O(n \log n)$ expected time. The working storage is $O(n)$.

LargestEmptyIsoRectangleTraits_2

Definition

The concept `LargestEmptyIsoRectangleTraits_2` describes the set of requirements to be fulfilled by any class used to instantiate the template parameter of the class `Largest_empty_iso_rectangle_2<T>`. This concept provides the types of the geometric primitives used in this class and some function object types for the required predicates on those primitives.

Types

`LargestEmptyIsoRectangleTraits_2::Point_2` The point type.

`LargestEmptyIsoRectangleTraits_2::Iso_rectangle_2`

The iso rectangle type.

`LargestEmptyIsoRectangleTraits_2::Compare_x_2`

Predicate object. Must provide the operator `Comparison_result operator()(Point_2 p, Point_2 q)` which returns *SMALLER*, *EQUAL* or *LARGER* according to the *x*-ordering of points *p* and *q*.

`LargestEmptyIsoRectangleTraits_2::Compare_y_2`

Predicate object. Must provide the operator `Comparison_result operator()(Point_2 p, Point_2 q)` which returns *SMALLER*, *EQUAL* or *LARGER* according to the *y*-ordering of points *p* and *q*.

`LargestEmptyIsoRectangleTraits_2::Less_x_2`

Predicate object. Must provide the operator `bool operator()(Point_2 p, Point_2 q)` which returns whether *p* is less than *q* according to their *x*-ordering.

`LargestEmptyIsoRectangleTraits_2::Less_y_2`

Predicate object. Must provide the operator `bool operator()(Point_2 p, Point_2 q)` which returns whether *p* is less than *q* according to their *y*-ordering.

Creation

Only a default constructor, copy constructor and an assignment operator are required. Note that further constructors can be provided.

`LargestEmptyIsoRectangleTraits_2 traits;` Default constructor.

`LargestEmptyIsoRectangleTraits_2 traits(LargestEmptyIsoRectangleTraits_2);`

Copy constructor

`LargestEmptyIsoRectangleTraits_2`

`traits = gtr`

Assignment operator.

Predicate functions

The following functions give access to the predicate and constructor objects.

<i>Compare_x_2</i>	<i>traits.compare_x_2_object()</i>
<i>Compare_y_2</i>	<i>traits.compare_y_2_object()</i>
<i>Less_x_2</i>	<i>traits.less_x_2_object()</i>
<i>Less_y_2</i>	<i>traits.less_y_2_object()</i>

Chapter 50

Optimal Distances

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr

This chapter describes how to compute the distance between the convex hulls of two given point sets in d -dimensional Euclidean space (*CGAL::Polytope_distance_d<Traits>*). Moreover, it is possible to compute the width of a point set in three dimensions (*CGAL::Width_3<Traits>*).

The obvious application is collision detection between convex bodies in space. In the spirit of the bounding volume application above, it also makes sense for nonconvex objects: a full intersection test between complicated objects could in a first stage be approximated with the test between the convex hulls of the objects. Only if the hulls intersect, a full intersection test is necessary.

To dampen fears concerning the performance of the distance computation, we want to mention that the convex hulls of the input point sets are not explicitly computed. This avoids a runtime which grows exponentially in d . In fact, the runtime is almost always linear in the size of the two point sets.

Optimal Distances

Reference Manual

Kaspar Fischer, Bernd Gärtner, Thomas Herrmann, Michael Hoffmann, and Sven Schönherr

This chapter describes concepts, classes, and functions for 2D all furthest neighbors, 3D width of a point set, and dD polytope distance.

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section ??.

CGAL::all_furthest_neighbors_2

Definition

The function *all_furthest_neighbors_2* computes all furthest neighbors for the vertices of a convex polygon P , i.e. for each vertex v of P a vertex f_v of P such that the distance between v and f_v is maximized.

```
#include <CGAL/all_furthest_neighbors_2.h>
```

```
template < class RandomAccessIterator, class OutputIterator, class Traits >
OutputIterator      all_furthest_neighbors_2(
                    RandomAccessIterator points_begin,
                    RandomAccessIterator points_end,
                    OutputIterator o,
                    Traits t = Default_traits)
```

computes all furthest neighbors for the vertices of the convex polygon described by the range $[points_begin, points_end)$, writes their indices (relative to $points_begin$) to o ¹ and returns the past-the-end iterator of this sequence.

Precondition: The points denoted by the non-empty range $[points_begin, points_end)$ form the boundary of a convex polygon P (oriented clock- or counterclockwise).

The geometric types and operations to be used for the computation are specified by the traits class parameter t . This parameter can be omitted if *RandomAccessIterator* refers to a point type from a *Kernel*. In this case, the kernel is used as default traits class.

Requirement:

1. If t is specified explicitly, *Traits* is a model for *AllFurthestNeighborsTraits_2*.
2. Value type of *RandomAccessIterator* is *Traits::Point_2* or – if t is not specified explicitly – *K::Point_2* where K is a model for *Kernel*.
3. *OutputIterator* accepts *int* as value type.

See Also

AllFurthestNeighborsTraits_2 page [2789](#)
CGAL::monotone_matrix_search page [3222](#)

Implementation

The implementation uses monotone matrix search[AKM⁺87]. Its runtime complexity is linear in the number of vertices of P .

¹i.e. the furthest neighbor of $points_begin[i]$ is $points_begin[i]$ -th number written to o

Example

The following code generates a random convex polygon p with ten vertices, computes all furthest neighbors and writes the sequence of their indices (relative to *points_begin*) to *cout* (e.g. a sequence of 4788911224 means the furthest neighbor of *points_begin*[0] is *points_begin*[4], the furthest neighbor of *points_begin*[1] is *points_begin*[7] etc.).

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>
#include <CGAL/all_furthest_neighbors_2.h>
#include <CGAL/IO/Ostream_iterator.h>
#include <iostream>
#include <vector>

typedef double FT;

struct Kernel : public CGAL::Cartesian<FT> {};

typedef Kernel::Point_2 Point;
typedef std::vector<int> Index_cont;
typedef CGAL::Polygon_2<Kernel> Polygon_2;
typedef CGAL::Random_points_in_square_2<Point> Generator;
typedef CGAL::Ostream_iterator<int, std::ostream> Oiterator;

int main()
{
    // generate random convex polygon:
    Polygon_2 p;
    CGAL::random_convex_set_2(10, std::back_inserter(p), Generator(1));

    // compute all furthest neighbors:
    CGAL::all_furthest_neighbors_2(p.vertices_begin(), p.vertices_end(),
                                   Oiterator(std::cout));

    std::cout << std::endl;

    return 0;
}
// -----
// ** EOF
// -----
```

AllFurthestNeighborsTraits_2

Definition

The concept `AllFurthestNeighborsTraits_2` defines types and operations needed to compute all furthest neighbors for the vertices of a convex polygon using the function `all_furthest_neighbors_2`.

Types

<code>AllFurthestNeighborsTraits_2:: FT</code>	model for <code>FieldNumberType</code> page 726 .
<code>AllFurthestNeighborsTraits_2:: Point_2</code>	model for <code>Kernel::Point_2</code> page 435 .
<code>AllFurthestNeighborsTraits_2:: Compute_squared_distance_2</code>	model for <code>Kernel::Compute_squared_distance_2</code> page ??.
<code>AllFurthestNeighborsTraits_2:: Less_xy_2</code>	model for <code>Kernel::Less_xy_2</code> page ??.
<code>AllFurthestNeighborsTraits_2:: Orientation_2</code>	model for <code>Kernel::Orientation_2</code> page 430 .

Operations

The following member functions return function objects of the types listed above.
`Compute_squared_distance_2`

	<code>t.compute_squared_distance_2_object()</code>
<code>Less_xy_2</code>	<code>t.less_xy_2_object()</code>
<code>Orientation_2</code>	<code>t.orientation_2_object()</code>

Has Models

`Cartesian<FieldNumberType>` page ??, `Homogeneous<RingNumberType>` page ??,
`Simple_cartesian<FieldNumberType>` page ??, `Simple_homogeneous<RingNumberType>` page ??.

See Also

`CGAL::all_furthest_neighbors_2` page [2787](#)

Notes

- `::Less_xy_2` and `::Orientation_2` are used for (expensive) precondition checking only. Therefore, they need not to be specified, in case that precondition checking is disabled.

CGAL::Width_3<Traits>

Definition

Given a set of points $\mathcal{S} = \{p_1, \dots, p_n\}$ in \mathbb{R}^3 . The width of \mathcal{S} , denoted as $\mathcal{W}(\mathcal{S})$, is defined as the minimum distance between two parallel planes of support of $\text{conv}(\mathcal{S})$; where $\text{conv}(\mathcal{S})$ denotes the convex hull of \mathcal{S} . The width in direction \mathbf{d} , denoted as $\mathcal{W}_{\mathbf{d}}(\mathcal{S})$, is the distance between two parallel planes of support of $\text{conv}(\mathcal{S})$, which are orthogonal to \mathbf{d} .

Subject to the applications of the width algorithm, several objects might be interesting:

1. The two parallel planes of support such that the distance between them is as small as possible. These planes are called width-planes in further considerations.
2. The width $\mathcal{W}(\mathcal{S})$, i.e., the distance between the width-planes.
3. The direction \mathbf{d}_{opt} such that $\mathcal{W}(\mathcal{S}) = \mathcal{W}_{\mathbf{d}_{opt}}(\mathcal{S})$

Note: There might be several optimal build directions. Hence neither the width-planes nor the direction \mathbf{d}_{opt} are unique – only the width is.

```
#include <CGAL/Width_3.h>
```

Requirements

The template parameter *Traits* is a model for *WidthTraits_3*. We provide the model *Width_default_traits_3<Kernel>* based on a three-dimensional CGAL kernel.

Types

<i>Width_3<Traits>::Traits</i>		traits class.
<i>typedef typename Traits::Point_3</i>	<i>Point_3;</i>	point type.
<i>typedef typename Traits::Plane_3</i>	<i>Plane_3;</i>	plane type.
<i>typedef typename Traits::Vector_3</i>	<i>Vector_3;</i>	vector type.
<i>typedef typename Traits::RT</i>	<i>RT;</i>	algebraic ring type.
<i>typedef typename Traits::ChullTraits</i>	<i>ChullTraits;</i>	traits class for the 3D convex hull algorithm.

Creation

```
template < class InputIterator >
Width_3<Traits> width( InputIterator first, InputIterator beyond);
```

creates a variable *width* initialized to the width of \mathcal{S} – with \mathcal{S} being the set of points in the range $[first, beyond)$.

Requirement: The value type of *InputIterator* is *Point_3*.

```
template < class Polyhedron >
Width_3<Traits> width( Polyhedron& P);
```

creates a variable *width* initialized to the width of the polyhedron *P*. Note that the vertex point coordinates are altered!

Precondition: *P* is a convex polyhedron.

Requirement: *Polyhedron* is a *CGAL::Polyhedron_3* with facets supporting plane equations where *Polyhedron::Point_3* \equiv *Point_3* and *Polyhedron::Plane_3* \equiv *Plane_3*.

Access Functions

```
void          width.get_squared_width( RT& width_num, RT& width_denom)
```

returns the squared width. For the reason of exact computation not the width itself is stored, but the *squared* width as a fraction: The numerator in *width_num* and the denominator in *width_denom*. The width of the point set \mathcal{S} is $\sqrt{\frac{width_num}{width_denom}}$.

```
void          width.get_width_planes( Plane_3& e1, Plane_3& e2)
```

The planes *e1* and *e2* are the two parallel supporting planes, which distance is minimal (among all such planes).

```
void          width.get_width_coefficients( RT& A, RT& B, RT& C, RT& D, RT& K)
```

The returned coefficients *A,B,C,D,K* have the property that width-plane *e1* is given by the equation $Ax + By + Cz + D = 0$ and width-plane *e2* by $Ax + By + Cz + K = 0$.

```
Vector_3      width.get_build_direction()
```

returns a direction \mathbf{d}_{opt} such that the width-planes *e1* and *e2* are perpendicular to \mathbf{d}_{opt} . The width of the point set is minimal in this direction.

```
void          width.get_all_build_directions( std::vector<Vector_3>& dir)
```

All the build directions are stored in the vector *dir*. It might happen that a certain body has several different build directions, but it is also possible to have only one build direction.

```
int           width.get_number_of_optimal_solutions()
```

returns the number of optimal solutions, i.e., the number of optimal build directions.

See Also

CGAL::Width_default_traits_3<K> page 2794
WidthTraits_3 page 2796

Implementation

Since the width of the point set S and the width of the convex hull of S ($\text{conv}(S)$) is the same, the algorithm uses the 3D convex hull algorithm CGAL provides.

The width-algorithm is not incremental and therefore inserting and erasing points cause not an ‘automatic’ update of the width. Instead you have to run the width-algorithm again even if the point set is extended by only one new point.

————— *advanced* —————

Large Numbers. Because there is no need for dividing values during the algorithm, the numbers can get really huge (all the computations are made using a lot of multiplications). Therefore it is strongly recommended to use a number type that can handle numbers of arbitrary length (e.g., *leda_integer* in combination with the homogeneous representation of the points). But these large numbers have a disadvantage: Operations on them are slower as greater the number gets. Therefore it is possible to shorten the numbers by using the compiler flag `-DSIMPLIFY`. For using this option it is required that the underlying number type provides the ‘modulo’ operation.

Information Output during the Computations. If during the algorithm the program should output some information (e.g., during the debugging phase) you can turn on the output information by giving the compiler flag `DEBUG`. In the file `width_assertions.h` you can turn on/off the output of some functions and additional informations by changing the defined values from 0 (no output) to 1 (output available). But then it is required that the `<<-operator` has to been overloaded for *Point_3*, *Plane_3*, *Vector_3* and *RT*.

————— *advanced* —————

Example

```
#include <CGAL/Homogeneous.h>
#include <CGAL/Width_default_traits_3.h>
#include <CGAL/Width_3.h>
#include <iostream>
#include <vector>

#if defined(CGAL_USE_GMP)
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#elif defined (CGAL_USE_LEDA)
#include <CGAL/leda_integer.h>
typedef leda_integer RT;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float RT;
#endif
```

```

typedef CGAL::Homogeneous<RT>           Kernel;

CGAL::Width_default_traits_3<K>

Definition

The class *Width_default_traits_3<K>* is a traits class for *Width_3<Traits>* using the three-dimensional CGAL kernel.

```
#include <CGAL/Width_default_traits_3.h>
```

Requirements

The template parameter *K* is a model for *Kernel*

Is Model for the Concepts

WidthTraits_3 page [2796](#)

Types

```
typedef typename K::Point_3      Point_3;
typedef typename K::Plane_3     Plane_3;
typedef typename K::Vector_3    Vector_3;
typedef typename K::RT          RT;
typedef Convex_hull_traits_3<K>  ChullTraits;
```

Creation

Width_default_traits_3<K> traits; default constructor.

Operations

<i>RT</i>	<i>traits.get_hx(Point_3 p)</i>	returns the homogeneous <i>x</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>traits.get_hy(Point_3 p)</i>	returns the homogeneous <i>y</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>traits.get_hz(Point_3 p)</i>	returns the homogeneous <i>z</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>traits.get_hw(Point_3 p)</i>	returns the homogenizing coordinate of point <i>p</i> .
<i>void</i>	<i>traits.get_point_coordinates(Point_3 p, RT& px, RT& py, RT& pz, RT& ph)</i>	returns all homogeneous coordinates of point <i>p</i> at once.
<i>RT</i>	<i>traits.get_a(Plane_3 f)</i>	returns the first coefficient of plane <i>f</i> .
<i>RT</i>	<i>traits.get_b(Plane_3 f)</i>	returns the second coefficient of plane <i>f</i> .
<i>RT</i>	<i>traits.get_c(Plane_3 f)</i>	returns the third coefficient of plane <i>f</i> .
<i>RT</i>	<i>traits.get_d(Plane_3 f)</i>	returns the fourth coefficient of plane <i>f</i> .
<i>void</i>	<i>traits.get_plane_coefficients(Plane_3 f, RT& a, RT& b, RT& c, RT& d)</i>	returns all four plane coefficients of <i>f</i> at once.

WidthTraits_3

Definition

This concept defines the requirements for traits classes of *Width_3<Traits>*.

Types

<i>WidthTraits_3:: Point_3</i>	The point type. The (in)equality tests must be available. Access to the point coordinates is done via the <i>get_..()</i> functions. Constructing a point is done with the <i>make_point()</i> operation.
<i>WidthTraits_3:: Plane_3</i>	The plane type. Access to the coefficients of the plane is made via the <i>get_..()</i> functions. Constructing a plane is done with the <i>make_plane()</i> operation.
<i>WidthTraits_3:: Vector_3</i>	The vector type. There is no need to access the coefficients of a vector; only constructing is required and is done with the <i>make_vector</i> operation.
<i>WidthTraits_3:: ChullTraits</i>	The traits class for using the convex hull algorithm. It must be a model of the concept <i>ConvexHullTraits_3</i> . This class is used only if the width is computed from a set of points.
<i>WidthTraits_3:: RT</i>	Ring type numbers. Internally all numbers are treated as ring type numbers, i.e., neither $/$ -operator nor $\sqrt{}$ nor other inexact operations are used. But because the algorithm does not use any divisions, but multiplication instead, the numbers can get really big. Therefore it is recommended to use a ring type number, that provides values of arbitrary length. Furthermore it is assumed that the underlying number type of <i>Point_3</i> , <i>Plane_3</i> and <i>Vector_3</i> equals <i>RT</i> .

Notes: If you want to compute the width of a *polyhedron* then you have to make sure that the point type in the traits class and the point type in the polyhedron class are the same! The same holds for *Traits::Plane_3* and *Polyhedron::Plane_3*.

Creation

Only a default constructor is required.

```
WidthTraits_3 traits;
```

Operations

Whatever the coordinates of the points are, it is required for the width-algorithm to have access to the homogeneous representation of points.

<i>RT</i>	<i>get_hx(Point_3 p)</i>	returns the homogeneous <i>x</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>get_hy(Point_3 p)</i>	returns the homogeneous <i>y</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>get_hz(Point_3 p)</i>	returns the homogeneous <i>z</i> -coordinate of point <i>p</i> .
<i>RT</i>	<i>get_hw(Point_3 p)</i>	returns the homogenizing coordinate of point <i>p</i> .
<i>void</i>	<i>get_point_coordinates(Point_3 p, RT& px, RT& py, RT& pz, RT& ph)</i>	returns all homogeneous coordinates of point <i>p</i> at once.
<i>RT</i>	<i>get_a(Plane_3 f)</i>	returns the first coefficient of plane <i>f</i> .
<i>RT</i>	<i>get_b(Plane_3 f)</i>	returns the second coefficient of plane <i>f</i> .

<i>RT</i>	<i>get_c(Plane_3 f)</i>	returns the third coefficient of plane <i>f</i> .
<i>RT</i>	<i>get_d(Plane_3 f)</i>	returns the fourth coefficient of plane <i>f</i> .
<i>void</i>	<i>get_plane_coefficients(Plane_3 f, RT& a, RT& b, RT& c, RT& d)</i>	returns all four plane coefficients of <i>f</i> at once.
<i>Point_3</i>	<i>make_point(RT hx, RT hy, RT hz, RT hw)</i>	returns a point of type <i>Point_3</i> with homogeneous coordinates <i>hx</i> , <i>hy</i> , <i>hz</i> and <i>hw</i> .
<i>Plane_3</i>	<i>make_plane(RT a, RT b, RT c, RT d)</i>	returns a plane of type <i>Plane_3</i> with coefficients <i>a</i> , <i>b</i> , <i>c</i> and <i>d</i> .
<i>Vector_3</i>	<i>make_vector(RT a, RT b, RT c)</i>	returns a vector of type <i>Vector_3</i> with the four homogeneous coefficients <i>a</i> , <i>b</i> , <i>c</i> and 1.

CGAL::Polytope_distance_d<Traits>

Definition

An object of the class *Polytope_distance_d<Traits>* represents the (squared) distance between two convex polytopes, given as the convex hulls of two finite point sets in d -dimensional Euclidean space \mathbb{E}_d . For point sets P and Q we denote by $pd(P, Q)$ the distance between the convex hulls of P and Q . Note that $pd(P, Q)$ can be degenerate, i.e. $pd(P, Q) = \infty$ if P or Q is empty.

Two inclusion-minimal subsets S_P of P and S_Q of Q with $pd(S_P, S_Q) = pd(P, Q)$ are called *pair of support sets*, the points in S_P and S_Q are the *support points*. A pair of support sets has size at most $d + 2$ (by size we mean $|S_P| + |S_Q|$). The distance between the two polytopes is *realized* by a pair of points p and q lying in the convex hull of S_P and S_Q , respectively, i.e. $\sqrt{\|p - q\|} = pd(P, Q)$. In general, neither the support sets nor the realizing points are necessarily unique.

The underlying algorithm can cope with all kinds of input, e.g. P and Q may be in non-convex position or points may occur more than once. The algorithm computes a pair of support sets S_P and S_Q with realizing points p and q which remain fixed until the next set, insert, or clear operation.

```
#include <CGAL/Polytope_distance_d.h>
```

Requirements

The template parameter *Traits* is a model for *OptimisationDTraits*.

We provide the models *Optimisation_d_traits_2*, *Optimisation_d_traits_3*, and *Optimisation_d_traits_d* using the two-, three-, and d -dimensional CGAL kernel, respectively.

Types

Polytope_distance_d<Traits>::Point typedef to *Traits::Point_d*. Point type used to represent the input points.

Polytope_distance_d<Traits>::FT typedef to *Traits::FT*. Number type used to return the squared distance between the two polytopes.

Polytope_distance_d<Traits>::ET typedef to *Traits::ET*. Number type used to do the exact computations in the underlying solver for quadratic programs (cf. **Implementation**).

Polytope_distance_d<Traits>::Point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the points of the two polytopes.

Polytope_distance_d<Traits>::Support_point_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *Point*. Used to access the support points.

Polytope_distance_d<Traits>:: Support_point_index_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *int*. Used to access the indices of the support points in the provided input order (starting from 0 in both point sets).

Polytope_distance_d<Traits>:: Coordinate_iterator

non-mutable model of the STL concept *RandomAccessIterator* with value type *ET*. Used to access the coordinates of the realizing points.

Creation

*Polytope_distance_d<Traits> poly_dist(Traits traits = Traits(),
int verbose = 0,
std::ostream& stream = std::cout)*

initializes *poly_dist* to *pd(0,0)*.

*template < class InputIterator1, class InputIterator2 >
Polytope_distance_d<Traits> poly_dist(InputIterator1 p_first,
InputIterator1 p_last,
InputIterator2 q_first,
InputIterator2 q_last,
Traits traits = Traits(),
int verbose = 0,
std::ostream& stream = std::cout)*

initializes *poly_dist* to *pd(P,Q)* with *P* and *Q* being the sets of points in the range $[p_first, p_last)$ and $[q_first, q_last)$, respectively.

Requirement: The value type of *InputIterator1* and *InputIterator2* is *Point*.

Precondition: All points have the same dimension.

— advanced —

If *verbose* is set to 1, 2, or 3 then some, more, or full verbose output of the underlying solver for quadratic programs is written to *stream*, resp.

— advanced —

Access Functions

int poly_dist.ambient_dimension()

returns the dimension of the points in *P* and *Q*. If *poly_dist* is *pd(0,0)*, the ambient dimension is -1 .

<i>int</i>	<i>poly_dist.number_of_points()</i>	returns the number of all points of <i>poly_dist</i> , i.e. $ P + Q $.
<i>int</i>	<i>poly_dist.number_of_points_p()</i>	returns the number of points in <i>P</i> .
<i>int</i>	<i>poly_dist.number_of_points_q()</i>	returns the number of points in <i>Q</i> .
<i>int</i>	<i>poly_dist.number_of_support_points()</i>	returns the number of support points of <i>poly_dist</i> , i.e. $ S_P + S_Q $.
<i>int</i>	<i>poly_dist.number_of_support_points_p()</i>	returns the number of support points in <i>S_P</i> .
<i>int</i>	<i>poly_dist.number_of_support_points_q()</i>	returns the number of support points in <i>S_Q</i> .
<i>Point_iterator</i>	<i>poly_dist.points_p_begin()</i>	returns an iterator referring to the first point in <i>P</i> .
<i>Point_iterator</i>	<i>poly_dist.points_p_end()</i>	returns the corresponding past-the-end iterator.
<i>Point_iterator</i>	<i>poly_dist.points_q_begin()</i>	returns an iterator referring to the first point in <i>Q</i> .
<i>Point_iterator</i>	<i>poly_dist.points_q_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_iterator</i>	<i>poly_dist.support_points_p_begin()</i>	returns an iterator referring to the first support point in <i>S_P</i> .
<i>Support_point_iterator</i>	<i>poly_dist.support_points_p_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_iterator</i>	<i>poly_dist.support_points_q_begin()</i>	returns an iterator referring to the first support point in <i>S_Q</i> .
<i>Support_point_iterator</i>	<i>poly_dist.support_points_q_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_p_indices_begin()</i>	returns an iterator referring to the index of the first support point in <i>P</i> .
<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_p_indices_end()</i>	returns the corresponding past-the-end iterator.
<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_q_indices_begin()</i>	returns an iterator referring to the index of the first support point in <i>Q</i> .

<i>Support_point_index_iterator</i>	<i>poly_dist.support_points_q_indices_end()</i> returns the corresponding past-the-end iterator.
<i>Point</i>	<i>poly_dist.realizing_point_p()</i> returns the realizing point of P . <i>Requirement:</i> An implicit conversion from ET to RT is available. <i>Precondition:</i> $pd(P, Q)$ is finite.
<i>Point</i>	<i>poly_dist.realizing_point_q()</i> returns the realizing point of Q . <i>Requirement:</i> An implicit conversion from ET to RT is available. <i>Precondition:</i> $pd(P, Q)$ is finite.
<i>ET</i>	<i>poly_dist.squared_distance()</i> returns the squared distance of <i>poly_dist</i> , i.e. $(pd(P, Q))^2$. <i>Requirement:</i> An implicit conversion from ET to RT is available. <i>Precondition:</i> $pd(P, Q)$ is finite.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_p_coordinates_begin()</i> returns an iterator referring to the first coordinate of the realizing point of P . <i>Note:</i> The coordinates have a rational representation, i.e. the first d elements of the iterator range are the numerators and the $(d+1)$ -st element is the common denominator.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_p_coordinates_end()</i> returns the corresponding past-the-end iterator.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_q_coordinates_begin()</i> returns an iterator referring to the first coordinate of the realizing point of Q . <i>Note:</i> The coordinates have a rational representation, i.e. the first d elements of the iterator range are the numerators and the $(d+1)$ -st element is the common denominator.
<i>Coordinate_iterator</i>	<i>poly_dist.realizing_point_q_coordinates_end()</i> returns the corresponding past-the-end iterator.
<i>ET</i>	<i>poly_dist.squared_distance_numerator()</i> returns the numerator of the squared distance of <i>poly_dist</i> .
<i>ET</i>	<i>poly_dist.squared_distance_denominator()</i> returns the denominator of the squared distance of <i>poly_dist</i> .

Predicates

<i>bool</i>	<i>poly_dist.is_finite()</i>	returns <i>true</i> , if $pd(P, Q)$ is finite, i.e. none of the two polytopes is empty.
<i>bool</i>	<i>poly_dist.is_zero()</i>	returns <i>true</i> , if $pd(P, Q)$ is zero, i.e. the two polytopes intersect (this implies degeneracy).
<i>bool</i>	<i>poly_dist.is_degenerate()</i>	returns <i>true</i> , iff $pd(P, Q)$ is degenerate, i.e. $pd(P, Q)$ is not finite.

Modifiers

<i>void</i>	<i>poly_dist.clear()</i>	resets <i>poly_dist</i> to $pd(\emptyset, \emptyset)$.
<i>template < class InputIterator1, class InputIterator2 ></i> <i>void</i>	<i>poly_dist.set(InputIterator1 p_first,</i> <i> InputIterator1 p_last,</i> <i> InputIterator2 q_first,</i> <i> InputIterator2 q_last)</i>	sets <i>poly_dist</i> to $pd(P, Q)$ with P and Q being the sets of points in the ranges $[p_first, p_last)$ and $[q_first, q_last)$, respectively. <i>Requirement:</i> The value type of <i>InputIterator1</i> and <i>InputIterator2</i> is <i>Point</i> . <i>Precondition:</i> All points have the same dimension.
<i>template < class InputIterator ></i> <i>void</i>	<i>poly_dist.set_p(InputIterator p_first, InputIterator p_last)</i>	sets <i>poly_dist</i> to $pd(P, Q)$ with P being the set of points in the range $[p_first, p_last)$ (Q remains unchanged). <i>Requirement:</i> The value type of <i>InputIterator</i> is <i>Point</i> . <i>Precondition:</i> All points in P have dimension <i>poly_dist.ambient_dimension()</i> if Q is not empty.
<i>template < class InputIterator ></i> <i>void</i>	<i>poly_dist.set_q(InputIterator q_first, InputIterator q_last)</i>	sets <i>poly_dist</i> to $pd(P, Q)$ with Q being the set of points in the range $[q_first, q_last)$ (P remains unchanged). <i>Requirement:</i> The value type of <i>InputIterator</i> is <i>Point</i> . <i>Precondition:</i> All points in Q have dimension <i>poly_dist.ambient_dimension()</i> if P is not empty.

void *poly_dist.insert_p(Point p)*

inserts *p* into *P*.

Precondition: The dimension of *p* equals *poly_dist.ambient_dimension()* if *poly_dist* is not *pd(0,0)*.

void *poly_dist.insert_q(Point q)*

inserts *q* into *Q*.

Precondition: The dimension of *q* equals *poly_dist.ambient_dimension()* if *poly_dist* is not *pd(0,0)*.

template < class InputIterator1, class InputIterator2 >
void *poly_dist.insert(InputIterator1 p_first,*
InputIterator1 p_last,
InputIterator2 q_first,
InputIterator2 q_last)

inserts the points in the range [*p_first*,*p_last*) and [*q_first*,*q_last*) into *P* and *Q*, respectively, and recomputes the (squared) distance.

Requirement: The value type of *InputIterator1* and *InputIterator2* is *Point*.

Precondition: All points have the same dimension. If *poly_dist* is not *pd(0,0)*, this dimension must be equal to *poly_dist.ambient_dimension()*.

template < class InputIterator >
void *poly_dist.insert_p(InputIterator p_first, InputIterator p_last)*

inserts the points in the range [*p_first*,*p_last*) into *P* and recomputes the (squared) distance (*Q* remains unchanged).

Requirement: The value type of *InputIterator* is *Point*.

Precondition: All points have the same dimension. If *poly_dist* is not empty, this dimension must be equal to *poly_dist.ambient_dimension()*.

template < class InputIterator >
void *poly_dist.insert_q(InputIterator q_first, InputIterator q_last)*

inserts the points in the range [*q_first*,*q_last*) into *Q* and recomputes the (squared) distance (*P* remains unchanged).

Requirement: The value type of *InputIterator* is *Point*.

Precondition: All points have the same dimension. If *poly_dist* is not empty, this dimension must be equal to *poly_dist.ambient_dimension()*.

Validity Check

An object *poly_dist* is valid, iff ...

- *poly_dist* contains all points of its defining set *P*,
- *poly_dist* is the smallest sphere containing its support set *S*, and
- *S* is minimal, i.e. no support point is redundant.

bool *poly_dist.is_valid(bool verbose = false, int level = 0)*

returns *true*, iff *poly_dist* is valid. If *verbose* is *true*, some messages concerning the performed checks are written to standard error stream. The second parameter *level* is not used, we provide it only for consistency with interfaces of other classes.

Miscellaneous

const Traits& *poly_dist.traits()* returns a const reference to the traits class object.

I/O

std::ostream& *std::ostream& os << poly_dist*

writes *poly_dist* to output stream *os*.
Requirement: The output operator is defined for *Point_d*.

std::istream& *std::istream& is >> poly_dist&*

reads *poly_dist* from input stream *is*.
Requirement: The input operator is defined for *Point_d*.

Implementation

The problem of finding the distance between two convex polytopes given as the convex hulls of two finite point sets can be formulated as an optimization problem with linear constraints and a convex quadratic objective function. The solution is obtained using our exact solver for quadratic programs [GS00].

The creation time is almost always linear in the number of points. Access functions and predicates take constant time, inserting a point might take up to linear time. The clear operation and the check for validity each take linear time.

PolytopeDistanceDTraits

Definition

This concept defines the requirements for traits classes of d -dimensional optimisation algorithms.

Types

<i>PolytopeDistanceDTraits:: Point_d</i>	point type used to represent the input points.
<i>PolytopeDistanceDTraits:: Rep_tag</i>	compile time tag to distinguish between Cartesian and homogeneous representation of the input points. <i>Rep_tag</i> has to be either <i>CGAL::Cartesian_tag</i> or <i>CGAL::Homogeneous_tag</i> .
<i>PolytopeDistanceDTraits:: RT</i>	number type used to represent the coordinates of the input points. It has to be a model for <i>RingNumberType</i> .
<i>PolytopeDistanceDTraits:: FT</i>	number type used to return either the squared radius of the smallest enclosing sphere or annulus, or the squared distance of the polytopes. <i>FT</i> has to be either <i>RT</i> or <i>CGAL::Quotient<RT></i> if the input points have Cartesian or homogeneous representation, respectively (cf. <i>Rep_tag</i>).
<i>PolytopeDistanceDTraits:: Access_dimension_d</i>	data accessor object used to access the dimension of the input points.
<i>PolytopeDistanceDTraits:: Access_coordinates_begin_d</i>	data accessor object used to access the coordinates of the input points.
<i>PolytopeDistanceDTraits:: Construct_point_d</i>	constructor object used to construct either the center of the smallest enclosing sphere or annulus, or the points realizing the distance between the two polytopes.

The following two number types are only needed for *CGAL::Min_annulus_d<Traits>* and *CGAL::Polytope_distance_d<Traits>*.

<i>PolytopeDistanceDTraits:: ET</i>	exact number type used to do the exact computations in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be an implicit conversion from <i>RT</i> to <i>ET</i> available.
<i>PolytopeDistanceDTraits:: NT</i>	fast (possibly inexact) number type used to speed up the pricing step in the underlying solver for linear programs. It has to be a model for <i>RingNumberType</i> . There must be implicit conversions from <i>RT</i> to <i>NT</i> and from <i>NT</i> to <i>ET</i> available.

Creation

Only default and copy constructor are required.

```
PolytopeDistanceDTraits traits;
```

```
PolytopeDistanceDTraits traits( PolytopeDistanceDTraits);
```

Operations

The following functions just return the corresponding function class object.

```
Access_dimension_d          traits.access_dimension_d_object()
```

```
Access_coordinates_begin_d  traits.access_coordinates_begin_d_object()
```

```
Construct_point_d          traits.construct_point_d_object()
```

CGAL::Polytope_distance_d_traits_3<K,ET,NT>

Definition

The class *Polytope_distance_d_traits_3<K,ET,NT>* is a traits class for the d -dimensional optimisation algorithms using the three-dimensional CGAL kernel.

```
#include <CGAL/Polytope_distance_d_traits_3.h>
```

Requirements

The template parameter K is a model for *Kernel*. Template parameters ET and NT are models for *RingNumberType*.

The second and third template parameter have default type `K::RT`.

Is Model for the Concepts

PolytopeDistanceDTraits page 2805

Types

Polytope_distance_d_traits_3<K,ET,NT>::Point_d typedef to *K::Point_3*.

Polytope_distance_d_traits_3<K,ET,NT>::Rep_tag typedef to *K::Rep_tag*.

Polytope_distance_d_traits_3<*K*,*ET*,*NT*>::*RT* typedef to *K*::*RT*.

Polytope_distance_d_traits_3<*K*,*ET*,*NT*>::*FT* typedef to *K*::*FT*.

Types

Polytope_distance_d_traits_d<*K*,*ET*,*NT*>:: *Point_d* typedef to *K*::*Point_d*.

Polytope_distance_d_traits_d<*K*,*ET*,*NT*>::*Rep_tag* typedef to *K*::*Rep_tag*.

Polytope_distance_d_traits_d $\langle K, ET, NT \rangle :: RT$ typedef to $K :: RT$.

Polytope_distance_d_traits_d<*K*,*ET*,*NT*>::*FT* typedef to *K*::*FT*.

```
Polytope_distance_d_traits_d<K,ET,NT>:: Access_dimension_d
```

```
typedef to K::Access_dimension_d.
```

$$\text{Polytope_distance_d_traits_d} \langle K, ET, NT \rangle :: \text{Access_coordinates_begin_d}$$

$$\text{typedef to } K :: \text{Access_coordinates_begin_d.}$$

```
Polytope_distance_d_traits_d<K,ET,NT>::Construct_point_d
```

```
typedef to K::Construct_point_d.
```

Polytope_distance_d_traits_d $\langle K, ET, NT \rangle:: ET$ second template parameter (default is $K::RT$).

Polytope_distance_d_traits_d $\langle K, ET, NT \rangle:: NT$ third template parameter (default is $K::RT$).

Creation

Polytope_distance_d_traits_d<*K,ET,NT*> *traits*; default constructor.

Polytope_distance_d_traits_d<*K,ET,NT*> *traits*(*Polytope_distance_d_traits_d*<*K,ET,NT*>);
copy constructor.

Operations

The following functions just return the corresponding function class object.

Access_dimension_d *traits.access_dimension_d_object*()

Access_coordinates_begin_d *traits.access_coordinates_begin_d_object*()

Construct_point_d *traits.construct_point_d_object*()

Chapter 51

Principal Component Analysis

Pierre Alliez and Sylvain Pion

Contents

51.1 Definitions	2813
51.2 Examples	2814
51.2.1 Bounding Box of a Point Set	2814
51.2.2 Centroid of a Point Set	2815
51.2.3 Barycenter of a Set of Weighted Points	2816
51.2.4 Best Fitting Line of a 2D Point Set	2817

This CGAL package provides functions to compute global information on the shape of a set of 2D or 3D objects such as points. It provides the computation of axis-aligned bounding boxes, centroids of point sets, barycenters of weighted point sets, as well as linear least squares fitting for point sets in 2D, and point sets as well as triangle sets in 3D. The sets are specified by iterator ranges of containers.

51.1 Definitions

A *bounding box* for a set of objects is a cuboid that completely contains the set. An *axis-aligned bounding box* is a bounding box aligned with the axes of the coordinate system.

A *centroid* is defined as average of position. A *barycenter* of weighted point sets is defined as weighted average of position. When all weights are equal the barycenter coincides with the centroid.

Given a point set, *linear least squares fitting* amounts to find the linear sub-space which minimizes the sum of squared distances from the points to their projection onto this linear sub-space. This problem is equivalent to search for the linear sub-space which maximizes the variance of projected points, the latter being obtained by eigen decomposition of the covariance matrix of the point set. Eigenvectors corresponding to large eigenvalues are the directions in which the data has strong component, or equivalently large variance. If eigenvalues are the same there is no preferable sub-space.

Given a triangle set, *linear least squares fitting* amounts to find the linear sub-space which minimizes the sum of squared distances from all points in the set to their projection onto this linear sub-space. This problem is equivalent to the one of fitting a linear sub-space to a point set, except that the covariance matrix is now derived from a continuous integral over the triangles instead of a discrete sum over the points.

Figure 51.1: Left: fitting a line to a 2D point set. Right: fitting a line and a plane to a 3D point set.

51.2 Examples

51.2.1 Bounding Box of a Point Set

In the following example we use STL containers of 2D and 3D points, and compute their axis-aligned bounding box. The kernel from which the input points come is automatically deduced by the function.

```
#include <CGAL/Cartesian.h>
#include <CGAL/bounding_box.h>

#include <list>
#include <iostream>

typedef double          FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Point_2      Point_2;
typedef K::Point_3      Point_3;

int main()
{
    // axis-aligned bounding box of 2D points
```

```

std::list<Point_2> points_2;
points_2.push_back(Point_2(1.0, 0.0));
points_2.push_back(Point_2(2.0, 2.0));
points_2.push_back(Point_2(3.0, 5.0));

K::Iso_rectangle_2 c2 = CGAL::bounding_box(points_2.begin(), points_2.end());
std::cout << c2 << std::endl;

// axis-aligned bounding box of 3D points
std::list<Point_3> points_3;
points_3.push_back(Point_3(1.0, 0.0, 0.5));
points_3.push_back(Point_3(2.0, 2.0, 1.2));
points_3.push_back(Point_3(3.0, 5.0, 4.5));

K::Iso_cuboid_3 c3 = CGAL::bounding_box(points_3.begin(), points_3.end());
std::cout << c3 << std::endl;

return 0;
}

```

File: examples/Principal_component_analysis/bounding_box.cpp

51.2.2 Centroid of a Point Set

In the following example we use STL containers of 2D and 3D points, and compute their centroid. The kernel from which the input points come is automatically deduced by the function.

```

#include <CGAL/Cartesian.h>
#include <CGAL/centroid.h>

#include <list>
#include <iostream>

typedef double FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Point_2 Point_2;
typedef K::Point_3 Point_3;

int main()
{
    // centroid of 2D points
    std::list<Point_2> points_2;
    points_2.push_back(Point_2(1.0, 0.0));
    points_2.push_back(Point_2(2.0, 2.0));
    points_2.push_back(Point_2(3.0, 5.0));

    Point_2 c2 = CGAL::centroid(points_2.begin(), points_2.end());
    std::cout << c2 << std::endl;

    // centroid of 3D points
    std::list<Point_3> points_3;

```

```

points_3.push_back(Point_3(1.0, 0.0, 0.5));
points_3.push_back(Point_3(2.0, 2.0, 1.2));
points_3.push_back(Point_3(3.0, 5.0, 4.5));

Point_3 c3 = CGAL::centroid(points_3.begin(), points_3.end());
std::cout << c3 << std::endl;

return 0;
}

```

File: examples/Principal_component_analysis/centroid.cpp

51.2.3 Barycenter of a Set of Weighted Points

In the following example we use STL containers of 2D and 3D weighted points, and compute their barycenter. The kernel from which the input points come is automatically deduced by the function.

```

#include <CGAL/Cartesian.h>
#include <CGAL/barycenter.h>

#include <list>
#include <iostream>
#include <utility>

typedef double FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Point_2 Point_2;
typedef K::Point_3 Point_3;

int main()
{
    // barycenter of 2D points
    std::list<std::pair<Point_2, FT> > points_2;
    points_2.push_back(std::make_pair(Point_2(1.0, 0.0), 1.0));
    points_2.push_back(std::make_pair(Point_2(2.0, 2.0), 2.0));
    points_2.push_back(std::make_pair(Point_2(3.0, 5.0), -2.0));

    Point_2 c2 = CGAL::barycenter(points_2.begin(), points_2.end());
    std::cout << c2 << std::endl;

    // barycenter of 3D points
    std::list<std::pair<Point_3, FT> > points_3;
    points_3.push_back(std::make_pair(Point_3(1.0, 0.0, 0.5), 1.0));
    points_3.push_back(std::make_pair(Point_3(2.0, 2.0, 1.2), 2.0));
    points_3.push_back(std::make_pair(Point_3(3.0, 5.0, 4.5), -5.0));

    Point_3 c3 = CGAL::barycenter(points_3.begin(), points_3.end());
    std::cout << c3 << std::endl;

    return 0;
}

```

File: examples/Principal_component_analysis/barycenter.cpp

51.2.4 Best Fitting Line of a 2D Point Set

In the following example we use an STL container of 2D points, and compute the best fitting line. The kernel from which the input points come is automatically deduced by the function.

```
#include <CGAL/Cartesian.h>
#include <CGAL/linear_least_squares_fitting_2.h>

typedef double          FT;
typedef CGAL::Cartesian<FT> K;
typedef K::Line_2       Line_2;
typedef K::Point_2      Point_2;

int main()
{
    std::list<Point_2> points;
    points.push_back(Point_2(1.0,0.0));
    points.push_back(Point_2(2.0,0.0));
    points.push_back(Point_2(3.0,0.0));

    Line_2 line;
    linear_least_squares_fitting_2(points.begin(),points.end(),line);

    return 0;
}
```

File: examples/Principal_component_analysis/linear_least_squares_fitting.cpp

Principal Component Analysis Reference Manual

Pierre Alliez and Sylvain Pion

This CGAL package provides functions to compute global information on the shape of a set of 2D or 3D objects such as points. It provides the computation of axis-aligned bounding boxes for point sets, centroids of point sets and triangle sets in 2D and 3D, barycenters of weighted point sets, as well as linear least squares fitting for point sets in 2D, and point sets and triangle sets in 3D. It assumes the set of kernel primitive elements to be stored into an iterator range of a container.

CGAL::barycenter

Definition

The function *barycenter* computes the barycenter (weighted center of mass) of a set of weighted 2D or 3D objects. The weight associated to each object is specified using a *std::pair* storing the object and its weight.

```
#include <CGAL/barycenter.h>
```

There is a set of overloaded *barycenter* functions for 2D and 3D weighted objects. The user can also optionally pass an explicit kernel, in case the default, based on *Kernel_traits* is not sufficient. The dimension is also deduced automatically.

```
template < typename InputIterator >
```

```
K::Point_2          barycenter( InputIterator first, InputIterator beyond)
```

computes the barycenter of a non-empty set of 2D weighted points. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type::first_type>::Kernel*. The value type must be *std::pair<K::Point_2, K::FT>*.

Precondition: first != beyond, and the sum of the weights is non-zero.

```
template < typename InputIterator, typename K >
```

```
K::Point_2          barycenter( InputIterator first, InputIterator beyond, K k)
```

computes the barycenter of a non-empty set of 2D weighted points. The value type must be *std::pair<K::Point_2, K::FT>*.

Precondition: first != beyond, and the sum of the weights is non-zero.

```
template < typename InputIterator >
```

```
K::Point_3          barycenter( InputIterator first, InputIterator beyond)
```

computes the barycenter of a non-empty set of 3D weighted points. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type::first_type>::Kernel*. The value type must be *std::pair<K::Point_3, K::FT>*.

Precondition: first != beyond, and the sum of the weights is non-zero.

```
template < typename InputIterator, typename K >
```

```
K::Point_3          barycenter( InputIterator first, InputIterator beyond, K k)
```

computes the barycenter of a non-empty set of 3D weighted points. The value type must be *std::pair<K::Point_3, K::FT>*.

Precondition: first != beyond, and the sum of the weights is non-zero.

CGAL::centroid page [2823](#)

CGAL::bounding_box

Definition

The function *bounding_box* computes the bounding box of a set of 2D or 3D objects.

```
#include <CGAL/bounding_box.h>
```

There is a set of overloaded *bounding_box* functions for 2D and 3D objects. The user can also optionally pass an explicit kernel, in case the default, based on *Kernel_traits* is not sufficient. The dimension is also deduced automatically.

```
template < typename InputIterator >
K::Iso_rectangle_2    bounding_box( InputIterator first, InputIterator beyond)
```

computes the bounding box of a non-empty set of 2D points. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type>::Kernel*. The value type must be *K::Point_2*.
Precondition: first != beyond.

```
template < typename InputIterator, typename K >
K::Iso_rectangle_2    bounding_box( InputIterator first, InputIterator beyond, K k)
```

computes the bounding box of a non-empty set of 2D points. The value type must be *K::Point_2*.
Precondition: first != beyond.

```
template < typename InputIterator >
K::Iso_cuboid_3       bounding_box( InputIterator first, InputIterator beyond)
```

computes the bounding box of a non-empty set of 3D points. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type>::Kernel*. The value type must be *K::Point_3*.
Precondition: first != beyond.

```
template < typename InputIterator, typename K >
K::Iso_cuboid_3       bounding_box( InputIterator first, InputIterator beyond, K k)
```

computes the bounding box of a non-empty set of 3D points. The value type must be *K::Point_3*.
Precondition: first != beyond.

CGAL::centroid

Definition

The function *centroid* computes the centroid (center of mass) of a set of 2D or 3D objects.

```
#include <CGAL/centroid.h>
```

There is a set of overloaded *centroid* functions for 2D and 3D objects. The user can also optionally pass an explicit kernel, in case the default, based on *Kernel_traits* is not sufficient. The dimension is also deduced automatically.

```
template < typename InputIterator >
K::Point_2          centroid( InputIterator first, InputIterator beyond)
```

computes the centroid of a non-empty set of 2D points. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type>::Kernel*. The value type must be *K::Point_2*.
Precondition: first != beyond.

```
template < typename InputIterator, typename K >
K::Point_2          centroid( InputIterator first, InputIterator beyond, K k)
```

computes the centroid of a non-empty set of 2D points. The value type must be *K::Point_2*.
Precondition: first != beyond.

```
template < typename InputIterator >
K::Point_3          centroid( InputIterator first, InputIterator beyond)
```

computes the centroid of a non-empty set of 3D points. *K* is *Kernel_traits<std::iterator_traits<InputIterator>::value_type>::Kernel*. The value type must be *K::Point_3*.
Precondition: first != beyond.

```
template < typename InputIterator, typename K >
K::Point_3          centroid( InputIterator first, InputIterator beyond, K k)
```

computes the centroid of a non-empty set of 3D points. The value type must be *K::Point_3*.
Precondition: first != beyond.

CGAL::linear_least_squares_fitting_2

Definition

The function *linear_least_squares_fitting_2* computes the best fitting 2D line of a 2D point set. The best fit line minimizes the sum of squared distances from the points to their projections onto the line.

```
#include <CGAL/linear_least_squares_fitting_2.h>
```

```
template < typename InputIterator, typename K>
typename K::FT      linear_least_squares_fitting_2( InputIterator first,
                                                    InputIterator beyond,
                                                    typename K::Line_2 & line,
                                                    typename K::Point_2 & centroid,
                                                    K k)
```

computes the best fitting 2D line of a 2D point set in the range *[first,beyond)*. The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any line (a horizontal line going through the centroid is output by default), and 1 means that the variance is null orthogonally to the best fitting line.

The class *K* is the kernel in which the type *InputIterator::value_type* is defined. It can be omitted and deduced automatically from the value type.

Requirements

1. *InputIterator::value_type* is equivalent to *K::Point_2*.
2. *line* is the best fitting line computed.
3. *centroid* is the centroid computed. This parameter can be omitted.

CGAL::linear_least_squares_fitting_3

Definition

The function *linear_least_squares_fitting_3* computes the best fitting 3D line or plane of 3D point sets or triangle sets. The best fit linear sub-space minimizes the sum of squared distances from the points to their projections onto the sub-space.

```
#include <CGAL/linear_least_squares_fitting_3.h>
```

```
template < typename InputIterator, typename K>
typename K::FT      linear_least_squares_fitting_3( InputIterator first,
                                                    InputIterator beyond,
                                                    typename K::Line_3 & line,
                                                    typename K::Point_3 & centroid,
                                                    K k)
```

computes the best fitting 3D line of a 3D point set or triangle set in the range *[first,beyond)*. The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any line (a horizontal line going through the centroid is output by default), and 1 means that the variance is null orthogonally to the best fitting line.

The class *K* is the kernel in which the type *InputIterator::value_type* is defined. It can be omitted and deduced automatically from the value type.

Requirements

1. *InputIterator::value_type* is equivalent to *K::Point_3* or *K::Triangle_3*.
2. *line* is the best fitting line computed.
3. *centroid* is the centroid computed. This parameter can be omitted.

```
template < typename InputIterator, typename K>
typename K::FT      linear_least_squares_fitting_3( InputIterator first,
                                                    InputIterator beyond,
                                                    typename K::Plane_3 & plane,
                                                    typename K::Point_3 & centroid,
                                                    K k)
```

computes the best fitting 3D plane of a 3D point set or triangle set in the range *[first,beyond)*. The value returned is a fitting quality between 0 and 1, where 0 means that the variance is the same along any plane (a horizontal plane going through the centroid is output by default), and 1 means that the variance is null orthogonally to the best fitting plane.

The class K is the kernel in which the type $InputIterator::value_type$ is defined. It can be omitted and deduced automatically from the value type.

Requirements

1. $InputIterator::value_type$ is equivalent to $K::Point_3$ or $K::Triangle_3$.
2. $plane$ is the best fitting plane computed.
3. $centroid$ is the centroid computed. This parameter can be omitted.

This chapter describes CGAL's interpolation package which implements natural neighbor coordinate functions as well as different methods for scattered data interpolation most of which are based on natural neighbor coordinates. The functions for computing natural neighbor coordinates in Euclidean space are described in Section 52.1, the functions concerning the coordinate and neighbor computation on surfaces are discussed in Section 52.2. In Section 52.3, we describe the different interpolation functions.

Scattered data interpolation solves the following problem: given measures of a function on a set of discrete data points, the task is to interpolate this function on an arbitrary query point. More formally, let $\mathcal{P} = \{\mathbf{p}_1, \dots, \mathbf{p}_n\}$ be a set of n points in \mathbb{R}^2 or \mathbb{R}^3 and Φ be a scalar function defined on the convex hull of \mathcal{P} . We assume that the function values are known at the points of \mathcal{P} , i.e. to each $\mathbf{p}_i \in \mathcal{P}$, we associate $z_i = \Phi(\mathbf{p}_i)$. Sometimes, the gradient of Φ is also known at \mathbf{p}_i . It is denoted $\mathbf{g}_i = \nabla\Phi(\mathbf{p}_i)$. The interpolation is carried out for an arbitrary query point \mathbf{x} on the convex hull of \mathcal{P} .

52.1 Natural Neighbor Coordinates

52.1.1 Introduction

Natural neighbor interpolation has been introduced by Sibson [Sib81] to interpolate multivariate scattered data. Given a set of data points \mathcal{P} , the natural neighbor coordinates associated to \mathcal{P} are defined from the Voronoi diagram of \mathcal{P} . When simulating the insertion of a query point \mathbf{x} into the Voronoi diagram of \mathcal{P} , the potential Voronoi cell of \mathbf{x} “steals” some parts from the existing cells.

Figure 52.1: 2D example: \mathbf{x} has five natural neighbors $\mathbf{p}_1, \dots, \mathbf{p}_5$. The natural neighbor coordinate $\lambda_3(\mathbf{x})$ is the ratio of the area of the pink polygon, $\pi_3(\mathbf{x})$, over the area of the total highlighted zone.

Let $\pi(\mathbf{x})$ denote the volume of the potential Voronoi cell of \mathbf{x} and $\pi_i(\mathbf{x})$ denote the volume of the sub-cell that would be stolen from the cell of \mathbf{p}_i by the cell of \mathbf{x} . The natural neighbor coordinate of \mathbf{x} with respect to the data point $\mathbf{p}_i \in \mathcal{P}$ is defined by

$$\lambda_i(\mathbf{x}) = \frac{\pi_i(\mathbf{x})}{\pi(\mathbf{x})}.$$

A two-dimensional example is depicted in Figure 52.1.

Various papers ([Sib80], [Far90], [Pip93], [Bro97], [HS00]) show that the natural neighbor coordinates have the following properties:

- (i) $\mathbf{x} = \sum_{i=1}^n \lambda_i(\mathbf{x}) \mathbf{p}_i$ (barycentric coordinate property).
- (ii) For any $i, j \leq n$, $\lambda_i(\mathbf{p}_j) = \delta_{ij}$, where δ_{ij} is the Kronecker symbol.
- (iii) $\sum_{i=1}^n \lambda_i(\mathbf{x}) = 1$ (partition of unity property).

For the case where the query point \mathbf{x} is located on the envelope of the convex hull of \mathcal{P} , the potential Voronoi cell of \mathbf{x} becomes infinite and :

$$\pi(\mathbf{x}) = \infty$$

$\lambda_i(\mathbf{x}) = 0$ for all data point \mathbf{p}_i of \mathcal{P} except for the two endpoints, let's say \mathbf{p} and \mathbf{q} , of the edge where \mathbf{x} lies.

The natural neighbor coordinate of \mathbf{x} with respect to these endpoints \mathbf{p} and \mathbf{q} will be :

$$\lambda_p(\mathbf{x}) = \frac{\|\mathbf{x} - \mathbf{q}\|}{\|\mathbf{q} - \mathbf{p}\|}$$

$$\lambda_q(\mathbf{x}) = \frac{\|\mathbf{x} - \mathbf{p}\|}{\|\mathbf{q} - \mathbf{p}\|}$$

Furthermore, Piper [Pip93] shows that the coordinate functions are continuous in the convex hull of \mathcal{P} and continuously differentiable except on the data points \mathcal{P} .

The interpolation package of CGAL provides functions to compute natural neighbor coordinates for 2D and 3D points with respect to Voronoi diagrams as well as with respect to power diagrams (only 2D), i.e. for weighted points. Refer to the reference pages *natural_neighbor_coordinates_2*, *natural_neighbor_coordinates_3* and *regular_neighbor_coordinates_2*.

In addition, the package provides functions to compute natural neighbor coordinates on well sampled point set surfaces. See Section 52.2 and the reference page *surface_neighbor_coordinates_3* for further information.

52.1.2 Implementation

Given a Delaunay triangulation or a Regular triangulation, the vertices in conflict with the query point are determined. The areas $\pi_i(\mathbf{x})$ are computed by triangulating the Voronoi sub-cells. The normalization factor $\pi(\mathbf{x})$ is also returned. If the query point is already located and/or the boundary edges of the conflict zone are already determined, alternative functions allow to avoid the re-computation.

52.1.3 Example for Natural Neighbor Coordinates

The signature of all coordinate computation functions is about the same.

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/natural_neighbor_coordinates_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};
typedef CGAL::Delaunay_triangulation_2<K> Delaunay_triangulation;
typedef std::vector< std::pair< K::Point_2, K::FT > >
Point_coordinate_vector;

int main()
{
    Delaunay_triangulation dt;

    for (int y=0 ; y<3 ; y++)
        for (int x=0 ; x<3 ; x++)
            dt.insert(K::Point_2(x,y));

    //coordinate computation
    K::Point_2 p(1.2, 0.7);
    Point_coordinate_vector coords;
    CGAL::Triple<
        std::back_inserter_iterator<Point_coordinate_vector>,
        K::FT, bool> result =
        CGAL::natural_neighbor_coordinates_2(dt, p,
        std::back_inserter(coords));
    if(!result.third){
        std::cout << "The coordinate computation was not successful."
        << std::endl;
    }
}
```

```

        std::cout << "The point (" <<p << ") lies outside the convex hull."
        << std::endl;
    }
    K::FT norm = result.second;
    std::cout << "Coordinate computation successful." << std::endl;
    std::cout << "Normalization factor: " <<norm << std::endl;
    std::cout << "done" << std::endl;
    return 0;
}

```

File: examples/Interpolation/nn_coordinates_2.cpp

52.1.4 Example for Regular Neighbor Coordinates

For regular neighbor coordinates, it is sufficient to replace the name of the function and the type of triangulation passed as parameter. A special traits class is needed.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Regular_triangulation_2.h>
#include <CGAL/Regular_triangulation_euclidean_traits_2.h>
#include <CGAL/regular_neighbor_coordinates_2.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};

typedef CGAL::Regular_triangulation_euclidean_traits_2<K> Gt;
typedef CGAL::Regular_triangulation_2<Gt> Regular_triangulation;
typedef Regular_triangulation::Weighted_point Weighted_point;
typedef std::vector< std::pair< Weighted_point, K::FT > >
    Point_coordinate_vector;

int main()
{
    Regular_triangulation rt;

    for (int y=0 ; y<3 ; y++)
        for (int x=0 ; x<3 ; x++)
            rt.insert(Weighted_point(K::Point_2(x,y), 0));

    //coordinate computation
    Weighted_point wp(K::Point_2(1.2, 0.7),2);
    Point_coordinate_vector coords;
    CGAL::Triple<
        std::back_inserter_iterator<Point_coordinate_vector>,
        K::FT, bool> result =
        CGAL::regular_neighbor_coordinates_2(rt, wp,
std::back_inserter(coords));
    if(!result.third){
        std::cout << "The coordinate computation was not successful."
        << std::endl;
        std::cout << "The point (" <<wp.point() << ") lies outside the convex hull."
        << std::endl;
    }
}

```

```

K::FT norm = result.second;
std::cout << "Coordinate computation successful." << std::endl;
std::cout << "Normalization factor: " << norm << std::endl;

std::cout << "done" << std::endl;
return 0;
}

```

File: examples/Interpolation/rn_coordinates_2.cpp

For surface neighbor coordinates, the surface normal at the query point must be provided, see Section 52.2.

52.2 Surface Natural Neighbor Coordinates and Surface Neighbors

This section introduces the functions to compute natural neighbor coordinates and surface neighbors associated to a set of sample points issued from a surface \mathcal{S} and given a query point \mathbf{x} on \mathcal{S} . We suppose that \mathcal{S} is a closed and compact surface of \mathbb{R}^3 , and let $\mathcal{P} = \{\mathbf{p}_1, \dots, \mathbf{p}_n\}$ be an ε -sample of \mathcal{S} (refer to Amenta and Bern [AB99]). The concepts are based on the definition of Boissonnat and Flötotto [BF02], [Flö03b]. Both references contain a thorough description of the requirements and the mathematical properties.

52.2.1 Introduction

Two observations lead to the definition of surface neighbors and surface neighbor coordinates: First, it is clear that the tangent plane $\mathcal{T}_{\mathbf{x}}$ of the surface \mathcal{S} at the point $\mathbf{x} \in \mathcal{S}$ approximates \mathcal{S} in the neighborhood of \mathbf{x} . It has been shown in [BF02] that, if the surface \mathcal{S} is well sampled with respect to the curvature and the local thickness of \mathcal{S} , i.e. it is an ε -sample, the intersection of the tangent plane $\mathcal{T}_{\mathbf{x}}$ with the Voronoi cell of \mathbf{x} in the Voronoi diagram of $\mathcal{P} \cup \{\mathbf{x}\}$ has a small diameter. Consequently, inside this Voronoi cell, the tangent plane $\mathcal{T}_{\mathbf{x}}$ is a reasonable approximation of \mathcal{S} . Furthermore, the second observation allows to compute this intersection diagram easily: one can show using Pythagoras' Theorem that the intersection of a three-dimensional Voronoi diagram with a plane \mathcal{H} is a two-dimensional power diagram. The points defining the power diagram are the projections of the points in \mathcal{P} onto \mathcal{H} , each point weighted with its negative square distance to \mathcal{H} . Algorithms for the computation of power diagrams via the dual regular triangulation are well known and for example provided by CGAL in the class *Regular_triangulation_2<Gt, Tds>*.

52.2.2 Implementation

Voronoi Intersection Diagrams

In CGAL, the regular triangulation dual to the intersection of a 3D Voronoi diagram with a plane \mathcal{H} can be computed by instantiating the *Regular_triangulation_2<Gt, Tds>* class with the traits class *Voronoi_intersection_2_traits_3<K>*. This traits class contains a point and a vector as class member which define the plane \mathcal{H} . All predicates and constructions used by *Regular_triangulation_2<Gt, Tds>* are replaced by the corresponding operators on three-dimensional points. For example, the power test predicate (which takes three weighted 2D points p', q', r' of the regular triangulation and tests the power distance of a fourth point t' with respect to the power circle orthogonal to p, q, r) is replaced by a *Side_of_plane_centered_sphere_2_3* predicate that tests the position of a 3D point t with respect to the sphere centered on the plane \mathcal{H} passing through the 3D points p, q, r . This approach allows to avoid the explicit constructions of the projected points and the weights which are very prone to rounding errors.

Natural Neighbor Coordinates on Surfaces

The computation of natural neighbor coordinates on surfaces is based upon the computation of regular neighbor coordinates with respect to the regular triangulation that is dual to $\text{Vor}(\mathcal{P}) \cap \mathcal{T}_x$, the intersection of \mathcal{T}_x and the Voronoi diagram of \mathcal{P} , via the function *regular_neighbor_coordinates_2*.

Of course, we might introduce all data points \mathcal{P} into this regular triangulation. However, this is not necessary because we are only interested in the cell of \mathbf{x} . It is sufficient to guarantee that all surface neighbors of the query point \mathbf{x} are among the input points that are passed as argument to the function. The sample points \mathcal{P} can be filtered for example by distance, e.g. using range search or k -nearest neighbor queries, or with the help of the 3D Delaunay triangulation since the surface neighbors are necessarily a subset of the natural neighbors of the query point in this triangulation. CGAL provides a function that encapsulates the filtering based on the 3D Delaunay triangulation. For input points filtered by distance, functions are provided that indicate whether or not points that lie outside the input range (i.e. points that are further from \mathbf{x} than the furthest input point) can still influence the result. This allows to iteratively enlarge the set of input points until the range is sufficient to certify the result.

Surface Neighbors

The surface neighbors of the query point are its neighbors in the regular triangulation that is dual to $\text{Vor}(\mathcal{P}) \cap \mathcal{T}_x$, the intersection of \mathcal{T}_x and the Voronoi diagram of \mathcal{P} . As for surface neighbor coordinates, this regular triangulation is computed and the same kind of filtering of the data points as well as the certification described above is provided.

52.2.3 Example for Surface Neighbor Coordinates

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>

#include <CGAL/point_generators_3.h>
#include <CGAL/copy_n.h>
#include <CGAL/Origin.h>

#include <CGAL/surface_neighbor_coordinates_3.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};
typedef K::FT Coord_type;
typedef K::Point_3 Point_3;
typedef K::Vector_3 Vector_3;
typedef std::vector< std::pair< Point_3, K::FT > >
    Point_coordinate_vector;

int main()
{
    int n=100;
    std::vector< Point_3> points;
    points.reserve(n);

    std::cout << "Generate " << n << " random points on a sphere."
        << std::endl;
    CGAL::Random_points_on_sphere_3<Point_3> g(1);
```

```

CGAL::copy_n( g, n, std::back_inserter(points));

Point_3 p(1, 0,0);
Vector_3 normal(p-CGAL::ORIGIN);
std::cout << "Compute surface neighbor coordinates for "
    << p << std::endl;
Point_coordinate_vector coords;
CGAL::Triple< std::back_insert_iterator<Point_coordinate_vector>,
    K::FT, bool> result =
    CGAL::surface_neighbor_coordinates_3(points.begin(), points.end(),
p, normal,
std::back_inserter(coords),
K());
if(!result.third){
    //Undersampling:
    std::cout << "The coordinate computation was not successful."
        << std::endl;
    return 0;
}
K::FT norm = result.second;

std::cout << "Testing the barycentric property " << std::endl;
Point_3 b(0, 0,0);
for(std::vector< std::pair< Point_3, Coord_type > >::const_iterator
it = coords.begin(); it!=coords.end(); ++it)
    b = b + (it->second/norm)* (it->first - CGAL::ORIGIN);

std::cout <<"    weighted barycenter: " << b <<std::endl;
std::cout << "    squared distance: " <<
    CGAL::squared_distance(p,b) <<std::endl;

std::cout << "done" << std::endl;
return 0;
}

```

File: examples/Interpolation/surface_neighbor_coordinates_3.cpp

52.3 Interpolation Methods

52.3.1 Introduction

Linear Precision Interpolation

Sibson [Sib81] defines a very simple interpolant that re-produces linear functions exactly. The interpolation of $\Phi(\mathbf{x})$ is given as the linear combination of the neighbors' function values weighted by the coordinates:

$$Z^0(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x}) z_i.$$

Indeed, if $z_i = a + \mathbf{b}' \mathbf{p}_i$ for all natural neighbors of \mathbf{x} , we have

$$Z^0(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x})(a + \mathbf{b}' \mathbf{p}_i) = a + \mathbf{b}' \mathbf{x}$$

by the barycentric coordinate property. The first example in Subsection 52.3.3 shows how the function is called.

Sibson's C^1 Continuous Interpolant

In [Sib81], Sibson describes a second interpolation method that relies also on the function gradient \mathbf{g}_i for all $\mathbf{p}_i \in \mathcal{P}$. It is C^1 continuous with gradient \mathbf{g}_i at \mathbf{p}_i . Spherical quadrics of the form $\Phi(\mathbf{x}) = a + \mathbf{b}^t \mathbf{x} + \gamma \mathbf{x}^t \mathbf{x}$ are reproduced exactly. The proof relies on the barycentric coordinate property of the natural neighbor coordinates and assumes that the gradient of Φ at the data points is known or approximated from the function values as described in [Sib81] (see Section 52.3.2).

Sibson's Z^1 interpolant is a combination of the linear interpolant Z^0 and an interpolant ξ which is the weighted sum of the first degree functions

$$\xi_i(\mathbf{x}) = z_i + \mathbf{g}_i^t (\mathbf{x} - \mathbf{p}_i), \quad \xi(\mathbf{x}) = \frac{\sum_i \frac{\lambda_i(\mathbf{x})}{\|\mathbf{x} - \mathbf{p}_i\|} \xi_i(\mathbf{x})}{\sum_i \frac{\lambda_i(\mathbf{x})}{\|\mathbf{x} - \mathbf{p}_i\|}}.$$

Sibson observed that the combination of Z^0 and ξ reconstructs exactly a spherical quadric if they are mixed as follows:

$$Z^1(\mathbf{x}) = \frac{\alpha(\mathbf{x})Z^0(\mathbf{x}) + \beta(\mathbf{x})\xi(\mathbf{x})}{\alpha(\mathbf{x}) + \beta(\mathbf{x})} \text{ where } \alpha(\mathbf{x}) = \frac{\sum_i \lambda_i(\mathbf{x}) \frac{\|\mathbf{x} - \mathbf{p}_i\|^2}{f(\|\mathbf{x} - \mathbf{p}_i\|)}}{\sum_i \frac{\lambda_i(\mathbf{x})}{f(\|\mathbf{x} - \mathbf{p}_i\|)}} \text{ and } \beta(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x}) \|\mathbf{x} - \mathbf{p}_i\|^2,$$

where in Sibson's original work, $f(\|\mathbf{x} - \mathbf{p}_i\|) = \|\mathbf{x} - \mathbf{p}_i\|$.

CGAL contains a second implementation with $f(\|\mathbf{x} - \mathbf{p}_i\|) = \|\mathbf{x} - \mathbf{p}_i\|^2$ which is less demanding on the number type because it avoids the square-root computation needed to compute the distance $\|\mathbf{x} - \mathbf{p}_i\|$. The theoretical guarantees are the same (see [Flö03b]). Simply, the smaller the slope of f around $f(0)$, the faster the interpolant approaches ξ_i as $\mathbf{x} \rightarrow \mathbf{p}_i$.

Farin's C^1 Continuous Interpolant

Farin [Far90] extended Sibson's work and realizes a C^1 continuous interpolant by embedding natural neighbor coordinates in the Bernstein-Bézier representation of a cubic simplex. If the gradient of Φ at the data points is known, this interpolant reproduces quadratic functions exactly. The function gradient can be approximated from the function values by Sibson's method [Sib81] (see Section 52.3.2) which is exact only for spherical quadrics.

Quadratic Precision Interpolants

Knowing the gradient \mathbf{g}_i for all $\mathbf{p}_i \in \mathcal{P}$, we formulate a very simple interpolant that reproduces exactly quadratic functions. This interpolant is not C^1 continuous in general. It is defined as follows:

$$I^1(\mathbf{x}) = \sum_i \lambda_i(\mathbf{x}) \left(z_i + \frac{1}{2} \mathbf{g}_i^t (\mathbf{x} - \mathbf{p}_i) \right)$$

52.3.2 Gradient Fitting

Sibson describes a method to approximate the gradient of the function f from the function values on the data sites. For the data point \mathbf{p}_i , we determine

$$\mathbf{g}_i = \min_{\mathbf{g}} \sum_j \frac{\lambda_j(\mathbf{p}_i)}{\|\mathbf{p}_i - \mathbf{p}_j\|^2} (z_j - (z_i + \mathbf{g}^t (\mathbf{p}_j - \mathbf{p}_i))),$$

where $\lambda_j(\mathbf{p}_i)$ is the natural neighbor coordinate of \mathbf{p}_i with respect to \mathbf{p}_i associated to $\mathcal{P} \setminus \{\mathbf{p}_i\}$. For spherical quadrics, the result is exact.

CGAL provides functions to approximate the gradients of all data points that are inside the convex hull. There is one function for each type of natural neighbor coordinate (i.e. *natural_neighbor_coordinates_2*, *regular_neighbor_coordinates_2*).

52.3.3 Example for Linear Interpolation

```
#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>

#include <CGAL/Interpolation_traits_2.h>
#include <CGAL/natural_neighbor_coordinates_2.h>
#include <CGAL/interpolation_functions.h>

struct K : CGAL::Exact_predicates_inexact_constructions_kernel {};
typedef CGAL::Delaunay_triangulation_2<K>          Delaunay_triangulation;
typedef CGAL::Interpolation_traits_2<K>            Traits;
typedef K::FT                                       Coord_type;
typedef K::Point_2                                  Point;

int main()
{
    Delaunay_triangulation T;
    std::map<Point, Coord_type, K::Less_xy_2> function_values;
    typedef CGAL::Data_access< std::map<Point, Coord_type, K::Less_xy_2 > >
                                   Value_access;

    Coord_type a(0.25), bx(1.3), by(-0.7);

    for (int y=0 ; y<3 ; y++)
        for (int x=0 ; x<3 ; x++){
            K::Point_2 p(x,y);
            T.insert(p);
            function_values.insert(std::make_pair(p,a + bx* x+ by*y));
        }
    //coordinate computation
    K::Point_2 p(1.3,0.34);
    std::vector< std::pair< Point, Coord_type > > coords;
    Coord_type norm =
        CGAL::natural_neighbor_coordinates_2
        (T, p, std::back_inserter(coords)).second;

    Coord_type res = CGAL::linear_interpolation(coords.begin(), coords.end(),
                                                norm,
                                                Value_access(function_values));

    std::cout << "    Tested interpolation on " << p << " interpolation: "
        << res << " exact: " << a + bx* p.x()+ by* p.y()<< std::endl;

    std::cout << "done" << std::endl;
    return 0;
}
```

```
}
```

An additional example in the distribution compares numerically the errors of the different interpolation functions with respect to a known function. It is distributed in the examples directory.

2D and Surface Function Interpolation Reference Manual

Julia Flötotto

Scattered data interpolation solves the following problem: given measures of a function on a set of discrete data points, the task is to interpolate this function on an arbitrary query point.

If the function is a linear function and given barycentric coordinates that allow to express the query point as the convex combination of some data points, the function can be exactly interpolated. If the function gradients are known, we can exactly interpolate quadratic functions given barycentric coordinates. Any further properties of these interpolation functions depend on the properties of the barycentric coordinates. They are provided in this package under the name *linear_interpolation* and *quadratic_interpolation*.

Natural neighbor interpolation

Natural neighbor coordinates are defined by Sibson in 1980 and are based on the Voronoi diagram of the data points. Interpolation methods based on natural neighbor coordinates are particularly interesting because they adapt easily to non-uniform and highly anisotropic data. This package contains Sibson's C^1 continuous interpolation method which interpolates exactly spherical quadrics (of the form $\Phi(\mathbf{x}) = a + \mathbf{b}'\mathbf{x} + \gamma \mathbf{x}'\mathbf{x}$) and Farin's C^1 continuous interpolation method based on Bernstein-Bézier techniques and interpolating exactly quadratic functions – assuming that the function gradient is known. In addition, Sibson defines a method to approximate the function gradients for data points that are in the interior of the convex hull. This method is exact for spherical quadrics.

This CGAL package implements Sibson's and Farin's interpolation functions as well as Sibson's function gradient fitting method. Furthermore, it provides functions to compute the natural neighbor coordinates with respect to a two-dimensional Voronoi diagram (i. e., from the Delaunay triangulation of the data points) and to a two-dimensional power diagram for weighted points (i. e., from their regular triangulation). Natural neighbor coordinates on closed and well-sampled surfaces can also be computed if the normal to the surface at the query point is known. The latter coordinates are only approximately barycentric, see [\[BF02\]](#).

For a more thorough introduction see the user manual.

CGAL::linear_interpolation

Definition

The function *linear_interpolation* computes the weighted sum of the function values which must be provided via a functor.

```
#include <CGAL/interpolation_functions.h>
```

```
template < class ForwardIterator, class Functor>
typename Functor::result_type
```

```
    linear_interpolation( ForwardIterator first,
                          ForwardIterator beyond,
                          typename          std::iterator_traits<ForwardIterator>::value_
type::second_type norm,
                          Functor function_values)
```

ForwardIterator::value_type is a pair associating a point to a (non-normalized) barycentric coordinate. *norm* is the normalization factor. Given a point, the functor *function_values* allows to access a pair of a function value and a Boolean. The Boolean indicates whether the function value could be retrieved correctly. This function generates the interpolated function value as the weighted sum of the values corresponding to each point of the point/coordinate pairs in the range *[first, beyond)*.

Precondition: $norm \neq 0$. *function_value(p).second == true* for all points *p* of the point/coordinate pairs in the range *[first, beyond)*.

Requirements

1. *ForwardIterator::value_type* is a pair of point/coordinate value, thus *ForwardIterator::value_type::first_type* is equivalent to a point and *ForwardIterator::value_type::second_type* is a field number type.
2. *Functor::argument_type* must be equivalent to *ForwardIterator::value_type::first_type* and *Functor::result_type* is a pair of the function value type and a Boolean value. The function value type must provide a multiplication and addition operation with the field number type *ForwardIterator::value_type::second_type* and a constructor with argument 0. A model of the functor is provided by the struct *Data_access*. It must be instantiated accordingly with an associative container (e.g. STL *std::map*) having the point type as *key_type* and the function value type as *mapped_type*.

CGAL::sibson_c1_interpolation

Definition

The function *sibson_c1_interpolation* interpolates the function values and the gradients that are provided by functors following the method described in [Sib81].

Parameters

The template parameter *Traits* is to be instantiated with a model of *InterpolationTraits*. *ForwardIterator::value_type* is a pair associating a point to a (non-normalized) barycentric coordinate. *norm* is the normalization factor. The range $[first, beyond)$ contains the barycentric coordinates for the query point *p*. The functor *function_value* allows to access the value of the interpolated function given a point. *function_gradient* allows to access the function gradient given a point.

```
#include <CGAL/interpolation_functions.h>
```

```
template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
std::pair< typename Functor::result_type, bool>
```

```
    sibson_c1_interpolation( ForwardIterator first,
                             ForwardIterator beyond,
                             typename      std::iterator_traits<ForwardIterator>::value_
type::second_type norm,
                             typename      std::iterator_traits<ForwardIterator>::value_
type::first_type p,
                             Functor function_value,
                             GradFunctor function_gradient,
                             Traits traits)
```

This function generates the interpolated function value at the point *p* using Sibson's Z^1 interpolant [Sib81].

If the functor *function_gradient* cannot supply the gradient of a point, the function returns a pair where the Boolean is set to *false*. If the interpolation was successful, the pair contains the interpolated function value as first and *true* as second value.

Precondition: *norm* $\neq 0$. *function_value(p).second == true* for all points *p* of the point/coordinate pairs in the range $[first, beyond)$.

Requirements

1. *Traits* is a model of the concept *InterpolationTraits*.
2. *ForwardIterator::value_type* is a point/coordinate pair. Precisely *ForwardIterator::value_type::first_type* is equivalent to *Traits::Point_d* and *ForwardIterator::value_type::second_type* is equivalent to *Traits::FT*.

3. *Functor::argument_type* must be equivalent to *Traits::Point_d* and *Functor::result_type* is a pair of the function value type and a Boolean. The function value type must provide a multiplication and addition operation with the type *Traits::FT* as well as a constructor with argument 0.
4. *GradFunctor::argument_type* must be equivalent to *Traits::Point_d* and *Functor::result_type* is a pair of the function's gradient type and a Boolean. The function gradient type must provide a multiplication operation with *Traits::Vector_d*.
5. A model of the functor types *Functor* (resp. *GradFunctor*) is provided by the struct *Data_access*. It must be instantiated accordingly with an associative container (e.g. STL *std::map*) having the point type as *key_type* and the function value type (resp. function gradient type) as *mapped_type*.
6. The number type *FT* provided by *Traits* must support the square root operation *sqrt()*.

```
template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type
```

```

        sibson_c1_interpolation_square( ForwardIterator first,
                                         ForwardIterator beyond,
                                         typename      std::iterator_traits<ForwardIterator>
::value_type::second_type norm,
                                         Functor function_value,
                                         GradFunctor function_gradient,
                                         Traits traits)

```

The same as above except that no square root operation is needed for *FT*.

CGAL::farin_c1_interpolation

Definition

The function *farin_c1_interpolation* interpolates the function values and the gradients that are provided by functors using the method described in [Far90].

```
#include <CGAL/interpolation_functions.h>
```

Parameters

RandomAccessIterator::value_type is a pair associating a point to a (non-normalized) barycentric coordinate. See *sibson_c1_interpolation* for the other parameters.

```
template < class RandomAccessIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type
```

```
    farin_c1_interpolation( RandomAccessIterator first,
                           RandomAccessIterator beyond,
                           typename std::iterator_traits<RandomAccessIterator>::value_
type::second_type norm,
                           Functor function_value,
                           GradFunctor function_gradient,
                           Traits traits)
```

generates the interpolated function value computed by Farin's interpolant [Far90]. See also *sibson_c1_interpolation*.

Precondition: *norm* $\neq 0$. *function_value(p).second* == *true* for all points *p* of the point/coordinate pairs in the range [*first*, *beyond*).

Precondition: The range [*first*, *beyond*) contains either one or more than three elements.

Requirements

Same requirements as for *sibson_c1_interpolation* only the iterator must provide random access and *Traits::FT* does not need to provide the square root operation.

CGAL::quadratic_interpolation

Definition

The function *quadratic_interpolation* interpolates the function values and first degree functions defined from the function gradients. Both, function values and gradients, must be provided by functors.

```
#include <CGAL/interpolation_functions.h>
```

Parameters

See *sibson_c1_interpolation*.

```
template < class ForwardIterator, class Functor, class GradFunctor, class Traits>
typename Functor::result_type
```

```
    quadratic_interpolation( ForwardIterator first,
                             ForwardIterator beyond,
                             typename std::iterator_traits<ForwardIterator>:: value_
type::second_type norm,
                             Functor function_value,
                             GradFunctor function_gradient,
                             Traits traits)
```

This function generates the interpolated function value as the weighted sum of the values plus a linear term in the gradient for each point of the point/coordinate pairs in the range $[first, beyond)$. See also *sibson_c1_interpolation*.

Precondition: $norm \neq 0$ $function_value(p).second == true$ for all points p of the point/coordinate pairs in the range $[first, beyond)$.

Requirements

Same requirements as for *sibson_c1_interpolation* only that *Traits::FT* does not need to provide the square root operation.

CGAL::Data_access<Map>

Definition

The struct *Data_access<Map>* implements a functor that allows to retrieve data from an associative container. The functor keeps a reference to the container. Given an instance of the container's key type, it returns a pair of the container's value type and a Boolean indicating whether the retrieval was successful.

This class can be used to provide the values and gradients of the interpolation functions.

```
#include <CGAL/interpolation_functions.h>
```

Parameters

The class *Data_access<Map>* has the container type *Map* as template parameter.

Types

```
typedef Map::mapped_type
                                Data_type;
typedef Map::key_type
                                Key_type;
```

Creation

Data_access<Map> *data_access*(*Map* *map*); Introduces a *Data_access* to the container *map*.

```
std::pair< Data_type, bool>
```

```
    data_access( Key_type p)
```

If there is an entry for *p* in the container *map*, then the pair of *map.find(p)* and *true* is returned. Otherwise, the Boolean value of the pair is *false*.

InterpolationTraits

Definition

Most interpolation functions are parameterized by a traits class that defines the primitives used in the interpolation algorithms. The concept `InterpolationTraits` defines this common set of requirements.

Types

<i>InterpolationTraits:: FT</i>	The number type must follow the model <i>FieldNumberType</i> .
<i>InterpolationTraits:: Point_d</i>	The point type on which the function is defined and interpolated.
<i>InterpolationTraits:: Vector_d</i>	The corresponding vector type.
<i>InterpolationTraits:: Construct_vector_d</i>	A constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Point_d a, Point_d b)</i> which produces the vector $b - a$ and <i>Vector_d operator() (Null_vector NULL_VECTOR)</i> which introduces the null vector.
<i>InterpolationTraits:: Construct_scaled_vector_d</i>	Constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Vector_d v, FT scale)</i> which produces the vector v scaled by a factor $scale$.
<i>InterpolationTraits:: Compute_squared_distance_d</i>	Constructor object for <i>FT</i> . Provides the operator: <i>FT operator() (Point_d a, Point_d b)</i> returning the squared distance between a and b .
<i>InterpolationTraits traits;</i>	default constructor.

Construction objects

The following functions that create instances of the above constructor object types must exist.

Construct_vector_d *traits.construct_vector_d_object()*

Construct_scaled_vector_d

traits.construct_scaled_vector_d_object()

Compute_squared_distance_d

traits.compute_squared_distance_d_object()

CGAL::natural_neighbor_coordinates_2

Definition

The function *natural_neighbor_coordinates_2* computes natural neighbor coordinates, also called Sibson's coordinates, for 2D points provided a two-dimensional triangulation and a query point in the convex hull of the vertices of the triangulation.

```
#include <CGAL/natural_neighbor_coordinates_2.h>
```

```
template < class Dt, class OutputIterator >
```

```
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
    natural_neighbor_coordinates_2( Dt dt,
                                   typename Dt::Geom_traits::Point_2 p,
                                   OutputIterator out,
                                   typename Dt::Face_handle start = typename
Dt::Face_handle())
```

computes the natural neighbor coordinates for p with respect to the points in the two-dimensional Delaunay triangulation dt . The template class Dt should be of type *Delaunay_triangulation_2*<*Traits*, *Tds*>. The value type of the *OutputIterator* is a pair of $Dt::Point_2$ and the coordinate value of type $Dt::Geom_traits::FT$. The sequence of point/coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful.

```
template <class Dt, class OutputIterator, class EdgeIterator >
```

```
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
    natural_neighbor_coordinates_2( Dt dt,
                                   typename Dt::Geom_traits::Point_2 p,
                                   OutputIterator out,
                                   EdgeIterator hole_begin,
                                   EdgeIterator hole_end)
```

The same as above. *hole_begin* and *hole_end* determines the iterator range over the boundary edges of the conflict zone of p in the triangulation. It is the result of the function *T.get_boundary_of_conflicts*(p , *std::back_inserter*(*hole*), *start*), see *Delaunay_triangulation_2*<*Traits*, *Tds*>.

```
template <class Dt, class OutputIterator>
```

```
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
    natural_neighbor_coordinates_2( Dt dt,
```

```
typename Dt::Vertex_handle vh,
OutputIterator out)
```

This function computes the natural neighbor coordinates of the point *vh->point()* with respect to the vertices of *dt* excluding *vh->point()*. The same as above for the remaining parameters.

Requirements

1. *Dt* are equivalent to the class *Delaunay_triangulation_2<Traits, Tds>*.
2. The traits class *Traits* of *Dt* is a model of the concept *DelaunayTriangulationTraits_2*. Only the following members of this traits class are used:

- *Construct_circumcenter_2*
- *FT*
- *Point_2*
- *construct_circumcenter_2_object*

Additionally, *Traits* must meet the requirements for the traits class of the *polygon_area_2* function.

3. *OutputIterator::value_type* is equivalent to *std::pair<Dt::Point_2, Dt::Geom_traits::FT>*, i.e. a pair associating a point and its natural neighbor coordinate.

See Also

CGAL::linear_interpolation [page 2843](#)
CGAL::sibson_c1_interpolation [page 2844](#)
CGAL::surface_neighbor_coordinates_3 [page 2864](#)
CGAL::regular_neighbor_coordinates_2 [page 2854](#)

Implementation

This function computes the area of the sub-cells stolen from the Voronoi cells of the points in *dt* when inserting *p*. The total area of the Voronoi cell of *p* is also computed and returned by the function. If *p* lies outside the convex hull, the coordinate values cannot be computed and the third value of the result triple is set to *false*.

CGAL::regular_neighbor_coordinates_2

Definition

The function *regular_neighbor_coordinates_2* computes natural neighbor coordinates, also called Sibson's coordinates, for weighted 2D points provided a two-dimensional regular triangulation and a (weighted) query point inside the convex hull of the vertices of the triangulation. We call these coordinates regular neighbor coordinates.

```
#include <CGAL/regular_neighbor_coordinates_2.h>
```

```
template < class Rt, class OutputIterator >
```

```
CGAL::Triple< OutputIterator, typename Rt::Geom_traits::FT, bool >
```

```
    regular_neighbor_coordinates_2( Rt rt,
                                   typename Rt::Weighted_point p,
                                   OutputIterator out,
                                   typename Rt::Face_handle start = typename
Rt::Face_handle())
```

computes the regular neighbor coordinates for p with respect to the weighted points in the two-dimensional regular triangulation rt . The template class Rt should be of type *Regular_triangulation_2*<*Traits*, *Tds*>. The value type of the *OutputIterator* is a pair of $Rt::Weighted_point$ and the coordinate value of type $Rt::Geom_traits::FT$. The sequence of point/coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful, i.e. if p lies inside the convex hull of the points in rt .

```
template <class Rt, class OutputIterator, class EdgeIterator, class VertexIterator >
```

```
CGAL::Triple< OutputIterator, typename Traits::FT, bool >
```

```
    regular_neighbor_coordinates_2( Rt rt,
                                   typename Traits::Weighted_point p,
                                   OutputIterator out,
                                   EdgeIterator hole_begin,
                                   EdgeIterator hole_end,
                                   VertexIterator hidden_vertices_begin,
```

VertexIterator hidden_vertices_end)

The same as above. *hole_begin* and *hole_end* determines the iterator range over the boundary edges of the conflict zone of *p* in the triangulation *rt*. *hidden_vertices_begin* and *hidden_vertices_end* determines the iterator range over the hidden vertices of the conflict zone of *p* in *rt*. It is the result of the function *T.get_boundary_of_conflicts(p, std::back_inserter(hole), std::back_inserter(hidden_vertices), start)*, see *Regular_triangulation_2<Traits, Tds>*.

```
template <class Rt, class OutputIterator>
CGAL::Triple< OutputIterator, typename Rt::Geom_traits::FT, bool >
```

```
regular_neighbor_coordinates_2( Rt rt,
                               typename Rt::Vertex_handle vh,
                               OutputIterator out)
```

This function computes the regular neighbor coordinates of the point *vh->point()* with respect to the vertices of *rt* excluding *vh->point()*. The same as above for the remaining parameters.

Requirements

1. *Rt* are equivalent to the class *Regular_triangulation_2<Traits, Tds>*.
2. The traits class *Traits* of *Rt* is a model of the concept *RegularTriangulationTraits_2*. It provides the number type *FT* which is a model for *FieldNumberType* and it must meet the requirements for the traits class of the *polygon_area_2* function. A model of this traits class is *Regular_triangulation_euclidean_traits_2<K, Weight>*.
3. *OutputIterator::value_type* is equivalent to *std::pair<Rt::Weighted_point, Rt::Geom_traits::FT>*, i.e. a pair associating a point and its regular neighbor coordinate.

Implementation

This function computes the areas stolen from the Voronoi cells of points in *rt* by the insertion of *p*. The total area of the Voronoi cell of *p* is also computed and returned by the function. If *p* lies outside the convex hull, the coordinate values cannot be computed and the third value of the result triple is set to *false*.

CGAL::natural_neighbor_coordinates_2 page [2852](#)

CGAL::sibson_gradient_fitting

Definition

The function *sibson_gradient_fitting* approximates the gradient of a function at a point p given natural neighbor coordinates for p and its neighbors' function values. The approximation method is described in [Sib81]. Further functions are provided to fit the gradient for all data points that lie inside the convex hull of the data points. One function exists for each type of natural neighbor coordinates.

```
#include <CGAL/sibson_gradient_fitting.h>
```

```
template < class ForwardIterator, class Functor, class Traits>
typename Traits::Vector_d
```

```
    sibson_gradient_fitting( ForwardIterator first,
                           ForwardIterator beyond,
                           typename      std::iterator_traits<ForwardIterator>::value_
type::second_type norm,
                           typename      std::iterator_traits<ForwardIterator>::value_
type::first_type p,
                           Functor f,
                           Traits traits)
```

This function estimates the gradient of a function at the point p given natural neighbor coordinates of p in the range $[first, beyond)$ and the function values of the neighbors provided by the functor f . *norm* is the normalization factor of the barycentric coordinates.

Requirements

1. *ForwardIterator::value_type* is a pair of point/coordinate value, thus *ForwardIterator::value_type::first_type* is equivalent to a point and *ForwardIterator::value_type::second_type* is a number type.
2. *Functor::argument_type* must be equivalent to *ForwardIterator::value_type::first_type* and *Functor::result_type* is the function value type. It must provide a multiplication and addition operation with the type *ForwardIterator::value_type::second_type*.
3. *Traits* is a model of the concept *GradientFittingTraits*.

```
template < class Dt, class OutputIterator, class Functor, class Traits>
```

OutputIterator *sibson_gradient_fitting_nn_2(Dt dt, OutputIterator out, Functor f, Traits traits)*

estimates the function gradients at all vertices of *dt* that lie inside the convex hull using the coordinates computed by the function *natural_neighbor_coordinates_2*. *OutputIterator::value_type* is a pair associating a point to a vector. The sequence of point/gradient pairs computed by this function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting sequence. The requirements are the same as above. The template class *Dt* must be equivalent to *Delaunay_triangulation_2<Gt, Tds>*.

template < class Rt, class OutputIterator, class Functor, class Traits>
OutputIterator *sibson_gradient_fitting_rn_2(Rt rt, OutputIterator out, Functor f, Traits traits)*

estimates the function gradients at all vertices of *rt* that lie inside the convex hull using the coordinates computed by the function *regular_neighbor_coordinates_2*. *OutputIterator::value_type* is a pair associating a point to a vector. The sequence of point/gradient pairs computed by this function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting sequence. The requirements are the same as above. The template class *Rt* must be equivalent to *Regular_triangulation_2<Gt, Tds>*.

Implementation

This function implements Sibson's gradient estimation method based on natural neighbor coordinates [[Sib81](#)].

GradientFittingTraits

Definition

The function *sibson_gradient_fitting* is parameterized by a traits class that defines the primitives used by the algorithm. The concept *GradientFittingTraits* defines this common set of requirements.

Types

<i>GradientFittingTraits:: FT</i>	The number type must follow the model <i>FieldNumberType</i> .
<i>GradientFittingTraits:: Point_d</i>	The point type on which the function is defined and interpolated.
<i>GradientFittingTraits:: Vector_d</i>	The corresponding vector type.
<i>GradientFittingTraits:: Aff_transformation_d</i>	defines a matrix type. Must provide the following member functions : <i>Aff_transformation tr.inverse ()</i> which gives the inverse transformation, and <i>Aff_transformation tr.transform(Vector v)</i> which returns the multiplication of <i>tr</i> with <i>v</i> .
<i>GradientFittingTraits:: Construct_vector_d</i>	A constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Point_d a, Point_d b)</i> which produces the vector <i>b - a</i> and <i>Vector_d operator() (Null_vector NULL_VECTOR)</i> which introduces the null vector.
<i>GradientFittingTraits:: Construct_scaled_vector_d</i>	Constructor object for <i>Vector_d</i> . Provides : <i>Vector_d operator() (Vector_d v,FT scale)</i> which produces the vector <i>v</i> scaled by a factor <i>scale</i> .
<i>GradientFittingTraits:: Construct_null_matrix_d</i>	Constructor object for <i>Aff_transformation_d</i> . Provides : <i>Aff_transformation_d operator()()</i> which introduces an affine transformation whose matrix has only zero entries.
<i>GradientFittingTraits:: Construct_scaling_matrix_d</i>	Constructor object for <i>Aff_transformation_d</i> . Provides : <i>Aff_transformation_d operator()(FT scale)</i> which introduces a scaling by a scale factor <i>scale</i> .

GradientFittingTraits:: Construct_sum_matrix_d

Constructor object for *Aff_transformation_d*. Provides :
Aff_transformation_d operator()(Aff_transformation_d tr1,
Aff_transformation_d tr2) which returns the sum of the two
matrices representing *tr1* and *tr2*.

GradientFittingTraits:: Construct_outer_product_d

Constructor object for *Aff_transformation_d*. Provides :
Aff_transformation_d operator()(Vector v) which returns the
outer product, i.e. the quadratic matrix $v^t v$.

Creation

GradientFittingTraits traits; default constructor.

Operations

The following functions that create instances of the above constructor object types must exist.

Construct_vector_d traits.construct_vector_d_object()

Construct_scaled_vector_d

traits.construct_scaled_vector_d_object()

Construct_null_matrix_d

traits.construct_null_matrix_d_object()

Construct_sum_matrix_d

traits.construct_sum_matrix_d_object()

Construct_outer_product_d

traits.construct_outer_product_d_object()

CGAL::Interpolation_gradient_fitting_traits_2<K>

Definition

Interpolation_gradient_fitting_traits_2<K> is a model for the concepts *InterpolationTraits* and *GradientFittingTraits*. It can be used to instantiate the geometric traits class of interpolation functions and of Sibson's gradient fitting function when applied on a function defined over a two-dimensional domain. The traits class is templated by a kernel class *K*.

```
#include <CGAL/Interpolation_gradient_fitting_traits_2.h>
```

CGAL::Voronoi_intersection_2_traits_3<K>

Definition

Voronoi_intersection_2_traits_3<K> is a model for the concept *RegularTriangulationTraits_2* and *InterpolationTraits*. It can be used to instantiate the geometric traits class of a two-dimensional regular triangulation. A three-dimensional plane is defined by a point and a vector that are members of the traits class. The triangulation is defined on 3D points. It is the regular triangulation of the input points projected onto the plane and each weighted with the negative squared distance of the input point to the plane. It can be shown that it is dual to the power diagram obtained by intersecting the three-dimensional Voronoi diagram of the input points with the plane. All predicates and constructions used in the computation of the regular triangulation are formulated on the three dimensional points without explicitly constructing the projected points and the weights. This reduces the arithmetic demands. The traits class is templated by a kernel class *K*.

```
#include <CGAL/Voronoi_intersection_2_traits_3.h>
```

CGAL::surface_neighbor_coordinates_3

Definition

The function *surface_neighbor_coordinates_3* computes natural neighbor coordinates for surface points associated to a finite set of sample points issued from the surface. The coordinates are computed from the intersection of the Voronoi cell of the query point p with the tangent plane to the surface at p . If the sampling is sufficiently dense, the coordinate system meets the properties described in the manual pages and in [BF02],[Fl603b]. The query point p needs to lie inside the convex hull of the projection of the sample points onto the tangent plane at p .

```
#include <CGAL/surface_neighbor_coordinates_3.h>
```

```
template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Triple< OutputIterator, typename Kernel::FT, bool >
```

```
    surface_neighbor_coordinates_3( InputIterator first,
                                   InputIterator beyond,
                                   typename Kernel::Point_3 p,
                                   typename Kernel::Vector_3 normal,
                                   OutputIterator out,
                                   Kernel K)
```

The sample points \mathcal{P} are provided in the range $[first, beyond)$. *InputIterator::value_type* is the point type *Kernel::Point_3*. The tangent plane is defined by the point p and the vector *normal*. The parameter K determines the kernel type that will instantiate the template parameter of *Voronoi_intersection_2_traits_3<K>*.

The natural neighbor coordinates for p are computed in the power diagram that results from the intersection of the 3D Voronoi diagram of \mathcal{P} with the tangent plane. The sequence of point/coordinate pairs that is computed by the function is placed starting at *out*. The function returns a triple with an iterator that is placed past-the-end of the resulting sequence of point/coordinate pairs, the normalization factor of the coordinates and a Boolean value which is set to true iff the coordinate computation was successful, i.e. if p lies inside the convex hull of the projection of the points \mathcal{P} onto the tangent plane.

```
template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Triple< OutputIterator, typename ITraits::FT, bool >
```

```
    surface_neighbor_coordinates_3( InputIterator first,
                                   InputIterator beyond,
                                   typename ITraits::Point_2 p,
                                   OutputIterator out,
```

ITraits traits)

the same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

The next functions return, in addition, a second Boolean value (the fourth value of the quadruple) that certifies whether or not, the Voronoi cell of p can be affected by points that lie outside the input range, i.e. outside the ball centered on p passing through the furthest sample point from p in the range $[first, beyond)$. If the sample points are collected by a k -nearest neighbor or a range search query, this permits to check whether the neighborhood which has been considered is large enough.

```
template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Quadruple< OutputIterator, typename Kernel::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                           InputIterator beyond,
                                           typename Kernel::Point_3 p,
                                           typename Kernel::Vector_3 normal,
                                           OutputIterator out,
                                           Kernel K)
```

Similar to the first function. The additional fourth return value is *true* if the furthest point in the range $[first, beyond)$ is further away from p than twice the distance from p to the furthest vertex of the intersection of the Voronoi cell of p with the tangent plane defined by $(p, normal)$. It is *false* otherwise.

```
template <class OutputIterator, class InputIterator, class Kernel>
CGAL::Quadruple< OutputIterator, typename Kernel::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                           InputIterator beyond,
                                           typename Kernel::Point_2 p,
                                           typename Kernel::FT max_distance,
                                           OutputIterator out,
                                           Kernel kernel)
```

The same as above except that this function takes the maximal distance from p to the points in the range $[first, beyond)$ as additional parameter.

```
template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Quadruple< OutputIterator, typename ITraits::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                           InputIterator beyond,
                                           typename ITraits::Point_2 p,
                                           OutputIterator out,
                                           ITraits traits)
```

The same as above only that the traits class must be instantiated by the user and without the parameter *max_distance*. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

```
template <class OutputIterator, class InputIterator, class ITraits>
CGAL::Quadruple< OutputIterator, typename ITraits::FT, bool, bool >
```

```
surface_neighbor_coordinates_certified_3( InputIterator first,
                                         InputIterator beyond,
                                         typename ITraits::Point_2 p,
                                         typename ITraits::FT max_distance,
                                         OutputIterator out,
                                         ITraits traits)
```

The same as above with the parameter *max_distance*.

The next function allows to filter some potential neighbors of the query point p from \mathcal{P} via its three-dimensional Delaunay triangulation. All surface neighbors of p are necessarily neighbors in the Delaunay triangulation of $\mathcal{P} \cup \{p\}$.

```
template < class Dt, class OutputIterator >
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
surface_neighbor_coordinates_3( Dt dt,
                               typename Dt::Geom_traits::Point_2 p,
                               typename Dt::Geom_traits::Vector_3 normal,
                               OutputIterator out,
                               typename Dt::Face_handle start = typename
```

```
Dt::Face_handle())
```

computes the surface neighbor coordinates with respect to the points that are vertices of the Delaunay triangulation dt . The type Dt must be equivalent to *Delaunay_triangulation_3*< Gt , Tds >. The optional parameter *start* is used as a starting place for the search of the conflict zone. It may be the result of the call $dt.locate(p)$. This function instantiates the template parameter *ITraits* to be *Voronoi_intersection_2_traits_3*< $Dt::Geom_traits$ >.

```
template < class Dt, class OutputIterator, class ITraits>
CGAL::Triple< OutputIterator, typename Dt::Geom_traits::FT, bool >
```

```
surface_neighbor_coordinates_3( Dt dt,
                               typename Dt::Geom_traits::Point_2 p,
                               OutputIterator out,
                               ITraits traits,
                               typename Dt::Face_handle start = typename
```

```
Dt::Face_handle())
```

The same as above only that the parameter *traits* instantiates the geometric traits class. Its type *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3*< K >.

Requirements

1. Dt is equivalent to the class *Delaunay_triangulation_3*.

2. *OutputIterator::value_type* is equivalent to *std::pair<Dt::Point_3, Dt::Geom_traits::FT>*, i.e. a pair associating a point and its natural neighbor coordinate.
3. *ITraits* is equivalent to the class *Voronoi_intersection_2_traits_3<K>*.

Implementation

This functions construct the regular triangulation of the input points instantiated with *Voronoi_intersection_2_traits_3<Kernel>* or *ITraits* if provided. They return the result of the function call *regular_neighbor_coordinates_2* with the regular triangulation and *p* as arguments.

CGAL::surface_neighbors_3

Definition

Given a set of sample points issued from a surface and a query point p , the function *surface_neighbors_3* computes the neighbors of p on the surface within the sample points. If the sampling is sufficiently dense, the neighbors are provably close to the point p on the surface (cf. the manual pages and [BF02],[Flö03b]). They are defined to be the neighbors of p in the regular triangulation dual to the power diagram which is equivalent to the intersection of the Voronoi cell of the query point p with the tangent plane to the surface at p .

```
#include <CGAL/surface_neighbors_3.h>
```

```
template <class OutputIterator, class InputIterator, class Kernel>
OutputIterator      surface_neighbors_3( InputIterator first,
                                         InputIterator beyond,
                                         typename Kernel::Point_3 p,
                                         typename Kernel::Vector_3 normal,
                                         OutputIterator out,
                                         Kernel K)
```

The sample points \mathcal{P} are provided in the range $[first, beyond)$. *InputIterator::value_type* is the point type *Kernel::Point_3*. The tangent plane is defined by the point p and the vector *normal*. The parameter K determines the kernel type that will instantiate the template parameter of *Voronoi_intersection_2_traits_3<K>*.

The surface neighbors of p are computed which are the neighbors of p in the regular triangulation that is dual to the intersection of the 3D Voronoi diagram of \mathcal{P} with the tangent plane. The point sequence that is computed by the function is placed starting at *out*. The function returns an iterator that is placed past-the-end of the resulting point sequence.

```
template <class OutputIterator, class InputIterator, class ITraits>
OutputIterator      surface_neighbors_3( InputIterator first,
                                         InputIterator beyond,
                                         typename ITraits::Point_2 p,
                                         OutputIterator out,
                                         ITraits traits)
```

the same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*.

The next functions return, in addition, a Boolean value that certifies whether or not, the Voronoi cell of p can be affected by points that lie outside the input range, i.e. outside the ball centered on p passing through the furthest sample point from p in the range $[first, beyond)$. If the sample points are collected by a k -nearest neighbor or a range search query, this permits to verify that a large enough neighborhood has been considered.

```
template <class OutputIterator, class InputIterator, class Kernel>
```

std::pair< OutputIterator, bool >

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename Kernel::Point_3 p,
                               typename Kernel::Vector_3 normal,
                               OutputIterator out,
                               Kernel K)
```

Similar to the first function. The additional third return value is *true* if the furthest point in the range $[first, beyond)$ is further away from p than twice the distance from p to the furthest vertex of the intersection of the Voronoi cell of p with the tangent plane defined by $(p, normal)$. It is *false* otherwise.

```
template <class OutputIterator, class InputIterator, class Kernel>
std::pair< OutputIterator, bool >
```

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename Kernel::Point_2 p,
                               typename Kernel::FT max_distance,
                               OutputIterator out,
                               Kernel kernel)
```

The same as above except that this function takes the maximal distance from p to the points in the range $[first, beyond)$ as additional parameter.

```
template <class OutputIterator, class InputIterator, class ITraits>
std::pair< OutputIterator, bool >
```

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename ITraits::Point_2 p,
                               OutputIterator out,
                               ITraits traits)
```

The same as above only that the traits class must be instantiated by the user. *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3<K>*. There is no parameter *max_distance*.

```
template <class OutputIterator, class InputIterator, class ITraits>
std::pair< OutputIterator, bool >
```

```
surface_neighbors_certified_3( InputIterator first,
                               InputIterator beyond,
                               typename ITraits::Point_2 p,
                               typename ITraits::FT max_distance,
                               OutputIterator out,
                               ITraits traits)
```

The same as above with the parameter *max_distance*.

The next function allows to filter some potential neighbors of the query point p from \mathcal{P} via its three-dimensional Delaunay triangulation. All surface neighbors of p are necessarily neighbors in the Delaunay triangulation of $\mathcal{P} \cup \{p\}$.

```
template < class Dt, class OutputIterator >
OutputIterator      surface_neighbors_3( Dt dt,
                                     typename Dt::Geom_traits::Point_2 p,
                                     typename Dt::Geom_traits::Vector_3 normal,
                                     OutputIterator out,
                                     typename Dt::Face_handle start = typename Dt::Face_
handle())
```

computes the surface neighbor coordinates with respect to the points that are vertices of the Delaunay triangulation dt . The type Dt must be equivalent to *Delaunay_triangulation_3*< Gt , Tds >. The optional parameter *start* is used for the used as a starting place for the search of the conflict zone. It may be the result of the call $dt.locate(p)$. This function instantiates the template parameter *ITraits* to be *Voronoi_intersection_2_traits_3*< $Dt::Geom_traits$ >.

```
template < class Dt, class OutputIterator, class ITraits>
OutputIterator      surface_neighbors_3( Dt dt,
                                     typename Dt::Geom_traits::Point_2 p,
                                     OutputIterator out,
                                     ITraits traits,
                                     typename Dt::Face_handle start = typename Dt::Face_
handle())
```

The same as above only that the parameter *traits* instantiates the geometric traits class. Its type *ITraits* must be equivalent to *Voronoi_intersection_2_traits_3*< K >.

Requirements

1. Dt is equivalent to the class *Delaunay_triangulation_3*.
2. *OutputIterator::value_type* is equivalent to $Dt::Point_3$, i.e. a point type.
3. *ITraits* is equivalent to the class *Voronoi_intersection_2_traits_3*< K >.

Implementation

These functions compute the regular triangulation of the sample points and the point p using a traits class equivalent to *Voronoi_intersection_2_traits_3*< K >. They determine the neighbors of p in this triangulation. The functions which certify the result need to compute, in addition, the Voronoi vertices of the cell of p in this diagram.

Lets say you want to maintain a sorted list of items (each item is associate with a real number key). You can imagine placing each of the items on the point on the real line corresponding to its key. Now, let the key for each item change continuously (i.e. no jumps are allowed). As long as no two (consecutive) items cross, the sorted order is intact. When two items cross, they need to be exchanged in the list and then the sorted order is once again correct. This is a trivial example of a kinetic data structure. The key observation is that the combinatorial structure which is maintained changes at discrete times (events) even though the basic building blocks are changing continuously.

This chapter describes a number of such kinetic data structures implemented using the Kinetic framework described in Chapter 54. We first, in Section 53.2 introduce kinetic data structures and sweepline algorithms. This section can be skipped if the reader is already familiar with the area. The next sections, Section 53.2.1 and Section 53.3 introduce the terms and give an overview of the framework. They are recommended reading for all readers, even if you are just using provided kinetic data structures. We then present kinetic data structures for Delaunay triangulations in two and three dimensions in Section 53.4.

If you are already familiar with kinetic data structures and know what you want to do, you might want to first take a look at the next section Section 53.1 which covers quick hints.

53.1 Quick Hints

This section gives quick answers to some questions people might have. It presumes knowledge of kinetic data structures and this framework.

How do I store extra information along with, for example, a kinetic Point.2?

See the example *Kinetic_framework/defining_a_simulation_traits.cpp* to see how to define a new *Simulation-Traits* class where the *ActiveObjectsTable* contains extra data along with the point.

Where is the best place to look if I want to write my own kinetic data structure?

We provide two simple kinetic data structures, first most trivial is *Kinetic_framework/trivial_kds.cpp* and a slightly more complicated one is:

```
#include <CGAL/Kinetic/Sort.h>
```

How can I use kinetic data structures to update Delaunay triangulations?

We are working on that one, but you will have to wait.

53.2 An Overview of Kinetic Data Structures and Sweep Algorithms

Kinetic data structures were first introduced in by Basch et. al. in 1997 [BGH97]. The idea stems from the observation that most, if not all, computational geometry structures are built using *predicates* — functions on quantities defining the geometric input (e.g. point coordinates), which return a discrete set of values. Many predicates reduce to determining the sign of a polynomial on the defining parameters of the primitive objects. For example, to test whether a point lies above or below a plane we compute the dot product of the point with the normal of the plane and subtract the plane's offset along the normal. If the result is positive, the point is above the plane, zero on the plane, negative below. The validity of many combinatorial structures built on top of geometric primitives can be verified by checking a finite number of predicates of the geometric primitives. These predicates, which collectively certify the correctness of the structure, are called *certificates*. For a Delaunay triangulation in three dimensions, for example, the certificates are one *InCircle* test per facet of the triangulation, plus a point plane orientation test for each facet or edge of the convex hull.

The kinetic data structures approach is built on top of this view of computational geometry. Let the geometric primitives move by replacing each of their defining quantities with a function of time (generally a polynomial). As time advances, the primitives trace out paths in space called *trajectories*. The values of the polynomial functions of the defining quantities used to evaluate the predicates now also become functions of time. We call these functions *certificate functions*. Typically, a geometric structure is valid when all predicates have a specific non-zero sign. In the kinetic setting, as long as the certificate functions maintain the correct sign as time varies, the corresponding predicates do not change values, and the original data structure remains correct. However, if one of the certificate functions changes sign, the original structure must be updated, as well as the set of certificate functions that verify it. We call such occurrences *events*.

Maintaining a kinetic data structure is then a matter of determining which certificate function changes sign next, i.e. determining which certificate function has the first real root that is greater than the current time, and then updating the structure and the set of certificate functions. In addition, the trajectories of primitives are allowed to change at any time, although C^0 -continuity of the trajectories must be maintained. When a trajectory update occurs for a geometric primitive, all certificates involving that primitive must be updated. We call the collection of kinetic data structures, primitives, event queue and other support structures a *simulation*.

Sweep line algorithms for computing arrangements in d dimensions easily map on to kinetic data structures by taking one of the coordinates of the ambient space as the time variable. The kinetic data structure then

maintains the arrangement of a set of objects defined by the intersection of a hyperplane of dimension $d - 1$ with the objects whose arrangement is being computed.

Time is one of the central concepts in a kinetic simulation. Just as static geometric data structures divide the continuous space of all possible inputs (as defined by sets of coordinates) into a discrete set of combinatorial structures, kinetic data structures divide the continuous time domain into a set of disjoint intervals. In each interval the combinatorial structure does not change, so, in terms of the combinatorial structure, all times in the interval are equivalent. We capitalize on this equivalence in the framework in order to simplify computations. If the primitives move on polynomial trajectories and the certificates are polynomials in the coordinates, then events occur at real roots of polynomials of time. Real numbers, which define the endpoints of the interval, are more expensive to compute with than rational numbers, so performing computations at a rational number inside the interval is preferable whenever possible. See Section 54.1.4 for an example of where this equivalence is exploited.

53.2.1 Terms Used

primitive The basic geometric types, e.g., the points of a triangulation. A primitive has a set of *coordinates*.

combinatorial structure A structure built on top of the primitives. The structure does not depend directly on the coordinates of the primitives, only on relationships between them.

trajectory The path traced out by a primitive as time passes. In other words how the coordinates of a primitive change with time.

snapshot The position of all the primitives at a particular moment in time.

static Having to do with geometric data structures on non-moving primitives.

predicate A function which takes the coordinates of several primitives from a snapshot as input and produces one of a discrete set of outputs.

certificate One of a set of predicates which, when all having the correct values, ensure that the combinatorial structure is correct.

certificate function A function of time which is positive when the corresponding certificate has the correct value. When the certificate function changes sign, the combinatorial structure needs to be updated.

event When a certificate function changes sign and the combinatorial structure needs to be updated.

53.3 An Overview of the Kinetic Framework

The provided kinetic data structures are implemented on top of the Kinetic framework presented in Chapter 54. It is not necessary to know the details of the framework, but some familiarity is useful. Here we presented a quick overview of the framework.

The framework is structured around five main concepts. See Figure 53.1 for a schematic of how a kinetic data structure interacts with the various parts. The main concepts are

- the *Kinetic::Simulator*. Models of this concept process events in the correct order and audit kinetic data structures. There should be one instance of a model of this concept per simulation.
- the *Kinetic::Kernel*. The structure of a *Kinetic::Kernel* is analogous to the static CGAL (i.e., non-kinetic) kernels in that it defines a set of primitives and functors which generate certificates from the primitives.

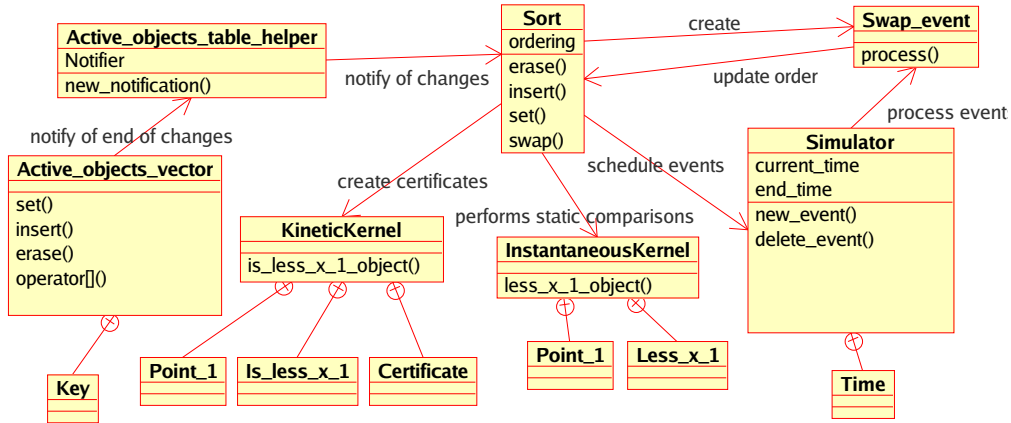

Figure 53.1: The figure shows the interaction between the *Kinetic::Sort<Traits, Visitor>* kinetic data structure and the various pieces of our package. Other, more complicated, kinetic data structures will also use the *Kinetic::InstantaneousKernel* in order to insert/remove geometric primitives and audit themselves. *Kinetic::Sort<Traits, Visitor>* uses the sorting functionality in the STL instead.

- the *Kinetic::ActiveObjectsTable*. Models of this concept hold a collection of kinetic primitives in a centralized manner. This structure centralizes management of the primitives in order to properly disseminate notifications when trajectories change, new primitives are added or primitives are deleted. There is generally one instance of a model of this concept per simulation.
- the *Kinetic::InstantaneousKernel*. Models of this concept allow existing non-kinetic CGAL data structures to be used on a snapshot of kinetic data. As a result, pre-existing static structures can be used to initialize and audit kinetic data structures.
- the *Kinetic::FunctionKernel*. This concept is the computational kernel of our framework. Models of this concept are responsible for representing, generating and manipulating the motional and certificate functions and their roots. It is this concept that provides the kinetic data structures framework with the necessary algebraic operations for manipulating event times. The *Kinetic::FunctionKernel* is discussed in detail in Section 54.2.

For simplicity, we added an additional concept, that of *Kinetic::SimulationTraits*, which wraps together a particular set of choices for the above concepts and is responsible for creating instances of each of the models. As a user of existing kinetic data structures, this is the only framework object you will have to create. The addition of this concept reduces the choices the user has to make to picking the dimension of the ambient space and choosing between exact and inexact computations. The model of *Kinetic::SimulationTraits* creates an instance each of the *Kinetic::Simulator* and *Kinetic::ActiveObjectsTable*. Handles for these instances as well as instances of the *Kinetic::Kernel* and *Kinetic::InstantaneousKernel* can be requested from the simulation traits class. Both the *Kinetic::Kernel* and the *Kinetic::Simulator* use the *Kinetic::FunctionKernel*, the former to find certificate failure times and the later to operate on them. For technical reasons, each supplied model of *Kinetic::SimulationTraits* also picks out a particular type of kinetic primitive which will be used by the kinetic data structures.

53.4 Using Kinetic Data Structures

There are five provided kinetic data structures. They are

Kinetic::Sort<Traits, Visitor> maintain a list of points sorted by x-coordinate.

Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation> maintain the Delaunay triangulation of a set of two dimensional points

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation> maintain the Delaunay triangulation of a set of three dimensional points.

Kinetic::Regular_triangulation_3<Traits, Visitor, Triangulation> maintain the regular triangulation of a set of waiting three dimensional points.

Kinetic::Enclosing_box_2<Traits>, *Kinetic::Enclosing_box_3<Traits>* restrict points to stay within a box by bouncing them off the walls.

53.4.1 A Simple Example

Using a kinetic data structure can be as simple as the following:

```
#include <CGAL/Kinetic/basic.h>

#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Insert_event.h>
#include <CGAL/Kinetic/Sort.h>

int main(int, char *[])
{
    typedef CGAL::Kinetic::Exact_simulation_traits Traits;

    typedef CGAL::Kinetic::Insert_event<Traits::Active_points_1_table> Insert_event;
    typedef Traits::Active_points_1_table::Data Moving_point;
    typedef CGAL::Kinetic::Sort<Traits> Sort;
    typedef Traits::Simulator::Time Time;

    Traits tr(0,100000);
    Sort sort(tr);
    Traits::Simulator::Handle sp= tr.simulator_handle();

    std::ifstream in("data/points_1");
    in >> *tr.active_points_1_table_handle();

    while (sp->next_event_time() != sp->end_time()) {
        sp->set_current_event_number(sp->current_event_number()+1);
    }

    return EXIT_SUCCESS;
};
```

File: examples/Kinetic_data_structures/sort.cpp

Using the other kinetic data structures is substantially identical. Please see the appropriate files in the demo/Kinetic_data_structures directory.

In the example, first the *Kinetic::SimulationTraits* object is chosen (in this case one that supports exact computations). Then the kinetic data structure is defined using the chosen traits object and a visitor class which logs changes to the sorted list. Next, instances of the two are created and a set of points is read from a file. Then, the simulator is instructed to process all the events until the end of the simulation. Finally, a record of what happened is printed to the terminal.

Several important things happen behind the scenes in this example. First, the *Kinetic::ActiveObjectsTable* which holds the moving points notifies the kinetic data structure that new points have been added to the simulation. Second, the *Kinetic::Sort<Traits,Visitor>* kinetic data structure registers its events with the *Kinetic::Simulator* by providing a time and a proxy object for each event. When a particular event occurs, the *Kinetic::Simulator* calls a function on the proxy object which in turn updates the kinetic data structure.

The example illustrates how to monitor the supplied data structures as they evolve by using a *Kinetic::SortVisitor* object—a small class whose methods are called whenever the kinetic data structure changes. Hooks for such visitor concepts are provided for all of the shipped kinetic data structures. In the case of kinetic sorting, the visitor's methods are called every time a new point is inserted in the sorted list, when one is removed, or when two points are swapped in the sorted order.

The visitor concept is quite powerful, allowing us, for example, to implement a data structure for computing and storing two-dimensional arrangements of *x*-monotone curves on top of the *Kinetic::Sort<Traits, Visitor>* data structure using about 60 lines of code. This sweepline code is presented in Section [53.4.4](#).

53.4.2 Creating Kinetic Primitives

One key part of the framework not shown is how to create kinetic primitives (rather than just reading them in from a file). There are two ways to construction the necessary motion functions (which are models of *Kinetic::FunctionKernel::Function*). The first is to create an array of polynomial coefficients and simply call the constructor as in:

```
typedef Traits::Kinetic_kernel::Motion_function F;
std::vector<F::NT> coefs;
coefs.push_back(F::NT(1.0));
coefs.push_back(F::NT(2.0));
F x(coefs.begin(), coefs.end());
```

A slightly more flexible way is to use a *Kinetic::FunctionKernel::ConstructFunction* object. To do this do the following:

```
typedef Traits::Kinetic_kernel::Function_kernel::Construct_function
CF; typedef Traits::Kinetic_kernel::Motion_function F; CF cf; F
x=cf(F::NT(1.0), F::NT(2.0));
```

The *Kinetic::FunctionKernel::ConstructFunction* can be passed (almost) an number of arguments and will construct a polynomial with those arguments are coefficients.

Once the motion functions are constructed, constructing the primitive is just like constructing the corresponding static object.

```
typedef Traits::Kinetic_kernel::Point_1 Point_1;
Point_1 p(x);
```

53.4.3 Visualization of Kinetic Data Structures

The framework includes Qt widgets for displaying kinetic data structures in two and three dimensions. The following example shows using the two dimensional widget with a Delaunay triangulation:

```
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Delaunay_triangulation_2.h>
#include <CGAL/Kinetic/Enclosing_box_2.h>
#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>
#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>
#include <CGAL/Kinetic/IO/Qt_widget_2.h>

int main(int argc, char *argv[]) {
    using namespace CGAL::Kinetic;
    typedef Exact_simulation_traits Traits;
    typedef Delaunay_triangulation_2<Traits> Del_2;
    typedef Enclosing_box_2<Traits> Box_2;
    typedef Qt_widget_2<Traits::Simulator> Qt_widget;
    typedef Qt_moving_points_2<Traits, Qt_gui> Qt_mps;
    typedef Qt_triangulation_2<Del_2, Qt_widget, Qt_mps> Qt_dt2;

    // create a simulation traits and add two KDSs:
    // a kinetic Delaunay triangulation and an enclosing box;
    // the moving points bounce against the walls of the enclosing box
    Traits tr;
    Box_2::Handle box = new Box_2(tr);
    Del_2::Handle kdel = new Del_2(tr);

    // register the simulator, set of moving points and
    // Delaunay triangulation with the kinetic Qt widget
    Qt_widget::Handle qt_w = new Qt_widget(argc, argv, tr.simulator_handle());
    Qt_mps::Handle qt_mps = new Qt_mps(qt_w, tr);
    Qt_dt2::Handle qt_dt2 = new Qt_dt2(kdel, qt_w, qt_mps);

    // read the trajectories of the moving points
    // the simulation traits automatically inserts them in the two KDSs
    // and schedules the appropriate kinetic events; as in the kinetic
    // sorting example this is done with appropriate notifications
    std::ifstream in("data/points_2");
    in >> *tr.active_points_2_table_handle();

    // run the interactive kinetic simulation
    return qt_w->begin_event_loop();
};
```

The example shows how to use a number of additional features of the framework. First, it shows that two kinetic data structures (*Kinetic::Delaunay_triangulation_2<Traits, Triangulation>* and *Kinetic::Enclosing_box_2<Traits>*) can coexist on the same set of points without any extra effort. Both interact with the moving points through the active objects table, and never need to directly interact with one another. Second, objects (like *qt_w*, *qt_mps* and *qt_dt2*) are all stored by using reference counted handles (*Object::Handle*). This allows them to share references to one another without the user having to worry about memory management and order of deletion. For example, the *Kinetic::Qt_triangulation_2<KineticDelaunay_2, QtWidget_2, Qt_moving_points_2>*

object needs a handle to the kinetic triangulation, in order to get the structure to display, and a handle to the *Active_points_1_table* to get the coordinates of the points.

Finally, the example shows how to use the graphical interface elements provided, see Figure 53.3. Our package includes Qt widgets for displaying kinetic geometry in two and three dimensions. In addition to being able to play and pause the simulation, the user can step through events one at a time and reverse the simulation to retrace what had happened. The three-dimensional visualization support is based on the Coin library <http://www.coin3d.org>.

Figure 53.2: *Some events from a Delaunay triangulation kinetic data structure:* The state of the two dimensional Delaunay triangulation immediately following the first events is shown. Green edges are ones which were just created. The pictures are screen shots from *demo/Kinetic_data_structures/Delaunay_triangulation_2.cpp*.

53.4.4 Extending Kinetic Data Structures

Here we present a simple example that uses the *Kinetic::Sort<Traits, Visitor>* kinetic data structure to compute an arrangement of algebraic functions. It wraps the sorting data structure and uses a visitor to monitor changes and map them to corresponding features in the arrangement. To see an example using this kinetic data structure read the example at *examples/Kinetic_data_structures/sweepline.cpp*.

First we define the visitor class. An object of this type is passed to the *Kinetic::Sort<Traits, Visitor>* data structure and turns events into calls on the arrangement structure. This class has to be defined externally since the arrangement will inherit from the sorting structure.

```
template <class Arrangement>
```

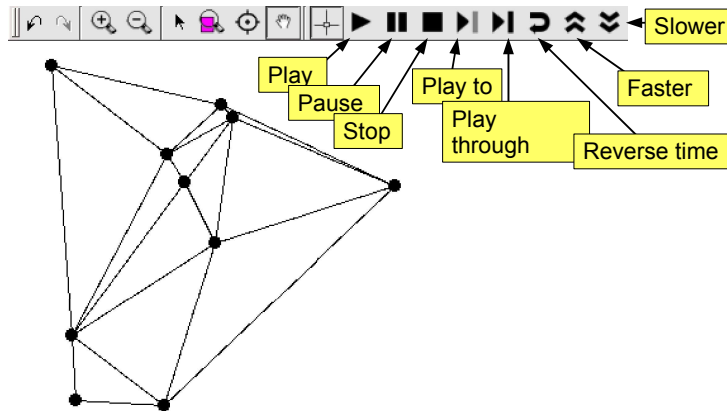

Figure 53.3: The figure shows the graphical user interface for controlling two-dimensional kinetic data structures. It is built on top of the *Qt_widget* and adds buttons to play, pause, step through and run the simulation backwards.

```
struct Arrangement_visitor: public Kinetic::Sort_visitor_base
{
    Arrangement_visitor(Arrangement *a):p_(a){}
    template <class Vertex_handle>
    void remove_vertex(Vertex_handle a) {
        p_>erase(a);
    }
    template <class Vertex_handle>
    void create_vertex(Vertex_handle a) {
        p_>insert(a);
    }
    template <class Vertex_handle>
    void after_swap(Vertex_handle a, Vertex_handle b) {
        p_>swap(a, b);
    }
    Arrangement *p_;
};
```

Now we define the actual arrangement data structure.

```
template <class TraitsT>
class Planar_arrangement:
    public Kinetic::Sort<TraitsT,
        Arrangement_visitor<Planar_arrangement<TraitsT> > > {
    typedef TraitsT Traits;
    typedef Planar_arrangement<TraitsT> This;
    typedef typename Kinetic::Sort<TraitsT,
        Arrangement_visitor<This> > Sort;
    typedef Arrangement_visitor<This> Visitor;
    typedef typename Traits::Active_objects_table::Key Key;

public:
```

```

typedef CGAL::Exact_predicates_inexact_constructions_kernel::Point_2 Approximate_point;
typedef std::pair<int,int> Edge;
typedef typename Sort::Vertex_handle Vertex_handle;

// Register this KDS with the MovingObjectTable and the Simulator
Planar_arrangement(Traits tr): Sort(tr, Visitor(this)) {}

Approximate_point vertex(int i) const
{
    return approx_coords_[i];
}

size_t vertices_size() const
{
    return approx_coords_.size();
}

typedef std::vector<Edge >::const_iterator Edges_iterator;
Edges_iterator edges_begin() const
{
    return edges_.begin();
}
Edges_iterator edges_end() const
{
    return edges_.end();
}

void insert(Vertex_handle k) {
    last_points_[*k]=new_point(*k);
}

void swap(Vertex_handle a, Vertex_handle b) {
    int swap_point= new_point(*a);
    edges_.push_back(Edge(swap_point, last_points_[*a]));
    edges_.push_back(Edge(swap_point, last_points_[*b]));
    last_points_[*a]= swap_point;
    last_points_[*b]= swap_point;
}

void erase(Vertex_handle a) {
    edges_.push_back(Edge(last_points_[*a], new_point(*a)));
}

int new_point(typename Traits::Active_objects_table::Key k) {
    double tv= CGAL::to_double(Sort::traits().simulator_handle()->current_time());
    double dv= CGAL::to_double(Sort::traits().active_objects_table_handle()->at(k).x()(tv));
    approx_coords_.push_back(Approximate_point(tv, dv));
    return approx_coords_.size()-1;
}

std::vector<Approximate_point > approx_coords_;
std::map<Key, int> last_points_;
std::vector<Edge> edges_;

```

```
};
```

Finally, we have to set everything up. To do this we use some special event classes: *Kinetic::Insert_event<ActiveObjectsTable>* and *Kinetic::Erase_event<ActiveObjectsTable>*. These are events which can be put in the event queue which either insert a primitive into the set of active objects or remove it. Using these, we can allow curves in the arrangement to begin or end in arbitrary places.

```
typedef CGAL::Kinetic::Insert_event<Traits::Active_points_1_table> Insert_event;
typedef CGAL::Kinetic::Erase_event<Traits::Active_points_1_table> Erase_event;
do {
    NT begin, end;
    Point function;
    // initialize the function and the beginning and end somewhere
    tr.simulator_handle()->new_event(Time(begin),
        Insert_event(function, tr.active_points_1_table_handle()));
    tr.simulator_handle()->new_event(Time(end),
        Erase_event(Traits::Active_points_1_table::Key(num),
            tr.active_points_1_table_handle()));
    ++num;
} while (true);
```

CGAL::Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>

Definition

The class *Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>* maintains a Delaunay triangulation on top of the points contained in a *Kinetic::ActiveObjectsTable*. It has one main method of interest, *triangulation()*, which returns the triangulation it is maintaining.

The class *Kinetic::Qt_triangulation_2<KineticTriangulation_2, QtWidget_2, QtMovingPoints_2>* displays a kinetic Delaunay triangulation using the Qt widget.

This class is a good example of a simple, but non-trivial, kinetic data structure.

The *Triangulation* template parameter must be a model of *CGAL::Delaunay_triangulation_2<Traits, Tds>* which uses *Traits::Default_instantaneous_kernel* as its geometric traits and a *Tds* whose face inherits from *Kinetic::Delaunay_triangulation_face_base_2<Traits, Base>*.

The optional *Visitor* parameter takes a model of *Kinetic::DelaunayTriangulationVisitor_2*. Methods on this object will be called whenever the triangulation changes.

```
#include <CGAL/Kinetic/Delaunay_triangulation_2.h>
```

Is Model for the Concepts

```
Ref_counted<T>
```

Types

```
Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>:: Triangulation
```

The template argument triangulation.

```
Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation>:: Visitor
```

The template argument for the visitor.

Creation

```
Kinetic::Delaunay_triangulation_2<Traits, Visitor, Triangulation> dt( Traits tr);
```

Maintain the Delaunay triangulation of the points in *tr.active_points_2_handle()*.

Operations

Triangulation *dt.triangulation()* Access the triangulation that is maintained.

Visitor& *dt.visitor()* Access the visitor.

Vertex_handle *dt.insert(Point_key k)*

Insert the point.

void *dt.erase(Vertex_handle h)*

Erase the vertex.

CGAL::Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>

Definition

The class *Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>* maintains a Delaunay triangulation on top of the points contained in a *Kinetic::ActiveObjectsTable*. It has one main method of interest. *triangulation()* which returns the triangulation it is maintaining. In addition, as an optimisation, you can turn on and off whether it is currently maintaining its certificates. This allows a large number of changes to the underlying points to be made at one time without recomputing the certificates each time a single point changes.

The class *Kinetic::Qt_triangulation_3<Traits>*, included as part of the demo code, displays a kinetic Delaunay triangulation in three dimensions using the Coin library.

The optional *Visitor* template argument is a model of *Kinetic::DelaunayTriangulationVisitor_3* and can be used to monitor changes in the kinetic data structure.

The optional *Triangulation* template argument must be a model of a *CGAL::DelaunayTriangulation_3* which uses *Traits::Default_instantaneous_kernel* as its geometric traits and has *Kinetic::Delaunay_triangulation_cell_base_3<Traits, Base>* as the cell type.

```
#include <CGAL/Kinetic/Delaunay_triangulation_3.h>
```

Types

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>::Triangulation

The template argument.

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>::Visitor

The template argument.

Creation

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation> dt(Traits tr);

Maintain the Delaunay triangulation of the points in *tr.active_points_3_handle()*.

Operations

*const Triangulation** *dt.triangulation()* Access the triangulation that is maintained.

bool *dt.has_certificates()* This method returns true if the *Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>* is currently maintaining certificates for a Delaunay triangulation.

<i>void</i>	<i>dt.set_has_certificates(bool tf)</i>	This method allows you to control whether the triangulation is maintaining certificates.
-------------	--	--

<i>Visitor</i> &	<i>dt.visitor()</i>	Access the visitor.
------------------	---------------------	---------------------

CGAL::Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation>

Definition

The concept *Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation>* provides a model of *Kinetic::DelaunayTriangulationVisitor_2* which tracks which edges were created in the most recent change.

Is Model for the Concepts

Kinetic::DelaunayTriangulationVisitor_2

Creation

Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation> *a*;
 default constructor.

Kinetic::Delaunay_triangulation_recent_edges_visitor_2<Triangulation>::iterator
 The iterator through the recently created edges.

Operations

<i>iterator</i>	<i>a.begin()</i>	Begin iteration through the recent edges.
<i>iterator</i>	<i>a.end()</i>	End iteration through the recent edges.
<i>bool</i>	<i>a.contains(Triangulation::Edge)</i>	Returns true if this edge exists in the set.

Kinetic::Delaunay_triangulation_2<Traits, Triangulation, Visitor>

Kinetic::DelaunayTriangulationVisitor_2

Definition

This concept is for proxy objects which get notified when a kinetic Delaunay triangulation changes.

Operations

void *v.pre_remove_vertex(Vertex_handle)*

The vertex is about to be deleted.

void *v.post_remove_vertex(Point_key)*

The vertex was just removed.

void *v.pre_insert_vertex(Point_key)*

The vertex is about to be inserted into the cell (although the *Cell_handle* might be *NULL*).

void *v.post_insert_vertex(Vertex_handle)*

The vertex was just inserted.

void *v.change_vertex(Vertex_handle)*

The trajectory of the point at the vertex changed.

void *v.create_face(Face_handle f)*

The face has just been made.

void *v.destroy_face(Face_handle f)*

The face is about to be destroyed.

void *v.pre_flip(Edge)* The edge is about to be flipped.

void *v.post_flip(Edge)* The edge was just created with a flip.

Has Models

Kinetic::DelaunayTriangulationVisitor_3

Definition

This concept is for proxy objects which get notified when a kinetic Delaunay triangulation changes.

Operations

void *v.pre_remove_vertex(Vertex_handle)*

The vertex is about to be deleted.

void *v.post_remove_vertex(Point_key, Cell_handle)*

The vertex was just removed.

void *v.pre_insert_vertex(Point_key, Cell_handle)*

The vertex is about to be inserted into the cell (although the *Cell_handle* might be *NULL*).

void *v.post_insert_vertex(Vertex_handle)*

The vertex was just inserted.

void *v.change_vertex(Vertex_handle)*

The trajectory of the point at the vertex changed.

void *v.create_cell(Cell_handle)*

The cell was just created and initialized.

void *v.destroy_cell(Cell_handle)*

The cell is about to be removed.

void *v.pre_edge_flip(Edge)*

The edge is about to be flipped.

void *v.post_edge_flip(Facet)*

The facet was just created with a flip.

void *v.pre_facet_flip(Facet)*

The facet is about to be flipped.

void *v.post_facet_flip(Edge)*

The edge was just created with a flip.

Kinetic::Delaunay_triangulation_visitor_base_3 a;

default constructor.

See Also

Kinetic::Delaunay_triangulation_3<Traits, Triangulation, Visitor>

CGAL::Kinetic::Enclosing_box_2<Traits>

Definition

The class *Kinetic::Enclosing_box_2<Traits>* keeps the points in the simulation inside of a box. Whenever the points come close to the wall of the box they bounce off of the wall.

Note that, in general, points hit the wall of the box at times which are not easily represented by standard (rational) number types. The resulting trajectories would also have non-rational coefficients, complicating and slowing the simulation. In order to handle this, the *Kinetic::Enclosing_box_2<Traits>* bounces the points at the nearest easily representable time before the point would leave the box.

```
#include <CGAL/Kinetic/Enclosing_box_2.h>
```

Types

<i>Kinetic::Enclosing_box_2<Traits>:: NT</i>	The number type used to represent the walls of the box and perform calculations. Generally this is <i>Traits::NT</i> .
--	--

Creation

```
Kinetic::Enclosing_box_2<Traits> eb( Traits, NT xmin, NT xmax, NT ymin, NT ymax);
```

This constructs a bounding box with the dimensions specified by the last 4 arguments. They are optional and will take the values ± 10 if omitted.

CGAL::Kinetic::Enclosing_box_3<Traits>

Definition

The class *Kinetic::Enclosing_box_3<Traits>* keeps the points in the simulation inside of a box. Whenever the points come close to the wall of the box they bounce off of the wall.

Note that, in general, points hit the wall of the box at times which are not easily represented by standard (rational) number types. The resulting trajectories would also have non-rational coefficients, complicating and slowing the simulation. In order to handle this, the *Kinetic::Enclosing_box_3<Traits>* bounces the points at the nearest easily representable time before the point would leave the box.

```
#include <CGAL/Kinetic/Enclosing_box_3.h>
```

Types

Kinetic::Enclosing_box_3<Traits>::NT The number type used to represent the walls of the box and perform calculations. Generally this is *Traits::NT*.

Creation

```
Kinetic::Enclosing_box_3<Traits> eb( Traits, NT xmin, NT xmax, NT ymin, NT ymax, NT zmin, NT zmax);
```

This constructs a bounding box with the dimensions specified by the last 6 arguments. They are optional and will take the values ± 10 if omitted.

CGAL::Kinetic::Erase_event<ActiveObjectsTable>

Definition

This event erases a point from the *ActiveObjectsTable* when it is processed.

```
#include <CGAL/Kinetic/Erase_event.h>
```

Is Model for the Concepts

Kinetic::Simulator::Event

Creation

```
Kinetic::Erase_event<ActiveObjectsTable> i( ActiveObjectsTable::Key k, ActiveObjectsTable::Handle t);
```

Erase the object *k* from the table *t* when processed.

See Also

Kinetic::ActiveObjectsTable, *Kinetic::Active_objects_vector<MovingObject>*.

Example

```
typedef CGAL::Kinetic::Exact_simulation_traits Simulation_traits;
typedef Simulation_traits::Kinetic_kernel::Point_2 Moving_point_2;
typedef CGAL::Kinetic::Insert_event<Simulation_traits::Active_points_2_table> Insert_event;
typedef CGAL::Kinetic::Delaunay_triangulation_2<Simulation_traits> KDel;

Simulation_traits tr;

KDel kdel(tr);

Moving_point_2 mp(Moving_point_2::NT(0),
                  Moving_point_2::NT(0));
tr.simulator_handle()->new_event(Simulation_traits::Simulator::Time(3),
                                Erase_event(*tr.active_objects_table_handle()->keys_begin(),
                                             tr.active_points_2_table_handle()));
```

Kinetic::EventLogVisitor

Definition

This concept is for visitors which maintain a text log of events.

Types

Kinetic::EventLogVisitor:: Event_iterator An iterator through strings defining the events that occurred.
Each event is represented by a *std::string*.

Operations

Event_iterator *v.events_begin()* Begin iterating through the events.

Event_iterator *v.events_end()*

Has Models

Kinetic::Delaunay_triangulation_event_log_visitor_3, *Kinetic::Delaunay_triangulation_event_log_visitor_2*,
Kinetic::Regular_triangulation_event_log_visitor_3, *Kinetic::Sort_event_log_visitor*

CGAL::Kinetic::Insert_event<ActiveObjectsTable>

Definition

This event inserts a point into the *ActiveObjectsTable* when it is processed.

```
#include <CGAL/Kinetic/Insert_event.h>
```

Is Model for the Concepts

Kinetic::Simulator::Event

Creation

```
Kinetic::Insert_event<ActiveObjectsTable> i( ActiveObjectsTable::Data o, ActiveObjectsTable::Handle t);
```

Insert the object o, into the table t when processed.

See Also

Kinetic::ActiveObjectsTable, *Kinetic::Active_objects_vector<MovingObject>*.

Example

```
typedef CGAL::Kinetic::Exact_simulation_traits Simulation_traits;
typedef Simulation_traits::Kinetic_kernel::Point_2 Moving_point_2;
typedef CGAL::Kinetic::Insert_event<Simulation_traits::Active_points_2_table> Insert_event;
typedef CGAL::Kinetic::Delaunay_triangulation_2<Simulation_traits> KDel;

Simulation_traits tr;

KDel kdel(tr);

Moving_point_2 mp(Moving_point_2::Coordinate(0),
                  Moving_point_2::Coordinate(0));
tr.simulator_handle()->new_event(Simulation_traits::Simulator::Time(3),
                                Insert_event(mp,
                                tr.active_points_2_table_handle()));
```

CGAL::Kinetic::Qt_moving_points_2<Traits, QWidget_2>

Definition

The class *Kinetic::Qt_moving_points_2<Traits, QWidget_2>* displays a set of moving points in 2D.

See Section [53.4.3](#) for an example using this class.

```
#include <CGAL/Kinetic/IO/Qt_moving_points_2.h>
```

Creation

```
Kinetic::Qt_moving_points_2<Traits, QWidget_2> a( QtGui::Handle,  
                                                Traits::Active_points_2_table::Handle)
```

default constructor.

See Also

Kinetic::Qt_widget_2<Simulator>.

CGAL::Kinetic::Qt_triangulation_2<KineticTriangulation_2, QtWidget_2, QtMovingPoints_2>

Definition

The class draws a triangulation into a *CGAL::Qt_widget_2*. This class is very simple and a good one to look at if you want to see how to draw your own two dimensional kinetic data structure.

See Section [53.4.3](#) for an example using this class.

```
#include <CGAL/Kinetic/IO/Qt_triangulation_2.h>
```

Creation

```
Kinetic::Qt_triangulation_2<KineticTriangulation_2,      QtWidget_2,      QtMovingPoints_2>      a(
KineticTriangulation_2::Handle,
                                                                QtWidget_
2::Handle,
                                                                QtMovingPoints_
2::Handle)
```

Construct the object and make all the connections with the appropriate other objects.

See Also

Kinetic::Qt_widget_2<Simulator>

CGAL::Kinetic::Qt_widget_2<Simulator>

Definition

The class *Kinetic::Qt_widget_2<Simulator>* implements a graphical interface for 2D kinetic data structures.

```
#include <CGAL/Kinetic/IO/Qt_widget_2.h>
```

Types

<i>Kinetic::Qt_widget_2<Simulator>::Listener</i>	The listener base to listen for when to update the picture. This class includes an extra method <i>Qt_widget widget()</i> which returns the <i>Qt_widget</i> object which can be used for drawing.
--	--

Creation

```
Kinetic::Qt_widget_2<Simulator> a( int argc, char *argv[], Simulator::Handle);
```

default constructor.

CGAL::Kinetic::Regular_triangulation_3<Traits, Visitor, Triangulation>

Definition

The class *Kinetic::Regular_triangulation_3<Traits, Visitor, Triangulation>* maintains a triangulation of set of moving weighted points. Its interface is the same as *Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>*.

The optional *Triangulation* template argument must be a model of *CGAL::RegularTriangulation_3* which has *Kinetic::Regular_triangulation_cell_base_3<Traits, Base>* as a cell base and *Kinetic::Regular_triangulation_vertex_base_3<Traits, Base>* as a vertex base.

```
#include <CGAL/Kinetic/Regular_triangulation_3.h>
```

See Also

Kinetic::Delaunay_triangulation_3<Traits, Visitor, Triangulation>. *Kinetic::RegularTriangulationVisitor_3*.

Example

```
#define CGAL_CHECK_EXACTNESS
#define CGAL_CHECK_EXPENSIVE

#include <CGAL/Kinetic/Regular_triangulation_exact_simulation_traits.h>
#include <CGAL/Kinetic/Regular_triangulation_3.h>

int main(int, char *[]) {
    typedef CGAL::Kinetic::Regular_triangulation_exact_simulation_traits Traits;
    typedef CGAL::Kinetic::Regular_triangulation_3<Traits> KDel;

    Traits tr(0,100000.0);
    KDel kdel(tr);

    Traits::Simulator::Handle sp= tr.simulator_handle();

    std::ifstream in("data/weighted_points_3");
    CGAL_assertion(in);
    in >> *tr.active_points_3_table_handle();

    std::cout << *tr.active_points_3_table_handle();

    std::cout << *tr.active_points_3_table_handle() << std::endl;

    kdel.set_has_certificates(true);

    sp->set_current_event_number(10000);
    return EXIT_SUCCESS;
};
```

Kinetic::Regular_triangulation_3<*Traits*, *Triangulation*, *Visitor*>

CGAL::Kinetic::Regular_triangulation_instantaneous_kernel<ActiveObjectsTable, StaticKernel>

Definition

The class *Kinetic::Regular_triangulation_instantaneous_kernel*<*ActiveObjectsTable*, *StaticKernel*> is an instantaneous kernel for use with a regular triangulation data structure. There is not currently a reason for the user to call this directly unless the user wants created their own simulation traits as it is included as part of the *Kinetic::Regular_triangulation_exact_simulation_traits*.

```
#include <CGAL/Kinetic/Regular_triangulation_instantaneous_kernel.h>
```

Is Model for the Concepts

CGAL::RegularTriangulationTraits_3, *Kinetic::InstantaneousKernel*

See Also

Kinetic::Regular_triangulation_3<*Traits*, *Visitor*, *Triangulation*>.

CGAL::Kinetic::Regular_triangulation_vertex_base_3<Traits, Base>

Definition

This is the base class for the vertices of the triangulation class used by *Kinetic::Regular_triangulation_3<Traits, Triangulation, Visitor>*.

```
#include <CGAL/Kinetic/Regular_triangulation_vertex_base_3.h>
```

Kinetic::RegularTriangulationVisitor_3

Definition

This concept is for proxy objects which get notified when a kinetic regular triangulation changes. It inherits all the methods of *DelaunayTriangulationVisitor_3*.

Is Model for the Concepts

Kinetic::DelaunayTriangulationVisitor_3

Operations

void *v.pre_move(Key, Cell)*

The point defined by *Key* is about to move from the cell.

void *v.post_move(Key, Cell)*

The point defined by *Key* just moved to the cell.

Has Models

Kinetic::Regular_triangulation_visitor_base_3, *Kinetic::Regular_triangulation_event_log_visitor_3*

CGAL::Kinetic::Regular_triangulation_visitor_base_3

Definition

The concept *Kinetic::Regular_triangulation_visitor_base_3* provides a model of *Kinetic::RegularTriangulationVisitor_3*. You can extend this class if you only want to implement a few methods from *Kinetic::RegularTriangulationVisitor_3*.

Is Model for the Concepts

Definition

The concept *Kinetic::Sort_event_log_visitor* provides a model of *SortVisitor* and *EventLogVisitor* which logs changes to the structure.

Is Model for the Concepts

Kinetic::SortVisitor, *Kinetic::EventLogVisitor*

See Also

Kinetic::Sort<*Traits*, *Visitor*>

CGAL::Kinetic::Sort<Traits, Visitor>

Definition

The class *Kinetic::Sort<Traits, Visitor>* maintains a sorted list of objects. It is the simplest kinetic data structure provided and is a good place to start when looking at the basics of implementing a kinetic data structure.

The *Kinetic::SortVisitor* can be used to monitor what is happening.

```
#include <CGAL/Kinetic/Sort.h>
```

Creation

Kinetic::Sort<Traits, Visitor> *s*(*Traits tr*); The basic constructor.

Types

Kinetic::Sort<Traits, Visitor>:: Visitor The type of the visitor.

Kinetic::Sort<Traits, Visitor>:: Traits The traits type.

Kinetic::Sort<Traits, Visitor>:: Vertex_handle The handle used to refer to vertex in the sorted list. Dereferencing this returns a *Key* into the *ActiveObjectsTable*.

Kinetic::Sort<Traits, Visitor>:: Handle A reference counted pointer to be used for storing references to the object.

Kinetic::Sort<Traits, Visitor>:: Const_handle A reference counted pointer to be used for storing references to the object.

Operations

Visitor& *s.visitor()* Access the visitor.

Traits& *s.traits()* Access the traits.

Vertex_handle *s.insert(Point_key k)* Insert the point.

void *s.erase(Vertex_handle k)*
Erase the point.

Iterator *s.begin()* Begin iterating through the ordered *Vertex_handles* (the iterator is convertible to *Vertex_handle*).

Iterator *s.end()* End iterating through the ordered *Vertex_handles* (the iterator is convertible to *Vertex_handle*).

Kinetic::Sort<*Traits*, *Visitor*>

Kinetic::SortVisitor

Definition

This concept is for proxy objects which have functions called on them when a *Kinetic::Sort<Traits, Visitor>*.

Operations

void *v.pre_remove_vertex(Vertex_handle)*

The vertex is about to be deleted.

void *v.post_remove_vertex(Point_key)*

The vertex was just removed.

void *v.pre_insert_vertex(Point_key)*

The vertex is about to be inserted into the cell (although the *Cell_handle* might be *NULL*).

void *v.post_insert_vertex(Vertex_handle)*

The vertex was just inserted.

void *v.change_vertex(Vertex_handle)*

Something changed at the vertex.

void *v.pre_swap(Vertex_handle, Vertex_handle)*

The pair of vertices is about to be exchanged.

void *v.post_swap(Vertex_handle, Vertex_handle)*

The pair of vertices was just swapped.

Has Models

Kinetic::Sort_visitor_base, Kinetic::Sort_event_log_visitor

This chapter describes a framework for implementing kinetic data structures and sweepline algorithms. If you just would like to use existing kinetic data structures, please read Chapter 53 instead. Readers wishing to brush up on their familiarity with kinetic data structures or better understand the terminology we use should read Section 53.2 of that chapter. A brief overview of the framework can be found in Section 53.3 (also of that chapter) and it too is recommended reading. Here we dive right in to discussing the architecture of the framework in Section 54.1 and finally we give several examples of using the framework to implement a kinetic data structure in Section 54.3. The framework makes heavy use of our *Polynomial_kernel* package to provide models of the *Kinetic::FunctionKernel* concept.

The framework was first presented at ALENEX [GKR04].

54.1 Architecture

This package provides a framework to allow exact implementation of kinetic data structures and sweepline algorithms. Below we discuss in detail each one of the first four major concepts which help in implementing kinetic data structures: the *Kinetic::Simulator*, the *Kinetic::Kernel*, the *Kinetic::ActiveObjectsTable* and the *Kinetic::InstantaneousKernel*. The *Kinetic::FunctionKernel* concept is discussed separately in Section 54.2.

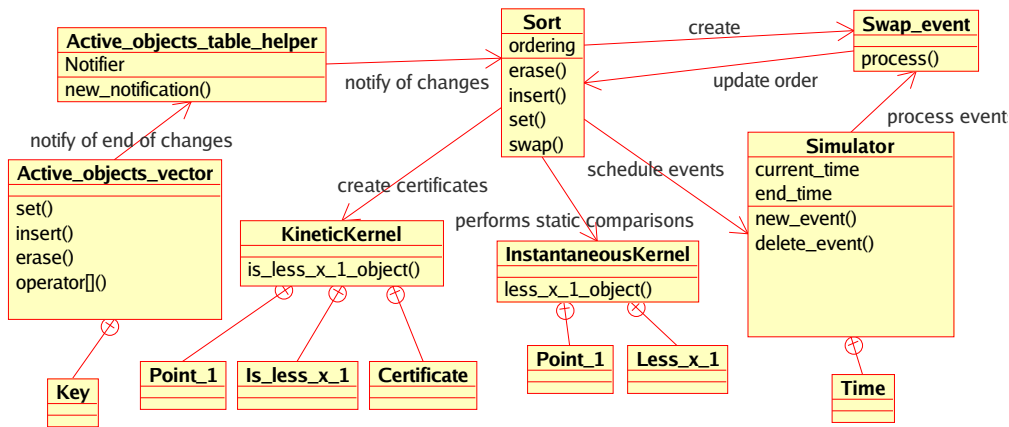

Figure 54.1: The figure, identical to the one in the overview of the previous chapter, shows the interaction between the *Kinetic::Sort<Traits, Visitor>* kinetic data structure and the various pieces of our framework. Other, more complicated, kinetic data structures will also use the *Kinetic::InstantaneousKernel* in order to insert/remove geometric primitives and audit themselves. *Kinetic::Sort<Traits, Visitor>* uses the sorting functionality in STL instead.

54.1.1 The *Kinetic::Simulator*

The *Kinetic::Simulator* is the central repository of all active events. It maintains the event queue and can use its knowledge of the events in the queue to find times for the kinetic data structures to easily check their own correctness (this will be discussed in more detail later in this section). Kinetic data structures call methods of the *Kinetic::Simulator* to schedule new events, deschedule old ones and access and change data contained in already scheduled events (the operations on existing events are performed using a key which was returned when the event was scheduled). For controlling the simulation, methods in the *Kinetic::Simulator* allow stepping through events, advancing time and even running the simulation backwards (that is we run the simulation with the time running in the opposite direction).

The kinetic sorting example in Figure 53.4.1 shows the basic usage of the *Kinetic::Simulator*. First, the *Simulator* is created by the *Kinetic::SimulationTraits*. The kinetic data structure gets a handle to the simulator from the traits class and uses the handle to add its events to the simulation. The *Kinetic::Simulator* is then told to advance time up until the end of the simulation, processing all events along the way.

Each event is represented by a *Kinetic::Simulator::Time* and an instance of a model of the *Kinetic::Simulator::Event* concept. Models of the *Kinetic::Simulator::Event* concept are responsible for taking the appropriate action in order to handle the kinetic event they represent. Specifically, the *Kinetic::Simulator::Event* concept specifies one method, *Kinetic::Simulator::Event::process()*, that is called when the event occurs. The body of the *Kinetic::Simulator::Event::process()* method typically simply calls a method of the kinetic data structure that created the event; for example in our kinetic sorting example, processing an event means calling the *Kinetic::Sort<Traits, Visitor>::swap(Iterator)* method of the kinetic sorting data structure.

In the model of the *Kinetic::Simulator* concept that we provide, *Kinetic::Default_simulator<FunctionKernel, EventQueue>*, any model of the *Kinetic::Simulator::Event* concept can be inserted as an event. This ability implies that events can be mixed at run time, which is essential when we want to support multiple kinetic data structures operating on the same set of moving geometric primitives.

The *Kinetic::Simulator::Time* concept is defined by the simulator, typically to be some representation of a root

of a polynomial, taken from the *Kinetic::FunctionKernel* (details of the algebraic side of the package will be discussed in Section 54.2). For most kinetic data structures *Kinetic::Simulator::Time* only needs to support comparisons (we need to compare events, in order to process them in the correct order) and a few other non-arithmetic operations.

When the failure times of certificates are sorted exactly (as opposed to when we numerically approximate the roots of the certificate polynomials) the correctness of kinetic data structures can be easily verified. Let I be an open interval between the last event processed and the next event to be processed. As was mentioned in the introduction kinetic data structures do not change combinatorially in I . In addition, although the static data structures can be degenerate at the roots defining the two ends of the interval, they are not, in general, degenerate in the interior. An independent check of the integrity of kinetic data structures can be provided by, for example, using an *Kinetic::InstantaneousKernel* (cf. Subsection 54.1.4) to rebuild the static version of the structure from scratch at some time interior to I and compare it to the kinetic version. This auditing can typically catch algorithmic or programming errors much closer to the time they arise in the simulation than, for example, using visual inspection. Such easy auditing is one of the powerful advantages of having an exact computational framework since, as with static data structures, when using inexact computations differentiating between errors of implementation and numeric errors is quite tricky.

Kinetic data structures receive alerts of appropriate times to audit themselves using a notification framework. The same framework is also used by the *Kinetic::ActiveObjectsTable* to alert kinetic data structures when the set of primitives changes (see Subsection 54.1.3). To use the notification framework, the kinetic data structure creates a proxy object which implements a standard *Listener* interface. It then registers this proxy with the *Kinetic::Simulator*. When the *Kinetic::Simulator* finds an appropriate time for the kinetic data structures to audit themselves it calls the function *Listener::new_notification(Type)* on each of the registered proxy objects. A helper for creating such proxy objects, called *Kinetic::Simulator_kds_listener<Listener, KDS>*, is provided by the framework. It translates the notification into a function call (*audit()*) on the kinetic data structure. Pointers in the notification framework are reference counted appropriately to avoid issues caused by the creation and destruction order of kinetic data structures and the simulator. See Section 54.1.5 for a more complete discussion of this part of the framework.

Internally the *Kinetic::Simulator* maintains a priority queue containing the scheduled events. The type of the priority queue is a template argument to our *Kinetic::Simulator* model and, as such, it can be replaced by the user. In our package, we provide two different types of priority queues, a heap and a two-list priority queue. A two-list queue is a queue in which there is a sorted front list, containing all events before some time and an unsorted back list. The queue tries to maintain a small number of elements in the front list, leaving most of them in the unsorted main pool. The two-list queue, although an unconventional choice, is our default queue when using exact computation because it minimizes comparisons involving events that are far in the future. These events are likely to be deleted before they are processed, so extra work done structuring them is wasted. Our experiments have shown that, for example, the two-list queue causes a 20% reduction in running time relative to a binary heap for Delaunay triangulations with degree 3 polynomial motions and 20 points.

54.1.2 The *Kinetic::Kernel*

The *Kinetic::Kernel* is structured very much like static CGAL kernels. It defines a number of primitives, which in the model provided are *Kinetic::Kernel::Point_1*, *Kinetic::Kernel::Point_2*, *Kinetic::Kernel::Point_3* and *Kinetic::Kernel::Weighted_point_3*. The primitives are defined by a set of Cartesian coordinates each of which is a function of time, a *Kernel::MotionFunction*. In addition it defines constructions and certificate generators which act on the primitives. The certificate generators are the direct analog of the non-kinetic predicates. Each certificate generator take a number of primitives as arguments, but instead of producing an element from a discrete set they produce a set of discrete failure times for the certificate. These failure times are wrapped in a model of *Kinetic::Certificate*.

A *Kinetic::Certificate* is a simple object whose primary function is to produce a *Kinetic::Simulator::Time* object

representing the failure time of the certificate. Since, the handling of most certificate failures involves creating a new certificate whose certificate function is the negation of the old certificate function, a *Kinetic::Certificate* object caches any work that could be useful to isolate future roots of the certificate function (such as the Sturm sequence of the certificate function). To illustrate this further, if you have two one-dimensional points with coordinate functions $p_0(t)$ and $p_1(t)$, the certificate that the first moving point is after the second corresponds to the inequality $p_0(t) - p_1(t) > 0$. When the certificate fails and the two points cross, the new certificate is $p_1(t) - p_0(t) > 0$, which is the negated version of the certificate just processed and which has the same roots.

The model of *Kinetic::Kernel* provided includes the certificate generators necessary for Delaunay triangulations (in one, two and three dimensions) and regular triangulations (in 3D). New certificates can be fairly easily added. An example is included in the distributed code.

54.1.3 The *Kinetic::ActiveObjectsTable*

The *Kinetic::ActiveObjectsTable* stores a set of kinetic primitives. Its purpose is to notify kinetic data structures when new primitives are added, when primitives are removed or when a trajectories change. Each primitive is uniquely identified by a Key, assigned by the table when the primitive is added, that can be used to change or remove it. We provide one model of the *Kinetic::ActiveObjectsTable* concept, called *Kinetic::Active_objects_vector<MovingObject>* which stores all the moving primitives in an *std::vector<D>*.

Notifications of changes to the set of active objects are handled using a setup similar to the *Kinetic::Simulator* audit time notification. We provide a helper class, *Kinetic::Active_objects_listener_helper<ActiveObjectsTable, KDS>*, which translates the notifications into *insert(Key)*, *erase(Key)* or *set(Key)* function calls on the kinetic data structure.

54.1.4 The *Kinetic::InstantaneousKernel*

The *Kinetic::InstantaneousKernel* allows existing CGAL data structures to be used on moving data as it appears at some instant of time. Models of this concept are, by definition, models of a CGAL Kernel or a traits class, and, therefore, can then be used as the traits class of CGAL's algorithms and data structures.

Consider for example the kinetic Delaunay data structure in either two or three dimensions. Internally, it uses a *Delaunay_triangulation_2<Traits, Tds>* or *Delaunay_triangulation_3<Traits, Tds>* to represent the triangulation, instantiated with a model of the *Kinetic::InstantaneousKernel* concept as its traits class. At initialization, as well as at times during the simulation when we want to insert a point to the kinetic Delaunay triangulation, a static version of the Delaunay triangulation is conceptually instantiated. More precisely, the time for the copy of the model of the *Kinetic::InstantaneousKernel* stored in the CGAL triangulation is set to be the current time (or rather, as discussed in the introduction, a more convenient time determined by the *Kinetic::Simulator* combinatorially equivalent to the current time). The kinetic data structure then calls the *Delaunay_triangulation_3<Traits, Tds>::insert(Point)* insert method to insert the point. The static insert method called uses various predicate functors on the moving points which evaluate to the values that the predicates have at that instant in time. Removal is handled in an analogous manner. Auditing of the geometric structure is easily handled in a similar manner (in the case of Delaunay triangulations by simply calling the *verify()* method after setting the time).

54.1.5 Miscellaneous: notification and reference management

We describe some coding conventions used, graphical display, notification and reference management support in the framework in the following sections.

Reference management

A number of objects need to maintain pointers to other independent objects. For example, each kinetic data structure must have access to the *Kinetic::Simulator* so that it can schedule and deschedule events. These pointers are all reference counted in order to guarantee that they are always valid. We provide a standard reference counting pointer and object base to facilitate this, namely *Ref.counted<Object>*.

Each shared object in the framework defines a type *Handle* which is the type for a reference counter pointer pointing to it. These should be used for storing pointers to the objects in order to avoid dangling pointers. In addition, many of the objects expect such pointers as arguments.

Runtime event passing

Runtime events must be passed from *notifiers*, namely the *Kinetic::ActiveObjectsTable* and the *Kinetic::Simulator* to *listeners*, typically the kinetic data structures. For example, kinetic data structures are notified when new primitives are added to the *Kinetic::ActiveObjectsTable*. On receiving the notification, it will add the new primitive to the combinatorial structure it is maintaining. The events are passed using a simple, standardized notification interface. To receive notifications, the listener first defines a small proxy class which inherits from a *Listener* base type provided by the notifier. On creation, the *Listener* base class registers itself with the notifier on construction (and unregisters itself on destruction).

When the some state of the notifier changes, it calls the *new_notification* method on the listener proxy object provided and passes it a label corresponding to the name of the field that changed. The proxy object can then call an appropriate method on the kinetic data structure or whatever the listening class is.

In order to unregister on destruction, the *Listener* must store a (reference counted) pointer to the object providing notifications. This pointer can be accessed through the *notifier()* field. The *Listener* object stores a reference counted pointer to the notifying object, while the notifying object stores a plain pointer to the *Listener*. It can do this since the *Listener* is guaranteed to unregister itself when it is destroyed. This avoids circular reference counted pointers as well as dangling pointers.

54.2 Algebraic Kernel

The interface between the algebraic kernel and the kinetic data structures package was kept quite minimal in order to ease the implementation of various underlying computation models. The interface is detailed in the reference page (*Kinetic::FunctionKernel*).

We provide models of the algebraic kernel that handle polynomial *Kinetic::Function* objects. The provided models perform

- exact computations using Sturm sequences to isolate roots
- exact computations using Descartes rule of sign in order to isolate roots (Sturm sequences are also used in order to properly handle even multiplicity roots)
- filtered exact computations using Descartes rule of sign
- numeric (inexact) root approximations
- numeric root approximations which take advantage of certain assumptions that can be made about the types of polynomials solved in the process of evaluating kinetic data structures

- a wrapper for `CORE::Expr` which implements the required concepts.

The exact models, which we implement the numerics for, handle non-square-free polynomials and polynomials with arbitrary field number type coefficients and are quite robust.

54.2.1 `Kinetic::FunctionKernel` customized for kinetic data structures

There are several modifications we can make to how the roots are handled to optimize for the case of kinetic data structures. The first are motivated by the question of how to handle degeneracies (certificate functions which have roots at the same time). Naively, there is no way to differentiate between a certificate which fails immediately when it is created and one whose function is momentarily 0, but will be valid immediately in the future. In order to handle such degeneracies we ensure that all the certificate function generators produce certificate functions which are positive when the corresponding certificates are valid. Then, if we have a degeneracy we can differentiate between a certificate which fails immediately and one which is simply degenerate by looking at the sign of the certificate function immediately following the root (equivalently, by looking at the derivative). In addition, this allows us, under the assumption that computations are performed exactly, to check that all certificates are not invalid upon creation.

The assumption that certificates are positive when valid is particular useful when using numeric solvers. Without it there is no reliable way to tell whether a root near the current time is the certificate having become valid just before the current time, or failing shortly in the future. Testing the sign of the function immediately after the root reliably disambiguates the two cases.

In addition, we have to specially handle even roots of functions. For the most part these can just be discarded as dropping an even root is equivalent to perturbing the simulation to remove the degeneracy. However, when we are using the *Kinetic::Simulator* to audit the kinetic data structures, they must be broken up in to two, equal, roots to avoid auditing at the degeneracy.

54.3 Examples

We provide a number of examples of different levels of usage of the kinetic data structures framework, both for kinetic data structures as well as sweepline algorithms.

To see how to use existing kinetic data structures, look at the examples in the previous chapter such as Section [53.4.1](#).

Here we cover implementing kinetic data structures. The examples explained are

- A trivial kinetic data structure which has all the parts of a full kinetic data structure but doesn't do much in Section [54.3.2](#).
- Adding a new type of certificate to a kernel in Section [54.3.3](#).

In order to see more detail about how to implement a kinetic data structure, the best place to start is the source code for the kinetic sorting data structure, *Kinetic::Sort<Traits, Visitor>*. Once you are familiar with that, *Kinetic::Delaunay_2<Traits, Triangulation, Visitor>* is the next step in complexity.

We will first explain in detail how a typical kinetic data structure uses the various pieces of the framework, then move on to showing the actual code for a simpler data structure.

54.3.1 Using the Pieces of the Package

Here we will explain how the kinetic sorting data structure uses the various pieces of the package. A schematic of its relationship to the various components is shown in the UML diagram in Figure 54.1. In this subsection we abuse, for reasons of simplicity of presentation, the concept/model semantics: when we refer to concepts we actually refer to an instance of a model of them.

As with most kinetic data structures, *Kinetic::Sort<Traits, Visitor>* maintains some sort of combinatorial structure (in this case a sorted doubly linked list), each element of which has a corresponding certificate in the event queue maintained by the simulator. In the case of sorting, there is one certificate maintained for each “edge” between two consecutive elements in the list.

On creation, the data structure is passed a copy of the *Kinetic::SimulationTraits* for this simulation, which it saves for future use. It gets a handle to the *Kinetic::ActiveObjectsTable* by calling the *Kinetic::SimulationTraits::active_points_1_table_handle()* method and registers a proxy with the table in order to receive notifications of changes to the point set. The *Kinetic::SimulationTraits* method returns a handle to, rather than a copy of, the *Kinetic::ActiveObjectsTable*, since the table must be shared between all the kinetic data structures using these points. The handles are reference counted pointers, thus saving the user from worrying about cleaning things up properly.

When new points are added to the model of the *Kinetic::ActiveObjectsTable*, the table calls the *new_notification()* method on the proxy of the kinetic data structure, which in turn calls the *insert(Point_key)* method of the kinetic data structure. The *Point_key* here is the key which uniquely identifies the newly inserted point in the table. The data structure then requests an instance of a model of the *Kinetic::InstantaneousKernel* from the *Kinetic::SimulationTraits*. It sets the time on the instantaneous kernel to the time value gotten from the *Kinetic::Simulator::current_time_nt()* method. This method returns a field number type that is between the previous and next event, as discussed in the introduction. An instance of the *Kinetic::InstantaneousKernel::Compare_x_1* predicate (wrapped in order to make it return *less*) and the STL function *std::upper_bound()* are then used to insert the new point in the sorted list. For each inserted object, the kinetic data structure removes the no longer relevant certificate from the event queue by calling the *Kinetic::Simulator::delete_event(Key)* function and creates two new certificates using a *Kinetic::Kernel::Compare_x_1* certificate functor. The new certificates are inserted in the event queue by calling the *Kinetic::Simulator::new_event(Time, Event)* method where *Kinetic::Simulator::Event* is a proxy object which instructs the sort kinetic data structure to swap two points when its *process()* method is called.

Now that the kinetic data structure has been initialized, the simulator is instructed to process all events. Each time an event occurs, the simulator calls the *process()* method on the corresponding proxy object. The proxy, in turn, tells the sort kinetic data structure to swap the two points whose order has changed.

The *Kinetic::Simulator* can periodically instruct the kinetic data structures to audit themselves. As is explained in Section 54.1.1, a proxy object maps the notification on to an *audit()* function call in the kinetic data structure. To audit itself the kinetic data structure builds a list of all the current points and uses *std::sort* to sort this list using a comparison function gotten from the *Kinetic::InstantaneousKernel*. This sorted list is compared to the maintained one to verify correctness. This auditing could also have been done by evaluating the *Kinetic::InstantaneousKernel* predicate for each sorted pair. Since auditing a kinetic data structure typically requires at least linear time in the size of the combinatorial structure, the auditing procedure in between events is deactivated by default. The user can however easily switch it on by defining the *CGAL_CHECK_EXACTNESS* and *CGAL_CHECK_EXPENSIVE* CGAL macros.

This general structure of the interaction between the kinetic data structure and the framework is shared by all of the provided kinetic data structures and has proved itself to go quite far.

54.3.2 The Trivial Kinetic Data Structure

To show how to implement such things, instead of presenting a full kinetic data structure, we present a trivial one which maintains one event in the queue which maintains one event in the queue, scheduled to occur one time unit after the last change was made to the set of active primitives. Two classes are defined, the *Trivial_event*, and the *Trivial_kds*. The event classes must be declared outside of the kinetic data structure so that the *operator<<* can be defined for them.

The kinetic data structure maintains the invariant that it was one event in the queue at all times. This event occurs one time unit after the last event or change in the set of objects occurs. As a result, the kinetic data structure has the main parts of a real one—it responds to changes in trajectories of the objects and certificate failures (when the event expires).

The public methods can be grouped into three sets which are shared with almost all other kinetic data structures:

- *has_certificates* and *set_has_certificates* which checks/sets whether the kinetic data structure is currently maintaining certificates.
- *insert*, *set*, *erase* which are called by the *Kinetic::Active_objects_listener_helper* in response to the addition, modification, or deletion of an object to, in or from the simulation.
- *audit* which is called periodically by the *Kinetic::Simulator_kds_listener* when kinetic data structures can easily audit themselves.

In addition, it has one method which is called when a certificate fails. The name/existence of such methods depend on the nature of the kinetic data structure in question.

Like many kinetic data structures, it takes a *Kinetic::SimulationTraits* as a template argument. This traits class defines the types needed for the simulation and is responsible for instantiating them.

```
#include <CGAL/Kinetic/Ref_counted.h>
#include <CGAL/Kinetic/Exact_simulation_traits.h>
#include <CGAL/Kinetic/Active_objects_listener_helper.h>
#include <CGAL/Kinetic/Simulator_kds_listener.h>
...

// This must be external since operator<< has to be defined
template <class KDS>
struct Trivial_event
{
    Trivial_event() {}
    Trivial_event(KDS* kds): kds_(kds) {}
}
void process() const
{
    kds_->process();
}
KDS* kds_;
};

template <class KDS>
std::ostream &operator<<(std::ostream &out,
    const Trivial_event<KDS> &) {
```

```

    out << "\"An event\"";
    return out;
}

template <class Traits>
struct Trivial_kds: CGAL::Kinetic::Ref_counted<Trivial_kds<Traits> >
{
    typedef Trivial_kds<Traits> This;
    typedef typename Traits::Active_points_1_table::Data Point;
    typedef typename Traits::Simulator::Time Time;
    typedef typename Traits::Active_objects_table::Key Point_key;
    typedef typename Traits::Simulator::Event_key Event_key;
    typedef CGAL::Kinetic::Active_objects_listener_helper<
        typename Traits::Active_points_1_table::Listener, This> Active_objects_helper;
    typedef CGAL::Kinetic::Simulator_kds_listener<
        typename Traits::Simulator::Listener, This> Simulator_helper;

    typedef Trivial_event<This> Event;

    Trivial_kds(Traits tr): has_certificates_(true),
        tr_(tr),
        nth_(tr.active_points_1_table_handle(), this),
        sh_(tr.simulator_handle(), this){}

    // this method is called with the value true when the event is processed
    void process(bool tf) {
        event_ = Event_key();
        set_has_certificates(false);
        set_has_certificates(true);
    }

    void audit() const
    {
        ...
    }

    void set_has_certificates(bool tf) {
        typename Traits::Simulator::Handle sp = tr_.simulator_handle();
        if (has_certificates_ != tf) {
            has_certificates_ = tf;
            if (has_certificates_) {
                bool ev = event_;
                CGAL_assertion(!ev);
                Time t = CGAL::to_interval(sp->current_time()).second+1;
                event_ = sp->new_event(t, Event(this));
            } else if (event_) {
                sp->delete_event(event_);
                event_ = Event_key();
            }
        }
    }

    bool has_certificates() const {

```

```

    return has_certificates_;
}

void insert(Point_key k) {
    if (has_certificates_) {
        set_has_certificates(false);
        set_has_certificates(true);
    }
}

void set(Point_key k) {
    if (has_certificates_) {
        set_has_certificates(false);
        set_has_certificates(true);
    }
}

void erase(Point_key k) {
    if (has_certificates_) {
        set_has_certificates(false);
        set_has_certificates(true);
    }
}

~Trivial_kds() {
    set_has_certificates(false);
}

protected:
    bool has_certificates_;
    Event_key event_;
    Traits tr_;
    Active_objects_helper nth_;
    Simulator_helper sh_;
};

```

54.3.3 Adding a New Certificate Type

The following example shows how to add a new type of certificate to a simulation.

First we code the actual certificate function generator. It must take some sort (or sorts) of kinetic primitives, compute some function from their coordinates.

```

template <class KineticKernel>
struct Positive_x_f_2 {
    typedef typename KineticKernel::Certificate_function result_type;
    typedef typename KineticKernel::Point_2 argument_type;
    result_type operator()(const argument_type &p) {
        return result_type(p.x() - result_type(0));
    }
};

```

Then we define a kinetic kernel which includes this predicate. To do this we wrap the function generator generator in a *Kinetic::Certificate_generator<Kernel, Generator>*. This wrapper uses the generator to create the certificate function and then the *Kinetic::FunctionKernel* to solve the certificate function. The result is wrapped in a *Kinetic::Certificate* object.

```
template <class FunctionKernel>
class My_kinetic_kernel:
public CGAL::Kinetic::Cartesian<FunctionKernel> {
    typedef CGAL::Kinetic::Cartesian<FunctionKernel> P;
    typedef My_kinetic_kernel<FunctionKernel> This;
public:
    typedef CGAL::Kinetic::internal::Certificate_generator<This, Positive_x_f_2<This> > Positive_x_2;
    Positive_x_2 positive_x_2_object() const
    {
        return Positive_x_2(P::function_kernel_object());
    }
};
```

Now we have the unfortunately rather messy part of assembling a new *Kinetic::SimulationTraits* model. This is done in two steps for convenience.

```
struct My_simulation_traits {
    typedef My_simulation_traits This;

    typedef CGAL::Exact_predicates_exact_constructions_kernel Static_kernel;
    //typedef CGAL::Regular_triangulation_euclidean_traits_3<Static_kernel_base> Static_kernel;
    typedef CGAL::POLYNOMIAL::Polynomial<Static_kernel::FT> Function;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function> Root_stack_traits;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits> Root_stack;
    typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;

    typedef CGAL::Kinetic::Handle_degeneracy_function_kernel<Function_kernel, false> Simulator_function_k
    struct Simulator_function_kernel: public Simulator_function_kernel_base{};

    typedef My_kinetic_kernel<Simulator_function_kernel> Kinetic_kernel;
    typedef CGAL::Kinetic::Two_list_pointer_event_queue<Function_kernel> Event_queue;
    typedef CGAL::Kinetic::Default_simulator<Simulator_function_kernel, Event_queue > Simulator;

    typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_1> Active_points_1_table;
    typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_2> Active_points_2_table;
    typedef CGAL::Kinetic::Active_objects_vector<Kinetic_kernel::Point_3> Active_points_3_table;
    // typedef Active_objects_vector<Kinetic_kernel::Weighted_point_3> Active_weighted_points_3_table;

    typedef CGAL::Kinetic::Default_instantaneous_kernel<This> Instantaneous_kernel;

    Active_points_1_table* active_points_1_table_handle() const { return ap1_.get();}
    Active_points_2_table* active_points_2_table_handle() const {return ap2_.get();}
    Active_points_3_table* active_points_3_table_handle() const {return ap3_.get();}
    //Active_weighted_points_3_table* active_weighted_points_3_table_handle() const {return awp3_.get();}

    Simulator* simulator_handle() const { return sim_.get();}
    const Static_kernel& static_kernel_object() const {return k_;}
    const Kinetic_kernel& kinetic_kernel_object() const {return kk_;}
```

```

Instantaneous_kernel instantaneous_kernel_object() const {
    return Instantaneous_kernel(*this);
}

My_simulation_traits(const Simulator::Time &lb,
    const Simulator::Time &ub): sim_(new Simulator(lb, ub)),
    ap1_(new Active_points_1_table()),
    ap2_(new Active_points_2_table()),
    ap3_(new Active_points_3_table())
{}

bool is_exact() const {
    return true;
}
protected:
    Simulator::Handle sim_;
    Active_points_1_table::Handle ap1_;
    Active_points_2_table::Handle ap2_;
    Active_points_3_table::Handle ap3_;
    //Active_weighted_points_3_table::Handle awp3_;
    Static_kernel k_;
    Kinetic_kernel kk_;
    Function_kernel fk_;
};

```

Now the simulation traits can be used by a kinetic data structure. Note that we define active point table for all dimensions. This is needed by the *Kinetic::InstantaneousKernel*, even if they are not used.

Kinetic Framework Reference Manual

Daniel Russel

54.4 Classified Reference Pages

Definition

Kinetic data structures are a way of adding motion to classical geometric data structures. CGAL provides a number of classes to aid implementation of kinetic data structures.

There are three levels at which the user can interact with the package. The user can use an existing kinetic data structure, write a new kinetic data structure, or replace parts of the framework. The first level is covered in the Chapter [54](#).

CGAL::Kinetic::Active_objects_listener_helper<ActiveObjectsTable, KDS>

Definition

The class *Kinetic::Active_objects_listener_helper*<*ActiveObjectsTable*, *KDS*> acts as an intermediate between a moving object table and a KDS. It translates the *ActiveObjectsTable::Listener::IS_EDITING* notification events into appropriate calls to *KDS::insert(Key)*, *KDS::set(Key)*, *KDS::erase(Key)*.

Kinetic data structures can still take advantage of the batch editing if they are careful. The methods (such as *KDS::set(Key)*) are called in lexicographical order in the *Keys*. So, when a KDS is preparing to update some certificate involving a recently set object, it can first check if the certificate involves another changed object which is lexicographically prior. If so, then the certificate has already been updated and can be skipped.

```
#include <CGAL/Kinetic/Active_objects_listener_helper.h>
```

Kinetic::Active_objects_vector<*MovingObject*>, *Kinetic::ActiveObjectsTable*.

Kinetic::ActiveObjectsTable

Definition

This container holds a set of objects of a particular type. It creates notifications using the standard *Multi_listener<Interface>* interface when a primitive changes or is added or deleted. Objects which are listening for events can then ask which primitives changed.

For speed, modifications to the *Kinetic::ActiveObjectsTable* can be grouped into editing sessions. A session is begun by calling *set_is_editing(true)* and ended by calling *set_is_editing(false)*. There is one type of notification, namely, *Listener::IS_EDITING* which occurs when the editing mode is set to false, signaling that a batch of changes is completed.

As an convenience, the change methods can be called without setting the editing state to true, this acts as if it were set to true for that one function call.

Types

<i>Kinetic::ActiveObjectsTable:: Key</i>	A key identifying an object in the table.
<i>Kinetic::ActiveObjectsTable:: Data</i>	The type being stored in the table.
<i>Kinetic::ActiveObjectsTable:: Listener</i>	The base class to derive from for listening for runtime events.

The following types are iterators. Each type, *Foo_iterator* has two corresponding methods *foo_begin* and *foo_end* which allow you to iterate through the objects in the set *Foo*.

<i>Kinetic::ActiveObjectsTable:: Key_iterator</i>	An iterator through all the valid keys in the table.
<i>Kinetic::ActiveObjectsTable:: Changed_iterator</i>	An iterator through all the objects which have been changed in the last editing session. The iterator iterates through the objects in lexicographical order.

<i>Kinetic::ActiveObjectsTable:: Inserted_iterator</i>	An iterator through all the objects which were added in the last editing session.
<i>Kinetic::ActiveObjectsTable:: Erased_iterator</i>	An iterator through all the objects which were deleted in the last editing session.

Creation

Operations

<i>Data</i>	<i>mot[Key key]</i>	Access the object referenced by the key.
<i>Data</i>	<i>mot.at(Key key)</i>	Access the object referenced by the key.
<i>void</i>	<i>mot.set_is_editing(bool is_editing)</i>	Set the editing state of the object. A notification is sent when the editing state is set to false after it has been true, i.e. the editing session is finished. This allows changes to be batched together.
<i>bool</i>	<i>mot.is_editing()</i>	Access the editing state.
<i>void</i>	<i>mot.set(Key key, Data object)</i>	This method changes the motion of one moving object. The position at the current time should not be different from the previous current position. However, at the moment I do not check this as there is no reference to time in the Kinetic::ActiveObjectsTable. If <i>is_editing()</i> is not true, then it is as if the calls <i>set_is_editing(true)</i> , <i>set(key, value)</i> and finally <i>set_is_editing(false)</i> were made. If it is true, then no notifications are created.
<i>Key</i>	<i>mot.insert_object(Data ob)</i>	Insert a new object into the table and return a <i>Key</i> which can be used to refer to it. See <i>set(Key, Data)</i> for a description of editing modes.
<i>void</i>	<i>mot.erase(Key key)</i>	Delete an object from the table. The object with <i>Key key</i> must already be in the table. This does not necessarily decrease the amount of storage used at all. In fact, it is unlikely to do so. See <i>set(Key,Data)</i> for an explaining of how the editing modes are used.
<i>void</i>	<i>mot.clear()</i>	Remove all objects from the table and free all storage.
<i>void</i>	<i>mot.is_set(Key)</i>	Returns true if the object has been set in the currently notified editing session. Note that this method can only be safely called when processing an <i>IS_EDITING</i> notification.
<i>void</i>	<i>mot.is_new(Key)</i>	Returns true if the object has been set in the currently notified editing session.
<i>void</i>	<i>mot.clear(Key)</i>	Returns true if the object has been set in the currently notified editing session.

Has Models

Kinetic::Active_objects_vector<MovingObject>

See Also

Multi_listener<Interface>, Kinetic::Active_objects_listener_helper<ActiveObjectsTable, KDS>

CGAL::Kinetic::Active_objects_vector<MovingObject>

Definition

MovingObjects are stored in a vector. This means that access is constant time, but storage is not generally freed. The only way to be sure is to remove all reference counts for the table or to call *clear()*.

#include <CGAL/Kinetic/Active_objects_vector.h>

Is Model for the Concepts

Kinetic::ActiveObjectsTable

CGAL::Kinetic::Cartesian<FunctionKernel>

Definition

This class provides a model of *Kinetic::Kernel* for use with general Cartesian geometry.

```
#include <CGAL/Kinetic/Cartesian.h>
```

Types

Kinetic::Cartesian<FunctionKernel>:: Certificate

This is a model of *Kinetic::Certificate*.

Kinetic::Cartesian<FunctionKernel>:: Point_1

Kinetic::Cartesian<FunctionKernel>:: Point_2

Kinetic::Cartesian<FunctionKernel>:: Point_3

Kinetic::Cartesian<FunctionKernel>:: Weighted_point_3

The following are functors which generate *Certificate* objects. Each has a corresponding *_object* method which creates the functor. They are models of *Kinetic::CertificateGenerator*.

Kinetic::Cartesian<FunctionKernel>:: Orientation_2

Kinetic::Cartesian<FunctionKernel>:: Orientation_3

Kinetic::Cartesian<FunctionKernel>:: Side_of_oriented_circle_2

Kinetic::Cartesian<FunctionKernel>:: Side_of_oriented_sphere_3

Kinetic::Cartesian<FunctionKernel>:: Power_test_3

Kinetic::Cartesian<FunctionKernel>:: Weighted_orientation_3

Kinetic::Cartesian<FunctionKernel>:: Compare_x_1

Kinetic::Cartesian<FunctionKernel>:: Compare_x_2

Kinetic::Cartesian<FunctionKernel>:: Compare_y_2

Kinetic::Cartesian<FunctionKernel>:: Compare_x_3

Kinetic::Cartesian<FunctionKernel>:: Compare_y_3

Kinetic::Cartesian<FunctionKernel>:: Compare_z_3

Kinetic::Cartesian<FunctionKernel>:: Compare_distance_2

Kinetic::Cartesian<FunctionKernel>:: Compare_distance_3

Is Model for the Concepts

Kinetic::Kernel.

Kinetic::Certificate

Definition

The `concept` represents certificate. Its main purpose is to provide a way of creating *Time* objects corresponding to when the certificate fails and to cache any useful work done in find the *Time* for later.

Operations

<i>Time</i>	<i>c.failure_time()</i>	Returns the next failure time.
<i>bool</i>	<i>c.will_fail()</i>	Returns true if the certificate will ever fail.
<i>void</i>	<i>c.pop_failure_time()</i>	Advances to the next failure time (the next root of the certificate functions).

See Also

Kinetic::Kernel.

Kinetic::CertificateGenerator

Definition

This functor allows you to create certificate objects of some type. The models of this “concept” take some set of arguments which depend on the certificate being computed (for example three points for a two dimensional orientation) followed by either one or two instances of the *Kinetic::Simulator::Time* concept. The functions either return a *Certificate* or the corresponding value at the current time (if only a time value rather than an interval is passed).

Operations

<i>Certificate</i>	<i>a(Args, Time begin, Time end)</i>	Return a <i>Certificate</i> object for the corresponding certificate.
<i>CGAL::Sign</i>	<i>a(Args, Time t)</i>	Compute the sign of the function at $\lim_{\delta \rightarrow 0} t + \delta$. This can be used to evaluate predicates at the current moment.

Has Models

All over the place.

See Also

Kinetic::KineticKernel

Example

Here you see how to use both functions on an orientation predicate.

```
KineticKernel::Point_2 a,b,c;
Simulator::Handle sh;
KineticKernel kk;

KineticKernel::Orientation_2 o2= kk.orientation_2_object();

KineticKernel::Certificate c= o2(a,b,c, sh->current_time(), sh->end_time());
if (c.will_fail()) {
    std::cout << "Certificate will fail" << std::endl;
}
// Compute the sign immediately following the current time
CGAL::Sign sn= o2(a,c,b, sh->current_time());
CGAL_postcondition(sn==CGAL::NEGATIVE);
```

Kinetic::FunctionKernel::ConstructFunction

Definition

The concept `is` used to construct functions.

Operations

<i>Function</i>	<i>a(NT a, ...)</i>	This family of methods takes a list of coefficients and returns a function. There can be any number of coefficients passed as arguments (up to about 25 in the current implementations).
-----------------	----------------------	--

See Also

FunctionKernel

Example

```
Function_kernel fk;
Function_kernel::Construct_function cf= fk.construct_function_object();
Function_kernel::Function f= cf(0,1,2,3,4,5);
```

Kinetic::EventQueue

Definition

The for priority queues used by the *Simulator*. The concept basically defines a priority queue which supports deletions and changes of items in the queue (but not their priorities). Items in the queue must implement the *Event* concept.

Types

Kinetic::EventQueue::Key The type used to access items in the queue in order to change or delete them.

Kinetic::EventQueue::Priority The priority type for items in the queue. This is typically the same as *Kinetic::Simulator::Time*

.

Creation

Kinetic::EventQueue *q*(*Priority start*, *Priority end*, *int size_hint*);

Construct a queue which will start at time start and run until time end.

Operations

template <class Event>

Key *q.insert(Priority, Event)*

Insert an event into the event queue. A *Key* which can be used to manipulated the event is returned.

void *q.erase(Key)*

Erase an event from the queue.

template <class Event>

void *q.set(Key, Event)*

Change the data in the event referred to by the key.

template <class Event>

Event& *q.get(Key)*

Access the event referred to by the passed key.

Priority *q.priority(Key)*

Return the priority of the event.

bool *q.empty()*

Return true if the queue is empty.

Priority *q.next_priority()*

Return the priority of the next event in the queue.

<i>void</i>	<i>q.process_next()</i>	Process the next <i>Event</i> by calling its process method with its <i>Priority</i> .
<i>void</i>	<i>q.set_end_priority()</i>	Set the priority beyond which to ignore events.
<i>bool</i>	<i>q.contains(Key)</i>	Return true if the queue contains the event and false if it does not. This is used for auditing events and can be slow if needed.

Has Models

Kinetic::Two_list_pointer_event_queue<FunctionKernel>,
FunctionKernel>.

Kinetic::Heap_pointer_event_queue<

Kinetic::Simulator::Event

Definition

The concept represents a single event. Models of should be passed to the *Kinetic::Simulator* when scheduling events which will in turn pass them to the *EventQueue*.

Operations

void *a.process()* This method is called when the event occurs. This method will only be called once per time this event is scheduled and the event will be removed from the queue immediately afterwards.

*void** *a.kds()* Return a *void ** which represents the KDS which this event belongs to. The pointer is used solely to tell if two events come from the same KDS for the purposes of handling degeneracy.

CGAL::Comparison_result

a.compare_concurrent(Key a, Key b)

The two events *a* and *b* occur at the same time (*this* has key *a*). This method returns a *CGAL::Comparison_result* which is used to order the two equal events. If *CGAL::EQUAL* is returned then *merge* will be called.

bool *a.merge_concurrent(Key a, Key b)*

The two events *a* and *b* occur at the same time (*this* has key *a*) and cannot be perturbed to be unequal. This event allows the KDS to merge event *b* with *a*. If it returns *true* then *b* is dropped from the event queue.

void *a.audit(Key this_key)* Audit that this is a valid event. To use this, kinetic data structure can check that this event is indeed pointed to by the correct part of the combinatorial structure.

std::ostream& *a.write(std::ostream&)*

Write the event to a stream.

Has Models

All over the place. *Kinetic::Event_base*.

See Also

Kinetic::EventQueue

Example

All of the kinetic data structures provided have models of Event. Here is the code implementing a swap event from the sorting kinetic data structure. Events occurring at equal times are perturbed so that the one that occurs first in the list is processed first (just to illustrate the idea).

```
template <class Certificate, class Id, class Root_enumerator>
class Swap_event {
    typedef Swap_event<class Certificate, class Id, class Root_enumerator> This;
public:
    Swap_event(Id o, Sort* sorter,
               const Certificate &s): left_object_(o),
                                   sorter_(sorter),
                                   s_(s) {}

    void process() {
        sorter_>swap(left_object_, s_);
    }
    void *kds() const {return sorter_;}
    CGAL::Comparison_result perturb_comparison(typename Sort::Event_key a, typename Sort::Event_key b) const {
        return CGAL::compare(std::distance(sorter_>objects_begin(), left_object_),
                             std::distance(sorter_>objects_begin(),
                                             sorter_>simulator_handle()->get_event<This>(b).left_object_));
    }
    bool merge(typename Sort::Event_key a, typename Sort::Event_key b) {
        return false;
    }
    Id left_object_;
    Sort* sorter_;
    Certificate s_;
};
```

Kinetic::FunctionKernel

Definition

The concept `Kinetic::FunctionKernel` encapsulates all the methods for representing and handling functions. The set is kept deliberately small to easy use of new `Kinetic::FunctionKernels`, but together these operations are sufficient to allow the correct processing of events, handling of degeneracies, usage of static data structures, run-time error checking as well as run-time verification of the correctness of kinetic data structures. The computation of a polynomial with the variable negated is used for reversing time in kinetic data structures and can be omitted if that capability is not needed.

Types

<code>Kinetic::FunctionKernel:: Function</code>	The type of function being handled.
<code>Kinetic::FunctionKernel:: NT</code>	The basic representational number type.
<code>Kinetic::FunctionKernel:: Root</code>	A type representing the roots of a <i>Function</i> .
<code>Kinetic::FunctionKernel:: Root_stack</code>	A model of <i>RootStack</i> . These objects can be created by calling the <i>root_stack_object</i> method with a <i>Function</i> and two (optional) <i>Root</i> objects. The enumerator then enumerates all roots of the function in the open interval defined by the two root arguments. They optional arguments default to positive and negative infinity.
<code>Kinetic::FunctionKernel:: Root_enumerator_traits</code>	The traits for the <i>Root_enumerator</i> class.
Each of the following types has a corresponding <i>type_object</i> method (not explicitly documented) which takes a <i>Function</i> as an argument.	
<code>Kinetic::FunctionKernel:: Sign_at</code>	A functor which returns the sign of a <i>Function</i> at a <i>NT</i> or <i>Root</i> .
<code>Kinetic::FunctionKernel:: Sign_after</code>	A functor which returns sign of a function immediately after a root.
The following type is used to construct functions from a list of coefficients. To get an instance use the <i>construct_function_object()</i> method.	
<code>Kinetic::FunctionKernel:: Construct_function</code>	This functor can be used create instances of <i>Function</i> . See its reference page <i>FunctionKernel::ConstructFunction</i> for more details.

The following functor likewise have a *type_object* method, but these take arguments other than a *Function*. The arguments are given below.

Kinetic::FunctionKernel:: Sign_between_roots This functor, creation of which requires two *Roots*, returns the sign of a passed function between the pair of roots.

Kinetic::FunctionKernel:: Differentiate This functor computes the derivative of a *Function*. Construction takes no arguments.

The following methods do not require any arguments to get the functor and take one *Function* as a functor argument.

Kinetic::FunctionKernel:: Negate_variable Map $f(x)$ to $f(-x)$.

Has Models

POLYNOMIAL::Kernel<RootStack>, POLYNOMIAL::Filtered_kernel<RootStack>.

See Also

Kinetic::RootEnumerator.

Example

We provide several models of the concept, which are not documented separately. The models of *Kinetic::SimulationTraits* all choose appropriate models. However, if more control is desired, we here provide examples of how to create the various supported *Kinetic::FunctionKernel*.

A Sturm sequence based kernel which supports exact comparisons of roots of polynomials (certificate failure times):

```
typedef CGAL::POLYNOMIAL::Polynomial<CGAL::Gmpq> Function;
typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function> Root_stack_traits;
typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits> Root_stack;
typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;
```

A wrapper for *CORE::Expr* which implements the necessary operations:

```
typedef CGAL::POLYNOMIAL::CORE_kernel Function_kernel;
```

A function kernel which computes approximations to the roots of the polynomials:

```
typedef CGAL::POLYNOMIAL::Polynomial<double> Function;
typedef CGAL::POLYNOMIAL::Root_stack_default_traits<Function> Root_stack_traits;
typedef CGAL::POLYNOMIAL::Numeric_root_stack<Root_stack_traits> Root_stack;
typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;
```

When using the function kernel in kinetic data structures, especially one that is in exact, it is useful to wrap the root stack. The wrapper checks the sign of the certificate function being solved and uses that to handle degeneracies. This is done by, for the inexact solvers

```
typedef Kinetic::Derivative_filter_function_kernel<Function_kernel> KDS_function_kernel;
```

and for exact solvers

```
typedef Kinetic::Handle_degeneracy_function_kernel<Function_kernel> KDS_function_kernel;
```

For exact computations, the primary representation for roots is the now standard choice of a polynomial with an associated isolating interval (and interval containing exactly one distinct root of a polynomial) along with whether the root has odd or even multiplicity and, if needed, the Sturm sequence of the polynomial. Two intervals can be compared by first seeing if the isolating intervals are disjoint. If they are, then we know the ordering of the respective roots. If not we can subdivide each of the intervals (using the endpoints of the other interval) and repeat. In order to avoid subdividing endlessly when comparing equal roots, once we subdivide a constant number of times, we use the Sturm sequence of p and $p'q$ (where p and q are the two polynomials and p' is the derivative of p) to evaluate the sign of the second at the root of the first one directly (note that this Sturm sequence is applied to a common isolating interval of the roots of interest of both polynomials).

Kinetic::FunctionKernel::Function

Definition

The concept represents a function.

Types

Function::NT The number type used in describing the function.

Function a(NT); Construct a constant function from a number.

Operations

NT *a(NT)* Evaluate the function at an *NT*.

See Also

FunctionKernel, *FunctionKernel::ConstructFunction*

Example

Several ways to create functions:

Using *Kinetic::ConstructFunction*:

```
Traits::Function_kernel::Construct_function cf= traits.function_kernel_object().construct_function_object();
Traits::Kinetic_kernel::Motion_function x= cf(0.0,1.0,2.0);
Traits::Kinetic_kernel::Motion_function y= cf(0.0,1.0,2.0);
Traits::Kinetic_kernel::Point_2 pt(x,y);
```

Using the constructor:

```
double coefs[]={1.0, 2.0, 3.0};
Traits::Kinetic_kernel::Motion_function z(coefs, coefs+3);
```

Using ring operations:

```
Traits::Kinetic_kernel::Motion_function z= x*z+y;
```

CGAL::Kinetic::Default_instantaneous_kernel<SimulationTraits>

Definition

This class provides a model of the *Kinetic::InstantaneousKernel* for use with general Cartesian Geometry. It provides all the predicates needed for Delaunay triangulations and regular triangulations.

```
#include <CGAL/Kinetic/Default_instantaneous_kernel.h>
```

Types

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Orientation_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Orientation_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Side_of_oriented_circle_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Side_of_oriented_sphere_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Power_test_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Weighted_orientation_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_x_1

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_x_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_y_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_x_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_y_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_z_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_distance_2

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Compare_distance_3

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Coplanar_orientation_3

Note that this one does not work if the current time is not a *NT*.

Kinetic::Default_instantaneous_kernel<SimulationTraits>:: Coplanar_side_of_bounded_circle_3

Note that this one does not work if the current time is not a *NT*.

Is Model for the Concepts

Kinetic::InstantaneousKernel

Kinetic::InstantaneousKernel

Definition

The concept `Kinetic::InstantaneousKernel` covers models that act as adaptors allowing CGAL static data structures to act on snapshots of kinetic data. Different methods for evaluating predicates are used depending on whether time is set using an *NT* or a *Time* object. Evaluating predicates when time is the former is much cheaper.

Types

Kinetic::InstantaneousKernel:: NT A number type which can be used to represent the current time. This must be a ring or field type.

Kinetic::InstantaneousKernel:: Time The type used to represent the current time. This type must be comparable.

Operations

<i>Time</i>	<i>a.time()</i>	Return the current time.
<i>NT</i>	<i>a.time_as_nt()</i>	Return the current time as an <i>NT</i> . As a precondition, <i>time_is_nt</i> must be true.
<i>bool</i>	<i>a.time_is_nt()</i>	Return true if the last time time was set, it was using an object of type <i>NT</i> .
<i>void</i>	<i>a.set_time(Time)</i>	Set the current time to have a certain value. All existing predicates are updated automatically.
<i>void</i>	<i>a.set_time(NT)</i>	Set the current time to be an instance of <i>NT</i> . With this more efficient techniques can be used. <i>time_is_nt()</i> must be true.
<i>Static_object</i>	<i>a.static_object(Key)</i>	Return a static object corresponding to the kinetic object at this instant in time. <i>time_is_nt()</i> must be true.

Has Models

Kinetic::Default_instantaneous_kernel

Key

Definition

The concept Key is a unique identifier for something in some sort of table. In general, they can be only created by the table and are returned when a appropriate *new_foo()* method is called on the table. There are two classes of values for a Key, valid and invalid. The latter cannot refer to something in a table. Use the method *is_valid()* to differentiate.

Key a;

The default constructor is guaranteed to construct an invalid key (i.e. one which is false when cast to a bool).

Operations

bool

a.is_valid()

This method returns false if the key was created using the default constructor or was otherwise created to be invalid.

std::ostream&

std::ostream& << Event

Write a text description of the key to a standard stream.

Has Models

Kinetic::Simulator::Event_key, Kinetic::Active_objects_vector<Object>::Key.

Kinetic::Kernel

Definition

The concept `Kinetic::Kernel` acts as the kinetic analog of a CGAL kernel. It provides some set of primitives and predicates acting on them. The predicates are instances of `Kinetic::CertificateGenerator` and can be used to either create *Certificates* or to evaluate instantaneous predicates.

Types

<i>Kinetic::Kernel:: Motion_function</i>	The type which is used to represent coordinates of moving primitives. It is a model of the concept <i>FunctionKernel::Function</i> . This is the analog of the CGAL kernel <i>RT</i> .
<i>Kinetic::Kernel:: Certificate</i>	The type representing the results of predicates. See <i>Kinetic::Certificate</i> .
<i>Kinetic::Kernel:: Function_kernel</i>	The type of the function kernel used. See <i>Kinetic::FunctionKernel</i> .

Operations

<i>Function_kernel</i>	<i>kk.function_kernel_object()</i>	Gets a copy of the function kernel.
------------------------	------------------------------------	-------------------------------------

Has Models

Kinetic::Cartesian<FunctionKernel>.

CGAL::Listener<Interface>

Definition

The *Listener<Interface>* class provides the core of the run time notification system used by the kinetic data structures package. In short, notifications are handled through proxy objects called listeners. In order to listen for notifications from an object, called the notifier, you make define a small class called a listener proxy, which inherits from the Listener interface defined by the notifier. When constructing your listner poxy, you pass a reference counted pointer to the notifier, which is used to register the proxy for notifications. When a notification occurs, the notifier calls the *new_notification* method on the proxy, passing the type of the notification. The proxy stores a reference counted pointer to the notifier, ensuring that there are never any dangling pointers in the system.

The class *Listener<Interface>* provides base class for listener proxy objects. A notifier should provide a class which inherits from this base. To use this base class, implement a class, here called *Interface*, which defines a type *Interface::Notification_type* and a type *Interface::Notifier_handle*.

The *Notification_type* is generally an enum with one value for each type of notification which can be used.

The *Notifier_handle* is the type of a (ref counted) pointer to the object providing the notifications. The ref counter pointer must provide a nested type *Pointer* which is the type of a raw pointer.

The *Listener<Interface>* maintains a ref counted pointer to the object performing notifications. It is registered for notifications on construction and unregistered on destruction using the function *set_listener(Listener<Interface>*)* on the object providing the notifications. The use of ref counted pointers means that as long as the notification object exists, the object providing the notifications must exist, ensuring that the object providing the notifications is not prematurely destroyed.

These objects cannot be copied since the notifier only support one listener. If copying and more than one listener are desired, the *Multi_listener<Interface>* base class should be used instead.

As a side note, Boost provides a similar functionality in the Boost.Signal package. However, it is quite a bit more complex (and flexible). This complexity add significantly to compile time and (although I did not test this directly), I suspect it is much slower at runtime due to the overhead of worrying about signal orders and not supporting single signals. In addition, it does not get on well with Qt due to collisions with the Qt moc keywords.

There is also the TinyTL library which implements signals. As of writing it did not have any easy support for making sure all pointers are valid, so it did not seem to offer significant code saving over writing my own.

```
#include <CGAL/Kinetic/Listener.h>
```

Types

Listener<Interface>::Notifier_handle

This type is inherited from the *Interface* template argument. It is a reference counted pointer type for the object providing notifications.

Listener<Interface>::Notification_type

The type (usually an enum) used to distinguish different types of notifications. This is inherited from the *Interface* template argument.

Creation

Listener<Interface> l(Notifier_handle np); The *Listener<Interface>* subscribes to events coming from the notifier and stores a pointer to the notifier.

Operations

Notifier_handle *l.notifier()* Return a pointer to the notifier.

virtual void *l.new_notification(Notification_type)*

This method is pure virtual. A class which wishes to receive events must inherit from this class and implement this method. The method will then be called whenever there is a notification.

See Also

Multi_listener<Interface>.

Example

Here is a simpler class that provides notifications:

```
struct Notifier: public CGAL::Kinetic::Ref_counted<Notifier>
{
public:
    Notifier(): data_(0), listener_(NULL){}

    struct Listener_interface
    {
    public:
        typedef enum Notification_type {DATA_CHANGED} Notification_type;
        typedef Notifier::Handle Notifier_handle;
    };

    typedef CGAL::Kinetic::Listener<Listener_interface> Listener;
    friend class CGAL::Kinetic::Listener<Listener_interface>;

    void set_data(int d) {
        data_=d;
        if (listener_ != NULL) listener_>new_notification(Listener_interface::DATA_CHANGED);
    }

protected:
    void set_listener(Listener *l) {
        listener_= l;
    }
    Listener* listener() const {return listener_;}
```

```

    int data_;
    Listener *listener_;
};

```

Now the listener:

```

struct My_listener: public Notifier::Listener, public CGAL::Kinetic::Ref_counted<My_listener>
{
    typedef Notifier::Listener::Notifier_handle PP;
    My_listener(PP p): P(p){}

    void new_notification(P::Notification_type nt) {
        ...
    }
};

```

CGAL::Multi_listener<Interface>

Definition

The class *Multi_listener<Interface>* implements a base class for listeners where more than one listener is allowed to subscribe to a notifier. See *Listener* for full documentation. This uses the function calls *new_listener()* and *delete_listener()* to register and unregister the listener (instead of *set_listener()*).

```
#include <CGAL/Kinetic/Multi_listener.h>
```

See Also

Listener<Interface>.

CGAL::Ref_counted<T>

Definition

The class *Ref_counted*<T> implements a base class for objects which are reference counted. To use it simply inherit from *Ref_counted*<T> (passing the type to be reference counted as the template argument) and then access the object through *Handle* objects rather than bare C++ pointers.

```
#include <CGAL/Kinetic/Ref_counted.h>
```

Types

Ref_counted<T>:: *Handle* A reference counted pointer to an Object.

Ref_counted<T>:: *Const_handle* A const reference counted pointer to an Object.

Creation

Ref_counted<T> *rc*; default constructor.

Operations

There are no methods which should be called by users of this class.

Kinetic::RootStack

Definition

The concept `Kinetic::RootStack` enumerates through roots of a function contained in a half open interval $[lb \dots ub)$.

Types

Kinetic::RootStack::Root The root of a function.

Kinetic::RootStack::Traits The traits class for this concept.

Creation

Kinetic::RootStack re; default constructor.

Kinetic::RootStack re(*Function f*, *Root lb*, *Root ub*, *Traits tr*);

Construct a `Kinetic::RootStack` over the roots of f in the half open interval $[lb$ to $ub)$.

Operations

void *re.pop()* Advance to the next root. As a precondition, `empty()` must be false.

Root *re.top()* Return the current root. As a precondition, `empty()` must be false. Note that the *Root* returned might not actually be in the interval (since the solver has not yet proved that there are no more roots).

bool *re.empty()* Return true if there are known to be no more roots left. There might not actually be any roots of the polynomial left in the interval, but the work necessary to prove this has been delayed.

See Also

Kinetic::FunctionKernel, *Kinetic::Certificate*.

Kinetic::SimulationTraits

Definition

This concept ties together the parts needed in order to run a kinetic data structure. We provide several models of this concept:

- *Kinetic::Exact_simulation_traits*
- *Kinetic::Inexact_simulation_traits*
- *Kinetic::Regular_triangulation_exact_simulation_traits*
- *Kinetic::Regular_triangulation_inexact_simulation_traits*

All support trajectories defined by polynomial coordinates. The *Exact* vs *Inexact* picks whether the roots of the certificate functions are compared exactly or approximated numerically. The regular triangulation models have weighted points of the appropriate dimension as the primitive used in the *Kinetic::InstantaneousKernel* and the *Kinetic::ActiveObjectsTable*.

Types

<i>Kinetic::SimulationTraits:: NT</i>	The number type used for representation.
<i>Kinetic::SimulationTraits:: Instantaneous_kernel</i>	A model of <i>Kinetic::InstantaneousKernel</i> which can be used to apply static CGAL data structures to snapshots of moving data.
<i>Kinetic::SimulationTraits:: Kinetic_kernel</i>	A model of <i>Kinetic::Kernel</i> .
<i>Kinetic::SimulationTraits:: Function_kernel</i>	A model of <i>Kinetic::FunctionKernel</i> .
<i>Kinetic::SimulationTraits:: Active_points_[123]_table</i>	A model of <i>Kinetic::ActiveObjectsTable</i> which holds the relevant kinetic primitives.
<i>Kinetic::SimulationTraits:: Simulator</i>	A model of <i>Kinetic::Simulator</i> which will be used by all the kinetic data structures.

Operations

Instantaneous_kernel *st.instantaneous_kernel_object()*

Get a new instantaneous kernel.

Kinetic_kernel *st.kinetic_kernel_object()*

Get a new kinetic kernel.

Function_kernel *st.function_kernel_object()*

Get a new function kernel.

Simulator::Handle *st.simulator_handle()* Return a pointer to the *Kinetic::Simulator* which is to be used in the simulation.

Active_points_[123]_table::Handle

st.active_points_[123]_table_handle()

Return a pointer to the *Kinetic::ActiveObjectsTable* which is to be used in the simulation.

Has Models

Kinetic::Exact_simulation_traits, *Kinetic::Inexact_simulation_traits*, *Kinetic::Regular_triangulation_exact_simulation_traits*, *Kinetic::Regular_triangulation_inexact_simulation_traits*

Example

The simulation traits class is simply there for convenience in order to bundle a set of related typedefs and create a few objects. As a result, creating your own requires little thought, and just copying and changing a few lines. An example is below which sets up to use the CORE Sturm sequences to solve polynomials rather than our own (faster) solvers. It can be found in `examples/Kinetic.framework/defining_a_simulation_traits.cpp`.

```
#include <CGAL/Polynomial/Sturm_root_stack_traits.h>
#include <CGAL/Polynomial/Sturm_root_stack.h>
#include <CGAL/Kinetic/Active_objects_vector.h>
#include <CGAL/Kinetic/Default_instantaneous_kernel.h>
#include <CGAL/Kinetic/Cartesian.h>
#include <CGAL/Kinetic/Handle_degeneracy_function_kernel.h>
#include <CGAL/Kinetic/Default_simulator.h>
#include <CGAL/Kinetic/Two_list_pointer_event_queue.h>
#include <CGAL/Exact_predicates_exact_constructions_kernel.h>

using namespace CGAL::Kinetic;

struct My_simulation_traits {
    typedef My_simulation_traits This;

    typedef CGAL::Exact_predicates_exact_constructions_kernel Static_kernel;
    //typedef CGAL::Regular_triangulation_euclidean_traits_3<Static_kernel_base> Static_kernel;
    typedef CGAL::POLYNOMIAL::Polynomial<Static_kernel::FT> Function;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack_traits<Function> Root_stack_traits;
    typedef CGAL::POLYNOMIAL::Sturm_root_stack<Root_stack_traits> Root_stack;
    typedef CGAL::POLYNOMIAL::Kernel<Function, Root_stack> Function_kernel;

    typedef CGAL::Kinetic::Handle_degeneracy_function_kernel<Function_kernel, false> Simulator_function_kernel;
    struct Simulator_function_kernel: public Simulator_function_kernel_base{};

    typedef Cartesian<Simulator_function_kernel> Kinetic_kernel;
    typedef Two_list_pointer_event_queue<Function_kernel> Event_queue;
    typedef Default_simulator<Simulator_function_kernel, Event_queue> Simulator;

    typedef Active_objects_vector<Kinetic_kernel::Point_1> Active_points_1_table;
    typedef Active_objects_vector<Kinetic_kernel::Point_2> Active_points_2_table;
    typedef Active_objects_vector<Kinetic_kernel::Point_3> Active_points_3_table;
    // typedef Active_objects_vector<Kinetic_kernel::Weighted_point_3> Active_weighted_points_3_table;

    typedef Default_instantaneous_kernel<This> Instantaneous_kernel;

    Active_points_1_table* active_points_1_table_handle() const { return ap1_.get();}
    Active_points_2_table* active_points_2_table_handle() const {return ap2_.get();}
    Active_points_3_table* active_points_3_table_handle() const {return ap3_.get();}
    //Active_weighted_points_3_table* active_weighted_points_3_table_handle() const {return awp3_.get();}

    Simulator* simulator_handle() const { return sim_.get();}
    const Static_kernel& static_kernel_object() const {return k_;}
    const Kinetic_kernel& kinetic_kernel_object() const {return kk_;}

    Instantaneous_kernel instantaneous_kernel_object() const {
```

```

        return Instantaneous_kernel(*this);
    }

    My_simulation_traits(const Simulator::Time &lb,
        const Simulator::Time &ub): sim_(new Simulator(lb, ub)),
        ap1_(new Active_points_1_table()),
        ap2_(new Active_points_2_table()),
        ap3_(new Active_points_3_table())
        //awp3_(new Active_weighted_points_3_table())
    {}

    bool is_exact() const {
        return true;
    }
protected:
    Simulator::Handle sim_;
    Active_points_1_table::Handle ap1_;
    Active_points_2_table::Handle ap2_;
    Active_points_3_table::Handle ap3_;
    //Active_weighted_points_3_table::Handle awp3_;
    Static_kernel k_;
    Kinetic_kernel kk_;
    Function_kernel fk_;
};

#endif

```

CGAL::Kinetic::Default_simulator<FunctionKernel, EventQueue>

Definition

The class *Kinetic::Default_simulator<FunctionKernel, EventQueue>* controls kinetic data structures by maintaining a concept of time and ensuring that events are processed when necessary.

```
#include <CGAL/Kinetic/Default_simulator.h>
```

Is Model for the Concepts

Kinetic::Simulator.

Creation

```
Kinetic::Default_simulator<FunctionKernel, EventQueue> sim( const Time start=Time(0),  
                                                             const Time end= Time::infinity())
```

Construct a *Kinetic::Default_simulator<FunctionKernel, EventQueue>* which will process events between times start and end (events outside this window will be discarded).

CGAL::Kinetic::Simulator_kds_listener<Listener, KDS>

Definition

The class *Kinetic::Simulator_kds_listener<Listener, KDS>* acts as a helper class for kinetic data structures which want to respond to *Simulator::Listener::HAS_AUDIT_TIME* notifications. When kinetic data structures can audit themselves, the *Kinetic::Simulator_kds_listener<Listener, KDS>* calls the *audit()* method on the kinetic data structure.

```
#include <CGAL/Kinetic/Simulator_kds_listener.h>
```

Creation

```
Kinetic::Simulator_kds_listener<Listener, KDS> a( Simulator::Handle, KDS *kds);
```

default constructor.

See Also

Kinetic::Simulator, *Listener<Interface>*.

CGAL::Kinetic::Simulator_objects_listener<Simulator_listener, KDS>

Definition

The class *Kinetic::Simulator_objects_listener<Simulator_listener, KDS>* is a helper for classes which wish to react to *Simulator::Listener::DIRECTION_OF_TIME* notifications. The helper object translates such notifications *reverse_time* function calls on the responder. See *Kinetic::Qt_moving_points_2* for a simple example of using this helper function.

```
#include <CGAL/Kinetic/Simulator_objects_listener.h>
```

Creation

```
Kinetic::Simulator_objects_listener<Simulator_listener, KDS> a( Simulator::Handle, KDS*);
```

default constructor.

See Also

Kinetic::Listener.

Kinetic::Simulator

Definition

The class `Kinetic::Simulator` controls kinetic data structures by maintaining a the current time and ensuring that events are processed when necessary.

In addition, the `Kinetic::Simulator` can call on the kinetic data structures to audit themselves at appropriate times. When the last event processed and the next to be processed have different times, then there is a rational value of time at which all kinetic data structures should be non-degenerate (since there are no events at that time). At such a time, kinetic data structures can easily verify their correctness by checking that all the certificate predicates have the correct value. When exactness checks are enabled, whenever the last event processed and the next event to be processed have different times, a `Kinetic::Simulator::Listener::HAS_AUDIT_TIME` notification is made. Kinetic data structures can listen for that event, and when it is made, they can call `Kinetic::Simulator::audit_time()` to get the time value and then verify that their structure is correct.

In addition, at such a time, the `Event::audit(Key)` is called on each event. This allows kinetic data structures to check that the event should be in the queue.

Typically, the simulator is created by the `Kinetic::SimulationTraits` class and kinetic data structures request a handle to it from there.

Events that occur at or after `Kinetic::Simulator::end_time()` will may not be processed. The exception are events which are scheduled using the `new_final_event(Event)` call which are guaranteed to occur after all other events (but have no particular order amongst themselves).

Types

<code>Kinetic::Simulator::Function_kernel</code>	The type of the function kernel used to instantiate this <code>Kinetic::Simulator</code> .
<code>Kinetic::Simulator::Listener</code>	Extend this base class to listen to notifications from this <code>Kinetic::Simulator</code> . There are two types of notifications: <code>HAS_AUDIT_TIME</code> and <code>DIRECTION_OF_TIME</code> . The first is made when kinetic data structures can perform an audit. The second is made when the direction of time is changed.
<code>Kinetic::Simulator::Time</code>	The representation type for times in the simulator. It is <code>Function_kernel::Root_enumerator::Root</code> .
<code>Kinetic::Simulator::Event_key</code>	The key to access scheduled <code>Event</code> in order to inspect or delete them.
<code>Kinetic::Simulator::NT</code>	The basic number type used in computations.
<code>Kinetic::Simulator::Handle</code>	A reference counted pointer to be used for storing references to the object.
<code>Kinetic::Simulator::Const_handle</code>	A reference counted pointer to be used for storing references to the object.

Creation

Kinetic::Simulator *sim*(*const Time start=Time(0)*, *const Time end= Time::infinity()*);

Construct a *Kinetic::Simulator* which will process events between times start and end (events outside this window will be discarded).

Operations

Function_kernel *sim.function_kernel_object()*

Access the *Function_kernel* object used by the *Kinetic::Simulator*.

Time *sim.current_time()* Return the current time.

void *sim.set_current_time(Time t)*

Set the current time to *t*, which cannot be less than *current_time*. Any events in the queue before time *t* are processed.

NT *sim.next_time_representable_as_nt()*

This function returns a time which can be represented using an instance of type *NT* which is shortly after the current time. You can then advance the current time to this one and act on the data structure using the return *nt*.

bool *sim.has_current_time_as_nt()*

Return true if there is a rational number which is equivalent to the current time. Equivalent means that it has the same ordering relation to all previous and scheduled events.

bool *sim.has_audit_time()* Returns true if the current time is a rational number and there are no events at the current time. This means that the simulation can be audited at this time.

Time *sim.next_event_time()* Return the time of the next event in the queue.

Time *sim.end_time()* Return the time the simulation will end. If time is running backwards, then this returns *Time::infinity()*.

void *sim.set_interval(Time t_cur, Time t_end)*

Set the current time to *t_{cur}* and the end time to *t_{end}*. The event queue must be empty. Use this method if you want to reset or extend the simulation.

<i>template <class Event></i> <i>Event_key</i>	<i>sim.new_event(Time t, const Event event)</i>	Schedule a new event at time <i>t</i> . The object <i>event</i> must implement the concept <i>Event</i> . The <i>Event_key</i> returned can be used to access or deschedule the event.
<i>template <class Event></i> <i>Event_key</i>	<i>sim.new_final_event(const Event event)</i>	Schedule a new event that will occur at the end of the simulation. This type of event is useful if, for example, you want to run for a while, change all motions, and then run some more.
<i>Event_key</i>	<i>sim.null_event()</i>	This method returns an <i>Event_key</i> which is guaranteed never to be assigned to any real event. This is a very useful placeholder for events which are known never to occur (and allows data structures to differentiate between uninitialized and never failing).
<i>void</i>	<i>sim.audit_event(Event_key)</i>	Performs some checks as to whether the key corresponds to a valid event. Generally, a event is valid if it is not defaultly constructed and either is in the queue or is the <i>null_event()</i> .
<i>bool</i>	<i>sim.empty()</i>	Return true if there are no more events.
<i>void</i>	<i>sim.delete_event(const Event_key k)</i>	Remove the event referenced by <i>k</i> from the event queue.
<i>template <class Ev></i> <i>typename Queue::Event_handle<Ev>::Handle</i>	<i>sim.event(const Event_key k, const Ev e)</i>	This method returns a pointer to an event, which can be used for recoving data, such as cached solvers, from that event. The second argument really shouldn't be there, but gcc seems to sometimes have issues if you try to specify the template value directly.
<i>Time</i>	<i>sim.event_time(Event_key k)</i>	Return the time at which the event referenced by <i>k</i> occurs.
<i>template <class Ev></i>		

<i>Event_key</i>	<i>sim.set_event(Event_key k, const Ev ev)</i>	Set the event referenced by key <i>k</i> to <i>ev</i> , for example if you want to change what happens when that event occurs. A new event key is returned.
<i>Sign</i>	<i>sim.direction_of_time()</i>	Return <i>POSITIVE</i> if time is running forwards or <i>NEGATIVE</i> if it is running backwards.
<i>void</i>	<i>sim.set_direction_of_time(Sign dir)</i>	Set which direction time is running.
<i>unsigned int</i>	<i>sim.current_event_number()</i>	Return the number of events which have been processed.
<i>void</i>	<i>sim.set_current_event_number(unsigned int i)</i>	Process all events up to the <i>i</i> th event. <i>i</i> cannot be less than <i>current_event_number</i> .

Has Models

Kinetic::Default_simulator<FunctionKernel, EventQueue>

Kinetic::Simulator::Time

Definition

The concept `time` represents time in the simulator.

Time $a(NT)$;

Construct an instance of time from a number type, where NT is the number type used in the simulation.

Operations

std::ostream& *std::ostream&* << *Time*

Write it to a stream.

double *to_double(Time)*

Return a double approximation of the time value.

std::pair<double, double>

to_interval(Time)

Return an interval containing the time value.

Comparisons with other *Kinetic::Simulator::Time* objects are supported.

Has Models

double, *Kinetic::FunctionKernel::Root*

Chapter 55

STL Extensions for CGAL

Michael Hoffmann, Lutz Kettner, Sylvain Pion, and Ron Wein

Contents

55.1 Doubly-Connected List Managing Items in Place	2981
55.2 Compact Container	2981
55.3 Multiset with Extended Functionality	2982
55.4 Functor Adaptors	2982

CGAL is designed in the spirit of the generic programming paradigm to work together with the Standard Template Library (STL) [C++98, Aus98]. This chapter documents non-geometric STL-like components that are not provided in the STL standard but in CGAL: a doubly-connected list managing items in place (where inserted items are not copied), a compact container, a multi-set class that uses three-valued comparisons and offers additional functionality, generic algorithms, iterators, functor adaptors for binding and swapping arguments and for composition, functors for projection and creation and adaptor classes around iterators and circulators. See also circulators in Chapter 57.

55.1 Doubly-Connected List Managing Items in Place

The class `In_place_list<T,bool>` manages a sequence of items in place in a doubly-connected list. Its goals are the flexible handling of memory management and performance optimization. The item type has to provide the two necessary pointers `&T::next_link` and `&T::prev_link`. One possibility to obtain these pointers is to inherit them from the base class `In_place_list_base<T>`.

The class `In_place_list<T,bool>` is a container quite similar to STL containers, with the advantage that it is able to handle the stored elements by reference instead of copying them. It is possible to delete an element only knowing its address and no iterator to it. This used to simplify mutually pointed data structures like a halfedge data structure for planar maps or polyhedral surfaces (the current design does not need this anymore). The usual iterators are also available.

55.2 Compact Container

The class `Compact_container<T, Allocator>` is an STL like container which provides a very compact storage for its elements. It achieves this goal by requiring `T` to provide access to a pointer in it, which is going to be used

by *Compact_container*<*T*, *Allocator*> for its internal management. The traits class *Compact_container_traits*<*T*> specifies the way to access that pointer. The class *Compact_container_base* can be used as a base class to provide the pointer, although in this case you do not get the most compact representation. The values that this pointer can have during valid use of the object are valid pointer values to 4 bytes aligned objects (i.e., the two least significant bits of the pointer need to be zero when the object is constructed). Another interesting property of this container is that iterators are not invalidated during *insert* or *erase* operations.

The main deviation from the STL container concept is that the ++ and -- operators of the iterator do not have a constant time complexity in all cases. The actual complexity is related to the maximum size that the container has had during its life time compared to its current size, because the iterator has to go over the "erased" elements as well, so the bad case is when the container used to contain lots of elements, but now has far less. In this case, we suggest to do a copy of the container in order to "defragment" the internal representation.

This container has been developed in order to efficiently handle large data structures like the triangulation and halfedge data structures. It can probably be useful for other kinds of graphs as well.

55.3 Multiset with Extended Functionality

The class *Multiset*<*Type*, *Compare*, *Allocator*> represents a multi-set of elements of type *Type*, represented as a red-black tree (see [CLRS01, Chapter 13] for an excellent introduction to red-black trees). It differs from the STL's *multiset* class-template mainly due to the fact that it is parameterized by a comparison functor *Compare* that returns the three-valued *Comparison_result* (namely it returns either *SMALLER*, *EQUAL*, or *LARGER*), rather than a *less* functor returning *bool*. Thus, it is possible to maintain the underlying red-black tree with less invocations of the comparison functor, which can considerably decrease running times, especially when comparing elements of type *Type* is an expensive operation.

Multiset<*Type*, *Compare*, *Allocator*> also guarantees that the order of elements sent to the comparison functor is fixed. For example, if we insert a new element *x* into the set (or erase an element from the set), then we always invoke *Compare*() (*x*, *y*) (and never *Compare*() (*y*, *x*)), where *y* is an element already stored in the set. This behavior, not supported by *std::multiset*, is sometimes crucial for designing more efficient comparison predicates.

The interface of *Multiset*<*Type*, *Compare*, *Allocator*> is in general derived from *std::multiset*. However, it extends the interface by offering some additional operations, such as: inserting of an element into the set given its *exact* position (and not just using an insertion hint); looking up keys whose type may differ from *Type*, as long as users supply a comparison functor *CompareKey*, between the keys and set elements; and catenating and splitting sets.

55.4 Functor Adaptors

The standard library contains some adaptors for binding functors, that is fixing one argument of a functor to a specific value thereby creating a new functor that takes one argument less than the original functor. Also, though non-standard, some STL implementations (such as SGI) provide adaptors to compose function objects. Unfortunately, these bind and compose adaptors are limited to unary and binary functors only, and these functors must not be overloaded.

Since there are a number of functors in CGAL that take more than two arguments, and since functors may also be overloaded, i.e., accept several different sets of arguments, we have to define our own adaptors to be used with CGAL functors.

CGAL::In_place_list_base<T>

Definition

The node base classes provides pointers to build linked lists. The class *In_place_sl_list_base*<T> provides a pointer *next_link* for a single linked list. The class *In_place_list_base*<T> provides an additional pointer *prev_link* for doubly linked lists. These names conform to the default parameters used in the template argument lists of the container classes. The pointers are public members.

```
#include <CGAL/In_place_list.h>
```

Variables

<i>T*</i>	<i>next_link</i> ;	forward pointer
<i>T*</i>	<i>prev_link</i> ;	backward pointer

CGAL::In_place_list<T,bool>

Definition

An object of the class *In_place_list*<*T*,*bool*> represents a sequence of items of type *T* that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence. The functionality is similar to the *list*<*T*> in the STL.

The *In_place_list*<*T*,*bool*> manages the items in place, i.e., inserted items are not copied. Two pointers of type *T** are expected to be reserved in *T* for the list management. The base class *In_place_list_base*<*T*> can be used to obtain such pointers.

The *In_place_list*<*T*,*bool*> does not copy element items during insertion (unless otherwise stated for a function). On removal of an item or destruction of the list the items are not deleted by default. The second template parameter *bool* is set to *false* in this case. If the *In_place_list*<*T*,*bool*> should take the responsibility for the stored objects the *bool* parameter could be set to *true*, in which case the list will delete removed items and will delete all remaining items on destruction. In any case, the *destroy()* member function deletes all items. Note that these two possible versions of *In_place_list*<*T*,*bool*> are not assignable to each other to avoid confusions between the different storage responsibilities.

```
#include <CGAL/In_place_list.h>
```

Parameters

The full class name is *In_place_list*<*T*, *bool managed* = *false*, *class Alloc* = *CGAL_ALLOCATOR(T)*>.

The parameter *T* is supposed to have a default constructor, a copy constructor and an assignment operator. The copy constructor and the assignment may copy the pointers in *T* for the list management, but they do not have to. The equality test and the relational order require the operators == and < for *T* respectively. These operators must not compare the pointers in *T*.

Types

```
In_place_list<T,bool>::iterator  
In_place_list<T,bool>::const_iterator
```

```
In_place_list<T,bool>::value_type  
In_place_list<T,bool>::reference  
In_place_list<T,bool>::const_reference  
In_place_list<T,bool>::size_type  
In_place_list<T,bool>::difference_type
```

```
In_place_list<T,bool>::reverse_iterator  
In_place_list<T,bool>::const_reverse_iterator
```

```
In_place_list<T,bool>::allocator_type
```

Creation

In_place_list<*T*,*bool*> *l*; introduces an empty list.

In_place_list<*T*,*bool*> *l*(*list*<*T*> *ll*); copy constructor. Each item in *ll* is copied.

In_place_list<*T*,*bool*> *l*(*size_type* *n*, *T* *t* = *T*());
introduces a list with *n* items, all initialized with copies of *t*.

template <*class InputIterator*>
In_place_list<*T*,*bool*> *l*(*InputIterator* *first*, *InputIterator* *last*);
a list with copies from the range [*first*,*last*).

In_place_list<*T*,*bool*> *l*(*const T** *first*, *const T** *last*);
non-member-template version.

In_place_list<*T*,*bool*> & *l* = *ll* assignment. Each item in *ll* is copied. Each item in *l* is deleted if the *bool* parameter is *true*.

void *l.swap*(*ll*) swaps the contents of *l* with *ll*.

void *l.destroy*() all items in *l* are deleted regardless of the *bool* parameter.

Comparison Operations

bool *l* == *ll* test for equality: Two lists are equal, iff they have the same size and if their corresponding elements are equal.

bool *l* < *ll* compares in lexicographical order.

Access Member Functions

iterator *l.begin*() returns a mutable iterator referring to the first element in *l*.
const_iterator *l.begin*() *const* returns a constant iterator referring to the first element in *l*.
iterator *l.end*() returns a mutable iterator which is the past-end-value of *l*.
const_iterator *l.end*() *const* returns a constant iterator which is the past-end-value of *l*.

bool *l.empty*() returns *true* if *l* is empty.
size_type *l.size*() returns the number of items in list *l*.
size_type *l.max_size*() returns the maximum possible size of the list *l*.

T& *l.front*() returns the first item in list *l*.
T& *l.back*() returns the last item in list *l*.

allocator_type

l.get_allocator() returns the allocator.

Insertion

void l.push_front(T&) inserts an item in front of list *l*.
void l.push_back(T&) inserts an item at the back of list *l*.

iterator l.insert(iterator pos, T& t)
iterator l.insert(T pos, T& t)* inserts *t* in front of *pos*. The return value points to the inserted item.

void l.insert(iterator pos, size_type n, T t = T())
void l.insert(T pos, size_type n, T t = T())*
inserts *n* copies of *t* in front of *pos*.

template <class InputIterator>
void l.insert(iterator pos, InputIterator first, InputIterator last)

template <class InputIterator>
void l.insert(T pos, InputIterator first, InputIterator last)*
inserts the range [*first*, *last*) in front of iterator *pos*.

As long as member templates are not supported, member functions using *T** instead of the general *InputIterator* are provided.

Removal

void l.pop_front() removes the first item from list *l*.
void l.pop_back() removes the last item from list *l*.
void l.erase(iterator pos) removes the item from list *l*, where *pos* refers to.
void l.erase(T pos)* removes the item from list *l*, where *pos* refers to.

void l.erase(iterator first, iterator last)
void l.erase(T first, T* last)*
removes the items in the range [*first*, *last*) from *l*.

Special List Operations

void l.splice(iterator pos, & x)
void l.splice(T pos, & x)* inserts the list *x* before position *pos* and *x* becomes empty. It takes constant time.
Precondition: & != &x.

void l.splice(iterator pos, & x, iterator i)

<i>void</i>	<i>l.splice(T* pos, & x, T* i)</i>	inserts an element pointed to by <i>i</i> from list <i>x</i> before position <i>pos</i> and removes the element from <i>x</i> . It takes constant time. <i>i</i> is a valid dereferenceable iterator of <i>x</i> . The result is unchanged if <i>pos</i> == <i>i</i> or <i>pos</i> == ++ <i>i</i> .
<i>void</i> <i>void</i>	<i>l.splice(iterator pos, & x, iterator first, iterator last)</i> <i>l.splice(T* pos, & x, T* first, T* last)</i>	inserts elements in the range [<i>first</i> , <i>last</i>) before position <i>pos</i> and removes the elements from <i>x</i> . It takes constant time if & <i>x</i> == & <i>l</i> ; otherwise, it takes linear time. [<i>first</i> , <i>last</i>) is a valid range in <i>x</i> . <i>Precondition</i> : <i>pos</i> is not in the range [<i>first</i> , <i>last</i>).
<i>void</i>	<i>l.remove(T value)</i>	erases all elements <i>e</i> in the list <i>l</i> for which <i>e</i> == <i>value</i> . It is stable. <i>Precondition</i> : a suitable <i>operator</i> == for the type <i>T</i> .
<i>void</i>	<i>l.unique()</i>	erases all but the first element from every consecutive group of equal elements in the list <i>l</i> . <i>Precondition</i> : a suitable <i>operator</i> == for the type <i>T</i> .
<i>void</i>	<i>l.merge(& x)</i>	merges the list <i>x</i> into the list <i>l</i> and <i>x</i> becomes empty. It is stable. <i>Precondition</i> : Both lists are increasingly sorted. A suitable <i>operator</i> < for the type <i>T</i> .
<i>void</i>	<i>l.reverse()</i>	reverses the order of the elements in <i>l</i> in linear time.
<i>void</i>	<i>l.sort()</i>	sorts the list <i>l</i> according to the <i>operator</i> < in time $O(n \log n)$ where $n = \text{size}()$. It is stable. <i>Precondition</i> : a suitable <i>operator</i> < for the type <i>T</i> .

Example

```
#include <CGAL/basic.h>
#include <cassert>
#include <algorithm>
#include <CGAL/In_place_list.h>

using CGAL::In_place_list_base;

struct item : public In_place_list_base<item> {
    int key;
    item() {}
    item( const item& i ) : In_place_list_base<item>(i), key(i.key) {}
    item( int i ) : key(i) {}
    bool operator== (const item& i) const { return key == i.key;}
    bool operator!= (const item& i) const { return ! (*this == i);}
    bool operator== (int i) const          { return key == i;}
    bool operator!= (int i) const          { return ! (*this == i);}
    bool operator<  (const item& i) const { return key < i.key;}
};

int main() {
    typedef CGAL::In_place_list<item,true> List;
    List l;
    item* p = new item(1);
    l.push_back(*p);
    l.push_back(*new item(2));
    l.push_front(*new item(3));
    l.push_front(*new item(4));
    l.push_front(*new item(2));
    List::iterator i = l.begin();
    ++i;
    l.insert(i, *new item(5));
    l.insert(p, *new item(5));
    int a[7] = {2,5,4,3,5,1,2};
    bool ok = std::equal(l.begin(), l.end(), a);
    assert(ok);
    l.sort();
    l.unique();
    assert(l.size() == 5);
    int b[5] = {1,2,3,4,5};
    ok = std::equal(l.begin(), l.end(), b);
    assert(ok);
    return 0;
}
```

File: examples/STL_Extension/in_place_list_prog.cpp

CGAL::Compact_container_base

Definition

The class *Compact_container_base* can be used as a base class for your own type *T*, so that *T* can be used directly within *Compact_container*<*T*, *Allocator*>. This class stores a *void ** pointer only for this purpose, so it may not be the most memory efficient way to achieve this goal. The other ways are to provide in *T* the necessary member functions so that the template *Compact_container_traits*<*T*> works, or to specialize it for the particular type *T* that you want to use.

```
#include <CGAL/Compact_container.h>
```

Operations

<code>void*</code>	<code>ccb.for_compact_container() const</code>	Returns the pointer necessary for <i>Compact_container_traits</i> < <i>T</i> >.
<code>void*&</code>	<code>ccb.for_compact_container()</code>	Returns a reference to the pointer necessary for <i>Compact_container_traits</i> < <i>T</i> >.

CGAL::Compact_container_traits<T>

Definition

The traits class *Compact_container_traits*<*T*> provides the way to access the internal pointer required for *T* to be used in a *Compact_container*<*T*, *Allocator*>. Note that this pointer needs to be accessible even when the object is not constructed, which means it has to reside in the same memory place as *T*.

You can specialize this class for your own type *T* if the default template is not suitable.

You can also use *Compact_container_base* as base class for your own types *T* to make them usable with the default *Compact_container_traits*<*T*>.

```
#include <CGAL/Compact_container.h>
```

Parameters

T is any type providing the following member functions:

```
void *t.for_compact_container() const;
void *&t.for_compact_container();
```

Operations

<i>static void*</i>	<i>cct.pointer(const T &t)</i>	Returns the pointer hold by <i>t</i> . The template version defines this function as: <i>return t.for_compact_container();</i>
<i>static void*&</i>	<i>cct.pointer(T &t)</i>	Returns a reference to the pointer hold by <i>t</i> . The template version defines this function as: <i>return t.for_compact_container();</i>

CGAL::Compact_container<T, Allocator>

Definition

An object of the class *Compact_container*<*T*, *Allocator*> is a container of objects of type *T*. It matches all the standard requirements for reversible containers, except that the complexity of its iterator increment and decrement operations is not always guaranteed to be amortized constant time.

This container is not a standard *sequence* nor *associative* container, which means the elements are stored in no particular order, and it is not possible to specify a particular place in the iterator sequence where to insert new objects. However, all dereferenceable iterators are still valid after calls to *insert()* and *erase()*, except those that have been erased (it behaves similarly to *std::list*).

The main feature of this container is that it is very memory efficient : its memory size is $N * \text{sizeof}(T) + o(N)$, where *N* is the maximum size that the container has had in its past history, its *capacity()* (the memory of erased elements is not deallocated until destruction of the container or a call to *clear()*). This container has been developed in order to store large graph-like data structures like the triangulation and the halfedge data structures.

It supports bidirectional iterators and allows a constant time amortized *insert()* operation. You cannot specify where to insert new objects (i.e. you don't know where they will end up in the iterator sequence, although *insert()* returns an iterator pointing to the newly inserted object). You can erase any element with a constant time complexity.

Summary of the differences with *std::list* : it is more compact in memory since it doesn't store two additional pointers for the iterator needs. It doesn't deallocate elements until the destruction or *clear()* of the container. The iterator does not have constant amortized time complexity for the increment and decrement operations in all cases, only when not too many elements have not been freed (i.e. when the *size()* is close to the *capacity()*). Iterating from *begin()* to *end()* takes $O(\text{capacity}())$ time, not *size()*. In the case where the container has a small *size()* compared to its *capacity()*, we advise to "defragment the memory" by copying the container if the iterator performance is needed.

The iterators themselves can be used as *T*, they provide the necessary functions to be used by *Compact_container_traits*<*T*>.

```
#include <CGAL/Compact_container.h>
```

Parameters

The parameter *T* is required to have a copy constructor and an assignment operator. It also needs to provide access to an internal pointer via *Compact_container_traits*<*T*>.

The equality test and the relational order require the operators == and < for *T* respectively.

The parameter *Allocator* has to match the standard allocator requirements, with value type *T*. This parameter has the default value *CGAL_ALLOCATOR*(*T*).

Types

Compact_container<*T*, *Allocator*>:: *value_type*

Compact_container<*T*, *Allocator*>:: *reference*

Compact_container<T, Allocator>:: const_reference
Compact_container<T, Allocator>:: pointer
Compact_container<T, Allocator>:: const_pointer
Compact_container<T, Allocator>:: size_type
Compact_container<T, Allocator>:: difference_type

Compact_container<T, Allocator>:: iterator
Compact_container<T, Allocator>:: const_iterator
Compact_container<T, Allocator>:: reverse_iterator
Compact_container<T, Allocator>:: const_reverse_iterator

Compact_container<T, Allocator>:: allocator_type

Creation

Compact_container<T, Allocator> c(Allocator a = Allocator());

introduces an empty container, eventually specifying a particular allocator *a* as well.

template <class InputIterator>

Compact_container<T, Allocator> c(InputIterator first, InputIterator last, Allocator a = Allocator());

a container with copies from the range [*first,last*), eventually specifying a particular allocator.

Compact_container<T, Allocator> c(cc);

copy constructor. Each item in *cc* is copied. The allocator is copied. The iterator order is preserved.

Compact_container<T, Allocator> & c = cc

assignment. Each item in *cc* is copied. The allocator is copied. Each item in *c* is deleted. The iterator order is preserved.

void c.swap(&cc)

swaps the contents of *c* and *cc* in constant time complexity. No exception is thrown.

Access Member Functions

iterator c.begin() returns a mutable iterator referring to the first element in *c*.

const_iterator c.begin() const returns a constant iterator referring to the first element in *c*.

iterator c.end() returns a mutable iterator which is the past-end-value of *c*.

<i>const_iterator</i>	<i>c.end()</i> <i>const</i>	returns a constant iterator which is the past-end-value of <i>c</i> .
<i>reverse_iterator</i>	<i>c.rbegin()</i>	
<i>const_reverse_iterator</i>	<i>c.rbegin()</i> <i>const</i>	
<i>reverse_iterator</i>	<i>c.rend()</i>	
<i>const_reverse_iterator</i>	<i>c.rend()</i> <i>const</i>	
<i>bool</i>	<i>c.empty()</i>	returns <i>true</i> iff <i>c</i> is empty.
<i>size_type</i>	<i>c.size()</i>	returns the number of items in <i>c</i> .
<i>size_type</i>	<i>c.max_size()</i>	returns the maximum possible size of the container <i>c</i> .
<i>size_type</i>	<i>c.capacity()</i>	returns the total number of elements that <i>c</i> can hold without requiring reallocation.
<i>Allocator</i>	<i>c.get_allocator()</i>	returns the allocator.
Insertion		
<i>iterator</i>	<i>c.insert(T t)</i>	inserts a copy of <i>t</i> in <i>c</i> and returns the iterator pointing to it.
<i>template <class InputIterator></i> <i>void</i>	<i>c.insert(InputIterator first, InputIterator last)</i>	inserts the range [<i>first</i> , <i>last</i>) in <i>c</i> .
<i>template <class InputIterator></i> <i>void</i>	<i>c.assign(InputIterator first, InputIterator last)</i>	erases all the elements of <i>c</i> , then inserts the range [<i>first</i> , <i>last</i>) in <i>c</i> .
<i>template < typename T1 ></i> <i>iterator</i>	<i>c.construct_insert(T1 t1)</i>	constructs an object of type <i>T</i> with the constructor that takes <i>t1</i> as argument, inserts it in <i>c</i> , and returns the iterator pointing to it. The same constructor exists for up to nine arguments.

Removal

<i>void</i>	<i>c.erase(iterator pos)</i>	removes the item pointed by <i>pos</i> from <i>c</i> .
<i>void</i>	<i>c.erase(iterator first, iterator last)</i>	removes the items from the range [<i>first</i> , <i>last</i>) from <i>c</i> .
<i>void</i>	<i>c.clear()</i>	all items in <i>c</i> are deleted, and the memory is deallocated. After this call, <i>c</i> is in the same state as if just default constructed.

Special Operation

<i>void</i>	<i>c.merge(&cc)</i>	adds the items of <i>cc</i> to the end of <i>c</i> and <i>cc</i> becomes empty. The time complexity is $O(c.capacity() - c.size())$. <i>Precondition:</i> <i>cc</i> must not be the same as <i>c</i> , and the allocators of <i>c</i> and <i>cc</i> need to be compatible : <i>c.get_allocator() == cc.get_allocator()</i> .
-------------	--------------------------	--

Comparison Operations

<i>bool</i>	<i>c == cc</i>	test for equality: Two containers are equal, iff they have the same size and if their corresponding elements are equal.
<i>bool</i>	<i>c != cc</i>	test for inequality: returns $!(c == cc)$.
<i>bool</i>	<i>c < cc</i>	compares in lexicographical order.
<i>bool</i>	<i>c > cc</i>	returns $cc < c$.
<i>bool</i>	<i>c <= cc</i>	returns $!(c > cc)$.
<i>bool</i>	<i>c >= cc</i>	returns $!(c < cc)$.

CGAL::Multiset<Type,Compare,Allocator>

Definition

An instance s of the parametrized data type *Multiset*<*Type*,*Compare*,*Allocator*> is a multi-set of elements of type *Type*, represented as a red-black tree (see [CLRS01, Chapter 13] for an excellent introduction to red-black trees). The main difference between *Multiset*<*Type*,*Compare*,*Allocator*> and STL's *multiset* is that the latter uses a less-than functor with a Boolean return type, while our *Multiset*<*Type*,*Compare*,*Allocator*> class is parameterized by a comparison functor *Compare* that returns the three-valued *Comparison_result* (namely it returns either *SMALLER*, *EQUAL*, or *LARGER*). It is thus possible to maintain the underlying red-black tree with less invocations of the comparison functor. This leads to a speedup of about 5% even if we maintain a set of integers. When each comparison of two elements of type *Type* is an expensive operation (for example, when they are geometric entities represented using exact arithmetic), the usage of a three-valued comparison functor can lead to considerable decrease in the running times.

Moreover, *Multiset*<*Type*,*Compare*,*Allocator*> allows the insertion of an element into the set given its *exact* position, and not just using an insertion hint, as done by *std::multiset*. This can further reduce the running times, as additional comparison operations can be avoided.

In addition, the *Multiset*<*Type*,*Compare*,*Allocator*> guarantees that the order of elements sent to the comparison functor is fixed. For example, if we insert a new element x into the set (or erase an element from the set), then we always invoke *Compare*() (x , y) (and never *Compare*() (y , x)), where y is an element already stored in the set. This behavior, not supported by *std::multiset*, is sometimes crucial for designing more efficient comparison predicates.

Multiset<*Type*,*Compare*,*Allocator*> also allows for look-up of keys whose type may differ from *Type*, as long as users supply a comparison functor *CompareKey*, where *CompareKey*() (key , y) returns the three-valued *Comparison_result* (key is the look-up key and y is an element of type *Type*). Indeed, it is very convenient to look-up equivalent objects in the set given just by their key. We note however that it is also possible to use a key of type *Type* and to employ the default *Compare* functor for the look-up, as done when using the *std::multiset* class.

— advanced —

Finally, *Multiset*<*Type*,*Compare*,*Allocator*> introduces the *catenate*() and *split*() functions. The first function operates on s and accepts a second set s' , such that the maximum element in s is not greater than the minimal element in s' , and concatenates s' to s . The second function splits s into two sets, one containing all the elements that are less than a given key, and the other contains all elements greater than (or equal to) this key.

— advanced —

Parameters

The *Multiset* class-template has three parameters:

- *Type* — the type of the stored elements.
- *Compare* — the comparison-functor type. This type should provide the following operator for comparing two *Type* elements, namely:

```
Comparison_result operator() (const Type& t1, const Type& t2) const;
```

The *CGAL::Compare*<*Type*> functor is used by default. In this case, *Type* must support an equality operator (*operator==*) and a less-than operator (*operator<*).

- *Allocator* — the allocator type.
CGAL_ALLOCATOR is used by default.

```
#include <CGAL/Multiset.h>
```

Assertions

The assertion and precondition flags for the *Multiset* class use *MULTISET* in their names (i.e., *CGAL_MULTISET_NO_ASSERTIONS* and *CGAL_MULTISET_NO_PRECONDITIONS*).

Types

In compliance with STL, the types *value_type* and *key_type* (both equivalent to *Type*), *reference* and *const_reference* (reference to a value-type), *key_compare* and *value_compare* (both equivalent to *Compare*), *size_type* and *difference_type* are defined as well.

```
Multiset<Type,Compare,Allocator>:: iterator  
Multiset<Type,Compare,Allocator>:: const_iterator
```

bi-directional iterators for the elements stored in the set.

```
Multiset<Type,Compare,Allocator>:: reverse_iterator  
Multiset<Type,Compare,Allocator>:: const_reverse_iterator
```

reverse bi-directional iterators for the elements stored in the set.

Creation

```
Multiset<Type,Compare,Allocator> s;
```

creates an an empty set *s* that uses a default comparison functor.

```
Multiset<Type,Compare,Allocator> s( Compare comp);
```

creates an an empty set *s* that uses the given comparison functor *comp*.

```
template <class InputIterator>  
Multiset<Type,Compare,Allocator> s( InputIterator first, InputIterator last, Compare comp = Compare());
```

creates a set *s* containing all elements in the range [*first*, *last*), that uses the comparison functor *comp*.

```
Multiset<Type,Compare,Allocator> s( other);
```

copy constructor.

```
Multiset<Type,Compare,Allocator>  
s = other
```

assignment operator.

<i>void</i>	<i>s.swap(& other)</i>	swaps the contents of <i>s</i> with those of the other set.
-------------	-----------------------------	---

Access Member Functions

<i>Compare</i>	<i>s.key_comp()</i>	the comparison functor used.
<i>Compare</i>	<i>s.value_comp()</i>	the comparison functor used (same as above). Both functions have a non-const version that return a reference to the comparison functor.

<i>bool</i>	<i>s.empty()</i>	returns <i>true</i> if the set is empty, <i>false</i> otherwise.
-------------	------------------	--

<i>size_t</i>	<i>s.size()</i>	returns the number of elements stored in the set.
---------------	-----------------	---

<i>size_t</i>	<i>s.max_size()</i>	returns the maximal number of elements the set can store (same as <i>size()</i>).
---------------	---------------------	--

<i>iterator</i>	<i>s.begin()</i>	returns an iterator pointing to the first element stored in the set (a <i>const</i> version is also available).
-----------------	------------------	---

<i>iterator</i>	<i>s.end()</i>	returns an iterator pointing beyond the last element stored in the set (a <i>const</i> version is also available).
-----------------	----------------	--

<i>reverse_iterator</i>	<i>s.rbegin()</i>	returns a reverse iterator pointing beyond the last element stored in the set (a <i>const</i> version is also available).
-------------------------	-------------------	---

<i>reverse_iterator</i>	<i>s.rend()</i>	returns a reverse iterator pointing to the first element stored in the set (a <i>const</i> version is also available).
-------------------------	-----------------	--

Comparison Operations

<i>bool</i>	<i>s == other</i>	returns <i>true</i> if the sequences of elements in the two sets are pairwise equal (using the comparison functor).
-------------	-------------------	---

<i>bool</i>	<i>s < other</i>	returns <i>true</i> if the element sequence in <i>s</i> is lexicographically smaller than the element sequence of <i>other</i> .
-------------	---------------------	--

Insertion Methods

<i>iterator</i>	<i>s.insert(Type x)</i>	inserts the element <i>x</i> into the set and returns an iterator pointing to the newly inserted element.
-----------------	--------------------------	---

<i>template <class InputIterator></i>	<i>s.insert(InputIterator first, InputIterator last)</i>	
<i>void</i>		inserts all elements in the range <i>[first, last)</i> into the set.

<i>iterator</i>	<i>s.insert(iterator position, Type x)</i>	inserts the element <i>x</i> with a given iterator used as a hint for the position of the new element. It Returns an iterator pointing to the newly inserted element.
-----------------	---	---

<i>iterator</i>	<i>s.insert_before(iterator position, Type x)</i>	inserts the element <i>x</i> as the predecessor of the element at the given position. <i>Precondition:</i> The operation does not violate the set order — that is, <i>x</i> is not greater than the element pointed by <i>position</i> and not less than its current predecessor.
-----------------	--	--

<i>iterator</i>	<i>s.insert_after(iterator position, Type x)</i>	inserts the element <i>x</i> as the successor of the element at the given position. <i>Precondition:</i> The operation does not violate the set order — that is, <i>x</i> is not less than the element pointed by <i>position</i> and not greater than its current successor.
-----------------	---	--

Removal Methods

<i>size_t</i>	<i>s.erase(Type x)</i>	erases all elements equivalent to <i>x</i> from the set and returns the number of erased elements.
---------------	-------------------------	--

<i>void</i>	<i>s.erase(iterator position)</i>	erases the element pointed by <i>position</i> .
-------------	------------------------------------	---

<i>void</i>	<i>s.clear()</i>	clears the set (erases all stored elements).
-------------	------------------	--

Look-up Methods

All methods listed in this section can also accept a *Type* element as a look-up key. In this case, it is not necessary to supply a *CompareKey* functor, as the *Compare* functor will be used by default.

<i>template <class Key, class CompareKey></i> <i>iterator</i>	<i>s.find(Key key, CompareKey comp_key)</i>	searches for the an element equivalent to <i>key</i> in the set. If the set contains objects equivalent to <i>key</i> , it returns an iterator pointing to the first one. Otherwise, <i>end()</i> is returned (a <i>const</i> version is also available).
--	--	---

template <class Key, class CompareKey>

size_t *s.count(Key key, CompareKey comp_key)*

returns the number of elements equivalent to *key* in the set.

template <class Key, class CompareKey>
iterator *s.lower_bound(Key key, CompareKey comp_key)*

returns an iterator pointing to the first element in the set that is not less than *key*. If all set elements are less than *key*, *end()* is returned (a *const* version is also available).

template <class Key, class CompareKey>
iterator *s.upper_bound(Key key, CompareKey comp_key)*

returns an iterator pointing to the first element in the set that is greater than *key*. If no set element is greater than *key*, *end()* is returned (a *const* version is also available).

template <class Key, class CompareKey>
std::pair<iterator,iterator>

s.equal_range(Key key, CompareKey comp_key)

returns the range of set elements equivalent to the given key, namely (*lower_bound(key)*, *upper_bound(key)*) (a *const* version is also available).

template <class Key, class CompareKey>
std::pair<iterator,bool>

s.find_lower(Key key, CompareKey comp_key)

returns a pair comprised of *lower_bound(key)* and a Boolean flag indicating whether this iterator points to an element equivalent to the given key (a *const* version is also available).

— advanced —

Special Operations

void *s.replace(iterator position, Type x)*

replaces the element stored at the given position with *x*.
Precondition: The operation does not violate the set order — that is, *x* is not less than *position*'s predecessor and not greater than its successor.

void *s.swap(iterator pos1, iterator pos2)*

swaps places between the two elements given by *pos1* and *pos2*.

Precondition: The operation does not violate the set order — that is, *pos1* and *pos2* store equivalent elements.

void *s.catenate(Self& s_prime)*

concatenates all elements in *s_prime* into *s* and clears *s_prime*. All iterators to *s* and to *s_prime* remain valid.

Precondition: The maximal element in *s* is not greater than the minimal element in *s_prime*.

template <class Key, class CompareKey>
void *s.split(Key key, CompareKey comp_key, Self& s_prime)*

splits *s* such that it contains all elements that are less than the given *key* and such that *s_prime* contains all other elements.

Precondition: *s_prime* is initially empty.

void *s.split(iterator position, Self& s_prime)*

splits *s* such that it contains all set elements in the range [*begin*, *position*) and such that *s_prime* contains all elements in the range [*position*, *end*()).

Precondition: *s_prime* is initially empty.

————— *advanced* —————

Implementation

Multiset uses a proprietary implementation of a red-black tree data-structure. The red-black tree invariants guarantee that the height of a tree containing n elements is $O(\log n)$ (more precisely, it is bounded by $2 \log_2 n$). As a consequence, all methods that accept an element and need to locate it in the tree (namely *insert*(*x*), *erase*(*x*), *find*(*x*), *count*(*x*), *lower_bound*(*x*), *upper_bound*(*x*), *find_lower*(*x*) and *equal_range*(*x*)) take $O(\log n)$ time and perform $O(\log n)$ comparison operations.

On the other hand, the set operations that accept a position iterator (namely *insert_before*(*pos*, *x*), *insert_after*(*pos*, *x*) and *erase*(*pos*)) are much more efficient as they can be performed at a *constant* amortized cost (see [GS78] and [Tar83] for more details). More important, these set operations require *no* comparison operations. Therefore, it is highly recommended to maintain the set via iterators to the stored elements, whenever possible. The function *insert*(*pos*, *x*) is safer to use, but it takes amortized $O(\min\{d, \log n\})$ time, where d is the distance between the given position and the true position of *x*. In addition, it always performs at least two comparison operations.

————— *advanced* —————

The *catenate*() and *split*() functions are also very efficient, and can be performed in $O(\log n)$ time, where n is the total number of elements in the sets, and without performing any comparison operations (see [Tar83] for the details). Note however that the size of two sets resulting from a split operation is initially unknown, as it is

impossible to compute it in less than linear time. Thus, the first invocation of *size()* on such a set takes linear time, and *not* constant time.

————— *advanced* —————

The design is derived from the STL *multiset* class-template (see, e.g. [MS96]), where the main differences between the two classes are highlighted in the class definition above.

CGAL::predecessor

Definition

The function *predecessor* returns the previous iterator, i.e. the result of *operator--* on a bidirectional iterator.

```
#include <CGAL/algorithm.h>
```

```
template <class BidirectionalIterator>
```

```
BidirectionalIterator predecessor( BidirectionalIterator it)
```

returns *--it*.

See Also

CGAL::successor [page 3008](#)

CGAL::successor

Definition

The function *successor* returns the next iterator, i.e. the result of *operator++* on a forward iterator.

```
#include <CGAL/algorithm.h>
```

```
template <class ForwardIterator>
```

```
ForwardIterator    successor( ForwardIterator it)
```

returns $++it$.

See Also

CGAL::predecessor page [3007](#)

CGAL::copy_n

Definition

The function *copy_n* copies *n* items from an input iterator to an output iterator which is useful for possibly infinite sequences of random geometric objects.¹

```
#include <CGAL/algorithm.h>
```

```
template <class InputIterator, class Size, class OutputIterator>
OutputIterator copy_n( InputIterator first, Size n, OutputIterator result)
```

copies the first *n* items from *first* to *result*. Returns the value of *result* after inserting the *n* items.

See Also

CGAL::Counting_iterator<*Iterator*, *Value*> page [3015](#)

¹The STL release June 13, 1997, from SGI contains an equivalent function, but it is not part of the ISO standard.

CGAL::min_max_element

Definition

The function *min_max_element* computes the minimal and the maximal element of a range. It is modeled after the STL functions *min_element* and *max_element*. The advantage of *min_max_element* compared to calling both STL functions is that one only iterates once over the sequence. This is more efficient especially for large and/or complex sequences.

```
#include <CGAL/algorithm.h>
```

```
template < class ForwardIterator >
std::pair< ForwardIterator, ForwardIterator >
```

```
min_max_element( ForwardIterator first, ForwardIterator last)
```

returns a pair of iterators where the first component refers to the minimal and the second component refers to the maximal element in the range $[first, last)$. The ordering is defined by *operator<* on the value type of *ForwardIterator*.

```
template < class ForwardIterator, class CompareMin, class CompareMax >
std::pair< ForwardIterator, ForwardIterator >
```

```
min_max_element( ForwardIterator first,
                  ForwardIterator last,
                  CompareMin comp_min,
                  CompareMax comp_max)
```

returns a pair of iterators where the first component refers to the minimal and the second component refers to the maximal element in the range $[first, last)$.

Requirement: *CompareMin* and *CompareMax* are adaptable binary function objects: $VT \times VT \rightarrow bool$ where *VT* is the value type of *ForwardIterator*.

Example

The following example program computes the minimal and maximal element of the sequence (3, 6, 5). Hence the output is *min* = 3, *max* = 6.

```
#include <CGAL/algorithm.h>
#include <vector>
#include <iostream>

using std::vector;
using std::pair;
using std::cout;
```

```

using std::endl;
using CGAL::min_max_element;

int main()
{
    vector< int > v;
    v.push_back(3);
    v.push_back(6);
    v.push_back(5);
    typedef std::vector< int >::iterator iterator;
    pair< iterator, iterator > p = min_max_element(v.begin(), v.end());
    cout << "min = " << *p.first << ", max = " << *p.second << endl;
    return 0;
}

```

File: examples/STL_Extension/min_max_element_example_noheader.cpp

CGAL::Emptyset_iterator

Definition

The class defines an *OutputIterator* that ignores everything written to it. One can think of it as being connected to `/dev/null`.

```
#include <CGAL/iterator.h>
```

Is Model for the Concepts

OutputIterator

Creation

```
Emptyset_iterator i;
```

default constructor.

CGAL::Const_oneset_iteratorpage ??

CGAL::Oneset_iterator<T>

Definition

The class *Oneset_iterator*<T> defines an *BidirectionalIterator* that always refers to one specific object of type *T*. Internally, *Oneset_iterator*<T> stores a pointer to the referred object.

```
#include <CGAL/iterator.h>
```

Is Model for the Concepts

BidirectionalIterator

Creation

```
Oneset_iterator<T> i( T& t);
```

creates an iterator referring to *t*.

See Also

CGAL::Emptyset_iterator page [3012](#)

CGAL::Const_oneset_iterator page ??

CGAL::Const_onese_iterator<T>

Definition

The class *Const_onese_iterator*<*T*> defines an *RandomAccessIterator* that always refers to a copy of a specific object of type *T*.

```
#include <CGAL/iterator.h>
```

Is Model for the Concepts

RandomAccessIterator

Creation

```
Const_onese_iterator<T> i( T& t);
```

creates an iterator that always refers to some copy of *t*. The copy is constructed by invoking *T*'s copy constructor and remains constant during *i*'s lifetime.

See Also

CGAL::Emptyset_iterator page [3012](#)
CGAL::Onese_iterator page ??

CGAL::Counting_iterator<Iterator, Value>

Definition

The iterator adaptor *Counting_iterator*<*Iterator*, *Value*> adds a counter to the internal iterator of type *Iterator* and defines equality of two instances in terms of this counter. It can be used to create finite sequences of possibly infinite sequences of values from input iterators.

#include <CGAL/iterator.h>

Is Model for the Concepts

InputIterator

Requirements

Iterator is a model for *InputIterator*.

Creation

Counting_iterator<*Iterator*, *Value*> *i*(*std::size_t* *n* = 0);

initializes the internal counter to *n* and *i* has a singular value.

Counting_iterator<*Iterator*, *Value*> *i*(*Iterator* *j*, *std::size_t* *n* = 0);

initializes the internal counter to *n* and *i* to *j*.

See Also

CGAL::copy_n page [3009](#)

CGAL::Insert_iterator<Container>

Definition

The output iterator *Insert_iterator*<*Container*> is similar to *std::insert_iterator*, but differs in that it calls the *insert()* function of the container without the iterator additional argument.

```
#include <CGAL/iterator.h>
```

Is Model for the Concepts

OutputIterator

Requirements

Container provides a member function *insert(const Container::const_reference&)*.

Creation

```
Insert_iterator<Container> i( Container &c);
```

initializes the internal container reference to *c*.

There is also a global function similar to *std::inserter*:

```
template < class Container >
```

```
Insert_iterator<Container>
```

```
inserter( Container &x)
```

Constructs *Insert_iterator*<*Container*>(x).

CGAL::N_step_adaptor<I,int N>

Definition

The adaptor *N_step_adaptor*<*I*,int *N*> changes the step width of the iterator or circulator class *I* to *N*. It is itself an iterator or circulator respectively. The behavior is undefined if the adaptor is used on a range [*i*, *j*) where *j* − *i* is not a multiple of *n*.

#include <CGAL/iterator.h>

Creation

N_step_adaptor<*I*,int *N*> *i*(*I* *j*); down cast.

CGAL::Filter_iterator<Iterator, Predicate>

Definition

The iterator adaptor *Filter_iterator*<*Iterator*, *Predicate*> acts as a filter on a given range. Whenever the iterator is in- or decremented, it ignores all iterators for which the given *Predicate* is true. The iterator category is the same as for *Iterator*.

Note: Boost also provides the same functionality via the *boost::filter_iterator* class. Unfortunately, the semantics chosen for accepting or rejecting elements based on the predicate's result are opposite as the semantic chosen here. What is more, the argument of the predicate is different: the predicate used with *boost::filter_iterator* must take the value type of the iterator, as argument, and not the iterator itself.

```
#include <CGAL/iterator.h>
```

Requirements

- *Iterator* is a model for *ForwardIterator*.
- *Predicate* is a functor: $Iterator \rightarrow bool$.

Creation

```
Filter_iterator<Iterator, Predicate> i;
```

```
Filter_iterator<Iterator, Predicate> i( Iterator e, Predicate p, Iterator c = e);
```

creates an iterator which filters values according to *p*. Initializes by taking the first valid iterator (according to *p*), starting at *c*, and stopping at *e* if none is found.

There is also a global function to help the use of *Filter_iterator*<*Iterator*, *Predicate*>:

```
template < class Iterator, class Predicate >
```

```
inline Filter_iterator< Iterator, Predicate >
```

```
filter_iterator( Iterator e, Predicate p, Iterator c = e)
```

Constructs *Filter_iterator*<*Iterator*, *Predicate*>(e, p, c).

CGAL::Join_input_iterator_1<Iterator, Creator>

Definition

The class *Join_input_iterator_1*<*Iterator*, *Creator*> joins an iterator and a creator function object. The result is again an iterator (of the same iterator category type as the original iterator) that reads an object from the stream and applies a creator function object to that object.

```
#include <CGAL/iterator.h>
```

Is Model for the Concepts

InputIterator

Types

Join_input_iterator_1<*Iterator*, *Creator*>::*value_type*

typedef to *Creator*::*result_type*.

Creation

```
Join_input_iterator_1<Iterator, Creator> join( Iterator i, Creator creator);
```

creates a join iterator from the given iterator *i* and the functor *creator*. Applies *creator* to each item read from *i*.

```
Join_input_iterator_1<Iterator, Creator> join( Iterator i);
```

creates a join iterator from the given iterator *i* and a default constructed instance of *Creator*. The latter instance is applied to each item read from *i*.

See Also

CGAL::Creator_1<*Arg*, *Result*> page [3069](#)

CGAL::Inverse_index<IC>

Definition

The class *Inverse_index*<IC> constructs an inverse index for a given range $[i, j)$ of two iterators or circulators of type *IC*. The first element *I* in the range $[i, j)$ has the index 0. Consecutive elements are numbered incrementally. The inverse index provides a query for a given iterator or circulator *k* to retrieve its index number. *Precondition*: The iterator or circulator must be either of the random access category or the dereference operator must return stable and distinguishable addresses for the values, e.g. proxies or non-modifiable iterator with opaque values will not work.

```
#include <CGAL/iterator.h>
```

Creation

<i>Inverse_index</i> <IC> <i>inverse</i> ;	invalid index.
<i>Inverse_index</i> <IC> <i>inverse</i> (<i>IC</i> <i>i</i>);	empty inverse index initialized to start at <i>i</i> .
<i>Inverse_index</i> <IC> <i>inverse</i> (<i>IC</i> <i>i</i> , <i>IC</i> <i>j</i>);	inverse index initialized with range $[i, j)$.

Operations

<i>std::size_t</i> <i>inverse</i> [<i>IC</i> <i>k</i>]	returns inverse index of <i>k</i> . <i>Precondition</i> : <i>k</i> has been stored in the inverse index.
<i>void</i> <i>inverse.push_back</i> (<i>IC</i> <i>k</i>)	adds <i>k</i> at the end of the indices.

Implementation

For random access iterators or circulators, it is done in constant time by subtracting *i*. For other iterator categories, an STL *map* is used, which results in a $\log j - i$ query time. The comparisons are done using the operator *operator<* on pointers.

CGAL::Random_access_value_adaptor<IC,T>

Definition

The class *Random_access_value_adaptor*<*IC*,*T*> provides a random access for data structures. It is derived from *Random_access_adaptor*<*IC*>. Instead of returning iterators from the *operator[]* methods, it returns the dereferenced value of the iterator. The iterator or circulator of the data structure are of type *IC*. Their value type is *T*.

```
#include <CGAL/iterator.h>
```

Operations

Creation and operations see *Random_access_adaptor*<*IC*>, with the exception of:

T& *random_access*[*size_type* *n*] returns a reference to the *n*-th item.
Precondition: n < number of items in *random_access*.

CGAL::swap_1

Definition

The function *swap_1* is used to swap the arguments of a functor. The result is a functor f' that calls the original functor f with the first two arguments exchanged, that is $f'(x, y, \dots) = f(y, x, \dots)$.

```
#include <CGAL/functional.h>
```

```
template < class F >
```

```
typename Swap<F,1>::Type
```

```
swap_1( F f)
```

returns a functor equivalent to f , but where the first two arguments are exchanged.

Requirement: F is a model for *AdaptableFunctor* with arity $2 \leq ar \leq 5$.

See Also

AdaptableFunctor page [3042](#)

CGAL::swap_2

Definition

The function *swap_2* is used to swap the arguments of a functor. The result is a functor f' that calls the original functor f with the second and third argument exchanged, that is $f'(x, y, z, \dots) = f(x, z, y, \dots)$.

```
#include <CGAL/functional.h>
```

```
template < class F >
```

```
typename Swap<F,2>::Type
```

```
swap_2( F f)
```

returns a functor equivalent to f , but where the second and third argument are exchanged.

Requirement: F is a model for *AdaptableFunctor* with arity $3 \leq ar \leq 5$.

CGAL::swap_3

Definition

The function `swap_3` is used to swap the arguments of a functor. The result is a functor f' that calls the original functor f with the third and fourth argument exchanged, that is $f'(w, x, y, z, \dots) = f(w, x, z, y, \dots)$.

```
#include <CGAL/functional.h>
```

```
template < class F >
```

```
typename Swap<F,3>::Type
```

```
swap_3( F f)
```

returns a functor equivalent to f , but where the third and fourth argument are exchanged.

Requirement: F is a model for *AdaptableFunctor* with arity $4 \leq ar \leq 5$.

CGAL::swap_4

Definition

The function *swap_4* is used to swap the arguments of a functor. The result is a functor f' that calls the original functor f with the fourth and fifth argument exchanged, that is $f'(v, w, x, y, z) = f(v, w, x, z, y)$.

```
#include <CGAL/functional.h>
```

```
template < class F >
```

```
typename Swap<F,4>::Type
```

```
    swap_4( F f)
```

returns a functor equivalent to f , but where the fourth and fifth argument are exchanged.

Requirement: F is a model for *AdaptableFunctor* with arity 5.

CGAL::bind_1

Definition

The function *bind_1* is used to bind the first argument of a functor to some specific value. The result is a functor that takes one argument less and calls the original functor where the first argument is set to the bound value.

```
#include <CGAL/functional.h>
```

```
template < class F, class A >
typename Bind< F, A, 1 >::Type    bind_1( F f, A a)
```

returns a functor equivalent to *f*, but where the first argument is bound (fixed) to *a*.

Requirement: F is a model for *AdaptableFunctor*.

<i>AdaptableFunctor</i>	page 3042

CGAL::bind_2

Definition

The function *bind_2* is used to bind the second argument of a functor to some specific value. The result is a functor that takes one argument less and calls the original functor where the second argument is set to the bound value.

```
#include <CGAL/functional.h>
```

```
template < class F, class A >
typename Bind< F, A, 2 >::Type    bind_2( F f, A a)
```

returns a functor equivalent to *f*, but where the second argument is bound (fixed) to *a*.

Requirement: F is a model for *AdaptableFunctor*.

CGAL::bind_3

Definition

The function *bind_3* is used to bind the third argument of a functor to some specific value. The result is a functor that takes one argument less and calls the original functor where the third argument is set to the bound value.

```
#include <CGAL/functional.h>
```

```
template < class F, class A >
typename Bind< F, A, 3 >::Type    bind_3( F f, A a)
```

returns a functor equivalent to *f*, but where the third argument is bound (fixed) to *a*.

Requirement: F is a model for *AdaptableFunctor*.

CGAL::bind_4

Definition

The function *bind_4* is used to bind the fourth argument of a functor to some specific value. The result is a functor that takes one argument less and calls the original functor where the fourth argument is set to the bound value.

```
#include <CGAL/functional.h>
```

```
template < class F, class A >
typename Bind< F, A, 4 >::Type    bind_4( F f, A a)
```

returns a functor equivalent to *f*, but where the fourth argument is bound (fixed) to *a*.

Requirement: F is a model for *AdaptableFunctor*.

<i>AdaptableFunctor</i>	page 3042

CGAL::bind_5

Definition

The function *bind_5* is used to bind the fifth argument of a functor to some specific value. The result is a functor that takes one argument less and calls the original functor where the fifth argument is set to the bound value.

```
#include <CGAL/functional.h>
```

```
template < class F, class A >
typename Bind< F, A, 5 >::Type    bind_5( F f, A a)
```

returns a functor equivalent to *f*, but where the fifth argument is bound (fixed) to *a*.

Requirement: F is a model for *AdaptableFunctor*.

CGAL::compare_to_less

Definition

The function *compare_to_less* is used to change a functor returning a *Comparison_result* to one which returns a *bool*. The returned functor will return *true* iff the original one returns *SMALLER*.

```
#include <CGAL/function_objects.h>
```

```
template < class F >
Compare_to_less< F >          compare_to_less( F f)
```

returns a functor equivalent to *f*, but which returns a *bool* instead of a *Comparison_result*.

Requirement: *F* is a model for *AdaptableFunctor*.

See Also

CGAL::Compare_to_less<F> page [3040](#)
AdaptableFunctor page [3042](#)

CGAL::compose

Definition

The function *compose* is used to compose functors f_0, \dots, f_n into each other, thereby creating a new functor f . The first argument f_0 always denotes the base functor, for which the remaining functors f_1, \dots, f_n provide the arguments. If we denote the arity of a functor f by $ar(f)$, then $ar(f) = \sum_{i=1}^n ar(f_i)$, i.e., the arguments of f are distributed among f_1, \dots, f_n according to their respective arity. Between one and three functors can be composed into the base functor, giving raise to a functor of arity at most five.

As an example, consider a binary functor f_0 and two functors f_1 and f_2 , with arity three and two, respectively. Composing f_1 and f_2 into f_0 yields a new functor

$$f : (x_0, x_1, x_2, x_3, x_4) \mapsto f_0(f_1(x_0, x_1, x_2), f_2(x_3, x_4))$$

with arity five.

```
#include <CGAL/functional.h>
```

```
template < class F0, class F1 >
typename Compose< F0, F1 >::Type
```

```
compose( F0 f0, F1 f1)
```

returns the functor $f0(f1(\cdot))$ with the same arity as $f1$.

Requirement: $f0$ is unary function (arity 1). $f0$ and $f1$ are models for *AdaptableFunctor*.

```
template < class F0, class F1, class F2 >
typename Compose< F0, F1, F2 >::Type
```

```
compose( F0 f0, F1 f1, F2 f2)
```

returns the functor $f0(f1(\cdot), f2(\cdot))$ with arity equal to $ar(f1) + ar(f2)$.

Requirement: $f0$ is binary function (arity 2). $f0, f1$, and $f2$ are models for *AdaptableFunctor*.

```
template < class F0, class F1, class F2, class F3 >
typename Compose< F0, F1, F2, F3 >::Type
```

```
compose( F0 f0, F1 f1, F2 f2, F3 f3)
```

returns the functor $f0(f1(\cdot), f2(\cdot), f3(\cdot))$ with arity equal to $ar(f1) + ar(f2) + ar(f3)$.

Requirement: $f0$ is ternary function (arity 3). $f0, f1, f2$, and $f3$ are models for *AdaptableFunctor*.

See Also

<i>CGAL::Compose</i> < <i>F0</i> , <i>F1</i> , <i>F2</i> , <i>F3</i> >	page 3039
<i>CGAL::compose_shared</i>	page 3035
<i>AdaptableFunctor</i>	page 3042

CGAL::compose_shared

Definition

The function *compose_shared* is used to compose functors f_0, \dots, f_n into each other, thereby creating a new functor f . The first argument f_0 always denotes the base functor, for which the remaining functors f_1, \dots, f_n provide the arguments. Contrary to the function *compose*, the arguments of f are not split among f_1, \dots, f_n , but instead shared by all the functors. Therefore, all the functors f_1, \dots, f_n must have the same arity, which is also the arity of the composed functor f . Two or three functors can be composed into the base functor, giving raise to a functor of arity at most five.

As an example, consider a binary functor f_0 and two binary functors f_1 and f_2 . Composing f_1 and f_2 into f_0 yields a new binary functor

$$f : (x_0, x_1) \mapsto f_0(f_1(x_0, x_1), f_2(x_0, x_1)) .$$

```
#include <CGAL/functional.h>
```

```
template < class F0, class F1, class F2 >
typename Compose_shared< F0, F1, F2 >::Type
```

```
compose_shared( F0 f0, F1 f1, F2 f2)
```

returns the functor $f0(f1(\cdot), f2(\cdot))$ with the same arity as $f1$ (and $f2$).

Requirement: $f0$ is *AdaptableFunctor* of arity 2. $f1$ and $f2$ are *AdaptableFunctors* having the same arity.

```
template < class F0, class F1, class F2, class F3 >
typename Compose_shared< F0, F1, F2, F3 >::Type
```

```
compose_shared( F0 f0, F1 f1, F2 f2, F3 f3)
```

returns the functor $f0(f1(\cdot), f2(\cdot), f3(\cdot))$ with the same arity as $f1$ (and $f2, f3$).

Requirement: $f0$ is *AdaptableFunctor* of arity 3. $f1, f2$, and $f3$ are *AdaptableFunctors* having the same arity.

CGAL::negate

Definition

The function *negate* is a functor adaptor. For a given functor *f*, it creates a new functor *f'* which is the negation of *f*. That is, $f' = !f$.

```
#include <CGAL/functional.h>
```

```
template < typename F >
```

```
typename Compose< std::logical_not<typename F::result_type>, F >::Type
```

```
    negate( F f)
```

returns the functor $!f$ with the same arity as *f*.

Requirement: *f* is a model for *AdaptableFunctor*. Unary negation is defined for *F::result_type*.

CGAL::Swap<F,i>

Definition

The class *Swap*<*F*,*i*> is used to specify the type of a functor where the arguments *i* and *i+I* have been swapped. The class is used in conjunction with the *swap* functions.

```
#include <CGAL/functional.h>
```

Types

$Swap\langle F, i \rangle :: Type$ the functor type.

Notes

This class encapsulates differences in implementation across various platforms. But in any case, *Type* refers to a model of *AdaptableFunctor*.

CGAL::Compose<F0,F1,F2,F3>

Definition

The class *Compose*<*F0*,*F1*,*F2*,*F3*> is used to specify the type of a composed functor, i.e., the functor that results from composing functors of type *F1*, *F2*, and *F3*, into a functor of type *F0*. The arguments *F2* and *F3* are optional, such that between two and four functors can participate in the composition. The class is used in conjunction with the *compose* function; see there for an explanation on how exactly the functors are combined.

```
#include <CGAL/functional.h>
```

Types

Compose<*F0*,*F1*,*F2*,*F3*>:: *Type* type of the composed functor.

Notes

This class encapsulates the differences in implementation of the composers across various platforms. But in any case, *Type* refers to a model of *AdaptableFunctor*.

See Also

CGAL::composepage [3033](#)
AdaptableFunctorpage [3042](#)

Definition

The class *Compare_to_less* $\langle F \rangle$ is used to convert a functor which returns a *Comparison_result* to a predicate (returning bool) : it will return true iff the return value of *F* is *SMALLER*. The class is used in conjunction with the *compare_to_less* function; see there for an explanation on how exactly the functors are combined.

```
#include <CGAL/function_objects.h>
```

Types

Compare_to_less<F>:: Type type of the composed functor.

AdaptableFunctor

Definition

The concept `AdaptableFunctor` defines an adaptable functor, i.e., a functor that can be used with function object adaptors such as binders and composers.

Types

AdaptableFunctor:: result_type

return type of the functor.

AdaptableFunctor:: Arity

defines the arity of the functor, i.e., the number of arguments it takes. The class has to be a specialization of `CGAL::Arity_tag<int>`, where the template parameter corresponds to the arity of the functor, e.g. `CGAL::Arity_tag<2>` for binary functors.

Operations

type0 *f.operator()(type1 a1, type2 a2, ..., typen an) const*

(as many arguments as defined by *Arity*)
returns *f(a1,...an)*.

Notes

Alternatively, the type *Arity* can be defined in a specialization of `CGAL::Arity_traits<>` for the functor. This is useful where existing classes cannot be changed easily, e.g. the functors from the standard library.

Has Models

All functors from the standard library, and all functors from the lower dimensional CGAL kernels. For all kernel functors, their arity is listed in the documentation. Some (few) of them are overloaded with operators of different arities; in this case one of these arities has been chosen as default arity. If you want to adapt the functor to a different arity, use the functor adaptor `CGAL::Set_arity<F,a>`.

AdaptableUnaryFunction

Definition

A model of concept *AdaptableUnaryFunction*, is an *AdaptableFunctor* with nested typedefs that define its argument type and result type.
The *Arity* is set to *CGAL::Arity_tag<1>*.

Refines

AdaptableFunctor

Types

```
typedef result_type      result_type;
typedef first_argument_type
                        argument_type;
```

```
typedef Arity_tag<1>    Arity;
```

Operations

```
result_type      operator()( argument_type x)
```

CGAL::Arity_tag<int>

Definition

The class *Arity_tag<int>* is used to define the arity of a functor, i.e., the number of arguments it takes. It is used as a compile time tag only, that is objects of this type are never created anywhere.

```
#include <CGAL/functional_base.h>
```

See Also

AdaptableFunctor.....page [3042](#)

CGAL::Arity_traits<F>

Definition

The class *Arity_traits*<*F*> is used to define the arity of a functor class *F*, i.e., the number of arguments it takes. It is used as a compile time tag only, that is objects of this type are never created anywhere. Specializations of *Arity_traits*<*F*> can be defined, where existing functors cannot be changed easily to contain their *Arity* type.

```
#include <CGAL/functional_base.h>
```

```
Arity_traits<F>:: Arity          F::Arity
```

See Also

AdaptableFunctor.....page [3042](#)
 CGAL::Arity_tag<int>.....page [3046](#)

Definition

The class *Set_arity* $\langle F, a \rangle$ is used to specify the type of a functor of type F whose arity has been set explicitly to a . The class is used in conjunction with the *set_arity* functions.

```
#include <CGAL/functional.h>
```

Types

$Set_arity\langle F, a \rangle :: Type$ the functor type.

Notes

This class encapsulates the differences in implementation across various platforms. But in any case, *Type* refers to a model of *AdaptableFunctor* with arity *a*.

CGAL::set_arity_0

Definition

The function *set_arity_0* is used to set the arity of a functor to zero. The result is a functor that takes no arguments and calls the original functor with no arguments.

```
#include <CGAL/functional.h>
```

```
template < class F >
Set_arity< F, 0 >::Type    set_arity_0( F f)
```

returns a functor equivalent to *f*, but which has arity zero.

Requirement: F is a model for *AdaptableFunctor*.

See Also

<i>CGAL::set_arity_5</i>	page 3054
<i>AdaptableFunctor</i>	page 3042

CGAL::set_arity_1

Definition

The function *set_arity_1* is used to set the arity of a functor to one. The result is a functor that takes one argument and calls the original functor with this argument.

```
#include <CGAL/functional.h>
```

```
template < class F >
Set_arity< F, 1 >::Type    set_arity_1( F f)
```

returns a functor equivalent to *f*, but which has arity one.

Requirement: F is a model for *AdaptableFunctor*.

<i>CGAL::set_arity_5</i>	page 3054
<i>AdaptableFunctor</i>	page 3042

CGAL::set_arity_2

Definition

The function *set_arity_2* is used to set the arity of a functor to two. The result is a functor that takes two arguments and calls the original functor with these arguments.

```
#include <CGAL/functional.h>
```

```
template < class F >
Set_arity< F, 2 >::Type    set_arity_2( F f)
```

returns a functor equivalent to *f*, but which has arity two.

Requirement: F is a model for *AdaptableFunctor*.

<i>AdaptableFunctor</i>	page 3042

CGAL::set_arity_3

Definition

The function *set_arity_3* is used to set the arity of a functor to three. The result is a functor that takes three arguments and calls the original functor with these arguments.

```
#include <CGAL/functional.h>
```

```
template < class F >
Set_arity< F, 3 >::Type    set_arity_3( F f)
```

returns a functor equivalent to *f*, but which has arity three.

Requirement: F is a model for *AdaptableFunctor*.

CGAL::set_arity_4

Definition

The function *set_arity_4* is used to set the arity of a functor to four. The result is a functor that takes four arguments and calls the original functor with these arguments.

```
#include <CGAL/functional.h>
```

```
template < class F >
Set_arity< F, 4 >::Type    set_arity_4( F f)
```

returns a functor equivalent to *f*, but which has arity four.

Requirement: F is a model for *AdaptableFunctor*.

<i>AdaptableFunctor</i>	page 3042

CGAL::set_arity_5

Definition

The function *set_arity_5* is used to set the arity of a functor to five. The result is a functor that takes five arguments and calls the original functor with these arguments.

```
#include <CGAL/functional.h>
```

```
template < class F >
Set_arity< F, 5 >::Type    set_arity_5( F f)
```

returns a functor equivalent to *f*, but which has arity five.

Requirement: F is a model for *AdaptableFunctor*.

Projection_object

Definition

The concept `Projection_object` is modeled after the STL concept *UnaryFunction*, but takes also care of (const) references.

Projection_object:: argument_type argument type.

Projection_object:: result_type result type.

Creation

Projection_object o; default constructor.

Operations

result_type& *o.operator()(argument_type &) const*
const result_type& *o.operator()(const argument_type &) const*

Has Models

<i>CGAL::Identity<Value></i>	page 3056
<i>CGAL::Dereference<Value></i>	page 3057
<i>CGAL::Get_address<Value></i>	page 3058
<i>CGAL::Cast_function_object<Arg, Result></i>	page 3059
<i>CGAL::Project_vertex<Node></i>	page 3060
<i>CGAL::Project_facet<Node></i>	page 3061
<i>CGAL::Project_point<Node></i>	page 3062
<i>CGAL::Project_normal<Node></i>	page 3063
<i>CGAL::Project_plane<Node></i>	page 3064
<i>CGAL::Project_next<Node></i>	page 3065
<i>CGAL::Project_prev<Node></i>	page 3066
<i>CGAL::Project_next_opposite<Node></i>	page 3067
<i>CGAL::Project_opposite_prev<Node></i>	page 3068

CGAL::Identity<Value>

Definition

The class *Identity*<Value> represents the identity function on *Value*.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object [page 3055](#)

Identity<Value>::*argument_type* typedef to *Value*.

Identity<Value>::*result_type* typedef to *Value*.

Creation

Identity<Value> *o*; default constructor.

Operations

result_type& *o.operator()*(*argument_type*& *x*) *const*

returns *x*.

const result_type& *o.operator()*(*const argument_type*& *x*) *const*

returns *x*.

CGAL::Dereference<Value>

Definition

The class *Dereference*<Value> dereferences a pointer (*operator**).

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object page [3055](#)

Dereference<Value>::*argument_type* typedef to *Value**.

Dereference<Value>::*result_type* typedef to *Value*.

Creation

Dereference<Value> *o*; default constructor.

Operations

result_type& *o.operator()*(*argument_type*& *x*) *const*

returns **x*.

const result_type& *o.operator()*(*const argument_type*& *x*) *const*

returns **x*.

CGAL::Get_address<Value>

Definition

The class *Get_address<Value>* gets the address of an lvalue (*operator&*).

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object page [3055](#)

Get_address<Value>:: argument_type typedef to *Value*.

Get_address<Value>:: result_type typedef to *Value**.

Creation

Get_address<Value> o; default constructor.

Operations

result_type& *o.operator()(argument_type& x) const*

returns *&x*.

const result_type& *o.operator()(const argument_type& x) const*

returns *&x*.

CGAL::Cast_function_object<Arg, Result>

Definition

The class *Cast_function_object*<Arg, Result> applies a C-style type cast to its argument.

#include <CGAL/function_objects.h>

Is Model for the Concepts

Projection_object page [3055](#)

Cast_function_object<Arg, Result>::*argument_type*

typedef to Arg.

Cast_function_object<Arg, Result>::*result_type*

typedef to Result.

Creation

Cast_function_object<Arg, Result> o; default constructor.

Operations

result_type& o.operator()(*argument_type*& x) const

returns (Result)x.

const *result_type*& o.operator()(const *argument_type*& x) const

returns (Result)x.

CGAL::Project_vertex<Node>

Definition

The class *Project_vertex<Node>* calls the member function *vertex()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object page [3055](#)

Project_vertex<Node>:: argument_type typedef to *Node*.

Project_vertex<Node>:: result_type typedef to *Node::Vertex*.

Creation

Project_vertex<Node> o; default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.vertex()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.vertex()*.

CGAL::Project_facet<Node>

Definition

The class `Project_facet<Node>` calls the member function `facet()` on an instance of type `Node`.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object

page 3055

Project_facet<Node>:: argument_type typedef to *Node*.

Project_facet<Node>::result_type typedef to *Node::Facet*.

Creation

Project_facet<*Node*> o; default constructor.

Operations

$$result_type\& \quad o.operator()(argument_type\& n) \text{ const}$$

returns *n.facet()*.

```
const result_type&      o.operator()( const argument_type& n) const
```

returns *n.facet()*.

CGAL::Project_point<Node>

Definition

The class *Project_point*<*Node*> calls the member function *point()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object page [3055](#)

Project_point<*Node*>::*argument_type* typedef to *Node*.

Project_point<*Node*>::*result_type* typedef to *Node*::*Point*.

Creation

Project_point<*Node*> *o*; default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.point()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.point()*.

CGAL::Project_normal<Node>

Definition

The class *Project_normal*<*Node*> calls the member function *normal()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object

page 3055

Project_normal<*Node*>:: *argument_type* typedef to *Node*.

Project_normal<Node>:: *result_type* typedef to *Node*::*Normal*.

Creation

Project_normal<Node> o; default constructor.

Operations

$$result_type\& \quad o.operator()(argument_type\& n) \text{ const}$$

returns *n.normal()*.

```
const result_type&      o.operator()( const argument_type& n) const
```

returns *n.normal()*.

CGAL::Project_plane<Node>

Definition

The class *Project_plane<Node>* calls the member function *plane()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object page [3055](#)

Project_plane<Node>:: argument_type typedef to *Node*.

Project_plane<Node>:: result_type typedef to *Node::Plane*.

Creation

Project_plane<Node> o; default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n.plane()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n.plane()*.

CGAL::Project_next<Node>

Definition

The class *Project_next<Node>* calls the member function *next()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object page [3055](#)

Project_next<Node>:: argument_type typedef to *Node**.

Project_next<Node>:: result_type typedef to *Node**.

Creation

Project_next<Node> o; default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n->next()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n->next()*.

CGAL::Project_prev<Node>

Definition

The class *Project_prev<Node>* calls the member function *prev()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object page [3055](#)

Project_prev<Node>:: argument_type typedef to *Node**.

Project_prev<Node>:: result_type typedef to *Node**.

Creation

Project_prev<Node> o; default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n->prev()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n->prev()*.

CGAL::Project_next_opposite<Node>

Definition

The class *Project_next_opposite<Node>* calls the member functions *next()*->*opposite()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object page [3055](#)

Project_next_opposite<Node>:: argument_type typedef to *Node**.

Project_next_opposite<Node>:: result_type typedef to *Node**.

Creation

Project_next_opposite<Node> *o*; default constructor.

Operations

result_type& *o.operator()(argument_type& n) const*

returns *n->next()*->*opposite()*.

const result_type& *o.operator()(const argument_type& n) const*

returns *n->next()*->*opposite()*.

CGAL::Project_opposite_prev<Node>

Definition

The class *Project_opposite_prev*<Node> calls the member functions *opposite()*->*prev()* on an instance of type *Node*.

```
#include <CGAL/function_objects.h>
```

Is Model for the Concepts

Projection_object [page 3055](#)

Project_opposite_prev<Node>:: *argument_type*

typedef to *Node**.

Project_opposite_prev<Node>:: *result_type*

typedef to *Node**.

Creation

Project_opposite_prev<Node> *o*;

default constructor.

Operations

result_type& *o.operator()*(*argument_type*& *n*) *const*

returns *n*->*opposite()*->*prev()*.

const result_type& *o.operator()*(*const argument_type*& *n*) *const*

returns *n*->*opposite()*->*prev()*.

CGAL::Creator_1<Arg, Result>

Definition

The concept *Creator₁* $\langle Arg, Result \rangle$ defines types and operations for creating objects from one argument.

```
#include <CGAL/function_objects.h>
```

Requirements

Arg is convertible to *Result*.

Creator_1 $\langle Arg, Result \rangle :: argument_type$ type of argument.

Creator_1<Arg, Result>:: result_type type of object to create.

result_type *c.operator()*(*argument_type a*) *const*

returns *result_type(a)*.

CGAL::Creator_2<Arg1, Arg2, Result>

Definition

The concept *Creator_2<Arg1, Arg2, Result>* defines types and operations for creating objects from two arguments.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a corresponding constructor.

Creator_2<Arg1, Arg2, Result>:: argument1_type type of first argument.

Creator_2<Arg1, Arg2, Result>:: argument2_type type of second argument.

Creator_2<Arg1, Arg2, Result>:: result_type type of object to create.

result_type *c.operator()(argument_type1 a1, argument_type2 a2) const*
returns *result_type(a1, a2)*.

CGAL::Creator_3<Arg1, Arg2, Arg3, Result>

Definition

The concept *Creator_3<Arg1, Arg2, Arg3, Result>* defines types and operations for creating objects from three arguments.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a corresponding constructor.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: argument1_type
```

type of first argument.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: argument2_type
```

type of second argument.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: argument3_type
```

type of third argument.

```
Creator_3<Arg1, Arg2, Arg3, Result>:: result_type
```

type of object to create.

```
result_type    c.operator()( argument_type1 a1, argument_type2 a2, argument_type3 a3) const
```

returns *result_type(a1, a2, a3)*.

CGAL::Creator_4<Arg1, Arg2, Arg3, Arg4, Result>

Definition

The concept *Creator_4<Arg1, Arg2, Arg3, Arg4, Result>* defines types and operations for creating objects from four arguments.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a corresponding constructor.

```
Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument1_type
```

type of first argument.

```
Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument2_type
```

type of second argument.

```
Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument3_type
```

type of third argument.

```
Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: argument4_type
```

type of 4th argument.

```
Creator_4<Arg1, Arg2, Arg3, Arg4, Result>:: result_type
```

type of object to create.

```
result_type    c.operator()(
                argument_type1 a1,
                argument_type2 a2,
                argument_type3 a3,
                argument_type4 a4) const
```

returns *result_type(a1, a2, a3, a4)*.

CGAL::Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>

Definition

The concept *Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>* defines types and operations for creating objects from five arguments.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a corresponding constructor.

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument1_type
```

type of first argument.

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument2_type
```

type of second argument.

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument3_type
```

type of third argument.

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument4_type
```

type of 4th argument.

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: argument5_type
```

type of 5th argument.

```
Creator_5<Arg1, Arg2, Arg3, Arg4, Arg5, Result>:: result_type
```

type of object to create.

```
result_type    c.operator()(
                argument_type1 a1,
                argument_type2 a2,
                argument_type3 a3,
                argument_type4 a4,
                argument_type5 a5) const
```

returns *result_type(a1, a2, a3, a4, a5)*.

CGAL::Creator_uniform_2<Arg, Result>

Definition

The concept *Creator_uniform_2*<Arg, Result> defines types and operations for creating objects from two arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from two *Arg* arguments.

Creator_uniform_2<Arg, Result>:: *argument_type*

type of arguments; typedef to *Arg*.

Creator_uniform_2<Arg, Result>:: *result_type* type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2) const*

returns *result_type(a1, a2)*.

CGAL::Creator_uniform_3<Arg, Result>

Definition

The concept *Creator_uniform_3*<Arg, Result> defines types and operations for creating objects from three arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from three *Arg* arguments.

Creator_uniform_3<Arg, Result>:: *argument_type*

type of arguments; typedef to *Arg*.

Creator_uniform_3<Arg, Result>:: *result_type* type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2, argument_type a3) const*

returns *result_type(a1, a2, a3)*.

CGAL::Creator_uniform_4<Arg, Result>

Definition

The concept *Creator_uniform_4<Arg, Result>* defines types and operations for creating objects from four arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from four *Arg* arguments.

Creator_uniform_4<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_4<Arg, Result>:: result_type type of object to create; typedef to *Result*.

```
result_type      c.operator()(
                    argument_type a1,
                    argument_type a2,
                    argument_type a3,
                    argument_type a4) const
```

returns *result_type(a1, a2, a3, a4)*.

CGAL::Creator_uniform_5<Arg, Result>

Definition

The concept *Creator_uniform_5<Arg, Result>* defines types and operations for creating objects from five arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from five *Arg* arguments.

```
Creator_uniform_5<Arg, Result>:: argument_type
                                     type of arguments; typedef to Arg.
```

```
Creator_uniform_5<Arg, Result>:: result_type    type of object to create; typedef to Result.
```

```
result_type    c.operator()(
                argument_type a1,
                argument_type a2,
                argument_type a3,
                argument_type a4,
                argument_type a5) const
                                     returns result_type(a1, a2, a3, a4, a5).
```

CGAL::Creator_uniform_6<Arg, Result>

Definition

The concept *Creator_uniform_6<Arg, Result>* defines types and operations for creating objects from six arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from six *Arg* arguments.

Creator_uniform_6<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_6<Arg, Result>:: result_type type of object to create; typedef to *Result*.

```
result_type      c.operator()(
                    argument_type a1,
                    argument_type a2,
                    argument_type a3,
                    argument_type a4,
                    argument_type a5,
                    argument_type a6) const
```

returns *result_type(a1, a2, a3, a4, a5, a6)*.

CGAL::Creator_uniform_7<Arg, Result>

Definition

The concept *Creator_uniform_7*<Arg, Result> defines types and operations for creating objects from seven arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from seven *Arg* arguments.

```
Creator_uniform_7<Arg, Result>:: argument_type
                                     type of arguments; typedef to Arg.
```

```
Creator_uniform_7<Arg, Result>:: result_type  type of object to create; typedef to Result.
```

```
result_type  c.operator()(
               argument_type a1,
               argument_type a2,
               argument_type a3,
               argument_type a4,
               argument_type a5,
               argument_type a6,
               argument_type a7) const
                                     returns result_type(a1, a2, a3, a4, a5, a6, a7).
```

CGAL::Creator_uniform_8<Arg, Result>

Definition

The concept *Creator_uniform_8<Arg, Result>* defines types and operations for creating objects from eight arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from eight *Arg* arguments.

Creator_uniform_8<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_8<Arg, Result>:: result_type type of object to create; typedef to *Result*.

```
result_type      c.operator()(
                    argument_type a1,
                    argument_type a2,
                    argument_type a3,
                    argument_type a4,
                    argument_type a5,
                    argument_type a6,
                    argument_type a7,
                    argument_type a8) const
```

returns *result_type(a1, a2, a3, a4, a5, a6, a7, a8)*.

CGAL::Creator_uniform_9<Arg, Result>

Definition

The concept *Creator_uniform_9<Arg, Result>* defines types and operations for creating objects from nine arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from nine *Arg* arguments.

Creator_uniform_9<Arg, Result>:: argument_type

type of arguments; typedef to *Arg*.

Creator_uniform_9<Arg, Result>:: result_type type of object to create; typedef to *Result*.

```
result_type      c.operator()(
    argument_type a1,
    argument_type a2,
    argument_type a3,
    argument_type a4,
    argument_type a5,
    argument_type a6,
    argument_type a7,
    argument_type a8,
    argument_type a9) const
```

returns *result_type(a1, a2, a3, a4, a5, a6, a7, a8, a9)*.

CGAL::Creator_uniform_d<Arg, Result>

Definition

The concept *Creator_uniform_d*<*Arg*, *Result*> defines types and operations for creating objects from two arguments of the same type.

```
#include <CGAL/function_objects.h>
```

Requirements

Result defines a constructor from three arguments: one *d* dimension and two *Arg* arguments.

Creator_uniform_d<*Arg*, *Result*>:: *argument_type*

type of arguments; typedef to *Arg*.

Creator_uniform_d<*Arg*, *Result*>:: *result_type* type of object to create; typedef to *Result*.

result_type *c.operator()(argument_type a1, argument_type a2) const*

returns *result_type*(*d*, *a1*, *a2*).

CGAL::Twotuple<T>

Definition

The *Twotuple*<*T*> class stores a homogeneous (same type) pair of objects of type *T*. A *Twotuple*<*T*> is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

```
#include <CGAL/Twotuple.h>
```

Requirements

T must be *Assignable*.

Types

```
typedef T      value_type;
```

Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element

Creation

<i>Twotuple</i> < <i>T</i> > <i>t</i> ;	introduces a <i>Twotuple</i> < <i>T</i> > using the default constructor of the elements.
---	--

<i>Twotuple</i> < <i>T</i> > <i>t</i> (<i>T</i> <i>x</i> , <i>T</i> <i>y</i>);	constructs a <i>Twotuple</i> < <i>T</i> > such that <i>e0</i> is constructed from <i>x</i> and <i>e1</i> is constructed from <i>y</i> .
--	---

CGAL::Threetuple<T>

Definition

The *Threetuple*<*T*> class stores a homogeneous (same type) triple of objects of type *T*. A *Threetuple*<*T*> is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

```
#include <CGAL/Threetuple.h>
```

Requirements

T must be *Assignable*.

Types

```
typedef T      value_type;
```

Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element
<i>T</i>	<i>e2</i> ;	third element

Creation

<i>Threetuple</i> < <i>T</i> > <i>t</i> ;	introduces a <i>Threetuple</i> < <i>T</i> > using the default constructor of the elements.
---	--

<i>Threetuple</i> < <i>T</i> > <i>t</i> (<i>T</i> <i>x</i> , <i>T</i> <i>y</i> , <i>T</i> <i>z</i>);	constructs a <i>Threetuple</i> < <i>T</i> > such that <i>e0</i> is constructed from <i>x</i> , <i>e1</i> is constructed from <i>y</i> and <i>e2</i> is constructed from <i>z</i> .
--	--

CGAL::Fourtuple<T>

Definition

The *Fourtuple<T>* class stores a homogeneous (same type) fourtuple of objects of type *T*. A *Fourtuple<T>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

```
#include <CGAL/Fourtuple.h>
```

Requirements

T must be *Assignable*.

Types

```
typedef T      value_type;
```

Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element
<i>T</i>	<i>e2</i> ;	third element
<i>T</i>	<i>e3</i> ;	fourth element

Creation

<i>Fourtuple<T></i> <i>t</i> ;	introduces a <i>Fourtuple<T></i> using the default constructor of the elements.
--------------------------------------	---

<i>Fourtuple<T></i> <i>t</i> (<i>T</i> <i>x</i> , <i>T</i> <i>y</i> , <i>T</i> <i>z</i> , <i>T</i> <i>t</i>);	constructs a <i>Fourtuple<T></i> such that <i>e0</i> is constructed from <i>x</i> , <i>e1</i> from <i>y</i> , <i>e2</i> from <i>z</i> and <i>e3</i> from <i>t</i> .
---	---

CGAL::Sixtuple<T>

Definition

The *Sixtuple*<*T*> class stores a homogeneous (same type) sextuple of objects of type *T*. A *Sixtuple*<*T*> is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

```
#include <CGAL/Sixtuple.h>
```

Requirements

T must be *Assignable*.

Types

```
typedef T      value_type;
```

Variables

<i>T</i>	<i>e0</i> ;	first element
<i>T</i>	<i>e1</i> ;	second element
<i>T</i>	<i>e2</i> ;	third element
<i>T</i>	<i>e3</i> ;	fourth element
<i>T</i>	<i>e4</i> ;	fifth element
<i>T</i>	<i>e5</i> ;	sixth element

Creation

<i>Sixtuple</i> < <i>T</i> > <i>t</i> ;	introduces a <i>Sixtuple</i> < <i>T</i> > using the default constructor of the elements.
---	--

<i>Sixtuple</i> < <i>T</i> > <i>t</i> (<i>T</i> <i>x</i> , <i>T</i> <i>y</i> , <i>T</i> <i>z</i> , <i>T</i> <i>t</i> , <i>T</i> <i>u</i> , <i>T</i> <i>v</i>);	constructs a <i>Sixtuple</i> < <i>T</i> > such that <i>e0</i> is constructed from <i>x</i> , <i>e1</i> from <i>y</i> , <i>e2</i> from <i>z</i> , <i>e3</i> from <i>t</i> , <i>e4</i> from <i>u</i> and <i>e5</i> from <i>v</i> .
--	--

CGAL::Triple<T1, T2, T3>

Definition

The Triple class is an extension of *std::pair*. *Triple<T1, T2, T3>* is a heterogeneous triple: it holds one object of type *T1*, one of type *T2*, and one of type *T3*. A *Triple<T1, T2, T3>* is much like a container, in that it "owns" its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

```
#include <CGAL/utility.h>
```

Requirements

T1, *T2* and *T3* must be *Assignable*. Additional operations have additional requirements.

Types

```
typedef T1    first_type;
typedef T2    second_type;
typedef T3    third_type;
```

Variables

<i>T1</i>	<i>first</i> ;	first element
<i>T2</i>	<i>second</i> ;	second element
<i>T3</i>	<i>third</i> ;	third element

Creation

<i>Triple<T1, T2, T3> t</i> ;	introduces a triple using the default constructor of the three elements.
-------------------------------------	--

<i>Triple<T1, T2, T3> t(T1 x, T2 y, T3 z);</i>	constructs a triple such that <i>first</i> is constructed from <i>x</i> , <i>second</i> is constructed from <i>y</i> , and <i>third</i> is constructed from <i>z</i> .
---	--

<i>template <class U, class V, class W></i> <i>Triple<T1, T2, T3> t(U u, V v, W w);</i>	constructs a triple such that <i>first</i> is constructed from <i>u</i> , <i>second</i> is constructed from <i>v</i> , and <i>third</i> is constructed from <i>w</i> . <i>Requirement:</i> Proper conversion operators exist from <i>U</i> to <i>T1</i> , <i>V</i> to <i>T2</i> , and <i>W</i> to <i>T3</i> .
---	--

```
template <class T1, class T2, class T3>
```

bool $x < y$

The comparison operator. It uses lexicographic comparison: the return value is true if the first element of x is less than the first element of y , and false if the first element of y is less than the first element of x . If neither of these is the case, then it returns true if the second element of x is less than the second element of y , and false if the second element of y is less than the second element of x . If neither of these is the case, then it returns the result of comparing the third elements of x and y . This operator may only be used if $T1$, $T2$ and $T3$ define the comparison operator.

template <*class* $T1$, *class* $T2$, *class* $T3$ >
bool $x == y$

The equality operator. The return value is true if and only the first elements of x and y are equal, the second elements of x and y are equal, and the third elements of x and y are equal. This operator may only be used if $T1$, $T2$ and $T3$ define the equality operator.

template <*class* $T1$, *class* $T2$, *class* $T3$ >
Triple< $T1$, $T2$, $T3$ >

make_triple($T1$ x , $T2$ y , $T3$ z)

Equivalent to *Triple*< $T1$, $T2$, $T3$ >(x , y , z).

CGAL::Quadruple<T1, T2, T3, T4>

Definition

The Quadruple class is an extension of *std::pair*. *Quadruple*<*T1*, *T2*, *T3*, *T4*> is a heterogeneous quadruple: it holds one object of type *T1*, one of type *T2*, one of type *T3*, and one of type *T4*. A *Quadruple*<*T1*, *T2*, *T3*, *T4*> is much like a container, in that it “owns” its elements. It is not actually a model of container, though, because it does not support the standard methods (such as iterators) for accessing the elements of a container.

```
#include <CGAL/utility.h>
```

Requirements

T1, *T2*, *T3* and *T4* must be *Assignable*. Additional operations have additional requirements.

Types

```
typedef T1    first_type;
typedef T2    second_type;
typedef T3    third_type;
typedef T4    fourth_type;
```

Variables

<i>T1</i>	<i>first</i> ;	first element
<i>T2</i>	<i>second</i> ;	second element
<i>T3</i>	<i>third</i> ;	third element
<i>T4</i>	<i>fourth</i> ;	fourth element

Creation

Quadruple<*T1*, *T2*, *T3*, *T4*> *t*;

introduces a quadruple using the default constructor of the four elements.

Quadruple<*T1*, *T2*, *T3*, *T4*> *t*(*T1* *x*, *T2* *y*, *T3* *z*, *T4* *w*);

constructs a quadruple such that *first* is constructed from *x*, *second* is constructed from *y*, *third* is constructed from *z*, and *fourth* is constructed from *w*.

```
template <class U, class V, class W, class X>
Quadruple<T1, T2, T3, T4> t( U u, V v, W w, X x );
```

constructs a quadruple such that *first* is constructed from *u*, *second* is constructed from *v*, *third* is constructed from *w*, and *fourth* is constructed from *x*.

Requirement: Proper conversion operators exist from *U* to *T1*, *V* to *T2*, *W* to *T3*, and *X* to *T4*.

template <class *T1*, class *T2*, class *T3*, class *T4*>

bool *x* < *y*

The comparison operator. It uses lexicographic comparison: the return value is true if the first element of *x* is less than the first element of *y*, and false if the first element of *y* is less than the first element of *x*. If neither of these is the case, then it returns true if the second element of *x* is less than the second element of *y*, and false if the second element of *y* is less than the second element of *x*. If neither of these is the case, then it returns true if the third element of *x* is less than the third element of *y*, and false if the third element of *y* is less than the third element of *x*. If neither of these is the case, then it returns the result of comparing the fourth elements of *x* and *y*. This operator may only be used if *T1*, *T2*, *T3*, and *T4* define the comparison operator.

template <class *T1*, class *T2*, class *T3*, class *T4*>

bool *x* == *y*

The equality operator. The return value is true if and only the first elements of *x* and *y* are equal, the second elements of *x* and *y* are equal, the third elements of *x* and *y* are equal, and the fourth elements of *x* and *y* are equal. This operator may only be used if *T1*, *T2*, *T3*, and *T4* define the equality operator.

template <class *T1*, class *T2*, class *T3*, class *T4*>

Quadruple<*T1*, *T2*, *T3*, *T4*>

make_quadruple(*T1* *x*, *T2* *y*, *T3* *z*, *T4* *w*)

Equivalent to *Quadruple*<*T1*, *T2*, *T3*, *T4*>(*x*, *y*, *z*, *w*).

CGAL::Boolean_tag<bool value>

Definition

Depending on *bool value* the class *Boolean_tag<bool value>* indicates that something is *true* or *false* respectively.

```
#include <CGAL/tags.h>
```

Constants

```
static const bool      value;
```

56.6 Arrangements as Models of the Boost Graph Concept	3108
56.6.1 Example for the Arrangement as Graph	3108
56.6.2 Example for the Dual of an Arrangement as Graph	3112

Many geometric data structures can be interpreted as graphs, as they consist of vertices, edges and faces. This is the case for the halfedge data structure, for the polyhedron, for arrangements and for triangulations. With means of duality one can also interpret faces as vertices and edges between adjacent faces as edges of the dual graph.

As the scope of CGAL is geometry and not graph algorithms, we provide the necessary classes and functions that allow to use the algorithms of the **Boost Graph Library (BGL)** [SLL02] for CGAL data structures.

56.1 A Short Introduction to the Boost Graph Library

The algorithms of the BGL operate on models of the various *graph concepts*. The *traits class* `boost::graph_traits` allows the algorithms to determine the types of vertices and edges. *Free functions* that operator on graphs allow the algorithms to obtain, for example, the source vertex of an edge, or all edges incident to a vertex. The algorithms use *property maps* to associate information to vertices and edges. The algorithms allow *visitors* to register callbacks that will be called during the execution of the algorithms. Finally, the graph algorithms use the *named parameter* mechanism, which allows to pass the arguments in arbitrary order.

Graph Concepts

The BGL introduces several graph concepts, which have different sets of characteristics and requirements, as for example whether one can enumerate all vertices or all edges, whether one only can get the outgoing edges of a vertex, or also the ingoing edges, or whether one can add and remove vertices and edges or not.

Graph concepts in the BGL manual: http://www.boost.org/libs/graph/doc/graph_concepts.html

The Graph Traits Class

The algorithms determine types with the help of the traits class *boost::graph_traits*. Such types are the *vertex_descriptor* which is equivalent to a vertex handle in CGAL data structures, the *vertex_iterator* which is similar to the vertex iterators in CGAL data structures, and the *out_edge_iterator* which is similar to edge circulators, which allow to enumerate the edges incident to a vertex. The latter two are similar and not equivalent, because their value type is a *vertex_descriptor*, whereas in CGAL handles, iterators, and circulators all have the same value type, namely the vertex type. Given a graph type *G* the declaration of a vertex descriptor looks as follows: *boost::graph_traits<G>::vertex_descriptor vd;*

The graph traits in the BGL manual: http://www.boost.org/libs/graph/doc/graph_traits.html

Free Functions for Exploring a Graph

The algorithms obtain incidence information with the help of global functions like *pair<vertex_iterator,vertex_iterator> vertices(const Graph& g);* for getting an iterator range which allows to enumerate all vertices, or *int num_vertices(const Graph&);* for getting the number of vertices of a graph, or *vertex_descriptor source(edge_descriptor, const Graph&);* for getting the source vertex of an edge. Note, that the way we have written the types is a simplification, that is in reality the signature of the first of the above functions is *pair<boost::graph_traits<Graph>::vertex_iterator,boost::graph_traits<Graph>::vertex_iterator> vertices(const Graph& g);*

The free functions required for graph concepts: http://www.boost.org/libs/graph/doc/graph_concepts.html

Property Maps

Another feature used heavily in the BGL is the *property map* which is offered by the Boost Property Map Library. Property maps are used to attach information to vertices and edges. It is again a traits class and some free functions for obtaining the property map from a graph, and for getting and putting properties.

The free functions are *get* and *put*. The first one is overloaded. One version allows to obtain a property map for a given property tag. For example *m = get(g, boost::vertex_index)* gives us a property map that associates an index in the range *[0, num_vertices(g))* to each vertex descriptor of the graph. The second version of the *get* function allows to read it as follows for a vertex descriptor *vd*: *int vdi = get(m, vd)*. Just as *get* allows to read data, *put* allows to write them. For example, the Dijkstra's shortest path algorithm writes the predecessor of each vertex, as well as the distance to the source in such a property map.

The data themselves may be stored in the vertex or edge, or they may be stored in an external data structure, or they may be computed on the fly. This is an "implementation detail" of the particular property map.

Property maps in the Boost manuals: http://www.boost.org/libs/property_map/property_map.html

Visitors

Visitors are objects that provide functions that get called at specified event points by the algorithm they visit. The notion of visitors is a design pattern, and also used in CGAL, e.g., the *Arr_observer<Arrangement>* in the arrangement package.

The functions as well as the event points are library specific. Event points in graph algorithms are, for example, when a vertex is traversed the first time, or when all outgoing edges of a vertex are traversed.

Visitors in the BGL manual: http://www.boost.org/libs/graph/doc/visitor_concepts.html

Named Parameters

The algorithms of the BGL often have many parameters. Although the default value is most often appropriate, one has to write them explicitly, if one only wants to deviate from the default for the last one. The solution to this problem is to first write a tag and then the parameter, which for Dijkstra's shortest path algorithm, might look as follows:

```
std::vector<vertex_descriptor> p(num_vertices(g));
std::vector<int> d(num_vertices(g));
vertex_descriptor s = vertex(A, g);
dijkstra_shortest_paths(g, s, predecessor_map(&p[0]).distance_map(&d[0]));
```

The named parameters in the example use the tags *predecessor_map* and *distance_map* and they are concatenated with the dot operator.

Named parameters in the BGL manual: http://www.boost.org/libs/graph/doc/bgl_named_params.html

56.2 Extensions of the BGL

CGAL provides the partial specializations and free functions such that several data structures become model of some of the BGL graph concepts. Furthermore, we define the new graph concept *HalfedgeGraph*, a traits class *halfedge_graph_traits*, and free functions for accessing opposite edges as well as the clockwise and counter-clockwise neighbor of an edge around a given vertex.

These extensions are used by the surface simplification algorithms which follow the design of the BGL as sketched in the previous section.

56.3 Header Files, Namespaces, and Naming Conventions

As we interface two libraries we have to explain what resides in which namespace, and what naming conventions we apply to what.

Partial specializations of the *boost::graph_traits<Graph>* for the CGAL package *Package* are in the namespace *boost* and in the headerfile *<CGAL/boost/graph/graph_traits_Package.h>*.

The *halfedge_graph_traits* class is in the namespace *CGAL*, but it is not capitalized as the *boost::graph_traits* is not. The same holds for the types and enums for vertex and edge properties.

56.4 Polyhedral Surfaces as Model of the Boost Graph Concept

The class *Polyhedron_3* is model of the graph concept. Furthermore this chapter introduces a new graph concept, the *HalfedgeGraph*.

56.4.1 Example: Minimum Spanning Tree of a Polyhedral Surface

The example code computes the minimum spanning tree on a polyhedral surface. More examples can be found in Chapter 38 on surface mesh simplification.

```
#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
#include <CGAL/boost/graph/properties_Polyhedron_3.h>
#include <CGAL/Unique_hash_map.h>

#include <iostream>
#include <algorithm>
#include <list>

#include "kruskal_min_spanning_tree.hpp"

typedef CGAL::Cartesian<double> Kernel;
typedef Kernel::Vector_3 Vector;
typedef Kernel::Point_3 Point;
typedef CGAL::Polyhedron_3<Kernel> Polyhedron;

typedef boost::graph_traits<Polyhedron const>::vertex_descriptor vertex_const_descriptor;
typedef boost::graph_traits<Polyhedron const>::vertex_iterator vertex_const_iterator;
typedef boost::graph_traits<Polyhedron const>::edge_descriptor edge_const_descriptor;

// The BGL makes heavy use of indices associated to the vertices
// We use a std::map to store the index

namespace CGAL
{
    // (but we define operator < for handles as is not predefined)
    bool operator< ( vertex_const_descriptor const& x, vertex_const_descriptor const& y )
    {
        return &*x < &*y ;
    }
}
```

```

typedef std::map<vertex_const_descriptor,int> VertexIndexMap;
VertexIndexMap vertex_id_map;

// A std::map is not a property map, because it is not lightweight
typedef boost::const_associative_property_map<VertexIndexMap> VertexIdPropertyMap;
VertexIdPropertyMap vertex_index_pmap(vertex_id_map);

void
kruskal(const Polyhedron& P)
{
    // associate indices to the vertices
    {
        vertex_const_iterator vb, ve;
        int index = 0;

        // boost::tie assigns the first and second element of the std::pair
        // returned by boost::vertices to the variables vit and ve
        for(boost::tie(vb,ve)=boost::vertices(P); vb!=ve; ++vb ){
            vertex_const_descriptor vd = *vb;
            vertex_id_map[vd]= index++;
        }
    }

    // We use the default edge weight which is the squared length of the edge
    // This property map is defined in graph_traits_Polyhedron_3.h

    // In the function call you can see a named parameter: vertex_index_map
    std::list<edge_const_descriptor> mst;
    boost::kruskal_minimum_spanning_tree(P, std::back_inserter(mst), boost::vertex_index_map(vertex_index_pmap));

56.4.2 Example: Using Vertices, and Edges with an ID

The following example program shows a call to the BGL Kruskal's minimum spanning tree algorithm accessing the `id()` field stored in a `Polyhedron` vertex.

The main function illustrates the access to the `id()` field.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Polyhedron_3.h>
#include <CGAL/Polyhedron_items_with_id_3.h>
#include <CGAL/IO/Polyhedron_iostream.h>
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
#include <CGAL/boost/graph/properties_Polyhedron_3.h>

#include <iostream>
#include <algorithm>
#include <list>

#include "kruskal_min_spanning_tree.hpp"

typedef CGAL::Cartesian<double> Kernel;
typedef Kernel::Vector_3 Vector;
typedef Kernel::Point_3 Point;

```

```

typedef CGAL::Polyhedron_3<Kernel,CGAL::Polyhedron_items_with_id_3> Polyhedron;

typedef boost::graph_traits<Polyhedron>::vertex_descriptor vertex_descriptor;
typedef boost::graph_traits<Polyhedron>::vertex_iterator vertex_iterator;
typedef boost::graph_traits<Polyhedron>::edge_descriptor edge_descriptor;

typedef boost::graph_traits<Polyhedron const>::vertex_descriptor vertex_const_descriptor;
typedef boost::graph_traits<Polyhedron const>::vertex_iterator vertex_const_iterator;
typedef boost::graph_traits<Polyhedron const>::edge_descriptor edge_const_descriptor;

void
kruskal( const Polyhedron& P)
{
    // We use the default edge weight which is the squared length of the edge
    // This property map is defined in graph_traits_Polyhedron_3.h

    // This function call requires a vertex_index_map named parameter which
    // when omitted defaults to "get(vertex_index,graph)".
    // That default works here because the vertex type supports the "id()"
    // field which is used by the vertex_index internal property.
    std::list<edge_const_descriptor> mst;
    boost::kruskal_minimum_spanning_tree(P, std::back_inserter(mst));

    vertex_const_iterator vb, ve;

    std::cout << "#VRML V2.0 utf8\n"
        "Shape {\n"
        "  appearance Appearance {\n"
        "    material Material { emissiveColor 1 0 0 }\n"
        "    geometry\n"
        "    IndexedLineSet {\n"
        "      coord Coordinate {\n"
        "        point [ \n";

    for(boost::tie(vb,ve) = boost::vertices(P); vb!=ve; ++vb){
        std::cout << (*vb)->point() << "\n";
    }

    std::cout << "]\n"
        "}\n"
        "coordIndex [\n";

    for(std::list<edge_const_descriptor>::iterator it = mst.begin(); it != mst.end(); ++it){
        std::cout << boost::source(*it,P)->id()
<< ", " << boost::target(*it,P)->id() << ", -1\n";
    }

    std::cout << "]\n"
        "}"#IndexedLineSet\n"
        "}"# Shape\n";
}

```

```

int main() {

    Polyhedron P;

    Point a(1,0,0);
    Point b(0,1,0);
    Point c(0,0,1);
    Point d(0,0,0);

    P.make_tetrahedron(a,b,c,d);

    // associate indices to the vertices using the "id()" field of the vertex.
    vertex_iterator vb, ve;
    int index = 0;

    // boost::tie assigns the first and second element of the std::pair
    // returned by boost::vertices to the variables vit and ve
    for(boost::tie(vb,ve)=boost::vertices(P); vb!=ve; ++vb ){
        vertex_descriptor vd = *vb;
        vd->id() = index++;
    }

    kruskal(P);
    return 0;
}

```

56.5 Triangulations as Models of the Boost Graph Concept

Triangulations have vertices and faces. Edges are pairs of a face and the index of the edge. Particular care has to be taken with the infinite vertex, and its incident edges. One can either use a *boost::filtered_graph*, which makes the infinite edges invisible, or one can have a property map that returns an infinite length for these edges.

A classical example for an algorithm that is a combination of computational geometry and graph theory is the *Euclidean Minimum Spanning Tree* for a point set in the plane. It can be computed by running the minimum spanning tree algorithm on a Delaunay triangulation of the point set.

56.5.1 Example: Euclidean Minimum Spanning Tree

In the following example we create a Delaunay triangulation and run Kruskal's minimum spanning tree algorithm on it. Because the vertex handles of the triangulation are not indices in an array, we have to provide a property map that maps vertex handles to int's in the range $[0, t.number_of_vertices())$.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/boost/graph/graph_traits_Delaunay_triangulation_2.h>

```

```

#include <boost/graph/kruskal_min_spanning_tree.hpp>
#include <boost/graph/filtered_graph.hpp>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;

typedef CGAL::Delaunay_triangulation_2<K> Triangulation;

// As we only consider finite vertices and edges
// we need the following filter

template <typename T>
struct Is_finite {

    const T* t_;

    Is_finite()
        : t_(NULL)
    {}

    Is_finite(const T& t)
        : t_(&t)
    { }

    template <typename VertexOrEdge>
    bool operator()(const VertexOrEdge& voe) const {
        return ! t_->is_infinite(voe);
    }
};

typedef Is_finite<Triangulation> Filter;
typedef boost::filtered_graph<Triangulation,Filter,Filter> Finite_triangulation;
typedef boost::graph_traits<Finite_triangulation>::vertex_descriptor vertex_descriptor;
typedef boost::graph_traits<Finite_triangulation>::vertex_iterator vertex_iterator;
typedef boost::graph_traits<Finite_triangulation>::edge_descriptor edge_descriptor;

// The BGL makes use of indices associated to the vertices
// We use a std::map to store the index
typedef std::map<vertex_descriptor,int> VertexIndexMap;
VertexIndexMap vertex_id_map;

// A std::map is not a property map, because it is not lightweight
typedef boost::associative_property_map<VertexIndexMap> VertexIdPropertyMap;
VertexIdPropertyMap vertex_index_pmap(vertex_id_map);

int
main(int, char*[])
{
    Triangulation t;
    Filter is_finite(t);
    Finite_triangulation ft(t, is_finite, is_finite);

    Point p ;
    while(std::cin >> p){

```

```

        t.insert(p);
    }

    vertex_iterator vit, ve;
    // Associate indices to the vertices
    int index = 0;
    // boost::tie assigns the first and second element of the std::pair
    // returned by boost::vertices to the variables vit and ve
    for(boost::tie(vit,ve)=boost::vertices(ft); vit!=ve; ++vit ){
        vertex_descriptor vd = *vit;
        vertex_id_map[vd]= index++;
    }

    // We use the default edge weight which is the squared length of the edge
    // This property map is defined in graph_traits_Triangulation_2.h

    // In the function call you can see a named parameter: vertex_index_map
    std::list<edge_descriptor> mst;
    boost::kruskal_minimum_spanning_tree(t,
std::back_inserter(mst),
vertex_index_map(vertex_index_pmap));

    std::cout << "The edges of the Euclidean mimimum spanning tree:" << std::endl;

    for(std::list<edge_descriptor>::iterator it = mst.begin(); it != mst.end(); ++it){
        edge_descriptor ed = *it;
        vertex_descriptor svd = boost::source(ed,t);
        vertex_descriptor tvd = boost::target(ed,t);
        Triangulation::Vertex_handle sv = svd;
        Triangulation::Vertex_handle tv = tvd;
        std::cout << "[ " << sv->point() << " | " << tv->point() << " ] " << std::endl;
    }

    return 0;
}

```

File: examples/BGL_triangulation_2/emst.cpp

56.5.2 Example: Storing the Vertex ID in the Vertex

The algorithms of the BGL extensively use of the indices of vertices. In the previous example we stored the index in a *std::map* and turned that map in a property map. This property map was then passed as argument to the shortest path function.

If the user does not pass explicitly a property map, the graph algorithms use the property map returned by the call *boost::get(boost::vertex_index,ft)*. This property map assumes that the vertex has a member function *id()* that returns a reference to an int. Therefore CGAL offers a class *Triangulation_vertex_base_with_id_2*. It is in the users responsibility to set the indices properly.

The example further illustrates that the graph traits also works for the Delaunay triangulation.

```

#include <CGAL/Exact_predicates_inexact_constructions_kernel.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Triangulation_vertex_base_with_id_2.h>
#include <CGAL/boost/graph/graph_traits_Delaunay_triangulation_2.h>

#include <boost/graph/dijkstra_shortest_paths.hpp>
#include <boost/graph/filtered_graph.hpp>

typedef CGAL::Exact_predicates_inexact_constructions_kernel K;
typedef K::Point_2 Point;

typedef CGAL::Triangulation_vertex_base_with_id_2<K> Tvb;
typedef CGAL::Triangulation_face_base_2<K> Tfb;
typedef CGAL::Triangulation_data_structure_2<Tvb,Tfb> Tds;
typedef CGAL::Delaunay_triangulation_2<K, Tds> Triangulation;

// consider finite vertices and edges.

template <typename T>
struct Is_finite {

    const T* t_;

    Is_finite()
        : t_(NULL)
    {}

    Is_finite(const T& t)
        : t_(&t)
    { }

    template <typename VertexOrEdge>
    bool operator()(const VertexOrEdge& voe) const {
        return ! t_>is_infinite(voe);
    }
};

typedef Is_finite<Triangulation> Filter;
typedef boost::filtered_graph<Triangulation,Filter,Filter> Finite_triangulation;
typedef boost::graph_traits<Finite_triangulation>::vertex_descriptor vertex_descriptor;
typedef boost::graph_traits<Finite_triangulation>::vertex_iterator vertex_iterator;

int
main(int, char*[])
{
    Triangulation t;
    Filter is_finite(t);
    Finite_triangulation ft(t, is_finite, is_finite);

    t.insert(Point(0,0));
    t.insert(Point(1,0));
    t.insert(Point(0.2,0.2));
    t.insert(Point(0,1));

```

```

t.insert(Point(0,2));

vertex_iterator vit, ve;
// associate indices to the vertices
int index = 0;

56.6 Arrangements as Models of the Boost Graph Concept

For the arrangements CGAL offers the graph traits for the arrangement itself as well as for its dual graph.

56.6.1 Example for the Arrangement as Graph

Arrangement instances are adapted to *boost* graphs by specializing the *boost:graph_traits* template for *Arrangement_2* instances. The graph-traits states the graph concepts that the arrangement class models (see below) and defines the types required by these concepts.

Figure 56.1: An arrangement of 7 line segments, as constructed by *ex_bgl_primal_adapter.cpp* and *ex_bgl_dual_adapter.cpp*. The breadth-first visit times for the arrangement faces, starting from the unbounded face f_0 , are shown in brackets.

In this specialization the *Arrangement_2* vertices correspond to the graph vertices, where two vertices are adjacent if there is at least one halfedge connecting them. More precisely, *Arrangement_2::Vertex_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. As halfedges are directed, we consider the graph to be directed as well. Moreover, as several interior-disjoint x -monotone curves (say circular arcs) may share two common endpoints, inducing an arrangement with two vertices that are connected with several edges, we allow parallel edges in our *boost* graph.

Given an *Arrangement_2* instance, we can efficiently traverse its vertices and halfedges. Thus, the arrangement graph is a model of the concepts *VertexListGraph* and *EdgeListGraph* introduced by the BGL. At the same time, we use an iterator adapter of the circulator over the halfedges incident to a vertex (*Halfedge_around_vertex_circulator* — see Section 20.2.2), so it is possible to go over the ingoing and outgoing edges of a vertex in linear time. Thus, our arrangement graph is a model of the concept *BidirectionalGraph* (this concept refines *IncidenceGraph*, which requires only the traversal of outgoing edges).

It is important to notice that the vertex descriptors we use are *Vertex_handle* objects and *not* vertex indices. However, in order to gain more efficiency in most BGL algorithm, it is better to have them indexed $0, 1, \dots, (n - 1)$, where n is the number of vertices. We therefore introduce the *Arr_vertex_index_map<Arrangement>* class-template, which maintains a mapping of vertex handles to indices, as required by the BGL. An instance of this class must be attached to a valid arrangement vertex when it is created. It uses the notification mechanism (see Section 20.7) to automatically maintain the mapping of vertices to indices, even when new vertices are inserted into the arrangement or existing vertices are removed.

In most algorithm provided by the BGL, the output is given by *property maps*, such that each map entry corresponds to a vertex. For example, when we compute the shortest paths from a given source vertex s to all other vertices we can obtain a map of distances and a map of predecessors — namely for each v vertex we have its distance from s and a descriptor of the vertex that precedes v in the shortest path from s . If the vertex descriptors are simply indices, one can use vectors to efficiently represent the property maps. As this is not the case with the arrangement graph, we offer the *Arr_vertex_property_map<Arrangement, Type>* template allows for an efficient mapping of *Vertex_handle* objects to properties of type *Type*. Note however that unlike the *Arr_vertex_index_map* class, the vertex property-map class is not kept synchronized with the number of vertices in the arrangement, so it should not be reused in calls to BGL functions in case the arrangement is modified in between these calls.

In the following example we construct an arrangement of 7 line segments, as shown in Figure 56.1, then use

Dijkstra's shortest-paths algorithm from the BGL to compute the graph distance of all vertices from the leftmost vertex in the arrangement v_0 . Note the usage of the *Arr_vertex_index_map* and the *Arr_vertex_property_map* classes. The latter one, instantiated by the type *double* is used to map vertices to their distances from v_0 .

56.6.2 Example for the Dual of an Arrangement as Graph

It is possible to give a dual graph representation for an arrangement instance, such that each arrangement face corresponds to a graph vertex and two vertices are adjacent iff the corresponding faces share a common edge on their boundaries. This is done by specializing the *boost::graph_traits* template for *Dual<Arrangement_2>* instances, where *Dual<Arrangement_2>* is a template specialization that gives a dual interpretation to an arrangement instance.

In dual representation, *Arrangement_2::Face_handle* is the graph-vertex type, while *Arrangement_2::Halfedge_handle* is the graph-edge type. We treat the graph edges as directed, such that a halfedge *e* is directed from *f*₁, which is its incident face, to *f*₂, which is the incident face of its twin halfedge. As two arrangement faces may

share more than a single edge on their boundary, we allow parallel edges in our *boost* graph. As is the case in the primal graph, the dual arrangement graph is also a model of the concepts *VertexListGraph*, *EdgeListGraph* and *BidirectionalGraph* (thus also of *IncidenceGraph*).

Since we use *Face_handle* objects as the vertex descriptors, we define the *Arr_face_index_map*<Arrangement> class-template, which maintains an efficient mapping of face handles to indices. We also provide the template *Arr_face_property_map*<Arrangement,Type> for associating arbitrary data with the arrangement faces.

In the following example we construct the same arrangement as in example *ex_bgl_primal_adapter.cpp* (see Figure 56.1), and perform breadth-first search on the graph faces, starting from the unbounded face. We extend the DCEL faces with an unsigned integer, marking the discover time of the face and use a breadth-first-search visitor to obtain these times and update the faces accordingly:

```
#include "arr_rational_nt.h"
#include <CGAL/Cartesian.h>
#include <CGAL/Arr_segment_traits_2.h>
#include <CGAL/Arr_extended_dcel.h>
#include <CGAL/Arrangement_2.h>

#include <boost/graph/dijkstra_shortest_paths.hpp>

#include <CGAL/graph_traits_Dual_Arrangement_2.h>
#include <CGAL/Arr_face_map.h>

#include "arr_print.h"

typedef CGAL::Cartesian<Number_type>           Kernel;
typedef CGAL::Arr_segment_traits_2<Kernel>      Traits_2;
typedef Traits_2::Point_2                      Point_2;

HalfedgeGraph

Definition

The concept HalfedgeGraph describes the requirements for a graph that is structurally equivalent to a polyhedral surface represented by a halfedge data structure, and it provides an interface for efficient access to the opposite edge of an edge, and to the successor and predecessor of an edge in the iterator range of the incoming edges of a vertex. Each vertex has a geometric position in space. As in a halfedge data structure we define the face adjacent to a halfedge to be to the *left* of the halfedge.

Requirements

For each *directed edge* $e = (v, w)$ its opposite edge $e' = (w, v)$ must be part of the graph.

The incoming edges of a vertex v have a fixed order, that is all calls of $in_edges(v, g)$ must return the same iterator range, modulo a cyclic permutation. The order must be *clockwise*.

As the HalfedgeGraph is equivalent to a polyhedral surface there must exist an embedding for the vertices and edges such that the ordered edges do not intersect.

Refines

IncidenceGraph
PropertyGraph

A model of HalfedgeGraph must have the *interior properties* $edge_is_border$ attached to its edges, and it must have $vertex_is_border$ and $vertex_point$ attached to its vertices.

Associated Types

$HalfedgeGraph::halfedge_graph_traits<HalfedgeGraph>::Point$

The type of the geometric location of a vertex.

Because (directed) edges must come in pairs, there is the additional notion of an *undirected edge*¹ for a pair of opposite directed edges. The number of undirected edges is exactly half the number of directed edges.

Note that the notion of directed and undirected edges does not imply the existence of two different types. The type $edge_descriptor$ is used for both. An undirected edge must be implicitly handled, and there is no requirement on which of the directed edges of the undirected edge must be used to represent it.

$HalfedgeGraph::halfedge_graph_traits<HalfedgeGraph>::undirected_edge_iterator$

An iterator that iterates over one and only one of the directed edges in each pair of opposite directed edges. The value type of the iterator is $boost::graph_traits<HalfedgeGraph>::edge_descriptor$.

¹ The directed edges are not called *halfedges* (as in a *HalfedgeDS*) because from the point of view of this graph, being a refinement of a BGL graph, each directed edge is an edge in itself. In other words, the unqualified term edge refers to one and only one directed edge and not to a pair.

Valid Expressions

Following the BGL design, the following graph operations are defined as free rather than member functions.

```
template<class Graph>
std::pair<typename halfedge_graph_traits<HalfedgeGraph>::undirected_edge_iterator,
typename halfedge_graph_traits<HalfedgeGraph>::undirected_edge_iterator>
```

```
undirected_edges( Graph g)
```

Returns the undirected edges of g .

An edge $e = (v, w)$ is said to be the *opposite edge* of edge $e' = (w, v)$.

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

```
opposite_edge( typename boost::graph_traits<Graph const>::edge_descriptor e,
               Graph g)
```

Returns the opposite edge of e .

An edge $e' = (v, w)$ is called the *clockwise neighbor* of edge $e = (u, w)$, and e the *counterclockwise neighbor* of e' , iff there exist two iterators it and it' in the iterator range $in_edges(w, g)$ such that $**it == e$ and $**it' == e'$, and $it' == it++$ or it is the last and it' the first iterator of the iterator range.

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

```
next_edge_cw( typename boost::graph_traits<Graph const>::edge_descriptor e,
              Graph g)
```

Returns the clockwise neighbor of e .

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

```
next_edge_ccw( typename boost::graph_traits<Graph const>::edge_descriptor e,
               Graph g)
```

Returns the counterclockwise neighbor of e .

A composition of these access functions yields an access function for the edge cycle adjacent to the same face. An edge $e' = (v, w)$ is called the *successor* of edge $e = (u, v)$, and e the *predecessor* of e' , iff e' is the clockwise neighbor of the opposite edge of e .

```
template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor
```

```
next_edge( typename boost::graph_traits<Graph const>::edge_descriptor e, Graph g)
```

Returns the successor of e .

template<class Graph>
typename boost::graph_traits<Graph const>::edge_descriptor

prev_edge(typename boost::graph_traits<Graph const>::edge_descriptor e,
Graph g)

Returns the predecessor of *e*.

boost::graph_traits< CGAL::Arrangement_2<Traits,Dcel> >

Definition

The class `graph_traits< CGAL::Arrangement_2<Traits,Dcel> >` is a partial specialization of `boost::graph_traits` for the class `Arrangement_2`. It provides the types associated to the `graph` concepts *BidirectionalGraph* and *EdgeAndVertexListGraph*.

```
#include <CGAL/boost/graph/graph_traits_Arrangement_2.h>
```

Types

```
typename CGAL::Arrangement_2::Vertex_handle
```

`vertex_descriptor;` The vertex descriptor.

```
typename CGAL::Arrangement_2::Halfedge_handle
```

`edge_descriptor;` The edge descriptor.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: vertex_iterator
```

An iterator corresponding to `CGAL::Arrangement_2::Vertex_iterator`, with the difference that its value type is a vertex descriptor and not `CGAL::Arrangement_2::Vertex`.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: edge_iterator
```

An iterator corresponding to `CGAL::Arrangement_2::Halfedge_iterator` with the difference that its value type is an edge descriptor and not `CGAL::Arrangement_2::Halfedge`.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: in_edge_iterator
```

An edge iterator which only iterates over the incoming edges around a vertex. It corresponds to a `CGAL::Arrangement_2::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Arrangement_2::Halfedge`.

```
graph_traits< CGAL::Arrangement_2<Traits,Dcel> >:: out_edge_iterator
```

An edge iterator which only iterates over the outgoing halfedges around a vertex. It corresponds to a `CGAL::Arrangement_2::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Arrangement_2::Halfedge`.

boost::sallow_parallel_edge_tag

edge_parallel_category;

Indicates that this graph does support multiedges.

boost::bidirectional_graph_tag

traversal_category;

Indicates that this graph is bidirectional.

typename Arrangement_2::size_type

vertices_size_type;

The size type of the vertex list.

typename Arrangement_2::size_type

edges_size_type;

The size type of the edge list.

typename Arrangement_2::size_type

degree_size_type;

The size type of the adjacency list.

The const specialization, *boost::graph_traits< CGAL::Arrangement_2< Traits, Dcel> const>* is also defined, using the constant handles in the arrangement.

boost::graph_traits< CGAL::Polyhedron_3<Traits> >

Definition

The class `graph_traits< CGAL::Polyhedron_3<Traits> >` is a partial specialization of `boost::graph_traits` for the class `Polyhedron_3`. It provides the types associated to the **graph** concepts *BidirectionalGraph* and *EdgeAndVertexListGraph*.

```
#include <CGAL/boost/graph/graph_traits_Polyhedron_3.h>
```

Types

```
typename CGAL::Polyhedron_3::Vertex_handle
```

`vertex_descriptor;` The vertex descriptor.

```
typename CGAL::Polyhedron_3::Halfedge_handle
```

`edge_descriptor;` The edge descriptor.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: vertex_iterator
```

An iterator corresponding to `CGAL::Polyhedron_3::Vertex_iterator`, with the difference that its value type is a vertex descriptor and not `CGAL::Polyhedron_3::Vertex`.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: edge_iterator
```

An iterator corresponding to `CGAL::Polyhedron_3::Halfedge_iterator` with the difference that its value type is an edge descriptor and not `CGAL::Polyhedron_3::Halfedge`.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: in_edge_iterator
```

An edge iterator which only iterates over the incoming edges around a vertex. It corresponds to a `CGAL::Polyhedron_3::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Polyhedron_3::Halfedge`.

```
graph_traits< CGAL::Polyhedron_3<Traits> >:: out_edge_iterator
```

An edge iterator which only iterates over the outgoing halfedges around a vertex. It corresponds to a `CGAL::Polyhedron_3::Halfedge_around_vertex_circulator` with the difference that its value type is an edge descriptor and not `CGAL::Polyhedron_3::Halfedge`.

boost::disallow_parallel_edge_tag

edge_parallel_category;

Indicates that this graph does not support multiedges.

boost::bidirectional_graph_tag

traversal_category;

Indicates that this graph is bidirectional.

typename Polyhedron_3::size_type

vertices_size_type;

The size type of the vertex list.

typename Polyhedron_3::size_type

edges_size_type;

The size type of the edge list.

typename Polyhedron_3::size_type

degree_size_type;

The size type of the adjacency list.

The const specialization, *boost::graph_traits< CGAL::Polyhedron_3<Traits> const>* is also defined, using the constant handles in the polyhedron.

boost::graph_traits<CGAL::Triangulation_2<GT, TDS>>

Definition

The triangulations of CGAL are all models of the concepts *BidirectionalGraph* and *VertexAndEdgeListGraph* of the Boost Graph Library [SLL02].

The class *graph_traits<CGAL::Triangulation_2<GT, TDS>>* is a partial specialization of the class *boost::graph_traits<G>*.

The mapping between vertices and edges of the triangulation and the graph is rather straightforward, but there are some subtleties. The value type of the BGL iterators is the vertex or edge descriptor, whereas in CGAL all iterators and circulators are also handles and hence have as value type *Vertex* or *Edge*.

The graph traits class for triangulations does not distinguish between finite and infinite vertices and edges. As the edge weight computed with the default property map of BGL algorithms (obtained with *boost::get(t, boost::edge_weight)*) is the length of the edge, the edge weight is not well defined for infinite edges. For algorithms that make use of the edge weight the user must therefore define a *boost::filtered_graph* or pass a property map to the algorithm that returns “infinity” for infinite edges.

Note also that when you derive from the class *CGAL::Triangulation_2* you must upcast the object in order to use this partial specialization.

For the user convenience, CGAL provides the partial specializations for all 2D triangulation classes.

```
#include <CGAL/boost/graph/graph_traits_Triangulation_2.h>
```

Types

```
typedef Triangulation::Vertex_handle
```

vertex_descriptor; The vertex descriptor.

```
graph_traits<CGAL::Triangulation_2<GT, TDS>>:: edge_descriptor
```

The edge descriptor. It is constructible from and convertible to *Triangulation::Edge*. The edge descriptor is not a simple typedef, but a proper class, because in an undirected graph the edges (u,v) and (v,u) must be equal. This is not the case for the *Edge* type of the triangulation.

```
graph_traits<CGAL::Triangulation_2<GT, TDS>>:: vertex_iterator
```

The vertex iterator type. Its value type is *vertex_descriptor*.

```
graph_traits<CGAL::Triangulation_2<GT, TDS>>:: edge_iterator
```

The edge iterator type, Its value type is *edge_descriptor*.

graph_traits<CGAL::Triangulation_2<GT, TDS>>:: out_edge_iterator

An iterator for the outgoing edges incident to a vertex. Its value type is *edge_descriptor*.

graph_traits<CGAL::Triangulation_2<GT, TDS>>:: in_edge_iterator

An iterator for the incoming edges incident to a vertex. Its value type is *edge_descriptor*.

graph_traits<CGAL::Triangulation_2<GT, TDS>>:: adjacency_iterator

An iterator for the vertices adjacent to a vertex. Its value type is *vertex_descriptor*.

typedef boost::undirected_tag

directed_category;

typedef boost::disallow_parallel_edge_tag

edge_parallel_category;

CGAL::halfedge_graph_traits< CGAL::Polyhedron_3<Traits> >

Definition

The class *halfedge_graph_traits< CGAL::Polyhedron_3<Traits> >* is a partial specialization of *CGAL::halfedge_graph_traits* for *Polyhedron_3*. It provides the types associated to the *HalfedgeGraph* concept.

```
#include <CGAL/boost/graph/halfedge_graph_traits_Polyhedron_3.h>
```

Types

halfedge_graph_traits< CGAL::Polyhedron_3<Traits> >::undirected_edge_iterator

An edge iterator that iterates over one of the two opposite edges forming an undirected edge.

The value type is *CGAL::Polyhedron_3::Halfedge_const_handle*.

typename CGAL::Polyhedron_3<Traits>::Point_3

Point;

The point type of the vertex.

CGAL::Triangulation_vertex_base_with_id_2<TriangulationTraits_2, TriangulationVertexBase_2>

Definition

The class *Triangulation_vertex_base_with_id_2* is a model of the concept *TriangulationVertexBase_2*, the base vertex of a 2D-triangulation. It provides an integer field that can be used to index vertices for BGL algorithms.

Note that the user is in charge to set the index correctly before running a graph algorithm.

```
#include <CGAL/Triangulation_vertex_base_with_id_2.h>
```

Parameters

The first template argument is the geometric traits class *TriangulationTraits_2* which provides the *Point_2*.

The second template argument is a vertex base class from which *Triangulation_vertex_base_with_id_2* derives. It has the default value *Triangulation_vertex_base_2<TriangulationTraits_2>*.

Is Model for the Concepts

CGAL::HalfedgeDS_halfedge_max_base_with_id<Refs>

Definition

The class *HalfedgeDS_halfedge_max_base_with_id<Refs>* is a model of the *HalfedgeDSHalfedge* concept. *Refs* is an instantiation of a *HalfedgeDS*. It is equivalent to *CGAL::HalfedgeDS_halfedge_base<Refs, CGAL::Tag_true, CGAL::Tag_true, CGAL::Tag_true>* with an added integer field which can be used to index halfedges in BGL algorithms. The class contains support for the previous, next, opposite, vertex and face pointers and the required type definitions. It can be used for deriving own halfedges.

Note that the user is in charge to set the index correctly before running a graph algorithm.

enum edge_is_border_t { edge_is_border};
```

The constant `edge_is_border` is a **property tag** which refers to the property of an edge of being a border edge.

`edge_is_border` is an **interior property**. That is, a **property map** for `edge_is_border` can be extracted from any model of a *HalfedgeGraph* using the BGL **PropertyGraph** interface:

```
boost::get(edge_is_border, graph)
```

The Boolean flag that indicates if the edge is a border can be directly accessed via:

```
boost::get(edge_is_border, graph, edge).
```

CGAL::vertex_is_border_t

```
#include <CGAL/boost/graph/properties.h>
```

```
enum vertex_is_border_t { vertex_is_border};
```

The constant `vertex_is_border` is a **property tag** which refers to the property of a vertex of being a border vertex.

`vertex_is_border` is an **interior property**, that is, a **property map** for `vertex_is_border` can be extracted from any model of a *HalfedgeGraph* using the BGL **PropertyGraph** interface:

```
boost::get(vertex_is_border, graph)
```

The Boolean flag that indicates if the vertex is a border can be directly accessed via:

```
boost::get(vertex_is_border, graph, edge)
```

CGAL::vertex_point_t

```
#include <CGAL/boost/graph/properties.h>
```

```
enum vertex_point_t { vertex_point};
```

The constant `vertex_point` is a **property tag** which refers to the geometric embedding property of a vertex of a *HalfedgeGraph*.

A *vertex_point* is an **interior property**, that is, a **property map** for a *vertex_point* can be extracted from any model of a *HalfedgeGraph* using the BGL **PropertyGraph** interface:

```
boost::get(vertex_point,graph)
```

A point of a vertex can be directly accessed via:

```
boost::get(vertex_point,graph,vertex)
```

```
boost::put(vertex_point,graph,vertex,newpoint)
```

57.1 Handles

Most data structures in CGAL use the concept of *Handle* in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A *Handle* is akin to a pointer to an object providing the dereference operator *operator**() and member access *operator->*() but no increment or decrement operators like iterators. A *Handle* is intended to be used whenever the referenced object is not part of a logical sequence.

Model for a handle A simple pointer T^* , an iterator or a circulator with value type T , are also handles.

57.2 Circulators

An introduction to the concept of circulators is given here. A couple of adaptors are presented that convert between iterators and circulators. Some useful functions for circulators follow. This chapter concludes with a discussion of the design decisions taken. For the full description of the circulator requirements, the provided base classes, the circulator tags, and the support for generic algorithms that work for iterators as well as for circulators please refer to the reference pages. Note that circulators are not part of STL, but of CGAL.

57.2.1 Introduction

The concept of iterators in STL is tailored for linear sequences [C++98, MS96]. In contrast, circular sequences occur naturally in many combinatorial and geometric structures. Examples are polyhedral surfaces and planar maps, where the edges emanating from a vertex or the edges around a facet form a circular sequence.

Since circular sequences do not allow for efficient iterators, we have introduced the new concept of *circulators*. They share most of the requirements of iterators, while the main difference is the lack of a past-the-end position in the sequence. Appropriate adaptors are provided between iterators and circulators to integrate circulators smoothly into the framework of STL. An example of a generic `contains` function illustrates the use of circulators. As usual for circular structures, a `do-while` loop is preferable, such that for the specific input, `c == d`, all elements in the sequence are reached.

```
template <class Circulator, class T>
bool contains( Circulator c, Circulator d, const T& value) {
    if (c != 0) {
        do {
            if (*c == value)
                return true;
        } while (++c != d);
    }
    return false;
}
```

Three circulator categories are defined: forward, bidirectional and random-access circulators. Given a circulator `c`, the operation `*c` denotes the item the circulator refers to. The operation `++c` advances the circulator by one item and `--c` steps a bidirectional circulator one item backwards. For random-access circulators `c+n` advances the circulator `n` steps. Two circulators can be compared for equality.

Circulators have a different notion of reachability and ranges than iterators. A circulator `d` is called *reachable* from a circulator `c` if `c` can be made equal to `d` with finitely many applications of the operator `++`. Due to the circularity of the sequence this is always true if both circulators refer to items of the same sequence. In particular, `c` is always reachable from `c`. Given two circulators `c` and `d`, the range `[c, d)` denotes all circulators obtained by starting with `c` and advancing `c` until `d` is reached, but does not include `d`, for `d ≠ c`. So far it is the same range definition as for iterators. The difference lies in the use of `[c, c)` to denote all items in the circular sequence, whereas for an iterator `i` the range `[i, i)` denotes the empty range. As long as `c != d` the range `[c, d)` behaves like an iterator range and could be used in STL algorithms. For circulators however, an additional test `c == NULL` is required that returns true if and only if the circular sequence is empty. As for C++, we recommend the use of 0 instead of `NULL`.

Besides the conceptual cleanness, the main reason for inventing a new concept with a similar intent as iterators is efficiency. An iterator is supposed to be a light-weight object – merely a pointer and a single indirection to advance the iterator. Although iterators could be written for circular sequences, we do not know of an efficient solution. The missing past-the-end situation in circular sequences can be solved with an arbitrary sentinel in the cyclic order, but this would destroy the natural symmetry in the structure (which is in itself a bad idea) and additional bookkeeping in the items and checking in the iterator advance method reduces efficiency. Another solution may use more bookkeeping in the iterator, e.g. with a start item, a current item, and a kind of winding-number that is zero for the `begin()`-iterator and one for the past-the-end situation¹. We have introduced the concept of circulators that allows light-weight implementations and the CGAL support library provides adaptor classes that convert between iterators and circulators (with the corresponding penalty in efficiency), so as to integrate this new concept into the framework of STL.

¹This is currently implemented as the adaptor class which provides a pair of iterators for a given circulator.

A serious design problem is the slight change of the semantic for circulator ranges as compared to iterator ranges. Since this semantic is defined by the intuitive operators `++` and `==`, which we would like to keep for circulators as well, circulator ranges can be used in STL algorithms. This is in itself a useful feature, if there would not be the definition of a full range $[c, c)$ that an STL algorithm will treat as an empty range. However, the likelihood of a mistake may be overestimated, since for a container `C` supporting circulators there is no `end()` member function, and an expression such as `std::sort(C.begin(), C.end())` will fail. It is easy to distinguish iterators and circulators at compile time, which allows for generic algorithms supporting both as arguments. It is also possible to protect algorithms against inappropriate arguments using the same technique, see the reference pages for circulators, specifically the *Assert_iterator* and *is_empty_range* functions.

Warning: Please note that the definition of a range is different from that of iterators. An interface of a data structure must declare whether it works with iterators, circulators, or both. STL algorithms always specify only iterators in their interfaces. A range $[c, d)$ of circulators used in an interface for iterators will work as expected as long as $c \neq d$. A range $[c, c)$ will be interpreted as the empty range like for iterators, which is different than the full range that it should denote for circulators.

57.2.2 Forward Circulator

A class *Circulator* that satisfies the requirements of a forward circulator with the value type *T*, supports the following operations. See the reference pages for the full set of requirements. Note that the stated return values are not required, only a return value that is convertible to the stated type is required. As for C++, we recommend the use of 0 instead of `NULL`.

Types

<i>Circulator::value_type</i>	the value type <i>T</i> .
<i>Circulator::reference</i>	either reference or const reference to <i>T</i> .
<i>Circulator::pointer</i>	either pointer or const pointer to <i>T</i> .
<i>Circulator::size_type</i>	unsigned integral type that can hold the size of the sequence.
<i>Circulator::difference_type</i>	signed integral type that can hold the distance between two circulators.
<i>Circulator::iterator_category</i>	circulator category <i>Forward_circulator_tag</i> .

Creation

<i>Circulator</i> <i>c</i> ;	a circulator equal to <i>NULL</i> denoting an empty sequence.
<i>Circulator</i> <i>c</i> (<i>d</i>);	a circulator equal to <i>d</i> .

Operations

<i>Circulator</i> &	<i>c</i> = <i>d</i>	Assignment.
<i>bool</i>	<i>c</i> == <i>NULL</i>	Test for emptiness.
<i>bool</i>	<i>c</i> != <i>NULL</i>	Test for non-emptiness, i.e. $!(c == NULL)$.
<i>bool</i>	<i>c</i> == <i>d</i>	<i>c</i> is equal to <i>d</i> if they refer to the same item.
<i>bool</i>	<i>c</i> != <i>d</i>	Test for inequality, i.e. $!(c == d)$.
<i>reference</i>	* <i>c</i>	Returns the value of the circulator. If <i>Circulator</i> is mutable $*c = t$ is valid. <i>Precondition:</i> <i>c</i> is dereferenceable.

<i>pointer</i>	$c \rightarrow$	Returns a pointer to the value of the circulator. <i>Precondition:</i> c is dereferenceable.
<i>Circulator&</i>	$++c$	Prefix increment operation. <i>Precondition:</i> c is dereferenceable. <i>Postcondition:</i> c is dereferenceable.
<i>Circulator</i>	$c++$	Postfix increment operation. The result is the same as that of: <i>Circulator tmp = c; ++c; return tmp; .</i>

57.2.3 Bidirectional Circulator

A class *Circulator* that satisfies the requirements of a bidirectional circulator with the value type T , supports the following operations in addition to the operations supported by a forward circulator.

Types

Circulator::iterator_category

circulator category *Bidirectional_circulator_tag*.

Operations

<i>Circulator&</i>	$--c$	Prefix decrement operation. <i>Precondition:</i> c is dereferenceable. <i>Postcondition:</i> c is dereferenceable.
<i>Circulator</i>	$c--$	Postfix decrement operation. The result is the same as that of <i>Circulator tmp = c; --c; return tmp; .</i>

57.2.4 Random Access Circulator

A class *Circulator* that satisfies the requirements of a random access Circulator for the value type T , supports the following operations in addition to the operations supported by a bidirectional Circulator. In contrast to random access iterators, no comparison operators are available for random access circulators.

Types

Circulator::iterator_category

circulator category *Random_access_circulator_tag*.

Operations

<i>Circulator</i> &	$c += \text{difference_type } n$	The result is the same as if the prefix increment operation was applied n times, but it is computed in constant time.
<i>Circulator</i>	$c + \text{difference_type } n$	Same as above, but returns a new circulator.
<i>Circulator</i>	$\text{difference_type } n + c$	Same as above.
<i>Circulator</i> &	$c -= \text{difference_type } n$	The result is the same as if the prefix decrement operation was applied n times, but it is computed in constant time.
<i>Circulator</i>	$c - \text{difference_type } n$	Same as above, but returns a new circulator.
<i>reference</i>	$c[\text{difference_type } n]$	Returns $*(c + n)$.
<i>difference_type</i>	$c - \text{Circulator } d$	returns the difference between the two circulators. The value will be in the interval $[1 - s, s - 1]$ if s is the size of the total sequence. The difference for a fixed circulator c (or d) with all other circulators d (or c) is a consistent ordering of the elements in the data structure. There has to be a minimal circulator d_{\min} for which the difference $c - d_{\min}$ to all other circulators c is non-negative.
<i>Circulator</i>	$c.\text{min_circulator}()$	Returns the minimal circulator c_{\min} in constant time.

57.2.5 Adaptors Between Iterators and Circulators

Algorithms working on iterator ranges can not be applied to circulator ranges in full generality, only to subranges (see the warning in Section 57.2.1). The following adaptors convert circulators to iterators and vice versa (with the unavoidable space and time penalty) to reestablish this generality.

```
#include <CGAL/circulator.h>
```

```
Container_from_circulator  container-like class with iterators built from a circulator
Circulator_from_iterator   circulator over a range of two iterators
Circulator_from_container  circulator for a container
```

The following example applies the generic `std::reverse()` algorithm from STL to a sequence given by a bidirectional circulator `c`. It uses the *Container_from_circulator* adaptor.

```
Circulator c; // c must be at least bidirectional.
CGAL::Container_from_circulator<Circulator> container(c);
std::reverse( container.begin(), container.end());
```

Another example defines a circulator c for a vector of int 's. However, since there are no elements in the vector, the circulator denotes an empty sequence. If there were elements in the vector, the circulator would implement a random access modulus the size of the sequence.

```
std::vector<int> v;
typedef CGAL::Circulator_from_iterator<
    std::vector<int>::iterator > Circulator;
Circulator c( v.begin(), v.end());
```

57.2.6 Functions on Circulators

A few functions deal with circulators and circulator ranges. The type C denotes a circulator. The type IC denotes either a circulator or an iterator. More on algorithms that work with circulators as well with iterators can be found in the reference pages.

```
#include <CGAL/circulator.h>
```

<i>circulator_size</i> ($C\ c$)	size of the sequence reachable by c
<i>circulator_distance</i> ($C\ c, C\ d$)	number of elements in the range $[c, d)$
<i>iterator_distance</i> ($IC\ ic1, IC\ ic2$)	number of elements in the range $[ic2, ic1)$
<i>is_empty_range</i> ($IC\ ic1, IC\ ic2$)	test the range $[ic2, ic1)$ for emptiness

Handles and Circulators

Reference Manual

Olivier Devillers, Lutz Kettner, Michael Seel, and Mariette Yvinec

Most data structures in CGAL use the concept of *Handle* in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A *Handle* is akin to a pointer to an object providing the dereference operator *operator**() and member access *operator->*() but no increment or decrement operators like iterators. A *Handle* is intended to be used whenever the referenced object is not part of a logical sequence.

The concept of iterators in STL is tailored for linear sequences. In contrast, circular sequences occur naturally in many combinatorial and geometric structures. Examples are polyhedral surfaces and planar maps, where the edges emanating from a vertex or the edges around a facet form a circular sequence.

We provide several functions, classes and macros to assist in working with circulators: distance computation, adaptor classes converting between circulators and iterators, base classes to ease the implementation of circulators, and support for generic algorithms that work with circulators as well as with iterators.

CGAL::Assert_circulator

Definition

Each of the following assertions, applicable to an iterator or a circulator or both, checks at compile time if its argument is of the kind stated in the assertions name, i.e. a circulator, an iterator, or a particular category of either an iterator or a circulator. Note that neither input nor output circulators exists.

```
#include <CGAL/circulator.h>
```

```
void          Assert_circulator( C c)
void          Assert_iterator( I i)
void          Assert_circulator_or_iterator( IC i)

void          Assert_input_category( I i)
void          Assert_output_category( I i)
void          Assert_forward_category( IC ic)
void          Assert_bidirectional_category( IC ic)
void          Assert_random_access_category( IC ic)
```

CGAL::circulator_distance

Definition

The distance of a circulator c to a circulator d is the number of elements in the range $[c, d)$. It is defined to be zero for a circulator on an empty sequence and it returns the size of the data structure when applied to a range of the form $[c, c)$.

```
#include <CGAL/circulator.h>
```

```
template <class C>  
C::difference_type      circulator_distance( C c, C d)
```

See Also

circulator_size, *iterator_distance*, *is_empty_range*, *Circulator*.

CGAL::circulator_size

Definition

The size of a circulator is the size of the data structure it refers to. It is zero for a circulator on an empty sequence. The size can be computed in linear time for forward and bidirectional circulators, and in constant time for random access circulators using the minimal circulator. The function *circulator_size(c)* returns the circulator size. It uses the *c.min_circulator()* function if *c* is a random access circulator.

```
#include <CGAL/circulator.h>
```

```
template <class C>  
C::size_type          circulator_size( C c)
```

circulator_distance, *iterator_distance*, *is_empty_range*, *Circulator*.

Circulator

Definition

Note: This specification is a revised version based on the C++ Standard [C++98], which is available now. In particular, iterator traits are now assumed and required.

Iterators in the STL were tailored for linear sequences. The specialization for circular data structures leads to slightly different requirements which we will summarize in the *circulators* concept. The main difference is that a circular data structure has no natural past-the-end value. As a consequence, a container supporting circulators will not have an `end()`-member function. The semantic of a circulator range differs from the semantic of an iterator range. For a circulator c the range $[c, c)$ denotes the sequence of all elements in the data structure. For iterators, this range defines the empty sequence. A separate test for an empty sequence has been added to the circulator requirements: A comparison $c == \text{NULL}$ for a circulator c is true for an empty sequence. As for C++, we recommend the use of 0 instead of `NULL`.

Similar to STL iterators, we distinguish between forward, bidirectional, and random access circulators². Most requirements for circulators are equal to those for iterators. We present the changes, please refer to [MS96, chapter 18] or [C++98] for the iterator requirements.

Past-the-end value: There is no past-the-end value for circulators.

Singular values: There are no singular values for circulators³

Empty sequence: The comparison $c == \text{NULL}$ (or $c == 0$) for a circulator c is `true` if c denotes an empty sequence, and `false` otherwise.

Dereferenceable values: A circulator that does not denote an empty sequence is dereferenceable.

Reachability: Each dereferenceable circulator can reach itself with a finite and non-empty sequence of applications of `operator++`.

Ranges: For any circulator c the range $[c, c)$ is a valid range. If the circulator refers to an empty sequence, the range $[c, c)$ denotes the empty range. Otherwise the circulator is dereferenceable and the range $[c, c)$ denotes the sequence of all elements in the data structure. *Remark:* When a circulator is used in a place of an iterator, as, for example, with an STL algorithm, it will work as expected with the only exception that, in STL algorithms, the range $[c, c)$ denotes always the empty range. This is not a requirement, but a consequence of the requirements stated here and the fact that the STL requirements for iterator ranges are based on the `operator++` and the `operator==`, which we use for circulators as well. In principle, we face here the difference between a `while` loop and a `do-while` loop.

Types: For a circulator of type C the following local types are required:

<code>C::value_type</code>	value type the circulator refers to.
<code>C::reference</code>	reference type used for the return type of <code>C::operator*()</code> .
<code>C::pointer</code>	pointer type used for the return type of <code>C::operator->()</code> .
<code>C::size_type</code>	unsigned integral type that can hold the size of a sequence
<code>C::difference_type</code>	signed integral type that can hold the distance between two circulators.
<code>C::iterator_category</code>	circulator category.

²Input circulators are a contradiction, since any circulator is supposed to return once to itself. Output circulators are not supported since they would be indistinguishable from output iterators.

³Since circulators must be implemented as classes anyway, there is no need to allow singular values for them. An un-initialized circulator does not have a singular value, but is supposed to refer to an empty sequence.

Forward Circulators

In the following, we assume that a and b are circulators of type C , r is of type $C\&$ (is assignable), and T denotes the value type of C . Let D be the distance type of C . As for $C++$, we recommend the use of 0 instead of $NULL$.

<code>C()</code>	a circulator equal to <i>NULL</i> denoting an empty sequence.
<code>a == NULL</code>	Returns <i>true</i> if a denotes an empty sequence, <i>false</i> otherwise. For simplicity, <code>NULL == a</code> is not required. The behavior for comparisons with pointer-like values different than <i>NULL</i> is undefined. A runtime assertion is recommended.
<code>a != NULL</code>	Returns <code>!(a == NULL)</code> .
<code>++r</code>	Like for forward iterators, but a dereferenceable circulator r will always be dereferenceable after <code>++r</code> (no past-the-end value). <i>Precondition:</i> r does not denote an empty sequence.
<code>r++</code>	Same as for <code>++r</code> .
<code>C::iterator_category</code>	circulator category <code>CBP_Forward_circulator_tag</code> .

Bidirectional Circulators

The same requirements as for the forward circulators hold for bidirectional iterators with the following change of the iterator category:

`C::iterator_category` circulator category `CBP_Bidirectional_circulator_tag`.

Random Access Circulators

The same requirements as for the bidirectional circulators hold for random access iterators with the following changes and extensions.

The idea of random access extends naturally to circulators using equivalence classes modulus the length of the sequence. With this in mind, the additional requirements for random access iterators hold also for random access circulators. The only exception is that the random access iterator is required to provide a total order on the sequence, which a circulator cannot provide⁴.

The difference of two circulators is not unique as for iterators. A reasonable requirement demands that the result is in a certain range $[1 - \text{size}, \text{size} - 1]$, where *size* is the size of the sequence, and that whenever a circulator a is fixed that the differences with all other circulators of the sequence form a consistent ordering.

For the adaptor to iterators a minimal circulator d_{\min} is required for which the difference $c - d_{\min}$ to all other circulators c is non negative.

<code>b - a</code>	limited range and consistent ordering as explained above.
<code>a.min_circulator()</code>	returns the minimal circulator from the range $[a, a)$.
<code>C::iterator_category</code>	circulator category <code>CBP_Random_access_circulator_tag</code> .

⁴One might define an order by splitting the circle at a fixed point, e.g. the start circulator provided from the data structure. This is what the adaptor to iterators will do. Nonetheless, we do not require this for circulators.

Const Circulators

As with iterators, we distinguish between circulators and const circulators. The expression `*a = t` with `t` of type `T` is valid for mutable circulators. It is invalid for const circulators.

Circulators in Container Classes

For a container `x` of type `X` that supports circulators `c` the following naming convention is recommended:

<code>X::Circulator</code>	the type of the mutable circulator.
<code>X::Const_circulator</code>	the type of the const circulator.
<code>c = x.begin()</code>	the start circulator of the sequence. It is of type <code>X::Circulator</code> for a mutable container or <code>X::Const_circulator</code> for a const container. There must not be an <code>end()</code> member function.

If a container will support iterators and circulators, the member function `circulator_begin()` is proposed. However, the support of iterators and circulators simultaneously is not recommended, since it would lead to fat interfaces. The natural choice should be supported, the other concept will be available through adaptors.

Example

A generic `contains` function accepts a range of circulators and a value. It returns *true* if the value is contained in the sequence of items denoted by the range of circulators. As usual for circular structures, a do-while loop is preferable, such that for the specific input, `c == d`, all elements in the sequence are reached. Note that the example simplifies if the sequence is known to be non-empty, which is for example the common case in polyhedral surfaces where vertices and facets have at least one incident edge.

```
template <class Circulator, class T>
bool contains( Circulator c, Circulator d, const T& value) {
    if (c != 0) {
        do {
            if (*c == value)
                return true;
        } while (++c != d);
    }
    return false;
}
```

```

#include <CGAL/basic.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/circulator.h>

typedef CGAL::Circulator_from_container< std::vector<int> > Circulator;
typedef CGAL::Container_from_circulator<Circulator> Container;
typedef Container::iterator Iterator;

int main() {
    std::vector<int> v;
    v.push_back(5);
    v.push_back(2);
    v.push_back(9);
    Circulator c( &v);
    Container container( c);
    std::sort( container.begin(), container.end());
    Iterator i = container.begin();
    assert( *i == 2);
    i++;    assert( *i == 5);
    i++;    assert( *i == 9);
    i++;    assert( i == container.end());
    return 0;
}

```

File: examples/Circulator/circulator_prog2.cpp

CGAL::Circulator_from_iterator<I>

Definition

The adaptor *Circulator_from_iterator<I>* converts two iterators of type *I*, a begin and a past-the-end value, to a circulator of equal category. The iterator must be at least of the forward iterator category. The circulator will be mutable or non-mutable according to the iterator. Iterators provide no *size_type*. This adapter assumes *std::size_t* instead.

```
#include <CGAL/circulator.h>
```

Types

```
typedef I          iterator;
```

In addition all types required for circulators are provided.

Creation

Circulator_from_iterator<I> *c*; a circulator *c* on an empty sequence.

Circulator_from_iterator<I> *c*(*I begin*, *I end*, *I cur = begin*);

a circulator *c* initialized to refer to the element **cur* in a range *[begin, end)*. The circulator *c* refers to a empty sequence if *begin==end*.

Circulator_from_iterator<I> *c*(*Circulator_from_iterator<I,T,Size,Dist>* *d*, *I cur*);

a copy of circulator *d* referring to the element **cur*. The circulator *c* refers to a empty sequence if *d* does so.

Operations

The adaptor conforms to the requirements of the respective circulator category. An additional member function *current_iterator()* returns the current iterator pointing to the same position as the circulator does.

See Also

Container_from_circulator, *Circulator_from_container*, *Circulator*.

Example

The following program composes two adaptors – from an iterator to a circulator and back to an iterator. It applies an STL sort algorithm on a STL vector containing three elements. The resulting vector will be [2 5 9] as it is checked by the assertions. The program is part of the CGAL distribution.

```

#include <CGAL/basic.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/circulator.h>

typedef std::vector<int>::iterator      I;
typedef CGAL::Circulator_from_iterator<I>      Circulator;
typedef CGAL::Container_from_circulator<Circulator> Container;
typedef Container::iterator      Iterator;

int main() {
    std::vector<int> v;
    v.push_back(5);
    v.push_back(2);
    v.push_back(9);
    Circulator c( v.begin(), v.end());
    Container container( c);
    std::sort( container.begin(), container.end());
    Iterator i = container.begin();
    assert( *i == 2);
    i++;    assert( *i == 5);
    i++;    assert( *i == 9);
    i++;    assert( i == container.end());
    return 0;
}

```

File: examples/Circulator/circulator_prog1.cpp

Another example usage for this adaptor is a random access circulator over the built-in C arrays. Given an array of type T^* with a begin pointer b and a past-the-end pointer e the adaptor *Circulator_from_iterator* $\langle T^* \rangle c(b,e)$ is a random access circulator c over this array.

CGAL::Circulator_tag

Definition

Iterators and circulators as well as different categories of circulators can be distinguished with the use of discriminating functions and the following circulator tags. A couple of base classes simplify the task of writing own circulators. They declare the appropriate tags and the local types needed for circulators. To use the tags or base classes only it is sufficient to include:

```
#include <CGAL/circulator_bases.h>
#include <CGAL/circulator.h>
```

Compile Time Tags

<code>struct Circulator_tag {};</code>	any circulator.
<code>struct Iterator_tag {};</code>	any iterator.
 <code>struct Forward_circulator_tag {};</code>	 derived from <code>forward_iterator_tag</code> .
<code>struct Bidirectional_circulator_tag {};</code>	derived from <code>bidirectional_iterator_tag</code> .
<code>struct Random_access_circulator_tag {};</code>	derived from <code>random_access_iterator_tag</code> .

Base Classes

```
template < class Category, class T, class Dist = std::ptrdiff_t, class Size = std::size_t, class Ptr = T*, class Ref
= T& >
struct Circulator_base {};

struct Forward_circulator_base {};
struct Bidirectional_circulator_base {};
struct Random_access_circulator_base {};
```

See Also

`query_circulator_or_iterator`, `Circulator_traits`, `Assert_circulator`,
`CGAL_For_all`, `is_empty_range`, `Circulator`.

Example

The above declarations can be used to distinguish between iterators and circulators and between different circulator categories. The assertions can be used to protect a templated algorithm against instantiations that do not fulfill the requirements. The following example program illustrates both.

```
#include <CGAL/basic.h>
#include <cassert>
#include <list>
#include <CGAL/circulator.h>
```

```

template <class C> inline int foo( C c, std::forward_iterator_tag) {
    CGAL::Assert_circulator( c);
    CGAL::Assert_forward_category( c);
    return 1;
}
template <class C> inline int foo( C c, std::random_access_iterator_tag) {
    CGAL::Assert_circulator( c);
    CGAL::Assert_random_access_category( c);
    return 2;
}
template <class I> inline int foo( I i, CGAL::Iterator_tag) {
    CGAL::Assert_iterator( i);
    return 3;
}

template <class C> inline int foo( C c, CGAL::Circulator_tag) {
    CGAL::Assert_circulator( c);
    typedef std::iterator_traits<C> Traits;
    typedef typename Traits::iterator_category iterator_category;
    return foo( c, iterator_category());
}
template <class IC> inline int foo( IC ic) {
    typedef CGAL::Circulator_traits<IC> Traits;
    typedef typename Traits::category category;
    return foo( ic, category());
}

int main() {
    typedef CGAL::Forward_circulator_base<int> F;
    typedef CGAL::Random_access_circulator_base<int> R;
    F f = F();
    R r = R();
    std::list<int> l;
    assert( foo( f) == 1);
    assert( foo( r) == 2);
    assert( foo( l.begin()) == 3);
    return 0;
}

```

File: examples/Circulator/circulator_prog3.cpp

Implementation

Since not all current compilers can eliminate the space needed for the compile time tags even when deriving from them, we implement a variant for each base class that contains a protected *void** data member called *_ptr*. Here, the allocated space in the derived classes can be reused.

<i>template <class T, class Dist, class Size></i>	
<i>class Forward_circulator_ptrbase {};</i>	forward circulator.
<i>template <class T, class Dist, class Size></i>	
<i>class Bidirectional_circulator_ptrbase {};</i>	bidirectional circulator.
<i>template <class T, class Dist, class Size></i>	

class Random_access_circulator_ptrbase {};

random access circulator.

CGAL::Circulator_traits<C>

Definition

The circulator traits class distinguishes between circulators and iterators. It defines a local type *category* that is identical to the type *Circulator_tag* if the iterator category of the argument *C* is a circulator category. Otherwise it is identical to the type *Iterator_tag*.

The local type *iterator_category* gives the corresponding iterator category for circulators, i.e. one of *forward_iterator_tag*, *bidirectional_iterator_tag*, or *random_access_iterator_tag*.

The local type *circulator_category* gives the corresponding circulator category for iterators, i.e. one of *Forward_circulator_tag*, *Bidirectional_circulator_tag*, or *Random_access_circulator_tag*.

```
#include <CGAL/circulator.h>
```

Types

<i>Circulator_traits<C>::category</i>	either <i>Iterator_tag</i> or <i>Circulator_tag</i> .
<i>Circulator_traits<C>::iterator_category</i>	corresponding iterator category for circulators.
<i>Circulator_traits<C>::circulator_category</i>	corresponding circulator category for iterator

Example

A generic function *bar* that distinguishes between a call with a circulator range and a call with an iterator range:

```
template <class I>
void bar( I i, I j, CGAL::Iterator_tag) {
    CGAL::Assert_iterator(i);
    // This function is called for iterator ranges [i,j).
}
template <class C>
void bar( C c, C d, CGAL::Circulator_tag) {
    CGAL::Assert_circulator(c);
    // This function is called for circulator ranges [c,d).
}
template <class IC>
void bar( IC i, IC j) { // calls the correct function
    return bar( i, j, typename CGAL::Circulator_traits<IC>::category());
}
```

CGAL::Container_from_circulator<C>

Definition

The adaptor *Container_from_circulator<C>* is a class that converts any circulator type *C* to a kind of container class, i.e. a class that provides an *iterator* and a *const_iterator* type and two member functions – *begin()* and *end()* – that return the appropriate iterators. By analogy to STL container classes these member functions return a const iterator in the case that the container itself is constant and a mutable iterator otherwise.

```
#include <CGAL/circulator.h>
```

Types

```
typedef C          Circulator;
Container_from_circulator<C>:: iterator
Container_from_circulator<C>:: const_iterator
Container_from_circulator<C>:: value_type
Container_from_circulator<C>:: reference
Container_from_circulator<C>:: const_reference
Container_from_circulator<C>:: pointer
Container_from_circulator<C>:: const_pointer
Container_from_circulator<C>:: size_type
Container_from_circulator<C>:: difference_type
```

Creation

```
Container_from_circulator<C> container;
```

any iterator of *container* will have a singular value.

```
Container_from_circulator<C> container( C c);
```

any iterator of *container* will have a singular value if the circulator *c* corresponds to an empty sequence.

Operations

<i>iterator</i>	<i>container.begin()</i>	the start iterator.
<i>const_iterator</i>	<i>container.begin() const</i>	the start const iterator.
<i>iterator</i>	<i>container.end()</i>	the past-the-end iterator.
<i>const_iterator</i>	<i>container.end() const</i>	the past-the-end const iterator.

The *iterator* and *const_iterator* types are of the appropriate iterator category. In addition to the operations required for their category, they have a member function *current_circulator()* that returns a circulator pointing to the same position as the iterator does.

See Also

Circulator_from_iterator, *Circulator_from_container*, *Circulator*.

Example

The generic `reverse()` algorithm from the STL can be used with an adaptor if at least a bidirectional circulator `c` is given.

```
Circulator c; // c is assumed to be a bidirectional circulator.
CGAL::Container_from_circulator<Circulator> container(c);
reverse( container.begin(), container.end());
```

Implementation

The iterator adaptor keeps track of the number of rounds a circulator has done around the ring-like data structure (a kind of winding number). It is used to distinguish between the start position and the end position which will be denoted by the same circulator internally. This winding number is zero for the *begin()*-iterator and one for the *end()*-iterator. It is incremented whenever the internal circulator passes the *begin()* position. Two iterators are equal if their internally used circulators and winding numbers are equal. This is more general than necessary since an iterator equal to *end()*-iterator is not supposed to be incremented any more, which is here still possible in a defined manner.

The implementation is different for random access iterators. The random access iterator has to be able to compute the size of the data structure in constant time. This is for example needed if the difference of the past-the-end iterator and the begin iterator is taken, which is exactly the size of the data structure. Therefore, if the circulator is of the random-access category, the adapter chooses the minimal circulator for the internal anchor position. The minimal circulator is part of the random access circulator requirements, see Page [3150](#). For the random access iterator the adaptor implements a total ordering relation that is currently not required for random access circulators.

CGAL_For_all

Definition

In order to write algorithms that work with iterator ranges as well as with circulator ranges we have to consider the difference of representing an empty range. For iterators this is the range $[i, i)$, while for circulators it would be $c == \text{NULL}$, the empty sequence test. The function *is_empty_range* provides the necessary generic test which accepts an iterator range or a circulator range and says whether the range is empty or not.

```
#include <CGAL/circulator.h>
```

A macro *CGAL_For_all*(*i*, *j*) simplifies the writing of such simple loops as the one in the example of the function *is_empty_range*. *i* and *j* can be either iterators or circulators. The macro loops through the range $[i, j)$. It increments *i* until it reaches *j*. The implementation looks like:

```
CGAL_For_all(i,j)  ≡  for ( bool _circ_loop_flag = ! ::CGAL::is_empty_range(i, j);
                          _circ_loop_flag;
                          _circ_loop_flag = ((++i) != (j))
                          )
```

Note that the macro behaves like a *for*-loop. It can be used with a single statement or with a statement block. For bidirectional iterators or circulators, a backwards loop macro *CGAL_For_all_backwards*(*i*, *j*) exists that decrements *j* until it reaches *i*.

Assert_circulator_or_iterator, *Circulator*.

Handle

Definition

Most data structures in CGAL use the concept of Handle in their user interface to refer to the elements they store. This concept describes what is sometimes called a trivial iterator. A Handle is akin to a pointer to an object providing the dereference operator *operator**() and member access *operator->*() but no increment or decrement operators like iterators. A Handle is intended to be used whenever the referenced object is not part of a logical sequence.

Like iterators, the handle can be passed as template argument to *std::iterators_traits* in order to extract its *value_type*, the type of the element pointed to. The *iterator_category* is *void*.

Refines

DefaultConstructible, CopyConstructible, Assignable, EqualityComparable

The default constructed object must be unique as far as the equality operator is concerned (this serves the same purpose as NULL for pointers). (Note that this is not a generally supported feature of iterators of standard containers.)

Creation

Dereference

<i>value_type</i> &	<i>*h</i>	returns the object pointed to.
<i>value_type</i> *	<i>h -></i>	returns a pointer to the object pointed to.

Has Models

pointers
const pointers
iterators
circulators

CGAL::is_empty_range

Definition

In order to write algorithms that work with iterator ranges as well as with circulator ranges we have to consider the difference of representing an empty range. For iterators this is the range $[i, i)$, while for circulators it would be $c == \text{NULL}$, the empty sequence test. The function *is_empty_range* provides the necessary generic test which accepts an iterator range or a circulator range and says whether the range is empty or not.

```
#include <CGAL/circulator.h>
```

```
template< class IC>
```

```
bool    is_empty_range( IC i, IC j)    is true if the range  $[i, j)$  is empty, false otherwise.  
                                             Precondition: IC is either a circulator or an iterator type. The range  $[i, j)$  is valid.
```

Example

The following function *process_all* accepts a range $[i, j)$ of an iterator or circulator *IC* and processes each element in this range:

```
template <class IC>
void process_all( IC i, IC j) {
    if (! CGAL::is_empty_range( i, j)) {
        do {
            process(*i);
        } while (++i != j);
    }
}
```

iterator_distance, *CGAL_For_all*, *Circulator_tag*, *Circulator_traits*, *Assert_circulator_or_iterator*, *Circulator*.

CGAL::iterator_distance

Definition

The following function returns the distance between either two iterators or two circulators. The return type is `ptrdiff_t` for compilers not supporting iterator traits yet.

```
#include <CGAL/circulator.h>
```

```
template <class IC>  
iterator_traits<IC>::difference_type    iterator_distance( IC ic1, IC ic2)
```

See Also

circulator_size, *circulator_distance*, *is_empty_range*, *Circulator_tag*,
Assert_circulator_or_iterator, *CGAL_For_all*, *Circulator*.

CGAL::query_circulator_or_iterator

Definition

The following function distinguishes between circulators and iterators. It is based on iterator traits [C++98, Mye95] and *Circulator_traits*.

```
#include <CGAL/circulator.h>
```

```
template <class I>
Iterator_tag    query_circulator_or_iterator( I i)
```

if the iterator category of *I* belongs to an iterator.

```
template <class C>
Circulator_tag  query_circulator_or_iterator( C c)
```

if the iterator category of *C* belongs to a circulator.

See Also

Circulator_tag, *Circulator_traits*, *Assert_circulator*, *Circulator*.

Chapter 58

Geometric Object Generators

Susan Hert, Michael Hoffmann, Lutz Kettner, and Sven Schönherr

Contents

58.1 Introduction	3167
58.1.1 Random Perturbations	3168
58.1.2 Adding Degeneracies	3168

58.2 Example Generating Degenerate Point Sets	3168
58.3 Example Generating Grid Points	3169
58.4 Examples Generating Segments	3171

58.1 Introduction

A variety of generators for geometric objects are provided in CGAL. They are useful as synthetic test data sets, e.g. for testing algorithms on degenerate object sets and for performance analysis.

Two kinds of point generators are provided: first, random point generators and second deterministic point generators. Most random point generators and a few deterministic point generators are provided as input iterators. The input iterators model an infinite sequence of points. The function `CGAL::copy_n()` can be used to copy a finite sequence; see Section 55.5. The iterator adaptor `Counting_iterator` can be used to create finite iterator ranges; see Section 55.5. Other generators are provided as functions that write to output iterators. Further functions add degeneracies or random perturbations.

In 2D, we provide input iterators to generate random points in a disc (`Random_points_in_disc_2`), in a square (`Random_points_in_square_2`), on a circle (`Random_points_on_circle_2`), on a segment (`Random_points_on_segment`), and on a square (`Random_points_on_square_2`). For generating grid points we provide three functions, `points_on_segment_2`, `points_on_square_grid_2` that write to output iterators and an input iterator `Points_on_segment_2`.

For 3D points, input iterators are provided for random points uniformly distributed in a sphere (`Random_points_in_sphere_3`) or cube (`Random_points_in_cube_3`) or on the boundary of a sphere (`Random_points_on_sphere_3`). For generating 3D grid points, we provide the function `points_on_cube_grid_3` that writes to an output iterator.

We also provide two functions for generating more complex geometric objects. The function *random_convex_set_2* computes a random convex planar point set of a given size where the points are drawn from a specific domain and *random_polygon_2* generates a random simple polygon from points drawn from a specific domain.

58.1.1 Random Perturbations

Degenerate input sets like grid points can be randomly perturbed by a small amount to produce *quasi*-degenerate test sets. This challenges numerical stability of algorithms using inexact arithmetic and exact predicates to compute the sign of expressions slightly off from zero. For this the function *perturb_points_2* is provided.

58.1.2 Adding Degeneracies

For a given point set certain kinds of degeneracies can be produced by adding new points. The *random_selection()* function is useful for generating multiple copies of identical points. The function *random_collinear_points_2()* adds collinearities to a point set.

58.1.3 Support Functions and Classes for Generators

The function *random_selection* chooses n items at random from a random access iterator range which is useful to produce degenerate input data sets with multiple entries of identical items.

58.2 Example Generating Degenerate Point Sets

We want to generate a test set of 1000 points, where 60% are chosen randomly in a small disc, 20% are from a larger grid, 10% are duplicates points, and 10% collinear points. A random shuffle removes the construction order from the test set. See Figure 58.1 for the example output.

```
#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/point_generators_2.h>
#include <CGAL/copy_n.h>
#include <CGAL/random_selection.h>

using namespace CGAL;

typedef Simple_cartesian<double>          R;
typedef R::Point_2                        Point;
typedef Creator_uniform_2<double,Point>   Creator;
typedef std::vector<Point>                Vector;

int main() {
    // Create test point set. Prepare a vector for 1000 points.
    Vector points;
    points.reserve(1000);
```

```

// Create 600 points within a disc of radius 150.
Random_points_in_disc_2<Point,Creator> g( 150.0);
CGAL::copy_n( g, 600, std::back_inserter(points));

// Create 200 points from a 15 x 15 grid.
points_on_square_grid_2( 250.0, 200, std::back_inserter(points),Creator());

// Select 100 points randomly and append them at the end of
// the current vector of points.
random_selection( points.begin(), points.end(), 100,
    std::back_inserter(points));

// Create 100 points that are collinear to two randomly chosen
// points and append them to the current vector of points.
random_collinear_points_2( points.begin(), points.end(), 100,
    std::back_inserter( points));

// Check that we have really created 1000 points.
assert( points.size() == 1000);

// Use a random permutation to hide the creation history
// of the point set.
std::random_shuffle( points.begin(), points.end(), default_random);

// Check range of values.
for ( Vector::iterator i = points.begin(); i != points.end(); i++){
assert( i->x() <= 251);
assert( i->x() >= -251);
assert( i->y() <= 251);
assert( i->y() >= -251);
}
return 0;
}

```

File: examples/Generator/random_degenerate_point_set.cpp

58.3 Example Generating Grid Points

The second example demonstrates the point generators with integer points. Arithmetic with *doubles* is sufficient to produce regular integer grids. See Figure [58.2](#) for the example output.

```

#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/point_generators_2.h>
#include <CGAL/copy_n.h>

using namespace CGAL;

```

Figure 58.1: Output of example program for point generators.

Figure 58.2: Output of example program for point generators working on integer points.

```
typedef Simple_cartesian<int>      R;
typedef R::Point_2                 Point;
typedef Creator_uniform_2<int,Point> Creator;

int main() {
    // Create test point set. Prepare a vector for 400 points.
    std::vector<Point> points;
    points.reserve(400);

    // Create 250 points from a 16 x 16 grid. Note that the double
    // arithmetic is sufficient to produce exact integer grid points.
    // The distance between neighbors is 34 pixel = 510 / 15.
    points_on_square_grid_2( 255.0, 250, std::back_inserter(points),Creator());

    // Lower, left corner.
    assert( points[0].x() == -255);
    assert( points[0].y() == -255);

    // Upper, right corner. Note that 6 points are missing to fill the grid.
    assert( points[249].x() == 255 - 6 * 34);
    assert( points[249].y() == 255);

    // Create 250 points within a disc of radius 150.
    Random_points_in_disc_2<Point,Creator> g( 150.0);
    CGAL::copy_n( g, 250, std::back_inserter(points));

    // Check that we have really created 500 points.
    assert( points.size() == 500);
    return 0;
}
```

Figure 58.3: Output of the first example program for the generic generator.

Figure 58.4: Output of the second example program for the generic generator without using intermediate storage.

File: examples/Generator/random_grid.cpp

58.4 Examples Generating Segments

The following two examples illustrate the use of the generic functions from Section 55.5 like *Join_input_iterator_2* to generate composed objects from other generators – here two-dimensional segments from two point generators.

We want to generate a test set of 200 segments, where one endpoint is chosen randomly from a horizontal segment of length 200, and the other endpoint is chosen randomly from a circle of radius 250. See Figure 58.3 for the example output.

```
#include <CGAL/Simple_cartesian.h>
#include <cassert>
#include <vector>
#include <algorithm>
#include <CGAL/Point_2.h>
#include <CGAL/Segment_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/copy_n.h>

using namespace CGAL;

typedef Simple_cartesian<double>          R;
typedef R::Point_2                        Point;
typedef Creator_uniform_2<double, Point>  Pt_creator;
```

```

typedef R::Segment_2          Segment;
typedef std::vector<Segment>   Vector;

int main() {
    // Create test segment set. Prepare a vector for 200 segments.
    Vector segs;
    segs.reserve(200);

    // Prepare point generator for the horizontal segment, length 200.
    typedef Random_points_on_segment_2<Point,Pt_creator> P1;
    P1 p1( Point(-100,0), Point(100,0));

    // Prepare point generator for random points on circle, radius 250.
    typedef Random_points_on_circle_2<Point,Pt_creator> P2;
    P2 p2( 250);

    // Create 200 segments.
    typedef Creator_uniform_2< Point, Segment> Seg_creator;
    typedef Join_input_iterator_2< P1, P2, Seg_creator> Seg_iterator;
    Seg_iterator g( p1, p2);
    CGAL::copy_n( g, 200, std::back_inserter(segs));

    assert( segs.size() == 200);
    for ( Vector::iterator i = segs.begin(); i != segs.end(); i++){
        assert( i->source().x() <= 100);
        assert( i->source().x() >= -100);
        assert( i->source().y() == 0);
        assert( i->target().x() * i->target().x() +
                i->target().y() * i->target().y() <= 251*251);
        assert( i->target().x() * i->target().x() +
                i->target().y() * i->target().y() >= 249*249);
    }
    return 0;
}

```

File: examples/Generator/random_segments1.cpp

The second example generates a regular structure of 100 segments; see Figure 58.4 for the example output. It uses the *Points_on_segment_2* iterator, *Join_input_iterator_2* and *Counting_iterator* to avoid any intermediate storage of the generated objects until they are used, which in this example means copied to a window stream.

```

#include <CGAL/Simple_cartesian.h>
#include <algorithm>
#include <vector>
#include <CGAL/point_generators_2.h>
#include <CGAL/function_objects.h>
#include <CGAL/Join_input_iterator.h>
#include <CGAL/Counting_iterator.h>

using namespace CGAL;

typedef Simple_cartesian<double>          R;

```

```

typedef R::Point_2                               Point;
typedef R::Segment_2                             Segment;
typedef Points_on_segment_2<Point>               PG;
typedef Creator_uniform_2< Point, Segment>       Creator;
typedef Join_input_iterator_2< PG, PG, Creator>   Segm_iterator;
typedef Counting_iterator<Segm_iterator,Segment> Count_iterator;
typedef std::vector<Segment>                     Vector;

int main() {
    // Create test segment set. Prepare a vector for 100 segments.
    Vector segs;
    segs.reserve(100);

    // A horizontal like fan.
    PG p1( Point(-250, -50), Point(-250, 50),50); // Point generator.
    PG p2( Point( 250,-250), Point( 250,250),50);
    Segm_iterator t1( p1, p2); // Segment generator.

Geometric Object Generators

Reference Manual

Susan Hert, Michael Hoffmann, Lutz Kettner, and Sven Schönherr

This chapter describes the functions and classes provided in CGAL that are useful for generating synthetic test data sets, *e.g.*, for testing algorithms on degenerate object sets and for performance analysis. These include a class for generating random numbers and function for selecting random items from a set of objects, generators for two-dimensional and three-dimensional points sets, a generator for random convex sets and one for simple polygons. The STL algorithm *std::random_shuffle* is useful with these functions and classes to to achieve random permutations for otherwise regular generators (*e.g.*, points on a grid or segment).

CGAL::default_random

Definition

The variable *default_random* is the default random numbers generator used for the generator functions and classes.

```
#include <CGAL/Random.h>
```

```
Random                default_random;
```

CGAL::perturb_points_2

Definition

The function *perturb_points_2* perturbs each point in a given range of points by a random amount.

```
#include <CGAL/point_generators_2.h>
```

```
template <class ForwardIterator>
void      perturb_points_2(
            ForwardIterator first,
            ForwardIterator last,
            double xeps,
            double yeps = xeps,
            Random& rnd = default_random,
            Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)
```

perturbs the points in the range $[first, last)$ by replacing each point with a random point from the $xeps \times yeps$ rectangle centered at the original point. Two random numbers are needed from *rnd* for each point.

Requirements

- *Creator* must be a function object accepting two *double* values *x* and *y* and returning an initialized point (*x,y*) of type *P*.
Predefined implementations for these creators like the default are described in Section 55.5.
- The *value_type* of the *ForwardIterator* must be assignable to *P*.
- *P* is equal to the *value_type* of the *ForwardIterator* when using the default initializer.
- The expressions *to_double((*first).x())* and *to_double((*first).y())* must result in the respective coordinate values.

CGAL::points_on_segment_2

Definition

The function *points_on_segment_2* generates a set of points equally spaced on a segment given the endpoints of the segment.

```
#include <CGAL/point_generators_2.h>
```

```
template <class P, class OutputIterator>
OutputIterator points_on_segment_2( P p, P q, std::size_t n, OutputIterator o)
```

creates n points equally spaced on the segment from p to q , i.e. $\forall i : 0 \leq i < n : o[i] := \frac{n-i-1}{n-1} p + \frac{i}{n-1} q$. Returns the value of o after inserting the n points.

CGAL::Points_on_segment_2<Point_2>

Definition

The class *Points_on_segment_2<Point_2>* is a generator for points on a segment whose endpoints are specified upon construction. The points are equally spaced

Is Model for the Concepts

PointGenerator page [3184](#)

Types

```
typedef std::input_iterator_tag      iterator_category;
typedef Point_2                     value_type;
typedef std::ptrdiff_t              difference_type;
typedef const Point_2*              pointer;
typedef Point_2                     reference;
```

Creation

Points_on_segment_2<Point_2> *g*(*Point_2* *p*, *Point_2* *q*, *std::size_t* *n*, *std::size_t* *i* = 0);

g is an input iterator creating points of type *P* equally spaced on the segment from *p* to *q*. *n* − *i* points are placed on the segment defined by *p* and *q*. Values of the index parameter *i* larger than 0 indicate starting points for the sequence further from *p*. Point *p* has index value 0 and *q* has index value *n* − 1. *Requirement:* The expressions *to_double(p.x())* and *to_double(p.y())* must result in the respective *double* representation of the coordinates of *p*, and similarly for *q*.

Operations

double *g.range()* returns the range in which the point coordinates lie, i.e. $\forall x : |x| \leq range()$ and $\forall y : |y| \leq range()$

.

Point_2 *g.source()* returns the source point of the segment.
Point_2 *g.target()* returns the target point of the segment.

CGAL::points_on_square_grid_2

Definition

The function *points_on_square_grid_2* generates a given number of points on a square grid whose size is determined by the number of points to be generated.

```
#include <CGAL/point_generators_2.h>
```

```
template <class OutputIterator, Creator creator>
OutputIterator      points_on_square_grid_2(
                    double a,
                    std::size_t n,
                    OutputIterator o,
                    Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)
```

creates the first n points on the regular $\lceil \sqrt{n} \rceil \times \lceil \sqrt{n} \rceil$ grid within the square $[-a, a] \times [-a, a]$. Returns the value of o after inserting the n points.

Requirements

- *Creator* must be a function object accepting two *double* values x and y and returning an initialized point (x, y) of type P . Predefined implementations for these creators like the default can be found in Section 55.5.
- The *OutputIterator* must accept values of type P . If the *OutputIterator* has a *value_type* the default initializer of the *creator* can be used. P is set to the *value_type* in this case.

CGAL::points_on_cube_grid_3

Definition

The function *points_on_cube_grid_3* generates a given number of points on a cubic grid whose size is determined by the number of points to be generated.

```
#include <CGAL/point_generators_3.h>
```

```
template <class OutputIterator, Creator creator>
OutputIterator      points_on_cube_grid_3(
    double a,
    std::size_t n,
    OutputIterator o,
    Creator creator = Creator_uniform_3<Kernel_traits<P>::Kernel::RT,P>)
```

creates the first n points on the regular $\lceil n^{1/3} \rceil \times \lceil n^{1/3} \rceil \times \lceil n^{1/3} \rceil$ grid within the cube $[-a, a] \times [-a, a] \times [-a, a]$. Returns the value of o after inserting the n points.

Requirements

- *Creator* must be a function object accepting three *double* values x , y , and z and returning an initialized point (x, y, z) of type P . Predefined implementations for these creators like the default can be found in Section 55.5.
- The *OutputIterator* must accept values of type P . If the *OutputIterator* has a *value_type* the default initializer of the *creator* can be used. P is set to the *value_type* in this case.

<code>CGAL::Random_points_in_iso_box_d<Point_d></code>	page 3205

Types

`PointGenerator::value_type` the type of point being generated.

Operations

`double` `pg.range() const` return an absolute bound for the coordinates of all generated points.

CGAL::random_collinear_points_2

Definition

```
#include <CGAL/point_generators_2.h>
```

```
template <class RandomAccessIterator, class OutputIterator>
OutputIterator      random_collinear_points_2(
                    RandomAccessIterator first,
                    RandomAccessIterator last,
                    std::size_t n,
                    OutputIterator first2,
                    Random& rnd = default_random,
                    Creator creator = Creator_uniform_2<Kernel_traits<P>::Kernel::RT,P>)
```

randomly chooses two points from the range $[first, last)$, creates a random third point on the segment connecting these two points, writes it to *first2*, and repeats this *n* times, thus writing *n* points to *first2* that are collinear with points in the range $[first, last)$. Three random numbers are needed from *rnd* for each point. Returns the value of *first2* after inserting the *n* points.

Requirements

- *Creator* must be a function object accepting two *double* values *x* and *y* and returning an initialized point (*x*,*y*) of type *P*. Predefined implementations for these creators like the default can be found in Section 55.5.
- The *value_type* of the *RandomAccessIterator* must be assignable to *P*. *P* is equal to the *value_type* of the *RandomAccessIterator* when using the default initializer.
- The expressions *to_double((*first).x())* and *to_double((*first).y())* must result in the respective coordinate values.

CGAL::random_convex_set_2

Definition

The function *random_convex_set_2* computes a random convex planar point set of given size where the points are drawn from a specific domain.

```
#include <CGAL/random_convex_set_2.h>
```

```
template < class OutputIterator, class PointGenerator, class Traits >
OutputIterator      random_convex_set_2(
                    int n,
                    OutputIterator o,
                    PointGenerator pg,
                    Traits t = Default_traits)
```

computes a random convex n -gon by writing its vertices (oriented counterclockwise) to o . The resulting polygon is scaled such that it fits into the bounding box as specified by pg . Therefore we cannot easily describe the resulting distribution.

Precondition: $n \geq 3$.

Requirements

1. *PointGenerator* is a model of the concept `PointGenerator`
2. *Traits* is a model of the concept `RandomConvexSetTraits_2`
3. *Point_generator::value_type* is equivalent to *Traits::Point_2* and *OutputIterator::value_type*.
4. if *Traits* is not specified, *Point_generator::value_type* must be *Point_2*< R > for some representation class R ,

The default traits class *Default_traits* is *Random_convex_set_traits_2*.

See Also

CGAL::Random_points_in_square_2<*Point_2*, *Creator*> page [3200](#)
CGAL::Random_points_in_disc_2<*Point_2*, *Creator*> page [3198](#)

Implementation

The implementation uses the centroid method described in [Sch96] and has a worst case running time of $O(r \cdot n + n \cdot \log n)$, where r is the time needed by pg to generate a random point.

Example

The following program displays a random convex 500-gon where the points are drawn uniformly from the unit square centered at the origin.

```
#include <CGAL/Cartesian.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_convex_set_2.h>

#include <iostream>
#include <iterator>

typedef CGAL::Cartesian< double >    K;
typedef K::Point_2                   Point_2;
typedef CGAL::Random_points_in_square_2<
    Point_2,
    CGAL::Creator_uniform_2< double, Point_2 > >
    Point_generator;

int main() {
    // create 500-gon and write it into a window:
    CGAL::random_convex_set_2(
        500,
        std::ostream_iterator<Point_2>(std::cout, "\n"),
        Point_generator( 0.5));
    return 0;
}
```

File: examples/Generator/random_convex_set.cpp

CGAL::random_polygon_2

Definition

The function *random_polygon_2* constructs a random simple polygon from points that are drawn from a specific domain. Though each simple polygon defined on this set of points has a non-zero probability of being constructed, some polygons may have higher probabilities than others. The overall distribution of the generated polygons is not known since it depends on the generated points.

```
#include <CGAL/random_polygon_2.h>
```

```
template < class OutputIterator, class PointGenerator, class Traits >
OutputIterator      random_polygon_2( int n,
                                     OutputIterator result,
                                     PointGenerator pg,
                                     Traits t = Default_traits)
```

computes a random simple polygon by writing its vertices (oriented counterclockwise) to *result*. The polygon generated will have a number of vertices equal to the number of unique points in the first *n* points generated by *pg*.

Requirements

1. *Traits* is a model of the concept `RandomPolygonTraits_2`
2. `PointGenerator::value_type` is equivalent to `Traits::Point_2` and `OutputIterator::value_type`.

The default traits class *Default_traits* is the kernel in which `Traits::Point_2` is defined.

See Also

`CGAL::Random_points_in_disc_2<Point_2, Creator>` [page 3198](#)
`CGAL::Random_points_in_square_2<Point_2, Creator>` [page 3200](#)

Implementation

The implementation is based on the method of eliminating self-intersections in a polygon by using so-called “2-opt” moves. Such a move eliminates an intersection between two edges by reversing the order of the vertices between the edges. No more than $O(n^3)$ such moves are required to simplify a polygon defined on *n* points [vLS82]. Intersecting edges are detected using a simple sweep through the vertices and then one intersection is chosen at random to eliminate after each sweep. The worse-case running time is therefore $O(n^4 \log n)$.

Example

The following program displays a random simple polygon with up to 100 vertices, where the vertex coordinates are drawn uniformly from the unit square centered at the origin.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Polygon_2.h>
#include <CGAL/point_generators_2.h>
#include <CGAL/random_polygon_2.h>
#include <CGAL/Random.h>
#include <CGAL/copy_n.h>

#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz RT;
#else
// NOTE: the choice of double here for a number type may cause problems
//       for degenerate point sets
#include <CGAL/double.h>
typedef double RT;
#endif

#include <fstream>
#include <list>

typedef CGAL::Cartesian<RT> K;
typedef K::Point_2 Point_2;
typedef std::list<Point_2> Container;
typedef CGAL::Polygon_2<K, Container> Polygon_2;
typedef CGAL::Creator_uniform_2<int, Point_2> Creator;
typedef CGAL::Random_points_in_square_2<Point_2, Creator> Point_generator;

const double RADIUS = 100;
const int MAX_POLY_SIZE = 100;

int main( )
{
    Polygon_2 polygon;
    std::list<Point_2> point_set;
    CGAL::Random rand;

    int size = rand.get_int(4, MAX_POLY_SIZE);

    // copy size points from the generator, eliminating duplicates, so the
    // polygon will have <= size vertices
    CGAL::copy_n_unique(Point_generator(RADIUS), size,
                        std::back_inserter(point_set));

    std::ostream_iterator< Point_2 > out( std::cout, " " );

CGAL::random_selection

Definition

random_selection chooses n items at random from a random access iterator range which is useful to produce degenerate input data sets with multiple entries of identical items.

```
#include <CGAL/random_selection.h>
```

```
template <class RandomAccessIterator, class Size, class OutputIterator, class Random>
OutputIterator      random_selection( RandomAccessIterator first,
                                     RandomAccessIterator last,
                                     Size n,
                                     OutputIterator result,
                                     Random& rnd = default_random)
```

chooses a random item from the range $[first, last)$ and writes it to *result*, each item from the range with equal probability, and repeats this n times, thus writing n items to *result*. A single random number is needed from *rnd* for each item. Returns the value of *result* after inserting the n items.

Precondition: *Random* is a random number generator type as provided by the STL or by *Random*.

CGAL::Random

Definition

The class *Randomis* a random numbers generator. It generates uniformly distributed random *bools*, *ints* and *doubles*. It can be used as the random number generating function object in the STL algorithm *random_shuffle*.

Instances of `Stream` can be seen as input streams. Different streams are *independent* of each other, i.e. the sequence of numbers from one stream does *not* depend upon how many numbers were extracted from the other streams.

It can be very useful, e.g. for debugging, to reproduce a sequence of random numbers. This can be done by either initialising deterministically or using the state functions as described below.

```
#include <CGAL/Random.h>
```

Types

<i>Random::State</i>	State type.
----------------------	-------------

Creation

Random random; introduces a variable *random* of type *Random*.

Random *random(long seed);* introduces a variable *random* of type *Random* and initializes its internal state using *seed*. Equal values for *seed* result in equal sequences of random numbers.

Random random(State state); introduces a variable *random* of type *Random* and initializes its internal state with *state*.

Operations

<i>bool</i>	<i>random.get_bool()</i>	returns a random <i>bool</i> .
-------------	--------------------------	--------------------------------

<code>template <int b></code>		
<code>int</code>	<code>random.get_bits()</code>	returns a random <i>int</i> value from the interval $[0, 2^b)$. This is supposed to be efficient.

int *random.get_int(int lower, int upper)*

returns a random *int* from the interval $[lower, upper)$.

double *random.get_double(double lower = 0.0, double upper = 1.0)*

returns a random *double* from the interval $[lower, upper)$.

int *random(int upper)* returns *random.get_int(0, upper)*.

State Functions

void *random.save_state(State& state)*
saves the current internal state in *state*.

void *random.restore_state(State state)*
restores the internal state from *state*.

Equality Test

bool *random == random2* returns *true*, iff *random* and *random2* have equal internal states.

Implementation

We use the C library function *erand48* to generate the random numbers, *i.e.*, the sequence of numbers depends on the implementation of *erand48* on your specific platform.

RandomConvexSetTraits_2

Definition

The concept `RandomConvexSetTraits_2` describes the requirements of the traits class for the function `random_convex_set_2`.

Has Models

`CGAL::Random_convex_set_traits_2<Kernel>` page [3196](#)

Types

<code>RandomConvexSetTraits_2:: Point_2</code>	point class.
<code>RandomConvexSetTraits_2:: FT</code>	class used for doing computations on point and vector coordinates (has to fulfill field type requirements).
<code>RandomConvexSetTraits_2:: Sum</code>	AdaptableBinaryFunction class: $Point_2 \times Point_2 \rightarrow Point_2$. It returns the point that results from adding the vectors corresponding to both arguments.
<code>RandomConvexSetTraits_2:: Scale</code>	AdaptableBinaryFunction class: $Point_2 \times FT \rightarrow Point_2$. <code>Scale(p,k)</code> returns the point that results from scaling the vector corresponding to p by a factor of k .
<code>RandomConvexSetTraits_2:: Max_coordinate</code>	AdaptableUnaryFunction class: $Point_2 \rightarrow FT$. <code>Max_coordinate(p)</code> returns the coordinate of p with largest absolute value.
<code>RandomConvexSetTraits_2:: Angle_less</code>	AdaptableBinaryFunction class: $Point_2 \times Point_2 \rightarrow bool$. It returns <code>true</code> , iff the angle of the direction corresponding to the first argument with respect to the positive x -axis is less than the angle of the direction corresponding to the second argument.

Operations

<code>Point_2</code>	<code>t.origin() const</code>	return origin (neutral element for the <code>Sum</code> operation).
----------------------	-------------------------------	---

RandomPolygonTraits_2

Definition

The concept `RandomPolygonTraits_2` describes the requirements for the traits class used by the function `random_polygon_2`.

Has Models

The CGAL kernels.

Types

<code>RandomPolygonTraits_2:: FT</code>	The coordinate type of the points of the polygon (<i>i.e.</i> , a field type)
<code>RandomPolygonTraits_2:: Point_2</code>	The point type of the polygon.
<code>RandomPolygonTraits_2:: Orientation_2</code>	Predicate object type that determines the orientation of three points. It must provide <i>Orientation operator</i> <code>(Point_2 p, Point_2 q, Point_2 r)</code> that returns <i>LEFT_TURN</i> , if <i>r</i> lies to the left of the oriented line <i>l</i> defined by <i>p</i> and <i>q</i> , returns <i>RIGHT_TURN</i> if <i>r</i> lies to the right of <i>l</i> , and returns <i>COLLINEAR</i> if <i>r</i> lies on <i>l</i> .
<code>RandomPolygonTraits_2:: Less_xy_2</code>	Binary predicate object type comparing <i>Point_2</i> s lexicographically. It must provide <i>bool operator</i> <code>(Point_2 p, Point_2 q)</code> that returns <i>true</i> iff $p <_{xy} q$. We have $p <_{xy} q$, iff $p_x < q_x$ or $p_x = q_x$ and $p_y < q_y$, where p_x and p_y denote the <i>x</i> and <i>y</i> coordinates of point <i>p</i> , resp.

Operations

The following two member functions returning instances of the above predicate object types are required.

<code>Less_xy_2</code>	<code>t.less_xy_2_object()</code>
<code>Orienation_2</code>	<code>t.orientation_2_object()</code>

CGAL::Random_convex_set_traits_2<Kernel>

Definition

The class *Random_convex_set_traits_2<Kernel>* serves as a traits class for the function *random_convex_set_2*.

#include <CGAL/Random_convex_set_traits_2.h>

Is Model for the Concepts

RandomConvexSetTraits_2 page [3194](#)

Types

typedef Kernel::Point_2

typedef Kernel::FT *Point_2;*
 FT;

Random_convex_set_traits_2<Kernel>:: Sum function object class derived from *std::binary_function<Point_2, Point_2, Point_2>*

Random_convex_set_traits_2<Kernel>:: Scale function object class derived from *std::binary_function<Point_2, Point_2, Point_2>*

Random_convex_set_traits_2<Kernel>:: Max_coordinate

 function object class derived from *std::unary_function<Point_2, FT>*

Random_convex_set_traits_2<Kernel>:: Angle_less

 function object class derived from *std::binary_function<Point_2, Point_2, bool>*

Creation

Random_convex_set_traits_2<Kernel> t; default constructor

Operations

Point_2 *t.origin() const* returns CGAL::ORIGIN.

CGAL::Random_points_in_cube_3<Point_3, Creator>

Definition

The class *Random_points_in_cube_3<Point_3, Creator>* is an input iterator creating points uniformly distributed in a half-open cube. The default *Creator* is *Creator_uniform_3<Kernel_traits<P>::Kernel::RT,P>*.

Is Model for the Concepts

InputIterator

PointGenerator page [3184](#)

```
#include <CGAL/point_generators_3.h>
```

Types

```
typedef std::input_iterator_tag      iterator_category;

Chapter 59

Spatial Sorting

Christophe Delage

Contents

59.1 Introduction	3207
59.2 Spatial Sorting	3207

59.1 Introduction

Many geometric algorithms implemented in CGAL are incremental, and thus their speed is dependent on the order of insertion. This package provides sorting algorithms that may considerably improve running times of such algorithms.

The rationale is to sort objects along a space-filling curve so that two objects close geometrically will be close in the insertion order with high probability. That way, parts of a data structure that will be looked at during an insertion will probably have been looked at in a recent insertion, and thus probably will be in cache memory instead of main memory.

As another side-effect, these sorting functions usually improve memory locality of the data structures produced by incremental algorithms, sometimes leading to speed ups in other algorithm using these data structures.

59.2 Spatial Sorting

CGAL provides a small set of sorting algorithms, currently implemented only for 2D and 3D points, although it is easy to extend them to other objects through a traits mechanism.

Given an iterator range of points, the function *hilbert_sort* sorts them along the space-filling Hilbert curve. Combined with a *std::random_shuffle*, the function *spatial_sort* will sort points in a way keeping enough randomness to retain theoretical optimality for some algorithms¹, and close enough to a space-filling curve to speed-up algorithms.

The 2D and 3D triangulation classes of CGAL internally sort points as described above, when the points are passed as an iterator range to a constructor or the *insert* method.

¹in fact, this has only been proved for Delaunay triangulation

CGAL::spatial_sort

Definition

The function *spatial_sort* sorts an iterator range of points in a way that improves space locality. Two points close in the order will be close geometrically, and two points close geometrically will have a high probability of being close in the order.

```
#include <CGAL/spatial_sort.h>
```

```
template <class RandomAccessIterator, class Traits>
void      spatial_sort( RandomAccessIterator begin,
                       RandomAccessIterator end,
                       Traits traits = Default_traits)
```

sorts the range $[begin, end)$ in place.

The default traits class *Default_traits* is the kernel in which the type *RandomAccessIterator::value_type* is defined.

Requirements

1. *RandomAccessIterator::value_type* is convertible to *Traits::Point_2* or *Traits::Point_3*.
2. *Traits* is a model for concept *SpatialSortingTraits_2* or *SpatialSortingTraits_3*.

Implementation

Creates an instance of *Multiscale_sort<Hilbert_sort_2<Traits>>* or *Multiscale_sort<Hilbert_sort_3<Traits>>* and calls its *operator()*.

CGAL::hilbert_sort

Definition

The function *hilbert_sort* sorts an iterator range of points along a Hilbert curve.

```
#include <CGAL/hilbert_sort.h>
```

```
template <class RandomAccessIterator, class Traits>
void      hilbert_sort( RandomAccessIterator begin,
                       RandomAccessIterator end,
                       Traits traits = Default_traits)
```

sorts the range *[begin,end)* in place.

The default traits class *Default_traits* is the kernel in which the type *RandomAccessIterator::value_type* is defined.

Requirements

1. *RandomAccessIterator::value_type* is convertible to *Traits::Point_2* or *Traits::Point_3*.
2. *Traits* is a model for concept *SpatialSortingTraits_2* or *SpatialSortingTraits_3*.

Implementation

Creates an instance of *Hilbert_sort_2<Traits>* or *Hilbert_sort_3<Traits>* and calls its *operator()*.

SpatialSortingTraits_2

Definition

All 2D spatial sorting algorithms provided in CGAL are parameterized by a traits class *Traits*, which defines the primitives (objects and predicates) that the sorting algorithms use. *SpatialSortingTraits_2* defines the complete set of primitives required in these functions and functors.

Types

SpatialSortingTraits_2:: Point_2 The point type on which the sorting algorithms operate.

SpatialSortingTraits_2:: Less_x_2

Binary predicate object type comparing *Point_2*s along the *x* coordinate. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p_x < q_x$, where p_x and q_x denote *x* coordinate of point *p* and *q*, respectively.

SpatialSortingTraits_2:: Less_y_2

Binary predicate object type comparing *Point_2*s along the *y* coordinate. Must provide *bool operator()(Point_2 p, Point_2 q)* where *true* is returned iff $p_y < q_y$, where p_y and q_y denote *y* coordinate of point *p* and *q*, respectively.

Creation

Only a copy constructor is required.

SpatialSortingTraits_2 traits(t);

Operations

The following member functions to create instances of the above predicate object types must exist.

Less_x_2 *traits.less_x_2_object()*

Less_y_2 *traits.less_y_2_object()*

Has Models

Any CGAL kernel.

CGAL::Hilbert_sort_2<Traits>

Definition

The function object *Hilbert_sort_2<Traits>* sorts iterator ranges of *Traits::Point_2* along a Hilbert curve.

Requirements

Traits is a model for *SpatialSortingTraits*.

Creation

Hilbert_sort_2<Traits> *o*(*const Traits &traits = Traits()*);

constructs an instance with *traits* as traits class instance.

Operations

```
template <class RandomAccessIterator>
void      o.operator()( RandomAccessIterator begin, RandomAccessIterator end) const
```

sorts the range [*begin*, *end*).

Requirement: *RandomAccessIterator::value_type* equals to *Traits::Point_2*.

SpatialSortingTraits_3

Definition

All 3D spatial sorting algorithms provided in CGAL are parameterized by a traits class *Traits*, which defines the primitives (objects and predicates) that the sorting algorithms use. *SpatialSortingTraits_3* defines the complete set of primitives required in these functions and functors.

Types

SpatialSortingTraits_3::Point_3 The point type on which the sorting algorithms operate.

SpatialSortingTraits_3::Less_x_3

Binary predicate object type comparing *Point_3*s along the *x* coordinate. Must provide *bool operator()(Point_3 p, Point_3 q)* where *true* is returned iff $p_x < q_x$, where p_x and q_x denote *x* coordinate of point *p* and *q*, respectively.

SpatialSortingTraits_3::Less_y_3

Binary predicate object type comparing *Point_3*s along the *y* coordinate. Must provide *bool operator()(Point_3 p, Point_3 q)* where *true* is returned iff $p_y < q_y$, where p_y and q_y denote *y* coordinate of point *p* and *q*, respectively.

SpatialSortingTraits_3::Less_z_3

Binary predicate object type comparing *Point_3*s along the *z* coordinate. Must provide *bool operator()(Point_3 p, Point_3 q)* where *true* is returned iff $p_z < q_z$, where p_z and q_z denote *z* coordinate of point *p* and *q*, respectively.

Creation

Only a copy constructor is required.

SpatialSortingTraits_3 traits(t);

Operations

The following member functions to create instances of the above predicate object types must exist.

Less_x_3
 traits.less_x_3_object()

Less_y_3
 traits.less_y_3_object()

Less_z_3
traits.less_z_3_object()

Has Models

Any CGAL kernel.

CGAL::Hilbert_sort_3<Traits>

Definition

The function object *Hilbert_sort_3<Traits>* sorts iterator ranges of *Traits::Point_3* along a Hilbert curve.

Requirements

Traits is a model for *SpatialSortingTraits_3*.

Creation

Hilbert_sort_3<Traits> *o*(*const Traits &traits* = *Traits*());

constructs an instance with *traits* as traits class instance.

Operations

```
template <class RandomAccessIterator>
void      o.operator()( RandomAccessIterator begin, RandomAccessIterator end) const
```

sorts the range [*begin*, *end*).

Requirement: *RandomAccessIterator::value_type* equals to *Traits::Point_3*.

CGAL::Multiscale_sort<Sort>

Definition

The class *Multiscale_sort*<*Sort*> represents a sorting algorithm adaptor. Given a range of n points:

1. it applies *Sort* on the last $(1 - \text{ratio}) \times n$ points,
2. it recurses on the first $\text{ratio} \times n$ points, stopping when there are less than *threshold* points.

Creation

Multiscale_sort<*Sort*> *o*(*const Sort* &*sort* = *Sort*(), *int threshold* = 1, *double ratio* = 0.5);

constructs an instance with *traits* as traits class instance.

Operations

```
template <class RandomAccessIterator>
void      o.operator()( RandomAccessIterator begin, RandomAccessIterator end) const
```

sorts the range [*begin*, *end*).

Requirement: *Sort::operator()(RandomAccessIterator begin, RandomAccessIterator end)* is defined.

Chapter 60

Monotone and Sorted Matrix Search

Michael Hoffmann

CGAL::monotone_matrix_search and *CGAL::sorted_matrix_search* are techniques that deal with the problem of efficiently finding largest entries in matrices with certain structural properties. Many concrete problems can be modelled as matrix search problems, and for some of them we provide explicit solutions that allow you to solve them without knowing about the matrix search technique. Examples are, the computation of all furthest neighbors for the vertices of a convex polygon, maximal k -gons inscribed into a planar point set, and computing rectangular p -centers.

Monotone and Sorted Matrix Search Reference Manual

Michael Hoffmann

This chapter describes concepts, classes, and functions for monotone and sorted matrix search.

Assertions

The optimization code uses infix *OPTIMISATION* in the assertions, e.g. defining the compiler flag *CGAL_OPTIMISATION_NO_PRECONDITIONS* switches precondition checking off, cf. Section ??.

CGAL::monotone_matrix_search

— advanced —

Definition

The function *monotone_matrix_search* computes the maxima for all rows of a totally monotone matrix.

More precisely, monotony for matrices is defined as follows.

Let K be a totally ordered set, $M \in K^{(n,m)}$ a matrix over K and for $0 \leq i < n$:

$$rmax_M(i) := \left\{ \min_{0 \leq j < m} j \mid M[i, j] = \max_{0 \leq k < m} M[i, k] \right\}$$

the (leftmost) column containing the maximum entry in row i . M is called monotone, iff

$$\forall 0 \leq i_1 < i_2 < n : rmax_M(i_1) \leq rmax_M(i_2) .$$

M is totally monotone, iff all of its submatrices are monotone (or equivalently: iff all 2×2 submatrices are monotone).

```
#include <CGAL/monotone_matrix_search.h>
```

```
template < class Matrix, class RandomAccessIC, class Compare_strictly >
void    monotone_matrix_search(
        Matrix m,
        RandomAccessIC t,
        Compare_strictly compare_strictly = less< Matrix::Value >())
```

computes the maximum (as specified by *compare_strictly*) entry for each row of m and writes the corresponding column to t , i.e. $t[i]$ is set to the index of the column containing the maximum element in row i . The maximum m_r of a row r is the leftmost element for which *compare_strictly*(m_r, x) is false for all elements x in r .

Precondition: t points to a structure of size at least $m.number_of_rows()$

Requirement:

1. *Matrix* is a model for *MonotoneMatrixSearchTraits*.
2. Value type of *RandomAccessIC* is *int*.
3. If *compare_strictly* is defined, it is an adaptable binary function: $Matrix::Value \times Matrix::Value \rightarrow bool$ describing a strict (non-reflexive) total ordering on *Matrix::Value*.

Implementation

The implementation uses an algorithm by Aggarwal et al.[AKM⁺87]. The runtime is linear in the number of rows and columns of the matrix.

_____ *advanced* _____

CGAL::Dynamic_matrix<M>

— *advanced* —

Definition

The class *Dynamic_matrix*<*M*> is an adaptor for an arbitrary matrix class *M* to provide the dynamic operations needed for monotone matrix search.

Requirements

M is a model for *BasicMatrix*.

`#include <CGAL/Dynamic_matrix.h>`

Is Model for the Concepts

MonotoneMatrixSearchTraits page [3226](#)

BasicMatrix page [3228](#)

Creation

Dynamic_matrix<*M*> *d*(*M* *m*); initializes *d* to *m*. *m* is *not* copied, we only store a reference.

Operations

int *d.number_of_columns()*
returns the number of columns.

int *d.number_of_rows()* returns the number of rows.

Entry *d(int row, int column)*
returns the entry at position (*row*, *column*).
Precondition:
 $0 \leq \text{row} < \text{number_of_rows}()$ and
 $0 \leq \text{column} < \text{number_of_columns}()$.

void *d.replace_column(int old, int new)*
replace column *old* with column number *new*.
Precondition:
 $0 \leq \text{old}, \text{new} < \text{number_of_columns}()$.

*Matrix** *d.extract_all_even_rows()*

returns a new **Matrix** consisting of all rows of *d* with even index, (i.e. first row is row 0 of *d*, second row is row 2 of *d* etc.).

Precondition: *number_of_rows()* > 0.

void *d.shrink_to_quadratic_size()*

deletes the rightmost columns, such that *d* becomes quadratic.

Precondition:

number_of_columns() ≥ *number_of_rows()*.

Postcondition:

number_of_rows() == *number_of_columns()*.

BasicMatrix page [3228](#)

Implementation

All operations take constant time except for *extract_all_even_rows* which needs time linear in the number of rows.

————— *advanced* —————

MonotoneMatrixSearchTraits

— *advanced* —

Definition

The concept `MonotoneMatrixSearchTraits` is a refinement of *BasicMatrix* and defines types and operations needed to compute the maxima for all rows of a totally monotone matrix using the function *monotone_matrix_search*.

Types

MonotoneMatrixSearchTraits::Value The type of a matrix entry.

Operations

int *m.number_of_columns() const*
returns the number of columns.

int *m.number_of_rows() const*
returns the number of rows.

Entry *m.operator()(int row, int column) const*
returns the entry at position (*row*, *column*).
Precondition:
 $0 \leq \text{row} < \text{number_of_rows}()$ and
 $0 \leq \text{column} < \text{number_of_columns}()$.

void *m.replace_column(int old, int new)*
replace column *old* with column number *new*.
Precondition:
 $0 \leq \text{old}, \text{new} < \text{number_of_columns}()$.

*Matrix** *m.extract_all_even_rows() const*
returns a new `Matrix` consisting of all rows of *m* with even index, (i.e. first row is row 0 of *m*, second row is row 2 of *m* etc.).
Precondition: *number_of_rows()* > 0.

void *m.shrink_to_quadratic_size()*

deletes the rightmost columns, such that *m* becomes quadratic.

Precondition:

number_of_columns() ≥ number_of_rows().

Postcondition:

number_of_rows() == number_of_columns().

Notes

- For the sake of efficiency (and in order to achieve the time bounds claimed for *monotone_matrix_search*), all these operations have to be realized in constant time – except for *extract_all_even_rows* which may take linear time.
- There is an adaptor *Dynamic_matrix* that can be used to add most of the functionality described above to arbitrary matrix classes.

BasicMatrix

advanced

Definition

A class has to provide the following types and operations in order to be a model for *BasicMatrix*.

Types

BasicMatrix::Value The type of a matrix entry. It has to define a copy constructor.

Operations

int *m.number_of_columns() const*
returns the number of columns.

int *m.number_of_rows() const*
returns the number of rows.

Entry *m.operator()(int row, int column) const*
returns the entry at position (*row*, *column*).
Precondition:
 $0 \leq \text{row} < \text{number_of_rows}()$ and
 $0 \leq \text{column} < \text{number_of_columns}()$.

advanced

CGAL::sorted_matrix_search

— *advanced* —

Definition

The function *sorted_matrix_search* selects the smallest entry in a set of sorted matrices that fulfills a certain feasibility criterion.

More exactly, a matrix $M = (m_{ij}) \in S^{r \times l}$ (over a totally ordered set S) is sorted, iff

$$\begin{aligned} \forall 1 \leq i \leq r, 1 \leq j < l : m_{ij} \leq m_{i(j+1)} \text{ and} \\ \forall 1 \leq i < r, 1 \leq j \leq l : m_{ij} \leq m_{(i+1)j} . \end{aligned}$$

Now let \mathcal{M} be a set of n sorted matrices over S and f be a monotone predicate on S , i.e.

$$f : S \longrightarrow \text{bool} \quad \text{with} \quad f(r) \implies \forall t \in S, t > r : f(t) .$$

If we assume there is any feasible element in one of the matrices in \mathcal{M} , there certainly is a smallest such element. This is the one we are searching for.

The feasibility test as well as some other parameters can (and have to) be customized through a traits class.

```
#include <CGAL/sorted_matrix_search.h>
```

```
template < class RandomAccessIterator, class Traits >
Traits::Value sorted_matrix_search( RandomAccessIterator f, RandomAccessIterator l, Traits t)
```

returns the element x in one of the sorted matrices from the range $[f, l)$, for which $t.is_feasible(x)$ is true and $t.compare(x, y)$ is true for all other y values from any matrix for which $t.is_feasible(y)$ is true.

Precondition:

1. All matrices in $[f, l)$ are sorted according to $Traits::compare_non_strictly$.
2. There is at least one entry x in a matrix $M \in [f, l)$ for which $Traits::is_feasible(x)$ is true.

Requirement:

1. *Traits* is a model for *SortedMatrixSearchTraits*.
2. Value type of *RandomAccessIterator* is *Traits::Matrix*.

See Also

SortedMatrixSearchTraits page [3234](#)

Implementation

The implementation uses an algorithm by Frederickson and Johnson[FJ83, FJ84] and runs in $O(n \cdot k + f \cdot \log(n \cdot k))$, where n is the number of input matrices, k denotes the maximal dimension of any input matrix and f the time needed for one feasibility test.

Example

In the following program we build a random vector $a = (a_i)_{i=1, \dots, 5}$ (elements drawn uniformly from $\{0, \dots, 99\}$) and construct a Cartesian matrix M containing as elements all sums $a_i + a_j$, $i, j \in \{1, \dots, 5\}$. If a is sorted, M is sorted as well. So we can apply *sorted_matrix_search* to compute the upper bound for the maximal entry of a in M .

```
#include <CGAL/Random.h>
#include <CGAL/Cartesian_matrix.h>
#include <CGAL/sorted_matrix_search.h>
#include <CGAL/functional.h>
#include <vector>
#include <algorithm>
#include <iterator>

typedef int Value;
typedef std::vector<Value> Vector;
typedef Vector::iterator Value_iterator;
typedef std::vector<Vector> Vector_cont;
typedef CGAL::Cartesian_matrix<std::plus<int>,
                               Value_iterator,
                               Value_iterator> Matrix;

int main()
{
    // set of vectors the matrices are build from:
    Vector_cont vectors;

    // generate a random vector and sort it:
    Vector a;
    const int n = 5;
    for (int i = 0; i < n; ++i)
        a.push_back(CGAL::default_random(100));
    std::sort(a.begin(), a.end());
    std::cout << "a = ( ";
    std::copy(a.begin(), a.end(), std::ostream_iterator<int>(std::cout, " "));
    std::cout << ")\n";

    // build a Cartesian matrix from a:
    Matrix M(a.begin(), a.end(), a.begin(), a.end());

    // search for an upper bound for max(a):
    Value bound = a[n-1];
    Value upper_bound =
    CGAL::sorted_matrix_search(
        &M, &M + 1,
        CGAL::sorted_matrix_search_traits_adaptor(
```

```

        CGAL::bind_2(std::greater_equal<Value>(), bound), M));
std::cout << "Upper bound for " << bound << " is "
        << upper_bound << "." << std::endl;

    return 0;
}
// -----
// ** EOF
// -----

```

CGAL::Sorted_matrix_search_traits_adaptor<F,M>

— advanced —

#include <CGAL/Sorted_matrix_search_traits_adaptor.h>

Definition

The class *Sorted_matrix_search_traits_adaptor*<*F*,*M*> can be used as an adaptor to create sorted matrix search traits classes for arbitrary feasibility test and matrix classes *F* resp. *M*.

Is Model for the Concepts

SortedMatrixSearchTraits page [3234](#)

Requirements

1. *M* is a model for *BasicMatrix* and
2. *F* defines a copy constructor and a monotone *bool operator()*(*const Value*&).

Creation

Sorted_matrix_search_traits_adaptor<*F*,*M*> *t*(*const F*& *m*);

initializes *t* to use *m* for feasibility testing.

Types

Sorted_matrix_search_traits_adaptor<*F*,*M*>::*Matrix*

typedef to *M*.

Sorted_matrix_search_traits_adaptor<*F*,*M*>::*Value*

typedef to *Matrix*::*Value*.

Sorted_matrix_search_traits_adaptor<*F*,*M*>::*Compare_strictly*

typedef to *std::less*<*Value*>.

Sorted_matrix_search_traits_adaptor<*F*,*M*>::*Compare_non_strictly*

typedef to *std::less_equal*<*Value*>.

Operations

Compare_strictly *t.compare_strictly()* *const*

returns the *Compare_strictly* object to be used for the search.

Compare_non_strictly

t.compare_non_strictly() *const*

returns the *Compare_non_strictly* object to be used for the search.

bool *t.is_feasible(const Value& a)*

uses the feasibility test given during creation.

└────────── *advanced* ─────────┘

SortedMatrixSearchTraits

— *advanced* —

Definition

The concept `SortedMatrixSearchTraits` defines types and operations needed to compute the smallest entry in a set of sorted matrices that fulfills a certain feasibility criterion using the function `sorted_matrix_search`.

Types

`SortedMatrixSearchTraits::Matrix` The class used for representing matrices. It has to be a model for `BasicMatrix`.

`typedef Matrix::Value`

`Value;` The class used for representing the matrix elements.

`SortedMatrixSearchTraits::Compare_strictly` An adaptable binary function class: $Value \times Value \rightarrow bool$ defining a non-reflexive total order on `Value`. This determines the direction of the search.

`SortedMatrixSearchTraits::Compare_non_strictly`

An adaptable binary function class: $Value \times Value \rightarrow bool$ defining the reflexive total order on `Value` corresponding to `Compare_strictly`.

Operations

`Compare_strictly` `t.compare_strictly() const`

returns the `Compare_strictly` object to be used for the search.

`Compare_non_strictly`

`t.compare_non_strictly() const`

returns the `Compare_non_strictly` object to be used for the search.

`bool` `t.is_feasible(const Value& a)`

The predicate to determine whether an element `a` is feasible. It has to be monotone in the sense that `compare(a, b)` and `is_feasible(a)` imply `is_feasible(b)`.

61.1 Which Programs can be Solved?

This package lets you solve *convex quadratic programs* of the general form

$$(\text{QP}) \quad \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0$$

$$\begin{aligned} \text{subject to } \mathbf{A}\mathbf{x} &\begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \\ \mathbf{l} &\leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in n real variables $\mathbf{x} = (x_0, \dots, x_{n-1})$. Here,

- \mathbf{A} is an $m \times n$ matrix (the constraint matrix),
- \mathbf{b} is an m -dimensional vector (the right-hand side),
- $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$ is an m -dimensional vector of relations from $\{\leq, =, \geq\}$,
- \mathbf{l} is an n -dimensional vector of lower bounds for \mathbf{x} , where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- \mathbf{u} is an n -dimensional vector of upper bounds for \mathbf{x} , where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- \mathbf{c} is an n -dimensional vector (the linear objective function), and
- c_0 is a constant.

If $D = 0$, the program (QP) is actually a *linear program*. Section 61.2.2 on robustness briefly discusses the case of D not being positive-semidefinite and therefore not defining a convex program.

Solving the program means to find an n -vector \mathbf{x}^* such that $\mathbf{A}\mathbf{x}^* \begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \mathbf{l} \leq \mathbf{x}^* \leq \mathbf{u}$ (a *feasible solution*), and with the smallest objective function value $\mathbf{x}^{*T} D \mathbf{x}^* + \mathbf{c}^T \mathbf{x}^* + c_0$ among all feasible solutions.

There might be no feasible solution at all, in which case the quadratic program is *infeasible*, or there might be feasible solutions of arbitrarily small objective function value, in which case the program is *unbounded*.

61.2 Design, Efficiency, and Robustness

The design of the package is quite simple. The linear or quadratic program to be solved is supplied in form of an object of a class that is a model of the concept *QuadraticProgram* (or some specialized other concepts, e.g. for linear programs). CGAL provides a number of easy-to-use and flexible models, see Section 61.3 below. The input data may be of any given number type, such as *double*, *int*, or any exact type.

Then the program is solved using the function *solve_quadratic_program* (or some specialized other functions, e.g. for linear programs). For this, you also have to provide a suitable *exact* number type *ET* used in the solution process. In case of input type *double*, solution methods that use floating-point-filtering are chosen by default for certain programs (in some cases, this is not appropriate, and the default should be changed; see Section 61.8 for details).

The output of this is an object of *Quadratic_program_solution<ET>* which you can in turn query for various things: what is the status of the program (optimally solved, infeasible, or unbounded?), what are the values of the optimal solution \mathbf{x}^* , what is the associated objective function value, etc.

You can in particular get *certificates* for the solution. In short, these are proofs that the output is correct. Thus, if you don't believe in the solution (whether it says "optimally solved", "infeasible", or "unbounded"), you can verify it yourself by using the certificates. Section 61.7 says more about this.

61.2.1 Efficiency

The concept *QuadraticProgram* (as well as the other specialized ones) require a *dense interface* of the program, in terms of *random-access iterators* over the matrices and vectors of (QP). Zero entries therefore play no special role and are treated like all other entries by the interface.

This has mainly historical reasons: the original motivation behind this package was low-dimensional geometric optimization where a dense representation is appropriate and efficient. In fact, the CGAL packages *Min_annulus_d<Traits>* and *Polytope_distance_d<Traits>* internally use the linear and quadratic programming solver.

As a user, however, you don't necessarily have to provide a dense *representation* of your program. You do not pass vectors or matrices to the solution functions, but rather specify the vectors and matrices through iterators. The iterator abstraction easily allows to build models that convert a sparse representation into a dense interface. The predefined models *Quadratic_program<NT>* and *Quadratic_program_from_mps<NT>* do exactly this; in using them, you can forget about the dense interface.

Nevertheless, if you care about efficiency, you cannot completely ignore the issue. If you think about a quadratic program in n variables and m constraints, its dense interface has $\Theta(n^2 + mn)$ entries, even if actually very few of them are nonzero. This has consequences for the complexity of the internal computations. In fact, a single iteration of the solution process has complexity at least $\Omega(mn)$, since usually, all entries of the matrix A are accessed. This implies that problems where $\min(n, m)$ is large cannot be solved efficiently, even if the number of nonzero entries in the problem description is very small.

We can actually be quite precise about performance, in terms of the following parameters.

- n : the number of variables (or columns of A),
- m : the number of constraints (or rows of A),
- e : the number of equality constraints,
- r : the rank of the quadratic objective function matrix D .

The time required to solve the problems is in most cases linear in $\max(n, m)$, but with a factor heavily depending on $\min(n, e) + r$. Therefore, the solver will be efficient only if $\min(n, e) + r$ is small.

Here are the scenarios in which this applies:

- Quadratic programs with a small number of variables, but possibly a large number of inequality constraints,
- Linear programs with a small number of equality constraints but possibly a large number of variables,
- Quadratic programs with a small number of equality constraints and D of small rank, but possibly with a large number of variables.

How small is small? If $\min(n, e) + r$ is up to 10, the solver will probably be very fast, even if $\max(n, m)$ goes into the millions. If $\min(n, m) + r$ is up to a few hundreds, you may still get a solution within reasonable time, depending on the problem characteristics.

If you have a problem where both n and e are well above 1,000, say, then chances are high that CGAL cannot solve it within reasonable time.

61.2.2 Robustness

Given that you use an *exact number type* in the function *solve_quadratic_program* (or in the other, specialized solution functions), the solver will give you *exact rational output*, for every convex quadratic program. It may

fail to compute a solution only if

1. The quadratic program is too large (see the previous subsection on efficiency).
2. The quadratic objective function matrix D is not positive-semidefinite (see the discussion below).
3. The floating-point filter used by default for certain programs and input type *double* fails due to a *double* exponent overflow. This happens in rare cases only, and it does not pay off to sacrifice the efficiency of the filtered approach in order to cope with these rare cases. There are means, however, to avoid such problems by switching to a slower non-filtered variant, see Section 61.8.1.
4. The solver internally cycles. This also happens in rare cases only. However, if you have a hunch that the solver cycles on your problem, there are means to switch to a slower variant that is guaranteed not to cycle, see Section 61.8.2.

The second item merits special attention. First, you may ask why the solver does not check that D is positive semidefinite. But recall that D is given by a dense interface, and it would therefore cost $\Omega(n^2)$ time already to access all entries of the matrix D . The solver itself gets away with accessing much less entries of D in the relevant case where r , the rank of D , is small.

Nevertheless, the solver contains some runtime checks that may detect that the matrix D is not positive-semidefinite. But you may as well get an “optimal solution” in this case, even with valid certificates. The validity of these certificates, however, depends on D being positive-semidefinite; if this is not the case, the certificates only prove that the solver has found a “critical point” of your (nonconvex) program, but there are no guarantees whatsoever that this is a global optimum, or even a local optimum.

61.3 How to Enter and Solve a Program

In this section, we describe how you can supply and solve your problem, using the CGAL program models and solution functions. There are two essentially different ways to proceed, and we will discuss them in turn. In short,

- you can let the model take care of your program data; you start from an empty program and then simply insert the non-zero entries, or read them from a file (more generally, any input stream) in *MPSFormat*. You can also change program entries at any time. This is usually the most convenient way if you don’t want to care about representation issues;
- you can maintain the data yourself and only supply suitable random-access iterators over the matrices and vectors. This is advantageous if you already have the data (explicitly, or implicitly encoded, for example through iterators) and want to avoid copying of data. Typically, this happens if you write generic iterator-based code.

Our running example is the following quadratic program in two variables:

$$\begin{array}{llll} \text{minimize} & x^2 + 4(y - 4)^2 & (= & x^2 + 4y^2 - 32y + 64) \\ \text{subject to} & x + y & \leq & 7 \\ & -x + 2y & \leq & 4 \\ & x & \geq & 0 \\ & y & \geq & 0 \\ & y & \leq & 4 \end{array}$$

Figure 61.1 shows a picture. It depicts the five inequalities of the program, along with the *feasible region* (green), the set of points that satisfy all the five constraints. The dashed elliptic curves represent *contour lines* of the objective function, i.e., along each dashed curve, the objective function value is constant.

The global minimum of the objective function is attained at the point $(0, 4)$, and the minimum within the feasible region appears at the point $(2, 3)$ marked with a black dot. The value of the objective function at this optimal solution is $2^2 + 4(3 - 4)^2 = 8$.

Figure 61.1: A quadratic program in two variables

61.3.1 Constructing a Program from Data

Here is how this quadratic program can be solved in CGAL according to the first way (letting the model take care of the data). We use *int* as the input type, and *MP_Float* or *Gmpz* (which is faster and preferable if GMP is installed) as the exact type for the internal computations. In larger examples, it pays off to use *double* as input type in order to profit from the automatic floating-point filtering that takes place then.

For examples how to work with the input type *double*, we refer to Sections 61.5 and 61.8.

Note: For the quadratic objective function, the entries of the matrix $2D$ have to be provided, rather than D . Although this is common to almost all quadratic programming solvers, it can easily be overlooked by a novice.

```
#include <iostream>
#include <cassert>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
```

```

#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program<int> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    // by default, we have a nonnegative QP with Ax <= b
    Program qp (CGAL::SMALLER, true, 0, false, 0);

    // now set the non-default entries:
    const int X = 0;
    const int Y = 1;
    qp.set_a(X, 0, 1); qp.set_a(Y, 0, 1); qp.set_b(0, 7); // x + y <= 7
    qp.set_a(X, 1, -1); qp.set_a(Y, 1, 2); qp.set_b(1, 4); // -x + 2y <= 4
    qp.set_u(Y, true, 4); // y <= 4
    qp.set_d(X, X, 2); qp.set_d (Y, Y, 8); // !!specify 2D!! x^2 + 4 y^2
    qp.set_c(Y, -32); // -32y
    qp.set_c0(64); // +64

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_quadratic_program(qp, ET());
    assert (s.solves_quadratic_program(qp));

    // output solution
    std::cout << s;
    return 0;
}

```

File: examples/QP_solver/first_qp.cpp

Assuming that GMP is installed, the output of the of the above program is:

```

status:          OPTIMAL
objective value: 8/1
variable values:
  0: 2/1
  1: 3/1

```

If GMP is not installed, the values are of course the same, but numerator and denominator might have a common divisor that is not factored out.

61.3.2 Constructing a Program from a Stream

Here, the program data must be available in *MPSFormat* (the *MPSFormat* page shows how our running example looks like in this format, and it briefly explains the format). Assuming that your working directory contains the file `first_qp.mps`, the following program will read and solve it, with the same output as before.

```
#include <iostream>
#include <fstream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program_from_mps<int> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    std::ifstream in ("first_qp.mps");
    Program qp(in);           // read program from file
    assert (qp.is_valid()); // we should have a valid mps file

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_quadratic_program(qp, ET());

    // output solution
    std::cout << s;
    return 0;
}
```

File: `examples/QP_solver/first_qp_from_mps.cpp`

61.3.3 Constructing a Program from Iterators

The following program again solves our running example from above, with the same output, but this time with iterators over data stored in suitable containers. You can see that we also store zero entries here (in *D*). For this toy problem, the previous two approaches (program from data/stream) are clearly preferable, but [Section 61.5](#) shows an example where it makes sense to use the iterator-based approach.

```
#include <iostream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
```

```

#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

// program and solution types
typedef CGAL::Quadratic_program_from_iterators
<int**,                                // for A
 int*,                                // for b
 CGAL::Const_onset_iterator<CGAL::Comparison_result>, // for r
 bool*,                                // for fl
 int*,                                // for l
 bool*,                                // for fu
 int*,                                // for u
 int**,                                // for D
 int*>                                // for c
Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    int Ax[] = {1, -1};                // column for x
    int Ay[] = {1, 2};                // column for y
    int* A[] = {Ax, Ay};              // A comes columnwise
    int b[] = {7, 4};                 // right-hand side
    CGAL::Const_onset_iterator<CGAL::Comparison_result>
        r( CGAL::SMALLER);            // constraints are "<="
    bool fl[] = {true, true};          // both x, y are lower-bounded
    int l[] = {0, 0};
    bool fu[] = {false, true};        // only y is upper-bounded
    int u[] = {0, 4};                 // x's u-entry is ignored
    int D1[] = {2};                   // 2D_{1,1}
    int D2[] = {0, 8};                 // 2D_{2,1}, 2D_{2,2}
    int* D[] = {D1, D2};              // D-entries on/below diagonal
    int c[] = {0, -32};
    int c0 = 64;                      // constant term

    // now construct the quadratic program; the first two parameters are
    // the number of variables and the number of constraints (rows of A)
    Program qp (2, 2, A, b, r, fl, l, fu, u, D, c, c0);

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_quadratic_program(qp, ET());

    // output solution
    std::cout << s;
    return 0;
}

```

File: examples/QP_solver/first_qp_from_iterators.cpp

Note 1: The example shows an interesting feature of this approach: not all data need to come from containers. Here, the iterator over the vector of relations can be provided through the class *Const_onese_iterator*<*T*>, since all entries of this vector are equal to *CGAL::SMALLER*. The same could have been done with the vector *fl* for the finiteness of the lower bounds.

Note 2: The program type looks a bit scary, with its total of 9 template arguments, one for each iterator type. In Section 61.5.1 we show how the explicit construction of this type can be circumvented.

61.4 Solving Linear and Nonnegative Programs

Let us reconsider the general form of (QP) from Section 61.1 above. If $D = 0$, the quadratic program is in fact a *linear program*, and in the case that the bound vectors l is the zero vector and all entries of u are ∞ , the program is said to be *nonnegative*. The package offers dedicated models and solution methods for these special cases.

From an interface perspective, this is just syntactic sugar: in the model *Quadratic_program*<*NT*>, we can easily set the default bounds so that a nonnegative program results, and a linear program is obtained by simply not inserting any D -entries. Even in the iterator-based approach (see *QP_solver/first_qp_from_iterators.cpp*), linear and nonnegative programs can easily be defined through suitable *Const_onese_iterator*<*T*>-style iterators.

The main reason for having dedicated solution methods for linear and nonnegative programs is efficiency: if the solver knows that the program is linear, it can save some computations compared to the general solver that unknowingly has to fiddle around with a zero D -matrix. As in Section 61.2.2 above, we can argue that checking in advance whether $D = 0$ is not an option in general, since this may require $\Omega(n^2)$ time on the dense interface.

Similarly, if the solver knows that the program is nonnegative, it will be more efficient than under the general bounds $\mathbf{l} \leq \mathbf{x} \leq \mathbf{u}$. You can argue that nonnegativity *is* something that could easily be checked in time $O(n)$ beforehand, but then again nonnegative programs are so frequent that the syntactic sugar aspect becomes somewhat important. After all, we can save four iterators in specifying a nonnegative linear program in terms of the concept *NonnegativeLinearProgram* rather than *LinearProgram*.

Often, there are no bounds at all for the variables, i.e., all entries of \mathbf{l} are $-\infty$, and all entries of \mathbf{u} are ∞ (this is called a *free* program). There is no dedicated solution method for this case (a free quadratic or linear program is treated like a general quadratic or linear program), but all predefined models make it easy to specify all sorts of default bounds, covering the free case.

61.4.1 The Linear Programming Solver

Let's go back to our first quadratic program from above and change it into a linear program by simply removing the quadratic part of the objective function:

$$\begin{array}{ll} \text{minimize} & -32y + 64 \\ \text{subject to} & x + y \leq 7 \\ & -x + 2y \leq 4 \\ & x \geq 0 \\ & y \geq 0 \\ & y \leq 4 \end{array}$$

Figure 61.2 shows how this looks like. We will not visualize a linear objective function with contour lines but with arrows instead. The arrow represents the (direction) of the vector $-c$, and we are looking for a feasible solution that is “extreme” in the direction of the arrow. In our small example, this is the unique point “on” the two constraints $x_1 + x_2 \leq 7$ and $-x_1 + x_2 \leq 4$, the point $(10/3, 11/3)$ marked with a black dot. The optimal objective function value is $-32(11/3) + 64 = -160/3$.

Figure 61.2: A linear program in two variables

Here is CGAL code for solving it, using the dedicated LP solver, and according to the three ways for constructing a program that we have already discussed in Section 61.3.

```
QP_solver/first_lp.cpp
QP_solver/first_lp_from_mps.cpp
QP_solver/first_lp_from_iterators.cpp
```

In all cases, the output is

```
status:          OPTIMAL
objective value: -160/3
variable values:
  0: 10/3
  1: 11/3
```

61.4.2 The Nonnegative Quadratic Programming Solver

If we go back to our first quadratic program and remove the constraint $y \leq 4$, we arrive at a nonnegative quadratic program:

$$\begin{array}{ll} \text{minimize} & x^2 + 4(y - 4)^2 \quad (= x^2 + 4y^2 - 32y + 64) \\ \text{subject to} & x + y \leq 7 \\ & -x + 2y \leq 4 \\ & x, y \geq 0 \end{array}$$

Figure 61.3 contains the illustration; since the constraint $y \leq 4$ was redundant, the feasible region and the optimal solution do not change.

Figure 61.3: A nonnegative quadratic program in two variables

The following programs (using the dedicated solver for nonnegative quadratic programs) will therefore again output

```
status:          OPTIMAL
objective value: 8/1
variable values:
  0: 2/1
  1: 3/1
```

```
QP_solver/first_nonnegative_qp.cpp
QP_solver/first_nonnegative_qp_from_mps.cpp
QP_solver/first_nonnegative_qp_from_iterators.cpp
```

61.4.3 The Nonnegative Linear Programming Solver

Finally, a dedicated model and function is available for nonnegative linear programs as well. Let's take our linear program from above and remove the constraint $y \leq 4$ to obtain a nonnegative linear program. At the same time we remove the constant objective function term to get a "minimal" input and a "shortest" program; the optimal value is $-32(11/3) = -352/3$.

$$\begin{array}{ll}
\text{minimize} & -32y \\
\text{subject to} & x + y \leq 7 \\
& -x + 2y \leq 4 \\
& x, y \geq 0
\end{array}$$

This can be solved by any of the following three programs

```

QP_solver/first_nonnegative_lp.cpp
QP_solver/first_nonnegative_lp_from_mps.cpp
QP_solver/first_nonnegative_lp_from_iterators.cpp

```

The output will always be

```

status:          OPTIMAL
objective value: -352/3
variable values:
  0: 10/3
  1: 11/3

```

61.5 Working from Iterators

Here we present a somewhat more advanced example that emphasizes the usefulness of solving linear and quadratic programs from iterators. Let's look at a situation in which a linear program is given implicitly, and access to it is gained through properly constructed iterators.

The problem we are going to solve is the following: given points p_1, \dots, p_n in d -dimensional space and another point p : is p in the convex hull of $\{p_1, \dots, p_n\}$? In formulas, this is the case if and only if there are real coefficients $\lambda_1, \dots, \lambda_n$ such that p is a convex combination of p_1, \dots, p_n :

$$p = \sum_{j=1}^n \lambda_j p_j, \quad \sum_{j=1}^n \lambda_j = 1, \quad \lambda_j \geq 0 \text{ for all } j.$$

The problem of testing the existence of such λ_j can be expressed as a linear program. It becomes particularly easy when we use the homogeneous representations of the points: if $q_1, \dots, q_n, q \in \mathbb{R}^{d+1}$ are homogeneous coordinates for p_1, \dots, p_n, p with positive homogenizing coordinates h_1, \dots, h_n, h , we have

$$q_j = h_j \cdot (p_j \mid 1) \text{ for all } j, \text{ and } q = h \cdot (p \mid 1).$$

Now, nonnegative $\lambda_1, \dots, \lambda_n$ are suitable coefficients for a convex combination if and only if

$$\sum_{j=1}^n \lambda_j (p_j \mid 1) = (p \mid 1),$$

equivalently, if there are μ_1, \dots, μ_n (with $\mu_j = \lambda_j \cdot h/h_j$ for all j) such that

$$\sum_{j=1}^n \mu_j q_j = q, \quad \mu_j \geq 0 \text{ for all } j.$$

The linear program now tests for the existence of nonnegative μ_j that satisfy the latter equation. Below is the code; it defines a function that solves the linear program, given p and p_1, \dots, p_n (through an iterator range). The only (mild) trickery involved is the construction of the nested iterator through a fixed column of the constraint matrix A . We get this from transforming the iterator through the points using a functor that maps a point to an iterator through its homogeneous coordinates.

```

#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin {
    typedef typename Point_d::Homogeneous_const_iterator result_type;
    result_type operator() (const Point_d& p) const {
        return p.homogeneous_begin();
    }
};

// function to solve the LP that tests whether a point is in the
// convex hull of other points; the type ET is an exact type used
// for the internal computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
    RandomAccessIterator begin,
    RandomAccessIterator end, const ET& dummy)
{
    // Constraint matrix type: A[j][i] is the i-th homogeneous coordinate of p_j
    typedef boost::transform_iterator
        <Homogeneous_begin<Point_d>, RandomAccessIterator> A_it;
    // Right-hand side type: b[i] is the i-th homogeneous coordinate of p
    typedef typename Point_d::Homogeneous_const_iterator B_it;
    // Relation type ("=")
    typedef CGAL::Const_onese_iterator<CGAL::Comparison_result> R_it;
    // input number type
    typedef typename CGAL::Kernel_traits<Point_d>::Kernel::RT RT;
    // Linear objective function type (c=0: we only test feasibility)
    typedef CGAL::Const_onese_iterator<RT> C_it;
    // the nonnegative linear program type
    typedef
        CGAL::Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>
        Program;

    // ok, we are prepared now: construct program and solve it
    Program lp (end-begin, // number of variables
        p.dimension()+1, // number of constraints
        A_it (begin), B_it (p.homogeneous_begin()),
        R_it (CGAL::EQUAL), C_it (0));
    return CGAL::solve_nonnegative_linear_program (lp, dummy);
}

```

File: examples/QP_solver/solve_convex_hull_containment_lp.h

To see this in action, let us call it with $p_1 = (0,0)$, $p_2 = (10,0)$, $p_3 = (0,10)$ fixed (they define a triangle) and all integral points p in $[0,10]^2$. We know that p is in the convex hull of $\{p_1, p_2, p_3\}$ if and only if its two coordinates sum up to 10 at most. As the exact type, we use *MP_Float* or *Gmpzf* (which is faster and preferable if GMP is installed).

```

#include <cassert>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include "solve_convex_hull_containment_lp.h"

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;

bool is_in_convex_hull (const Point_d& p,
std::vector<Point_d>::const_iterator begin,
std::vector<Point_d>::const_iterator end)
{
    CGAL::Quadratic_program_solution<ET> s =
        solve_convex_hull_containment_lp (p, begin, end, ET(0));
    return !s.is_infeasible();
}

int main()
{
    std::vector<Point_d> points;
    // convex hull: simplex spanned by {(0,0), (10,0), (0,10)}
    points.push_back (Point_d ( 0.0,  0.0));
    points.push_back (Point_d (10.0,  0.0));
    points.push_back (Point_d ( 0.0, 10.0));
    for (int i=0; i<=10; ++i)
        for (int j=0; j<=10; ++j) {
            // (i,j) is in the simplex iff i+j <= 10
            bool contained = is_in_convex_hull
(Point_d (i, j), points.begin(), points.end());
            assert (contained == (i+j<=10));
        }

    return 0;
}

```

File: examples/QP_solver/convex_hull_containment.cpp

61.5.1 Using Makers

You already noticed in the previous example that the actual template arguments for *CGAL::Nonnegative_linear_program_from_iterators*<*A_it*, *B_it*, *R_it*, *C_it*> can be quite elaborate, and this only gets worse if you plug more iterators into each other. In general, you want to construct a program from given expressions for the iterators,

but the types of these expressions are probably very complicated and difficult to look up.

You can avoid the explicit construction of the type `CGAL::Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>` if you only need an expression of it, e.g. to pass it directly as an argument to the solving function. Here is an alternative version of `QP_solver/solve_convex_hull_containment_lp.h` that shows how this works. In effect, you get shorter and more readable code.

```
#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin {
    typedef typename Point_d::Homogeneous_const_iterator result_type;
    result_type operator() (const Point_d& p) const {
        return p.homogeneous_begin();
    }
};

// function to test whether point is in the convex hull of other points;
// the type ET is an exact type used for the computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
    RandomAccessIterator begin,
    RandomAccessIterator end, const ET& dummy)
{
    // construct program and solve it
    return CGAL::solve_nonnegative_linear_program
        (CGAL::make_nonnegative_linear_program_from_iterators
            (end-begin, // n
            p.dimension()+1, // m
            boost::transform_iterator
                <Homogeneous_begin<Point_d>, RandomAccessIterator>(begin), // A
            typename Point_d::Homogeneous_const_iterator (p.homogeneous_begin()), // b
            CGAL::Const_onset_iterator<CGAL::Comparison_result>(CGAL::EQUAL), // ~
            CGAL::Const_onset_iterator
                <typename CGAL::Kernel_traits<Point_d>::Kernel::RT> (0)), dummy); // c
}
```

File: examples/QP_solver/solve_convex_hull_containment_lp2.h

61.6 Important Variables and Constraints

If you have a solution \mathbf{x}^* of a linear or quadratic program, the “important” variables are typically the ones that are not on their bounds. In case of a nonnegative program, these are the nonzero variables. Going back to the example of the previous Section 61.5, we can easily interpret their importance: the nonzero variables correspond to points p_j that actually contribute to the convex combination that yields p .

The following example shows how we can access the important variables, using the iterators *basic_variable_indices_begin()* and *basic_variable_indices_end()*.

We generate a set of points that form a 4-gon in $[0,4]^2$, and then find the ones that contribute to the convex combinations of all 25 lattice points in $[0,4]^2$. If the lattice point in question is not in the 4-gon, we simply output this fact.

```
#include <cassert>
#include <vector>
#include <CGAL/Cartesian_d.h>
#include <CGAL/MP_Float.h>
#include "solve_convex_hull_containment_lp2.h"

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;
typedef CGAL::Quadratic_program_solution<CGAL::MP_Float> Solution;

int main()
{
    std::vector<Point_d> points;
    // convex hull: 4-gon spanned by {(1,0), (4,1), (4,4), (2,3)}
    points.push_back (Point_d (1, 0)); // point 0
    points.push_back (Point_d (4, 1)); // point 1
    points.push_back (Point_d (4, 4)); // point 2
    points.push_back (Point_d (2, 3)); // point 3

    // test all 25 integer points in  $[0,4]^2$ 
    for (int i=0; i<=4; ++i)
        for (int j=0; j<=4; ++j) {
            Point_d p (i, j);
            Solution s = solve_convex_hull_containment_lp
(p, points.begin(), points.end(), CGAL::MP_Float());
            std::cout << p;
            if (s.is_infeasible())
std::cout << " is not in the convex hull\n";
            else {
assert (s.is_optimal());
std::cout << " is a convex combination of the points ";
Solution::Index_iterator it = s.basic_variable_indices_begin();
Solution::Index_iterator end = s.basic_variable_indices_end();
for (; it != end; ++it) std::cout << *it << " ";
std::cout << std::endl;
            }
        }
    return 0;
}
```

File: examples/QP_solver/important_variables.cpp

It turns out that exactly three of the four points contribute to any convex combination, even though there are lattice points that lie in the convex hull of less than three of the points. This shows that the set of basic variables that we access in the example does not necessarily coincide with the set of important variables as defined above.

In fact, it is only guaranteed that a non-basic variable attains one of its bounds, but there might be basic variables that also have this property. In linear and quadratic programming terms, such a situation is called a *degeneracy*.

There is also the concept of an important constraint: this is typically a constraint in the system $A\mathbf{x} \leq \mathbf{b}$ that is satisfied with equality at \mathbf{x}^* . Program *QP_solver/first_qp_basic_constraints.cpp* shows how these can be accessed, using the iterators *basic_constraint_indices_begin()* and *basic_constraint_indices_end()*.

Again, we have a disagreement between “basic” and “important”: it is guaranteed that all basic constraints are satisfied with equality at \mathbf{x}^* , but there might be non-basic constraints that are satisfied with equality as well.

61.7 Solution Certificates

Suppose the solver tells you that the problem you have entered is infeasible. Why should you believe this? Similarly, you can quite easily verify that a claimed optimal solution is feasible, but why is there no better one?

Certificates are proofs that the solver can give you in order to convince you that what it claims is indeed true. The archetype of such a proof is *Farkas Lemma* [MG06].

Farkas Lemma: *Either* the inequality system

$$\begin{array}{rcl} A\mathbf{x} & \leq & \mathbf{b} \\ \mathbf{x} & \geq & 0 \end{array}$$

has a solution \mathbf{x}^* , *or* there exists a vector \mathbf{y} such that

$$\begin{array}{rcl} \mathbf{y} & \geq & 0 \\ \mathbf{y}^T A & \geq & 0 \\ \mathbf{y}^T \mathbf{b} & < & 0, \end{array}$$

but not both.

Thus, if someone wants to convince you that the first system in the Farkas Lemma is infeasible, that person can simply give you a vector \mathbf{y} that solves the second system. Since you can easily verify yourself that the \mathbf{y} you got satisfies this second system, you now have a certificate for the infeasibility of the first system, assuming that you believe in Farkas Lemma.

Here we show how the solver can convince you. We first set up an infeasible linear program with constraints of the type $A\mathbf{x} \leq \mathbf{b}, \mathbf{x} \geq 0$; then we solve it and ask for a certificate. Finally, we verify the certificate by simply checking the inequalities of the second system in Farkas Lemma.

```
#include <cassert>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact integral type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpz.h>
typedef CGAL::Gmpz ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif
```

```

// program and solution types
typedef CGAL::Nonnegative_linear_program_from_iterators
<int**,                                     // for A
 int*,                                     // for b
 CGAL::Comparison_result*,                 // for r
 int*>                                     // for c
Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

// we demonstrate Farkas Lemma: either the system
//      A x <= b
//      x >= 0
// has a solution, or there exists y such that
//      y >= 0
//      y^TA >= 0
//      y^Tb < 0
// In the following instance, the first system has no solution,
// since adding up the two inequalities gives x_2 <= -1:
//      x_1 - 2x_2 <= 1
//      -x_1 + 3x_2 <= -2
//      x_1,   x_2 >= 0

int main() {
    int  Ax1[] = { 1, -1};                // column for x1
    int  Ax2[] = {-2,  3};                // column for x2
    int*  A[] = {Ax1, Ax2};               // A comes columnwise
    int   b[] = {1, -2};                  // right-hand side
    CGAL::Comparison_result
        r[] = {CGAL::SMALLER, CGAL::SMALLER}; // constraints are "<="
    int   c[] = {0, 0};                   // zero objective function

    // now construct the linear program; the first two parameters are
    // the number of variables and the number of constraints (rows of A)
    Program lp (2, 2, A, b, r, c);

    // solve the program, using ET as the exact type
    Solution s = CGAL::solve_nonnegative_linear_program(lp, ET());

    // get certificate for infeasibility
    assert (s.is_infeasible());
    Solution::Infeasibility_certificate_iterator y =
        s.infeasibility_certificate_begin();
    // check y >= 0
    assert (y[0] >= 0);
    assert (y[1] >= 0);
    // check y^T A >= 0
    assert (y[0] * A[0][0] + y[1] * A[0][1] >= 0);
    assert (y[0] * A[1][0] + y[1] * A[1][1] >= 0);
    // check y^T b < 0
    assert (y[0] * b[0] + y[1] * b[1] < 0);

    return 0;
}

```

File: examples/QP_solver/infeasibility_certificate.cpp

There are similar certificates for optimality and unboundedness that you can see in action in the programs *QP_solver/optimality_certificate.cpp* and *QP_solver/unboundedness_certificate.cpp*. The underlying variants of Farkas Lemma are somewhat more complicated, due to the mixed relations in \geq and the general bounds. The certificate section of *Quadratic_program_solution<ET>* gives the full picture and mathematically proves the correctness of the certificates.

61.8 Customizing the Solver

Sometimes it is necessary to alter the default behavior of the solver. This can be done by passing a suitably prepared object of the class *Quadratic_program_options* to the solution functions. Most options concern “soft” issues like verbosity, but there are two notable case where it is of critical importance to be able to change the defaults.

61.8.1 Exponent Overflow in Double Using Floating-Point Filters

The filtered version of the solver that is used for some problems by default on input type *double* internally constructs double-approximations of exact multiprecision values. If these exact values are extremely large, this may lead to *infinite double* values and incorrect results. In debug mode, the solver will notice this through a certificate cross-check in the end (or even earlier). In this case, it is advisable to explicitly switch to a non-filtered *pricing strategy*, see *Quadratic_program_pricing_strategy*.

Hint: If you have a program where the number of variables n and the number of constraints m have the same order of magnitude, the filtering will usually have no dramatic effect on the performance, so in that case you might as well switch to *QP_PARTIAL_DANTZIG* to be safe from the issue described here (see *QP_solver/cycling.cpp* for an example that shows how to change the pricing strategy).

61.8.2 The Solver Internally Cycles

Consider the following program. It reads a nonnegative linear program from the file *cycling.mps* (which is in the example directory as well), and then solves it in verbose mode, using *Bland’s rule*, see *Quadratic_program_pricing_strategy*.

```
#include <iostream>
#include <fstream>
#include <CGAL/basic.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
```

```

#endif

// program and solution types
typedef CGAL::Quadratic_program_from_mps<double> Program;
typedef CGAL::Quadratic_program_solution<ET> Solution;

int main() {
    std::ifstream in ("cycling.mps");
    Program lp(in);          // read program from file
    assert (lp.is_valid()); // we should have a valid mps file...
    assert (lp.is_linear()); // ... and it should be linear...
    assert (lp.is_nonnegative()); // as well as nonnegative

    // solve the program, using ET as the exact type
    // choose verbose mode and Bland pricing
    CGAL::Quadratic_program_options options;
    options.set_verbosity(1);          // verbose mode
    options.set_pricing_strategy(CGAL::QP_BLAND); // Bland's rule
    options.set_auto_validation(true); // automatic self-check
    Solution s = CGAL::solve_nonnegative_linear_program(lp, ET(), options);
    assert (s.is_valid());             // did the self-check succeed?

    // output solution
    std::cout << s;
    return 0;
}

```

File: examples/QP_solver/cycling.cpp

If you comment the line

```
options.set_pricing_strategy(CGAL::QP_BLAND);          // Bland's rule
```

you will see that the solver cycles: the verbose mode outputs the same sequence of six iterations over and over again. By switching to *QP.BLAND*, the solution process typically slows down a bit (it may also speed up in some cases), but now it is guaranteed that no cycling occurs.

In general, the verbose mode can be of use when you are not sure whether the solver “has died”, or whether it simply takes very long to solve your problem. We refer to the class *Quadratic_program_options* for further details.

61.9 Some Benchmarks

Here we want to show what you can expect from the solver’s performance in a specific application; we don’t know whether this application is typical in your case, and we make no claims whatsoever about the performance in other applications.

Still, the example shows that the performance can be dramatically affected by switching between pricing strategies, and we give some hints on how to achieve good performance in general.

The application is the one already discussed in Section 61.5 above: testing whether a point is in the convex hull of other points. To be able to switch between pricing strategies, we add another parameter of type *Quadratic_program_options* to the function *solve_convex_hull_containment_lp* that we pass on to the solution function:

```
#include <boost/config.hpp>
#include <boost/iterator/transform_iterator.hpp>
#include <CGAL/Kernel_traits.h>
#include <CGAL/QP_options.h>
#include <CGAL/QP_models.h>
#include <CGAL/QP_functions.h>

// unary function to get homogeneous begin-iterator of point
template <class Point_d>
struct Homogeneous_begin {
    typedef typename Point_d::Homogeneous_const_iterator result_type;
    result_type operator() (const Point_d& p) const {
        return p.homogeneous_begin();
    }
};

// function to test whether point is in the convex hull of other points;
// the type ET is an exact type used for the computations
template <class Point_d, class RandomAccessIterator, class ET>
CGAL::Quadratic_program_solution<ET>
solve_convex_hull_containment_lp (const Point_d& p,
    RandomAccessIterator begin,
    RandomAccessIterator end, const ET& dummy,
    const CGAL::Quadratic_program_options& o)
{
    // construct program and solve it
    return CGAL::solve_nonnegative_linear_program
        (CGAL::make_nonnegative_linear_program_from_iterators
            (end-begin, // n
             p.dimension()+1, // m
             boost::transform_iterator
                <Homogeneous_begin<Point_d>, RandomAccessIterator>(begin), // A
             typename Point_d::Homogeneous_const_iterator (p.homogeneous_begin()), // b
             CGAL::Const_oneseq_iterator<CGAL::Comparison_result>(CGAL::EQUAL), // ~
             CGAL::Const_oneseq_iterator
                <typename CGAL::Kernel_traits<Point_d>::Kernel::RT> (0)), // c
            dummy, o);
}
```

File: examples/QP_solver/solve_convex_hull_containment_lp3.h

Now let us test containment of the origin in the convex hull of n random points in $[0, 1]^d$ (it will most likely not be contained, and it turns out that this is the most expensive case). In the program below, we use $d = 10$ and $n = 100,000$, and we comment on some other combinations of n and d below (feel free to experiment with still other values).

```
#include <vector>
#include <CGAL/Cartesian_d.h>
```

```

#include <CGAL/MP_Float.h>
#include <CGAL/Random.h>
#include <CGAL/Timer.h>
#include "solve_convex_hull_containment_lp3.h"

// choose exact floating-point type
#ifdef CGAL_USE_GMP
#include <CGAL/Gmpzf.h>
typedef CGAL::Gmpzf ET;
#else
#include <CGAL/MP_Float.h>
typedef CGAL::MP_Float ET;
#endif

typedef CGAL::Cartesian_d<double> Kernel_d;
typedef Kernel_d::Point_d Point_d;

int main()
{
    const int d = 10;          // change this in order to experiment
    const int n = 100000;      // change this in order to experiment

    // generate n random d-dimensional points in  $[0,1]^d$ 
    CGAL::Random rd;
    std::vector<Point_d> points;
    for (int j = 0; j < n; ++j) {
        std::vector<double> coords;
        for (int i = 0; i < d; ++i)
            coords.push_back(rd.get_double());
        points.push_back (Point_d (d, coords.begin(), coords.end()));
    }

    // benchmark all pricing strategies in turn
    CGAL::Quadratic_program_pricing_strategy strategy[] = {
        CGAL::QP_CHOOSE_DEFAULT,          // QP_PARTIAL_FILTERED_DANTZIG
        CGAL::QP_DANTZIG,                 // Dantzig's pivot rule...
        CGAL::QP_PARTIAL_DANTZIG,         // ... with partial pricing
        CGAL::QP_BLAND,                   // Bland's pivot rule
        CGAL::QP_FILTERED_DANTZIG,        // Dantzig's filtered pivot rule...
        CGAL::QP_PARTIAL_FILTERED_DANTZIG // ... with partial pricing
    };

    CGAL::Timer t;
    for (int i = 0; i < 6; ++i) {
        // test strategy i
        CGAL::Quadratic_program_options options;
        options.set_pricing_strategy (strategy[i]);
        t.reset(); t.start();
        // is origin in convex hull of the points? (most likely, not)
        solve_convex_hull_containment_lp
            (Point_d (d, CGAL::ORIGIN), points.begin(), points.end(),
             ET(0), options);
        t.stop();
        std::cout << "Time (s) = " << t.time() << std::endl;
    }
}

```

```

    }

    return 0;
}

```

File: examples/QP_solver/convex_hull_containment_benchmarks.cpp

If you compile with the macros `NDEBUG` or `CGAL_QP_NO_ASSERTIONS` set (this is essential for good performance!), you will see runtimes that qualitatively look as follows (on your machine, the actual runtimes will roughly be some fixed multiples of the numbers in the table below, and they might vary with the random choices). The default choice of the pricing strategy in that case is `QP_PARTIAL_FILTERED_DANTZIG`.

strategy	runtime in seconds	
<i>CGAL::QP_CHOOSE_DEFAULT</i>	—	0.32
<i>CGAL::QP_DANTZIG</i>	—	10.7
<i>CGAL::QP_PARTIAL_DANTZIG</i>	—	3.72
<i>CGAL::QP_BLAND</i>	—	3.65
<i>CGAL::QP_FILTERED_DANTZIG</i>	—	0.43
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	—	0.32

We clearly see the effect of filtering: we gain a factor of ten, roughly, compared to the next best non-filtered variant.

61.9.1 $d = 3, n = 1,000,000$

The filtering effect is amplified if the points/dimension ratio becomes larger. This is what you might see in dimension three, with one million points.

strategy	runtime in seconds	
<i>CGAL::QP_CHOOSE_DEFAULT</i>	—	1.34
<i>CGAL::QP_DANTZIG</i>	—	47.6
<i>CGAL::QP_PARTIAL_DANTZIG</i>	—	15.6
<i>CGAL::QP_BLAND</i>	—	16.02
<i>CGAL::QP_FILTERED_DANTZIG</i>	—	1.89
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	—	1.34

In general, if your problem has a high variable/constraint or constraint/variable ratio, then filtering will typically pay off. In such cases, it might be beneficial to encode your problem using input type *double* in order to profit from the filtering (but see the issue discussed in Section 61.8.1).

61.9.2 $d = 100, n = 100,000$

Conversely, the filtering effect deteriorates if the points/dimension ratio becomes smaller.

strategy	runtime in seconds	
<i>CGAL::QP_CHOOSE_DEFAULT</i>	—	3.05
<i>CGAL::QP_DANTZIG</i>	—	78.4
<i>CGAL::QP_PARTIAL_DANTZIG</i>	—	45.9
<i>CGAL::QP_BLAND</i>	—	33.2
<i>CGAL::QP_FILTERED_DANTZIG</i>	—	3.36
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	—	3.06

61.9.3 $d = 500, n = 1,000$

If the points/dimension ratio tends to a constant, filtering is no longer a clear winner. The reason is that in this case, the necessary exact calculations with multiprecision numbers dominate the overall runtime.

strategy		runtime in seconds
<i>CGAL::QP_CHOOSE_DEFAULT</i>	—	2.65
<i>CGAL::QP_DANTZIG</i>	—	5.55
<i>CGAL::QP_PARTIAL_DANTZIG</i>	—	5.6
<i>CGAL::QP_BLAND</i>	—	4.46
<i>CGAL::QP_FILTERED_DANTZIG</i>	—	2.65
<i>CGAL::QP_PARTIAL_FILTERED_DANTZIG</i>	—	2.61

In general, if you have a program where the number of variables and the number of constraints have the same order of magnitude, then the saving gained from using the filtered approach is typically small. In such a situation, you should consider switching to a non-filtered variant in order to avoid the rare issue discussed in [Section 61.8.1](#) altogether.

Linear and Quadratic Programming Solver

Classes

There is a class that represents the solution of a linear or quadratic program. An instance of this class is returned by any of the solution functions below.

<i>CGAL::Quadratic_program_solution</i> <ET>	page 3278
--	---------------------------

We offer a number of predefined models for the above program concepts. The following two are simultaneously models for all four concepts and are probably the most convenient models; they allow you to construct linear or quadratic programs entry by entry, or from streams in *MPSFormat*. At any time, you can query these programs for linearity and nonnegativity and thus select the appropriate solution function.

<i>CGAL::Quadratic_program</i> <NT>	page 3289
(for linear and quadratic programs that own their data and are built entry-wise)	
<i>CGAL::Quadratic_program_from_mps</i> <NT>	page 3292
(for linear and quadratic programs read from an input stream in <i>MPSFormat</i> ; the constructed program can also be manipulate entry-wise)	

Then there are specific models for any of the four program concepts above; these are useful if you want to maintain the program data yourself, since they simply wrap random access iterators over the program data and involve no further copying of data.

CGAL::Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it> page 3296
(for quadratic programs that wrap given iterators, without copying data)

CGAL::Linear_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, C_it> page 3298

QuadraticProgram

Definition

A model of QuadraticProgram describes a convex quadratic program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{smallmatrix} \geq \\ \leq \end{smallmatrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in n real variables $\mathbf{x} = (x_0, \dots, x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- \mathbf{b} is an m -dimensional vector (the right-hand side),
- $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$ is an m -dimensional vector of relations from $\{\leq, =, \geq\}$,
- \mathbf{l} is an n -dimensional vector of lower bounds for \mathbf{x} , where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- \mathbf{u} is an n -dimensional vector of upper bounds for \mathbf{x} , where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- \mathbf{c} is an n -dimensional vector (the linear objective function), and
- c_0 is a constant.

The description is given by appropriate *random-access* iterators over the program data, see below. The program therefore comes in *dense* representation which includes zero entries.

Has Models

Quadratic_program<NT>

Quadratic_program_from_mps<NT>

Quadratic_program_from_iterators<*A_it*, *B_it*, *R_it*, *FL_it*, *L_it*, *FU_it*, *U_it*, *D_it*, *C_it*>

Types

QuadraticProgram::A_iterator

A random access iterator type to go columnwise over the constraint matrix A . The value type is a random access iterator type for an individual column that goes over the entries in that column.

QuadraticProgram::B_iterator

A random access iterator type to go over the entries of the right-hand side \mathbf{b} .

QuadraticProgram::R_iterator

A random access iterator type to go over the relations $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$. The value type of *R_iterator* is *CGAL::Comparison_result*.

<i>QuadraticProgram:: FL_iterator</i>	A random access iterator type to go over the existence (finiteness) of the lower bounds $l_j, j = 0, \dots, n-1$. The value type of <i>FL_iterator</i> is <i>bool</i> .
<i>QuadraticProgram:: L_iterator</i>	A random access iterator type to go over the entries of the lower bound vector l .
<i>QuadraticProgram:: UL_iterator</i>	A random access iterator type to go over the existence (finiteness) of the upper bounds $u_j, j = 0, \dots, n-1$. The value type of <i>UL_iterator</i> is <i>bool</i> .
<i>QuadraticProgram:: U_iterator</i>	A random access iterator type to go over the entries of the upper bound vector u .
<i>QuadraticProgram:: D_iterator</i>	A random access iterator type to go rowwise over the matrix $2D$. The value type is a random access iterator type for an individual row that goes over the entries in that row, up to (and including) the entry on the main diagonal.
<i>QuadraticProgram:: C_iterator</i>	A random access iterator type to go over the entries of the linear objective function vector <i>c</i> .

Operations

<i>int</i>	<i>qp.get_n()</i>	returns the number <i>n</i> of variables (number of columns of <i>A</i>) in <i>qp</i> .
<i>int</i>	<i>qp.get_m()</i>	returns the number <i>m</i> of constraints (number of rows of <i>A</i>) in <i>qp</i> .
<i>A_iterator</i>	<i>qp.get_a()</i>	returns an iterator over the columns of <i>A</i> . The corresponding past-the-end iterator is <i>get_a()+get_n()</i> . For $j = 0, \dots, n-1$, $*(get_a() + j)$ is a random access iterator for column <i>j</i> .
<i>B_iterator</i>	<i>qp.get_b()</i>	returns an iterator over the entries of b . The corresponding past-the-end iterator is <i>get_b()+get_m()</i> .
<i>R_iterator</i>	<i>qp.get_r()</i>	returns an iterator over the entries of $\begin{smallmatrix} \geq \\ \leq \end{smallmatrix}$. The corresponding past-the-end iterator is <i>get_r()+get_m()</i> . The value <i>CGAL::SMALLER</i> stands for \leq , <i>CGAL::EQUAL</i> stands for $=$, and <i>CGAL::LARGER</i> stands for \geq .
<i>FL_iterator</i>	<i>qp.get_fl()</i>	returns an iterator over the existence of the lower bounds $l_j, j = 0, \dots, n-1$. The corresponding past-the-end iterator is <i>get_fl()+get_n()</i> . If $*(get_fl() + j)$ has value <i>true</i> , the variable x_j has a lower bound given by $*(get_l() + j)$, otherwise it has no lower bound.
<i>L_iterator</i>	<i>qp.get_l()</i>	returns an iterator over the entries of l . The corresponding past-the-end iterator is <i>get_l()+get_n()</i> . If $*(get_fl() + j)$ has value <i>false</i> , the value $*(get_l() + j)$ is not accessed. <i>Precondition:</i> if both $*(get_fl() + j)$ and $*(get_fu() + j)$ have value <i>true</i> , then $*(get_l() + j) \leq *(get_u() + j)$

<i>FU_iterator</i>	<i>qp.get_fu()</i>	returns an iterator over the existence of the upper bounds $u_j, j = 0, \dots, n - 1$. The corresponding past-the-end iterator is <i>get_fu()+get_n()</i> . If <i>*(get_fu()+j)</i> has value <i>true</i> , the variable x_j has an upper bound given by <i>*(get_u()+j)</i> , otherwise it has no upper bound.
<i>L_iterator</i>	<i>qp.get_u()</i>	returns an iterator over the entries of u . The corresponding past-the-end iterator is <i>get_u()+get_n()</i> . If <i>*(get_fu()+j)</i> has value <i>false</i> , the value <i>*(get_u()+j)</i> is not accessed. <i>Precondition:</i> if both <i>*(get_fl()+j)</i> and <i>*(get_fu()+j)</i> have value <i>true</i> , then <i>*(get_l()+j) ≤ *(get_u()+j)</i>
<i>D_iterator</i>	<i>qp.get_d()</i>	returns an iterator over the rows of $2D$. The corresponding past-the-end iterator is <i>get_d()+get_n()</i> . For $i = 0, \dots, n - 1$, <i>*(get_d()+i)</i> is a random access iterator for the entries in row i below or on the diagonal. The valid range of this iterator is guaranteed to have length $i + 1$ but not more. Values to the right of the diagonal are deduced from the symmetry requirement on D .
<i>C_iterator</i>	<i>qp.get_c()</i>	returns an iterator over the entries of c . The corresponding past-the-end iterator is <i>get_c()+get_n()</i> .
<i>std::iterator_traits<C_iterator>::value_type</i>		
	<i>qp.get_c0()</i>	returns the constant term c_0 of the objective function.

Requirements

The value types of all iterator types (nested iterator types, respectively, for *A_iterator* and *D_iterator*) must be convertible to some common *IntegralDomain ET*.

LinearProgram

Definition

A model of LinearProgram describes a linear program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad \mathbf{A}\mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in n real variables $\mathbf{x} = (x_0, \dots, x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- \mathbf{b} is an m -dimensional vector (the right-hand side),
- $\begin{matrix} \geq \\ \leq \end{matrix}$ is an m -dimensional vector of relations from $\{\leq, =, \geq\}$,
- \mathbf{l} is an n -dimensional vector of lower bounds for \mathbf{x} , where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- \mathbf{u} is an n -dimensional vector of upper bounds for \mathbf{x} , where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- \mathbf{c} is an n -dimensional vector (the linear objective function), and
- c_0 is a constant.

The description is given by appropriate *random-access* iterators over the program data, see below. The program therefore comes in *dense* representation which includes zero entries.

LinearProgram

NonnegativeQuadraticProgram

MPSFormat

MPS is a commonly used file format for storing linear and quadratic programs according to the concepts *QuadraticProgram*, *LinearProgram*, *NonnegativeQuadraticProgram*, and *NonnegativeLinearProgram*, see also [http://en.wikipedia.org/wiki/MPS_\(format\)](http://en.wikipedia.org/wiki/MPS_(format)).

CGAL supports a large subset of this format, but there are MPS files around that we cannot read (for example, files that encode integrality constraints on the variables). Also, there might be some other MPS-based solvers that will not be able to read the MPS files written by CGAL, since we do not strictly adhere to the very rigid layout requirements of the original MPS format.

Let's look at an example first. The quadratic program

$$\begin{array}{ll} \text{minimize} & x^2 + 4(y - 4)^2 \quad (= x^2 + 4y^2 - 32y + 64) \\ \text{subject to} & \begin{array}{ll} x + y & \leq 7 \\ -x + 2y & \leq 4 \\ x & \geq 0 \\ y & \geq 0 \\ y & \leq 4 \end{array} \end{array}$$

has the following description in MPS format.

```
NAME first_qp
ROWS
  N obj
  L c0
  L c1
COLUMNS
  x0 c0 1
  x0 c1 -1
  x1 obj -32
  x1 c0 1
  x1 c1 2
RHS
  rhs obj -64
  rhs c0 7
  rhs c1 4
BOUNDS
  UP BND x1 4
QMATRIX
  x0 x0 2
  x1 x1 8
ENDATA
```

Here comes a semiformal description of the format in general.

NAME section

This (mandatory) section consists of a single line starting with `NAME`. Everything starting from the first non-whitespace after that until the end of the line constitutes the name of the problem.

ROWS section

In the (mandatory) `ROW` section, you find one line for every constraint, where the letter `L` indicates relation \leq , letter `G` stands for \geq , and `E` for $=$. In addition, there is a row for the linear objective function (indicated by letter `N`). In that section, names are assigned to the constraints (here: `c0`, `c1`) and the objective function (here: `obj`). An MPS file may encode several linear objective functions by using several rows starting with `N`, but we ignore all but the first.

COLUMNS section

The (mandatory) `COLUMNS` section encodes the constraint matrix A and the linear objective function vector c . Every line consists of one or two sequences of three tokens *jival*, where j is the name of a variable (here, we have variables `x0`, `x1`), i is the name of a constraint or the objective function, and val is the value A_{ij} (if i names a constraint), or c_j (if i names the linear objective function). Values for pairs (i, j) that are not specified in this section default to 0. Otherwise, for every pair (i, j) , the *last* specified value determines A_{ij} or c_j .

RHS section

This (mandatory) section encodes the right-hand side vector b and the constant term c_0 in the objective function. The first token in every line is an identifier (here: `rhs`). An MPS file may encode several right-hand sides b by using several such identifiers, but we ignore all lines having an identifier different from that of the first line.

The right-hand side identifier is succeeded by one or two sequences of tokens *ival*, where i names a constraint or the linear objective function, and val specifies the value b_i (if i names a constraint), or $-c_0$ (if i names the linear objective function). Values that are not specified in this section default to 0. Otherwise, for every i , the *last* specified value determines b_i or $-c_0$.

BOUNDS section

This (optional) section encodes the lower and upper bound vectors l and u for the variables. The default bounds for any variable x_j are $0 \leq x_j \leq \infty$; the `BOUNDS` section is used to override these defaults. In particular, if there is no `BOUNDS` section, the program is nonnegative and actually a model of the concept *NonnegativeQuadraticProgram* or *NonnegativeLinearProgram*.

The first token in every line is succeeded by an (optional) identifier (here: `BND`). An MPS file may encode several bound vectors l and u by using several such identifiers, but we ignore all lines having an identifier different from that of the first line. The first token t itself determines the type of the bound, and the token j after the bound identifier names the variable to which the bound applies. In case of bound types `FX`, `LO`, and `UP`, there is another

token *val* that specifies the bound value. Here is how bound type and value determine a bound for variable x_j . There may be several bound specifications for a single variable, and they are processed in order of appearance.

bound type	resulting bound
FX	$x_j = val$ (x_j becomes a fixed variable)
LO	$x_j \geq val$ (upper bound remains unchanged)
UP	$x_j \leq val$ (lower bound remains unchanged, except if $val < 0$; then, a zero lower bound is reset to $-\infty$)
FR	$-\infty \leq x_j \leq \infty$ (previous bounds are discarded)
MI	$x_j \geq -\infty$ (upper bound remains unchanged)
PL	$x_j \leq \infty$ (lower bound remains unchanged)

QMATRIX / QUADOBJ / DMATRIX section

This (optional) section encodes the quadratic objective function matrix D . Every line is a sequence *ijval* of three tokens, where both *i* and *j* name variables, and *val* is the value $2D_{i,j}$ (in case of QMATRIX or QUADOBJ), or D_{ij} (in case of DMATRIX).

In case of QMATRIX and DMATRIX, *all* nonzero entries must be specified: if there is a line *ijval*, then there must also be a line *jival*, since D is required to be symmetric. In case of QUADOBJ, only the entries of $2D$ on or below the diagonal must be specified, entries above the diagonal are deduced from symmetry. It is not allowed to specify two or more *different* nonzero values for an unordered pair $\{i, j\}$.

If this section is missing or does not contain nonzero values, the program is a model of the concept *LinearProgram*.

Miscellaneous

Our MPS format also supports an (optional) RANGES section, but we don't explain this here.

Quadratic_program_from_mps<NT>

CGAL::Quadratic_program_solution<ET>

#include <CGAL/QP_solution.h>

Definition

An object of class *Quadratic_program_solution*<ET> represents the solution of a linear or convex quadratic program of the general form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in n real variables $\mathbf{x} = (x_0, \dots, x_{n-1})$.

If $D = 0$, the program is a linear program; if the variable bounds are $\mathbf{x} \geq 0$, we have a nonnegative program. Objects of type *Quadratic_program_solution*<ET> are returned by any of the four functions *solve_quadratic_program*, *solve_linear_program*, *solve_nonnegative_quadratic_program*, and *solve_nonnegative_linear_program*.

Example

QP_solver/first_qp.cpp

Terminology

If there is no \mathbf{x} that satisfies all the (in)equalities, the program is called *infeasible*, otherwise, it is *feasible*, and any \mathbf{x} that satisfies all (in)equalities is called a *feasible solution*.

If the objective function value becomes arbitrarily small over the *feasible region* (the set of feasible solutions), the program is called *unbounded*, and *bounded* otherwise.

Any program that is both feasible and bounded has at least one feasible solution \mathbf{x}^* whose objective function value is not larger than that of any other feasible solution. This is called an *optimal solution*.

Every convex quadratic program (even if it is infeasible or unbounded) has a 'solution' in form of an object of the class *Quadratic_program_solution*<ET>.

Types

Quadratic_program_solution<ET>:: *ET* The exact number type that was used to solve the program.

Quadratic_program_solution<ET>:: *Variable_value_iterator*

An iterator type with value type *Quotient*<ET> to go over the values of the variables in the solution.

Quadratic_program_solution<ET>:: Variable_numerator_iterator

An iterator type with value type *ET* to go over the numerators of the variable values with respect to a common denominator.

Quadratic_program_solution<ET>:: Index_iterator

An iterator type with value type *int* to go over the indices of the basic variables and the basic constraints.

Quadratic_program_solution<ET>:: Optimality_certificate_iterator

An iterator type with value type *Quotient<ET>* to go over an *m*-vector λ that proves optimality of the solution.

Quadratic_program_solution<ET>:: Optimality_certificate_numerator_iterator

An iterator type with value type *ET* to go over the numerators of the vector λ with respect to a common denominator.

Quadratic_program_solution<ET>:: Infeasibility_certificate_iterator

An iterator type with value type *ET* to go over an *m*-vector λ that proves infeasibility of the solution.

Quadratic_program_solution<ET>:: Unboundedness_certificate_iterator

An iterator type with value type *ET* to go over an *n*-vector \mathbf{w} that proves unboundedness of the solution.

Creation

Quadratic_program_solution<ET> sol; constructs a void instance of *Quadratic_program_solution<ET>* that is associated to no program.

Objects of type *Quadratic_program_solution<ET>* can be copied and assigned.

Objects of type *Quadratic_program_solution<ET>* that are associated to an actual program are returned by any of the four functions *solve_quadratic_program*, *solve_linear_program*, *solve_nonnegative_quadratic_program*, and *solve_nonnegative_linear_program*.

Example

QP_solver/first_qp.cpp

Operations

<i>bool</i>	<i>sol.is_void()</i>	returns <i>true</i> iff <i>sol</i> is not associated to a program. The condition <i>!sol.is_void()</i> is a precondition for all access methods below.
-------------	----------------------	--

Solution status

Here are the access methods for the status of the solution.

<i>bool</i>	<i>sol.is_optimal()</i>	returns <i>true</i> iff <i>sol</i> is an optimal solution of the associated program.
-------------	-------------------------	--

<i>bool</i>	<i>sol.is_infeasible()</i>	returns <i>true</i> iff the associated program is infeasible.
-------------	----------------------------	---

<i>bool</i>	<i>sol.is_unbounded()</i>	returns <i>true</i> iff the associated program is unbounded.
-------------	---------------------------	--

Quadratic_program_status

<i>sol.status()</i>	returns the status of the solution; this is one of the values <i>QP_OPTIMAL</i> , <i>QP_INFEASIBLE</i> , and <i>QP_UNBOUNDED</i> , depending on whether the program associated to <i>sol</i> has an optimal solution, is infeasible, or is unbounded.
---------------------	---

<i>int</i>	<i>sol.number_of_iterations()</i>	returns the number of iterations that it took to solve the program associated to <i>sol</i> .
------------	-----------------------------------	---

Solution values

The actual solution (variable and objective function values) can be accessed as follows.

<i>Quotient<ET></i>	<i>sol.objective_value()</i>	returns the objective function value of <i>sol</i> .
---------------------------	------------------------------	--

<i>ET</i>	<i>sol.objective_value_numerator()</i>	returns the numerator of the objective function value of <i>sol</i> .
-----------	--	---

<i>ET</i>	<i>sol.objective_value_denominator()</i>	returns the denominator of the objective function value of <i>sol</i> .
-----------	--	---

Variable_value_iterator

<i>sol.variable_values_begin()</i>	returns a random-access iterator over the values of the variables in <i>sol</i> . The value type is <i>Quotient<ET></i> , and the valid iterator range has length <i>n</i> .
------------------------------------	--

Variable_value_iterator

sol.variable_values_end()

returns the corresponding past-the-end iterator.

Variable_numerator_iterator

sol.variable_numerators_begin()

returns a random-access iterator *it* over the values of the variables in *sol*, with respect to a common denominator of all variables. The value type is *ET*, and the valid iterator range has length *n*.

Variable_numerator_iterator

sol.variable_numerators_end()

returns the corresponding past-the-end iterator.

ET

sol.variables_common_denominator()

returns the common denominator of the variable values as referred to by the previous two methods.

Basic variables and constraints

The solution of a linear or quadratic program distinguishes 'important' variables (the ones not attaining one of their bounds), and 'important' constraints (the ones being satisfied with equality). The following methods grant access to them.

Index_iterator

sol.basic_variable_indices_begin()

returns a random access iterator over the indices of the basic variables. The value type is *int*. It is guaranteed that any variable that is not basic in *sol* attains one of its bounds. In particular, if the bounds are of type $x \geq 0$, all non-basic variables have value 0.

Index_iterator

sol.basic_variable_indices_end()

returns the corresponding past-the-end iterator.

int

sol.number_of_basic_variables()

returns the number of basic variables, equivalently the length of the range determined by the previous two iterators.

Example

QP_solver/important_variables.cpp

Index_iterator *sol.basic_constraint_indices_begin()*

returns a random access iterator over the indices of the basic constraints in the system $A\mathbf{x} \geq \mathbf{b}$. The value type is *int*. It is guaranteed that any basic constraint is satisfied with equality. In particular, if the system is of type $A\mathbf{x} = \mathbf{b}$, all constraints are basic.

Index_iterator *sol.basic_constraint_indices_end()*

returns the corresponding past-the-end iterator.

int *sol.number_of_basic_constraints()*

returns the number of basic constraint, equivalently the length of the range determined by the previous two iterators.

Example

QP_solver/first_qp_basic_constraints.cpp

Output

```
template <typename ET>
std::ostream&            std::ostream& out << sol
```

writes the status of *sol* to the stream *out*. In case the status is *QP.OPTIMAL*, the optimal objective value and the values of the variables at the optimal solution are output as well. For more detailed information about the solution (like basic variables/constraints) please use the dedicated methods of *Quadratic_program_solution<ET>*.

Validity

The following four methods allow you to check whether *sol* indeed solves the program that you intended to solve. The methods use the certificates described in the advanced section below and thus save you from validating the certificates yourself (if you believe in the correctness of these methods; otherwise, you can look at their implementation to convince yourself).

By passing a suitable option to the solution function, you can make sure that this check is done automatically after the solution of the program, see *Quadratic_program_options*. If the check fails, a logfile is generated that contains the details, and an error message is written to *std::cerr* (see *QP_solver/cycling.cpp* for an example that uses this option).

```
template <class QuadraticProgram>
```

<i>bool</i>	<i>sol.solves_quadratic_program(QuadraticProgram qp)</i>	returns <i>true</i> iff <i>sol</i> solves the quadratic program <i>qp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .
-------------	---	---

QP_solver/first_qp.cpp

<i>template <class LinearProgram></i>		
<i>bool</i>	<i>sol.solves_linear_program(LinearProgram lp)</i>	returns <i>true</i> iff <i>sol</i> solves the linear program <i>lp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .

QP_solver/first_lp.cpp

<i>template <class NonnegativeQuadraticProgram></i>		
<i>bool</i>	<i>sol.solves_nonnegative_quadratic_program(NonnegativeQuadraticProgram qp)</i>	returns <i>true</i> iff <i>sol</i> solves the nonnegative quadratic program <i>qp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .

QP_solver/first_nonnegative_qp.cpp

<i>template <class NonnegativeLinearProgram></i>		
<i>bool</i>	<i>sol.solves_nonnegative_linear_program(NonnegativeLinearProgram lp)</i>	returns <i>true</i> iff <i>sol</i> solves the nonnegative linear program <i>lp</i> . If the result is <i>false</i> , you can get a message that describes the problem, through the method <i>get_error()</i> .

QP_solver/first_nonnegative_lp.cpp

<i>bool</i>	<i>sol.is_valid()</i>	returns <i>false</i> iff the validation through one of the previous four functions has failed.
-------------	-----------------------	--

<i>std::string</i>	<i>sol.get_error()</i>	returns an error message in case any of the previous four validation functions has returned <i>false</i> .
--------------------	------------------------	--

————— advanced —————

Certificates

A certificate is a vector that admits a simple proof for the correctness of the solution. Any non-void object of *Quadratic_program_solution<ET>* comes with such a certificate.

Lemma 1 (optimality certificate): A feasible n -vector \mathbf{x}^* is an optimal solution of (QP) if an m -vector λ with the following properties exist.

1. if the i -th constraint is of type \leq (\geq , respectively), then $\lambda_i \geq 0$ ($\lambda_i \leq 0$, respectively).
2. $\lambda^T (A\mathbf{x}^* - \mathbf{b}) = 0$.
- 3.

$$(\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)_j \begin{array}{ll} \geq 0, & \text{if } x_j^* = l_j < u_j \\ = 0, & \text{if } l_j < x_j^* < u_j \\ \leq 0, & \text{if } l_j < u_j = x_j^*. \end{array}$$

Proof: Let \mathbf{x} be any feasible solution. We need to prove that

$$\mathbf{c}^T \mathbf{x} + \mathbf{x}^T D \mathbf{x} \geq \mathbf{c}^T \mathbf{x}^* + \mathbf{x}^{*T} D \mathbf{x}^*.$$

For this, we argue as follows.

$$\begin{aligned} \mathbf{c}^T \mathbf{x} + 2\mathbf{x}^{*T} D \mathbf{x} &\geq \mathbf{c}^T \mathbf{x} + 2\mathbf{x}^{*T} D \mathbf{x} + \lambda^T (A\mathbf{x} - \mathbf{b}) && \text{(by } A\mathbf{x} \preceq \mathbf{b} \text{ and 1.)} \\ &= (\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)\mathbf{x} - \lambda^T \mathbf{b} \\ &\geq (\mathbf{c}^T + \lambda^T A + 2\mathbf{x}^{*T} D)\mathbf{x}^* - \lambda^T \mathbf{b} && \text{(by } \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \text{ and 3.)} \\ &= \mathbf{c}^T \mathbf{x}^* + 2\mathbf{x}^{*T} D \mathbf{x}^* && \text{(by 2.)} \end{aligned}$$

After adding $\mathbf{x}^T D \mathbf{x} - \mathbf{x}^T D \mathbf{x} - \mathbf{x}^{*T} D \mathbf{x}^* = -\mathbf{x}^{*T} D \mathbf{x}^*$ to both sides of this inequality, we get

$$\mathbf{c}^T \mathbf{x} + \mathbf{x}^T D \mathbf{x} - (\mathbf{x} - \mathbf{x}^*)^T D (\mathbf{x} - \mathbf{x}^*) \geq \mathbf{c}^T \mathbf{x}^* + \mathbf{x}^{*T} D \mathbf{x}^*,$$

and since D is positive semidefinite, we have $(\mathbf{x} - \mathbf{x}^*)^T D (\mathbf{x} - \mathbf{x}^*) \geq 0$ and the lemma follows.

Optimality_certificate_iterator

sol.optimality_certificate_begin()

returns a random access iterator over the optimality certificate λ as given in Lemma 1, with respect to the solution \mathbf{x}^* obtained from *sol.variable_values_begin()*. The value type is *Quotient<ET>*, and the valid iterator range has length m .
Precondition: *sol.is_optimal()*

Optimality_certificate_iterator

sol.optimality_certificate_end()

returns the corresponding past-the-end iterator.

Optimality_certificate_numerator_iterator

sol.optimality_certificate_numerators_begin()

returns a random access iterator over the numerator values of the optimality certificate λ , with respect to the common denominator returned by *sol.variables_common_denominator()*. The value type is *ET*, and the valid iterator range has length m .

Optimality_certificate_numerator_iterator

sol.optimality_certificate_numerators_end()

returns the corresponding past-the-end iterator.

Example

QP_solver/optimality_certificate.cpp

Lemma 2 (infeasibility certificate): The program (QP) is infeasible if an m -vector λ with the following properties exist.

1. if the i -th constraint is of type \leq (\geq , respectively), then $\lambda_i \geq 0$ ($\lambda_i \leq 0$, respectively).
- 2.

$$\lambda^T A_j \begin{array}{ll} \geq 0 & \text{if } u_j = \infty \\ \leq 0 & \text{if } l_j = -\infty. \end{array}$$

- 3.

$$\lambda^T \mathbf{b} < \sum_{j: \lambda^T A_j < 0} \lambda^T A_j u_j + \sum_{j: \lambda^T A_j > 0} \lambda^T A_j l_j.$$

Proof: Let us assume for the purpose of obtaining a contradiction that there is a feasible solution \mathbf{x} . Then we get

$$\begin{aligned} 0 &\geq \lambda^T (\mathbf{Ax} - \mathbf{b}) && \text{(by } \mathbf{Ax} \leq \mathbf{b} \text{ and 1.)} \\ &= \sum_{j: \lambda^T A_j < 0} \lambda^T A_j x_j + \sum_{j: \lambda^T A_j > 0} \lambda^T A_j x_j - \lambda^T \mathbf{b} \\ &\geq \sum_{j: \lambda^T A_j < 0} \lambda^T A_j u_j + \sum_{j: \lambda^T A_j > 0} \lambda^T A_j l_j - \lambda^T \mathbf{b} && \text{(by } \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \text{ and 2.)} \\ &> 0 && \text{(by 3.),} \end{aligned}$$

and this is the desired contradiction $0 > 0$.

Infeasibility_certificate_iterator

sol.infeasibility_certificate_begin()

returns a random access iterator over the infeasibility certificate λ as given in Lemma 2. The value type is *ET*, and the valid iterator range has length m .

Precondition: *sol.is_infeasible()*

Infeasibility_certificate_iterator

sol.infeasibility_certificate_end()

returns the corresponding past-the-end iterator.

Example

QP_solver/infeasibility_certificate.cpp

Lemma 3 (unboundedness certificate:) Let \mathbf{x}^* be a feasible solution of (QP). The program (QP) is unbounded if an n -vector \mathbf{w} with the following properties exist.

1. if the i -th constraint is of type $\leq (\geq, =, \text{ respectively})$, then $(A\mathbf{w})_i \leq 0 ((A\mathbf{w})_i \geq 0, (A\mathbf{w})_i = 0, \text{ respectively})$.
- 2.

$$w_j \begin{array}{ll} \geq 0 & \text{if } l_j \text{ is finite} \\ \leq 0 & \text{if } u_j \text{ is finite.} \end{array}$$

3. $\mathbf{w}^T D\mathbf{w} = 0$ and $(\mathbf{c}^T + 2\mathbf{x}^{*T} D)\mathbf{w} < 0$.

The vector \mathbf{w} is called an *unbounded direction*.

Proof: For a real number t , consider the vector $\mathbf{x}(t) := \mathbf{x}^* + t\mathbf{w}$. By 1. and 2., $\mathbf{x}(t)$ is feasible for all $t \geq 0$. The objective function value of $\mathbf{x}(t)$ is

$$\begin{aligned} \mathbf{c}^T \mathbf{x}(t) + \mathbf{x}(t)^T D\mathbf{x}(t) &= \mathbf{c}^T \mathbf{x}^* + t\mathbf{c}^T \mathbf{w} + \mathbf{x}^{*T} D\mathbf{x}^* + 2t\mathbf{x}^{*T} D\mathbf{w} + t^2 \mathbf{w}^T D\mathbf{w} \\ &= \mathbf{c}^T \mathbf{x}^* + \mathbf{x}^{*T} D\mathbf{x}^* + t(\mathbf{c}^T + 2\mathbf{x}^{*T} D)\mathbf{w} + t^2 \mathbf{w}^T D\mathbf{w}. \end{aligned}$$

By condition 3., this tends to $-\infty$ for $t \rightarrow \infty$, so the problem is indeed unbounded.

Unboundedness_certificate_iterator

sol.unboundedness_certificate_begin()

returns a random access iterator over the unbounded direction \mathbf{w} as given in Lemma 3, with respect to the solution \mathbf{x}^* obtained from *sol.variable_values_begin()*. The value type is *ET*, and the valid iterator range has length n .
Precondition: *sol.is_unbounded()*

Unboundedness_certificate_iterator

sol.unboundedness_certificate_end()

returns the corresponding past-the-end iterator.

Example

QP_solver/unboundedness_certificate.cpp

CGAL::Quadratic_program_status

#include <CGAL/QP_solution.h>

Definition

This is an enumeration type containing the values *QP_OPTIMAL*, *QP_INFEASIBLE*, and *QP_UNBOUNDED*. It indicates the status of a linear or quadratic program solution as represented by an object of type *Quadratic_program_solution*<ET>.

See Also

Quadratic_program_solution<ET>

CGAL::Quadratic_program<NT>

#include <CGAL/QP_models.h>

Definition

An object of class *Quadratic_program<NT>* describes a convex quadratic program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in n real variables $\mathbf{x} = (x_0, \dots, x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- \mathbf{b} is an m -dimensional vector (the right-hand side),
- $\begin{matrix} \geq \\ \leq \end{matrix}$ is an m -dimensional vector of relations from $\{\leq, =, \geq\}$,
- \mathbf{l} is an n -dimensional vector of lower bounds for \mathbf{x} , where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- \mathbf{u} is an n -dimensional vector of upper bounds for \mathbf{x} , where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- \mathbf{c} is an n -dimensional vector (the linear objective function), and
- c_0 is a constant.

If $D = 0$, the program is a linear program; if the variable bounds are $x \geq 0$, we have a nonnegative program.

This class allows you to build your program entry by entry, using the set-methods below.

If you only need to wrap existing (random-access) iterators over your own data, then you may use any of the four models *Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>*, *Linear_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, C_it>*, *Nonnegative_quadratic_program_from_iterators<A_it, B_it, R_it, D_it, C_it>*, and *Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>*.

If you want to read a quadratic program in *MPSFormat* from a stream, please use the model *Quadratic_program_from_mps<NT>*.

Is Model for the Concepts

QuadraticProgram

LinearProgram

NonnegativeQuadraticProgram

NonnegativeLinearProgram

Types

Quadratic_program<NT>::NT

The number type of the program entries.

Creation

Quadratic_program<NT> *qp*(*CGAL::Comparison_result* *default_r* = *CGAL::EQUAL*,
bool *default_fl* = *true*,
NT *default_l* = 0,
bool *default_fu* = *false*,
NT *default_u* = 0)

constructs a quadratic program with no variables and no constraints, ready for data to be added. Unless relations are explicitly set, they will be of type *default_r*. Unless bounds are explicitly set, they will be as specified by *default_fl* (finite lower bound?), *default_l* (lower bound value if lower bound is finite), *default_fu* (finite upper bound?), and *default_u* (upper bound value if upper bound is finite). If all parameters take their default values, we thus get equality constraints and bounds $x \geq 0$ by default. Numerical entries that are not explicitly set will default to 0.

Precondition: if *default_fl* = *default_fu* = *true*, then $\text{default_l} \leq \text{default_u}$

Operations

<i>bool</i>	<i>qp.is_linear()</i>	returns <i>true</i> if and only if <i>qp</i> is a linear program.
<i>bool</i>	<i>qp.is_nonnegative()</i>	returns <i>true</i> if and only if <i>qp</i> is a nonnegative program.
<i>void</i>	<i>qp.set_a</i> (<i>int</i> <i>j</i> , <i>int</i> <i>i</i> , <i>NT</i> <i>val</i>)	sets the entry A_{ij} in column <i>j</i> and row <i>i</i> of the constraint matrix <i>A</i> of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_b</i> (<i>int</i> <i>i</i> , <i>NT</i> <i>val</i>)	sets the entry b_i of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_r</i> (<i>int</i> <i>i</i> , <i>CGAL::Comparison_result</i> <i>rel</i>)	sets the entry \geq_i of <i>qp</i> to <i>rel</i> . <i>CGAL::SMALLER</i> means that the <i>i</i> -th constraint is of type “ \leq ”, <i>CGAL::EQUAL</i> means “ $=$ ”, and <i>CGAL::LARGER</i> encodes “ \geq ”. An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_l</i> (<i>int</i> <i>j</i> , <i>bool</i> <i>is_finite</i> , <i>NT</i> <i>val</i> = <i>NT</i> (0))	if <i>is_finite</i> , this sets the entry l_j of <i>qp</i> to <i>val</i> , otherwise it sets l_j to $-\infty$. An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.

<i>void</i>	<i>qp.set_u(int j, bool is_finite, NT val = NT(0))</i>	if <i>is_finite</i> , this sets the entry u_j of <i>qp</i> to <i>val</i> , otherwise it sets u_j to ∞ . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c(int j, NT val)</i>	sets the entry c_j of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c0(NT val)</i>	sets the entry c_0 of <i>qp</i> to <i>val</i> . An existing entry is overwritten.
<i>void</i>	<i>qp.set_d(int i, int j, NT val)</i>	sets the entries $2D_{ij}$ and $2D_{ji}$ of <i>qp</i> to <i>val</i> . Existing entries are overwritten. <i>qp</i> is enlarged if necessary to accomodate these entries. <i>Precondition:</i> $j \leq i$

Quadratic_program_from_mps<NT>

CGAL::Quadratic_program_from_mps<NT>

#include <CGAL/QP_models.h>

Definition

An object of class *Quadratic_program_from_mps<NT>* describes a convex quadratic program of the general form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in n real variables $\mathbf{x} = (x_0, \dots, x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- \mathbf{b} is an m -dimensional vector (the right-hand side),
- $\begin{matrix} \geq \\ \leq \end{matrix}$ is an m -dimensional vector of relations from $\{\leq, =, \geq\}$,
- \mathbf{l} is an n -dimensional vector of lower bounds for \mathbf{x} , where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- \mathbf{u} is an n -dimensional vector of upper bounds for \mathbf{x} , where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- \mathbf{c} is an n -dimensional vector (the linear objective function), and
- c_0 is a constant.

If $D = 0$, the program is a linear program; if the variable bounds are $x \geq 0$, we have a nonnegative program.

The program data are read from an input stream in *MPSFormat*. This is a commonly used format for encoding linear and quadratic programs that is understood by many solvers. All values are expected to be readable into type *NT*. The constructed program can be further manipulated by using the set-methods below.

Is Model for the Concepts

QuadraticProgram

LinearProgram

NonnegativeQuadraticProgram

NonnegativeLinearProgram

Types

Quadratic_program_from_mps<NT>::NT

The number type of the program entries.

Creation

Quadratic_program_from_mps<NT> *qp*(*std::istream& in*);

reads *qp* from the input stream *in*.

Operations

bool *qp.is_valid()* returns *true* if and only if an MPS-encoded quadratic program could be extracted from the input stream.

std::string *qp.get_error()* if *!qp.is_valid()*, this method returns an error message explaining why the input does not conform to the *MPSFormat*.

std::string *qp.variable_name_by_index*(*int j*)

returns the name of the *j*-th variable.
Precondition: *j* must not refer to a variable that has been added later, using one of the set methods below.

int *qp.variable_index_by_name*(*std::string name*)

returns the index of the variable with name *name*. If there is no variable with this name, the result is -1 .

std::string *qp.constraint_name_by_index*(*int i*)

returns the name of the *i*-th constraint.
Precondition: *i* must not refer to a constraint that has been added later, using one of the set methods below.

int *qp.constraint_index_by_name*(*std::string name*)

returns the index of the constraint with name *name*. If there is no constraint with this name, the result is -1 .

bool *qp.is_linear()* returns *true* if and only if *qp* is a linear program.

bool *qp.is_nonnegative()* returns *true* if and only if *qp* is a nonnegative program.

void *qp.set_a*(*int j*, *int i*, *NT val*)

sets the entry A_{ij} in column *j* and row *i* of the constraint matrix *A* of *qp* to *val*. An existing entry is overwritten. *qp* is enlarged if necessary to accomodate this entry.

<i>void</i>	<i>qp.set_b(int i, NT val)</i>	sets the entry b_i of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_r(int i, CGAL::Comparison_result rel)</i>	sets the entry \geq_i of <i>qp</i> to <i>rel</i> . <i>CGAL::SMALLER</i> means that the <i>i</i> -th constraint is of type “ \leq ”, <i>CGAL::EQUAL</i> means “ $=$ ”, and <i>CGAL::LARGER</i> encodes “ \geq ”. An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_l(int j, bool is_finite, NT val = NT(0))</i>	if <i>is_finite</i> , this sets the entry l_j of <i>qp</i> to <i>val</i> , otherwise it sets l_j to $-\infty$. An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_u(int j, bool is_finite, NT val = NT(0))</i>	if <i>is_finite</i> , this sets the entry u_j of <i>qp</i> to <i>val</i> , otherwise it sets u_j to ∞ . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c(int j, NT val)</i>	sets the entry c_j of <i>qp</i> to <i>val</i> . An existing entry is overwritten. <i>qp</i> is enlarged if necessary to accomodate this entry.
<i>void</i>	<i>qp.set_c0(NT val)</i>	sets the entry c_0 of <i>qp</i> to <i>val</i> . An existing entry is overwritten.
<i>void</i>	<i>qp.set_d(int i, int j, NT val)</i>	sets the entries $2D_{ij}$ and $2D_{ji}$ of <i>qp</i> to <i>val</i> . Existing entries are overwritten. <i>qp</i> is enlarged if necessary to accomodate these entries. <i>Precondition:</i> $j \leq i$

```
#include <CGAL/QP_models.h>
```

Definition

An object of class *Quadratic_program_from_iterators*<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it> describes a convex quadratic program of the form

$$\begin{aligned} \text{(QP)} \quad & \text{minimize} \quad \mathbf{x}^T D \mathbf{x} + \mathbf{c}^T \mathbf{x} + c_0 \\ & \text{subject to} \quad A \mathbf{x} \begin{matrix} \geq \\ \leq \end{matrix} \mathbf{b}, \\ & \quad \quad \quad \mathbf{l} \leq \mathbf{x} \leq \mathbf{u} \end{aligned}$$

in n real variables $\mathbf{x} = (x_0, \dots, x_{n-1})$. Here,

- A is an $m \times n$ matrix (the constraint matrix),
- \mathbf{b} is an m -dimensional vector (the right-hand side),
- $\begin{matrix} \geq \\ \leq \end{matrix}$ is an m -dimensional vector of relations from $\{\leq, =, \geq\}$,
- \mathbf{l} is an n -dimensional vector of lower bounds for \mathbf{x} , where $l_j \in \mathbb{R} \cup \{-\infty\}$ for all j
- \mathbf{u} is an n -dimensional vector of upper bounds for \mathbf{x} , where $u_j \in \mathbb{R} \cup \{\infty\}$ for all j
- D is a symmetric positive-semidefinite $n \times n$ matrix (the quadratic objective function),
- \mathbf{c} is an n -dimensional vector (the linear objective function), and
- c_0 is a constant.

This class is simply a wrapper for existing iterators, and it does not copy the program data.

It frequently happens that all values in one of the vectors from above are the same, for example if the system $Ax \begin{matrix} \geq \\ \leq \end{matrix} b$ is actually a system of equations $Ax = b$. To get an iterator over such a vector, it is not necessary to store multiple copies of the value in some container; an instance of the class *Const_oneseq_iterator*<T>, constructed from the value in question, does the job more efficiently.

CGAL::make_quadratic_program_from_iterators

```
#include <CGAL/QP_models.h>
```

This template function creates an instance of *Quadratic_program_from_iterators*<*A_it*, *B_it*, *R_it*, *FL_it*, *L_it*, *FU_it*, *U_it*, *D_it*, *C_it*> from given iterators. This function can be useful if the types of these iterators are too complicated (or of too little interest for you) to write them down explicitly.

```
template < A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it >
Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>

    make_quadratic_program_from_iterators( int n,
                                           int m,
                                           A_it a,
                                           B_it b,
                                           R_it r,
                                           FL_it fl,
                                           L_it l,
                                           FU_it fu,
                                           U_it u,
                                           D_it d,
                                           C_it c,
                                           std::iterator_traits<C_it>::value_type c0 =
```

returns an instance of *Quadratic_program_from_iterators*<*A_it*, *B_it*, *R_it*, *FL_it*, *L_it*, *FU_it*, *U_it*, *D_it*, *C_it*>, constructed from the given iterators.

Example

The following example demonstrates the typical usage of makers with the simpler function *make_nonnegative_linear_program_from_iterators*.

```
QP_solver/solve_convex_hull_containment_lp2.h
QP_solver/convex_hull_containment2.cpp
```

See Also

```
Quadratic_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, D_it, C_it>
```

CGAL::make_linear_program_from_iterators

```
#include <CGAL/QP_models.h>
```

This template function creates an instance of *Linear_program_from_iterators*<*A_it*, *B_it*, *R_it*, *FL_it*, *L_it*, *FU_it*, *U_it*, *C_it*> from given iterators. This function can be useful if the types of these iterators are too complicated (or of too little interest for you) to write them down explicitly.

```
template < A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, C_it >
Linear_program_from_iterators<A_it, B_it, R_it, FL_it, L_it, FU_it, U_it, C_it>

    make_linear_program_from_iterators( int n,
                                        int m,
                                        A_it a,
                                        B_it b,
                                        R_it r,
                                        FL_it fl,
                                        L_it l,
                                        FU_it fu,
                                        U_it u,
                                        C_it c,
                                        std::iterator_traits<C_it>::value_type c0 =

std::iterator_traits<C_it>::value_type(0))
```

returns an instance of *Linear_program_from_iterators*<*A_it*, *B_it*, *R_it*, *FL_it*, *L_it*, *FU_it*, *U_it*, *C_it*>, constructed from the given iterators.

Example

The following example demonstrates the typical usage of makers with the simpler function *make_nonnegative_linear_program_from_iterators*.

```
QP_solver/solve_convex_hull_containment_lp2.h
QP_solver/convex_hull_containment2.cpp
```

```

CGAL::make_nonnegative_quadratic_program_from_iterators

```
#include <CGAL/QP_models.h>
```

This template function creates an instance of *Nonnegative_quadratic_program_from_iterators*<*A_it*, *B_it*, *R_it*, *D_it*, *C_it*> from given iterators. This function can be useful if the types of these iterators are too complicated (or of too little interest for you) to write them down explicitly.

```
template < A_it, B_it, R_it, D_it, C_it >
```

```
Nonnegative_quadratic_program_from_iterators <A_it, B_it, R_it, D_it, C_it>
```

```
    make_nonnegative_quadratic_program_from_iterators( int n,
                                                         int m,
                                                         A_it a,
                                                         B_it b,
                                                         R_it r,
                                                         D_it d,
                                                         C_it c,
                                                         std::iterator_traits<C_it>
```

```
::value_type c0 = std::iterator_traits<C_it>::value_type(0))
```

returns an instance of *Nonnegative_quadratic_program_from_iterators*<*A_it*, *B_it*, *R_it*, *D_it*, *C_it*>, constructed from the given iterators.

Example

The following example demonstrates the typical usage of makers with the simpler function *make_nonnegative_linear_program_from_iterators*.

```
QP_solver/solve_convex_hull_containment_lp2.h
QP_solver/convex_hull_containment2.cpp
```

```

CGAL::make_nonnegative_linear_program_from_iterators

```
#include <CGAL/QP_models.h>
```

This template function creates an instance of *Nonnegative_linear_program_from_iterators*<*A_it*, *B_it*, *R_it*, *C_it*> from given iterators. This function can be useful if the types of these iterators are too complicated (or of too little interest for you) to write them down explicitly.

```
template < A_it, B_it, R_it, C_it >
```

```
Nonnegative_linear_program_from_iterators <A_it, B_it, R_it, C_it>
```

```
    make_nonnegative_linear_program_from_iterators( int n,
                                                    int m,
                                                    A_it a,
                                                    B_it b,
                                                    R_it r,
                                                    C_it c,
                                                    std::iterator_traits<C_it>::value_
```

```
type c0 = std::iterator_traits<C_it>::value_type(0))
```

returns an instance of *Nonnegative_linear_program_from_iterators*<*A_it*, *B_it*, *R_it*, *C_it*>, constructed from the given iterators.

Example

```
QP_solver/solve_convex_hull_containment_lp2.h
```

```
QP_solver/convex_hull_containment2.cpp
```

See Also

```
Nonnegative_linear_program_from_iterators<A_it, B_it, R_it, C_it>
```

CGAL::solve_quadratic_program

```
#include <CGAL/QP_functions.h>
```

This function solves a quadratic program, using some exact Integral Domain *ET* for its computations. Various options may be provided, see *Quadratic_program_options*.

```
template <QuadraticProgram, ET>
Quadratic_program_solution<ET>
```

```
    solve_quadratic_program( QuadraticProgram qp,
                             ET,
                             Quadratic_program_options options = Quadratic_
program_options())
```

returns the solution of the quadratic program *qp*, solved with exact number type *ET*.

Requirements

ET is a model of the concepts *IntegralDomain* and *RealEmbeddable*; it must be an exact type, and all entries of *qp* are convertible to *ET*.

Here are some recommended combinations of input type (the type of the *qp* entries) and *ET*.

input type	—	<i>ET</i>
<i>double</i>	—	<i>MP_Float</i> , <i>Gmpzf</i> , or <i>Gmpq</i>
<i>int</i>	—	<i>MP_Float</i> , or <i>Gmpz</i>
any exact type <i>NT</i>	—	<i>NT</i>

Note: by default, this function performs a large number of runtime-checks to ensure consistency during the solution process. However, these checks slow down the computations by a considerable factor. For maximum efficiency, it is advisable to define the macros `CGAL_QP_NO_ASSERTIONS` or `NDEBUG`.

Example

QP_solver/first_qp.cpp

CGAL::Quadratic_program_options

```
#include <CGAL/QP_options.h>
```

Definition

This is a class used for passing options to the linear and quadratic programming solvers. Currently, we support only options referring to

1. the verbosity,
2. the pricing strategy (see *Quadratic_program_pricing_strategy*),
3. the validation mode (see the Validity section of *Quadratic_program_solution*)

The idea is that this list grows in the future.

Creation

Quadratic_program_options options; constructs an instance of *Quadratic_program_options* where all available options are at their defaults.

Operations

Here we just have set/get pairs for any option type.

Verbosity

void options.set_verbosity(int verbosity)

sets the verbosity of the solver to the value *verbosity* when *options* is passed to any of the four solution functions. The provided value must be a number between 0 and 5. Verbosity 0 is the default and results in the solver running silently. Verbosity 1 prints a short summary of every iteration. Higher verbosity values print more information about the solution process, but these are mainly for debugging purposes and have no effect if you compile with `CGAL_QP_NO_ASSERTIONS` or `NDEBUG`.

int options.get_verbosity()

returns the verbosity level of *options*.

Pricing strategy

void *options.set_pricing_strategy(Quadratic_program_pricing_strategy pricing_strategy)*

sets the pricing strategy of the solver to the value *pricing_strategy* when *options* is passed to any of the four solution functions. The pricing strategy controls how the solver proceeds from any intermediate solution. The provided value must be *QP_FULL_EXACT* (the default), or *QP_EXACT_BLAND*. The latter value guarantees that the solver does not internally cycle.

Quadratic_program_pricing_strategy

options.get_pricing_strategy()

returns the pricing strategy of *options*.

Validation mode

void *options.set_auto_validation(bool validate)*

sets the automatic validation mode of the solver to the value *validate*. The default is *false*. By providing value *true* you can tell the solver to automatically check whether the program has correctly been solved, see the Validity section of the class *Quadratic_program_solution*.

bool *options.get_auto_validation()*

returns the validation mode of *options*.

Example

QP_solver/cycling.cpp

solve_nonnegative_linear_program

CGAL::Quadratic_program_pricing_strategy

```
#include <CGAL/QP_options.h>
```

Definition

This is an enumeration type containing the values *QP_CHOOSE_DEFAULT*, *QP_DANTZIG*, *QP_PARTIAL_DANTZIG*, *QP_FILTERED_DANTZIG*, *QP_PARTIAL_FILTERED_DANTZIG*, and *QP_BLAND*.

It indicates the pricing strategy to be used in solving a linear or quadratic program. This strategy determines how the solver gets from one intermediate solution to the next during any of its iterations.

Here we briefly describe when to choose which strategy.

QP_CHOOSE_DEFAULT

This is the default value of the pricing strategy in *Quadratic_program_options*, and it lets the solver choose the strategy that it thinks is most appropriate for the problem at hand. There are only few reasons to deviate from this default, but you are free to experiment, of course.

QP_PARTIAL_DANTZIG

If the input type is **not** *double*, this is usually the best choice for linear and quadratic programs of medium size.

QP_DANTZIG

If the input type is **not** *double*, this can sometimes make a difference (be faster or slower) than *QP_PARTIAL_DANTZIG* for problems with a high variable/constraint or constraint/variable ratio.

QP_PARTIAL_FILTERED_DANTZIG

If the input type **is** *double*, this is usually the best choice for linear and quadratic programs of medium size. If the input type is not *double*, this choice is equivalent to *QP_PARTIAL_DANTZIG*.

Note: filtered strategies may in rare cases fail due to double exponent overflows, see Section [61.8.1](#). In this case, the slower fallback option is the non-filtered variant *QP_PARTIAL_DANTZIG* of this strategy.

QP_FILTERED_DANTZIG

If the input type **is** *double*, this can sometimes make a difference (be faster or slower) than *QP_PARTIAL_FILTERED_DANTZIG* for problems with a high variable/constraint or constraint/variable ratio. If the input type is not *double*, this choice is equivalent to *QP_DANTZIG*.

Note: filtered strategies may in rare cases fail due to double exponent overflows, see Section [61.8.1](#). In this case, the slower fallback option is the non-filtered variant *QP_DANTZIG* of this strategy.

QP_BLAND

This is hardly ever the most efficient choice, but it is guaranteed to avoid internal cycling of the solution algorithm, see Section [61.8.2](#).

Quadratic_program_options

CGAL::print_quadratic_program

```
#include <CGAL/QP_functions.h>
```

This function writes a quadratic program to an output stream (in *MPSFormat*). The time complexity is $\Theta(n^2 + mn)$, even if the program is very sparse.

```
template <QuadraticProgram>
void      print_quadratic_program( std::ostream& out,
                                   QuadraticProgram qp,
                                   std::string problem_name = std::string("MY_MPS"))
```

writes the quadratic program *qp* to *out* in *MPSFormat*. The name of the program will be the one provided by *problem_name*.

Requirements

Output operators are defined for all entry types of *qp*.

Example

QP_solver/print_first_qp.cpp

62.1 Timers

CGAL provides classes for measuring the user process time and the real time. The class *CGAL::Timer* is the version for the user process time and the class *CGAL::Real_timer* is the version for the real time.

Instantiations of both classes are objects with a state. The state is either *running* or it is *stopped*. The state of an object *t* is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occurs while the timer is running it counts as the first interval.

62.2 Memory Size

CGAL provides access to the memory size used by the program with the *CGAL::Memory_sizer* class. Both the virtual memory size and the resident size are available (the resident size does not account for swapped out memory nor for the memory which is not yet paged-in).

62.3 Profiling

CGAL provides a way to count the number of times a given line of code is executed during the execution of

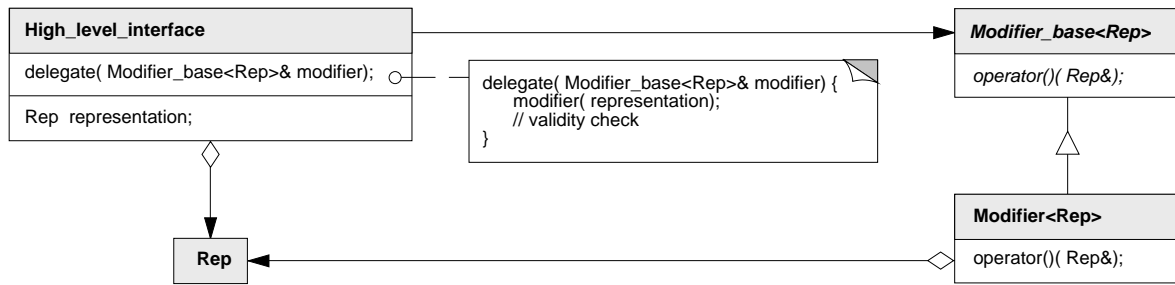

Figure 62.1: Class diagram for the modifier. It illustrates the safe access to an internal representation through an high-level interface.

a program. Such *CGAL::Profile_counter* counters can be added at critical place in the code, and at the end of the execution of a program, the count is printed on *std::cerr*. A macro *CGAL_PROFILER* can be used to conveniently place these counters anywhere. They are disabled by default and activated by the global macro *CGAL_PROFILE*.

62.4 Unique Hash Map

The class *Unique_hash_map* implements an injective mapping between a set of unique keys and a set of data values. This is implemented using a chained hashing scheme and access operations take $O(1)$ expected time. Such a mapping is useful, for example, when keys are pointers, handles, iterators or circulators that refer to unique memory locations. In this case, the default hash function is *Handle_hash_function*.

62.5 Union-find

CGAL also provides a class *Union_find* that implements a partition of values into disjoint sets. This is implemented with union by rank and path compression. The running time for m set operations on n elements is $O(n\alpha(m,n))$ where $\alpha(m,n)$ is the extremely slowly growing inverse of Ackermann's function.

62.6 Protected Access to Internal Representations

High level data structures typically maintain integrity of an internal data representation, which they protect from the user. A minimal while complete interface of the data structure allows manipulations in the domain of valid representations. Additional operations might benefit from being allowed to access the internal data representation directly. An example are intermediate steps within an algorithm where the internal representation would be invalid. We present a general method to accomplish access in a safe manner, such that the high level data structures can guarantee validity after the possibly compromising algorithm has finished its work. An example are polyhedral surfaces in the Basic Library, where a construction process like for a file scanner could be performed more efficiently on the internal halfedge data structure than by using the high-level Euler operators of the polyhedron.

The solution provided here is inspired by the strategy pattern [GHJV95], though it serves a different intent, see Figure 62.1. The abstract base class *Modifier_base<R>* declares a pure virtual member function *operator()* that accepts a single reference parameter of the internal representation type. The member function *delegate()* of the

high-level interface calls this *operator()* with its internal representation. An actual modifier implements this virtual function, thus gaining access to the internal representation. Once, the modifier has finished its work, the member function *delegate()* is back in control and can check the validity of the internal representation. Summarizing, a user can implement and apply arbitrary functions based on the internal representation and keeps the benefit of a protected high-level interface. User provided modifiers must in any case return a valid internal representation or the checker in the high-level interface is allowed (and supposed) to abort the program. The indirection via the virtual function invocation is negligible for operations that consists of more than a pointer update or integer addition.

Timers, Hash Map, Union-find, Modifiers Reference Manual

Lutz Kettner, Sylvain Pion, and Michael Seel

This chapter describes classes for measuring user process time and real time as well as the memory size.

A hash map `CGAL::Unique_hash_map` is offered that is specialized on unique hash values of type `std::size_t`, i.e., it is particularly useful for pointers, handles, iterators, and circulators as key values.

Furthermore, a union-find data structure and the modifier base class is documented.

CGAL::Handle_hash_function

Definition

The class *Handle_hash_function* is a model for the *UniqueHasFunction* concept. It is applicable for all key types with pointer-like functionality, such as handles, iterators, and circulators. Specifically, for a *key* value the expression `&*key` must return a unique address.

```
#include <CGAL/Handle_hash_function.h>
```

Is Model for the Concepts

UniqueHashFunction.....page 3336

Creation

Handle_hash_function *hash*; default constructor.

Operations

<i>template <class Handle></i>		
<i>std::size_t</i>	<i>hash(Handle key)</i>	returns unique hash value for any <i>Handle</i> type for which &*key gives a unique address.
		<i>Requirement:</i> The type <i>std::iterator_traits<Handle>::value_</i> <i>type</i> has to be defined (which it is already for pointers, han- dles, iterators, and circulators).

See Also

CGAL::Unique_hash_map<Key,Data,UniqueHashFunction>page 3334

Implementation

Plain type cast of `&*key` to `std::size_t` and divided by the size of the `std::iterator_traits<Handle>::value_type` to avoid correlations with the internal table size, which is a power of two.

CGAL::Memory_sizer

Definition

The class *Memory_sizer* allows to measure the memory size used by the process. Both the virtual memory size and the resident size are available (the resident size does not account for swapped out memory nor for the memory which is not yet paged-in).

```
#include <CGAL/Memory_sizer.h>
```

Types

The memory sizes are given in bytes.

```
typedef std::size_t    size_type;
```

Creation

```
Memory_sizer m;           Default constructor.
```

Operations

```
size_type
```

```
    m.virtual_size()
```

Returns the virtual memory size.

```
size_type
```

```
    m.resident_size()
```

Returns the resident memory size.

Implementation

Accessing this information requires the use of non-portable code. Currently, there is support for Linux platforms and the Microsoft and Intel compiler on Windows. If a platform is not supported, the two member functions return 0.

CGAL::Modifier_base<R>

Definition

Modifier_base<R> is an abstract base class providing the interface for any modifier. A modifier is a function object derived from *Modifier_base<R>* that implements the pure virtual member function *operator()*, which accepts a single reference parameter *R*& on which the modifier is allowed to work. *R* is the type of the internal representation that is to be modified.

```
#include <CGAL/Modifier_base.h>
```

Types

```
typedef R      Representation;           the internal representation type.
```

Operations

```
virtual void    modifier.operator()( R& rep)    Postcondition: rep is a valid representation.
```

Example

The following fragment defines a class *A* with an internal representation *i* of type *int*. It provides a member function *delegate()*, which gives a modifier access to the internal variable and checks validity thereafter. The example modifier sets the internal variable to 42. The example function applies the modifier to an instance of class *A*.

```
class A {
    int i; // protected internal representation
public:
    void delegate( CGAL::Modifier_base<int>& modifier) {
        modifier(i);
        CGAL_postcondition( i > 0); // check validity
    }
};

struct Modifier : public CGAL::Modifier_base<int> {
    void operator()( int& rep) { rep = 42;}
};

void use_it() {
    A a;
    Modifier m;
    a.delegate(m); // a.i == 42 and A has checked that A::i > 0.
}
```

CGAL::Real_timer

Definition

```
#include <CGAL/Real_timer.h>
```

The class *Real_timer* is a timer class for measuring real time. A timer *t* of type *Real_timer* is an object with a state. It is either *running* or it is *stopped*. The state is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occurs while the timer is running it counts as the first interval.

Creation

Real_timer t; state is *stopped*.

Operations

<i>void</i>	<i>t.start()</i>	<i>Precondition:</i> state is <i>stopped</i> .
<i>void</i>	<i>t.stop()</i>	<i>Precondition:</i> state is <i>running</i> .
<i>void</i>	<i>t.reset()</i>	reset timer to zero. The state is unaffected.
<i>bool</i>	<i>t.is_running()</i>	<i>true</i> if the current state is running.
<i>double</i>	<i>t.time()</i>	real time in seconds, or 0 if the underlying system call failed.
<i>int</i>	<i>t.intervals()</i>	number of start/stop-intervals since the last reset.
<i>double</i>	<i>t.precision()</i>	smallest possible time step in seconds, or -1 if the system call failed.
<i>double</i>	<i>t.max()</i>	maximal representable time in seconds.

Implementation

The timer class is based in the C function *gettimeofday()* on POSIX systems, the C function *_ftime()* on MS Visual C++, the C function *ftime()* on Borland C++, and *time()* on Metrowerks Codewarrior. The system calls to these timers might fail, in which case a warning message will be issued through the CGAL error handler and the functions return with the error codes indicated above. The *precision* method computes the precision dynamically at runtime at its first invocation.

CGAL::Timer

Definition

```
#include <CGAL/Timer.h>
```

The class *Timer* is a timer class for measuring user process time. A timer *t* of type *Timer* is an object with a state. It is either *running* or it is *stopped*. The state is controlled with *t.start()* and *t.stop()*. The timer counts the time elapsed since its creation or last reset. It counts only the time where it is in the running state. The time information is given in seconds. The timer counts also the number of intervals it was running, i.e. it counts the number of calls of the *start()* member function since the last reset. If the reset occurs while the timer is running it counts as the first interval.

Creation

Timer t; state is *stopped*.

Operations

<i>void</i>	<i>t.start()</i>	<i>Precondition:</i> state is <i>stopped</i> .
<i>void</i>	<i>t.stop()</i>	<i>Precondition:</i> state is <i>running</i> .
<i>void</i>	<i>t.reset()</i>	reset timer to zero. The state is unaffected.
<i>bool</i>	<i>t.is_running()</i>	<i>true</i> if the current state is running.
<i>double</i>	<i>t.time()</i>	user process time in seconds, or 0 if the underlying system call failed.
<i>int</i>	<i>t.intervals()</i>	number of start/stop-intervals since the last reset.
<i>double</i>	<i>t.precision()</i>	smallest possible time step in seconds, or -1 if the system call failed.
<i>double</i>	<i>t.max()</i>	maximal representable time in seconds.

Implementation

The timer class is based in the C function *std::clock()* on PC systems and the C function *getrusage()* on standard POSIX systems. The counter for the *std::clock()* based solution might wrap around (overflow) after only about 36 minutes. This won't happen on POSIX systems. The system calls to these timers might fail, in which case a warning message will be issued through the CGAL error handler and the functions return with the error codes indicated above. The *precision* method computes the precision dynamically at runtime at its first invocation.

CGAL::Union_find<T,A>

Definition

An instance P of the data type $Union_find<T,A>$ is a partition of values of type T into disjoint sets. The template parameter A has to be a model of the allocator concept as defined in the C++ standard. It has a default argument $CGAL_ALLOCATOR(T)$.

Types

$Union_find<T,A>::value_type$ values stored in items (equal to T).

$Union_find<T,A>::handle$ handle to values.

$Union_find<T,A>::iterator$ iterator over values.

There are also constant versions $const_handle$ and $const_iterator$.

$Union_find<T,A>::allocator$ allocator.

Creation

$Union_find<T,A> P;$ creates an instance P of type $Union_find<T,A>$ and initializes it to the empty partition.

Operations

$allocator$ $P.get_allocator()$ the allocator of P .

$std::size_t$ $P.number_of_sets()$ returns the number of disjoint sets of P .

$std::size_t$ $P.size()$ returns the number of values of P .

$std::size_t$ $P.bytes()$ returns the memory consumed by P .

$std::size_t$ $P.size(const_handle p)$ returns the size of the set containing p .

$void$ $P.clear()$ reinitializes P to an empty partition.

$handle$ $P.make_set(T x)$ creates a new singleton set containing x and returns a handle to it.

$handle$ $P.push_back(T x)$ same as $make_set(x)$.

<i>template</i>	<i><class Forward_iterator></i>	
<i>void</i>	<i>P.insert(Forward_iterator first, Forward_iterator beyond)</i>	insert the range of values referenced by <i>[first,beyond)</i> . <i>Requirement:</i> value type of <i>Forward_iterator</i> is <i>T</i> .
<i>handle</i>	<i>P.find(handle p)</i>	returns a canonical handle of the set that contains <i>p</i> , i.e., <i>P.same_set(p,q)</i> iff <i>P.find(p)</i> and <i>P.find(q)</i> return the same handle. <i>Precondition:</i> <i>p</i> is a handle in <i>P</i> .
<i>const_handle</i>	<i>P.find(const_handle p)</i>	
<i>void</i>	<i>P.unify_sets(handle p, handle q)</i>	unites the sets of partition <i>P</i> containing <i>p</i> and <i>q</i> . <i>Precondition:</i> <i>p</i> and <i>q</i> are in <i>P</i> .
<i>bool</i>	<i>P.same_set(const_handle p, const_handle q)</i>	returns true iff <i>p</i> and <i>q</i> belong to the same set of <i>P</i> . <i>Precondition:</i> <i>p</i> and <i>q</i> are in <i>P</i> .
<i>iterator</i>	<i>P.begin()</i>	returns an iterator pointing to the first value of <i>P</i> .
<i>iterator</i>	<i>P.end()</i>	returns an iterator pointing beyond the last value of <i>P</i> .

Implementation

Union_find $\langle T, A \rangle$ is implemented with union by rank and path compression. The running time for m set operations on n elements is $O(n\alpha(m, n))$ where $\alpha(m, n)$ is the extremely slow growing inverse of Ackermann's function.

CGAL::Unique_hash_map<Key,Data,UniqueHashFunction>

Definition

An instance *map* of the parameterized data type *Unique_hash_map<Key,Data,UniqueHashFunction>* is an injective mapping from the set of keys of type *Key* to the set of variables of type *Data*. New keys can be inserted at any time, however keys cannot be individually deleted.

An object *hash* of the type *UniqueHashFunction* returns a unique integer index *hash(key)* of type *std::size_t* for all objects *key* stored in *map*. The template parameter has as default the *Handle_hash_function* that hashes all types of pointers, handles, iterators, and circulators.

All variables are initialized to *default_data*, a value of type *Data* specified in the definition of *map*.

```
#include <CGAL/Unique_hash_map.h>
```

Types

<i>Unique_hash_map<Key,Data,UniqueHashFunction>::Key</i>	the <i>Key</i> type.
<i>Unique_hash_map<Key,Data,UniqueHashFunction>::Data</i>	the <i>Data</i> type.
<i>Unique_hash_map<Key,Data,UniqueHashFunction>::Hash_function</i>	the unique hash function type.

In compliance with STL, the types *key_type*, *data_type*, and *hasher* are defined as well.

Creation

```
Unique_hash_map<Key,Data,UniqueHashFunction> map( Data default = Data(),
                                                    std::size_t table_size = 1,
                                                    Hash_function fct = Hash_function())
```

creates an injective function *map* from *Key* to the set of unused variables of type *Data*, sets *default_data* to *default*, passes the *table_size* as argument to the internal implementation, and initializes the hash function with *fct*.

```
Unique_hash_map<Key,Data,UniqueHashFunction> map( Key first1,
                                                    Key beyond1,
                                                    Data first2,
                                                    Data default = Data(),
                                                    std::size_t table_size = 1,
                                                    Hash_function fct = Hash_function())
```

creates an injective function *map* from *Key* to the set of unused variables of type *Data*, sets *default_data* to *default*, passes the *table_size* as argument to the internal implementation, initializes the hash function with *fct*, and inserts all keys from the range *[first1,beyond1)*. The data variable for each inserted *key* is initialized with the corresponding value from the range *[first2,first2 + (beyond1-first1))*.

Precondition: The increment operator must be defined for values of type *Key* and for values of type *Data*. *beyond1* must be reachable from *first1* using increments.

Operations

<i>Data</i>	<i>map.default_value()</i>	the current <i>default_value</i> .
<i>Hash_function</i>	<i>map.hash_function()</i>	the current hash function.
<i>bool</i>	<i>map.is_defined(Key key)</i>	returns true if <i>key</i> is defined in <i>map</i> . Note that there can be keys defined that have not been inserted explicitly. Their variables are initialized to <i>default_value</i> .
<i>void</i>	<i>map.clear()</i>	resets <i>map</i> to the injective function <i>map</i> from <i>Key</i> to the set of unused variables of type <i>Data</i> . The <i>default_data</i> remains unchanged.
<i>void</i>	<i>map.clear(Data default)</i>	resets <i>map</i> to the injective function <i>map</i> from <i>Key</i> to the set of unused variables of type <i>Data</i> and sets <i>default_data</i> to <i>default</i> .
<i>Data&</i>	<i>map.operator[](const Key& key)</i>	returns a reference to the variable <i>map(key)</i> . If <i>key</i> has not been inserted into <i>map</i> before, <i>key</i> is inserted and initialized with <i>default_value</i> .
<i>const Data&</i>	<i>map.operator[](const Key& key) const</i>	returns a const reference to the variable <i>map(key)</i> . If <i>key</i> has not been inserted into <i>map</i> before, a const reference to the <i>default_value</i> is returned. However, <i>key</i> is not inserted into <i>map</i> .
<i>Data</i>	<i>map.insert(Key first1, Key beyond1, Data first2)</i>	<p>inserts all keys from the range $[first1, beyond1)$. The data variable for each inserted <i>key</i> is initialized with the corresponding value from the range $[first2, first2 + (beyond1 - first1))$. Returns $first2 + (beyond1 - first1)$.</p> <p><i>Precondition:</i> The increment operator must be defined for values of type <i>Key</i> and for values of type <i>Data</i>. <i>beyond1</i> must be reachable from <i>first1</i> using increments.</p>

See Also

UniqueHashFunction.....page [3336](#)
CGAL::Handle_hash_function.....page [3327](#)

Implementation

Unique_hash_map is implemented via a chained hashing scheme. Access operations *map[i]* take expected time $O(1)$. The *table_size* parameter passed to chained hashing can be used to avoid unnecessary rehashing when set to the number of expected elements in the map. The design is derived from the STL *hash_map* and the LEDA type *map*. Its specialization on insertion only and unique hash values allow for a more time- and space-efficient implementation, see also [MN00, Chapter 5]. This implementation makes also use of sentinels that lead to defined keys that have not been inserted.

UniqueHashFunction

Definition

UniqueHashFunction is a concept for a hash function with unique hash values. An instance *hash* for a model of the UniqueHashFunction concept is a function object. It maps objects of its domain type *Key* to the integral image type *std::size_t*. The image values have to be unique for all keys in the domain type *Key*.

Refines

STL concept HashFunction.

Types

typedef std::size_t *result_type*; type of the hash value.

Creation

UniqueHashFunction *hash*(*hash2*); copy constructor.

UniqueHashFunction& *hash* = *hash2* assignment.

Operations

std::size_t *hash*(*Key* *key*) returns unique hash value for the *key* value.

Chapter 63

IO Streams

Andreas Fabri, Geert-Jan Giezeman, and Lutz Kettner

Contents

63.1 Output Operator	3338
63.2 Input Operator	3338
63.3 IO for non-CGAL types	3339
63.3.1 Using Output Formatting	3339
63.3.2 Customizing Output Formatting	3340
63.4 Colors	3341
63.5 Stream Support	3341

All classes in the CGAL kernel provide input and output operators for IO streams. Classes external to CGAL are also supported, by means of *offormat* (Section 63.3). The basic task of such an operator is to produce a representation of an object that can be written as a sequence of characters on devices as a console, a file, or a pipe. In CGAL we distinguish between a raw ascii, a raw binary and a pretty printing format.

```
enum Mode { ASCII = 0, BINARY, PRETTY};
```

In *ASCII* mode, objects are written as a set of numbers, e.g. the coordinates of a point or the coefficients of a line, in a machine independent format. In *BINARY* mode, data are written in a binary format, e.g. a double is represented as a sequence of four byte. The format depends on the machine. The mode *PRETTY* serves mainly for debugging as the type of the geometric object is written, as well as the data defining the object. For example for a point at the origin with Cartesian double coordinates, the output would be *PointC2(0.0, 0.0)*. At the moment CGAL does not provide input operations for pretty printed data. By default a stream is in *ASCII* mode.

CGAL provides the following functions to modify the mode of an IO stream.

```
IO::Mode set_mode( std::ios& s, IO::Mode m)
```

```
IO::Mode set_ascii_mode( std::ios& s)
```

```
IO::Mode set_binary_mode( std::ios& s)
```

```
IO::Mode set_pretty_mode( std::ios& s)
```

The following functions allow to test whether a stream is in a certain mode.

IO::Mode *get_mode(std::ios& s)*

bool *is_ascii(std::ios& s)*

bool *is_binary(std::ios& s)*

bool *is_pretty(std::ios& s)*

63.1 Output Operator

CGAL defines output operators for classes that are derived from the class *ostream*. This allows to write to ostreams as *cout* or *cerr*, as well as to strstreams and fstreams. The output operator is defined for all classes in the CGAL kernel and for the class *Color* as well. Let *os* be an output stream.

ostream& *ostream& os << Class c* Inserts object *c* in the stream *os*. Returns *os*.

Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >    Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >    Segment;

int main()
{
    Point p(0,1), q(2,2);
    Segment s(p,q);

    CGAL::set_pretty_mode(std::cout);
    std::cout << p << std::endl << q << std::endl;

    std::ofstream f("data.txt");
    CGAL::set_binary_mode(f);
    f << s << p ;

    return 1;
}
```

63.2 Input Operator

CGAL defines input operators for classes that are derived from the class *istream*. This allows to read from istreams as *cin*, as well as from strstreams and fstreams. The input operator is defined for all classes in the CGAL kernel. Let *is* be an input stream.

istream& is >> Class c Extracts object *c* from the stream *is*. Returns *is*.

Example

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >    Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >    Segment;

int
main()
{
    Point p, q;
    Segment s;

    CGAL::set_ascii_mode(std::cin);
    std::cin >> p >> q;

    std::ifstream f("data.txt");
    CGAL::set_binary_mode(f);
    f >> s >> p;

    return 1;
}
```

63.3 IO for non-CGAL types

63.3.1 Using Output Formatting

To ensure that non-CGAL types are formatted correctly (i.e., respecting *IO::Mode*), *oformat* can be used. For types with a *Output_rep* specialization, the respective output routine of *Output_rep* will be called by *oformat*. Otherwise, the stream output operator will be called.

Example

```
std::cout << CGAL::oformat( myobject );
```

Optional, you can provide a second template parameter *F* as a formatting tag:

Example

```
std::cout << CGAL::oformat( myobject, My_formatting_tag() );
```

For a list of formatting tags supported by the type `T`, please refer to the documentation of the respective type.

63.3.2 Customizing Output Formatting

In some situations, you want to control the output formatting for a type `T`. For external types (third party libraries etc.), there might be problems if their stream output operator does not respect `IO::Mode`. The purpose of *Output_rep* is to provide a way to control output formatting that works independently of the object's stream output operator.

Instead of putting `T` directly into an output stream, `T` is wrapped into an output representation *Output_rep*. For convenience, a function *oformat* exists which constructs an instance of *Output_rep*.

If you do not specialize *Output_rep* for `T`, `T`'s stream output operator is called from within *Output_rep*, by default. If you want another behaviour for your type `T`, you have to provide a specialization for that type. Furthermore, you can provide specializations with a second template parameter (a formatting tag). The second template parameter defaults to *Null_tag* and means *default behaviour*.

For example, specializing *Output_rep* for `CORE::BigRat` (without a formatting tag parameter) could look like this:

Example

```
template <class F>
class Output_rep< ::CORE::BigRat, F> {
    const ::CORE::BigRat& t;
public:
    Output_rep( const ::CORE::BigRat& tt) : t(tt) {}

    std::ostream& operator()( std::ostream& out) const {
        switch (get_mode(out)) {
            case IO::PRETTY:{
                if(CGAL_CORE_DENOMINATOR(t) == ::CORE::BigRat(1))
                    return out <<CGAL_CORE_NUMERATOR(t);
                else
                    return out << CGAL_CORE_NUMERATOR(t)
                               << "/"
                               << CGAL_CORE_DENOMINATOR(t);
                break;
            }

            default:
                return out << CGAL_CORE_NUMERATOR(t)
                           << "/"
                           << CGAL_CORE_DENOMINATOR(t);
        }
    }
};
```

63.4 Colors

An object of the class *CGAL::Color* is a color available for drawing operations in many CGAL output streams.

Each color is defined by a triple of integers (r, g, b) with $0 \leq r, g, b \leq 255$, the so-called *rgb-value* of the color. There are 11 predefined *Color* constants available: *BLACK*, *WHITE*, *GRAY*, *RED*, *GREEN*, *DEEPBLUE*, *BLUE*, *PURPLE*, *VIOLET*, *ORANGE*, and *YELLOW*.

63.5 Stream Support

Three classes are provided by CGAL as adaptors to input and output stream iterators. The class *Istream_iterator* is an input iterator adaptor and is particularly useful for classes that are similar but not compatible to *std::istream*. Similarly, the class *Ostream_iterator* is an output iterator adaptor. The class *Verbose_ostream* can be used as an output stream. The stream output operator `<<` is defined for any type. The class stores in an internal state a stream and whether the output is active or not. If the state is active, the stream output operator `<<` uses the internal stream to output its argument. If the state is inactive, nothing happens.

IO Streams

Reference Manual

Andreas Fabri, Geert-Jan Giezeman, and Lutz Kettner

All classes in the CGAL kernel provide input and output operators for IO streams. CGAL provides three different printing mode, defined in the enum *Mode*, as well as different functions to set and get the printing mode.

CGAL::Color

Definition

An object of the class *Color* is a color available for drawing operations in many CGAL output streams. Each color is defined by a triple of integers (r, g, b) with $0 \leq r, g, b \leq 255$, the so-called *rgb-value* of the color.

```
#include <CGAL/IO/Color.h>
```

Creation

Color *c*; creates a color with rgb-value (0,0,0), i.e. black.

Color c(int red, int green, int blue); creates a color with rgb-value (*red, green, blue*).

Operations

<i>bool</i>	$c == q$	Test for equality: Two colors are equal, iff their rgb-values are equal.
-------------	----------	--

<i>bool</i>	$c \neq q$	Test for inequality.
-------------	------------	----------------------

<i>int</i>	<i>c.red()</i>	returns the red component of <i>c</i> .
<i>int</i>	<i>c.green()</i>	returns the green component of <i>c</i> .
<i>int</i>	<i>c.blue()</i>	returns the blue component of <i>c</i> .

Constants

The following constants are predefined:

<i>const Color</i>	<i>BLACK</i> = <i>Color</i> (0, 0, 0);	Black.
<i>const Color</i>	<i>WHITE</i> = <i>Color</i> (255, 255, 255);	White.
<i>const Color</i>	<i>RED</i> = <i>Color</i> (255, 0, 0);	Red.
<i>const Color</i>	<i>GREEN</i> = <i>Color</i> (0, 255, 0);	Green.
<i>const Color</i>	<i>BLUE</i> = <i>Color</i> (0, 0, 255);	Blue.
<i>const Color</i>	<i>VIOLET</i> = <i>Color</i> (255, 0, 255);	Violet.
<i>const Color</i>	<i>ORANGE</i> = <i>Color</i> (255, 170, 0);	Orange.

CGAL::operator>>

Definition

CGAL defines input operators for classes that are derived from the class *istream*. This allows to read from istreams as *cin*, as well as from strstreams and fstreams. The input operator is defined for all classes in the CGAL kernel.

istream& *istream*& *is* >> *Class c* Extracts object *c* from the stream *is*. Returns *is*.

CGAL::Istream_iterator<T,Stream>

Definition

The class *Istream_iterator*<*T*,*Stream*> is an input iterator adaptor for the input stream class *Stream* and value type *T*. It is particularly useful for classes that are similar but not compatible to *std::istream*.

```
#include <CGAL/IO/Istream_iterator.h>
```

Creation

Istream_iterator<*T*,*Stream*> *i*;
creates an end-of-stream iterator *i*. This is a past-the-end iterator, and it is useful when constructing a range.

Istream_iterator<*T*,*Stream*> *i*(*Stream*& *s*);
creates an input iterator *i* reading from *s*. When *s* reaches end of stream, this iterator will compare equal to an end-of-stream iterator created using the default constructor.

Operations

i fulfills the requirements for an input iterator.

CGAL::Mode

Definition

All classes in the CGAL kernel provide input and output operators for IOStreams. The basic task of such an operator is to produce a representation of an object that can be written as a sequence of characters on devices as a console, a file, or a pipe. The enum *Mode* distinguish between three different printing formats.

In *ASCII* mode, numbers e.g. the coordinates of a point or the coefficients of a line, are written in a machine independent format. In *BINARY* mode, data are written in a binary format, e.g. a double is represented as a sequence of four byte. The format depends on the machine. The mode *PRETTY* serves mainly for debugging as the type of the geometric object is written, as well as the data defining the object. For example for a point at the origin with Cartesian double coordinates, the output would be *PointC2(0.0, 0.0)*. At the moment CGAL does not provide input operations for pretty printed data. By default a stream is in *ASCII* mode.

```
enum Mode { ASCII = 0, BINARY, PRETTY};
```

CGAL::Ostream_iterator<T,Stream>

Definition

The class *Ostream_iterator*<*T*,*Stream*> is an output iterator adaptor for the output stream class *Stream* and value type *T*.

```
#include <CGAL/IO/Ostream_iterator.h>
```

Creation

Ostream_iterator<*T*,*Stream*> *o*(*Stream*& *s*); creates an output iterator *o* writing to *s*.

Operations

o fulfills the requirements for an output iterator.

Implementation

The *operator**() in class *Ostream_iterator*<*T*,*Stream*> uses a proxy class.

CGAL::operator<<

Definition

CGAL defines output operators for classes that are derived from the class *ostream*. This allows to write to ostreams as *cout* or *cerr*, as well as to strstreams and fstreams. The output operator is defined for all classes in the CGAL kernel and for the class *Color* as well. Let *os* be an output stream.

```
ostream&          ostream& os >> Class c
```

Inserts object *c* in the stream *os*. Returns *os*.

```
#include <CGAL/basic.h>
#include <iostream>
#include <fstream>

#include <CGAL/Cartesian.h>
#include <CGAL/Segment_2.h>

typedef CGAL::Point_2< CGAL::Cartesian<double> >    Point;
typedef CGAL::Segment_2< CGAL::Cartesian<double> >    Segment;

int main()
{
    Point p(0,1), q(2,2);
    Segment s(p,q);

    CGAL::set_pretty_mode(std::cout);
    std::cout << p << std::endl << q << std::endl;

    std::ofstream f("data.txt");
    CGAL::set_binary_mode(f);
    f << s << p ;

    return 1;
}
```

CGAL::Input_rep<T,F>

Definition

The definition of *Input_rep* is completely symmetric to *Output_rep*.

CGAL::Output_rep<T,F>

Definition

The purpose of *Output_rep* is to provide a way to control output formatting that works independently of the object's stream output operator.

If you don't specialize *Output_rep* for *T*, *T*'s stream output operator is called from within *Output_rep*, by default. If you want another behaviour for your type *T*, you have to provide a specialization for that type. Furthermore, you can provide specializations with a second template parameter (a formatting tag). The second template parameter defaults to *Null_tag* and means DEFAULT BEHAVIOUR.

Specializations of *Output_rep* should provide the following features:

```
template< class F >
struct Output_rep< Some_type, F > {
    Output_rep( const Some_type& t );
    std::ostream& operator()( std::ostream& out ) const;
};
```

You can also specialize for a formatting tag *F*.

CGAL::iformat

The definition of the function *iformat* is completely symmetric to *oformat*.

CGAL::oformat

Definition

Convenience function to construct an output representation (*Output_rep*) for type T .

```
template <class T>  
Output_rep<T>
```

```
oformat( T t)
```

Generic IO for type T .

```
template <class T, typename F>  
Output_rep<T,F>
```

```
oformat( T t, F)
```

Generic IO for type T with formatting tag.

CGAL::set_ascii_mode

Mode *set_ascii_mode(std::ios& s)*

sets the mode of the IO stream *s* to be the *ASCII* mode. Returns the previous mode of *s*.

CGAL::Verbose_ostream

Definition

The class *Verbose_ostream* can be used as an output stream. The stream output operator << is defined for any type. The class *Verbose_ostream* stores in an internal state a stream and whether the output is active or not. If the state is active, the stream output operator << uses the internal stream to output its argument. If the state is inactive, nothing happens.

```
#include <CGAL/IO/Verbose_ostream.h>
```

Creation

```
Verbose_ostream verr( bool active = false, std::ostream& out = std::cerr);
```

creates an output stream with state set to *active* that writes to the stream *out*.

Operations

```
template < class T >
Verbose_ostream&      verr << T t
```

Example

The class *Verbose_ostream* can be conveniently used to implement for example the *is_valid()* member function for triangulations or other complex data structures.

```
bool is_valid( bool verbose = false, int level = 0) {
    Verbose_ostream verr( verbose);
    verr << "Triangulation::is_valid( level = " << level << ' ' << endl;
    verr << "    Number of vertices = " << size_of_vertices() << endl;
    // ...
}
```

Chapter 64

Geomview

Andreas Fabri and Sylvain Pion

Contents

64.1 Definition	3365
64.2 Implementation	3365
64.3 Example	3366

64.1 Definition

This chapter presents the CGAL interface to Geomview¹, which is a viewer for three-dimensional objects, originally developed at the Geometry Center in Minneapolis².

Geomview 1.8.1 is required.

Note: In releases up to and including 2.2, CGAL used to have the following requirement : the last line in the startup file `.geomview` must be (*echo "started"*). This is no longer necessary.

An object of the class *Geomview_stream* is a stream in which geometric objects can be inserted and where geometric objects can be extracted from. The constructor starts Geomview either on the local either on a remote machine.

Not all but most classes of the CGAL kernel have output operators for the *Geomview_stream*. 2D objects are embedded in the *xy*-plane. Input is only provided for points. Polyhedron and 2D and 3D triangulations have output operators for the *Geomview_stream*.

64.2 Implementation

The constructor forks a process and establishes two pipes between the processes. The forked process is then overlaid with Geomview. The file descriptors *stdin* and *stdout* of Geomview are hooked on the two pipes.

¹<http://www.geomview.org/>

²<http://www.geom.umn.edu/>

All insert operators construct expressions in *gcl*, the Geomview command language, which is a subset of LISP. These expressions are sent to Geomview via the pipe. The extract operators notify *interest* for a certain kind of events. When such an event happens Geomview sends a description of the event in *gcl* and the extract operator has to parse this expression.

In order to implement further insert and extract operators you should take a look at the implementation and at the Geomview manual.

64.3 Example

The following program outputs successively a 2D Delaunay triangulation (projected), a 3D Delaunay, and a terrain from the set of points.

```
#include <CGAL/Cartesian.h>
#include <iostream>

#ifndef CGAL_USE_GEOMVIEW
int main()
{
    std::cout << "Geomview doesn't work on Windows, so..." << std::endl;
    return 0;
}
#else

#include <fstream>
#include <unistd.h> // for sleep()

#include <CGAL/Triangulation_euclidean_traits_xy_3.h>

#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/Delaunay_triangulation_3.h>

#include <CGAL/IO/Geomview_stream.h>
#include <CGAL/IO/Triangulation_geomview_ostream_2.h>
#include <CGAL/IO/Triangulation_geomview_ostream_3.h>

#include <CGAL/intersections.h>

typedef CGAL::Cartesian<double> K;

typedef K::Point_2 Point2;
typedef CGAL::Triangulation_euclidean_traits_xy_3<K> Gt3;
typedef Gt3::Point Point3;

typedef CGAL::Delaunay_triangulation_2<K> Delaunay;
typedef CGAL::Delaunay_triangulation_2<Gt3> Terrain;

typedef CGAL::Delaunay_triangulation_3<K> Delaunay3d;

int main()
{
    CGAL::Geomview_stream gv(CGAL::Bbox_3(-100, -100, -100, 600, 600, 600));
```

```

gv.set_line_width(4);
// gv.set_trace(true);
gv.set_bg_color(CGAL::Color(0, 200, 200));
// gv.clear();

Delaunay D;
Delaunay3d D3d;
Terrain T;
std::ifstream iFile("data/points3", std::ios::in);
Point3 p;

while ( iFile >> p )
{
    D.insert( Point2(p.x(), p.y()) );
    D3d.insert( p );
    T.insert( p );
}

// use different colors, and put a few sleeps/clear.

gv << CGAL::BLUE;
std::cout << "Drawing 2D Delaunay triangulation in wired mode.\n";
gv.set_wired(true);
gv << D;

#if 1 // It's too slow ! Needs to use OFF for that.

⁴<http://www.geom.umn.edu/>

CGAL::Geomview_stream

Definition

An object of the class *Geomview_stream* is a stream in which geometric objects can be inserted and where geometric objects can be extracted from. The constructor starts Geomview either on the local either on a remote machine.

```
#include <CGAL/IO/Geomview_stream.h>
```

Creation

```
Geomview_stream gs( Bbox_3 bbox = Bbox_3(0,0,0, 1,1,1),
                   const char *machine = NULL,
                   const char *login = NULL)
```

Introduces a Geomview stream *gs* with a camera that sees the bounding box. The command *geomview* must be in the user's *PATH*. If *machine* and *login* are not *NULL*, Geomview is started on the remote machine using *rsh*.

Operations

Output Operators for CGAL Kernel Classes

At the moment not all classes of the CGAL kernel have output operators. 2D objects are embedded in the *xy*-plane.

```
template <class R>
Geomview_stream&      Geomview_stream& G << Point_2<R> p
```

Inserts the point *p* into the stream *gs*.

```
template <class R>
Geomview_stream& G << Point_3<R> p
```

Inserts the point p into the stream gs .

```
template <class R>
Geomview_stream& G << Segment_2<R> s
```

Inserts the segment s into the stream gs .

```
template <class R>
Geomview_stream& G << Segment_3<R> s
```

Inserts the segment s into the stream gs .

```
template <class R>
Geomview_stream& G << Ray_2<R> r
```

Inserts the ray r into the stream gs .

```
template <class R>
Geomview_stream& G << Ray_3<R> r
```

Inserts the ray r into the stream gs .

```
template <class R>
Geomview_stream& G << Line_2<R> l
```

Inserts the line l into the stream gs .

```
template <class R>
Geomview_stream& G << Line_3<R> l
```

Inserts the line l into the stream gs .

```
template <class R>
Geomview_stream& G << Triangle_2<R> t
```

Inserts the triangle t into the stream gs .

```
template <class R>
Geomview_stream& G << Triangle_3<R> t
```

Inserts the triangle t into the stream gs .

```
template <class R>
```

```
Geomview_stream&      Geomview_stream& G << Tetrahedron_3<R> t
```

Inserts the tetrahedron t into the stream gs .

```
template <class R>
Geomview_stream&      Geomview_stream& G << Sphere_3<R> s
```

Inserts the sphere s into the stream gs .

```
Geomview_stream&      Geomview_stream& G << Bbox_2 b
```

Inserts the bounding box b into the stream gs .

```
Geomview_stream&      Geomview_stream& G << Bbox_3 b
```

Inserts the bounding box b into the stream gs .

```
template < class InputIterator >
void      gs.draw_triangles( InputIterator begin, InputIterator end)
```

$[begin;end)$ is an iterator range with value type $Triangle_3<R>$. This method uses the OFF format to draw several triangles at once, which is much faster than drawing them one by one.

Input Operators for CGAL Kernel Classes

At the moment input is only provided for points. The user has to select a point on the *pick plane* with the right mouse button. The pick plane can be moved anywhere with the left mouse button, before a point is entered.

```
template <class R>
Geomview_stream&      Geomview_stream& G >> Point_3<R>& p
```

Extracts the point p from the stream gs . The point is echoed by default, and it depends on the stream echo mode status.

Output Operators for CGAL Basic Library Classes

```
#include <CGAL/IO/Polyhedron_geomview_ostream.h>
```

```
template <class Traits, class HDS>
Geomview_stream&      Geomview_stream &G << Polyhedron_3<Traits,HDS> P
```

Inserts the polyhedron P into the stream gs .

```
#include <CGAL/IO/Triangulation_geomview_ostream.2.h>
```

```
template <class GT, class TDS>
Geomview_stream&      Geomview_stream &G << Triangulation_2<GT,TDS> T
```

Inserts the 2D triangulation T into the stream gs . The actual output depends on whether the stream is in wired mode or not. Also note that in the case of terrains (when $GT::Point_2$ is $Point_3<R>$), then the 3D terrain is displayed.

```
#include <CGAL/IO/Triangulation_geomview_ostream_3.h>
```

```
template <class GT, class TDS>
Geomview_stream&      Geomview_stream &G << Triangulation_3<GT,TDS> T
```

Inserts the 3D triangulation T into the stream gs . The actual output depends on whether the stream is in wired mode or not.

Colors

Geomview distinguishes between edge and face colors. The edge color is at the same time the color of vertices.

```
Geomview_stream&      gs << Color c
```

Makes c the color of vertices, edges and faces in subsequent IO operations.

```
Color                  gs.set_bg_color( Color c)
```

Changes the background color. Returns the old value.

```
Color                  gs.set_vertex_color( Color c)
```

Changes the vertex color. Returns the old value.

```
Color                  gs.set_edge_color( Color c)
```

Changes the edge color. Returns the old value.

```
Color                  gs.set_face_color( Color c)
```

Changes the face color. Returns the old value.

Miscellaneous

```
void                  gs.clear()
```

Deletes all objects.

```
void                  gs.pickplane()
```

Creates a pickplane (useful after a clear).

```
void                  gs.look_recenter()
```

Positions the camera in a way that all objects can be seen.

<i>int</i>	<i>gs.get_line_width()</i>	Returns the line width.
<i>int</i>	<i>gs.set_line_width(int w)</i>	Sets the line width to <i>w</i> . Returns the previous value.
<i>double</i>	<i>gs.get_vertex_radius()</i>	Returns the radius of vertices.
<i>double</i>	<i>gs.set_vertex_radius(double r)</i>	Sets the radius of vertices to <i>d</i> . Returns the previous value.
<i>string</i>	<i>gs.get_new_id(string s)</i>	Used to obtain unique identifier names passed to Geomview. On successive calls with the same <i>s</i> value, it will return a string which is <i>s</i> appended with the numbers 0, then 1, then 2... Note that all counters are reset when <i>clear()</i> is called.
<i>bool</i>	<i>gs.set_wired(bool b)</i>	Sets wired mode. In wired mode, some structures output only there edges, not there surfaces. Returns the previous value. By default, wired mode is off.
<i>bool</i>	<i>gs.get_wired()</i>	Returns <i>true</i> iff wired mode is on.

— advanced —

Advanced and Developers Features

The following functions are helpful if you develop your own insert and extract functions. The following functions allow to pass a string from Geomview and to read data sent back by Geomview.

<i>Geomview_stream&</i>	<i>gs << string s</i>	Inserts string <i>s</i> into the stream.
<i>Geomview_stream&</i>	<i>gs >> char* s</i>	Extracts a string <i>s</i> from the stream. <i>Precondition:</i> You have to allocate enough memory.
<i>Geomview_stream&</i>	<i>gs << int i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode.
<i>Geomview_stream&</i>	<i>gs << unsigned int i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode.
<i>Geomview_stream&</i>	<i>gs << long i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode. Currently implemented by converting to int, so it can be truncated on 64 bit platforms.

<i>Geomview_stream</i>	<i>gs << unsigned long i</i>	Inserts <i>i</i> into the stream. Puts whitespace around if the stream is in ascii mode. Currently implemented by converting to unsigned int, so it can be truncated on 64 bit platforms.
<i>Geomview_stream</i>	<i>gs << double d</i>	Inserts double <i>d</i> into the stream. Puts whitespace around if the stream is in ascii mode.
<i>bool</i>	<i>gs.set_trace(bool b)</i>	Sets tracing on. The data that are sent to <i>Geomview</i> are also sent to <i>cerr</i> . Returns the previous value. By default tracing is off.
<i>bool</i>	<i>gs.get_trace()</i>	Returns <i>true</i> iff tracing is on.
<i>bool</i>	<i>gs.set_raw(bool b)</i>	Sets raw mode. In raw mode, kernel points are output without headers and footers, just the coordinates (in binary or ascii mode). This allows the implementation of the stream functions for other objects to re-use the code for points internally, by temporary saving the raw mode to true, and restoring it after. Returns the previous value. By default, raw mode is off.
<i>bool</i>	<i>gs.get_raw()</i>	Returns <i>true</i> iff raw mode is on.
<i>bool</i>	<i>gs.set_echo(bool b)</i>	Sets echo mode. In echo mode, when you select a point in Geomview, the point is actually sent back to Geomview. Returns the previous value. By default, echo mode is on.
<i>bool</i>	<i>gs.get_echo()</i>	Returns <i>true</i> iff echo mode is on.
<i>bool</i>	<i>gs.set_binary_mode(bool b = true)</i>	Sets whether we are in binary mode.
<i>bool</i>	<i>gs.set_ascii_mode(bool b = true)</i>	Sets whether we are in ascii mode.
<i>bool</i>	<i>gs.get_binary_mode()</i>	Returns <i>true</i> iff <i>gs</i> is in binary mode.
<i>bool</i>	<i>gs.get_ascii_mode()</i>	Returns <i>true</i> iff <i>gs</i> is in ascii mode.

_____ *advanced* _____

Implementation

The constructor forks a process and establishes two pipes between the processes. The forked process is then overlaid with Geomview. The file descriptors *stdin* and *stdout* of Geomview are hooked on the two pipes.

All insert operators construct expressions in *gcl*, the Geomview command language, which is a subset of LISP. These expressions are sent to Geomview via the pipe. The extract operators notify *interest* for a certain kind of events. When such an event happens Geomview sends a description of the event in *gcl* and the extract operator has to parse this expression.

In order to implement further insert and extract operators you should take a look at the implementation and at the Geomview manual.

QT is a GUI toolkit¹ for cross-platform application development.

65.1 Introduction

This chapter describes the *Qt_widget* package which provides an interface between CGAL and the GUI toolkit QT . The *Qt_widget* package allows to build QT applications showing two dimensional CGAL objects and algorithms.

The atom of the QT user interface is called a widget. A widget receives mouse, keyboard and other events from the window system, and paints a representation of itself on the screen. Widgets are rectangular, and the different widgets of an application are sorted in a Z-order. Widgets can have a parent widget and children. A widget is clipped by its parent and by the widgets in front of it.

¹<http://www.trolltech.com>

The most important class in the package is the class *Qt_widget* which implements a widget providing a drawing area and output stream operators for CGAL two dimensional objects. *Qt_widget* also provides zooming and panning functionalities.

The *Qt_widget* allows to attach *layers*. Layers usually draw on the drawing area of the widget. Layers can be activated and deactivated, and what you see in the drawing area is the overlay of all attached activated layers. Layers can also be used for entering input, and CGAL provides input *layers* for the two-dimensional CGAL objects.

The package includes also the class *Qt_widget_standard_toolbar* providing a standard toolbar for controlling the basic functionality of the *Qt_widget*.

The following sections describe the main class as well as the helper classes in more detail and give examples that can be taken as starting points for new applications.

Remark: The *Qt_widget* is distributed under the QPL, which is Trolltech's open source license. For more details on the QPL see <http://www.trolltech.com/developer/licensing/qpl.html>.

65.2 Qt_widget

The class *Qt_widget* is derived from the class *QWidget* which is the base class of all QT user interface objects.

The *Qt_widget* provides output operators for two dimensional CGAL objects. There are operators defined for output of: points, segments, lines, rays, circles, triangles, rectangles, polygons, conics, and all type of triangulations. Also some operators are defined to set *Qt_widget*'s properties, like background and fill color, as well as line width and point size.

As the following examples show, simple applications can be written without the layers.

65.2.1 Example: Hello Segment

The first example draws a red segment on an orange background.

```
#include <CGAL/basic.h>

#ifdef CGAL_USE_QT
#include <iostream>
int main(int, char*){
    std::cout << "Sorry, this demo needs QT..." << std::endl; return 0;}
#else
#include <CGAL/Cartesian.h>
#include <CGAL/IO/Qt_widget.h>

#include <qapplication.h>

typedef CGAL::Cartesian<int> Rep;
typedef CGAL::Point_2<Rep> Point_2;
typedef CGAL::Segment_2<Rep> Segment;

int main( int argc, char **argv )
{
    QApplication app( argc, argv );
    CGAL::Qt_widget *w = new CGAL::Qt_widget();
    app.setMainWidget( w );
    w->resize(600, 600);
    w->set_window(0, 600, 0, 600);
    w->show();
    w->lock();
    *w << CGAL::BackgroundColor(CGAL::ORANGE) << CGAL::RED;
    *w << Segment(Point_2(100,100), Point_2(400,400));
    w->unlock();
    return app.exec();
}
#endif
```

File: demo/Qt_widget/hellosegment.cpp

We follow the QT naming conventions for material properties, for example, the *CGAL::BackgroundColor* above.

All the drawing code should be put between *Qt_Widget*'s *lock()* and *unlock()* functions. See the manual reference pages of *Qt_widget*. Doing like this, the window will be updated only once, when *Qt_widget* finds the last *unlock()*. This way you can avoid the window flickering.

This example has a severe drawback: when you resize the window it is empty, as nothing is redrawn. This style of programs makes only sense, if you quickly want to validate output of a geometric computation. As in any event driven GUI application, QT provides a callback mechanism so that the window system can update the drawing whenever necessary. This is the topic of the next example.

65.2.2 Example: Signals and Slots

This example is slightly more involved and uses the signal/slots mechanism of QT.

The main widget shows a Delaunay triangulation. Every time the mouse button is pressed over the widget, a point is input and inserted in the Delaunay triangulation. The result of this insertion appears immediately. Furthermore, the drawing is updated every time the window is resized.

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_QT
#include <iostream>
int main(int, char*){
    std::cout << "Sorry, this demo needs QT..." << std::endl; return 0;}
#else
#include <CGAL/Cartesian.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/IO/Qt_widget_Triangulation_2.h>
#include <CGAL/IO/Qt_widget.h>
#include <qapplication.h>
#include <qmainwindow.h>

typedef CGAL::Cartesian<double>          K;
typedef K::Point_2                       Point_2;
typedef CGAL::Delaunay_triangulation_2<K> Delaunay;

Delaunay dt;

class My_window : public QMainWindow {
    Q_OBJECT
public:
    My_window(int x, int y)
    {
        widget = new CGAL::Qt_widget(this);
        widget->resize(x,y);
        widget->set_window(0, x, 0, y);

        connect(widget, SIGNAL(redraw_on_back()),
            this, SLOT(redraw_win()));

        connect(widget, SIGNAL(s_mousePressEvent(QMouseEvent*)),
            this, SLOT(mousePressEvent(QMouseEvent*)));

        setCentralWidget(widget);
    };
private slots:
    void redraw_win()
    {
        *widget << dt;
    }

    void mousePressEvent(QMouseEvent *e)
    {
        dt.insert(Point_2(widget->x_real(e->x()), widget->y_real(e->y())));
    }
};
```

```

        widget->redraw();
    }

private: // private data member
    CGAL::Qt_widget* widget;
};

//moc_source_file : tutorial2.cpp
#include "tutorial2.moc"

int main( int argc, char **argv )
{
    QApplication app( argc, argv );
    My_window *w = new My_window(400,400);
    app.setMainWidget( w);
    w->show();
    return app.exec();
}
#endif

```

File: demo/Qt_widget/tutorial2.cpp

QT applications are event driven and respond to user interaction. For example, when a user clicks on a menu item or on a toolbar button, the application executes some codes. The programmer of an application has to be able to relate events to the relevant code. QT provide for that the signals/slots mechanism:

Signals. Each QT widget declares a set of signals which, using the keyword *emit* can be emitted by member functions under some circumstances. Signals are declared by using the keyword *signals:* just like an access specifier in your class declaration.

Slots. A slot is just a member function declared under a public (or private) slots section.

Connect. Signals and slots can be connected together using the method *connect*. This method needs to know four things: the object that sends out the signal, the signal, the object to which belong the connected slot and the slot connected to the signal. For instance, the statement:

```

connect(widget, SIGNAL(redraw_on_back()),
        this, SLOT(redraw_win()));

```

connects the signal *redraw_on_back()* of the widget *widget* to the slot *redraw_win()* of the *QMainWindow* *this*. Signals and slots can have any type of arguments, but a signal and a slot connected together must have the same arguments types.

Every class that defines at least a signal or a slot must be derived from the class *QObject* and must use the macro *Q_OBJECT* inside the private section of its declaration. You also need to run *moc*, the *Meta Object Compiler* supplied with QT on the file that contains the class declaration.

moc is a pre-compiler that produces the *meta object* code of each class that uses the macro *Q_OBJECT*. This *meta object* code is needed by the signal/slot mechanism. There are several methods to compile the outputs of *moc*. In CGAL, we have chosen to include the outputs of *moc* in a source files. See the QT documentation on *moc* for other possibilities.

The line *//moc_source_file : tutorial2.cpp* is for users that use makefiles. This line tells to the CGAL makefile generator that *tutorial2.cpp* should be the file that *moc* should be run on.

Let us come back to the control flow in the above example. The main widget of the application is the widget *w* of class *My_window*. The creator of *My_window* triggers the creation of a *Qt_widget* accessible through the pointer *widget*. When the mouse button is pressed in its drawing area, the *Qt_widget* emits the signal *s_mousePressEvent(QMouseEvent*)* connected to the slot *mousePressEvent(QMouseEvent*)* of *My_window*. This slot inserts the point in the Delaunay triangulation and calls the method *redraw()* of *Qt_widget*. The *redraw()* method of *Qt_widget* emits the signal *redraw_on_back()*. This signal is connected to the slot *redraw_win()* of *My_window* which actually draws the triangulation. Note that the *Qt_widget* emits the same signal *redraw_on_back()* when the window is resized. Thus, the signals/slots connection ensures that the triangulation is redrawn each time the redrawing is needed.

— advanced —

There are several ways to draw something with *Qt_widget*. One way is to use the signals *redraw_on_back()*, *redraw_on_front()*. This way you can bring your drawings before all or after all the other drawings. An other option is to use the *QPainter* instance of *Qt_widget* that you can get calling *get_painter()* method. The most recommended way is to use layers, that are described in the next section.

— advanced —

Note that in that example, the *My_window* constructor calls *new* to allocate a new *Qt_widget* object but *delete* is never called to deallocate it. This does not mean that there is a memory leak. It is in Qt's responsibility to free widgets that have a parent. In that example the *My_window* object is the parent of *widget* and will deallocate it automatically at its destruction.

65.3 Layers

65.3.1 Using Layers to Draw

In the examples from the previous section the code for drawing on the widget was in the *redraw_win()* function. As soon as the applications are more involved it leads to a more modular design if one delegates the drawing task to *layers*. For example, if the application displays a Delaunay triangulation, the corresponding Voronoi diagram, and at the same time highlights the nearest vertex to the mouse coordinates, it makes sense to have three independent layers. Besides better code, layers have the advantage that they can be activated and deactivated at runtime. Finally, more modularity means a higher potential for reuse.

A layer can be *attached* to a *Qt_widget*. The *redraw()* member function of the *Qt_widget* calls the method *Qt_widget_layer::draw()* of all attached layers, in the order that they were attached. It is a very simple rule: the last layer attached will be drawn on top.

Also a layer can be *activated* and *deactivated*. Only active layers are drawn, and by default a layer is activated when it gets attached. Note that deactivating and activating do not influence the order of layers. You can change the order only by attaching and detaching it.

CGAL provides a base class so that users can write their own layers. All the layers have to derive from this base class *Qt_widget_layer* to have the functionality described.

65.3.2 Example: Using a Layer to Draw

Example

```

#include <CGAL/Cartesian.h>
#include <CGAL/Point_2.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/IO/Qt_widget_Delaunay_triangulation_2.h>
#include <CGAL/IO/Qt_widget.h>
#include <CGAL/IO/Qt_widget_layer.h>
#include <qapplication.h>

typedef CGAL::Cartesian<double>          Rep;
typedef CGAL::Point_2<Rep>              Point;
typedef CGAL::Delaunay_triangulation_2<Rep> Delaunay;

Delaunay dt;

class My_layer : public CGAL::Qt_widget_layer{
    void draw(){
        *widget << dt;
    }
};

class My_window : public CGAL::Qt_widget {
public:
    My_window(int x, int y)
    {
        resize(x,y);
        attach(&layer);
    };
private:
    //this method is called when the user presses the mouse
    void mousePressEvent(QMouseEvent *e)
    {
        Qt_widget::mousePressEvent(e);
        dt.insert(Point(x_real(e->x()), y_real(e->y())));
        redraw();
    }
    My_layer layer;
};

int main( int argc, char **argv )
{
    QApplication app( argc, argv );
    My_window *W = new My_window(400,400);
    app.setMainWidget(W);
    W->show();
    W->set_window(0, 400, 0, 400);
    return app.exec();
}

```

This example defines a class derived from *Qt_widget_layer*. In the member function *draw()* is the code for drawing the triangulation. In *My_Window* class you need an instance of *My_Layer* and you will have to attach it, if you want to see what the layer draws on the screen.

As you see, this example is very similar to the previous one, but the code for drawing the triangulation is no longer in the *redraw_win()* function, but in a layer.

65.3.3 Using Layers to Build New Objects

The main purpose of layers is to have more modular code for drawing on the widget. Things are similar for handling input. In the previous examples, input went through the `Qt_widget::mousePressedEvent()` callback, which interpreted the input. In applications where you have different kinds of input, e.g., segments and polygons in an arrangement demo, this quickly leads to unreadable, difficult to maintain code, especially as typically more than one event callback is involved. The proper way of decomposition, is delegation of the event handling to a *layer*.

A layer for `Qt_widget` receives all the events from `Qt_widget` if it is active and can provide some functionality like input objects for `Qt_widget`. Notice that the layers receive events in the order they have been attached. Layers can have internal state, because for entering complex objects it needs several events. Therefore layers must have functions to initialize state when they are activated and to clean up when they are deactivated.

CGAL provides some predefined input layers. You can have a lot of layers attached that could be active in the same time. You have to take care how you manage the events if you do not want to have conflicts. A conflict is when two attached layers that are active need both the same event and getting and using it might not have such a good effect in your application. For example the predefined layers that builds a new line and a new circle produce bad visual effects when are both active.

You can resolve conflicts by using *layers* exclusive. If you have several layers that can not be active at the same time without creating conflicts, you can resolve that by letting the user not activate more than one of those at a time.

— advanced —

In all the CGAL demos that are provided, the layers are used with a toolbar and buttons. To activate and deactivate a layer you have to click one of the toolbar buttons. There are layers that need exclusive use. This is accomplished by grouping the buttons in one group, and making that group exclusive. The group class is `QButtonGroup` that comes with QT.

— advanced —

We first show how to use layers and then how they work.

65.3.4 Example: How to Use a Layer

In the previous section, you could insert new points in the triangulation by clicking on the widget. This example shows how the same can be achieved with the help of a layer.

We attach the predefined layer `Qt_widget.get_point` to the widget, and connect the signal emitted by the widget to the function that handles the input. When the user clicks with the left mouse button, the layer creates a point and passes it to the widget. The widget then emits a signal that gets passed to the connected slot `My_Window::get_new_object(CGAL::Object)`.

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_QT
#include <iostream>
int main(int, char*){
    std::cout << "Sorry, this demo needs QT..." << std::endl; return 0;}
#else
#include <CGAL/Cartesian.h>
```

```

#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/IO/Qt_widget_Delaunay_triangulation_2.h>
#include <CGAL/IO/Qt_widget.h>
#include <CGAL/IO/Qt_widget_layer.h>
#include <CGAL/IO/Qt_widget_get_point.h>

#include <qapplication.h>
#include <qmainwindow.h>

typedef CGAL::Cartesian<double>          Rep;
typedef CGAL::Point_2<Rep>              Point_2;
typedef CGAL::Delaunay_triangulation_2<Rep> Delaunay;

Delaunay dt;

class My_Layer : public CGAL::Qt_widget_layer{
    void draw(){
        *widget << dt;
    }
};

class My_Window : public QMainWindow {
    Q_OBJECT
public:
    My_Window(int x, int y){
        widget = new CGAL::Qt_widget(this, "CGAL Qt_widget");
        setCentralWidget(widget);
        resize(x,y);
        widget->attach(&get_point);
        widget->attach(&v);
        connect(widget, SIGNAL(new_cgal_object(CGAL::Object)),
                this, SLOT(get_new_object(CGAL::Object)));
        widget->set_window(0, 600, 0, 600);
    };
private: //members
    CGAL::Qt_widget_get_point<Rep> get_point;
    My_Layer v;
    CGAL::Qt_widget *widget;
private slots:
    void get_new_object(CGAL::Object obj)
    {
        Point_2 p;
        if (CGAL::assign(p, obj)) {
            dt.insert(p);
        }
        widget->redraw();
    }
}; //endclass

// moc_source_file : layer.cpp
#include "layer.moc"

int main( int argc, char **argv )
{

```

```

    QApplication app( argc, argv );
    My_Window *W = new My_Window(600,600);
    app.setMainWidget( W );
    W->show();
    return app.exec();
}
#endif

```

File: demo/Qt_widget/layer.cpp

The *Qt_widget* forwards all events that it receives to the attached and active layers. If a layer is attached but not active, it does not get the events. It is put in a passive state. Activating and deactivating the layer does not mean that the object is destructed.

65.3.5 Example: How Layers Work

The following is an example of a *layer* that creates CGAL points when the user clicks the left mouse button over the widget.

```

#include <CGAL/IO/Qt_widget.h>
#include <CGAL/IO/Qt_widget_layer.h>
#include <qcursor.h>

#ifndef CGAL_QT_WIDGET_GET_POINT_BUTTON
#define CGAL_QT_WIDGET_GET_POINT_BUTTON Qt::LeftButton
#endif

namespace CGAL {
template <class R>
class Qt_widget_get_point : public Qt_widget_layer
{
public:
    typedef typename R::Point_2    Point;
    typedef typename R::FT          FT;

    Qt_widget_get_point(const QCursor c=QCursor(Qt::crossCursor),
                        QObject* parent = 0, const char* name = 0) :
        Qt_widget_layer(parent, name), cursor(c) {};

private:
    bool is_pure(Qt::ButtonState s){
        if((s & Qt::ControlButton) ||
           (s & Qt::ShiftButton) ||
           (s & Qt::AltButton))
            return 0;
        else
            return 1;
    }
    void mousePressEvent(QMouseEvent *e)
    {
        if(e->button() == CGAL_QT_WIDGET_GET_POINT_BUTTON

```

```

        && is_pure(e->state()))
    {
        FT x, y;
        widget->x_real(e->x(), x);
        widget->y_real(e->y(), y);
        widget->new_object(make_object(Point(x, y)));
    }
};

void activating()
{
    oldcursor = widget->cursor();
    widget->setCursor(cursor);
};

void deactivating()
{
    widget->setCursor(oldcursor);
};

QCursor cursor;
QCursor oldcursor;
};
} // namespace CGAL

```

The *Qt_widget* forwards mouse and keyboard events to the attached layer. In the above example only the *mousePressEvent* member function is overloaded.

Tools that create new CGAL objects, must call the member function *Qt_widget::new_object(CGAL::Object)*. The *Qt_widget* then emits the signal *new_cgal_object(CGAL::Object)*. This signal can be routed to any slot of other object accepting a *CGAL::Object*, with the following connect statement:

```

connect(qt_widget_ptr, SIGNAL(new_cgal_object(CGAL::Object)),
        any_other_object_ptr, SLOT(any_other_slot(CGAL::Object)));

```

The first argument must be a pointer to an instance of *Qt_widget*. In the example we connect it to *MyWindow::get_new_object(CGAL::Object)*.

65.4 The Standard Toolbar

The *Qt_widget* allows to zoom and pan. This functionality is accessible through the class *Qt_widget_standard_toolbar*. The example further down shows how to use it in your application.

The functionality of the toolbar is as follows from the left to right:

History back: Go back into the transformation history

History forth: Go forth into the transformation history

Zoom In: The scaling factor is multiplied by two, keeping the same center.

Zoom Out: The scaling factor is divided by two, keeping the same center.

Point tool: Deactivate the layers corresponding to the three following buttons which form an exclusive group

Focus on Point: Lets you choose the center of the region where you want to focus.

Focus on the Region: The area in the rectangle that you selected will be magnified to best fit in the window.

Hand Tool: Used for translate. Click to select the first point of translation and drag to select the second point.

Mouse Coordinates Layer: Mouse coordinates are displayed on the status bar of your window. You can deactivate this layer if you click on it. To activate it again just click one more time.

Example

```
#include <CGAL/basic.h>

#ifndef CGAL_USE_QT
#include <iostream>
int main(int, char*){
    std::cout << "Sorry, this demo needs QT..." << std::endl; return 0;}
#else
#include <CGAL/Cartesian.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/IO/Qt_widget_Delaunay_triangulation_2.h>

#include <qapplication.h>
#include <qmainwindow.h>

#include <CGAL/IO/Qt_widget.h>
#include <CGAL/IO/Qt_widget_standard_toolbar.h>
#include <CGAL/point_generators_2.h>

typedef CGAL::Cartesian<double> Rep;
typedef CGAL::Point_2<Rep> Point_2;
typedef CGAL::Delaunay_triangulation_2<Rep> Delaunay;

Delaunay dt;

class My_window : public QMainWindow{
    Q_OBJECT
public:
    My_window(int x, int y)
    {
        widget = new CGAL::Qt_widget(this);
        setCentralWidget(widget);
        resize(x,y);
        widget->show();
        widget->set_window(0, x, 0, y);
    }
};
```

```

    CGAL::Random_points_in_disc_2<Point_2> g(500);
    for(int count=0; count<100; count++) {
        dt.insert(*g++);
    }

    //How to attach the standard toolbar
    std_toolbar = new CGAL::Qt_widget_standard_toolbar(widget, this,
        "Standard Toolbar");

    connect(widget, SIGNAL(redraw_on_back()),
        this, SLOT(redraw_win()) );
}

private slots: //functions
    void redraw_win()
    {
        *widget << dt;
    }

private: //members
    CGAL::Qt_widget *widget;
    CGAL::Qt_widget_standard_toolbar *std_toolbar;
};

// moc_source_file: standard_toolbar.cpp
#include "standard_toolbar.moc"

int main( int argc, char **argv )
{
    QApplication app( argc, argv );
    My_window W(600,600);
    app.setMainWidget( &W );
    W.show();
    W.setCaption("Using the Standard Toolbar");
    return app.exec();
}
#endif

```

File: demo/Qt_widget/standard_toolbar.cpp

This example generates 100 points and inserts them in a Delaunay triangulation. Using the standard toolbar you can zoom in, zoom out, translate.

65.5 The Help Window

We provide a class in the *Qt_widget* library that was taken from an example of *Qt* and adapted to our needs. This class has the functionality of a rich text browser with hypertext navigation. You can also PRINT, GO BACK, GO FORWARD or GO HOME. This class is called *Qt_help_window* and you can use it to display hypertext support in your application. It is used in a lot of demos provided in the distribution.

Example

```
#include <CGAL/IO/Qt_help_window.h>

....
QString home = "help/index.html";
Qt_help_window *help = new Qt_help_window(home, ".", 0, "help viewer");
help->resize(400, 400);
help->setCaption("Demo HowTo");
help->show();
```

65.6 Some Predefined Icons

CGAL provides some icons defined in some header files. The icons are pixmaps, having the extension *.xpm*. Their location is */include/CGAL/IO/pixmaps*.

To use a pixmap in your code you have to include the right file, and to know the names of the pixmaps. The names of the pixmaps are composed of two parts, the name of the file and the tag *xpm*. So for example the arrow pixmap has the name *arrow_xpm*, the line pixmap has the name *line_xpm*, and so on. There are also pixmaps files that contain small icons. The name of the smaller pixmaps contain a *small* at the middle of it like *point_small_xpm*. In the tutorials and demos, almost all the pixmaps are used for the toolbar buttons, like this:

Example

```
#include <CGAL/IO/pixmaps/point.xpm>

QIconSet set(QPixmap( (const char**)point_small_xpm ),
             QPixmap( (const char**)point_xpm ));

QToolButton *point_button;
point_button = new QToolButton(toolbar_ptr, "POINT INPUT BUTTON");
point_button->setIconSet(set);
point_button->setTextLabel("POINT INPUT LAYER");
```

65.7 What Shall I Use?

The previous sections presented different ways of writing QT based applications. We recommend to use layers for the drawing task and for input handling, even if you write tiny applications, because in general they grow over time. Layers are a little bit more overhead, but it pays off in the long run, as you then do not have to completely reorganize your code, to add layers.

Qt_widget

Reference Manual

Laurent Rineau and Radu Ursu

Qt_widget is the base widget class that CGAL provide as support for 2D CGAL users.

CGAL::Qt_widget

Definition

An object of type *Qt_widget* is a two-dimensional window for graphical IO. It is a class that is designed to help CGAL users to visualize easily CGAL objects and for advanced users to interact with them. This widget is designed for 2D CGAL objects only.

```
#include <CGAL/IO/Qt_widget.h>
```

Inherits From

QWidget

Types

The widget class also defines the following enum type to specify which kind of point representation do you want to use:

```
enum PointStyle { PIXEL, CROSS, PLUS, CIRCLE, DISC, RECT, BOX};
```

Creation

```
Qt_widget win( QWidget *parent = 0, const char *name = );
```

Constructs a widget which is a child of *parent*, with the name *name*. The default visible area is between ranges *xmin* = -1, *xmax* = 1, *ymin* = -1, *ymax* = 1. By default the X and Y scale factors are equal.

Qt_widget provides scaling support. You can use a scaling factor for your objects as well as you can draw the objects with one scale and look at the objects with different scales. Also there is a possibility to tell the widget that you want that the visible area should be mapped to a certain interval, and the widget adjust the scaling factor according to that.

```
void win.set_window( double x_min, double x_max, double y_min, double y_max, bool u = false)
```

Map the widget coordinates to the interval defined by the rectangle with given coordinates. This method should be called after *resize()* from *QWidget*. If *u* is *true* the X and Y scale factors will not be equal and the widget will not keep the aspect ratio.

```
void win.set_x_scale( double xscale)
```

Set the current X scaling factor. Actually the scales are recomputed when you resize, so this method is not used very often.

void *win.set_y_scale(double yscale)*

Set the current Y scaling factor. Actually the scales are recomputed when you resize, so this method is not used very often.

— *advanced* —

You should have the same scaling factor for X and Y if you want to keep the aspect ratio of your objects.

— *advanced* —

void *win.zoom(double ratio)* Multiply the X and Y scaling factors by *ratio*, then calls *redraw*.
The center of the visible area remains the same.

void *win.zoom(double ratio, double xc, double yc)*

Multiply the X and Y scaling factors by *ratio*, then calls *redraw*.
The center of the visible area becomes (xc, yc).

void *win.move_center(const double distx, const double disty)*

Move the center of the widget with *distx* on the X axis and *disty* on the Y axis.

void *win.set_center(const double x, const double y)*

Set the center of the widget to (x, y).

void *win.add_to_history()* Deprecated: This function adds the current viewport and transformations to history. You should use *save()* public slot from *Qt_widget_history* object.

void *win.clear_history()* Deprecated: Clears the history. This means that there are no elements in the history list. Call this method when you want to reinitialize the history list. You should use *clear_history()* method from *Qt_widget_standard_toolbar* or the *clear()* public slot from *Qt_widget_history* object.

public slots:

bool *win.back()*
bool *win.forth()* Deprecated: This slots permit to walk into history. Return *true* if succeeded. These slots are deprecated. You should use the *backward()* and *forward()* methods of *Qt_widget_history* object, or the *back()* and *forward()* public slots from *Qt_widget_standard_toolbar* object.

void *win.clear()* Clear the screen. The properties of the widget remain the same after calling this member function. You can see a list of the properties that you can set at the properties description.

<i>void</i>	<i>win.lock()</i>	Locks the widget, keeping the widget from being refreshed. If you lock the widget you should verify that you unlock it somewhere. The number of <i>lock()</i> calls should be the same with the number of <i>unlock()</i> calls. Lock and unlock calls can be nested.
<i>void</i>	<i>win.unlock()</i>	Unlocks the widget, and calls <i>do_paint()</i> . The widget is only unlocked if the number of unlock calls is equal to the number of lock calls.
<i>void</i>	<i>win.do_paint()</i>	Refresh the widget calling <i>paintEvent(QPaintEvent *e)</i> for the <i>Qt_widget</i> only if the widget is unlocked. This mean that <i>redraw()</i> is called if and only if the widget is unlocked.
<i>void</i>	<i>win.redraw()</i>	If you derive from <i>Qt_widget</i> you have to overload this function and put your code for drawing here if you don't use <i>layers</i> . The best way is to attach layers to the widget and call this method. This method redraws the layers attached and active. Before drawing the layers, redraw clear the screen and emit <i>redraw_on_back()</i> . Emit <i>redraw_on_front()</i> at the end.
<i>void</i>	<i>win.print_to_ps()</i>	Redraws all the attached and active layers into a Postscript device. It could be a file or a printer. This method also use signals as <i>redraw_on_back()</i> or <i>redraw_on_front()</i> .

Properties

You can set the properties of the functions through this functions as well as with the help of manipulators described later. The function naming convention has changed for this member functions, to *Qt* convention.

<i>void</i>	<i>win.setColor(QColor c)</i>	Set the current pen color of the widget to be <i>c</i> .
<i>void</i>	<i>win.setBackgroundColor(QColor c)</i>	Set the current background color to be <i>c</i> .
<i>void</i>	<i>win.setFillColor(QColor c)</i>	Set the current fill color of the widget to be <i>c</i> .
<i>void</i>	<i>win.setFilled(bool f)</i>	Set the status of the widget to true or false concerning filling the objects: polygons, circles, rectangles ...
<i>void</i>	<i>win.setLineWidth(unsigned int i)</i>	Set the current line width of the widget.
<i>void</i>	<i>win.setPointSize(unsigned int i)</i>	Set the current point size of the widget.

<i>void</i>	<i>win.setPointStyle(PointStyle s)</i>	Set the current point style of the widget to <i>s</i> . <i>PointStyle</i> is an enumeration declared in <i>Qt_widget</i> .
-------------	---	--

<i>void</i>	<i>win.setRasterOp(RasterOp r)</i>	Set the current raster operation.
-------------	-------------------------------------	-----------------------------------

Layers

<i>void</i>	<i>win.attach(Qt_widget_layer* s)</i>	Add the layer <i>s</i> in the list of layers. The last added will be on top of the screen. Also the events are forwarded to layers in the order they have been attached.
-------------	--	--

<i>void</i>	<i>win.detach(Qt_widget_layer* s)</i>	Remove the layer <i>s</i> from the list. <i>s</i> is a pointer to an existing layer.
-------------	--	--

New CGAL Objects

<i>void</i>	<i>win.new_object(CGAL::Object obj)</i>	This function should be called by the tools that create CGAL objects. It then emits the signal <i>new_cgal_object(CGAL::Object)</i> . Slots of other components can be connected to this signal.
-------------	--	--

Access Functions

Note that we use also types from *Qt* here.

<i>QColor</i>	<i>win.color()</i>	Returns the current pen color. The color returned is a Qt class.
<i>QColor</i>	<i>win.backgroundColor()</i>	Returns the current widget background color. The color returned is a Qt class.
<i>QColor</i>	<i>win.fillColor()</i>	Returns the current color used for filling the objects. The color returned is a Qt class.
<i>PointStyle</i>	<i>win.pointStyle()</i>	Returns the current point style. <i>PointStyle</i> is an enumeration declared in <i>Qt_widget</i> .
<i>uint</i>	<i>win.pointSize()</i>	Returns the current point size.

<i>uint</i>	<i>win.lineWidth()</i>	Returns the current line width.
<i>RasterOp</i>	<i>win.rasterOp()</i>	Return the current raster operation.
<i>double</i>	<i>win.x_min()</i>	Returns the left <i>x</i> coordinate of the widget.
<i>double</i>	<i>win.y_min()</i>	Returns the lower <i>y</i> coordinate of the widget.
<i>double</i>	<i>win.x_max()</i>	Returns the right <i>x</i> coordinate of the widget.
<i>double</i>	<i>win.y_max()</i>	Returns the upper <i>y</i> coordinate of the widget.

————— *advanced* —————

The coordinates of the screen are mapped to a certain interval that you can choose with *set_window* member function. The scale of the objects you can visualize is computed and maintained the same for both axes to keep the aspect ratio of the objects. You should use *x_real* or *y_real* to get the real world coordinates, for your screen coordinates. If you are using *gmp* you can use this functions with *Gmpq* as second parameter. You may need it when you work with rationals. The double from the other function could be more complex and can make you loose speed in computations. Computing with rational coordinates directly could increase the speed, rather than computing with complex double coordinates.

double *win.x_real(int x)*
double *win.y_real(int y)*

template<class FT>
void *x_real(int x, FT&)* Returns the *x* real world coordinate of the *Qt_widget*.

template<class FT>
void *y_real(int y, FT&)* Returns the *y* real world coordinate of the *Qt_widget*.

void *win.x_real(int, Gmpq&)*
void *win.y_real(int, Gmpq&)*

————— *advanced* —————

int *win.x_pixel(double x)* This method is the opposite of *x_real* method. Converts the world coordinates in screen coordinates. If you want to get an integer between 0 and width, you should pass an *x* between *xmin* and *xmax*.

int *win.y_pixel(double y)* This method is the opposite of *y_real* method. Converts the world coordinates in screen coordinates. If you want to get an integer between 0 and height, you should pass an *y* between *ymin* and *ymax*.

————— *advanced* —————

Painter and Pixmap

In order that layers can draw on the drawing area of a widget, they have to access the underlying pixmap and painter.

Qt_widget use as a backbuffer for drawing a pixmap defined inside the class, i.e. an object of type *QPixmap*. The *QPixmap* class is an off-screen pixel-based paint device. One common use of the *QPixmap* class is to enable smooth updating of widgets. The *QPainter* class paints on paint devices. There is an object of type *QPainter* defined in *Qt_widget* that uses as a paint device the *QPixmap* object.

QPixmap& *win.get_pixmap()* Returns the current pixmap.

QPainter& *win.get_painter()* Returns the current painter.

└────────── advanced ─────────┘

Signals

```
void      win.s_mousePressEvent( QMouseEvent *e)
void      win.s_mouseReleaseEvent( QMouseEvent *e)
void      win.s_mouseMoveEvent( QMouseEvent *e)
void      win.s_paintEvent( QPaintEvent *e)
void      win.s_resizeEvent( QResizeEvent *e)
void      win.s_wheelEvent( QMouseEvent *e)
void      win.s_mouseDoubleClickEvent( QMouseEvent *e)
void      win.s_keyPressEvent( QKeyEvent *e)
void      win.s_keyReleaseEvent( QKeyEvent *e)
void      win.s_enterEvent( QEvent *e)
void      win.s_leaveEvent( QEvent *e)
void      win.s_event( QEvent *e)
```

The *Qt_widget* receives the events through virtual functions. This is the mechanism that *Qt* offers for dispatching events. This signals are called every time an event is dispatched to a virtual function. For example if *Qt_widget* receives *mousePressEvent(QMouseEvent *e)* emits *s_mousePressEvent(e)*. This is very useful when you have only a pointer to *Qt_widget*. It is enough to connect this slot to your function to receive the event.

void *win.new_cgal_object(CGAL::Object)*

Triggered when a new object from a tool is received. The user should catch this signal if it's working with tools that provide CGAL objects as input.

void *win.custom_redraw()* Deprecated: Emitted in the *redraw()* function after the layers are drawn.

void *win.redraw_on_back()* Emmitted in *redraw()* method before calling layer's redraw.

void *win.redraw_on_front()* Emmitted in *redraw()* method after calling layer's redraw.

void *win.rangesChanged()* Emmitted each time (xmin, xmax) and (ymin, ymax) ranges are changed.

Operators for Output

The output operator is defined for all geometric classes in the CGAL kernel.

```
template<class R>
Qt_widget&      & win << Point_2<R> p
```

```
template<class R>
Qt_widget&      & win << Segment_2<R> s
```

```
template<class R>
Qt_widget&      & win << Line_2<R> l
```

```
template<class R>
Qt_widget&      & win << Ray_2<R> r
```

```
template<class R>
Qt_widget&      & win << Triangle_2<R> t
```

```
template<class R>
Qt_widget&      & win << Iso_rectangle_2<R> r
```

```
template<class R>
Qt_widget&      & win << Circle_2<R> c
```

To use the other operators described you have to include the right header.

```
#include <CGAL/IO/Qt_widget_Polygon_2.h>
template<class Tr, class Co>
Qt_widget&      & win << Polygon_2<Tr,Co> pol
```

```
#include <CGAL/IO/Qt_widget_Min_ellipse_2.h>
template<class Traits_>
Qt_widget&      & win << Min_ellipse_2<Traits_> min_ellipse
```

```
#include <CGAL/IO/Qt_widget_Optimisation_ellipse_2.h>
template<class Traits_>
Qt_widget&      & win << Optimisation_ellipse_2<Traits_> oe
```

```
#include <CGAL/IO/Qt_widget_Optimisation_circle_2.h>
template<class Traits>
Qt_widget&      & win << Optimisation_circle_2<Traits> oc
```

```
#include <CGAL/IO/Qt_widget_Conic_2.h>
template<class R>
Qt_widget&      & win << Conic_2<R> c
```

```
#include <CGAL/IO/Qt_widget_Triangulation_2.h>
template <class Gt, class Tds>
Qt_widget&      & win << Triangulation_2<Gt, Tds> t
```

```

#include <CGAL/IO/Qt_widget_Alpha_shape_2.h>
template <class Dt>
Qt_widget&      & win << Alpha_shape_2<Dt> As

#include <CGAL/IO/Qt_widget_Delaunay_triangulation_2.h>
template<class Gt, class Tds>
Qt_widget&      & win << Delaunay_triangulation_2<R> dt

#include <CGAL/IO/Qt_widget_Constrained_triangulation_2.h>
template<class Gt, class Tds>
Qt_widget&      & win << Constrained_triangulation_2<Gt, Tds> t

#include <CGAL/IO/Qt_widget_Regular_triangulation_2.h>
template<class Gt, class Tds>
Qt_widget&      & win << Regular_triangulation_2<Gt, Tds> t

```

Manipulators for *Qt_widget*

A *manipulator* is an object which can be inserted in the *Qt_widget*, via the operator <<, to change the context for further drawing.

Here, we simply document the use of these operators which is all the user needs to know to modify the state of a stream.

<i>Qt_widget</i> &	& win << <i>BackgroundColor</i>	Sets the color used for background color.
<i>Qt_widget</i> &	& win << <i>FillColor</i>	Sets the color used for filling the objects.
<i>Qt_widget</i> &	& win << <i>LineWidth</i>	Sets the width of the line for drawing objects.
<i>Qt_widget</i> &	& win << <i>PointSize</i>	Sets the size of the points.
<i>Qt_widget</i> &	& win << <i>noFill</i>	Sets the state of <i>Qt_widget</i> concerning filling the objects to be false.
<i>Qt_widget</i> &	& win << <i>Color c</i>	Sets the color used as the <i>Qt_widget</i> <i>FillColor</i> .
<i>Qt_widget</i> &	& win << <i>PointStyle ps</i>	Sets the point style for <i>Qt_widget</i> .

Example

In the given example, we create an object of type *Qt_widget* and then we use the operators for output and the manipulators to show some of the widget's functionality.

```

#include <CGAL/Cartesian.h>
#include <CGAL/Bbox_2.h>
#include <list>
#include <CGAL/Polygon_2.h>
#include <CGAL/IO/Qt_widget_Polygon_2.h>
#include <qapplication.h>
#include <CGAL/IO/Qt_widget.h>

typedef CGAL::Cartesian<int>   Rep;

    *W << p;
    *W << Ray(Point(200,400), Point(180,430))
        << Ray(Point(200,400), Point(180,370));
    W->unlock();

    return app.exec();
}

```

CGAL::Qt_widget_layer

Definition

The *Qt_widget_layer* serves as a base class for layers. Layers are classes that draw on the drawing area of a *Qt_widget* and receive events from it. You can attach and detach layers on the *Qt_widget*. All the attached layers will receive the events if they are active. The same for drawing, all the active layers that are attached will be drawn.

```
#include <CGAL/IO/Qt_widget_layer.h>
```

Inherits From

QObject

Creation

```
Qt_widget_layer layer( QObject *parent = 0, const char* name = 0);
```

The default constructor. The parameters *parent* and *name* are passed to the *QObject* constructor.

<i>virtual void</i>	<i>layer.mousePressEvent(QMouseEvent *)</i>	
<i>virtual void</i>	<i>layer.mouseReleaseEvent(QMouseEvent *)</i>	
<i>virtual void</i>	<i>layer.wheelEvent(QMouseEvent *)</i>	
<i>virtual void</i>	<i>layer.mouseDoubleClickEvent(QMouseEvent *)</i>	
<i>virtual void</i>	<i>layer.mouseMoveEvent(QMouseEvent *)</i>	
<i>virtual void</i>	<i>layer.keyPressEvent(QKeyEvent *)</i>	
<i>virtual void</i>	<i>layer.keyReleaseEvent(QMouseEvent *)</i>	
<i>virtual void</i>	<i>layer.enterEvent(QEvent *)</i>	
<i>virtual void</i>	<i>layer.leaveEvent(QEvent *)</i>	
<i>virtual bool</i>	<i>layer.event(QEvent *)</i>	These virtual functions can be overloaded in the derived class. They are called by the <i>Qt_widget</i> to which the layer is attached.

<i>bool</i>	<i>layer.is_active()</i>	Returns <i>true</i> if this layer is active.
-------------	--------------------------	--

Public Slots

<i>virtual void</i>	<i>layer.draw()</i>	This virtual member function must be overloaded. This is where the drawing code goes.
---------------------	---------------------	---

<i>void</i>	<i>layer.stateChanged(int s)</i>	
-------------	-----------------------------------	--

This slot is provided to change the layer's state from activated to deactivated and reverse if it is triggered. The layer is activated if *s* is 2, or it is deactivated if *s* is 0. These values match with the signal *stateChanged(int)* in the *QPushButton* widget.

<i>void</i>	<i>layer.toggle(bool b)</i>	This slot is provided to change the layer's state from activated to deactivated and reverse if it is triggered. The layer is activated if <i>b</i> is <i>true</i> , or it is deactivated if <i>b</i> is <i>false</i> . These values match with the signal <i>toggled(bool)</i> in the <i>QPushButton</i> widget.
<i>bool</i>	<i>layer.activate()</i>	Activate and return <i>true</i> if it was not active.
<i>bool</i>	<i>layer.deactivate()</i>	Deactivate and return <i>true</i> if it was active.

Protected

<i>Qt_widget*</i>	<i>widget;</i>	The widget a layer is attached to or 0 otherwise.
<i>virtual void</i>	<i>layer.activating()</i>	You should overload this function if you want to have initializing code for your layer. This function is called every time the layer is activated.
<i>virtual void</i>	<i>layer.deactivating()</i>	You should overload this function if you want to write clean up code for your layer. This function is called every time the layer is deactivated.

Signals

<i>void</i>	<i>layer.activated(*l)</i>	This signal is emitted every time this layer is activated.
<i>void</i>	<i>layer.deactivated(*l)</i>	This signal is emitted every time this layer is deactivated.

Example

The following example of a layer draws the points of a triangulation in green.

```
#include <CGAL/IO/Qt_widget_layer.h>

namespace CGAL {

template <class T>
class Qt_layer_show_points : public Qt_widget_layer {
public:
    typedef typename T::Point          Point;
    typedef typename T::Segment        Segment;
    typedef typename T::Vertex         Vertex;
    typedef typename T::Vertex_iterator Vertex_iterator;

    Qt_layer_show_points(T &t) : tr(t){};

    void draw()
    {
        Vertex_iterator it = tr.vertices_begin(),
            beyond = tr.vertices_end();
```

```

        *widget << CGAL::GREEN << CGAL::PointSize (3)
            << CGAL::PointStyle (CGAL::DISC);
    while(it != beyond) {
        *widget << (*it).point();
        ++it;
    }
};
private:
    T &tr;

}; //end class

} // namespace CGAL

```

CGAL::Qt_widget_get_point<T>

Definition

An object of type *Qt_widget_get_point<T>* creates a CGAL point, every time the left mouse button is clicked.

```
#include <CGAL/IO/Qt_widget_get_point.h>
```

Parameters

The full template declaration of *Qt_widget_get_point* states one parameter:

```
template < class T >
class Qt_widget_get_point;
```

If T is one of the CGAL kernels you don't need additional types. If not, the parameter T has to provide this types:

Types

```
typedef T::Point_2
```

Point_2; This should be a Point type

```
typedef T::FT    FT;
```

FT; This should be a Field type

Inherits From

Qt_widget_layer

Creation

```
Qt_widget_get_point<T> getpoint( const QCursor c=QCursor(Qt::crossCursor),
                                QObject* parent = 0,
                                const char* name = 0)
```

c is the cursor that this layer will use when is active. *parent* is the parent widget and *name* is the name you give to this layer.

CGAL::Qt_widget_get_segment<T>

Definition

An object of type *Qt_widget_get_segment<T>* creates a CGAL segment in this way: one left click on the mouse will be the first point and the second point of the segment will be considered at the coordinates where the left mouse button is pressed for the second time. You can always cancel the creation process by pressing the ESC key. The use of *Qt_widget_get_segment<T>* requires that the mouse tracking is enabled for widgets attaching it.

```
#include <CGAL/IO/Qt_widget_get_segment.h>
```

Parameters

The full template declaration of *Qt_widget_get_segment* states one parameter:

```
template < class T >
class Qt_widget_get_segment;
```

If T is one of the CGAL kernels you don't need additional types. If not, the parameter T has to provide this types:

Types

```
typedef T::Point_2
```

Point_2; This should be a Point type

```
typedef T::Segment_2
```

Segment_2; This should be a Segment type

```
typedef T::FT    FT;
```

This should be a Field type

Inherits From

Qt_widget_layer

Creation

```
Qt_widget_get_segment<T> getsegment( const QCursor c=QCursor(Qt::crossCursor),
                                     QObject* parent = 0,
                                     const char* name = 0)
```

c is the cursor that this layer will use when is active. *parent* is the parent widget and *name* is the name you give to this layer.

CGAL::Qt_widget_get_line<T>

Definition

An object of type *Qt_widget_get_line<T>* creates a CGAL line in this way: one left click on the mouse will be the first point and the second point that generate the line will be considered at the coordinates where the left mouse button is pressed for the second time. You can always cancel the creation process by pressing the ESC key. The use of *Qt_widget_get_line<T>* requires that the mouse tracking is enabled for widgets attaching it.

```
#include <CGAL/IO/Qt_widget_get_line.h>
```

Parameters

The full template declaration of *Qt_widget_get_line* states one parameter:

```
template < class T >
class Qt_widget_get_line;
```

If T is one of the CGAL kernels you don't need additional types. If not, the parameter T has to provide this types:

Types

```
typedef T::Point_2
```

Point_2; This should be a Point type

```
typedef T::Line_2
```

Line_2; This should be a Line type

```
typedef T::FT    FT;
```

This should be a Field type

Inherits From

Qt_widget_layer

Creation

```
Qt_widget_get_line<T>    getline( const QCursor c=QCursor(Qt::crossCursor),
                                QObject* parent = 0,
                                const char* name = 0)
```

c is the cursor that this layer will use when is active. *parent* is the parent widget and *name* is the name you give to this layer.

CGAL::Qt_widget_get_circle<T>

Definition

An object of type *Qt_widget_get_circle<T>* creates a CGAL circle in this way: one left click on the mouse will be the center of the circle and the second point will be considered at the coordinates where the left mouse button is pressed for the second time, the distance between those 2 representing the radius of the new circle. You can always cancel the creation process by pressing the ESC key. The use of *Qt_widget_get_circle<T>* requires that the mouse tracking is enabled for widgets attaching it.

```
#include <CGAL/IO/Qt_widget_get_circle.h>
```

Parameters

The full template declaration of *Qt_widget_get_circle* states one parameter:

```
template < class T >
class Qt_widget_get_circle;
```

If T is one of the CGAL kernels you don't need additional types. If not, the parameter T has to provide this types:

Types

```
typedef T::Point_2
```

Point_2; This should be a Point type

```
typedef T::Circle_2
```

Circle_2; This should be a Circle type

```
typedef T::FT    FT;
```

This should be a Field type

Inherits From

Qt_widget_layer

Creation

```
Qt_widget_get_circle<T> getcircle( const QCursor c=QCursor(Qt::crossCursor),
                                   QObject* parent = 0,
                                   const char* name = 0)
```

c is the cursor that this layer will use when is active. *parent* is the parent widget and *name* is the name you give to this layer.

CGAL::Qt_widget_get_iso_rectangle<T>

Definition

An object of type *Qt_widget_get_iso_rectangle<T>* creates a CGAL iso_rectangle this way one left click will be the first generator point, and second point will be considered at the coordinates where the left mouse button is pressed for the second time. You can always cancel the creation process by pressing the ESC key. The use of *Qt_widget_get_iso_rectangle<T>* requires that the mouse tracking is enabled for widgets attaching it.

```
#include <CGAL/IO/Qt_widget_get_iso_rectangle.h>
```

Parameters

The full template declaration of *Qt_widget_get_iso_rectangle* states one parameter:

```
template < class T >
class Qt_widget_get_iso_rectangle;
```

If T is one of the CGAL kernels you don't need additional types. If not, the parameter T has to provide this types:

Types

```
typedef T::RT    RT;           This should be a Ring type
```

Inherits From

Qt_widget_layer

Creation

```
Qt_widget_get_iso_rectangle<T> getisor( const QCursor c=QCursor(Qt::crossCursor),
                                         QObject* parent = 0,
                                         const char* name = 0)
```

c is the cursor that this layer will use when is active. *parent* is the parent widget and *name* is the name you give to this layer.

CGAL::Qt_widget_get_polygon<Polygon>

Definition

An object of type *Qt_widget_get_polygon<Polygon>* creates a CGAL polygon. A new vertex is inserted every time the left mouse button is pressed. The polygon is returned on a right click. You can use the *Escape* key if you want to remove your last entered point in the polygon. The use of *Qt_widget_get_polygon<Polygon>* requires that the mouse tracking is enabled for widgets attaching it.

```
#include <CGAL/IO/Qt_widget_get_polygon.h>
```

Parameters

The full template declaration of *Qt_widget_get_polygon* states one parameter:

```
template < class Polygon >
class Qt_widget_get_polygon;
```

Polygon should be a CGAL Polygon, or should provide the following types:

Types

```
typedef Polygon::Point_2
```

```
Point_2;
```

```
typedef Polygon::Segment_2
```

```
Segment2;
```

```
typedef Polygon::Edge_const_iterator
```

```
ECI;
```

```
typedef Polygon::Vertex_iterator
```

```
VI;
```

```
typedef Polygon::FT
```

```
FT;
```

Inherits From

```
Qt_widget_tool
```

Creation

```
Qt_widget_get_polygon<Polygon> getpoly( const QCursor c=QCursor(Qt::crossCursor),  
                                           QObject* parent = 0,  
                                           const char* name = 0)
```

c is the cursor that this layer will use when is active. *parent* is the parent widget and *name* is the name you give to this layer.

CGAL::Qt_widget_get_simple_polygon<Polygon>

Definition

An object of type *Qt_widget_get_simple_polygon<Polygon>* creates a CGAL simple polygon. A new vertex is inserted every time the left mouse button is pressed, if the polyline entered so far is simple. A right click closes the polygon, if it is simple. You can use the *Escape* key if you want to remove your last entered point in the polygon.

```
#include <CGAL/IO/Qt_widget_get_simple_polygon.h>
```

Parameters

The full template declaration of *Qt_widget_get_simple_polygon* states one parameter:

```
template < class Polygon >
class Qt_widget_get_simple_polygon;
```

Polygon should be a CGAL Polygon, or it should provide the following types:.

Types

```
typedef Polygon::Point_2
```

```
Point_2;
```

```
typedef Polygon::Segment_2
```

```
Segment2;
```

```
typedef Polygon::Edge_const_iterator
```

```
ECI;
```

Inherits From

```
Qt_widget_layer
```

Creation

```
Qt_widget_get_simple_polygon<Polygon> getspoly( const QCursor c=QCursor(Qt::crossCursor),
                                                QObject* parent = 0,
                                                const char* name = 0)
```

c is the cursor that this layer will use when is active. *parent* is the parent widget and *name* is the name you give to this layer.

CGAL::Navigation_layer

```
#include <CGAL/IO/Navigation_layer.h>
```

Inherits From

Qt_widget_layer

Creation

```
Navigation_layer nav_layer( QObject* parent = 0, const char* name = 0);
```

parent is the parent widget and *name* is the name you give to this layer.

This layer is used to provide basic navigation control over the *Qt_widget*. When this layer is attached and active, you may use the arrows to navigate the equivalent in world coordinates of 10 pixels in the desired direction. You can also use the PageUp, PageDown keys to scroll the equivalent in world coordinates of half screenheight on the Y axes.

CGAL::Custom_zoom_layer

```
#include <CGAL/IO/Custom_zoom_layer.h>
```

Inherits From

Custom_zoom_layer

Creation

```
Custom_zoom_layer zoom_layer( QObject* parent = 0, const char* name = 0);
```

parent is the parent widget and *name* is the name you give to this layer.

The standard toolbar already provide zooming functionality, but this layer comes to complete the latest. When this layer is attached and active, zooming functionality could be used anytime. To zoom in x2 you must press the + key on your keyboard. To zoom out x2 you must press the - key on your keyboard. You can also use the mouse to zoom to a region defined by one rectangle. To define the rectangle you must press Ctrl+LeftMouseButton for the first corner of the rectangle, you may release, then move, then press Ctrl+LeftMouseButton once again to define the second corner.

CGAL::Qt_widget_standard_toolbar

Definition

The standard toolbar includes the basic tools used for zooming and translating in a *Qt_widget*.

```
#include <CGAL/IO/Qt_widget_standard_toolbar.h>
```

Inherits From

QToolBar

Creation

```
Qt_widget_standard_toolbar toolbar( Qt_widget *w,
                                   QMainWindow *mw,
                                   QWidget* parent,
                                   bool newline = true,
                                   const char* name = 0)
```

This constructor creates a new toolbar, called *name*, in your application, containing all the standard tools. The first parameter *w* is a non-null pointer to the *Qt_widget* object on which the toolbar functionalities act. The second parameter *mw* is a pointer to the *QMainWindow* that manages the toolbar. The later is added to the top area of the *QMainWindow*, unless *mw=0*. *mw*, *parent*, *newline*, *name* are passed to the *QMainWindow* constructor (with first parameter *label="Qt_widget standard toolbar"*).

```
Qt_widget_standard_toolbar toolbar( Qt_widget *w, QMainWindow *parent = 0, const char* name = 0);
```

Simplified version of the previous one. The *parent* is the *QMainWindow* that manages the toolbar.

*const QToolBar**

toolbar.toolbar()

Deprecated: (in CGAL-2.4 the standard toolbar was not derived from *QToolBar*) Returns a pointer to the *QToolBar* *this* itself.

public slots:

void toolbar.back() Goes back in the history list of the standard toolbar.

void toolbar.forward() Goes forward in the history list of the standard toolbar.

void toolbar.clear_history() Clears the history list of the standard toolbar.

Example

```

#include <CGAL/Cartesian.h>
#include <CGAL/Point_2.h>
#include <CGAL/Delaunay_triangulation_2.h>
#include <CGAL/IO/Qt_widget_Delaunay_triangulation_2.h>

#include <qapplication.h>
#include <qmainwindow.h>

#include <CGAL/IO/Qt_widget.h>
#include <CGAL/IO/Qt_widget_layer.h>
#include <CGAL/IO/Qt_widget_standard_toolbar.h>

typedef CGAL::Cartesian<double>          Rep;
typedef CGAL::Point_2<Rep>              Point;
typedef CGAL::Delaunay_triangulation_2<Rep> Delaunay;

Delaunay dt;

class My_layer : public CGAL::Qt_widget_layer{
    void draw(){
        *widget << CGAL::BLACK;
        *widget << dt;
    }
};

class My_widget : public CGAL::Qt_widget {
public:
    My_widget(QMainWindow* c) : CGAL::Qt_widget(c) {};
private:
    //this event is called only when the user presses the mouse
    void mousePressEvent(QMouseEvent *e)
    {
        Qt_widget::mousePressEvent(e);
        dt.insert(Point(x_real(e->x()), y_real(e->y())));
        redraw();
    }
};

class My_window : public QMainWindow{
public:
    My_window(int x, int y)
    {
        widget = new My_widget(this);
        setCentralWidget(widget);
        resize(x,y);
        widget->set_window(0, x, 0, y);

        //How to attach the standard toolbar
        stoolbar = new CGAL::Qt_widget_standard_toolbar(widget, this,
                                                         "Standard toolbar");
        widget->attach(&v);
    }
private:
    My_widget *widget;

```

```

    My_layer v;
    CGAL::Qt_widget_standard_toolbar *stoolbar;
};

int main( int argc, char **argv )
{
    QApplication app( argc, argv );
    My_window W(400,400);
    app.setMainWidget( &W );
    W.show();
    W.setCaption("Using the Standard Toolbar");
    return app.exec();
}

```

This example is implemented in the fifth tutorial. You can look over the code to see how the code works.

CGAL::Qt_widget_history

Definition

This class provides basic functionality to manipulate intervals of *Qt_widget* class. *Qt_widget* knows about the current visible area that is specified through an interval. The default one is (-1, 1, -1, 1). This class is mostly used by the *Qt_widget_standard_toolbar* to provide the backward and the forward navigation through the different intervals.

```
#include <CGAL/IO/Qt_widget_history.h>
```

Inherits From

QObject

Creation

```
Qt_widget_history history( Qt_widget* parent, const char *name = 0);
```

parent is the parent widget that has to be a *Qt_widget* and *name* is the name of the history. This will create a history object that can deal with the *Qt_widget* visualisation intervals. Each time the visible area will change, it's interval will be stored in the history list.

public slots:

<i>void</i>	<i>history.save()</i>	This saves the widget visible area in the history list.
<i>void</i>	<i>history.backward()</i>	This goes back in the list of saved intervals.
<i>void</i>	<i>history.forward()</i>	This goes forward in the list of saved intervals.
<i>void</i>	<i>history.clear()</i>	This will clear the entire history list.

signals:

<i>void</i>	<i>history.backwardAvailable(bool)</i>
<i>void</i>	<i>history.forwardAvailable(bool)</i>

This two signals are emitted when there are available items in the history list as regards to the current position in the list.

CGAL::Qt_help_window

Definition

This class is a specialization of the *QTextBrowser* class, that provides a rich text browser with hypertext navigation. It has couple more functionalities as navigation support and printing.

```
#include <CGAL/IO/Qt_help_window.h>
```

Inherits From

QMainWindow

Creation

```
Qt_help_window hw( QString home_, QString path, QWidget* parent = 0, const char *name=0);
```

home_ is the name of the file considered as home, *path* is the path to this file, *parent* is the parent widget, and *name* is the name of this help class.

public slots:

<i>void</i>	<i>hw.print()</i>	This prints the current displayed page to the printer device of your choice.
-------------	-------------------	--

Example

```
#include <CGAL/IO/Qt_help_window.h>
//...
QString home;
home = "help/index.html";
CGAL::Qt_help_window *help = new
